**Osteoblast-specific Deletion of *Lrp6* Reveals Distinct Roles for *Lrp5* and *Lrp6* in Bone Development.** C. R. Zylstra<sup>\*1</sup>, C. Wan<sup>\*2</sup>, K. K. VanKoeveering<sup>\*1</sup>, A. K. Sanders<sup>\*1</sup>, C. Lindvall<sup>\*1</sup>, T. L. Clemens<sup>2</sup>, B. O. Williams<sup>1</sup>. <sup>1</sup>Van Andel Research Institute, Grand Rapids, MI, USA, <sup>2</sup>University of Alabama Birmingham, Birmingham, AL, USA.

Mutations in the Wnt co-receptors *Lrp5* and *Lrp6* produce striking alterations in bone mass in both humans and mice, but precisely how these co-receptors mediate Wnt actions is unclear. Wnt ligands activate several signaling cascades, including the canonical pathway that inhibits APC-mediated degradation of Beta-catenin. Previously, we found that mice carrying conditional deletion of Beta-catenin in mature osteoblasts developed severe osteopenia accompanied by increased osteoclastogenesis. *Lrp5*-deficient mice have low bone mass, but are viable and fertile and do not exhibit alterations in osteoclast function. One potential explanation for these differences is that the highly related *Lrp6* might exert overlapping, or distinct, roles in bone development. Consistent with this, we previously found that mice carrying global mutations in both *Lrp5* and *Lrp6* display synergistic deficiencies in bone mass. However, the fact that these mutations were present in all cells of these mice did not allow us to unambiguously determine that these effects were due to altered regulation of osteoblasts. To gain insight into this question, we created mice carrying a conditional allele of *Lrp6* (*Lrp6*-flox). Offspring from matings of these mice with mice expressing Cre recombinase driven by the human osteocalcin promoter (OC-cre) have significantly lower bone mass demonstrating that *Lrp6* is required for the normal bone acquisition. When the OC-*Lrp6*-flox/flox mice are mated with mice globally deficient in *Lrp5*, the offspring develop severe osteopenia and essentially phenocopied mice lacking Beta-catenin in osteoblasts (OC-cre;Beta-catenin-flox/flox mice); mice die within four weeks of birth displaying severe osteopenia associated with reduced bone formation and increased bone resorption. These findings suggest that both *Lrp5* and *Lrp6* are required to fully activate beta-catenin in mature osteoblasts and provide the first direct genetic evidence for a role of *Lrp6* in osteoblast differentiation and/or function.

## 1002

**G171V and A214V *Lrp5* Knock-in Mice Have Increased Bone Mass and Strength, and Can Help Precisely Define the In Vivo Functions of *Lrp5* During Bone Growth and Homeostasis.** Y. Cui<sup>\*1</sup>, P. J. Niziolek<sup>\*2</sup>, A. G. Robling<sup>2</sup>, M. L. Warman<sup>\*3</sup>. <sup>1</sup>Genetics, Case Western Reserve University, Cleveland, OH, USA, <sup>2</sup>Department of Biomedical Engineering, Purdue University, West Lafayette, IN, USA, <sup>3</sup>Departments of Orthopaedics and Genetics, Children's Hospital Boston and Harvard Medical School, Boston, MA, USA.

Low-density-lipoprotein receptor-related protein 5 (LRP5), a co-receptor in the Wnt signaling pathway, modulates bone mass. In humans, loss-of-function mutations in LRP5 reduce bone mass, while certain missense mutations increase it. In contrast to several strains of *Lrp5* knockout mice, only one mouse with a missense mutation causing increased bone mass has been published. In this mouse, the human LRP5 receptor (G171V) was over-expressed using a type I collagen promoter fragment. Consequently, this transgenic mouse may not accurately reflect the effect of an endogenous mutation. Therefore, we created two strains of mice with *Lrp5* knock-in mutations (G171V and A214V). In these knock-in mice the mutated *Lrp5* alleles are expressed at the same level as their wild-type counterparts. We compared 4-month-old male knock-in mice to their wild-type relatives. In mice with G171V or A214V mutations we observed significant increases in skull thickness (90-102%), L5 vertebral BV/TV (40-65%) and Tb.Th (35-51%), and decreases in L5 vertebral Tb. Sp (18-22%), with no change in Tb.N. We also found significantly increased bone strength as determined by three-point femur bending tests. Stiffness, ultimate force, and energy to failure were increased in the mutant mice by 50-100%. Similar patterns were observed in females and in 1 and 2-month-old animals. We next looked at younger animals to determine when these differences began to emerge. At 4-days-of-life we found no difference in the timing of secondary centers of ossification by alizarin red/alcian blue staining, but histomorphometric measurements revealed differences in trabecular bone volume. When creating these knock-in alleles, we noticed that the allele acted as a hypomorph when the floxed Neo selection cassette remained intact. Therefore, by removing the selection cassette using Cre recombinase that is expressed at different stages of osteoblast development, we can determine when expression of the mutant receptor is necessary or sufficient to cause the increased bone mass phenotype. In summary, we have created two strains of *Lrp5* missense mutant mice that model the human high bone mass phenotypes and can provide novel insights regarding the precise role(s) of *Lrp5* in the development and homeostasis of the skeleton. These mice can also be used to look at the non-skeletal consequences of *Lrp5* missense mutations that may enhance Wnt signaling.

## 1003

**Transgenic Over-Expression of the Wnt Antagonist Kremen-2 in Osteoblasts Leads to Severe Impairment of Bone Formation and Increased Bone Resorption.** J. Schulze<sup>\*</sup>, S. Seitz, M. Schneebauer<sup>\*</sup>, M. Amling, T. Schinke. Center for Biomechanics and Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Hamburg, Germany.

Since the identification of *LRP5* mutations in patients with either osteoporosis or osteosclerosis, the Wnt signaling pathway is considered to be of hallmark importance in the regulation of osteoblast differentiation and function. *Lrp5* encodes a co-receptor for ligands of the Wnt family, and its deletion in mice results in decreased bone formation. Interestingly however, mice with an osteoblast-specific inactivation of  $\beta$ -catenin, the major intracellular mediator of Wnt stimulation, display normal bone formation, but increased bone resorption, thereby demonstrating that the regulation of Wnt signaling in osteoblasts is more complex than previously anticipated. In this study we analyzed the role of Kremen-2 (*Krm2*), a transmembrane protein serving as a receptor for molecules of the Dkk family that antagonize Wnt signaling through binding to *Lrp5* or *Lrp6*. We first analyzed the expression pattern of *Krm2* in tissues and primary osteoblasts and observed predominant expression in bone and non-mineralized osteoblasts, but virtually no expression in mineralized cultures. Since the latter observation was exactly the opposite as observed for *Dkk1*, we asked the question, whether the transgenic over-expression of *Krm2* under the control of an osteoblast-specific *Colla1* promoter fragment would result in decreased bone formation, as it has been described for *Dkk1*-transgenic mice. The histologic analysis of the *Colla1-Krm2* mice revealed a striking reduction of bone mass compared to wildtype littermates (BV/TV:  $2.7 \pm 0.7$  vs.  $12.8 \pm 4.1$  % at 24 weeks of age), leading to reduced biomechanical stability. Dynamic histomorphometry revealed that bone formation was almost completely abolished in the transgenic mice at the age of 6 weeks and thereafter (BFR/BS:  $18 \pm 11$  vs.  $112 \pm 24 \mu\text{m}^3/\mu\text{m}^2/\text{y}$ ). In addition, we observed a three-fold elevation of osteoclast numbers, demonstrating that bone resorption is also affected in *Colla1-Krm2* mice. We next isolated primary osteoblasts and found lower levels of  $\beta$ -catenin in transgenic cultures, resulting in a decreased production of Opg. Moreover, we failed to detect Wnt3-dependent phosphorylation of *Lrp6* in transgenic cultures, thereby suggesting that the striking differences between *Colla1-Krm2* and *Lrp5*-deficient mice may be due to an additional inactivation of *Lrp6*-dependent signaling by *Krm2*. Taken together, our data demonstrate that *Krm2* is a potent inhibitor of bone formation and a potential target for osteoanabolic therapy.

## 1004

**Deletion of the Dkk1 Co-receptors Kremen 1 and Kremen 2 in Mice Leads to Increased Bone Formation and Bone Mass.** H. Saito<sup>\*1</sup>, K. Ellwanger<sup>\*2</sup>, P. Clément-Lacroix<sup>\*3</sup>, E. Hesse<sup>1</sup>, N. Maltry<sup>\*3</sup>, J. Niedermeyer<sup>\*2</sup>, R. W. Lee<sup>\*2</sup>, G. Rawadi<sup>\*3</sup>, H. Westphal<sup>\*4</sup>, C. Niehrs<sup>\*2</sup>, R. Baron<sup>1</sup>. <sup>1</sup>Oral Medicine Infection and Immunity, Harvard School of Dental Medicine, Boston, MA, USA, <sup>2</sup>DKFZ, Heidelberg, Germany, <sup>3</sup>Galapagos, Romainville, France, <sup>4</sup>National Institute of Child Health and Human Development, Bethesda, MD, USA.

Kremen1 and 2 (*Krm1*, -2) and LRP5/6 are transmembrane co-receptors for Dickkopf1 (*Dkk1*), an antagonist of Wnt/ $\beta$ -catenin signaling, a pathway that is essential for bone formation and bone homeostasis. We and others have previously shown that *Dkk1* haploinsufficiency leads to increased bone formation and bone mass whereas overexpression leads to osteopenia. However, the physiological relevance of Kremens in mammals as Wnt modulators is unresolved and their role in bone remodeling is unknown. We therefore generated and characterized *Krm* mutant mice and found that double mutants show enhanced Wnt signaling. To clarify the role of Kremens on osteoblast (OB) differentiation, mutant and wild-type mice calvarial OBs were cultured for 21 days and the expression of OB differentiation markers (*Runx2*, *Osx*, and *ALP*) was analyzed at day 0 and 3 by quantitative RT-PCR. OB differentiation markers were increased in mice lacking both *Krm1* and *Krm2* at both time-points in a gene dose-dependent manner. In vivo, single deletion of *Krm1* or *Krm2* was not sufficient to induce significant changes in bone volume (BV) or BFR but the double knockout mice showed a marked and significant increase in trabecular BV. A detailed histomorphometric analysis showed that trabecular BV/TV and trabecular number (Tb.N) were significantly increased and trabecular separation (Tb.sp) was significantly decreased in *Krm1*-/- *Krm2*-/- mice. Bone formation parameters (osteoblast surface: Ob.S/BS, number of osteoblast: N.Ob/BS, osteoid surface: OS/BS, bone formation rate: BFR/BV, BFR/BS, BFR/TV and mineral apposition rate: MAR) were significantly increased in *Krm1*-/- *Krm2*-/-. Bone resorption parameters (osteoclast surface: Oc.S/BS, number of osteoclast: N.Oc/BS and eroded surface: ES/BS) showed only a trend towards reduction, indicating that the high bone mass was primarily due to an increase in bone formation. Most importantly, triple knockouts in which *Dkk1* was haploinsufficient failed to show significant changes in BV/TV above and beyond the *Krm1*-2 double knockouts. Thus, our study provides the first genetic evidence for a functional interaction of Kremens with *Dkk1* as negative regulators of Wnt/ $\beta$ -catenin signaling and trabecular bone formation.

## 1005

**Deletion of the Wnt Signaling Antagonist Secreted Frizzled Related Protein 4 (sFRP4) in Mice Induces Opposite Bone Formation Phenotypes in Trabecular and Cortical Bone.** H. Saito<sup>\*1</sup>, R. Hinkle<sup>\*2</sup>, D. Ebert<sup>\*2</sup>, C. Blanton<sup>\*2</sup>, N. Jaiswal<sup>\*2</sup>, L. Elenich<sup>\*2</sup>, D. Cody<sup>\*2</sup>, R. Baron<sup>1</sup>, G. Sabataskos<sup>2</sup>. <sup>1</sup>Oral Medicine Infection and Immunity, Harvard School of Dental Medicine, Boston, MA, USA, <sup>2</sup>Procter and Gamble Pharmaceuticals, Mason, OH, USA.

Both canonical and non-canonical Wnt signaling have been shown to increase bone formation rates (BFR) by increasing osteoblast (OB) proliferation, differentiation and activity. Consequently, components of the Wnt signaling pathway constitute potential drug target for osteo-anabolism. sFRP4 is a member of the sFRP family of Wnt inhibitors that functions as a Frizzled decoy receptor, antagonizing the activity of Wnt ligands and therefore, unlike Dkk1 and Sclerostin, suppressing both canonical and non-canonical pathway activation. To determine whether sFRP4 affected OB differentiation we transfected human Mesenchymal Stromal Cells (hMSC) with siRNA against sFRP4 *in vitro*. In the presence of BMP-2, down-regulation of sFRP4 mRNA expression in hMSCs resulted in a significant increase in alkaline phosphatase mRNA expression, suggesting that sFRP4 exerts a negative effect on OB differentiation. To further elucidate the role of sFRP4 *in vivo* we generated sFRP4 knock out mice. sFRP4 heterozygote (+/-) and homozygote (-/-) deficient mice are healthy, viable and develop normally. Femurs from male and female sFRP4 wild type, +/- or -/- mice were analyzed at 10, 22 and 44 weeks of age using uCT. A pronounced increase in trabecular bone (Tb) in sFRP4+/- and -/- mice was observed, with significant increases in bone volume (BV/TV) in the secondary spongiosa. Further investigation of the bone phenotype of the sFRP4 -/- revealed that the increase in Tb was associated with significant increases in Tb number and thickness and decreases in Tb separation. Static and dynamic histomorphometry further confirmed that this effect was due to increased OB differentiation and activity as demonstrated by significant increases in OB surface and number, mineralizing surface and mineral apposition rate (MAR). Consequently, at all ages and in both genders the BFR was increased over 250%. No changes were observed in bone resorption. Interestingly however, this marked increase in BFR and BV/TV in Tb was associated with a significant thinning of cortical bone in sFRP4+/- mice and an overall increase in the external diameter. The periosteal and the endosteal MAR were significantly reduced when in sFRP4+/- mice. Thus, deletion of sFRP4, which is expected to antagonize both canonical and non-canonical Wnt signaling, favors strongly BFR and BV/TV in Tb but may have opposite effects on cortical bone, at least in growing mice. This is in contrast with deletion of Dkk1 or Sclerostin which are expected to mostly activate canonical Wnt signaling.

## 1006

**Mice Lacking the Wnt Receptor Frizzled-9 Display Osteopenia Caused by Decreased Bone Formation.** J. Albers<sup>1</sup>, M. Gebauer<sup>\*1</sup>, F. Friedrich<sup>\*1</sup>, J. Schulze<sup>\*1</sup>, M. Priemel<sup>1</sup>, U. Francke<sup>\*2</sup>, M. Amling<sup>1</sup>, T. Schinke<sup>1</sup>. <sup>1</sup>Center for Biomechanics and Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>2</sup>Department of Genetics, Stanford University, Stanford, CA, USA.

The Wnt signalling pathway plays a key role in the regulation of bone formation, which is best underscored by the identification of mutations within the human *LRP5* gene causing either osteoporosis or osteosclerosis. *LRP5* encodes a co-receptor for ligands of the Wnt family, whose interaction with serpentine receptors of the Frizzled (Fzd) family is crucial for the initiation of intracellular signalling pathways. Thus, the identification of Wnt and Fzd family members specifically required for signalling in osteoblasts is one of the most important goals of current skeletal research. Using Affymetrix Gene Chip hybridization we observed that among the 10 known genes encoding Fzd receptors, only *Fzd9* is differentially regulated together with known osteoblast marker genes in primary mouse osteoblasts. To analyze, whether the expression of *Fzd9* in osteoblasts is required to regulate bone formation *in vivo*, we analyzed the skeletal phenotype of *Fzd9*-deficient mice. While we did not observe significant differences compared to wildtype littermates at the age of 6 weeks, our histomorphometric analysis at 24 and 72 weeks of age revealed a more than 40 % decrease of the trabecular bone volume in the *Fzd9*-deficient mice. Dynamic histomorphometry further revealed that this osteopenia is explained by a 50 % reduction of the bone formation rate, while bone resorption is unaffected. Likewise, *Fzd9*-deficient calvarial osteoblasts display a decreased rate of proliferation and a delayed matrix mineralization compared to wildtype cultures. Thus, to identify potential downstream targets of Wnt signalling in osteoblasts, we performed Affymetrix Gene Chip hybridization using wildtype and *Fzd9*-deficient cultures. In line with observations from *Lrp5*-deficient mice, we did not observe major changes in the expression of well-established osteoblast marker genes, such as *Runx2*, *Osteocalcin* or *Bone Sialoprotein*. We did however identify more than 200 genes, whose expression was reduced at least 2-fold in the absence of *Fzd9*, thereby suggesting that some of them may be relevant in the regulation of bone formation. Taken together, given the striking similarities between *Lrp5*- and *Fzd9*-deficient mice, our data suggest that *Fzd9* is one of the relevant Wnt receptors in osteoblasts, at least in mice. Since serpentine receptors are considered to be excellent drug targets, we believe that these data are also of immediate clinical relevance.

## 1007

**Dlk1/FA1 Is a Novel Factor Enhancing Osteoclastogenesis and Inhibiting Bone Formation *in vitro* and *in vivo*.** B. M. Abdallah<sup>\*1</sup>, N. Ditzel<sup>\*1</sup>, G. A. Traustadottir<sup>\*1</sup>, A. F. Schilling<sup>\*2</sup>, M. Amling<sup>\*3</sup>, M. Kassem<sup>1</sup>. <sup>1</sup>Endocrine Research Laboratory (KMEB), Odense University Hospital, Odense, Denmark, <sup>2</sup>Center for Biomechanics, University Medical Center Hamburg, Hamburg, Germany, <sup>3</sup>Center for Biomechanics, University Medical Center Hamburg, Hamburg, Germany.

Dlk1/FA-1 (delta-like 1/fetal antigen-1) is a trans-membrane protein belonging to Notch family whose expression is known to modulate the differentiation signals of mesenchymal and hematopoietic stem cells in bone marrow. We have recently demonstrated an endocrine function of circulating soluble form of Dlk1 (named FA1) as an inhibitor of bone formation in adult mice. Here, we investigated the physiological role of gain and loss function of Dlk1/FA1 on skeletal remodeling using osteoblast-specific-Dlk1 over-expressing mice (Col1-Dlk1) and Dlk1-deficient mice. Interestingly, Col1-Dlk1 mice displayed growth retardation and significantly reduced total body weight and bone mineral density (BMD) by 30% and 23% respectively. The bone loss phenotype was due to the reduced trabecular bone volume fraction and the inhibitory effect of Dlk1/FA1 on bone formation rate. In contrast, Dlk1<sup>-/-</sup> mice displayed increased BMD and trabecular BV/TV fraction by 18% and 40% respectively. At cellular level, the total number of bone marrow (BM)-derived CFU-F as well as alkaline phosphatase positive (ALP+) CFU-F from Col1-Dlk1 mice were dramatically reduced compared to wild type mice (WT). In addition, FACS-sorted calvaria dlk1/FA1+ cells from Col1-Dlk1 mice displayed reduced *in vitro* osteoblast differentiation and impaired *in vivo* ectopic bone formation capacity. Histological analysis revealed increased bone resorption surfaces (stained positive for TRAP) in Col1-Dlk1 bones by 42% compared to WT. *In vitro*, higher osteoclast (OC) number and increased OC resorptive activity were observed in OC cultures derived from BM of Col1-Dlk1 compared to WT. Purified FA1 protein did not stimulate differentiation of BM cells into OC but osetoblastic-dlk1/FA1+ cells in co-culture system with BM cells, markedly increased the number of TRAP+ OC suggesting that dlk1/FA1 exerts its stimulatory effect on osteoclastogenesis via an osteoblast-mediated effects. In supporting to these data, our microarray analysis on osteoblastic dlk1/FA1+ cells vs WT control revealed marked stimulation of bone resorption-related inflammatory cytokines (approx. 33% of total up-regulated genes with >2 fold). In conclusion, our data demonstrate a novel role for Dlk1/FA1 in bone biology. Dlk1 exerts a dual role in bone remodeling: it inhibits bone formation and stimulates bone resorption and thus may function as resorption-formation "coupling factor".

## 1008

**Twisted Gastrulation-Deficient Mice Exhibit Osteopenia through Enhanced Osteoclast Function.** J. Sotillo<sup>\*1</sup>, K. C. Mansky<sup>2</sup>, A. E. Carlson<sup>\*1</sup>, T. Schwarz<sup>\*2</sup>, B. MacKenzie<sup>\*3</sup>, E. Jensen<sup>\*1</sup>, A. Petryk<sup>\*4</sup>, R. Gopalakrishnan<sup>1</sup>. <sup>1</sup>Diagnostic and Biological Sciences, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Developmental and Surgical Sciences, University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>Pediatrics, University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Pediatrics and Genetics Cell Biology and Development, University of Minnesota, Minneapolis, MN, USA.

Bone morphogenetic proteins (BMPs), growth factors involved in skeletogenesis, are regulated by extracellular proteins like Twisted gastrulation (Twsg1). Using Twsg1-deficient (*Twsg1*<sup>-/-</sup>) mice, our goal was to assess the role of Twsg1 in postnatal bone homeostasis. Micro-CT analysis demonstrating the integrity of trabecular and cortical morphology showed severe reduction in bone of *Twsg1*<sup>-/-</sup> mice when compared to wild-type (WT) mice. Consistent with previous reports, *in vivo* and *in vitro* indices of osteoblast (OB) function, including mineral apposition rate and markers of OB differentiation (osteocalcin and alkaline phosphatase) assessed via qRT-PCR and ELISA were not significantly different between WT and *Twsg1*<sup>-/-</sup> mice. However, to our surprise, *Twsg1*<sup>-/-</sup> mice exhibit increased bone resorption compared to WT mice characterized by larger and increased number of osteoclasts (OCs), increased area of resorption pits and increased serum carboxy-terminal collagen crosslinks (CTX) and tartrate resistant acid phosphatase (TRACP 5b) levels. Furthermore, enhanced osteoclastogenesis *in vitro* was associated with upregulation of key genes involved in OC differentiation (nuclear factor of activated T-cells (NFATc1) and Cathepsin K) and enhanced precursor cell fusion as there was increased expression of dendritic cell-specific transmembrane protein (DC-STAMP), a molecule necessary for cell fusion, with concomitant increased nuclei number per multinucleated OCs. Interestingly, this phenotype is not due to altered ability of OBs to sustain osteoclastogenesis as both serum levels and gene expression of receptor activator for nuclear factor- $\kappa$ B ligand (RANKL) and osteoprotegerin were not different between genotypes. To see if the effects of Twsg1 deficiency could be reversed, *Twsg1*<sup>-/-</sup> OCs were treated with increasing concentrations of Noggin, a BMP antagonist. As expected, we observed dose-dependent attenuation of osteoclastogenesis, suggesting that (1) *Twsg1*<sup>-/-</sup> OCs exhibit enhanced BMP activity resulting in increased osteoclastogenesis and (2) during normal OC maturation, Twsg1 behaves as a critical BMP antagonist. Together, our results indicate that the osteopenia exhibited in Twsg1-deficiency is mediated through increased OC function and not through reduced OB activity. These novel findings suggest that by regulating BMP activity, Twsg1 is a key regulator of OC function.

## 1009

**In the Absence of NF- $\kappa$ B2, TNF Induces Osteoclast Formation *in vivo* Independent of RANKL/RANK and More Severe Arthritis in TNF-Tg Mice.** Z. Yao, L. Xing, B. F. Boyce. Pathology, University of Rochester, Rochester, NY, USA.

TNF plays a central role in bone loss following sex steroid deficiency and in rheumatoid arthritis. It induces osteoclast (Ocl) formation from Ocl precursors (OCPs) from RANKL $^{-/-}$  or RANK $^{-/-}$  mice *in vitro*, but not when it is administered to these mice *in vivo*; this discrepancy and why TNF induces fewer Ocls than RANKL *in vitro* remain unexplained, despite both of these cytokines activating NF- $\kappa$ B to induce Ocl formation. RANKL activates both the canonical and non-canonical NF- $\kappa$ B pathways, but TNF activates only the former. Activation of the latter pathway by RANKL leads to processing of the inhibitory NF- $\kappa$ B2 p100 protein to p52, which along with RelB goes to the nucleus to induce OCP differentiation. Here, we investigated the hypothesis that TNF induces NF- $\kappa$ B2 p100 expression to limit Ocl formation *in vitro* and *in vivo*. TNF induced strong p100 protein expression in RANK $^{-/-}$  or RANKL $^{-/-}$  OCPs *in vitro*, similar to wt cells, but RANKL did not. We generated RANK/nfkb2 or RANKL/nfkb2 double knockout (dKO) mice and found that TNF induced significantly more Ocls from their OCPs ( $436 \pm 17$  and  $442 \pm 23$ /well) *in vitro* than from wt cells ( $34 \pm 5$ /well), the maximal number reaching that of RANKL-treated wt cells ( $475 \pm 37$ ). TNF induced similar numbers of Ocls from TRAF6 $^{-/-}$  as from wt OCPs. We next injected TNF (0.5 $\mu$ g, twice daily for 5 d) over the calvaria of dKO and single RANK or RANKL KO mice. TNF induced only occasional Ocls in the RANK $^{-/-}$  and RANKL $^{-/-}$  mice, but importantly induced large numbers of actively resorbing ocls in the dKO mice. We generated TNF-transgenic (TNF-Tg)/nfkb2 $^{-/-}$  mice to determine the effect of absence of NF- $\kappa$ B2 on TNF-induced arthritis and osteoporosis. Arthritis occurred earlier and was more severe in the TNF-Tg/nfkb2 $^{-/-}$  than in TNF-Tg mice (inflammatory synovial tissue area  $0.28 \pm 0.09$  mm $^2$  vs.  $0.11 \pm 0.1$  mm $^2$ ; and Ocl number  $23.5 \pm 4.1$ /mm $^2$  vs.  $2.8 \pm 4.1$ /mm $^2$ ). TNF-Tg/nfkb2 $^{-/-}$  mice had significantly lower tibial cortical thickness ( $0.11 \pm 0.02$  mm vs.  $0.17 \pm 0.01$  mm) and trabecular bone volume ( $11.1 \pm 3.6$  % vs.  $15.8 \pm 3.8$  %) than TNF-Tg mice by  $\mu$ -CT analysis. Finally, TNF dose-dependently inhibited RANKL induced ocl formation from M-CSF-stimulated wt spleen and bone marrow cells ( $420 \pm 44$  vs.  $124 \pm 25$  and  $644 \pm 28$  vs.  $291 \pm 34$  per well). In summary, in the absence of NF- $\kappa$ B2, TNF induces ocl differentiation *in vivo* independent of RANKL-RANK-TRAF6 signaling and more severe arthritis and bone loss in TNF-Tg mice. We conclude that TNF-induced NF- $\kappa$ B2 p100 expression limits TNF and RANKL-mediated ocl differentiation and that p100 deficiency accelerates TNF-induced arthritis and bone loss. Thus, increasing NF- $\kappa$ B2 p100 levels in OCPs should limit bone loss in a variety of erosive bone diseases.

## 1010

**SLP-76 Couples Syk to the Osteoclast Cytoskeleton *in vitro* and *in vivo*.** J. Reeve<sup>1</sup>, W. Zou<sup>1</sup>, Y. Lu<sup>\*1</sup>, G. Koretzky<sup>\*2</sup>, F. P. Ross<sup>1</sup>, S. L. Teitelbaum<sup>1</sup>. <sup>1</sup>Pathology, Washington University in St. Louis, Saint Louis, MO, USA, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, USA.

Optimal bone resorption requires organization of the osteoclast (OC) cytoskeleton into actin rings. These unique structures create a sealing zone between the cell surface and matrix, thereby isolating the resorptive microenvironment from the general extracellular space. Organization of the osteoclast cytoskeleton requires activation of the  $\alpha$ v $\beta$ 3 integrin, which in turn, forms a functional complex with a number of signaling molecules including the tyrosine kinase, Syk, and the guanine nucleotide exchange factor, Vav3. Both Syk and Vav3 are required for integrin-mediated OC spreading, actin ring formation and bone resorption. SLP-adaptor proteins (SLP-76 and BLNK) are Syk substrates in other hematopoietic cells and both contain Vav binding sites. We find that in OCs, integrin-engagement induces both SLP-76 and BLNK phosphorylation in a Syk-dependent manner, raising the possibility that SLP-76 or BLNK links Syk to Vav3 during integrin-mediated cytoskeletal reorganization. While BLNK $^{-/-}$  OCs are normal, SLP-76 $^{-/-}$  OCs exhibit retarded spreading and have decreased adhesion-induced Vav3 phosphorylation. Additionally, the ability of SLP-76 $^{-/-}$  OCs to resorb bone, *in vitro*, is reduced 2.3-fold, as measured by medium CTx. However, unlike Syk null OCs, those lacking SLP-76 retain some bone resorptive capacity *in vitro*, suggesting that another mediator, such as BLNK, also links Syk to the cytoskeleton. We confirmed such is the case by establishing that OCs lacking both BLNK and SLP-76 (DKO) have a substantially greater defect in spreading, actin ring formation and bone resorption than those deficient in only SLP-76. Furthermore, the defective DKO phenotype can be rescued by retroviral reconstitution with WT-SLP-76, but not SLP-76 in which three functional tyrosines are mutated to phenylalanine. Because absence of SLP-76 induces embryonic lethality we explored this issue *in vivo* by generating radiation chimera mice in which SLP-76 or SLP-76 and BLNK are absent in marrow cells. WT radiation chimeras served as control. Following marrow reconstitution, PTH(1-34) was injected to stimulate bone resorption. Confirming dysfunctional OCs, PTH-stimulated serum CTx in chimeric mice lacking only SLP-76, and those deficient in both SLP-76 and BLNK, was reduced 30% and 41%, respectively, relative to control. Collectively, both *in vivo* and *in vitro* studies demonstrate that SLP-76 plays an important role in OC function mainly through its role in cytoskeletal reorganization and is a potential anti-resorptive therapeutic target.

**Cbl-PI3K Interaction Regulates Osteoclast Function, Differentiation and Survival.** N. Adapala\*, M. Barbe, M. Amin\*, F. Safadi, S. Popoff, A. Sanjay. Anatomy and Cell biology, Temple University, Philadelphia, PA, USA.

Cbl is an adaptor protein and an E3 ligase that plays both positive and negative roles in several signaling pathways that affect various cellular functions. Cbl has 22 tyrosines of which Y<sup>731</sup> is unique to Cbl (it is not present on Cbl-b, the other family member) and is phosphorylated by Syk and Src family kinases in response to growth factors, cytokines and integrin activation. Phosphorylated CblY<sup>731</sup> creates a binding site for the p85 regulatory subunit of phosphatidylinositol 3 kinase (PI3K) which also plays an important role in the regulation of actin cytoskeleton and bone resorption by osteoclasts. To further investigate the role of Cbl-PI3K interaction in bone homeostasis, we examined the knock-in mice (Cbl<sup>YF/YF</sup>) in which the PI3K binding site in Cbl is ablated due to the mutation in the regulatory tyrosine. Gross analyses revealed that the Cbl<sup>YF/YF</sup> mice are smaller in size than the wild type (WT) mice. The delayed growth was first apparent 3 days after birth; this trend continued for 2 weeks. The delay in growth occurred simultaneously with a lag in the growth of long bones. Histological analysis of the tibiae from 12 weeks old Cbl<sup>YF/YF</sup> mice showed that the amount of the cancellous bone was increased relative to the tibiae from the age matched WT mice. Histomorphometric analysis of the tibiae demonstrated an increase in the bone volume in the Cbl<sup>YF/YF</sup> mice as compared to the WT mice (WT,  $7.6 \pm 1.10$ ; Cbl<sup>YF/YF</sup>  $12.46 \pm 1.36$ ,  $p=0.001$  vs. WT). Interestingly, although the numbers of osteoclasts as compared to the WT mice were higher in Cbl<sup>YF/YF</sup> mice ( $WT\ 3.5/mm^2 \pm 0.7$ ; Cbl<sup>YF/YF</sup>  $7.5/mm^2 \pm 0.7$ ,  $p=0.029$  vs. WT), serum levels of C-terminal collagen telopeptide (CTX), a marker for osteoclast activity, were three fold less than in the WT mice ( $WT\ 1.8$  ng/ml  $\pm 0.5$ ; Cbl<sup>YF/YF</sup>  $0.66$  ng/ml  $\pm 0.12$ ;  $p=0.023$  vs. WT). This data suggest that Cbl<sup>YF/YF</sup> osteoclasts although more in numbers are inefficient in resorbing bone. Cbl and PI3K have been implicated in RANK-RANKL signaling, therefore to further investigate the role of Cbl-PI3K interaction, we examined *in vitro* osteoclast differentiation and survival in response to RANKL. Non-adherent bone marrow cells were cultured in the presence of 30ng/ml of M-CSF for two days and then with M-CSF and 50 ng/ml of RANKL. Two days after the addition of RANKL, 1.5-fold increase in multinucleated TRAP positive osteoclasts was seen in Cbl<sup>YF/YF</sup> cultures as compared to WT cultures in agreement with the *in vivo* data. Osteoclast survival in response to RANKL (50 ng/ml) was also enhanced 2.5-fold in the Cbl<sup>YF/YF</sup> osteoclasts as compared to WT osteoclasts. Cumulatively, these *in vivo* and *in vitro* results show that binding of Cbl to PI3K modulates osteoclast differentiation, survival and function.

**Wnt5a Regulates Osteoclast Differentiation in Physiological and Pathological Conditions.** K. Maeda<sup>\*1</sup>, Y. Kobayashi<sup>\*2</sup>, A. Ishihara<sup>\*2</sup>, N. Udagawa<sup>3</sup>, I. Takada<sup>\*4</sup>, S. Kato<sup>4</sup>, M. Nishita<sup>\*5</sup>, Y. Minami<sup>\*5</sup>, K. Marumo<sup>\*1</sup>, N. Takahashi<sup>2</sup>. <sup>1</sup>Department of Orthop. Surg., The Jikei Univ., Tokyo, Japan, <sup>2</sup>Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, <sup>3</sup>Department of Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan, <sup>4</sup>Laboratory of Nuclear Signaling, IMCB, Univ. of Tokyo, Tokyo, Japan, <sup>5</sup>Deptment of Physiology and Cell Biology, Kobe Univ., Kobe, Japan.

Wnts exert two types of signals,  $\beta$ -catenin ( $\beta$ -cat)-dependent (canonical) and  $\beta$ -cat-independent (non-canonical) pathways. The canonical pathway has been reported to suppress bone resorption due to up-regulation of OPG expression and suppression of RANKL expression in osteoblasts (OB). However, the roles of the non-canonical pathway in bone resorption are not elucidated. Here, we analyzed the effects of Wnt5a, a non-canonical Wnt ligand, on osteoclast (OC) formation *in vitro* and *in vivo*. (1) Wnt5a enhanced RANKL-induced OC formation from mouse bone marrow macrophages (BMM $\phi$ ). Wnt5a activated c-Jun N-terminal kinase and protein kinase C, but failed to increase the cytoplasmic accumulation of  $\beta$ -cat in BMM $\phi$ . (2) The role of Ror2, a co-receptor of Wnt5a, in OC formation was examined using short hairpin RNA interference. The knockdown of Ror2 abolished the stimulatory effect of Wnt5a on RANKL-induced OC formation in BMM $\phi$  cultures. (3) Semi-quantitative RT-PCR analysis revealed that the expression level of Wnt5a mRNA was much higher in OB than in BMM $\phi$ . (4) Addition of GST-soluble Ror2 (sRor2), a decoy receptor of Wnt5a, to BMM $\phi$  cultures also abolished the stimulatory effect of Wnt5a on RANKL-induced OC formation. sRor2 inhibited  $1\alpha,25$ -dihydroxyvitamin D $_3$  [ $1\alpha,25(OH)_2D_3$ ]-induced OC formation in co-cultures of OB and BMM $\phi$  in a dose-dependent manner. (5) The number of OC in the proximal portion of femora was significantly lower in Wnt5a $^{-/-}$  mice and Wnt5a $^{+/+}$  mice than in wild type (WT) mice at E18.5.  $1\alpha,25(OH)_2D_3$ -induced OC formation was significantly impaired in co-culture of WT-derived BMM $\phi$  and Wnt5a $^{-/-}$ -derived OB. The osteoclast formation was rescued when adding back Wnt5a to Wnt5a $^{-/-}$ -derived OB using a retrovirus expression system. These results suggest that Wnt5a secreted by OB promotes OC formation through Ror2. (6) Wnt5a has been shown to be expressed in rheumatoid arthritis (RA) synovium. We tested whether administration of sRor2 can prevent the bone loss associated with RA, using a type II collagen-induced RA model. Daily injection of sRor2 suppressed joint destruction and inhibited OC formation in the joint of RA mice. Taken together, our results suggest that Wnt5a is involved not only in physiological bone remodeling but also in pathological bone loss in RA.

## 1013

**$\beta$ -catenin Directly Binds to a Specific Intracellular Domain of PTH/PTHrP Receptor and Regulates the Signaling in Chondrocytes during Endochondral Ossification.** F. Yano<sup>1</sup>, U. Chung<sup>1</sup>, T. Ikeda<sup>1</sup>, Y. Kawasaki<sup>1</sup>, H. Kawaguchi<sup>1</sup>, H. A. W. Tawfeek<sup>2</sup>, M. J. Mahon<sup>2</sup>, G. V. Segre<sup>2</sup>, N. Ogata<sup>1</sup>.  
<sup>1</sup>Sensory & Motor System Medicine, Tissue Engineering, Univ. of Tokyo, Tokyo, Japan, <sup>2</sup>Endocrine Unit, MGH, Boston, MA, USA.

Although the PTH/PTHrP receptor (PTH1R) is known to be coupled to G $\alpha$ s and G $\alpha$ q pathways, involvement of other molecules that interact with the intracellular C-terminal domains in the signal transduction, cell surface localization, internalization, and recycling has been suggested. The present yeast two-hybrid assay to search for proteins that interact with the C-terminus has identified  $\beta$ -catenin, a critical regulator of cytoskeleton and canonical Wnt signaling. Further two-hybrid assays by deletion and mutagenesis in the C-terminus revealed that the region of amino acid sequence between L582 and W587 was essential for binding with  $\beta$ -catenin. Stably transfected GFP-labeled PTH1R in HEK293 cells was shown to be co-localized with endogenous  $\beta$ -catenin on the plasma membrane by immunocytochemistry. Immunoprecipitation / immunoblotting confirmed the physical association between PTH1R and  $\beta$ -catenin, which was decreased by PTH (1-34) treatment in the cells. The association was further shown to require binding of scaffolding peptides Axin and APC with the complex. The cAMP accumulation induced by PTH treatment was decreased by overexpression of constitutively-active  $\beta$ -catenin, whereas it was increased by knockdown of  $\beta$ -catenin by the siRNA. In addition, the cells overexpressing a PTH1R mutant with deletion of the  $\beta$ -catenin-binding region above enhanced the cAMP accumulation under the PTH stimulation. Finally, since PTH/PTHrP is known to be a crucial regulator of endochondral ossification by inhibiting hypertrophic differentiation of growth plate chondrocytes, we examined the involvement of the PTH1R /  $\beta$ -catenin signaling in chondrocyte differentiation. Immunohistochemical analyses of the mouse growth plate revealed that PTH1R and  $\beta$ -catenin, as well as Axin and APC, were co-localized mainly in the pre-hypertrophic chondrocytes. In cultured mouse chondrogenic ATDC5 cells transfected with luciferase-reporter gene construct containing the promoter of type X collagen (COL10), a representative marker of hypertrophic differentiation of chondrocyte, suppression of the COL10 transcriptional activity by PTH (1-34) treatment was abolished by the overexpression of constitutively active  $\beta$ -catenin. In addition, a decrease of endogenous COL10 mRNA level after the PTH treatment in ATDC5 cells was significantly restored by the constitutively active  $\beta$ -catenin overexpression. These lines of evidence provide a novel mechanism regulating the PTH/PTHrP signal through direct interaction of  $\beta$ -catenin with the C-terminus of the receptor in chondrocytes.

## 1014

**PTH Signaling through LRP5/6 in Osteoblasts.** M. Wan<sup>1</sup>, C. Yang<sup>1</sup>, X. Wu<sup>1</sup>, J. Li<sup>1</sup>, H. Yuan<sup>1</sup>, X. He<sup>2</sup>, S. Nie<sup>1</sup>, C. Chang<sup>1</sup>, X. Cao<sup>1</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Harvard Medical School, Boston, MA, USA.

Recent studies demonstrated that PTH increased the expression level of  $\beta$ -catenin, a key component of the canonical Wnt pathway and a positive regulator of bone metabolism. Here we characterize a novel pathway through which PTH stabilizes  $\beta$ -catenin in osteoblasts. We found that PTH stimulated  $\beta$ -catenin-responsive luciferase reporter and enhanced the cytosolic abundance of  $\beta$ -catenin in UMR106 cells and mouse primary preosteoblasts. In both rat and mouse models, PTH single-dose treatment stimulated  $\beta$ -catenin expression within hours in most of the osteoblasts at trabecular bone. Importantly, treatment of preosteoblasts with conditioned medium containing Fz8CRD, a competitive inhibitor of Wnt, did not inhibit PTH-induced  $\beta$ -catenin stabilization. The results suggest the effect of PTH is not through sensitizing Wnt-stimulated signaling. To determine the mechanism underline this phenomenon, we found that PTH induced the formation of ternary complex of PTH ligand, PTH1R and LRP5/6 by immunoprecipitation assays, in vitro pull down assays and photo-bleaching based FRET approach. PTH-induced recruitment of LRP5/6 resulted in rapid phosphorylation LRP5/6, which is required for the subsequent binding of Axin to LRP5/6. In rats, PTH stimulated phosphorylation of LRP5/6 in osteoblasts at trabecular bone in 30 minutes and peaked at 8 hours after single-dose injection. We then examined the effect of sclerostin, an inhibitor of LRP5/6, on PTH-activated LRP5/6- $\beta$ -catenin signaling. Treatment of the cells with conditioned medium containing sclerostin dramatically inhibited PTH-induced LRP6/axin binding, indicating sclerostin is also an antagonist for PTH signaling. Interestingly, PTH, but not Wnt3a, single-dose treatment in mice suppressed the expression of sclerostin in osteocytes. The results implicate that PTH-suppressed sclerostin serves as a positive feed back for PTH-activated  $\beta$ -catenin signaling pathway. Mouse models of long term PTH administration were also analyzed. Levels of both  $\beta$ -catenin and phosphorylated LRP5/6 were significantly increased in the osteoblasts of trabecular bone sections when PTH was intermittently administered, but neither  $\beta$ -catenin nor phosphorylated LRP5/6 level was stimulated with continuous PTH treatment. These findings reveal a novel signaling pathway of PTH and also provide alternative interpretations of the effects of LRP5/6 and  $\beta$ -catenin on bone formation, which until now have been considered to affect the canonical Wnt signaling pathway exclusively.

**Parathyroid Hormone Stimulates Hematopoiesis and Increases Survival in Irradiated Mice.** Z. Zhang<sup>1</sup>, B. Li<sup>1</sup>, C. Fu<sup>1</sup>, X. Wang<sup>1</sup>, J. Tong<sup>1</sup>, D. Miao<sup>2</sup>, M. Qiu<sup>3</sup>. <sup>1</sup>Public Health School, Suzhou University, Suzhou, China, <sup>2</sup>Institute of Dental Research, Nanjing Medical University, Nanjing, China, <sup>3</sup>Department of Endocrine, General Hospital, Tianjing Medical University, Tianjing, China.

The mechanisms of bone and blood formation have traditionally been viewed as distinct, unrelated processes, but evidence suggests that they are interrelated. Based on observations that hematopoietic precursors reside close to endosteal surfaces, it was hypothesized that osteoblasts are a key component in the regulation of the hematopoietic stem cell (HSC) niche, and it has been shown that osteoblasts produce many factors essential for the survival, renewal, and maturation of hematopoietic stem cells (HSCs). It has been reported that hematopoiesis is severely altered in mice with an induced osteoblast deficiency. Parathyroid hormone (PTH) has been approved for the treatment of osteoporosis because it is highly effective stimulating bone formation and reducing fractures. In this study, we sought to determine whether PTH administration could enhance the hematopoietic recovery and survival of irradiated mice. C57Bl/6 male mice were exposed to sublethal and lethal doses of irradiation and human PTH (1-34) (80microgram/kg) was subsequently injected intraperitoneally once daily for four weeks in these mice. Whole blood was collected from the tails of mice on sequential days following irradiation and the blood cell numbers were determined by a hematocyte counter. Bone marrow progenitors were studied by determining colony forming units and hematopoietic stem cells were studied using the exogenous spleen colony assay. Histology and immunohistochemistry were also performed in tibia. PTH treatment facilitated the recovery of circulating white blood cell and platelet counts following radiation exposure. PTH-treated mice also demonstrated accelerated bone marrow cellular recovery, radioprotection of bone marrow progenitors and enhanced stem cell survival following irradiation compared with controls. In addition, increased staining of alkaline phosphatase, N-cadherin and osteopontin were found in sections of tibias from PTH treated mice and significantly increased mRNA expression of SDF-1 and VEGF in femurs. Remarkably, 60% of PTH-treated mice survived 1 month following 10Gy  $\gamma$ -ray exposure, which was 100% lethal in vehicle-treated mice. These data suggest that PTH, using a dosing schedule known to increase osteoblasts, can improve the hematopoietic recovery and survival of irradiated mice. PTH alteration of the bone marrow microenvironment might underly this effect.

**Knockout of the Parathyroid Hormone -Related Protein (PTHrP) Gene in Breast Cancer Cells Inhibits Tumor Progression and Metastatic spread in vivo: Modulation of Cell proliferation, Apoptosis and Angiogenesis Markers.** J. Li<sup>1</sup>, A. Karaplis<sup>2</sup>, P. M. Siegel<sup>3</sup>, W. J. Muller<sup>3</sup>, R. Kremer<sup>1</sup>. <sup>1</sup>Calcium Research Laboratory, McGill University, Montreal, QC, Canada, <sup>2</sup>Sir Mortimer B. Davis Jewish General Hospital, Montreal, QC, Canada, <sup>3</sup>Biochemistry, McGill University, Montreal, QC, Canada.

Previous studies suggest that PTHrP may promote growth and invasion of tumor cells. In this study, mice carrying a conditional PTHrP allele were crossed with the PyVMT transgenic mouse mammary tumor model and then with a separate transgenic strain expressing Cre in the mammary epithelium (MMTV-Cre). Homozygous (PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup>), heterozygous (PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup>) and control (PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>-</sup> and PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup>) animal models were generated. Tumors were harvested, minced trypsinized and 1X10<sup>6</sup> cells injected into mammary fat pads of syngeneic 5-week old FVB mice non-tumor bearing mice of the same strain. Tumor growth overtime of PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup> cells and of PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup> cells was reduced by 85% (P<0.01) and 45% (P<0.01) respectively as compared to tumor growth of control cells. Similar results were observed with cells isolated from PyVMT-PTHrP<sup>fllox/lox</sup>, PyVMT-PTHrP<sup>fllox/lox</sup> tumors, transfected with adeno-Cre GFP or adeno-GFP selected by flow cytometry and reimplanted into the mammary fat pad. Markers of tumor progression including Neu, cyclin D1 and Ki67 were reduced by over 80% and 40% respectively in animals transplanted with homozygous and heterozygous cells as compared to control cells. In addition, AKT signaling was markedly altered in both homozygous and heterozygous animals with a significant inhibition of AKT1 (30%) and stimulation AKT2 (50%). Finally, a strong inhibition of angiogenesis (over 50%) in adjacent blood vessels and a strong increase (3 fold) in apoptosis of tumor cells were observed in transplanted knockout tumors as compared to controls. We also compared metastatic spread to lungs independent of primary tumor growth by comparing animals with similar tumor size ( $\approx 2.3$  mm<sup>3</sup>) sacrificed at 7 weeks, 11 weeks and 13 weeks post-tumor implantation in animals transplanted with control PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup> and heterozygous PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup> and homozygous PyVMT-PTHrP<sup>fllox/lox</sup>-Cre<sup>+</sup> cells respectively. At sacrifice 100% control, 42% heterozygous and 14% homozygous animals had metastatic spread to lungs. Overall, our study demonstrates that PTHrP ablation strongly inhibits breast cancer progression through activation/inactivation of key signaling events of the cell machinery. These data suggest that PTHrP maybe a useful target to inhibit both breast tumor growth and its metastatic spread.

**Increased Bone Volume and Correction Of HYP Mouse Hypophosphatemia in the Klotho/HYP Mouse.** C. Brownstein<sup>\*1</sup>, C. Gundberg<sup>\*2</sup>, R. Lifton<sup>\*1</sup>, T. Carpenter<sup>\*3</sup>. <sup>1</sup>Genetics, Yale University, New Haven, CT, USA, <sup>2</sup>Orthopaedics & Rehabilitation, Yale University, New Haven, CT, USA, <sup>3</sup>Pediatrics, Endocrinology, Yale University, New Haven, CT, USA.

Inactivating mutations of PHEX, the disease-causing gene in X-linked hypophosphatemia, result in increased circulating FGF23, a bone-derived phosphaturic factor. FGF23 is linked to Klotho, which converts FGFR1 into a specific receptor for FGF23. Knockout of Klotho (the Klotho mouse) results in a complex bone phenotype and hyperphosphatemia (Kuro-o, 1997), in distinct contrast to XLH.

We examined the effects of deleting both Klotho and PHEX by creating a double knockout (DKO) mouse line. Inactivating mutations in both Klotho and PHEX resulted in correction of low serum phosphate levels seen in PHEX null (HYP) mice, indicating that Klotho is epistatic to PHEX (Klotho  $12.5 \pm 1.9$  mg/dl, HYP  $3.9 \pm 1.3$  mg/dl, DKO  $11.6 \pm 2.2$  mg/dl). FGF23 levels remained elevated in all groups except wild-type (Klotho  $2688 \pm 102$  pg/ml, HYP  $1620 \pm 446$  pg/ml, DKO  $1533 \pm 35$  pg/ml), indicating that Klotho is necessary for FGF23 to have phosphaturic activity. 1,25 dihydroxyvitamin D (1,25D) levels in the DKO were indistinguishable from Klotho mice (Klotho  $173 \pm 21$  pg/ml, HYP  $27 \pm 19$  pg/ml, DKO  $195 \pm 81$  pg/ml), demonstrating that Klotho is a necessary mediator of FGF23's effect on lowering 1,25D. Moreover, the Klotho null phenotype and decreased lifespan persisted in DKO.

At age 6 weeks, PINP levels were dramatically reduced in DKO mice (Klotho,  $222 \pm 79$  ng/ml, HYP  $150 \pm 140$  ng/ml, wt  $432 \pm 217$  ng/ml, DKO  $22 \pm 12$  ng/ml;  $p = 0.013$ , wt vs. DKO). The addition of Klotho insufficiency resulted in correction of hypomineralization seen in HYP mice (trabecular apparent density: HYP  $63 \pm 88$  mg/ccm vs. DKO  $503 \pm 59$  mg/ccm, Klotho  $352 \pm 70$  mg/ccm, wt  $233 \pm 37$  mg/ccm,  $p < 0.015$  for all comparisons). Cortical porosity in DKO mice was improved in comparison to HYP (DKO  $2.6 \pm 1.7\%$ , HYP  $7.8 \pm 4.3\%$ ,  $p = 0.029$ ) and indistinguishable from Klotho (Klotho  $1.4 \pm 1.2\%$ , wt  $0.2 \pm 0.3\%$ ). Finally, DKO mice had greater trabecular bone volume (BV/TV) than all groups (DKO  $56.2 \pm 6.3\%$ , Klotho  $32.5 \pm 10.3\%$ , HYP  $8.6 \pm 7.7\%$ , wt  $21.4 \pm 3.4\%$ ;  $p < 0.004$ ); the overabundant unmineralized osteoid typical of HYP mouse appears to mineralize with the additional deletion of the Klotho gene, resulting in an extremely dense skeletal phenotype, moreso than in WT or even Klotho null mice. Paradoxically, by the time this phenotype is evident there is biochemical evidence of low bone formation.

**Ablation of the Galnt3 Gene in Mice Leads to Low Circulating Fgf23 Concentrations and Hyperphosphatemia Despite Increased Fgf23 Gene Expression.** S. Ichikawa<sup>\*1</sup>, A. H. Sorenson<sup>\*1</sup>, T. A. Fritz<sup>\*2</sup>, A. Moh<sup>\*3</sup>, D. S. Mackenzie<sup>\*1</sup>, S. L. Hui<sup>\*1</sup>, M. J. Econs<sup>\*4</sup>. <sup>1</sup>Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Section on Biological Chemistry, NIDDK, National Institutes of Health, Bethesda, MD, USA, <sup>3</sup>Microbiology and Immunology, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>4</sup>Medicine and Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA.

Familial tumoral calcinosis is characterized by ectopic calcifications and hyperphosphatemia. Three genes associated with this disease are fibroblast growth factor 23 (FGF23), Klotho (KL), and UDP-N-acetyl-alpha-D-galactosamine:polypeptide N-acetylgalactosaminyltransferase 3 (GALNT3). GALNT3 encodes an enzyme that O-glycosylates FGF23 in a furin-like convertase recognition sequence, thereby preventing proteolytic processing of FGF23 and allowing secretion of intact FGF23. Ablation of

Fgf23 and Kl in mice results in severe hyperphosphatemia as well as vascular and soft-tissue calcifications. In this study, we generated mice deficient in Galnt3. Mice with a homozygous deletion of Galnt3 were hyperphosphatemic as seen in patients with tumoral calcinosis. Galnt3-deficient mice also exhibited inappropriately normal 1,25-dihydroxyvitamin D [1,25(OH)<sub>2</sub>D] level and decreased alkaline phosphatase activity. In response to hyperphosphatemia, Galnt3-deficient mice had significantly increased Fgf23 expression in the bone, but decreased circulating intact Fgf23 levels, compared to wild-type and heterozygous mice. Renal expression of sodium-phosphate co-transporter IIa and Kl were also elevated in Galnt3-deficient mice. Histological and radiographic analyses of homozygous mice revealed no apparent calcifications or abnormalities in the tissues evaluated. Interestingly, Galnt3-deficient males, but not females, showed growth retardation, infertility, and significantly increased bone mineral density (BMD). In summary, ablation of Galnt3 enhanced expression of the Fgf23 gene, but impaired secretion of Fgf23, leading to decreased circulating Fgf23 and hyperphosphatemia. Our findings provide the evidence that Galnt3 plays an essential role in proper secretion of Fgf23 in mice.

**Histomorphometric Changes by Teriparatide in Alendronate Pre-treated Women with Osteoporosis.** J. J. Stepan<sup>1</sup>, H. Dobnig<sup>2</sup>, D. B. Burr<sup>3</sup>, J. Li<sup>4</sup>, Y. L. Ma<sup>\*5</sup>, A. Sipos<sup>\*5</sup>, H. Petto<sup>\*5</sup>, I. Pavo<sup>5</sup>. <sup>1</sup>Institute of Rheumatology, Charles University Faculty of Medicine, Prague, Czech Republic, <sup>2</sup>Internal Medicine, Medical University, Graz, Austria, <sup>3</sup>Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>4</sup>Department of Biology, Indiana University-Purdue University, Indianapolis, IN, USA, <sup>5</sup>Lilly Research Laboratories, Indianapolis, IN, USA.

Teriparatide (TPTD) treatment increases trabecular bone volume similarly in postmenopausal women with osteoporosis irrespective of alendronate (ALN) pre-treatment or being treatment naïve (TN). Our aim was to investigate the effect of TPTD on osteoid matrix production and primary mineralization in patients after long-term ALN treatment. Sixty-six postmenopausal women with osteoporosis (mean age of 68.0 years, 62% with prevalent fractures) entered this prospective, non-randomized study and started with 20µg/day subcutaneous TPTD: thirty-eight stopped previous ALN treatment (mean duration of 63.6 months) while twenty-eight were previously TN. From 45 patients valid biopsies were available at baseline and after 24-month TPTD administration. At baseline, when compared with TN patients, the indices of matrix formation (osteoid perimeter) and primary mineralization (mineralizing surface) were significantly lower in the ALN group. After switching to TPTD, the indices of matrix formation and bone turnover increased and reached a similar level in both groups, resulting in a more marked percentage increase in the ALN group. Mineralizing surface also increased in both groups, however even a greater percentage increase in the ALN group could not fully compensate for the suppressed baseline. Consequently, after TPTD treatment, mineralizing surface was still significantly less in patients pre-treated with ALN (Table). Our results support the finding of a similar trabecular bone volumetric increase after 24 months by teriparatide irrespective of ALN pre-treatment driven by greater percentage changes of elevated bone formation activities.

	Baseline		After treatment with TPTD		Median of % Change from Baseline per Patients	
	Treatment naïve (n = 16)	Alendronate pre-treated (n = 29)	Treatment naïve (n = 16)	Alendronate pre-treated (n = 29)	Treatment naïve (n = 16)	Alendronate pre-treated (n = 29)
3D Bone volume/tissue volume (%)	18.1	18.6	20.3	20.5	17.8 <sup>b</sup>	28.4 <sup>b</sup>
Osteoid perimeter/trab.perim. (%)	6.24	3.96 <sup>a</sup>	11.29	9.82	67.5 <sup>b</sup>	230.9 <sup>b</sup>

Changes in bone mineral density (BMD) may only account for 30% of fracture risk reduction following therapy. Other factors including trabecular micro-architecture contribute to fracture risk. High resolution MRI (MicroMRI), examines trabecular microstructure and provides an index of the trabecular rods and plates. To examine trabecular changes in microarchitecture and conventional BMD (trabecular and cortical combined) in postmenopausal women with osteoporosis on antiresorptive versus anabolic therapy, we recruited 10 women on an antiresorptive bisphosphonate (risedronate, 35mg once weekly) and 10 women who just initiated anabolic treatment with teriparatide (20 mcg subcutaneous daily). The mean age was 70 years. Outcomes included BMD by DXA of the spine, total hip and right ultra distal radius (UD radius). MicroMRI was examined using a right bird cage wrist coil with a Sigma 1.5 Tesla MRI scanner and analyzed by MicroMRI Inc. (Philadelphia, PA). MicroMRI indices included: BV/TV (bone volume/total volume), Surf (topological surface density), Curv (topological curve density), Surf/Curv (surface to curve ratio, number of platelike to rodlike trabeculae, higher values indicate intact trabeculae); Erosion Index =(ratio of topological parameters that decrease with improvement).

Table: Percent Change Over 12 Months (Mean ± SEM)

Site	Risedronate (%)	Teriparatide (%)	Between Rx differences (p-value)
PA Spine BMD	0.6 ± 0.9	6.8 ± 1.8**	0.008
Total Hip BMD	-0.1 ± 0.6	3.3 ± 0.9 **	0.009
UD Radius BMD	0.9 ± 1.2	0.9 ± 1.0	0.968
BV/TV	7.3 ± 3.0*	1.4 ± 1.6	0.090
Surf	10.5 ± 4.0*	1.1 ± 3.1	0.078
Surf/Curv	14.8 ± 5.7*	5.3 ± 6.1	0.276
Erosion Index	-13.3 ± 3.2**	-2.4 ± 5.8	0.129

\*p < 0.05, \*\*p < 0.01 within group change

There were no significant differences in baseline BMD or microMRI indices between the 2 groups. After 12 months of therapy, indices of microMRI suggest improvement with an antiresorptive despite maintenance of conventional BMD. Anabolic therapy significantly improved hip and spine BMD without change in wrist BMD or microMRI trabecular indices. We conclude that measures of microMRI provide additional information about changes in structural integrity while on therapy that are not demonstrable with conventional BMD. New bone formation from teriparatide may require time to mineralize before structural changes are observed on microMRI. Further studies are needed to determine how these structural changes lead to fracture reduction.

**The A Allele at Valine80 of the CYP19 Gene Is a Risk factor for Aromatase Inhibitors Associated Bone Loss.** N. Napoli, C. Ma\*, A. Rastelli\*, J. Yarramaneni\*, G. Moskowitz\*, M. Ellis\*, R. C. Villareal. Medicine, Washington University School of Medicine, St Louis, MO, USA.

Third generation aromatase inhibitors (AIs) have been reported to cause bone loss and increase the incidence of fractures. Genetic polymorphisms of the CYP19 gene are associated with differences in bone mineral density (BMD) and bone loss and even response to estrogen therapy. The objective of this study was to determine if polymorphisms of the CYP19 gene are also important determinants of bone loss in postmenopausal women taking AIs for breast cancer.

BMD was measured by dual energy x-ray absorptiometry, serum estradiol by radioimmunoassay, interleukin-6 (IL-6) and urinary N-telopeptide (NTx) by Elisa. DNA sequencing for 5 polymorphisms in the CYP19 gene were done by Pyrosequencing (Biotage AB, Uppsala, Sweden).

To date, 130 postmenopausal women with ER+ breast cancer (stage I-IIIa) participated in the study. In the 80 women who came for the 6-month follow-up, we found a significant reduction in estradiol (13.0±0.7 vs. 8.9±0.72 pg/ml, p<0.001) and a significant increase in IL-6 levels. A trend for an increase in urinary NTx (nmolBCE/mmolCre) in the 38 women with available urine samples (51.3±6.1 vs. 65.6±6.2, p=0.10) was also noted. Analysis of BMD (% change) at the 6-month follow-up showed minor bone loss in the lumbar spine, femoral neck and total hip (-1.02±0.4, -1.25±0.4, and 0.71±0.3, respectively). However, analysis according to the G/A base change at Valine80 showed significant bone loss in women carrying the A allele compared to those with the GG genotype in the femoral neck (AA=-2.75±0.9, AG=-1.37±0.6 and GG=0.66±0.8, p=0.02) and in the total hip (AA+AG=-1.1±0.4, GG=0.32±0.6, p<0.05). Moreover, IL-6 levels were significantly increased among the women carrying the AA genotype (AA= +528.2±132.8, AG=+90.9±76.7, and GG=+23.3±118.8, p=0.01). In the 45 women who returned for their one-year follow-up, a trend for greater bone loss in the femoral neck was once again observed (AA=-4.29±1.38, AG=-1.21±0.99, and GG=-0.12±1.37, p=0.08).

In conclusion our data suggest that patients with the AA genotype at Valine80 are at increased risk for AI-induced bone loss. This bone loss is perhaps mediated by the increase in proinflammatory cytokines resulting from profound estrogen deprivation. This subset of patients may represent as the best candidates for bone loss prevention at the initiation of AIs.

## 1022

**What Proportion of Older Women Would Receive Drug Treatment Under the New NOF Guidelines?** M. G. Donaldson<sup>1</sup>, P. M. Cawthon<sup>1</sup>, J. T. Schousboe<sup>2</sup>, K. E. Ensrud<sup>3</sup>, B. C. Taylor<sup>3</sup>, J. A. Cauley<sup>4</sup>, T. A. Hillier<sup>5</sup>, D. M. Black<sup>6</sup>, D. C. Bauer<sup>6</sup>, S. R. Cummings<sup>1</sup>. <sup>1</sup>San Francisco Coordinating Center, San Francisco, CA, USA, <sup>2</sup>Park Nicolette Health Services, Minneapolis, MN, USA, <sup>3</sup>Univ. of MN and CCDOR VA Medical Center, Minneapolis, MN, USA, <sup>4</sup>Univ of Pittsburgh, Pittsburgh, PA, USA, <sup>5</sup>Kaiser Permanente Center for Health Research, Portland, OR, USA, <sup>6</sup>Univ of California San Francisco, San Francisco, CA, USA.

The new National Osteoporosis Foundation (NOF) guidelines include drug treatment recommendations based on the WHO 10-year probabilities of hip and other osteoporotic fractures. The NOF recommends drug treatment for postmenopausal women aged 50 and older who have any of the criteria listed in the Table. It is not known what proportion of women aged 65 years and older would be recommended for drug treatment under those guidelines.

We used data from the Study of Osteoporotic Fractures (SOF) a prospective study of community-dwelling Caucasian women recruited from 4 US communities from population-based listings and mass mailings. The participants were recruited in 1986-7 before widespread publicity about osteoporosis and were not recruited on the basis of any risk factors for osteoporosis. Participants were  $\geq 65$  years (n=6025, mean age=71). Characteristics of the SOF participants are similar to those of white women  $\geq 65$  in the population-based NHANES III survey: for example, SOF participants had slightly higher FN BMD (0.65 vs 0.62 g/cm<sup>2</sup>) and similar history of fracture (17 vs 16%). We used baseline data to determine the proportion of women who would be recommended for drug treatment based on the NOF guidelines (except criterion A only history of hip fracture was included and E for which data were unavailable).

NOF guidelines would recommend 73% (n=4374) of women  $\geq 65$  years in SOF for drug treatment. Among those over 75 years, 94% would be recommended for treatment. Applying criterion B alone and D alone would recommend 43.6% and 57.1% of women respectively for drug treatment.

The NOF guidelines recommend drug treatment for about 73% of Caucasian women  $\geq 65$  years, and more than 90%  $\geq 75$  years. These results may underestimate the proportion of women recommended for drug treatment because history of clinical vertebral fracture and secondary causes of osteoporosis were not included. Before promoting widespread drug treatment of elderly women, it would be important to confirm the evidence and assumptions that underlie these recommendations.

NOF drug treatment criteria and proportion of women selected for treatment	
A: hip fracture	1.6 (99)
B: T-score $\leq -2.5$ at femoral neck, total hip or spine*	42.3 (2560)
Osteopenia (low bone mass)†: AND:	
C: other prior fractures	12.8 (769)
D: U.S. WHO 10-yr probability of:	
hip fracture $\geq 3\%$	9.6 (576)
any major osteoporosis-related fracture $\geq 20\%$	6.1 (370)
Total recommended for drug treatment	73% (4374)

## 1023

**Incorporating FRAX™ Algorithms in Models of Cost-effectiveness.** O. Ström<sup>\*1</sup>, F. Borgström<sup>\*1</sup>, E. McCloskey<sup>2</sup>, O. Anders<sup>\*2</sup>, H. Johansson<sup>\*2</sup>, J. A. Kanis<sup>2</sup>. <sup>1</sup>3/Innovus, Stockholm, Sweden, <sup>2</sup>WHO Collaborating Centre for Metabolic Bone Diseases, Sheffield, United Kingdom.

In modelling cost-effectiveness of osteoporosis treatments, fracture risk has generally been calculated with risk adjustments based on age, bone mineral density and previous fractures. The use of these components alone in case finding neglects other clinical risk factors (CRFs) which contribute to fracture risk and thus to cost-effectiveness. The aim of this study was to merge a previously published cost-effectiveness model (<http://www.iofbonehealth.org>) with a fracture risk algorithm (FRAX™) based on CRFs in individual patients.

The cost-effectiveness model based on Swedish data was merged with the FRAX™ fracture risk algorithm. The algorithm was used to calculate the individual risk contribution of the different CRFs, which were; prior fragility fracture, parental history of hip fracture, high alcohol consumption, rheumatoid arthritis, cigarette smoking and use of glucocorticoids. The algorithm produced relative risks for hip fractures and major non-hip fractures, which was used for vertebral, wrist and other fractures. Simulations comprised different combinations of CRFs, and a 5-year treatment costing 742 \$/year that reduced the risk of all fracture types by 35%. Residual linearly declining effect was assumed for 5 years.

The base-case scenario was a woman with T-score of -2.5 SD and no other CRFs. As seen in Table 1, the addition of any single CRF in 60, 70 and 80 year old women had a marked impact on the cost-effectiveness of treatment vs. no treatment.

The FRAX™ algorithm in combination with the cost-effectiveness model facilitates and improves estimation of the cost-effectiveness in patients with different combinations of clinical risk factors.

**Table 1. Cost/QALY gained in women with a T-score of -2.5 and different single CRFs**

Scenario	Cost/QALY (\$)		
	60 years	70 years	80 years
Base-case (T-score -2.5)	66,161	30,796	Cost-saving
Prior fracture	32,270	9,367	Cost-saving
Parental fracture history	40,880	354	Cost-saving
Current smoker	43,800	9,728	Cost-saving
Glucocorticoid use	32,388	3,850	Cost-saving
Secondary osteoporosis	45,693	14,390	Cost-saving
Alcohol (>3 units/day)	45,238	12,980	Cost-saving

**Incremental Costs Associated with Selected Skeletal Fractures.** M. L. Kilgore<sup>\*1</sup>, M. A. Morrissey<sup>\*1</sup>, D. Becker<sup>\*1</sup>, L. C. Gary<sup>\*1</sup>, H. Yun<sup>\*1</sup>, J. R. Curtis<sup>2</sup>, K. G. Saag<sup>2</sup>, R. Matthews<sup>\*3</sup>, W. Smith<sup>\*3</sup>, E. Delzell<sup>\*3</sup>. <sup>1</sup>Health Care Organization and Policy, UAB School of Public Health, Birmingham, AL, USA, <sup>2</sup>Medicine, UAB School of Medicine, Birmingham, AL, USA, <sup>3</sup>Epidemiology, UAB School of Public Health, Birmingham, AL, USA.

The purpose of this study is to estimate the costs of care for fractures that are or could be related to osteoporosis.

We used a national 5% sample of Medicare beneficiaries from 1999 to 2005. The data were structured longitudinally, with patient months as the units of observation. Time was indexed relative to incident hip, spine, forearm, leg, clavicle, pelvis, and humerus fractures identified using ICD-9 codes paired with physician service or inpatient claims. Costs were estimated using payments from all sources for Medicare covered services, expressed in 2007 dollars. Costs were characterized as directly related to fractures if the primary diagnosis code associated with the service was for the fracture. We examined patterns of costs over time relative to fractures and calculated associated incremental costs as the difference between payments for services subsequent to the fracture and average costs in the period preceding the fracture.

The pattern of costs relative to the month of a pelvic fracture diagnosis is similar to that for others and is presented as an example (figure).

Costs increased precipitously in the index month, then declined below baseline levels (reflecting zero costs for decedents).

The table shows average costs associated with fractures, incremental costs (change from baseline), and the direct fracture treatment costs (claims with a primary fracture diagnosis). Skeletal fractures were associated with substantial increases in costs for health services, most of which accrued in the first six months following the fracture.

	Number of Fracture Types and Associated Costs					Incremental Costs*	Direct Costs†
	Number	Baseline	6 Months	Year 1	Year 2		
Hip	90,039	7,823	36,180	41,275	8,188	28,357	14,045
Spine	69,867	7,643	19,542	25,000	9,246	11,899	2,913
Distal Forearm	37,998	4,955	12,903	17,008	7,905	7,948	1,601
Pelvis	27,661	8,750	26,873	32,284	8,755	18,123	3,229
Clavicle	8,125	7,556	18,007	24,043	8,627	10,451	1,073
Humerus	37,342	6,720	19,878	24,773	8,471	13,158	3,909
Forearm	47,833	5,087	13,340	17,537	8,009	8,253	1,823
Leg	43,475	7,897	30,192	35,282	8,599	22,295	4,002

\*Difference between first six months and baseline.

†Associated with a primary fracture diagnosis, first six months.

The higher proportion of costs were for health services not directly connected to fracture treatment; direct costs of care for a pelvis fracture, for example, accounted for only 17.8% of the incremental increase in average costs in the first six months following a fracture compared with baseline costs.

## 1025

**Bisphosphonates and Osteoporotic Fractures in Highly Compliant/Persistent Postmenopausal Women.** M. M. Wilkes<sup>\*1</sup>, N. J. Roberta<sup>\*1</sup>, W. W. Chan<sup>\*2</sup>, E. M. Lewiecki<sup>3</sup>. <sup>1</sup>Hygeia Associates, Grass Valley, CA, USA, <sup>2</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, <sup>3</sup>New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

**Purpose:** Randomized clinical trials have demonstrated fracture risk reduction by bisphosphonate treatment in women with postmenopausal osteoporosis. The extent to which those results apply to routine clinical practice has remained uncertain. Recent observational studies have investigated fracture reduction by bisphosphonate using large clinical databases generated in the course of routine practice. These studies have created an opportunity to compare the magnitude of apparent treatment benefit in randomized trials with that in day-to-day clinical medicine. To capitalize on this opportunity, a cross-design synthesis has been conducted of placebo-controlled randomized trials and of observational studies assessing treatment effects in highly compliant/persistent patients.

**Methods:** Eligible studies of both types evaluated the effects of bisphosphonates on clinical fractures in women with postmenopausal osteoporosis. Standard meta-analytic methodology was applied. Twenty randomized trials with 44878 total patients and 7 observational studies with 107560 total patients were included in the meta-analysis.

**Results:** Data pertaining to all clinical fractures were available from 7 of the included randomized trials with 23769 total patients and 5 included observational studies with 68928 total patients. The pooled odds ratio (OR) for all clinical fractures in the randomized trials of 0.762 and 95% confidence interval (CI) of 0.680-0.855 indicated significant fracture reduction by bisphosphonate. The magnitude of the effect in the observational studies was closely similar (pooled OR, 0.776; CI, 0.721-0.835). The small difference in pooled OR between the two categories of studies was not statistically significant ( $p = 0.86$ ). The pooled OR for all 12 studies with data for all clinical fractures (0.763; CI, 0.715-0.815) indicated a significant 24% fracture reduction. The odds of nonvertebral, vertebral and hip fractures were also significantly lowered by bisphosphonate treatment both in randomized trials and observational studies.

**Conclusions:** Bisphosphonate treatment effects in randomized trials and observational studies coincided closely. These results suggest that the anti-fracture benefits of bisphosphonates among highly compliant/persistent patients in the "real world" are similar to those previously documented in randomized trials.

## 1026

**Subtrochanteric And Diaphyseal Femur Fractures in Patients Treated with Alendronate: A Register-Based National Cohort Study.** B. Abrahamsen<sup>1</sup>, P. Eiken<sup>\*2</sup>, R. Eastell<sup>3</sup>. <sup>1</sup>Department of Medicine F, Copenhagen University Hospital, Hellerup, Denmark, <sup>2</sup>Department of Cardiology and Endocrinology, Hillerød Hospital, Hillerød, Denmark, <sup>3</sup>Metabolic Bone Centre, Northern General Hospital, Sheffield, United Kingdom.

Recent reports (*NEJM* 2008;358:1303) have found alendronate(*aln*) use to be common in patients with subtrochanteric or proximal diaphyseal fracture of the femur, but it is unknown if these fractures are osteoporotic by nature or the result of excessive suppression of bone turnover.

We conducted a register-based cohort analysis in a tertiary prevention setting to test the hypothesis that the increase in the risk of these "atypical" femur fractures in patients treated with *aln* exceeded their increase in the risk of typical osteoporotic femur fractures.

All patients born 1945 or earlier who presented at Danish hospitals with fractures in the period 1996-2005 were identified. Fracture patients without baseline hip fracture were then entered into the tertiary prevention matched cohort analysis, where each patient who began *aln* and remained on treatment for at least 6 months ( $N=5187$ , mean exposure 2.5y) was assigned two untreated fracture controls ( $N=11160$ ). Matching was done by age, sex and location of index fracture.

	Subtrochanteric	Diaphyseal	Hip
Rate in alendronate treated vs untreated cohort (per 1000 person years)	1.9 vs 1.0	1.1 vs 0.6	17.0 vs 11.0
<i>Cox prop. hazards analysis:</i>			
OR, unadjusted	1.8 (1.0-3.1)	1.8 (0.9-3.7)	1.5 (1.3-1.8)
OR, adjusted for sex and age	1.8 (1.0-3.0)	1.8 (0.9-3.7)	1.5 (1.3-1.8)
OR, adjusted for sex, age, comedications and Charlson index	1.6 (0.9-2.8)	1.9 (0.9-4.0)	1.4 (1.2-1.7)

While *aln* use was associated with an increased risk of a new subtrochanteric fracture ( $p<0.05$ ), this was equally true for hip fracture ( $p<0.001$ ). The increased risk of diaphyseal fracture was not statistically significant ( $p=0.10$ ).

Our findings did not confirm the hypothesis that subtrochanteric or diaphyseal fractures with *aln* treatment occurred with a frequency over and above that expected for a typical osteoporotic fracture. These findings suggest that subtrochanteric fractures should be attributed to osteoporosis and not to *aln* treatment.

**Disclosures:** B. Abrahamsen, Nycomed 1, 4; Roche 1, 3; Servier 1; Novartis 2, 3. This study received funding from: Kaptajnlejnant Harald Jensen og Hustrus Fond.

## 1027

**Relationship of Bone Turnover Marker (PINP) and Changes in Femoral Neck Bone Mineral Density to Fracture Risk in Women with Postmenopausal Osteoporosis Treated with Once-Yearly Zoledronic Acid 5 mg (ZOL): The HORIZON-PFT Study.** P. D. Delmas<sup>1</sup>, F. Munoz<sup>\*1</sup>, F. Cosman<sup>2</sup>, S. Boonen<sup>3</sup>, D. Black<sup>4</sup>, N. B. Watts<sup>5</sup>, D. Kendler<sup>6</sup>, E. F. Eriksen<sup>\*7</sup>, P. Mesenbrink<sup>\*8</sup>, R. Eastell<sup>9</sup>. <sup>1</sup>INSERM Research Unit 831 and University of Lyon, Lyon, France, <sup>2</sup>Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>3</sup>Katholieke Universiteit Leuven, Leuven, Belgium, <sup>4</sup>University of California, San Francisco, San Francisco, CA, USA, <sup>5</sup>University of Cincinnati Bone Health and Osteoporosis Center, Cincinnati, OH, USA, <sup>6</sup>Osteoporosis Research Centre, Vancouver, BC, Canada, <sup>7</sup>Novartis Pharma AG, Basel, Switzerland, <sup>8</sup>Novartis Pharmaceuticals Corp, East Hanover, NJ, USA, <sup>9</sup>University of Sheffield, Sheffield, United Kingdom.

Several studies have shown that reduction in bone turnover markers (BTMs) as a result of antiresorptive therapy, especially bisphosphonates, is associated with reduced risk of fracture. BTM change may be more predictive of fracture than bone mineral density (BMD) change. The associations between changes in BTM or BMD and fracture incidence were assessed in a subgroup of 1132 patients who had procollagen type 1 amino-terminal propeptide (PINP) levels measured at baseline and 1 year, from the randomized, double-blind, placebo-controlled HORIZON Pivotal Fracture Trial in which patients received three annual infusions of ZOL 5 mg. PINP (lower and upper quartile bounds) decreased from a median of 50 (33-67) at baseline to 18 (13-26) ng/ml at 1 year. The table shows the adjusted hazard ratio (HR)/odds ratio (OR) and 95% confidence interval (CI) associated with 1 standard deviation (SD) decrease in PINP level (1 SD of PINP is 27 ng/ml) at 1 year for risk of future fracture. Lower PINP levels were associated with a lower fracture risk after adjusting for baseline confounders. In contrast, femoral neck and total hip BMD increases (5.06 % at 3 years) were not consistently associated with fracture incidence. The HRs for the association between a 1% increase in BMD at 1 and 3 years and the incidence of all clinical fractures were 0.98 (0.94-1.01),  $P=0.19$  and 0.96 (0.92-0.99),  $P=0.03$ , respectively, and for nonvertebral fractures were 0.99 (0.95-1.01),  $P=0.62$  and 0.97 (0.93-1.01),  $P=0.09$ . In summary, PINP levels achieved after 1 year of therapy are significantly associated with the risk of vertebral and nonvertebral fracture, contrasting with the poor predictive value of BMD increase.

Table. Association between PINP level at 1 year and risk of future fracture.

Fracture category	Adjusted HR/OR <sup>2</sup> (95% CI)
Any clinical <sup>1</sup>	0.76 (0.59,0.96)*
Non-vertebral <sup>1</sup>	0.73 (0.56, 0.95)*
Hip	0.36 (0.20, 0.63)**
Morphometric vertebral <sup>2</sup>	0.60 (0.39, 0.99)*

## 1028

**Effect of Once-Yearly Zoledronic Acid 5 mg Infusion on Fracture Incidence in Postmenopausal Osteoporosis: Subgroup Analysis of the Horizon PFT Study.** R. Eastell<sup>1</sup>, D. M. Black<sup>2</sup>, S. Boonen<sup>3</sup>, S. R. Cummings<sup>2</sup>, P. D. Delmas<sup>4</sup>, L. Palermo<sup>\*2</sup>, P. Mesenbrink<sup>\*5</sup>, J. A. Cauley<sup>6</sup>. <sup>1</sup>University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>University of California, San Francisco, San Francisco, CA, USA, <sup>3</sup>Katholieke Universiteit Leuven, Leuven, Belgium, <sup>4</sup>INSERM Research Unit 831 and University of Lyon, Lyon, France, <sup>5</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, <sup>6</sup>University of Pittsburgh, Pittsburgh, PA, USA.

In the 3-year, multicenter, double-blind, placebo-controlled HORIZON-PFT study, a once-yearly infusion of zoledronic acid (ZOL) 5 mg significantly reduced fracture risk in women with postmenopausal osteoporosis ( $n=3875$ ; mean age, 73 years). Patients were randomized to a single 15-minute infusion of ZOL or placebo at baseline, 12 and 24 months. Primary endpoint was incidence of new vertebral fractures and hip fractures at 3 years, with non-vertebral fractures as a secondary endpoint. In a subgroup analysis, fracture risk reduction and treatment-factor interaction were evaluated across 14 determinants of response. Preplanned subgroups (9 of 9) were age, bone mineral density (BMD) T-score and baseline vertebral fracture status, race, weight/body mass index, geographical region, prior bisphosphonate (BP) use, creatinine clearance, and baseline use of osteoporosis medications. *Post hoc* subgroups were hip BMD, smoking, height loss since age 25 years, fall in past 12 months, and daily activity. ZOL significantly reduced the risk of vertebral fractures in all subgroups of age, creatinine clearance and BMI (all  $P<0.0001$ ). Greater effects of ZOL on vertebral fracture risk were observed in younger women (adjusted odds ratio [OR], 0.18 [95% CI 0.10,0.31] in women  $<70$  years vs 0.37 [95% CI 0.27,0.52] in women  $\geq 75$  years), women with creatinine clearance  $\geq 60$  mL/min vs  $<60$  mL/min (OR, 0.21 [95% CI 0.14,0.29] vs 0.35 [95% CI 0.25,0.48]), and overweight or obese women (body mass index [BMI]  $\geq 25$  kg/m<sup>2</sup>; OR, 0.22 [95% CI 0.15,0.31] vs BMI 19-24.9 kg/m<sup>2</sup> (OR, 0.38 [95% CI 0.27,0.53])). Significant treatment-by-factor interactions ( $P<0.05$ ) were observed for ZOL with age, creatinine clearance and BMI. The most frequent treatment-related adverse events with ZOL were pyrexia (16.0%), myalgia (9.4%) and influenza-like illness (7.8%). In conclusion, once-yearly ZOL was effective in all subgroups analyzed for vertebral fractures, but was most effective at reducing risk of vertebral fracture in women younger than 70 years, with better renal function or with higher BMI.

## 1029

**Long-Term Treatment with Oral Bisphosphonates in Postmenopausal Women: Effects on the Degree of Mineralization and Microhardness of Bone.** G. Boivin, Y. Bala\*, R. D. Chapurlat, P. D. Delmas. INSERM Unité 831, University of Lyon, Lyon, France.

The degree of mineralization (DMB) is a major determinant of bone quality. In postmenopausal osteoporotic (PMOP) women treated with alendronate (ALN, 10 mg/day) for 2-3 yrs, DMB was significantly increased compared to placebo (PLA), accounting for the main part of the increase in bone density (1). Due to suggestions that long-term use of bisphosphonates (BPs) might be deleterious at the tissue level, we explored the DMB and microhardness in iliac bone biopsies obtained after long-term treatment with BPs in PMOP women from an outpatient clinic. Parameters of secondary mineralization were measured in bone samples from 45 PMOP women (age  $68 \pm 9$  yrs) after BPs therapy (32 on oral ALN only and 13 mainly on oral risendronate = RIS) for 3 to 12 yrs (mean  $6.5 \pm 2.0$  yrs). Results were compared with values from untreated control subjects (CTRL), from PMOP women treated with calcium and vitamin D (PLA) and PMOP patients treated for 3 yrs with ALN [3-ALN (1)]. Quantitative microradiography (2) of  $100 \pm 1 \mu\text{m}$ -thick sections allowed measurement of DMB ( $\text{g}/\text{cm}^3$ ) and Heterogeneity Index of the distribution of DMB (HI  $\text{g}/\text{cm}^3$ ), separately on cortical, cancellous and total bone (= cortical + cancellous). Vickers microhardness (Hv  $\text{kg}/\text{mm}^2$ ) was calculated in 18 3-ALN. DMB, HI and Hv of bone were similar in cortical and cancellous bone allowing results to be reported for total bone tissue. Among women treated long-term, DMB ( $1.13 \pm 0.07$  after ALN,  $1.10 \pm 0.07$  after RIS), but not HI ( $0.21 \pm 0.06$  after ALN,  $0.20 \pm 0.06$  after RIS), was significantly higher ( $p < 0.001$ ) than CTRL (DMB =  $1.09 \pm 0.08$ , HI =  $0.25 \pm 0.08$ ) and PLA (DMB =  $1.07 \pm 0.06$ , HI =  $0.28 \pm 0.12$ ), but DMB was significantly lower ( $p < 0.01$ ) than in 3-ALN (DMB =  $1.19 \pm 0.06$ , HI =  $0.23 \pm 0.07$ ). Hv in 3-ALN ( $42.77 \pm 1.82$ ) was similar to Hv from untreated osteoporotic patients ( $44.10 \pm 4.72$ ). There was no association between DMB, HI or Hv and the duration of BP-therapy and the parameters of bone remodeling (BFR, MS/BS, AcF). There was no difference between women treated with ALN or RIS. Although bone remodeling was markedly suppressed in these women treated long-term with BPs (3), no hypermineralization of bone tissue was found, and hardness was no different to controls. To conclude, after long-term treatment of PMOP women with oral BPs, DMB was preserved and there was no deleterious effect on bone microhardness. Our data show that mineralization increases during the first 3 yrs of BP therapy, then tends to decline to untreated values despite the persistence of low bone turnover.

**Potential Mediators of the Reduction in Mortality with Zoledronic Acid after Hip Fracture.** C. Colón-Emeric<sup>1</sup>, P. Mesenbrink<sup>2</sup>, K. Lyles<sup>3</sup>, C. Pieper<sup>4</sup>, S. Boonen<sup>5</sup>, P. Delmas<sup>6</sup>, E. Eriksen<sup>7</sup>, J. Magaziner<sup>7</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC, USA, <sup>2</sup>Novartis Pharmaceuticals Corporation, New Jersey, NJ, USA, <sup>3</sup>VA Medical Center, Durham, NC, USA, <sup>4</sup>Leuven University Center, Leuven, Belgium, <sup>5</sup>Hôpital Edouard Herriot, Lyon, France, <sup>6</sup>Novartis Pharma AG, Basel, Switzerland, <sup>7</sup>University of Maryland, Baltimore, MD, USA.

Zoledronic acid reduces the risk of death by 28% in patients with recent hip fracture, but the mediators of this effect are not completely known. We performed a retrospective analysis of the HORIZON-RFT clinical trial database using stepwise Cox-proportional Hazards modeling to characterize the causes of death, and explore potential mechanisms for the reduction in mortality. The analysis included 2111 patients with recent hip fracture randomized and treated with zoledronic acid or placebo infusion yearly. Causes of mortality were reported by the investigator and adjudicated by a blinded, central review committee. Models included baseline covariates associated with greater risk of death, and time-dependent covariates occurring during the study period including subsequent fracture, change in bone mineral density, infections, cardiac arrhythmias, and falls. In a model adjusted for baseline risk factors, zoledronic acid reduced the risk of death by 25% (95% CI 3-42%). Males experienced a greater mortality benefit (6.4% absolute risk reduction) than females (2.8%), with a particularly marked reduction in cardiac-related deaths (incidence 2.9% vs. 7.7%). Subjects living in a nursing facility at baseline, and subjects with greater levels of cognitive impairment did not experience a major reduction in deaths. Adding subsequent fractures to the model, we found that they were significantly associated with higher risk of death (HR 1.72, 95% CI 1.17-2.51), but explained only approximately 2% more of the zoledronic acid effect. Adjusting for other time-dependent risk factors decreased the death risk reduction by zoledronic acid; however, no treatment-by-factor interactions suggested treatment with zoledronic acid combined with the presence of any risk factors influenced the risk of death in any cohort. Compared to the placebo arm, there was a similar incidence of, but decreased death from pneumonia, neoplasms, and cardiovascular disease in subjects treated with zoledronic acid, suggesting that the drug may influence physiologic reserve. We conclude that zoledronic acid's death benefit is not fully mediated through a reduction in secondary fractures, but may also have an impact on physiologic reserve and ability to recover from acute illnesses.

**New data on the impact of renal function on the relationship between 25-hydroxyvitaminD and Parathyroid Hormone.** B. Misra, D. J. McMahon, S. J. Silverberg, J. P. Bilezikian. College of Physicians and Surgeons, Columbia University, New York, NY, USA.

Although both low 25-hydroxyvitamin D [25(OH)D] levels and creatinine clearance <60 cc/min are causes of secondary hyperparathyroidism, little is known about how the relationship between 25(OH)D and PTH varies as a function of creatinine clearance (CrCl). The National Health and Nutrition Examination Survey (NHANES) in 2003-2004 measured parathyroid hormone (PTH), calcium, creatinine, and 25(OH)D in over 6000 individuals. We analyzed data from 2370 individuals  $\geq 45$  with corrected calcium concentration in the normal range (8.5-10.2mg/dL). We then determined mean PTH and % of subjects with elevated PTH ( $\geq 65\text{pg}/\text{mL}$ ) according to CrCl. In those with CrCl <60cc/min, mean PTH increases (even within the normal range) for each 5ng/mL decrease in 25(OH)D. In those with CrCl  $\geq 60\text{cc}/\text{min}$ , PTH levels do not begin to rise into the frankly abnormal range until 25(OH)D levels are markedly reduced. The % of subjects with elevated PTH increases as 25(OH)D falls regardless of renal function. Multiple regression models of PTH and 25(OH)D reveal significant linear, quadratic and cubic relationships for those with CrCl <60cc/min ( $R^2=0.1322$ ), while there is only a weak linear relationship in those with CrCl  $\geq 60\text{cc}/\text{min}$  ( $R^2=0.0891$ ). The stronger association between 25(OH)D and PTH when the CrCl is reduced could be a function of calcium intake, about which data are unavailable, or it may speak to the accumulation of PTH metabolites. The results of this study substantiate a complex relationship between 25(OH)D and PTH, suggesting that the association is stronger when renal function is impaired. The data demonstrate that PTH levels may rise within the normal range as 25(OH)D falls, and suggest an inflection point below which 25(OH)D insufficiency dramatically stimulates PTH levels in the CrCl <60cc/min group. Finally, in those with better renal function, PTH does not rise until vitamin D deficiency is marked. The data support the need for further investigation of the impact of renal function on the relationship between PTH and 25(OH)D.

**Pretransplant Parathyroid Function Predicts Laboratory and Bone Mineral Density Changes after Kidney and Kidney Pancreas Transplantation.** G. J. Elder<sup>1</sup>, R. Mainra<sup>2</sup>. <sup>1</sup>Centre for Transplant and Renal Research, Westmead Millennium Institute, Sydney, Australia, <sup>2</sup>Division of Nephrology, St. Paul's Hospital, Saskatoon, SK, Canada.

Patients with CKD stage 5 undergoing kidney (K) or kidney pancreas (KP) transplantation often have low calcitriol, suboptimal 25OHD and elevated iPTH levels. We investigated interactions of these hormones and biochemical responses over the 1<sup>st</sup> post-transplant year.

Of 346 patients undergoing transplantation (K: 234, KP: 112), 150 were followed for  $\geq 12$  months. Their median age was 42 years (range 18-68). Bloods were collected just before transplantation (baseline) and at 6, 12 and 52 weeks after transplantation for biochemistry, levels of 25OHD (adequacy  $\geq 60$  nmol/L), calcitriol (normal range 36-120 pmol/L) and iPTH (normal range 1-6.8 pmol/L). BMD by DXA was assessed at baseline and 12 months. Pre-transplant categories of iPTH <1, 1-3 and >3-times the upper normal range of the assay were used to evaluate influences of pre-existing parathyroid function on post-transplant laboratory data and BMD. Patients with 25OHD <60 nmol/L received cholecalciferol supplementation by 6 weeks. Values are shown as mean $\pm$ SD.

Baseline levels of 25OHD fell by 6 weeks (67 $\pm$ 33 nmol/L to 49 $\pm$ 23 nmol/L;  $p < 0.0001$ ) and were lower for KP recipients at these time points ( $p < 0.0001$  for each). Calcitriol levels rose from 36 $\pm$ 36 pmol/L (baseline) to 85 $\pm$ 56 pmol/L at 6 weeks and 111 $\pm$ 60 pmol/L at 12 weeks ( $p < 0.0001$  for each interval). The mean calcitriol level of 122 pmol/L at 52 weeks exceeded the assay upper range. Baseline iPTH was 45 $\pm$ 44 pmol/L. Pretransplant iPTH categories predicted post-transplant levels of iPTH and calcitriol ( $p < 0.0001$  and  $p = 0.028$  respectively; ANOVA repeat measures) and levels of phosphate (negative interaction;  $p = 0.04$ ). Pretransplant iPTH levels <1 and >3-times the assay upper normal range predicted 6 week levels of 25OHD (47 $\pm$ 23 vs. 59 $\pm$ 24 pmol/L;  $p = 0.0196$ ) and calcium (2.35 vs. 2.45 mmol/L;  $p = 0.002$ ). Higher pre-transplant iPTH levels predicted lower femoral neck BMD at baseline ( $p = 0.0028$ ) and 52 weeks ( $p = 0.0195$ ), but increased annual gain in BMD ( $p = 0.0003$ ), which remained significant after adjustment for transplant type and bisphosphonate use.

These data demonstrate that pre-transplant iPTH levels predict early post-transplant rises in calcitriol and changes in levels of iPTH, 25OHD, calcium and phosphate. The calcitriol response is inconsistent with a dominant early FGF-23 effect. Pretransplant parathyroid activity is an important influence on post-transplant laboratory indices and BMD.

## 1033

**Patients with Kidney Disease and Low 1/3 Radius and Femoral Neck BMD have Markedly Abnormal Cortical and Trabecular Microstructure by High-resolution Peripheral QCT.** T. L. Nickolas<sup>1</sup>, E. A. Stein<sup>1</sup>, V. Thomas<sup>\*1</sup>, H. F. Eisenberg<sup>\*1</sup>, D. J. McMahon<sup>1</sup>, M. B. Leonard<sup>2</sup>, E. Shane<sup>1</sup>. <sup>1</sup>Medicine, Columbia University, New York, NY, USA, <sup>2</sup>Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Fractures (FXs) are increased in end stage kidney disease (ESKD) and chronic kidney disease (CKD). In normal adults, areal BMD (BMD) of the spine and hip by DXA strongly predict FX. Associations between central DXA and FX in ESKD are weak, likely because concomitant hyperparathyroidism is associated with cortical (Ct) bone loss and preserved trabecular (Tb) bone. DXA does not distinguish Ct from Tb bone. BMD at the 1/3-radius (1/3R; 95% Ct bone) may be associated with FX in ESKD, but no data are available on relationships between 1/3R BMD and Ct and Tb microstructure in ESKD and CKD.

High resolution peripheral QCT (HRpQCT; XtremeCT, Scanco Medical AG; resolution 82 µm) distinguishes between Ct and Tb bone and quantifies Tb microstructure at the radius (RAD) and tibia (TIB). We performed RAD and TIB HRpQCT in 42 subjects with CKD (age 51-88, GFR 4-59 mL/min), hypothesizing those with low 1/3R BMD (T score ≤ -2.0) would have abnormal Ct and preserved Tb microstructure. We also assessed associations between HRpQCT and low BMD at the lumbar spine (LS), total hip (TH) and femoral neck (FN).

Low BMD was uncommon at the LS (10%) and TH (17%), while 45% had T-scores ≤ -2 at the 1/3R and/or FN. Subjects with low 1/3R or FN BMD were similar regarding GFR, race and gender (Table), but older than those with T<sub>z</sub> ≥ -1.9. Low 1/3R and FN BMD were associated with lower RAD Ct thickness (23% and 22%, respectively) and Tb density (30%; 21%), bone volume (29%; 21%) and number (15%; 10%), and higher Tb separation (TbSp) (40%; 27%) and standard deviation of TbSp (100%; 63%) reflecting inhomogeneity of the Tb network. Tb associations were weaker at the FN than 1/3R. Low LS and TH BMD were not associated with Ct or Tb structure. TIB HRpQCT relationships were similar to RAD at all BMD sites.

In summary, Ct and Tb microarchitecture at weight bearing and non-weight bearing sites are markedly abnormal in CKD patients with T scores ≤ -2.0 at the peripheral 1/3R and central FN. DXA of the 1/3R and FN may be more clinically relevant than LS and TH for identifying CKD patients with poor bone microstructure. Further studies are needed to elucidate relationships of these abnormalities to bone strength, and the ability of 1/3R and FN DXA, and HRpQCT Ct and Tb parameters at RAD and TIB to predict FX in CKD.

**Cardiovascular Manifestations of Mild Primary Hyperparathyroidism.** M. D. Walker<sup>1</sup>, J. Fleischer<sup>1</sup>, S. Homma<sup>\*1</sup>, T. Rundek<sup>\*2</sup>, D. J. McMahon<sup>1</sup>, A. Tineo<sup>\*1</sup>, J. Udesky<sup>\*1</sup>, R. Lui<sup>\*1</sup>, R. Sacco<sup>\*2</sup>, S. J. Silverberg<sup>1</sup>. <sup>1</sup>College of Physicians and Surgeons, Columbia University, New York, NY, USA, <sup>2</sup>University of Miami, Miami, FL, USA.

Severe primary hyperparathyroidism (PHPT) is associated with cardiovascular (CV) calcification and increased CV mortality. This prospective study of patients with PHPT seeks to determine whether the mild PHPT seen today still poses a risk to the CV system. Fifty patients (84% female; age ± SD 62 ± 8 yrs, range 48-75; serum calcium 10.5 ± 0.5 mg/dl; PTH 116 ± 50 pg/ml) have been enrolled. Blood pressure (BP) was 123 ± 17/ 75 ± 11 mm Hg. Lipids were mildly elevated: total cholesterol 210 ± 34, HDL 68 ± 17, LDL 123 ± 31, triglycerides 97 ± 56 mg/dl. Valvular calcifications, seen in classical PHPT, were uncommon (14%). Left ventricular (LV) mass was increased in 20 patients (40%), although only 8/20 had hypertension and none had diabetes. Systolic LV function and wall motion were normal. Carotid ultrasound showed plaque in 19 (38%), and increased carotid intima-medial thickness (IMT), a subclinical marker of atherosclerosis. On functional testing of the heart (diastolic function by mitral pulse wave velocity, deceleration time, isovolumic relaxation time, tissue doppler E velocity), peripheral vasculature (endothelial

function: brachial artery flow-mediated dilation, FMD) and carotid (distensibility), only carotid stiffness was abnormal.

CV Test	Mean ± SD	Normal Range	Abnormal
LV mass (g/m <sup>2</sup> )	99 ± 25	43-115	40%
IMT (mm)	0.96 ± 0.10 mm	0.7-0.9	66%
Mitral Pulse Wave E/A	1.1 ± .37	.75-1.5	33%
Deceleration Time (msec)	163 ± 30	>140	21%
Isovolumic relaxation time (msec) (IVRT)	83 ± 17	50-102	15%
Tissue Doppler E' Velocity (cm/sec)	11.4 ± 3	<15	15%
FMD (%)	4.8 ± 3.3	3-7%	32%
Carotid STRAIN (%)	10.2 ± 8.0	6-12%	6%
Carotid STIFFNESS	6.4 ± 3.0	< 6	44%

Higher PTH levels were associated with increased systolic (r = 0.4; p = 0.009) and diastolic (r = 0.3; p = 0.03) BP, and decreased vascular compliance (carotid stiffness: r = 0.4, p = .01; and strain r = -0.43, p = .005). Serum calcium levels correlated with IVRT (r = 0.36, p = 0.01) and strain (r = -0.29, p = 0.04). The relationships remained significant controlling for age and duration of PHPT. A regression model including calcium, PTH and their interaction explained 22.5% of the variation in IVRT and 17% of the variation in BP.

In summary, these patients had increased IMT and carotid stiffness which are risk factors for CV events. Increased LV mass, seen in severe PHPT, was also common. Some measures were associated with severity of PHPT: carotid compliance was lowest in those with highest PTH and calcium levels. In conclusion, patients with mild PHPT have structural and functional CV abnormalities consistent with increased vascular stiffness in the carotid vascular bed which may increase their CV risk.

## 1035

**Abdominal Aortic Calcification (AAC) Detected on Lateral DXA Spine Images is Associated with Coronary Artery Disease.** J. T. Schousboe<sup>1</sup>, D. Clafin<sup>\*2</sup>, E. Barrett-Connor<sup>2</sup>. <sup>1</sup>Park Nicollet Clinic; Division of Health Policy & Management, Univ of Minn, Minneapolis, MN, USA, <sup>2</sup>Univ of Calif San Diego, San Diego, CA, USA.

**Background:** Abdominal aortic calcification (AAC) on lateral spine DXA images intended for vertebral fracture assessment (VFA) may be predictive of incident myocardial infarction or stroke. The association of AAC on VFA images with other subclinical measures of cardiovascular disease has not been reported.

**Methods:** 200 men and 223 women without prior history of clinical coronary disease had clinical cardiovascular disease risk factors assessed and coronary artery calcium (CAC) scored with electron beam computed tomography (EBCT) at the 8<sup>th</sup> study visit of the Rancho Bernardo long-term observational study of heart and other chronic diseases. Of these participants, 107 men and 116 women had VFA images done at the 9<sup>th</sup> study visit a mean 3.5 years later. 106 VFA's were fully evaluable for AAC using previously validated 24-point and 8-point semi-quantitative scores. The association between CAC quartile and AAC tertile was assessed by ordinal logistic regression models, adjusting for age, sex, blood pressure, total and HDL cholesterol, smoking status, presence of diabetes, and visceral to subcutaneous fat ratio. The sensitivity and specificity of AAC to detect those in the top quartile of CAC score was assessed with receiver operating curve (ROC) analyses.

**Results:** The multivariable-adjusted odds of CAC being one quartile higher with AAC scores in the top and middle tertiles, respectively compared to the bottom tertile of AAC are shown in the table

AAC Measure	AAC Tertile (Score)	Odds Ratio of Higher Quartile of CAC Associated with Elevated AAC (95% C.I.)
AAC-24	Bottom (0 or 1)	1.0 (Reference)
	Middle (2-4)	2.63 (0.85 - 7.91)
	Top (≥ 5)	7.36 (2.36 - 20.99)
AAC-8	Bottom (0 or 1)	1.0 (Reference)
	Middle (2)	1.97 (0.71 - 5.45)
	Top (≥ 3)	3.32 (1.17 - 9.40)

An AAC-24 score of ≥ 5 had sensitivity and specificity, respectively, of 65% and 70% to detect those in the highest quartile of CAC (score ≥ 400). AAC-8 score of ≥ 3 had sensitivity and specificity, respectively, of 45% and 78% to detect those in the top CAC quartile.

**Conclusions:** A high level of AAC detected on VFA images obtained with lateral DXA is strongly associated with coronary artery disease. Its presence should prompt re-assessment of the person's coronary risk disease profile and management of those risks that are modifiable.

**Disclosures:** J.T. Schousboe, Roche, Inc. 2.

## 1036

**PTH Reverses Abnormal Bone Remodeling and Structure in Hypoparathyroidism.** M. R. Rubin<sup>1</sup>, D. W. Dempster<sup>2</sup>, J. Sliney<sup>\*1</sup>, D. J. McMahon<sup>1</sup>, H. Zhou<sup>2</sup>, T. Nickolas<sup>\*1</sup>, E. M. Stein<sup>1</sup>, J. P. Bilezikian<sup>1</sup>. <sup>1</sup>Columbia University, New York, NY, USA, <sup>2</sup>Helen Hayes Hospital, New York, NY, USA.

Hypoparathyroidism (HypoPT) is characterized by atypical structural and dynamic properties of bone. We have reported that iliac crest bone biopsies show increased bone volume and suppressed bone turnover. We hypothesized that PTH treatment would restore these properties to normal. 16 HypoPT subjects (11 women; age 52 ± 12 yr) were treated with 100 µg of hPTH(1-84)[PTH] every other day for 2 yrs. Iliac crest bone biopsies were performed before (n=16) and after 1 (n=9) or 2 (n= 7) yrs of treatment. Bone remodeling variables were significantly increased at 1 yr, including osteoid thickness (2.2 ± 2 to 3.9 ± 2 lam #, p=0.02), mineralized perimeter (1.1 ± 5 to 7.9 ± 7%, p=0.001), mineral apposition rate (0.6 ± 0.3 to 0.9 ± 0.4 µm/d, p=0.01), bone formation rate (0.009 ± 0.1 to 0.08 ± 0.1 µm<sup>3</sup> / µm<sup>2</sup>/d, p=0.001), osteoid perimeter (2.5 ± 5 to 9.9 ± 7%, p= 0.002) and bone resorption rate (2.3 ± 19 to 24.2 ± 26 µm/d, p=0.004). At 2 yrs, some histomorphometric variables of bone remodeling remained significantly above baseline values including mineralized perimeter (1.1 ± 3 to 3.0 ± 4%, p= 0.001) and mineral apposition rate (0.6 ± 0.3 to 0.7 ± 0.4 µm/d, p= 0.03), although these were lower than the 1 yr values. Only osteoid perimeter continued to increase at 2 yrs (2.5 ± 9 to 13.9 ± 14%, p=0.006). After 2 yrs of treatment, structural parameters by histomorphometry revealed a decrease in cancellous bone volume (26.0 ± 6 to 21.7 ± 9%; p=0.04), an increase in trabecular separation (434.8 ± 8 to 499.1 ± 113 µm, p=0.01), and an increase in cortical porosity at both 1 (6.7 ± 4 to 10.2 ± 5%, p= 0.02) and 2 (6.6 ± 3 to 8.8 ± 4%, p= 0.03) yrs. Trabecular width, trabecular number and cortical width did not change. These data show that PTH treatment of HypoPT restores atypical structural and dynamic skeletal properties towards normal. The dynamic changes occur within the first year of therapy, with most markers of bone remodeling returning to baseline levels by 2 yrs. Further structural changes emerge after 2 yrs. Whether these changes have an impact on bone strength remains to be seen, but it would appear that PTH is a highly beneficial therapy in HypoPT.

## 1037

**Osteocyte-specific Ablation of Canonical Wnt Signaling Induces Severe Osteoporosis.** I. Kramer<sup>\*1</sup>, C. Halleux<sup>1</sup>, P. Brander Weber<sup>\*2</sup>, J. Q. Feng<sup>\*3</sup>, J. Boisclair<sup>\*2</sup>, H. Keller<sup>1</sup>, M. Kneissel<sup>1</sup>. <sup>1</sup>Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland, <sup>2</sup>Pathology Laboratories, Novartis, Basel, Switzerland, <sup>3</sup>Biomedical Sciences, Baylor College of Dentistry, TX A&M Health Science Center, Dallas, TX, USA.

The potent osteocyte expressed bone formation inhibitor sclerostin encoded by the *Sost* gene appears to function as an inhibitor of canonical Wnt signaling by directly binding to Lrp5/6 Wnt co-receptors. Canonical Wnt signaling plays a crucial role in bone metabolism by controlling both osteoblast and osteoclast differentiation and activity. However, the role of canonical Wnt signaling in osteocytes remains to be elucidated. To investigate the *in vivo* function of the canonical Wnt signaling pathway in osteocytes we generated osteocyte-specific *beta-catenin* (*Ctnnb1*) deficient mice by crossing *Ctnnb1*<sup>loxP/loxP</sup> conditional mutant and *Dmp1-Cre* mice to obtain osteocyte-specific hetero- and homozygous (*Ctnnb1*<sup>loxP/loxP</sup>; *Dmp1-Cre*) *Ctnnb1* loss-of-function mice. We analyzed the bone phenotype in the appendicular and axial skeleton of male and female mice during growth at 6-12 weeks of age by *in vivo* and *ex vivo* peripheral quantitative and micro-computed tomography (pQCT and micro-CT) and DEXA. *Dmp1-Cre* induced *Ctnnb1* deficiency resulted in severe osteoporosis with a striking bone loss in the appendicular and axial skeleton, growth retardation and premature lethality by 2-3 month of age in both sexes. Total bone mass and density as measured by DEXA were strongly reduced by up to 60% in the tibia and femur and over 75% in lumbar vertebrae of osteocyte-targeted *Ctnnb1* mutant mice compared to control littermates. There was a progressive dramatic reduction in cancellous bone volume in both long bones with a strong decrease to complete loss of trabecular bone. Cortical bone thickness was reduced by about 50% with a concomitant outward drift and an increase in cross-sectional area in the metaphyseal region, while diaphyseal bone diameter was decreased. Histology revealed increased osteoclast activity. In contrast to homozygous *Ctnnb1* deletion *Dmp1-Cre* induced *Ctnnb1* heterozygosity caused only minor, mostly insignificant decreases in bone mass and density. Together, these results are reminiscent of the recently published bone phenotype of mice in which *beta-catenin* was deleted from the osteoblast stage onwards suggesting a previously underestimated role for canonical Wnt signaling in osteocytes in control of bone homeostasis that has not been addressed so far. In summary, we conclude that *Dmp1-Cre* induced loss of canonical Wnt signaling in osteocytes leads to severe bone loss and osteoporosis at young age.

**PTH Receptor Signaling in Osteocytes Increases Bone Mass and the Rate of Bone Remodeling Through Wnt/LRP5-dependent and -independent Mechanisms, Respectively.** C. A. O'Brien<sup>1</sup>, C. Galli<sup>1</sup>, L. Plotkin<sup>1</sup>, K. Vyas<sup>\*1</sup>, P. Cazer<sup>\*1</sup>, J. J. Goellner<sup>1</sup>, S. Berryhill<sup>\*1</sup>, W. Webb<sup>\*1</sup>, A. Robling<sup>2</sup>, M. Bouxsein<sup>3</sup>, E. Schipani<sup>4</sup>, C. H. Turner<sup>5</sup>, R. S. Weinstein<sup>1</sup>, R. L. Jilka<sup>1</sup>, S. C. Manolagas<sup>1</sup>, T. M. Bellido<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>2</sup>Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>3</sup>Orthopedic Surgery, Beth Israel Deaconess Medical Center Harvard Medical School, Boston, MA, USA, <sup>4</sup>Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, <sup>5</sup>Orthopedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Chronic elevation of PTH increases bone remodeling and leads to either loss or gain of cancellous bone depending on the balance between resorption and formation. PTH also suppresses expression of the osteocyte-specific Wnt antagonist sclerostin, the product of the *Sost* gene. This evidence, together with the well-documented role of Wnt signaling on osteoblast production, survival, and function, suggests a mechanism by which PTH may increase osteoblast number and bone formation by acting on osteocytes. We addressed the functional consequences of PTH actions in osteocytes by generating transgenic mice expressing a constitutively active PTH receptor 1 exclusively in these cells using the osteocyte-specific dentin matrix protein-1 promoter (DMP1-caPTH1R1 mice). DMP1-caPTH1R1 mice exhibit a 2-fold increase in bone, detected at 3.5 weeks by histomorphometry and at 8 weeks by DEXA. Osteoblast number and trabecular width were elevated and osteoblast apoptosis was reduced in DMP1-caPTH1R1 mice. Surprisingly, osteoclast number was also increased. Transcripts for both osteoblast- and osteoclast-specific genes were elevated in bones from DMP1-caPTH1R1. Plasma levels of osteocalcin and CTX and urinary levels of DPD were increased, confirming that DMP1-caPTH1R1 mice exhibit high bone formation and resorption. *Sost* mRNA and sclerostin protein were strikingly decreased in the transgenic mice. Consistent with this, Wnt signaling was elevated, as demonstrated by increased expression of the Wnt/β catenin target genes Axin 2, SMAD6, BMP4, and naked, and by elevated β-galactosidase activity in bones from the Wnt reporter mice TCF-βgal crossed with DMP1-caPTH1R1 mice. Crossing DMP1-caPTH1R1 mice with mice lacking the Wnt co-receptor LRP5 attenuated the high bone mass phenotype but not the increase in bone remodeling. These findings demonstrate that PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, revealing two previously unappreciated roles for osteocytes in the skeletal actions of PTH.

**PTH-induced Bone Mass Gain Is Blunted But Not Abolished in *SOST* Overexpressing and Deficient Mice.** I. Kramer<sup>\*1</sup>, G. G. Loots<sup>\*2</sup>, H. Keller<sup>1</sup>, M. Kneissel<sup>1</sup>. <sup>1</sup>Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland, <sup>2</sup>Biosciences and Biotechnology Division, Chemistry, Materials and Life Sciences Directorate, Lawrence Livermore National Laboratory, Livermore, CA, USA.

PTH signaling down-regulates expression of the bone formation inhibitor *SOST*. To test whether *SOST* suppression contributes to the bone anabolic action of intermittent PTH treatment, we subjected male BAC transgenic mice overexpressing human *SOST* and male mice lacking endogenous *SOST* (targeted knockout) to daily injections of 100 microg/kg hPTH(1-34) or vehicle for a two-month-period. Bone changes were monitored *in vivo* in the distal femur metaphysis and *ex vivo* in the entire femur by pQCT. Animals were sacrificed 4 hours after the final PTH application and RNA was extracted from long bone diaphyses for *SOST* expression analysis by real-time PCR. Consistent with its role as a bone formation inhibitor increased *SOST* gene dosage resulted in mild but significant osteopenia. Intermittent PTH treatment repressed endogenous mouse *SOST* by about 50%. Comparable suppression levels were observed for human *SOST* expressed from the BAC transgene under the control of its own proximal promoter and its downstream enhancer, resulting in a relative excess of *SOST* in PTH treated BAC transgenic mice. PTH treatment induced substantial increases in bone mineral content and density in wildtype mice due to cortical and cancellous bone gain. Both PTH-induced cortical and cancellous bone gain was significantly attenuated, but not abolished in *SOST* overexpressing mice. *SOST* deficient mice display a progressive distinct high bone mass phenotype. We hence initiated PTH treatment in these mice at 6 weeks of age to avoid a situation in which further intervention-induced bone gain might not have been achievable anymore. *SOST* was absent in knockout mice and was suppressed by about 50% in wildtype littermates following PTH application. PTH induced substantial increases in bone mass and density in the femur of growing wildtype mice. This was predominantly related to cortical thickening. *SOST* deficient mice showed small non-significant PTH-induced increases in bone mass and density and cortical thickening. In conclusion, our data support the hypothesis that bone mass gain induced by intermittent PTH treatment relies in part on *SOST* repression, since bone gain was attenuated in mice with higher *SOST* levels and in mice lacking *SOST*. Furthermore, the results from the BAC transgenic mouse model demonstrate that human *SOST* is regulated by intermittent PTH treatment in a similar manner as mouse *SOST*. The finding that PTH-induced bone gain is not completely abolished in *SOST* overexpressing or deficient mice is in line with the fact that PTH uses multiple pathways to promote bone formation.

**Adenylyl Cyclase 6 Mediates Primary Cilia-Regulated Decreases in cAMP in Bone Cells Exposed to Dynamic Fluid Flow.** R. Y. Kwon<sup>\*1</sup>, S. Temiyasathit<sup>\*2</sup>, P. Tummala<sup>\*3</sup>, C. C. Quah<sup>\*3</sup>, C. R. Jacobs<sup>3</sup>. <sup>1</sup>Department of Mechanical Engineering, Stanford University, Stanford, CA, USA, <sup>2</sup>Department of Bioengineering, Stanford University, Stanford, CA, USA, <sup>3</sup>VA Medical Center, Palo Alto, CA, USA.

Primary cilia function as mechanosensory organelles in several tissue types. Recently, our lab showed that they mediate osteogenic and anti-resorptive responses in bone cells exposed to fluid flow. However, the second messenger system(s) involved has not been determined. In this study, our goals were to determine (1) whether exposing bone cells to dynamic flow alters intracellular levels of cyclic adenosine monophosphate (cAMP), a ubiquitous second messenger molecule, and (2) the role of primary cilia in mediating this process. To investigate this, we exposed MLO-Y4 osteocyte-like cells to oscillatory flow (1Hz, 1Pa) and quantified intracellular cAMP levels. We found that exposure to 2 minutes of flow induced a significant decrease in cAMP ( $0.62 \pm 0.07^{**}$ ;  $p < 0.001$ ;  $n = 17$ ). To assess the role of primary cilia in mediating this process, we treated the cells with siRNA targeted against polaris, a protein necessary for primary cilia formation. Treatment significantly lessened flow-induced decreases in cAMP (control siRNA:  $0.57 \pm 0.08$ , polaris siRNA:  $0.89 \pm 0.04$ ;  $p < 0.001$ ;  $n \geq 9$ ). To further investigate the relationship between primary cilia and cAMP, we immunostained the cells for all nine different membrane-bound isoforms of adenylyl cyclase (AC1-9), the enzyme that synthesizes cAMP. Interestingly, we found that one isoform, AC6, was highly localized to primary cilia, and treating the cells with siRNA targeted against AC6 significantly diminished flow-induced decreases in cAMP (control siRNA:  $0.57 \pm 0.08$ , AC6 siRNA:  $1.07 \pm 0.10$ ;  $p = 0.001$ ;  $n \geq 6$ ). Previous studies have shown that binding of  $Ca^{2+}$  to AC6 inhibits cAMP synthesis and that entry of  $Ca^{2+}$  through cilium-localized mechanosensitive ion channels is important for transduction of flow in renal epithelial cells and cholangiocytes. In our studies, blocking stretch-activated ion channels using gadolinium chloride eliminated flow-induced decreases in cAMP (no treatment:  $0.62 \pm 0.07$ , gadolinium chloride:  $1.02 \pm 0.08$ ;  $p = 0.001$ ;  $n \geq 9$ ). Taken together, our findings suggest that AC6 mediates primary cilia-regulated decreases in cAMP in bone cells exposed to short bouts of oscillatory flow, and that activation of mechanosensitive ion channels is necessary for this process. In addition, our findings are consistent with the hypothesis that flow-induced decreases in cAMP are due to inhibition of AC6 by  $Ca^{2+}$  entry through stretch-activated ion channels localized to primary cilia, although further investigation is necessary in this regard.

**In Vivo Load Activated Propagation of  $\beta$ -catenin Signaling in Osteocytes through Coordinated Downregulation of Inhibitors of Lrp5.** N. A. Kim-Weroha<sup>\*1</sup>, A. Ferris<sup>\*1</sup>, B. Holladay<sup>\*1</sup>, S. P. Kotha<sup>2</sup>, M. A. Kamel<sup>1</sup>, M. L. Johnson<sup>1</sup>. <sup>1</sup>Oral Biology, UMKC School of Dentistry, Kansas City, MO, USA, <sup>2</sup>UConn School of Engineering, Storrs, CT, USA.

The Lrp5/Wnt/ $\beta$ -catenin signaling pathway is critical for bone formation in response to mechanical load. Osteocytes, thought to be the transducers of load, express two major inhibitors of Lrp5; Dkk1 and sclerostin. We have previously shown that the prostaglandin signaling pathway crosstalks with  $\beta$ -catenin signaling through Akt mediated inhibition of GSK-3 $\beta$  *in vitro*. Prostaglandin is essential for load induced bone formation and its release could enable osteocytes to respond rapidly to load, even in the presence of these Lrp5 inhibitors. To test this model *in vivo* we examined the timing of  $\beta$ -catenin signaling versus Dkk1 and sclerostin expression in bone subjected to loading (forearm compression, 100 cycles, 2 Hz, ~4000 $\mu$ E) in TOPGAL ( $\beta$ -catenin reporter) mice.  $\beta$ -catenin activity was monitored by  $\beta$ -gal staining and changes in Dkk1 and sclerostin were detected by immunostaining in the ulna midshaft region. The number of  $\beta$ -gal positive osteocytes in regions of maximal strain increased by 1.5, 1.8 and 2.6 fold, respectively, at 1, 4 and 24 hr post loading (N=4 per time) ( $p < .01$ ) to ~40% of the osteocytes (baseline ~15%), suggesting a rapid activation of  $\beta$ -catenin signaling in a subset of osteocytes and propagation to connecting osteocytes over time. Whereas osteocytes responded rapidly to loading,  $\beta$ -gal positive cells on the bone surface were not observed until 24 hr post loading suggesting slower propagation to the bone surface. At baseline, Dkk1/sclerostin were co-expressed in ~80% of the osteocytes in regions of maximal strain and >98% of the osteocytes in neutral strain regions. At 1 and 4 hours post loading, no statistically significant changes in the number of Dkk1 or sclerostin positive osteocytes were observed, but  $\beta$ -catenin signaling was observed in both Dkk1/sclerostin positive and negative osteocytes. However, by 24 hr post loading, the number of osteocytes positive for Dkk1/sclerostin was decreased by 50% ( $p < .01$ ) and most of the cells with activated  $\beta$ -catenin signaling expressed low or undetectable levels of these inhibitors, suggesting a reciprocal relationship between  $\beta$ -catenin activation and downregulation of the inhibitors in osteocytes over 24 hrs. The data support our model of a rapid activation of  $\beta$ -catenin signaling independent of Lrp5 thereby circumventing inhibition by Dkk1 and sclerostin, potentially through a PGE<sub>2</sub> crosstalk mechanism followed by a longer term Lrp5-dependent amplification of  $\beta$ -catenin signaling that requires the downregulation of Dkk1 and sclerostin. Such a model provides a molecular mechanism for the propagation of mechanical strain related responses.

## 1042

**Transcriptional Regulation of Connexin 43 by  $\beta$ -catenin, a Pathway Activated by PGE<sub>2</sub>-PI3K-GSK-3 Signaling in Mechanically Loaded Osteocytes.** X. Xia<sup>\*1</sup>, S. Harris<sup>2</sup>, L. F. Bonewald<sup>3</sup>, E. Sprague<sup>\*4</sup>, J. X. Jiang<sup>1</sup>. <sup>1</sup>Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, <sup>2</sup>Periodontics, University of Texas Health Science Center, San Antonio, TX, USA, <sup>3</sup>Oral Biology, University of Missouri, School of Dentistry, Kansas City, MO, USA, <sup>4</sup>Radiology, University of Texas Health Science Center, San Antonio, TX, USA.

Primary osteocytes and osteocyte-like MLO-Y4 cells express large amounts of connexin 43 (Cx43) which forms gap junctions and hemichannels. Osteocytes can only form gap junctions at the connecting tips of their dendritic processes leaving hemichannels along the extensive cell membrane surfaces of the dendrites and cell body. Fluid flow shear stress (FFSS) induces the opening of hemichannels in MLO-Y4 cells associated with the release of prostaglandin, an important bone modulator. The released prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) binds to EP2/4 receptor activating the cAMP-PKA signaling pathway, which leads to an increase in the expression of Cx43 and consequently gap junction function. To identify the steps in this signaling cascade, we searched for potential crosstalk with the  $\beta$ -catenin pathway. Both FFSS and PGE<sub>2</sub> increased the phosphorylation levels of Akt suggesting that PI3 kinase (PI3K) signaling pathways are activated by FFSS through PGE<sub>2</sub> in MLO-Y4 osteocyte-like cells. PI3K specific inhibitor, LY294002, but not a MAPK inhibitor, PD98059 attenuated the stimulatory effect of PGE<sub>2</sub> on Cx43 expression. FFSS and PGE<sub>2</sub> stimulated the phosphorylation levels of glycogen synthase kinases 3 $\alpha$  and 3 $\beta$  (GSK-3 $\alpha/\beta$ ) and this increase was blocked by PI3K inhibitor, but not MAPK inhibitor suggesting that the inactivation of GSK-3 activity was also mediated by PI3K activation. Application of FFSS and PGE<sub>2</sub>, and subsequent PI3K activation led to the stabilization and nuclear translocation of  $\beta$ -catenin. Knockdown of  $\beta$ -catenin expression by siRNA resulted in a reduction in Cx43 protein expression. Furthermore, chromatin immunoprecipitation (ChIP) assay demonstrates the association of  $\beta$ -catenin with Cx43 DNA promoter, suggesting that  $\beta$ -catenin regulates Cx43 expression at the level of gene transcription. Together, these results suggest that FFSS through PGE<sub>2</sub> release activates PI3K-AKT signaling, which leads to GSK-3 inactivation and the activation of  $\beta$ -catenin pathway resulting in an increase in Cx43. Therefore, the PI3K-AKT/ $\beta$ -catenin signaling pathway plays an essential role in regulating gap junction and hemichannel function through transcriptional regulation of Cx43 expression in response to FFSS induced prostaglandin release.

**MIA3, a Novel Secreted Factor, Regulates Chondrogenic Differentiation in the Developing Mouse Embryo.** M. J. Solloway, D. Grant<sup>\*</sup>, K. Phamluong<sup>\*</sup>, A. Peterson<sup>\*</sup>. Molecular Biology, Genentech, Inc., South San Francisco, CA, USA.

MIA3 belongs to a family of four secreted proteins (MIA, MIA2, MIA3, OTOR) which are unique in that they contain an extracellular SH3 domain. These molecules have been implicated in regulating chondrogenesis via poorly characterized mechanisms: *Mia* is expressed exclusively in the developing skeleton, and treatment of differentiating mesenchymal stem cells with MIA protein stabilizes a chondrogenic phenotype while inhibiting osteogenic differentiation. However, null mice are viable and display subtle ultrastructural defects in collagen deposition. In order to further characterize the role(s) played by the MIA proteins in skeletogenesis, we generated an allele of MIA3 lacking the extracellular SH3 domain. Embryos lacking this ubiquitously expressed protein die near term and display a striking delay in the progression of chondrogenesis and mineralization as well as severe edema. This phenotype is overtly similar to that seen in embryos lacking the chondrocyte/osteoblast-specific transcription factor *Runx2*, and *Runx2* expression is strongly downregulated in the *Mia3* mutant bone anlagen. Several other markers of chondrogenic maturation are also severely misregulated in the mutant bone, including PTH/PTHrP receptor, *Ihh*, and Collagen type I. In support of this observation, treatment of differentiating ATDC5 teratocarcinoma cells with the purified MIA3 SH3 domain stimulates the early stages of chondrogenesis while delaying later chondrogenic maturation. In summary, our analysis of *Mia3* embryos uncovers a novel role for this gene in coordinating chondrocyte differentiation throughout the skeleton, and these observations are confirmed using an in vitro model of chondrogenesis.

**PTHrP Prevents Chondrocyte Premature Hypertrophy by Inducing Cyclin D1-Dependent Runx2 and 3 Phosphorylation and Degradation.** R. Xie<sup>1</sup>, M. Zhang<sup>\*2</sup>, M. Zhu<sup>1</sup>, W. Hou<sup>\*1</sup>, R. Shen<sup>1</sup>, Q. Wang<sup>\*2</sup>, T. Zhu<sup>\*2</sup>, D. Chen<sup>1</sup>. <sup>1</sup>Orthopaedics, University of Rochester, Rochester, NY, USA, <sup>2</sup>Medical College of Nankai University, Tianjin, China.

PTHrP maintains chondrocytes in a proliferative state. In PTHrP KO mice, premature chondrocyte hypertrophy was observed. The mechanism by which PTHrP prevents chondrocytes from premature hypertrophy is not fully understood. *Runx2* and *3* are required for chondrocyte maturation. In *Runx2* and *3* double KO mice, chondrocyte hypertrophy was completely inhibited. We recently demonstrated that cell cycle protein cyclin D1 induces *Runx2* phosphorylation, ubiquitination and degradation. In the present studies, we tested the hypothesis that PTHrP regulates protein stability of *Runx2* and *3* through cyclin D1. We found that cyclin D1 induced *Runx3* degradation in a dose-dependent manner and *Runx3* directly interacts with CDK4. A conserved CDK recognition site, the SP motif, was identified in the C-terminal region of *Runx3* by sequence analysis (aa 356-359). Pulse-chase experiments showed that the mutation of *Runx3* at serine-356 to alanine (SA-*Runx3*) increased the half-life of *Runx3*. In contrast, a serine-356 to glutamic

acid mutation (SE-*Runx3*) accelerated *Runx3* degradation. In addition, SA-*Runx3* was resistant to cyclin D1-induced degradation. GST-*Runx3* was strongly phosphorylated by CDK4 in vitro. In contrast, CDK4 had no effect on the phosphorylation of SA-*Runx3*. While both WT and SE-mutant *Runx3* were ubiquitinated, the SA-mutant *Runx3* was not. The cyclin D1-induced *Runx3* degradation was completely blocked by the proteasome inhibitor PS1. SA-*Runx3* had a greater and SE-*Runx3* had a lesser induction of the 6xOSE2-Luc *Runx* reporter and ALP activity compared to WT *Runx3* in C3H10T1/2 cells. To investigate the role of cyclin D1 in chondrocyte proliferation and hypertrophy, we analyzed growth plate morphology and gene expression of cyclin D1 KO mice. The proliferating zone was significantly reduced and expression of chondrocyte differentiation marker genes and ALP activity were enhanced in postnatal cyclin D1 KO mice. PTHrP significantly suppressed protein levels of both *Runx2* and *3* in primary chondrocytes derived from WT mice. In contrast, the suppressive effect of PTHrP on *Runx2* and *3* protein levels was completely abolished in primary chondrocytes derived from cyclin D1 KO mice. Our findings demonstrate that the cell cycle proteins cyclin D1/CDK4 induce *Runx2* and *3* phosphorylation, ubiquitination, and proteasome degradation. PTHrP suppresses *Runx2* and *3* protein levels in chondrocytes through cyclin D1. These results suggest that PTHrP may prevent chondrocytes from premature hypertrophy by inducing degradation of *Runx2* and *3* in a cyclin D1-dependent manner.

**Transcription Factor Dmrt2 Controls Endochondral Ossification Through Regulating Type 10 Collagen (Col10a1) Gene Expression.** K. Ono<sup>\*1</sup>, K. Hata<sup>1</sup>, E. Nakamura<sup>\*2</sup>, A. Sugita<sup>\*1</sup>, K. Amano<sup>\*1</sup>, M. Nakanishi<sup>\*1</sup>, Y. Takigawa<sup>\*1</sup>, R. Nishimura<sup>1</sup>, S. Takenoshita<sup>\*3</sup>, T. Yoneda<sup>1</sup>. <sup>1</sup>Biochem, Osaka Univ Grad Sch Dent, Suita, Japan, <sup>2</sup>Biochem, Osaka Univ Sch Dent, Suita, Japan, <sup>3</sup>Surgery II, Fukushima Med Univ Grad Sch Med, Fukushima, Japan.

Dmrt (doublesex and mab-3-related transcription factor) genes encode a large family of transcription factors which play important roles in sex differentiation. Recent genetic studies have reported that loss of DMRT1/2 causes not only sex reversal but also growth retardation, scoliosis and malformation of fingers in human and that *Dmrt2*-deficient mice shows malformation of rib and sternum, suggesting that *Dmrt* genes are also involved in vertebrate skeletal development. In the present study, we investigated the role of *Dmrt2* in endochondral ossification that plays a central role in vertebral skeletal development. As a first approach to address this, we examined the expression of *Dmrt2* in chondrocytes. RT-PCR analysis revealed that *Dmrt2* was the only *Dmrt* family member strongly expressed in E11.5-E14.5 mouse hind limbs. Immunohistochemical analysis further demonstrated that *Dmrt2* was strongly expressed in pre-hypertrophic zone but weakly in proliferative and late-hypertrophic zone in E14.5 tibia. *Dmrt2* was also expressed in primary mouse chondrocytes in culture. The expression of *Dmrt2* was increased during chondrogenic differentiation in C3H10T1/2 cells treated with BMP2. We next investigated the effects of *Dmrt2* on chondrocyte differentiation. Overexpression of *Dmrt2* using adenovirus system reduced type 2 collagen (Col2a1) expression but increased Col10a1 expression in BMP2-treated C3H10T1/2 cells. *Dmrt2* also markedly increased Col10a1 expression in primary mouse chondrocytes in the presence of BMP2, whereas it decreased markers for early chondrocyte differentiation such as Col2a1, aggrecan and Col11a1. Moreover, knockdown of *Dmrt2* using siRNA suppressed Col10a1 expression. Finally, we studied the molecular basis of *Dmrt2* functions. *Dmrt2* reduced Sox9-induced Col2a1 expression. Reporter assay using Col2a1 promoter revealed that *Dmrt2* decreased Sox9 transcriptional activity. In contrast, *Dmrt2* directly transactivated Col10a1 gene promoter presumably through binding to the putative *Dmrt2* binding element in Col10a1 promoter. In conclusion, our results show that *Dmrt2* is expressed at high levels in pre-hypertrophic chondrocytes and inhibits Col2a1 expression and stimulates Col10a1 expression, suggesting that *Dmrt2* regulates cartilage differentiation through inhibiting early-stage and promoting late-stage chondrocyte differentiation. Further elucidation of *Dmrt2* function in chondrogenesis would contribute to better understanding of the mechanism underlying endochondral ossification.

**Conditional Deletion of Fibronectin Results in a Scoliosis-Like Phenotype.**Q. Chen<sup>1</sup>, H. Zhao<sup>\*1</sup>, J. Zhao<sup>\*1</sup>, D. M. Pacicca<sup>\*2</sup>, R. Fassler<sup>\*3</sup>, S. L. Dallas<sup>1</sup>.<sup>1</sup>Univ. of Missouri, Kansas City, Kansas City, MO, USA, <sup>2</sup>Children's Mercy Hospitals & Clinics, Kansas City, MO, USA, <sup>3</sup>Max Planck Institute of Biochemistry, Martinsried, Germany.

Congenital scoliosis is a condition of lateral curvature of the spine due to a developmental abnormality. Fibronectin (FN) is an extracellular matrix (ECM) glycoprotein that is expressed at sites of bone formation and is critical for osteoblast function. Although a role for FN in scoliosis has not been reported, we have generated transgenic mice in which FN is deleted in the osteoblast lineage. The mice exhibit a scoliosis-like phenotype, suggesting a potential role for FN in this disease. Mice with a floxed FN gene were crossed with mice expressing Cre recombinase driven by the 3.6kb Col1a1 promoter. Numbers of FNcKO mice were 60% less than expected, suggesting embryonic lethality. Surviving mice showed vertebral deformities resembling scoliosis. 100% of the FNcKO mice showed tail deformities (kinky tail), ranging from involvement of a single vertebra to all tail vertebrae. Deformities included fusions, hemivertebrae as well as block, asymmetric and abnormally segmented vertebrae. In a subgroup of mice with severe tail deformities, fusion of lumbar vertebrae, kyphosis and lateral spine curvatures were seen at birth and became more severe with age. FNcKO mice also showed significantly decreased bone mineral density and bone mineral content and a mild/moderate short stature. As FN controls assembly of several other ECM proteins, we next determined whether the phenotype of FNcKO mice was due to abnormal ECM assembly. Decreased FN in the skeleton was associated with decreased type I collagen and fibrillin-1, two ECM proteins implicated in scoliosis. FN deletion was also associated with reduced BMP signaling in osteoblasts, as shown by decreased phospho-Smad 1/5/8 staining. A key role for FN in assembly of bone ECM proteins was confirmed by infecting FN floxed osteoblasts with adenoviral Cre recombinase to delete FN in vitro. This resulted in a 90% reduction in FN, accompanied by impaired assembly of type I collagen, decorin, biglycan, LTBP1 and fibrillin-1, a known regulator of BMPs. Assembly of these matrix molecules was rescued by supplementation with FN. In the embryo, FN is localized at somite boundaries and disruption of FN in avian embryos inhibits somite formation. Conventional FN gene deletion is embryonic lethal at E8.5, with embryos failing to form somites. By examining FNcKO embryos, we found that the tail phenotype was apparent by E12.5, suggesting defective somitogenesis and/or resegmentation. These data suggest that misregulation of FN may play a role in scoliosis by regulating assembly of ECM proteins and/or altering ECM regulated growth factor pathways critical for axial skeleton patterning, bone growth and development.

**Activation of  $\beta$ -Catenin Signaling in Articular Chondrocytes Leads to Osteoarthritis-like Phenotype in Adult  $\beta$ -Catenin Conditional Activation Mice.**

D. Tang, M. Zhu, Q. Wu, M. Chen, C. Xie, R. N. Rosier, R. J. O'Keefe, M. Zuscik, D. Chen. Orthopaedics, University of Rochester, Rochester, NY, USA.

Osteoarthritis (OA) is a degenerative joint disease and the mechanism of its pathogenesis is poorly understood. Recent human genetic association studies demonstrate that mutations in the *Frzb* gene predispose patients to OA, suggesting that the Wnt/ $\beta$ -catenin signaling may play a key role in the development of OA. However, direct genetic evidence for  $\beta$ -catenin in this disease has not been reported. Since chondrocyte-specific activation of the  $\beta$ -catenin gene (targeted by *Col2a1-Cre*) is embryonic lethal, we have generated inducible  $\beta$ -catenin conditional activation (cAct) mice via breeding of  $\beta$ -catenin<sup>fl<sup>Ex3</sup>/fl<sup>Ex3</sup></sup> mice with *Col2a1-CreER<sup>T2</sup>* transgenic mice. Deletion of exon 3 of the  $\beta$ -catenin gene results in the production of a stabilized  $\beta$ -catenin protein which is resistant to phosphorylation by GSK-3 $\beta$ . In this study, tamoxifen was administered to the 3- and 6-month-old *Col2a1-CreER<sup>T2</sup>*;  $\beta$ -catenin<sup>fl<sup>Ex3</sup>/fl<sup>Ex3</sup></sup> mice and tissues were harvested for histologic analysis 2 months after tamoxifen induction. Over expression of  $\beta$ -catenin protein was detected by immunostaining in articular cartilage tissues of  $\beta$ -catenin cAct mice. In 5-month-old  $\beta$ -catenin cAct mice, reduction of Safranin O staining in articular cartilage tissue and reduced articular cartilage area were observed. In 8-month-old  $\beta$ -catenin cAct mice, cell cloning, surface fibrillation, vertical clefting and osteophyte formation were observed. Complete loss of articular cartilage layers and the formation of new woven bone in subchondral bone area were found in  $\beta$ -catenin cAct mice. Expression of chondrocyte marker genes, such as *aggrecan*, *Mmp-9*, *Mmp-13*, *Alp*, *Oc*, and *colX* was significantly increased (3 to 6-fold) in articular chondrocytes derived from  $\beta$ -catenin cAct mice. *Bmp2* but not *Bmp4* expression was also significantly up-regulated (6-fold increase) in these cells. In vitro studies further demonstrated that Wnt3a-induced expression of chondrocyte marker genes, such as *Alp*, *Oc* and *colX*, was completely inhibited by noggin in articular chondrocyte cell cultures, suggesting that Wnt3a regulates the expression of these chondrocyte marker genes in a *Bmp*-dependent mechanism. In addition, we also found that  $\beta$ -catenin protein is over expressed in knee joint samples from patients with OA. Our findings indicate that activation of  $\beta$ -catenin signaling in articular chondrocytes in adult mice leads to the premature chondrocyte differentiation and the development of an OA-like phenotype. This study provides direct and definitive evidence about the role of  $\beta$ -catenin in the development of OA.

**In vivo Knockdown of GEP, a Novel Growth Factor in Cartilage, Led to Defects in Cartilage and Osteoarthritis.**B. Jiang<sup>\*1</sup>, Y. Zhang<sup>\*2</sup>, Y. Xie<sup>\*1</sup>, L. Kong<sup>\*2</sup>, F. Guo<sup>\*2</sup>, Z. Cao<sup>\*1</sup>, J. Q. Feng<sup>1</sup>, C. Liu<sup>2</sup>. <sup>1</sup>Department of Biomedical Sciences, Baylor College of Dentistry, Texas A&M University System Health Science Center, Dallas, TX, USA, <sup>2</sup>Department of Orthopaedic Surgery, NYU Hospital for Joint Diseases, New York, NY, USA.

In searching for proteins critical for cartilage formation and function, we identified a previously unknown growth factor, granulin/epithelin precursor (GEP) in cartilage. In situ hybridization assays showed that GEP is highly expressed in growth plate and articular cartilage during both embryonic and postnatal development. Real time RT-PCR and Western blotting assays showed that GEP were upregulated by BMP2 during chondrogenesis. Additions of recombinant GEP into high-density human postnatal mesenchymal stem cell pellets, significantly increase expression levels of Sox9 (10-fold), Sox 5 and 6 (40-fold), Ihh (100-fold), and Runx2 (6-folds), Col II (30-fold), Aggrecan (50-fold), and Col X (120-fold), respectively. In contrast, GEP completely inhibits mRNA levels of PTHrP, and PTH receptor 1, two negative regulators of chondrogenesis. Furthermore, GEP is more potent than BMP2 in inducing chondrogenic markers such as Col X at an equivalent dosage level. We also created GEP knockdown mice where siGEP RNA is driven by the U6 promoter, a ubiquitous promoter that is disturbed by a loxP-flanked neomycin cassette (Note that the siGEP RNA expression will be activated only when crossed to Cre transgenic mice whose Cre removes the neomycin). Next, U6-ploxPneo-GEP transgenic mice were crossed to Sox2-Cre transgenic mice, where Cre enzyme is activated in early mesenchymal cells, for tissue-specific knockdown of GEP. GEP mRNA/protein levels in these mice were undetectable in cartilage, and these mice display a sharp reduction in skeletal length, bone volumes, and cortical bone thickness. The knockdown growth plate is only half size of that in WT, and shows a sharp reduction of Col II, alkaline phosphatase, and Col X. The 10-mo-old mice display an osteoarthritis phenotype in large and small joints such as joint space narrowing, reduction of articular chondrocytes in number, extracellular matrix and sclerotic subchondral bone formation, osteophytes, and subchondral sclerosis (increased bone density). Finally we showed that both mRNA and protein levels of GEP were upregulated in arthritis patients. Based on the above findings we conclude that GEP, a novel growth factor in cartilage, is critical for chondrogenesis; and that GEP null mice are a new arthritis model.

**Prolyl 3-Hydroxylase 1 and CRTAP are Mutually Stabilizing in the Endoplasmic Reticulum Collagen Prolyl 3-Hydroxylation Complex.**

W. Chang, A. M. Barnes\*, W. A. Cabral\*, J. C. Marini. Bone and Extracellular Matrix Branch, NICHD, NIH, Bethesda, MD, USA.

Osteogenesis Imperfecta is a heritable bone disease characterized by increased skeletal fragility and growth deficiency. Classical dominant OI is caused by mutations in the two genes encoding type I collagen. We recently identified null mutations in cartilage associated protein (CRTAP) and prolyl 3-hydroxylase 1 (P3H1/LEPRE1) as the cause of two novel recessive forms of OI, Types VII and VIII, respectively. CRTAP and P3H1, along with cyclophilin B, form a complex in the endoplasmic reticulum (ER) which modifies the  $\alpha 1$  chain of types I and II collagen by 3-hydroxylation of the Pro986 residue. The interactions of CRTAP and P3H1 in this complex are unknown. In this investigation, we used cultured dermal fibroblasts from type VII and VIII OI probands to demonstrate that CRTAP and P3H1 are mutually protective in the ER complex. P3H1 is absent on Western blots of CRTAP-null fibroblast lysates and, conversely, CRTAP is minimally detectable on Western blots of LEPRE1-null lysates. Real-time RT-PCR amplification yielded increased *LEPRE1* or *CRTAP* mRNA levels in cells which have null mutations and low levels of the other transcript. Therefore, absence of either CRTAP or P3H1 from cells with a null mutation in the other gene must be presumed to result from loss of normal mutual stabilization. In contrast, cyclophilin B, the third component of the complex, was equally abundant in control and both sets of mutant cell lines. Also, parental carriers of *CRTAP* or *LEPRE1* mutations have near-normal levels of the other protein. Stable transfection of a full-length *CRTAP* expression plasmid into *CRTAP* null fibroblasts restored both CRTAP and P3H1 protein levels. Stable transfection with a series of *CRTAP* deletion constructs demonstrated that deletions of portions of exon 1 or 4, which may be crucial for CRTAP folding or interactions with P3H1 in the complex, failed to restore P3H1 protein levels on Western blots. Expression of a construct with a deletion of the region encoding the only TPR-like motif in CRTAP results in partial restoration of P3H1 levels. We are also examining the trafficking of CRTAP in *LEPRE1*-null cells. Immunofluorescence microscopy demonstrated reduced levels of CRTAP in *LEPRE1*-null cells, while CRTAP localization in these cells is being determined. CRTAP is detectable in the conditioned media of control and *LEPRE1*-null fibroblasts. Since P3H1 has an ER retention signal, absence of the P3H1 may lead to increased CRTAP secretion. We are currently examining the levels of P3H1 secretion from *CRTAP*-null fibroblasts, as well as the proteosomal and non-proteosomal pathways of degradation that the null cells may be utilizing to handle the chronic ER stress from abnormally modified collagen.

**Defects in Mesenchymal Stem Cell Self-Renewal Lead to an Osteopenic Phenotype in *Bmi-1* Null Mice.** H. W. Zhang\*, J. Ding\*, J. L. Jin\*, D. S. Miao. The Research Center for Bone and Stem Cells, Nanjing Medical University, Nanjing, China.

Previous studies have demonstrated that the oncogene *Bmi-1* plays an important role in maintaining the self-renewal of neural and hematopoietic stem cells, but its role in maintaining the self-renewal of bone marrow mesenchymal stem cells (BM-MSCs) is currently unknown. In the present studies, we have analyzed the skeletal phenotype of *Bmi-1*<sup>-/-</sup> mice and determined the role of *Bmi-1* in BM-MSC function. Changes in cell proliferation and differentiation were examined in BM-MSCs isolated from 3-week-old *Bmi-1*<sup>-/-</sup> mice. *Bmi-1*<sup>-/-</sup> mice exhibited skeletal growth retardation associated with reduced chondrocyte proliferation and increased chondrocyte apoptosis, demonstrated by immunostaining for the proliferating cell nuclear antigen and by TUNEL staining, respectively. Histomorphometric analysis showed that bone mineral density, trabecular bone volume, osteoblast number, the alkaline phosphatase and type I collagen positive area of metaphyseal region and the mineral apposition rate were all significantly reduced in *Bmi-1*<sup>-/-</sup> mice. However, the number of adipocytes within bone marrow was increased in 2- and 4-week-old *Bmi-1*<sup>-/-</sup> mice. The reduced bone formation in *Bmi-1*<sup>-/-</sup> mice was associated with decreased gene expression of alkaline phosphatase, type I collagen and osteocalcin. The increased adipocyte formation was associated with increased expression of Ppar- $\gamma$  in bone tissue of *Bmi-1*<sup>-/-</sup> mice. In contrast, *Bmi-1* deficiency does not affect osteoclast formation. The numbers of TRAP-positive multi-nucleated osteoclasts and the ratio of RANKL and OPG gene expression were not altered in *Bmi-1*<sup>-/-</sup> mice. Bone marrow cell cultures showed that the efficiency of CFU-F formation was decreased. The percentage of alkaline phosphatase-positive CFU-F was significantly reduced accompanied by down-regulation of Runx2 protein expression. The efficiency of adipocyte formation was significantly increased associated with up-regulation of Ppar- $\gamma$  protein expression in BM-MSCs derived from *Bmi-1*<sup>-/-</sup> mice. Reduced proliferation and increased apoptosis of BM-MSCs were associated with up-regulation of the senescence-associated tumor suppressor genes including p16, p19 and p27 in *Bmi-1*<sup>-/-</sup> mice. Our results indicate that *Bmi-1* plays a critical role in maintaining the self-renewal of BM-MSCs by inhibiting the expression of tumor suppressor genes such as p16, p19 and p27. *Bmi-1* promotes Runx2 expression and BM-MSC differentiation into osteoblasts and down-regulates Ppar- $\gamma$  expression and inhibits their differentiation into adipocytes.

**Aberrant *Phex* Function in Osteocytes Has Limited Effects on Bone Mineralization in X-Linked Hypophosphatemia (XLH).** B. Yuan\*<sup>1</sup>, J. Q. Feng<sup>2</sup>, Y. Xing<sup>1</sup>, J. Meudt<sup>1</sup>, P. S. Rowe<sup>3</sup>, M. K. Drezner<sup>\*1</sup>. <sup>1</sup>University of Wisconsin, Madison, WI, USA, <sup>2</sup>Texas A&M Health Science Center, Dallas, TX, USA, <sup>3</sup>University of Kansas, Kansas City, KS, USA.

Patients with XLH and *hyp*-mice, with a deletion in the *Phex* gene, manifest hypophosphatemia, renal phosphate (Pi) wasting, and rickets/osteomalacia. Since targeted deletion of *Phex* in osteoblasts/osteocytes, using an *Osteocalcin* promoter Cre-loxP strategy, results in development of a classical *HYP* phenotype, osteoblast lineage cells alone are undoubtedly the physiologically relevant site for *Phex* mutations. Whether aberrant *Phex* function in both osteoblasts and osteocytes is necessary for the renal and bone phenotype in *hyp*-mice, however, remains unknown. Yet, novel therapeutic strategies for XLH are limited by such absent information. Thus, we generated mice with conditional DMP1-promoted *Phex* knockout, predominantly in osteocytes, (*DMP1-Phex*<sup>fllox/y</sup>) and compared their phenotype to that in normal and *hyp*-mice. Serum Pi in *DMP1-Phex*<sup>fllox/y</sup> (3.37 $\pm$ 0.27) and *hyp*-mice (3.32 $\pm$ 0.1) was significantly less ( $p < 0.001$ ) than in normals (6.16 $\pm$ 0.25). Moreover, the reduction in serum Pi in *DMP1-Phex*<sup>fllox/y</sup> mice was due to diminished renal Pi transport, associated with decreased renal Npt2 mRNA and protein levels, comparable to those in *hyp*-mice. Like *hyp*-mice, the *DMP1-Phex*<sup>fllox/y</sup> mice also exhibited increased bone FGF-23 production, evidenced by a 4.5 fold mRNA increase. With enhanced FGF-23 production, *DMP1-Phex*<sup>fllox/y</sup> mice had a significant increase in serum FGF-23 compared to normals (820 $\pm$ 58 vs 75.6 $\pm$ 5.7 pg/ml,  $p < 0.0001$ ) but, despite manifesting a substantial overlapping range of values with those in *hyp*-mice, had levels significantly less than in the mutants (1200 $\pm$ 61 pg/ml). Surprisingly, however, although femur radiographs documented *DMP1-Phex*<sup>fllox/y</sup> mice had a comparable rachitic phenotype to that in *hyp*-mice and an overlapping range of circulating FGF-23 prevailed, bone histomorphometrics revealed that targeted knockouts exhibited osteomalacia extraordinarily less severe than in the mutants with osteoid surface 3.5 fold less (8.7 $\pm$ 1.2% vs 30.0 $\pm$ 5.3%;  $p < 0.0001$ ). These data indicate that abnormal *Phex* function in osteocytes is sufficient to alone produce the renal XLH phenotype. However, the *Phex* mutation in osteocytes results in an extraordinarily mild osteomalacic mineralization disorder unlike that in *hyp*-mice or that reported in mice with *Phex* deletion in osteoblasts and osteocytes. Thus, together the data indicate that aberrant *Phex* function in the osteoblast exerts primary control over bone mineralization in XLH, most likely through downstream effects of *Phex* dysfunction, including release of local factors, such as ASARM peptides, potent mineralization inhibitors.

**Deletion of the *GNAS* Antisense Transcript Results in Parent-Of-Origin Specific *GNAS* Imprinting Defects and Phenotypes Including PTH-Resistance.** S. Chillambhi<sup>\*1</sup>, S. Turan<sup>\*1</sup>, D. Hwang<sup>\*2</sup>, H. Chen<sup>\*2</sup>, H. Jüppner<sup>1</sup>, M. Bastepe<sup>1</sup>. <sup>1</sup>Endocrine Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, <sup>2</sup>Department of Nephrology, Kaohsiung Medical University, Kaohsiung, Taiwan.

Pseudohypoparathyroidism type-Ib (PHP-Ib) is characterized by renal resistance to parathyroid hormone (PTH) causing hypocalcemia, hyperphosphatemia, and increased PTH levels without Albright's Hereditary Osteodystrophy. Patients with PHP-Ib show imprinting defects of the *GNAS* locus, including either an isolated loss of A/B imprinting or broad epigenetic defects of the maternal allele. Deletions within the neighboring *STX16* locus have been identified in patients with isolated loss of A/B imprinting, whereas NESP55/*GNAS* antisense exon 3-4 deletions have been identified in familial cases with broad imprinting changes. We now identified a novel 5.1-kb deletion removing two exons of the antisense (AS) transcript in affected individuals and carriers of a not-yet-reported kindred with this disorder. The novel deletion overlaps with the previously identified NESP55/antisense exon 3-4 deletion by ~1.5 kb, but does not include NESP55. On maternal transmission the deletion leads to PHP-Ib and disrupts imprinting throughout the maternal *GNAS* allele, including partial gain of imprinting at NESP55 and complete loss of imprinting at the AS promoter, XL $\alpha$ s, and A/B. Unlike the previously described PHP-Ib deletions, the novel deletion also alters *GNAS* imprinting on paternal transmission, causing relaxation of imprinting at NESP55. Based on RT-PCR using total RNA from LCLs of one PHP-Ib patient and his mother, the mutant AS transcript is not expressed, consistent with the changes observed in NESP55 imprinting. In addition, individuals with paternal inheritance of the novel deletion exhibit a modest gain of A/B imprinting, which, based on data from previous mouse models, is predicted to de-repress paternal Gs $\alpha$  expression and, thereby, to increase its level in the proximal renal tubule. Accordingly, serum PTH was below the normal range in an individual who inherited the deletion paternally, suggesting increased PTH sensitivity. These findings redefine the boundaries of the *cis*-acting element that controls imprinting on the maternal *GNAS* allele and reveal a novel *cis*-acting mechanism underlying the tissue-specific silencing of paternal Gs $\alpha$  expression.

**7B2 Protein Mediated Inhibition of DMP1 Cleavage in Osteoblasts Enhances FGF-23 Production in *Hyp*-Mice.** B. Yuan<sup>1</sup>, J. Meudt<sup>\*1</sup>, J. Q. Feng<sup>\*2</sup>, M. K. Drezner<sup>1</sup>. <sup>1</sup>University of Wisconsin, Madison, WI, USA, <sup>2</sup>Texas A&M Health Science Center, Dallas, VT, USA.

Increased serum FGF-23 levels in *hyp*-mice, a murine homologue of X-linked hypophosphatemia (XLH), result from inhibition of FGF-23 degradation and enhanced production of FGF-23. We found previously that decreased *Phex*-dependent osteoblast production of 7B2, a helper protein for subtilisin-like proprotein convertase 2 (SPC2), decreases SPC2/7B2 proteolytic activity, causing elevated serum FGF-23 in *hyp*-mice. This elevation is due to diminished SPC2/7B2 proteolysis of FGF-23 and to downstream effects of SPC2/7B2, which increase FGF-23 mRNA. The mechanism by which decreased SPC2/7B2 activity exerts such effects on FGF-23 mRNA, however, remains unknown. Observations that DMP1 null mice have hypophosphatemic rickets with elevated FGF-23 mRNA and that DMP1 in osteoblasts/osteocytes is cleaved into N- and C-terminal fragments, which localize to the nucleus, suggest DMP1 cleavage may modulate FGF-23 gene expression. Therefore, we investigated if SPC2/7B2 proteolysis of DMP1 underlies increased FGF-23 production in *hyp*-mice. Transfection of full-length DMP1 into murine osteoblasts (TMOB) revealed FGF-23 mRNA was down regulated compared to that in controls (0.46 $\pm$ 0.1 vs 1.02 $\pm$ 0.1 fold;  $p < 0.001$ ). In contrast, transfection of DMP1 cDNA, mutated at the proteolytic cleavage site, caused no change in FGF-23 mRNA, indicating DMP1 cleavage is requisite for down-regulation of FGF-23 production. To determine if DMP1 cleavage is SPC2/7B2 dependent, we treated full-length DMP1 transfected TMOB cells with Dec, an SPC inhibitor. Such treatment dose dependently blocked DMP1 processing into N- and C-terminal fragments. In addition, cotransfection of TMOB cells with full-length DMP1, SPC2 and 7B2 constructs resulted in Western blot evidence of enhanced DMP1 cleavage into N- and C-terminal fragments (1.6 $\pm$ 0.2 vs 1.0 $\pm$ 0.2; 2.0 $\pm$ 0.1 vs 1.0 $\pm$ 0.1 fold;  $p < 0.01$ ). These data established that SPC2/7B2 cleavage of intact DMP1 may regulate FGF-23 mRNA. To assess if diminished DMP1 cleavage regulates FGF-23 production in *hyp*-mice with decreased SPC2/7B2 activity, we evaluated osseous production of DMP1 N- and C-terminal fragments. In *hyp*-mouse bone intact DMP1 is increased (2.8 $\pm$ 0.5 vs 1.0 $\pm$ 0.5 fold;  $p < 0.01$ ) while C- and N-terminal fragments are significantly reduced (1.6 $\pm$ 0.4 vs 3.7 $\pm$ 0.3; 1.8 $\pm$ 0.1 vs 2.8 $\pm$ 0.4 fold;  $p < 0.01$ ), consistent with decreased proteolysis of the intact protein. Thus, inactivating *Phex* mutations in XLH, and the resultant decreased osteoblast 7B2 concentration and diminished SPC2/7B2 activity, not only lessen FGF-23 degradation, but significantly limit DMP1 N- and C-terminal fragment production, decreasing the inhibitory effects of these fragments on FGF-23 mRNA and enhancing FGF-23 production.

**Relative Efficacy of “Treating” versus “Preventing” Infantile Hypophosphatasia in Akp2<sup>-/-</sup> mice by Enzyme Replacement Therapy.** I. Lemire<sup>\*1</sup>, T. P. Loise<sup>\*1</sup>, P. Leonard<sup>\*1</sup>, G. Boileau<sup>\*2</sup>, H. Landy<sup>\*1</sup>, R. Hefi<sup>\*1</sup>, M. P. Whyte<sup>3</sup>, P. Crine<sup>1</sup>, J. L. Millan<sup>4</sup>. <sup>1</sup>Enobia Pharma, Inc., Montreal, QC, Canada, <sup>2</sup>University of Montreal, Montreal, QC, Canada, <sup>3</sup>Shriners Hospitals for Children and Washington University, St. Louis, MO, USA, <sup>4</sup>Sanford Children's Health Research Center, Burnham Institute for Medical Research, La Jolla, CA, USA.

Hypophosphatasia (HPP) is the inborn-error-of-metabolism that features rickets or osteomalacia due to loss-of-function mutation(s) within the gene that encodes the tissue-nonspecific isoenzyme of alkaline phosphatase (TNALP). TNALP null mice (Akp2<sup>-/-</sup>) phenocopy infantile HPP extremely well. We recently showed that enzyme replacement therapy (EzRT) using a bone-targeted recombinant form of human TNALP, i.e., sALP-FcD10, prevented the various manifestations of infantile HPP in this model. Now we have tested whether EzRT could rescue Akp2<sup>-/-</sup> mice with advanced disease. We evaluated a daily bolus s.c. injection of 8.2 mg/Kg sALP-FcD10 in Akp2<sup>-/-</sup> mice (n= 17) versus vehicle (n=16) starting at day 15 (at the 75th percentile of their life expectancy) and continued treatment until day 43-45 (“rescue” cohort). A “prevention” cohort of Akp2<sup>-/-</sup> mice (n=21) received the same bolus amount daily starting on day 1 while WT mice (n=30) without EzRT served as controls. None of the Akp2<sup>-/-</sup> mice receiving vehicle alone survived past day 24, while 9/17 of the mice in the rescue cohort survived to day 39, and 4/16 lived to day 43. In the prevention cohort, 20/21 mice survived to complete the study at day 44. The growth curve of the Akp2<sup>-/-</sup> mice on preventive treatment from day 1 was essentially identical to the growth curve of WT mice. For the rescue cohort, the growth rates were improved but the mice remained smaller than the controls. Radiographs of the feet at necropsy indicated that 2/16 (12.5%) of the Akp2<sup>-/-</sup> mice treated with vehicle and 7/17 (41.2%) of the Akp2<sup>-/-</sup> mice receiving sALP-FcD10 had normal x-rays, showing that EzRT brought a statistically significant improvement in bone mineralization. Next we evaluated different dosing intervals on the rescue of Akp2<sup>-/-</sup> mice. Mice were started on EzRT at day 12 and were injected s.c. with vehicle (RV), 8.2 mg/Kg daily to days 46/47 (RTx-1) or 8.2 mg/Kg daily for 7 days followed by 24.6 mg/Kg every 3 days (RTx-3) or followed by 57.4 mg/Kg every 7 days (RTx-7). The median survival was 19.5 days for RV, 21.0 days for RTx-7, 30.5 days for RTx-3, and 37.5 days for RTx-1. In all cases, survival was statistically increased when compared to the RV group. Thus, there is a clear benefit of bone-targeted EzRT in Akp2<sup>-/-</sup> mice with well-established HPP. Dosing less frequently than daily can also statistically improve their survival.

**World Health Organization (WHO) Absolute Fracture Models in Older Women: How Does Prediction Vary for Incident Hip and Non-spine Fractures Across T-Scores?** T. A. Hillier<sup>1</sup>, J. A. Cauley<sup>2</sup>, J. H. Rizzo<sup>\*1</sup>, K. L. Pedula<sup>\*1</sup>, K. K. Vesco<sup>\*1</sup>, B. C. Taylor<sup>\*3</sup>, D. C. Bauer<sup>4</sup>, K. E. Ensrud<sup>3</sup>, D. M. Black<sup>4</sup>, S. R. Cummings<sup>4</sup>. <sup>1</sup>Center for Health Research, Kaiser Permanente, Portland, OR, USA, <sup>2</sup>U Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>VAMC & U of MN, Minneapolis, MN, USA, <sup>4</sup>San Francisco Coordinating Center, CPMC Research Institute and UCSF, San Francisco, CA, USA.

Bone mineral density (BMD) is a strong predictor of fracture, yet most fractures occur in women with normal or low bone mass (LBM), not those with frank osteoporosis. Moreover, whether to treat the majority of women who have LBM is a clinical conundrum. The WHO Collaborative Metabolic Bone Disease group recently developed absolute probability of fracture models incorporating clinical risk factors with femoral neck (fn) BMD to enhance overall prediction of hip and other osteoporotic fractures, but it is unknown how the WHO model will predict fractures among women with LBM. To evaluate the overall sensitivity and specificity of the WHO 10-yr probabilities of hip and osteoporotic fracture models (U.S. Caucasian) to predict observed hip and non-traumatic non-spine fractures among women with normal or LBM, we stratified women age 65 and over in the Study of Osteoporotic Fractures (SOF) cohort based on initial DXA fnBMD: Normal (T-score [T]  $\geq -1.0$ ; n=1,154); LBM ( $-2.5 < T < -1.0$ ; n=3,791) and Osteoporotic ( $T \leq -2.5$ ; n=1,307). Receiver Operator Characteristics (ROC) curves assessed overall sensitivity and specificity to predict observed hip and other non-spine fractures with AreaUnder-the-Curve (AUC) using the 10 year probabilities of hip and other osteoporotic fractures, respectively, calculated by the WHO group which included clinical risk factors at baseline and fnBMD. Over a follow-up of 10.0 years, 368 women suffered an incident hip fracture and 1,734 women experienced at least one non-spine fracture. AUC for WHO 10 year probabilities for all women, stratified by initial fnBMD are in Table.

	Normal	Low Bone Mass	Osteoporotic	p-value
Hip Fracture				
Observed, n	14	176	178	
WHO AUC (95% CI)	0.79 (0.67, 0.90)	0.69 (0.65, 0.73)	0.59 (0.55, 0.64)	0.0003
Non-spine Fracture				
Observed, n	188	1034	512	
WHO AUC (95% CI)	0.59 (0.55, 0.64)	0.58 (0.56, 0.60)	0.63 (0.59, 0.66)	0.07

The WHO model predicted hip fractures better in women with normal and LBM than in those with osteoporosis. Prediction with the WHO model was similar across all BMD strata for non-spine fractures.

In summary, the WHO model predicted incident hip and other non-spine fractures even among women with normal and low bone mass. Although few women with normal bone mass suffered a hip fracture, the WHO model may offer particular utility to this group.

**The Population Burden of First and Repeat Low-trauma Fractures: The Canadian Multicentre Osteoporosis Study.** S. A. Jamal<sup>1</sup>, L. Langsetmo<sup>2</sup>, R. G. Josse<sup>1</sup>, A. Papaioannou<sup>3</sup>, J. D. Adachi<sup>3</sup>, W. P. Olszynski<sup>4</sup>, D. A. Hanley<sup>5</sup>, C. S. Kovacs<sup>6</sup>, N. Kreiger<sup>7</sup>, D. Goltzman<sup>2</sup>. <sup>1</sup>Medicine, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Medicine, McGill University, Montreal, QC, Canada, <sup>3</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>4</sup>Medicine, University of Saskatchewan, Saskatchewan, MB, Canada, <sup>5</sup>Medicine, University of Calgary, Calgary, AB, Canada, <sup>6</sup>Medicine, Memorial University, St. Johns, NL, Canada, <sup>7</sup>University of Toronto, Toronto, ON, Canada.

Traditional T score risk categories fail to identify some men and women at high fracture risk, as the majority of fractures occur in men and women with T scores above -2.5. The objective of our study was to determine the contribution of first and repeat fractures, with and without consideration of T score risk categories, to the fracture burden among Canadian men and women.

We studied 2179 men and 5269 women, aged 50 to 90, participating in CaMos. We included all low trauma fractures that occurred over 7 years of follow up (incident fractures) and classified them as either first or repeat fractures. Analyses were stratified by sex, fracture status (first vs. repeat) and BMD categories based on T score ( $\geq -1$  normal;  $-1$  to  $-2.5$  osteopenic;  $\leq -2.5$  osteoporotic). All estimates were age-standardized using 2001 Canadian census data.

There were a total of 128 fractures in men and 577 fractures in women. The incidence of repeat fracture was at least double the incidence of first fracture within each 5-year age group, and each BMD category. An estimated 75% of all fractures in men were a first fracture and 25% were repeat fractures. Considering T score categories among men: 25% of all fractures occurred with normal BMD, 54% with osteopenic BMD, and 21% with osteoporotic BMD. An estimated 60% of all fractures in women were a first fracture and 40% were repeat fractures. Considering T score categories among women, 10% of fractures occurred with normal BMD, 51% with osteopenic BMD, and 39% with osteoporotic BMD. Only 13% of all fractures in men, and 19% of all fractures in women were a first fracture occurring with osteoporotic BMD.

Our findings demonstrate that repeat fracture is an important contribution to overall fracture burden, particularly among women. Indeed, the overall fracture burden of repeat fracture is similar to that of osteoporotic BMD in men and is greater than the contribution of osteoporotic BMD in women. Our results highlight the fact that while osteoporosis by BMD testing is a strong risk factor for fracture, additional factors, including prevalent fracture can strongly and independently contribute to fracture burden.

**A Comparison of Prediction Models for Hip, Osteoporotic, and Any Clinical Fracture in Older Women: Is More Better?** K. E. Ensrud<sup>1</sup>, L. Lui<sup>2</sup>, B. Taylor<sup>\*1</sup>, J. Schousboe<sup>3</sup>, M. Donaldson<sup>2</sup>, H. Fink<sup>1</sup>, J. Cauley<sup>4</sup>, T. Hillier<sup>5</sup>, W. Browner<sup>\*2</sup>, D. Black<sup>\*6</sup>, S. Cummings<sup>2</sup>. <sup>1</sup>U of MN / VAMC, Mpls, MN, USA, <sup>2</sup>CPMCRI, SF, CA, USA, <sup>3</sup>U of MN, Mpls, MN, USA, <sup>4</sup>U Pitt, Pittsburgh, PA, USA, <sup>5</sup>Kaiser Permanente, Portland, OR, USA, <sup>6</sup>UCSF, SF, CA, USA.

While advanced age and low bone mineral density (BMD) are strongly associated with increased fracture (fx) risk, many other independent risk factors for fx have been identified. Thus, recent efforts by the WHO Metabolic Bone Disease Group have focused on developing a clinical risk factor index with and without femoral neck (fn) BMD to enhance fx prediction. However, it is uncertain whether prediction with models incorporating this index is superior to that based on a parsimonious model.

To compare the predictive validity of a simple model based on age and fnBMD alone (base model) with that of the more complex WHO models (10 year fx probabilities for hip and osteoporotic fx incorporating age plus WHO clinical risk factors, with and without fnBMD), we conducted a prospective cohort study in 6242 women aged ≥65 years enrolled in the Study of Osteoporotic Fractures. Fractures (including hip fx, osteoporotic [hip/clinical spine/wrist/humerus] fx, and any clinical fx) were ascertained during 10 years of follow-up. Area under the curve (AUC) statistics from receiver operating characteristic (ROC) curve analysis were compared for the base model vs. WHO models. The results were cross-validated using the 10-fold cross validation procedure.

AUC comparisons revealed no differences between the base model vs. the WHO model with fnBMD in discriminating hip, osteoporotic, or any clinical fx (table). However, the base model was superior to the WHO model without fnBMD in predicting these fx. For a given fx category, the proportion of fx events that occurred among women in the highest quartile of risk was similar across the 3 models. For example, the % of women experiencing a hip fx in the high risk quartile was 15.3 for the base model, 14.5 for the WHO model with fnBMD, and 14.1 for the WHO model without fnBMD.

In conclusion, a simple model based on age and fnBMD alone predicts 10-year risk of hip, osteoporotic, and any clinical fx in older women as well as more complex WHO models, suggesting that the addition of clinical risk factor information to age and fnBMD alone does not enhance prediction of these fx in older women.

AUC Statistic for Models Predicting 10 Yr Risk of Hip, Osteoporotic & Any Clinical Fracture

Model	Hip Fx*	Osteoporotic Fx†	Any Clinical Fx‡
Base model (age & fnBMD)	0.76	0.69	0.63
WHO model w/ fnBMD	0.75	0.69	0.64
WHO model w/o fnBMD	0.71‡	0.64‡	0.61‡

\*WHO models based on hip fx probability

†WHO models based on osteoporotic fx probability

## 1058

**Differences in Fall Rates and Predictors of Falls by Sex?** R. L. Fullman<sup>1</sup>, P. M. Cawthon<sup>1</sup>, K. A. Faulkner<sup>2</sup>, K. L. Stone<sup>1</sup>, H. Fink<sup>3</sup>, E. Barrett-Connor<sup>4</sup>, K. Ensrud<sup>3</sup>, M. C. Nevitt<sup>\*5</sup>, E. Orwoll<sup>6</sup>, S. R. Cummings<sup>1</sup>. <sup>1</sup>CPMCRI, San Francisco, CA, USA, <sup>2</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>VAMC & University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>UCSD, San Diego, CA, USA, <sup>5</sup>UCSF, San Francisco, CA, USA, <sup>6</sup>OHSU, Portland, OR, USA.

To examine differences in rates and predictors of falls by sex in older adults, we examined data from 9,289 Caucasian women from the Study of Osteoporotic Fractures (SOF) and 5,346 Caucasian men from the Osteoporotic Fractures in Men (MrOS) Study. Participants were aged ≥ 65, ambulatory and community living at enrollment. A number of predictors were assessed using similar protocols, including anthropometric and physical function measures, medical conditions and lifestyle factors, and were considered for inclusion in analyses. Incident falls during the first year of follow-up were ascertained on tri-annual questionnaires (response rate > 99%). Generalized Estimating Equations were used to calculate Risk Ratios (RR) and 95% Confidence Intervals (CI) for incident fall risk in each sex separately. Variables that were associated with fall risk in age adjusted models at the p<.05 level were included in multivariate (MV) models for each cohort.

The average age of women (73.8 years) and men (73.7 years) was similar (chi-square p value=0.07). During follow-up (average 0.99 years in both sexes), 25.7% of men and 26.3% of women reported a fall and 12.0% of men and 9.8% of women reported multiple falls. We identified several factors that were significantly related to fall risk or had similar RR estimates in men and women (Table). Walking for exercise was protective in men but associated with increased fall risk in women. Similarly, better physical performance, such as greater grip strength and faster walking speed, were associated with decreased fall risk in men, but were unassociated with fall risk in women. Factors not significant in either sex include: body mass index, height, self-reported health, visual acuity, using arms to stand, stroke, diabetes and current alcohol use.

In conclusion, fall rates in men and women are similar, but men report slightly more multiple falls. The predictors of falls in both sexes are generally similar with the history of falls being the strongest predictor in each cohort. However a few factors, such as walking for exercise, seem to differentially influence fall risk.

Predictor	Selected Predictors of Falls		p for interaction
	Men RR (95% CI)	Women RR (95% CI)	
Age (5 years)	1.03 (0.97, 1.09)	1.07 (1.01, 1.13)	0.52
Fall in the Past 12 months (yes)	2.80 (4.46, 3.18)	2.96 (2.68, 3.26)	0.63
Grip Strength (per SD, kg)	0.87 (0.81, 0.94)	0.96 (0.91, 1.02)	0.63
Walking Speed (per SD, m/s2)	0.90 (0.84, 0.98)	0.98 (0.92, 1.04)	<0.01
Trouble with Dizziness (yes)	1.27 (1.11, 1.45)	1.21 (1.07, 1.36)	0.01
Walking for Exercise (yes)	0.87 (0.77, 0.98)	1.16 (1.05, 1.28)	<0.01
> High School Education	1.14 (0.99, 1.33)	1.31 (1.18, 1.45)	<0.01

**Substantial Adverse Outcomes Follow Non-Hip Non-Vertebral Fragility Fractures.** J. R. Center, D. Bliuc, T. V. Nguyen, J. A. Eisman. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Although osteoporosis and osteoporotic fractures are an important and growing public health problem, most of the attention and research has focussed on hip and vertebral fractures. The aim of this study was to examine the impact of non-hip, non-vertebral fractures.

All low trauma fractures occurring from April 1989 to May 2007 were recorded from 2245 women and 1760 men aged 60+ living in Dubbo, Australia and followed up for subsequent fracture and mortality.

There were 952 low-trauma fractures in women and 343 in men followed by 290 subsequent fractures in women and 74 in men with 461 deaths in women and 197 in men. Non-hip non-vertebral fractures accounted for almost 50% (n=659) of these initial fractures and preceded 54% (n=196) of subsequent fractures and 43% (n=200) of all deaths. Re-fracture rate following a non-hip non-vertebral fracture was increased 1.7-fold in women (95% CI 1.5-2.0) and a 2.3-fold in men (95% CI 1.6- 3.2). Similarly, standardised mortality ratios (SMR) were higher following non-hip non-vertebral fractures; SMR 1.50 (1.30-1.73) in women and 1.48 (1.18-1.85) in men. These were not as high as following hip or vertebral fracture [post hip and vertebral re-fracture rate increased 2.3-fold (1.9- 2.8) for women and 4.5-fold (3.2-6.3) for men and SMR 2.1 (1.8-2.4) for women and 2.6 (2.1-3.1) for men].

Non-hip non-vertebral fractures were particularly associated with increased mortality in those >70 years. In men, the associated mortality risk in those >70 was increased by 80% for the first 5 years post fracture [SMR 1.8 (1.2-2.7) for 70-79 year olds and SMR 1.9 (1.3-2.7) for 80+ year olds]. In women the SMR was 1.6 (1.2-2.2) for 70-79 year olds and 1.4 (1.1-1.8) for 80+ year olds. Of interest, rib fracture, which constituted a major grouping (31 in women and 31 in men), was associated with increased mortality risk that was significant in women, SMR 2.3 (1.6-3.2) and borderline in men SMR 1.4 (0.96-2.0).

Importantly the premature mortality following the non-hip non-vertebral fractures contributed to 28% of excess deaths in women and 31% of excess deaths in men and thus is clinically significant.

In summary this often ignored group of fractures not only constitutes half of all low trauma fractures but contributes significantly to the associated poor outcomes of re-fracture and premature mortality. Efforts to prevent non-hip non-vertebral fractures should be a priority and studies should include these fractures, as well as hip and vertebral fractures, as primary outcomes.

**Disclosures:** J.R. Center, None.

## 1060

**The Absolute Risk for Subsequent Fractures Fluctuates over Time.** T. van Geel<sup>\*1</sup>, P. Geusens<sup>2</sup>, K. Huntjens<sup>\*2</sup>, S. van Helden<sup>\*3</sup>. <sup>1</sup>Department of General Practice, Maastricht University, Maastricht, Netherlands, <sup>2</sup>Department of Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands, <sup>3</sup>Department of General Surgery and Trauma Surgery, Maastricht University Medical Centre, Maastricht, Netherlands.

The relative risk (RR) of subsequent fracture is double that of having a first fracture. Some studies indicate that this risk is even higher within short term after a first fracture. We analyzed the yearly absolute risk (AR) for a subsequent fracture, taking into account the time relation between menopause and first fracture and between first and subsequent fracture.

A population-based study in 4203 postmenopausal women aged between 50 and 90 years, who completed questionnaires about location and time of X-ray confirmed clinical fractures. The yearly AR and percentage (%) of all first and subsequent fractures were calculated over time using Cox regression, with a mean follow up of 40 years for a 1<sup>st</sup> fracture from menopause onwards and of 20 years for a subsequent fracture from the time of a first fracture onwards.

The mean 1-year AR of a first fracture was 1% and slightly increased over 40 years of follow up after menopause, resulting in 4% of all subsequent fractures occurring each year from menopause on. The 1-year AR of a subsequent fracture fluctuated over time and was 6% within 1 year after a first fracture, progressively decreasing to 2.5% during the 5<sup>th</sup> year and 1% during the 20<sup>th</sup> year. As a result, 23% of all subsequent fractures occurred within one year of a first fracture, and 50% within 5 years (Figure 1). The AR (1a) and % of all subsequent fractures (1b) of a 1<sup>st</sup> fracture (from onset of menopause) and a subsequent fracture (from the time of 1<sup>st</sup> fracture), indicating a window of opportunity to prevent subsequent fractures (grey area)

The yearly AR of a 1<sup>st</sup> fracture from menopause on slightly increases over time, but fluctuates over time for subsequent fracture after a first fracture. These results indicate a window of opportunity to prevent a subsequent fracture within short term after a first fracture.

**Anabolic Daily Intermittent PTH 1-84 Reduces Bone Blood Vascular Bed and Induces Dramatic Changes in the Bone/Vessel Spatial Relationship.** R. Prisby<sup>1</sup>, Z. Peter<sup>2</sup>, A. Guignandon<sup>1</sup>, A. Vanden-Bossche<sup>1</sup>, L. Malaval<sup>1</sup>, L. Vico<sup>1</sup>, E. Peyrin<sup>2</sup>, M. Lafage-Proust<sup>1</sup>. <sup>1</sup>LBTO, INSERM 890, Saint-Etienne, France, <sup>2</sup>ESRF-Grenoble, INSERM- U630/CNRS/UMR- 5220, INSA, Lyon, France.

Intermittent parathyroid hormone (PTH) is a current treatment of osteoporosis. However, its mechanisms of action remain to be fully elucidated. PTH promotes osteoblastic expression of VEGF, an angiogenic factor. Bone vascularisation and osteogenesis are functionally coupled. Thus, we hypothesized that PTH might enhance bone mass via stimulation of bone angiogenesis. According to baseline tibial bone volume/tissue volume (BV/TV) assessed by  $\mu$ CT, 24 Wistar male rats (300g) were assigned to two groups: PTH and Control (CON) and were given either PTH 1-84 (100 $\mu$ g/kg/d) or 0.9% saline, respectively, 5 days/wk for 4 wks. After sacrifice, rats were perfused with a barium sulfate solution for opacification of bone vessels. Tibiae were processed for bone histomorphometry. Femora were collected for Synchrotron Radiation Computerized Tomography (SR- $\mu$ CT) imaging (voxel size: 2.8 $\mu$ m, energy: 25 keV). Expectedly, PTH treatment significantly increased tibial BV/TV (150%) in association with higher BFR (76%) and reduced (61%) osteoclast number compared to CON. Moreover, marrow adipocyte number was reduced 50% in the PTH group. The number of blood vessels in the II spongiosa was 46% lower in the PTH group. In contrast, the number of sinusoid bundles in the bone marrow was 33% higher than in CON. These results are illustrated in Figure 1: 3D image of bone marrow vascular bed in femur assessed by SR- $\mu$ CT. Blood vessel number negatively correlated ( $r^2 = -0.572$ ,  $p = 0.004$ ) with BV/TV. Histogram distribution of vessel distance from trabecular bone surfaces or osteoid seams was analyzed using ImageJ (NIH free software) on Goldner-stained sections ( $n=30$  fields/ group, X100). Overall, vessels from the CON group were closer to bone surfaces than those in the PTH group; however, vessels from the PTH group were closer to osteoid seams than in the CON group. Contrary to our hypothesis, these data demonstrate that while intermittent PTH 1-84 treatment enhanced osteogenesis, it did not induce bone angiogenesis. However, the spatial distribution of the vasculature within the IISF is markedly altered with PTH. Therefore the relation between the bone vasculature and osteogenesis may involve a modification of the functional properties of the bone vessel resistance. Figure 1:

**Effects of Parathyroid Hormone on Fracture Repair in Glucocorticoid Treated Mice.** J. Li, A. R. Doyon<sup>\*</sup>, I. K. Ferries<sup>\*</sup>. Department of Biology, Indiana University-Purdue University Indianapolis, Indianapolis, IN, USA.

Long-term use of glucocorticoid (GC) reduces bone mass and strength which leads to a greater risk of fracture. GC treatment may also hinder fracture repair. In this study, we established a GC induced fracture nonunion animal model and investigated the effects of parathyroid hormone 1-34 (PTH) on fracture repair using this animal model. Four-month-old Swiss-Webster male mice were randomly divided into five groups. Three groups of GC treated mice were given with prednisolone that was slowly released from the

subcutaneously implanted pellets at the rate of 1.4 mg/kg/day. Placebo pellets were implanted into the animals in two placebo groups. Three weeks later, fracture surgery was carried out in all the animals. Osteotomy at midshaft femurs was performed under general anesthesia. Stainless steel pins were then inserted into the medullary cavity to stabilize the fracture site. Following fracture surgery, three GC groups were treated subcutaneously with vehicle, PTH at a low dose (40  $\mu$ g/kg/day) and a high dose (80  $\mu$ g/kg/day), respectively. Two Placebo groups were given vehicle and PTH at a dose of 40  $\mu$ g/kg/day, respectively. Radiographs, DXA, and mechanical testing (4-point bending) were used to evaluate the fracture repair at four weeks after fracture surgery. Compared to the placebo mice treated with vehicle, GC significantly reduced bone mineral density and bone mineral content of left intact femurs by 14% and 11% ( $p<0.05$ ) as well as decreased ultimate force by 22% ( $p<0.01$ ). Both low and high doses of PTH treatment prevented bone loss at the intact femurs in GC treated animals and preserved mechanical integrity, while PTH significantly enhanced bone mass of the intact femurs in placebo animals. Callus development at the fracture sites in GC animals treated with vehicle was significantly suppressed compared to that in placebo animals in term of callus area revealed by radiographs and callus mineral content (11%;  $p<0.05$ ) and density (14%;  $p<0.05$ ). In GC groups, PTH significantly increased callus mineral content compared with vehicle, despite the observation that callus under low dose PTH treatment was significantly less than that in placebo groups. Although PTH markedly improved ultimate force in placebo animals by 80% ( $p<0.001$ ), PTH did not increase ultimate bending forces in GC treated animals. These data indicate that PTH can restore GC induced bone loss and maintain mechanical properties of the intact bone. Normally PTH accelerates fracture repair. In GC treated mice, PTH increases callus formation but fails to improve mechanical properties compared to vehicle treatment, suggesting that the anabolic effect of PTH on fracture healing can be attenuated by GC administration in mice.

## 1063

**A Fusion Protein of Parathyroid Hormone (PTH) and a Collagen Binding Domain Shows Superior Efficacy and Longer Duration of Action Compared to PTH(1-34) as an Anabolic Bone Agent in Normal Female Mice.** T. Ponnappakkam<sup>1</sup>, R. Katikaneni<sup>1</sup>, A. Ponnappakkam<sup>1</sup>, E. Miller<sup>1</sup>, O. Matsushita<sup>2</sup>, J. Sakon<sup>3</sup>, R. C. Gensure<sup>1</sup>. <sup>1</sup>Pediatrics, Ochsner Clinic Foundation, New Orleans, LA, USA, <sup>2</sup>Microbiology, Kiseto University, Tokyo, Japan, <sup>3</sup>Chemistry, University of Arkansas, Fayetteville, AR, USA.

Osteoporosis affects nearly 10 million Americans. Despite application of current therapies, osteoporotic hip fractures result in costs of ~18 billion dollars per year. Anabolic agents such as parathyroid hormone show superior efficacy to antiresorptives (i.e. bisphosphonates), but have not been widely accepted in part because of inconvenient dosing (daily injection). We have developed a fusion protein of parathyroid hormone PTH(1-33) and a collagen binding domain (CBD) (PTH-CBD), designed to be retained in collagen-containing tissues and extend the duration of the anabolic bone effect. We compared the efficacy and duration of PTH-CBD to PTH(1-34) and vehicle control using a variety of dosing intervals in normal young female C57BL/6J mice (Jackson Laboratories). To determine the optimal dose of PTH-CBD, mice received a single subcutaneous injection of PTH-CBD at doses ranging from 0.05 mg/kg to 3 mg/kg, and BMD was measured each month. The optimal response (fastest time to reach peak BMD) was seen at 320 mcg/kg (molar equivalent to 80 mcg/kg of PTH(1-34)). Comparing the optimal PTH-CBD dose to that of PTH(1-34), monthly intraperitoneal dosing of PTH-CBD (320 mcg/kg) for 6 months achieved a higher peak BMD than did 2 weeks of daily administration of PTH(1-34) (80 mcg/kg) (PTH-CBD:  $81\pm3$ , PTH(1-34):  $75\pm3$ , vehicle:  $64\pm2$  mg/cm<sup>2</sup>,  $p<0.05$ ). These increases in BMD were sustained for an additional 6 months following the dosing interval (PTH-CBD:  $71\pm3$ , PTH(1-34):  $63\pm3$ , vehicle:  $54\pm2$  mg/cm<sup>2</sup>,  $p<0.05$ ). Serum alkaline phosphatase levels were elevated in the PTH-CBD group at the end of the study, indicating an anabolic mechanism of action (PTH-CBD:  $118\pm49$ , PTH(1-34):  $40\pm18$ , vehicle:  $32\pm8$  IU/L,  $p<0.05$ ). In a separate study, a single dose of PTH-CBD (320 mcg/kg) showed superior efficacy to 2 weeks of daily administration of PTH(1-34) (80 mcg/kg) (PTH-CBD:  $76\pm2$  vs. PTH(1-34):  $71\pm2$ , vehicle:  $67\pm1$  mg/cm<sup>2</sup>,  $p<0.05$ ). The gains in BMD were sustained for at least 5 months following the injection of PTH-CBD, while the BMD in the group which received PTH(1-34) returned to control levels (PTH-CBD:  $79\pm2$ , PTH:  $66\pm1$ , vehicle:  $63\pm1$  mg/cm<sup>2</sup>,  $p<0.05$ ). There was no additional benefit observed with administration of a second dose of PTH-CBD three months after the first one. The overall results suggest that a single dose of PTH-CBD provides superior efficacy and longer duration of action compared to daily PTH(1-34) in increasing BMD in normal female mice through an anabolic mechanism.

**The Roles of Zoledronic Acid in Bone Healing and Osteoblast Functions.** J. Zhang\*, Q. Tu, J. Chen. General Dentistry, Tufts University School of Dental Medicine, Boston, MA, USA.

Recently the use of bisphosphonates has been linked to osteonecrosis of the jaw (ONJ). The mechanisms of how bisphosphonates possibly cause the development of ONJ remain to be determined.

To investigate the mechanisms of ONJ, 21 mice were divided into 3 groups which were injected with: zoledronic acid (250µg/kg), zoledronic acid (100µg/kg), and PBS, once a week for 4 weeks. One week after the last drug injection, the second and third right mandibular molars were extracted and bone defects were created in the diaphysis area of the right femurs using dental burs. One week after surgery, the bone tissues were isolated. H&E staining, TRAP staining, and ALP staining were performed. Moreover, MC3T3 cells were treated with zoledronic acid at different concentrations (0-5000ng/ml). Proliferation assay and real-time RT-PCR were performed. Mandibular bone healing was significantly retarded in 1 of the 7 mice (14.3%) injected with zoledronic acid (250µg/kg). There was no new bone formation and the bone defect was filled with inflammatory soft tissues. In PBS or zoledronic acid (100µg/kg) group, no wound healing delay was detected, which indicated that the dose of 250µg/kg is necessary to induce ONJ with an incidence similar to the reported clinical incidence (0.8% to 12%). There was no retardation in femoral bone healing process. TRAP staining showed that in the femurs from the zoledronic acid (250µg/kg and 100µg/kg) groups, Oc.N/BS was decreased by 32.27% and 8.93%, respectively, while in the mandibles, Oc.N/BS was decreased in zoledronic acid groups (250µg/kg and 100µg/kg) by 36.34% and 12.90%, respectively. ALP staining showed that in femoral growth plate area there was no significant difference in Ob. N/BS among the three groups. The proliferation rate of MC3T3 cells treated with zoledronic acid at lower concentrations (10ng/ml and 100ng/ml) was increased at earlier time points (24- and 48hrs) before being decreased by longer drug treatment (72hrs). The proliferation rate of MC3T3 treated with zoledronic acid at higher concentration (5000ng/ml) was decreased at all time points. Real-time RT-PCR demonstrated that MC3T3 cells treated with zoledronic acid at 10ng/ml showed an increase in the expression levels of BSP and EphB4, while cells treated with zoledronic acid at higher concentration (5000ng/ml) showed decreased levels of BSP and EphB4. In conclusion, zoledronic acid-induced osteoclast decrease in mandibles was more pronounced than that in long bones, suggesting a different response to zoledronic acid between these two distinct bone tissues. We speculate that a lower level of osteoblast proliferation and gene expressions in response to bisphosphonate therapy may delay the bone wound healing process in the mandible.

**Studying Cellular Uptake and Distribution of Bisphosphonate *in vivo* Using Fluorescently-labelled Analogues of Risedronate.** A. J. Roelofs\*, E. P. Coxon\*, M. W. Lundy\*, F. H. Ebetino\*, J. F. Bala\*, B. A. Kashemirov\*, C. E. McKenna\*, M. J. Rogers\*. <sup>1</sup>Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>Procter & Gamble Pharmaceuticals, Cincinnati, OH, USA, <sup>3</sup>Dept of Chemistry, University of Southern California, Los Angeles, CA, USA.

Bisphosphonates (BPs) are effective anti-resorptive agents due to their bone-targeting properties and efficient internalisation by bone-resorbing osteoclasts. However, it is still unclear exactly where BPs localise within the skeleton, and whether non-osteoclast cells are directly affected by these drugs *in vivo*. We have synthesised fluorescein-risedronate (FAM-RIS), Alexa Fluor 647-risedronate (AF647-RIS) and rhodamine-3-PEHPC (RHO-3-PEHPC) to help address these questions. Three-day old rabbits were subcutaneously injected with either 0.5 mg/kg FAM-RIS or 0.9 mg/kg AF647-RIS (both molar equivalent to ~0.2 mg/kg RIS) and sacrificed 24 hours later. Using confocal microscopy, FAM-RIS and AF647-RIS uptake could be detected in osteoclasts in histological sections or in osteoclasts that had been purified *ex vivo* using immunomagnetic beads. In addition, while uptake of FAM-RIS by bone marrow cells (BMCs) was hardly detectable by flow cytometry, preliminary experiments revealed uptake of AF647-RIS *in vivo* in a subpopulation of rabbit BMCs, a subset of which were CD14+. These findings confirm osteoclasts as the main cell type that internalises BPs *in vivo*, but suggest that bone marrow monocytes may also be directly affected by BPs.

Histological analysis of rabbit ulnae and vertebrae revealed strong labelling of FAM-RIS around vascular channels in cortical bone. Osteocytic lacunae in close proximity to these vascular channels also showed FAM-RIS binding. Moreover, FAM-RIS localized to the lacunae of newly embedded osteocytes. Similar results were obtained with adult mice. This supports the proposal that BPs may exert direct, extracellular effects on osteocytes *in vivo*, although our findings suggest that only a small subset of osteocytes may be exposed to BP. To investigate the effect of differences in bone affinity on skeletal distribution, rats were injected subcutaneously with a combination of FAM-RIS and RHO-3-PEHPC (an analogue of RIS with lower bone affinity), and sacrificed 1 or 7 days later. Some differences in localisation were observed after 1 day, but more strikingly, FAM-RIS, but not RHO-3-PEHPC, additionally labelled the surface of bone that had formed during the 7 days following injection. These observations illustrate the concept that BP can recycle to other bone surfaces *in vivo* and that this is dependent on relative bone affinity. These findings may help to explain differences in the duration of action of BPs with different bone affinities.

**Risedronate Prevents Early Radiation-Induced Bone Loss at Multiple Skeletal Sites.** J. S. Willey<sup>1</sup>, E. W. Livingston\*, L. C. Bowman\*, M. E. Robbins\*, J. D. Bourland\*, T. A. Bateman<sup>1</sup>. <sup>1</sup>Bioengineering, Clemson University, Clemson, SC, USA, <sup>2</sup>Department of Radiation Oncology, Wake Forest University Baptist Medical Center, Winston-Salem, NC, USA.

Bone irradiation during cancer therapy can lead to atrophy and increased risk of fracture at several skeletal sites, particularly the hip. Late radiation-induced bone loss has been attributed to damaged osteoblasts and vascularity. In contrast, little attention has been given to increased osteoclast activity as a contributor to radiation-induced osteoporosis. Our aim was to identify if radiation increases osteoclast activity resulting in acute bone loss. Thirteen-week old C57BL/6 mice (n=6/group) received whole body radiation with 2 Gy X rays (140kVp). A 1 mm region of the proximal tibia distal to the growth plate was analyzed via microCT (µCT 80; Scanco). Relative to non-irradiated control, bone volume fraction (BV/TV; -42%), trabecular connectivity (ConnD; -82%) and number (Tb.N; -24%) were lower 2 weeks after exposure (P < 0.05). Circulating TRAP5b was significantly elevated on Days 1 (+50%) and 3 (+14%). TRAP-stained sections at Day 3 had increased osteoclast number (N.Oc/BS; +80%; P < 0.05) and osteoclast surface (Oc.S/BS; +210%; P < 0.001). Skeletally mature mice (twenty-week old; n=12/group) were then irradiated (2 Gy) with or without subcutaneous injections of risedronate (0.1 mg/kg/wk). MicroCT analysis was performed at 3 sites: Proximal tibia; distal femoral metaphysis extending 1 mm proximal to the growth plate; and a region of the body of the 5<sup>th</sup> lumbar vertebra (L5). Bones were collected 1, 2, and 3 weeks after irradiation. Body mass was not affected by treatments. From animals only receiving radiation, significantly lower BV/TV relative to control was observed at all three skeletal sites and at all three time points. ConnD was significantly lower after irradiation at all time points in the proximal tibia; at Weeks 2 and 3 in the distal femur; and at Week 3 in L5. Tb.N in the distal femur was significantly lower than control at all time points, and was lower in L5 at Week 2 and Week 3. Structure model index (SMI) values indicated more rod-like trabeculae after radiation in L5 at all time points, but starting at Week 2 at the distal femur. Evidence of bone loss or deterioration was entirely absent at all time points in animals receiving both radiation and risedronate. Overall, radiation + risedronate treatment resulted in more plate-like trabeculae in the femur and L5. This study demonstrated a rapid loss of trabecular bone after whole body radiation at several skeletal sites. Changes were preceded by an increase in osteoclast number. As risedronate prevented the atrophy, an increase in osteoclast activity likely contributed to the radiation-induced bone loss.

**Finite Element Analysis Performed on Radius and Tibia HR-pQCT Images Provides New Insights for Fracture Status Assessment.** N. Vilayphiou\*, S. Boutroy\*, E. Sornay-Rendu\*, B. Van Rietbergen\*, F. Munoz\*, P. D. Delmas<sup>1</sup>. <sup>1</sup>INSERM Unit 831 and Université de Lyon, Lyon, France, <sup>2</sup>Department of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands.

The contribution to skeletal fragility assessment of cortical (Ct) and trabecular (Tb) bones properties, and of finite element analysis (FEA) derived mechanical properties have already been reported in patients with wrist fracture (fx) (Boutroy et al., JBMR 2008). We extended here the FEA to a larger population, including patients with vertebral and other peripheral fragility fx. This case-control study used both areal BMD measured by DXA, and FEA on *in vivo* HR-pQCT images of the distal radius and tibia (XtremeCT, Scanco Medical AG) in 101 women (74 ± 8 yrs) who previously sustained a fragility fx, and 101 age-matched controls, all from the OFELY cohort. The results were analysed by a principal component (PC) analysis (PCA) to test the contribution of FEA to fx status assessment.

We observed that areal and volumetric BMD, Ct thickness and Tb number, thickness, separation and distribution were significantly worse in cases than controls, with differences ranging from -6% to 37%. FEA-derived stiffness and failure load were 12% lower in cases than in controls (p<0.001). In both groups the load was mostly carried by the cortex, except at the very distal end of the tibia where the Tb bone carried more load. Tb bone carried 6 to 12% more load in controls than in cases at the distal radius (p<0.05), implying that the load distribution was more uniform in controls. Moreover many correlations were found between results of the radius and the tibia (|r|>0.6, p<0.01).

We conducted a PCA in the 202 women to reduce the number of variables. It resulted in defining 3 PCs, for which the odds ratio (OR) for fx occurrence were computed. One PC included stiffness, failure load, areal and volumetric BMDs and Ct thickness, explaining 52% of the variance at the radius and 48% at the tibia, with OR = 1.82 [1.33-2.49] and 1.87 [1.36-2.56] respectively. A second PC was made of Tb number and distribution, explaining 15% and 10% of the variance, with OR = 1.71 [1.28-2.29] and 1.87 [1.16-2.19]. A third PC explained respectively 10% and 20% of the variance, with OR = 1.61 [1.19-2.18] and 1.16 [0.88-1.54], and was composed by the distribution of load between Ct and Tb bone.

For this population including several kinds of fx, results at the radius confirm the previous study done only for wrist fx. Moreover and despite their limits, results obtained at the tibia are also associated with the fx status. In conclusion FEA applied on those two peripheral sites measured by HR-pQCT seems to provide useful information in addition to DXA and microarchitecture measurement for the assessment of fx risk.

**Geometric Evidence of a Modeling Defect in Type 2 Diabetic Women Enrolled in the Women's Health Initiative as a Potential Explanation for Increased Fracture Risk.** M. S. LeBoff<sup>1</sup>, R. Garg<sup>\*1</sup>, T. Beck<sup>\*2</sup>, J. Cauley<sup>3</sup>, G. Wu<sup>4</sup>, B. Lewis<sup>5</sup>, D. Nelson<sup>6</sup>, A. LaCroix<sup>7</sup>, Z. Chen<sup>4</sup>. <sup>1</sup>Endocrine, Diabetes, and Hypertension, Brigham and Women's Hospital, Boston, MA, USA, <sup>2</sup>Johns Hopkins University, Baltimore, MD, USA, <sup>3</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>University of Arizona, Tucson, AZ, USA, <sup>5</sup>University of Alabama, Birmingham, AL, USA, <sup>6</sup>Wayne State University, Detroit, MI, USA, <sup>7</sup>Fred Hutchinson Cancer Center, Seattle, WA, USA.

Diabetes increases the risk of fractures, yet bone mineral density (BMD) in patients with type 2 diabetes (T2DM) tends to be higher than in non-diabetic controls. We hypothesized that while BMD and the underlying geometry may be higher in an absolute sense, it is actually lower after accounting for the increased body weight in women with T2DM. Participants from the multi-ethnic, Women's Health Initiative Observational Study from the 3 BMD centers were included in this cross-sectional study. T2DM, defined by age at diagnosis > 20 years and no history of ketoacidosis, was self-reported. These analyses include 3 groups of women: 1) T2DM women on diet or oral hypoglycemic agents (n=299); 2) T2DM women on insulin therapy (with or without oral agents) (n=128); and 3) Non-diabetic controls (n=5520). Presence of undiagnosed diabetes in the control group cannot be ruled out. Hip structural analyses (HSA) in the femoral narrow neck (NN), intertrochanter, and shaft regions were done using the validated Beck's method on hip scans from dual energy x-ray absorptiometry (DXA). We compared HSA BMD and section modulus (SM) (bending strength) at the NN with and without correcting for total body DXA lean body mass as an index of hip muscle load. Women in all three groups were of similar ages (64.5, 64.3, 63.7 yrs, respectively) and heights, but those with T2DM were heavier, with greater lean body weight vs. controls (p<0.001). In both diabetic groups, absolute BMD and SM were higher vs. controls (Fig.). However, after adjusting for lean body weight, diabetic women had significantly lower BMD and SM. Among the diabetic women, women on insulin had the poorest bending strength.

Adjusted for lean body weight, the BMD and bending strength in the femoral neck are significantly lower in diabetic women vs. controls, with the poorest measures in those on insulin. This may be due to defective bone modeling adaptation in the diabetic women and may explain the higher fracture risk in patients with T2DM.

**Concentration of Insulin-Like Growth Factor (IGF-I) in Human Cortex Bone is Highly Correlated with Fracture Toughness of the Bone.** G. Sroga<sup>\*</sup>, D. Vashishth, Rensselaer Polytechnic Institute, Troy, NY, USA.

Insulin-like growth factor-I (IGF-I) is an abundant protein of bone matrix and is believed to play an important role during bone development and remodeling [1,2]. Any changes in IGF-I levels should therefore alter the amount as well as the quality of bone's extracellular matrix (ECM). Studies to date have only explored the relationships between IGF-I levels, bone mass and whole bone fracture properties and the effects of IGF-I on bone matrix quality remain unknown. In this study we report the age-related changes in bone matrix level IGF-I and its relationship to material level fracture properties indicative of bone's resistance to crack propagation.

Ten specimens of mechanically tested human cortical bone (posterior cortex) from male and female cadavers (age range 26 to 89 years) were used to isolate IGF-I (per g of dry weight bone) using methods published previously [1, 2]. Measurement of the concentration of IGF-I was conducted using an enzyme-linked immunosorbent assay (ELISA) (Oibt, GmbH, GE) according to the manufacturer's protocol. The normalized values of triplicate assays were then averaged and tested for correlation with fracture toughness of bone measured using crack propagation test [3].

The concentration of IGF-I in human tibial posterior cortex bone was inversely related to the age ( $R^2 = 0.69$ ;  $p < 0.05$ ). Concentrations of IGF-I in the eighth decade were on average about 2.4-fold lower than in the second decade of human subjects. IGF-I levels showed a positive and highly correlated non-linear relationship with fracture toughness of bone ( $r^2 = 0.83$ ;  $y = 0.85 + 0.004 \ln(x)/x^2$ ;  $y =$  fracture toughness,  $x =$  IGF-I bone matrix

concentration).

To our knowledge this is the first study on the relationship between bone matrix levels of IGF-I and material level measurement of bone quality. The results show a positive association between matrix level IGF-I and bone's resistance to propagation of fracture. As IGF-I level increase post-natally up to the juvenile phase and decrease thereafter well into the old age, these results suggest that IGF-I induced bone matrix changes may initially exert a protective influence on the skeleton and then become a source of weakness with aging. Further studies should be conducted to investigate the role of IGF-I on bone fracture.

**Association Between Femoral Neck BMD and the Factor-of-Risk for Hip Fracture Derived from Direct Measurements of Strength In Human Cadaveric Femora.** B. J. Roberts<sup>\*</sup>, E. J. Thrall<sup>\*</sup>, M. L. Bouxsein, Orthopedic Surgery, Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, USA.

Areal BMD derived from DXA is currently the gold standard for diagnosis of osteoporosis; however, up to half of hip fractures occur in individuals who are not diagnosed as osteoporotic by DXA-based criteria. As fractures occur when the force applied to a bone exceeds its strength, a biomechanical approach to fracture risk assessment comparing the applied load-to-bone strength ratio, termed the factor of risk ( $\Phi$ ), may be useful. The aim of this study was to further explore this biomechanical approach by directly measuring femoral strength in elderly human cadaveric specimens and computing the factor of risk for hip fracture. We obtained 73 human cadaveric femurs (48 women and 25 men, aged  $74.2 \pm 8.7$ yr, range 55 to 98 yrs) with no evidence of prior fracture or metastatic lesions. We measured femoral neck (FN) aBMD by DXA, and then mechanically tested the femurs to failure at impact loading rates in a sideways fall configuration. The force applied to the hip during a sideways fall was computed from individual height and weight, after accounting for trochanteric soft tissue thickness which was estimated from body mass index using a previously published relationship (JBMR, 22:25-31, 2007). Women had lower FN aBMD ( $p=0.008$ ) and femoral failure load ( $4882 \pm 2209$  N vs  $2893 \pm 1099$  N,  $p < 0.001$ ), and higher  $\Phi$  (though not significantly) than men ( $\Phi = 1.76 \pm 0.74$  vs  $1.54 \pm 0.86$ ,  $p = 0.28$ ).  $\Phi$  was plotted against FN aBMD to determine the ability of a BMD-based diagnosis of osteoporosis to identify those specimens with a factor of risk greater than 1 (Figure). 53/ 54 (98%) specimens that had a FN aBMD t-score below -2.5 also had a  $\Phi > 1$ . However, 10/19 (53%) specimens with FN aBMD t-score above -2.5 had  $\Phi > 1$ . These data indicate that whereas a BMD-based diagnosis of osteoporosis is highly correlated with fracture risk, as assessed by the factor of risk, in our sample about 50% of individuals not designated as 'osteoporotic' would be at high risk for hip fracture should they experience a sideways fall. In sum, our findings strongly support the investigation of new methods of fracture risk prediction that consider the loads applied to the hip during a fall, and that incorporate other characteristics, such as bone geometry and/or microarchitecture, to improve estimates of bone strength.

**Increased Non-enzymatic Glycation of Cancellous Bone due to Decrease in Remodeling During Alendronate Therapy of Osteoporotic Women.** D. Vashishth<sup>1</sup>, C. Bertholon<sup>\*2</sup>, E. Gineyts<sup>2</sup>, P. Chavassieux<sup>2</sup>, G. Boivin<sup>2</sup>, P. D. Delmas<sup>2</sup>. <sup>1</sup>INSERM Unit 831 University of Lyon & Rensselaer Polytechnic Institute, Troy, NY, USA, <sup>2</sup>INSERM Unit 831 University of Lyon, Lyon, France.

Treatment of osteoporotic postmenopausal women by alendronate (ALN) increases bone mineral density (BMD) by reducing turnover and increasing the mean degree of mineralization (DMB) [1,2]. Canine studies, however, suggest that reduction in turnover also has the potential to reduce the efficacy of ALN treatment by causing collagen crosslink formation through the process of non-enzymatic glycation (NEG) and increasing the propensity of bone to fracture [3,4].

Here we conducted analyses on human iliac crest biopsies, obtained from an ALN clinical trial [1], to determine collagen modifications and their relationships to bone quality and remodeling. We quantified enzymatic [pyridinoline (PYD) and deoxypyridinoline (DPD)] and non-enzymatic [pentosidine (PEN)] crosslinks in cancellous and cortical bone compartments of 100 µm-thick transiliac bone biopsy sections obtained from women at 2 years from the start of the treatment with ALN at dose of 10 mg/day (N=9) or placebo (PLB, N=15). Collagen crosslinks were compared between ALN and PLB groups and tested for correlation with measures of bone structure (BV/TV, Tb.Th, Tb. Sp, Tb.N), mineralization (DMB) and remodeling (MAR, MS/BS, BFR/BS, AcF, FP). Based on outlier analysis, data from 4 women (3 PLB and 1 ALN) were eliminated for non-parametric analyses.

Compared to PLB, ALN group showed significant (p=0.006) accumulation of PEN, in cancellous (ALN=17±3; PLB=8±3 nmol/mol of collagen) and not in cortical bone tissue. PYD and DPD were not different in cancellous or cortical bone tissues between ALN and PLB groups (p>0.05). Out of all measures of bone quality and remodeling, PEN correlated with BV/TV (r' = -0.52; p=0.01), DMB (r' = 0.57; p=0.008), BFR/BS (r' = -0.49; p=0.03), AcF (r' = -0.43; p=0.07) and MS/BS (r' = -0.54; p=0.01). PYD and DPD showed no correlation with any of the measured variables.

In conclusion, this study demonstrates that two years of ALN therapy of postmenopausal women results in post-translational modification of bone collagen through PEN. These effects are evident in cancellous and not in cortical bone and are localized in bone matrix with higher levels of DMB. Moreover, accumulation of PEN can be explained partially by remodeling suppression and low bone volume fraction. Further studies should be devoted to collagen changes induced by antiresorptive therapy and to their potential impact on antifracture efficacy.

## 1072

**Transition From Alendronate to Denosumab in Ovariectomized Cynomolgus Monkeys Maintained or Improved Cortical and Trabecular Bone Mass, Without Altering the Linear Relationship Between Bone Mass and Bone Strength.** M. S. Ominsky<sup>1</sup>, S. Y. Smith<sup>2</sup>, F. Vlasseros<sup>\*2</sup>, R. Samadfam<sup>\*2</sup>, P. J. Kostenuik<sup>1</sup>. <sup>1</sup>Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA, <sup>2</sup>Charles River Laboratories Preclinical Services Montreal, Inc., Montreal, QC, Canada.

The safety and efficacy of transitioning from a bisphosphonate to denosumab (DMAb, a fully human RANKL Ab) were examined in ovariectomized cynomolgus monkeys (cynos). Adult cynos (> 7 years old) were ovariectomized (OVX) and treated with vehicle (Veh, n=20), alendronate (ALN, n=21; 50 µg/kg IV biweekly), or denosumab (DMAb, n=11; 25 mg/kg SC monthly). After 6 months, animals from each of the Veh (n=10) and ALN (n=11) groups were switched from their previous treatment to denosumab (Veh-DMAb and ALN-DMAb), while the remaining animals continued treatment on Veh or ALN. The original DMAb group remained on DMAb for 12 months total. Serum calcium and BMD were monitored throughout the 12-month study. Strength testing was performed at the femur diaphysis, femur neck, and lumbar vertebrae.

Initiation of ALN or DMAb treatment resulted in transient decreases in serum calcium relative to vehicle controls. Pretreatment with ALN significantly reduced the denosumab-mediated calcium decrease compared to the Veh-DMAb group. One year of ALN or DMAb treatment resulted in significant increases from baseline in BMD at cancellous (lumbar spine DXA) and cortical (tibia diaphysis pQCT) sites. BMD continued to increase at both sites in the ALN-DMAb group after transition to denosumab. Transition from ALN to DMAb was also associated with significantly greater whole body BMD (vs. baseline), which was not observed with ALN alone.

Destructive compression testing of lumbar vertebral trabecular cores revealed significantly greater peak load and stiffness in DMAb and ALN-DMAb groups (p<0.05 vs. Veh), but not in the ALN alone group. No significant differences were found in extrinsic bone strength parameters at the femur neck and femur diaphysis, or in intrinsic strength parameters derived from the femur diaphysis for any group. Further evidence of normal material properties was demonstrated by strong and similar linear correlations within and across each group for load versus BMC at the femur diaphysis (overall r<sup>2</sup>=0.80), femur neck (r<sup>2</sup>=0.53), vertebral bodies (r<sup>2</sup>=0.69), and vertebral trabecular cores (r<sup>2</sup>=0.83).

In summary, transition from ALN to DMAb in adult OVX cynos resulted in maintenance or improvements in cortical and trabecular bone mass parameters, with no apparent safety concerns regarding serum calcium or bone strength. The linear relationship between bone mass and bone strength was preserved in all groups, suggesting that bone mass continued to predict bone strength independent of these treatment regimens.

## 1073

**Ccrn4l, A Peripheral Clock Gene, Influences Stromal Cell Allocation, Bone Mass, and Marrow Adiposity in Mice and Humans.** M. Kawai<sup>1</sup>, C. Ackert-Bicknell<sup>2</sup>, B. A. Lecka-Czernik<sup>3</sup>, J. P. Rodriguez<sup>4</sup>, A. M. Pino<sup>\*4</sup>, S. Rios<sup>\*4</sup>, C. B. Green<sup>\*5</sup>, C. J. Rosen<sup>1</sup>. <sup>1</sup>Research Institute, Maine Medical Center, Scarborough, ME, USA, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>3</sup>University of Toledo, Toledo, OH, USA, <sup>4</sup>Universidad de Chile, Santiago, Chile, <sup>5</sup>University of Virginia, Charlottesville, VA, USA.

Rosiglitazone (ROZ) treatment of mesenchymal stromal cells (MSCs) causes suppression of osteoblast (OB) specific genes and increased adipocytic pathway genes. One such transcript is *Ccrn4l* (also called *nocturnin*) a gene originally cloned from *Xenopus* retinae. *Ccrn4l* is a peripheral clock gene that encodes a deadenylase expressed in bone, fat, liver and stem cells. Hepatic *Ccrn4l* mRNA exhibits a circadian rhythm, being highest at ZT 1200, lowest at 2400. Aging, high fat feeding and ROZ induce hepatic *Ccrn4l* mRNA but decrease hepatic *Igf1*mRNA. Thus, we hypothesized that *Ccrn4l* was a downstream mediator of *Pparg*, and a negative regulator of both IGF-1 and osteoblastogenesis. To test that hypothesis, we characterized the time course of *Ccrn4l* expression in adipocytes, as well as human and mouse MSCs, and phenotyped the skeleton of *Ccrn4l* -/- mice. We cultured primary calvarial OBs from 1 wk Swiss Webster females in 10% FCS x 7 days, followed by β-GP + ascorbic acid. At day 0 by RT-PCR, *Ccrn4l* transcripts were present, but during OB differentiation, *Ccrn4l* mRNA was suppressed. If calvarial OBs were cultured in adipogenic media (MDI: IBMX, insulin, dexamethasone, ROZ), *Ccrn4l* transcripts increased and were related to adipocyte number. In 3T3-L1 cells exposed to MDI+ROZ, *Ccrn4l* expression and protein levels were increased by 9hrs, and sustained, as was *Pparg* mRNA while *Igf1* transcripts declined after 12hrs and remained low until day 5. In human MSCs isolated from patients undergoing hip replacement, with osteoporosis (OP) or without (OA), *Ccrn4l* expression was present at baseline and higher in OP vs. OA patients (p<0.05), as was *Pparg* mRNA; *Ccrn4l* mRNA was maintained when cultured in MDI, but suppressed in osteoblastic media. Addition of 1,25 (OH)D<sub>2</sub> did not alter *Ccrn4l* expression in MSCs with either media. In vivo, *Ccrn4l* -/- mice had increased cortical vBMD and trabecular distal femoral BV/TV vs. B6 (p<0.03), due to greater trabecular thickness (p<0.003). Bone marrow adipocytes were reduced by 50% in *Ccrn4l* -/- vs. B6 (p<0.05). In sum, *Ccrn4l* expression is maintained in MSCs that undergo adipogenesis, while it is suppressed during OB differentiation. Global deletion of *Ccrn4l* results in high bone mass and a phenocopy of *Pparg* +/- mice. We postulate that *Ccrn4l* is a downstream mediator of *Pparg* activation, essential for circadian clock regulation in bone. One gene target for *Ccrn4l* may be *Igf1*, thus providing a critical link between the fate of MSCs as adipocytes and nutrient status.

## 1074

**Osterix Is Required for Skeletal Growth and Bone Homeostasis after Birth.** X. Zhou<sup>\*1</sup>, Z. Zhang<sup>\*1</sup>, J. Q. Feng<sup>2</sup>, B. G. Darnay<sup>3</sup>, J. Kim<sup>4</sup>, B. de Crombrughe<sup>5</sup>. <sup>1</sup>M.D. Anderson, Houston, TX, USA, <sup>2</sup>Biomedical Sciences, Baylor College of Dentistry, Dallas, TX, USA, <sup>3</sup>Experimental Therapeutics, M.D. Anderson, Houston, TX, USA, <sup>4</sup>Molecular Medicine, Cell and Matrix Research Institute, Daegu, Republic of Korea, <sup>5</sup>Molecular Genetics, M.D. Anderson, Houston, TX, USA.

Osterix (Osx) is a transcription factor required for osteoblast differentiation and bone formation during embryonic development. We hypothesize that Osx is also needed for bone formation and bone homeostasis postnatally. Osx is expressed specifically in all osteoblasts and osteocytes and at a lower level in hypertrophic chondrocytes postnatally. To circumvent the neo-natal lethality of Osx-null mice, we successfully deleted Osx after birth using CAG-CreER: a tamoxifen-inducible cre recombinase under the control of the CMV/βactin promoter. By QPCR, the expression level of Osx in the humerus of day 24 tamoxifen-treated CAG-CreER; Osx-/flox mouse was about 1% of the tamoxifen-treated wild type control. Postnatal Osx-null mutants displayed a novel skeletal phenotype. These mice were characterized by the disappearance of bone trabeculae, thin and porous cortical bones, and a massive accumulation of mineralized cartilage tissue. Both primary osteoblasts isolated from calvaria and bone marrow stromal cells of Osx mutants failed to form any mineralized nodules in vitro; calcein incorporation was almost completely absent in lumbar vertebrae and long bones of tamoxifen-treated CAG-CreER; Osx-/flox mice, indicating that Osx is required for bone formation postnatally. By In situ hybridization, the Col2a1 expression pattern in the mutant remained unchanged comparing to the wild type controls, eliminating the possibility of ectopic cartilage formation due to loss of Osx. Osteoclasts, although reduced in numbers, appear to function normally. We postulate that the removal of mineralized cartilage is a function that is dependent on the presence of Osx, but the exact mechanism of this function is still unclear. Inactivation of Osx also inhibited expression of osteocyte markers and severely affected the morphology of osteocytes and their dendritic extensions, suggesting that Osx also plays a key role in regulating and maintaining osteocyte functions.

Taken together, our data substantiate the hypothesis that Osx is needed for skeletal growth and homeostasis after birth, and identify Osx as the first transcription factor required for osteoblast differentiation and new bone formation, as well as osteocyte function postnatally. These results provide new insights into postnatal skeletal morphogenesis and remodeling, which in turn should facilitate the development of preventive and therapeutic procedures for common bone diseases including osteoporosis.

**Disclosures:** X. Zhou, None.

## 1075

**Mice Lacking the Novel Transmembrane Protein Osteopotential Develop Catastrophic Defects in Bone Modeling.** M. L. Sohaskey<sup>\*1</sup>, Y. Jiang<sup>2</sup>, J. Zhao<sup>\*2</sup>, A. Mohr<sup>\*3</sup>, F. Roemer<sup>\*3</sup>, R. M. Harland<sup>\*1</sup>. <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, CA, USA, <sup>2</sup>Osteoporosis and Arthritis Lab, Dept. of Radiology, University of Michigan Medical School, Ann Arbor, MI, USA, <sup>3</sup>Osteoporosis and Arthritis Research Group, University of California, San Francisco, CA, USA.

In vertebrates, bone modeling coordinated by bone-forming osteoblasts and bone-resorbing osteoclasts generates and ensures the integrity of the developing skeleton. Dysregulation of this process leads to pathophysiological changes and metabolic bone disease. In an insertional mutagenesis screen for essential regulators of mammalian development, we identified *Osteopotential* (*Opt*), a gene encoding a novel transmembrane protein widely expressed in the developing embryo. Mice homozygous for an insertional mutation in the *Opt* locus die predominantly at birth of undetermined causes. Mice surviving this perinatal crisis period develop striking skeletal abnormalities similar to those seen in humans and genetically engineered mouse models having severe forms of the brittle bone disease osteogenesis imperfecta (OI), in particular OI type V. Abnormalities include hemorrhaging around limbs, deformation of long bones, and aberrantly healed fractures evidenced by the formation of hyperplastic calluses on ribs and long bones. Surviving *Opt* homozygous mutants exhibit a marked decrease in the amount of trabecular and cortical bone relative to normal littermates. Consistent with the hypothesis that this low bone mass results from a primary defect in osteoblast differentiation, *ex vivo* studies using primary calvarial osteoblast cultures reveal a cell-autonomous impairment of differentiation in *Opt* mutant osteoprogenitors, despite a normal proliferative index. Moreover, differentiating calvarial osteoblast cultures from *Opt*-deficient mice synthesize markedly reduced levels of Type I collagen protein despite normal transcription of *Col1a2*. Surprisingly, osteoclast function also appears to be compromised in *Opt* mutant mice, implying a state of low bone turnover in which increased bone resorption does not contribute to the fragility of the *Opt* mutant skeleton. When overexpressed in cultured cell lines and primary osteoblasts, *Opt* co-localizes with the endoplasmic reticulum markers Calnexin and PDI. In addition, *Opt* efficiently translocates across ER-derived microsomal membranes *in vitro*, suggesting that *Opt* is an integral membrane protein of the endoplasmic reticulum. Collectively, these data are important in establishing how mutagenesis of *Opt* results in a dramatic failure of bone modeling in the mouse. Our findings may also provide valuable mechanistic insight into the etiology of recessive forms of OI demonstrating no genetic linkage to either Type I procollagen locus.

**Ligand Activation of the Engineered G<sub>s</sub>-coupled Receptor Rs1 in Osteoblasts Promotes Trabecular Bone Formation.** E. Hsiao<sup>1</sup>, S. Millard<sup>2</sup>, A. Louie<sup>\*2</sup>, B. Boudignon<sup>\*</sup>, C. Manalac<sup>\*1</sup>, W. Lu<sup>\*2</sup>, B. Halloran<sup>2</sup>, B. Conklin<sup>\*1</sup>, R. Nissenson<sup>2</sup>. <sup>1</sup>GICD, J. David Gladstone Institutes, San Francisco, CA, USA, <sup>2</sup>Endocrine Unit, VA Medical Center, San Francisco, CA, USA.

Osteoblasts express a number of G-protein coupled receptors (GPCRs) that regulate intracellular cAMP levels through the G<sub>s</sub> and G<sub>i</sub> pathways. We previously described a mouse model that expresses an engineered G<sub>s</sub>-coupled receptor, Rs1, in maturing osteoblasts using the Collagen 1 alpha 2.3 kb promoter fragment (Coll(2.3)-tTA/TetO-Rs1 mice). In this model, dramatic trabecular bone formation was induced by basal Rs1 signaling activity from embryogenesis through adulthood, but the bone growth was significantly attenuated if Rs1 expression was delayed until after 4 wks of age. In this study, we sought to identify whether the phenotypic changes resulting from basal Rs1 activity could be induced by activating Rs1 with the synthetic agonist RS67333. Rs1 expression in Coll(2.3)-tTA/TetO-Rs1 mice was suppressed until 4 weeks of age by administration of doxycycline. After an additional 4-6 weeks off of doxycycline to allow Rs1 expression, mice were treated with either continuous RS67333 infusion by osmotic pump (3 mg/kg/day for 10 weeks) or with daily injections of RS67333 (3 mg/kg/day as a single daily dose for 4 weeks). Mutant mice treated with continuous RS67333 showed a significant increase in whole body DEXA bone mineral density as compared to agonist-treated wildtype littermates (0.108 +/- 0.020 vs. 0.054 +/- 0.002 g/cm<sup>2</sup>, p=0.004). Examination of the left femurs from individual animals showed wide variation in the degree of bone formation, as observed by microCT analysis of total femur bone volumes (105.8 +/- 95.0 vs. 20.9 +/- 0.4 mm<sup>3</sup>, p=0.26). The most severely affected femurs showed expansion of trabecular bone with loss of cortical bone and bone marrow space, resembling the changes induced by basal Rs1 signaling when Rs1 was expressed during embryogenesis and throughout postnatal life. In contrast, a 4 week course of intermittent, daily administration of RS67333 caused no detectable changes in cortical thickness or bone volume, although 5 of 8 animals showed an increase in trabecular bone within the secondary spongiosum. Our data indicate that continuous activation of Rs1 by a synthetic ligand in adult animals can reproduce the trabecular bony expansion seen with basal Rs1 activity from gestation. In addition, this study indicates that engineered receptors activated solely by synthetic ligands (RASSLs) such as Rs1 can be used to control and examine the temporal effects of G-protein signaling in osteoblasts.

## 1077

**Expression of an Engineered G<sub>s</sub>-coupled Receptor, Rs1, in Mature Osteoblasts is Sufficient to Drive A Dramatic Anabolic Skeletal Response.** S. M. Millard<sup>1</sup>, B. Boudignon<sup>1</sup>, A. Louie<sup>\*1</sup>, W. Lu<sup>\*1</sup>, B. P. Halloran<sup>1</sup>, B. Conklin<sup>\*2</sup>, R. A. Nissenson<sup>1</sup>. <sup>1</sup>Endocrine Research Unit, VA Medical Center, San Francisco, CA, USA, <sup>2</sup>Gladstone Institutes, University of California, San Francisco, CA, USA.

To examine the role of G<sub>s</sub>-coupled signaling pathways in osteoblasts we used targeted expression of an engineered constitutively active G<sub>s</sub>-coupled receptor, Rs1. Previously it has been described that expressing Rs1 in maturing and mature osteoblasts *in vivo* using the Collagen 1 alpha 2.3 kb promoter induces a dramatic anabolic skeletal response, including a striking expansion of what appear to be early osteoblast lineage cells. Conceptually, these cells may be derived from either an expansion of Rs1 expressing cells, which fail to subsequently fully differentiate, or from an osteoblast progenitor population which can respond to paracrine signals generated by Rs1 expressing cells. To distinguish between these possibilities we have expressed Rs1 under control of the osteocalcin promoter, to restrict transgene expression to mature osteoblasts. MicroCT imaging of femurs from OC:Rs1 mice show a massive and generalized increase in mineralized bone by 9 weeks of age. The precise extent of the mineralized expansion varied greatly, both between animals, and between different bones of the same animal. Histomorphometry showed a marked increase in bone cellularity and osteoid with disorganized trabecular bone. Expression of Runx2 and alkaline phosphatase (abundantly present in early osteoblast lineage cells) was upregulated 5 fold and 6.5 fold, respectively, in RNA isolated from the tibiae of 9wk old OC:Rs1 animals as compared to littermate controls. Osteocalcin expression (restricted to mature osteoblasts) was modestly upregulated by only 2 fold. These data support the notion that the increased bone cellularity observed in the OC:Rs1 animals resulted from a preferential expansion of early osteoblast lineage cells. The findings suggest that G<sub>s</sub> coupled signaling in mature osteoblasts generates a paracrine signal which positively regulates cells earlier in the osteoblast lineage. The expression of RANKL, a known target of cAMP dependent G<sub>s</sub> signaling, was upregulated by 7 fold in RNA from the tibiae of 9 wk old OC:Rs1 mice and the RANKL:OPG ratio, an important determinant of osteoclastogenic activity, was increased by 2 fold at the RNA level. Furthermore, histomorphometric analysis revealed a striking increase in TRAP positive staining cells in OC:Rs1 mice. Thus, G<sub>s</sub> signaling in mature osteoblasts drives a large increase in bone formation and bone resorption. The former appears to result from paracrine control of the number of early osteoblasts whereas the latter likely arises from a G<sub>s</sub>-induced increase in the osteoclastogenic activity of mature osteoblasts.

## 1078

**Jagged1 Stimulation by Parathyroid Hormone(1-34) (PTH) in Mature Osteoblasts Is not Required for Hematopoietic Stem Cell (HSC) Expansion.** J. Weber<sup>\*</sup>, B. Gigliotti<sup>\*</sup>, R. Porter<sup>\*</sup>, A. Olm-Shipman<sup>\*</sup>, B. Frisch<sup>\*</sup>, J. Smith<sup>\*</sup>, L. M. Calvi. Department of Medicine, University of Rochester School of Medicine, Rochester, NY, USA.

Osteoblasts regulate HSC in the bone marrow microenvironment. Osteoblastic-HSC interactions could be exploited to expand HSC, however the signals required are unknown. We have defined a murine model in which PTH expands HSC. Our data suggested that PTH may expand HSC by stimulating the ligand Jagged1 in osteoblasts, activating its Notch receptor(s) in HSC and increasing their self-renewal. Moreover, PTH increased Jagged1 only in a subset of osteoblasts *in vivo*. Based on these data, we hypothesized that PTH may specifically stimulate Jagged1 in mature osteoblasts, and that the PTH-dependent HSC increase may require osteoblastic Jagged1. To test whether PTH regulates Jagged1 depending on osteoblastic differentiation, unmineralized vs mineralizing MC3T3-E1 (MC3T3) cells were treated with a single dose of PTH and Jagged1 was quantified by real time RT-PCR. As we hypothesized, PTH increased Jagged1 only in mineralizing, osteocalcin (OC) positive MC3T3 cells. In contrast, in spite of expression of the PTH receptor, unmineralized MC3T3s did not upregulate Jagged1 after PTH. The Adenylate Cyclase (AC) stimulator Forskolin and PTH(1-31), which preferentially activates Protein Kinase A (PKA), also increased Jagged1 in mineralizing MC3T3 cells, suggesting that this effect is AC/PKA-dependent. In contrast, the Protein Kinase C stimulating Phorbol Ester and PTH(13-34) did not induce Jagged1. To test *in vivo* whether expression of Jagged1 in mature osteoblasts is required for the PTH-dependent HSC expansion, mice expressing the Cre recombinase (Cre) under the control of the human OC promoter were crossed with mice in which LoxP sites flank the first 2 coding exons of the Jagged1 gene. Cre targeting to osteoblasts and osteocytes was confirmed *in vivo* by the enhanced GFP reporter mouse strain Z/EG. Mice lacking osteoblastic Jagged1 were fertile and viable, and did not have any dramatic bone or hematopoietic phenotype. Adult male mice lacking osteoblastic Jagged1 and control littermates were treated with intermittent PTH or vehicle (n=5/group). HSC from the bone marrow, quantified by flow cytometric analysis as Lin-Sca-1-c-kit<sup>+</sup> (LSK) cells, were similar in all vehicle-treated mice. PTH treatment increased LSK equally in controls and in mice lacking osteoblastic Jagged1. In summary, while PTH stimulates Jagged1 specifically in mature osteoblasts, Jagged1 expression is not required *in vivo* for the PTH-dependent expansion of HSC. These data challenge whether Notch mediates the PTH-dependent HSC increase. Further studies are in progress to establish *in vivo* whether the Notch signaling pathway is required for osteoblastic-HSC interactions.

**Critical Role of TGF- $\beta$  Signaling Pathways in Skeletal Development.** T. Matsunobu<sup>\*1</sup>, A. B. Kulkarni<sup>\*1</sup>, S. Karlsson<sup>\*2</sup>, Y. Yamada<sup>\*1</sup>. <sup>1</sup>Laboratory of Cell and Developmental Biology, National Institute of Dental and Craniofacial Research/NIH, Bethesda, MD, USA, <sup>2</sup>Molecular Medicine and Gene Therapy, Lund Strategic Center for Stem Cell Biology and Cell Therapy, Lund University, Lund, Sweden.

Transforming growth factor- $\beta$  (TGF- $\beta$ ) initiates its diverse cellular responses during development by forming a specific cell surface complex consisting of TGF- $\beta$  and TGF- $\beta$  type I (T $\beta$ R/Alk5) and type II receptors, which activates downstream signaling through Smad-dependent and/or -independent pathways such as MAPK pathways. The precise role in vivo has not been fully understood since gene targeting of TGF- $\beta$  signaling-related genes in mice has resulted in phenotypes varying from early embryonic lethality to normal at birth. In this study, we conditionally deleted ALK5 in the skeletal progenitors by Dermo1-Cre to determine the role of TGF- $\beta$  signaling in skeletogenesis. The conditional ALK5 knockout mice (ALK5CKO) were perinatal lethal, and skeletal preparation and histological examinations revealed that ALK5CKO had severe bone and perichondrium formation defects with less mineralization, partial joint fusion, and abnormal cartilaginous ectopic protrusions formed from the resting/proliferative zones. Immunohistochemical analysis showed that osteoblast proliferation activity and the expression of osteoblast differentiation markers were systemically decreased in ALK5CKO calvaria and limbs. To understand the mechanism of the bone formation defect in ALK5CKO, we further generated genetically modulated mice with ALK5<sup>flox/flox</sup>; ROSA26 to visualize Cre-mediated ALK5 inactivation by X-Gal staining, and we carried out metatarsal organ culture and primary neonatal calvarial cell culture. The proliferation of perichondrial cells in the metatarsal explants as well as the primary calvarial cells was reduced in part through the inhibition of JNK-MAPK and Smad pathways when ALK5 was inactivated. We also found that ALK5-deficient calvarial cells showed inhibition of MAPKs activity, and reduced osteogenic differentiation activity as evident by reduced alkaline phosphatase activity and mineralization. In contrast, adipocytogenesis was elicited even though the cells were cultured in osteogenic differentiation conditions in part through the inhibition of p38-MAPK and Smad pathways. These results suggest that TGF- $\beta$  signaling positively regulates the commitment of common osteoblast/adipocyte progenitors toward osteoblast lineage and osteoprogenitor proliferation and differentiation during skeletogenesis through Smad-dependent and -independent pathways. Our findings demonstrate an important in vivo function of TGF- $\beta$  signaling pathways in bone development by selecting different downstream pathways.

**TGF $\beta$  Inhibits BMP Signaling and Osteogenesis Through the TGF $\beta$  and BMP R-Smad Direct Interaction.** O. Korchynski, P. ten Dijke\*. Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands.

Bone morphogenetic proteins (BMP) and transforming growth factors  $\beta$  (TGF $\beta$ ) belong to the same TGF $\beta$  superfamily of cytokines. Interestingly, signalling pathways mediating BMP and TGF $\beta$  signals were found to counteract each other in the multiple physiological situations including bone destruction due to periprosthetic osteolysis and inhibition of TGF $\beta$ -promoted metastasis formation by BMPs. BMPs and TGF $\beta$ s transduce most of their signals through the intracellular Smad proteins. In the current study we describe a novel molecular mechanism underlying the negative crosstalk between the BMP and TGF $\beta$  pathways. Upon ligand stimulation endogenous BMP pathway-restricted (R-Smad) Smad1 and Smad5 form a transient complex with the endogenous activated TGF $\beta$ /Activin R-Smads, namely Smad2 and Smad3. This complex formation leads to the inhibition of BMP6 and BMP7-driven transcription and their direct target genes Id1, Smad6 and Smad7 mRNA expression as well as of Id1 and Msx2 and Msx1 promoters activation. As a result BMP6/7-induced both early and late osteoblast differentiation is strongly inhibited by TGF $\beta$ . Neither Smad1/5/8 phosphorylation nor their affinity to DNA binding is affected upon TGF $\beta$  treatment. Ectopic expression of Smad2 and Smad3 strongly exacerbates the inhibitory effect of TGF- $\beta$  on BMP response and subsequently osteogenesis. Smad1 or Smad5 overexpression or treatment with the specific TGF $\beta$ R-I/ALK5 kinase inhibitor SB431542 completely rescue BMP signaling from being inhibited by TGF $\beta$ . shRNA-mediated knockdown of Smad2 and Smad3 expression converts TGF $\beta$  from the inhibitor of BMP response into an activator of BMP signaling. Adenovirally delivered shRNA constructs that knockdown Smad2 and Smad3 expression or treatment with SB431542 inhibitor efficiently rescue BMP-induced osteoblast differentiation from the inhibition by TGF $\beta$ . Chromatin immunoprecipitation assay (ChIP) performed with an RNA Polymerase II-specific antibody revealed that BMP-induced transcription is indeed inhibited with a TGF $\beta$  treatment. Interestingly, co-ChIP assay reveals both BMP R-Smads (Smad1/5/8) and TGF $\beta$  R-Smad, Smad2 to be a part of common transcriptional complex bound to the BMP target genes promoters. Thus, simultaneous activation of both BMP and TGF $\beta$  pathways causes a formation of the complex between activated BMP R-Smads and activated TGF $\beta$ /Activin R-Smads leading to the inhibition of both BMP and TGF $\beta$ -driven transcription.

**A BMP-2-stimulated Signaling Niche in Osteoblasts Comprising of Smad and PI 3 Kinase/Akt Regulates NFATc1 Expression and Its Nuclear Translocation.** C. C. Mandal<sup>1</sup>, G. G. Choudhury<sup>\*2</sup>, S. Ganapathy<sup>\*1</sup>, S. E. Harris<sup>3</sup>, N. Ghosh-Choudhury<sup>1</sup>. <sup>1</sup>Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>2</sup>Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>3</sup>Periodontics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

The transcription factor NFATc1 acts as a master regulator of osteoclast differentiation under the control of osteoblast-derived protein factors. However, its function in osteoblasts (OB) is still evolving. To study osteoblastic NFATc1 regulation, we generated OB-specific BMP-2 knock out (BMP-2 cKO) mice by crossing homozygous BMP-2 floxed mice with 3.6kb collagen type I-Cre mice. These mice have reduced bone mass, radio-opacity and bone mineral density. Immunohistochemical staining of bone sections showed significant reduction in NFATc1 expression. Phosphorylation of Smad 1/5, the downstream transcription factors in BMP-2 signaling, was also significantly prevented in the BMP-2cKO mice. To examine the mechanism of NFATc1 expression, we used cultured OB. BMP-2 increased NFATc1 mRNA and protein expression within 4 hours, resulting in its translocation to the nucleus as determined by real time qRT-PCR-PCR, immunoblotting and immunofluorescence, respectively. Actinomycin-D completely inhibited BMP-2-stimulated NFATc1 protein expression, indicating the involvement of a delayed early transcriptional mechanism. Transient transfection assays using a NFATc1 promoter-driven luciferase reporter plasmid (NFAT-Luc) showed 5-fold increase in NFATc1 transcription by BMP-2. Adenoviral expression of inhibitory Smad 6 blocked BMP-2-induced NFATc1 protein expression and its nuclear translocation. Furthermore, expression of Smad 6 prevented BMP-stimulated NFATc1 transcription. Transfection of Smad 5 increased NFATc1 transcription in the absence of BMP-2, confirming the involvement of BMP-specific Smads in the expression of NFATc1 in OB. We have established a requirement of PI 3 kinase/Akt signaling in OB differentiation. Therefore, we tested the involvement of this lipid kinase cascade in NFATc1 expression. Expression of dominant negative PI 3 kinase or Akt significantly inhibited BMP-2-induced transcription of NFATc1 as judged by the transient reporter transfection assays. Also PTEN (a lipid phosphatase), which acts as an inhibitor of PI 3 kinase signaling, and dominant negative Akt significantly blocked BMP-2-induced nuclear translocation of NFATc1. Together these data for the first time show a role of NFATc1 downstream of BMP-2 in mouse bone development. Furthermore, our results provide novel evidence for the presence of a cross-talk between Smad and PI 3 kinase/Akt signaling for BMP-2-induced NFATc1 regulation.

**Point Mutation of Endofin at PP1c-Binding Domain Induces Angiogenesis and Bone Formation in Mice by Sensitizing BMP Signaling.** F. Zhang\*, W. Shi\*, T. Qiu, X. Wu, C. Wan, Y. Wang, T. Clemens, M. Wan, X. Cao. University of Alabama at Birmingham, Birmingham, AL, USA.

We have identified Endosome-associated FYVE-domain protein (endofin) as a Smad anchor for receptor activation in BMP signaling. Endofin binds Smad1 preferentially and enhances Smad1 phosphorylation and nuclear localization upon BMP stimulation. Endofin contains a protein-phosphatase-binding motif, which recruits protein phosphatase1 (PP1c) to negatively modulate BMP signals through receptor dephosphorylation of the BMP type I receptor. Point mutation of endofin at PP1c-binding domain (F872A) virtually abolished the interaction between PP1c and endofin. As a result, BMP signaling was sensitized and osteoblast differentiation was enhanced. To further determine whether this endofin mutant affects osteoblast activity and bone formation *in vivo*, transgenic mice were generated in which this mutant (F872A) was overexpressed in osteoblasts driven by a 2.3 kb Col I promoter. The expression of the mutant endofin (F872A) was detected in 4 different transgenic lines by Western blot. X-ray analysis revealed that bone density of the entire skeleton was elevated at 4 months of age in all 4 transgenic lines. Analysis of femur by  $\mu$ CT showed that trabecular volume was increased by 11% compared to wild type litter mates. Consistently, the trabecular bone thickness and number are also significantly increased, whereas the trabecular bone separation was decreased. Immunostaining of tibia sections demonstrated that the level of phosphorylated Smad1 was enhanced in osteoblasts from the transgenic mice. To directly assess the impact of the mutation on bone vasculature we performed contrast-enhanced  $\mu$ CT imaging.  $\mu$ CT imaging of vasculature in Microfil-perfused bones revealed a striking increase in the density of the vasculature, with progressively increased vessel numbers with age. Quantitative analysis showed that vessel surface and volume were both increased in mutant mice relative to controls. These observations suggest that enhanced BMP signaling with consequent upregulation of the production of angiogenic factors promotes formation of the bone vasculature. Consistent with this idea, the expression of *Vegf* was upregulated in trabecular bone of the mutant mice. Taken together, disruption of PP1c binding motif of endofin elevates the level of phosphorylated Smad1 and augments bone formation partially by stimulating angiogenesis.

## 1083

**NADPH Oxidase / Nox Signaling Stimulates Myofibroblast Mx2 Transcription Via Hydrogen Peroxide.** C. Lai\*, E. Huang\*, J. Shao, O. Sierra, R. Cohen\*, D. Towler. Internal Medicine, Washington University in St. Louis, St. Louis, MO, USA.

Aortofemoral calcification is prevalent in type II diabetes (T2DM), increasing risk for lower extremity amputation. LDLR<sup>-/-</sup> mice fed high fat diets develop T2DM, and accumulate aortic calcium, mediated via osteogenic mechanisms. The TNF- $\alpha$  dependent low-grade inflammation of T2DM activates pro-calcific aortic Mx2-Wnt signaling. Since TNF- $\alpha$  promotes oxidative stress via NADPH oxidase (Nox), we examined contributions of reactive oxygen species and Nox isoforms to Mx2 expression. Treatment of aortic adventitial myofibroblasts with TNF upregulated Mx2 expression within 2 hours, achieving 5- fold induction by 3 hours. While IL1- $\beta$  could also induce Mx2, IL-1 $\alpha$  and IL-6 could not. Pretreatment of cells with 10  $\mu$ M diphenyliodonium (DPI) - an inhibitor of all Nox enzymes -- inhibited Mx2 induction. The effects of DPI were phenocopied by treatment with resveratrol or ebelen, cell-permeant reactive oxygen scavengers that mimic the activity of peroxidases. Antisense oligonucleotides (ASOs) specific for Nox1 and Nox2 significantly impaired signaling, reducing TNF induction of Mx2 by 50%. By contrast, Nox3 ASO enhanced Mx2 induction, while Nox4 ASO was without effect. Administration of 20 ng/gm Nox1 ASO + 20 ng/gm Nox2 ASO intraperitoneally for 5 days reduced aortic expression of Mx2 in SM22-TNF $\alpha$  transgenic mice by 54% (p = 0.002) as compared to cohorts receiving 40 ng/gm control ASO. SIN-1, a superoxide precursor, had no effect on myofibroblast expression of Mx2. However, H202 dose-dependently upregulated Mx2, recapitulating the response to TNF. Two major regions of the Mx2 gene - the BMP2 and Wnt regulated enhancer (BMPRE) located between -4660 and -2874 relative to the transcription start site, and the YY1-regulated 0.4 kb proximal promoter region - were evaluated for H202 responsiveness. In transfected CH310T1/2 cells, 0.2 mM H202 stimulated (2.4 - fold, p < 0.001) the transcription driven by the Mx2 promoter fragment -498 to +26 cloned upstream of the luciferase reporter of pGL2. H202 stimulated transcription driven by the Mx2 BMPRE 4.8 - fold (p < 0.001) when placed upstream of the RSV minimal promoter of RSVLUC (also in pGL2). By contrast, H202 did not stimulate RSVLUC activity, or transcription driven by several other promoters. Sequential 5'- deletion of the proximal promoter element mapped H202 responses to nucleotides -69 to +26 within the Mx2 gene. Two MEF2-like cognates were identified that assembled specific protein complexes increased by H202 treatment. Thus, Nox1 and Nox2 contribute to TNF induction of Mx2 in vascular myofibroblasts. H202 generated by Nox activity upregulates Mx2 gene transcription in part via the Mx2 BMPRE and novel regulatory elements in the proximal promoter.

**Targeted Overexpression of the Nuclear FGF2 isoforms in Osteoblasts induces Hypophosphatemia via Modulation of FGF23 and Klotho in Mice.** L. Xiao<sup>1</sup>, J. Coffin<sup>\*2</sup>, T. Carpenter<sup>3</sup>, M. Hurley<sup>1</sup>. <sup>1</sup>School of Medicine, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT, USA, <sup>3</sup>School of Medicine, Yale University, New Haven, CT, USA.

We previously examined mice in which a 3.6kb fragment of the type I collagen 5' regulatory region (Col3.6) drives expression of the nuclear (HMW) FGF2 isoforms in pre-osteoblasts and osteoblasts (HMWTg). Vector only transgenic mice (Col3.6-IRES-GFPsaph, VTg) were also developed. The bone phenotype of HMWTg mice included osteomalacia, decreased bone mineral density (BMD) and dwarfism compared to VTg, which was associated with hypophosphatemia. In the current study we examined whether decreased serum phosphate (pi) in HMWTg mice was due to renal wasting. Twenty-four h urine Pi was significantly increased in HMWTg compared with VTg mice (0.10 $\pm$ 0.02 vs. 0.04 $\pm$ 0.01 mgs/24h, p<0.05). To determine whether an increase in dietary Pi could rescue the bone phenotype, 21 days old male VTg mice and HMWTg mice were fed a normal diet (1% calcium, 0.67% phosphorous and 4.4 IU vitaminD/g) or a high Pi diet (1.1% calcium, 2% phosphorous and 2.2 IU/g vitamin D) for 4 weeks. BMD was (0.047 $\pm$ 0.001; 0.036 $\pm$ 0.004; 0.046 $\pm$ 0.001 g/cm<sup>2</sup>) in VTg-Normal diet, HMWTg-Normal diet and HMWTg-High Pi diet respectively. Reduced BMD in HMWTg was reversed by the high Pi diet but not by a normal diet (compared with VTg-Normal diet). In addition, the dwarfism in HMWTg was partially reversed in HMWTg with High Pi but not a normal Pi diet. Since the HMWTg bone phenotype was similar to FGF23 transgenic mice (Larsson et al., 2004), FGF23 was measured. Serum FGF23 was significantly increased in HMWFGFTg mice compared with VTg mice (282 $\pm$ 56 vs. 97 $\pm$ 7 pg/ml, p<0.05). To explore the mechanism(s) involved in renal Pi wasting, RNA was extracted from marrow stromal cells (MSCs) or kidneys and genes of interest were determined by Real-Time PCR. There were significant increases p<0.05 in FGF23 (1.95 $\pm$ 0.39 vs. 1.00 $\pm$ 0.00); and PHEX (4024 $\pm$ 1297 vs. 264 $\pm$ 21), in MSCs from HMWTg vs. VTg. In kidneys, there were significant increases p<0.05 in mRNA normalized to VTg for FGFR1C (1.28 $\pm$ 0.06 vs. 1.00 $\pm$ 0.00); FGFR3C (1.73 $\pm$ 0.26 vs. 1.00 $\pm$ 0.00); and Klotho (4.95 $\pm$ 1.35 vs. 1.00 $\pm$ 0.00) in HMWTg vs. VTg. In contrast, mRNA of the renal Na<sup>+</sup>/Pi co-transporter Npt2a was decreased (0.61 $\pm$ 0.14 vs. 1.00 $\pm$ 0.00, p<0.05) in HMWTg vs. VTg mice. We propose that overexpression of HMWFGF2 resulted in increased FGF23 in bone, which was released into the systemic circulation. FGF23 exerted its effect on the kidney by signaling via FGFRs and Klotho to down regulate Npt2a, which in turn caused kidney Pi wasting, osteomalacia and decreased BMD. This study suggests that a Pi regulating system may be evident in mice, which involves a cascade of signals involving multiple FGFs.

**Inhibition of HIF1 $\alpha$  Alone or Combined with TGF $\beta$  Blockade Prevents Breast Cancer Bone Metastases.** L. A. Kingsley<sup>1</sup>, K. S. Mohammad<sup>1</sup>, M. Niewolna<sup>\*1</sup>, T. LaVallee<sup>\*2</sup>, J. M. Chirgwin<sup>1</sup>, T. A. Guise<sup>1</sup>. <sup>1</sup>Endocrinology, University of Virginia, Charlottesville, VA, USA, <sup>2</sup>EntreMed, Rockville, MD, USA.

Cancer cells frequently metastasize to bone, which is hypoxic and rich in growth factors. Previously we showed bone metastases are hypoxic, and 1% O<sub>2</sub> increased hypoxia-inducible factor (HIF)1 $\alpha$  in MDA-MB-231 breast cancer cells. Combined treatment with 1% O<sub>2</sub> and TGF $\beta$  additively increased mRNA expression of prometastatic factors VEGF and CXCR4, suggesting that HIF1 $\alpha$  promotes bone metastasis via crosstalk with TGF $\beta$ .

Stable MDA-MB-231 clones expressing shRNA against HIF1 $\alpha$  (shHIF1 $\alpha$ ) with a  $\geq$ 90% decrease in HIF1 $\alpha$  mRNA and protein expression were selected. Expression of HIF-target genes VEGF and CXCR4 was decreased compared to parental and non-target shRNA (shCtrl) cells. Two stable shHIF1 $\alpha$  clones were inoculated into the left cardiac ventricle of female nude mice (N=5-10/group). HIF1 $\alpha$  knockdown improved survival compared to mice that received parental or shCtrl cells (16 or 8d, P<0.05) and decreased osteolytic area on x-ray (P<0.001).

In the MDA-MB-231 bone metastases mouse model, we tested a drug with anti-HIF1 $\alpha$  activity, 2-methoxyestradiol (2ME2), in a bioavailable formulation. As a preventive therapy, 2ME2 (150mg/kg/d ip) decreased osteolytic area (P<0.005) and hindlimb tumor area by histomorphometry (P<0.05), while bone volume was increased (P $\leq$ 0.0001), compared to vehicle-treated mice. 2ME2 increased BMD, measured by DXA, at the femur (P<0.05) and tibia (P $\leq$ 0.0001). Development of established lesions was unaffected when treatment was initiated 14d after cell inoculation. Hypoxyprom-1 immunostaining for hypoxia was decreased in bone metastases from 2ME2-treated mice compared to controls. 2ME2 inhibited mammary fat pad tumor growth 27d post tumor inoculation (P $\leq$ 0.001) and decreased mRNA expression of HIF1 $\alpha$  and VEGF.

Combined blockade of TGF $\beta$  signaling and HIF1 $\alpha$  was tested by stably expressing shHIF1 $\alpha$  in MDA-MB-231 cells carrying a dominant-negative TGF $\beta$  type II receptor (T $\beta$ R2 $\Delta$ cyt). These cells cause fewer bone metastases and have decreased expression of the osteolytic factor PTHrP. Survival of mice receiving T $\beta$ R2 $\Delta$ cyt/shHIF1 $\alpha$  cells was extended by 7d compared to mice receiving cells with T $\beta$ R2 $\Delta$ cyt alone and >14d compared to mice receiving parental cells (P<0.0001). Osteolytic area was decreased in T $\beta$ R2 $\Delta$ cyt/shHIF1 $\alpha$  tumor bearing mice compared to T $\beta$ R2 $\Delta$ cyt/shCtrl (P<0.05) and parental (P<0.001).

Our results show that hypoxia/HIF1 $\alpha$  signaling promotes bone metastasis, which were inhibited by preventively targeting HIF1 $\alpha$  with 2ME2. Bone metastases were further inhibited by blocking both HIF1 $\alpha$  and TGF $\beta$  signaling. Combined targeting of HIF1 $\alpha$  and TGF $\beta$  could treat bone metastases more effectively than single-agent interventions.

**Important Contribution of the Immune System in Regulating the Tumor/Bone Vicious Cycle Independent from Osteoclasts.** K. Zhang\*, A. Hirbe\*, K. Weilbaecher, D. Novack, R. Faccio. Washington University, St. Louis, MO, USA.

While blockade of OC activity has been shown to be effective in decreasing tumor burden and associated bone erosion in animal models of bone metastasis, one third of patients diagnosed with breast cancer develop recurrent bone metastases even when treated with bisphosphonates, potent inhibitors of osteoclastic resorption, suggesting that additional factors beyond the OC are controlling tumor growth in bone. Here, we provide new data demonstrating that broadly immune deficient animals with an accompanying defect in OC development and function (PLC $\gamma$ 2<sup>-/-</sup> mice), are more susceptible to tumor growth in bone compared to wild-type immunocompetent mice. Intracardiac injection of luciferase-labeled B16 melanoma cells (B16-FL) into PLC $\gamma$ 2<sup>-/-</sup> mice yields a 2-fold increase in bone tumor burden compared to WT mice at day 8 and 10 as measured by bioluminescence imaging (p<0.001) and by histologic analysis (p=0.03). Despite the fact that cancer cells almost completely replaced the bone marrow, PLC $\gamma$ 2<sup>-/-</sup> mice still showed a 3-fold decrease in OC number compared to WT littermates (p=0.007) and protection from tumor-associated bone destruction. Thus, in this model system, OC deficiency was not sufficient to prevent tumor growth in bone.

We hypothesized that a lack of tumor surveillance, caused by poor immune cell function, caused enhanced tumor growth in bone. To show that cells of hematopoietic origin were responsible for increased bone metastasis, we injected B16-FL cells in lethally irradiated C57BL/6 mice transplanted with bone marrow from WT or PLC $\gamma$ 2<sup>-/-</sup> donors. Similarly to the null animals, tumor growth was increased in the bones of PLC $\gamma$ 2<sup>-/-</sup> transplant recipients (p=0.004 Day 8, p=0.01 Day 10). To further explore the possibility the immune cells contribute to regulation of bone metastasis, we turned to Lyn deficient mice, which have a hyperactive immune system and more responsive OCs, the opposite of PLC $\gamma$ 2<sup>-/-</sup> mice. Lyn<sup>-/-</sup> animals display significant inhibition of cancer cell growth in the bones following either intracardiac (p<0.01 Day 10) or intratibial injection (p<0.03 Day 10) of B16-FL cells. Again, despite an OC phenotype which should encourage tumor growth in bone, immune hyperactivity predominated and decreased bone metastasis. These two models, in which alterations in immune and OC activities are expected to have opposing effects on bone metastasis, both demonstrate a dominance of immunity over bone resorption. Thus, our data challenges the paradigm of the vicious cycle activation of osteoclastic bone resorption by tumor cells releases tumor growth factors from bone, suggesting that the immune system plays a role in regulating tumor growth in bone independent from osteoclasts.

**TGF- $\beta$  Signaling in Stromal Cells Facilitates Osteoblastic Lesions in Prostate Cancer.** X. Li<sup>\*1</sup>, J. A. Sterling<sup>2</sup>, S. A. Munoz<sup>\*2</sup>, G. R. Mundy<sup>2</sup>, N. A. Bhowmick<sup>\*1</sup>. <sup>1</sup>Department of Urologic Surgery, Vanderbilt Center for Bone Biology, Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN, USA, <sup>2</sup>Department of Medicine, Vanderbilt Center for Bone Biology, Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN, USA.

Advanced prostate cancer metastasizes to bone in approximately 90% of patients to form predominantly osteoblastic lesions, although the factors that mediate this process remain unclear. We reasoned that TGF- $\beta$  signaling in the host stromal cells of the bone microenvironment may be important, since (i) active TGF- $\beta$  is present there in relatively large amounts; (ii) TGF- $\beta$  signaling in stromal cells has been shown to enhance tumor initiation and progression in other situations (Science 2004, 303: 848). To test this, we compared the different stromal effect on LNCaP prostate cancer tumor growth between conditional knockout of the TGF- $\beta$  receptor type II in the stromal compartment (Tgfr2<sup>flloxEx2/loxEx2</sup>) and control (Tgfr2<sup>flloxEx2/loxEx2</sup>) mice. We found LNCaP tumor growth in tissue recombination xenograft models in the context of either the prostate stromal cells or the bone from Tgfr2<sup>flloxEx2</sup> mice to be significantly increased ( $n \geq 4$ ). No tumor grew when LNCaP cells were xenografted alone. This suggested an important role for TGF- $\beta$  signaling in stromal cell regulation of prostate cancer growth. When similar tissue recombinants of LNCaP-C4-2 with prostate stroma were inoculated via intra-tibial injections, we observed the progression of lytic, mixed, and finally osteoblastic lesions in the bone injected with LNCaP-C4-2 cells alone during a 13.5 week study. In addition, the osteoblastic lesions were smaller than those by LNCaP-C4-2 with either Tgfr2<sup>flloxEx2</sup> or Tgfr2<sup>flloxEx2/loxEx2</sup> prostate stroma recombinants. Interestingly, the bone with LNCaP-C4-2/Tgfr2<sup>flloxEx2</sup> prostate stroma injection developed directly to mixed and osteoblastic lesions within seven weeks without an obvious osteolytic phase. In vitro analyses of LNCaP-C4-2 cells indicated that conditioned media from Tgfr2<sup>flloxEx2/loxEx2</sup> and Tgfr2<sup>flloxEx2</sup> stromal cells decreased the expression of the osteolytic factor, PTHrP, by 2 and 20-fold respectively, when compared to LNCaP-C4-2 cells alone, suggesting that the absence of TGF- $\beta$  signaling in the stroma reduces the expression of osteolytic factors by the tumor cells. Taken together, these data indicate that TGF- $\beta$  signaling in the host stroma suppresses prostate cancer growth and the nature of the subsequent osteoblastic lesions. Specifically, TGF- $\beta$  responsiveness of the bone modulates the transition from primarily osteolytic to osteoblastic lesions.

**Host Bone Marrow-Derived Stromal Cells Promote Myeloma Initiation and Development of Osteolysis.** J. A. Fowler, G. R. Mundy, S. T. Lwin\*, C. M. Edwards. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

In multiple myeloma (MM), the interaction between neoplastic plasma cells and the bone marrow (BM) microenvironment results in malignant proliferation of these cells, and a characteristic osteolytic bone disease. The 5T Radl murine model of MM is a spontaneous model occurring in aged C57BL/KaLwRij (KaLwRij) mice and propagated by inoculation of myeloma cells (either freshly isolated or the established 5TGM1 cell line) into mice of the same strain. Since myeloma grows in KaLwRij mice, but not in closely related C57BL6 mice, this suggests the KaLwRij BM creates a unique and permissive milieu for MM and that host cells from this microenvironment promote myelomagenesis. To test this, we utilized an established murine bone marrow stromal cell line (BMSCs) isolated from myeloma-bearing KaLwRij mice. These cells express vimentin and FSP-1, but not  $\alpha$ -SMA, consistent with a fibroblast phenotype. However, these cells did not demonstrate osteogenic or adipogenic differentiation potential characteristic of mesenchymal stem cells. Non-permissive C57BL6 or permissive KaLwRij mice were inoculated with 5TGM1-GFP MM cells  $\pm$  BMSCs. There was no difference in tumor burden in KaLwRij mice co-inoculated with 5TGM1 MM cells and BMSCs compared with 5TGM1 cells alone, suggesting that BMSCs do not directly increase MM growth. In striking contrast, 4 weeks following inoculation, C57BL6 mice inoculated with 5TGM1 or BMSCs alone did not develop MM but C57BL6 mice inoculated with 5TGM1 and BMSCs developed MM identical to that of the syngeneic KaLwRij mice. Tumor burden was demonstrated by an increase in serum paraprotein (134.65% increase compared with mice inoculated with 5TGM1 cells alone) and GFP-positive tumor cells in BM (55%) and spleen (7.22%). Osteolytic bone disease was confirmed by  $\mu$ CT analysis, with a significant increase in osteolytic lesions and decrease in bone volume. Histomorphometric analysis confirmed myeloma associated bone disease demonstrated by a 40% increase in osteoclast number and a 62% decrease in osteoblast number, compared with mice inoculated with 5TGM1 cells alone. Taken together, our results suggest that BMSCs derived from KaLwRij mice promote MM in mice in which MM otherwise does not develop. Thus, in myeloma, BMSCs promote initiation of the disease and subsequent osteolysis, demonstrating a critical role for host-derived BMSCs in the pathogenesis of MM.

**Stat3 Induces Osteoblastic Bone Metastases Through Up-regulating the Expression of Shh and a Calcium Channel TRPM8 in the LNCaP Human Prostate Cancer Cells.** H. Kanzaki, H. Yono\*, P. Williams\*, A. Farias\*, T. Yoneda. Medicine, Endocrinology, UT Health Science Center San Antonio, San Antonio, TX, USA.

Prostate cancer preferentially metastasizes to bone and develops osteoblastic lesions with infrequent osteoclastic lesions through yet-unknown mechanisms. Signal transducers and activators of transcription 3 (Stat3), which is one of the oncogenic signaling molecules, is constitutively activated in human prostate cancer. Moreover, Stat3 is known to be involved in the promotion of osteoblast proliferation. These results collectively suggest Stat3 plays a role in the development of osteoblastic bone metastases in prostate cancer. To study this, we introduced a constitutive-active Stat3 cDNA into the LNCaP human prostate cancer cells (LNCaP/Stat3c cells). LNCaP/Stat3c cells showed increased proliferation and anchorage-independent growth compared with parental LNCaP cells. Histological examination revealed that left cardiac ventricle inoculation of these cells into male nu/nu mice developed predominantly osteolytic lesions with numerous TRAP-positive osteoclasts in the tibiae at 12 week. Of note, osteoblastic lesions began to emerge after 16 weeks and the majority of bone marrow cavity was replaced by osteoblastic lesions after 20 weeks. Parental LNCaP cells failed to develop bone metastases. We then studied the role of sonic hedgehog (Shh) in the osteoblastic bone metastases in this model. Shh is shown to be an autocrine factor up-regulated in aggressive prostate cancer and a stimulator of bone development. RT-PCR showed increased Shh mRNA expression and its downstream signaling molecules including PTCH1, Gli1 and Gli2 in LNCaP/Stat3c cells and western analysis displayed elevated Shh production. Cyclopamine (5mg/kg), an inhibitor of hedgehog pathway, significantly decreased LNCaP/Stat3c tumor growth, tumor-associated osteoblastic lesions and TRAP-positive osteoclast number. Finally, we examined the role of TRPM8, a Ca<sup>2+</sup>-permeable channel which was initially identified in human prostate cancer, reasoning that extracellular calcium is critical to the development of osteoblastic bone metastases in prostate cancer. TRPM8 mRNA expression was elevated in LNCaP/Stat3c cells compared with parental LNCaP cells. TRPM8 overexpression induced Shh expression, whereas TRPM8 knockdown reduced it. Increase in extracellular calcium up-regulated Shh expression. In conclusion, we established an animal model of osteoblastic bone metastases of human prostate cancer. Our results using this model suggest Ca<sup>2+</sup>/TRPM8/Shh axis plays an important role in the development of osteoblastic bone metastases of prostate cancer.

**DKK1 Is Regulated by mRNA Stability and Epigenetic Mechanisms in Bone Metastasis.** K. L. Clines\*, J. M. Chirgwin, T. A. Guise, G. A. Clines. Medicine, University of Virginia, Charlottesville, VA, USA.

Osteoblastic bone metastasis is a complication of advanced prostate and breast cancer, resulting in pain and pathologic fracture. Tumor-produced endothelin-1 (ET-1) activates the osteoblast endothelin A receptor and increases pathologic new bone formation. Dickkopf homolog 1 (DKK1), a secreted negative regulator of canonical Wnt signaling, is a target of ET-1. ET-1 reduces Dkk1 mRNA and protein secretion in murine primary osteoblasts. Human cancer cells in bone secrete DKK1, whose concentrations are inversely related to osteoblast activity in bone metastasis. We hypothesize that osteoblastic bone metastases depend on decreased DKK1 secretion from two sources in the microenvironment: from osteoblasts and from tumor cells. ET-1 suppresses osteoblast DKK1 expression, while tumor expression of DKK1 is not well understood.

DKK1 down-regulation by ET-1 in the osteoblast was explored using *Dkk1*/luciferase reporter constructs. ET-1 did not change *Dkk1* promoter (1.7 kb) activity in murine primary osteoblasts. We then examined whether ET-1 decreases *Dkk1* mRNA stability via the 3'UTR, a 1.3 kb segment containing consensus binding elements for AUF1 and miRNAs. ET-1 significantly reduced (0.52 X,  $p=0.0005$ ) luciferase activity in a construct containing the *Dkk1* 3'UTR indicating that ET-1 regulates osteoblast *Dkk1* via message stability.

We next examined relative expression of *DKK1* and its CpG island methylation in prostate and breast cancer cell lines. Using real-time RT PCR, we found C4-2B, C4-2, LNCaP prostate and T47D breast lines had low *DKK1* expression while ZR-75.1, MCF-7, MDA-MB-231 breast and PC3 prostate lines had significant *DKK1* expression. *DKK1* contains a 5' 233 bp CpG island encompassing the transcriptional start site with 18 potential cytosine methylation sites. Changes in CpG methylation patterns are one mechanism responsible for gene misexpression during tumorigenesis. Methylation-specific sequencing of the *DKK1* CpG island was performed on the human cancer cells. Methylation was detected in the cancer cell lines with the lowest *DKK1* expression while the sequence was unmethylated in cells with the highest *DKK1* expression.

These observations are consistent with a model for osteoblastic bone metastases in which DKK1 production is decreased in both cancer cells and osteoblasts. The mechanisms involve both static epigenetic promoter silencing and dynamic control of *DKK1* mRNA stability via its 3'UTR. *DKK1* mRNA stability can be regulated by tumor-produced ET-1, while the factors that control its basal promoter activity via CpG island methylation are presently unknown. Understanding the regulation of *DKK1* gene expression in tumor and bone may lead to novel therapies for osteoblastic metastases.

**Large-scale Meta-analysis of Genome-wide Association (GWA) Scans for Osteoporosis Traits: the GEFOS Consortium.** F. Rivadeneira<sup>1</sup>, F. Kavvoura<sup>2</sup>, D. Karasik<sup>3</sup>, B. Richards<sup>4</sup>, B. Halldórsson<sup>5</sup>, Y. Hsu<sup>6</sup>, S. Demissie<sup>6</sup>, A. Cupples<sup>6</sup>, C. Zillikens<sup>1</sup>, C. van Duijn<sup>1</sup>, K. Estrada<sup>1</sup>, J. van Meurs<sup>1</sup>, H. Pols<sup>1</sup>, U. Thorsteinsdóttir<sup>5</sup>, M. Brown<sup>7</sup>, T. Spector<sup>4</sup>, S. Ralston<sup>8</sup>, D. Kiel<sup>3</sup>, J. Ioannidis<sup>2</sup>, U. Styrkarsdóttir<sup>5</sup>, A. Uitterlinden<sup>1</sup>. <sup>1</sup>Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Ioannina University, Ioannina, Greece, <sup>3</sup>HSL, Harvard University, Boston, MA, USA, <sup>4</sup>Kings College, London, United Kingdom, <sup>5</sup>deCODE Genetics, Reykjavík, Iceland, <sup>6</sup>Boston University, Boston, MA, USA, <sup>7</sup>University Queensland, Brisbane, Australia, <sup>8</sup>University Edinburgh, Edinburgh, United Kingdom.

GWA is a hypothesis-free search for genetic determinants which has been successful identifying variants associated with disease. **GEFOS** is a consortium of GWA studies on osteoporosis and fracture. In this first effort, we performed meta-analysis of 56785 SNPs present in all genotyping platforms used by 6 GWA studies, summing to 18304 Caucasian subjects in relation to femoral neck (FN) and lumbar spine (LS) bone mineral density (BMD). The consortium included **deCODE** (n~6700;IS; Illumina317), **Rotterdam** (n~4900;NL; Illumina550), **Framingham** (n~3600; US; Affymetrix500), **Twins UK** (n~2300 women;UK;Illumina317), **ERF** (n~700;NL; Illumina317); and **AOGC** (n~140;AU;Illumina317) studies. SNPs with  $MAF < 0.05$ ,  $p_{HWE} < 0.0001$  and marker call < 0.95 were excluded. BMD measured by DXA was analyzed within-populations as absolute differences in mean gender- and age-adjusted standardized values across genotypes. **METAL** was used for a first meta-analytical screen to select hits associated at  $p < 1 \times 10^{-4}$ , which were then meta-analysed using inverse-variance meta-analysis (**IVMA**) of group-level data with fixed and random effects models using **STATA**. Evidence of genome-wide significance (**GWS**) was set at  $p < 5 \times 10^{-8}$  and suggestive evidence (**sGWS**) at  $p < 1 \times 10^{-5}$ . No **GWS** hits were identified by any independent study. Meta-analyses from the 6 studies returned 46 SNPs associated with LS (35 SNPs) and FN BMD (21 SNPs) at  $p < 1 \times 10^{-4}$ . After **IVMA** in the combined-sex analyses four loci remained **GWS** at  $2.8 \times 10^{-11} < p < 2.9 \times 10^{-8}$  (LS 4 and FN 2) while 7 more were **sGWS** at  $1.0 \times 10^{-7} < p < 3.9 \times 10^{-6}$  (LS 6 and FN 2). Effect sizes for the **GWS** hits ranged between .06 and .09 SDs per allele copy. Two of the **sGWS** observed sex-specificity in males. None of the **GWS** or **sGWS** hits revealed significant heterogeneity ( $pQ < 0.10$  or  $I^2 > 50\%$ ). All loci annotate to novel loci with exception of the **LRP5 rs3736228**, which was **sGWS** and replicated earlier at **GWS** level in a large-scale consortium (**GENOMOS**). In conclusion, we have identified 13 loci associated with LS and FN BMD. These SNPs and several more await further replication in independent **GENOMOS** samples (n > 50,000). Meta-analysis with extended genome coverage in **GEFOS** is underway for BMD, fracture and other bone traits.

**Genome-Wide Association Study of BMD and Hip Geometry Indices. The Framingham Osteoporosis Study.** Y. H. Hsu<sup>1</sup>, S. Demissie<sup>2</sup>, K. Cho<sup>2</sup>, Y. Zhou<sup>2</sup>, E. Bianchi<sup>3</sup>, S. L. Ferrari<sup>3</sup>, L. A. Cupples<sup>2</sup>, D. Karasik<sup>1</sup>, D. P. Kiel<sup>1</sup>. <sup>1</sup>Hebrew SeniorLife and Harvard Med. Sch., Boston, MA, USA, <sup>2</sup>Biostat., BU, Sch Public Health, Boston, MA, USA, <sup>3</sup>Div. of Bone Dis., Geneva Univ. Hosp., Geneva, Switzerland.

Despite significant progress in understanding the genetic basis for osteoporosis, efforts to identify genes associated with BMD and bone geometry traits have been incomplete. With the completion of the HapMap project, GWA became a promising tool to dissect complex diseases. We have undertaken a GWA study using the Affymetrix 550K SNP chips to localize susceptibility genes for BMD at the lumbar spine and femoral neck and geometric indices of the hip (femoral neck-shaft angle, femoral neck length and narrow-neck width) in the Framingham Osteoporosis Study. 433,510 SNPs passed quality control criteria (call rate  $\geq 95\%$ , HWE  $p \geq 10^{-6}$  and  $MAF \geq 0.01$ ) in 2073 women and 1554 men (mean age 62.5 yrs) from 677 extended pedigrees. We conducted population- and family-based analyses, using sex-specific residual trait values adjusted for age, height, BMI, and estrogen/menopause (women). For population-based analyses, we used linear-mixed effects (LME) models that account for individual correlations within families. A principle component analysis (EIGENSTRAT) for all SNPs was performed to explicitly model differences of individuals' ancestral genetic background. The first 4 principle components (PCs) were significantly associated with bone traits; therefore, to minimize spurious associations from population substructure, we adjusted for PCs in LME models. After adjustment, the  $\lambda_{GC}$  were  $\leq 1.02$ . Family-based association test (FBAT) weighted by rank order of LME statistics was used to estimate the genome-wide significance. To test whether associated genes were expressed in bone, we measured mRNA of PTH-differentiated primary osteoblasts and further examined an embryonic mouse gene expression database for in situ localization in skeletal tissue. Several associations with bone traits achieved genome-wide significance level ( $p < 10^{-8}$ ), i.e. SNPs on **BMP10**, **PTPRD**, **MYC**, **SLC16A4**, **IL6** and **PRKG1** genes. All excepted for **BMP10** and **MYC** were expressed in osteoblasts. In addition, a gene-set enrichment analysis by Gene Ontology annotation for the genes selected from the most significant SNPs suggested significant clustering of genes involved in central nervous system (CNS) development. The 100 most significant SNPs from each trait are being further evaluated in > 2650 men and 5850 women from 2 independent studies (Rotterdam and the UK Twins Studies). In conclusion, our results reveal novel candidate genes and pathways to further elucidate the etiology of osteoporosis through the determination of BMD and bone geometry. Our findings further suggest an interaction between the CNS and skeleton.

**Genome-wide Association Study (GWAS) and Subsequent Replication Studies Identified ADAMTS18 and TGFBR3 as Novel Osteoporosis Risk Genes.** D. Xiong<sup>1</sup>, L. Zhao<sup>2</sup>, R. R. Recker<sup>2</sup>, J. M. Zmuda<sup>3</sup>, H. Deng<sup>1</sup>. <sup>1</sup>Departments of Orthopedic Surgery and Basic Medical Sciences, University of Missouri - Kansas City, Kansas City, MO, USA, <sup>2</sup>Osteoporosis Research Center, Creighton University, Omaha, NE, USA, <sup>3</sup>Department of Epidemiology, Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA.

Osteoporosis is a most common, highly heritable bone disease leading to fractures that severely impair the health and life quality of patients. We conducted a genomewide association study (GWAS) and several subsequent replication studies to identify alleles associated with BMD (bone mineral density) and risk of osteoporosis. We first used DNA microarray technology to examine ~500,000 SNP markers in 1000 unrelated homogeneous Caucasian subjects and tested them for association with BMD. For replication, we genotyped significant SNPs from GWAS in a) one sample of 593 unclear families having 1972 Caucasian subjects; b) one Chinese cohort composed of 350 hip fracture (HF) patients and 350 healthy controls; and c) one cohort from the Caribbean Island of Tobago composed of 908 men of West African ancestry. The original GWAS detected two novel BMD genes, namely ADAMTS18 (ADAM metalloproteinase with thrombospondin type 1 motif, 18;  $P = 4.17E-07$  and  $5.75E-07$  for allelic association with hip BMD at rs11864477 and rs16945612) and TGFBR3 (transforming growth factor, beta receptor III;  $P = 3.47E-08$  for haplotypic association with spine BMD at rs17131547). Replication studies showed that the same SNPs consistently associated with BMD variation in the independent sample of Caucasian nuclear families ( $P$  values = 0.0071 and 0.033 for allelic association with spine BMD and hip BMD at rs16945612; and  $P = 0.021$  for allelic association with spine BMD at rs17131547); as well as significantly associated with hip fracture (HF) in the Chinese sample ( $P = 0.019$  at rs16945612). The significance of TGFBR3 to BMD phenotypes were also successfully replicated at rs17131547 in the Tobago sample of West African ancestry ( $P$  values = 0.0067 and 0.031 for lumbar spine BMD and total body BMD;  $P$  values = 0.0011, 4.93E-04, 0.0054, 0.013, and 2.82E-04 for BMD measured at total hip, intertrochanter, femoral neck, trochanter and Ward's triangle, respectively). Bioinformatics analyses based on the identified significant SNPs and their highly correlated SNPs suggest several novel potentially significant functional mechanisms underlying bone metabolism and bone mass variation. Our data, for the first time, clearly demonstrated that ADAMTS18 and TGFBR3 are critical genetic factors determining human BMD variation and osteoporosis fracture risk.

**Use of Genetic Markers in Prediction of Fractures.** V. Gudnason<sup>1</sup>, T. Aspelund<sup>1</sup>, A. V. Smith<sup>1</sup>, K. Siggeirsdóttir<sup>1</sup>, G. Eiriksdóttir<sup>1</sup>, B. Y. Jonsson<sup>2</sup>, T. F. Lang<sup>3</sup>, L. J. Launer<sup>4</sup>, T. B. Harris<sup>4</sup>. <sup>1</sup>Icelandic Heart Association, Kopavogur, Iceland, <sup>2</sup>University Hospital, Malmö, Sweden, <sup>3</sup>UCSF, San Francisco, CA, USA, <sup>4</sup>NIA, Bethesda, MD, USA.

Modeling risk for low trauma fractures has been incorporated into risk calculators, such as the one from WHO (www.shef.ac.uk/FRAX/). There is increasing interest to add genetic information to these conventional risk prediction models of fractures. We assess the use of genetic markers from three genes previously shown to have independent and interactive effects enhancing the risk of fractures at a population level (JBM:21:1443). We used data from the AGES-Reykjavik study, a population based study of 2300 men and women recruited between September 2002 and February 2004. Average age was 76 (SD=6) years, with a mean follow up of 4.6 years. Information on measurements for the fracture prediction model (age, sex, height, weight, BMD, previous fracture, family history of fracture, bone medication and smoking) was available for 879 men and 1133 women with 158 low trauma incident fractures of which 47 were hip fractures all verified from medical records and X-rays. Markers from three unlinked genes, Estrogen Receptor 1 (ESR1) haplotype derived from rs6557170 and rs985694, Estrogen Receptor 2 (ESR2) rs7159462 and Insulin Like Growth Factor 1 (IGF1) rs10860861, were used for genetic association analyses. For risk modeling the genotype information was added as an ordinal predictor with categories 1, 2 or 3 according to the number of fracture associated genotypes carried. Power analyses showed that the AGES-Reykjavik sample can identify Hazard Ratio (HR) of at least 1.4 for the given frequencies of the SNPs. The fracture associated allele frequencies were ESR1 haplotype 0.15, ESR2 0.10, IGF1 0.49. All were in HW equilibrium and were associated with incident fractures with HR of 1.5, ( $p = 0.01$ ), 1.4 ( $p = 0.05$ ) and 1.5 ( $p = 0.02$ ) respectively, after adjustment for age, sex, medication use and previous fracture. The area under the ROC curve (AUC) was 0.73 for the model predicting fractures using the clinical risk factors. When the haplotype and SNP information was added as a genotype score 1, 2 or 3 there was a stepwise increase in their HR and with information from all three genes the AUC went up to 0.75 ( $p < 0.05$  for difference). Using solely the genetic markers with age for prediction gave AUC 0.63. Using clinical measurements is a reasonable way for prediction of fractures. Using genetic information cannot replace the clinical measurements and adds only 2% to the AUC associated with the prediction model which is of limited clinical value. However the increase in HR observed with increased number of genetic markers carried may suggest that a model including more genes could become of clinical relevance.

## 1095

**Simply Ask Them About Their Balance - Fracture Prediction in a Nationwide Cohort Study in Twins.** K. Michaëlsson<sup>1</sup>, H. Wagner<sup>\*1</sup>, H. Melhus<sup>2</sup>, R. Gedeberg<sup>\*3</sup>, N. L. Pedersen<sup>\*4</sup>. <sup>1</sup>Section of Orthopaedics, Department of Surgical Sciences, Uppsala, Sweden, <sup>2</sup>Section of Clinical Pharmacology, Department of Medical Sciences, Uppsala, Sweden, <sup>3</sup>Section of Anesthesiology and Intensive Care, Department of Surgical Sciences, Uppsala, Sweden, <sup>4</sup>Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden.

The principal causal components of an osteoporotic fracture are a fall and weakened bone strength. While bone quality measures have been frequently studied, the ability of simple measures of impaired balance to predict fracture risk has received less attention.

Computer-assisted telephone interviews were conducted between 1998 and 2000 among 24,598 (84% of eligible) Swedish twins, 55 years of age and older. An impaired balance at the time of interview was reported by 2757 (12%) of the twins. Efforts were made to interview members of a pair within a month. An identical second interview performed among 105 twins two weeks after the first interview enabled reliability testing. The kappa statistics for the question regarding impaired balance was 0.81 (95% CI 0.60-1.00) indicating almost perfect agreement. Hip, any osteoporotic and any fracture identified by linkage to the National Hospital Discharge Register were used as outcomes. Fracture risk associated with impaired balance was analyzed in pairs of twins discordant for impaired balance. For these associations, we used conditional logistic regression to estimate odds ratios (ORs), and 95 percent (%) confidence intervals (CIs). We wanted each twin in the pair to have a similar time at risk. Since mortality risk was associated with impaired balance, we adjusted for the unequal lengths of the follow-up periods due to death. Thus, twin pairs where one twin died before end of follow-up (15%) were excluded from the analysis.

In a pair-wise conditional logistic regression analysis, the odds ratio (OR) of hip fracture was 3.13 (95% CI 1.62-6.05) for twins with an impaired balance compared to the co-twin with a normal balance. This estimate was not attenuated if we also considered previously recognized clinical risk factors for osteoporotic fractures in the model (HR 2.96; 95% CI 1.27-6.90). Approximately one third of all hip fractures were attributable to an impaired balance. The population attributable risk was 0.37 (95% CI 0.15-0.59). The OR of any fracture and any osteoporotic fracture for a twin with an impaired balance was 2.00 (1.29-3.11) and 2.39 (95% CI 1.49-3.82) compared to the co-twin with a normal balance. The adjusted ORs for these outcomes were 2.26 (95% CI 1.34-3.85) and 2.96 (95% CI 1.55-5.67), respectively. These results imply that a self-reported impaired balance is a novel and readily assessed risk factor for fractures in the elderly.

**Proximal Femoral Fragility and Age-Related White Matter Lesions by Brain MRI in Elderly Subjects: the Age Gene/Environment Susceptibility Study-Reykjavik.** T. F. Lang<sup>1</sup>, T. Hughes<sup>\*2</sup>, G. Sigurdsson<sup>\*3</sup>, G. Sigurdsson<sup>4</sup>, T. B. Harris<sup>\*2</sup>, K. Siggeirsdottir<sup>\*3</sup>, V. Gudnason<sup>\*3</sup>, L. Launer<sup>\*2</sup>. <sup>1</sup>Radiology, University of California, San Francisco, San Francisco, CA, USA, <sup>2</sup>Laboratory of Epidemiology and Biometry, National Institute on Aging, Bethesda, MD, USA, <sup>3</sup>Icelandic Heart Association, Kopavogur, Iceland, <sup>4</sup>Endocrinology, Landspítali, Reykjavik, Iceland.

**Purpose:** White matter lesions (WML) correspond to age-related microvascular changes in the white matter fiber tracts of the brain which are thought to disrupt neural networks responsible for lower extremity motor control. Previous studies have linked increased WML load with impaired gait, falls and hip fracture. Because bone remodeling is also under partial neural control, we hypothesized that WML's would also correlate to altered bone mineral density (BMD) and bone structure.

**Methods:** 4091 study participants (aged 66-99 years, 2338 women, 1753 men) had full brain MRI (1.5T system, including PD/T2 and FLAIR sequences) to detect WML. Subcortical (sWML) and periventricular (pWML) lesion loads were assessed semi-quantitatively from the MRI and related to femoral neck (FN) and total femur (TF) trabecular BMD (tBMD) and cortical tissue to total tissue volume ratios (c/t, a measure of cortical thickness) derived from hip QCT. The cohort was stratified into quartiles of sWML and pWML, and multiple regression (SASv9.2) was used to examine trends across quartiles and to compare tBMD and c/t in the highest quartile (HI) to the other three quartiles (REF). Least square means were computed for each quartile with adjustment for age, height, body mass index, diabetes, stroke history, smoking, hypertension, education and coronary arterial calcium. Analyses were carried out separately by gender.

**Results:** Only women showed statistically significant relationships between bone variables and WML's. In women, all bone measures tended to decline with increasing WML quartile, but the decrease was significant only for TF c/t (sWML: 2.2%, p=0.016; pWML 2.5%, p=0.008). As shown in the Table, the HI quartiles of sWML and pWML had significantly lower TF tBMD, TF c/t and FN c/t than the REF group.

**Conclusions:** These findings suggest that WML's may affect skeletal as well as neuromuscular risk factors for fracture, potentially through effects on muscles that may load bone or through effects on neural control of bone remodeling.

**Table:** \*, p<0.05 ; ^, p<0.01

**ER $\alpha$  Deletion in Cells of the Monocyte/Macrophage Lineage Increases Osteoclastogenesis and Abrogates the Pro-apoptotic Effect of E<sub>2</sub> on Osteoclasts.** M. Martin-Millan, M. Almeida, E. Ambrogini, X. Qui\*, A. Warren\*, R. S. Shelton\*, R. S. Weinstein, R. L. Jilka, T. Bellido, C. A. O'Brien, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Estrogens attenuate osteoclastogenesis and stimulate osteoclast apoptosis. It remains unclear, however, whether these effects are cell autonomous and whether are mediated via *cis* or *trans* interactions of the estrogen receptor (ER $\alpha$  or  $\beta$ ) with DNA or kinase-mediated extranuclear actions of the ERs. To resolve these issues, we selectively deleted ER $\alpha$  in cells of the monocyte/macrophage lineage. Specifically, we generated mice in which exon 3 of the ER $\alpha$  was flanked by loxP sites (ER $\alpha^{fl/fl}$ ) and subsequently crossed with mice that express the Cre-recombinase enzyme under the control of the murine M Lysozyme (LysM-Cre) gene that is expressed in early precursors of the monocyte/macrophage lineage. The efficiency and specificity of the deletion was determined by measuring mRNA levels of ER $\alpha$  in macrophages (generated by culturing non-adherent bone marrow (BM) cells with 100 ng/ml M-CSF), osteoclasts (generated by culturing non-adherent BM cells with 30 ng/ml M-CSF and 30 ng/ml RANKL), and other non-bone tissues by real time PCR. Whereas ER $\alpha$  mRNA in macrophages and osteoclasts from the ER $\alpha^{fl/fl}$ ;LysM-Cre mice was significantly decreased as compared to the ER $\alpha^{fl/fl}$  controls, ER $\alpha$  expression was indistinguishable between the ER $\alpha^{fl/fl}$ ;LysM-Cre and the ER $\alpha^{fl/fl}$  in spleen and liver. To determine the effect of the deletion on osteoclastogenesis, triplicate BM cultures from each of 7 animals per genotype were established in the presence of RANKL and M-CSF. After 4 d TRAPase positive cells with 3 or more nuclei were enumerated. The number of osteoclasts in the cultures from the ER $\alpha^{fl/fl}$ ;LysM-Cre mice was 2-fold higher than those from ER $\alpha^{fl/fl}$  mice (723  $\pm$  SD 210 per well versus 347  $\pm$  82). Moreover, 17 $\beta$ -estradiol (E<sub>2</sub>) at 10<sup>-8</sup> M or 10<sup>-7</sup> M had no effect on osteoclast apoptosis in the cultures from the ER $\alpha^{fl/fl}$ ;LysM-Cre, as measured by *in situ* end-labeling, whereas it induced a 2.5-fold increase of osteoclast apoptosis in the ER $\alpha^{fl/fl}$ . E<sub>2</sub> also stimulated osteoclast apoptosis in cultures from knock-in mice in which classical ER $\alpha$  signaling through ERE sites has been selectively eliminated while preserving non-classical signaling (ER $\alpha^{NEK1/-}$ ). These results provide compelling evidence that the effect of estrogens on osteoclastogenesis and osteoclast apoptosis are cell autonomous and mediated via an extranuclear function of the ER $\alpha$ .

**The Longevity Gene SIRT-1 Independently Controls Both Osteoblast and Osteoclast Function.** J. R. Edwards<sup>1</sup>, K. Zainabadi<sup>\*2</sup>, S. T. Lwin<sup>\*1</sup>, F. Eleftheriou<sup>1</sup>, S. Munoz<sup>\*1</sup>, M. M. Moore<sup>\*1</sup>, L. Guarente<sup>\*2</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA, <sup>2</sup>Dept of Biology, MIT, Cambridge, MA, USA.

The normal aging process is associated with osteoporotic bone loss, occurring through combined defects in both osteoblast and osteoclast regulation. Since there is a strong genetic component in age-related bone loss, we have examined the effects of longevity-associated genes on maintenance of bone mass in genetic mouse models. We have focused on the sirtuin gene family, which directly regulate lifespan in lower organisms and are strongly linked to cell replication, proliferation and survival. The prototype of this gene family in vertebrates is the well-conserved histone deacetylase Silent Information Regulator T-1 (SIRT-1). We have previously shown that pharmacological manipulation of SIRT-1 in osteoblastic cells can alter mineralization rates and osteogenic gene expression, and also influence osteoclast formation rates from precursor cells. To determine the *in vivo* role of SIRT-1 in skeletal development and bone remodeling, we have now generated and characterized osteoclast-, osteoblast-specific and double knockout murine models, using  $\mu$ CT and Piximus scanning, histomorphometric analysis of lumbar vertebrae and long bones, and primary bone cell cultures. Germline deletion of SIRT-1 results in a dramatic bone loss in male and female mice at 1, 4 and 11 mths of age. This is associated with a 27% increase in osteoclasts (p<0.05) and a 39% decrease in osteoblast numbers compared to WT animals (p<0.05). SIRT-1 KO in cells of the osteoblast lineage using the 2.3 Coll1 $\alpha$ 1 promoter generated a mouse model with 25% less BV/TV than floxed control animals (4mth, p<0.01). This was accompanied by a decrease in osteoblast number and activity, evidenced by decreased ObS/BS (22%) and bone formation rate (23%)(p<0.05). Deletion of SIRT-1 in osteoclast precursor cells, including monocytes and macrophages, using the lysozyme M promoter, also resulted in decreased BV/TV (31%, p<0.01), but unlike the above SIRT-1 Ob KO model, osteoclast numbers were increased compared to control mice (34%, p<0.05). The combined breeding of these models to generate an osteoblast/osteoclast-specific SIRT-1 KO resulted in up to 29% less BV/TV than control animals. These findings indicate that SIRT-1 controls bone mass by independently regulating both the osteoblast and osteoclast lineage. These findings identify a novel molecular link between aging, osteoclast and osteoblast function and bone loss.

**Oxidative Stress Stimulates the Synthesis of PPAR $\gamma$ 2, and Ligand-Activated PPAR $\gamma$ 2 Sequesters  $\beta$ -catenin Leading to Suppression of TCF-mediated Transcription: an Explanation for the Age-related Decrease in Osteoblastogenesis and Increase in Adipogenesis.** M. Almeida, E. Ambrogini, L. Han, S. C. Manolagas, R. L. Jilka. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Age-related bone loss is associated with decreased production of osteoblasts and increased production of adipocytes, but the molecular mechanisms underlying this phenomenon have not been elucidated. In C57BL/6 mice, age-related bone loss is temporally associated with reduced osteogenic Wnt/ $\beta$ -catenin signaling and increased expression of PPAR $\gamma$ 2, which is required for adipogenesis. Old mice also exhibit increased levels of reactive oxygen species (ROS), oxidized lipid ligands of PPAR $\gamma$  like 9-HODE, as well as 4-hydroxynonenal (4-HNE), a metabolite of oxidized lipids that increases oxidative stress. Moreover, the age-related decrease in Wnt/ $\beta$ -catenin signaling is due to diversion of  $\beta$ -catenin from TCF- to FoxO-mediated transcription in response to increased oxidative stress. In view of evidence that Wnt/ $\beta$ -catenin signaling suppresses the synthesis of PPAR $\gamma$ 2, we hypothesized that the age-related increase in PPAR $\gamma$  is due to the ROS-induced diversion of  $\beta$ -catenin to FoxO. In support of this hypothesis, 100  $\mu$ M H<sub>2</sub>O<sub>2</sub> or 20  $\mu$ M 4-HNE increased the expression of PPAR $\gamma$ 2 in the uncommitted C2C12 mesenchymal cell line; and this effect was reversed by activation of  $\beta$ -catenin with lithium or Wnt3a. Interestingly, 9-HODE and rosiglitazone promoted the association of PPAR $\gamma$ 2 with  $\beta$ -catenin in C2C12 cell in co-immunoprecipitation experiments, suggesting a mechanism by which increased levels of PPAR $\gamma$  and its ligands could further reduce Wnt/ $\beta$ -catenin signaling. Consistent with this notion, Wnt3a-induced activation of TCF-mediated transcription was reduced by PPAR $\gamma$ 2 overexpression in C2C12 cells. And, 9-HODE and rosiglitazone inhibited Wnt/ $\beta$ -catenin-mediated transcription in a PPAR $\gamma$ 2-dependent fashion in osteoblastic OB-6 cells that conditionally express PPAR $\gamma$ 2. Furthermore, rosiglitazone increased PPAR $\gamma$ 2 expression. Collectively, these results indicate that the age-related increase in oxidative stress not only reduces Wnt/ $\beta$ -catenin signaling but also stimulates PPAR $\gamma$ 2 gene transcription. The increased levels of PPAR $\gamma$ 2 combined with an age-related increase in oxidized lipid ligands of this receptor results in sequestration of  $\beta$ -catenin, which further reduces Wnt/ $\beta$ -catenin signaling; and further stimulates PPAR $\gamma$ 2 synthesis. The consequence of this self-amplifying cascade is reduced production of osteoblasts coupled with increased production of adipocytes which are invariable features of old age in mice and humans.

**Overexpression of Secreted Frizzled-Related Protein 1 Inhibits Bone Formation and Attenuates PTH Bone Anabolic Effects.** W. Yao, Z. Cheng, C. Busse\*, A. Pham\*, M. Shahnazari\*, N. Lane. Center for Healthy Aging, UC Davis Medical Center, Sacramento, CA, USA.

**Introduction.** Secreted Frizzled-related protein 1 (sFRP1) is a soluble antagonist of the Wnt signaling pathway and sFRP1 null mice have less age-related bone loss as compared to their wild-type (WT) mice. Since Wnt signaling is critical for osteoblast maturation, skeletal acquisition and maintenance, we hypothesized that over-expression of sFRP1 (sFRP1-Tg) would reduce osteoblast number and activity such that these animals would have an altered bone phenotype and bone acquisition with PTH treatment compared to wild-type mice. To test these hypotheses we evaluated the bone phenotype of sFRP1-Tg mice and their response to the anabolic agent, PTH, compared to the WT in both female and male mice.

**Methods.** Three-month-old WT or sFRP1-Tg male and female mice (n=7-12/group) were treated with PTH (1-34) (40  $\mu$ g/d, 5x/wk) or Vehicle for 2 weeks. Osteoblastic and osteoclast maturation and function were accessed by primary bone marrow stromal cell and osteoclast cultures. Bone mass and micro architecture from the distal femoral metaphysis was measured by microCT. Bone turnover was assessed with biochemical markers (osteocalcin, OPG, TRAP5b and CTX-I). Real-time PCR was performed from whole bone extracts and used to monitor the expression of several genes that regulate osteoblast maturation and function (Runx2; osterix, osteocalcin). Statistical analyses were performed using a two-way ANOVA with genotype (sFRP1-Tg) and treatment (PTH) being the factors.

**Results.** Male, but not the females have lower trabecular bone mass (-32%) at 3 months of age. Genes associated with osteoblast maturation (Runx2, osterix) and function (osteocalcin), serum osteocalcin, surface based bone formation [mineral apposition rate (MAR) and bone formation rate (BFR)], were significantly decreased in sFRP1-Tg mice in both genders compared to WT mice. Bone resorption, measured by serum CTX-1 and osteoclast surface were similar between sFRP1-Tg and WT mice *in vivo* but was higher in sFRP1-Tg mice *in vitro* (p < 0.05). Human PTH (1-34) treatment for 2 weeks increased trabecular volume (female, +156% and male +319%) in WT mice as compared to 84% in female or 103% in male sFRP1-Tg + PTH mice (p < 0.05 for PTH and genotype). The magnitude of the increase in surface based bone formation (MAR and BFR) was lower in sFRP1-Tg + PTH mice compared to the WT + PTH (p < 0.05).

**Conclusion.** Overexpression of sFRP1 inhibited osteoblast maturation and function, and attenuated PTH's anabolic action on bone. The gender differences in bone phenotype of this sFRP1-Tg animal and gender specific response to PTH is being further investigated.

**The Neglected Role of Intracortical Remodeling in Age-Related Bone Loss.**

R. Zebaze\*, A. Ghasem\*, A. Bohte\*, S. Iuliano-Burns\*, B. Kim\*, E. Mackie<sup>1</sup>, R. Price<sup>2</sup>, E. Seeman<sup>1</sup>. <sup>1</sup>Endocrinology, University of Melbourne, Melbourne, Australia, <sup>2</sup>University of Western Australia, Perth, Australia.

Vertebral fractures and trabecular bone loss are the flagships of osteoporosis. However 80% of fractures are non-vertebral, 86% occur after age 60 yrs and 80% of bone is cortical. These contradictions challenge prevailing notions of 'accelerated' trabecular loss and 'slower' age-related cortical bone loss. We quantified trabecular, intracortical and endocortical microarchitecture at the subtrochanteric region in post-mortem specimens from 12 women aged 29 to 87 using high resolution (HR)-CT (Viva-CT, 12  $\mu$ m resolution) and scanning electron microscopy (SEM) and measured cortical and trabecular bone diminution in 123 healthy women aged 20 to 91 years using HR-pQCT at the distal radius (Scanco).

Specimens from women <50 yrs had similar amounts of surface (perimeter available for remodeling) enveloping trabecular (0.6m) and cortical (0.5 m) bone but intracortical surface was 4 fold higher than trabecular surfaces in 60-70 yr olds (2 vs 0.46 m) and 6 fold higher in 70-80 yr olds (2.3 vs 0.38 m). 80+ yr olds had mostly intra-cortical surface. This shift of surface from trabecular to cortical bone alone accounted for the age-related diminution of bone mass *in vivo*. At peak there was 226.1g of distal radial bone mass, 17.1g was lost during the first 15yrs after menopause (50-65 yrs); similar amounts of cortical (7.9g) and trabecular (9.7g) bone were lost because similar amounts of surface (~0.5 m) enveloped these compartments. However, this constituted relatively more trabecular (22% or 9.7/43.6g) than cortical (4.3%, 7.9/182.5g) bone loss because similar surface enveloped less trabecular (43.6g) than cortical (182.5g) bone.

At 65 yrs there remained 174.3g cortical and 34.7g trabecular bone. Twice the amount of cortical (55.2g) than trabecular (22.9g) was lost during the next 15 yrs because cortical bone had 4 times more surface. After age 80, the diminution in bone mass (16.3g) was largely cortical (14.6g).

As shown using 3D mapping, most cortical bone loss occurs by increasing intracortical porosity which increased the surface available for remodeling from 0.5 to >2 meters after 65 yrs. Adjacent to the marrow, coalesce of pores contributed to cortical thinning by 'trabecularizing' the cortex. In old age a large proportion (~ 70% after age 80) of the 'trabeculae' in the marrow contained osteons reflecting their cortical origin.

Thus, across age most bone loss was cortical (72.2g, 68%) and of the 106.5g lost from 50 yr, 84% was lost after 65 yrs, mostly by accelerated intracortical resorption rather than endocortical or trabecular bone resorption. These findings challenge prevailing views and reconcile the epidemiology of fractures to its pathogenesis and structural basis.

**Disclosures:** R. Zebaze, None.

## 1102

**Toward a Physiologically-Based Definition of Hypogonadism in Men: Dose-Response Relationship Between Testosterone and Bone Resorption.** J. S. Finkelstein, S. M. Burnett-Bowie, A. F. Moore\*, B. F. Jones\*, L. F. Borges\*, J. M. Youngner\*, C. W. Hahn\*, C. V. Barry\*, B. Z. Leder. Department of Medicine, Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Bone resorption increases and bone mineral density (BMD) decreases when adult men become severely hypogonadal i.e. when serum testosterone (T) levels are in the castrate range. Because T levels decline with aging, the decrease in T may be responsible, at least in part, for changes in BMD as men age. The T level at which these changes begins is unknown, however. To address this question, we clamped the T level of normal men at levels ranging from prepubertal to high normal and assessed changes in bone resorption. 237 healthy men, age 20-50, were treated with goserelin acetate (Zoladex®, AstraZeneca LP, Wilmington DE, 3.6 mg sc q4 wk) to induce severe hypogonadism and randomized to receive 1 of 5 T gel doses (AndroGel®, Solvay Pharmaceuticals, Marietta, GA) or placebo daily for 16 weeks (Group 1: placebo gel, Group 2: 1.25g, Group 3: 2.5g, Group 4: 5g, Group 5: 10g). A sixth group received placebo goserelin acetate and placebo T gel. Study subjects and investigators were blinded to treatment assignment. Serum total T, bio-available T, estradiol (E), and N-telopeptide (NTX) levels were measured every 4 wks. Spine and hip BMD were measured by DXA and spine BMD by QCT at 0 and 16 wks. Mean baseline T levels ranged from 506 to 575 ng/dL. Mean (SE) serum total T levels from all visits after baseline are shown in the Figure. Mean baseline E levels ranged from 18.9 to 23.6 pg/mL. Mean serum E levels during treatment were  $10.9 \pm 0.6$ ,  $11.2 \pm 0.7$ ,  $13.5 \pm 0.6$ ,  $17.7 \pm 1.1$ , and  $23.1 \pm 1.5$  pg/mL in groups 1-5, respectively. There was a strong relationship between T dose and the percent change in NTX (Figure). NTX began to increase when the T dose fell from 2.5 to 1.25 g/day. As expected in this short-term study, BMD did not change. These results demonstrate that there is a strong dose-response relationship between T dose and NTX in men. Bone resorption begins to increase at a T dose that results in a mean serum T level between 187 and 332 ng/dL and a mean serum E level between 11.2 and 13.5 pg/mL. It is likely that a similar T level would result in bone loss if sustained. These data provide a physiological framework for defining hypogonadism in men with respect to skeletal homeostasis and help provide an objective basis for determining an intervention threshold to prevent hypogonadal bone loss in adult men.

## 1103

**Preterm Birth and Bone Mineral Density in Young Adulthood: The Helsinki Study of Very Low Birth Weight Adults.** P. Hovi\*, S. Andersson\*, A. Järvenpää\*, J. G. Eriksson\*, S. Strang-Karlsson\*, E. Kajantie\*, O. Mäkitie\*. <sup>1</sup>Department of Health Promotion and Chronic Disease Prevention, National Public Health Institute, Helsinki, Finland, <sup>2</sup>Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland.

Very-low-birth-weight (VLBW, <1500 g) infants have compromised bone mass accrual during childhood. Whether this results in subnormal peak bone mass and increased risk of osteoporosis in adulthood is unknown.

The Helsinki Study of VLBW Adults is a multidisciplinary cohort study representative of all VLBW births within the larger Helsinki area 1978 - 1985. This study evaluated skeletal health in 144 subjects with VLBW, born at a mean gestational age of 29.2 weeks, mean birth weight 1126 g, and birth weight z score of -1.2, compared with 139 born at term, matched for sex, age, and birth hospital. Data on perinatal and neonatal characteristics were collected from hospital records. Present calcium and vitamin D intake and physical activity were assessed with a questionnaire. Lumbar spine, femoral neck and whole body bone mass and bone mineral density (BMD) and body composition were measured by dual energy x-ray absorptiometry (Hologic Discovery A) at age 18.5 to 27.1 years (mean 22.6 years).

The VLBW subjects had, in comparison to subjects born at term, 2.4-fold odds (95% confidence interval [CI], 1.5 to 4.1) of having a lumbar spine BMD z score within the osteopenic or osteoporotic range. After adjusting for VLBW subjects' shorter height, the odds ratio was 1.8 (95% CI, 1.1 to 3.2). The VLBW adults had a 0.51 unit (95% CI, 0.28 to 0.75) lower lumbar spine and a 0.56 unit (95% CI, 0.34 to 0.78) lower femoral neck z score for BMD. These differences remained statistically significant after adjustment for the VLBW adults' shorter height and lower self-reported exercise intensity: 0.26 units (95% CI, 0.01 to 0.51) for the lumbar spine and 0.40 units (95% CI, 0.17 to 0.64) for the femoral neck. Adjustment for calcium or vitamin D intake had no impact on the differences. None of the BMD values were associated with weight z scores at birth or at 36 or at 40 weeks of postmenstrual age, or with duration of assisted ventilation or oxygen therapy.

Young adults with VLBW, studied close to the age of peak bone mass, have significantly lower BMD than do their peers born at term. This indicates that compromised childhood bone mass accrual in preterm children translates into increased risk for osteoporosis at adult age. Our findings suggest vigilance in osteoporosis prevention in the increasing proportion of the population with VLBW.

## 1104

**Background UVB Exposure in Pregnancy and Skeletal Development in Childhood.** A. Sayers\*, J. Tobias. Academic Rheumatology, University of Bristol, Bristol, United Kingdom.

In a previous small prospective study, maternal vitamin D levels were found to be associated with bone mineral content (BMC) of the child at age nine, suggesting a possible role of maternal vitamin D status in programming of skeletal development (Javaid et al, 2006, Lancet 367). We investigated whether an equivalent association exists in the larger Avon Longitudinal Study of Parents and Children (ALSPAC), using erythral UV (eUV) derived from meteorological monitoring data during the third trimester of pregnancy as a proxy measure of background UVB exposure, and hence a surrogate for maternal vitamin D status. This followed a preliminary study in 346 expectant mothers from ALSPAC, in which we confirmed a strong association between eUV and serum 25-hydroxy-vitaminD, both measured in the last trimester of pregnancy ( $p=0.0075 \times 10^{-27}$ ,  $r^2=0.3127$ ).

We investigated associations between birth length, birth weight and eUV. There was a strong positive association between eUV and crown heel length ( $p=0.000038$ ,  $N=10584$ ), such that those in the lowest 5% of UV exposure (low winter) were 0.28cm shorter than those with the highest 5% (high summer). In contrast, there was no association between eUV and birth weight. Subsequently, we examined the relationship between eUV and skeletal parameters measured at age 9.9 years using total body DXA scans. Erythral UV showed a strong association with height ( $p=0.017$ ,  $N=7444$ ) which resulted in 0.5 cm difference between high and low summer. In addition, positive associations were observed with total body less head (TBLH) bone mineral density (BMD) ( $p<0.00001$ ), BMC ( $p<0.00001$ ), and bone area (BA) ( $p<0.00002$ ) ( $N=7336$ ). BMD, BMC and BA were 0.008 g.cm<sup>-2</sup>, 27.1 g and 22.9cm<sup>2</sup> higher respectively, in mothers with eUV levels in the highest 5% (high summer) versus lowest 5% (low winter). These effects were attenuated to varying degrees after adjusting for height, following which differences between high and low summer for BMD, BMC and BA were 0.005 g.cm<sup>-2</sup>, 15.0 g, 6 cm<sup>2</sup> respectively,  $p<0.001$  for every effect.

We conclude that maternal vitamin D status, as reflected by eUV, exerts an important influence both on longitudinal bone growth in utero, and skeletal growth in subsequent childhood, as reflected by height and TBLH BA measurements at age 9.9. In addition, maternal eUV showed strong associations with TBLH BMC and BMD, which were only partially attenuated by adjusting for height, implying that as well as influencing skeletal growth in childhood, maternal vitamin D status exerts persisting effects on those metabolic processes which regulate 'volumetric' bone density.

**Disclosures:** A. Sayers, None.

**A Clinical Tool for Adjusting BMD Z-Scores for Body Size in Growing Children?** B. Zemel<sup>1</sup>, H. Kalkwarf<sup>2</sup>, V. Gilsanz<sup>3</sup>, J. Lappe<sup>4</sup>, S. Oberfield<sup>5</sup>, J. Shepherd<sup>6</sup>, S. Mahboubi<sup>7</sup>, M. Frederick<sup>8</sup>, K. Winer<sup>9</sup>. <sup>1</sup>Pediatrics, University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Cincinnati Children's Medical Center, Cincinnati, OH, USA, <sup>3</sup>Radiology, Los Angeles Children's Hospital, Los Angeles, CA, USA, <sup>4</sup>Creighton University, Omaha, NE, USA, <sup>5</sup>Columbia University, New York, NY, USA, <sup>6</sup>University of California San Francisco, San Francisco, CA, USA, <sup>7</sup>Radiology, The Children's Hospital of Philadelphia, Philadelphia, PA, USA, <sup>8</sup>CTASC, Baltimore, MD, USA, <sup>9</sup>NICHHD, Bethesda, MD, USA.

Body size has a strong influence on bone outcomes in children, yet there is no consensus on how to consider these effects in clinical assessment. Children at-risk for poor bone accrual frequently have poor growth and delayed maturation. In the clinical setting, commonly used adjustment techniques consist of substituting "height age" (Ht-Age) or bone age for chronological age (ChronAge) in the calculation of BMD Z-scores (BMD-Z). However, these approaches have never been validated. The goal of this study was to assess these techniques and test alternatives that can be applied in the clinical setting to assess the impact of growth status on BMD-Z.

Data on 1554 healthy children from the NICHHD Bone Mineral Density in Childhood Study (BMDCS) were used. Subjects were evaluated annually on 4 occasions (5875 observations). Lumbar spine DXA scans were obtained on Hologic Delphi/Discovery bone densitometers following standard techniques. Bone age was assessed by a single radiologist. HtAge was determined as the age at which a child's height was equal to the median for the CDC height charts. Height Z-scores (HAZ) were calculated using the CDC growth charts, and BMD-Z were calculated based on the BMDCS.

An adjustment method was considered to be biased if the adjusted z-score had a mean that was significantly different from zero among children with rapid/slow growth or maturation. BMD-Z results for substituting HtAge for ChronAge were:  $0.6 \pm 1.2$  ( $p<0.0001$ ) if  $HAZ<-1$  and  $-0.5 \pm 1.0$  ( $p<0.0001$ ) if  $HAZ>1$ . Results for substituting bone age for ChronAge to calculate BMD-Z were:  $0.6 \pm 1.1$  ( $p<0.0001$ ) for bone age delay  $<-2$  yrs and  $-0.8 \pm 0.9$  ( $p<0.0001$ ) for bone age delay  $>2$ . An alternative approach utilized age and gender-specific simple regression models of HAZ on BMD-Z to calculate a predicted BMD-Z. HAZ adjusted BMD-Z was defined as observed minus predicted BMD-Z. HAZ Adjusted BMD-Z was  $0.1 \pm 0.9$  if  $HAZ<-1$  and  $0.0 \pm 1.0$  if  $HAZ>1$ .

These findings discredit the substitution of bone age or Ht-Age for ChronAge to calculate an adjusted BMD-Z. Adjusting for HAZ gives an unbiased adjustment for the effects of growth on BMD-Z. This simple approach accounts for the age-specific relationship between height status and BMD, and avoids the comparison of children across different ages where stages of pubertal development may differ.

**Influence of Pubertal Timing on Bone Trait Acquisition: Predetermined Trajectory Detectable Five Years Before Menarche.** T. Chevalley, J. P. Bonjour, S. Ferrari, R. Rizzoli. Service of Bone Diseases, Department of Rehabilitation and Geriatrics, University Hospitals of Geneva, Switzerland.

Late menarche is a risk factor for osteoporosis. It is associated with low peak bone mass (PBM) that may be due to reduced exposure time to estrogen. Nevertheless, menarcheal age (MENA) is under strong genetic influence, as shown by twin and familial studies. Therefore, it is possible that in addition to the mechanism of reduced estrogen exposure time from MENA to PBM time attainment, bone deficit may be present before any sign of pubertal maturation would become clinically patent. We tested this hypothesis in a cohort of healthy girls prospectively followed up from 8 to 20 yrs of age with intermediate bone assessment at 9.0, 10.0, 12.5 and 16.5 yrs. Mean MENA ( $\pm$ SD) was  $13.0 \pm 1.2$  yrs ( $n=124$ ). The cohort was segregated according to the median of MENA in EARLY ( $12.1 \pm 0.7$  yrs) and LATE ( $14.0 \pm 0.7$  yrs) subgroups. At  $20.4 \pm 0.6$  yrs, Z-scores of areal bone mineral density (aBMD) in EARLY and LATE were: Radial Metaphysis:  $+0.19$  vs.  $-0.17$ ,  $p=0.046$ ; Radial Diaphysis:  $+0.19$  vs.  $-0.18$ ,  $p=0.042$ ; Femoral Neck:  $+0.18$  vs.  $-0.18$ ,  $p=0.042$ ; Femoral Trochanter  $+0.10$  vs.  $-0.09$ ,  $p=0.282$ ; Femoral Diaphysis:  $+0.16$  vs.  $-0.15$ ,  $p=0.086$ ; Lumbar spine:  $+0.15$  vs.  $-0.14$ ,  $p=0.107$ . Differences in Z-score at 20.4 years of age between EARLY and LATE were observed not only at 16.5, 12.5 and 10 yrs, i.e. during pubertal maturation, but also before the onset of pubertal maturation. Indeed, between age 8 and 9 yrs two-way ANOVA indicated that the significant age-dependent bone growth ( $P=0.0001$ ) did not interact with the influence of future MENA ( $P=0.0042$ ). The figure illustrates the differences in mean Z-score of the 6 skeletal sites between EARLY and LATE MENA from prepuberty to PBM attainment at 20.4 yrs of age. In this group the reduced aBMD in LATE was associated with lower cortical volumetric bone density and thickness in both distal radius and tibia ( $P<0.05$ ) as measured by high resolution peripheral computerized tomography (HR-pQCT). In conclusion, in healthy female subjects, the negative influence of relatively later menarcheal age, 14.0 vs 12.1 yrs, on macro and microstructural bone traits observed at time of peak bone mass attainment, is associated with a predetermined deficit already observable a few years before the onset of pubertal maturation.

**A Three Year School-Curriculum-Based Exercise Program in Prepubertal Children Increases Bone Mineral Accrual and Bone Size but Do Not Influence Femoral Neck Structure.** B. Lofgren, G. Alwis\*, C. Lindén\*, H. G. Ahlberg, M. Dencker\*, P. Gardsell\*, M. K. Karlsson. Department of Clinical Science, Clinical and Molecular Osteoporosis Unit, Malmö, Sweden.

Most exercise intervention studies in children, evaluating the accrual of bone mineral content (BMC), include volunteers and specifically designed osteogenic exercise programs. No trial exceeds 24 months. The purpose of the this study was to evaluate if a population based 36 months moderate intense exercise program leads to skeletal benefits. 45 girls and 75 boys aged 7-9 years were included in a school-curriculum-based exercise intervention program of general physical activity for 40 minutes per school day. 42 matched girls and 54 boys assigned to the Swedish curriculum of 60 minutes training per week served as controls. BMC were estimated by dual X-ray absorptiometry of total body, lumbar spine, femoral neck and trochanter. Bone width was measured at third lumbar vertebra and femoral neck. Hip structural analyses (HSA) evaluated the structural properties of the femoral neck [cross-sectional area (CSA), section modulus (Z) and cross-sectional moment of inertia (CSMI)]. Height and weight were measured. Physical activity was estimated through questionnaires and by accelerometers. Children were followed annually for three years whereafter changes were calculated for each individual as the ratio of the slope fitted to all measurements. Group discrepancy was expressed in SD units (annual changes divided by SD for annual changes). No group differences were found at baseline in age, anthropometrics or bone parameters. Boys and girls in the intervention group had around double subjectively estimated weekly duration of physical activity (both  $p<0.001$ ) and by accelerometers measured most intense activities ( $>10000$  counts per minutes; both  $p<0.01$ ) than the controls. There were no group differences in accelerometer measured lower intensities. The BMC gain in the intervention girls was mean 0.8 SD higher in lumbar spine ( $p=0.003$ ), mean 0.5 SD higher in femoral neck ( $p=0.03$ ) and mean 1.1 SD higher in trochanter ( $p=0.0003$ ) and the gain in the third lumbar vertebra width mean 0.5 SD higher ( $p=0.05$ ) than in the control girls. The BMC gain in the intervention boys was mean 0.8 SD higher in lumbar spine ( $p=0.002$ ) and mean 0.7 SD higher in the trochanter ( $p=0.04$ ) while the gain in third lumbar vertebra width was mean 0.3 SD higher ( $p=0.04$ ) than in the control boys. No group differences were found in femoral neck structural changes. A school-based exercise program for three years in 7-9-year-old children is associated with a higher duration of total and intense physical activities, activities known as key features of osteogenic stimuli, and a higher accrual of BMC and bone width than in children at a lower level of exercise.

**Vitamin D Dose Response Study in Canadian Infants.** K. Trussler\*, C. Rodd<sup>1</sup>, S. Gallo\*, C. Vanstone\*, A. Khamessan\*, M. L'Abbe\*, H. Weiler<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada, <sup>2</sup>Europharm International Canada Inc, Montreal, QC, Canada, <sup>3</sup>Bureau of Nutritional Sciences, Health Canada, Ottawa, ON, Canada.

In 2004, Health Canada reaffirmed its policy recommendation that all breastfed infants receive a daily vitamin D<sub>3</sub> supplement of 400 IU/day in an effort to reduce vitamin D deficiency. However, clinicians continue to diagnose vitamin D deficiency in infants. It was hypothesized that this recommendation may be inadequate to achieve optimal vitamin D status for 97% of infants. Additionally, it has been proposed that 2000 IU/day may be beneficial for the prevention of chronic disease. Optimal status has not been defined for the infant population and value of 75 nmol/L was used based on adult literature. The primary objective of this study was to determine the serum concentrations (mean  $\pm$  SE) for 25(OH)D in each of the treatment doses (400 IU, 800 IU, 1200 IU, 1600 IU) in breastfed infants, 8 weeks after the start of supplementation. Breastfed infants ( $n=32$ ) were recruited from the greater Montréal area and were randomly assigned to one of four study groups (400, 800, 1200, or 1600 IU/d of vitamin D<sub>3</sub> provided in-kind from Europharm International Canada Inc). Supplementation began at 4 weeks of age and continued to 12 weeks of age. Blood samples obtained at baseline, 4 and 8 weeks thereafter were analyzed for total serum 25(OH)D (Osteia ELISA, Immunodiagnostic systems Ltd, UK). Repeated measures ANOVA accounted for the within-subject serial correlations and demonstrated that treatment ( $p<0.003$ ) and time ( $p<0.001$ ) were significant predictors of serum 25(OH)D levels. Mean values for each treatment-time are given in Table 1. While after 8 weeks of supplementation, the mean serum 25(OH)D concentration in the 400 IU/day group exceeded 75 nmol/L, 3 infants receiving 400 IU/day and 3 receiving 800 IU/day did not achieve this level. In contrast only 1 infant in the 1200 IU/day group and 0 infants in the 1600 IU/day group failed to meet the 75 nmol/L cutoff. This data represents pilot observations from the first dose response study using the Vitamin D<sub>3</sub> isoform. Continued evaluation to one year of age will establish optimal intakes in association with measures of bone health.

Table 1 Mean serum 25(OH)D (nmol/L) at baseline, 4 and 8 weeks of supplementation

	400 IU/day	800 IU/day	1200 IU/day	1600 IU/day
Baseline	82.9 $\pm$ 8.0	69.7 $\pm$ 14.6	53.7 $\pm$ 7.3	97.1 $\pm$ 10.9
4 weeks	100.5 $\pm$ 17.1	149.4 $\pm$ 8.2	133.4 $\pm$ 23.7	202.0 $\pm$ 31.3
8 weeks	76.7 $\pm$ 4.6	139.3 $\pm$ 37.5	202.6 $\pm$ 35.7	332.0 $\pm$ 71.3

**Deletion of Zfp521, an Antagonist to Runx2 and Ebf1 Transcriptional Activity, Leads to Osteopenia and a Defect in Matrix Mineralization in Mice.** R. Kiviranta<sup>1</sup>, H. Saito<sup>\*1</sup>, D. Correa<sup>\*1</sup>, L. Neff<sup>\*1</sup>, G. C. Rowe<sup>\*1</sup>, E. Hesse<sup>1</sup>, S. Warming<sup>\*1</sup>, N. A. Jenkins<sup>\*2</sup>, W. C. Horne<sup>1</sup>, N. G. Copeland<sup>\*3</sup>, R. Baron<sup>1</sup>. <sup>1</sup>Harvard Schools of Medicine and Dental Medicine, Boston, MA, USA, <sup>2</sup>Cancer Genetics Laboratory, Institute of Molecular and Cell Biology, Singapore, Singapore, <sup>3</sup>Cancer Genetics Laboratory, Institute of Molecular and Cell Biology, Boston, Singapore.

We recently identified a novel zinc-finger protein 521 (Zfp521) that is expressed at high levels in prehypertrophic chondrocytes and in osteoblasts (Ob). Zfp521 interacts with Runx2 and early B-cell factors (Ebfs) and antagonizes their transcriptional activity. Surprisingly however, overexpression of Zfp521 in vivo lead to a dramatic increase in Ob numbers, bone formation rates and bone mass with no changes in bone resorption. To further elucidate the role of Zfp521 in Ob differentiation we used shRNA to knockdown Zfp521 expression in MC3T3-E1 cells and in primary osteoblasts. In MC3T3-E1 cells knockdown of Zfp521 resulted in increased Ob differentiation and depletion of Zfp521 in primary cells lead to increased bone nodule formation. As Zfp521 also regulates early B-cell factor (Ebf) activity during B-cell differentiation and Ebf1 and Ebf2 knockout mice have opposing bone phenotypes, we determined whether Ebf1 or Ebf2 were targets of Zfp521 in osteoblasts. Overexpression of Ebfs in MC3T3-E1 cells and in primary Obs enhanced, whereas overexpression of Zfp521 repressed, Ob differentiation. To better establish the physiological role of Zfp521 in bone we then analyzed Zfp521 knockout mice. At 3 weeks of age the trabecular bone volume and cortical thickness were markedly decreased in Zfp521<sup>-/-</sup> tibias despite increased expression levels of a highly homologous family member Zfp423, another inhibitor of Ebf transcriptional activity. Osteopenia was associated with an increase in N.Ob/BS and N.Oc/BS. There were also more Ob precursors in the bone marrow of Zfp521<sup>-/-</sup> mice, as tested in a colony forming unit assay. The osteoid surface was highly increased, and matrix mineralization appeared to be impaired despite normal serum calcium and phosphate. In culture Zfp521<sup>-/-</sup> calvarial Obs formed more mineralized bone nodules than controls, confirming an increase in Ob precursors. In the knockout cells the expression of Ebf2, a known regulator of OPG expression, and Ebf1 were decreased at day 7 of the cultures, possibly explaining the increased number of osteoclasts and the osteopenia. In conclusion, inactivation of Zfp521 leads to enhanced Ob differentiation possibly via increased transcriptional activity of Runx2 and Ebfs, and to increased osteoclast numbers leading to low bone mass. We conclude that Zfp521 is a novel regulator of bone homeostasis.

**Altered Long Bone Structure in Recessive Null and Dominant Negative Connexin43 (Gjal) Mouse Mutants.** S. K. Grimston<sup>1</sup>, M. Watkins<sup>1</sup>, M. D. Brodt<sup>\*2</sup>, M. J. Silva<sup>2</sup>, R. Civitelli<sup>1</sup>. <sup>1</sup>Division of Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA, <sup>2</sup>Department of Orthopedic Surgery, Washington University in St. Louis, St. Louis, MO, USA.

Connexin43 (Cx43) is the major gap junction protein present in bone cells and it is involved in bone development and adult skeletal growth. We and others have observed large marrow area and thin cortices in the tibial diaphysis of *Gjal* deficient mice. To gain further insight on such structural abnormalities, we analyzed femora of 3 different *Gjal* mouse mutants; conditional knockout driven by either a 2.3kb fragment of the  $\alpha_1(I)$  collagen promoter (*ColCre;Gjal*<sup>-flox</sup>; or ColcKO, n=13), or the *Dermo1* promoter (*DM1Cre;Gjal*<sup>-flox</sup>; or DM1cKO, n=5), and conditional induction of an oculodentodigital dysplasia mutation, also driven by DM1 (*DM1Cre;Gjal*<sup>+G138R</sup>; or DM1cODDD, n=7). Relative to wild type (WT) littermates,  $\mu$ CT scans revealed a consistent pattern of significantly thinner cortices (87 $\pm$ 17%\*, 84 $\pm$ 7%\*, 91 $\pm$ 6%\* of WT) and larger marrow area (162 $\pm$ 41%\*, 169 $\pm$ 26%\*, 131 $\pm$ 37%\*) in ColcKO, DM1cKO and DM1cODDD, respectively. While there were no differences in cortical area among the 3 mutants, femoral total tissue area was larger (131 $\pm$ 23%\*, 139 $\pm$ 13%\*, 119 $\pm$ 18%\*) and second area moment of inertia was greater (175 $\pm$ 53%\*, 161 $\pm$ 36%\*, 129 $\pm$ 29%\*) in ColcKO, DM1cKO and DM1cODDD relative to their WT littermates, respectively. Although these findings are compatible with greater resistance to bending, 3-point bending test showed that ColcKO actually have a significantly decreased ultimate force relative to WT (78.2 $\pm$ 6.6%\*), implying that Cx43 deletion alters the material properties of long bones. Larger but thinner bones also suggest increased endocortical bone resorption with only partial compensatory increase in periosteal bone apposition. Consistent with this hypothesis, endocortical porosity, measured as a percent of total cortical area, was significantly higher in DM1cKO, relative to their WT littermates (13.8 $\pm$ 10.8%\* vs 2.9 $\pm$ 2.7%), however histological analyses showed no significant differences in osteoclast number. These common structural abnormalities of long bones observed in 3 different *Gjal* mutant models demonstrate that deficiency of, or interference with Cx43 alters bone architecture in a manner similar to what is observed in aging or disuse. The less severe phenotype of DM1cODDD mice is consistent with a dominant negative action of the Cx43 G138R mutant protein. Finally, the similar degree of structural changes in DM1cKO and ColcKO, relative to their respective WT littermates, suggests that Cx43 in osteoblasts and/or osteocytes is key for maintaining normal cortical bone structure and resistance to load.

\*p<0.05 vs. WT littermates.

**Notch Inhibits Nuclear Factor of Activated T-Cells (NFAT) Transactivation in Osteoblast Cultures.** S. Zanotti, A. Smerdel-Ramoya, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Notch are transmembrane receptors that determine cell differentiation, and in bone, Notch inhibits osteoblastogenesis and osteoclastogenesis. In the Notch canonical pathway, interactions with Notch ligands result in the release of the intracellular domain of Notch (NICD), which translocates to the nucleus where it interacts with the CSL family of nuclear factors to activate the transcription of target genes, such as *hair enhancer of split 1 (hes1)*. Notch inhibits Wnt signaling and NICD interacts with Runx2; however, not all of the effects of Notch on osteoblastogenesis are explained by these interactions. NFATs are transcription factors that determine cell differentiation and function. Dephosphorylation of specific serines by calcineurin induces NFAT translocation to the nucleus and transactivation, whereas their phosphorylation induces NFAT nuclear export, inhibiting transactivation. NFATc1 and c2 regulate osteoblastogenesis and osteoclastogenesis. Consequently, we asked whether Notch inhibited these cellular events by regulating the activity of NFAT. In mesenchymal cells, Forkhead Box Protein O1 (FoxO1) forms a complex with NICD/CSL, and is required for the inhibitory effects of Notch on myotube differentiation. Since FoxO1 can inhibit NFAT signaling, we examined its role in Notch signaling and in the effects of Notch on NFAT activation. To study Notch/NFAT/FoxO1 interactions, ST-2 stromal cells were transfected with an NICD expression vector, and osteoblasts from *Rosa<sup>notch</sup>* mice, where NICD is induced following the deletion of a STOP cassette by CRE recombination, were used. The effects of NICD on NFAT transactivation and localization were examined. NICD inhibited the transactivation of a reporter construct containing nine copies of an NFAT binding motif, both in ST-2 cells and *Rosa<sup>notch</sup>* cells. In accordance with the inhibition of NFAT transactivation, NICD increased cytoplasmic and decreased nuclear levels of NFATc1. To determine whether FoxO1 participates in the inhibition of NFAT by Notch, the activity of Notch was tested in the context of FoxO1 downregulation by RNA interference. Notch induced the transactivation of CSL and the transcription of its target gene *hes1* in ST-2 cells and in *Rosa<sup>notch</sup>* osteoblasts. These effects were inhibited by FoxO1 downregulation, indicating that FoxO1 is necessary for the activation of the Notch canonical signaling pathway in osteoblasts. However, FoxO1 downregulation did not rescue the inhibitory effect of NICD on the transactivation of the NFAT reporter construct. In conclusion, Notch inhibits NFAT transactivation through a CSL and FoxO1 independent mechanism, and induces the nuclear export of NFATc1.

**FOXO1 Signaling in the Control of Bone Mass.** M. Rached<sup>\*1</sup>, M. Ogita<sup>\*1</sup>, R. A. DePinho<sup>\*2</sup>, J. P. Bilezikian<sup>1</sup>, S. Kousteni<sup>1</sup>. <sup>1</sup>Department of Medicine, Division of Endocrinology, College of Physicians & Surgeons, Columbia University, New York, NY, USA, <sup>2</sup>Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA.

Regulation of development, metabolic homeostasis and oxidative stress responses share many features. Several molecules that regulate responsiveness to oxidative stress are also utilized by signaling cascades that are associated with prolongation of lifespan. Molecules that well exemplify this point are a family of ubiquitous transcription factors known as FOXOs. FOXO1, one of three FOXO homologs, regulates cell proliferation, differentiation and survival in response to oxidative stress and increases lifespan in model biologic systems. We show that FOXOs, and in particular *Foxo1*, are expressed in osteoblastic cell lines, calvaria-derived osteoblastic cells and also in osteoblasts and osteocytes in the bone of young (10-day old) and adult (2 month-old) mice. Treatment of osteoblastic cell lines and calvaria-derived osteoblastic cells with the oxidative stress inducer H<sub>2</sub>O<sub>2</sub> had a dual effect on FOXO1 activity. Initially, it promoted *Foxo1*-mediated transcription as measured by the expression of endogenous *Foxo1* transcriptional targets Superoxide Dismutase 2 (*Sod2*), *Gadd45*, and a *Foxo1* reporter. At the same time, H<sub>2</sub>O<sub>2</sub> induced changes to inactivate FOXO1 (phosphorylation, cytoplasmic retention). Moreover, in this setting, FOXO1 maintained a balance between proliferation and survival of osteoblasts as measured by cell based assays and the expression or activity of cell-cycle (*cyclins D1* and *D2*, *p27kip1*), DNA damage (*Gadd45*) or anti-oxidant defense (*Sod2*) genes. FOXO1 also counteracted the adverse effects of H<sub>2</sub>O<sub>2</sub> on osteoblast survival. *In vivo*, *Foxo1* expression progressively decreased with age in C57Bl/6 mice. The decrease in *Foxo1* expression correlated with increased levels of Reactive Oxygen Species (ROS) in bone marrow cells derived from the aging animals. The expression and activity of *Sod2* were also reduced in femoral extracts with age. Moreover, *Foxo1* haploinsufficiency decreased bone mass and compromised bone microarchitecture in adult mice. Structural changes representing loss of trabecular connectivity and thus, reduced bone strength, concomitantly with increased bone diameter resemble the phenotype of aging bone. Deletion of *Foxo1* specifically from osteoblasts decreased *Sod2* activity in bone extracts, indicating attenuation of FOXO1 activity in bone. Further, it reduced osteoblast numbers, bone formation rate and bone volume without affecting the osteoclast numbers. These studies provide a link between pathways that regulate oxidative stress, longevity and skeletal homeostasis under the control of FOXO1 signaling. They also suggest that FOXO1 may prevent or delay skeletal aging.

**Age-related Bone Loss in Mice Associated with Ubiquitin Ligase Smurf1 Degradation of JunB Protein and Reduced Osteoblast Proliferation.** L. Zhao<sup>\*1</sup>, J. Huang<sup>\*2</sup>, R. Guo<sup>\*1</sup>, D. Chen<sup>2</sup>, Y. E. Zhang<sup>\*3</sup>, B. F. Boyce<sup>1</sup>, L. Xing<sup>1</sup>. <sup>1</sup>Department of Pathology and Lab. Medicine, University of Rochester Medical Center, Rochester, NY, USA, <sup>2</sup>Department of Orthopaedics, University of Rochester Medical Center, Rochester, NY, USA, <sup>3</sup>Laboratory of Cellular and Molecular Biology, Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA.

Bone mass and bone formation rates are increased in Smad ubiquitin regulatory factor 1 (Smurf1) <sup>-/-</sup> mice (aged 4-8 months), suggesting that the ubiquitin ligase, Smurf1, negatively regulates bone volume with age. Smurf1 negatively regulates differentiated osteoblast functions by promoting ubiquitination and proteasomal degradation of bone morphogenetic protein (BMP) signaling molecules. However, it is not known if Smurf1 regulates the stability of other proteins in osteoblasts. We hypothesized that Smurf1 may target factors that regulate cell growth. Thus, we screened for a PY motif, the Smurf1 targeting sequence, in proteins known to control cell growth and found a PPXY sequence in JunB, suggesting that JunB may be a new target for Smurf1. Here, we used a combination of biochemical and genetic approaches to determine if Smurf1 affects JunB protein ubiquitination and degradation and has functional consequences in osteoblasts. We found that bone marrow cells from Smurf1<sup>-/-</sup> mice formed more (96 ± 1/dish vs. 52 ± 4, p<0.05) and more extensive (4943 ± 573 mm<sup>2</sup> vs 2053 ± 341, p<0.05) ALP<sup>+</sup> colonies than WT cells. JunB protein levels were increased (2.2-fold) in calvarial and bone marrow osteoblasts derived from Smurf1<sup>-/-</sup> mice compared to WT cells. Smurf1 over-expression decreased steady-state levels of JunB protein (21.6-fold), and this was attenuated by the proteasomal inhibitor, MG132. Over-expression of WT Smurf1, but not a catalytically inactive mutant Smurf1, increased the accumulation of ubiquitinated JunB protein. Immunoprecipitation experiments indicated that Smurf1 binds directly to JunB through its PY motif. Mutated JunB (PPVY to PPVF) abolished the interaction between Smurf1 and JunB as well as Smurf1-mediated JunB ubiquitination and degradation. JunB promotes cell growth in several cell types by regulating transcription of cyclins. We found that the expression level of cyclin D1 and the activity of a cyclin D1-luciferase reporter construct were significantly increased in Smurf1<sup>-/-</sup> osteoblasts compared to WT cells. Furthermore, knock-down of JunB with RNAi abolished the increase in cyclin D1 levels in Smurf1<sup>-/-</sup> cells. Thus, we have identified JunB as a new target of Smurf1 E3 ligase in osteoblasts and demonstrated that the regulation of JunB protein stability via proteasomal degradation affects osteoblast function. Inhibition of Smurf1 in osteoblasts could be a mechanism to limit age-related osteoporosis.

**Conditional Deletion of BMP2 Gene in Early Osteoblasts Leads to Reduction in the Total Bone Marrow (BM) Mesenchymal Stem Cells and Their Capacity to Form Osteoblast Precursors.** W. Yang<sup>1</sup>, M. A. Harris<sup>1</sup>, Y. Cui<sup>\*1</sup>, C. Skinner<sup>\*1</sup>, X. Chen<sup>1</sup>, Y. Lai<sup>\*1</sup>, A. Lichtler<sup>2</sup>, B. Kream<sup>\*2</sup>, Y. Mishina<sup>3</sup>, S. E. Harris<sup>1</sup>. <sup>1</sup>U Texas HSC San Antonio, San Antonio, TX, USA, <sup>2</sup>U Connecticut Medical CTR, Farmington, CT, USA, <sup>3</sup>NIEHS, Research Triangle Park, NC, USA.

BMP2 is thought to be essential for multipotential mesenchymal stem cells (MSCs) fate direction to osteogenic precursors. BMP2 has also been reported to mobilize osteogenic stem cells to the site of bone formation. However, the role and mechanism of endogenous BMP2 in MSCs fate and capacity is unrevealed. Using an early osteoblast selective BMP2 conditional knockout (BMP2-cKO) mouse model (3.6col1a1-cre), we have previously demonstrated that BMP2 is necessary for postnatal bone formation. Bone marrow from 3-month BMP2-cKO mice demonstrates reduction of both hematopoietic and stromal cells (BMSCs) components. We compared the BMSCs obtained from femurs and tibiae of BMP2-cKO mice to those from BMP2 heterozygous (BMP2-Het) and wild-type (WT) mice. The total BMSCs from the BM of BMP2-cKO mice is reduced 50%. Mesenchymal colony-forming unit (CFU) assays with BMSCs were then performed. CFU-F assays indicate there is a BMP2 gene dose-dependent reduction of MSCs population with 86% reduction for BMP2-cKO and 44% reduction for BMP2-Het compared to WT mice. CFU-OB assays demonstrate BMP2-cKO mice have a 90% reduction in osteogenic-potency compared to WT. The replication capacity of MSCs was examined by replating assays. MSCs were first expanded by plating on WT BM cell - derived extracellular matrix (ECM) that has the capacity to maintain MSC multipotential state. Equal numbers of expanded MSCs from BMP2-cKO, BMP2-Het and WT were then tested for CFU-F and CFU-OB. Replication capacity of MSCs with deletion of BMP2 is reduced 60% and differentiation capacity reduced 48%. Defects of MSCs capacity to form CFU-F in the absence of BMP2 could be caused by deficient BM microenvironment or intrinsic to the MSCs. Thus, we compared MSCs' self-renewal in ECM microenvironment to those on plastic. The results show that BMP2-cKO MSCs cannot be rescued by normal BM microenvironment. This suggests the defect in the MSCs of the BMP2-cKO animals is intrinsic to the MSCs population. One hypothesis is that BMP2 dependent gene expression in early osteoblasts is sending signals to the MSCs niche and population and affecting the stem cell quality and state of these multipotential precursors.

**Class IA Phosphatidylinositol 3-kinases Are Indispensable for Osteoclast Function by Regulating Cytoskeletal Organization and Cell Death.** M. Nakamura<sup>1</sup>, M. Iwasawa<sup>1</sup>, Y. Nagase<sup>1</sup>, T. Nakamura<sup>2</sup>, S. Kato<sup>2</sup>, K. Ueki<sup>\*3</sup>, J. Luo<sup>\*4</sup>, L. C. Cantley<sup>\*4</sup>, K. Nakamura<sup>1</sup>, S. Tanaka<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, <sup>2</sup>Institute of Molecular and Cellular Biosciences, the University of Tokyo, Tokyo, Japan, <sup>3</sup>Department of Endocrinology, the University of Tokyo Faculty of Medicine, Tokyo, Japan, <sup>4</sup>Department of Systems Biology, Harvard Medical School, Boston, MA, USA.

Phosphatidylinositol 3-kinases (PI3Ks) are a family of enzymes that phosphorylate phosphatidylinositol lipids at the 3' position. They are divided into 3 classes based on their structures and substrates. Class IA PI3Ks regulate signaling pathways downstream of receptor-type and non receptor-type tyrosine kinases such as c-Fms and Src. They consist of an adaptor subunit p85 (α and β), and a catalytic subunit p110 (α, β, δ). Previous studies have reported that class IA PI3Ks play an important role in osteoclast activity by using specific inhibitors such as wortmannin although the exact role of the molecules in the skeletal tissue in vivo still remains unknown. To elucidate the role of class IA PI3Ks in osteoclasts, we generated osteoclast-specific p85α and β double knockout mice. Since conventional p85α knockout mice die within 3 weeks, we generated osteoclast-specific p85α knockout (p85α cKO) mice by crossing *pik3r1* (p85α, p55α, p50α) flox mice and cathepsin K-Cre knockin mice. In p85α cKO mice, p85α expression was specifically reduced in osteoclasts but not in osteoblasts or other tissues. They were then crossed with *pik3r2* (p85β) knockout mice to generate osteoclast-specific p85α&β double knockout (p85 dKO) mice. Akt activation in response to M-CSF stimulation was reduced in osteoclasts derived from p85α cKO mice, and almost completely abolished in p85 dKO osteoclasts. Radiological and histological analysis showed an increased bone mass in p85α cKO mice compared to control littermates with no statistical significance. While no abnormality was observed in the skeletal tissue of p85β KO mice, p85 dKO mice exhibited about 1.5 fold increase in bone mass compared to p85β KO littermates (p<0.05). Eroded surface was reduced by 50% while there was no significant difference in osteoclast number. Osteoclasts differentiated from p85α cKO and p85 dKO mice bone marrow cells (αKO OCs and dKO OCs) showed impaired spreading and actin ring formation, and their bone-resorbing activity was remarkably suppressed. dKO OCs exhibited an increased cell death after cytokine withdrawal, and the proapoptotic phenotype was completely restored by M-CSF treatment, which activated Erk but not Akt in the cells. From these observations, we conclude that class IA PI3Ks are indispensable for osteoclast function by regulating cytoskeletal organization and cell death.

**The Role of LIM kinase 1 in Osteoclast Cytoskeletal Remodeling and Bone Resorption.** T. Kawano\*, M. Zhu\*, K. Insogna. Department of Medicine, Yale University, New Haven, CT, USA.

LIM kinase 1 (LIMK1) is a serine/threonine kinase that phosphorylates and inactivates the actin-severing protein, cofilin. Depending on the cellular context, inactivation of LIMK1 has been reported to either increase or reduce cytoskeletal remodeling and cell motility. The role of LIMK1 in regulating the activity of osteoclasts has not been explored. We therefore examined the skeletal phenotype of 8-9 week-old LIMK1 k/o mice and found that total body and femur BMD were lower in the knock-out animals (428 vs. 447 10<sup>-4</sup> grms/cm<sup>2</sup> and 623 vs. 670 10<sup>-4</sup> grms/cm<sup>2</sup>; p<0.05 and p=0.06 respectively). Dynamic bone histomorphometry did not indicate changes in the rate of bone formation in the k/o animals, however serum levels of CTX tended to be higher (40±8 vs. 29±3 ng/ml) suggesting the possibility of higher rates of resorption. Consistent with this hypothesis, osteoclasts generated by co-culture from LIMK1 k/o mice resorbed significantly more bone in 48 hrs when plated on dentine slices than did osteoclasts from heterozygous animals as quantified by the concentration of CTX in the supernatant of these cultures (p=0.02). Since LIMK1 regulates actin remodeling, the cytoskeletal response to CSF1 was assessed in mature osteoclasts freshly isolated from LIMK1<sup>-/-</sup> and LIMK1<sup>+/-</sup> mice. LIMK1 k/o osteoclasts demonstrated a significantly greater increase in cell area in response to treatment with CSF1 for 15 min than the LIMK1<sup>+/-</sup> cells (62±10 vs. 29±4 %, p<0.001). In other cells, LIMK1 inactivates cofilin and we next sought to determine if the exaggerated cytoskeletal response to CSF1 observed in the LIMK1 k/o osteoclasts reflected increased amounts of unphosphorylated (i.e. activated cofilin) present in the cytosol of these cells. Western blot analysis demonstrated that, in untreated cells, there was 50% less phosphorylated cofilin present in the LIMK1<sup>-/-</sup> osteoclasts than in cells prepared from LIMK1<sup>+/-</sup> mice. In response to 15 min of treatment with CSF1, the amount of phosphorylated cofilin present increased in both groups of cells but the ratio of phosphorylated/dephosphorylated cofilin remained lower in the LIMK1<sup>-/-</sup> osteoclasts. Thus, after 15 minutes, there was 45% less phosphorylated cofilin present in the k/o cells. These data indicate that, in the genetic absence of LIMK1, osteoclasts resorb more bone and, as a likely consequence, bone mass is reduced in LIMK1 k/o mice. One reason for this cellular phenotype may be an increase in the amount of active cofilin in LIMK1<sup>-/-</sup> osteoclasts resulting in increased responsiveness to proresorptive cytokines such as CSF1 that are known to induce cytoskeletal remodeling and motility as a part of the resorptive process.

**TSH Inhibits the Expression of High Mobility Group Box Protein (HMGB), a Regulator of TNF $\alpha$  Transcription, in Osteoclastogenesis.** R. Baliram\*, K. Yamoah\*, H. Amano\*, E. Abe\*. <sup>1</sup>Endocrinology, Mt. Sinai School of Medicine, New York, NY, USA, <sup>2</sup>Pharmacology, School of Dentistry, Showa University, Tokyo, Japan.

We have previously shown that enhanced osteoclast formation in TSHR (thyroid stimulating hormone receptor)-null mice is due to TNF $\alpha$  overexpression in osteoclast progenitors. The crucial role of TNF $\alpha$  is further evidenced by additional experiments indicating that cultures of bone marrow cells from TSHR<sup>-/-</sup>TNF $\alpha$ <sup>-/-</sup> mice exhibit normal osteoclast formation. Therefore, we sought to elucidate the molecular mechanism of TNF $\alpha$  expression in osteoclast progenitors by mapping a *cis* regulatory element in the mouse TNF $\alpha$  promoter (using 5' deletion analysis) and by analyzing protein binding to the mapped sequence by EMSA (electrophoretic mobility shift assay). Our results indicate that nucleotides -157 bp to -137 bp in the TNF $\alpha$  promoter are responsible for RANKL-induced transcriptional activity and that the binding of the nuclear factors to this sequence is enhanced by RANKL and IL-1/TNF $\alpha$  treatment. We called this sequence RSS, for RANKL-responsive sequence, and we purified the binding proteins by affinity column chromatography and identified them by mass spectrometry. The proteins were high mobility group box proteins (HMGBs: HMGB1 and HMGB2), which are responsible for transcription, replication, recombination and DNA repair. These proteins are secreted in pathological conditions such as inflammation and sepsis. Further experiments showed that (1) binding of HMGBs to the RSS occurs only in the presence of RANKL (ChIP, chromatin immunoprecipitation), (2) TSH inhibits HMGB1 and HMGB2 expression in osteoclast progenitors, (3) knocking down of the expression of either HMGB1 or HMGB2 with siRNAs results in a significant reduction in the expression of TNF $\alpha$  and TRAP (tartrate resistant acid phosphatase), and (4) treatment with recombinant HMGBs significantly enhances TNF $\alpha$ , IL-1 and IL-6 expression, as well as osteoclast formation, in RAW-C3 cells and bone marrow cell cultures. Moreover, we found a direct correlation between HMGBs and TNF $\alpha$  expression and osteoclast formation in TSHR-null mice and TNF $\alpha$ -null mice. These results indicate that TSH inhibits osteoclastogenesis in bone remodeling by altering the expression of HMGBs and TNF $\alpha$ .

**Three RANK Cytoplasmic Motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQG<sup>604-609</sup>, play a Critical Role in TNF $\alpha$ /IL-1-mediated Osteoclastogenesis.** J. Jules, Z. Shi\*, X. Feng. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

RANK contains 3 TRAF-binding motifs (T1: PFQEP<sup>369-373</sup>; T2: PVQEET<sup>559-564</sup> & T3: PVQEQG<sup>604-609</sup>) that regulate osteoclast biology. RANK also has a TRAF-independent motif (IVVY<sup>535-538</sup>) that commits bone marrow macrophages (BMMs) to the osteoclast lineage. Notably, TNF $\alpha$ /IL-1-induced osteoclastogenesis requires priming of BMMs by RANKL. Using chimeric receptors, we have shown that the IVVY motif primes BMMs in TNF $\alpha$ /IL-1-induced osteoclastogenesis (ASBMR 2007). Briefly, we developed 2 chimeras: WT & Mu. While WT comprises the human Fas external domain linked to the transmembrane & intracellular domains of normal RANK, Mu has inactivating mutations in the IVVY motif. The chimeras are activated by a human Fas activating antibody (Fas-AB), specific to human Fas, without affecting endogenous RANK or Fas. BMMs expressing WT or Mu were pre-treated with Fas-AB/M-CSF for 18h, followed with TNF $\alpha$  or IL-1 plus M-CSF for 96h. WT, but not Mu, promoted osteoclastogenesis, supporting a vital role for the IVVY motif in priming BMMs in TNF $\alpha$ /IL-1-mediated osteoclastogenesis. Here, we further addressed the issue by inserting the IVVY motif to TNFR1 to determine if the addition of this motif renders TNFR1 capable of mediating osteoclastogenesis. TNFR1 or TNFR1-I (bearing IVVY motif) was expressed in BMMs from TNFR1<sup>-/-</sup>R2<sup>-/-</sup> mice. While TNFR1 failed to form osteoclasts in response to TNF $\alpha$ , TNFR1-I could mediate osteoclastogenesis, confirming the role of the IVVY motif in priming BMMs. Also, we have recently found that the IVVY motif and TRAF-binding motifs in the RANK do not function independently, inferring a functional crosstalk between them. This suggests that TRAF-binding motifs may also regulate TNF $\alpha$ /IL-1-mediated osteoclastogenesis by crosstalk with the IVVY motif in the lineage commitment. To test this, we prepared a chimera mutant bearing inactivating mutations in all 3 TRAF motifs (M). BMMs expressing WT or M were treated with hFas-AB/M-CSF for 18h, followed with TNF $\alpha$  or IL-1 plus M-CSF for 96h. While WT formed osteoclasts, M failed to do so, indicating that one or more of TRAF motifs are implicated in TNF $\alpha$ /IL-1-mediated osteoclastogenesis. Then, we generated M1, M2 and M3 which contain mutations in T1, T2, & T3, respectively. The abilities of M2 and M3 but not M1 to form osteoclasts were impaired, indicating that T2 & T3 are functional. This was further supported by a study with a mutant chimera containing mutations in both T2 and T3, which failed completely to mediate TNF $\alpha$ /IL-1-induced osteoclastogenesis. Thus, we conclude that 3 RANK motifs (IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> & PVQEQG<sup>604-609</sup>) play a vital role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis.

**Lyn, Opposite to c-Src, Negatively Regulates Osteoclastogenesis *in vitro* and *in vivo* via Its Interaction with SHP-1 and Gab2.** H. Kim\*, F. Ross\*, S. Teitelbaum\*, R. Faccio\*. <sup>1</sup>Pathology, Washington University, St. Louis, MO, USA, <sup>2</sup>Orthopedics, Washington University, St. Louis, MO, USA.

The non-receptor tyrosine kinase, c-Src, is a rate-limiting activator of osteoclast function and Src kinase inhibitors are therefore candidate anti-osteoporosis drugs. While c-Src is central to osteoclast activity, but not differentiation, by affecting  $\alpha$ v $\beta$ 3 integrin and M-CSF dependent pathways, we find Lyn, another member of Src family kinases is, in contrast, a negative regulator of osteoclastic bone resorption. Absence of Lyn enhances RANKL-mediated differentiation of osteoclast precursors without affecting M-CSF-dependent proliferation and survival. In further contrast to c-Src, Lyn deficiency does not impact the activity of the mature resorptive cell, indicating that the two Src family kinases exert opposite functions in the osteoclast. More importantly our data indicate that mice lacking Lyn undergo accelerated osteoclastogenesis and bone loss *in vivo* in response to RANKL. Daily, supracalvarial RANKL injections for 6 days, double the percent osteoclast surface in the calvaria of mutant mice as compared to WT ( $P < 0.01$ ) and significantly increase serum TRACP5b and collagen type 1 fragments, markers of global bone resorption, respectively 3.7 and 2.5 fold ( $P < 0.01$  compared to WT). Mechanistically, Lyn forms an intraosteoclastic complex with receptor activator of NF- $\kappa$ B (RANK), the tyrosine phosphatase SHP1 and the adapter protein Gab2. Upon RANKL exposure, Gab2 is phosphorylated and leads to activation of AP1 and NF- $\kappa$ B pathways, thereby promoting osteoclast differentiation. In Lyn<sup>-/-</sup> cultures, we found enhanced and prolonged Gab2 phosphorylation, and sustained JNK and NF- $\kappa$ B signaling. The effect of Lyn deficiency on Gab2 activation was specific for RANKL since we did not detect any difference in WT and Lyn<sup>-/-</sup> cells stimulated with M-CSF. Finally and consistent with our findings in Lyn null cells, analysis of osteoclasts from *me<sup>o</sup>/me<sup>o</sup>* mice, which bear a natural inactivating SHP-1 mutation, revealed enhanced Gab2 phosphorylation and JNK and NF- $\kappa$ B activation in response to RANKL stimulation. Thus, by activating SHP-1, Lyn modulates RANKL-evoked Gab2 phosphorylation, a critical event in OC development. Here, for the first time we establish that Lyn also regulates the osteoclast and does it in a manner antithetical to that of c-Src. Therefore, the most pragmatic aspect of our findings is that successful therapeutic inhibition of c-Src, in the context of the osteoclast, will require its stringent targeting.

**Syk Tyrosine 317 Negatively Regulates Osteoclast Function.** W. Zou, J. Reeve, F. P. Ross, S. L. Teitelbaum. Pathology, Washington University School of Medicine, St. Louis, MO, USA.

The  $\alpha v \beta 3$  integrin and c-Fms, the M-CSF receptor, stimulate the resorptive capacity of the differentiated osteoclast by organizing its cytoskeleton via the tyrosine kinase, Syk in a process requiring the kinase activity of c-Src. Thus, Syk-deficient osteoclasts fail to spread or form actin rings, in vitro and in vivo. These cytoskeletal defects of Syk<sup>-/-</sup> osteoclasts arrest their bone resorptive capacity resulting in enhanced skeletal mass. Syk activation is associated with prominent phosphorylation of tyrosine (Y) 317, residing in the protein's linker region. To determine if this phosphorylated Syk residue regulates osteoclast function, we retrovirally transduced Syk<sup>-/-</sup> macrophages with WT Syk or non-phosphorylatable SykY317F and differentiated them into osteoclasts. As expected, expression of WT Syk rescues the cytoskeletal abnormalities of Syk<sup>-/-</sup> osteoclasts. Furthermore, and in keeping with unaltered osteoclast number in Syk<sup>-/-</sup> mice, SykY317F does not affect osteoclastogenesis. Surprisingly, however, SykY317F not only rescues the cytoskeletal abnormalities of Syk<sup>-/-</sup> osteoclasts, but cells expressing the non-phosphorylatable mutant actually spread more effectively than WT. Additionally, SykY317F osteoclasts form larger actin rings and resorptive pits than WT and demonstrate a 3-fold enhancement of bone resorption, as measured by medium CTx. These results establish that SykY317F negatively regulates osteoclast function. The amino acid sequence surrounding SykY317 mirrors the motif recognized by the phosphotyrosine-binding domain of c-Cbl, which acts as an E3 ubiquitin ligase. While SykY317F does not affect M-CSF- and integrin-induced Syk kinase activity and Cbl phosphorylation, it disrupts Syk/Cbl association as determined by immunoblot. Furthermore, SykY317F abolishes M-CSF- and integrin-stimulated Syk ubiquitination and degradation thereby enhance activity of the downstream cytoskeleton-organizing molecules, SLP76, Plc $\gamma$ 2 and Vav3, to levels higher than those seen with WT Syk. Thus, SykY317 negatively regulates the tyrosine kinase's ability to organize the osteoclast cytoskeleton by accelerating proteasome-mediated Syk degradation. Butressing this posture, blocking Syk degradation by the proteasome inhibitor, MG132, increases integrin-induced SLP76 activation. In summary, our data suggests a model that SykY317 negatively regulates osteoclast function via regulating Syk degradation by associating with ubiquitin ligase c-Cbl and its downstream molecules activation.

**Crosstalk Between Androgen Receptor and Wnt Signaling Mediates Sexual Dimorphism During Bone Mass Accrual.** Y. Gabet<sup>\*1</sup>, T. Noh<sup>\*1</sup>, J. Cogan<sup>\*1</sup>, A. Tank<sup>\*1</sup>, T. Sasaki<sup>\*2</sup>, B. Criswell<sup>\*1</sup>, A. Dixon<sup>\*1</sup>, J. Tam<sup>\*3</sup>, T. Kohler<sup>\*4</sup>, E. Segev<sup>\*3</sup>, L. Kockeritz<sup>\*5</sup>, J. Woodgett<sup>\*5</sup>, R. Müller<sup>\*4</sup>, Y. Chai<sup>\*2</sup>, E. Smith<sup>\*1</sup>, I. Bab<sup>\*3</sup>, B. Frenkel<sup>1</sup>. <sup>1</sup>Biochemistry & Molecular Biology, Institute for Genetic Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, <sup>2</sup>Center for Craniofacial Molecular Biology, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, <sup>3</sup>Bone Laboratory, Institute for Dental Sciences, Faculty of Dental Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel, <sup>4</sup>Institute for Biomechanics, ETH Zürich, Zürich, Switzerland, <sup>5</sup>Ontario Cancer Institute, Princess Margaret Hospital, Toronto, ON, Canada.

In humans and mice alike, bone remodeling is strongly dependent on the Wnt signaling pathway. Androgen receptor (AR) mediates the sexual dimorphism observed in many tissues and here we demonstrate a protective skeletal effect of AR by interacting with Wnt. We investigated the role of *Lef1*, one of the four transcription factors that transmit Wnt signaling to the genome, in bone mass accrual *in vivo*. Because *Lef1*<sup>-/-</sup> mice die perinatally, we assessed the bone phenotype of *Lef1*<sup>+/-</sup> males and females at 4, 13, 17 and 34 weeks of age by  $\mu$ CT. *Lef1*<sup>+/-</sup> female mice showed significantly reduced bone mass accrual in the distal femoral metaphyses and lumbar vertebral bodies. This was attributable to a decreased bone formation, assessed by vital calcein labeling. Remarkably, bone mass was not affected in *Lef1*<sup>+/-</sup> males. We also analyzed femora of mice haploinsufficient for *Gsk3 $\beta$* , a negative regulator of the Wnt pathway. Similarly, females were substantially more responsive than males to *Gsk3 $\beta$*  haploinsufficiency, displaying in this case a high bone mass phenotype. In osteoblast cultures, real-time PCR revealed a 2.5-fold increase in *Lef1* expression induced by AR activation, suggesting interaction between AR and Wnt. Thus, to test if changes in *Lef1* expression affect Wnt signaling in bone, we transiently expressed *Lef1* in *Lef1*<sup>-/-</sup> primary osteoblasts resulting in strong stimulation of the transfected super-TOPFLASH Wnt reporter. Therefore, we hypothesized that lack of AR signaling leads to suboptimal Wnt activity in females, hence the relative sensitivity of the female skeleton to changes in Wnt signaling. Indeed, similar to female *Lef1*<sup>+/-</sup>, male *Lef1*<sup>+/-</sup> mice lacking functional AR (*Lef1*<sup>+/-</sup>;AR<sup>flm</sup>) also displayed a low bone mass (LBM) phenotype compared to *Lef1*<sup>+/-</sup>;AR<sup>flm</sup>, demonstrating that AR signaling protects against *Lef1*<sup>+/-</sup>-related LBM. Together, the gender-preferential effects of both *Lef1* and *Gsk3 $\beta$*  haploinsufficiencies suggest that the skeleton is more responsive to variations in Wnt signaling in females compared to males, and that crosstalk between AR and Wnt mediates gender differences in bone mass accrual.

**Osteoblastic Androgen Receptor Regulates Cortical Bone Mineral Density.** Y. Imai<sup>1</sup>, T. Nakamura<sup>2</sup>, T. Matsumoto<sup>\*2</sup>, K. Inoue<sup>\*3</sup>, S. Kondoh<sup>\*3</sup>, T. Sato<sup>\*4</sup>, K. Takaoka<sup>1</sup>, S. Kato<sup>2</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, <sup>2</sup>Nuclear Signaling, IMCB, University of Tokyo, JST/ERATO, Tokyo, Japan, <sup>3</sup>Nuclear Signaling, IMCB, University of Tokyo, Tokyo, Japan, <sup>4</sup>Laboratory of Molecular Traffic, Department of Molecular and Cellular Biology, Institute for Molecular and Cellular Regulation, Gunma University, Gunma, Japan.

Androgen and estrogen sex steroid hormones regulate bone homeostasis through their specific nuclear receptors, Estrogen Receptors (ERs) and Androgen Receptors (ARs). We previously reported that osteoclastic ERs control osteoclast lifespan through Fas/Fas ligand signaling in trabecular bone<sup>1</sup>. Moreover, results of bone analysis in conventional AR knockout mice (ARKO) revealed bone loss in both trabecular and cortical bone with a high rate of turnover in bone metabolism<sup>2</sup>. However, the molecular mechanisms of bone mass control by AR remain unclear.

To clarify the functions of AR in both osteoclasts and osteoblasts, we generated both osteoclast- and osteoblast-specific conditional ARKO mice (OcARKO and ObARKO) using Cathepsin K-Cre mice, Col1a1(2.3kb)-Cre mice, and AR floxed mice. Bone phenotypes were examined by soft X-ray, bone mineral density (BMD) measurement, and bone histomorphometry.

There were no differences in body weight between control mice and OcARKO or ObARKO, regardless of gender. At 8 weeks of age, OcARKO exhibited osteopenia in trabecular bone such as distal femur and a high rate of turnover in bone metabolism, in which bone resorption was more rapid than in control mice. On the other hand, female ObARKO exhibited no differences in BMD of the long bones such as femur and tibia when compared to the control mice, though the results of DEXA suggested a tendency for cortical bone of male ObARKO mice to be less in volume than that in male control mice. Although it has been believed that androgens have osteoprotective effects, especially in males, whether the effects of androgens in bone tissue are direct or indirect has not been determined. Our studies revealed that osteoclastic ARs participate in regulating trabecular bone resorption, osteoblastic ARs maintain cortical bone formation, and ARs have direct effects in bone tissue.

**Estrogen Receptor- $\alpha$  Expression in Mesenchymal Cells Is Crucial for the Bone Protective Effects of Estrogen.** M. K. Lagerquist<sup>1</sup>, C. Håkansson<sup>\*1</sup>, S. H. Windahl<sup>1</sup>, A. E. Börjesson<sup>\*1</sup>, C. Jochems<sup>\*1</sup>, M. C. Antal<sup>\*2</sup>, A. Krust<sup>\*2</sup>, P. Chambon<sup>\*2</sup>, P. Angel<sup>\*3</sup>, H. Carlsten<sup>\*1</sup>, C. Ohlsson<sup>1</sup>. <sup>1</sup>Inst. of Medicine, Gothenburg, Sweden, <sup>2</sup>IGBMC, Illkirch, France, <sup>3</sup>DKFZ, Heidelberg, Germany.

Estrogen exerts bone protective effects by attenuating bone resorption in ovariectomized (ovx) mice. However, it is still debated whether osteoclasts, T-lymphocytes or cells of mesenchymal origin (e.g. osteoblasts and bone marrow stromal cells) are the primary target cells for this effect. The aim of this study was to *in vivo* investigate whether mesenchymal cells are involved in the bone protective effects of estrogen. For this purpose we used Col1 $\alpha$ 2-Cre mice in which expression of the Cre recombinase is driven by a P1-derived artificial chromosome that harbors the entire Col1 $\alpha$ 2 gene (Florin *et al*, Genesis, 2004). These mice were crossed with ER $\alpha$ -loxP mice to generate mice lacking ER $\alpha$  expression in osteoblasts, chondrocytes and fibroblasts but not in osteoclasts (Col1 $\alpha$ 2-ER $\alpha$ <sup>-/-</sup> mice). The Col1 $\alpha$ 2-ER $\alpha$ <sup>-/-</sup> mice and wild type mice were ovx at four months of age and treated with 17 $\beta$ -estradiol (E2) pellets (160 ng/mouse/day), or placebo for three weeks. Total body and spine bone mineral densities (BMD) were analyzed by dual-X ray absorptiometry. Trabecular BMD and cortical thickness were analyzed by peripheral quantitative computer tomography scans of femur while the trabecular bone structure (BV/TV, trabecular number and trabecular thickness) was analyzed by  $\mu$ CT.

In control mice, E2 increased total body BMD (+15%, p<0.01), spine BMD (+25%, p<0.01), trabecular BMD (+145%, p<0.05), cortical thickness (+16%, p<0.01), BV/TV (+267%, p<0.05), trabecular number (+233%, p<0.05) and trabecular thickness (+9%, p<0.01) compared to placebo treatment. Importantly, in the Col1 $\alpha$ 2-ER $\alpha$ <sup>-/-</sup> mice, E2 treatment did not have any effect on these bone parameters (Fig).

In conclusion, our results demonstrate that mesenchymal cells are important primary target cells for the effects of E2 on trabecular and cortical bone. These findings suggest that not only osteoclasts but also osteoblasts/bone marrow stromal cells are crucial primary target cells for the bone protective effect of estrogen.

## 1124

**A Novel Estrogen Receptor  $\alpha$  Variant Signals Rapidly from the Caveolae of Traditional ER $\alpha$ -negative Cells.** R. A. Chaudhri<sup>\*</sup>, R. Olivares-Navarrete<sup>\*</sup>, M. Liou<sup>\*</sup>, Z. Schwartz, B. D. Boyan. Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

Estrogen receptor alpha (ER $\alpha$ 66) regulates expression of many genes upon binding to its ligand 17 $\beta$ -estradiol (E2) in the cytosol. Recently, a novel variant of ER $\alpha$ , ER $\alpha$ 36, was identified, differing from ER $\alpha$ 66 by lacking both transcriptional activation domains but retaining the DNA-binding and ligand-binding domains as well as partial dimerization (Wang *et al.*, BBRC, 2005). We previously showed that rapid E2-dependent PKC activation in ER $\alpha$ -positive MCF7 cells, as well as in ER $\alpha$ -negative HCC38 cells, is membrane-mediated (Boyan *et al.*, Steroids, 2005). The membrane action of E2 is supported by studies using E2 conjugated to BSA (E2-BSA), which cannot cross the cell membrane, but elicits many similar effects as E2 such as PKC activation. E2 and E2-BSA rapidly increase PKC activity without new gene expression or protein synthesis and traditional ER $\alpha$  antibodies or ER antagonists do not block this effect (Boyan *et al.*, 2003). The goal of our study was to determine if ER $\alpha$ 36 is present in cell membranes and if it is responsible for E2-dependent PKC activation. We hypothesized that ER $\alpha$ 66-negative HCC38 cells carry ER $\alpha$ 36 and that it mediates the E2 membrane effect. ER $\alpha$  mRNA was

verified by RTPCR. Whole cell lysates and caveolae fractions from confluent cultures of MCF7 and HCC38 cells were examined by Western blot for the ER $\alpha$  variants. MCF7 and HCC38 cells were examined by immunocytochemistry for the localization of ERs. PKC activity was measured in confluent cultures treated with E2 for 9, 90 and 270 min. ER $\alpha$ 36 antibody was used to block the E2 effect. RTPCR showed both cell types express ER $\alpha$ . ER $\alpha$ 66 immunoblots showed that MCF7 cells have both ER $\alpha$  variants, but HCC38 cells do not contain ER $\alpha$ 66. Immunoblots also showed that ER $\alpha$ 36 exists in both cell types and is found in caveolae fractions of HCC38 cells. Immunocytochemistry showed ER $\alpha$ 36 throughout the cells, and peri-nuclear ER $\alpha$ 66 in MCF7 cells only. E2 caused a dose-dependent increase in PKC activity at 9 min in both cell types, which was inhibited when cells were treated with ER $\alpha$ 36 antibody. In contrast, ER $\alpha$ 66 antibody had no effect on PKC activity. Thus, HCC38 cells, traditionally negative for ER $\alpha$ , express ER $\alpha$  mRNA due to the shared sequence homology of the ER $\alpha$  variants. However, Western blot and immunocytochemistry show that ER $\alpha$ 66 exists only in MCF7 cells, while ER $\alpha$ 36 is present in both cell types, localized throughout the cell and exhibits colocalization to caveolin-1. This is consistent with previous literature showing that HCC38 cells are negative for ER $\alpha$  expression. PKC results demonstrate that E2-dependent PKC activity is present in HCC38 cells and is blocked by ER $\alpha$ 36 antibody, indicating that ER $\alpha$ 36 is responsible for the non-genomic, rapid effect of E2 on PKC activity.

**Estrogen Suppresses RANKL-induced Osteoclastic Differentiation of Human Monocytes Via an ER-alpha Associated Cytoplasmic Signaling Complex, but ER-alpha Is Downregulated During Osteoclastic Differentiation.** L. J. Robinson<sup>\*</sup>, B. B. Yaroslavskiy<sup>\*</sup>, R. D. Griswold<sup>\*</sup>, E. D. Zadorozny<sup>\*</sup>, H. C. Blair. Pathology and Cell Biology, University of Pittsburgh, Pittsburgh, PA, USA.

The effects of estrogen on bone cell survival and differentiation are controversial. Studies in mice have suggested that estrogen reduces bone resorption by inducing apoptosis of osteoclasts. Because there may be significant species differences, we studied this issue in human cells. Estrogen receptor expression was evaluated using quantitative real-time PCR. CD14-selected human monocytes lack estrogen receptor(ER)-beta; ER-alpha is expressed but levels decline markedly during osteoclastic differentiation, decreasing to essentially undetectable levels. Estrogen effects on non-transformed human monocytes were rapid and significant: inhibition of RANKL-induced osteoclastic differentiation occurred at 0.5 nM estradiol with 40-50% reduction in osteoclast numbers and activity at 10 nM estradiol. Apoptosis did not occur at significant frequency during human osteoclast differentiation *in vitro* with or without estrogen. Estrogen had acute effects on RANKL signal transduction in osteoclast precursors. Inhibition of NF-kB translocation was clearly seen within 30 minutes of RANKL stimulation. The estrogen effect was durable, with osteoclast differentiation suppressed 14 days after addition of RANKL when estradiol was withdrawn after 18 hours. An intermediate protein that binds ER-alpha in the presence of estrogen, BCAR1, was abundant in CD14 cells. Co-immune precipitation showed estrogen dependent formation of ER-alpha-BCAR1 complexes. Complex formation was enhanced by RANKL, and the RANK signaling protein Traf6 precipitated with the complex. Estradiol reduced RANKL stimulated phosphorylation of Ikb. This effect was abolished by knockdown of BCAR1, although osteoclast differentiation was also curtailed. Other studies suggested that deletion of ER-alpha under a cathepsin K promoter eliminate osteoclast apoptosis. At least in human osteoclasts, this approach would be problematical in that bone cells including mineralising osteoblasts produce cathepsin K (P<0.003) while unmodified osteoclasts bear little, if any, ER-a. We conclude that, in pure populations of human cells, estrogen reduces osteoclast formation, a cytoplasmic complex including ER-alpha and BCAR1 is a major mediator of this activity, and that BCAR1 is required for efficient osteoclast differentiation.

**Biochemical Characterization of ERalpha Co-regulators in Multinucleated Mature Osteoclasts.** I. Takada<sup>\*</sup>, M. Youn<sup>\*</sup>, Y. Imai<sup>\*</sup>, S. Kato. Nuclear Signalling, Institute of Molecular and Cellular Bioscience, University of Tokyo, Tokyo, Japan.

Molecular basis of transcriptional regulation in osteoclasts at epigenetic levels is largely unknown, particularly no specific transcriptional co-regulators are characterized. Mature osteoclasts are multinuclear macrophage-like cells derived from the bone marrow hematopoietic stem cells. Recent studies show that several transcriptional factors regulate osteoclast differentiation. Selective ablation of ER $\alpha$  in mature osteoclasts in ER $\alpha$ <sup>Doc/Doc</sup> female mice resulted in trabecular bone loss caused by increased apoptosis due to upregulation of Fas ligand expression (Nakamura *et al.*, Cell 130:811-23, 2007). ER $\alpha$  is a member of nuclear hormone receptor superfamily and regulates the expression of target genes upon binding cognate ligands such as 17 $\beta$ -estradiol (E<sub>2</sub>) and SERMs (selective estrogen receptor modulators). Ligand-activated ER $\alpha$  binds to estrogen response elements and E<sub>2</sub>-bound ER $\alpha$  forms nuclear complexes with various co-activators including histone modifying enzymes (de-/acetyltransferases, methyltransferases, demethylases, Ub-ligases) and chromatin remodeling factors. In general, compositions of ER $\alpha$ -associated complex components and their expression levels are distinct among different tissues. However, transcriptional co-regulators of ER $\alpha$  in mature osteoclasts remain to be biochemically characterized.

To address this issue, we established a large scale osteoclast cell culture system to purify

ER $\alpha$ -associating proteins from multinucleated mature osteoclasts. First, we prepared nuclear extracts from osteoclasts and confirmed their purity by Western blotting using transcription factors as nucleus-specific markers. Then, we applied biochemical purification techniques by using a GST-fused ER $\alpha$  protein column or immobilized anti-ER $\alpha$  antibody column. Protein complexes eluted from these affinity columns were separated by SDS-PAGE and their components identified by MALDI-TOF/MS. Significantly, in addition to the known co-activators common for other ER $\alpha$  target cells, we have identified in these complexes new histone modifying enzymes and signaling factors. We showed that levels of these novel component-encoding mRNAs were induced in a RANKL-dependent manner during osteoclast differentiation. Finally, we tested modulation of the ER $\alpha$ -dependent transactivation by these novel components and identified several of them as transcriptional co-activators. Thus, in this study we demonstrated the existence of osteoclast-specific transcriptional co-regulators supporting ER $\alpha$  function.

## 1127

**The Predictive Validity of the WHO FRAX Model, Bone Mineral Density and Prevalent Vertebral Fracture for Incident Radiographic Vertebral Fractures.** M. G. Donaldson<sup>1</sup>, L. Palermo<sup>2</sup>, J. T. Schousboe<sup>3</sup>, K. E. Ensrud<sup>4</sup>, M. C. Hochberg<sup>5</sup>, S. R. Cummings<sup>1</sup>. <sup>1</sup>San Francisco Coordinating Center, San Francisco, CA, USA, <sup>2</sup>Univ California San Francisco, San Francisco, CA, USA, <sup>3</sup>Park Nicollet Health Services, Minneapolis, MN, USA, <sup>4</sup>Univ of MN and CCDOR VA Medical Center, Minneapolis, MN, USA, <sup>5</sup>Univ of Maryland, Baltimore, MD, USA.

The validity of the WHO 10-year probability of osteoporotic fracture model ('WHO FRAX model') for prediction of vertebral fracture has not been tested. We analyzed how well the WHO model for osteoporotic fractures (with and without femoral neck BMD (FN BMD)) predicted the risk of vertebral fracture. We also compared the predictive validity of the WHO FRAX model, femoral neck BMD, and prevalent vertebral fracture detected by radiographs at baseline alone or in combination.

We analyzed data from the placebo groups of FIT (3.8 yrs follow-up, n=3221) with odds ratios (OR) and areas under receiver operating characteristics (ROC) curves (AUC).

The WHO FRAX model, with and without FN BMD, predicted incident radiographic vertebral fracture (Table). The AUC was significantly greater for the WHO FRAX model with FN BMD (model C) than the WHO FRAX model alone (model B) (p=0.002). Prevalent vertebral fracture is significantly associated with incident vertebral fracture (model D) (RR 4.5). Prevalent vertebral fracture plus age and FN BMD (model F) predicted incident radiographic vertebral fracture as well as prevalent vertebral fracture combined with the WHO FRAX model with FN BMD (model G) (p= 0.76). However, baseline vertebral fracture status plus age and FN BMD (model F), predicted incident radiographic vertebral fracture a significantly better than the WHO FRAX model with FN BMD (model C) (p=0.0017), Table.

The WHO FRAX model (with and without FN BMD) predicts vertebral fracture. However, the WHO FRAX model alone does not significantly improve the prediction of vertebral fracture when FN BMD and age are known. A model including baseline radiographic vertebral fracture, FN BMD and age is the strongest predictor of future vertebral fracture. Given the strong association between prevalent vertebral fracture and incident vertebral fracture, it may be important to consider these in future revisions of the WHO FRAX model.

Predictors	OR*(95% CI)	AUC (95%CI)
A: FN BMD + Age	1.6 (1.7, 1.9)	0.71 (0.67, 0.74)
B: WHO 10-year risk of osteoporotic fracture <sup>†</sup>	1.8 (1.5, 2.0)	0.68 (0.65, 0.71)
C: WHO 10-year risk of osteoporotic fracture <sup>†</sup> + FN BMD	1.9 (1.7, 2.2)	0.71 (0.68, 0.74)
D: Baseline vertebral fracture	4.5 (3.4, 6.0)	0.68 (0.64, 0.71)
E: Baseline vertebral fracture + age	3.8 (2.8, 5.0)	0.73 (0.70, 0.76)
F: Baseline vertebral fracture + age + FN BMD	3.3 (2.5, 4.5)	0.76 (0.72, 0.79)
G: Baseline vertebral fracture + WHO 10-year risk osteoporotic fracture + FN BMD	3.3 (2.4, 4.4)	0.75 (0.72, 0.78)

\*OR: A (per 1SD decrease in FN BMD); B/C (per 1SD increase in WHO ); D/E/F/G (presence of baseline vertebral fracture)

<sup>†</sup>WHO models include age

AUC: Area Under the Curve

## 1128

**Incident Vertebral Fracture is Predicted by Prevalent Vertebral Fracture as Identified by the Algorithm-Based Qualitative Method, but Not by Non-osteoporotic Short Vertebral Height. The Rancho-Bernardo Study.** G. Jiang<sup>\*1</sup>, E. Barrett-Connor<sup>2</sup>, D. L. Schneider<sup>\*2</sup>, R. Eastell<sup>1</sup>, L. Ferrar<sup>\*1</sup>. <sup>1</sup>Academic Unit of Bone Metabolism, NGH, University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>Department of Family & Preventive Medicine, University of California San Diego, San Diego, CA, USA.

Osteoporotic vertebral fracture (OVF) is a strong predictor of incident fracture risk. The algorithm-based qualitative method (ABQ) identifies fewer prevalent vertebral fractures than other methods, because short height without depression at the central endplate is excluded as non-osteoporotic short vertebral height (SVH). The ABQ method has not been applied previously for the identification of incident OVF. The aims of this analysis were to 1) evaluate the identification of OVF by ABQ and 2) test the association between prevalent and incident OVF identified by ABQ.

An experienced radiologist applied the ABQ method to assess paired thoracic and lumbar spine radiographs (lateral projection) obtained over an average of 10 years follow-up in 255 men and 390 women (ages 49 to 88, mean 66 years, median 65 years) participating in the population-based Rancho Bernardo Study. For the identification of incident OVF, radiographs from both visits were assessed alongside each other. Participants were classified as follows: i) OVF, ii) SVH (no OVF) or iii) normal (no OVF, no SVH); participants with both OVF and SVH (in a different vertebra) were classified to the OVF group.

The prevalence of OVF was 10% (n = 62). There was a trend towards higher prevalence in men (12%) than in women (8%). The most common site of OVF was the thoraco-lumbar junction. The prevalence of SVH was 24% (n = 152) and was similar in men (27%) and in women (25%), with vertebral anterior height approximately 25% shorter than expected. These were mainly in the mid-thoracic region. The 10 year incidence of OVF was 5% (n = 35), tended to be lower in men (4%) than in women (7%). The incidence of OVF in those with prevalent OVF was much higher (18%) than in those with SVH (3%). The relative risk (logistic regression analysis) of incident OVF was 5.02 (95% CI: 2.33 to 10.8, P<0.01) and 0.74 (95% CI: 0.27 to 2.02, P=0.54) for participants with prevalent OVF and SVH respectively.

Conclusions: 1) OVF identified by ABQ had a trend towards higher incidence but lower prevalence in women than in men; 2) prevalent OVF by the ABQ method was a strong predictor of incident OVF; 3) SVH without evidence of OVF was more common than OVF but did not predict incident OVF.

## 1129

**Spine Shape Predicts Vertebral Fractures in Postmenopausal Women.** M. Bruijine<sup>\*1</sup>, P. Pettersen<sup>\*2</sup>, A. Ghosh<sup>\*3</sup>, M. Sorensen<sup>3</sup>, M. Nielsen<sup>\*4</sup>. <sup>1</sup>Biomedical Imaging Group, Erasmus MC - University Medical Center Rotterdam, Rotterdam, Netherlands, <sup>2</sup>Center for Clinical and Basic Research, Ballerup, Denmark, <sup>3</sup>Nordic Bioscience, Herlev, Denmark, <sup>4</sup>Department of Computer Science, University of Copenhagen, Copenhagen, Denmark.

Early diagnosis and treatment of patients at high risk of developing fragility fractures is crucial in the management of osteoporosis. The purpose of this study was to investigate whether the shape of the spine as can be observed from lateral X-rays is indicative for the risk of future development of fragility fractures in the spine.

The study included 568 elderly women of whom 455 maintained skeletal integrity during the mean observation period of 4.8 years and 113 sustained at least one vertebral fracture in the same period. At baseline, none of the women had experienced a previous osteoporotic fracture, and the two groups were not significantly different in terms of age (66.2 ± 0.2 vs. 66.1 ± 0.4), spine BMD (0.77 ± 0.004 vs. 0.76 ± 0.008), body weight (64.7 ± 0.4 vs. 64.6 ± 0.8), height (160.6 ± 0.3 vs. 161 ± 0.5), and number of years since menopause. A radiologist annotated the corner points and mid points of the vertebral end plates of each vertebra from L5 to T4 on digitized lateral radiographs taken at the baseline visit. These points together describe a combination of factors characterizing the spinal shape, including the shape and the size of individual vertebral bodies and intervertebral disks, alignment of vertebrae, and spinal curvature. The positions of the points were subsequently used as the input features to train a pattern classification system to discriminate between spines of women maintaining skeletal health and spines sustaining a fracture in the near future (regularized linear discriminant analysis). Applied to an annotated X-ray image of an unfractured spine, this classification model then provides a measure of the probability that the spine will develop a fracture.

In a leave-one-out experiment, in which the classification models were constructed from a training set excluding any images of the patient under study, fracture probability measures were significantly different between the two groups at baseline (0.26 ± 0.02 vs. 0.18 ± 0.006, p < 10<sup>-6</sup>). Incident fractures could be predicted from the baseline image with 80% accuracy; the area under the ROC curve (AUC) was 0.65, and the odds ratio (OR) for fracture 5.2 [95% CI 2.3, 11.6]. Significant predictive value remained after adjustment for age and spine BMD (p < 10<sup>-6</sup>, AUC=0.66, OR=2.0 [1.0, 3.9]). Measures of spine shape can predict vertebral fractures in postmenopausal women, independent of age and spine BMD. The herein presented computer based diagnostic tool could be a useful supplement to existing approaches to fracture risk assessment.

**Thoracic Kyphosis Index as a Risk Factor for Incident Vertebral Fractures and Alteration of Quality of Life in Postmenopausal Women with Osteoporosis.** C. Roux<sup>1</sup>, K. Briot<sup>1</sup>, S. Kolta<sup>1</sup>, R. Said-Nahal<sup>1</sup>, C. Benhamou<sup>2</sup>, J. Fechtenbaum<sup>1</sup>. <sup>1</sup>Rheumatology, Cochin Hospital, Paris, France, <sup>2</sup>Rheumatology, Orleans Hospital, Orleans, France.

Thoracic kyphosis, frequent in the elderly and in postmenopausal osteoporosis has been associated with impairment in global health, but limited prospective data exist. The objectives of this study were to assess quantitatively the thoracic kyphosis, the relationship between thoracic kyphosis and the risk of incident fractures, and the influence of thoracic kyphosis on quality of life in osteoporotic patients.

This study was performed on women with postmenopausal osteoporosis from the placebo groups of SOTI<sup>1</sup> and TROPOS<sup>2</sup> studies, aiming to demonstrate the efficacy of strontium ranelate against vertebral and non-vertebral fractures. Patients underwent lateral radiographs of the thoracic and lumbar spine at baseline and annually over 3 years (standardized procedures). Vertebral fractures were assessed (Genant score), and a kyphosis index at baseline (KI) was defined on lateral thoracic radiographs as the ratio BD/AC (AC= line from the anterior superior edge of T4 to the anterior inferior edge of T12; BD= perpendicular line from the furthest superior or inferior posterior point of T7, T8 or T9 vertebrae to AC line) expressed as a %. An assessment of quality of life was performed with the SF-36® generic questionnaire and the disease-specific QUALIOST® questionnaire.

The study was conducted in 2017 patients (mean age of 73.4±/6.1), with a mean lumbar spine T score of -3.06±/1.52; a mean hip T-score of -2.97±/0.66, and a mean KI of 25.41±/5.26. Patients in the highest KI tertile had significantly more new vertebral fractures (RR = 1.52 (95%CI 1.19; 1.96) p<0.001), over the study period (incidence 27.36%), compared to those in the medium tertile (incidence 19.07%) or in the lowest tertile (incidence 17.31%) (RR= 1.70 (95%CI 1.32; 2.21) p<0.001). The differences remained statistically significant after adjustment on the presence of prevalent fracture, confirming that the KI clearly participates in the risk for vertebral fractures. For both SF 36 and QUALIOST, changes in the physical score reflected significantly a better status for patients in the lowest tertile of KI as compared to patients in the highest tertile of KI.

These prospective results demonstrate that thoracic kyphosis is a risk factor for vertebral fractures over 3 years, and influences the quality of life in patients suffering osteoporosis. The thoracic kyphosis index is therefore a relevant tool for assessment of post menopausal women with osteoporosis.

**Three Methods of Lumbar Spine DXA Analysis as a Means to Predict Male Fracture.** K. E. Hansen<sup>1</sup>, L. Palermo<sup>2</sup>, A. N. Jones<sup>3</sup>, R. D. Blank<sup>1</sup>, H. A. Fink<sup>3</sup>, E. Orwall<sup>4</sup>. <sup>1</sup>U of WI School of Medicine & Public Health, Madison, WI, USA, <sup>2</sup>Epidemiology Department, UCSF, San Francisco, CA, USA, <sup>3</sup>VAMC, Minneapolis, MN, USA, <sup>4</sup>Oregon Health & Science University, Portland, OR, USA.

The DXA L1-L4 T-score (spine-T) is a weaker predictor of fracture (fx) in men than the femoral neck T-score (FN-T), likely from spurious elevation of bone mineral density (BMD) by spine osteoarthritis. We hypothesized that an osteoporosis diagnosis using the lowest vertebral body T-score (low-T) would predict fx better than spine-T, the International Society for Clinical Densitometry determined spine T-score (ISCD-T) or the L1-L4 T-score using female reference data (female-T).

We performed a case-control study within the Osteoporotic Fractures in Men (MROS) Study, a prospective cohort of men aged ≥65 years. Cases (n=484) were all men with incident clinical fracture by February 2007 and controls were randomly selected men without fx (n=1509). We determined four T-scores from each baseline BMD scan. An ISCD-T was possible for 1205 men. We determined sensitivity, specificity, positive and negative predictive value (PPV, NPV) and area under the curve (AUC) for each method of spine analysis. In logistic regression analysis, we controlled for other covariates that may influence fx risk, deriving odds ratios (OR) with 95% confidence intervals (CI) for fx based on an osteoporosis diagnosis by each analytic method.

Using a T-score threshold of -2.5 to diagnose osteoporosis, each analytic method demonstrated similar sensitivity, specificity, PPV and NPV. All four T-scores highly correlated (r=0.961 to 0.998). In 1993 men, the AUC for each method ranged from 0.529 to 0.558 (p=0.004, low-T vs. lumbar-T and p=0.003, low-T vs. female-T) with similar overlapping OR for fx (OR 1.99-2.68) in unadjusted analyses. In 1205 men for whom four T-scores were possible, the AUC ranged from 0.542 to 0.584 (p=0.002 for low-T vs. lumbar-T, p=0.01 for ISCD-T vs. low-T and p=0.002 for low-T vs. female-T) with similar OR for fx (OR 1.96-2.55) in unadjusted analyses. In analyses controlling for other covariates influencing fx risk including the FN-T, each method gave similar additional information on the OR for fx.

We conclude that lumbar spine T-scores provide additional information on fx risk in men beyond that provided by the FN-T. However, when using an arbitrary T-score threshold of -2.5 to diagnose spine osteoporosis, no lumbar spine analytic method is clearly superior to the others.

	Method	Sensitivity & Specificity	PPV & NPV	Adjusted OR (95% CI)
n=1993	Lumbar-T	14 & 93	38 & 77	1.56 (1.08, 2.27)
	Low-T	27 & 84	36 & 78	1.66 (1.26, 2.19)
	Female-T	10 & 96	45 & 77	2.10 (1.33, 3.32)
n=1205	Lumbar-T	22 & 88	38 & 76	1.47 (1.00, 2.17)
	ISCD-T	28 & 83	37 & 77	1.55 (1.09, 2.21)
	Low-T	41 & 76	37 & 79	1.81 (1.33, 2.47)
	Female-T	15 & 94	45 & 76	2.04 (1.28, 3.26)

**Cortical Porosity Is Increased in Male Osteoporosis with Vertebral Fracture.** A. Ostertag<sup>1</sup>, M. Cohen-Solal<sup>1</sup>, C. Marty<sup>1</sup>, D. Chappard<sup>2</sup>, M. C. de Vernejoul<sup>1</sup>. <sup>1</sup>606, INSERM and Paris 7 University, Paris, France, <sup>2</sup>922, INSERM and Angers University, Angers, France.

In men, vertebral fractures are poorly associated with bone density, and both cortical and trabecular micro-architectural changes could contribute to bone fragility. Bone histomorphometry makes it possible to investigate both the thickness and porosity of cortical bone, which has been reported to have a major impact on the biomechanical properties of bone. We therefore conducted a transversal study using iliac crest biopsies to investigate the trabecular and cortical bone structure in men with or without vertebral fractures. We selected 93 bone biopsies from male patients with idiopathic osteoporosis (defined as a T-score <-2.5), between 40 and 70 years of age. Patients were divided into two groups on the basis of the presence (n=46) or absence (n=47) of prevalent vertebral fracture (VFX). We measured micro-architectural indices in trabecular and cortical bone by histomorphometry at the iliac crest. Patients with VFX had lower trabecular bone volume (BV/TV: 12.4 ± 3.8 versus 14.7 ± 3.1 % (m ± SD)), p <0.01, higher trabecular separation (Tb.Sp: 871 ± 279 versus 719 ± 151 µm, p<0.01), and higher marrow star volume (V\*<sub>m.space</sub>: 16.17 ± 12.57 versus 9.45 ± 4.66 mm<sup>3</sup>, p<0.01). Cortical thickness was the same in patients with or without VFX, whereas cortical porosity (Ct.Po) was higher in patients with VFX (6.5 ± 2.6 versus 5.0 ± 2.0 %, p <0.01), because their Haversian canals had higher mean areas (8291 ± 4135 versus 5438 ± 2809 µm<sup>2</sup>, p<0.001). There was no correlation between any trabecular and cortical micro-architectural parameters. Using a logistic regression model, we evaluated the VFX as a function of the V\*<sub>m.space</sub> and Ct.Po, adjusted for age. The odds-ratio of having a VFX was 3.89 (95% CI 1.19-12.7, p=0.02) for the third tertile of V\*<sub>m.space</sub> (adjusted on age and Ct.Po), and 4.07 (95% CI 1.25-13.3, p=0.02) for the third tertile of Ct.Po (adjusted on age and V\*<sub>m.space</sub>).

Finally, we assessed the bone balance in the cortical bone. We observed that in patients with fractures, the osteon diameter was the same, but the Haversian canal diameter was non-significantly higher in patients with VFX. As a consequence, wall thickness was identical at the BMU level, and the balance was non-significantly lower in patients with fractures. In conclusion, our data show that both trabecular and cortical bone microarchitecture contribute independently to vertebral fractures in men with idiopathic osteoporosis. In contrast to data reported in women, in men it is cortical porosity, and not cortical width, that is associated with vertebral fractures. This suggests that the cortical deficit is different in men and in women with fragility fractures.

**Paget's Disease of Bone: A Histologic and Histomorphometric Analysis of Bone Biopsies from 754 Patients.** S. Seitz<sup>1</sup>, M. Priemel<sup>1</sup>, J. Zustin<sup>2</sup>, F. T. Beil<sup>1</sup>, T. Schinke<sup>1</sup>, K. Püschel<sup>3</sup>, J. Semmler<sup>4</sup>, H. Minne<sup>3</sup>, M. Amling<sup>1</sup>. <sup>1</sup>Center for Biomechanics, Experimental Trauma Surgery & Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>2</sup>Department of Bone Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>3</sup>Department of Forensic Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>4</sup>Immanuel Hospital, Berlin, Germany, <sup>5</sup>Clinic Fürstenthof, Bad Pyrmont, Germany.

Paget's disease of bone (PDB) is the second most common metabolic bone disease. Although characteristic histological features of PDB are often described, quantitative analysis on the histological and especially on the histomorphometrical level is rare. Therefore, the aim of this study was to analyze, on the basis of the Hamburg Bone Register, PDB in terms of incidence, skeletal distribution, malignant transformation, as well as histological and histomorphometrical characteristics. Bone biopsies and patient files of 754 cases (330 women and 424 men) with histologically proven PDB were reviewed in a retrospective study. The peak incidence of PDB was between 70 and 80 years of age, and 72% of the patients with PDB were older than 60 years. The majority of monoostotic skeletal manifestation was localized at the pelvis, followed by the spine and the femur. Histological evaluation was performed on undecalcified sections of all cases. Quantitative static histomorphometry was performed on a representative subgroup of 247 biopsies derived from patients with manifestation of PDB at the iliac crest and compared to iliac crest bone biopsies of an age- and sex-matched control group from skeletal healthy patients using the Osteomeasure system according to ASBMR standards. Here we observed a more than 2-fold increase of bone volume in the biopsies derived from patients with PDB, accompanied by a 6-fold increase of osteoid volume, indicating a high turn over status or a defect of bone matrix mineralization. Cellular parameters demonstrated a more than 20-fold increase in osteoclast and osteoblast number. Paget sarcoma was diagnosed in 6 of 754

patients, suggesting a risk of malignant transformation in 0.8 % of the affected patients. Taken together, our study characterizes PDB in Germany on the basis of one of the largest cohorts of patients with histologically proven PDB. Moreover, for the first time a quantitative histomorphometric approach was taken for more than 200 cases, where we were able to demonstrate local high bone mass lesions as a result of an increase of both osteoclast and osteoblast indices.

Amling<sup>1</sup>. <sup>1</sup>Department of Trauma-, Hand- and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Center of Biomechanics and Skeletal Biology, Hamburg, Germany, <sup>2</sup>Department of Clinical Chemistry, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>3</sup>Department of Forensic Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Although it is well established that bone mineral density decreases with age, a complete analysis of bone quality can only be achieved by a full histomorphometric evaluation of biopsies. This is especially important, since current techniques to quantify bone mineral density, such as DXA or qCT, cannot distinguish between low bone mass with normal matrix mineralization and osteomalacia. Thus, to evaluate bone status in Northern Germany, an area known for its high prevalence of vitamin D insufficiency, we examined 1180 iliac crest biopsies from male and female individuals aged between 20 to 99 years, excluding all patients who had signs of secondary osteopathies at autopsy. All biopsies were embedded undecalcified and processed histologically. Histomorphometric parameters, including bone volume, trabecular number, trabecular thickness, trabecular separation and osteoid volume, were quantified using the Osteomeasure system according to ASBMR standards. Statistical analysis was performed by student's t-test. Consistent with previously described studies involving less samples we found a significant reduction of the trabecular bone volume with age. This was mostly explained by a significant reduction of trabecular number, while trabecular thickness only changed moderately with age. Most importantly however, we observed that more than 25% of the individuals displayed a pathologic increase of non-mineralized bone matrix, i.e. an osteoid volume exceeding 2%. Interestingly, measuring the 25-OH-cholecalciferol levels in the serum of these individuals revealed that all of them had levels below 75nmol/l, while none of the patients above this threshold presented osteomalacia. Moreover, by combining the data of all individuals, we observed unexpected low serum levels of 25-OH-cholecalciferol (mean: 22.35 nmol/l SD:  $\pm 17.66$ ), which were even more reduced in individuals analyzed between October and March. Thus, since osteoid volume did not increase with age, it appears that the high prevalence of osteomalacia in Northern Germany is mostly caused by insufficient UV-light, as it has already been suggested in studies from countries with similar latitude relating vitamin D and PTH.

**Effects of Aromatase Inhibitor Therapy on Bone Mineral Density in Hypogonadal Elderly Men.** B. Z. Leder, M. Dere\*, S. M. Burnett-Bowie. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Androgens and estrogens independently regulate bone metabolism in men though the relative influence of each is unknown. Recently, aromatase inhibition (AI) has been proposed as a therapeutic intervention in older men with hypogonadism. Preliminary studies have demonstrated that aromatase inhibitors normalize serum androgens in hypogonadal men while lowering serum estrogens modestly. Whereas the combination of increasing serum androgens and decreasing estrogens may have advantages over standard testosterone (T) therapy in some organ systems (such as the prostate), the net effects on skeletal integrity are unknown.

To assess the effects of sustained AI on the skeleton in hypogonadal men age 60+, we randomized 69 men (mean age 66 $\pm$ 5) with T levels between 150-300 ng/dL on a single measure or between 300-350 ng/dL on two consecutive measures (mean 328 $\pm$ 92 ng/dL) to receive the aromatase inhibitor anastrozole (1 mg po QD) or matching placebo for 1 year. Gonadal steroids were measured at months 3, 6 and 12, while BMD of the spine, fem neck and total hip was measured at baseline and month 12 (DXA). Bone turnover markers are being analyzed and will be reported.

Subjects were well matched. The changes in hormone levels and BMD are plotted below. In the anastrozole group, mean T increased from 321 $\pm$ 94 ng/dL at baseline to 525 $\pm$ 139 ng/dL at wk 12 (p<0.0001 vs baseline and PBO). At wk 48, mean serum T remained significantly higher than baseline and PBO (476 $\pm$ 146 ng/dL) but lower than at wk 12 (p=0.03 wk 12 vs. wk 48). Changes in BioT (by direct measurement) revealed a similar pattern. As expected, anastrozole therapy modestly but significantly lowered estradiol levels; from 15 $\pm$ 4 pg/mL at baseline to 12 $\pm$ 4 pg/mL at month 3, remaining stable thereafter (p<0.001 vs baseline and PBO). BMD at all sites was unaffected by AI (P=NS compared to baseline and PBO)

In summary, anastrozole therapy significantly increased serum T and modestly lowered estradiol in men 60+ with symptomatic hypogonadism. Despite the decrease in estradiol, BMD at all sites remained stable. The lack of BMD changes suggests that AI therapy will not adversely affect skeletal integrity in older hypogonadal men. This lack of an effect may be due to the relatively small decrease in serum estradiol, the concomitant increase in T, or both. Assessment of bone turnover markers and geometry of DXA bone images may provide further insight into the effects of this intervention on the skeleton.

**Mechanism of Action of the Anti-Aging Agent Resveratrol on bone.** M. Zhao<sup>1</sup>, S. Ko<sup>\*1</sup>, J. R. Edwards<sup>1</sup>, I. R. Garrett<sup>2</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Vanderbilt Center for Bone Biology, Medicine/Clinical Pharmacology, Vanderbilt University, Nashville, TN, USA, <sup>2</sup>Bone and Drug Device R&D, Orthobiologics Zimmer, Inc, Austin, TX, USA.

The anti-aging natural product resveratrol has been shown to increase bone mass in rats, but the mechanism of action is unknown. Recently, we have found that the longevity-associated gene SIRT-1, an NAD<sup>+</sup>-dependent histone deacetylase, is required for maintenance of normal bone mass, since mice null for SIRT-1 have decreased bone mass associated with decreased osteoblast differentiation and increased osteoclast activity. Independently, resveratrol has been shown to be an agonist of SIRT-1. Therefore, we determined if the mechanism of action of resveratrol on bone formation is mediated by agonist effects on SIRT-1 in osteoblasts. We examined the expression profile of the SIRT-1 gene in 2T3 osteoblastic cells, and found that SIRT-1 mRNA expression correlated with osteoblast differentiation. We then found that resveratrol treatment dose-dependently increased SIRT-1 mRNA expression in 2T3 osteoblasts and promoted osteoblast differentiation of these cells, as assessed by real time PCR and ALP activity. Next, we determined the relationship between SIRT-1, eNOS and resveratrol. Our reasons for doing this were several-fold. eNOS null mice have decreased bone mass (Armour et al, 2001), indicating that eNOS is required for normal postnatal bone formation, and the eNOS null mouse bone phenotype mimics that of the SIRT-1 bone phenotype. SIRT-1 has been shown to activate eNOS in other cell types, because of its deacetylase activity. Thus, we hypothesized that resveratrol, a SIRT-1 agonist, may sequentially increase both SIRT-1 and eNOS in osteoblasts. Therefore, we examined the effects of resveratrol on eNOS enzymatic activity and mRNA expression in osteoblasts. We found that resveratrol not only dose-dependently increased production of the eNOS product nitric oxide (NO), but also enhanced eNOS mRNA expression in osteoblasts. Next, we examined the effects of eNOS/NO on BMP-2 expression in osteoblasts. We found that incubation of 2T3 osteoblastic cells or calvarial bone organ culture with NO donors (SNP, NOC22) enhanced BMP-2 mRNA expression, osteoblast differentiation and bone formation. Using eNOS knockout mice, we found that eNOS deficiency in osteoblasts inhibited BMP-2 transcription and osteoblast differentiation. Importantly, we found that administration of resveratrol to eNOS null osteoblasts did not enhance BMP-2 gene expression and cell differentiation. Together, these data suggest that resveratrol increases SIRT-1 expression and activity, and in turn eNOS expression and activity, and by this mechanism, stimulates BMP-2 expression, osteoblast differentiation and bone formation.

**Stimulation of Fracture Healing by Recombinant Human Platelet-Derived Growth Factor BB (rhPDGF-BB) Combined with  $\beta$ -Tricalcium Phosphate/Collagen Matrix in a Diabetic Rat Fracture Model.** L. Al-Zube<sup>1</sup>, E. A. Breitbart<sup>\*1</sup>, A. M. Simon<sup>\*1</sup>, J. P. O'Connor<sup>\*1</sup>, C. S. Young<sup>2</sup>, G. Bradica<sup>\*3</sup>, C. E. Hart<sup>\*2</sup>, D. S. Perrien<sup>2</sup>, S. Lin<sup>2</sup>. <sup>1</sup>NJMS-UMDNJ, Newark, NJ, USA, <sup>2</sup>BioMimetic Therapeutics, Inc., Franklin, TN, USA, <sup>3</sup>Kensey Nash Corporation, Exton, PA, USA.

Diabetes impairs fracture healing and has become a significant challenge in orthopedic surgery. rhPDGF-BB is a potent growth factor that is chemotactic and mitogenic to mature osteoblasts, osteoprogenitor cells and mesenchymal stem cells and synergizes with VEGF to enhance neovascularization. This study evaluated the use of rhPDGF-BB (PDGF), combined with an injectable  $\beta$ -TCP/collagen matrix formulation (GEM OS2), to enhance fracture healing in a diabetic rat. Male BB Wistar rats that spontaneously develop diabetes at ~85 days of age were used for the study. Upon diabetic conversion, blood glucose levels were maintained between 300 and 500 mg/dl representing poorly controlled Type 1 diabetes. 2 wk after conversion, rats were divided among 4 treatment groups: fracture alone (Untreated), fracture+buffer+ $\beta$ -TCP/collagen (Matrix), fracture+0.3 mg/ml PDGF+ $\beta$ -TCP/collagen (Low Dose), and fracture+1.0 mg/ml PDGF+ $\beta$ -TCP/collagen (High Dose). A closed mid-diaphyseal femoral fracture was created by blunt trauma and stabilized by an intramedullary Kirschner wire. After stabilization, the fracture was exposed, test compound implanted, and wound closed. BrdU staining at 4 d post-fracture revealed proliferation in the callus region was significantly higher for both PDGF groups compared to Untreated and Matrix groups ( $p < 0.05$ ). Torsion testing at 8 wk demonstrated a significant increase ( $p < 0.05$ ) in torque to failure as a percentage of the contralateral limb for the Low Dose group compared to Untreated and Buffer groups. Histological analysis at 12 wk showed a significant increase ( $p < 0.02$ ) in percent mineralized area in the calluses from the High Dose group compared to the other three groups. Diabetes impairs the fracture healing process beginning with a reduction in early cellular proliferation and ending with a decrease in biomechanical properties of the fracture callus. These data demonstrated that rhPDGF-BB can increase cellular proliferation in the early diabetic callus leading to improved mechanical properties and accelerated histological maturation at later time points. These results suggest a therapeutic potential for local rhPDGF-BB treatment in normalizing impaired fracture healing, specifically through stimulating cellular proliferation.

**Anti-Sclerostin Antibody Increases Bone Mass by Stimulating Bone Formation and Inhibiting Bone Resorption in a Hindlimb-Immobilization Rat Model.** W. S. S. Jee<sup>1</sup>, X. Li<sup>2</sup>, X. Y. Tian<sup>\*1</sup>, C. Paszty<sup>2</sup>, H. Z. Ke<sup>2</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT, USA, <sup>2</sup>Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA.

Anti-sclerostin monoclonal antibody (Scl-Ab) has been shown to increase bone mass and bone strength by stimulating modeling-based bone formation in an ovariectomy-induced bone loss rat model. Experimental evidence has suggested that over-loading decreases sclerostin expression and under-loading/diuse increases sclerostin expression. The purpose of this study was to determine the effects of Scl-Ab in an immobilization/diuse-induced bone loss model in which there is both a decrease in bone formation and an increase in bone resorption in the immobilized limb. Ten-month-old male S-D rats were divided into normal weight-bearing (normal-loaded, NL) and right hindlimb immobilization (under-loaded, UL) groups. Both NL and UL animals were administered Scl-Ab at 5 or 25 mg/kg by s.c. injection, 2x/week for 4 weeks. Trabecular bone histomorphometric analyses were performed on proximal metaphysis of the immobilized right tibia. Compared with NL controls, short-term (4 weeks) UL in these adult male rats induced a significant increase in eroded surface (ErS/BS, +39%), an index of bone resorption, and a significant decrease in mineral apposition rate (MAR, -25%) and bone formation rate (BFR/BS, -30%), indices of bone formation. Treatment with Scl-Ab at 5 or 25 mg/kg in UL rats induced dose-dependent and significant increases in BV/TV by 45% and 59%, Tb.Th by 38% and 70%, mineralizing surface (MS/BS) by 73% and 121%, MAR by 53% and 76% and BFR/BS by 166% and 294%, and a dose-dependent and significant decrease in ErS/BS by 33% and 42%, respectively, compared with UL rats treated with vehicle. Bone mass and bone formation parameters of the immobilized hindlimb in UL rats treated with Scl-Ab at both doses were significantly higher than in NL rats treated with vehicle, indicating that Scl-Ab treatment not only prevents the UL-induced decrease in bone formation and increase in bone resorption, but also causes increases in bone formation and bone mass above and beyond what is found in the NL vehicle group. Interestingly, the impact of Scl-Ab on bone formation and bone resorption was less pronounced in the immobilized hindlimb of UL rats as compared to its effects on hindlimb of NL rats, suggesting a role for mechanical loading in the magnitude of the response to Scl-Ab treatment. Nonetheless, these data demonstrate that Scl-Ab treatment can significantly increase bone mass in unloaded bone and, additionally, that this is achieved by a simultaneous increase in bone formation and decrease in bone resorption.

**The Effects of Alendronate or Denosumab on Cortical and Trabecular Bone Mass, Bone Strength, and Bone Mass-Strength Relationships in Mice.** M. S. Ominsky<sup>1</sup>, X. Li<sup>1</sup>, H. Tan<sup>\*1</sup>, F. J. Asuncion<sup>1</sup>, M. Barrero<sup>1</sup>, X. Y. Tian<sup>\*2</sup>, K. S. Warmington<sup>\*1</sup>, D. Dwyer<sup>\*1</sup>, M. Grisanti<sup>1</sup>, M. Stolina<sup>1</sup>, W. S. Jee<sup>\*2</sup>, W. S. Simonet<sup>1</sup>, H. Z. Ke<sup>1</sup>, P. J. Kostenuik<sup>1</sup>. <sup>1</sup>Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA, <sup>2</sup>University of Utah School of Medicine, Salt Lake City, UT, USA.

Denosumab (DMAb, a fully human anti-RANKL antibody) and alendronate (ALN, a bisphosphonate) have been shown to reduce bone turnover and to increase bone mass and bone strength in preclinical studies. The extent to which treatment-related increments in bone mass predict changes in bone strength with these two therapeutic classes has not been previously evaluated in the same study. DMAb does not recognize murine RANKL, so this study was performed with "huRANKL" knock-in mice that exclusively express a chimeric (human/murine) form of RANKL that is inhibited by denosumab. Female huRANKL mice (6-8-months-old,  $n = 9$ /group) were treated twice weekly with vehicle (Veh), DMAb (25 mg/kg IV), or alendronate (ALN, 100  $\mu$ g/kg SC) for 6 months. BMD was assessed by DXA, and lumbar vertebrae (LV), tibiae and femurs were collected for histomorphometry, micro-CT, and strength testing. DMAb and ALN each reduced trabecular and cortical bone turnover, as shown by significant reductions in mineralizing surface in LV-2 and at the endocortical surface of the tibia diaphysis. DMAb and ALN significantly increased DXA BMD of the leg and LV1-5, and both agents also increased cortical bone mass at the femur diaphysis and LV-5 by micro-CT. DMAb significantly increased trabecular bone volume and trabecular vBMD at the distal femur and LV-5 compared to Veh, while ALN did not. Three-point testing of femur diaphyses showed significant increases in peak load with DMAb and with ALN (+23 to +25%), whereas compression testing of LV-5 showed significantly greater peak load with DMAb (+53%) but not with ALN (+17% vs. Veh). Linear regression analyses of peak load versus vBMC at both sites revealed positive correlations for each treatment group, including Veh controls (combined  $R^2 = 0.56-0.66$ ). Peak load for each site also showed significant inverse correlations with bone turnover parameters such as serum TRACP-5b and mineralizing surface. These results suggest that bone strength in these mice was related to the degree of bone turnover suppression, with greater suppression predicting higher strength values. The linear relationship between bone mass and bone strength, which was evident in Veh controls, was not significantly altered by 6 months of DMAb or ALN, suggesting that material properties of trabecular and cortical bone were maintained. These data suggest that increments in bone mass with DMAb or ALN might be reasonable surrogates for improvements in bone strength under these conditions.

**Androgen Receptor Disruption Increases the Osteogenic Response to Mechanical Loading in Male Mice.** F. Callewaert<sup>\*1</sup>, K. Venken<sup>\*1</sup>, A. Bakker<sup>\*2</sup>, J. Schrooten<sup>\*1</sup>, B. Van Meerbeek<sup>\*1</sup>, S. Boonen<sup>1</sup>, R. Bouillon<sup>1</sup>, G. Verhoeven<sup>\*1</sup>, D. Vanderschueren<sup>1</sup>. <sup>1</sup>Katholieke Universiteit Leuven, Leuven, Belgium, <sup>2</sup>Vrije Universiteit Amsterdam, Amsterdam, Netherlands.

Androgen receptor (AR) and estrogen receptor- $\alpha$  (ER $\alpha$ ) activation are both required to optimize bone mass in male mice. Bone tissue also responds to mechanical loading by increasing bone formation. ER $\alpha$  is involved in the adaptive response of bone to loading, albeit only shown in female mice. To what extent either AR or ER $\alpha$  or both affect the bone's osteogenic response to loading in male mice is not known. Therefore, the role of AR and/or ER $\alpha$  activation in the response to *in vivo* loading was investigated in male and female knockout (KO) mice. The left ulnae of 20-22 week-old male WT ( $n=9$ ), ARKO ( $n=7$ ), ER $\alpha$ KO ( $n=7$ ) and AR-ER $\alpha$  double KO (dKO,  $n=9$ ) mice, as well as the left ulnae of female WT ( $n=7$ ) and ER $\alpha$ KO ( $n=8$ ) mice were subjected to dynamic axial loading for 3 days a week during 2 weeks. Each loading session consisted of 40 cycles with a peak compressive load of 2.5 N. Following each load cycle, there was a rest period of 14.9 s. The right ulnae of these mice served as the nonloaded controls. Bone responses to loading were determined via dynamic histomorphometry, following calcein injections on day 3 and 12 of the loading period.

Compared with the nonloaded ulnae, mechanical loading significantly increased the periosteal bone formation rate (PsBFR) in male WT, ARKO, ER $\alpha$ KO and dKO mice ( $p < 0.05$ ). In female mice, a significant increase in PsBFR occurred only in WT ( $p < 0.01$ ), not in ER $\alpha$ KO mice ( $p = 0.21$ ). Bone formation on the endocortical surfaces of the ulnae was not significantly affected by mechanical loading. In male mice, the loading-induced increase in PsBFR was significantly higher in ARKO (+320%,  $p < 0.05$  vs. WT) and dKO mice (+256%,  $p < 0.05$  vs. WT) compared with WT mice (+114%). This resulted from a higher increase in the periosteal mineral apposition rate (PsMAR) in ARKO and dKO mice compared with WT mice, while the periosteal mineralizing perimeter (PsMinPm) increased to a similar extent in all male groups. ER $\alpha$  disruption did not affect the AR-related increase in PsBFR following loading in dKO mice. Inactivation of ER $\alpha$  in male mice had no apparent effect on the response to loading, since the PsMinPm, PsMAR and PsBFR increased to a similar extent in male ER $\alpha$ KO compared with WT mice. In contrast, ER $\alpha$  inactivation in female mice prevented the loading-induced increase of the PsBFR ( $p < 0.01$  vs. WT).

We conclude that ER $\alpha$  is required for the full osteogenic response to loading in female mice, while ER $\alpha$  disruption in male mice has no apparent effect. In contrast, AR inactivation increases the bone's response to loading in male mice, indicating that AR activation limits the response to loading.

**Disclosures:** F. Callewaert, None.

## 1141

**Low Bone Mass and Decreased Biomechanical Response in Beta 1 Adrenergic Receptor KO but not in Beta 2 Adrenergic Receptor KO Mice.** N. Bonnet, D. Pierroz, S. Ferrari. Geneva University Hospital and Faculty of Medicine, Division of Bone Diseases, Geneva, Switzerland.

Beta 2 adrenergic receptor-deficient mice (*Adrb2R* KO) have high bone mass consecutive to increased bone formation and decreased bone resorption, whereas mice deficient for both beta 1 and 2 adrenergic receptors (*Adrb1-2R* KO) have low bone mass. We raised the hypothesis that  $\beta 1$  and  $\beta 2$  adrenergic signaling may exert opposite effects on bone. To further investigate the role of *Adrb1R* and *Adrb2R* on bone, 3 month-old female *Adrb2R* KO, *Adrb1R* KO and their respective wild type (WT) littermates, as well as *Adrb1-2R* double KO mice were subjected to cyclic axial compression strain (40 cycles, peak 1500 microstrain) of the left tibia for 7 min, 3 days/week during 2 weeks (n=7 mice for each group). The non-loaded right tibia served as a paired control. Bone mass was analyzed by DXA and trabecular and cortical microarchitecture by ex-vivo microCT. Compared to WT littermates, *Adrb2R* KO had higher trabecular bone volume fraction (BV/TV) and thickness (Tb.Th) (+52% and +19% respectively,  $p<0.05$ ) but similar cortical bone volume (C.BV) at the non-loaded tibia, whereas *Adrb1R* KO had lower BV/TV, Tb. number (Tb.N) and C.BV (-45%, -14% and -12% respectively,  $p<0.05$  vs WT). Mechanical stimulation significantly increased BMD in WT littermates and *Adrb2R* KO mice, but not in *Adrb1R* KO nor *Adrb1-2R* KO mice (Table).

Group	Loaded-unloaded tibia BMD (mg/cm <sup>2</sup> )		Unloaded tibia BMD gain (%)		Loaded tibia BMD gain (%)	
	KO	WT	KO	WT	KO	WT
<i>Adrb2R</i>	6 ± 0.5 *	4 ± 0.5 *	0	+1.85	+8.1 *	+6.6 *
<i>Adrb1R</i>	0 ± 0.5 #	9 ± 0.5 *	-1.85	-1.72	+1.72 #	+7.4 *
<i>Adrb12R</i>	1 ± 1	NA	-1.75	NA	0	NA

\*  $p<0.05$  for compression effect; #  $p<0.05$  vs WT littermate. NA, not available.

Hence, the BMD response to compression was significantly greater in *Adrb2R* KO than *Adrb1R* KO and *Adrb1-2R* KO mice. Similarly, BV/TV and Tb.Th increased in loaded tibias of WT littermates and *Adrb2R* KO mice, but not in *Adrb1R* KO nor *Adrb1-2R* KO mice. Moreover, *Adrb2R* KO mice had a significant increase of C.BV at the tibial midshaft in response to mechanical stimulation (+11%,  $p<0.01$  by paired T-test), whereas other groups did not.

These results confirm that *Adrb2R* KO mice have high bone mass whereas *Adrb1R* KO mice have low bone mass. Furthermore, the response to mechanical loading was preserved and possibly increased in *Adrb2R* KO mice, consistent with  $\beta 2$ -adrenergic inhibitory effects on bone formation, whereas mechanical loading was not effective in absence of  $\beta 1$ -adrenergic signalling, consistent with *Adrb1* stimulatory effects on bone formation. The lack of mechanical response in *Adrb1-2R* KO mice further suggests that  $\beta 1$ -adrenergic effects on bone may predominate on  $\beta 2$ -adrenergic effects.

**Anabolic Response to Skeletal Loading in Mice with Targeted Disruption of Pleiotrophin Gene.** C. Kesavan, S. Mohan. Musculoskeletal Disease Center, Jerry L Pettis VA Medical Center, Loma Linda, CA, USA.

Bone formation induced by mechanical loading (ML) results from increased recruitment, proliferation and differentiation of osteoblast lineage cells. Pleiotrophin (PTN), an extracellular matrix associated protein, implicated in diverse functions, is also involved in recruitment of the osteoblasts to the site of bone formation. In a recently published study using whole genome microarray approach to identify the genes and the signal pathways responsible for ML-induced bone formation, we found that PTN expression was increased by 4-fold in response to ML in a good responder C57BL/6J (B6) mice. Furthermore, transgenic overexpression of PTN in mice resulted in increased bone formation. Therefore, we sought to determine whether the anabolic effects of ML on bone formation are mediated by PTN. We first evaluated time course effects of ML on expression levels of PTN gene using real time RT-PCR in 10 week old female B6 mice. A 9N load was applied using a four-point bending device at 2Hz frequency for 36 cycles, once per day for 2, 4 and 12 days on the right tibia and the left tibia was used as internal control. Four-point bending caused an acute increase in PTN expression (2-fold) within 2 days of loading and further increased (3 to 6 fold) with continued loading (4 to 12 days). The increase in PTN expression in response to ML was also seen in 16 and 36-week old mice. Based on these findings, we next used mice with targeted disruption of PTN gene to evaluate the cause and effect relationship between the change in PTN expression and ML induced changes in bone response. Since the mechanical strain produced by a given load depends largely on bone size, we measured periosteal circumference in the tibia of knockout (KO) and control mice and found no differences ( $4.55\pm 0.24$  vs  $4.69\pm 0.21$ ,  $p=0.50$ ). We, therefore, applied 9N load for both groups of mice (n=6-7). Quantitative analysis of ML-induced skeletal response measured by pQCT showed that two weeks of four point bending increased vBMD and bone size by 8% and 6% respectively in the PTN KO mice compared to the 11% and 8% increases seen in the littermate control mice. Although BMD and bone size response to ML were reduced by 23% ( $p=0.21$ ) and 18% ( $p=0.13$ ) respectively in PTN KO mice compared to control mice, these changes were not statistically significant. The issue of whether lack of significant difference in ML response between PTN KO and control mice is due to compensation by other members of PTN family is being pursued. In conclusion, our findings using PTN KO mice seem to suggest that PTN is not a key upstream mediator of the anabolic effects of ML on the skeleton.

**Inhibition of Bone Biomechanical Response to Physical Activity and Loading in Mice Lacking Periostin.** N. Bonnet<sup>1</sup>, S. Conway<sup>\*2</sup>, S. Ferrari<sup>1</sup>. <sup>1</sup>Geneva University Hospital and Faculty of Medicine, Division of Bone Diseases, Geneva, Switzerland, <sup>2</sup>Indiana University School of Medicine, Wells Center for Pediatric Research, Indiana, IN, USA.

Periostin is an osteoblast-specific factor involved in cell recruitment and adhesion. We previously reported that periostin-deficient mice (POSTN <sup>-/-</sup>) mice have low bone mass and altered cancellous and cortical bone microarchitecture. Here we investigate the role of periostin on bone microstructure and strength in response to active and passive mechanical stimuli.

Three month-old female POSTN <sup>-/-</sup>, <sup>+/+</sup> and <sup>+/-</sup> mice were subjected to treadmill exercise (EXE) (45min/day, 5days/week) for 5 weeks or left untrained (UN). Another group of mice received direct mechanical stimulation by cyclic axial compression strain (40 cycles, peak 1500 microstrain), applied to the left tibia for 7 min, 3 days/week for a period of 2 weeks, while the right unloaded tibia served as paired control. Bone mass was analyzed by DXA, trabecular and cortical microarchitecture by ex-vivo microcomputed tomography, biomechanical properties by 3 point bending, and bone formation indices by histomorphometry of the tibia.

In <sup>+/+</sup> mice, EXE significantly increased BMD gain at the tibia compared to UN ( $+6.2\pm 3\text{mg/cm}^2$  vs  $+0.8\pm 2\text{mg/cm}^2$ ,  $p<0.05$ ), as well as trabecular bone volume fraction (Tb. BV/TV) and Tb. number (TbN) (+25% and +16%, respectively, in EXE vs UN,  $p<0.01$ ). Similar trends were observed on cortical bone volume (C.BV) and thickness (C.Th) at the tibial midshaft. Histomorphometric analysis indicated higher MAR, BFR and MP/BP at periosteum in EXE vs UN (+316%, +550% and +364%, respectively,  $p<0.01$ ). In contrast, exercise had no effect on BMD, BV/TV, TbN, C.Th, or bone formation indices in POSTN <sup>-/-</sup> nor <sup>+/-</sup> mice. As a consequence, the stiffness, elastic energy and the Young modulus were significantly higher in EXE vs UN among <sup>+/+</sup> mice (+36%, +25% and +30% respectively,  $p<0.05$ ), but not <sup>-/-</sup> nor <sup>+/-</sup> mice. Following axial compression, the loaded tibia had a significantly higher C.BV, C.Th, and periosteal MP/BP compared to the non-loaded tibia in both <sup>+/+</sup> and <sup>+/-</sup> mice, whereas <sup>-/-</sup> mice remained unaffected.

These results indicate that periostin plays an important role in the mechanotransduction of physical activity and loading stimuli. The cellular and molecular mechanisms by which periostin decreases the threshold for bone formation are currently under investigation.

**Regulation of Parameters of Bone Quality by MMP-2 and MMP-9.** J. S. Nyman<sup>1</sup>, S. Thiolloy<sup>\*2</sup>, C. C. Lynch<sup>\*1</sup>, C. A. Patil<sup>\*3</sup>, T. Yoshii<sup>\*1</sup>, E. O'Quinn<sup>\*1</sup>, A. Mahadevan-Jansen<sup>\*3</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Orthopaedics and Rehabilitation, Vanderbilt Center for Bone Biology, Nashville, TN, USA, <sup>2</sup>Cancer Biology, Vanderbilt University School of Medicine, Nashville, TN, USA, <sup>3</sup>Biomedical Engineering, Vanderbilt University, Nashville, TN, USA.

Bone quality is regulated independent of bone size, and one aspect of bone quality is type I collagen. Factors influencing collagen integrity have not been fully characterized. Gelatinases could be one such factor because they process denatured collagen and are expressed by bone cells. To test the hypothesis that gelatinases affect bone quality, we characterized the compositional, architectural, and biomechanical properties of bones in mice null for 2 gelatinases, MMP-2 and -9.

The left femur and left tibia of wild-type, MMP-2 or MMP-9 null mice (FVB background) were harvested at 16 weeks of age. Subsequently, we assessed 1) geometrical and structural properties of the diaphysis, trabecular bone architecture of the metaphysis and bone mineral density (BMD) by  $\mu$ CT; 2) compositional properties by Raman spectroscopy; and 3) biomechanical properties by three point bending. One-way ANOVA tested for statistically significant differences, followed by pair-wise comparisons when indicated. Femurs from MMP-2 null mice have reduced BMD and thinner cortices compared to wild-type controls. Raman spectroscopy further revealed that the tissue mineral of the null mice had poorer crystal structure (greater carbonate substitution) than that of controls. In addition, MMP-2 null femurs were 48% weaker and 32% less stiff than control femurs. When accounting for the structure of the diaphysis using the moment of inertia, the material yield strength and modulus was less in the MMP-2 null than in the control mice. In the tibia, MMP-2 deficiency caused a significant 30% decrease in bone volume fraction, and this loss was due to fewer numbers of trabeculae, not thinner trabeculae. Interestingly, MMP-9 deletion had a markedly different effect in that null femurs had a lower moment of inertia, greater BMD, thicker cortices, and higher modulus than the controls. MMP-9 did not have any effect on trabecular bone volume and architecture in the tibia. The present findings demonstrate that MMP-2 contributes to bone quality by influencing volumetric BMD, mineral lattice structure, and trabecular architecture independent of bone size. MMP-9 appears to influence bone structure and has modest effects on BMD and modulus of cortical bone. These differential roles for the gelatinases are surprising given the significant substrate overlap between the proteases. Our results have important implications in understanding how proteases contribute to bone quality and for the therapeutic development of protease inhibitors that could control specific aspects of bone quality.

**NFATc1 Mediates HDAC-dependent Transcriptional Repression of Osteocalcin Expression During Osteoblast Differentiation.** M. K. Choo\*, H. Yeo\*, M. Zayzafoon. Department of Pathology, The University of Alabama at Birmingham, Birmingham, AL, USA.

Nuclear Factor of Activated T Cells (NFAT) is a transcription factor that plays a crucial role in the activation of T lymphocytes. We recently reported that the *in vivo* and *in vitro* pharmacologic or genetic suppression of NFAT signaling increases osteoblast differentiation and bone formation. To investigate the mechanism by which NFATc1 regulates osteoblast differentiation, we established an osteoblast cell line that overexpresses a constitutively active NFATc1 (ca-NFATc1). The activation of NFATc1 in ca-NFATc1 cells was demonstrated by the nuclear localization of NFATc1 protein using western blotting and immunofluorescence staining techniques and by an increase in NFAT transactivation (700 %) as compared to parent or GFP-transduced MC3T3-E1 osteoblasts. The activation of NFATc1 in osteoblasts dramatically inhibited osteoblast differentiation and function, demonstrated by inhibition of alkaline phosphatase activity and mineralization and by an 85% decrease in osteocalcin gene expression, a late marker of osteoblast differentiation. NFATc1-inhibition of osteocalcin gene expression was due to a 70% repression of the osteocalcin promoter activity and more specifically by an 80% decrease in TCF/LEF transactivation, which has previously been shown to be an important regulatory element of this promoter. This repression occurs through the action of histone deacetylase 3 (HDAC3). Here, we show the decrease in total HDAC activity during osteoblast differentiation that leads to hyperacetylation of histones H3 and H4 in MC3T3-E1 osteoblasts is completely blocked by the overexpression of NFATc1. Specifically, we demonstrate by immunoprecipitation assay that NFATc1 and HDAC3 can physically interact. Furthermore, we show by chromatin immunoprecipitation (ChIP) assay that the association of HDAC3 with NFATc1 at the TCF/LEF consensus sequence of the osteocalcin promoter is decreased in MC3T3-GFP cells during osteoblast differentiation. However, the overexpression of NFATc1 sustains the presence of HDAC3 at TCF/LEF sequence on the osteocalcin promoter resulting in hypoacetylation of histones H3 and H4, and ultimately causing a persistent inhibition of osteocalcin gene expression and osteoblast differentiation. These results indicate that NFATc1 acts as a transcriptional co-repressor of osteocalcin promoter in an HDAC3-dependent manner.

**Circulating Osteoblast Lineage Cells Increase with PTH Treatment of Hypoparathyroidism.** M. R. Rubin, D. Dempster, S. Cremers, H. Zhou, D. McMahon, J. Sliney\*, S. Kousteni, J. Shah\*, J. S. Manavalan\*. Columbia, New York, NY, USA.

It has been hypothesized that PTH increases bone formation by increasing the supply of osteoblast precursors. These cells can be detected in the peripheral blood (PB) by flow cytometry using antibodies specific for osteoblast-specific ligands, such as osteocalcin (OCN), CD34 (an early hematopoietic stem cell marker) and CD146 (an early mesenchymal stem cell marker). To evaluate the effects of PTH deficiency and replacement on these cells, we studied 9 hypoparathyroid (hypoPT) subjects (1 male; 4 postmenopausal; 53 ± 9 yrs) at baseline in comparison to 9 age-, sex- and menopause-matched controls (Ctls). HypoPT subjects were also studied after 1, 2, 3 and 6 months (mo) of PTH(1-84) treatment (100 µg qod). Changes in osteoblast precursors in HypoPT were correlated with changes in biochemical markers of bone formation at these intervals (n=9) and with dynamic histomorphometric variables of bone formation with quadruple-labeled iliac crest bone biopsies after 3 mo of PTH treatment (n=2).

At baseline, the percent of PB cells expressing OCN (%OCN+ cells) in HypoPT was significantly lower than in Ctls (1.1 ± 1 vs 2.3 ± 1%, p=0.004). With PTH treatment, % OCN+ cells increased from baseline (1.1 ± 1%), to 1 mo (2.5 ± 2%, p=0.009), peaked at 2 mo (4.5 ± 2%, p<0.0001), started to fall at 3 mo (2.9 ± 3%, p=0.002) and returned to baseline levels by 6 mo (0.9 ± 3%, p=NS). The proportion of OCN+ cells that did not express CD34 (OCN+/CD34-) rose with PTH treatment (baseline: 48 ± 17%; 1 mo: 68 ± 17%, p<0.0001; 2 mo: 76 ± 17%, p<0.0001; 3 mo: 78 ± 18%, p<0.0001; 6 mo: 73 ± 27%, p<0.0001). Within the OCN+/CD34- population, the proportion of cells that were CD146+ (OCN+/CD34-/CD146+) increased with PTH treatment from baseline to 6 mo (8.3 ± 14 to 19.2 ± 21%, p=0.02).

The increase in the %OCN+/CD34-/CD146+ cells with PTH treatment was associated with increases in biochemical markers of bone formation, including P1NP (slope 1.8 ± 0.8; p=0.04), BSAP (slope 0.45 ± 0.2; p=0.006) and osteocalcin (slope 0.30 ± 0.14; p=0.04). Increases in osteoblast precursors also predicted increases in histomorphometric variables of bone formation: as % total OCN+ cells increased, so did cancellous osteoblast perimeter (slope 0.75 ± 0.2; p=0.02), and as % OCN+/CD34- cells increased, so did intracortical mineralized perimeter (slope 0.20 ± 0.08; p=0.04).

HypoPT subjects have reduced osteoblast lineage cells compared to normals. With PTH treatment, they experience a clinically significant increase in the number of such cells, specifically those with a more mature (OCN+/CD34-) phenotype. Moreover, the close association with biochemical and histomorphometric indices suggests that these circulating cells with osteoblast characteristics might be representative of osteoblast activities in bone.

**Telomerase Deficiency Leads to Decrease Bone Mass and Impaired Mesenchymal Stem Cells (MSC) Functions in Telomerase Deficient (TERC<sup>-/-</sup>) Mice.** H. Saeed\*, B. Abdallah, M. Kassem. KMEB lab, Department of Endocrinology, OUH, University of Southren Denmark, Odense, Denmark.

We have previously demonstrated that telomere shortening leads to *in vitro* replicative senescence of human mesenchymal stem cells (MSC) and telomerase over expression leads to telomere elongation, extended life span and enhanced bone formation (Simonsen et al (2002), Nature Biotechnology 20:592). In order to study the role of telomerase in MSC biology *in vivo*, we studied the phenotype of telomerase deficient mice caused by absence of telomerase RNA component (TERC<sup>-/-</sup>). TERC<sup>-/-</sup> displayed diminish bone mass already at 3 month of age and during 12 month follow up period (BMD (gm/cm<sup>3</sup>): TERC<sup>-/-</sup> 0.04173 vs. wild type (WT) 0.05941, p<0.0005). The decreased bone mass was associated with reduced total number of CFU-F and alkaline phosphatase positive (AP+) colonies compared to WT (P<0.005). Moreover, MSC revealed lower proliferation rate, accumulation of senescent cells, increased DNA damage (high levels of γH2AX staining) and decreased osteoblastic (OB) differentiation marker expression compared with WT. Similar impairment of *in vitro* OB differentiation of TERC<sup>-/-</sup> mouse embryonic fibroblast (MEF) was observed as well as decreased ectopic bone formation capacity when the cells implanted subcutaneously in immune deficient mice. Osteogenic super-array analysis of group of TERC<sup>-/-</sup> bone samples revealed decreased expression of several genes, like Tgfb1, Runx2, Tfp11, collagens, Igf1, Dmp1, Twist1, Phex, Tuf1 and more, known to be involved in osteoblast commitment, proliferation and maturation. Our data demonstrate that telomerase plays an important role in maintenance of stem cell functions and activation of telomerase in MSC can be a novel strategy for abolishing age-related bone loss.

**Targeted Disruption of PPARγ in Bone Marrow Stromal Cells Reveals Its Role in Aging-Induced Bone Loss.** G. Ou\*<sup>1</sup>, C. Isaacs<sup>2</sup>, M. Hamrick<sup>3</sup>, K. Ding<sup>1</sup>, S. Yang<sup>\*4</sup>, F. Gonzalez<sup>\*5</sup>, B. Kream<sup>6</sup>, X. Shi<sup>7</sup>. <sup>1</sup>Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Institute of Molecular Medicine & Genetics, and Department of Orthopaedics, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Cell Biology, Medical College of Georgia, Augusta, GA, USA, <sup>4</sup>Department of Orthopaedic Surgery, Wayne State University, Detroit, MI, USA, <sup>5</sup>Laboratory of Molecular Carcinogenesis, National Cancer Institute, NIH, Bethesda, MD, USA, <sup>6</sup>Departments of Medicine and Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, <sup>7</sup>Institute of Molecular Medicine & Genetics, and Department of Pathology, Medical College of Georgia, Augusta, GA, USA.

Peroxisome proliferator-activated receptor gamma-2 (PPARγ2), a key regulator of adipogenesis, has been implicated in osteoblast differentiation and bone formation. However, due to the embryonic lethality of global PPARγ gene knockout, the effect of tissue-specific PPARγ deficiency on bone development is unknown. Using a Cre/LoxP system we generated mice in which PPARγ gene is selectively ablated from the bone marrow stromal/progenitor cells (BMSCs), the precursors of the osteoblasts and the adipocytes, and examined the bone phenotype of these mice. We provide evidence to show that 1) the 3.6kb rat type I collagen promoter DNA fragment, which was previously thought to target preosteoblasts, is active and drives the expression of Cre recombinase robustly in BMSCs; 2) PPARγ null BMSCs attain significantly enhanced osteogenic differentiation capability in the expense of a complete loss of the ability for adipogenic differentiation; and 3) mice with BMSC-specific PPARγ gene knockout show increased bone mass preferentially at the spine of older mice, but not the younger ones, which is strikingly different from the PPARγ heterozygous mice as reported previously. Since bone remodeling is a key event maintaining the balance of bone metabolism throughout the life, these studies suggest that reducing the levels of PPARγ expression or inhibition of its activity would be promising strategies for reduction or prevention of bone loss induced by aging or medication such as anti-diabetic TZDs.

**Progressive Lipodystrophy in the Osteosclerotic Mice Over-expressing Fra1.** J. Luther<sup>\*1</sup>, M. Megges<sup>\*1</sup>, F. Driessler<sup>\*1</sup>, V. Mandic<sup>\*1</sup>, C. Zech<sup>\*1</sup>, G. Schett<sup>\*2</sup>, J. David<sup>\*2</sup>. <sup>1</sup>Bone Cell Differentiation, Deutsches Rheuma-Forschungszentrum, Berlin, Germany, <sup>2</sup>Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany.

A link between bone and fat mass has been established the last few years suggesting that common molecular mechanism are shared between osteoblast and adipocyte differentiation. We therefore analyzed the role the osteogenic transcription factor Fra1 in fat. *In vitro*, the adipogenic differentiation of primary osteoblast (POBs) isolated from the calvaria of pups over-expressing Fra1 (*fra1*-tg mice) was found to be drastically reduced when compared to wild type littermates. This effect was Fra1-dependent since constitutive or inducible over-expression of Fra1 in adipogenic cell line strongly inhibited adipocyte differentiation. It was not due to decreased cell growth. At the molecular level, the response to insulin as measured by ERK and AKT activation was unaffected. Although, the expression of key regulator of mesenchymal cell fate decision (i.e. *Runx2*, *Sox9* and *MyoD*) was unchanged; we found the adipogenic transcription factors *C/ebpβ* and *C/ebpα* to be down regulated in *fra1*-tg POBs and in adipogenic cell lines over-expressing Fra1. Consequently, *Pparγ* was also down-regulated in Fra1 over-expressing cells. The relevance of these observations was established by the finding that *fra1* transgenic (*fra1*-tg) mice that developed progressive osteosclerosis due to increased osteoblast differentiation are also developing a parallel drastic progressive lipodystrophy leading to total absence of fat tissue. The phenotype was found to be more pronounced in the females than in the males. Histologically, when present, the fat tissue appears to be immature and to be expressing high level of *Fra1* and lower level of the adipogenic marker *aP2* and *Glut4* as well as *C/ebpβ*.

Thus, our data suggest that Fra1 is promoting osteoblastogenesis and inhibiting adipogenesis this latter being caused by C/EBPβ and C/EBPα down-regulation. In addition, they demonstrate that increased bone mass can be observed in lean mice.

**Abrogation of Cbl-PI3K Interaction in Mice Results in Increased Bone Volume and Osteoblast Proliferation.** T. A. Brennan<sup>1</sup>, N. Adapala<sup>\*1</sup>, Y. Yingling<sup>2</sup>, F. Safadi<sup>1</sup>, S. Popoff<sup>1</sup>, P. Marie<sup>\*3</sup>, M. Barbe<sup>1</sup>, A. Sanjay<sup>1</sup>. <sup>1</sup>Anatomy and Cell biology, Temple University, Philadelphia, PA, USA, <sup>2</sup>Kinesiology, Temple University, Philadelphia, PA, USA, <sup>3</sup>INSERM, Paris, France.

The mammalian members of Cbl family, Cbl and Cbl-b proteins function as E3 ubiquitin ligases and although both proteins are highly homologous in the tyrosine kinase binding and the RING finger domains, there are significant differences between the two proteins in the C-terminal half. One major difference is the presence of the regulatory tyrosine 731 in the C-terminal half of Cbl. When phosphorylated this tyrosine moiety binds to the p85 subunit of phosphatidylinositol 3 kinase (PI3K). PI3K is known to regulate osteoblast apoptosis and survival. We have shown that both the SH2 and the SH3 domains of p85 bind to Cbl. However, substitution of the tyrosine 731 to phenylalanine (Y731F) completely abolishes the binding between Cbl and PI3K indicating that the tyrosine 731 is the major PI3K binding site on Cbl. Recent report suggests that Cbl negatively regulates osteoblast differentiation modulating PI3K/AKT signaling. To investigate the impact of abrogation of Cbl-PI3K interaction on the mouse skeleton we examined the bone phenotype of the Cbl<sup>Y731F</sup> knock-in mice, in which the regulatory tyrosine is substituted to phenylalanine. In contrast to the adult Cbl<sup>-/-</sup> mice, which do not have any overt bone phenotype, micro CT analysis indicated that the bone volume in the Cbl<sup>Y731F</sup> was significantly increased as compared to the control mice (WT 7.45% ± 1.11; Cbl<sup>Y731F</sup> 12.17% ± 1.36; p=0.002 vs. WT). Similarly, trabecular thickness, separation, and numbers were also increased. In contrast to the Cbl<sup>-/-</sup> mice, in which the numbers of osteoblasts were similar to the control mice, there was a 2-fold increase in the numbers of osteoblasts in the age-matched Cbl<sup>Y731F</sup> mice (WT 53/mm<sup>2</sup> ± 2.8; Cbl<sup>-/-</sup> 57/mm<sup>2</sup> ± 0.7. p= n.s. vs. WT; Cbl<sup>Y731F</sup> 104/mm<sup>2</sup> ± 1.4; p=0.001 vs. WT). Increase in bone volume also affects the ability of bones to resist stress therefore we analyzed the mechanical strength of tibiae and femurs from the 12 week-old Cbl<sup>Y731F</sup> and WT mice. A three point bending strength test of whole bone comparing the WT and Cbl<sup>Y731F</sup> tibiae and femur suggested a trend towards increased stiffness (WT 1892 Nmm<sup>2</sup> ± 228; Cbl<sup>Y731F</sup> 2165 Nmm<sup>2</sup> ± 227) and peak moment (WT 29 Nmm ± 0.07; Cbl<sup>Y731F</sup> 28 Nmm ± 1.9) in the Cbl<sup>Y731F</sup> samples indicating increased strength of the adult Cbl<sup>Y731F</sup> bones. Ex vivo analysis of bone marrow-derived Cbl<sup>Y731F</sup> osteoblasts showed a 2-fold increase in proliferation as compared to the WT cells. Taken together, these results show that attenuation of Cbl-PI3K interaction results in increased bone volume and osteoblast proliferation.

**Akt Regulates Skeletal Development Through GSK3, mTOR, and FoxOs.** S. Rokutanda<sup>\*1</sup>, T. Fujita<sup>\*1</sup>, N. Kanatani<sup>\*1</sup>, C. A. Yoshida<sup>\*1</sup>, A. Mizuno<sup>\*2</sup>, T. Komori<sup>1</sup>. <sup>1</sup>Department of Cell Biology, Unit of Basic Medical Sciences, Nagasaki University, Nagasaki, Japan, <sup>2</sup>Department of Oral and Maxillofacial Surgery, Unit of Translational Medicine, Nagasaki University, Nagasaki, Japan.

Akt/protein kinase B is a serine/threonine protein kinase, that is stimulated by IGFs-IGF receptor signaling through PI3K. The lipid product of PI3K, PIP3, recruits PDK1 and Akt to the plasma membrane and Akt is subsequently phosphorylated by PDK1 and by mTORC2 leading to full activation.

The IGFs-IGF receptor-PI3K-Akt pathway plays key roles in skeletal growth and endochondral ossification. Mice deficient either in *Igf1*, *Igf1r* or *Akt1/Akt2* showed retardation of skeletal growth and endochondral ossification. However, the downstream signaling pathways through which Akt regulates those events remain to be clarified.

To shed light on these issues, we generated and analyzed chondrocyte-specific transgenic mice expressing constitutively active Akt (myristoylated Akt; myrAkt) or dominant negative (dn)-Akt under a *Col2a1* promoter. MyrAkt transgenic mice had thickened and shortened endochondral bones. Mineralization was reduced in the limbs but enhanced in the cranial base and vertebrae due to deceleration and acceleration of chondrocyte maturation respectively. Chondrocyte proliferation was stimulated by myrAkt in the resting layer of the limbs and in the vertebrae, but it was inhibited in the limb's proliferating layer. Akt also enhanced cartilage matrix production and cell growth in both limb and vertebral skeletons. On the contrary, dn-Akt transgenic mice had smaller skeletons than wild-type mice, and chondrocyte maturation, proliferation and cartilage matrix production were inhibited, indicating that Akt positively regulates chondrocyte maturation and proliferation, cartilage matrix production, and cell growth in skeletal development.

To understand how Akt regulates these cellular processes, we focused on major Akt downstream signaling molecules: GSK3, mTOR, and FoxOs. Using organ culture systems, we revealed that the Akt-mTOR pathway is responsible for positive regulation of all four cellular processes, that the Akt-FoxO pathway enhances chondrocyte proliferation but inhibits chondrocyte maturation and cartilage matrix production, and that the Akt-GSK3 pathway negatively regulates chondrocyte maturation, proliferation and matrix production in the limbs but not in vertebrae due to less GSK3 expression in the vertebrae.

These findings indicate that Akt positively regulates the cellular processes of skeletal growth and endochondral ossification, tuning the Akt-mTOR, Akt-FoxO, and Akt-GSK3 pathways accordingly to each skeletal element.

**Dwarfism and Osteopenia in Mice with Inactivated Hypoxia-Response Element in the VEGF Gene Promoter.** C. Maes<sup>1</sup>, L. Coenegrachts<sup>\*1</sup>, I. Stockmans<sup>\*1</sup>, N. Smets<sup>\*1</sup>, P. Carmeliet<sup>\*2</sup>, R. Bouillon<sup>1</sup>, G. Carmeliet<sup>1</sup>.

<sup>1</sup>Laboratory of Experimental Medicine & Endocrinology, K.U.Leuven, Leuven, Belgium, <sup>2</sup>V.I.B. Vesalius Research Center, K.U.Leuven, Leuven, Belgium.

VEGF plays multiple crucial roles in cartilage and bone. One of the most potent inducers of VEGF expression is hypoxia, mediated largely through stabilization of the transcription factor hypoxia-inducible factor (HIF) that interacts with the hypoxia-responsive element (HRE) in the VEGF gene promoter. Previous studies provided evidence for important physiological functions for hypoxia and HIF in cartilage and bone. Here, we analyzed the contribution of HIF-mediated transcriptional regulation of VEGF, by investigating bone metabolism in mice lacking the HRE in the VEGF gene promoter (VEGF<sup>HRE</sup> mice).

VEGF<sup>HRE</sup> mice were born at ratios lower than the Mendelian expectation, but surviving mice (1/7) appeared healthy until past 6 months of age, when they started to develop neurodegenerative disease as reported. In newborn as well as 14-week-old mice, we documented 25-40% reduced VEGF protein levels in VEGF<sup>HRE</sup> bones compared with WT (P<0.001), without overt effects on the bone vascularization (histomorphometric analysis of PECAM-1 staining at 1 or 6 days after birth). Throughout life, VEGF<sup>HRE</sup> mice were smaller than their WT littermates. Body weights were reduced by 30% until postnatal day 6, but even by 60% at 4 weeks of age. VEGF<sup>HRE</sup> tibias were 20% shorter than those of 4-week-old WT littermates. The impaired postnatal growth was associated with significantly thinner growth plates displaying imbalanced differentiation, as evidenced by the reduced ratio of immature to mature chondrocyte zones. Strikingly, VEGF<sup>HRE</sup> mice displayed a severe deficit in mineralized bone mass at 4 weeks of age (bone volume/total volume (BV/TV) 3.89% versus 7.78% in WT; P<0.01) that drastically aggravated with age. By 14 weeks BV/TV was reduced to 20% (females) or 30% (males) of WT values, as measured by histomorphometry and micro-CT. This severe osteopenia in VEGF<sup>HRE</sup> mice was characterized by increased bone turnover. Parameters indicative of osteoclast formation (TRAP staining of bone sections, RANKL expression levels) or activity (urine DPD excretion) were significantly increased. Concomitantly, parameters denoting osteoblast differentiation or functioning were significantly higher as well (expression of Runx2 and osteocalcin, dynamic bone formation (MAR, BFR), relative osteoid surface). The underlying mechanism is our current focus of investigation.

In conclusion, the dwarfism and severe osteopenia of VEGF<sup>HRE</sup> mice underscore the importance of HIF-regulated VEGF expression in cartilage and bone metabolism and suggest a novel role for (mild changes in the levels of) VEGF in the development of age-related osteoporosis.

**Deletion of the Oxygen-sensor PHD2 in Chondrocytes Results in Increased Cartilage and Bone Mineralization.** K. Laperre<sup>\*1</sup>, P. Fraaij<sup>\*2</sup>, R. Van Looveren<sup>\*1</sup>, R. Bouillon<sup>1</sup>, P. Carmeliet<sup>\*2</sup>, G. Carmeliet<sup>1</sup>. <sup>1</sup>Laboratory of Experimental Medicine and Endocrinology, K.U.Leuven, Leuven, Belgium, <sup>2</sup>VIB Vesalius Research Center, K.U.Leuven, Leuven, Belgium.

During bone development, the avascular growth plate progressively enlarges resulting in a hypoxic centre. Consequently, hypoxia inducible factor (HIF $\alpha$ ) becomes stabilized which is crucial for chondrocyte survival and angiogenic invasion. When normoxia is restored, HIF $\alpha$  is targeted for proteasomal degradation after hydroxylation by prolyl-hydroxylase-domain containing proteins (PHD1, PHD2 and PHD3).

Here we analyzed the contribution of PHD2 in growth plate homeostasis. We therefore generated chondrocyte-specific PHD2 null mice by crossing PHD2<sup>fl/fl</sup> with collagen 2-cre mice (PHD2<sup>fl/Col2</sup><sup>Cre+</sup>) resulting in a selective and efficient deletion of PHD2. Accordingly, cultured PHD2 null chondrocytes displayed highly increased HIF1 $\alpha$  levels. PHD2<sup>fl/Col2</sup><sup>Cre+</sup> neonates were born at the expected Mendelian ratio and were morphologically indistinguishable from their littermates. However, they quickly became growth retarded and at the age of 14 weeks showed a significant decrease in body weight and femur length. Remarkably, this decreased bone length was associated with increased growth plate mineralization and enhanced trabecular bone volume. In vivo and in vitro analyses did not reveal major differences in osteoblast or osteoclast number or function. However, cartilage matrix was still abundantly present in trabecular bone suggesting impaired matrix remodeling. The chondrocyte phenotype was therefore further investigated.

The growth plates of PHD2<sup>fl/Col2</sup><sup>Cre+</sup> neonates were significantly shorter, due to a decreased length of the proliferating zone. The number and proliferation of chondrocytes was however not altered and no evidence was found for increased apoptosis. Gene expression of Ihh and PTHrP also did not differ between genotypes. On the other hand, the amount of matrix between chondrocytes was decreased in mutant neonates, and could explain the reduced length of this zone. The differentiation to hypertrophic chondrocytes seemed normal as the length of this zone and collagen 10 and MMP13 mRNA levels were similar in both genotypes. Yet, the cartilage matrix was more mineralized in mutant mice. This may be explained by the increase in metaphyseal vascularisation, likely resulting from enhanced VEGF gene expression in the growth plate. In addition, preliminary data suggest that chondrocyte aerobic metabolism is changed in PHD2<sup>fl/Col2</sup><sup>Cre+</sup> mice which may contribute to the altered matrix formation and mineralization.

Taken together, PHD2 expression in chondrocytes is important for normal matrix production and mineralization by regulating HIF-dependent angiogenic and metabolic pathways.

**Chondrocyte-derived Ihh Is Required for Osteoblast Differentiation Despite Reconstitution of a Normal Growth Plate.** Y. Maeda<sup>\*1</sup>, E. Schipani<sup>\*2</sup>, B. Lanske<sup>1</sup>. <sup>1</sup>Developmental Biology, HSDM, Boston, MA, USA, <sup>2</sup>Endocrine Unit, MGH and HMS, Boston, MA, USA.

Indian hedgehog (*Ihh*) is essential for chondrocyte proliferation/differentiation and osteoblast differentiation during prenatal endochondral bone formation. We generated tamoxifen-inducible conditional *Ihh* knockout mice (*Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>), in which the *Ihh* gene was ablated from chondrocytes after birth. Our results demonstrated that *Ihh* expression in postnatal chondrocytes is essential for maintaining a growth plate, and for sustaining trabecular bone and eventual bone growth after birth. A decrease in expression of Wnt target genes suggested that *Ihh* activates osteoblast differentiation via the Wnt signaling pathway in postnatal life. However, loss of trabecular bone in the *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup> mutants could be secondary to their growth plate abnormalities. Therefore, to examine the direct role of *Ihh* on postnatal bone formation, maintenance of a growth plate in the mutants would be required. To rescue the growth plate of the *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup> mice we mated them to *col2a1*-constitutively active PTH/PTHrP receptor transgenic mice (Jansen, J). *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice were born with the expected Mendelian ratio and subsequently injected with tamoxifen at P0 to produce *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice. 7 days later, at P7, loss of *Ihh* and *patched* expression was confirmed. In contrast to the long bones of *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup> which exhibit a disorganized growth plate, the one of *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice appeared to be relatively normal showing all layers of chondrocytes. Expression of coll X in the *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice was found to be similar to control mice (*Ihh*<sup>fl/fl</sup>), whereas *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup> mice showed excessive coll X expression. Interestingly, expression of beta-catenin, a Wnt signaling target, was still decreased in the bone collar of *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice when compared to normal mice, suggesting a direct role of chondrocyte-derived *Ihh* on osteoblast formation that was independent of loss of a growth plate. At P14, *Col2a1-Cre ER*<sup>+</sup>; *Ihh*<sup>td/d</sup>; J mice were smaller in size and displayed a disorganized growth plate with accelerated hypertrophic chondrocyte differentiation as demonstrated by increased collagen X expression, indicating an insufficient expression of the constitutively active *PTHrP* at this stage. In summary, we have demonstrated that a Jansen receptor expressed from chondrocytes can rescue the postnatal growth plate abnormalities in mice lacking *Ihh* expression in chondrocytes. Postnatal expression of *Ihh* in chondrocyte, however, is required for normal induction of Wnt signaling and, therefore, required for normal osteoblast differentiation.

**Regulation of Osteonectin/SPARC by microRNA-29.** K. Kapinas, C. B. Kessler<sup>\*</sup>, A. M. Delany. Center for Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Matricellular proteins are fundamental regulators of bone remodeling, and the matricellular protein osteonectin (SPARC, BM-40) is the most abundant non-collagenous matrix protein in bone. Osteonectin is critical for the maintenance of bone mass. It promotes osteoblast differentiation and survival, and balances bone formation and resorption in response to PTH. However, the mechanisms regulating its expression remain poorly understood. We sought to characterize the post-transcriptional mechanisms regulating osteonectin in osteoblasts. Using luciferase-mouse osteonectin 3' untranslated region (UTR) reporter constructs, we found that the full length (1 Kb) 3' UTR repressed reporter gene expression by 80% in transiently transfected MC3T3-E1 osteoblasts. Deletion mutagenesis showed that this repression was mediated by the proximal 220 bases of the 3' UTR. The proximal 3' UTR contains a well-conserved motif with potential binding sites for microRNAs (miRs) -29a and -29c, and it repressed gene expression in MC3T3 cells by decreasing mRNA abundance and protein translation. qRT-PCR showed that miR-29a and -29c are expressed in osteoblasts. Transfection of miRNA inhibitors specific for miR-29a or -29c relieved repression mediated by the proximal 3' UTR, indicating that the miRNAs act on this region.

Since bioinformatics suggests that other genes important for osteoblast function may also be targets for miR-29, we determined whether miR-29a and -29c were regulated during osteoblastic differentiation in vitro. In MC3T3 cells, miR-29a, but not miR-29c, was increased 5 fold during osteoblastic differentiation. In parallel, osteonectin mRNA and protein levels were decreased. We previously showed that fibroblast growth factor-2 (FGF-2) decreased osteonectin mRNA stability in MC3T3 cells. Here, we found that FGF-2 increased the expression of miR-29a 3 fold, suggesting a means for controlling transcript stability.

Primary cultures of mouse calvarial osteoblasts were somewhat different from MC3T3 cells with respect to miRNA expression and osteonectin. Both miR-29a and -29c were increased 7 fold during osteoblastic differentiation. Osteonectin transcripts remained relatively unchanged during this time, whereas osteonectin protein levels were decreased. In these cultures, miR29 may repress osteonectin translation, in the absence of changes in transcript stability. Regulation of osteonectin, and likely other matrix components, by the miR-29 family may be critical for appropriate osteoblast differentiation and normal bone balance. Further, this important regulatory mechanism is probably active in other tissues where miR-29 and osteonectin are co-expressed, including adipose, brain, and eye.

**Conditional Knockout of the Ca<sup>2+</sup>-sensing Receptor in Osteoblasts Alters Regulators of Wnt Signaling, Delays Cell Differentiation, and Promotes Apoptosis in Bone.** W. Chang, C. Tu<sup>\*</sup>, T. Chen<sup>\*</sup>, D. Bikle, D. Shoback. Endocrine Unit, VA Medical Center, University of California San Francisco, San Francisco, CA, USA.

Extracellular Ca<sup>2+</sup>-sensing receptors (CaSRs) mediate cellular responses to changes in the extracellular Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>e</sub>) in the parathyroid and kidney. High [Ca<sup>2+</sup>]<sub>e</sub> alter signal transduction, gene expression, and bone remodeling, and it is hypothesized that this occurs via CaSRs in osteoblasts (OBs) and other cells in the bone microenvironment. To test the role of CaSR in skeletal growth and development in vivo, we generated mice (<sup>OB</sup>CaSR<sup>Δflox/Δflox</sup>) with conditional knockout of the CaSR gene in OB lineage cells by breeding novel floxed-CaSR (CaSR<sup>lox/flox</sup>) mice with transgenic mice expressing Cre recombinase (Cre) under the control of 2.3 kb type 1 collagen promoter. <sup>OB</sup>CaSR<sup>Δflox/Δflox</sup> mice were growth-retarded and died within 3 weeks of birth. These mice showed severely undermineralized skeletons with excessive osteoid accumulation, as assessed by both micro-computed tomography and bone histology. Skeletal defects were evident at birth and persisted throughout life. Quantitative real-time PCR (qPCR) analyses demonstrated significant reductions in the expression of early and late markers of differentiation, type I collagen, alkaline phosphatase, dentin matrix protein-1, osteocalcin, and sclerostin by from 35 to 90% in bones from <sup>OB</sup>CaSR<sup>Δflox/Δflox</sup> vs control mice, confirming a delay in OB differentiation. The expression of transcription factors RUNX2 and Osterix was unchanged. Furthermore, CaSR knockout significantly suppressed expression of IGF1 and that of two survival genes -- BCL2 and BCL2-like 1 (BCL2L1) in bone. There was also increased expression of interleukin-10 (IL-10), an inducer of apoptosis. The changes in IGF1, BCL2, BCL2L1, and IL-10 expression are consistent with increased apoptosis, confirmed by enhanced TUNEL staining, in OBs and osteocytes in bone from <sup>OB</sup>CaSR<sup>Δflox/Δflox</sup> vs control mice. We next used a Wnt/β-catenin qPCR-based microarray to test whether changes in this pathway critical for OB survival and differentiation and bone formation were involved in the mediating phenotypic changes in bone from the CaSR knockout mice. There were statistically significant decreases in expression of critical effectors of the canonical Wnt pathway (LRP5, Lef, TCF, β-catenin) and increases in expression of pathway inhibitors (sFRP1 and 4). Several Wnts (10 of 17 assayed) were decreased including Wnts 1, 3a and 10, modulators of bone cell differentiation. Our data support the concept that CaSR signaling in OBs critically regulates survival, differentiation, and functions in bone by regulating a number of signaling pathways including IGF1 and Wnts.

**Post-mitotic Preosteoblasts Are the Targets of the Anabolic Actions of Intermittent PTH on Periosteal Bone.** R. L. Jilka<sup>1</sup>, C. A. O'Brien<sup>1</sup>, A. A. Ali<sup>1\*</sup>, P. Roberson<sup>1\*</sup>, A. DeLoose<sup>1\*</sup>, V. Dusevich<sup>2\*</sup>, L. Bonewald<sup>2</sup>, R. S. Weinstein<sup>1</sup>, S. C. Manolagas<sup>1</sup>. <sup>1</sup>Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>2</sup>Dept. of Oral Biology, University of Missouri-Kansas City, Kansas City, MO, USA.

Intermittent administration of parathyroid hormone (PTH) stimulates bone formation on the surface of cancellous and periosteal bone by increasing the number of osteoblasts; and, at least in mice, the increase in cancellous osteoblasts is largely due to attenuation of their apoptosis. However, the mechanism responsible for the anabolic effect of PTH on periosteal bone is unknown. We report that daily injections of 100 ng/g of PTH(1-34) to 4-6 mo old mice increased the number of osteoblasts on the periosteum of lumbar vertebrae by 2-3 fold as early as after 2 days. However, the prevalence of apoptotic periosteal osteoblasts was only 0.2% in vehicle treated animals, which is ~20-fold lower than that of cancellous osteoblasts. Moreover, PTH did not have a discernable effect on periosteal osteoblast apoptosis. Osteoclasts were rarely seen on the surface of periosteal bone of either vehicle or PTH-treated mice, indicating that PTH anabolism at the periosteum is independent of osteoclasts. Administration of BrdU for 4 days failed to label periosteal osteoblasts under either basal conditions or following administration of PTH. Cancellous osteoblasts, on the other hand, were labeled under basal conditions, but PTH did not increase the percentage of BrdU-positive cells, arguing against a pro-proliferative effect of the hormone at either site. Consistent with the above, ganciclovir-induced ablation of replicating osteoblast progenitors in mice expressing thymidine kinase under the control of the rat 3.6kb Col1A1 promoter resulted in disappearance of osteoblasts from cancellous bone over a 7-14 day period, whereas periosteal osteoblasts were unaffected. However, 14 days of pre-treatment with ganciclovir prevented PTH anabolism on periosteal bone. Collectively, these results indicate that PTH increases periosteal osteoblast number by acting on post-mitotic progeny of replicating progenitors. We conclude that, in cancellous bone, attenuation of mature osteoblast apoptosis by PTH is responsible for increasing osteoblast number because their rate of apoptosis is high, making this effect of the hormone profound. However, in periosteal bone where the rate of osteoblast apoptosis is low, PTH must exert pro-differentiating and/or pro-survival effects on post-mitotic pre-osteoblasts. Targeting the latter cell is an effective mechanism for increasing osteoblast number in periosteal bone where the production of osteoblasts from replicating progenitors is slow.

**Target Ablation of PTH/PTHrP Receptor (PPR) in Osteocytes Induces Hypocalcemia and Impairs Bone Structure.** P. P. Divieti<sup>1</sup>, W. F. Powell<sup>1\*</sup>, T. Kobayashi<sup>1</sup>, S. Harris<sup>2</sup>, F. Bringhurst<sup>1</sup>. <sup>1</sup>Endocrine Unit, Mass General Hospital, Harvard Medical School, Boston, MA, USA, <sup>2</sup>Department of Periodontic, University of Texas Health Center at San Antonio, San Antonio, TX, USA.

Osteocytes comprise over 90% of all bone cells, yet little is known of their function(s) or of the involvement of systemic hormones in regulating their activity. Parathyroid hormone (PTH), is a major physiologic regulator of calcium, phosphorus and skeletal homeostasis. Clinically, PTH is the only available anabolic agent to treat osteoporosis. Cells of the osteoblastic lineage are key targets of PTH action in bone, and recent evidence suggests that osteocytes might be important in the anabolic effects of PTH. To better understand the role of PTH signaling through PPRs in osteocytes and to determine the role(s) of these cells in mediating the effects of the hormone on bone we have generated mice in which PPR expression is specifically ablated in osteocytes. Transgenic mice in which the 10Kb-DMP1 promoter drives a tamoxifen-inducible Cre expression (10Kb-DMP1-Cre-ERT2) were mated with PPR(fl/fl) animals to create double heterozygotes, which then were mated with PPR(fl/fl) mice to generate DMP1-Cre/PPR(fl/fl) animals or osteocyte selective PPR-cKO mice, when given tamoxifen. PTH selectively inhibits sclerostin expression in osteocytes, and in the PPR-cKO mice, PTH no longer inhibits sclerostin. To further assess PTH signaling in osteocytes, we subjected 6 week old PPR-cKO and control mice to 2 weeks of low calcium diet (0.02% calcium) after a 1 week of pretreatment followed by continuous treatment with tamoxifen. Interestingly, PPR-cKO animals displayed a significantly lower ionized and total calcium levels compared to littermate controls. To further study the role of PPR in osteocytes in young animals we performed a series of experiments in which PPR-cKO and control littermates were injected with tamoxifen at day 3, 5 and 7 postnatally and then maintained on a weekly dose of tamoxifen for the length of the study. Mice were then either sacrificed at 21 days or subjected to a low calcium diet for 2 additional weeks. Blood was collected for calcium measurement and bones were fixed and processed for histological analysis. PPR-cKO mice were 18.5 % smaller than control littermates, as assessed by their body weights. Histological analysis revealed a reduction in trabecular bone and a delay in the secondary ossification center in PPR-cKO animals. Moreover, 5 weeks old PPR-cKO mice fed a low calcium diet had a plasma total calcium level that was significantly lower than in littermate controls, similar of what we previously reported for adult mice. This data further supports a key role of PTH signaling and PPR in osteocytes for proper bone modelling and remodelling, as well as a key role in calcium homeostasis.

**The Impact of PTH on Cells of the Hematopoietic Lineage: *in vivo* and *in vitro* Studies.** F. Pirihi, A. Koh\*, J. Berry\*, P. Kamarajan\*, Y. Kapila\*, L. K. McCauley. Periodontics and Oral Medicine, University of Michigan School of Dentistry, Ann Arbor, MI, USA.

Parathyroid hormone (PTH) and parathyroid hormone-related protein function in diverse roles, from epithelial-mesenchymal interactions to skeletogenesis and carcinogenesis. PTH is currently under investigation for its potential as a therapeutic agent to stimulate hematopoiesis and bone marrow engraftment; however, the mechanisms for this action are unknown. IL-6 is upregulated by PTH and is also a major regulator of hematopoietic stem cells (HSCs); hence, it was hypothesized that IL-6 is important for the PTH-mediated hematopoietic cell expansion. *In vitro* and *in vivo* experiments were performed utilizing PTH and the tyrosine kinase receptor ligand FLT-3L, known to increase HSCs *in vivo*. Numbers of adherent and non-adherent hematopoietic cells increased after 8 days when whole bone marrow cultures were treated with a single application of FLT-3L. PTH alone did not alter cell numbers but acted synergistically with FLT-3L, further increasing adherent and non-adherent cell populations. In non-adherent cells, PTH combined with FLT-3L increased cyclinD1 mRNA levels while decreasing cell apoptosis as observed with FACS analysis by Annexin V and Propidium Iodide. To evaluate the PTH effect on hematopoietic cells *in vivo*, animals received daily injections of 50 µg/kg of PTH or vehicle for 3 weeks, bone marrow was isolated, and FACS analysis was performed. PTH increased the lin-sca1+ ckit+ population, reflecting increased HSCs. Subsequently, IL-6-deficient mice were utilized *ex vivo* to determine the IL-6 dependence for PTH-cell-expansion. In IL-6-deficient bone marrow cultures, adherent and non-adherent populations failed to amplify in the presence of FLT-3L and PTH. Using bone marrow derived from wild type mice, IL-6 synergized with FLT-3L to increase the non-adherent cell population, suggesting that IL-6 could mimic the PTH effect. In conclusion, PTH increases hematopoietic stem cells *in vivo*. PTH acts in conjunction with FLT-3L to increase hematopoietic and bone marrow stromal cells *ex vivo* through a decrease in apoptosis and an increase in proliferation. Moreover, IL-6 is a critical mediator of bone marrow cell expansion. These findings suggest that PTH mediates hematopoietic cell pool expansion through the upregulation of IL-6.

**Skeletal Dysmorphology of Mice Lacking the Mid-Region, Nuclear Localization Sequence and C-Terminus of Parathyroid Hormone-Related Protein.** R. E. Toribio<sup>1</sup>, H. A. Brown<sup>1\*</sup>, C. M. Novince<sup>2\*</sup>, L. M. Gooding<sup>1\*</sup>, S. T. Shu<sup>1\*</sup>, J. L. Werbeck<sup>1\*</sup>, L. K. McCauley<sup>2</sup>, J. Foley<sup>3\*</sup>, T. J. Rosol<sup>1</sup>. <sup>1</sup>College of Veterinary Medicine, The Ohio State University, Columbus, OH, USA, <sup>2</sup>School of Dentistry, University of Michigan, Ann Arbor, MI, USA, <sup>3</sup>School of Medicine, Indiana University, Bloomington, IN, USA.

Parathyroid hormone (PTH)-related protein (PTHrP) is a pleiotropic factor with multiple physiological functions, including regulation of morphogenesis, cell proliferation, differentiation, and apoptosis, and transplacental calcium transport. PTHrP exerts many of its skeletal actions by binding to the PTH-1 receptor (PTH1R) via its N-terminus. However, *in vitro* studies suggest that some of the effects of PTHrP on cell function may not be mediated by the N-terminus, but rather by the mid-region, a nuclear localization sequence (NLS), and the C-terminus.

The goal of this study was to determine if the mid-region, NLS, and C-terminus of PTHrP have *in vivo* functions on skeletal development. To address this question we engineered a knock-in mouse lacking PTHrP-(67-137) which encompasses these three domains (PTHrP<sup>Δ67-137</sup>). The presence of the mRNA and protein for PTHrP<sup>Δ67-137</sup> was demonstrated in fetal tissues.

PTHrP<sup>Δ67-137</sup> pups had an abnormal phenotype characterized by smaller weight at birth, a domed head, short snout, short limbs (chondrodysplasia), and a hunched back when compared to PTHrP<sup>Δ67-137/+</sup> and PTHrP<sup>+/+</sup>. Mutant pups failed to thrive and most of them died by day 5 (some lived up to 3 weeks). MicroCT and histomorphometry revealed decreased bone mass, trabecular thickness, trabecular number, and cortical bone thickness. PTHrP<sup>Δ67-137</sup> pups had craniofacial dysmorphology (spherical skull) with decreased calvarial bone density and thickness. Dental eruption was delayed (day 9 vs. day 7) and incisors were discolored and deformed. Long bones had shorter growth plates, decreased chondrocyte number, increased TUNEL labeling and TRAP+ cells, and decreased bone marrow cellularity. No *in vitro* differences in osteoblast or osteoclast proliferation were found. Bone and calvarial mRNA expression revealed overexpression of *Fgf1*, *Fgf3*, *tuftelin 1*, *IL-6*, *Itga3*, and *P63*, and underexpression of *Ambn*, *Mmp9*, *Bcl-2*, *Sost*, *Alp*, *Ocn*, *Phex*, and *Sox9*. Hematology and blood chemistry showed hypocalcemia, hypoglycemia, hypolipemia, hypoinsulinemia, and leukopenia. Serum osteocalcin was decreased in mutants, but no differences in serum PTH and TRAP 5b were found.

These findings support our hypothesis that the mid-region, NLS, and C-terminus of PTHrP have essential physiological functions in skeletal development and viability. It also suggests PTHrP plays a role in the interactions between hematopoietic precursors and skeletal development, and that PTHrP participates in the energy metabolism.

## 1161

**Cloning and Functional Analysis of Human Nurr1 (NR4A2) Promoter: Critical Role in the Regulation of CYP27B1 by Parathyroid Hormone and CREB Phosphorylation.** J. D. Sisler<sup>\*1</sup>, A. Maiti<sup>2</sup>, S. C. Ramage<sup>2</sup>, M. A. Forster<sup>\*3</sup>, M. J. Beckman<sup>\*1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA, <sup>2</sup>Orthopedic Surgery, Virginia Commonwealth University, Richmond, VA, USA, <sup>3</sup>Physiology and Biophysics, Virginia Commonwealth University, Richmond, VA, USA.

Parathyroid hormone (PTH) is the central activator of renal proximal 1-alpha-hydroxylase (CYP27B1), the enzyme responsible for synthesis of 1,25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>). Involvement of the orphan nuclear receptor Nurr1 (NR4A2) was recently established in the PTH-mediated pathway of CYP27B1 activation. To determine the connection between NR4A2 and CYP27B1 in response to PTH, we created a murine proximal tubule epithelial cell model (MPCT), stably transfected with human PTHR1. In MPCT cells, transfected human CYP27B1 promoter activation, as well as endogenous mRNA and protein levels was optimally increased in response to 50nM of PTH at 12 hours. Transfection of MPCT cells with dominant negative constructs for CREB phosphorylation (CREB-133) and DNA-binding (K-CREB) abolished CYP27B1 promoter activity and blocked PTH-mediated increase in CYP27B1. Thus, regulation of CYP27B1 promoter was dependent on phospho-CREB activation. Next, a 1,938 bp segment of 5'-sequence upstream of the human NR4A2 start site was acquired by *in silico* screening from the Ensembl web interface, PCR cloned, sequence verified and subcloned into a pGL3-Luc reporter vector. A TF-Search analysis of transcription factor binding sites depicted a consensus CREB site at the promoter proximal end (-120 to +1 bp). Responsiveness of the full-length human NR4A2 promoter to PTH was maximal at 1 hour and diminished after 2 hours. The endogenous regulation of NR4A2 mRNA following PTH treatment correlated with the promoter activity and showed a maximal induction of 15-fold within the 2 hour period. Three distinct constructs were generated using site-directed mutagenesis of key bases within the putative CREB binding site of the human NR4A2 promoter and were used to establish the loss of PTH-mediated induction of NR4A2. In addition, knock-down of NR4A2 in MPCT cells by a specific siRNA obstructed the association between PTH-mediated early gene activation of NR4A2 at 1 hour and the increase of CYP27B1 at 12 hours. Taken together, these findings demonstrate that PTH control of immediate early induction of NR4A2 in renal proximal tubule epithelial cells is a critical step in the molecular mechanism to activate CYP27B1 gene expression, and provide new insights into the indirect link between phospho-CREB activation and stimulation of renal 1 $\alpha$ -hydroxylation by PTH.

**Mechanical Unloading Partially Rescues Hypophosphatemic Rickets in Dmp1-null Mice.** D. Ma<sup>\*1</sup>, S. Yu<sup>1</sup>, R. Zhang<sup>\*1</sup>, B. Yuan<sup>2</sup>, Y. Xie<sup>\*1</sup>, M. Drezner<sup>2</sup>, S. Dallas<sup>3</sup>, L. Bonewald<sup>3</sup>, J. Feng<sup>1</sup>. <sup>1</sup>Biomedical Sciences, Baylor College of Dentistry, TX A&MHSC, Dallas, TX, USA, <sup>2</sup>Medicine, School of Medicine, Univ. Wisconsin, Madison, WI, USA, <sup>3</sup>Oral Biology, School of Dentistry, UMKC, Kansas City, MO, USA.

Our recent studies suggest that the osteocyte is an endocrine cell that controls phosphate homeostasis through FGF23, as osteocytes in *Dmp1* null bone highly express FGF23, which is released into the circulation and causes severe hypophosphatemic rickets. To further validate these observations, neutralizing antibodies against FGF23 (kindly provided from Kirin, Japan) or PBS were injected into 6 day-old *Dmp1* null and control pups i.p. every other day starting at day 6. Mice were sacrificed at day 15. Serum phosphate (Pi) levels were significantly higher in the *Dmp1* null group injected with FGF23 antibody compared to the PBS injected group further supporting a physiological role of FGF23 in the control of Pi homeostasis. Not only did the Pi level return to normal (from 5.73 $\pm$ 0.47 mg% to 9.96  $\pm$ 0.3 mg%; age=15 day-old, N=5) but so did many of the bone defects. A significant improvement was seen in growth plate morphology, secondary ossification, long bone length, and bone mineralization. Histological analysis showed that defects in osteocyte maturation and morphology were greatly improved as reflected by alkaline phosphatase, E11, and FGF23 expression largely returning to normal. Osteocyte cell and lacunar morphology was also improved as determined by light and scanning electron microscopy.

Osteocytes are generally known and accepted to be the "professional" mechanosensory cells, sending signals of (re)modeling in response to loading. Therefore, we hypothesized that mechanical loading may regulate phosphate homeostasis through osteocytes. The tail suspension approach was used to determine if unloading of the hindlimbs of *Dmp1* nulls would improve or reverse the hypophosphatemic rickets. None of the unloaded tibias from the *Dmp1* null animals fractured (n=5) compared to 50% of the tibias from normal ambulatory *Dmp1* null animals (n=8). Therefore unloading ameliorates the tendency of tibias from the null animals to spontaneously fracture. Pi levels and the rickets phenotype were partially rescued from average 3.63 mg% (N=3, age=2-mo) to 4.98 mg% (N=2, age=2-mo) in the tail suspended null animals as was the morphology of the osteocyte lacuno-canalicular system as determined by resin-casted SEM images. These data support the concept that mechanical unloading and potentially loading may influence Pi homeostasis through osteocytes, and may have clinical implications for the treatment of children with hypophosphatemic rickets.

**Hip Fracture Patients at High Risk of Second Hip Fracture.** J. Ryg<sup>\*1</sup>, L. Rejnmark<sup>2</sup>, S. Overgaard<sup>\*3</sup>, K. Brixen<sup>1</sup>, P. Vestergaard<sup>2</sup>. <sup>1</sup>Dept of Endocrinology, Odense University Hospital, Odense, Denmark, <sup>2</sup>Dept of Endocrinology, Aarhus University Hospital, Aarhus, Denmark, <sup>3</sup>Dept of Orthopedic Surgery, Odense University Hospital, Odense, Denmark.

In hip fracture (Hfx) patients, little is known about time frame and risk factors of 2nd Hfx, as well as the ensuing mortality. The aim of study was to elucidate incidence of 2nd Hfx and subsequent mortality. A nationwide population-based cohort of all 169,145 patients with first Hfx in Denmark during 1977-2001 was followed for up to 25 years and compared with the background population. Data on fractures, vital status, and socio-demographic variables were retrieved from national registers and 2nd Hfx were validated against surgical procedures. Median [range] follow-up was 3.8 years [0-25 years] corresponding to 1,041,177 patient years. The majority of patients were women (72.4%) being older than males (78.6 $\pm$ 11.1 vs. 72.8 $\pm$ 16.3 years, p<0.05) (mean  $\pm$ SD). Any prior fracture was seen in 21.7% of women and 17.3% of men (p<0.05). A total of 27,834 patients (5,369 men; 22,465 women) suffered a 2nd Hfx during the study period. The cumulative incidence was 9% after 1 year and 20% after 5 years, being significantly higher than expected (2% and 12%, respectively, p<0.05). The RR of 2nd Hfx was increased by 11.8 (95% CI 11.2-12.5) 1 month after first Hfx, 2.2 (95% CI 2.0-2.5) at 1 year, and did not normalise until 15 years (RR 1.01, 95% CI 1.0-1.02). Adjusting for mortality revealed a significantly higher Hfx free 5-year survival in men and the youngest age-groups in both sexes (Table). Females (HR 1.36, 95% CI 1.32-1.40), age (HR 1.68, 95% CI 1.60-1.76 in patients above 85 years), alcoholism (HR 1.61, 95% CI 1.51-1.72), any prior fracture (HR 1.08, 95% CI 1.04-1.11), and living alone (HR 1.06, 95% CI 1.04-1.09) were significant risk factors for 2nd Hfx in a Cox' proportional hazard model. Both sexes had a higher mortality at 1 and 5 years following 2nd Hfx compared to the background population (men 1-year: 27% vs. 9%, p<0.05, 5-years 64% vs. 40%, p<0.05, women 1-year 21% vs. 10%, p<0.05, 5-years 58% vs. 41%, p<0.05).

Table: Hfx free 5-year survival (mean  $\pm$ SD) following first Hfx adjusted for mortality.

Age (years)	Men (%)	Women (%)	Total (%)	p (Men vs. Women)
<50	90.5 $\pm$ 0.5	84.1 $\pm$ 0.8	88.3 $\pm$ 0.4	<0.05
50-59	85.7 $\pm$ 0.7	80.6 $\pm$ 0.6	82.6 $\pm$ 0.5	<0.05
60-69	85.2 $\pm$ 0.5	80.6 $\pm$ 0.4	82.0 $\pm$ 0.3	<0.05
70-79	83.3 $\pm$ 0.4	78.8 $\pm$ 0.3	79.8 $\pm$ 0.2	<0.05
80-89	80.9 $\pm$ 0.6	76.7 $\pm$ 0.3	77.4 $\pm$ 0.2	<0.05
$\geq$ 90	79.6 $\pm$ 2.1	76.7 $\pm$ 0.8	77.2 $\pm$ 0.7	<0.05

In conclusion, patients with Hfx have a twofold risk of 2nd Hfx, the following mortality is significantly increased, and time span between fractures allow preventive measures in the majority of patients. We propose that programs for secondary prevention should be developed and tested.

**Pattern of Death after Hip Fracture among Institutionalized Older People: 5 Year Followup.** P. N. Sambrook<sup>1</sup>, J. S. Chen<sup>\*1</sup>, L. M. March<sup>\*1</sup>, J. M. Simpson<sup>\*2</sup>, I. D. Cameron<sup>\*3</sup>, R. G. Cumming<sup>\*4</sup>, M. J. Seibel<sup>5</sup>. <sup>1</sup>University of Sydney, Institute of Bone & Joint Research, Sydney, Australia, <sup>2</sup>University of Sydney, School of Public Health, Sydney, Australia, <sup>3</sup>University of Sydney, Rehabilitation Studies Unit, Sydney, Australia, <sup>4</sup>University of Sydney, Centre for Education and Research on Ageing, Sydney, Australia, <sup>5</sup>University of Sydney, ANZAC Research Institute, Sydney, Australia.

An increasing risk of death post hip fracture has been well documented. However, the duration of the excess mortality remains unclear especially in very frail older people. In this study, we compared 229 hip fracture cases and 229 controls matched by age (within 5 years), gender, institution type and follow-up period from the FREE study cohort of 2005 institutionalized older people. The study sample consists of 90 males and 368 females with a mean age of 86 (range: 67-102) years followed for 5 years. Among the cases, death rates at 3, 6, 9 and 12 months were 26%, 35%, 42% and 45% respectively. The corresponding death rates for the controls were 9%, 16%, 20% and 27% respectively. The Kaplan-Meier survival curves for the cases and controls show that the greatest excess mortality occurred in the first three months after the hip fracture. This excess risk was reduced to zero at about 9 months after the fracture (see figure 1). The findings are supported by piecewise Cox regression analysis of the data. For example the hazard ratio of death for the cases compared to the controls was 3.25 (95% CI: 1.98-5.35; P<0.001) at 3 months, 1.93 (95% CI: 1.15-3.23; P=0.01) for the period of 3 - 9 months and 1.16 (95% CI: 0.87-1.55; P=0.32) for the period beyond 9 months following a fracture. Results remained unchanged after adjusting for age, gender, institution type, weight, cognitive function and number of medications. Conditional logistic regression analysis of the data gave similar results. In summary, among the frail elderly, mortality due to hip fracture is increased only for the first 9 months after the fracture. After that, death rates for those with and without hip fractures are similar for up to 5 years. Intensive medical attention should be given to frail older people to reduce mortality after a recent hip fracture.

**Femoral Strength, Bone Density, and Aging in Women and Men.** T. M. Keaveny<sup>1</sup>, D. L. Kopperdahl<sup>1</sup>, P. F. Hoffmann<sup>1</sup>, S. Amin<sup>2</sup>, L. J. Melton<sup>2</sup>, S. Khosla<sup>2</sup>. <sup>1</sup>O. N. Diagnostics, Berkeley, CA, USA, <sup>2</sup>Mayo Clinic, Rochester, MN, USA.

Low bone mineral density (BMD) at the hip as measured by DXA is a well-established risk factor for hip fracture in both women and men but has only modest predictive sensitivity, and its relation to bone strength is not fully understood. Because femoral strength depends on volumetric BMD and 3D bone geometry, both of which differ by sex (Riggs, JBM 2004), the strength-BMD relation may depend on sex and the nature of the BMD measurement: areal BMD (in g/cm<sup>2</sup>), volumetric BMD (in g/cm<sup>3</sup>), or bone mineral content (BMC in g). Resolving these issues is critical to understanding the etiology of age-related hip fracture. Toward this end, we used finite element (FE) analysis of hip QCT scans to relate femoral strength, volumetric BMD (combined cortical and trabecular), areal BMD (femoral neck), and BMC (femoral neck) for an age-stratified (age 20-90 years) cohort of n=679 men and women, randomly sampled from the general population in Rochester MN. Strength was simulated for a sideways fall, and the load-to-strength ratio  $\Phi$  was also calculated using mass and height information and FE strength. Results (Figure) indicated that, by decade, the proportion of individuals having "low" bone strength (< 3000 N) was always greater for women; decreases in strength initiated during menopause for women and a decade later for men; and age-related strength loss was accentuated for women starting in the seventh decade. The proportion of those having high (worse) values of the load-to-strength ratio ( $\Phi > 1.0$ ) was greater in young men than in young women, was similar between the sexes in the fifth and sixth decades, and was higher in women starting in the seventh decade. For the same value of femoral strength, women had higher volumetric BMD and lower BMC than men (p<0.0001), but similar areal BMD. Taken together, these results provide new insight into the relation between femoral strength and clinical measures of bone density for men versus women, and suggest a structural mechanism based on integral bone strength for the known higher fracture incidence of women at advanced age.

**Secular Trends in Swedish Hip Fracture Incidence 1987-2002.** B. E. Rosengren<sup>1</sup>, H. G. Ahlberg<sup>1</sup>, M. K. Karlsson<sup>1</sup>, D. Mellström<sup>2</sup>. <sup>1</sup>Department of Clinical Sciences, Lund University and Department of Orthopaedics UMAS Malmö, Clinical and Molecular Osteoporosis Research Unit, Malmö, Sweden, <sup>2</sup>Departments of Internal Medicine and Geriatrics, The Sahlgrenska Academy at Göteborg University, Center for Bone Research at the Sahlgrenska Academy, Göteborg, Sweden.

The last fifty years, hip fracture incidence has been reported to increase in the western world. During the last decade, several studies have disputed this when reporting an unchanged or decreased hip fracture incidence. The aim of this study was to evaluate if a decline in hip fracture incidence was evident also in Sweden and how the growing population at risk influence the absolute number of hip fractures. The study evaluated the annual, gender specific, total number and age-adjusted incidence of hip fractures in all individuals aged 50 years or more in Sweden from 1987 to 2002 by use of central national data. Time-trend analysis was done by linear regression analysis. The annual number of hip fractures was unchanged over time in women with 10404 fractures year 1987 and 9866 year 2002 (-14.9 per year (95% CI=-41.4-11.6; p=0.25) but increased in men from 3699 year 1987 to 4190 year 2002 (39.1 per year (95% CI=21.6-56.7; p<0.001). The mean age when sustaining a hip fracture increased in women from 79.7 year 1987 to 81.7 year 2002 (0.13 per year (95% CI=0.12-0.14; p<0.001); and in men from 77.3 year 1987 to 79.1 year 2002 (0.11 per year (95% CI=0.10-0.13; p<0.001). Age-adjusted hip fracture incidence (per 10 000) declined over time in woman from 68.4 year 1987 to 51.9 year 2002 (-1.0 per year (95% CI=-1.1--0.89); p<0.001) and in men from 28.9 year 1987 to 26.0 year 2002 (-0.15 per year (95% CI=-0.27--0.04; p<0.05). This study infers that there has been a decreased age-adjusted hip fracture incidence in both women and men aged 50 years or older in Sweden between 1987 and 2002. Due to shifts within the populations at risk, the annual absolute number of hip fractures was unchanged in women but increased in men during the study period.

Disclosures: B.E. Rosengren, None.

**Hip Strength Estimates by Finite Element Analysis and Fracture Prediction in Women and Men.** S. Amin<sup>1</sup>, D. Kopperdahl<sup>2</sup>, L. J. Melton<sup>1</sup>, E. Atkinson<sup>1</sup>, B. L. Riggs<sup>1</sup>, T. Keaveny<sup>3</sup>, S. Khosla<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN, USA, <sup>2</sup>O.N. Diagnostics, Berkeley, CA, USA, <sup>3</sup>University of California, Berkeley, CA, USA.

Hip bone density, a surrogate measure of bone strength at the hip, is an especially important predictor of fracture risk. Finite element [FE] analyses may provide better overall assessment of bone strength and, when combined with estimated bone loads from falls, offer improved site-specific fracture prediction. Whether FE estimates of fall load relative to bone strength at a specific site, such as the hip, will be equally useful predictors of overall or osteoporotic fracture risk is unclear. In an age-stratified, random sample of 580 community adults age  $\geq 35$  yrs, we measured femoral neck [FN] total volumetric BMD (vBMD, mg/cm<sup>3</sup>) using quantitative computed tomography, from which FE models were used to assess bone strength at the hip during a simulated sideways fall. The load to strength ratio for a fall (factor-of-risk [ $\Phi$ ]) was then estimated. We used age-adjusted logistic regression models to examine prediction of prevalent fractures, generally, and of osteoporotic fractures (fracture of the hip, vertebrae or distal forearm), specifically. Among 314 women (mean  $\pm$  SD) age: 61  $\pm$  15 yrs) and 266 men (62  $\pm$  16 yrs), 152 women and 131 men had a prevalent fracture after the age of 35 yrs. Two women and one man had a hip fracture. Estimates of FN vBMD, hip strength and  $\Phi$  were comparable predictors of both prevalent overall fracture and osteoporotic fracture (see Table). Odds ratios are presented per SD decrease in FN vBMD and hip strength, and per SD increase in  $\Phi$ . The c-statistic (the predictive probability of the model, and equivalent to the area under a ROC curve) from the different models were similar.

Women	Any Fracture		Osteoporotic Fracture	
	Odds Ratio (95% CI)	c-Statistic	Odds Ratio (95% CI)	c-Statistic
FN Total vBMD (mg/cm <sup>3</sup> )	1.5 (1.1, 2.1)	0.76	1.5 (1.0, 2.2)	0.81
Hip Strength (N)	1.3 (0.9, 1.8)	0.75	1.4 (0.9, 2.2)	0.80
$\Phi$	1.5 (1.1, 2.1)	0.76	1.5 (1.1, 2.1)	0.80
<b>Men</b>				
FN Total vBMD (mg/cm <sup>3</sup> )	1.6 (1.2, 2.2)	0.78	2.0 (1.3, 2.9)	0.71
Hip Strength (N)	1.3 (0.9, 1.8)	0.77	1.8 (1.2, 2.6)	0.70
$\Phi$	1.3 (0.9, 1.8)	0.77	1.9 (1.3, 2.6)	0.69

While FE model estimates of hip strength and  $\Phi$  are likely to provide better information than FN vBMD regarding hip fracture risk specifically, these estimates appear to be equally effective predictors of overall and osteoporotic fracture risk generally. Additional work on refining load estimation during falls may further improve fracture prediction.

**Protective Effect of Total and Supplemental Vitamin C Intake on the Risk of Hip Fracture: A 17-Year Follow-Up from the Framingham Osteoporosis Study.** S. Sahni<sup>1</sup>, M. T. Hannan<sup>2</sup>, D. R. Gagnon<sup>\*3</sup>, J. Blumberg<sup>\*1</sup>, L. A. Cupples<sup>3</sup>, D. P. Kiel<sup>2</sup>, K. L. Tucker<sup>1</sup>. <sup>1</sup>JM USDA HNRCA, Tufts Univ., Boston, MA, USA, <sup>2</sup>Hebrew SeniorLife, Boston, MA, USA, <sup>3</sup>Boston Univ. SPH, Boston, MA, USA.

Vitamin C may influence bone health by reducing oxidative stress and subsequent bone resorption, and by playing a role in collagen formation. Therefore, we evaluated associations of vitamin C intake (total, dietary and supplemental) with incident hip fracture and non-vertebral osteoporotic fracture, over 15 to 17-y of follow-up in the Framingham Osteoporosis Study. 366 men and 592 women completed a food frequency questionnaire in 1988-89 and were followed for non-vertebral fracture until 2003 and hip fracture until 2005. Tertiles or categories of vitamin C intake (each for total, dietary and supplemental) were created, adjusting for total energy intake (residual method). Hazard ratios (HR) were estimated using Cox-proportional hazards regression adjusting for sex, age, BMI, height, smoking, physical activity index, total energy intake, alcohol intake, multivitamin use and current estrogen use (in women only). Supplemental and dietary vitamin C intakes were adjusted for each other. Final models were examined for attenuation by adding femoral bone mineral density (FN-BMD).

Mean age was 75 y  $\pm$  5.0. Over follow-up, 100 hip fractures and 180 non-vertebral fractures. Subjects in the highest tertile of total vitamin C intake had significantly fewer hip fractures or non-vertebral fractures compared to subjects in the lowest tertile (Table 1). Subjects in the highest category of supplemental vitamin C intake had significantly lower risk of hip and non-vertebral fracture compared to non-supplement users. Dietary vitamin C intake was not associated with risk of fracture (all  $P > 0.17$ ). The associations for hip fracture did not change after adjustment for baseline FN-BMD.

These results suggest that vitamin C may reduce the risk of fracture by 50% or more in elderly men and women, especially when vitamin C supplements are used. The observation that the risk for fracture may be independent of BMD suggests the possibility of effects on the bone matrix, muscle or other risk factors.

Table 1. Inverse association of carotenoid intake and the risk of hip fracture as well as non-vertebral osteoporotic fracture in the elderly men and women of the Framingham Osteoporosis Study.

## 1169

**Histomorphometric and Biochemical Bone Formation Responses to First and Second Cycles of Teriparatide Treatment.** R. Lindsay<sup>1</sup>, F. Cosman<sup>1</sup>, M. Boström<sup>2</sup>, H. Zhou<sup>1</sup>, J. Nieves<sup>1</sup>, D. W. Dempster<sup>1</sup>. <sup>1</sup>Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>2</sup>Hospital for Special Surgery, New York, NY, USA.

We have shown that teriparatide (TPTD) given in 3 month (mos) cycles with 3 mos off intervals produces a similar BMD response after 15 mos compared to continuous treatment. Here, we performed iliac biopsies, using our quadruple labeling technique, during the first cycle of TPTD administration (7.5 weeks) and during the second cycle of TPTD administration (7.5 mos) in 37 women. Prior to TPTD administration, women were treatment naïve (n=18) or on prior and ongoing alendronate (n=19). In alendronate treated women, there was a greater relative increase in mineral apposition rate (MAR) during both the first (0.356  $\mu\text{m}/\text{d}$ ;  $p=0.002$ ) and second TPTD cycles (0.320  $\mu\text{m}/\text{d}$ ;  $p=0.001$ ) compared to the treatment naïve group (0.178  $\mu\text{m}/\text{d}$ , first cycle;  $p=0.001$  vs 0.114  $\mu\text{m}/\text{d}$ , second cycle;  $p=0.04$ ) but baseline MAR was lower in alendronate-treated than treatment-naïve women. Mineralized perimeter (Mdp) increased in both alendronate-treated (2.7%, first cycle and 0.93 %, second cycle; both  $p<0.01$ ) and treatment naïve women (3.87 %, first cycle;  $p=0.003$  and 1.59 %, second cycle;  $p=0.13$ ), but baseline Mdp was much lower on alendronate. Although bone formation rate (BFR= Mdp  $\times$  MAR) increased in both alendronate treated and treatment naïve women during both first and second cycles of TPTD treatment (Figure), it increased to a lesser degree in alendronate treated subjects than in naïve subjects during both TPTD cycles since this variable is heavily influenced by Mdp. The histomorphometric data are consistent with the biochemical changes in bone formation as assessed by P1NP (Figure).

These data indicate that TPTD can stimulate new bone formation during 2 discrete cycles of therapy in women who are both treatment-naïve and those on prior and ongoing alendronate therapy; however, in the presence of alendronate, the dramatic limitation of actively remodeling surface available for TPTD stimulation may provide a mechanism for the so-called blunting effect of alendronate on TPTD-induced BMD response.

## 1170

**Treatment with Daily Subcutaneous Teriparatide (1-34) Compared with Daily Subcutaneous Parathyroid Hormone (1-84) in Women with Severe Postmenopausal Osteoporosis: A Randomized, Head-To-Head Study.** M. Bevilacqua<sup>\*1</sup>, L. J. Dominguez<sup>\*2</sup>, E. Chebat<sup>\*1</sup>, V. Righini<sup>\*1</sup>, M. Barrella<sup>\*1</sup>, M. Massarotti<sup>3</sup>, M. Barbagallo<sup>\*2</sup>. <sup>1</sup>Ospedale L. Sacco-Polo Universitario, Milan, Italy, <sup>2</sup>Geriatric Unit, University of Palermo, Palermo, Italy, <sup>3</sup>Humanitas, Milan, Italy.

**INTRODUCTION:** Teriparatide (TRP) and parathyroid hormone (PTH) are available for the treatment of severe osteoporosis. A 12-month, head-to-head study was performed to compare these two drugs in women with severe osteoporotic vertebral fractures. **SUBJECTS AND METHODS:** 70 patients from one single site were randomized to daily, self-administered, sc TRP (N=35, 20  $\mu\text{g}/\text{day}$ ) or PTH (N=35, 100  $\mu\text{g}/\text{day}$ ). Patients were admitted to the study after a comprehensive evaluation and eventual correction of vitamin D deficiency and secondary hyperparathyroidism. Endpoint was bone turnover markers change at 3, 6, and 12 months of treatment. Tolerability was evaluated by adverse experience (AE) reporting. **RESULTS:** After PTH treatment, there were significant increases at 6 and 12 months in N-Middle osteocalcin ( $\Delta\%$  +547% and +876%), P1NP (+270% and +493%) and N-telopeptide (+227% and +458%) ( $p<0.01$  for all vs. basal). The increases were greater than those observed with TRP (osteocalcin +260% and +550%; P1NP +277% and +457%; N-telopeptide +108% and +346%;  $p<0.01$  for all vs. PTH). Nevertheless, the increase in femoral BMD was similar for both treatments (PTH +3.8%, TRP +3.7%;  $p=NS$ ). The increase of osteocalcin was significantly correlated with  $i\text{Ca}^{++}$  increase ( $p<0.01$ ). Considering a cut-off point  $>1.3 \text{ mmol/L}$ , a similar number of patients in TRP- and PTH-treatment had a high ionized calcium (10 in TRP and 11 in PTH group). However, the mean concentration of ionized calcium was significantly higher at all three evaluations for PTH-treated group (TRP:  $1.18 \pm 0.02 \text{ mmol/L}$ ,  $1.32 \pm 0.08 \text{ mmol/L}$ ,  $1.32 \pm 0.05 \text{ mmol/L}$ ; PTH:  $1.21 \pm 0.02 \text{ mmol/L}$ ,  $1.35 \pm 0.1 \text{ mmol/L}$ ,  $1.41 \pm 0.1 \text{ mmol/L}$ ;  $\xi$  at 3, 6, and 12 months, respectively; \*means  $p<0.001$  vs. basal;  $\xi$  means  $p<0.01$  vs. TRP). Two patients withdrew from the treatment in the first month in each group because of vertigo with TRP, and because of nausea with PTH, and were replaced. No other significant differences were seen between treatment groups in the incidence of AE. **CONCLUSIONS:** TRP and PTH induced similar increases in femoral BMD after 12-month treatment, with significantly higher increases in ionized calcium with PTH. The implications and consequences of the significantly greater increase in bone turnover markers seen with PTH compared to TRP need to be further explored.

**Disclosures:** M. Bevilacqua, None.

## 1171

**Teriparatide versus Alendronate for Treatment of Glucocorticoid-Induced Osteoporosis: 36-month Results.** K. G. Saag<sup>1</sup>, J. R. Zanchetta<sup>2</sup>, J. P. Devogelaer<sup>3</sup>, R. A. Adler<sup>4</sup>, K. See<sup>5</sup>, G. P. Dalsky<sup>5</sup>, K. Krohn<sup>5</sup>, J. H. Krege<sup>5</sup>, M. R. Warner<sup>5</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Instituto de Investigaciones Metabólicas -IDIM, Buenos Aires, Argentina, <sup>3</sup>Université catholique de Louvain, Brussels, Belgium, <sup>4</sup>McGuire VAMC, Richmond, VA, USA, <sup>5</sup>Eli Lilly and Company, Indianapolis, IN, USA.

The purpose of this study was to compare the efficacy of teriparatide versus alendronate in patients with glucocorticoid-induced osteoporosis (GIOP). This was a multicenter, double-blind, 36-month clinical trial in patients who had taken glucocorticoids for  $\geq 3$  months (prednisone equivalent  $\geq 5$  mg/day). The 36-month results are reported here (18-month results reported by Saag et al. NEJM 2007). Patients were randomly assigned to teriparatide 20  $\mu$ g/day (n=214) or alendronate 10 mg/day (n=214). Bone mineral density (BMD) was measured by dual energy x-ray absorptiometry. A mixed model repeated measures analysis was used to analyze BMD at each timepoint and ANOVA was used to analyze endpoint BMD (last observation carried forward). At baseline, the median glucocorticoid dose was 7.5 mg/day in both groups, and the mean [ $\pm$ SE] lumbar spine BMD T-score was 2.4[0.1] and 2.5[0.1] in the teriparatide and alendronate groups, respectively. At the lumbar spine and femoral neck, BMD increased significantly more in the teriparatide compared with alendronate group (Table). Fewer patients had new radiographic vertebral fractures in the teriparatide (3/173, 1.7%) versus alendronate group (13/169, 7.7%) (p=0.007). The number of patients with new nonvertebral fractures was not significantly different between groups (teriparatide 16/214 [7.5%] versus alendronate 15/214 [7.0%]; p=0.843). There was no significant difference between groups in the number of patients with  $\geq 1$  adverse event (91% teriparatide versus 86% alendronate, p=0.116). Significantly more teriparatide patients reported nausea, dyspnea, insomnia, and viral infection; significantly more alendronate patients reported polyarthrititis, weight decreased, and hepatic enzyme increased. Hypercalcemia was reported as an adverse event in 1 patient in the teriparatide group and none in the alendronate group. In this 36-month trial of GIOP, patients treated with teriparatide had greater increases in BMD and fewer new vertebral fractures compared with patients treated with alendronate. Both treatments were generally well tolerated.

Mean % Change [ $\pm$ SE] from baseline in BMD (g/cm <sup>3</sup> )				
Time point (months)	n	Alendronate	n	Teriparatide
Lumbar Spine 18	148	3.8 $\pm$ 0.6*	156	8.0 $\pm$ 0.6*†
24	131	5.2 $\pm$ 0.7*	136	9.8 $\pm$ 0.7*†
36	112	5.3 $\pm$ 0.8*	123	11.0 $\pm$ 0.8*†

**Teriparatide in Bisphosphonate-resistant Osteoporosis - Clinical and MicroCT Data. The "BBB-Study".** B. Mucche<sup>1</sup>, B. Jobke<sup>2</sup>, M. Hellmich<sup>1</sup>, J. Semler<sup>1</sup>. <sup>1</sup>Metabolic Diseases and Osteology, Immanuel-Krankenhaus, Berlin, Germany, <sup>2</sup>Dept. of Radiology - MQIR, UCSF, San Francisco, CA, USA.

There are cases of relevant progression of osteoporosis (OPO) despite of good compliance to at least 1 year of bisphosphonate treatment (BIS). Teriparatide (TPD) is an option, but used only in a minority with limited experience about the effects of previous treatments on lab, BMD and bone structure. Data of a 18months prospective study are presented. METHODS: 25 women (age 69 $\pm$ 9 ys) with progression of severe OPO during BIS (3.5 (1...7) ys; new fragility fractures = 14, BMD decline >3.5% = 11 pts, 12 ALN/13 RIS) were recruited for 18 months TPD treatment. All received 500 mg Ca & 400 IU D3. DEXA scans of lumbar spine and hip were performed every 6 months on a GE Lunar Prodigy, lab specimen (calcium, BAP and crosslaps) at months 0, 1, 3, 6, 12 & 18. Paired bone biopsies from the iliac crest by Yamshidi puncture were taken at M 0, 6 & 18. RESULTS: 20 pts finished the study. BMD T-scores M0/M6/M12/M18: LS -2.96/-2.56/-2.24/-2.10 (p<0.05, but NS between M12-M18), FN -2.21/-2.32/-2.29/-2.23 (NS), TH -2.23/-2.22/-2.19/-2.11 (NS). Lab M0/M1/M3/M6: calcium no clinically relevant change (p<0.001 only at M3 vs. M0; 4 pts with intermittend asymptomatic hypercalcaemia); BAP 14.4/20.5/20.3/28.4/24.7/21.1 (increase p<0.001 until M6 followed by a decrease; ULN=21.4 mg/l); crosslaps 239/350/553/850/594/469 mcg/l (increase p3.5ys delayed change of crosslaps slightly until M3. Neither use of ALN vs. RIS, nor fracture vs. BMD decline influenced the results. MicroCT(M0/M6/M18): BV/TV 6.31/8.24/8.16% (p<0.05 at M6, NS between M6/M18). Tissue density 1.074/1.065/1.024 (NS at M6, p<0.01 at M18). Connectivity density 2.09/3.12/4.75 (NS at M6, p<0.01 at M18). SMI 2.05/1.76/1.73 (p=0.05 at M6, NS at M18). TbN 1.09/1.24/1.15 (p<0.01 at M6 only). TbTh 0.121/0.129/0.118 (NS). TbSp 0.907/0.810/0.884 (NS). CONCLUSIONS: TPD proved to have positive anabolic effects on BIS resistant osteoporosis. Early (< M6), continuous increases of BAP and crosslaps were detected without correlation to duration or type of previous BIS. Afterwards bone turnover declined despite ongoing TPD. BMD at LS also increased already at M6. Bone structural

parameters (BV/TV, SMI, TbN) significantly improved early during treatment. Histological cellular turnover corresponded with lab turnover markers with increases in 75% (M6) followed by a decrease in 57% (M18). Bone structural parameters (BV/TV, SMI, TbN) significantly improved early during treatment followed by a marked increase in structural heterogeneity (SD TbSp) and intrabascular resorption in 84% at M18. Our data suggests further studies with remitting cycles of 6 months TPD followed by antiresorptive agents to optimize positive effects of teriparatide.

**A Novel Calcium-sensing Receptor Antagonist Leads to Dose-Dependent Transient Release of Parathyroid Hormone after Oral Administration to Healthy Volunteers - an Initial Proof-of-Concept for a Potential New Class of Anabolic Osteoporosis Therapeutics.** L. Widler<sup>1</sup>, R. Gamse<sup>1</sup>, K. Seuwen<sup>1</sup>, T. Buhl<sup>1</sup>, R. Beerli<sup>1</sup>, W. Breitenstein<sup>1</sup>, S. Gyaw<sup>2</sup>, C. Reynolds<sup>3</sup>, G. Bruin<sup>3</sup>, R. Belleli<sup>3</sup>, L. Klickstein<sup>3</sup>, M. R. John<sup>3</sup>. <sup>1</sup>Novartis Institutes of Biomedical Research, Basel, Switzerland, <sup>2</sup>Parexel International, Baltimore, MD, USA, <sup>3</sup>Exploratory Development, Novartis Pharma AG, Basel, Switzerland.

Antagonism of the calcium-sensing receptor in parathyroid glands leads to parathyroid hormone (PTH) release via stimulation of an endogenous hormone-release mechanism. Calcilytics are a new class of molecules which aim to exploit this mechanism. In order to mimic the known bone-anabolic PK profile of s.c. administered PTH, a drug must release PTH transiently and robustly. In a dose-limited exploratory IND study, two compounds were tested for their ability to stimulate PTH-release. This report focuses on one compound, ATF936, a quinazolin-2-one derivative. ATF936 was administered orally to 12 healthy male volunteers in a randomized, within-subject dose-rising, double-blind, active comparator, placebo-controlled single dose study. Weekly dose-escalations occurred at 6, 20, 40, 70 and 140 mg. Blood samples for safety, PK, and pharmacodynamic analyses were obtained frequently over each 24-h post-dose period. Elevations in plasma intact and bioactive PTH closely followed the linear PK profiles of ATF936. The median time to maximum PTH concentration (Tmax) was 1 h and PTH concentrations decreased fairly rapidly after Tmax, reaching the placebo levels approx. 12 h post-dose. The maximum mean post-dose PTH concentration (Cmax) was increased 1.9 to 5.9-fold relative to the average individual baseline for doses between 40 and 140 mg. For the 140 mg dose, the geometric mean PTH Cmax was 18.6 pmol/L (CV 35.5%). 24-h post-dose PTH was within baseline levels. There were no significant effects on serum calcium. Only a small transient increase at 4 h post-dose was observed at 140 mg, similar to the effect of Forteo. ATF936 was well tolerated at all doses and no serious adverse events were reported. Adverse event frequency, safety laboratory values, vital signs or 12-lead ECG intervals did not suggest any compound-related adverse effects. In conclusion, the observed transient PTH-release after administration of a single dose of the oral calcilytic ATF936, which had a profile close to that observed with s.c. PTH, constitutes a proof-of-concept in man. Further development of this promising class of compounds might yield a novel pharmaceutical approach for oral bone anabolic osteoporosis therapy.

## 1174

**Ronacaleret, a Novel Calcium-Sensing Receptor Antagonist, Demonstrates Potential as an Oral Bone-Forming Therapy in Healthy Postmenopausal Women.** L. A. Fitzpatrick<sup>1</sup>, E. Brennan<sup>\*2</sup>, S. Kumar<sup>1</sup>, C. Matheny<sup>\*1</sup>, B. Yi<sup>\*1</sup>, M. McLaughlin<sup>\*1</sup>, J. Phillips<sup>\*1</sup>, L. Skordos<sup>\*1</sup>, D. Ethgen<sup>1</sup>. <sup>1</sup>GlaxoSmithKline, Collegeville, PA, USA, <sup>2</sup>Previously with GlaxoSmithKline. Current address: IndiPharm LLC, Haverford, PA, USA.

Short-term antagonism of calcium-sensing receptors (CaR) on parathyroid cells results in the transient release of endogenous parathyroid hormone (PTH), which stimulates bone formation. The purpose of this study was to assess the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of ronacaleret, a CaR antagonist being investigated as an oral treatment for osteoporosis.

This 2-session, single-blind, placebo-controlled, randomized, parallel-group, dose-rising study was conducted in multiple US centers. Subjects were split into 3 cohorts plus placebo; each subject participated in a single-dose session and a 28-day repeat-dose session. Doses were 75 mg, 175 mg, or 475 mg. Bone biomarker measurements (osteocalcin [OC], type I procollagen [PINP], bone specific alkaline phosphatase [BSAP] and carboxy-terminal collagen crosslinks [CTX]) were performed prior to dosing and 24 h postdose for each session.

All subjects were postmenopausal women (mean age, 55 years). Bone biomarker analysis (n=65) indicated a net bone-formation effect with dose-dependent increases in the bone-formation markers OC, PINP and BSAP at day 28 (mean percent change from baseline of 63%, 79% and 35%, respectively, for 475 mg [ $p < 0.05$ ], relative to placebo) and no significant change in the bone resorption marker CTX.

Ronacaleret AUC and Cmax (n=53) increased with increasing dose, although slightly less than dose proportionally. Mean terminal half-life was 4 to 5 h, with negligible accumulation of ronacaleret with repeat dosing. Median Tmax ranged from 2 to 2.5 h following repeat dosing. There was a dose- and concentration-dependent increase in maximal postdose PTH concentration (adjusted mean change of PTH from baseline on day 28 of 287%, 551% and 885% for 75 mg, 175 mg and 475 mg ronacaleret, respectively; n=75) and total serum calcium.

In the safety population (n=81), all AEs were considered mild or moderate. Headache, constipation and diarrhea were more frequent in subjects who received ronacaleret than in those who received placebo; however, no obvious dose responses were observed and most subjects did not require treatment. No serious AEs or deaths were reported.

Single and repeat doses of ronacaleret were well tolerated. The dose-dependent increases in endogenous PTH, calcium and bone-formation markers support further investigation of ronacaleret as a novel oral bone-forming treatment for patients with osteoporosis.

## 1175

**How Does Body Fat Influence Bone Health In Childhood? A Mendelian Randomisation Approach.** J. H. Tobias<sup>1</sup>, N. Timpson<sup>\*2</sup>, A. Sayers<sup>\*1</sup>, G. Davey-Smith<sup>\*2</sup>. <sup>1</sup>CSNB, University of Bristol, Bristol, United Kingdom, <sup>2</sup>Social Medicine, University of Bristol, Bristol, United Kingdom.

Fat mass may be a positive determinant of bone mass in children, but the evidence is conflicting, possibly reflecting the influence of confounding factors. The recent identification of common genetic variants related to obesity in children provides an opportunity to implement a Mendelian randomization study of obesity and bone outcomes in childhood, which is less subject to confounding and several biases than are conventional approaches. 7470 children from the Avon Longitudinal Study of Parents and Children (ALSPAC) who underwent total body DXA scans using a Lunar Prodigy at mean 9.9 years were matched to those who had been genotyped for the *MC4R* rs17782313 and *FTO* rs939609 markers of obesity previously identified from genome-wide association studies. The relationship between total body fat mass tertile as measured by DXA and total body, spinal upper and lower limb bone mineral content (BMC) was analysed by linear regression. Instrumental variable (IV) effects on BMC were derived from regressions in which *MC4R* and *FTO* markers were used in combination as markers of obesity; these estimate the causal effect of body fat on bone outcomes. 5192 and 2878 children were available for IV analyses involving total body and spinal BMC respectively. In linear regression analyses, total fat mass was strongly related to BMC of the total body (1.26, 1.25-1.27), spine (1.25, 1.23-1.26), upper limb (1.24, 1.23-1.25) and lower limb (1.30, 1.29-1.30) (effects shown as ratios of geometric means per fat mass tertile, with 95% CI). IV regressions revealed equivalent effects as follows: total body (1.22, 1.13-1.32), spine (1.25, 1.15-1.35), upper limb (1.23, 1.13-1.34) and lower limb (1.24, 1.15-1.34). Similar results were obtained after adjusting for height and puberty, when trunk fat mass was used in place of total fat, and when bone area was used instead of bone mass. However, in analyses where total body BMC adjusted for bone area was the outcome (reflecting volumetric bone density), linear regression with fat mass showed no association (0.999, 0.997-1.000), whereas IV regression revealed a weak positive effect (1.028, 1.005-1.051). In conclusion, when *MC4R* and *FTO* markers were used as IVs for fat mass, very similar associations with BMC were seen to those with fat mass as measured by DXA, confirming that fat mass is on the causal pathway for bone mass in children. In addition, whereas fat mass had little effect on volumetric density, IVs exerted a weak positive effect, implying that conventional estimates may under-estimate the true effect of body fatness or that both *MC4R* and *FTO* influence skeletal development via pathways that are independent of fat mass.

**Genetic Variation in *LRP5* Associates with Metabolic Characteristics in Healthy Prepubertal Children.** S. Lappalainen<sup>\*1</sup>, A. Saarinen<sup>\*2</sup>, P. Utriainen<sup>\*1</sup>, R. Voutilainen<sup>\*1</sup>, J. Jääskeläinen<sup>\*1</sup>, O. Mäkitie<sup>3</sup>. <sup>1</sup>Department of Pediatrics, Kuopio University and University Hospital, Kuopio, Finland, <sup>2</sup>Folkhälsan Institute of Genetics, Biomedicum Helsinki, and Department of Medical Genetics, University of Helsinki, Helsinki, Finland, <sup>3</sup>Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland.

Several studies have indicated that Wnt signaling plays a role in metabolism and in adrenocortical function. Polymorphisms in the low-density lipoprotein receptor-related protein 5 gene (*LRP5*) have been associated with obesity and hypercholesterolemia. Mice lacking *lrp5* have reduced glucose-induced insulin secretion and increased cholesterol levels. Both *LRP5* and *WNT4* are expressed in the human adrenal cortex, and *Wnt4* knockout mice show altered steroidogenesis. We hypothesized that genetic variation in *LRP5* associates with metabolic characteristics in children.

We performed a cross-sectional association study in 97 healthy prepubertal children. *LRP5* genotypes were determined by direct sequencing. Three single nucleotide polymorphisms (SNPs) in *LRP5* were selected for single marker analyses: c.1647C>T (p.F549F), c.3357A>G (p.V1119V) and c.3989C>T (p.A1330V). Single marker associations with clinical-metabolic characteristics, including adrenal function, glucose tolerance and lipid profile, were examined with age and gender as covariates.

Sixteen SNPs in *LRP5* were found in the 79 girls and 18 boys [age; mean (SD) 7.5 (0.9) yr]. SNP A1330V associated with higher dehydroepiandrosterone sulfate (DHEAS) levels [A/A, n = 87 vs. A/a, n = 9; mean (95 % confidence interval), 0.8 (0.7, 0.9) umol/L vs. 1.4 (0.8, 2.3),  $p = 0.01$ ]. It associated also with higher levels of total [4.2 (4.0, 4.3) mmol/L vs. 4.7 (4.1, 5.4),  $p = 0.02$ ] and low-density lipoprotein cholesterol [2.4 (2.3, 2.5) mmol/L vs. 2.9 (2.3, 3.6),  $p = 0.02$ ], as did SNP V1119V (n = 72 vs. n = 25;  $p = 0.04$  and  $p = 0.03$ , respectively). SNP F549F associated with higher systolic blood pressure [n = 91 vs. n = 6; 100 (98, 102) mmHg vs. 108 (95, 121),  $p = 0.04$ ]. There were no differences in the parameters of glucose metabolism, serum HDL or triglyceride levels between the genotype groups.

The observed differences in serum DHEAS levels between *LRP5* genotype groups suggest that altered Wnt signaling may modulate adrenal hormone profile during childhood. The significant associations between the *LRP5* genotypes and several metabolic characteristics provide further evidence for a significant role of the Wnt signaling pathway in regulation of multiple metabolic pathways. As novel pharmacotherapies targeting Wnt signaling are being developed for the treatment of osteoporosis it is important to recognize extra-skeletal implications of altered Wnt signaling.

**Childhood Cortical Bone and Skeletal Age Show Bivariate Genetic Linkage to Chromosome 2p.** D. L. Duren<sup>1</sup>, J. Blangero<sup>\*2</sup>, R. J. Sherwood<sup>\*1</sup>, J. E. Curran<sup>\*2</sup>, T. Dyer<sup>\*2</sup>, S. A. Cole<sup>\*2</sup>, S. A. Czerwinski<sup>\*1</sup>, W. C. Chumlea<sup>\*1</sup>, M. Lee<sup>1</sup>, A. C. Choh<sup>\*1</sup>, E. W. Demerath<sup>\*3</sup>, R. M. Siervogel<sup>1</sup>, B. Towne<sup>\*1</sup>. <sup>1</sup>Community Health, Wright State University, Dayton, OH, USA, <sup>2</sup>Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, <sup>3</sup>School of Public Health, University of Minnesota, Minneapolis, MN, USA.

The coordinated yet distinct processes of childhood skeletal growth, maturation, and mineralization are essential components of healthy children. The genetic regulation of each process appears to be distinct, but it is also likely that they have some shared genetic basis. We present an analysis of the genetic architecture of bone health in 10-year-old children, prior to the rapid changes in bone associated with puberty. We analyzed radiographic cortical thickness of the second metacarpal and skeletal maturation of the hand-wrist using the FELS method (Roche et al., 1988) in 600 children from the Fels Longitudinal Study examined at chronological age 10 years. These children are from 144 nuclear and extended families. An initial set of 440 of these individuals have been genotyped for ~ 400 autosomal markers spaced approximately every 10 cM. A variance components-based linkage analysis method (SOLAR; Almasy and Blangero, 1998) was used to obtain uni- and bi-variate multipoint LOD scores. Univariate linkage analysis of medial cortical bone revealed a suggestive LOD score (2.29) for linkage to markers on chromosome 2p. We followed this with a bivariate linkage analysis of medial cortical thickness and skeletal age, and found significant linkage (LOD = 3.07) to markers on chromosome 2p25 (between markers D2S319 and D2S2211), indicating an increased linkage signal over that of medial cortical thickness alone to the same chromosomal position. The location of this linkage is in close proximity to a region identified by independent studies of adult bone mass that have identified potential positional candidate genes. Given that results of the current study are based on bone mass and maturation in 10-year-old children, this replication of linkage to this region is both exciting and promising for future gene identification in this sample. Our future work will continue this research emphasizing the identification of specific genes or sets of genes that influence bone mass, strength, and maturation independently and jointly throughout childhood development.

## 1178

**The Extracellular Matrix Protein Periostin Regulates Periosteal Apposition.** R. K. Fuchs<sup>1</sup>, M. Galley<sup>2\*</sup>, J. Doyle<sup>2\*</sup>, F. Klene<sup>1\*</sup>, S. J. Conway<sup>3\*</sup>, S. J. Warden<sup>1</sup>, D. B. Burr<sup>4</sup>. <sup>1</sup>Physical Therapy, Indiana University, Indianapolis, IN, USA, <sup>2</sup>Biomedical Engineering, Purdue University, Indianapolis, IN, USA, <sup>3</sup>Herman B. Wells Center for Pediatric Research, Indiana University, Indianapolis, IN, USA, <sup>4</sup>Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

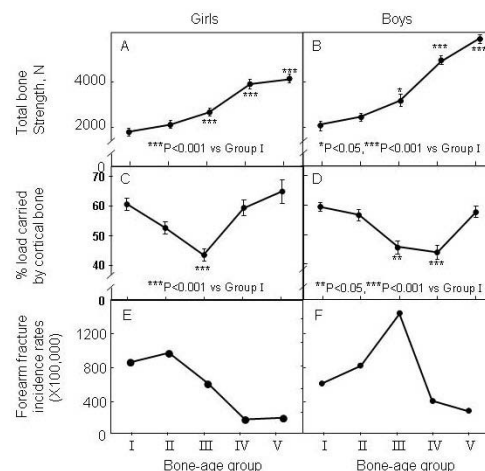

The identification of molecular pathways involved in regulating bone size is necessary to facilitate the development of novel therapies for preventing and treating osteoporosis. Periosteal expansion is well known to augment bone size during growth and aging, with resultant increases in bone strength; however, the genetic regulation of periosteal apposition remains unknown. The goal of this study was to examine the role of periostin (originally named osteoblast specific factor-2) in regulating cortical bone architecture and strength using a genetically-modified mouse model lacking a functional periostin gene. Periostin is an extracellular matrix protein preferentially expressed by immature osteoblasts located on periosteal bone surfaces. Based on the surface specificity of periostin we hypothesized that mice deficient in periostin (*peri*<sup>-/-</sup>) would have reduced bone size and strength when compared to wild-type controls (*peri*<sup>+/+</sup>). Ten mice per gender (male and female) and genotype (*peri*<sup>-/-</sup> and *peri*<sup>+/+</sup>) were evaluated. *In vivo* whole body bone mineral density (BMD; g/cm<sup>3</sup>) was assessed by dual energy x-ray absorptiometry (DXA) at 4-wk intervals from 4 to 16 wk. Upon euthanasia, the femur was excised and bone quantity of the total femur was assessed by DXA, geometry of the femoral mid-diaphysis was quantified by micro-CT, and biomechanical properties of the femoral diaphysis were evaluated by 3-point bending. *Peri*<sup>-/-</sup> mice had significantly reduced whole body BMD at 4, 8, 12, and 16 wk of age (all *p*<0.05). At 16 wk, femurs from *peri*<sup>-/-</sup> mice had significantly reduced BMD, cortical bone area, resistance to strain, and breaking strength when compared to *peri*<sup>+/+</sup> mice (all *p*<0.05). There were no significant genotype by gender interactions for any of the skeletal outcome measures (all *p*>0.05). Based on the surface-specificity of periostin, these data indicate that periostin may be involved in the regulation of bone size via periosteal apposition, and thus may be a novel target for the treatment of bone disease.

## 1179

**Microfinite Element Modeling Reveals That Transient Deficits In Cortical Bone May Underlie The Adolescent Peak In Forearm Fractures.** S. Kirmani<sup>1</sup>, D. Christen<sup>2</sup>, G. H. van Lenthe<sup>2</sup>, P. R. Fischer<sup>1\*</sup>, M. L. Boussein<sup>3</sup>, B. L. Riggs<sup>1</sup>, L. J. Melton<sup>1</sup>, S. Amin<sup>1</sup>, J. Peterson<sup>1\*</sup>, L. McCready<sup>1\*</sup>, R. Müller<sup>1</sup>, S. Khosla<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN, USA, <sup>2</sup>ETH Zurich, Zurich, Switzerland, <sup>3</sup>Harvard Medical School, Boston, MA, USA.

The incidence of distal forearm fractures peaks during the adolescent growth spurt, but the biomechanical basis for this is unclear. Thus, we studied the distal radius of healthy 6-21 yr-old males (n = 61) and females (n = 66) using high-resolution pQCT (XtremeCT, Scanco, voxel size 82 microns). Subjects were classified into 5 groups by bone age (BA): Group I (pre-puberty, BA 6-8 yrs), Group II (early puberty, BA 9-11 yrs), Group III (mid-puberty, BA 12-14 yrs), Group IV (late puberty, BA 15-17 yrs) and Group V (post-puberty, BA 18-21 yrs). Compared to Group I, trabecular parameters (bone volume, density, trabecular number, and trabecular thickness) did not change in girls (*P* > 0.2), but increased in boys (*P* < 0.05) from late puberty onwards. Cortical thickness and volumetric BMD decreased from pre- to mid-puberty in girls (*P* < 0.01) but were unchanged in boys (*P* > 0.05) before rising to higher levels at the end of puberty (*P* < 0.001). Total bone strength, assessed using microfinite element (μFE) models, increased linearly across age groups in both sexes, with boys showing greater bone strength than girls after mid-puberty (*P* < 0.01) (Fig. A, B). Because the proportion of load borne by cortical vs. trabecular bone reflects, in part, the relative strengths of these compartments, we also evaluated how this changed during growth. As shown in Fig. C and D, the proportion of load borne by cortical bone (derived from the μFE models) decreased transiently during puberty in both sexes, mirroring the incidence of distal forearm fractures previously reported in this community (Fig. E, F). Since cadaveric studies (Osteoporosis Int 14:345, 2003) have demonstrated that cortical bone is a critical determinant of failure load at the wrist, the observed transient shift of load-bearing from cortical to trabecular bone in both sexes during puberty, and the concordance of this with the incidence of adolescent fractures, suggest that regional deficits in cortical bone may underlie the adolescent peak in forearm fractures. Further studies comparing adolescents with and without forearm fractures are needed to test whether children with fractures have greater deficits in cortical bone than children without fractures.

**Contribution of the Vertebral Posterior Elements in AP DXA Scans.** D. C. Lee, P. Campbell<sup>\*</sup>, V. Gilsanz, T. A. L. Wren. Childrens Hospital Los Angeles, University of Southern California, Los Angeles, CA, USA.

Because dual energy x-ray absorptiometry (DXA) is a two-dimensional projection technique, anterior-posterior (AP) measurements of the spine include the posterior elements as well as the vertebral body. This may be a disadvantage since the posterior elements likely contribute little to vertebral fracture resistance. This study used quantitative computed tomography (QCT) to quantify the impact of the posterior elements in DXA AP spine measures.

We examined 325 children (163 girls, 162 boys) age 6-21 yr, with both DXA and QCT. QCT data were acquired for a 10mm thick slice at the midportion of L3. QCT measures were calculated both including and excluding the posterior elements. DXA AP spine data were analyzed for the 10mm slice corresponding to the QCT scan region and for the entire L3 vertebra. Bone mineral content (BMC, g) and density (DXA aBMD, g/cm<sup>2</sup>; QCT vBMD, g/cm<sup>3</sup>) were determined and compared using Pearson's correlation. The posterior elements accounted for 51 ± 4% (range 39-65) of the total BMC. Nevertheless, the BMC measured by DXA and QCT correlated strongly for both the 10mm slice and the whole vertebra (*r* = .94). The relationships were weaker when excluding the posterior elements (*r* = .88). Weaker correlations were observed when comparing BMD measured by DXA and QCT (*r* = .73-.82). Our results indicate that even though the vertebral posterior elements account for half the BMC measured by DXA, the contribution of the posterior elements is relatively consistent. DXA therefore provides a reasonable measure of total BMC. However, DXA BMD values are less dependable, particularly as a measure of density of the vertebral body. We conclude that BMC is a more informative measure of bone in the lumbar spine of pediatric subjects than BMD and should therefore be the preferred measure.

	Correlation coefficients of DXA/QCT BMD/BMC measures.			
	DXA L3	DXA 10mm	QCT total	QCT vertebral body
DXA L3	1.00	.93 (BMC)	.94 (BMC)	.88 (BMC)
DXA 10mm	.91 (BMD)	1.00	.94 (BMC)	.88 (BMC)
QCT total	.79 (BMD)	.82 (BMD)	1.00	.95 (BMC)
QCT vertebral body	.73 (BMD)	.76 (BMD)	.90 (BMD)	1.00

**Specific Inactivation of AF-1 in Estrogen Receptor- $\alpha$  (ER $\alpha$ ) Results in Growth Plate Closure while Total Inactivation of ER $\alpha$  Results in Increased Growth Plate Width in Elderly Female Mice.** A. E. Börjesson<sup>\*1</sup>, S. H. Windahl<sup>1</sup>, M. Antal<sup>\*2</sup>, A. Krust<sup>\*2</sup>, P. Chambon<sup>\*2</sup>, C. Ohlsson<sup>1</sup>. <sup>1</sup>Department of Medicine, Center for Bone Research, Sahlgrenska Academy, Göteborg University, Gothenburg, Sweden, <sup>2</sup>Institut de Génétique et de Biologie Moléculaire et Cellulaire, Illkirch, France.

Estrogen affects skeletal growth and promotes growth plate fusion in humans. In rodents, the growth plates do not fuse directly after sexual maturation, but prolonged treatment with high levels of estradiol has the capacity to fuse the growth plates. The DNA binding domain of estrogen receptor- $\alpha$  (ER $\alpha$ ) is surrounded by transcription activation function 1 (AF-1, N-terminal, ligand independent) and AF-2 (ligand dependent). AF-1 activity is promoter and cellular context dependent. The *in vivo* role of AF1 is unknown. The aim of the present study was to *in vivo* determine the role of AF-1 in the modulation of ER $\alpha$ -mediated effects in the growth plate. The skeletal growth and growth plate morphology of elderly (16-19 months of age) female mice with specific inactivation of AF-1 in ER $\alpha$  (ER $\alpha$ AF-1<sup>0</sup>) and mice with total inactivation of ER $\alpha$  (ER $\alpha$ KO) were compared with wild type mice. The lengths of both femur and tibia were increased in ER $\alpha$ <sup>-/-</sup> mice (Femur + 6.0%, Tibia +8.3%,  $p < 0.001$ ) but decreased in ER $\alpha$ AF-1<sup>0</sup> mice (Femur - 4.0%, Tibia -4.9%,  $p < 0.001$ ) compared with wild type mice. Importantly, the proximal tibial growth plate was closed in all ER $\alpha$ AF-1<sup>0</sup> mice, while it was open in all wild type mice (Fig). In contrast, ER $\alpha$ KO mice displayed increased growth plate width compared with wild type mice (ER $\alpha$ KO 111 $\pm$ 5  $\mu$ m, wild type 92 $\pm$ 4  $\mu$ m,  $p < 0.05$ , Fig). In conclusion, specific inactivation of AF-1 in ER $\alpha$  results in inhibited longitudinal bone growth due to growth plate closure while total inactivation of ER $\alpha$  results in enhanced bone growth in elderly female mice. Our data indicate that for the regulation of growth plate width/closure in elderly female mice, specific inactivation of AF-1 results in a hyperactive ER $\alpha$  AF2 transcription activation function, promoting growth plate closure.

**DNA Demethylation for Hormone-Induced Transcriptional Derepression.** M. Kim<sup>\*1</sup>, F. Ohtake<sup>\*1</sup>, I. Takada<sup>\*1</sup>, K. Takeyama<sup>\*1</sup>, H. Shibuya<sup>\*2</sup>, S. Kato<sup>1</sup>. <sup>1</sup>Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, <sup>2</sup>Department of Molecular Cell Biology, Mineral Research Institute and School of Biomedical Science, Tokyo Medical and Dental University, Tokyo, Japan.

Epigenetic modifications at the histone level affect gene regulation in response to extracellular signals. However, regulated epigenetic modifications at the DNA level, especially active DNA demethylation, in gene activation is not well understood. Here we report that DNA methylation/demethylation is hormonally switched to control transcription of the CYP27B1 gene. Reflecting the vitamin D (VD)-mediated transrepression of the CYP27B1 gene through the nVDRE, methylation of CpG sites (5mCpG) are induced by VD in this gene promoter. Conversely, treatment with PTH, a hormone known to activate the CYP27B1 gene, induces active demethylation of the 5mCpG sites in this promoter. Biochemical purification of a complex associated with the nVDRE-binding protein (VDIR) identified DNA methyl transferases, Dnmt1 and 3b for methylation of CpG sites, as well as a DNA glycosylase, MBD4. Phosphorylation of MBD4 by PTH-activated PKC potentiates its DNA glycosylase activity for 5mCpG. The association of DNA ligase I and polymerase  $\beta$  in the MBD4-bound promoter suggests a base excision repair process for DNA demethylation. Such PTH-induced DNA demethylation and subsequent transcriptional derepression are impaired in MBD4<sup>-/-</sup> mice. Thus, the present findings suggest that methylation switching at the DNA level contributes to, at least in part, the hormonal controls of transcription.

**Characterization of Interactions Between the Unliganded VDR and Effectors of the Canonical Wnt Signaling Pathway.** H. F. Luderer, M. B. Demay. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Ligand-independent functions of the Vitamin D Receptor (VDR) in keratinocyte stem cells are essential for normal hair follicle regeneration in mice. Previous studies demonstrated that the VDR is necessary for synergistic activation of Wnt reporter genes by LEF-1 and  $\beta$ -catenin in primary keratinocytes. Furthermore, when co-expressed in COS-7 cells, the VDR is present in a complex with  $\beta$ -catenin and LEF-1. While these data suggest that the VDR acts with  $\beta$ -catenin and LEF-1 to activate Wnt signaling in keratinocytes, the specific protein-protein interactions involved remain undefined. The purpose of this study was to identify and characterize the protein-protein interactions between the unliganded VDR and key effectors of the canonical Wnt signaling pathway. To determine if  $\beta$ -catenin and/or LEF-1 bind the VDR directly, a GST-fusion system was employed. An N-terminal GST-fusion of the wild type VDR was engineered in pGEX-5x-1 and expressed in bacteria. GST-VDR was bound to glutathione sepharose beads in the absence of ligand and then incubated with nuclear extracts isolated from COS-7 cells expressing endogenous  $\beta$ -catenin with or without LEF-1-HA. Proteins were eluted using reduced glutathione and subjected to Western analysis for detection of LEF-1-HA, endogenous  $\beta$ -catenin, and the VDR. While LEF-1 co-eluted with the GST-VDR,  $\beta$ -catenin did not. These data suggest that the unliganded VDR interacts with LEF-1 independently of  $\beta$ -catenin. To test whether the interaction between the VDR and LEF-1, was indeed ligand independent, similar experiments were performed using GST-L233SVDR, a VDR mutant unable to bind ligand. The L233SVDR mutant retained the ability to bind to LEF-1, demonstrating that ligand is not necessary for this interaction. This is in contrast with previous investigations demonstrating that liganded VDR interacts with  $\beta$ -catenin. Based on the observation that the effects of the VDR on the hair follicle are ligand-independent, it is likely that a VDR-LEF1 interaction plays a significant role in maintaining hair follicle homeostasis. Additional studies will be directed at determining which domains of the VDR are required and whether other effectors of canonical Wnt signaling also contribute to this interaction.

**A Genetic Model to Study 1,25 dihydroxyvitamin D Action in Classical and Non-classical Target Tissues.** Y. Xue<sup>\*</sup>, J. Fleet. Dept. of Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

1,25 dihydroxyvitamin D (VD) plays a vital role in maintaining calcium (Ca) and bone metabolism through vitamin D receptor (VDR) activation in the bone, kidney, and intestine. VD has been proposed to have effects in addition to the control of Ca metabolism but the function of VD in its non-classical target tissues is still unclear and the strong interdependency between VD action and Ca metabolism confounds studies in VDR knockout mice (KO) or vitamin D deficient mice. Previously, we recovered the disrupted Ca metabolism of VDR knockout mice by intestine-specific transgenic expression of human VDR (mVDR<sup>-/-</sup>, hVDR<sup>+/+</sup>; KO/TG). In this model, intestinal Ca absorption was recovered leading to normalized serum calcium, serum parathyroid hormone, and growth (bone length and body size) with improved femoral bone mass at 3 mo. To further study the role of VDR in its non-classical target tissues, we fed male mVDR<sup>+/+</sup> and KO/TG mice with AIN76A diet (0.5% Ca; 0.3% phosphorus (P)) and mVDR<sup>-/-</sup> with rescue diet (2% Ca, 1.2% P, 20% lactose (KO\_R)). At the 10 mo, serum calcium and PTH were recovered but urinary Ca was elevated (>8-fold) in both KO\_R and KO/TG (i.e. urinary Ca reabsorption requires VDR). Several parameters were normalized in KO/TG but not in KO\_R: duodenal calbindin D<sub>9k</sub> and TRPV6 mRNA (64% and 96% lower, respectively), body length (5% lower), femur length (8% lower), whole body bone mineral density (BMD) (22% lower), and heart size as % of body weight (BW) (30% higher). Thus, intestine-specific transgenic VDR recovery offers a benefit not met by the high Ca rescue diet. In contrast, body weight was reduced in KO\_R (34% lower) and partially recovered in KO/TG mice (20% lower). This was due to significant reductions in lean body mass (DEXA: KO\_R 19% lower; KO/TG 14% lower) as well as total body (DEXA), epididymal, and retroperitoneal fat mass (each 63% lower in KO\_R; 45% lower in KO/TG). This shows that has a VDR unique role in the control of fat and lean mass beyond that due to changes in Ca metabolism.

**Vitamin D Delays Breast Cancer Progression in the PyVMT Transgenic Mouse Model: Local Conversion of the Precursor 25(OH)<sub>2</sub>D<sub>3</sub> into 1,25(OH)<sub>2</sub>D<sub>3</sub> Is Safer and More Effective than Systemic Administration of 1,25(OH)<sub>2</sub>D<sub>3</sub>.** L. Rossdeutsch<sup>1</sup>, D. Haug<sup>1</sup>, J. Li<sup>1</sup>, T. Reinhardt<sup>2</sup>, W. Muller<sup>1</sup>, R. Kremer<sup>1</sup>. <sup>1</sup>Department of Medicine, McGill University Health Center, McGill University, Montreal, QC, Canada, <sup>2</sup>National Animal Disease Center United States Department of Agriculture Research, Ames, IA, USA.

Metabolic activation of 1,25(OH)<sub>2</sub>D<sub>3</sub> occurs at extra renal sites in several organs including breast. The purpose of this study was to determine if this local tumoral 25OHD<sub>3</sub>-1 $\alpha$ hydroxylase expression modulates any or all of the stages of breast tumor progression. For this purpose we used the PyVMT breast cancer mouse model in which the oncoprotein, polyomavirus middle T antigen (PyMT) is under the control of mouse mammary tumor virus LTR (MMTV LTR) and faithfully reproduces all stages of human breast cancer. Four week old females were treated prior to mammary intraepithelial neoplasia with either vehicle, 25OHD<sub>3</sub> (2000 pM/24h) or 1,25(OH)<sub>2</sub>D<sub>3</sub> (12pM/24h) for a total of 8 weeks. 1 $\alpha$ hydroxylase expression was measured and remained unchanged throughout the various stages of tumor progression. Kaplan Meier analysis indicated that mice treated with 25OHD<sub>3</sub> or 1,25(OH)<sub>2</sub>D<sub>3</sub> had a significant delay in tumor onset as compared to vehicle-treated animals (25OHD<sub>3</sub>=27days>1,25(OH)<sub>2</sub>D<sub>3</sub>=23days>Control =9days, P<.05). Furthermore, tumor growth overtime was significantly reduced in both 25OHD<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> treated groups in comparison to the placebo treated group (25OHD<sub>3</sub> 58.0  $\pm$  2.0 % (P<.002) >1,25(OH)<sub>2</sub>D<sub>3</sub> 45.1  $\pm$  2.2 % (P<.002)>Control). In addition, the expression of biomarkers and histological indices of tumor progression in 25OHD<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> treated animals were markedly delayed as compared to vehicle-treated animals. However, mean circulating 1,25(OH)<sub>2</sub>D<sub>3</sub> and calcium concentrations remained unchanged in 25OHD<sub>3</sub>-treated animals (2.39 $\pm$ .1mmol/L) but increased significantly in 1,25(OH)<sub>2</sub>D<sub>3</sub>-treated animals (3.19 $\pm$ .09 mmol/L P<.05) as compared to vehicle-treated (2.38 $\pm$ .02 mmol/L). Moreover, tumoral levels of 1,25(OH)<sub>2</sub>D<sub>3</sub> in mice treated with 25OHD<sub>3</sub> were significantly higher as compared to both 1,25(OH)<sub>2</sub>D<sub>3</sub> and vehicle-treated animals (25OHD<sub>3</sub>=390 $\pm$ 16.7pg/g>1,25(OH)<sub>2</sub>D<sub>3</sub>=326 $\pm$ .26.8pg/g>Control =182 $\pm$ .10.5pg/g, P<.05). Finally, 25OHD<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>-treated animals had a significant decrease in the mean number and surface area of lung metastases as compared to vehicle-treated animals (P<.05). Our data indicate that metabolic activation of 25OHD<sub>3</sub> in the mammary epithelium delays tumor progression and is more potent than systemic administration of 1,25(OH)<sub>2</sub>D<sub>3</sub> without inducing significant side effects. Our data suggest that strategies aimed at increasing local tissue concentrations of 1,25(OH)<sub>2</sub>D<sub>3</sub> may provide a novel and safe approach in the prevention of breast cancer.

**The Rapid-Nontranscriptional Action of 1,25-(OH)<sub>2</sub>D<sub>3</sub> Induces IL-6 Production in Osteoclast Precursors Expressing Measles Virus Nucleocapsid Protein (MVNP).** Y. Hiruma<sup>1</sup>, S. Ishizuka<sup>2</sup>, G. D. Roodman<sup>3</sup>, N. Kurihara<sup>1</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Bone & Calcium Metab., Teijin Institute for Biomedical Research, Tokyo, Japan, <sup>3</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Osteoclasts (OCL) from patients with Paget's disease (PD) produce high levels of IL-6 and express MVNP. Targeting MVNP to the OCL lineage in transgenic mice results in formation of bone lesions and OCL characteristic of PD (PD-OCL). The capacity of MVNP to induce PD-OCL results in part from its capacity to induce both hyper-responsivity of OCL precursors to 1,25-(OH)<sub>2</sub>D<sub>3</sub> through increased expression of a VDR co-activator, TAF<sub>II</sub>-17, and high levels of IL-6 in the local bone microenvironment. However the molecular mechanisms responsible are still unclear. Since 1,25-(OH)<sub>2</sub>D<sub>3</sub> can induce both genomic and rapid-nontranscriptional actions of VDR, we determined the contribution of both activities of VDR to PD-OCL formation by human OCL precursors expressing MVNP. To determine the contribution of each pathway, we treated OCL precursors expressing MVNP or empty vector (EV) with either 1,24R-(OH)<sub>2</sub>-lumisterol<sub>3</sub> (1,24-Lu), which induces rapid-nontranscriptional actions of VDR, 1 $\beta$ ,25-(OH)<sub>2</sub>D<sub>3</sub> (1 $\beta$ ), a strong antagonist for the rapid-nontranscriptional effects of VDR, and (23S)-25-Dehydro-1 $\alpha$ -(OH)<sub>2</sub>-26,23-lactone (TEI-9647), a pure antagonist for the genomic actions of 1,25-(OH)<sub>2</sub>D<sub>3</sub>. 1,24-Lu increased OCL formation and bone resorption by MVNP transduced OCL precursors. However, in contrast to OCLs induced by 1,25-(OH)<sub>2</sub>D<sub>3</sub>, 1,24-Lu did not induce PD-OCL. Further, TEI-9647 inhibited the formation of PD-OCL (increased OCL number and nuclei per OCL) in OCL expressing MVNP. Thus, the genomic effects of VDR are required for development of PD-OCL. We confirmed that 1,24-Lu did not increase VDR mediated transcription in the presence of high levels of TAF<sub>II</sub>-17, using a modified mammalian two-hybrid assay. 1,25-(OH)<sub>2</sub>D<sub>3</sub> but not 1,24-Lu increased VDR mediated transcription in the presence of high levels of TAF<sub>II</sub>-17. We then examined which actions of VDR were responsible for the increased production of IL-6 by MVNP expressing OCL. 1,24-Lu induced IL-6 expression by OCL and this was blocked by either a p38MAPK inhibitor or by 1 $\beta$ . These results suggest that both the genomic and the rapid-nontranscriptional actions of VDR are required for MVNP to induce PD-OCL.

**C/EBP $\beta$  / p57<sup>Kip2</sup> Signaling Maintains Transition from Proliferation to Hypertrophic Differentiation of Chondrocytes during Skeletal Growth.** M. Hirata, F. Kugimiya, S. Ohba, N. Kawamura, T. Ogasawara, Y. Kawasaki, T. Ikeda, K. Nakamura\*, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine & Tissue Engineering, University of Tokyo, Tokyo, Japan.

This study investigated the role of CCAAT/enhancer-binding protein  $\beta$  (C/EBP $\beta$ ), a multi-functional transcription factor, in chondrocytes during skeletal growth. C/EBP $\beta$  was shown by immunohistochemistry to be localized mainly in late proliferative and pre-hypertrophic chondrocytes of the mouse growth plate. The homozygous deficient (C/EBP $\beta$ <sup>-/-</sup>) mice exhibited dwarfism from embryonic stages. The growth plate showed elongation of the proliferative zone and delay of the chondrocyte hypertrophy determined by BrdU uptake and type X collagen (COL10) immunostaining, respectively. In cultures of primary chondrocytes from C/EBP $\beta$ <sup>-/-</sup> ribs, cell proliferation determined by XTT assay was enhanced, while hypertrophic differentiation determined by COL10, MMP-13 and VEGF mRNA levels as well as ALP and Alizarin red stainings was suppressed. In contrast, retroviral overexpression of C/EBP $\beta$  in the wild-type chondrocytes suppressed the proliferation and enhanced the hypertrophic differentiation, suggesting the involvement of C/EBP $\beta$  in the transition from proliferation to hypertrophic differentiation of chondrocytes. A DNA cell cycle histogram in C3H10T1/2 cells revealed that the C/EBP $\beta$  overexpression caused accumulation of cells in the G0/G1 fraction. A microarray analysis identified several cell cycle factors as transcriptional targets of C/EBP $\beta$ , and among them p57<sup>Kip2</sup>, a cyclin-dependent kinase inhibitor, was shown by real-time RT-PCR to be most strongly up-regulated by the C/EBP $\beta$  overexpression and down-regulated by the C/EBP $\beta$  deficiency (C/EBP $\beta$ <sup>-/-</sup>) in chondrocytes. p57 was co-localized with C/EBP $\beta$  in the growth plate, which was dramatically decreased by the C/EBP $\beta$  deficiency. In HuH-7 cells transfected with a luciferase-reporter gene construct containing the p57 promoter region, the transcriptional activity was enhanced by C/EBP $\beta$  co-transfection. Deletion, mutagenesis, and tandem-repeat analyses of the luciferase assay identified the core responsive element to be between the -150 and -130 bp region containing a putative consensus site for C/EBP. The electrophoretic mobility shift assay revealed the binding of nuclear extracts of C/EBP $\beta$ -overexpressed COS7 cells with the oligonucleotide including this region, whose specificity was verified by the C/EBP $\beta$  antibody supershift. Finally, knockdown of p57 by siRNA inhibited the C/EBP $\beta$ -induced hypertrophic differentiation in cultured chondrocytes. We conclude that C/EBP $\beta$  directly transactivates p57 at a C/EBP element to maintain transition from proliferation to hypertrophic differentiation of chondrocytes during skeletal growth.

**Dexamethasone Triggers Mitochondrial Apoptosis Through Bax in Proliferative Growth Plate Chondrocytes Causing Growth Retardation.** F. Zaman<sup>1</sup>, D. Chrystis<sup>\*1</sup>, K. Huntjens<sup>\*1</sup>, M. Takigawa<sup>\*2</sup>, B. Fadeel<sup>\*3</sup>, L. Savendahl<sup>\*1</sup>. <sup>1</sup>Woman and Child Health, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Okayama University, Tokyo, Japan, <sup>3</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Dexamethasone (Dexa), a widely used glucocorticoid in children, causes severe growth retardation after long-term treatment. Investigating the deleterious effect of Dexa on growth, we have previously shown that Dexa induces apoptosis in proliferative chondrocytes. However, it is still unknown whether Dexa targets mitochondria by regulating the Bcl-2 family of proteins to induce apoptosis in proliferative chondrocytes. To address this, we have used an array of model system both in vitro (human HCS-2/8 proliferative chondrocytes, cultured fetal rat metatarsal bones) and in vivo (rat tibia growth plate). Fluorescent immunohistochemistry and Western immunoblot was performed to study the regulation of pro- and anti-apoptotic proteins. Apoptosis and cytochrome c release was quantified by ELISA. Gene silencing was performed with small interfering RNAs (siRNAs). When investigating mitochondrial-mediated apoptosis in HCS-2/8 proliferative chondrocytes, we found that Dexa (25 micromolar) induced conformational changes in Bax and increased its levels 3-fold (p<0.001 vs. control). We further verified Bax-conformational changes and its translocation into mitochondria in cultured fetal rat metatarsal bones and in the tibia growth plate of rats treated with Dexa. In addition, we observed greater mitochondrial depolarization (p<0.001 vs. control) and cytochrome c release (p<0.01 vs. control) in Dexa treated HCS chondrocytes. Interestingly, Dexa treatment in HCS cells not only altered the expression of Bcl-xS/L (p<0.01 vs. control) but also suppressed the levels of the inhibitor of apoptosis protein-2 by 25 % (p<0.01 vs. control). Suppression of the pro-apoptotic protein Bid with siRNA partially rescued chondrocytes from Dexa-induced apoptosis. Interestingly, Bax-suppression with siRNA completely rescued chondrocytes from apoptosis (p<0.01 vs. Dexa), suggesting Bax as a key regulator of apoptosis in these cells. In conclusion, we report for the first time that Dexa triggers apoptosis in chondrocytes by regulating the Bcl-2 family member of proteins. We found that the pro-apoptotic protein Bax acts as a key regulator of mitochondrial-mediated apoptosis. These results not only identify potential upstream and downstream therapeutic targets in Dexa-induced apoptosis but also indicate a significant role of the Bcl-2 family member of proteins. Based on these data, we speculate that glucocorticoid treatment in vitro and in vivo triggers mitochondrial mediated apoptosis in growth plate chondrocytes and thereby cause growth retardation.

**Novel MMP13-derived Peptides Demonstrate Non-covalent Interaction of MMP13 with the TGF $\beta$  Large Latent Complex.** A. A. Selim<sup>\*1</sup>, S. M. Routson<sup>\*2</sup>, S. Lau<sup>\*2</sup>, M. D'Angelo<sup>2</sup>. <sup>1</sup>Biomedical Technology Research Group, KFUPM, Dhahran, Saudi Arabia, <sup>2</sup>Center for Chronic Disorders of Aging, Philadelphia College of Osteopathic Medicine, Philadelphia, PA, USA.

Dysregulated TGF $\beta$  activation has been indicated in the pathology of osteoarthritis. We have proposed a model of the mechanism of release of the TGF $\beta$  large latent complex by MMP13 that places the catalytic domain of MMP13 in alignment with the protease-sensitive hinge region of LTBP1, the site of release of this molecule from the extracellular matrix. Our bioinformatics-based model predicted that the hemopexin-like domains of MMP13 can non-covalently interact with the calcium-EGF-like domains of Latent TGF $\beta$  Binding Protein (LTBP1).

To test this proposed interaction, we designed three peptides from the hemopexin-like domain of MMP13 that are most likely to interact with LTBP1: MMP13-7, MMP13-10 and MMP13-19. We tested total binding of these fluorescence-labeled peptides with cartilage tissue extracts or LTBP1 immunoprecipitated proteins from cartilage tissue extracts. Specificity of binding was tested by displacement with 10-fold non-labeled peptide and controls included scrambled sequence of the same amino acid composition. Binding data demonstrated that MMP13-19 peptide had the most significant total binding and specific binding compared to the scrambled peptide. Hypertrophic cartilage extracts bound four times more MMP13-19 peptide than scrambled control and cartilage tissue extract immunoprecipitated with antibody to LTBP1 demonstrated three times more binding affinity for MMP13-19 peptide than the scrambled control. Specific binding was demonstrated by displacement of the MMP13-19 peptide binding in cartilage tissue extracts ( $p < 0.001$  compared to MMP13-19 fluorescent peptide binding). MMP13-7 had no significant total or specific binding and MMP13-10 had modest total and specific binding. These data suggest that the peptide sequence of the hemopexin-like domain, equivalent to MMP13-19, could competitively inhibit MMP13 non-covalent binding to LTBP1 in the TGF $\beta$  large latent complex resulting in decreased TGF $\beta$  activation. It is known that increased TGF $\beta$  activation plays an important role in osteoarthritis pathology. Therefore, these data indicate that the MMP13-19 peptide may have potential therapeutic applications for osteoarthritis.

**Targeted Disruption of Nuclear Factor-E2 Related Factor-1 (Nrfl) in Osteoblasts Leads to Reduced Bone Size and Dramatic Alterations in Trabecular Bone Microstructure in Mice.** J. Kim<sup>\*1</sup>, W. Xing<sup>2</sup>, J. Chan<sup>\*3</sup>, S. Mohan<sup>4</sup>. <sup>1</sup>MDC, JLP VA Med Ctr, Loma Linda, CA, USA, <sup>2</sup>LLU, Loma Linda, CA, USA, <sup>3</sup>UC at Irvine, Irvine, CA, USA, <sup>4</sup>MDC, JLP VA Med Ctr, Loma Linda, CA, USA.

We recently showed that Nrfl is involved in mediating ascorbic acid (AA)-induced osterix expression and osteoblast (OB) differentiation via binding to antioxidant response element of mouse osterix promoter. Based on our *in vitro* data that Nrfl regulates genes critical for OB differentiation, we hypothesized that Nrfl expressed in OBs plays a key role in regulating bone formation (BF). To test this hypothesis, we used a Cre-loxP approach to disrupt Nrfl specifically in OB lineage cells. Transgenic mice expressing Cre recombinase under the control of the promoter/enhancer unit of Col1a2 gene were crossed with Nrfl loxP mice to generate Cre+ (Nrfl KO) and Cre- (WT) loxP homozygous mice. Disruption of Nrfl expression in OBs of KO mice was confirmed by real time PCR. Skeletal phenotypic measurements by PIXImus revealed 11% and 9% reduction ( $P < 0.01$ ,  $n = 9$ ) in total BMC and bone area in the KO mice at 8 weeks. Body weight or length was unaffected in the KO mice. pQCT analysis of femurs at 8 weeks revealed a 10% reduction in mid diaphysis cross sectional area in the KO mice.  $\mu$ CT analysis of the femur metaphysis revealed that trabecular bone volume/total volume and trabecular numbers were decreased by 65% and 53% respectively in the Nrfl conditional KO mice as compared with littermate controls ( $P < 0.01$ ). Trabecular separation was increased by 2.5-fold ( $P < 0.01$ ) in the KO mice. To determine if decreased peak bone mass in Nrfl deficient mice is caused by reduced BF, we performed *in vitro* nodule assay using primary cultures of bone marrow stromal cells derived from conditional KO and control mice. Alizarin red stained mineralized nodule area was reduced significantly in OBs derived from Nrfl KO mice compared to control mice ( $7 \pm 3\%$  versus  $22 \pm 5\%$ ,  $P < 0.05$ ). Because we previously found that suppression of Nrfl expression using siRNA blocked AA effects on osterix expression, we next determined if AA effect on osterix expression can be rescued by Nrfl overexpression in OBs derived from KO mice. Primary cultures of Nrfl deficient OBs

were infected with adenoviral (Ad) Nrfl or Ad-GFP prior to evaluation of AA effects on osterix expression. We found that Nrfl overexpression increased osterix expression by 4-fold compared to GFP overexpression ( $P < 0.01$ ) in AA dependent manner. In summary: 1) Targeted disruption of Nrfl in OBs results in decreased peak bone mass caused by reduced bone size and trabecular bone volume; 2) Lack of Nrfl influenced OB differentiation and osterix expression. In conclusion, our data provide the first *in vivo* experimental evidence that Nrfl produced by OBs is involved in regulating osterix expression, OB differentiation and BF.

**Mice Deficient in Bone Sialoprotein (BSP) Display Impaired Modeling and Remodeling and Respond to Ovariectomy but not to the Cortical Anabolic Effect of PTH.** N. Wade-Gueye<sup>\*1</sup>, M. Boudiffa<sup>\*1</sup>, N. Laroche<sup>\*1</sup>, A. Vandenbossche<sup>\*1</sup>, J. Aubin<sup>2</sup>, L. Vico<sup>1</sup>, M. Lafage-Proust<sup>1</sup>, L. Malaval<sup>1</sup>. <sup>1</sup>LBTO, INSERM 890, Saint-Etienne, France, <sup>2</sup>Dept. of Molecular Genetics, University of Toronto, Toronto, ON, Canada.

Bone sialoprotein (BSP) is a member of the Small Integrin-Binding Ligand N-Linked Glycoprotein (SIBLING) family, and highly expressed by bone cells. BSP interacts with both integrins and mineralized matrix, suggesting a role in osteogenesis and bone remodeling, but details remain unclear. We previously showed that adult BSP knockout (KO) mice exhibit a higher trabecular bone mass than wild type (WT), with lower bone formation and reduced osteoclast surfaces and numbers. To determine whether primary ossification is also affected by lack of BSP, we ablated femur bone marrow, an approach that induces intense medullar bone formation followed by resorption. Using longitudinal  $\mu$ CT, we found that 1 week after surgery, more primary bone was formed in the ablated marrow cavity of WT than KO mice (BV/TV:  $30.2 \pm 4.9\%$  vs  $13.8 \pm 3.8\%$ , mean  $\pm$  SEM,  $p < 0.05$ ,  $n = 10$ /group). In contrast, 2 weeks postsurgery, resorption of newly formed bone was more advanced in WT than in KO (BV/TV:  $-70\%$ , and KO:  $-17\%$ , wk1 vs wk2,  $p < 0.05$ ). We next asked whether the lower rate of bone turnover can be increased by catabolic (ovariectomy: OVX) or anabolic (intermittent PTH) hormonal challenges. Tibial trabecular bone volume was decreased 2 (WT:  $-40\%$ , KO:  $-28\%$ ,  $p < 0.05$ , vs baseline) and 4 weeks after OVX (WT:  $-46\%$ , KO:  $42\%$ ,  $p < 0.05$ , vs baseline). Bone formation rate (BFR) was transiently increased at 2 weeks only (WT:  $+49\%$ , KO:  $+52\%$ ,  $p < 0.01$  vs respective SHAM), while osteoclast numbers and surfaces were higher, 2 and 4 weeks after OVX in both genotypes. After one month of daily PTH 1-84 treatment, trabecular BV/TV was significantly decreased in WT ( $-30\%$ ,  $p < 0.05$ ,  $n = 8$ ) but not KO mice, while trabecular thickness increased ( $p < 0.05$ ) in tibia, femur and vertebra of both genotypes. In femur and vertebra, dynamic bone formation parameters (MAR, MS/BS and BFR/BS) and osteoclastic parameters were increased significantly by PTH in both genotypes. In contrast, femoral cortical bone area and thickness were significantly increased by PTH in WT ( $+10.7$  and  $13.2\%$ , respectively vs baseline,  $p < 0.05$ ) but not KO mice. In conclusion, BSP deficiency reduces both bone formation and resorption in both modeling and remodeling. However, the lower bone turnover can be stimulated by hormonal challenges. In particular, bone formation is increased, as shown transiently after OVX and in a more sustained way, although with site-specific differences, with PTH treatment. Our data suggest that the effects of BSP deficiency can be compensated, perhaps via overexpression of another SIBLING family member.

**In Vivo Downregulation of *Mustn1* mRNA Leads to Musculoskeletal Defects.** R. P. Gersch<sup>\*1</sup>, A. Kirmizitas<sup>\*2</sup>, G. Thomsen<sup>\*2</sup>, M. Hadjiargyrou<sup>1</sup>. <sup>1</sup>Biomedical Engineering, SUNY, Stony Brook, Stony Brook, NY, USA, <sup>2</sup>Biochemistry and Cell Biology, SUNY, Stony Brook, Stony Brook, NY, USA.

Previously, our lab reported on the isolation and characterization of the MusculoSkeletal Temporally Activated Novel Gene (*Mustang* or *Mustn1*), encoding for a 9.6 kDa nuclear protein that is involved in fracture repair. We further determined that *Mustn1* is necessary but not sufficient for pre-chondrocyte proliferation, differentiation, and matrix production *in vitro* via overexpression and RNA interference experiments. These data suggest that *Mustn1* may play a crucial role in the early stages of chondrogenesis, both during fracture repair as well as development. In the case of the latter, whole mount *in situ* analysis of *Mustn1* in wild type mice at stages 8.5-9.5dpc reveal expression in a broad range of tissues, such as the branchial arches, primitive heart, regions of the cranium, somites, and neural tube. During limb development 10.5-11.5dpc, *Mustn1* expression becomes restricted to areas promoting chondrogenesis, such as the craniofacial region, limb buds, and somites. At 12.5dpc *Mustn1* expression expands to include tissues undergoing endochondral and intramembranous ossification. These experiments were also repeated in *Xenopus laevis* and showed similar patterning of expression, with *Mustn1* localizing predominately to the craniofacial region as well as somites. This is not surprising considering *Mustn1*'s high protein homology (67%) between the two species. Further analysis of *Mustn1* temporal expression by RT-PCR revealed an increase during stages 14-19, corresponding to somite production and mesodermal development before reaching a plateau through stage 35. Lastly, morpholino oligonucleotides were designed against *Xenopus Mustn1* and injected into both blastomeres at the two-cell stage to ensure knockdown throughout the developing embryo. While control morpholino injected tadpoles were unaffected, gross morphological defects were observed in the craniofacial region of *Mustn1* morpholino treated specimens resulting in disruption of normal

craniofacial formation and an over production of tissue in the dorsal region of the head. In addition, tail and somite development were abnormal, with the presence of many "kinks" resulting in circular swimming by the tadpoles. Taken together, these experiments support the hypothesis that *Mustn1* expression is necessary for musculoskeletal development. Future work will focus on elucidating how *Mustn1* is involved in the regulation of chondrogenic genes and help to understand the process of cartilage and muscle formation both in *X. laevis* as well as mammals.

**Ablation of IGF-I Signaling in Osteoprogenitors Decreases Bone Formation and Blunts the Skeletal Response to PTH.** Y. Wang, R. K. Long\*, H. Z. Elalieh\*, D. D. Bikle. Endocrine Unit, University of California, San Francisco/ San Francisco VA Medical Center, San Francisco, CA, USA.

We and others have demonstrated that insulin-like growth factor-I (IGF-I) signaling regulates the functions of osteoblasts and osteoclasts, and mediates the anabolic actions of parathyroid hormone (PTH) on bone, although the cellular targets and mechanisms remain uncertain. To examine more specifically the cells involved, we generated mice with targeted knockout of IGF-I receptor (IGF-IR) gene in osteoprogenitors (OG) (<sup>OG</sup>IGF-IR<sup>-/-</sup>) by breeding loxP-flanked IGF-IR alleles in exon 3 (floxed-IGF-IR) mice with mice carrying the Cre recombinase transgene controlled by the osterix promoter (gift from Dr. Andrew McMahon). <sup>OG</sup>IGF-IR<sup>-/-</sup> mice grow normally with no difference in body weight at least through 7 weeks. A marked reduction of IGF-IR expression in osteoblasts was shown by immunohistochemistry in 2 day old <sup>OG</sup>IGF-IR<sup>-/-</sup> neonates. Compared with their wild-type (WT) littermates, osteoblast proliferation as assessed by the number of PCNA positive cells was reduced by 50%. At 3 weeks, histology revealed less trabecular bone (H&E staining) and mineralization (Von Kossa staining) in the <sup>OG</sup>IGF-IR<sup>-/-</sup> mice. Quantitative real-time PCR (Q-PCR) analysis demonstrated that the mRNA levels of alkaline phosphatase (ALP) decreased by 48% in the <sup>OG</sup>IGF-IR<sup>-/-</sup> mice compared with WT. At 7 weeks, micro-CT analysis showed significantly decreased trabecular bone volume (BV/TV), connectivity density, trabecular number and thickness (35%, 34%, 16% and 11%, respectively) and increased trabecular separation (23%) in the <sup>OG</sup>IGF-IR<sup>-/-</sup> mice compared to WT.

To evaluate the skeletal response to PTH, 3 week old <sup>OG</sup>IGF-IR<sup>-/-</sup> and WT mice were treated with vehicle or PTH (80 µg/kg bw) for 1 hr. As analyzed by Q-PCR, PTH significantly increased the mRNA levels of RANKL and ephrin 2 in the WT mice (13 fold and 3.7 fold, respectively), but these effects were blunted in the <sup>OG</sup>IGF-IR<sup>-/-</sup> mice. Our data indicate that the IGF-IR in osteoprogenitors is critical for osteoblast proliferation, differentiation and development/maintenance of normal trabecular bone volume and structure. The anabolic effects of PTH on bone require IGF-I signaling in the osteoprogenitors.

**Ephrin B1 Reverse Signaling Regulates Bone Formation via Influencing Osteoblast Activity in Mice.** W. Xing, J. Kim\*, J. Wergedal, S. Mohan. Musculoskeletal Disease Center, Jerry L Pettis VA Medical Center, Loma Linda, CA, USA.

Interaction of ephrin B1 with its receptors via cell-cell contact leads to the activation of a bidirectional signal in which both the receptor-mediated forward signaling and the ephrin B1-mediated reverse signaling activate downstream signaling cascades. Because disruption of ephrin B1 gene in mice results in perinatal lethality and skull defects whereas double knockouts of ephrin B2 and B3 receptors, the key receptors for ephrin B1 ligand, fails to show overt bone phenotypes, we hypothesized that ephrin B1 might be a key member of ephrin family members in regulating bone formation. To study the function of ephrin B1 in bone, we recently generated osteoblast (OB) specific ephrin B1 conditional knockout (KO) and demonstrated that targeted disruption of ephrin B1 gene in OBs results in decreased bone size, BMD and trabecular bone volume. To identify the target cell types and cellular processes affected in the ephrin B1 conditional KO mice, we performed histomorphometric analyses at 4-weeks of age. Bone formation rate (BFR) decreased by 58% (P<0.05) at the endosteum of the femur midshaft in the KO mice. Because of reduced bone size in the KO mice, BFR was adjusted for bone surface (BS). BFR/BS was also decreased by 43% in the KO mice (P<0.05). To determine if the reduced BFR in ephrin B1 conditional KO mice is caused by impairment in the differentiated functions of OBs, we measured mineral apposition rate (MAR) in the KO and control littermates. MAR decreased by 43% (P<0.05) in the KO mice. Consistent with these data, measurement of BFR and MAR at another site of femur, third trochanter, revealed a 41% (P=0.01) and 29% (P=0.02) decrease in BFR/BS and MAR, respectively in the KO mice compared to gender-matched littermates. In order to determine if lack of OB produced ephrin B1 also influences osteoclasts, we measured bone resorption by evaluation of tartrate resistant acid phosphatase (TRAP) covered bone surface at the periosteum and endosteum of femur midshaft. The percentage of TRAP surface was not different in the KO mice compared to control mice neither at the periosteum (19.0 vs. 21.3, P=0.68) nor at the endosteum (11.9 vs. 12.9, p=0.78), thus suggesting bone resorption was not affected in the ephrin B1 OB-specific conditional KO mice. Based on our data, we conclude that ephrin B1 produced by OBs is an important regulator of OB activity, bone formation and peak bone mass.

**Endorphins Regulate Bone Material Properties by Actions through Dynorphin.** P. A. Baldock<sup>1</sup>, I. Wong<sup>\*1</sup>, M. M. McDonald<sup>2</sup>, R. F. Enriquez<sup>\*1</sup>, C. Schwarzer<sup>\*3</sup>, D. G. Little<sup>2</sup>, A. Sainsbury<sup>\*4</sup>, H. Herzog<sup>\*4</sup>, J. A. Eisman<sup>1</sup>. <sup>1</sup>Bone and Mineral Program, Garvan Institute of Medical Research, Sydney, NSW, Australia, <sup>2</sup>Orthopaedic Research & Biotechnology, The Children's Hospital at Westmead, Sydney, NSW, Australia, <sup>3</sup>Pharmacology, Innsbruck Medical University, Innsbruck, Austria, <sup>4</sup>Neuroscience Program, Garvan Institute of Medical Research, Sydney, NSW, Australia.

Identification of sympathetic links from the hypothalamus to bone has increased our understanding of neural regulation of bone. Of these, leptin and neuropeptide Y remain major areas of interest. The dynorphins, a member of the endorphin family are known to regulate leptin and NPY. Dynorphins are predominantly expressed within the central nervous system, with actions via the kappa opioid receptor on pain, addiction and depression. Their peripheral expression appears limited to adrenal, testis and pancreas. In the hypothalamus, dynorphin is expressed in leptin-responsive neurons and pre-prodynorphin is co-expressed with neuropeptide Y.

To investigate its potential role in bone homeostasis, we examined the bone phenotype of Dynorphin knockout mice (Dyn<sup>-/-</sup>), which lack the pre-prodynorphin gene and thus all five dynorphin peptides.

Their body weight mice was not different to wild type despite a (17%) decrease in adipose mass. Dyn<sup>-/-</sup> mice showed reduced central NPY expression, a change shown previously to increase cortical bone mass and no changes in leptin, despite adiposity changes.

Cancellous bone volume was elevated in Dyn<sup>-/-</sup> mice compared to wild type (11.9% ±1 vs 8.8 ±0.6 p<0.02). Bone resorption was greater in Dyn<sup>-/-</sup> mice, as indicated by both osteoclast surface (11.9% ± 0.7 vs 7.9 ±0.7, p<0.01) and osteoclast number (4.4/mm ± 0.2 vs 3.3 ±0.3, p<0.05). However, these changes were overridden by an increased mineral apposition rate in Dyn<sup>-/-</sup> (2.4µm/d ±0.2 vs 1.6 ±0.1, p<0.02).

Cortical bone volume, in contrast, was reduced in Dyn<sup>-/-</sup> mice without change in bone length. Femoral BMD by DXA was reduced (60mg/cm<sup>2</sup> ±2 vs 72 ±4, p<0.05) as was BMC (23mg ±1 vs 30 ±2, p=0.05). A similar reduction in cortical BMD and BMC by pQCT across the femur was not accompanied by changes in bone dimensions or cortical thickness or area. These findings strongly indicate a change in bone material properties.

Importantly, Dyn<sup>-/-</sup> mice showed reduced central NPY expression, a change shown previously to increase cortical bone mass and no changes in leptin, despite adiposity changes. This study reveals for the first time a connection between the dynorphin system and bone. The loss of dynorphin signalling resulted in a change in bone material properties not explained by the NPY or leptin pathways. This study identifies a novel central mechanism for regulation of bone, with potential links to higher brain functions.

**Wnt7a and Wnt7b Evoke Overlapping Yet Distinct Transcriptional Responses During the Osteogenic Programming of Mesenchymal Progenitors by Msx2.** S. Cheng, J. Shao, D. Towler. Internal Medicine, Washington University in St. Louis, St. Louis, MO, USA.

We previously demonstrated that paracrine Wnt/ beta-catenin signaling mediates the osteogenic activity of *Msx2* in vitro and in vivo. *Msx2* increases the expression of *Wnt7a* and *Wnt7b*, ligands for LRP5 and LRP6 that play crucial roles during skeletal development. In C3H10T1/2 cells, RNAi "knockdown" demonstrates that both *Wnt7a* and *Wnt7b* contribute to *Msx2* osteogenic actions via *LRP6*, quantifying alkaline phosphatase (ALP) as an osteoblast marker. Moreover, *Wnt7* co-localizes with *Msx2* in perivascular venues during the orthotopic and heterotopic mineralization induced by a *CMV-Msx2* transgene. Therefore, we examined the mechanisms whereby *Wnt7a* and *Wnt7b* control gene transcription in mesenchymal cells, using the C3H10T1/2 cell line as a model for study. Transient co-transfection of either *pcDNA3-Wnt7a* or *pcDNA-Wnt7b* upregulated activity of the TOPGLOW luciferase reporter, indicating that both ligands can activate canonical beta-catenin pathways in C3H10T1/2 cells. However, *Wnt7a* was consistently more effective than *Wnt7b* in upregulating either TOPGLOW or LEFLUC (5-fold vs. 2-fold; p < 0.05). By contrast, transcription driven by NFAT - a family of nuclear factors that dimerizes with osterix to enhance collagen synthesis and bone formation -- was induced only by *Wnt7b*, and not by *Wnt7a*. Western blot analysis and immunofluorescence confirmed that *Wnt7b* upregulated NFATc1 protein levels and NFATc1 nuclear accumulation. Both *Wnt7a* and *Wnt7b* inhibited *PPAR-gamma2* and *Osteopontin* promoter activities to similar extents. To better understand the impact of *Wnt7a* vs. *Wnt7b* signaling on osteoblast lineage allocation and differentiation, we generated *SFG-Wnt7a* and *SFG-Wnt7b* retroviral vectors, using transduced C3H10T1/2 cultured under osteogenic and adipogenic conditions. *SFG-Wnt7b* upregulated *Msx2* and *ALP*, suppressed adipogenic *PPAR-gamma* expression, and accelerated matrix mineralization and osteoblast maturation - including the induction of *Dkk2*. Moreover, *SFG-Wnt7b* profoundly suppressed the expression of *Dkk1* and *osteopontin* -- two negative regulators of osteoblast-mediated mineralized matrix formation. The suppression of *Dkk1* by *Wnt7b* is mediated via *Msx2*, since siRNA to *Msx2* substantially reversed inhibition. Detailed comparison with *SFG-Wnt7a* is ongoing. Thus, *Wnt7a* and *Wnt7b* exert overlapping yet distinct actions on osteoblast gene transcription. Given the differences of *Wnt7a* and *Wnt7b* on beta-catenin vs. NFAT transcription, these two Wnts provide distinct signals downstream of *Msx2* during osteogenesis. Along with NFAT and osterix, *Msx2* mediates aspects of *Wnt7b* actions, potentiating a "feed-forward" loop that accelerates mineralization and osteoblast differentiation.

**T Cells Amplify The Anabolic Action of PTH Through Wnt10b Signaling.** M. Terauchi<sup>1</sup>, M. S. Nanes<sup>1</sup>, M. Weitzmann<sup>\*1</sup>, M. Zayzafoon<sup>\*2</sup>, M. Weitzmann<sup>\*1</sup>, T. F. Lane<sup>\*3</sup>, R. Pacifici<sup>1</sup>. <sup>1</sup>Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA, <sup>2</sup>University of Alabama Birmingham, Birmingham, AL, USA, <sup>3</sup>University of California, Los Angeles, Los Angeles, CA, USA.

Intermittent PTH treatment promotes bone anabolism in part by activating Wnt signaling in osteoblasts (OBs). However, the nature and the source of the Wnt ligand involved are unknown. T cells express PTH receptors and produce Wnt10b, a Wnt ligand that stimulates osteoblastogenesis, suggesting the possibility that T cells may regulate the anabolic activity of iPTH by producing Wnt10b. To investigate this hypothesis 5 week-old TCR $\beta$  <sup>-/-</sup>, nude, RAG2 <sup>-/-</sup> and class I and II MHC <sup>-/-</sup> mice, strains which lack T cells, were treated for 4 weeks with iPTH via sq injection of human PTH 1-34, 80  $\mu$ g/kg/day (iPTH).  $\mu$ CT analysis of the femoral metaphysis showed that iPTH induced anabolism was blunted by 70-100 % in T cell deficient mice, as compared to WT controls. 4-point bending tests revealed that iPTH increased stiffness, failure load, and maximum load in WT mice but not in T cell deficient mice. Bone histomorphometry and serum osteocalcin (a marker of bone formation) and CTX (a marker of resorption), revealed that the lack of T cells blunts iPTH induced bone anabolism by blocking both formation and resorption. Mechanistic studies in TCR $\beta$  <sup>-/-</sup> mice revealed that in vivo iPTH treatment failed to stimulate CFU-ALP formation in bone marrow cultures, an index of the number of stromal cells with osteogenic potentials. iPTH increased proliferation, differentiation, life span, and Wnt-dependent gene expression in pre-OB derived from WT but not TCR $\beta$  <sup>-/-</sup> mice, suggesting that T cells regulate OBs at all levels of their life cycle. Moreover, iPTH increased Wnt10b production by CD8<sup>+</sup> T cells 3 fold and T cell produced Wnt10b activated Wnt dependent genes in OBs. Demonstrating that T cell produced Wnt10b plays a pivotal role, iPTH failed to promote bone anabolism in TCR $\beta$  <sup>-/-</sup> mice reconstituted with T cells from Wnt10b <sup>-/-</sup> mice, while it induced a full anabolic response in TCR $\beta$  <sup>-/-</sup> mice reconstituted with WT T cells. In summary, this study indicates that T cells represent a regulatory component of the BM microenvironment involved in the anabolic response to iPTH. Bone anabolism is induced by signaling in OBs, but T cells play a permissive role by producing Wnt10b in response to direct or indirect stimulation by PTH. Understanding the cross-talk between T cells and OBs may thus yield novel therapeutic strategies for potentiating bone anabolic agents.

## 1198

**High Bone Turnover in Mice Lacking the Growth Factor Midkine.** C. Neunaber, P. Catala-Lehnen, R. P. Marshall<sup>\*</sup>, T. Schinke, M. Amling. Center for Biomechanics and Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Pleiotrophin (Ptn) and Midkine (Mdk) comprise a family of heparin-binding growth factors with similar activities on proliferation, survival and migration of various cell types. The physiologic function of both molecules is still not fully clarified, since mice lacking either *Ptn* or *Mdk* do not display major abnormalities, despite specific and rather mild behavioural defects. Interestingly, while the transgenic over-expression of *Ptn* in osteoblasts has been described to trigger increased bone formation, our own analysis of *Ptn*-deficient mice did not reveal any difference in terms of bone development or remodelling compared to wildtype littermates. Together with the results from an Affymetrix Gene Chip hybridization showing that *Mdk* expression increases with osteoblast differentiation, this observation prompted us to analyze the skeletal phenotype of *Mdk*-deficient mice at 6, 12 and 18 months of age. While the trabecular bone volume was not different from wildtype littermates in 6 months old mice, we observed a high bone mass phenotype in the *Mdk*-deficient mice starting at the age of 12 months (BV/TV: 24.1  $\pm$  4.8 % vs. 12.5  $\pm$  2.4 %). Dynamic histomorphometry further revealed that the bone formation rate was more than 2-fold increased compared to wildtype littermates (BFR/BS: 247  $\pm$  15  $\mu$ m<sup>3</sup>/ $\mu$ m<sup>2</sup>/y vs. 115  $\pm$  14  $\mu$ m<sup>3</sup>/ $\mu$ m<sup>2</sup>/y), indicating that Mdk is a negative regulator of osteoblast function *in vivo*. Surprisingly, the high bone mass phenotype of the *Mdk*-deficient mice was accompanied by an increase of bone resorption, as determined by measuring TRAP activities and collagen degradation products in the serum. Moreover, we observed increased cortical porosity and development of hyperostotic lesions in the *Mdk*-deficient mice, indicative of a high bone turnover phenotype. Interestingly, this phenotype developed with normal serum levels of Pth, Calcitonin, Rankl and Opg, thereby suggesting a direct effect of Mdk on bone cells. This is further supported by our previous observation that the gene *Piprz1*, encoding a tyrosine phosphatase whose action can be antagonized by Mdk binding, is strongly expressed in differentiated osteoblasts, and that *Piprz1*-deficient mice display an osteopenia at 12 months of age. Taken together, our results identify the growth factor midkine as an important regulator of both, bone formation and bone resorption, at least in mice. However, if such a function could also be demonstrated in human bone cells, Mdk would certainly be an attractive target for osteoanabolic therapy.

**PHEX Cleavage of SIBLING-ASARM Peptides as a Mechanism Underlying Osteomalacia in X-Linked Hypophosphatemia.** W. N. Addison<sup>\*1</sup>, Y. Nakano<sup>\*1</sup>, T. P. Loisel<sup>\*2</sup>, P. Crine<sup>2</sup>, M. D. McKee<sup>1</sup>. <sup>1</sup>Faculty of Dentistry, McGill University, Montreal, QC, Canada, <sup>2</sup>Enobia Pharma, Montreal, QC, Canada.

Mice with X-linked hypophosphatemic rickets (*Hyp*), caused by inactivating mutations of the *PheX* gene, have osteomalacic bones and a marked elevation of acidic, serine- and aspartate-rich motif (ASARM) peptides. ASARM peptides inhibit mineralization, and are derived from members of the SIBLING (small integrin-binding ligand N-linked glycoproteins) family of mineral-regulating proteins which include matrix extracellular phosphoglycoprotein (MEPE) and osteopontin (OPN). The mechanisms by which *PheX* inactivation leads to ASARM peptide accumulation, and inhibition of matrix mineralization, are still unknown. In the present study, we have examined the effects of PHEX interaction with OPN-derived ASARM (OpnASARM) and MEPE-derived ASARM (MepeASARM) peptides using an *in vitro* osteoblast culture model, mass spectrometry and mineral-binding assays. Treatment of MC3T3-E1 osteoblast cultures with phosphorylated OpnASARM peptides (with 5 phosphoserines [OpnAs5] or 3 phosphoserines [OpnAs3]) and a phosphorylated MepeASARM (with 3 phosphoserines [MepeAs3]) caused dose-dependent inhibition of mineralization. Binding of phosphorylated OpnASARM and MepeASARM to hydroxyapatite crystals was confirmed by a hydroxyapatite-peptide binding assay. Nonphosphorylated ASARM peptide showed little or no binding to hydroxyapatite and did not inhibit osteoblast culture mineralization, demonstrating the importance of ASARM phosphorylation in regulating mineralization. A recombinant, soluble secreted form of human PHEX enzyme rescued the inhibition of culture mineralization by OpnAs3 and MepeAs3 (but not by OpnAs5), and mass spectrometry of cleaved peptides obtained after incubations with PheX identified all forms of both OpnASARM and MepeASARM as substrates for PHEX. Enzymatic cleavage occurred at amide linkages between serine and glutamate, or between serine and aspartate. Cell proliferation (MTT assay) was normal after treatment with all peptides, and alkaline phosphatase activity and collagen deposition was unaffected by all peptides except OpnAs5 which slightly decreased collagen deposition. In conclusion, these data demonstrate for the first time that inhibition of mineralization by mineral-binding SIBLING ASARM peptides can be rescued by enzymatic degradation by PHEX, identifying a mechanism by which loss of PHEX activity can lead to extracellular matrix accumulation of ASARM resulting in the osteomalacia of XLH.

**Oxytocin Inhibits Bone Formation Through the Activation of the Sympathetic Tone: A New Candidate in the Central Regulation of Bone Formation.** C. Camerino. Dept. of Human Anatomy and Histology, University of Bari, Bari, Italy.

The neuropeptide Oxytocin (OT) is an hypothalamic hormone produced in the paraventricular (PVN) and supraoptic (SON) nuclei of the hypothalamus. It has been reported that oxytocin neurons in the PVN nucleus are a component of a leptin-sensitive signaling circuit between the hypothalamus and caudal brain stem. Indeed, hindbrain projection of OT neurons in the parvocellular paraventricular nucleus are hypothesized to transmit leptin signaling from the hypothalamus to the nucleus of the solitary tract. Knock out mice deficient in oxytocin (OTKO) display significantly increased body weight and 40% increase in fat pad weight compared to wild type (WT) littermates. This phenotype is evident at both 4 and 6 months of age. OTKO mice present also higher fasting glucose levels compared to WT. The results from Insulin Tolerance Test and Glucose Tolerance Test clearly show an insulin resistance state and lower ability to counteract the increase of glycaemia following a glucose bolus. Liver steatosis was also evident in the oldest animals thus confirming a diabetic status. Food intake did not show any significant difference between the OTKO and WT mice at both ages. Interestingly, OTKO mice displayed a 90% increase in plasma leptin concentration compared to the WT. Hyperleptinaemia is considered to reflect a state of leptin resistance that is accompanied by obesity, hypogonadism and paradoxically high bone mass. The paradox of leptin resistance has been the first evidence linking energy and skeletal homeostasis through the activation of the sympathetic nervous system. To investigate if hyperleptinaemia following OT deficiency had an impact on bone formation we measured the epinephrine levels and performed a  $\mu$ CT analysis of both vertebrae and long bones of OTKO mice. Interestingly, we found that in OTKO mice epinephrine levels were three times lower than in WT thus indicating a lower sympathetic tone. The results of  $\mu$ CT indicated that OTKO mice have a denser appendicular skeleton with increased mineralization of the lumbar vertebrae as well as of the femurs probably due to a *de novo* bone formation by osteoblast, which is a direct target of the sympathetic nervous system. The femurs of OTKO display a larger diameter of the medial diaphysis and a thicker skull. Based on these results we suggest that OT can be a new candidate in the central regulation of bone homeostasis and a mediator of the antiproliferative action of sympathetic tone on bone formation.

**Rachitic Defects in *tcirg1*-Dependent Osteopetrosis Are Caused by Impaired Gastric Acidification.** T. Schinke<sup>1</sup>, A. F. Schilling<sup>1</sup>, A. Baranowsky<sup>\*1</sup>, A. Huebner<sup>\*1</sup>, A. Schulz<sup>\*2</sup>, J. Zustin<sup>\*3</sup>, M. Gebauer<sup>\*1</sup>, M. Priemel<sup>1</sup>, A. Villa<sup>4</sup>, A. Teti<sup>5</sup>, M. Amling<sup>1</sup>. <sup>1</sup>Center for Biomechanics, Experimental Trauma Surgery & Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>2</sup>Department of Pediatrics, University Medical Center Ulm, Ulm, Germany, <sup>3</sup>Department of Bone Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>4</sup>Human Genome Department, Istituto di Tecnologie Biomediche, CNR, Segrate, Milan, Italy, <sup>5</sup>Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

*TCIRG1* is the most commonly mutated gene in patients with autosomal recessive osteopetrosis (ARO). It encodes one subunit of the vacuolar proton pump, required for extracellular acidification by osteoclasts. Interestingly, while the initial characterization of *Tcirg1*-deficient *oc/oc* mice also revealed rachitic defects of the growth plates, a phenotype termed osteopetrorickets (OPR), the impact of *TCIRG1* on skeletal mineralization has been overlooked in ARO patients, since biopsies were only analyzed following decalcification. Thus, in order to estimate the prevalence of OPR, we performed histomorphometry on non-decalcified bone biopsies from ARO patients and observed an osteoid volume (OV/BV) above 5 % in half of the cases, which prompted us to elucidate the molecular basis of OPR using genetically modified mouse models. While we did not observe a pathologic enrichment of osteoid in osteopetrotic *Src*<sup>-/-</sup> mice, the OV/BV in *oc/oc* mice was above 20 %. The cause of this mineralization defect is a severe hypocalcemia, which is best underscored by the finding that the OV/BV was below 2 %, when serum calcium in the *oc/oc* mice was normalized by a high calcium diet. Since we did not observe increased renal calcium loss in the *oc/oc* mice, we next analyzed *Tcirg1* expression in the gastrointestinal tract. Here we found strong and specific expression in parietal cells of the stomach, which was confirmed by immunohistochemistry on human tissues. Moreover, we found that this expression is also of functional relevance, since the gastric pH was pathologically increased in *oc/oc* mice and in a patient with *TCIRG1*-dependent ARO. To demonstrate that this novel function of *Tcirg1* contributes to the OPR phenotype, we next analyzed achlorhydric *Cckbr*<sup>-/-</sup> mice, where we found no enrichment of osteoid, but a mild hypocalcemia accompanied by elevated PTH. In order to block PTH-induced bone resorption in these mice, we crossed them with *Src*<sup>-/-</sup> mice and observed that the combined deletion of *Cckbr* and *Src* led to OPR. Taken together, our data demonstrate a previously unknown function of *TCIRG1* in gastric acidification that contributes to the skeletal abnormalities caused by *TCIRG1* deficiency.

**Impairment of Osteoblast lineage Differentiation leads to Increased Osteoclastogenesis in Osteogenesis Imperfecta Murine.** H. T. Li<sup>\*1</sup>, X. Jiang<sup>\*1</sup>, J. Delaney<sup>\*2</sup>, I. Bilic-Curcic<sup>\*2</sup>, D. W. Rowe<sup>1</sup>, I. Kalajzic<sup>1</sup>. <sup>1</sup>Dept. of Reconstructive Sciences, Uni. of Conn. Health Center, Farmington, CT, USA, <sup>2</sup>Dept. of Genetics and Dev. Biology, Uni. of Conn. Health Center, Farmington, CT, USA.

Osteogenesis imperfecta murine (OIM) is a mouse model that resembles severe type III human OI. Our study aims to address the prospective role of impairment of osteoblastic differentiation as a mechanism for this disease. Potentially, it is the combination of impaired osteogenic differentiation with increased bone resorption that leads to diminished bone mass. We have previously developed transgenic mice that express GFP at distinct stages of osteoblast differentiation; pOBCol3.6GFP (preosteoblast) and pOBCol2.3GFP (osteoblast/osteocytes). Using the crosses of these transgenic mice with the OIM model, we assessed osteoblast maturation and the mechanism of increased osteoclastogenesis. Cultures from the 2.3GFPoim/oim mice showed a marked reduction of cells expressing GFP relative to 2.3GFP<sup>+/+</sup> littermates. Similar number of 3.6GFP<sup>+</sup> cells between the <sup>+/+</sup> and oim/oim mice were observed. Conventional osteoblast differentiation markers as lower expression of AP, Col1a1, BSP, OC and mineralization in oim/oim mice confirmed the GFP data. Histological analysis of the 3.6GFPoim/oim mice showed an increased number of GFP positive cells lining the endocortical surface compared to 3.6GFP<sup>+/+</sup> mice. In contrast GFP expression was similar between 2.3GFPoim/oim and 2.3GFP<sup>+/+</sup> mice. These data indicate that the lineage is under continuous stimulation, while only a proportion of cells attain the mature osteoblast stage.

To assess the osteoclastogenic ability of cells at different stages during osteoblastogenesis, we co-cultured preosteoblasts (3.6GFP<sup>+</sup>) or mature osteoblasts (2.3GFP<sup>+</sup>) isolated by FACS with bone marrow derived osteoclast progenitors (BMMc). The immature osteoblasts exhibit a stronger potential to support osteoclast formation and differentiation, revealed by increased osteoclast number and activity. We confirmed the presence of a higher Rankl/Opg ratio in sorted immature osteoblasts. These results implied that the accumulated immature osteoblasts in oim/oim could be the driving force for augmented osteoclastogenesis. Indeed, increased osteoclast formation was observed when oim/oim derived osteoblasts were cocultured with osteoclast progenitors as compared with osteoblasts derived from <sup>+/+</sup> mice.

Our data indicates that the osteoblast lineage maturation is a critical aspect underlying the pathophysiology of the osteogenesis imperfecta.

**ACVR1 Knock-In Mouse Model for Fibrodysplasia Ossificans Progressiva (FOP).** S. A. Chakkalakal<sup>\*1</sup>, D. Zhang<sup>\*1</sup>, T. Raabe<sup>\*2</sup>, J. Richa<sup>\*2</sup>, K. Hankenson<sup>3</sup>, F. S. Kaplan<sup>4</sup>, E. M. Shore<sup>5</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>2</sup>Department of Genetics, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>3</sup>Department of Animal Biology, University of Pennsylvania of Veterinary Medicine, Philadelphia, PA, USA, <sup>4</sup>Departments of Orthopaedic Surgery and Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>5</sup>Departments of Orthopaedic Surgery and Genetics, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP) is a rare genetic disorder of endochondral bone formation characterized by abnormalities of the developing embryonic skeleton, such as malformation of the great toes, and by progressive postnatal heterotopic ossification in soft connective tissues. All patients with these classic clinical features of FOP have the identical single nucleotide substitution (c.617G>A; R206H) in the gene encoding ACVR1/ALK2, a type I BMP receptor. The human and mouse ACVR1 genes are highly homologous and a mouse ACVR1 knock-in of the c.617G>A; R206H mutation would provide a much needed in vivo model for FOP. ACVR1 sequences from a C57BL/6 BAC library were inserted into the retrieval vector PL253 by a BAC recombineering strategy. Recombineering was also used to replace ACVR1 codon 206 (CGC>CAC) in murine exon 5, followed by addition of a neor marker gene flanked by FLP recombinase target sites. This targeting vector was electroporated into C57BL/6 ES cells that were then G418 (neor) selected. About 300 G418-positive colonies were isolated and grown, and homologous recombination was verified by Southern analysis in sixteen clones. Three positive ES cell clones were injected into blastocysts from Balb-c mice (white coat color) in order to detect genetically chimeric pups by chimeric black/white coat color. Twenty-seven chimeric pups were born, several with 70-90% black coat indicating a high proportion of cells with the mutant ACVR1 allele. Analysis of young chimeras through physical examination, histology, and X-ray/microCT analyses revealed phenotypes consistent with those of human FOP patients including malformed toes and post-natal heterotopic bone formation. These data provide the first direct in vivo evidence that the FOP c.617G>A; R206H ACVR1 mutation induces the characteristic clinical phenotype observed in FOP patients. Further development of this mouse model to obtain heterozygous germline transmission will generate a stable animal model to investigate the cellular and molecular mechanisms leading to the skeletal malformations and ectopic bone formation in FOP and provide a system for developing and testing treatments for FOP and other conditions of misregulated bone formation.

## 1204

**Osteoblast and Osteoclast Involvement in the Pathogenesis of a Mouse Model for Craniometaphyseal Dysplasia (CMD).** I. Chen<sup>\*</sup>, J. Wang<sup>\*</sup>, B. Koczon-Jaremk<sup>\*</sup>, E. Reichenberger. Reconstructive Sciences, UCHC, Farmington, CT, USA.

Craniometaphyseal dysplasia (CMD) is a monogenic human disorder characterized by progressive thickening of craniofacial bones concurrent with widened and radiolucent metaphyses in long bones. Mutations for autosomal dominant CMD have been identified in the *ANK* gene (*ANKH*). A knock-in (KI) mouse model expressing the human *Ank* mutation (Phe377del) replicates many features of CMD. Here, we study the mutational effect on osteoblasts and osteoclasts in *Ank*<sup>KI/KI</sup> mice.

We performed skeletal analyses by biochemical markers and histomorphometry. We studied osteoblast defects using calvarial osteoblast and bone marrow stromal cell cultures by real time PCR, immunocytochemistry, alkaline phosphatase (ALP) and von Kossa/Alizarin red S staining. To study osteoclasts *in vitro*, we derived osteoclasts from mouse bone marrow macrophage precursors (BMMs) and human or mouse peripheral blood cultures. We determined osteoclast numbers and activity by TRAP staining and resorption assays.

*Ank*<sup>KI/KI</sup> mice have higher numbers of osteoblasts and osteoclasts, which, however, did not lead to increased bone formation or resorption. Serum ALP and TRAP5b were increased but levels of the N-terminal propeptide of type I procollagen (measure of bone formation) and the type I collagen cross-linked C-terminal telopeptide (marker of osteoclast activity) were normal. Histomorphometry showed increased osteoblast surface and osteoclast number in femoral and calvarial sections but mineral apposition and bone formation rates were comparable to *Ank*<sup>+/+</sup> mice. *Ank*<sup>KI/KI</sup> osteoblast cultures showed significantly reduced mineral nodules and expression of *Bglap*, *Phex* and *Mmp13* at the mineralization stage while ALP staining and other differentiation markers, such as *Col1*, *Bsp*, *Tnap* appeared comparable to *Ank*<sup>+/+</sup> cultures thus indicating defective osteoblast mineralization. *Ank*<sup>KI/KI</sup> BMM cultures formed significantly fewer TRAP<sup>+</sup> cells (nuclei ≥3) and showed decreased mineral resorption. Osteoclast-like cells of the same size generally carried significantly more nuclei in *Ank*<sup>KI/KI</sup> BMM cultures suggesting an enhanced fusion of precursors. However, *Ank*<sup>KI/KI</sup> multinucleated cells showed diminished actin ring formation and failed to enlarge in size. Results from peripheral blood cultures suggested that the degree of osteoclast formation depends on the available number of precursors in CMD patients and *Ank*<sup>KI/KI</sup> mice. Our study suggests that the CMD-like phenotype in mice and most likely CMD in humans is caused by a complex mechanism involving both, osteoblasts and osteoclasts. We believe that studies of this *Ank*<sup>KI/KI</sup> model could potentially lead to a novel therapeutic approach for CMD.

**Cardiovascular Diseases as Forecasters of Hip Fracture: A Nationwide Cohort Study in Twins.** K. Michaëlsson<sup>1</sup>, U. Sannerby<sup>\*1</sup>, H. Melhus<sup>2</sup>, R. Gedeberg<sup>\*3</sup>, L. Byberg<sup>\*1</sup>, N. L. Pedersen<sup>\*4</sup>. <sup>1</sup>Section of Orthopaedics, Department of Surgical Sciences, Uppsala, Sweden, <sup>2</sup>Section of Clinical Pharmacology, Department of Medical Sciences, Uppsala, Sweden, <sup>3</sup>Section of Anesthesiology and Intensive Care, Department of Surgical Sciences, Uppsala, Sweden, <sup>4</sup>Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden.

Cardiovascular disease (CVD) and osteoporotic fractures are frequent health problems in the elderly. Recent studies indicate common etiologies for these diseases. However, the influence of different CVD diagnoses on fracture risk is uncertain. With a large twin analysis we can both examine the association between CVD, also in subcategories, and fracture risk, and evaluate the relative importance of genetics to lifestyle for this association.

We used a nation-wide cohort study, including all 33,432 Swedish twins born 1896-1944, and still alive in 1972. The Swedish Inpatient Registry identified twins with cardiovascular diseases and hip fracture. Cox's proportional hazards regression models were used with time-varying exposure of cardiovascular disease and covariate information including comorbidity to assess hazard ratios of hip fracture with 95% confidence intervals. Both twins in a pair were followed through an identical period of time, i.e. if one twin had a fracture or died, the co-twin was censored at the same date to avoid different follow-up time.

Of all women and men, 35% and 43%, respectively, had had a cardiovascular disease before censoring. A hip fracture was recorded for 1836 twins. CVD was associated with an increased future rate of hip fracture in both sexes. Any type of CVD, conferred a future adjusted HR of 1.71 (95% CI 1.51-1.92) for hip fracture, with similar estimates for women and men. The rate was three-fold higher within the first year after any CVD event. There was an especially increased risk of hip fracture after a diagnosis of heart failure (HR 2.86; 95% CI 2.31-3.53). This estimate was even higher within the first year after the diagnosis of heart failure (HR 14.52; 95% CI 10.35-20.37). We found a modest increased risk for hip fracture after a diagnosis of hypertension (HR 1.58; 95% CI 1.29-1.94) and ischemic heart disease (HR 1.36; 95% CI 1.15-1.62). Expectedly, there was an increased hip fracture risk after a history of stroke - HR 2.61 (95% CI 2.21-3.08). The increased risks were reduced by a within-pair comparison in monozygotic twins. This attenuation was especially marked for the diagnosis of heart failure but to a lesser degree for stroke.

Clinicians should have an increased awareness for the substantial increased risk of hip fracture after a recent diagnosis of CVD. Our generally attenuated estimates with the co-twin control analysis are an indication of shared genetic influences for CVD and osteoporotic fractures.

**Higher Bone Mineral Density is Associated with Increased Odds of Carotid Atherosclerosis in Postmenopausal Women Not Currently Using Estrogen Therapy.** G. A. Laughlin<sup>\*</sup>, E. Barrett-Connor. Family and Preventive Medicine, University of California San Diego, La Jolla, CA, USA.

Clinical and animal studies suggest that osteoporosis and atherosclerotic cardiovascular disease are biologically linked, perhaps through calcium-mediated processes or via reduced blood flow secondary to vascular disease. To test these hypotheses, we examined the association of bone mineral density (BMD) with a measure of overall atherosclerotic burden that is not directly calcium-dependent, intima media thickness (IMT) of the carotid arteries. Participants were 758 community-dwelling men and women, ages 55-97 (mean=75); 204 women were currently using estrogen therapy (ET), 245 were past or never users. IMT of the internal and the common carotid artery (ICA and CCA, respectively) was higher ( $p<.001$ ) in men (1.67 and 1.02 mm) than women (1.43 and 0.95 mm), but did not differ significantly by current ET. Carotid atherosclerosis was defined as IMT  $> 80^{\text{th}}$  sex-specific percentile for either the ICA or CCA, or stenosis  $\geq 25\%$ . In logistic regression analyses adjusting for factors common to osteoporosis and cardiovascular disease, higher BMD at the hip, femoral neck and lumbar spine was associated with significantly higher (not lower) odds of carotid atherosclerosis for women not using ET, but not for men or for women who were estrogen users (Table). In addition, the adjusted prevalence of osteoporosis (T-score  $\leq 2.0$ ) for women not using ET was significantly lower ( $p<.05$ ) at all three bone sites in those with carotid atherosclerosis versus those without. Osteoporosis prevalence did not differ by carotid atherosclerosis status for men or for women who were using ET. These results suggest that reduced blood flow secondary to atherosclerosis is not a biological basis for the widely reported association of osteoporosis and cardiovascular disease. The positive atherosclerosis-BMD association in women without ET was independent of factors common to bone and heart disease, and is unexplained.

**Calcium Intake Is Not Associated with Increased Coronary Artery Calcification: The Framingham QCT Study.** E. J. Samelson<sup>1</sup>, J. M. Massaro<sup>\*2</sup>, C. S. Fox<sup>\*3</sup>, K. L. Tucker<sup>4</sup>, S. L. Booth<sup>\*4</sup>, T. J. Wang<sup>\*5</sup>, K. E. Broe<sup>1</sup>, S. D. Berry<sup>1</sup>, M. T. Hannan<sup>1</sup>, R. R. McLean<sup>1</sup>, L. A. Cupples<sup>\*2</sup>, C. J. O'Donnell<sup>\*3</sup>, D. P. Kiel<sup>\*1</sup>. <sup>1</sup>Inst for Aging Research, Hebrew SeniorLife, Harvard Med Sch, Boston, MA, USA, <sup>2</sup>Boston Univ School of Public Health, Boston, MA, USA, <sup>3</sup>NHLBI, Framingham, MA, USA, <sup>4</sup>Tufts Univ, Boston, MA, USA, <sup>5</sup>MA General Hosp, Harvard Med Sch, Boston, MA, USA.

Adequate calcium (Ca) intake is known to protect the skeleton. However, whether there is an increased risk of myocardial infarction (MI) among women taking Ca supplements compared to placebo is controversial. Even small, adverse effects of Ca intake on cardiovascular disease (CVD) could have major public health consequences since Ca supplements are widely used. We assessed the association between total Ca intake and coronary artery calcification (CAC), a direct measure of atherosclerosis that predicts risk of MI independent of other risk factors.

Participants included 690 women and 588 men in the Framingham Offspring Study (mean age 60 years, range 36-83 years) who attended clinic visits in 1998-2001 and completed food frequency questionnaires and CT examinations performed 4 years later in 2002-05. CAC was scored using the Agatston method. ANCOVA was used to calculate mean log-transformed CAC score across quartiles (1=low) of total Ca intake (from diet and supplements) adjusted for age, BMI, smoking, alcohol consumption, vitamin D supplement use, energy intake, and for women, menopause status and estrogen use.

Mean ( $\pm$ SD) total Ca intake was 1184 mg ( $\pm$ 565 mg) in women and 883 mg ( $\pm$ 456 mg) in men; 64% of women and 26% of men used Ca supplements. Mean CAC was 2.36 ( $\pm$ 2.44) in women and 4.32 ( $\pm$ 2.54) in men and ranged from 0 to 8.52.

While mean age-adjusted CAC score appeared to decrease with increasing total Ca intake, the trend was not significant after multivariable adjustment (Table). Results were similar for dietary Ca and Ca supplement use as well as for analyses that (1) additionally adjusted for diabetes, hypertension, CVD, total cholesterol, and aspirin use, (2) stratified by vitamin D intake from diet and/or supplements, and (3) excluded individuals with CVD.

While adequate Ca intake is important to bone health, effects on CVD risk are less clear. Our study does not support the hypothesis that high Ca intake increases coronary artery calcification, an important measure of atherosclerosis burden. Trials of Ca supplementation dosage used in clinical practice are warranted.

Mean Coronary Artery Calcification (CAC) Score by Quartile of Total Calcium (Ca) Intake

**Subclinical Thyroid Disease Predicts Risk of Hip Fracture: The Cardiovascular Health Study.** J. S. Lee<sup>\*1</sup>, H. A. Fink<sup>\*2</sup>, J. A. Vu<sup>\*1</sup>, P. Buzkova<sup>\*3</sup>, L. D. Carbone<sup>4</sup>, Z. Chen<sup>\*5</sup>, A. R. Cappola<sup>6</sup>, J. Robbins<sup>1</sup>. <sup>1</sup>Internal Medicine, University of California Davis, Sacramento, CA, USA, <sup>2</sup>Internal Medicine, VA Medical Center, Minneapolis, MN, USA, <sup>3</sup>Biostatistics, University of Washington, Seattle, WA, USA, <sup>4</sup>Internal Medicine, University of Tennessee, Memphis, TN, USA, <sup>5</sup>Internal Medicine, University of Arizona, Tucson, AZ, USA, <sup>6</sup>Internal Medicine, University of Pennsylvania, Pittsburgh, PA, USA.

Thyroid hormone influences bone metabolism, but whether subclinical thyroid disease is related to risk of hip fracture is unclear. We evaluated whether biochemically-defined subclinical thyroid disease predicts the risk of incident hip fracture in older men and women. Participants were U.S. community-based men and women aged  $\geq 65$  years during 1989-90 in the prospective cohort Cardiovascular Health Study. Baseline serum thyroid-stimulating hormone (TSH) levels were measured in everyone, free thyroxine was measured if TSH was outside the reference 0.1-4.5 mU/L, and subjects were classified as subclinical hyperthyroidism, subclinical hypothyroidism, and euthyroid. 51 subjects with overt hyper/hypothyroidism were excluded from analyses due to small sample size. Incident hip fractures were validated by medical records (mean follow-up 12.5 y). Cox regression models were conducted to estimate hazard ratios for hip fracture by subclinical thyroid disease group. Risks of incident hip fracture were 2.07-fold higher in men with subclinical hypothyroidism and 3.31-fold higher in men with subclinical hyperthyroidism, while no associations were observed in women (Table). Additional adjustment for other risk factors of hip fracture and excluding those taking thyroid hormone or thyroid-altering medications did not materially alter the results. In conclusion, subclinical hypo- and hyperthyroidism are independent predictors for subsequent hip fracture in community dwelling older men.

**Hazard ratios (95% CI) for hip fracture**

Thyroid status	Number of Hip Fracture	Age-adjusted	MV-adjusted*
Men			
Euthyroid (n=1159)	58	1	1
Subclinical hypothyroid (n=184)	18	1.86 (1.09-3.15)	2.07 (1.16-3.67)
Subclinical hyperthyroid (n=29)	4	3.07 (1.11-8.48)	3.31 (1.01-10.85)
Women			
Euthyroid (n=1694)	198	1	1
Subclinical hypothyroid (n=359)	36	0.87 (0.61-1.24)	0.83 (0.57-1.21)
Subclinical hyperthyroid (n=142)	17	1.06 (0.65-1.74)	0.94 (0.54-1.63)

**Higher Bone Mineral Density Loss in Older Men with Diabetes: The Osteoporotic Fractures in Men Study.** E. S. Strotmeyer<sup>1</sup>, R. M. Boudreau<sup>\*1</sup>, L. M. Marshall<sup>2</sup>, A. V. Schwartz<sup>3</sup>, D. C. Bauer<sup>3</sup>, E. Barrett-Connor<sup>\*4</sup>, E. S. Orwoll<sup>2</sup>, J. A. Cauley<sup>1</sup>. <sup>1</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Oregon Health & Science University, Portland, OR, USA, <sup>3</sup>University of California, San Francisco, CA, USA, <sup>4</sup>University of California, San Diego, CA, USA.

Type 2 diabetes (DM) is associated with increased fracture risk despite generally higher bone mineral density (BMD) vs. non-diabetic adults. Older diabetic women have higher BMD loss (Schwartz et al 2005). We analyzed BMD change over 4.6 $\pm$ 0.4 years in 5,995 community dwelling men aged  $\geq 65$  years in the Osteoporotic Fractures in Men (MrOS) Study. DM was defined as self-report diagnosis, hypoglycemic medication use or fasting glucose (FG)  $\geq 126$  mg/dl. Impaired FG (IFG) was defined as FG  $\geq 100$  and  $<126$  mg/dl. Total hip and femoral neck BMD, total lean mass (LM) and fat mass (FM) were measured by DXA (QDR 4500W, Hologic Inc). Men missing BMD change or DM/IFG status were excluded. Of 4,094 men (age 72.8 $\pm$ 5.4 years; 91% white), 14% had DM and 37% had IFG. Adjusting for age, race, LM and FM, hip BMD was highest in DM and intermediately higher in IFG vs. normal FG at baseline (0.986 vs. 0.963 vs. 0.947 g/cm<sup>2</sup>; p<0.05) and follow-up (0.972 vs. 0.952 vs. 0.939 g/cm<sup>2</sup>; p<0.05). LM loss was highest in DM and intermediately higher in IFG vs. normal FG (-2.8 vs. -1.0 vs. 1.5 kg; p<0.05), with no FM change differences. Men with DM had significantly higher annualized % hip BMD loss vs. normal FG men after adjustment (Table). Higher hip BMD loss in DM occurred due to a concurrent higher BMC loss and lower area increase. Initial hip BMD did not attenuate results, suggesting that loss occurs regardless of initial BMD in DM. Adjusting for baseline fasting insulin level, smoking, drinking, physical activity, and medication use (corticosteroid, statin, thiazide, thyroid and osteoporosis medication) did not change associations. Thiazolidinedione (TZD) use in DM (N=48) was associated with 2x greater % BMD loss vs. DM not using TZDs (-1.028 vs. -0.496 %; p<0.05); however did not explain the higher BMD loss in DM vs. non-DM men. Results were similar for annualized % femoral neck BMD loss, though not significant for BMC or area. DM, but not IFG, was associated with 60% greater hip BMD loss, which was not explained by initial BMD, LM loss, or medication use. This BMD loss may have important implications for increased fracture risk in older diabetic adults.

Annualized % change	DM	IFG	Normal FG
Total hip BMD

**Predictors of Poor Outcomes Following Osteoporotic Fractures in Elderly Women and Men: An 18 Year Prospective Study.** D. Bliuc, N. D. Nguyen, T. V. Nguyen, J. A. Eisman, J. R. Center. Bone and Mineral Program, Garvan Institute of Medical Research, Sydney, Australia.

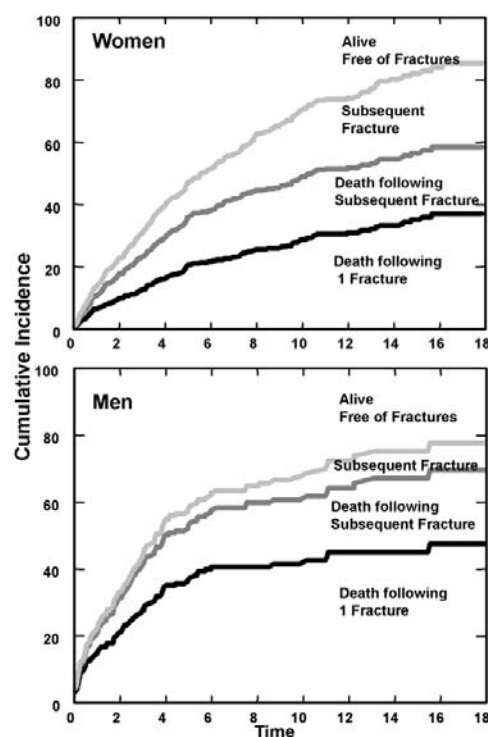

Osteoporotic fractures increase re-fracture and mortality risk. Although these severe outcomes are related, they are usually studied separately. The aims of this study were to examine the risk of either one or both of these outcomes following all osteoporotic fractures and to determine their predictors over 18-year in women and men aged 60+.

All subjects (n=1295) sustaining low trauma fractures from Dubbo Osteoporosis Epidemiology Study were followed (April 1989- May 2007). Bone mineral density, postural stability, quadriceps strength, physical activity, co-morbidities, calcium intake, smoking and anthropometric measurements were assessed 2-yearly in a subgroup (n=636) participating in the detailed study. Cumulative incidences of re-fracture and mortality were computed separately for women and men and the predictors for these outcomes were assessed by Cox Proportional Hazard Model for multiple events.

There were 952 fractures in women and 343 in men, followed by 290 subsequent fractures in women and 74 in men, and 461 deaths in women and 197 in men. The highest re-fracture and mortality risk was observed in the first 5-8 year period (Fig 1). By the end of 8 years 26 % women and 41% men had died and a further 37% women and 24 % men re-fractured. Approximately 50% of women and 75% of men with re-fracture died in the first 5 years post-fracture. Mortality risk was higher in men than women, but ongoing fracture continued to occur in those women who survived such that by the end of the study there were only 20% of subjects alive with no further fractures.

In the detailed study group, re-fracture independently increased mortality risk [HR: 4.32 (3.40- 5.49) and 2.32 (1.43- 3.48) for women and men, respectively]. Other independent predictors for mortality included older age, lower femoral neck BMD, physical inactivity and more falls in women and older age, low calcium intake, and quadriceps weakness in men.

This study has shown the cumulative risk of multiple adverse events following an initial fracture. Those who survive the initial fracture have increased re-fracture risk and further increase in mortality risk. These findings highlight the need for prevention of both initial and subsequent fractures.

**Increases in BMD Observed with Anti-Sclerostin Antibody Treatment Are Reversible: A Longitudinal Ovariectomized Rat Study.** X. Li, K. Warmington\*, Q. T. Niu\*, M. Grisanti, H. Tan, D. Dwyer\*, M. Stolina, W. S. Simonet, P. J. Kostenuik, C. Paszty, H. Z. Ke. Amgen Inc., Thousand Oaks, CA, USA.

Anti-sclerostin monoclonal antibody (Scl-Ab) is a new anabolic agent that stimulates bone formation and increases bone mass and bone strength in animal models of osteoporosis. However, the effects of discontinuing treatment have not been studied in ovariectomized (OVX) rats. In this study, we examined the BMD response during treatment with Scl-Ab and after its discontinuation. Female SD rats at 5.5 months of age were sham-operated or OVX and left untreated for 7.5 months to allow for the development of osteopenia. OVX rats were then administered Scl-Ab at 12.5 or 25 mg/kg by weekly s.c. injection, for a period of 8 weeks (8-10/group). Thereafter, treatment was discontinued for another 16 weeks. BMD of lumbar vertebrae (LV-BMD) and of femur and tibia (FT-BMD) was determined before treatment, and at weeks 4, 6, 8, 10, 12, 16, 20 and 24 by DXA. OVX rats had significantly lower LV-BMD (-18%) and FT-BMD (-9%) than sham controls before the initiation of treatment. In OVX rats treated with either dose level of Scl-Ab, LV-BMD rapidly and significantly increased to the level of sham controls by the first 6 weeks of treatment (Figure). The LV-BMD was maintained at the increased level between the week 6 and week 12 time points. Thereafter, LV-BMD in the low dose group decreased by 8% at week 16, then by 10% and 13% at weeks 20 and 24, respectively, compared with the peak BMD at week 12. In the high dose group, LV-BMD decreased gradually by 3%, 6% and 11% at weeks 16, 20 and 24, respectively. Similarly FT-BMD rapidly and significantly increased, for both dose levels, to the level of sham controls by the first 6 weeks of treatment. In contrast to LV-BMD, FT-BMD was maintained at the increased level between the week 6 and week 20 time points. FT-BMD at week 24 was slightly decreased by 2.4% and 2.5% from those at week 20 in low and high dose groups, respectively. In summary, the increased BMD in lumbar spine and long bones, resulting from Scl-Ab treatment, was maintained for a period of time even after discontinuation of therapy. Thereafter, a decrease in BMD was observed. We conclude that increased bone mass induced by Scl-Ab treatment in OVX rats is reversible, with BMD decreasing over time upon discontinuation of treatment.

**A Short Treatment with an Antibody to Sclerostin Can Inhibit Bone Loss in an Ongoing Model of Colitis.** A. Eddleston\*, D. Marshall\*, A. Moore\*, P. Stephens\*, M. Muzylak\*, M. Marenzana\*, M. K. Robinson. Inflammation Biology, UCB-Celltech, Slough, United Kingdom.

Sclerostin is an osteocyte-produced protein which regulates the anabolic activity of osteoblasts. A neutralizing antibody to sclerostin has been reported to reverse ovariectomy-induced bone loss in a rats (Warmington et. al. 2005 J. Bone Miner Res 20 S22). The mouse CD4+CD45Rb<sup>high</sup> T cell transfer model of colitis is a chronic disease model in which animals develop inflammation-induced bone loss (Byrne et. al. 2005 Gut 54, 78-86). We have investigated the ability of a neutralizing antibody to sclerostin (Scl-ab) to inhibit bone loss in a modification of the model described by Byrne that features a more synchronous onset of colitis. CD4+CD45Rb<sup>high</sup> T cells isolated from Balb/c mice were cultured in vitro with IL-12 and anti-IL-4 to skew them towards a Th1 phenotype before transfer into SCID mice (5x10<sup>5</sup> cells per mouse). Scl-ab or an isotype-matched control antibody (Cntrl-ab) were dosed at 10mg/kg sc weekly starting at day 50 after cell transfer by which time colitis was apparent. At this point animals receiving T cells had significantly lower bone mass than a control group not receiving cells (day 50 femoral BMD in mice without cell transfer 80.8±1.5mg/cm<sup>2</sup> vs cell transfer group 73.2±2.6mg/cm<sup>2</sup> p<0.05). Antibody dosing continued until day 69 when the experiment was terminated. Dosing with Scl-ab had no effect on the severity of colitis (assessed by symptoms, weight loss and histology) however by the end of the experiment mice dosed with Scl-ab had significantly higher femoral and total BMD than mice dosed with Cntrl-ab (femoral BMD 73.4±3.4mg/cm<sup>2</sup> vs 64.5±2mg/cm<sup>2</sup> p<0.05, total

BMD 55.0±1.5mg/cm<sup>2</sup> vs 49.7±1.4mg/cm<sup>2</sup> p<0.01). Micro-CT at the distal femur in these animals showed that the Scl-ab treated animals had significantly more trabecular bone volume and increased trabecular thickness than Cntrl-ab treated animals (BV/TV+58% p<0.001, Tb.th +46% p<0.001). At the femoral mid-shaft cortical bone was significantly thicker (Cs.th +15% p<0.001) in Scl-ab treated animals. A four-point bending test showed that femurs from Scl-ab treated animals had significantly greater bone strength when compared with femurs from animals receiving Cntrl-ab (maximum load +67% p<0.01 and energy to failure +86% p<0.01). The Scl-ab treated animals also had significantly higher levels of circulating osteocalcin (p<0.01) but significantly lower levels of circulating TRAP5b (p<0.01) than those dosed with Cntrl-ab.

In conclusion a neutralizing antibody to sclerostin inhibits inflammation-induced bone loss in a chronic mouse model of colitis but does not reduce inflammation.

**Effects of Co-treatment with an Anti-Sclerostin Monoclonal Antibody and Alendronate in Ovariectomized Rats.** X. Li, K. Warmington\*, Q. T. Niu\*, E. Asuncion, M. Grisanti, D. Dwyer\*, H. Tan, W. S. Simonet, M. Ominsky, M. Stolina, P. J. Kostenuik, C. Paszty, H. Z. Ke. Amgen Inc., Thousand Oaks, CA, USA.

Anti-sclerostin monoclonal antibody (Scl-Ab) is a new anabolic agent which has been shown to increase bone formation, bone mass and bone strength in rodents and primates. More recently, in a placebo controlled Phase I trial in postmenopausal women, Scl-Ab was shown to increase serum markers of bone formation. For anabolic agents, there is general interest in determining whether or not anabolic activity is blunted by co-treatment with an anti-catabolic agent such as alendronate (ALN), which is known to inhibit bone resorption and preserve bone mass in animal models and in humans. In the current study, we examined whether co-treatment with ALN would result in a blunting of the anabolic effects of Scl-Ab in ovariectomized (OVX) rats. Female SD rats at 6.5 months of age were sham-operated or OVX and left untreated for 3.5 months, allowing for significant bone loss to occur. OVX rats were then treated for 6 weeks (10/group) with Scl-Ab (1x/week, s.c., 25 mg/kg), or ALN (2x/week, s.c., 0.028 mg/kg) alone or in combination. Micro-CT analysis of the 5<sup>th</sup> lumbar vertebrae revealed that, over the 6 week duration of the study, there was further trabecular bone loss in vehicle-treated OVX rats compared with pre-treatment OVX controls. As expected, ALN alone prevented this bone loss but did not restore bone mass in OVX rats. Scl-Ab alone not only prevented the further trabecular bone loss, but also restored trabecular vBMC, vBMD and trabecular bone volume, and improved trabecular architecture to levels of sham controls. In addition, Scl-Ab increased cortical area and cortical thickness of cortical shell to the levels higher than those of sham controls. Interestingly, trabecular bone mass and architecture, as well as cortical bone mass, did not differ significantly between the Scl-Ab alone and Scl-Ab plus ALN groups, indicating that ALN did not blunt the bone restorative effects of Scl-Ab in OVX rats. Consistent with this, histomorphometric analysis showed that Scl-Ab alone and Scl-Ab plus ALN were equally effective at increasing mineralizing surface, mineral apposition rate and bone formation rate, on both the periosteal and the endocortical surface of the tibial shaft. Furthermore, Scl-Ab alone and Scl-Ab plus ALN were equally effective at increasing serum osteocalcin, a bone formation marker. These results demonstrate that the anabolic responses to Scl-Ab treatment were not impaired by co-treatment with alendronate in OVX rats.

**Fully Human anti-DKK1 Antibodies Increase Bone Formation and Resolve Osteopenia in Mouse Models of Estrogen-Deficiency Induced Bone Loss.** H. Glantschnig\*, R. Hampton\*, N. Wei\*, K. Scott\*, P. Nantermet\*, J. Zhao\*, F. Chen\*, J. Fisher\*, Q. Su\*, B. Pennypacker\*, T. Cusick\*, P. Sandhu\*, A. Reszka\*, W. Strohl\*, O. Flores\*, F. Wang\*, D. Kimmel\*, Z. An\*. <sup>1</sup>Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA, <sup>2</sup>Biologics Research, Merck Research Laboratories, West Point, PA, USA.

Genetic studies have linked both osteoporotic and high bone mass (HBM) phenotypes to mutations within the LDL-receptor related protein 5 (LRP5). LRP5 and 6 are co-receptors for Wnt-ligands and bind inhibitory Dickkopf (DKK) proteins. Amino-acid substitutions leading to HBM-phenotypes desensitize LRP5 to the inhibitory function of DKK1. DKK1 is expressed in adult bone, and treatment modalities that diminish LRP/DKK1 binding may act as stimulators of bone mass accrual. Here we describe the development and the *in-vitro* and *in-vivo* characterization of functionally neutralizing anti-DKK1 monoclonal antibodies (mAbs).

Screening of CAT-libraries identified single-chain antibodies and full IgGs with high-affinity for *Rhesus macaque* and *Mouse sp.* DKK1, but not DKK2 and DKK4. Full IgGs were funneled through a series of functional *in-vitro* assays validating that selected antibodies block receptor-ligand interaction, neutralize DKK1-function in osteoblastic differentiation, and as expected, block DKK1 inhibition of Wnt-signaling. To evaluate pharmacologic efficacy *in-vivo*, selected anti-DKK1 mAbs were tested by sub-cutaneous injection in young and adult mice, and evaluated in a mouse model of estrogen-deficiency-induced osteopenia. Fully-human anti-DKK1 mAbs were found to have prolonged half-lives in mice (~17 days), dose-dependently reduced bioavailable DKK1 in serum and were tolerated well over treatment periods up to 8 weeks. mAbs (0.5 - 10 mpk/ 2x wk) elicited significant dose-dependent increases in BMD in young mice at the central and distal femur (4 wks).

Importantly, in osteopenic adult animals administration of DKK1-mAb (2 mpk/1-2x wk) resulted in significant stimulation of serum-PINP and new bone formation (2-fold) at endocortical surfaces and trabecular bone regions. This was paralleled by partial-to-complete resolution of osteopenia (BMD) in femur and lumbar-vertebral bones at 8 wks. Further, testing of antibodies in *Rhesus macaques* (10 mpk) resulted in a pharmacodynamic response (PINP), implicating that a bone-forming mechanism had been engaged.

In conclusion, we provide pharmacologic evidence for Wnt-pathway modulation by neutralizing DKK1-bioactivity resulting in resolution of osteopenia in animal models. Thus, fully-human anti-DKK1 mAbs exhibit the potential as bone-anabolic agents for the treatment of diseases characterized by low bone mass.

**R-Spondin1 Reduces Bone Loss in Human TNF Transgenic and Ovariectomized Mice.** J. Zhao<sup>1</sup>, K. Kim<sup>\*1</sup>, M. Binnerts<sup>\*1</sup>, G. Kroenke<sup>\*2</sup>, J. Katzenbeisser<sup>\*2</sup>, A. Abo<sup>\*1</sup>, G. Schett<sup>\*2</sup>. <sup>1</sup>Research, Nuvelo, Inc., San Carlos, CA, USA, <sup>2</sup>Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nurnberg, Erlangen, Germany.

Wnt proteins are key mediators for bone formation and appear to protect the macro- and micro-architecture of periarticular bone during inflammation. Blocking of Wnts by natural antagonists, such as Dickkopf-1 (DKK1), results in enhanced breakdown of bone. To further explore the Wnt pathway during pathological bone remodeling, we investigated whether R-Spondin1 (RSp1), an inducer of the Wnt signaling pathway, reduces inflammatory bone resorption and postmenopausal bone loss in mouse models. RSp1 synergistically stimulated the activation of the Wnt pathway by Wnt3A by antagonizing DKK-1 using TCF reporter assay in osteoblastic C2C12 cells. RSp1 also amplified the Wnt-mediated osteogenic differentiation including alkaline phosphatase and osteoprotegerin in C2C12 cell line. Treatment with RSp1 achieved a significant protection of periarticular bone loss in arthritic human TNF transgenic (hTNFtg) mice. Bone erosions were smaller and osteoclast numbers were decreased upon RSp1 treatment in hTNFtg mice. RSp1 also protected cartilage loss and induced osteophyte formation although no effect on synovial inflammation was seen in hTNFtg mice. Likewise, RSp1 administration alleviated ovariectomy-induced bone loss in mice. We found that RSp1 substantially inhibited the suppressing effect of estrogen deficiency on femoral bone mineral density and content in mice. Moreover, RSp1 stimulated the new bone formation in trabecular bone in ovariectomized mice. In conclusion, RSp1 reduces bone loss during experimental arthritis and osteoporosis in mouse models by stimulating the bone anabolic pathway. Activation of Wnt signaling by RSp1 may thus be a potent strategy to protect the bone from pathological degradation. Currently, we are investigating the role of RSp1 in reducing ovariectomy-induced osteoporosis and collagen-induced arthritis in rat models.

## 1216

**Transition from Alendronate to Denosumab Resulted in Further Reductions in Local and Systemic Bone Turnover Parameters and Reduced Cortical Porosity in Ovariectomized Cynomolgus Monkeys.** M. S. Ominsky<sup>1</sup>, J. Jolette<sup>2</sup>, S. Y. Smith<sup>2</sup>, F. Vlasseros<sup>\*2</sup>, R. Samadpour<sup>\*2</sup>, P. J. Kostenuik<sup>1</sup>. <sup>1</sup>Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA, <sup>2</sup>Charles River Laboratories Preclinical Services Montreal, Inc., Montreal, QC, Canada.

The effects of transition from the bisphosphonate alendronate (ALN) to the RANK ligand inhibitor denosumab (DMAb) on local and systemic bone turnover parameters were studied in adult ovariectomized (OVX) cynomolgus monkeys (cynos). OVX cynos (>7 years old) were treated with vehicle (Veh, n=20), ALN (n=21; 50 µg/kg IV 2/week), or DMAb (n=11; 25 mg/kg SC monthly). After 6 months, animals from each of the Veh (n=10) and ALN groups (n=11) were switched to DMAb for an additional 6 months (Veh-DMAb and ALN-DMAb), while the remaining 10 animals in these groups continued on Veh or ALN. The original DMAb group remained on DMAb for 12 months total. Serum biomarkers were monitored, and dynamic histomorphometry was performed at the rib, tibial diaphysis, proximal tibia, lumbar vertebra (L2), and ilium. Strength of L5-6 trabecular cores was tested by compression.

DMAb and ALN significantly reduced serum biomarkers of bone resorption (CTx) and formation (osteocalcin, OC) throughout the 12 month treatment period, with significantly greater reductions observed in the DMAb group. Upon transition from ALN to DMAb, serum CTx and OC levels were further reduced to the levels observed with DMAb alone. Dynamic histomorphometry of trabecular bone (iliac crest, L2 and proximal tibia) and of cortical bone (ribs, tibial diaphysis) showed significant reductions in bone turnover parameters after 12 months of DMAb or ALN. For most parameters at most skeletal sites, cortical and trabecular turnover suppression with DMAb and with ALN-DMAb was numerically or statistically greater than with ALN. Cortical porosity at the rib and tibial diaphysis was significantly lower with DMAb and with ALN-DMAb ( $p < 0.05$  vs Veh), but not with ALN alone.

Relationships between local bone turnover suppression and bone strength were studied by measuring peak load of L5-6 trabecular cores and by dynamic histomorphometry of trabecular bone from L2. Peak load of L5-6 trabecular cores was significantly greater in the DMAb and ALN-DMAb groups ( $p < 0.05$  vs. Veh), but not with continuous ALN. With all groups, L5-6 peak load was inversely correlated with L2 BFR ( $R = -0.53$ ) and osteoclast surface ( $R = -0.47$ ).

In summary, transition from ALN to DMAb resulted in further reductions in local and systemic bone turnover parameters compared to continuous ALN treatment in OVX cynos. Bone strength was maintained or improved by transition from ALN to DMAb, and bones

with the greatest strength values exhibited the lowest levels of bone turnover regardless of treatment.

**Loss of a Single Bim Allele Recovers the Defective Osteoclast Function in bcl-2-/- Mice but Does Not Restore the Anabolic Action of PTH.** Y. Nagase<sup>1</sup>, M. Iwasawa<sup>1</sup>, T. Akiyama<sup>1</sup>, Y. Kadono<sup>1</sup>, N. Ogata<sup>1</sup>, Y. Oshima<sup>1</sup>, M. Nakamura<sup>1</sup>, T. Yasui<sup>1</sup>, T. Miyamoto<sup>2</sup>, K. Nakamura<sup>1</sup>, S. Tanaka<sup>1</sup>. <sup>1</sup>The University of Tokyo, Tokyo, Japan, <sup>2</sup>Department of Orthopaedic Surgery, Cell Differentiation, Keio University School of Medicine, Tokyo, Japan.

Anti-apoptotic molecule Bcl-2 resides on the mitochondrial outer membrane, and inhibits apoptosis by suppressing cytochrome *c* release from mitochondria. We previously reported that Bcl-2 promoted the differentiation, activation and survival of both osteoblasts and osteoclasts by analyzing *bcl-2*<sup>-/-</sup> mice. However, *bcl-2*<sup>-/-</sup> mice die at about 2 weeks of age due to renal failure and immunodeficiency, and further analysis of the skeletal tissues of the mice is not possible. We found that loss of a single *bim* allele ameliorated the ill health and early death of *bcl-2*<sup>-/-</sup> mice. We therefore generated *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice by interbreeding with *bcl-2*<sup>+/-</sup> mice and *bcl-2*<sup>-/-</sup>*bim*<sup>-/-</sup> mice, and compared the skeletal tissue of *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice with that of *bcl-2*<sup>+/-</sup>*bim*<sup>+/-</sup> littermates (control) to analyze the role of Bcl-2 in the skeletal tissue. Although both mice grew normally into adults, *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice displayed an osteopenia compared to *bcl-2*<sup>+/-</sup>*bim*<sup>+/-</sup> mice. Bone histomorphometric analysis demonstrated that *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice reduced bone volume whereas they exhibited restoration of bone resorption which was impaired by *bcl-2* homozygous deficiency. Osteoclasts generated from *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> bone marrow cells displayed normal bone-resorbing activity, while the mineralization activity of osteoblasts generated from *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> calvarial cells was still impaired as well as *bcl-2* deficient osteoblasts. This indicates that inactivation of a single *bim* allele restores the defective function caused by *bcl-2* deficiency in osteoclasts, but is not enough to rescue the defective function in Bcl-2 deficient osteoblasts. We next examined the effect of intermittent PTH administration on bone mass in the mice. While intermittent PTH administration markedly increased the trabecular bone volume in *bcl-2*<sup>+/-</sup>*bim*<sup>+/-</sup> mice (control), it did not affect the bone volume of *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice. The osteoid surface was significantly increased in PTH administered *bcl-2*<sup>-/-</sup>*bim*<sup>+/-</sup> mice as compared to *bcl-2*<sup>+/-</sup>*bim*<sup>+/-</sup> mice, indicating that the mineralization of the mice is still attenuated. Collectively, these data indicate that loss of a single *bim* allele recovers the defective osteoclast function in *bcl-2*<sup>-/-</sup> mice but does not restore the anabolic action of PTH, and additionally Bcl-2 is indispensable for anabolic actions of PTH.

**R740S, a Dominant V-ATPase a3 Mutation, Causes Osteopetrosis in Mice.** N. Ochotny<sup>\*1</sup>, A. M. Fleniken<sup>\*2</sup>, C. Owen<sup>\*2</sup>, R. A. Zirngibl<sup>\*3</sup>, L. R. Osborne<sup>\*2</sup>, J. E. Henderson<sup>\*4</sup>, S. L. Adamson<sup>\*2</sup>, J. Rossant<sup>\*2</sup>, M. F. Manolson<sup>1</sup>, J. E. Aubin<sup>2</sup>. <sup>1</sup>Faculty of Dentistry, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Centre for Modeling Human Disease, Samuel Lunenfeld Research Institute, Mt. Sinai Hospital, Toronto, ON, Canada, <sup>3</sup>Molecular Genetics, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Bone Centre, McGill University, Montreal, QC, Canada.

Bone resorption involves osteoclast-mediated acidification via a vacuolar-type H<sup>+</sup>-ATPase (V-ATPase) localized to the ruffled border at the bone surface. V-ATPases are proton pumps composed of 13 subunits including the 'a' subunit. Of the 4 'a' isoforms in mammals a3 is enriched in osteoclasts where it is essential for bone resorption. Humans with homozygous a3 mutations are severely osteopetrotic and do not live past 6 years without treatment (bone marrow transplant), while their heterozygous parents have no detectable phenotype. Homozygous a3<sup>-/-</sup> mice have severe osteopetrosis and die by 6 weeks; a3<sup>+/-</sup> mice have no reported abnormalities. We identified an a3 missense mutation (R740S) during a mouse genome-wide ethylnitrosourea (ENU) mutagenesis screen for dominant point mutations affecting bone mineral density (BMD). The mouse a3 R740 residue is perfectly conserved in mammalian and yeast 'a' isoforms, and in yeast is essential for proton translocation. Our objective was to characterize the molecular and cellular mechanisms underlying osteopetrosis in Atp6i<sup>R740S/+</sup> mice. We employed DEXA, faxitron and micro-CT to quantify the BMD, visualize the skeleton and determine static histomorphometric parameters. Spleen cells were cultured with RANKL-MCSF and osteoclasts generated were replated onto dentine slices to quantify osteoclastogenesis and resorption respectively. Atp6i<sup>R740S/+</sup> intercrosses revealed that mice homozygous for the R740S mutation died at birth or soon after, in contrast to both a3<sup>-/-</sup> and a3<sup>+/-</sup> mice. Atp6i<sup>R740S/+</sup> mice have normal appearance, size and weight but exhibit higher BMD, greater trabecular bone mass and greater bone volume as percent of tissue volume compared with wildtype (WT) littermates, suggesting deficient bone resorption. Fewer and smaller (fewer nuclei/cell) osteoclasts formed in spleen cell cultures from Atp6i<sup>R740S/+</sup> versus WT mice and Atp6i<sup>R740S/+</sup> osteoclasts had decreased resorption activity on dentine slices. As heterozygote mice and humans with only one functional a3-encoding gene do not display any phenotype, the dominant R740S mutation is likely not related to haploinsufficiency of transcripts or translated protein. Also, there is only one copy of the a3 subunit per V-ATPase complex making it unlikely that mutant a3 interacts with and inactivates WT a3. R740S is the first dominant mutation of a3 that results in osteopetrosis.

## 1219

**Mitogen-Activated Protein Kinase Phosphatase-1 Protects Bone Mass Via Negative Regulation of Osteoclast Differentiation and Activation.** J. Carlson<sup>\*1</sup>, F. Mercan<sup>\*2</sup>, Q. Zhang<sup>3</sup>, A. Bennett<sup>\*2</sup>, A. Vignery<sup>3</sup>. <sup>1</sup>Comparative Medicine, Yale School of Medicine, New Haven, CT, USA, <sup>2</sup>Pharmacology, Yale School of Medicine, New Haven, CT, USA, <sup>3</sup>Orthopaedics, Yale School of Medicine, New Haven, CT, USA.

Multinucleate osteoclasts (OC) are essential for bone development, homeostasis and repair and play a critical role in diseases such as osteoporosis and inflammatory arthritis. Mitogen-activated protein kinases (MAPK) transduce extracellular signals into cellular responses, which include gene expression, cell growth, differentiation, and apoptosis, and play a key role in OC formation and activation. While all MAPKs become activated during OCgenesis, p38 plays a central role in RANKL-induced OC differentiation and activation. MAPK phosphatases (MKP) are responsible for regulating MAPK signaling, yet their role in the differentiation of OC remains unknown. MKP-1 is an inducible nuclear MKP that inactivates all MAPKs, with a preference for p38 over JNK and ERK. We had discovered that MKP-1 transcripts are transiently induced at the onset of fusion in macrophages, and therefore asked whether MKP-1 regulates OC differentiation and/or activation. We first confirmed the induced expression of MKP-1 in spleen cell-derived mouse OC. We then found that in the absence of MKP-1, OC, as well as the actin ring they form to resorb bone, are smaller, yet resorb calcium-phosphate substrate more efficiently than wild-type OC. We then stimulated OC from MKP-1-null and wild-type mice with RANKL for increasing times, and subjected the cell lysates to western blot analysis. We found that absence of MKP-1 leads to potent hyper activation of p38, and to some extent ERK, which suggested that MKP-1 regulates MAPK signaling downstream of RANK in OC. To challenge OCgenesis *in vivo*, 2-month old MKP-1-deficient and wild-type mice were subjected to ovariectomy (OVX) or used as age-matched controls (n=8). We used soft X-ray, microCT, pQCT and dynamic histomorphometry to analyze distal femurs. MKP-1-null mice had a 19% lower trabecular density than wild types. While OVX decreased trabecular bone density in all mice, absence of MKP-1 led to 8% decrease in density and 12% decrease in thickness of cortical bone. Femurs from MKP-1-null mice had a lower number and a smaller surface area of trabeculae, and contained fewer OC that covered less bone surface than wild-types. These data strongly suggested that OC that lack MKP-1 become hyperactive in response to estrogen depletion. We conclude that MKP-1 regulates MAPK-dependent signaling and functions as a critical conduit for these kinases in the differentiation and activation of OC, with MKP-1 acting predominantly through p38 MAPK. MKP-1 might therefore offer a novel target to prevent bone loss in response to estrogen deficiency or inflammation.

**Rac 1 and 2, in Combination, Mediate Osteoclast Function and Survival.** M. R. Croke<sup>1</sup>, H. Zhao<sup>1</sup>, D. A. Williams<sup>\*2</sup>, S. L. Teitelbaum<sup>1</sup>, F. P. Ross<sup>1</sup>. <sup>1</sup>Pathology and Immunology, Washington University, Saint Louis, MO, USA, <sup>2</sup>Hematology and Oncology, Children's Hospital Boston, Boston, MA, USA.

Osteoclastic bone resorption requires reorganization of the actin cytoskeleton, which, in other cells, is mediated by the Rho family of GTPases. One member of this family, namely Rac, is activated in osteoclasts by occupancy of surface receptors, including c-Fms and the  $\alpha\beta 3$  integrin, which polarize the osteoclast and promote formation of its unique cytoskeletal structure, the actin ring. However, whether Rac, itself, is required for osteoclast cytoskeletal organization and resorptive function is unknown. There are 3 known murine Rac GTPase isoforms, namely Rac1, 2 and 3. Because hematopoietic lineage cells, of which osteoclasts are derived, express only Rac 1 and 2, we utilized mice lacking these two isoforms in osteoclast precursors and/or the mature resorptive cell. Mice deficient in both isoforms (Rac dKO), in combination, develop severe osteopetrosis. Cells isolated from the marrow of Rac dKO mice differentiate into osteoclasts under the aegis of RANKL and M-CSF and their expression of the osteoclast differentiation markers, c-Src and cathepsin K is comparable to WT. On the other hand, Rac dKO osteoclasts fail to organize their cytoskeleton when generated on bone as manifest by a non-polarized phenotype, complete absence of actin rings and lack of ruffled membranes. The morphological abnormalities translate into dysfunctional resorption, exemplified by absence of pit formation on bone and diminished release of collagen degradation products into the medium. We also find that Rac dKO, osteoclast precursors, in the form of marrow macrophages, undergo accelerated apoptosis, as compared to WT, during initial exposure to RANKL, an event mediated by failure of the osteoclastogenic cytokine to activate Akt in the dual-deleted cells. Thus, Rac 1 and 2, in combination, not only are essential for organization of the osteoclast cytoskeleton, and hence the cells capacity to resorb bone, but also promote RANKL-mediated survival.

## 1221

**The Cannabinoid Receptor GPR55 Affects Osteoclast Function *in vitro* and Bone Mass *in vivo***. L. Whyte<sup>\*1</sup>, E. Ryberg<sup>\*2</sup>, S. Ridge<sup>\*1</sup>, K. Mackie<sup>\*3</sup>, P. Greasley<sup>\*2</sup>, R. Ross<sup>\*1</sup>, M. J. Rogers<sup>1</sup>. <sup>1</sup>Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>Dept of Lead Generation, AstraZeneca, MoeIndal, Sweden, <sup>3</sup>School of Medicine, University of Aberdeen, Aberdeen, United Kingdom.

Mice lacking either CB<sub>1</sub> or CB<sub>2</sub> cannabinoid receptors have been shown previously to have abnormal bone phenotypes, while synthetic and endogenous ligands for these receptors affect bone cell function *in vitro* and *in vivo*. GPR55 is structurally distinct from CB<sub>1</sub> and CB<sub>2</sub> but has recently been found to bind cannabinoids. The aim of this study was to investigate whether GPR55 plays a role in osteoclast function and bone physiology. Human osteoclasts were generated from peripheral blood monocytes of healthy donors. Using immunostaining and quantitative PCR we found that GPR55 is expressed in human osteoclasts and that GPR55 mRNA increases during differentiation. To study the functional role of GPR55, human osteoclasts were treated with O1602, a selective GPR55 ligand. In the presence of 1nM-1µM O1602 there was no effect on the formation of  $\alpha\beta 3$ -positive osteoclasts. However, when cells were cultured on dentine, O1602 increased the proportion of osteoclasts with F-actin rings (with 50nM, 236%±31 of control; p<0.01) and increased resorption area (217%±28 of control; p<0.01). Furthermore, the GPR55 antagonist cannabidiol (CBD, 1µM) significantly inhibited the increase in resorption and F-actin rings seen after treatment with 50nM O1602 alone (p<0.0001). Using a pulldown assay we also found that treatment of human osteoclasts with 1µM O1602 resulted in an increase in GTP-bound Rho. This is consistent with the proposed coupling of GPR55 to G $\alpha_{12/13}$  and with the stimulatory effects of O1602 on osteoclast polarisation. Consistent with the stimulatory effect of O1602 on osteoclasts *in vitro*, micro CT analysis of tibiae and femorae from male knockout and littermate control wildtype mice revealed that trabecular bone volume was significantly increased in GPR55<sup>-/-</sup> mice. In 12 wk old male mice, TBV was increased by 36% (p<0.01) in the tibia and by 71% (p<0.05) in the femur; in 8 month old male mice TBV increased by 33% (p<0.05) in the tibia and by 28% (p<0.05) in the femur. Consistent with this, bone surface increased by 46% (p<0.05) in the tibia and by 55% (p<0.05) in the femur of 8 month old male mice, while trabecular number also increased by 46% (p<0.05) in the tibia and by 55% (p<0.05) in the femur. This was not seen in female mice of the same age.

Taken together, these data demonstrate for the first time that, in addition to CB<sub>1</sub> and CB<sub>2</sub>, the cannabinoid receptor GPR55 plays a role in bone physiology. Further studies are now necessary to identify the endogenous ligands of GPR55 and its role in direct or indirect actions on osteoclasts or other bone cells *in vivo*.

**PGC-1 $\beta$  and Iron Uptake in the Mitochondrial Activation of Osteoclasts.** K. Ishii<sup>\*1</sup>, K. Iwai<sup>\*2</sup>, S. Takeshita<sup>1</sup>, M. Ito<sup>3</sup>, N. Shimohata<sup>\*2</sup>, S. Taketani<sup>\*4</sup>, H. Aburatani<sup>\*5</sup>, C. J. Lelliott<sup>\*6</sup>, A. Vidal-Puig<sup>\*7</sup>, K. Ikeda<sup>1</sup>. <sup>1</sup>Dept of Bone and Joint Disease, National Center for Geriatrics and Gerontology, Obu, Japan, <sup>2</sup>Department of Molecular Cell Biology, Osaka City University, Osaka, Japan, <sup>3</sup>Department of Radiology, Nagasaki University Hospital, Nagasaki, Japan, <sup>4</sup>Department of Biotechnology, Kyoto Institute of Technology, Kyoto, Japan, <sup>5</sup>Genomescience Division, University of Tokyo, Tokyo, Japan, <sup>6</sup>R&D, AstraZeneca, Molndal, Sweden, <sup>7</sup>Department of Clinical Biochemistry, Cambridge University, Cambridge, United Kingdom.

Osteoclasts are acid-secreting polykaryons that are rich in mitochondria. The mechanism by which mitochondrial biogenesis is stimulated and how this is linked with the osteoclast differentiation program remain unknown. We found the transcription of PGC-1 $\beta$  (PPAR $\gamma$  coactivator) to be drastically induced during osteoclast differentiation by CREB in response to increased ROS, and that knockdown of PGC-1 $\beta$  inhibited the differentiation as well as mitochondrial gene expression in osteoclasts. PGC-1 $\beta$ -deficient mice exhibited impaired bone resorption with osteopetrosis-like histological features. In parallel, transferrin receptor (TfR) 1 mRNA, which was barely detectable in bone marrow macrophages (BMMs), was markedly induced along with osteoclast differentiation. Detailed biochemical analysis revealed that iron regulatory protein (IRP)2 senses a heightened iron demand in osteoclasts, and, by binding to the iron-responsive elements (IRE) of TfR1, leads to TfR1 upregulation through stabilization of its mRNA. By binding to the increased TfR1 on the cell surface, the addition of holo-Tf (i.e. preformed iron-Tf complex) as well as apo-Tf markedly and dose-dependently stimulated the formation of TRAP-positive osteoclasts from BMMs, along with an increased production of heme and iron-sulfur clusters in mitochondria. These effects were inhibited by iron chelation with desferrioxamine (DFO). The pit area resorbed by mature osteoclasts was also significantly increased by Tf and decreased by DFO, suggesting that iron uptake through TfR1 promotes osteoclast formation as well as the bone-resorbing function of mature osteoclasts. Treatment of female mice with DFO significantly inhibited bone resorption and bone loss following OVX, suggesting that iron is an important regulator of osteoclastic bone resorption *in vivo*. In conclusion, it is suggested that activation of CREB, a major osteoclastogenic signal downstream of RANK/ITAM, is deployed to induce the transcription of PGC-1 $\beta$ . PGC-1 $\beta$  drives mitochondrial gene expression, and, coupled with the increased iron uptake through the upregulated TfR1, plays an important role in bone resorption by coordinating the stimulation of mitochondrial biogenesis and respiration in osteoclasts.

**Evidence for a Role of Prolactin in Calcium Homeostasis: Regulation of Intestinal TRPV6 and Intestinal Calcium Absorption by Prolactin.** D. V. Ajibade<sup>\*1</sup>, P. Dhawan<sup>1</sup>, B. S. Benn<sup>\*1</sup>, M. B. Meyer<sup>\*2</sup>, J. W. Pike<sup>2</sup>, S. S. Christakos<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, UMDNJ, Newark, NJ, USA, <sup>2</sup>Biochemistry, University of Wisconsin, Madison, WI, USA.

Although 1,25(OH)<sub>2</sub>D<sub>3</sub> is an essential regulator of intestinal calcium (Ca<sup>2+</sup>) absorption, it has been suggested that prolactin (PRL) can also affect intestinal Ca<sup>2+</sup> transport. Increased Ca<sup>2+</sup> transport has been observed in vitamin D deficient pregnant and lactating rats, indicating that a factor besides 1,25(OH)<sub>2</sub>D<sub>3</sub> is involved in intestinal Ca<sup>2+</sup> transport. To investigate the possibility of PRL as a hormone involved in Ca<sup>2+</sup> homeostasis, vitamin D deficient male mice were injected with 1,25(OH)<sub>2</sub>D<sub>3</sub> (1ng/g bw), PRL (1ug/g bw), or PRL + 1,25(OH)<sub>2</sub>D<sub>3</sub> and changes in the expression of TRPV6, the apical Ca<sup>2+</sup> channel proposed to be a rate limiting step in the process of active intestinal calcium absorption, were examined. We found that PRL alone significantly induced duodenal TRPV6 mRNA levels 3 fold 4h after injection. Duodenal calbindin-D<sub>9k</sub> mRNA levels were unaltered by PRL. A single i.p. injection of 1,25(OH)<sub>2</sub>D<sub>3</sub> resulted in a 4-6 fold induction in both duodenal TRPV6 mRNA and calbindin-D<sub>9k</sub> mRNA 12h after injection. When a combination of 1,25(OH)<sub>2</sub>D<sub>3</sub> and PRL was given to vitamin D deficient male mice (12h and 4 h prior to termination respectively), a 2.5 and a 3-4 fold enhancement of the 1,25(OH)<sub>2</sub>D<sub>3</sub> induction of duodenal TRPV6 mRNA and calbindin-D<sub>9k</sub> mRNA levels respectively was observed (p<0.05 compared to 1,25(OH)<sub>2</sub>D<sub>3</sub> treatment alone). In addition, using the everted gut sac assay, combined treatment with PRL and 1,25(OH)<sub>2</sub>D<sub>3</sub> resulted in a significant enhancement in duodenal Ca<sup>2+</sup> transport compared to mice treated with 1,25(OH)<sub>2</sub>D<sub>3</sub> alone (1.5 fold enhancement; PRL +1,25(OH)<sub>2</sub>D<sub>3</sub>; p<0.05 compared to mice treated with 1,25(OH)<sub>2</sub>D<sub>3</sub> alone). Injection of PRL alone did not result in a significant induction in Ca<sup>2+</sup> transport. In order to further understand mechanisms that may be involved in the enhancement of TRPV6 expression by PRL, studies were done using the hTRPV6 promoter (-7000/+160). Using vitamin D receptor and PRL receptor transfected CV1 cells, 1,25(OH)<sub>2</sub>D<sub>3</sub> treatment (10<sup>-8</sup>M) alone or PRL treatment (1ug/ml) in the presence of STAT5 resulted in a 4-5 fold increase in TRPV6 transcription. A combination of PRL and 1,25(OH)<sub>2</sub>D<sub>3</sub> treatment in the presence of STAT5 resulted in a cooperative effect and a maximum induction of transcription of 20-25 fold. These findings indicate, for the first time, that PRL alone can regulate TRPV6 and that PRL has cooperative effects with 1,25(OH)<sub>2</sub>D<sub>3</sub> in regulating intestinal Ca<sup>2+</sup> transport proteins as well as intestinal Ca<sup>2+</sup> transport. These findings indicate that PRL is involved in Ca<sup>2+</sup> homeostasis and is an important modulator of the intestinal effect of 1,25(OH)<sub>2</sub>D<sub>3</sub>.

**Transgenic Expression of Human FSH in Female Mice Has an Anabolic Effect on Bone.** R. Kalak<sup>\*</sup>, C. M. Allan<sup>\*</sup>, K. J. McTavish<sup>\*</sup>, C. R. Dunstan, H. Zhou, M. J. Seibel, D. J. Handelsman<sup>\*</sup>. ANZAC Research Institute, The University of Sydney, Australia.

It was recently observed that female mice deficient in the FSH beta-subunit or receptor are protected from bone loss despite severe estrogen deficiency (1). The authors speculated that the postmenopausal elevation in FSH levels is responsible for the bone loss in women after the menopause. We previously developed a human FSH-expressing transgenic (tg-FSH) mouse model that features progressively increasing levels of circulating human FSH with increasing age (from 2.7 IU/L in 5 wk old mice to 6 IU/L in 6 month old mice) (2) independent of pituitary secretion, while serum estradiol levels remain normal. This model provides a unique opportunity to determine the in vivo effects of increased FSH activity on bone distinct from effects of estrogen deficiency.

We performed microcomputed tomography of the L3 vertebra and the tibia of 6-month-old female tg-FSH and wild-type (WT) mice (n= 10/ group). Trabecular bone was analysed for both vertebrae and tibiae. Cortical bone area and thickness were measured for tibiae. Vertebral trabecular bone volume (BV/TV) was increased by 50% (p=0.021) in tg-FSH as compared to WT mice due to increased trabecular number (TbN) (+42%, p=0.015) and reduced trabecular separation (TbSp) (-16%, p=0.004). Trabecular thickness (TbTh) was not significantly different between the two groups (Fig.1)

Tibial cortical bone area (+9%, p=0.024) and cortical thickness (+13%, p=0.034) were significantly increased in tg-FSH animals while tibial lengths were similar. In contrast, differences in tibial trabecular bone parameters were less pronounced: BV/TV (+88%, p=0.068), TbN (+76%, p=0.056), TbSp (-8%, p=0.364), TbTh (+3% and p=0.522) (Fig. 1). Changes in the different skeletal sites were correlated, consistent with a systemic effect. There was wider variation of vertebral and tibial BV/TV among tg-FSH compared with WT mice.

This study shows for the first time an anabolic effect of human FSH on mouse bone. While the mechanism of this effect remains uncertain, our data do not support the concept that FSH directly causes bone loss.

**Local Osteocyte Defect in Dmp1 Null Mice Causes Overproduction of Fgf23.** S. Liu, J. Zhou<sup>\*</sup>, W. Tang<sup>\*</sup>, L. D. Quarles. The Kidney Institute, University of Kansas Medical Center, Kansas City, KS, USA.

Inactivating mutations of DMP1 leads to increased FGF23 expression in bone osteocytes and consequent FGF23-mediated renal phosphate wasting and impaired 1- $\alpha$  hydroxylase activity. The mechanism whereby inactivating DMP1-mutations stimulates FGF23 production by osteocytes is not clear. To determine if the increased FGF23 expression is due to an intrinsic abnormality of bone, we explanted long bones from 4.5 day-old wild-type (WT) and Dmp1-null/Fgf23 promoter-reporter mice (Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> and Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> respectively) into the back muscles of either WT or Dmp1-null recipients. By three weeks, the explanted bones had successfully engrafted and undergone linear growth in the recipients. GFP expression remained increased in osteocytes of Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> bone explanted into WT mice, whereas GFP expression remained low in Dmp1<sup>+/+</sup>/Fgf23<sup>+/GFP</sup> bone explanted into either Dmp1<sup>-/-</sup> or WT mice, consistent with an intrinsic abnormality leading to increased FGF23 expression. Paradoxically, GFP expression was suppressed when Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> bone was explanted into Dmp1<sup>-/-</sup> mice, suggesting an age-dependent suppression of Fgf23 by a systemic factor in adult Dmp1 null mice. To confirm the local abnormality of osteocyte function is responsible for increased Fgf23 expression in Dmp1 null mice, we cultured bone marrow stromal cells (BMSC) derived from Dmp1<sup>+/+</sup>/Fgf23<sup>+/GFP</sup> and Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> mice for 18 days under differentiating conditions. The Fgf23 promoter driven GFP expression was markedly increased in osteocyte-like cells embedded in mineralization nodules of Dmp1<sup>-/-</sup>/Fgf23<sup>+/GFP</sup> derived BMSC, but not in nodules generated by BMSC from Dmp1<sup>+/+</sup>/Fgf23<sup>+/GFP</sup> mice. To determine if Dmp1 directly regulates Fgf23 promoter activity, we cotransfected a full-length Dmp1 cDNA construct with an 8 kb Fgf23 promoter-luciferase reporter construct into Ros17/2.8 osteoblasts. We found that over-expression of Dmp1 had no significant effect on Fgf23 promoter activity *in vitro*, suggesting that the observed local effects of Dmp1 deficiency to increase Fgf23 gene expression *in vivo* and *ex vivo* may not involve direct Dmp1 transcriptional activity. Further studies are needed to determine whether the intrinsic increase in Fgf23 expression by osteocytes of Dmp1<sup>-/-</sup> mice represents Dmp1-dependent abnormalities in osteocyte development/function or alterations in extracellular matrix-derived autocrine/paracrine factors caused by Dmp1 deficiency.

**The PTH 1 receptor (PTH1R) Stimulates Bone Formation Through a Distinct  $\beta$ -Arrestin Dependent Pathway Independent of G Protein Activation.** D. Gesty-Palmer, R. F. Spurney, P. J. Flannery\*, L. Yuan\*. Department of Medicine, Duke University Medical Center, Durham, NC, USA.

Intermittent administration of PTH (1-34) has anabolic effects on bone that have been conventionally attributed to classical G protein signaling mechanisms. Our recent studies have shown that PTH (1-34) stimulation of the PTH1R can activate two independent signaling mechanisms one G protein-dependent and the other  $\beta$ -arrestin-dependent (J Biol Chem 281:10856, 2006). Moreover, we have demonstrated that these two distinct signaling mechanisms (G protein *versus*  $\beta$ -arrestin) are pharmacologically separable through the use of biased ligands capable of preferentially activating one pathway or the other. To investigate  $\beta$ -arrestin dependent signaling in bone, we employed a " $\beta$ -arrestin biased ligand" (D-Trp<sup>12</sup>, Tyr<sup>34</sup>)-PTH(7-34), (PTH- $\beta$ arr), to determine whether G protein independent signals transmitted by  $\beta$ -arrestin contribute directly to the PTH1R stimulated anabolic response in bone. Our results show that PTH- $\beta$ arr induces bone formation in mice with an anabolic response similar to PTH(1-34), which activates both mechanisms. In  $\beta$ -arrestin 2 null mice, the increase in bone mass induced by PTH- $\beta$ arr is absent and the anabolic response to PTH(1-34) is attenuated by 50%. The  $\beta$ -arrestin dependent pathway enhances bone mineral density primarily by increasing trabecular bone mass with little effect on cortical bone. Additionally, while PTH- $\beta$ arr increases markers of bone formation such as serum osteocalcin, it does not appear to stimulate markers of bone resorption such as urine deoxypyridinoline (DPD). We conclude that G protein independent/ $\beta$ -arrestin dependent signaling contributes to a distinct anabolic component of PTH1R stimulated bone formation. Selective activation of this newly discovered mechanism may form the basis for a new class of pharmacologic agents which have valuable therapeutic properties for the treatment of metabolic bone diseases such as osteoporosis.

**Association between Cx43 and  $\beta$ -Arrestin is Required for cAMP-Dependent Osteoblast Survival Induced by PTH.** L. I. Plotkin, G. Frera\*, K. Vyas\*, S. C. Manolagas, T. Bellido. Endocrinology, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas for Med. Sci., Little Rock, AR, USA.

Inhibition of osteoblast apoptosis via activating the cAMP/PKA pathway contributes, at least in part, to the increased bone mass induced by intermittent PTH administration to mice. This anabolic response is attenuated in mice with osteoblast-specific deletion of connexin (Cx) 43 or in heterozygous Cx43 null mice. Moreover, PTH-induced elevation of cAMP is blunted in osteosarcoma cells with reduced expression of Cx43. Based on these lines of evidence we aimed herein to determine whether Cx43 is required for prevention of osteoblast apoptosis by PTH. We report that PTH did not inhibit etoposide-induced apoptosis in osteoblastic Ob-6 cells expressing Cx45, which prevents Cx43 action, or Cx43 $\Delta$ 245 - a truncated Cx43 dominant negative (dn) mutant. Furthermore, PTH did not prevent apoptosis in Ob-6 cells in which Cx43 expression was silenced with a lentivirus containing a specific short-hairpin (sh) RNA (Cx43 $\Delta$  cells), whereas the hormone was effective in cells treated with scrambled shRNA (control) cells. Consistent with this, PTH increased the expression of the cAMP-responsive genes IL-6, RANKL, c-fos and Nur77 in control cells but not in Cx43 $\Delta$  cells. However, PTH receptor expression was not reduced in Cx43 $\Delta$  cells. Moreover, the stable cAMP analog dibutyryl cAMP (DBA) prevented apoptosis and increased the expression of cAMP target genes in both Cx43 $\Delta$  and control cells. Taken together, these results suggested that Cx43 levels modulate cAMP-mediated responses induced by PTH downstream of the PTH receptor. Cx43 interacts with  $\beta$ -arrestin and  $\beta$ -arrestin decreases PTH-induced cAMP responses in osteoblastic cells. This evidence raised the possibility that Cx43 plays a permissive role by sequestering  $\beta$ -arrestin, thereby allowing cAMP responses, including osteoblast survival, induced by PTH. Consistent with this hypothesis, we found that over-expression of  $\beta$ -arrestin blocked the anti-apoptotic effect of PTH, but not that of DBA, in control Cx43-expressing cells. Moreover, over-expression of Cx43 as well as a dn  $\beta$ -arrestin mutant rescued the anti-apoptotic effect of PTH in Cx43 $\Delta$  cells. We conclude that Cx43 is required for the anti-apoptotic effect of PTH on osteoblasts due to its interaction with  $\beta$ -arrestin and subsequent potentiation of PTH-induced cAMP responses. These findings provide a molecular explanation for the attenuated anabolic effect of intermittent PTH administration in Cx43 deficient mice.

**Inhibitory Role of G $\alpha$ q / PKC $\delta$  Signal in the Bone Anabolic Action of PTH.** N. Ogata<sup>1</sup>, F. Yano<sup>1</sup>, U. Chung<sup>1</sup>, N. Wettschureck<sup>\*2</sup>, S. Offerman<sup>\*2</sup>, G. V. Segre<sup>3</sup>, K. Nakamura<sup>\*1</sup>, H. Kawaguchi<sup>1</sup>. <sup>1</sup>Sensory & Motor System Medicine, Bone & Cartilage Regenerative Medicine, Univ. of Tokyo, Tokyo, Japan, <sup>2</sup>Pharmakologisches Institut, Univ. of Heidelberg, Heidelberg, Germany, <sup>3</sup>Endocrine Unit, MGH, Boston, MA, USA.

G $\alpha$ s-cAMP and G $\alpha$ q-PLC are the major signal pathways underlying G protein-coupled receptors. Contrary to the well-known bone anabolic action of the G $\alpha$ s signal in osteoblasts, we have reported that the G $\alpha$ q signal inhibits bone formation by analyses of transgenic mice with osteoblast-specific overexpression of a constitutively active G $\alpha$ q transgene (CA-G $\alpha$ q). The present study sought to examine the involvement of the G $\alpha$ q signal in the bone anabolic action of PTH whose receptor is known to be G protein-coupled. Although the subcutaneous injection of rhPTH (1-34) (0.08 mg/kg x 5 times X 4 weeks) caused about a 10% increase of bone volume in 8-week-old wild-type mice, this effect was not seen in the CA-G $\alpha$ q transgenic littermates. In the culture of osteoblastic MC3T3-E1 cells, stable overexpression of the CA-G $\alpha$ q inhibited their differentiation determined by ALP activity, which was abrogated by addition of GF109203X, an inhibitor of protein kinase C (PKC). Among the 13 PKC family members, PKC $\delta$  was shown to be most strongly induced by the CA-G $\alpha$ q overexpression by immunoblotting.

We further created double knockout (DKO) mice deficient in osteoblast-specific G $\alpha$ q and global G $\alpha$ 11, a G $\alpha$ q subfamily member that also activates PLC, by crossing COL1-Cre transgenic mice and mice with the G $\alpha$ q gene flanked by loxP / global ablation of G $\alpha$ 11 (G $\alpha$ q-*fl/fl*;G $\alpha$ 11<sup>-/-</sup>). Although histomorphometric analyses revealed that bone volume and turnover of the DKO mice were normal under physiological conditions, the bone anabolic effect of the rhPTH (1-34) injection shown above was significantly enhanced in the DKO mice as compared to that in the wild-type littermates, confirming inhibition of the PTH action by the endogenous G $\alpha$ q signaling as well. In the culture of primary mouse calvarial osteoblasts, intermittent treatment of rhPTH (10 nM) stimulated differentiation and matrix synthesis determined by ALP activity and mRNA levels of osteogenesis markers. These effects were markedly enhanced in the cells from the G $\alpha$ q/G $\alpha$ 11 DKO mice, which were restored by addition of PMA, an activator of PKC, to the levels of the wild-type osteoblasts. Protein level of PKC $\delta$  and its subcellular translocation to membrane enhanced by the rhPTH treatment in wild-type osteoblasts were suppressed in the DKO osteoblasts. Contrarily, cAMP accumulation in response to rhPTH was similar between cells of the two genotypes.

These lines of results demonstrate the inhibitory role of the G $\alpha$ q / PKC $\delta$  signal in the bone anabolic action of PTH, suggesting that suppression of the signal may lead to a novel treatment with PTH against osteoporosis.

**Disruption of the Syndecan-1/Integrin Axis is a Novel Target for Myeloma Therapy.** Y. Yang<sup>1</sup>, J. P. Ritchie<sup>\*1</sup>, B. Ell<sup>\*2</sup>, A. C. Rapraeger<sup>\*2</sup>, R. D. Sanderson<sup>\*1</sup>. <sup>1</sup>Dept. of Pathology, Center for Metabolic Bone Disease, University of Alabama in Birmingham, Birmingham, AL, USA, <sup>2</sup>Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI, USA.

In myeloma, malignant plasma cells invade and grow within the bone marrow microenvironment leading to osteolytic destruction of bone. Myeloma cell surfaces are enriched with the heparan sulfate proteoglycan syndecan-1 that via its extracellular core protein domain promotes activation of  $\alpha_v\beta_3$  and  $\alpha_v\beta_5$  integrins. The  $\alpha_v\beta_3$  integrin in particular drives myeloma progression by promoting tumor proliferation and angiogenesis and by regulating osteoclast differentiation and activation that leads to bone lysis. Synstatin is a peptide mimic of the syndecan-1 core protein that blocks the syndecan-1-mediated activation of  $\alpha_v\beta_3$  and  $\alpha_v\beta_5$  integrins. The purpose of this study was to assess the ability of synstatin to inhibit myeloma growth *in vivo*. Three mouse models of myeloma were utilized in this study --- a subcutaneous (s.c.) model in which human myeloma cells were injected s.c. into SCID mice (SCID-s.c.), a SCID-hu model, in which tumor cells were injected into fragments of human fetal bone implanted in SCID mice, and a syngenic model, in which murine myeloma cells are injected s.c. into Balb/c mice. Ten days after injection of tumor cells animals were treated with synstatin peptide for 4 weeks by constant delivery using Alzet osmotic pumps. Analysis of the levels of human immunoglobulin light chain in murine sera revealed that synstatin significantly ( $P < 0.002$ ) inhibited tumor growth 11-fold in the SCID-s.c. model and 3-fold in the SCID-hu model. In the syngenic model, tumor volumes revealed that synstatin reduced tumor growth by 17-fold ( $P < 0.002$ ). Immunohistochemistry performed on tumors from SCID-s.c. mice demonstrated that synstatin inhibits proliferation of cells within the tumor ( $1451 \pm 171/\text{mm}^2$  Ki-67 positive cells in treated vs.  $3111 \pm 148/\text{mm}^2$  positive cells in controls,  $P = 0.0001$ ). Synstatin also significantly inhibits angiogenesis, compared to controls (microvessel density of  $21 \pm 9/\text{mm}^2$  to  $39 \pm 10/\text{mm}^2$ , respectively;  $P = 0.01$ ) as assessed by CD34 staining of tumor tissue. We conclude that synstatin significantly inhibits myeloma tumor growth *in vivo* and thus may provide a novel therapeutic approach to this deadly cancer.

**Prostaglandin E Receptor EP4 Antagonist Attenuates Growth and Metastases of Cancer.** M. Takita<sup>1</sup>, S. Yokoyama<sup>\*1</sup>, M. Inada<sup>1</sup>, T. Maruyama<sup>\*2</sup>, C. Miyaura<sup>1</sup>. <sup>1</sup>Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, <sup>2</sup>Discovery Research Laboratory, Minase Research Institute, Ono Pharmaceutical, Co., Ltd., Osaka, Japan.

Bone metastasis of cancer is accompanied by severe bone destruction with increased bone resorption. We recently reported that prostaglandin E (PGE) produced by host cells play a key role in bone metastasis, and the PGE signal is mediated by EP4 receptor, a subtype of PGE receptors (EP1-EP4), expressed in host cells. EP4 antagonist suppressed osteolysis due to bone metastasis of mouse malignant melanoma B16 cells. In this study, we examined the role of host-derived PGE and EP4 receptor in tumor growth and visceral metastases in various tissues using B16 melanoma cells. When B16 cells were introduced to C57BL/6 mice by iv injection, metastases were detected as black spots in bone, lung, liver, and kidney on day 18 after injection. Bone mineral density (BMD) measured by DEXA showed significant decrease of BMD in femurs with B16 metastasis. When EP4 antagonist was orally administered to mice injected with B16 cells, metastases were markedly suppressed not only in bone, but also in lung, liver, and kidney. When B16 cells were implanted subcutaneously into C57BL/6 mice, B16 cells grew rapidly to form solid tumor with angiogenesis. Topical administration of EP4 antagonist markedly suppressed the growth of solid tumor on days 11-18 after sc implantation of B16 cells. Expression of cyclooxygenase-2 (COX-2), membrane-bound PGE synthase-1 (mPGES-1), EP4, and CD31 mRNAs was clearly detected in B16 tumor, but not in cultured B16 cells. Neither PGE2 nor EP4 antagonist affected the proliferation of B16 cells in vitro. In addition, cultured B16 cells did not produce PGE2 at all. When mPGES-1-null mice were used in this study, the growth of B16 solid tumor was limited compared with wild-type mice. Metastasis in various tissues also attenuated in mPGES-1-null mice lacking PGE synthesis. These results suggest that PGE2 produced by host cells binds to EP4 receptor expressed in host cells of various tissues, and enhances tumor growth and metastases of cancer in vivo. Here we show that EP4 antagonist is a possible candidate for the therapy of cancer with metastases.

**Activin A Mediates Multiple Myeloma (MM) Bone Disease which Is Reversed by RAP-011, a Soluble Activin Receptor.** S. Vallet<sup>\*1</sup>, S. Mukherjee<sup>\*2</sup>, N. Vaghela<sup>\*1</sup>, T. Hideshima<sup>\*3</sup>, S. Pozzi<sup>\*1</sup>, L. Santo<sup>\*3</sup>, D. Cirstea<sup>\*3</sup>, J. Seehra<sup>\*4</sup>, D. T. Scadden<sup>\*2</sup>, K. C. Anderson<sup>\*3</sup>, N. Raju<sup>1</sup>. <sup>1</sup>Massachusetts General Hospital, Dana Farber Cancer Institute, Boston, MA, USA, <sup>2</sup>Massachusetts General Hospital, Boston, MA, USA, <sup>3</sup>Dana Farber Cancer Institute, Boston, MA, USA, <sup>4</sup>Accelaron Pharma Inc, Cambridge, MA, USA.

MM is characterized by complex interactions between plasma cells and the bone microenvironment, resulting in imbalanced bone remodeling. This results in bone destruction which is a consequence of cytokine secretion inducing increased osteoclast (OC) function or decreased osteoblast (OB) formation. Activin, a member of the TNF- $\alpha$  superfamily, is a coupling factor in bone remodeling and our data suggest its potential role as a mediator of MM bone disease. We observed 4 fold increased activin A expression levels in bone marrow plasma of MM patients compared to normal controls (average  $103 \pm 132$  vs  $25 \pm 19.3$  pg/ml). Activin levels appeared to correlate with disease activity where more than 60% of MM patients at diagnosis had high activin levels, versus patients in remission who had levels comparable to normal controls. The main source of activin in MM were bone marrow stromal cells (BMSCs) and OCs (median levels in 72h culture supernatant are 2094 and 1396 pg/ml respectively), while OBs secreted low levels of activin (median:200 pg/ml). No activin was detected in MM cells. Interestingly, MM cells stimulated activin A secretion when cocultured with MM-derived BMSC (by  $109\% \pm 83$ ). This was associated with an increase in IL6 secretion by BMSCs resulting in MM cell growth. Moreover, activin A in combination with RANKL and M-CSF stimulated OC differentiation via induction of a three-fold increase in precursor cell proliferation. To test the role of targeting activin A with therapeutic intent, we used a chimeric antibody that binds activin via the extracellular domain of activin receptor IIA, RAP-011 (Accelaron Pharma Inc., Cambridge). In effect, RAP-011 inhibited MM cell growth induced by BMSCs with concomitant reduction in IL6 levels. RAP-011 impaired osteoclastogenesis by 40% ( $p < 0.05$ ) and almost completely abrogated OC function. Interestingly, RAP-011 enhanced OB activity (by 37.5%,  $p < 0.01$ ) of BMSCs differentiated in osteogenic media, assessed by mineral content at day 21. This was confirmed by quantitative-PCR analysis of osteocalcin and bone sialoprotein genes. These data therefore suggest that activin A is involved in development of MM bone disease and can be effectively targeted by a novel antibody. RAP-011 not only inhibits MM cell proliferation in the microenvironment, but has bone-anabolic effects via inhibition of OC formation and stimulation of OB differentiation. These effects of RAP-011 make it an attractive therapeutic tool to test in future clinical trials of MM.

## 1232

**Thrombospondin-1 and CD47 Regulate Osteoclastogenesis but have Distinct Effects on Bone Metastasis.** Ö. Uluçkan<sup>\*1</sup>, H. Deng<sup>\*1</sup>, J. L. Prior<sup>\*2</sup>, D. Piwnica-Worms<sup>\*2</sup>, W. A. Frazier<sup>\*3</sup>, K. N. Weilbaecher<sup>1</sup>. <sup>1</sup>Departments of Medicine and Cell Biology and Physiology, Division of Oncology, Washington University in St Louis, St Louis, MO, USA, <sup>2</sup>Molecular Imaging Center, Mallinckrodt Institute of Radiology, Washington University in St Louis, St Louis, MO, USA, <sup>3</sup>Department of Biochemistry and Molecular Biophysics, Washington University in St Louis, St Louis, MO, USA.

Thrombospondin-1 (TSP1) and its receptor CD47, a five-transmembrane protein of the Immunoglobulin superfamily, augment platelet aggregation by binding to  $\alpha$ IIb $\beta$ 3 integrin. We have previously shown that the  $\beta$ 3 integrins on platelets and osteoclasts (OC) play critical roles in bone metastasis. We thus hypothesized that TSP1 and CD47 will also augment  $\alpha$ v $\beta$ 3 function in OCs and thus affect bone metastasis. We observed that TSP1-/- mice have increased bone mineral density and decreased serum CTX levels compared to WT controls, consistent with an OC defect. OC defects are frequently associated with decreased tumor burden in bone. However, tumor burden in bone was unchanged in TSP1-/- mice after intra-cardiac delivery of luciferase labeled B16 osteolytic murine melanoma cells. Notably, loss of TSP1 is reported to enhance tumor angiogenesis through an interaction with CD36, not CD47, which could partially explain these unexpected results. Thus, we evaluated osteoclastogenesis and bone metastasis in CD47-/- mice. Compared to TSP1-/- mice, we observed a statistically significant but more modest increase in trabecular bone volume and decrease in CTX levels in CD47-/- mice. In vitro, the number of multinucleated TRAP-positive OCs formed by differentiating CD47-/- bone marrow macrophages was decreased. Tumor burden in bone after intra-cardiac and intra-tibial inoculation of tumor cells was decreased in CD47-/- mice, in contrast to TSP1-/- mice. We also observed a decrease in tumor-associated bone destruction in CD47-/- mice. Subcutaneous tumor growth was not different between WT and CD47-/- mice. Our results demonstrate that TSP1 and its receptor CD47 alter bone volume in mice but have distinct effects on bone metastasis. We postulate that the anti-angiogenic role of TSP1 could account for the difference in the tumor growth in bone between TSP1-/- and CD47-/- mice. Our results suggest that therapies aimed at inhibiting angiogenesis via TSP1 might have adverse effects on bone, whereas CD47 might be a safer target for the treatment of bone metastasis.

**Fibroblast Growth Factor Receptor (FGFR) Signalling in the Pathogenesis of Osteosarcoma.** D. Weekes<sup>\*</sup>, T. Kashima, A. E. Grigoriadis. King's College London, London, United Kingdom.

Osteosarcoma (OS) is a highly malignant bone-forming tumour and is the most common primary malignancy of the skeleton, occurring primarily in children and adolescents, and also in the elderly as a secondary complication in Paget's Disease of Bone (PDB). There are no curative systemic therapies available for the treatment of OS, which currently relies heavily on surgical intervention and adjuvant chemotherapy, although many patients do not benefit from this treatment and develop recurrent or metastatic disease. The molecular mechanisms responsible for osteoblast transformation and tumour progression in both children as well as in PDB are not known, thus, identification of novel molecular therapeutic targets is of great importance.

Deregulated FGFR signalling has recently been implicated in the pathogenesis of breast and prostate cancer, however, whether it is also involved in skeletal malignancies has not been established. Our analysis of a transgenic mouse model of OS caused by overexpression of the c-Fos proto-oncogene demonstrated that induction of exogenous c-Fos expression in osteoblasts resulted in upregulation of FGFR1 RNA and protein expression, suggesting that FGFR1 is a novel c-Fos/AP-1 target gene. Further, immunohistochemistry studies showed high FGFR1 levels in tumours as well as at early sites of tumour formation, implicating deregulated FGFR1 signalling in tumour initiation. In murine osteoblasts, c-Fos and bFGF cooperated in stimulating anchorage-independent growth of non-transformed murine osteoblasts and c-Fos overexpression resulted in enhanced bFGF-dependent p38 and pERK MAPK signalling. Moreover, the FGFR signalling inhibitor, SU5402, as well as overexpression of dominant-negative FGFR1 constructs, inhibited anchorage-independent growth of c-Fos transgenic OS cells by over 50%.

These results in mice led us to investigate the role of FGF signalling in the pathogenesis of human OS. Treatment of U2OS human OS cells with bFGF stimulated colony growth in soft agar by 4-fold, and SU5402 completely abolished U2OS colony growth and inhibited MG63 cell colony growth by 75%, suggesting that FGF signalling is an important factor in the transformed state of human OS cells. To validate this notion, we performed Tissue Microarray analysis on primary human OS and demonstrated that over 60% of primary core biopsies expressed high levels of FGFR1, which increased to 85% for FGFR1 in matched biopsies taken after chemotherapy. These data implicate for the first time, signalling via FGFR1 as a possible mechanism of deregulated osteoblast growth during tumour initiation and for OS cell survival, and suggest that this pathway may represent a novel therapeutic target for OS treatment.

**Systemic Interleukin 8 Increases Bone Resorption *In Vivo*.** J. D. Dilley<sup>\*1</sup>, A. A. Carver<sup>\*1</sup>, J. M. Bracey<sup>\*2</sup>, N. S. Akel<sup>\*2</sup>, R. A. Skinner<sup>\*1</sup>, W. R. Hogue<sup>\*1</sup>, F. L. Swain<sup>\*2</sup>, P. Lahiji<sup>\*3</sup>, J. J. Maher<sup>\*3</sup>, M. S. Bendre<sup>\*4</sup>, D. Gaddy<sup>2</sup>, L. J. Suva<sup>2</sup>.  
<sup>1</sup>Orthopaedic Surgery, UAMS, Little Rock, AR, USA, <sup>2</sup>Orthopaedic Surgery & Physiology and Biophysics, UAMS, Little Rock, AR, USA, <sup>3</sup>Rice Liver Center Laboratory, UCSF, San Francisco, CA, USA, <sup>4</sup>Pathology, MD Anderson, Houston, TX, USA.

Skeletal metastases and the subsequent osteolysis connote a dramatic change in the prognosis for the cancer patient and significantly increase the morbidity associated with disease. Recently, we and others reported that breast and prostate cancer cells secrete the chemokine interleukin 8 (IL-8), and that IL-8 directly stimulates osteoclast formation *in vitro*, independent of any requirement for RANKL. IL-8 expression has also been negatively linked to the estrogen receptor (ER) status of cancer cell lines, implicating increased IL-8 expression in ER- breast cancer cells with the increased invasive potential of the tumor lines *in vivo*. In light of these studies, we examined IL-8 expression in primary human breast tumors in relation to ER status and determined the skeletal phenotype of male and female IL-8 transgenic (TG) mice. Tumor samples from 44 ER+ and 30 ER- invasive ductal breast carcinomas were immunostained for IL-8. All cases examined stained positive for IL-8 expression, with no significant differences observed in the intensity of IL-8 staining between ER+ and ER- samples, highlighting the important differences between primary tumors and tumor-derived cell lines. To investigate the osteoclastogenic activity of IL-8 *in vivo*, TG mice with a liver-specific transgene encoding human IL-8 were examined. Offspring were genotyped by quantitation of circulating human IL-8 levels in whole blood (84.5 ng/ml, versus 0.12 ng/ml in WT mice). IL-8 TG mice are profoundly osteopenic, with significantly increased bone resorption compared to WT mice, resulting in an inherently low bone volume, decreased trabecular number, increased trabecular spacing and significantly decreased cortical bone strength, related to the profound cortical thinning and increased endocortical resorption. Histological evaluation of the long bones demonstrated a dramatic increase in adipocyte numbers and apparent decreases in osteoblasts on the bone surface. These data demonstrate that IL-8 is expressed by primary breast tumors and suggest that tumor-derived IL-8 may play a role in tumor development and facilitate increases in bone resorption, leading to osteolytic bone lesions. In addition, IL-8 expression *in vivo* elicits profound increases in osteoclastogenesis and adipogenesis, suggesting a local role for IL-8 in the bone marrow microenvironment.

**Osteoporosis Diagnosis and Incident Fracture as a Function of Prior Fractures Site in a Large Clinical Cohort.** W. D. Leslie<sup>1</sup>, J. F. Tsang<sup>\*2</sup>, L. M. Lix<sup>\*3</sup>.  
<sup>1</sup>Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, <sup>2</sup>Department of Radiology, University of Manitoba, Winnipeg, MB, Canada, <sup>3</sup>Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada.

Prior fractures are a known risk factor for future osteoporotic fractures. The objective of this study was to assess the importance of prior fracture site on the strength of this relationship.

We identified 21444 women age 45 y or older undergoing baseline hip assessment with DXA (1990-2002) from a population-based database which contains all clinical DXA test results for the Province of Manitoba, Canada. These were linked to longitudinal health service records for physician billings and hospitalizations to identify non-trauma ICD-9-CM fracture codes that preceded DXA (prevalent fractures from 1987 until testing date) or followed DXA (incident fractures from testing date until 2004). ICD-9-CM codes with fewer than 50 cases were excluded. Osteoporosis diagnosis (femoral neck [FN] NHANES-III T-score -2.5 or lower, N=6030 [28.1%]) and incident 'osteoporotic' fractures (hip, clinical spine, wrist, humerus during mean 4.2 y of follow up, N=1202 [5.6%]) were studied in age-adjusted multiple regression methods (logistic and Cox proportional hazards models) in relation to prior fracture site.

The number of prior fracture sites was correlated with lower FN T-score (p<0.0001) and higher risk for incident fractures (p<0.0001). The site most strongly associated with an osteoporotic FN T-score was ICD-820 Neck of femur (OR 1.76, 95% CI 1.53-2.02). In age-adjusted multivariate regression, only ICD-805 Vertebral (HR 2.65, 95% CI 2.12-3.30), ICD-812 Humerus (3.04, 95% CI 2.47-3.75), ICD-813 Radius/ulna (1.44, 95% CI 1.18-1.77), and ICD-820 Femur neck (1.51, 95% CI 1.07-2.12) were independently associated with incident osteoporotic fractures. Simultaneous adjustment for femoral neck BMD slightly only weakened these associations. Many common fracture sites did not contribute independent fracture risk information, including ICD-807 Ribs/sternum, ICD-814 Carpal bones, ICD-823 Tibia/fibula, ICD-824 Ankle, and ICD-825 Tarsal/metatarsal bones.

We conclude that site of prior fracture is an important consideration in identifying women at risk for osteoporosis and future osteoporotic fractures. Fracture risk assessment systems should emphasize the importance of prior fractures affecting the hip, spine, wrist, and humerus.

**Fracture Risk and Incidence of Falls in Younger Postmenopausal Women (age 50-64 yrs): Rresults from National Osteoporosis Risk Assessment Survey (NORA).** E. Barrett-Connor<sup>1</sup>, S. G. Sajjan<sup>\*2</sup>, E. S. Siris<sup>3</sup>, T. Fan<sup>\*2</sup>, P. D. Miller<sup>\*4</sup>, S. S. Sen<sup>\*2</sup>.  
<sup>1</sup>University of California, San Diego, La Jolla, CA, USA, <sup>2</sup>Merck & Co., Inc, Whitehouse Station, NJ, USA, <sup>3</sup>Columbia University Medical Center, New York, NY, USA, <sup>4</sup>Colorado Center for Bone Research, Lakewood, CO, USA.

This study examined the association between the NORA-based tree algorithm for fracture risk (Chen et al., OI 2007) and self-reported future osteoporotic fractures and falls in postmenopausal women (PMW) between 50 and 64 years of age. Participants had no history of osteoporosis or bone-specific medication use at baseline, and completed year 1, year 2, and/or year 5 year follow-up surveys. Incident fracture rates (IFR) (see Table) were calculated dividing women with new fractures by person-years of follow-up. Relative risks (RR) for future fractures were calculated for women with the various combinations of risk factors for fracture using the Cox regression models. The tree algorithm for fracture risk included baseline personal history of fracture, a peripheral BMD T-score ≤ -1.1, and, self-reported fair/poor health status. A total of 3,192 women reported 3,451 future fractures. The prior history of fracture was the most important determinant of future fracture. The most important risk factors for falls were the prior history of fracture and fair/poor health status. Similar findings were observed for the algorithm without the BMD- T score. A simple 3 item tree-based algorithm identified relatively young PMW with a five fold increased risk of future osteoporotic fracture. Results were almost as good without a peripheral BMD measurement. Any PMW with a history of fracture and who reports fair or poor health should be evaluated for appropriate fracture prevention management.

Risk Factors	N	IFR (95% CI) Per 1,000 women-year follow-up	Relative risk of future fracture (95% CI)	% of Women reported a fall in the last 12-months at 1st follow-up survey
Prior history of fracture	5562	27.8 (25.6, 29.9)	4.9 (4.5, 5.5)	22.4
BMD-T score ≤ -1.1 with no fracture history	22710	12.6 (11.9, 13.3)	2.2 (2.0, 2.4)	16.6
Fair/Poor health with BMD-T score > -1.1 and no fracture history	8466	10.4 (9.3, 11.5)	1.8 (1.6, 2.1)	23.6
Excellent-Good health status with BMD-T score > -1.1 and no fracture history	54823	5.7 (5.4, 6.0)	Reference	16.2

**Risk Factors for Subsequent Fractures within the Next Year in Patients Presenting with a Clinical Fracture.** P. Geusens<sup>1</sup>, G. Willems<sup>\*2</sup>, S. van Helden<sup>\*3</sup>.  
<sup>1</sup>Internal Medicine/Rheumatology, University Hospital, Maastricht, Netherlands, <sup>2</sup>University Hospital, Maastricht, Netherlands, <sup>3</sup>Surgery, University Hospital, Maastricht, Netherlands.

**Background:** Patients presenting with a clinical vertebral or non-vertebral fracture have a high risk of subsequent clinical fractures within one year.

**Objectives:** In a prospective study we investigated the association between baseline bone- and fall-related risk factors and the risk of subsequent clinical fractures within one year after a clinical fracture.

**Methods:** At baseline, clinical bone-related risks, bone mineral density (BMD, at the spine and hip) and fall risks were assessed, based on the Dutch guidelines of osteoporosis and fall prevention. Accordingly, the fracture nurse gave general instructions about life style and fall prevention. In addition, patients with osteoporosis were prescribed bisphosphonates, calcium and vitamin D. During follow-up fall and fracture incidence were recorded by telephone questionnaire.

**Results:** A total of 31 patients (3.6%) out of 866 consecutively evaluated patients had a subsequent fracture within 1 year (18 at the upper limb, 17 at the lower limb, 5 multiple simultaneous fractures and 1 other). An incident fall was reported by 185 (21.4%), 113

(13.0%) had one fall, 72 (8%) had two or more falls. Nearly all subsequent fractures (94%) resulted from a fall. In patients with an incident fall, fracture incidence was 15% in patients with osteoporosis, 18% in osteopenia and 8% when BMD was normal. In patients without an incident fall, the incidence was 0.6%, 0% and 1.2%, respectively. In a multivariate analysis including baseline age, sex, fall risks, BMD and incident falls, the only determinant of a subsequent fracture was an incident fall ( $p<0.001$ ). Incident falls were related to sex (relative risk (RR) of women versus men: 1.50, 95% confidence interval (CI): 1.08-2.08) and the presence of one or more fall risks at baseline (RR: 1.75, CI: 1.01-3.04).

**Conclusion:** We conclude that in patients presenting with a clinical fracture, fall risk evaluation contributes to the recognition of subjects who have an increased risk for a subsequent clinical fracture within one year.

**Disclosures:** P. Geusens, None.

## 1238

**Independent Contribution of Hip Geometry to Incident Fracture Prediction in a Large Clinical Cohort.** W. D. Leslie<sup>1</sup>, H. J. Prior<sup>2\*</sup>, P. Pahlavan<sup>3</sup>. <sup>1</sup>Department of Medicine, University of Manitoba, Winnipeg, MB, Canada, <sup>2</sup>Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada, <sup>3</sup>St. Boniface General Hospital, Winnipeg, MB, Canada.

Although hip geometry is known to contribute to femur strength and fracture discrimination in cross-sectional studies, there are few data on prediction of incident fractures.

We assessed hip and non-hip osteoporotic fracture outcomes in 30,953 women aged 50 years or older (mean  $66\pm 10$ ) who underwent baseline hip DXA with a single scanner configuration (Prodigy, GE Lunar) through the Manitoba BMD Program. All hip scans were processed with a single version of analysis software (enCore v12) to generate multiple indices of hip geometry (hip axis length=HAL, cross sectional moment of inertia=CSMI, cross sectional area=CSA, strength index=SI) in addition to conventional BMD (total hip T-score=TH and femoral neck T-score=FN, NHANES III reference data). Population-based administration health data were linked to the scan results in order to determine fracture outcomes. During mean 3.7 years of follow up (range up to 9.6 years) we identified operated hip fractures (N=270) and non-hip osteoporotic fractures (clinical spine, wrist, humerus; N=1,269). Cox proportional hazards models constructed to assess the effect of hip geometry variables on fractures were sequentially adjusted for age, age+BMD, and age+BMD+weight+height.

Unadjusted mean values for HAL, CSMI, CSA, SI and TH were significantly different for hip fracture vs. non-fracture women (all  $P<0.0001$ ) and non-hip fracture vs. non-fracture women (all  $P<0.0001$ ). In age-adjusted models CSMI, CSA, SI and TH were significant predictors of hip and non-hip fractures; HAL was only significant for hip fractures. When fully adjusted (for age+BMD+weight+height), HAL (HR 1.22, 95% CI 1.06-1.40) and SI (HR 1.23, 95% CI 1.09-1.40) were still significant predictors of hip fractures but not of non-hip fractures. Similar results were seen when FN was substituted for TH in the fully adjusted model: HAL HR 1.32 (95% CI 1.17-1.50) and SI HR 1.16 (95% CI 1.03-1.30). Addition of HAL or SI to models that included BMD gave a significant improvement in hip fracture prediction (log-likelihood ratio test  $P<0.005$ ).

We conclude that some hip geometry parameters (HAL and SI) make a small but significant independent contribution to hip fracture prediction. Hip geometry does not affect non-hip fracture risk when adjusted for other factors.

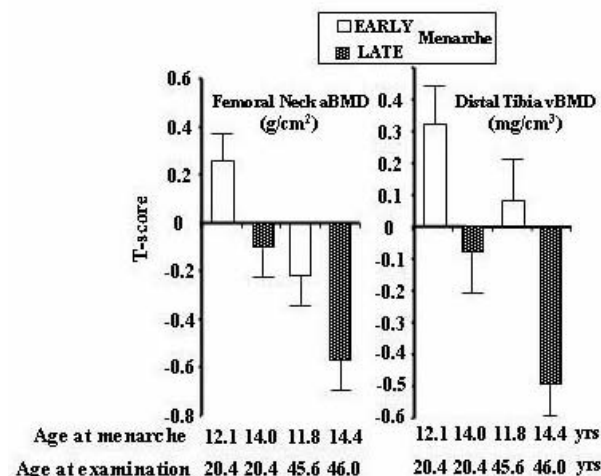

Hazard ratios for incident fracture per SD.		
	Hip fractures HR (95%CI)	Non-hip fractures HR (95%CI)
<b>Age-adjusted</b>

**Deleterious Effect of Late Menarcheal Age on Bone Microstructure in Both Distal Radius and Tibia: No Interaction with Age Dependent Premenopausal Bone Loss in Weight-Bearing Skeletal Sites.** T. Chevalley, J. P. Bonjour, S. Ferrari, R. Rizzoli. Service of Bone Diseases, Department of Rehabilitation and Geriatrics, Geneva University Hospitals, Switzerland.

Late menarche is a risk factor for fragility fractures. We hypothesized that pubertal timing-dependent alterations in bone structural components would persist from peak bone mass (PBM) to menopause, independent of any premenopausal bone loss that can be observed in weight-bearing skeletal sites. The influence of menarcheal age (MENA) was examined in healthy young adult (YAD,  $20.4\pm 0.6$  ( $\pm$ SD) years,  $n=124$ ) and premenopausal middle-aged (PREMENO,  $45.8\pm 3.4$  yrs,  $n=120$ ) women. Areal bone mineral density (aBMD) was measured in both distal radius and femoral neck by DXA. Volumetric bone mineral density (vBMD) was measured by high resolution peripheral computerized tomography (HR-pQCT) in both distal radius and distal tibia. Median of MENA was  $13.0\pm 1.2$  and  $13.1\pm 1.7$  years in YAD and PREMENO, respectively. After segregation by the median of MENA in EARLY and LATE subgroups, the significant negative influence of LATE MENA was observed in both distal radius ( $P=0.039$ ) and femoral neck ( $P=0.004$ ) aBMD. Microstructure analysis indicated a marked deleterious effect of LATE MENA in vBMD of both distal radius ( $P=0.006$ ) and distal tibia ( $P=0.0005$ ). Cortical thickness was also reduced in LATE vs EARLY MENA in both distal radius ( $P=0.027$ ) and distal tibia ( $P=0.004$ ). As illustrated in the figure the negative effect of age between YAD and PREMENO was additive to LATE MENA in both femoral neck aBMD and distal tibia vBMD. In conclusion, in healthy women a 1.9-2.6 yrs later menarcheal age is negatively associated with areal and volumetric BMD as well as cortical thickness in both upper and lower limbs. This influence of pubertal timing is observed in early twenties and a few years prior to menopause. The negative influence of aging from early twenties to mid-forties on both aBMD and vBMD as assessed at weight-bearing skeletal sites does not attenuate the influence of MENA. Alterations in both bone mineral mass and microstructural components may explain the increased risk of fragility fractures associated with later menarcheal age.

## 1240

**Performance of QUS In Comparison to DXA For Prediction Of Prospective Fractures Among Older Men and Women: The EPIC-Norfolk Study.** A. Moayyeri, S. Kaptoge, R. Luben\*, S. Bingham\*, N. J. Wareham\*, J. Reeve, K. T. Khaw\*. Public Health and Primary Care, The University of Cambridge, Cambridge, United Kingdom.

The role of quantitative ultrasound (QUS) in the management of osteoporosis is debated. Although QUS of the heel is known to be correlated with bone mineral density (BMD), the performance of QUS for prediction of fractures in comparison to dual-energy X-ray absorptiometry (DXA), the current reference standard for diagnosis of osteoporosis, is unclear. We examined this in a sample of men and women in the European Prospective Investigation into Cancer (EPIC)-Norfolk who had both heel QUS and hip DXA between 1995 and 1997 and were followed for incident fractures up to March 2007. From 1,454 participants (701 men) aged 65-76 years at baseline, 79 suffered a fracture over 15.567 person-years of follow-up (mean 10.3±1.4 years). In a sex-stratified multivariate Cox proportional-hazard model including age, height, weight, past history of fracture, smoking, alcohol intake and DXA total hip BMD, 1 SD decrease in BMD was associated with a hazard ratio for fracture of 2.28 (95% CI 1.75-2.98). In a multivariate model with heel broadband ultrasound attenuation (BUA) in place of BMD, hazard ratio for 1 SD decrease in BUA was 2.02 (95% CI 1.54-2.65). While the global measures of model fit (including Bayesian and Akaike's information criteria, LR chi-square, D-statistic, Nagelkerke's and Cox-Snell R-square) slightly favored the model with DXA measure, measures of discrimination (area under ROC curve 0.685 vs. 0.679) and calibration (Hosmer-Lemeshow statistic 0.82 vs. 0.45) showed relative superiority of the model with BUA. Using the alternate Cox models with DXA and BUA, we calculated exact 10-year absolute risk (probability) of fracture for all participants and categorized them in three groups of <5%, 5% to <15%, and ≥15%. Comparison of groupings based on DXA vs. BUA models showed a total reclassification of 24.9% of participants. The predicted risks for individual participants using BUA model were closer to the observed risks (especially among the 52.2% reclassified highest-risk group). This study shows that the power of QUS for prediction of prospective fractures and calculation of 10-year probability of fractures among the elderly is comparable to that of DXA. Given the ease and low cost of ultrasound, risk assessment tools (such as newly-developed FRAX tool) may include QUS measures in their algorithms to attain more accurate estimates of fracture risk. Further studies or meta-analyses are required to clarify whether QUS with clinical risk factors would be cost-effective for primary care case-finding when DXA is not available.

**Strontium Ranelate Prevents the Progression of Thoracic Kyphosis in Postmenopausal Women with Osteoporosis.** C. Roux<sup>1</sup>, K. Briot<sup>1</sup>, S. Kolta<sup>1</sup>, R. Said-Nahal<sup>\*1</sup>, C. Benhamou<sup>2</sup>, J. Fechtenbaum<sup>1</sup>. <sup>1</sup>Rheumatology, Cochin Hospital, Paris, France, <sup>2</sup>Rheumatology, Orleans Hospital, Orleans, France.

Thoracic kyphosis, frequent in the elderly and in postmenopausal osteoporosis, has been associated with impairment in global health. It can be caused by vertebral fractures, and by degenerative spine changes (intervertebral disc space narrowing, deformities of the anterior part of the vertebrae and reduced spinal muscles strength). The objective of this study was to assess the effect on thoracic kyphosis progression over a 3-year treatment with strontium ranelate which reduces the risk of vertebral, non vertebral and hip fractures. This study was performed in women with postmenopausal osteoporosis from SOTI<sup>1</sup> and TROPOS<sup>2</sup> studies, aiming to demonstrate the efficacy of strontium ranelate against vertebral and non-vertebral fractures. Patients underwent lateral radiographs of the thoracic and lumbar spine at baseline and annually over 3 years (standardized procedures). The level of thoracic kyphosis was reflected by a kyphosis index, defined on lateral thoracic radiographs as the ratio BD/AC (AC= line from the anterior superior edge of T4 to the anterior inferior edge of T12; BD= perpendicular line from the furthest superior or inferior posterior point of T7, T8 or T9 vertebrae to AC line) expressed as a %.

The population consisted of 4055 women with postmenopausal osteoporosis (2038 in the strontium ranelate group and 2017 in the placebo group). Baseline characteristics were similar: mean age 73.5; mean lumbar spine T-score of -3.06; mean hip T-score of -2.97, and mean KI of 25.4. Over 3 years, there was a significant increase from baseline in kyphotic index for all patients. However, this increase was significantly lower (p=0.003) in patients treated with strontium ranelate: +3.71±7.69% than in the placebo group: +4.70±7.32%. After exclusion of patients having either prevalent or incident thoracic vertebral fractures, in a subset of 1193 patients (634 in the strontium ranelate group and 559 in the placebo group), the change in the strontium ranelate group was still lower (p<0.001) than in the placebo group (+ 2.72±7.17% versus 4.34±6.54%, respectively).

These prospective results demonstrate that thoracic kyphosis increases over time in postmenopausal women with osteoporosis. Strontium ranelate decreased the progression of this thoracic kyphosis over 3 years, regardless of the presence or not of vertebral fractures. This effect of strontium ranelate possibly reflects additional benefit on spinal components besides its efficacy in decreasing vertebral fractures.

**Prevention of Non-vertebral Fractures with Oral Vitamin D Is Dose Dependent: a Meta-analysis of RCTs.** H. A. Bischoff-Ferrari<sup>1</sup>, W. C. Willett<sup>\*2</sup>, J. B. Wong<sup>\*3</sup>, A. Stuck<sup>\*4</sup>, H. B. Staehelin<sup>\*5</sup>, J. E. Orav<sup>\*6</sup>, A. Thoma<sup>\*1</sup>, D. P. Kiel<sup>7</sup>, J. Henschkowski<sup>\*1</sup>. <sup>1</sup>Rheumatology and Institute of Physical Medicine, University of Zurich, Zurich, Switzerland, <sup>2</sup>Dept. of Nutrition, Harvard School of Public Health, Boston, MA, USA, <sup>3</sup>Division of Clinical Decision Making, New England Medical Center, Boston, MA, USA, <sup>4</sup>Geriatrics, University of Bern, Bern, Switzerland, <sup>5</sup>Geriatrics, University of Basel, Basel, Switzerland, <sup>6</sup>Biostatistics, Harvard School of Public Health, Boston, MA, USA, <sup>7</sup>Gerontology, Harvard Medical School, Boston, MA, USA.

**Background:** Anti-fracture efficacy with supplemental vitamin D (cholecalciferol = D3, ergocalciferol = D2) has been questioned by recent trials.

**Aim:** We performed a meta-analysis on the efficacy of supplemental vitamin D in preventing non-vertebral and hip fractures among older individuals (age 65+).

**Studies included:** We included double-blind randomized controlled trials (RCTs) of oral vitamin D with or without calcium supplementation compared with calcium or placebo. 12 RCTs (n=42,279) for non-vertebral fractures and 8 RCTs for hip fractures (n = 40,886) met our inclusion criteria.

**Results:** The pooled relative risk (RR) for prevention of non-vertebral fractures by vitamin D was 0.86 (95% CI, 0.77-0.96), and for hip fractures was 0.91 (95% CI, 0.78-1.05), but with significant heterogeneity for both endpoints. Including all trials, anti-fracture efficacy increased significantly with higher received dose (dose\*adherence) and higher achieved blood 25-hydroxyvitamin D levels (25(OH)D) for any non-vertebral fractures (dose\*adherence: p=0.003; 25(OH)D: p = 0.04) and for hip fractures (dose\*adherence: p=0.07; 25(OH)D: p = 0.009). Consistently, heterogeneity was resolved by pooling trials with a higher received dose of more than 400 IU/day separately. With the higher dose, the pooled RR for any non-vertebral fractures including 9 trial was 0.80 (95% CI, 0.72 -0.89; n = 33,265) and the pooled RR for hip fracture including 5 trials was 0.82 (95% CI, 0.69 - 0.97; n = 31,872). For the higher received dose, non-vertebral fracture reduction was significant among community-dwelling (-29%) and institutionalized older individuals (-15%), and was independent of additional calcium supplementation. **Conclusion:** Non-vertebral fracture prevention with vitamin D is dose-dependent, and a higher dose should reduce fractures by at least 20% for individuals over age 65 years.

## 1243

**A Randomized Trial of Balloon Kyphoplasty and Nonsurgical Care for Acute Vertebral Fracture: Who Responds Best?** S. Cummings<sup>1</sup>, D. Wardlaw<sup>\*2</sup>, J. Van Meirhaeghe<sup>\*3</sup>, L. Bastian<sup>\*4</sup>, J. Tillman<sup>\*5</sup>, J. Ranstam<sup>\*6</sup>, R. Eastell<sup>7</sup>, P. Shabe<sup>\*8</sup>, K. Talmadge<sup>9</sup>, S. Boonen<sup>9</sup>. <sup>1</sup>University of California, San Francisco, CA, USA, <sup>2</sup>Woodend Hospital, Aberdeen, United Kingdom, <sup>3</sup>Algemeen Ziekenhuis St. Jan, Brugge, Belgium, <sup>4</sup>Klinikum Leverkusen, Leverkusen, Germany, <sup>5</sup>Medtronic Spine LLC, Sunnyvale, CA, USA, <sup>6</sup>Lund University Hospital, Lund, Sweden, <sup>7</sup>University of Sheffield, Sheffield, United Kingdom, <sup>8</sup>Advance Research Associates, Mountain View, CA, USA, <sup>9</sup>Katholieke Universiteit, Leuven, Belgium.

Balloon kyphoplasty aims to improve quality of life and reduce pain and disability by treating vertebral deformity and stabilizing the fracture with bone cement. We tested the efficacy of kyphoplasty versus nonsurgical care and analyzed 1 year outcomes to identify patients who may benefit most from the procedure.

Patients with 13 acute vertebral compression fractures were randomly assigned to kyphoplasty (N=149) or nonsurgical care (N=151). Overall, patients assigned to kyphoplasty had statistically significant improvements in quality of life; the SF-36 physical component summary (PCS) improved 3.4 (95% CI, 1.55.3) and Euroqol-5D (EQ-5D) improved 0.13 (95% CI, 0.050.22) points more than nonsurgical care. Kyphoplasty resulted in more pain relief (1.6 points; 95% CI 1.22.1), less Roland-Morris back disability (3.1 points; 95% CI, 1.94.3) and 2.4 (95% CI 1.13.7) fewer days of limited activity (within a two-week period). To identify patients who may benefit most from kyphoplasty, we analyzed the effect of kyphoplasty on outcomes in patients with higher (≥18 points) or lower (<18) baseline Roland-Morris disability scores (Table). We also tested the effects of kyphoplasty in patients above or below the median age of 74 years.

Each disability group had better improvement with kyphoplasty. A larger treatment effect of kyphoplasty was observed in those with greater disability; there was a significant treatment by subgroup interaction for Roland-Morris scores and disability days (p<0.05). The effects of kyphoplasty were similar for patients ≥74 years (range 74-95) and <74 years (range 44-73).

Compared to nonsurgical care, balloon kyphoplasty improved quality of life and reduced back pain and disability and did not increase the risk of vertebral fracture over 1 year. The effects may be somewhat greater in those with the highest Roland-Morris scores. The effects of kyphoplasty are similar for elderly and younger patients.

Outcome Measure (Range of the Scale)	12-Month Difference of Kyphoplasty Minus Control (Mean and 95% CI)	
	High Roland-Morris Disability (≥18 points at baseline)	Low Roland-Morris Disability (<18 points at baseline)
Roland-Morris (0-24 points)*	-4.6 (-6.2 to -3.0)	-1.5 (-3.3 to 0.2)
Roland-Morris (0-100 %)*	-23 (-33 to -13)	-13 (-23 to -2)
Back Pain (0-10 points)*	-1.8 (-2.4 to -1.2)	-1.4 (-2.1 to -0.8)
Disability Days (0-14 days)*	-3.6 (-5.4 to -2.1)	-1.0 (-2.9 to 0.9)
EQ-5D (0-1 point)	0.17 (0.05 to 0.29)	0.10 (-0.03 to 0.23)
SF-36 PCS (0-100 points)	4.4 (1.9 to 6.9)	2.4 (-0.5 to 5.2)

\*Demerit scales; lower scores are better

**Effects of a Targeted Bone and Muscle Loading Program on QCT Bone Geometry and Strength, Muscle Size and Function in Older Men: An 18-month RCT.** S. Kukuljan<sup>\*1</sup>, C. Nowson<sup>\*1</sup>, S. Bass<sup>1</sup>, K. Sanders<sup>\*2</sup>, G. C. Nicholson<sup>2</sup>, R. M. Daly<sup>3</sup>. <sup>1</sup>School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia, <sup>2</sup>Clinical and Biomedical Sciences, Barwon Health, The University of Melbourne, Geelong, Australia, <sup>3</sup>Department of Medicine, The University of Melbourne, Western Hospital, Melbourne, Australia.

We have previously shown that an 18 month community-based, multi-component exercise program, with or without additional calcium-vitamin D<sub>3</sub>, was effective for improving FN aBMD in older men. In this study we examine the effects of the exercise program on QCT measured bone geometry and strength, and muscle size and functional performance. Men (n=180) aged 61±7 years (±SD) were randomised to an exercise or non-exercise group with or without additional calcium-vitamin D<sub>3</sub> (fortified milk: 1000 mg/d calcium and 800 IU/d vitamin D<sub>3</sub>). The exercise consisted of high intensity (60-85% 1RM) resistance and power training (RT) and weight-bearing impact exercise (1.5-9.7 BW) performed 3 days/wk. QCT was used to assess mid-femur and mid-tibia total (TotAr), cortical (CortAr), medullary areas (MedAr), volumetric BMD (vBMD), polar moment of area (Ip), muscle cross-sectional area (CSA) and distal tibia trabecular vBMD. Gait (6-m walk), dynamic balance (step-test) and sway were also assessed. 172 men (95%) completed the study; exercise attendance averaged 63% and compliance with the fortified milk averaged 90%. Muscle CSA and gait speed improved in the exercise compared to non-exercise groups (1.0 vs -0.8%, p<0.01; -3.0 vs -1.1 seconds, p<0.05). ITT analyses revealed that there were no exercise-by-calcium-vitamin D<sub>3</sub> interactions, nor any main effects of exercise or calcium-vitamin D<sub>3</sub> on any QCT bone parameters. However, subgroup analyses of the exercise group revealed that the average number of jumps per session, but not the average RT load per session over the 18 month study, correlated with change in mid-femur CortAr (r=-0.32, p<0.001), MedAr (r=-0.30, p<0.01) and Ip (r=0.22, p=0.05). When expressed as tertiles, men who performed at least 65 jumps per session had a net 0.5 to 0.7% gain in mid-femur CortAr compared to those in the lowest two tertiles (≤35 or 36-64 jumps per session), independent of RT load, or the non-exercise group (all p<0.05). This can be attributed to reduced medullary expansion (net difference 0.5 to 1.2%) and not periosteal apposition. In conclusion, this study indicates that a multi-component resistance and weight-bearing exercise program can enhance muscle size and function in older men, and that bone geometry adapts to a given number of impact loads (≥65 jumps/session), and not the total resistance training load. In contrast, increased dietary calcium-vitamin D<sub>3</sub> had no effect on bone geometry or strength in this group of older well nourished men.

## 1245

**Alendronate and Indapamid Alone or in Combination in the Management of Idiopathic Hypercalciuria Associated with Osteoporosis: a Randomized-Controlled Trial.** A. Giusti<sup>1</sup>, A. Barone<sup>\*1</sup>, G. Pioli<sup>2</sup>, G. Girasole<sup>3</sup>, V. Siccardi<sup>\*3</sup>, E. Palummeri<sup>1</sup>, G. Bianchi<sup>3</sup>. <sup>1</sup>Gerontology, Galliera Hospital, Genoa, Italy, <sup>2</sup>Gerontology, ASMN Hospital, Reggio Emilia, Italy, <sup>3</sup>Rheumatology, La Colletta, Genoa, Italy.

The role of bisphosphonates (BSF) in the treatment of patients with idiopathic hypercalciuria (IHC) associated with osteoporosis is still uncertain. To evaluate the effect of alendronate alone or in combination with indapamid on bone mineral density (BMD) and 24-hours calciuria (CaU), 67 post-menopausal women with IHC (CaU>4mg/kg/die) and low BMD [T-score<-2.0 at lumbar spine (LS), femoral neck (FN) or total hip (TH)] from two centres of Northern Italy, were randomised to receive: indapamid 2.5 mg daily alone (20 patients, IND group), alendronate 70 mg weekly alone (25 patients, ALN group) or the combination therapy (22 patients, ALIND group). Throughout the study, all subjects received daily calcium supplements, depending on their dietary intake, to maintain a daily input of 1,000 mg. Patients were instructed to increase water intake up to 2000 ml daily. The percentage change of BMD at LS, FN and TH, and the variation of 24-hours CaU from baseline at 1-year were the primary outcomes. Serum calcium, PTH and bone alkaline phosphatase were also measured. Patients in the 3 groups were similar with regard to baseline characteristics. After 1-year,

CaU values significantly decreased from baseline in all groups (IND, 239±78 vs. 364±44, p<.001) (ALN, 279±68 vs. 379±79, p<.001) (ALIND, 191±68 vs. 390±55, p<.001). The mean % decrease of CaU in ALIND group (-50%) was significantly greater compared to ALN (-24%, p<.001) and IND (-35% p=.012). BMD did not significantly changed from baseline after 1 year of treatment with indapamid (LS: +1±3.1%; FN: -0.3±3.5%; TH: -0.4±3.1%), while showed a significant increase from baseline in the other 2 groups (ALN; LS: +5.8±4.2%, p<.001; FN: +3.9±7.9%, p=.018; TH: +2±3.6%, p=.006) (ALIND; LS: +8.2±5.3%, p<.001; FN: +4.9±6.7%, p=.007; TH: +2.9±4.2%, p=.004). In addition, patients in the combination group (ALIND) showed a significantly higher increase of BMD at LS compared to ALN (p=.04).

These results show a benefit on BMD and CaU, of BSF<sup>†</sup> therapy in IHC associated with osteoporosis. The combination therapy demonstrated a reduction of CaU and an increase in LS BMD superior to that observed with alendronate alone. Our results support a new potential approach with BSF associated to thiazide diuretics in the management of post-menopausal women with IHC and associated bone loss.

**Osteonecrosis of the Jaw: Zoledronic Acid 5 mg Experience in a Variety of Osteoporosis Indications.** J. Grbic<sup>1</sup>, D. Black<sup>2</sup>, K. Lyles<sup>3</sup>, D. Reid<sup>4</sup>, C. Bucci-Rechtweg<sup>\*5</sup>, P. Mesenbrink<sup>\*6</sup>, E. Orwoll<sup>7</sup>, E. Eriksen<sup>8</sup>. <sup>1</sup>Columbia University College of Dental Medicine, New York, NY, USA, <sup>2</sup>University of California, San Francisco, CA, USA, <sup>3</sup>VA Medical Center, Durham, NC, USA, <sup>4</sup>University of Aberdeen, Aberdeen, United Kingdom, <sup>5</sup>Novartis Pharmaceuticals Corporation, New Jersey, NJ, USA, <sup>6</sup>Novartis Pharmaceuticals Corporation, New Jersey, NJ, USA, <sup>7</sup>Portland VA Medical Center, Portland, OR, USA, <sup>8</sup>Novartis Pharma AG, Basel, Switzerland.

Currently bisphosphonates (BPs) constitute the primary therapeutic option for the treatment of osteoporosis, and the iv. BP zoledronic acid (ZOL), has demonstrated significant reduction of osteoporotic fractures at vertebral and non-vertebral sites. BPs have, however, been associated with Osteonecrosis of the Jaw (ONJ), characterized by exposed bone in the oral cavity. We have previously reported on the prospective assessment of ONJ incidence in the ZOL pivotal fracture trial (Study 2301) [J Am Dent Assoc. 2008 Jan;139(1):32-40]. In the current report, we analyzed the overall incidence of ONJ after completion of 3 additional studies ZOL studies, comprising a total of 11,000 patients. Moreover, we analyzed the distribution of the biomarker S-CTX, where levels below 0.1 ng/ml have been postulated as an indicator of increased ONJ risk [J Oral Maxillofac Surg. 2007 Dec;65(12):2397-410]. The studies included the uses of ZOL in the treatment of postmenopausal osteoporosis (N=7714), prevention of recurrent fracture after hip fracture (N=2111), treatment of glucocorticoid-induced osteoporosis (N=833), and male osteoporosis (N=302). The new studies included patients, thought to be at higher risk for the development of ONJ due to treatment with glucocorticoids and a high prevalence of diabetes. No spontaneous reports of ONJ were received for any of the additional studies. And after extensive review of all maxillofacial events with adjudication, the only two cases meeting the definition of ONJ remained the two cases previously described in patients with post-menopausal osteoporosis (one on placebo and one on ZOL). Among the 7714 patients enrolled in study 2301, the fraction of patients exhibiting S-CTX values < 0.1 ng/ml at months 6, 12, 24 and 36 were 60.8%, 30.9%, 20.4% and 16.1%, respectively. For the patient on placebo with adjudicated ONJ, S-CTX ranged between 0.26 and 0.37 ng/ml. S-CTX was not available for the patient on ZOL. In conclusion, in more than 11,000 patients, of which half were treated with zoledronic acid, no spontaneous reports of ONJ were received. Only 2 patients (1 on placebo, 1 on BP) met adjudication criteria for ONJ, thus no indication of increased risk of ONJ after treatment with ZOL. No association between low S-CTX and ONJ was established.

## 1247

**Loss or Gain of FoxO Function in Osteoclasts and Osteoblasts Alters the Rate of Apoptosis and BMD in Mice.** E. Ambrogini<sup>1</sup>, C. A. O'Brien<sup>1</sup>, M. Martin-Millan<sup>1</sup>, J. Paik<sup>\*2</sup>, R. A. DePinho<sup>\*2</sup>, L. Han<sup>1</sup>, A. Warren<sup>\*1</sup>, R. S. Shelton<sup>\*1</sup>, X. Qui<sup>\*1</sup>, J. Goellner<sup>1</sup>, R. L. Jilka<sup>1</sup>, M. Almeida<sup>1</sup>, S. C. Manolagas<sup>1</sup>. <sup>1</sup>Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA, <sup>2</sup>Center for Applied Cancer Science and Dept of Medical Oncology, Dana-Farber Cancer Institute, Depts of Medicine and Genetics, Harvard Medical School, Boston, MA, USA.

FoxO transcription factors influence cell proliferation, apoptosis, differentiation, metabolic responses, as well as resistance against oxidative stress (OS). Based on evidence that diversion of  $\beta$ -catenin from Wnt/TCF- to FoxO-mediated transcription by OS suppresses osteoblastogenesis, we investigated the role of FoxOs in bone metabolism *in vivo*, using mice in which we overexpressed FoxO3a in osteoblasts or mice with conditional deletion of FoxO1, 3a, and 4 (Mx-Cre<sup>+</sup>;FoxO1,3,4<sup>L/L</sup>). FoxO3a overexpression in osteoblasts was accomplished by creating a transgene with a transcriptional/translational stop cassette, flanked by loxP sites, inserted between the hybrid CMV-chicken  $\beta$ -actin promoter and a cDNA encoding an HA-tagged human FoxO3a. Mice carrying the transgene were then crossed with mice expressing the Cre recombinase under the control of the human osteocalcin promoter (OCN-Cre). Expression of the FoxO3a transgene was detected in calvaria and vertebrae but not liver or spleen, and resulted in increased expression of the FoxO-target genes Gadd45 and Bim. Importantly, these mice exhibited a significant increase in lumbar spine bone mineral density at 6 weeks. Deletion of FoxOs in Mx-Cre<sup>+</sup>;FoxO1,3,4<sup>L/L</sup> was achieved by induction of interferon using polyinosine-polycytidylic acid (pI-pC) injections. Four weeks later, mice were sacrificed and gene expression was determined. FoxO1, 3a, and 4 levels were decreased in liver (>98%), spleen (50-90%), as well as in calvaria and L4 (45-75%), as compared to Mx-Cre<sup>+</sup>;FoxO1,3,4<sup>L/L</sup> (control) mice. In addition, expression of the three FoxO isoforms was reduced (75-90%) in osteoblasts generated by culturing bone marrow derived stromal cells from Mx-Cre<sup>+</sup> mice for ten days in the presence of ascorbic acid, along with a decrease in the expression of the FoxO-target genes Gadd45 and p27<sup>Kip1</sup>. Finally, the expression of all three FoxOs was dramatically reduced (>99%) in mature osteoclasts from Mx-Cre<sup>+</sup>;FoxO1,3,4<sup>L/L</sup> mice obtained by culturing non adherent bone marrow cells in the presence of M-CSF and RANKL. FoxO deletion was associated with an increase in the basal rate of osteoclast apoptosis, as determined by caspase 3 activity. Collectively, these preliminary findings indicate that FoxOs play an important role in both osteoblasts and osteoclasts and influence bone mass.

**Coactivator MBF1 Binds to JunD and Protects Its Transcriptional Activity Against Oxidative Stress to Prevent Age-Related Suppression of Osteoblast Differentiation.** S. Kido, R. Kuriwaka<sup>\*</sup>, T. Matsumoto. Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medical Sciences, Tokushima, Japan.

Oxidative stress reduces osteoblast number and suppresses bone formation, leading to the age-related loss of bone. We have demonstrated that anti-adipogenic cytokine, IL-11, was expressed in osteoblasts in an AP-1-dependent manner, and that DNA binding activity of JunD was reduced without change in its protein level in aged mice. Therefore, there is a possibility that reduced JunD activity may be caused by post-translational modification of JunD by an age-related increase in oxidative stress. MBF1, a transcriptional coactivator, directly binds to Fos and Jun to prevent oxidative damage and preserves their DNA binding activity. To determine potential roles of MBF1 in age-related reduction in bone formation, we first examined MBF1 expression in mice at different ages. In young mice, MBF1 protein was expressed in all tissues examined, whereas the amount of MBF1 decreased in many tissues including bone of aged mice. Cultured osteoblasts also expressed MBF1, and knockdown of MBF1 by siRNA in ST2 cells reduced the number of ALP<sup>+</sup> cells. In contrast, stable transfection of ST2 cells with MBF1 enhanced osteoblastogenesis and inhibited adipogenesis. When wild-type ST2 cells were treated with hydrogen peroxide, most cells died, whereas ST2 cells transfected with MBF1 survived even in the presence of hydrogen peroxide. DNA precipitation assay demonstrated that MBF1 forms complex with JunD on an AP-1 site of IL-11 promoter via binding to a basic region of JunD. MBF1 binding to JunD also enhanced AP-1-dependent IL-11 gene transcription even in the presence of hydrogen peroxide. These results demonstrate that MBF1 binds to a basic region of JunD and protects from oxidative damage to enhance transcriptional activation of IL-11 gene. It is suggested that reduced MBF1 protein expression in osteoblasts may play a role in age-related impairment of osteoblast differentiation by suppressing IL-11 transcription via a reduction in JunD activity, and that MBF1 can be a new target against age-related loss of bone.

**Changes in Marrow Cell Dynamics and Bone Geometry with Aging in Thrombospondin-2 Null Mice.** S. P. Terkhorh<sup>1</sup>, S. Tomassini<sup>\*2</sup>, C. Price<sup>\*1</sup>, R. A. Ruberte-Thiele<sup>\*1</sup>, J. A. Combs<sup>\*1</sup>, K. J. Jepsen<sup>\*2</sup>, K. D. Hankenson<sup>1</sup>. <sup>1</sup>Animal Biology, University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Leni & Peter W. May Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Thrombospondin-2 is a 450 kDa trimeric matricellular protein that is highly expressed by mesenchymal lineage cells in bone, but not hematopoietic cells. Previous studies by our group have shown that thrombospondin 2 (TSP2) regulates marrow stromal cell (MSC) proliferation. When TSP2 is knocked out (TSP2-null) there is an increase in MSC number. Furthermore, TSP2-null mice examined at four months of age show increased endocortical bone formation and a reduction in marrow area. The purpose of this study was to assess the influence of TSP2 on the MSC pool and bone geometry in relationship to aging. Femurs and tibias were removed from wild type and TSP2-null mice, aged 14 and 20 months. Total bone marrow was extracted from one femur and tibia and plated for CFU-F assay. At 14 months there was a surprising reduction in the relative CFU-F number in the TSP2-null mice, but the TSP2-null mice show a 2-fold increase in total marrow cell number relative to wild type (WT). At 20 months of age the total marrow cell number in TSP2-null mice was actually less than the WT, but the relative CFU-F increased, suggesting that TSP2 regulates the MSC pool in an age-dependent manner. Next, microcomputerized tomography was used to assess bone geometry. In earlier experiments, we observed that bones of younger mice consistently show increased cortical thickness and reduced marrow area due to endocortical bone formation. In this study, at 14 months of age, the TSP2-null mice have an increased marrow area, because of endocortical expansion, as well as increased periosteal circumference when compared to WT mice. 20-month-old TSP2-null mice continued to demonstrate periosteal and endocortical expansion, but at this age, TSP2-null and TSP2 expressing mice exhibited similar geometric properties in bone. We conclude that TSP2 regulates the MSC pool in an age-dependent manner which corresponds to changes in bone geometry. TSP2-null mice have significant endocortical resorption, greater than WT mice, that occurs from 4 months to 14 months of age, with a concomitant decrease in CFU-F concentration. However, CFU-F concentration increases from the period of 14 to 20 months, and endocortical bone changes are equivalent during this period. Importantly, our results also show that TSP2 may influence hematopoietic cells in the marrow environment. There is two-fold increase in TSP2-null total marrow cells at 14 months relative to WT, but a reduction at 20 months. We propose that TSP2, produced by MSC in the marrow, could be an additional matricellular component of the HSC niche.

**Endogenous Glucocorticoids Are Critical for the Development of Skeletal Fragility with Aging in Mice.** R. S. Weinstein, C. A. O'Brien, P. K. Roberson<sup>\*</sup>, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

The adverse skeletal effects of hyperglucocorticoidism in humans and mice are well known, but far less is known of the contribution of glucocorticoids to the aging skeleton. Nonetheless, the decline in bone strength is disproportionately greater than the loss of bone mass with both glucocorticoid excess and aging. In addition, both conditions decrease bone vascularity and interstitial fluid volume. To establish whether endogenous glucocorticoids contribute to the development of skeletal fragility with aging, we searched for and found that aging increased serum corticosterone levels, adrenal weight and 11 $\beta$ -hydroxysteroid dehydrogenase type 1 expression (the enzyme that amplifies glucocorticoid activation) in murine bone and that dehydration compromised the resistance to deformation and energy required to break bones in young but not old mice. Next, we determined the impact of aging in transgenic mice overexpressing 11 $\beta$ -hydroxysteroid dehydrogenase type 2 (the enzyme that inactivates glucocorticoids) under the control of the osteocalcin promoter (OG2-11 $\beta$ -HSD2 mice), a model for deflecting glucocorticoid action from osteoblasts and osteocytes. At 21-months-of-age, vertebral and femoral strength were 18 to 19% greater in the OG2-11 $\beta$ -HSD2 mice when compared to the wild-type animals (WT) ( $p < 0.05$ ). In addition, the decrease in vertebral BMD observed between 16 and 21 months-of-age in the WT controls was less in the OG2-11 $\beta$ -HSD2 mice (-6.3% vs. -0.2%,  $p < 0.04$ ). Moreover, the OG2-11 $\beta$ -HSD2 mice had 9% more femoral BMD at 21-months-of-age than the WT animals. Bone volume and trabecular number in the vertebrae (as measured by  $\mu$ CT) were 10 to 16% greater and trabecular spacing was 13% lower in the OG2-11 $\beta$ -HSD2 mice than in the WT animals ( $p < 0.03$ ). The OG2-11 $\beta$ -HSD2 mice also demonstrated a 57 to 47% lower prevalence of osteoblast and osteocyte apoptosis when compared with WT animals ( $p < 0.02$ ). Furthermore, osteocyte-lacunar-canalicular fluid volume (as determined by quantitative epifluorescence of Procion Red injected into a tail vein) and vascular volume and surface area in the vertebrae and femora (as determined by  $\mu$ CT imaging of bones perfused with lead chromate) were 74 to 115% greater in the OG2-11 $\beta$ -HSD2 mice than in the WT animals ( $p < 0.02$ ). The attenuation of the adverse effects of age on bone strength, mass, cancellous architecture, osteoblast and osteocyte apoptosis, osteocyte-lacunar-canalicular fluid volume and vasculature in the 21-month-old OG2-11 $\beta$ -HSD2 mice strongly suggests that age-related hyperglucocorticoidism compromises bone strength, at least in part, through decreased bone fluid volume.

**Calorie Restriction Prevents Age-Related Trabecular Bone Loss via SIRT-1.** J. R. Edwards<sup>1</sup>, S. T. Lwin<sup>\*1</sup>, J. S. Nyman<sup>1</sup>, E. C. O'Quinn<sup>\*1</sup>, K. Zainabadi<sup>\*2</sup>, S. A. Munoz<sup>\*1</sup>, L. Guarente<sup>\*2</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA, <sup>2</sup>Dept of Biology, MIT, Cambridge, MA, USA.

Calorie restriction (CR) increases lifespan in a variety of organisms including yeast, worms and flies. This effect is mediated by the longevity gene, Sir2. CR also prolongs lifespan in rodents and is associated with increased expression of the mammalian homologue of Sir2, SIRT-1. We have found that mice deficient in SIRT-1 have a low bone mass phenotype. Accordingly, we hypothesized that CR may enhance bone mass in mice via stimulatory effects on SIRT-1. To test this, we examined the effects of CR (~60% normal diet) under two circumstances, firstly in mice 16mths old after 4 mths CR, and secondly in mice 12 mths old after 8 mths CR (n=10). Cortical and trabecular bone mass was assessed by uCT scanning and histomorphometric analysis of undecalcified lumbar vertebrae and decalcified long bones. We found that aged mice subjected to CR were considerably leaner at  $23.4g \pm 1.1$  compared to AL-fed controls ( $31.9g \pm 1.5$ ,  $p < 0.001$ ). Consistent with the effects of CR to enhance SIRT-1 expression, CR-fed animals had a significantly higher total Bone Mineral Density (mg HA/ccm) at  $185.7 \pm 11.5$  compared to  $140.3 \pm 6.0$  in AL-fed controls ( $p < 0.01$ ). This corresponded with a significantly higher trabecular BV/TV in the CR mice ( $10.8\% \pm 0.4\%$  compared to  $6.7\% \pm 0.5\%$ ,  $p < 0.0001$ ), with no significant change in cortical bone. Next we determined whether these effects were dependent on SIRT-1. Mice lacking the SIRT-1 gene are significantly leaner than WT control animals ( $20.2g \pm 0.9$  compared to  $37.0g \pm 1.9$  respectively,  $p < 0.001$ ). In addition, SIRT-1 KO mice have a profound decrease in BMD (46%) and BV/TV (44%) compared to WT mice, along with a dramatic thinning of trabeculae ( $31.7\mu m \pm 1.5$  compared to  $63.2\mu m \pm 3.4$  respectively,  $p < 0.001$ ). However, SIRT-1 KO mice placed on a CR diet failed to demonstrate any retention of trabecular bone mass compared to AL-fed SIRT-1 KO animals. These studies describe the profound effects of a CR diet on bone mass, and indicate that part of this effect is dependent on the longevity-associated gene, SIRT-1.

**Bone Marrow Stromal Cell Aging Directly Alters Bone Formation.** B. M. Boudignon, F. Lima<sup>\*</sup>, A. J. Gong<sup>\*</sup>, B. P. Halloran. Endocrine unit, Veteran Affairs Medical Center San Francisco, San Francisco, CA, USA.

Age-related or senile osteoporosis is characterized by a marked decrease in bone formation and disruption of the normal balance between bone formation and resorption. The changes in bone that occur with aging reflect autonomous changes in the BMSCs as well as changes in the systemic and marrow micro-environments which feedback to indirectly regulate BMSC activity. To begin to dissect out the autonomous and non-autonomous effects of aging on BMSC function, we implanted BMSC from animals of different ages into a common host. This normalized the systemic and marrow environments permitting us to focus on the effects of age on the ability of BMSC to form bone in vivo. BMSCs from young (6 weeks), adult (6 months) and old (22 months) C57Bl/6J mice were cultured for 10 days, harvested and implanted sub-cutaneously in collagen sponges (Gelfoam) in nude mice. After 2 months the sponges formed mineralized structures (ossicles). These were collected and examined using microCT analysis and histomorphometry. The morphology of the ossicles varied dramatically across age. Cells from young animals produced randomly distributed calcium deposits with little or no structure. Cells from old animals produced cortical bone-like shells surrounding a marrow cavity containing hematopoietic components and adipocytes. The cortical shell and marrow cavity were well vascularized and trabecular-like structures were found throughout the core. Active bone formation on trabeculae and on the inside (endocortical) surface of the shell was observed. Osteocytes were found throughout the cortical and trabecular bone. Cells from adult animals produced partial shell-like structures (old phenotype) along with regions of randomly distributed calcium deposits (young phenotype). Our data suggest that aging has a dramatic effect on the autonomous ability of BMSCs to form bone in vivo. This supports the idea that senescent changes in the mesenchymal stem cells contribute to the changes in bone associated with aging.

**Availability of Cytoplasmic  $\beta$ -Catenin Impacts Mechanical Signaling in Osteoblasts.** N. Case<sup>1</sup>, M. Ma<sup>\*1</sup>, B. Sen<sup>\*1</sup>, Z. Xie<sup>\*1</sup>, T. S. Gross<sup>2</sup>, J. Rubin<sup>1</sup>. <sup>1</sup>Medicine, UNC, Chapel Hill, NC, USA, <sup>2</sup>Orthopaedics, U. Washington, Seattle, WA, USA.

$\beta$ -catenin signaling is implicated in propagating the effects of mechanical loading on bone anabolism.  $\beta$ -catenin is found in membrane-bound and soluble cytoplasmic pools, suggesting compartmentalized roles. Tonic phosphorylation of  $\beta$ -catenin by GSK3 $\beta$  promotes degradation, decreasing cytoplasmic  $\beta$ -catenin under resting conditions. Here we compared the interrelated effects of GSK3 $\beta$  inactivation, membrane sequestration by caveolin-1 and mechanical strain on  $\beta$ -catenin signaling in CIMC-4 pre-osteoblast cells. LiCl treatment was first used to inactivate GSK3 $\beta$  causing cytoplasmic levels of active (dephospho) and total  $\beta$ -catenin to increase as expected. This was reflected by increased TopFlash  $\beta$ -catenin reporter activity ( $164 \pm 28\%$  of control) and upregulation of the  $\beta$ -catenin target gene WISP1 to  $183 \pm 13\%$ . We next established that alteration of caveolin-1, a membrane protein known to sequester  $\beta$ -catenin, affected  $\beta$ -catenin signaling. siRNA targeting caveolin-1 (siCav) increased cytoplasmic  $\beta$ -catenin levels, and Topflash activity was doubled in cells transfected with siCav compared to control siRNA transfected cells. Conversely, overexpression of caveolin-1 decreased  $\beta$ -catenin levels. Knockdown of caveolin-1 and LiCl had additive effects on  $\beta$ -catenin signaling: inhibition of GSK3 $\beta$  with LiCl increased TopFlash activity by ~3-fold in siCav transfected cells. Both of these independent regulators of  $\beta$ -catenin signaling further influenced mechanical control of  $\beta$ -catenin activation. Mechanical strain (2%, 0.17Hz) stimulated a rapid, transient  $\beta$ -catenin response. Active  $\beta$ -catenin translocated to the nucleus by 15 min, causing upregulation of WISP1 at 4 h ( $165 \pm 5\%$  of control). Total  $\beta$ -catenin protein was increased at 1 h and temporally followed a strain associated inactivation of GSK3 $\beta$ . Strain-induced  $\beta$ -catenin translocation was not sufficient to cause enhanced TopFlash activity but when LiCl was present, strain increased TopFlash activity ( $188 \pm 33\%$  of LiCl alone). Thus, a transient mechanical signal causing activation of  $\beta$ -catenin could be amplified by a state of decreased  $\beta$ -catenin turnover. Knockdown of caveolin-1 also enhanced the strain response: strain upregulation of WISP1 was absent in cultures treated with control siRNA, but strain-induced WISP1 was significantly increased in siCav treated cultures. In summary, alteration of  $\beta$ -catenin availability through decreased degradation or sequestration enhanced the ability of mechanical input to stimulate  $\beta$ -catenin signaling. These independent effects thus can combine to promote  $\beta$ -catenin action. This suggests that effects of exercise on the skeleton should be enhanced by strategies that increase the availability of cytoplasmic  $\beta$ -catenin.

**Deletion of the G Protein Subunit  $G\alpha$  in Early Osteoblasts Leads to Accelerated Osteoblast Maturation and Formation of Woven Bone with Abnormal Osteocytes, Resulting in Severe Osteoporosis.** J. Y. Wu<sup>1</sup>, C. Maes<sup>1</sup>, M. Chen<sup>\*2</sup>, L. S. Weinstein<sup>\*2</sup>, H. M. Kronenberg<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Metabolic Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, USA.

$G\alpha$  is a heterotrimeric G protein subunit which mediates cyclic-AMP-dependent signaling downstream of G protein-coupled receptors, including the parathyroid hormone (PTH)/PTH-related peptide (PTHrP) receptor (PPR). Deletion of  $G\alpha$  early in the osteoblast lineage in Osterix-Cre; $G\alpha$ (fl/fl) mice leads to severe osteoporosis with fractures at birth, the result of a low turnover state characterized by failure of bone formation and the abnormal persistence of woven bone. Markedly reduced expression of the terminally differentiated osteoblast marker osteocalcin suggested an impairment of osteoblastic maturation; however, primary calvarial osteoblasts isolated from mutant mice demonstrate accelerated mineralization when cultured under osteogenic conditions. Consistent with enhanced osteoblast maturation in vivo,  $G\alpha$  conditional knockout mice exhibit thicker cortical bone throughout late embryogenesis. Osteocytes, derived from mature osteoblasts embedded in mineralized matrix, are present at significantly increased density in mutant mice. However, the osteocytic canalicular network is disrupted in mutant mice, and transmission electron microscopy reveals abnormal morphology of mutant osteocytes. These findings confirm that mice lacking  $G\alpha$  in osteoblasts fail to produce lamellar bone. Furthermore, expression of characteristic osteocyte genes is disturbed in the mutant mice. Expression of E11, a protein normally localized to early osteocytes along the endosteal or periosteal surface, is found throughout the thickness of cortical bone. In addition, expression of Sost mRNA, a marker of late osteocytes that encodes the protein sclerostin and is suppressed by continuous PTH administration, is markedly increased in mutant mice. These results suggest that in the absence of  $G\alpha$ , osteoblast maturation may be pathologically accelerated, leading to the formation of exclusively woven bone with extreme fragility. Other consequences of the lack of  $G\alpha$  signaling, such as suppressed osteocalcin and enhanced Sost expression, may also contribute to abnormal bone structure and function.

## 1255

**Endogenous  $G_i$  Signaling in Osteoblasts Negatively Regulates Cortical Bone Formation.** S. M. Millard<sup>1</sup>, A. Louie<sup>\*1</sup>, C. Manalac<sup>\*2</sup>, W. Lu<sup>\*1</sup>, N. Cotte<sup>\*2</sup>, B. Boudignon<sup>1</sup>, B. P. Halloran<sup>1</sup>, B. Conklin<sup>\*2</sup>, R. A. Nissenson<sup>1</sup>.<sup>1</sup>Endocrine Research Unit, VA Medical Center, San Francisco, CA, USA,<sup>2</sup>Gladstone Institutes, University of California, San Francisco, CA, USA.

We have recently shown that expression of an engineered  $G_i$  coupled receptor under control of the Collagen I alpha 2.3 kb promoter results in severe trabecular osteopenia, yet little is known about the physiological role of endogenous  $G_i$  signaling in osteoblasts. In this study, we have investigated the skeletal effects of blocking  $G_i$  signaling in osteoblasts *in vivo*. This was accomplished by transgenic expression in osteoblasts of the catalytic subunit of pertussis toxin (PTX), which inhibits receptor-mediated activation of  $G_i$  signaling. Mice expressing PTX in osteoblasts under the control of the Collagen I alpha 2.3kb promoter were significantly smaller at weaning. These mice grew faster than their littermates immediately following weaning and maintained body weights at 85% of their littermate controls from 8wks of age (8wk males: 25.1±1.0 vs 29.0±0.2 gm, p<0.05; 8wk females: 21.1±0.4 vs 24.1±0.4 gm, p<0.001). MicroCT analysis of the femoral midshaft showed that despite their smaller stature the transgenic animals have an 8-12% increase in cortical bone volume (12wk males: 0.41±0.03 vs 0.36±0.01 mm<sup>3</sup>, p<0.05; 12wk females: 0.35±0.04 vs 0.32±0.01 mm<sup>3</sup>, p<0.05). The medullary volume was significantly reduced (by 22-28%), while total cortical volume at this site showed a non-significant trend to be reduced (by 6-10%). Col1(2.3):PTX transgenic mice displayed increased serum levels of osteocalcin, a marker of bone formation. Serum levels of pyridinolines, a marker of bone resorption, were unchanged. Furthermore, the expression ratio of RANKL:OPG, an important determinant of osteoclastogenesis, was found to be unchanged in RNA isolated from the tibiae of Col1(2.3):PTX mice. Together these data imply that increased cortical bone volume in the osteoblast-specific Col1(2.3):PTX transgenic mice results from increased cortical bone formation. Cancellous bone in the secondary spongiosa of the distal femur was also analyzed by microCT. Although data did not show any change in fractional bone volume (BV/TV) we found significant changes in structural indexes of the trabecular network. Mice expressing PTX in osteoblasts showed increased trabecular number and connectivity density associated with a reduced trabecular thickness. The present results indicate that signaling by endogenous  $G_i$ -coupled receptors in osteoblasts plays an important role in restraining endocortical bone formation and in modulating trabecular bone structure.

**Wnt/LRP5-Independent Inhibition of Osteoblastic Cell Differentiation by Sclerostin.** J. Caverzasio. Service of Bone Diseases, Dept of Rehabilitation and Geriatrics, University of Geneva, Geneva, Switzerland.

Bone diseases associated with mutations or deletions in the Sost gene indicate that sclerostin (SCT) is a major regulator of bone formation. SCT is a member of the DAN family of glycoproteins that shares the capacity to inhibit BMP activity but studies in osteoblasts indicated that SCT is not a classical BMP antagonist. Recent reports documented that SCT antagonizes canonical Wnt signaling by binding to the Wnt coreceptor low protein receptor-related protein 5 (LRP5). These studies have been performed in either *Xenopus* embryos or HEK293 cells transfected with plasmids encoding proteins of interest. So far, however, a direct antagonistic effect of SCT on activation of LRP5/6 by Wnts in osteoblastic cells has not been yet documented.

In the present study, we confirmed that SCT (2.5-10 µg/ml) inhibits alkaline phosphatase activity induced by either BMP-2 in MC3T3-E1 cells or by Wnt3a and BMP-2 in C3H10T1/2 cells (-40% to -60%). In C3H10T1/2 cells, SCT also decreased matrix mineralization induced by either BMP-2 (-60%) or Wnt3a (-50%). Surprisingly, however, a similar inhibitory effect of SCT (-80%) was also observed on matrix mineralization induced by the selective GSK3β inhibitor, SB216763, acting downstream of the Wnt/LRP5/6 receptor. In C3H10T1/2 cells, Wnt3a induced a time related increase in phosphoLRP5/6 (activated LRP5/6) that was maximal after 15 min and maintained for several hours. This effect preceded cytosolic accumulation of β-catenin at 6 h and 24 h measured by Western blot. Whereas DKK1 (2.5 µg/ml) completely blunted activation of LRP5/6, SCT had no effect on this response. In this analysis, we noted an early and transient activation of ERK1,2 by SCT. Therefore, we studied whether SCT can trigger activation of signaling molecules in MC3T3-E1 and C3H10T1/2 cells. Interestingly, in both cell lines, SCT rapidly and transiently (5'-60') activated Akt (4-5x), PKC (5-6x) and ERK1,2 (6-7x) suggesting activation of a receptor system. Studies are in progress to determine the receptor activated by SCT and its role in regulating osteoblastic cell differentiation.

In conclusion, this study failed to document an antagonistic effect of SCT on activation of LRP5/6 in response to Wnt3a in osteogenic cells. Moreover, inhibition of osteoblastic cell differentiation induced by SCT was observed in absence of activation of the Wnt/LRP5 receptor when β-catenin was activated by a selective GSK3β inhibitor. Finally, we found that SCT can activate receptor signaling pathways in osteoblastic and mesenchymal cells. These observations strongly suggest that in osteoblastic cells, SCT may activate a receptor system that negatively regulates osteoblastic cell differentiation induced by BMPs and Wnts.

## 1257

**Critical Role of Connexin43 (Cx43) in Postnatal Skeletal Growth and Bone Mass Acquisition.** M. P. Watkins<sup>1</sup>, S. Grimston<sup>1</sup>, D. Ornitz<sup>\*2</sup>, R. Civitelli<sup>1</sup>.<sup>1</sup>Bone and Mineral Diseases, Washington University in St Louis, St Louis, MO, USA, <sup>2</sup>Molecular Biology and Pharmacology, Washington University in St Louis, St Louis, MO, USA.

Cx43 is the major gap junction protein expressed in osteoblasts and osteocytes. Mice with conditional ablation of the Cx43 gene (*Gjal*) in mature osteoblasts and osteocytes - obtained using Cre driven by the 2.3kb fragment of the  $\alpha_1(I)$  collagen promoter (*ColCre;Gjal<sup>-/-</sup>*; *ColcKO*) - develop a lower than normal peak bone mass, but have no major skeletal malformations. However, craniofacial abnormalities are present in *Gjal* null mice and in oculodentodigital dysplasia, caused by loss of function *Gjal* mutations. To gain further insights on the cellular defects brought about by *Gjal* deficiency, we have used the *Dermol* promoter, which is active during embryogenesis, to ablate *Gjal* in osteochondroprogenitor cells (*DM1-Cre;Gjal<sup>-/-</sup>*; *DM1cKO*). We have previously reported that *DM1cKO* mice are more severely osteopenic than are *ColcKO*, but they also exhibit stunted postnatal growth, with >10% shorter long bones relative to wild type (WT) littermates. Consistent with decreased BMD we observed a 57±12% decrease in trabecular bone and a 62±11% decrease in cortical thickness by histomorphometry. Growth plate width was also significantly decreased in *DM1cKO* mice (34±10% of WT), with an apparent decrease in proliferating and hypertrophic chondrocytes, consistent with the short *DM1cKO* limb bones. Further  $\mu$ CT analysis confirmed decreased cortical thickness (84±7%) as well as a significantly larger marrow area (169±26%) in the *DM1cKO* compared to wildtype (WT) litter mates. However, no differences were observed in either static (osteoblast and osteoclast number per bone surface) or dynamic bone formation indices (mineral apposition or bone formation rate) in *DM1cKO* relative to WT litter mates. *In vitro* analysis of bone marrow progenitor cells using colony forming unit (CFU) assays revealed an unexpected 57±11% increase in CFU-fibroblast in *DM1cKO* compared to WT, and a similar increase in CFU-osteoblast (57±17% of WT). *Gjal* ablation in *DM1cKO* CFUs was confirmed by β-galactosidase staining. This increase in uncommitted and osteogenic bone marrow precursors may represent a compensatory mechanism that partially offsets an osteoblast differentiation defect consistently reported in *Gjal* deficiency. Our results also suggest that Cx43 is involved in both longitudinal bone growth, through an effect on growth plate chondrocytes, and in postnatal acquisition of normal bone mass and microarchitecture, via modulation of osteoblast differentiation.

## 1258

**Overexpression of Lef1ΔN Increases Bone Mass in Mice.** F. Secreto\*, L. H. Hoepfner\*, B. Stensgard\*, G. Evans\*, T. E. Hefferan, M. J. Yaszemski, J. J. Westendorf. Department of Orthopedic Surgery, Mayo Clinic, Rochester, MN, USA.

Activation of the canonical Wnt/beta-catenin pathway facilitates osteoblast specification from mesenchymal progenitors and enhances bone mass and strength. One unanswered question is how does canonical Wnt signaling promote proliferation of immature osteoblasts, but not expansion of mature osteoblasts and osteocytes, while at the same time promoting survival of these mature and terminally differentiated cells. Our preliminary data suggest that these stage-specific responses could in part be mediated by different isoforms of lymphoid enhancer binding factor-1 (Lef-1). Lef1 is a member of the T-cell factor family of transcription factors responsible for regulating Wnt-dependent gene expression. We previously reported that Lef1 protein levels decline with osteoblast maturation. We recently discovered that a naturally occurring N-terminal truncated isoform of Lef-1, called Lef1ΔN, increases significantly in MC3T3 cells and primary calvarial osteoblasts (COB) prior to osteocalcin gene expression. Because the expression profile of Lef1ΔN suggested that this transcription factor might contribute to terminal osteoblast differentiation, we developed transgenic mice expressing Lef1ΔN in a tissue-specific manner under the control of the (2.3)Col1a1 promoter. The FLAG-tagged Lef1ΔN was only detected in RNA isolated from calvaria and brain, with calvarial expression being 10-fold higher than in the brain. Primary COB cultures derived from neonatal mice carrying the Lef1ΔN transgene had increased expression of collagen 1α1 and bone sialoprotein RNAs as compared to cultures derived from wild-type mice. Additionally, the number of alizarin-positive nodules present in Lef1ΔN transgene-positive COB cultures was greater than in wild-type COB cultures. Micro-CT analyses of trabecular bone revealed that Lef1ΔN transgenic mice (as compared to wild-type controls) have increased bone volume density (Tibia: +9.44%, Femur: +7.92%), increased trabecular number (Tibia: +7.64%, Femur: +5.77%), and decreased trabecular separation (Tibia: -8.18%, Femur: -6.81%). No sex-linked differences were observed; however, the Lef1ΔN-dependent increases in bone parameters were lost in all mice following sexual maturation. Lef1ΔN retains a low-affinity beta-catenin binding domain and activates Lef1 responsive promoters *in vitro*, but at a 10-fold lower rate than full-length Lef1. In contrast to full-length Lef1, Lef1ΔN does not block Runx2-dependent activation of the osteocalcin promoter. Together these data suggest that Lef1ΔN promotes bone mass accrual and that the isoform switch from Lef1 to Lef1ΔN is crucial for proper osteoblast differentiation.

**TRIP-1 is eIF3i: A Key Regulator of Osteoblast Activity.** D. M. Metz-Estrella\*, T. Sheu\*, J. Puzas. Orthopaedics, University of Rochester, Rochester, NY, USA.

The overall control of bone formation by osteoblasts requires regulation of both gene expression for the control of cell number and protein synthesis for the control of cell activity. Numerous bone-related diseases such as osteomalacia, rickets, calcium deficiency, etc are characterized by increased numbers of osteoblasts yet the rate of new bone formation is very slow due to the inactivity of the cells themselves. Thus, control over the translation of structural and regulatory proteins in osteoblasts must play an important role. In this regard, translation initiation factors would be a central point of focus for regulating bone formation. eIF3 is a translation initiation factor complex of 750 kDa. The "i" subunit of eIF3 (i.e. eIF3i) shares identity with TRIP-1 (TGFbeta-Receptor-Interacting-Protein-1), a protein discovered to interact with tartrate resistant acid phosphatase (TRAP). The TRIP-1/TRAP interaction regulates the activity of osteoblasts within the resorption lacunae. Our hypothesis is that up-regulation of TRIP-1 will increase the overall synthetic pathways of osteoblasts and increase bone formation.

In order to explore this hypothesis, we performed in vitro protein:protein interaction experiments and cell culture assays to evaluate bone formation markers in osteoblasts. We have also created a doxycycline-inducible tissue-specific transgenic mouse that over expresses TRIP-1 in osteoblasts. These animals were analyzed with micro CT methodology.

Our results indicate that TRIP-1 is phosphorylation target of the TGFbeta receptor and that it has strong binding affinity for the MH1 domain of Smad3. Together, this complex can translocate into the nucleus. Perhaps more importantly, TRIP-1 can also be phosphorylated by mTOR, a central kinase in the regulation of energy utilization and protein translation. TRIP-1-transfected osteoblasts show little change in proliferation, however, mice treated with doxycycline to induce TRIP-1 show an increase in skeletal parameters. That is, preliminary experiments demonstrate that mice, when treated with doxycycline for three weeks, show a 48% increase in total bone volume; a 45% increase in bone volume/total volume; a 10-15% increase in trabecular number and trabecular thickness and a 60% increase in connectivity.

Our data support the hypothesis that the TGFbeta pathway, and perhaps other Smad-dependent pathways, can regulate post-transcriptional activity of osteoblasts. The molecular intermediate we have examined, i.e. TRIP-1, is perfectly positioned to participate in both transcriptional and translation regulation of osteoblast activity. Studying these processes as separate, yet coordinated, regulators of bone formation may provide a molecular explanation for the tissue-level changes seen in some bone diseases.

## 1260

**An Evaluation of Circulating Osteoprogenitor Cells During Fracture Healing Using Parabiotic Mice.** T. Barisic-Dujmovic\*, D. J. Adams\*, L. Wang\*, S. H. Clark\*. <sup>1</sup>Genetics and Developmental Biology, University of Connecticut, Farmington, CT, USA, <sup>2</sup>Department of Orthopaedic Surgery New England Musculoskeletal Institute, University of Connecticut, Farmington, CT, USA, <sup>3</sup>Department of Reconstructive Sciences, University of Connecticut, Farmington, CT, USA.

Osteoprogenitors are mesenchymal cells localized in the bone. Recent studies have suggested the existence of osteoblastic precursor cells in the circulation, but the origin of these cells in vivo is not clear. Parabiotic pairs of pOBcol2.3GFPcyan (a marker of mature osteoblasts and osteocytes) and pOBcol3.6GFPtopaz (expressed in preosteoblasts and osteoblasts) transgenic mice were created to determine if osteoblastic cells originating from one parabiont can home to a bone fracture site created in the other parabiont. Utilizing two different GFP isoforms (topaz and cyan) permits microscopic visualization of both transgene reporters within the same animal using fluorescence-specific filters.

Parabiotic pairs of mice were created by surgically joining two transgenic mice; one mouse carried the pOBcol2.3GFPcyan transgene while its partner carried the pOBcol3.6GFPtopaz transgene. Four weeks after parabiosis surgery a transverse fracture of the tibia was created in one parabiont with a blunt guillotine after an intramedullary pin had been placed in the bone. Two different sets of experiments were conducted. In the first set, the tibial fracture was created in the pOBcol3.6GFPtopaz parabiont. Samples from the fractured bone, as well as from the contra lateral bone, were examined for pOBcol2.3GFP transgene expression at time points ranging from day 14 to day 50 post-fracture. Microscopic analyses have shown no evidence of pOBcol2.3GFP transgene expression in the fracture callus or other long bones isolated from the pOBcol3.6GFPtopaz parabiont. In the second set of experiments, the tibial fracture was created in the pOBcol2.3GFPcyan parabiont. Bone samples from the fractured tibia were examined for pOBcol3.6GFPtopaz transgene expression. A weak GFP signal indicating the presence of cells bearing the pOBcol3.6GFPtopaz transgene was detected on the trabecular surfaces of the fracture callus isolated from the pOBcol2.3GFPcyan parabiont. These GFP positive cells were also present in the other long bones of the pOBcol2.3cyan parabiont. However, these pOBcol3.6GFPtopaz positive cells were not osteoblasts, as they did not deposit bone matrix and were positive for TRAP expression based on a fluorescence-based ELF97 TRAP staining assay. This cellular phenotype of the GFP+ engrafted cells is consistent with a myeloid lineage, specifically osteoclasts. This study demonstrated that circulating osteoprogenitor cells do not home physiologically to the fractured bone.

**Tissue-specific Knockout (KO) of the Ca<sup>2+</sup>-sensing Receptor (CaSR) in Chondrocytes Inhibits IGF1 Signaling and Delays Differentiation in the Growth Plate.** C. Tu\*, H. Elalich\*, T. Chen\*, D. Shoback, D. Bikle, W. Chang. Endocrine Unit, VA Medical Center, University of California San Francisco, San Francisco, CA, USA.

Raising the extracellular [Ca<sup>2+</sup>] ([Ca<sup>2+</sup>]<sub>e</sub>) promotes the terminal differentiation of cultured growth plate chondrocytes (GPCs) potentially by activating the CaSR. To examine the role of the CaSR in growth plate development in vivo, we generated cartilage-specific CaSR KO (CaSR<sup>lox/lox</sup>) mice using Cre/lox recombination by breeding floxed-CaSR (CaSR<sup>lox/lox</sup>) mice with transgenic (Tg) mice expressing Cre driven by a Col(II) promoter [JBM 22 (Suppl 1): S50, 2007]. The homozygous KO is embryonic lethal. Because of the death of CaSR<sup>lox/lox</sup> embryos in utero before embryonic stages E12-13, we generated a tamoxifen (Tam)-inducible KO model to study the role of CaSRs in late embryonic and postnatal development. CaSR<sup>lox/lox</sup> mice were bred with Tg <sup>Cre-ER</sup><sup>Tam</sup> mice which express cDNA encoding a fusion protein (Cre-ER<sup>Tam</sup>) containing Cre and a mutated ligand-binding domain of the estrogen receptor conferring Tam sensitivity. The Cre-ER<sup>Tam</sup> is controlled by a mouse Col(II) promoter for cartilage-specific expression. Homozygous <sup>Cre-ER</sup><sup>Tam</sup>/CaSR<sup>lox/lox</sup> mice are viable and fertile. A single maternal injections of 4OH-Tam 2-3 days before birth induced excision of CaSR gene in <sup>Cre-ER</sup><sup>Tam</sup>/CaSR<sup>lox/lox</sup> neonates. Immunohistochemistry and quantitative (q) PCR confirmed a marked reduction in CaSR protein and RNA expression, respectively, in growth plates from <sup>Cre-ER</sup><sup>Tam</sup>/CaSR<sup>lox/lox</sup> mice vs controls not injected with Tam or not containing Cre. Histology of cartilage sections from <sup>Cre-ER</sup><sup>Tam</sup>/CaSR<sup>lox/lox</sup> growth plates revealed 20% expansion of the hypertrophic zone and decreased mineralization in that zone. qPCR analyses of RNAs from the epiphyseal growth plates of the KO mice demonstrated decreased expression of type X collagen, RUNX2, and osteopontin -- markers of mature and terminally differentiated GPCs -- compared to controls. Expression of early differentiation markers -- aggrecan and type II collagen -- was unchanged, supporting a selective impact on chondrocyte maturation and terminal differentiation in the KO mice. There were also significant decreases in both RNA and protein levels for the IGF1 and IGF1 receptor (R) in growth plates from KO mice by qPCR and immunohistochemistry, respectively, suggesting that local IGF1/IGF1R signaling in GPCs might be reduced. This is supported by the observation that high [Ca<sup>2+</sup>]<sub>e</sub>-induced differentiation was significantly reduced in GPCs with IGF1Rs knocked-out in culture. This work demonstrates a critical role for CaSRs in growth plate development in vivo and an interaction between CaSR and IGF1/IGF1R signaling during GPC differentiation.

## 1262

**ADAMTS-7, A Direct Targeting Molecule of PTHrP, Is a Novel Potent Mediator of Chondrogenesis.** X. Bai\*, D. Wang\*, Y. Luan\*, T. Kobayashi\*, H. M. Kronenberg\*, C. Liu\*. <sup>1</sup>New York University, New York, NY, USA, <sup>2</sup>Massachusetts General Hospital, Boston, MA, USA, <sup>3</sup>Massachusetts General Hospital, Boston, MA, USA.

We previously reported that ADAMTS-7, a metalloproteinase that belongs to ADAMTS family, was important for the degradation of cartilage oligomeric matrix protein (COMP) and its level was significantly elevated in arthritis (Liu, et al, *FASEB J.* 2006; 20(7):988). ADAMTS-7 contains a zinc catalytic domain followed by non-catalytic ancillary domains, including a disintegrin domain, a thrombospondin domain, a cysteine-rich domain, a spacer-1 domain, three thrombospondin motifs, a spacer-2 domain, and a C-terminal four thrombospondin motifs. Here we report the effects of these domains of ADAMTS-7 on the extracellular matrix interaction and proteolytic activities. The cysteine-rich domain was essential for ADAMTS-7 to interact with extracellular matrix. The weaker proteolytic activity was detected with the ADAMTS-7 catalytic domain alone and the sequential inclusion of each carboxyl-terminal domain influenced its activity against COMP. Our studies also suggest a critical role of ADAMTS-7 in chondrogenesis. Using RT-PCR and Western blotting assays, we showed that both mRNA and protein levels of ADAMTS-7 were upregulated during differentiation of chondrocytes. ADAMTS-7 significantly inhibited chondrogenesis, as revealed by mRNA levels of both early and later genes critical for chondrogenesis such as Sox9 (75% reduction), collagen type II (72% reduction), and collagen X (90% reduction) and Alcian blue staining. In addition, its inhibitory activity strictly depends on its enzymatic activity, since its point mutant lacking enzymatic activity failed to do so. To determine the potential mechanisms by which ADAMTS-7 negatively regulates chondrogenesis, we studied the effects of ADAMTS-7 on PTHrP/IHH signaling. ADAMTS-7 induced PTHrP 6- to 10-fold at all time points tested (day 3, 5, 7, 10) and inhibited IHH (45% reduction at day 7) during chondrogenesis. We further showed that PTHrP strongly induced mRNA and protein levels of ADAMTS-7 in chondrocytes. Importantly, knocking down ADAMTS-7 via the siRNA silencing or blocking ADAMTS-7 protein activity via anti-ADAMTS-7 antibodies almost abolished the effects of PTHrP on chondrogenesis in vitro. Using an immunohistochemistry assay, we showed that ADAMTS-7 was highly expressed in the proliferating and prehypertrophic chondrocytes of growth plates and that ADAMTS-7 was hardly detectable in PTHrP null growth plates at day E18.5 in vivo. Our findings demonstrate for the first time that ADAMTS-7, a downstream molecule of PTHrP in cartilage, is a novel negative regulator of chondrocyte differentiation.

**Expansion of Mesenchymal Progenitors in an *in vivo* Model of Constitutive Activation of the PTH/PTHrP Receptor.** M. Ohishi, L. E. Purton\*, E. Schipani. Massachusetts General Hospital, Boston, MA, USA.

Transgenic mice expressing constitutively active PTH/PTHrP receptors in osteoblasts (PPR\*Tg) show a considerable expansion of a stromal cell population in trabecular bone areas. A similar histological finding has also been described in hyperparathyroidism and in fibrous dysplasia in humans. In situ hybridization demonstrated that, differently from mature osteoblasts, PPR\*Tg stromal cells produce only modest amount of type I collagen mRNA, whereas osteocalcin mRNA is undetectable in these cells. In order to further characterize this population, PPR\*Tg mice were bred with transgenic mice that express green fluorescent protein (GFP) in mature osteoblasts but not in more immature cells (2.3kb Col1 GFP, kindly donated by Dr. Rowe UConn). Histological analysis of adult tibias isolated from PPR\*Tg/2.3kb Col1 GFP double mutant mice showed GFP accumulation in osteoblasts, but not in stromal cells. Collectively, these data indicate that PPR\*Tg stroma is enriched in immature cells at early stage of osteogenic differentiation. We thus investigated whether the stromal expansion observed in PPR\*Tg mice is associated to an increase in mesenchymal stem cells (MSCs)/progenitors. The number of CFU-Fs was significantly higher in the bone marrow (BM) isolated from 6-8 week old PPR\*Tg mice in comparison to controls, suggesting an expansion of the MSC/progenitor pool in mutants. Because CFU-Fs may include a heterogeneous population of cells, we explored the use of flow cytometry to identify MSCs/progenitors. The percentage of the BM Sca1+CD45-CD31- population, which has been reported to be enriched in MSCs/progenitors, showed no difference between control and PPR\*Tg. Since the specificity of CD45 as a marker of hematopoietic cells has been recently challenged, we then pursued a genetic approach, rather than the CD45/CD31 negative selection, to define BM mesenchymal cells by flow cytometry. Reporter mice expressing GFP upon excision of a stop cassette by Cre recombinase whose transcription was driven by the Prx1 mesenchymal enhancer (Prx1Cre/ZEG), were crossed with PPR\*Tg mice to generate PPR\*Tg/Prx1Cre/ZEG mice. Flow cytometry of BM cells isolated from PPR\*Tg/Prx1Cre/ZEG mice showed a dramatic increase in GFP-expressing cells when compared to controls (0.322±0.12% vs 0.0136±0.014%, p<0.01). Most of these GFP positive cells were also CD45 positive. More importantly, a subset of them expressed Sca1 and was significantly expanded in mutants. In summary, we have identified in the mouse BM a population that is likely of mesenchymal origin, expresses Sca1 and is expanded in PPR\*Tg. It will now be important to study whether this population differentiates *in vitro* into the various mesenchymal lineages.

**Parathyroid Hormone Related Protein (PTHrP) Nuclear Localization Sequence and C-terminus Regulate Craniofacial Development.** C. M. Novince<sup>1</sup>, A. J. Koh\*<sup>1</sup>, H. A. Brown\*<sup>2</sup>, J. C. Hu\*<sup>1</sup>, T. J. Rosol<sup>2</sup>, L. K. McCauley<sup>1</sup>, R. E. Toribio\*<sup>2</sup>. <sup>1</sup>School of Dentistry, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>College of Veterinary Medicine, The Ohio State University, Columbus, OH, USA.

Parathyroid hormone related protein (PTHrP) plays an integral role in skeletal development, especially endochondral bone growth and tooth eruption, via intracrine, autocrine, and paracrine means. The PTHrP intracrine anti-apoptotic activity is mediated by a nuclear localization sequence (NLS) in the mid-region of the molecule. The purpose of this study was to determine the role of the PTHrP NLS and C-terminus in craniofacial development. Homologous recombination was used to knock-in (KI) full length PTHrP absent the coding region for amino acids 67-137 in mice. PTHrP KI mice and littermates were sacrificed at 2 days of age for tissue harvest. Skulls were imaged via micro-CT, and mandibles and vertebrae processed for histomorphometric analysis. Calvariae were digested and osteoblasts isolated for proliferation, and mineralization in culture. Spleens were dissociated and mononuclear cells analyzed for osteoclastogenesis. Femurs and tibiae were analyzed for gene expression via real time PCR, and cell populations via flow cytometry. The skulls of KI mice demonstrated doming of the cranium, and foreshortening and narrowing of the maxilla. Histologically, large islands of red blood cells were found in the bone marrow of KI mice. KI mandibles had reduced total bone area, reduced percent bone area, and fewer and more flattened trabeculae than wildtype (WT). KI mice had more TRAP+ osteoclastic cells per bone perimeter. Incisors of KI mice did not extend as far posteriorly in the body of the mandible, and KI molars had a haphazard cellular organization, decreased matrix accumulation, and abnormal cuspal formation. *In vitro*, PTHrP KI and WT calvarial osteoblasts were similar with respect to morphology, proliferation, and mineralization. KI and heterozygous (HET) spleen derived TRAP+ osteoclasts did not differ with respect to morphology or numbers. Interestingly, the bone marrow of KI mice had higher interleukin-6 expression versus WT, whereas PTH/PTHrP receptor expression was similar in WT and KI mice. The frequency of hematopoietic stem cells (Lin-Sca-1+c-Kit+ cells) showed a trend toward an increase in KI versus HET bone marrow. In summary, lack of the PTHrP NLS and C-terminus resulted in a severe skeletal phenotype characterized by reduced bone area, defective tooth development and altered hematopoietic marrow composition. The PTHrP 67-137 region appears to be a critical regulator of physiologic bone and tooth development. Additional cellular and molecular studies will further elucidate the roles and mechanisms of the PTHrP NLS and C-terminus in skeletal development.

**A Transcription Factor Znf219 Regulates Chondrocyte Differentiation Through Forming Transcription Factory Complex with Sox9.** Y. Takigawa<sup>\*1</sup>, K. Hata<sup>\*1</sup>, S. Muramatsu<sup>\*2</sup>, K. Amano<sup>\*1</sup>, K. Takada<sup>\*3</sup>, A. Matsuda<sup>\*2</sup>, R. Nishimura<sup>1</sup>, T. Yoneda<sup>1</sup>. <sup>1</sup>Biochem, Osaka Univ Grad Sch Dent, Osaka, Japan, <sup>2</sup>Asahi Kasei Pharma, Shizuoka, Japan, <sup>3</sup>Orthod, Osaka Univ Grad Sch Dent, Osaka, Japan.

Gene targeting approaches demonstrated that Sox9, an HMG-containing transcription factor, is necessary for chondrogenesis. Mutations of SOX9 gene in human result in Campomelic dysplasia characterized by severe chondrodysplasia. Sox9 regulates chondrogenic genes including type II (COL2a1) and XI collagen (COL11a2), and aggrecan by forming a molecular complex, namely transcription factory, with Sox5 and Sox6. Although these studies clearly indicate an essential role of Sox9 for chondrogenesis, molecular mechanism by which Sox9 regulates chondrogenesis is not fully understood. Especially, identification of the components of the Sox9 transcription factory has not been accomplished yet. As an approach to address this, we attempted to identify transcriptional partners of Sox9 and examine their functional roles in chondrocyte differentiation. We generated a full-length cDNA library from a chondrogenic cell line, ATDC5, and screened the cDNA library using the COL2a1 luciferase reporter construct. We isolated the Znf219 gene, which contains nine zinc finger domains. RT-PCR showed Znf219 mRNA expression in primary chondrocytes. Whole mount *in situ* hybridization using E11.5 mouse embryos demonstrated that Znf219 expression was specifically observed in the developing limb buds where COL2a1 and Sox9 were strongly expressed. Moreover, Znf219 markedly up-regulated the transcriptional activity of Sox9 for the COL2a1 gene promoter. Co-immunoprecipitation experiments showed that Znf219 physically associated with Sox9. In addition, DsRed-tagged Znf219 was well co-localized with Venus-tagged Sox9 in the nuclei. These results suggest that Znf219 forms transcription factory with Sox9 during chondrocyte differentiation. To examine the functional role of Znf219 in chondrocyte differentiation, we overexpressed Znf219 in the C3H10T1/2 mesenchymal cells using the adenovirus gene delivery system. Znf219 overexpression dramatically enhanced Sox9-induced mRNA expression of COL2a1, aggrecan and COL11a2 mRNA. Consistent with this, knockdown of Znf219 using micro RNA system inhibited Sox9-induced COL2a1, aggrecan and COL11a2 expression. Furthermore, overexpression of a dominant-negative Znf219 mutant inhibited BMP2-induced chondrocyte differentiation of C3H10T1/2 cells and mouse embryo limb bud cells. In conclusion, our results suggest that Znf219 functions as a molecular component of the transcription factory formed by Sox9 and plays an important role in early-stage of chondrocyte differentiation.

**The Wnt Target Gene Twist1 Inhibits Sox9, the Master Regulator of Chondrogenesis.** S. Gu<sup>\*</sup>, M. Reinhold<sup>\*2</sup>, M. Naski<sup>3</sup>. <sup>1</sup>Biochemistry, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>2</sup>Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>3</sup>Pathology & Biochemistry, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Canonical Wnt signaling strongly inhibits chondrogenesis. Data show that lack of canonical Wnt signaling during early bone formation leads to expansion of chondrocytes, whereas augmented Wnt signaling represses chondrocyte differentiation. We hypothesized that Wnt-signaling strongly inhibits chondrogenesis through Wnt-dependent gene expression. In previous work we showed that Wnt signaling induces Twist1 and that Twist1 inhibits chondrogenesis. Here we provide evidence that Twist1 inactivates cartilage development by directly inhibiting the expression and activity of the master regulator of chondrogenesis, Sox9. We demonstrate a reciprocal relationship of Twist1 and Sox9 expression in chondrocytic cells and significantly, knockdown of Twist1 expression leads to increased Sox9 expression. In addition to regulating Sox9 expression, Twist1 inhibits the transcriptional activity of Sox9. Transcription assays show that Twist1 inhibits Sox9 activity and that the C-terminus of Twist1 is required for the inhibition. *In-vitro* binding experiments show that Sox9 and Twist1 form a stable complex. Complex assembly requires the C-terminus of Twist1 but not the C-terminal transactivation domain of Sox9. Dimerization of Twist1 with other basic-helix-loop-helix transcription factors is not required for the binding to or the inhibition of Sox9. The lack of a requirement for dimerization suggested that Twist1 may recruit a co-repressor and thereby represses Sox9. We find that Twist1 binds avidly to histone deacetylases, but this interaction does not appear to be required for the inhibition of Sox9 by Twist1. We hypothesize that Twist1 inhibits Sox9 through steps that alter DNA binding or the recruitment of co-activators. These data indicate that Sox9 expression and activity are tightly regulated by Twist1. This suggests that the earliest steps of chondrogenesis are decided by the balance of Twist1 and Sox9.

## 1267

**Glucocorticoid Signalling Through Osteoblasts Is Essential for Cranial Skeletal Development.** H. Zhou, W. Mak\*, R. Kalak\*, J. Street\*, C. Fong-Yee\*, Y. Zheng\*, C. R. Dunstan, M. J. Seibel. Bone Research Program, ANZAC Research Institute, The University of Sydney, Sydney, Australia.

Glucocorticoids (GC) play an important role in bone cell differentiation and mesenchymal lineage commitment (1). Using Col2.3-HSD2 transgenic (tg) mice in which GC signaling is abrogated in mature osteoblasts, we investigated the role of endogenous GC signalling in early skeletal development.

Neonatal tg mice develop a distinct cranial phenotype characterised by bone hypoplasia and osteopenia, disorganised and poorly mineralised frontal, parietal and interparietal bones and increased suture patency. These changes were apparent as early as E15.5. In addition, ectopic differentiation of cartilage in the sagittal suture and a postnatal defect in parietal cartilage removal were observed in tg mice, resulting in ectopic cartilage below the sutures and abundant remnant cartilage underneath the parietal and inter-parietal bones. When compared to wild type (WT) mice, the cranial cartilage in neonatal tg animals demonstrated reduced cartilage removal and chondrocyte apoptosis. mRNA and protein expression of MMP14, an enzyme essential for calvarial cartilage removal, were also profoundly reduced in parietal bone and cartilage. Concurrently, the accumulation of  $\beta$ -catenin protein, an upstream regulator of MMP14 expression, was reduced in tg cranial chondrocytes and osteoprogenitor cells in suture areas; probably due to a lack of Wnt signaling from neighbouring osteoblasts. mRNA expression for Wnt9a and Wnt10b was reduced 40% and 50% respectively in osteoblasts of tg parietal bone compared to WT littermates. Also, Wnt9a was undetectable by in situ hybridisation in tg calvarial osteoblasts but was strongly expressed in the WT. Exogenous Wnt3a protein, delivered by supracalvarial injection, rescued the phenotype confirming Wnt signalling as a key mediator in this process (Fig. 1).

We conclude that endogenous glucocorticoids stimulate the expression and secretion of Wnt proteins in mature osteoblasts, in keeping with our previous results (1). Wnt signalling induces a) parietal cartilage chondrocytes to initiate MMP14-mediated cartilage degradation; and b) mesenchymal progenitor cells to differentiate towards the osteoblast lineage. Thus glucocorticoids and osteoblasts play an essential role in the intricate development of intramembranous bone.

**Notch Signaling Inhibits Chondrogenesis and Subsequently Promotes Chondrocyte Maturation.** Y. Dong<sup>1</sup>, A. Jesse<sup>\*1</sup>, R. Kopan<sup>\*2</sup>, T. Gridley<sup>\*3</sup>, T. Honjo<sup>\*4</sup>, R. J. O'Keefe<sup>1</sup>, M. J. Hilton<sup>1</sup>. <sup>1</sup>Department of Orthopaedics and Rehabilitation, University of Rochester, Rochester, NY, USA, <sup>2</sup>Department of Developmental Biology, Washington University School of Medicine, St. Louis, MO, USA, <sup>3</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>4</sup>Department of Immunology and Genomic Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan.

The Notch signaling pathway governs differentiation and cell fate determination in many organ systems during development. Until recently the role of Notch signaling in the skeletal system has largely gone unexplored. While prior work has implicated Notch signaling, primarily via Notch 1 and 2 receptors, in regulating chondrocyte maturation and bone marrow mesenchymal progenitor cell differentiation, the molecular details remain unclear. Our current studies define the mechanisms by which Notch regulates chondrogenesis and chondrocyte maturation both *in vitro* and *in vivo*. We first characterized expression of all Notch pathway components during limb-bud cell micromass differentiation. *Notch1* and *Hes1*, a classical Notch target gene, were prominently expressed during the earliest stages of chondrogenesis. In contrast, *Notch2* and the molecular targets *Hey1* and *HeyL* were induced later during chondrocyte maturation. These data suggest potential early and late functions of Notch signaling during cartilage development that may be coordinated by separate Notch signaling mechanisms. Supporting this notion, micromass cultures treated with DAPT, a Notch signaling inhibitor, enhanced chondrogenesis and subsequently delayed chondrocyte terminal maturation. Furthermore, we analyzed the *in vivo* effect of Notch gain and loss-of-function specifically in the limb mesenchyme. Skeletal staining, histology, and molecular analyses of *Prx1Cre*;

*Rosa-NICD<sup>+/+</sup>* embryos, which sustain Notch signaling in the limb mesenchyme, show a significant inhibition of chondrogenesis as predicted by our *in vitro* data. To further assess whether Notch regulates various aspects of cartilage development via canonical signaling mechanisms, we removed the canonical Notch transcriptional effector, RBPJk, using the same *Prx1Cre* transgene. Analyses of *Prx1Cre*; *RBPJk<sup>+/+</sup>* embryos revealed an enhancement in chondrogenesis followed by a robust delay in the progression of chondrocyte maturation. Together these results demonstrate that RBPJk-dependent Notch signaling inhibits chondrogenesis and subsequently promotes chondrocyte maturation, likely via differential regulation of *Hes/Hey* target genes during cartilage development.

**A Mouse with a Ser1386Pro Mutation in the C-propeptide Domain of *col2a1* Provides a Model for Spondyloepiphyseal Dysplasia Congenita.** C. T. Esapa<sup>1</sup>, T. Hough<sup>\*2</sup>, S. Testori<sup>\*1</sup>, R. Head<sup>\*1</sup>, E. Crane<sup>\*1</sup>, C. Chan<sup>\*1</sup>, M. Brown<sup>3</sup>, S. Brown<sup>\*2</sup>, P. Croucher<sup>4</sup>, R. Cox<sup>\*2</sup>, M. Cheeseman<sup>\*2</sup>, R. V. Thakker<sup>1</sup>. <sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>MRC Harwell, Mammalian Genetics Unit and Mary Lyon Centre, Harwell, United Kingdom, <sup>3</sup>University of Queensland, Queensland, Australia, <sup>4</sup>University of Sheffield, Sheffield, United Kingdom.

Investigations of skeletal dysplasias which are often inherited have yielded important insights in the molecular mechanisms of bone development, osteoporosis and osteoarthritis. However, these studies have been hampered by the lack of available patients and affected families. To overcome this limitation, we have investigated mice treated with the chemical mutagen N-ethyl-N-nitrosourea (ENU) for hereditary bone disorders and established a mouse model designated, *Longpockets*. Mice were kept in accordance with national welfare guidelines and project license restrictions. Mice heterozygous<sup>+/+</sup> for the *Longpockets* mutation were found to have severely disproportionately short humeri that lead to shortened forelimbs. In addition, *Longpockets<sup>+/+</sup>* mice had moderately shortened hindlimbs and flattened vertebrae. Histology revealed gross disorganization and early closure of the humeral growth plate with flattened epiphyses, consistent with the features of spondyloepiphyseal dysplasia congenita (sedc). Micro-computed tomography scanning of *Longpockets<sup>+/+</sup>* mice revealed the development by 8 weeks of age, of knee erosions, consistent with arthritis. *Longpockets<sup>+/+</sup>* mice were found to die perinatally. Positional cloning studies mapped *Longpockets* to a 5Mb region on chromosome 15 which contains the cartilage-expressed genes *col2a1*, *wnt1* and *wnt10b*. We hypothesized that *Longpockets* may be due to a *col2a1* mutation. DNA sequence analysis identified a T to C transition at nucleotide 4156. This altered a highly conserved serine residue at position 1386 to a proline residue. Western blot analysis using a *col2a1* antibody and lysates from mouse embryonic fibroblasts (MEFS) of wild type<sup>+/+</sup> and *Longpockets<sup>+/+</sup>* embryos revealed an absence of the mature 100 kDa type II collagen protein in the MEFS<sup>+/+</sup>, which instead had lower molecular weight breakdown products. Transient transfection of wild type *col2a1* and Ser1386Pro mutant c-myc constructs in COS-7 cells and confocal microscopy revealed perinuclear aggregation and retention of the mutant protein in the endoplasmic reticulum. Thus, our studies have established a novel mouse model for a dominantly inherited form of sedc that is due to a missense mutation in the C-propeptide domain of *col2a1* and that is likely associated with arthritis of the knee. These results will help to elucidate further the *in vivo* role of the *col2a1* C-propeptide domain in the assembly and trafficking of type II collagen.

**The -301T/C of Sclerostin(SOST) Modulates Bone Mineral Density by Wnt and Estrogen Signaling Pathways.** Q. Y. Huang, G. H. Y. Li\*, A. W. C. Kung. The University of Hong Kong, Hong Kong, China.

Osteoporosis is a complex disease influenced by both genetic and environmental factors. Accumulating evidence shows that genes which cause monogenic diseases also contribute to similar complex disease in the general population. We sought to determine whether the allelic variation in seven monogenic bone disease genes (*CLCN7*, *TCIRG1*, *SOST*, *CA2*, *CSTK*, *TGFB1* and *SLC26A2*) contributes to osteoporosis / bone mineral density (BMD) variation in the normal Chinese population. We conducted a gene-wide and tag SNP-based association study in 1,243 case-control Chinese subjects. The cases were subjects with low BMD (Z-scores  $\leq -1.28$ , equivalent to the lowest 10 percent of the population) at either the L1-4 lumbar spine or femoral neck. Control subjects had high BMD (Z-score  $\geq +1.0$ ) at the corresponding sites. Twenty-two tag SNPs (tSNPs) from seven monogenic bone disease genes were selected based on the CHB panel of the Phase II HapMap Project ( $r^2 > 0.8$  and minor allele frequency  $> 0.2$ ), and were genotyped using the high-throughput sequenom platform. Allelic and haplotype association analyses were conducted by Haploview and binary logistic regression analyses. Gene-gene interactions were investigated using multifactor dimensionality reduction method. AlIBaba 2.1 was applied to predict the putative transcription factor binding sites at the promoter polymorphism. The promoter SNP rs1230399 (-301T/C) of *SOST* showed significant genotypic and allelic associations with BMD at all skeletal sites measured ( $P = 0.04$ - $0.001$ ), including the lumbar spine, femoral neck, trochanter and total hip. The haplotype CC consisting of rs1230399 and rs865429 showed consistent associations with high BMD at femoral neck and spine ( $P = 0.005$ ,  $0.002$ , respectively). Importantly, this association has been replicated in the Caucasian population. Functional analysis showed that the rs1230399 was located at the core consensus recognition site of two important transcription factors C/EBP $\alpha$  and FOXA1 which were involved in the Wnt and estrogen signaling pathway. T $\rightarrow$ C mutation abolishes the binding of both C/EBP $\alpha$  and FOXA1 to *SOST*. In addition, significant gene-gene interactions were identified for *SOST*/*CLCN7* and *TGFB1*. In conclusion, the C-allele of -301T>C variant of *SOST* was associated with high BMD. The variant may mediate BMD by Wnt and estrogen signaling pathways.

**Role of *Ostm1* in Bone, Hematopoiesis and Neuronal Development.** A. Griffiths\*, C. Héraud\*, M. Pata\*, B. Maranda\*, J. Yacher<sup>1</sup>. <sup>1</sup>Institut de recherches cliniques de Montréal (IRCM), Montreal, QC, Canada, <sup>2</sup>CHUL-CHUQ, Laval, QC, Canada.

Autosomal recessive malignant osteopetrosis is a rare disorder due to a failure of the hematopoietic lineage derived osteoclast. These active osteoclasts have the unique property to resorb bone matrix and a lack of bone resorption leads to an abnormal increase in bone mass characteristic of osteopetrosis. Our laboratory characterized the *grey-lethal* gene (*Ostm1*) from the spontaneous osteopetrotic *gl* mutant, and isolated the human *OSTM1* homologue and the first *OSTM1* mutation. This mouse mutant displayed a total absence of *Ostm1* transcript whereas it is normally detected at high levels in hematopoietic tissues and in the brain. In an attempt to correct the *gl* osteoclast phenotype we targeted *Ostm1* expression to committed osteoclasts with a TRAP-*Ostm1* transgene. However, this osteoclast expression was inefficient to correct *gl*/*gl* defects, suggesting that *Ostm1* is required in other or additional cell types. Functional rescue was then undertaken by directing *Ostm1* expression in all myeloid lineages including osteoclasts with a PU1-*Ostm1*-BAC transgene. All *gl*/*gl*-PU1-*Ostm1* BAC transgenic mice expressed *Ostm1* in hematopoietic cells and displayed full rescue of osteopetrosis and thrive normally at three weeks. However by 5 weeks of age these *gl*/*gl* transgenic mice became overtly ill and died prematurely with a lifespan of approximately 6-7 weeks compared to three weeks for *gl*/*gl* mice. Analysis of *gl*/*gl* PU1-*Ostm1*-BAC transgenic mice showed neurological anomalies with a significant neurodegeneration in brain cortex, hippocampus and cerebellum. Precisely, these *gl*/*gl*-PU1-*Ostm1* BAC transgenic mice accumulated with age neuronal cytoplasmic inclusions associated with cell loss. Our simultaneous characterization of a patient with an additional *OSTM1* mutation associated with neurodegeneration further supported a key role of *OSTM1* in the CNS. Taken together, our results demonstrated that the *Ostm1* gene plays a major functional role in neuronal development independently of the hematopoietic and osteoclast lineage.

**Molecular Consequences of a Mutant *Dlx3* Affecting Bone Homeostasis in Tricho-Dento-Osseous Syndrome.** O. Duverger\*, D. Lee\*, M. Q. Hassan\*, S. X. Chen\*, F. Jaisser\*, J. B. Lian\*, M. I. Morasso\*. <sup>1</sup>NIAMS/NIH, Bethesda, MD, USA, <sup>2</sup>UMass Medical School, Worcester, MA, USA, <sup>3</sup>College de France, Paris, France.

The homeodomain protein *Dlx3* plays a crucial role during embryonic development. *Dlx3* was shown to be expressed in diverse secretory cells of mineralized tissues: in craniofacial bone and tooth (intramembranous ossification) as well as in the appendicular skeleton (endochondral ossification). Functional studies have further demonstrated that *Dlx3* is a key regulator of bone differentiation. In humans, a frameshift mutation in the

coding sequence of the *DLX3* gene results in an ectodermal dysplasia called Tricho-Dento- Osseous syndrome (TDO). The main features of this autosomal dominant disorder are defects in hair, teeth and bone (increased density of both craniofacial and appendicular bone). In order to investigate the functional alterations caused by the mutated *Dlx3*<sup>TDO</sup> isoform *ex vivo*, we used a tetracycline-inducible osteoblastic cell line and calvarial-derived osteoblasts in which the expression of *Dlx3*<sup>WT</sup> and/or *Dlx3*<sup>TDO</sup> could be regulated and monitored. Immunocytochemical analysis revealed that both *Dlx3*<sup>WT</sup> and *Dlx3*<sup>TDO</sup> recombinant proteins are targeted to the nucleus. However, as demonstrated by Electrophoresis Mobility Shift Assay (EMSA), *Dlx3*<sup>TDO</sup> is not able to bind to the canonical *Dlx3* binding site. Furthermore, we demonstrate that the frameshifted C-terminal domain in *Dlx3*<sup>TDO</sup> is accountable for the loss of DNA binding activity since the C-terminal domain in *Dlx3*<sup>WT</sup> is not required for DNA binding activity. Although *Dlx3*<sup>TDO</sup> alone cannot bind to a *Dlx3* responsive element, when *Dlx3*<sup>WT</sup> and *Dlx3*<sup>TDO</sup> are co-expressed they form a complex that can bind DNA. Concomitant with the inability to bind DNA, *Dlx3*<sup>TDO</sup> has a defective transcriptional activity. Moreover, the transcriptional activity of *Dlx3*<sup>WT</sup> is significantly reduced in the presence of the mutated isoform, indicating that *Dlx3*<sup>TDO</sup> has a dominant negative effect on *Dlx3*<sup>WT</sup> transcriptional activity. The use of mouse models of the TDO syndrome will be an invaluable tool to understand how these functional effects of the mutation translate into the hair, teeth and bone phenotype in TDO syndrome.

**T $\beta$ RI Inhibitor Rescues Uncoupled Bone Remodeling in Two Different Animal Disease Models.** X. Wu<sup>1</sup>, W. Lei\*, Y. Tang<sup>1</sup>, T. R. Nagy\*, W. Van Hul<sup>3</sup>, M. Wan<sup>1</sup>, X. Cao<sup>1</sup>. <sup>1</sup>Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Department of Nutrition Sciences, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>3</sup>Department of Medical Genetics, University of Antwerp, Antwerp, Belgium.

Bone remodeling is a dynamic process beginning with resorption of a volume of bone by osteoclasts and replaced with new bone formation by osteoblasts throughout life. Bone resorption and formation in each remodeling cycle are precisely coupled to sustain bone mass and architecture. Disruption in coupling is often associated with bone diseases. The uncoupling mechanisms underlying these bone diseases have not been elucidated. TGF $\beta$ 1 is one of the most abundant cytokines deposited in the bone matrix. The active TGF $\beta$ 1 is released during bone resorption, and recruits osteoprogenitors during bone remodeling. Here we generated two different mouse models with uncoupled bone phenomenon and demonstrated that high levels of active TGF $\beta$ 1 in the bone marrow that cause the uncoupled bone remodeling. Camurati-Engelmann Disease (CED) is an inherited bon hyperparathyroidism mouse model e disease associated with amino acid substitutions in the latency-associated peptide (LAP), but not in the mature TGF $\beta$ 1 peptide. In examining cellular function of six different CED-derived TGF $\beta$ 1, we found that mutations in LAP cause premature release of mature TGF $\beta$ 1 upon secretion and TGF $\beta$ 1 mutants are hyperactive to induce phosphorylation of Smad2 and luciferase transcription activity. First we have established a mouse model, in which a CED-derived TGF $\beta$ 1 mutant was transgenic. High levels of active TGF $\beta$ 1 were detected only in bone marrow and matrix of the TGF $\beta$ 1 mutant mice. A typical progressive diaphyseal dysplasia in CED patients was observed in the long bones of CED mice with about 50% tibia fractures. CED-derived mutation-caused release of active TGF $\beta$ 1 in the bone marrow uncoupled bone resorption and formation. Most importantly, treatment of TGF $\beta$ 1 mutant mice with the TGF $\beta$  type I receptor (T $\beta$ RI) inhibitor for 6 weeks rescued the uncoupled bone resorption and bone formation and completely prevented tibial fractures in TGF $\beta$ 1 mutant mice. Furthermore, we examined hyperparathyroidism mouse model by continuous infusion of PTH(1-34). The mice had high bone turnover phenotype with uncoupled bone resorption and formation. Similar to CED mice, a high level of activated TGF $\beta$ 1 in the bone marrow of the mice was observed. Again injection of T $\beta$ RI inhibitor rescued the bone phenotype of hyperparathyroidism mice. Thus, abnormal activated TGF $\beta$ 1-induced uncoupled bone remodeling implicates a general pathological mechanism for bone coupling disorders. T $\beta$ RI inhibitor is implicated as a potential agent for the treatment of CED and hyperparathyroidism patients.

**CFTR Regulates Osteoblast Bone Formation Independent of Chloride Conductance.** L. A. Kingsley<sup>1</sup>, C. R. McKibbin\*, K. L. Clines\*, S. E. Gabriel\*, P. A. Friedman<sup>3</sup>, G. A. Clines<sup>1</sup>. <sup>1</sup>Medicine, University of Virginia, Charlottesville, VA, USA, <sup>2</sup>Pediatrics, University of North Carolina, Chapel Hill, NC, USA, <sup>3</sup>Pharmacology, University of Pittsburgh, Pittsburgh, PA, USA.

Low BMD and increased risk of fracture are associated with cystic fibrosis (CF), a recessive human genetic disease caused by mutations of the cystic fibrosis transmembrane regulator (CFTR). CF bone disease is an emerging complication of CF patients who are now living longer due to advances in lung disease management. Chronic illness, malnutrition, vitamin D deficiency, glucocorticoids and hypogonadism have all been proposed to be responsible for CF bone disease. However, recent epidemiological investigations and knockout animal models suggest a direct link between CFTR inactivation in bone and low BMD.

We investigated the biology of CFTR in bone. First, we assessed CFTR expression in bone and found by real-time RT PCR that it was expressed in the osteoblast but not the

osteoclast. Murine calvarial organ cultures from CFTR KO mice had reduced bone formation compared to calvariae from WT littermates ( $6430 \mu\text{m}^2$  vs.  $16440 \mu\text{m}^2$ ,  $p=0.0023$ ). Altered chloride ( $\text{Cl}^-$ ) conductance and secretory function are responsible for most CF-related diseases. However, the CFTR-specific  $\text{Cl}^-$  channel inhibitor CFTR<sub>inh</sub>-172 had no effect on bone formation in calvarial organ cultures. These results suggest that CFTR has effects in bone independent of  $\text{Cl}^-$  conductance. We then examined whether CFTR inactivation alters the expression of osteoblast differentiation markers. No significant differences in Runx2, osterix, collagen I and osteocalcin mRNA concentrations were observed between osteoblasts derived from CFTR KO and WT mice. These results suggest that the pool of KO and WT cultured osteoblasts were at a similar stage of differentiation.

We then tested direct effects of CFTR in the osteoblast. CFTR associates in a membrane macromolecular complex with NHERF-1 and NHERF-2 (PDZ adaptor protein  $\text{Na}^+/\text{H}^+$  exchanger regulatory factors). Another macromolecular complex between NHERF and the parathyroid hormone receptor (PTH1R) retards PTH1R endocytosis and recycling. We hypothesize the existence of a novel PTH1R-NHERF-CFTR macromolecular complex. Preliminary data show that CFTR inactivation decreases uptake of labeled PTH by osteoblasts compared to WT cells, suggesting that CFTR mutations may impair normal bone remodeling by dysregulating osteoblast PTH signaling. The direct actions of CFTR in bone are largely an unexplored area of CF research. Defining the mechanisms of bone loss and determining optimal treatments are critical because CF patients are now living longer and the incidence of fractures is expected to increase.

**Alendronate Transiently Impairs Removal of Alveolar Bone and Healing of the Root Socket After Tooth Extraction in Rats.** J. I. Aguirre, M. K. Altman\*, S. E. Franz\*, A. C. F. Bassit\*, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Osteonecrosis of the jaw (ONJ) has been identified as a potential complication of bisphosphonate (BP) treatment. Although ONJ occurs most frequently in cancer patients treated IV with nitrogen-containing BPs, it has also been reported to occur, although with a much lower incidence, in postmenopausal women treated with alendronate (ALN). Since tooth extraction is one of the most important risk factors for ONJ, we performed this dental procedure in ALN-treated rats to evaluate its potential as a novel animal model for ONJ. For this purpose, 2 month-old rats were injected SC twice weekly with vehicle or a dose of ALN comparable to that used to treat postmenopausal osteoporosis ( $15 \mu\text{g/kg}$  bw). Treatments were administered for 4 weeks before the first mandibular molar was extracted, and continued during the post-extraction (PE) period until rats were sacrificed at 10, 21, 35, and 70 days PE. The left mandibles were collected to assess the effects of ALN on alveolar bone in the interdental area between the first and second molars, and on bone healing within the distal root socket by determining osteo- and angiogenesis using histomorphometry. We found that ALN-treated rats had increased alveolar bone volume and height at 10 days PE. The interdental alveolar bone appeared to protrude into the oral cavity in 30% of the ALN-treated animals. However, these parameters progressively decreased in ALN-treated rats to the level of vehicle-treated rats by 35 and 70 days PE. In addition, a 2.5-fold increase in the percentage of empty osteocytic lacunae was found in alveolar bone of ALN-treated rats at 10 days PE. ALN also induced decreases in osteoblast, mineralizing, and eroded surfaces in the alveolar bone at 10, but not at 21 days PE. Within the root socket, woven bone volume decreased by approximately 70% in ALN-treated rats only at 10 days PE. Decreases in osteoblast and eroded surfaces, but not in osteoclast surface and number, were also observed in ALN-treated rats only at 10 days PE. Remarkably, ALN-treated rats exhibited decreased blood vessel area, perimeter, and number within the root socket by 35-40% at 10 days PE, but not at later times. These findings indicate that ALN transiently impairs angiogenesis and bone formation during the early stages of bone healing after tooth extraction in rats. These data also indicate that ALN delays the removal of interdental alveolar bone after tooth extraction. Although ONJ was not detected in ALN-treated rats, it is possible that treatment with higher oncology doses of a more potent BP would result in the observed transient effects becoming more persistent and ultimately developing into an ONJ-like lesion.

**The Recalculation of Genome Scans on a Common Genetic Map Enhances Our Ability to Identify Common Bone Density QTL in New and Historical Data.** C. L. Ackert-Bicknell<sup>1</sup>, S. Tsaih<sup>\*1</sup>, M. Marion<sup>\*1</sup>, Z. Lu<sup>\*1</sup>, A. Cox<sup>\*1</sup>, R. Smith<sup>\*1</sup>, R. Korstanje<sup>\*1</sup>, W. G. Beamer<sup>1</sup>, J. Wergedal<sup>2</sup>, G. A. Churchill<sup>\*1</sup>, B. J. Paigen<sup>\*1</sup>. <sup>1</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>2</sup>J.L. Pettis Memorial VA Medical Center, Loma Linda, CA, USA.

Many quantitative trait loci (QTL) for bone mineral density (BMD) have been reported in the mouse, covering nearly every chromosome. The genetic maps used in these studies have evolved over 85 years from assemblies of unrelated data sets. As a result, there are many inconsistencies with regards to marker order and relative positions. A new genetic map has been created based on 15,000 polymorphic markers genotyped 2293 mice from 80 separate pedigrees of a heterogeneous stock of outbred mice. In this new map, the order of and distance between markers have been corrected and this new genetic map shows high correlation with the physical map of the mouse genome. All published bone trait QTLs were mapped using the old genetic map, suggesting that the locations of the QTL peaks

may be mis-mapped: negatively impacting candidate gene identification and cross-species homology studies. We have recalculated the peak position and confidence intervals (CIs) for BMD QTLs using raw data from five of the original mapping crosses (B6x129, B6xC3H, B6xC3H, NZBxSM and NZBxRF). Across the genome, we found that 60% of the QTL peaks were shifted by more than 4 cM when recomputed on the new genetic map; 28.3% of the QTL peaks were off by more than 10 cM; and 3% of the peaks were off by 20 cM or more. We found one peak on Chr 11 that shifted by 49.5 cM and one peak on Chr 10 that shifted 60.3 cM, as compared to the peak location reported in the literature. This shift of QTL peaks was not uniform across all chromosomes as some original maps for individual chromosomes proved more accurate. We observed that for some chromosomes, such as Chr 1, little movement was observed for QTL peaks (average shift =  $2.37 \pm 0.44$  cM), whereas for other chromosomes, such as Chr 4, all QTLs were significantly shifted (average shift =  $16.81 \pm 1.6$  cM). Due the availability of the C57BL/6J reference sequence, we are now able to provide precise physical locations of the QTL peaks and CIs. In this study we have shown that computation of QTL locations from raw data using the updated genetic map can substantially improve the quality and consistency of historical QTL reports. As the identification of candidate genes relies on accurately projecting the genetic map onto the physical map, our results may partially explain the paucity of identified genes known to underlie these bone QTLs. The shifts observed in this study have encouraged us to expanded our analysis to include all available data sets used for the identification of BMD and bone strength QTLs. Our results from this QTL recalculation project will be deposited in a publicly accessible QTL database.

**Serum 25 Hydroxyvitamin D (25(OH)D) and the Risk of Hip and Non-spine Fractures in Older Men.** J. A. Cauley<sup>1</sup>, N. Parimi<sup>\*2</sup>, K. Ensrud<sup>3</sup>, D. Bauer<sup>4</sup>, S. Cummings<sup>4</sup>, A. Hoffman<sup>\*5</sup>, J. Shikany<sup>\*6</sup>, E. Barrett-Connor<sup>7</sup>, E. Orwoll<sup>8</sup>. <sup>1</sup>Univ of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>California Pacific Med Ctr Research Institute, San Francisco, CA, USA, <sup>3</sup>Univ of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Univ of California at San Francisco, San Francisco, CA, USA, <sup>5</sup>Stanford Univ, Stanford, CA, USA, <sup>6</sup>Univ of Alabama at Birmingham, Birmingham, AL, USA, <sup>7</sup>Univ of California at San Diego, San Diego, CA, USA, <sup>8</sup>Oregon Health & Science Univ, Portland, OR, USA.

Vitamin D deficiency is common in older adults, including cases of acute hip fracture (fx). However, few prospective studies have tested the hypothesis that serum measures of total 25(OH)D predict fractures. We performed a case cohort study of 436 men with incident non-spine fx, 81 men with incident hip fx identified over an average of 5.3 years and a random sample of 1608 men. All subjects were enrolled in the Osteoporotic Fractures in Older Men Study (MrOS). 25(OH)D was measured in fasting baseline serum using LC-MS; interassay CV%, 4.4%. Modified Cox proportional hazards models were used to calculate the relative hazard (RH) (95% confidence intervals) of fx by one standard deviation (SD) increase in vitamin D and across quartiles of vitamin D. Nonparametric smoothing techniques (spline analyses) were used to evaluate the linearity of the models. Base models adjusted for age, season, clinic, race, height and weight. Subsequent models added in adjustments for neuromuscular function, total hip BMD or history of falls. The mean 25(OH)D was 24.6ng/ml in non-spine fx; 21.2ng/ml in hip fx and 25.2ng/ml in controls (non-spine fx vs controls,  $p=0.14$ ; hip fx vs controls,  $p<0.0001$ ). A one SD increase in 25(OH)D was associated with a 39% lower risk of hip fx (Relative Hazard (RH)=0.61; 95% confidence interval (CI), 0.46-0.83). Adjustment for neuromuscular function and falls had little effect. Men with the lowest 25(OH)D (Quartile 1) had greater than a two fold increased risk of hip fracture, Table. Further adjustment for BMD attenuated this association. However, spline analysis showed no significant threshold of 25(OH)D where fx risk was increased; risk of hip fx decreased with increasing 25(OH)D. Circulating 25(OH)D levels were unrelated to non-spine fractures. In conclusion, men with lower 25(OH)D have an increased risk of hip fx. The stronger association with hip fx may reflect a link between Vitamin D deficiency and frailty.

Table: RH(95%CI) of hip fracture across quartile of 25(OH)D

Quartile 25(OH)D ng/ml	Model 1 <sup>a</sup> RH (95% CI)	Model 2 <sup>b</sup> RH (95% CI)
1 (3.31 - <19.9)	2.49 (1.16, 5.36)	1.69 (0.76, 3.77)
2 (19.9 - <25.1)	1.49 (0.69, 3.26)	0.97 (0.43, 2.22)
3 (25.1 - <29.9)	1.01 (0.43, 2.34)	0.70 (0.28, 1.73)

**Gonadotropins, Bone Loss and Fracture in Men: the MrOS Study.** D. C. Bauer<sup>1</sup>, S. L. Harrison<sup>2</sup>, J. A. Cauley<sup>3</sup>, S. R. Cummings<sup>2</sup>, H. A. Fink<sup>4</sup>, A. Hoffman<sup>5</sup>, E. Orwoll<sup>6</sup>. <sup>1</sup>UCSF, San Francisco, CA, USA, <sup>2</sup>California Pacific Medical Center, San Francisco, CA, USA, <sup>3</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>VA Medical Center, Minneapolis, MN, USA, <sup>5</sup>Stanford, Palo Alto, CA, USA, <sup>6</sup>OHSU, Portland, OR, USA.

Sex hormone deficiency is associated with bone loss and fracture in older men and women, but the independent effects of gonadotropin levels are unknown. Recent rodent studies suggest FSH may regulate bone mass via a direct effect on osteoclasts.

We performed a prospective case-cohort analysis in the Osteoporosis in Men (MrOS) study to determine if FSH or LH levels were associated with bone loss or non-spine fracture risk. At the baseline visit hip DXA (Hologic QDR4500) was measured and fasting serum was archived at -190C in 5995 men over 65. Incident non-spine fractures were confirmed centrally and repeat hip DXA was obtained after a mean follow-up of 4.6 yr. After excluding 73 men using hormonal or other bone-active therapy, we used baseline serum to measure FSH and LH (Beckman Coulter) in 320 men with non-spine fracture (including 62 hip fractures) and 1193 randomly selected men. Baseline sex hormone levels (free estradiol and free testosterone by mass spectrometry) were also available. Bone loss was examined using age-adjusted linear regression models in 872 men from the randomly selected cohort who returned for follow-up BMD, and fractures were examined using age-adjusted Cox models that account for the case-cohort sampling.

Both FSH and LH levels increased with age ( $r=0.26-0.27$ ,  $p<0.001$ ). Higher FSH levels were associated with greater hip bone loss (Figure); results were similar for LH and after adjustment for sex hormone levels. Compared to men without non-spine fracture, those with fracture were significantly older (74.9 yr. vs. 73.7), had lower leg strength (194.2 watts vs. 208.9) and had lower total hip BMD (0.90 gm/cm<sup>2</sup> vs. 0.96), but mean FSH ( $\pm$ SD) and LH were similar among men with and without fracture (FSH: 15.2 $\pm$ 16.6 mIU/ml vs. 14.2 $\pm$ 14.0,  $p=0.81$ ; LH: 7.0 $\pm$ 6.7 mIU/ml vs. 6.6 $\pm$ 5.3,  $p=0.73$ ). Neither FSH nor LH were associated with non-spine or hip fracture risk. For example, after adjustment for age the RH for non-spine fracture per SD increase in FSH was 1.01 (CI: 0.88, 1.17).

We conclude that in older men higher levels of FSH and LH are associated with greater hip bone loss, independent of sex hormone levels, but gonadotropin levels are unrelated to fracture risk in this population.

## 1279

**Older Men with Low Serum Estradiol and High Serum SHBG Have an Increased Risk of Fractures.** L. Vandenput<sup>1</sup>, D. Mellström<sup>1</sup>, H. Mallmin<sup>2</sup>, A. H. Holmberg<sup>3</sup>, M. Lorentzon<sup>1</sup>, A. Odén<sup>4</sup>, H. Johansson<sup>1</sup>, E. S. Orwoll<sup>5</sup>, F. Labrie<sup>6</sup>, M. K. Karlsson<sup>3</sup>, Ö. Ljunggren<sup>2</sup>, C. Ohlsson<sup>1</sup>. <sup>1</sup>Center for Bone Research at the Sahlgrenska Academy, Departments of Internal Medicine and Geriatrics, University of Gothenburg, Gothenburg, Sweden, <sup>2</sup>Department of Medical Sciences, University of Uppsala, Uppsala, Sweden, <sup>3</sup>Clinical and Molecular Osteoporosis Research Unit, Lund University and Department of Orthopaedics, Malmö University Hospital, Malmö, Sweden, <sup>4</sup>Consulting Statistician, Gothenburg, Sweden, <sup>5</sup>Bone and Mineral Unit, Department of Medicine, Oregon Health and Science University, Portland, OR, USA, <sup>6</sup>Laboratory of Molecular Endocrinology and Oncology, Laval University Hospital Research Center and Laval University, Québec, QC, Canada.

Osteoporosis-related fractures constitute a major health concern not only in women but also in men. To investigate the predictive role of serum sex steroids for fracture risk in men, serum sex steroids were analyzed by the specific gas chromatography-mass spectrometry technique at baseline in older men (n=2639, mean 75 years of age) of the prospective population-based MrOS Sweden cohort. Fractures occurring after baseline were validated (average follow-up of 3.3 years).

The incidence for having at least one validated fracture after baseline was 20.9/1000 person-years. Estradiol (E2; hazard ratio (HR) per SD decrease 1.34, 95% confidence interval 1.22-1.49), free estradiol (fE2; HR per SD decrease 1.41, 1.28-1.55), testosterone (T; HR per SD decrease 1.27, 1.16-1.39) and free testosterone (fT; HR per SD decrease 1.32, 1.21-1.44) were all inversely while sex hormone-binding globulin (SHBG; HR per SD increase 1.41, 1.22-1.63) was directly related to fracture risk. Multivariable proportional hazards regression models, adjusted for age, suggested that fE2 and SHBG ( $p<0.001$ ), but not fT, were independently associated with fracture risk. Further sub-analyses of fracture type demonstrated that fE2 was inversely associated with clinical vertebral fractures (HR per SD decrease 1.57, 1.36-1.80), non-vertebral osteoporosis fractures (HR per SD decrease 1.42, 1.23-1.65) and hip fractures (HR per SD decrease 1.44, 1.18-1.76). The inverse relation between serum E2 and fracture risk was non-linear with a strong relation below 16 pg/ml for E2 and 0.3 pg/ml for fE2.

In conclusion, older Swedish men with low serum E2 levels and high SHBG levels have an increased risk of fractures.

**Disclosures:** L. Vandenput, None.

## 1280

**Post-Fracture Mortality in Men: Contributions of Sex Hormones and Bone Mineral Density as Risk Factors.** T. V. Nguyen<sup>1</sup>, N. D. Nguyen<sup>1</sup>, C. Meier<sup>2</sup>, J. A. Eisman<sup>1</sup>, M. J. Seibel<sup>3</sup>. <sup>1</sup>Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, <sup>2</sup>Division of Endocrinology, Diabetes and Clinical Nutrition, University Hospital Basel, Basel, Switzerland, <sup>3</sup>Bone Research Program, ANZAC Research Institute, the University of Sydney, Sydney, Australia.

Although mortality risk is increased among men with fracture, it is not clear what factors contribute to the risk. Moreover, the relationship between sex hormones and mortality in men is controversial, with some but not all studies suggesting that low levels of testosterone were associated with increased mortality risk. We examined the effect of sex hormones on the risk of post-fracture mortality.

Total testosterone and sex hormone-binding globulin (SHBG) were measured by tandem mass spectrometry in 609 men whose aged was at least 60 years (as of 1989) and whose health status had been monitored for 18 years with biannual clinic visits. During the follow-up period, fractures and mortality were ascertained. In addition to basic clinical and anthropometric variables, baseline bone mineral density (BMD, GE-Lunar Prodigy) was also measured in all men. The association between baseline testosterone and fracture or mortality was analyzed by the Cox's proportional hazards model with adjustment for covariates.

During the follow-up period, 113 sustained a fracture and 275 men died; among whom 69 died following a fracture. Fracture was associated with a 50% increase in the risk of mortality (RR 1.5, 95% CI: 1.4 - 1.6). Lower levels of testosterone were associated with an increased risk of mortality (RR 1.7, 95% CI: 1.2 - 2.6) and of fracture (1.5; 95% CI: 1.2 - 1.8) after adjusting for SHBG. More importantly, the risk of mortality after a fracture was significantly increased in those with lower total testosterone levels (RR 3.1, 95% CI: 1.4 - 7.0) after adjusting for SHBG, body weight and age. In multivariate analysis, lower total testosterone, lower BMD (or weight), lower SHBG and advancing age were independent risk factors of post-fracture mortality. These factors collectively accounted for ~60% of total mortality risk.

These results indicate that sex hormones were independent predictors of post-fracture mortality in elderly men, and that mortality should be considered as an important component of osteoporosis outcomes. These data also suggest that it is possible to identify men at high risk of post-fracture mortality.

## 1281

**Cortical Cross Sectional Area in Young Adult Men Is Inversely Related to Risk of Hip Fracture in Their Older Relatives - The GOOD Study.** M. Lorentzon, R. Rudäng\*, D. Mellström, C. Ohlsson. Internal Medicine, Center for Bone Research at the Sahlgrenska Academy (CBS), Göteborg, Sweden.

Peak bone mass is to a large extent genetically determined and believed to be a predictor of future risk of osteoporosis. It is still unclear whether it is the volumetric bone mineral density (vBMD) or bone size at the age of peak bone mass that confers the risk of future osteoporotic fracture. The aim of the present study was to investigate which of these bone parameters in young men (age 18.9±0.6 years, n=1066) included in the Gothenburg Osteoporosis and Obesity Determinants (GOOD) study, that were associated with X-ray verified hip fractures in their parents and grand parents. Using the Swedish multi-generation register, 5901 relatives of the young men in the GOOD-study were identified. The Swedish in-patient care register was used to search for hip fracture data on these relatives. In total, 366 relatives had sustained a hip fracture. Bone parameters were measured in the GOOD-study subjects using both DXA and pQCT. The 320 GOOD-study subjects with a relative with at least one hip fracture had lower areal BMD (aBMD) of the lumbar spine (1.22±0.15 vs. 1.25±0.15 g/cm<sup>2</sup>; p<0.01), radius (0.57±0.06 vs. 0.58±0.06; p=0.04), and total body (1.24±0.10 vs. 1.25±0.10; p=0.04), than the 746 GOOD-study subjects without a relative with a hip fracture. The reduced aBMD at the radius, in the subjects with a relative with at least one hip fracture, was due to a smaller cortical cross sectional area (CSA; 94.8±12 vs. 96.7±12 mm<sup>2</sup>; p=0.02) and lower trabecular volumetric BMD (215±41 vs. 221±41 mg/cm<sup>3</sup>; p=0.02). Using a binary logistic regression (with age of relatives (age deceased or current age), GOOD-study subject age, height, weight, physical activity, calcium intake, and smoking as covariates) we found that lumbar spine aBMD (p<0.01) and cortical CSA (p<0.01) were inversely and independently related to risk of hip fracture in the relatives.

Every SD decrease in the radius cortical CSA, of the GOOD-study subjects, was associated with 1.25 (95% CI: 1.06-1.49) times increased risk of hip fracture in their relatives. Our results suggest that aBMD and especially cortical CSA at the age of peak bone mass are important determinants in predicting osteoporotic fractures in the elderly.

**Distribution and Rate of Clinical Fractures in Older Men Without Osteoporosis: the Osteoporotic Fractures in Men (MrOS) Study.** H. A. Fink<sup>1</sup>, T. L. Blackwell<sup>\*2</sup>, B. C. Taylor<sup>\*1</sup>, K. E. Ensrud<sup>1</sup>, J. A. Cauley<sup>3</sup>, L. Marshall<sup>\*4</sup>, E. S. Orwoll<sup>4</sup>. <sup>1</sup>VA Medical Center, Minneapolis, MN, USA, <sup>2</sup>California Pacific Medical Center, San Francisco, CA, USA, <sup>3</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>Oregon Health Science University, Portland, OR, USA.

Low BMD strongly predicts future fractures (fx) in populations, but not all patients with fx have low BMD. We examined the proportion of older men with incident fx across BMD categories and, within each BMD category, the distribution of fx types.

We used data from MrOS, a prospective cohort study in men aged ≥65 yrs. From total hip, femoral neck and lumbar spine BMD measured by DXA, men were categorized as osteoporotic (T-score ≤-2.5 any site), normal (T-score ≥-1 all sites), or low bone mass. Self-reported incident fx collected every 4 months were centrally confirmed by radiology reports.

Of 5985 men with BMD measured at all sites, 36% had normal BMD, 54% low bone mass, and 10% osteoporosis. Rate of any clinical fx was lowest in men with normal BMD (9.4 per 1000 person-yr) and greatest in men with osteoporosis (38.3 per 1000 person-yr). However, among men with clinical fx (n=608), 78% were not osteoporotic at any site (21% normal BMD, 57% low bone mass). Analogously, among men with hip fx (n=104), 63% were not osteoporotic at any site (6% normal BMD, 57% low bone mass). Distribution of fx type differed as a function of BMD category. In fx cases with normal BMD (n=128), the most frequent fx types were rib/chest/sternum (23%), ankle/foot/toe (20%), spine (11%), and hand/finger (10%), with fewer men having wrist (6%) or hip (5%) fx. By contrast, in fx cases with osteoporosis (n=134), the most frequent fx types were hip (29%), spine (22%), rib/chest/sternum (19%), and wrist (13%), with fewer men experiencing fx of ankle/foot/toe (8%) or hand/finger (4%). These patterns were similar among men with traumatic fx (n=92), in that 85% were not osteoporotic at any site, and that of traumatic fracture cases with normal BMD, only 5.3% had fx at hip, spine or wrist, and of traumatic fx cases with osteoporosis, 29% had fx at hip, spine or wrist.

In this older male cohort, while incident fx rates were approximately 4-fold higher in men with osteoporosis than in those with normal BMD, nearly 80% of men with any fx and over 60% of men with hip fx were not osteoporotic at either hip or spine. Of men with incident fx, those with normal BMD infrequently had fx at hip, spine or wrist, a pattern appearing more pronounced for men with traumatic fx. In contrast, most incident fx in men with osteoporosis occurred at these "traditional" osteoporosis sites. Future studies should examine risk factors for fx, including for specific fx types, in men without osteoporosis.

**Disclosures:** H.A. Fink, None.

## 1283

**Elevated Production of Interleukin 1β (IL-1β) and Tumor Necrosis Factor α (TNF-α) by Peripheral Blood Mononuclear Cells (PBMC) is Associated with Increased Hip Fracture Risk in Elders: The Framingham Osteoporosis Study.** R. R. McLean<sup>1</sup>, R. Roubenoff<sup>\*2</sup>, M. T. Hannan<sup>1</sup>, L. A. Cupples<sup>\*3</sup>, D. P. Kiel<sup>1</sup>. <sup>1</sup>Hebrew SeniorLife & Harv Med Sch, Boston, MA, USA, <sup>2</sup>Friedman Sch of Nutr Sci & Policy, Tufts Univ, Boston, MA, USA, <sup>3</sup>BU Sch of Public Health, Boston, MA, USA.

Age-related bone loss may be partly mediated by the local skeletal effects of inflammatory cytokines, and previous studies suggest that elevated serum concentrations of inflammatory markers are associated with greater risk of osteoporotic fracture. Spontaneous cytokine production by PBMC, however, may provide a better indication of an individual's *in vivo* inflammatory activity than serum concentrations. We prospectively examined the associations of spontaneous PBMC production of the inflammatory markers IL-1β, interleukin 1 receptor antagonist (IL-1ra), TNF-α, and interleukin 6 (IL-6) with the risk of hip fracture among elderly participants in the population-based Framingham Study Original Cohort. Non-fasting blood samples were drawn from 274 men and 428 women (mean age 78 years, range 72-94) in 1992-94 (baseline) and total PBMC production (ng/mL) of IL-1β, IL-1ra, TNF-α and IL-6 were measured in unstimulated cells using radioimmunoassays. Quartiles of markers were created (Q1=low). Incident hip fractures were ascertained from baseline through December 2005. Sex- and age-adjusted hip fracture incidence rates (IR, per 1000 person-yrs) and 95% confidence intervals (CI) were calculated for quartiles of each marker. Hip fracture hazard ratios (HR) and 95% CIs were calculated across quartiles (Q1 referent) using Cox proportional hazards regression, adjusting for sex and baseline covariates: age (yrs), weight (lbs), height (in), alcohol consumption (oz/wk), current smoking (y/n) and daily use of aspirin or NSAIDs (y/n). Median follow-up time was 9.5 years (range 0.01-14.4) and 69 incident hip fractures occurred. Due to a consistent threshold effect after Q1, the upper three quartiles were combined (Q2-4).

Inflammatory marker ranges, sex- and age-adjusted hip fracture incidence rates (95% CI), and multivariable-adjusted\* hip fracture hazard ratios (95% CI) per marker quartiles.

Marker	Quartile	Range (ng/mL)	IR (per 1000 p-y)	HR
IL-1β	Q1	0.04, 1.84	7.4 (2.7, 12.0)	1.00
	Q2-4	1.88, 42.0	13.0 (9.6, 16.4)	1.98 (1.03, 3.81)
IL-1ra	Q1	0.11, 6.60	7.9 (2.9, 12.9)	1.00
	Q2-4	6.80, 72.0	12.8 (9.3, 16.4)	1.79 (0.95, 3.39)
TNF-α	Q1	0.04, 2.16	7.6 (3.1, 12.2)	1.00
	Q2-4	2.20, 40.0	13.0 (9.5, 16.4)	1.94 (1.01, 3.72)
IL-6	Q1	0.04, 1.96	11.1 (5.4, 16.7)	1.00
	Q2-4	2.00, 20.0	11.9 (8.6, 15.2)	1.15 (0.65, 2.03)

\*Adjusted for sex, age, weight, height, alcohol, smoking, and aspirin/NSAID use

Participants in Q2-4 of IL-1β and TNF-α had a two-fold increased hip fracture risk, while those with elevated IL-1ra tended to have 79% higher risk. IL-6 was not associated with hip fracture. Our results suggest that elevated PBMC production of IL-1β and TNF-α may be risk factors for hip fracture in older men and women, providing further evidence that inflammation may be an important mediator of osteoporotic fracture risk among community-dwelling elders.

**IGFBP-2 and Bone Loss in Aging Women and Men.** S. Amin, L. J. Melton, E. Atkinson\*, S. Achenbach\*, R. Robb\*, J. Camp\*, B. L. Riggs, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Low estradiol does not fully explain age-related bone loss, and we have shown that high IGF binding protein-2 [IGFBP-2] predicts low bone density and high bone turnover, cross-sectionally, in aging men and women. We therefore examined the role of high IGFBP-2 on longitudinal bone loss assessed using QCT. In an age-stratified, random sample of community adults, we measured serum IGFBP-2 at baseline. At baseline and 3 yr follow-up, we measured trabecular volumetric bone mineral density [vBMD] (g/cm<sup>3</sup>) at the lumbar spine [LS] and femoral neck [FN], and cortical vBMD and thickness (mm) at the FN. Using peripheral QCT (Densiscan, Scanco), we assessed radius and tibia trabecular and cortical vBMD annually over the 3 yrs. We used unadjusted and age-adjusted Spearman correlations to describe the relation between IGFBP-2 and annualized rates of bone loss [% loss/yr], stratified by menopausal status in women, and age (< vs. ≥50 years) in men. We then adjusted for bioavailable estradiol [bio E<sub>2</sub>] (pg/ml), measured using mass spectroscopy. We studied 223 women (79 premenopausal, age range and mean IGFBP-2: 21-55 yrs, 545 ng/ml; 144 postmenopausal, 42-97 yrs, 593 ng/ml), and 303 men (119 men, 22-49 yrs, 302 ng/ml; 184 men, 50-91 yrs, 520 ng/ml), not on hormones or bisphosphonates, who had baseline and follow-up scans for at least one site. Adjusting for age, we found no association between IGFBP-2 and bone loss in premenopausal women or men <50 yrs. In postmenopausal women, high IGFBP-2 was associated with bone loss at all sites except the LS, whereas in men ≥ 50 yrs, it was associated with trabecular bone loss at the tibia and LS only. Following additional adjustment for bio E<sub>2</sub>, findings were unchanged in premenopausal women and men; however in postmenopausal women, high IGFBP-2 was then only associated with cortical bone loss at the tibia and FN (see Table).

	Postmenopausal Women		Men ≥ 50 years	
	Mean %Loss/Yr	Un-/Age-/Age+Bio E <sub>2</sub> - %Loss/Yr	Mean %Loss/Yr	Un-/Age-/Age+Bio E <sub>2</sub> - Adjusted Correlations
LS Trabecular vBMD	-1.6	0.02/-0.03/0.03	-1.3	-0.33*/-0.22*/-0.21*
FN Trabecular vBMD	-1.9	-0.30*/-0.28*/-0.16	-1.0	-0.24*/-0.08/-0.09
FN Cortical vBMD	-0.8	-0.26*/-0.31*/-0.24*	-0.04	-0.15/-0.06/-0.08
FN Cortical Thickness	-0.6	-0.30*/-0.19*/-0.14	-0.9	-0.23*/-0.06/-0.01
Radius Trabecular vBMD	-0.8	-0.07/-0.19*/-0.05	-0.5	-0.08/-0.14/-0.13
Radius Cortical vBMD	-0.5	-0.17*/-0.19*/-0.08	-0.4	-0.23*/-0.07/-0.08
Tibia Trabecular vBMD	-0.8	-0.35*/-0.25*/-0.11	-0.2	-0.12/-0.19*/-0.18*
Tibia Cortical vBMD	-0.6	-0.32*/-0.30*/-0.21*	-0.2	-0.10/-0.05/-0.03

\* p<0.05

In older women, cortical bone loss at weight-bearing sites is influenced by high IGFBP-2. In older men, who have greater cortical apposition with aging than women, IGFBP-2 did not influence cortical bone loss. In older women, low estradiol is likely dominant for trabecular bone loss, while in older men, who have higher estradiol than older women, high IGFBP-2 contributes to trabecular loss at the LS and tibia. These results provide further insights on likely differences in hormonal regulation of bone loss, not only by age and gender, but by bone compartment, and suggest a role of the IGF system in age-related bone loss.

**Effect of Denosumab vs Alendronate on Bone Turnover Markers and Bone Mineral Density Changes at 12 Months Based on Baseline Bone Turnover Level.** J. P. Brown<sup>1</sup>, C. Deal<sup>2</sup>, L. H. de Gregorio<sup>3</sup>, L. C. Hofbauer<sup>4</sup>, H. Wang<sup>5</sup>, M. Austin<sup>5</sup>, R. B. Wagman<sup>6</sup>, R. Newmark<sup>5</sup>, C. Libanati<sup>5</sup>, J. San Martin<sup>5</sup>. <sup>1</sup>CHUQ Laval University, Quebec City, QC, Canada, <sup>2</sup>Cleveland Clinic, Cleveland, OH, USA, <sup>3</sup>SYNARC/CCBR, Rio de Janeiro, Brazil, <sup>4</sup>Technical University Medical Center, Dresden, Germany, <sup>5</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>6</sup>Amgen Inc. and Stanford University School of Medicine, San Francisco and Stanford, CA, USA.

Denosumab, an investigational RANKL inhibitor, suppresses osteoclast-mediated bone resorption by a different mechanism than bisphosphonates. We directly compared the effect of denosumab vs brand alendronate (ALN) on bone turnover marker (BTM) changes, and BMD changes based on the baseline levels of serum C-telopeptide (sCTX) and procollagen type 1 N-propeptide (PINP) in a phase 3 study of postmenopausal women with low BMD.

Postmenopausal women (lumbar spine or total hip T-score ≤ -2.0) were randomized 1:1 to receive subcutaneous (SC) denosumab injection (60 mg, every 6 months [Q6M]) + oral placebo weekly or oral ALN (70 mg) weekly + SC placebo injection Q6M. All received calcium and vitamin D. BTM changes from baseline were assessed over 12 months. BMD

gains at the total hip, lumbar spine, femoral neck, and radius at month 12 were compared across quartiles of baseline sCTX.

Subjects (N = 1189; 594 denosumab; 595 ALN; mean age 64 yrs) had a mean lumbar spine T-score of -2.6. With denosumab sCTX decreased by a median of 89%, 77%, and 74% vs 61%, 73%, and 76% with ALN at month 1, 6, and 12, respectively ( $P \leq 0.0001$  month 1 and 6;  $P = 0.5$  month 12). Median PINP decreases at these times were: 26%, 72%, and 72% for denosumab vs 11%, 62%, and 65% for ALN ( $P < 0.0001$  all times). As reported earlier, denosumab resulted in significantly greater gains in BMD vs ALN ( $P \leq 0.0003$  all sites). BMD increases at the total hip were greater for subjects in both groups with higher baseline bone turnover; BMD gains were significantly greater for denosumab vs ALN regardless of baseline bone turnover (table - sCTX; PINP not shown). Results were similar for BMD gains at the lumbar spine, femoral neck, and radius. Adverse events were similar for each group.

Denosumab suppressed bone remodeling and increased BMD at all measured sites more than ALN. BMD gains were consistent across different levels of baseline bone turnover. The differences in results between these drugs may be due to their different mechanism of inhibiting bone turnover.

	Table. Baseline sCTX by Quartile and Percent Change in Total Hip BMD at Month 12			
	sCTX < 0.447 ng/mL	sCTX 0.477 to < 0.631 ng/mL	sCTX 0.631 to < 0.836 ng/mL	sCTX ≥ 0.836 ng/mL
Denosumab				
N	136	135	145	159
Mean % BMD change at 12 months (95% CI)	2.7 (2.3 - 3.1)	3.2 (2.8 - 3.6)	3.6 (3.2 - 3.9)	4.3 (3.9 - 4.7)

**A Phase III Study of the Effects of Denosumab on Vertebral, Nonvertebral, and Hip Fracture in Women with Osteoporosis: Results from the FREEDOM Trial.** S. R. Cummings<sup>1</sup>, M. R. McClung<sup>2</sup>, C. Christiansen<sup>3</sup>, E. Siris<sup>4</sup>, S. Adami<sup>5</sup>, S. Kutilek<sup>6</sup>, I. R. Reid<sup>7</sup>, J. R. Zanchetta<sup>8</sup>, J. San Martin<sup>9</sup>, C. Libanati<sup>9</sup>, S. Siddhanti<sup>9</sup>, A. Wang<sup>9</sup>, P. D. Delmas<sup>10</sup>. <sup>1</sup>San Francisco Coordinating Center, CPMC Research Institute & UCSF, San Francisco, CA, USA, <sup>2</sup>Oregon Osteoporosis Center, Portland, OR, USA, <sup>3</sup>Center for Clinical and Basic Research, Ballerup, Denmark, <sup>4</sup>Columbia University Medical Center, New York, NY, USA, <sup>5</sup>University of Verona, Verona, Italy, <sup>6</sup>Center for Clinical and Basic Research, Pardubice, Czech Republic, <sup>7</sup>University of Auckland, Auckland, New Zealand, <sup>8</sup>University of Salvador, Buenos Aires, Argentina, <sup>9</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>10</sup>Universite of Lyon 1 and INSERM Research Unit 831, Lyon, France.

Background: Denosumab, an investigational fully human monoclonal antibody to RANKL, is an inhibitor of osteoclast differentiation, proliferation, and function that is currently being investigated as a treatment for osteoporosis. Clinical trials completed to date have shown that denosumab rapidly decreased bone resorption and increased hip, spine, distal radius, and total body bone mineral density.

Methods: FREEDOM (Fracture REduction Evaluation of Denosumab in Osteoporosis every 6 Months) is a phase III trial for which the primary outcome is the effect of denosumab on risk of new vertebral fracture. Secondary outcomes include denosumab's effect on risk of nonvertebral fracture and hip fracture. A total of 7,868 women were recruited from 214 clinical centers in 32 countries. Subjects were between ages 60 and 90 years (mean age=72.3 years) and had osteoporosis (lumbar spine or total hip T-score <-2.5 and ≥-4.0). The mean lumbar spine T-score was -2.8, and 23% of subjects had prevalent vertebral fractures at baseline.

Participants were randomly assigned to receive denosumab 60 mg every 6 months by subcutaneous injection or matching placebo for 3 years. All participants received elemental calcium 1000 mg/d and vitamin D 400-800 IU/d.

The study remained blinded at the time this abstract was written. As of March 2008, 84% of participants either completed or are ongoing. The last patient visit will be completed in May 2008.

Results: The complete 3-year results, including the effect of denosumab on new vertebral, nonvertebral, and hip fractures, along with safety data, will be available for presentation at the time of the ASBMR meeting.

**The Effects of Lasofoxifene on Bone Turnover Markers: the PEARL Trial.**

**R. Eastell<sup>1</sup>, D. M. Reid<sup>2</sup>, S. Vukicevic<sup>\*3</sup>, J. Thompson<sup>\*4</sup>, D. Thompson<sup>4</sup>, S. R. Cummings<sup>5</sup>, P. D. Delmas<sup>6</sup>.** <sup>1</sup>Metabolic Bone Centre, Northern General Hospital and the University of Sheffield, Sheffield, South Yorkshire, United Kingdom, <sup>2</sup>Applied Medicine, University of Aberdeen Medical School, Foresterhill, Aberdeen, United Kingdom, <sup>3</sup>Department of Anatomy, Zagreb Medical School, Zagreb, Croatia, <sup>4</sup>Pfizer Inc, New London, CT, USA, <sup>5</sup>San Francisco Coordinating Center, CPMC Research Institute and University of California, San Francisco, CA, USA, <sup>6</sup>INSERM Research Unit, University of Lyon, Lyon, France.

Lasofloxifene (LASO) is a potent new selective estrogen receptor modulator that decreases bone turnover, improves bone density and reduces LDL-cholesterol levels. Phase II trials suggested that these effects may be stronger than observed with raloxifene. We tested the effects of LASO on bone turnover markers in the phase III Postmenopausal Evaluation And Risk-reduction with Lasofloxifene (PEARL) trial to examine the magnitude of response and the proportion of women returned to the lower half of the reference interval for young women (a putative goal of therapy). PEARL enrolled 8,556 women aged 59 to 80 years who had osteoporosis defined as a lumbar spine (LS) or femoral neck (FN) T-score < -2.5, and excluded women with a T-score < -4.5 at either site, > 3 radiographic vertebral fractures (VFX), or a VFX within the previous year. Participants received calcium (1,000 mg/d) and vitamin D (400-800 IU/d) and were randomly assigned to 0.25 mg/d, 0.5 mg/d of LASO or placebo. We measured serum bone alkaline phosphatase (b ALP) (Quidel), PINP, osteocalcin (OC), and CTX (Roche Elecsys) in 1104 women aged 59 to 80 (mean, 68 years) at baseline, 1, 3, 6, 12, 24 and 36 months. We found the nadir in bone turnover markers at 12 months and so we report these results in the table that shows the median % change and the median level on treatment (and 95% confidence intervals) and the reference interval in healthy young women (\*Glover et al, Bone 2008).

	LASO 0.25, % change	LASO 0.5, % change	Placebo, % change	LASO 0.25, Median	LASO 0.5, Median	Placebo, Median	Ref Interval*
b ALP, IU/L	-29 (-31, -26)	-27 (-29, -26)	-4 (-6, -1)	17 (16, 17)	16 (16, 17)	22 (21, 22)	9 to 29
PINP, ng/mL	-46 (-48, -44)	-46 (-50, -43)	-4 (-8, -1)	27 (26, 29)	25 (24, 27)	45 (42, 49)	16 to 69
OC, ng/mL	-45 (-47, -44)	-46 (-50, -43)	-6 (-8, -2)	11 (11, 12)	10 (10, 11)	18 (17, 19)	7 to 28
CTX, ng/mL	-48 (-51, -45)	-53 (-55, -48)	-1 (-5, 2)	0.23 (0.21, 0.25)	0.20 (0.18, 0.22)	0.40 (0.37, 0.42)	0.11 to 0.69

Thus, both doses of LASO induced significant reductions in bone turnover markers as compared to placebo. The median marker level on treatment was in the lower half of the reference interval for healthy young women, a level associated with low risk of fracture.

**The Effects of Lasofoxifene on Fractures and Breast Cancer: 3-Year Results From the PEARL Trial.**

**S. R. Cummings<sup>1</sup>, R. Eastell<sup>2</sup>, K. Ensrud<sup>3</sup>, D. M. Reid<sup>4</sup>, S. Vukicevic<sup>5</sup>, A. LaCroix<sup>6</sup>, U. Sriram<sup>7</sup>, D. Thompson<sup>8</sup>, J. R. Thompson<sup>9</sup>, P. D. Delmas<sup>10</sup>.** <sup>1</sup>CPMC Res. Inst., San Francisco, CA, USA, <sup>2</sup>Northern General Hospital, Sheffield, United Kingdom, <sup>3</sup>U. of Minnesota, Minneapolis, MN, USA, <sup>4</sup>U. of Aberdeen Medical School, Aberdeen, United Kingdom, <sup>5</sup>Zagreb Medical School, Zagreb, Croatia, <sup>6</sup>U. of Washington, Seattle, WA, USA, <sup>7</sup>Saint Joseph Hospital, Chicago, IL, USA, <sup>8</sup>Pfizer Inc, New London, CT, USA, <sup>9</sup>Pfizer Inc., New London, CT, USA, <sup>10</sup>INSERM, U. of Lyon, Lyon, France.

Lasofloxifene (LASO) is a new potent SERM that decreases bone turnover and improves BMD. We tested the effects of LASO on clinical outcomes in the Postmenopausal Evaluation And Risk-reduction with LASO (PEARL) Trial. PEARL enrolled 8,556 women age 59 - 80 years with a lumbar spine (LS) or femoral neck (FN) T-score ≤ -2.5, and excluded women with a T-score < -4.5 at either site, >3 radiographic vertebral fractures (VFX), or a VFX in the previous year. Participants received calcium (1,000 mg) and vitamin D (400-800 IU) and were randomly assigned to LASO 0.25 mg/d, 0.5 mg/d or placebo (PBO). The primary outcome, time to new or worsening VFX, was assessed by ≥1 category change in semiquantitative (SQ) grade confirmed by ≥20% and ≥4 mm decrease in vertebral height or 'binary' SQ rating. Non-vertebral fractures (NonVFX), ER+ breast cancer (BrCa), venous thromboembolic events (VTE), stroke, and CHD were adjudicated by panels of external experts. Compared with PBO, 3 years of LASO improved BMD at the spine (3.3% for both doses, P < 0.001) and FN (2.7% for 0.25 mg and 3.3% for 0.5 mg/d, P < 0.001). LASO 0.25 mg and 0.5 mg reduced VFX by 31 and 42% (P<0.002; table). The 0.5 mg dose decreased the risk of NonVFX by 22% (P=0.02); a 14% decrease with 0.25 mg was not statistically significant (P=0.13). LASO 0.25 mg and 0.5 mg/d reduced the risk of ER+ BrCa by 84% and 67%, respectively. LASO treatment increased the risk of VTE, but not stroke or CHD. Two cases of endometrial cancer occurred in the PBO group, 2 in the 0.25 mg, and 1 in the 0.5 mg LASO groups. Hot flushes, muscle spasm, vaginal discharge, candidiasis, uterine polyps and prolapse occurred more often; back pain, arthralgia, insomnia, hyperlipidemia, hypertension, and gastritis occurred less often with LASO.

At 3 years LASO showed no increased risk of CHD or endometrial cancer and an increased risk of VTE. The benefits at 3 years demonstrated a decreased risk of VFX and ER+ breast cancer, and with the 0.5 mg/d dose, a significantly decreased risk of NonVFX.

Cumulative Outcomes of 3 years treatment with lasofloxifene versus placebo (Rate per 1,000 subjects over 3 years)

Outcome	PBO	LASO 0.25 mg	HR (95% CI)	P-value	LASO 0.5 mg	HR (95% CI)	P-value	LASO pooled	HR (95% CI)	P-value

**Ergocalciferol Is Not Bioequivalent to Cholecalciferol In Vitamin D Insufficient Hip Fracture Cases.**

**P. Glendenning<sup>1</sup>, H. Seymour<sup>\*2</sup>, M. J. Gillett<sup>\*1</sup>, G. T. Chew<sup>\*2</sup>, P. Goldswain<sup>\*2</sup>, C. Inderjeeth<sup>\*3</sup>, S. Vasikaran<sup>\*1</sup>, M. Taranto<sup>\*1</sup>, A. Musk<sup>\*1</sup>, W. D. Fraser<sup>4</sup>.** <sup>1</sup>Biochemistry, Royal Perth Hospital, Perth, Australia, <sup>2</sup>Geriatric Medicine, Royal Perth Hospital, Perth, Australia, <sup>3</sup>Aged Care, Sir Charles Gairdner Hospital, Perth, Australia, <sup>4</sup>Clinical Biochemistry, University of Liverpool, Liverpool, United Kingdom.

Vitamin D insufficiency is commonly associated with hip fracture. In this patient group, the equipotency of ergocalciferol and cholecalciferol has not been studied in a randomised, double-blind, placebo controlled trial or with measurement of 25OHD by high performance liquid chromatography (HPLC) as the primary outcome variable.

Our study compared the effects of cholecalciferol and ergocalciferol supplementation on circulating 25-hydroxyvitamin D (25OHD) and parathyroid hormone (PTH) levels in vitamin D insufficient hip fracture patients. 95 hip fracture patients with vitamin D insufficiency (25OHD < 50 nmol/L) were randomised to treatment with either ergocalciferol 1000 IU daily plus matching placebo (n=48) or cholecalciferol 1000 IU daily plus matching placebo (n=47) for 3 months. The primary outcome variable was total 25OHD concentration measured by HPLC; secondary endpoints were total 25OHD measured by radioimmunoassay (RIA), intact PTH (iPTH) and bioactive (1-84) PTH (wPTH).

70 patients (73.7%) completed the study with paired samples for analysis. Cholecalciferol supplementation resulted in a greater increase in HPLC measured total 25OHD than supplementation with an equivalent dose of ergocalciferol (P = 0.010). Results were similar for total 25OHD measured by DiaSorin RIA (P < 0.001). Changes in iPTH and wPTH were not significantly different between treatments.

In vitamin D insufficient hip fracture patients, supplementation with cholecalciferol 1000 IU daily for 3 months was more effective in increasing circulating total 25 OHD than an equivalent dose of ergocalciferol.

**Case Finding for the Management of Osteoporosis with FRAX - Assessment and Intervention Thresholds for the UK.** J. E. Compston<sup>1</sup>, E. McCloskey<sup>\*2</sup>, H. Johansson<sup>\*3</sup>, O. Strom<sup>\*3</sup>, F. Borgstrom<sup>\*3</sup>, A. Oden<sup>\*3</sup>, J. Kanis & the National Osteoporosis Guideline Group<sup>\*3</sup>. <sup>1</sup>Department of Medicine, University of Cambridge, Cambridge, United Kingdom, <sup>2</sup>Northern General Hospital, Osteoporosis Centre, Sheffield, United Kingdom, <sup>3</sup>University of Sheffield, WHO Collaborating Centre for Metabolic Bone Diseases, Sheffield, United Kingdom.

The FRAX tool has recently become available to compute the 10-year probability of fractures in men and women from clinical risk factors (CRFs) with or without the measurement of femoral neck bone mineral density (BMD). The aim of this study was to develop a case-finding strategy for men and women from the UK at high risk of osteoporotic fracture by delineating the fracture probabilities at which BMD testing or intervention should be recommended. Fracture probabilities were computed using the FRAX tool calibrated to the epidemiology of fracture and death in the UK. Intervention thresholds, underpinned by cost-effectiveness analysis, were set by age, based on the fracture probability at which intervention became cost-effective in women with a history of a prior osteoporosis related fracture. Assessment thresholds for the measurement of BMD followed current practice guidelines in the UK where individuals are considered to be eligible for assessment in the presence of one or more CRF. An upper assessment threshold (i.e. a fracture probability above which patients could be treated without recourse to BMD) was based on optimisation of the positive predictive value of the assessment tool. The consequences of assessment and intervention thresholds on the requirement for BMD tests and interventions were assessed using the distribution of clinical risk factors and femoral neck BMD for women in the source cohorts used for the development of the FRAX. The intervention threshold at the age of 50 years corresponded to a ten-year probability of a major osteoporotic fracture of 7.5%. This rose progressively with age to 30% at the age of 80 years. Assessment thresholds (6-9% at the age of 50 years) also rose with age (18-36% at the age of 80 years). The use of these thresholds in a case-finding strategy would identify 6-20 % of women as eligible for BMD testing and 23-46% as eligible for treatment, depending on age. This study provides a method of developing management algorithms for osteoporosis from the estimation of fracture probabilities, rather than those based on BMD alone or BMD with single or multiple CRFs.

**A Randomized, Double-Blind, Placebo-Controlled Study of Odanacatib (MK-822) in the Treatment of Postmenopausal Women with Low Bone Mineral Density: 24-Month Results.** M. McClung<sup>\*1</sup>, H. Bone<sup>\*2</sup>, F. Cosman<sup>\*3</sup>, C. Roux<sup>\*4</sup>, N. Verbruggen<sup>\*5</sup>, C. Hustad<sup>6</sup>, C. DaSilva<sup>\*6</sup>, A. Santora<sup>\*6</sup>, A. Ince<sup>\*6</sup>. <sup>1</sup>Oregon Osteoporosis Center, Portland, OR, USA, <sup>2</sup>Michigan Bone and Mineral Center, Detroit, MI, USA, <sup>3</sup>Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>4</sup>Cochin Hospital, University of Paris, Paris, France, <sup>5</sup>Merck Research Laboratories, Brussels, Belgium, <sup>6</sup>Merck Research Laboratories, Rahway, NJ, USA.

Odanacatib, a selective inhibitor of cathepsin K, has been shown to rapidly and reversibly decrease bone resorption in both preclinical and Phase I clinical studies. A randomized, double-blind, 1-year dose-ranging trial with a 1-year extension was performed in postmenopausal women with low bone mineral density (BMD) to evaluate the safety and efficacy of weekly doses of placebo, 3, 10, 25 or 50 mg of odanacatib on BMD and biochemical indices of bone turnover.

Postmenopausal women (N=399, mean age: 64.2 ± 7.8 years) with BMD T-scores ≤ -2.0 at the lumbar spine, femoral neck, trochanter, or total hip and ≥ -3.5 at all sites were randomized to receive placebo or 1 of 4 doses of odanacatib. All participants also received weekly 5600 IU vitamin D3 supplements and daily 500-mg calcium supplements if normal consumption was <1000 mg calcium/day. 320 women from the 12-month base study continued into the 1-year extension, and 280 women completed 2 years of treatment. Participants and investigators remained blinded to treatment allocation during the extension period. The primary endpoint was the percent change vs. baseline in lumbar spine BMD. Other endpoints included the percent change vs. baseline in BMD measurements at the proximal femur, total body, and distal forearm, as well as in biochemical markers of bone resorption and bone formation.

Twenty-four months of treatment produced progressive dose-related increases in BMD vs. baseline. With the 50-mg dose of odanacatib, lumbar spine and total hip BMD increased 5.5% and 3.2%, respectively, whereas BMD at these sites was essentially unchanged with placebo (-0.2% and -0.9%). Urinary N-telopeptide (NTx/Cr) and bone-specific alkaline phosphatase (BSAP) decreased 52% and 13%, respectively, with the 50-mg dose, whereas uNTx/Cr decreased 5% and BSAP increased 3% with placebo. The safety profile of odanacatib was generally favorable, with no dose-related trends in any adverse experiences. Rash was reported in 4.8% of those in the 50-mg group and in 7.9% of those in the placebo group.

These results show that 2 years of odanacatib treatment was generally well-tolerated and increased lumbar spine and total hip BMD in postmenopausal women with low BMD.

## 1292

**C-telopeptide and Bone Alkaline Phosphatase Predict Morphometric Vertebral Fracture Risk in a Pivotal Phase III Trial of Toremifene in Men on ADT.** M. R. Smith<sup>\*1</sup>, R. A. Morton<sup>\*2</sup>, M. L. Hancock<sup>\*2</sup>, G. Barnette<sup>\*2</sup>, D. Rodriguez<sup>\*2</sup>, K. A. Veverka<sup>2</sup>, M. Steiner<sup>\*2</sup>. <sup>1</sup>Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>GTx, Inc., Memphis, TN, USA.

Hypogonadism is a primary risk factor for male osteoporosis. Castrate levels of testosterone and estrogen are rapidly achieved and sustained in men undergoing androgen deprivation therapy (ADT) for prostate cancer. We conducted a prospective trial to determine whether or not toremifene, a SERM, prevents fractures in men on ADT. A total of 1389 men with prostate cancer were randomly assigned to receive 80 mg toremifene or placebo once daily for 24 months. All subjects were on ADT for ≥6 months, had a serum PSA ≤4 ng/mL, were ≥70 years of age or were at or below WHO thresholds for spine or hip bone mineral density at baseline. The primary endpoint was met with a 54% reduction in new onset morphometric vertebral fractures (MVF; p=0.032) in the intent-to-treat population. An analysis of serum markers of bone turnover revealed a marked suppression of bone specific alkaline phosphatase (bALP), osteocalcin (OC), and C-telopeptides (CTX) in subjects taking toremifene relative to placebo and baseline values. The most common adverse events were joint pain, dizziness, back pain, and extremity pain. In addition, we evaluated whether the serum markers of bone turnover could predict fracture risk. bALP exhibited significantly greater increases from baseline to months 12 and 24 (0.04±1.64, p=0.05 and 4.33±3.06, p=0.01, respectively) among those subjects with a MVF compared to subjects with no MVF. Subjects not experiencing a MVF showed a decrease in mean bALP from baseline to both 12 and 24 months (-1.91±0.42 and -3.73±0.35, respectively). Absolute changes in CTx from baseline to both 12 and 24 months differed significantly (p=0.04 and p=0.02, respectively) between subjects who incurred a MVF and those who did not. CTx increased nearly 14% from baseline to 24 months (p=0.02) in patients who incurred MVF. The prognostic significance of the absolute and percent change from baseline of the three bone turnover markers on the development of a MVF were evaluated in a Cox regression model as time dependent covariates. Increases in CTx were associated with a significantly (p<0.01) greater hazard for the development of a MVF. Percent increases in bALP, though not absolute change, were significantly associated with increased hazard for developing a MVF (p<0.01). Changes in OC were similar to those observed for other bone markers though results did not reach statistical significance. In conclusion, these data indicate that the serum bone turnover markers CTx and bALP predict fracture risk in men on ADT.

## 1293

**Trabecular Risk of Fracture, Caused by Disuse, is Strongly Influenced by Baseline Morphology.** E. Ozcivici, S. Judex. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

Genetic variations affect the magnitude of disuse induced bone loss. Here, a genetically heterogeneous mouse population was subjected to mechanical unloading to determine if specific aspects of the trabecular structure can predict changes in its mechanical properties when exposed to a strong catabolic stimulus (disuse). F2 female progeny of BALB (high mechanosensitivity) and C3H (low mechanosensitivity) inbred mouse strains (n=359) were hindlimb unloaded for 3 weeks. At baseline (16wk) and endpoint (19wk), the distal femoral metaphysis was scanned by in vivo microCT and converted into finite element models to simulate a uniaxial compression test. Disuse induced longitudinal changes in peak Von-Mises (VM) stresses were calculated for each mouse and stratified by their respective percentiles (Low Responders, LR: -10-14% change, n=54; Intermediate Responders, IR: 24-29% change, n=54; High Responders, HR: 42-92% change, n=54). F2 mice that were subjected to 3wk of hindlimb unloading lost 43% of their trabecular BV/TV, accompanied by losses in Conn.D, Tb.N, Tb.Th that amounted to 38%, 17%, and 18%, respectively (p<0.05). As a consequence of this deterioration, both peak stress levels and skewness of the stress distributions (an indicator of trabecular load bearing efficiency) increased by 27% and 104%, respectively (p<0.05). Disuse induced changes in peak stresses were normally distributed (R2>0.95). At baseline, no significant differences in trabecular structure were observed between the low (LR) and intermediate (IR) response groups. In contrast, those mice that experienced the greatest changes in VM stresses (HR) had significantly smaller BV/TV (-22%), Tb.N (-10%), and Tb.Th (-8%) than the IR group. Despite these differences in morphology, bone mechanical properties were similar between the three groups at baseline. Consistent with the changes in VM stresses, loss of BV/TV was much greater in HR mice (-58%) than in IR (-44%), or LR mice (-23%). Linear multiple regressions showed strong correlations between baseline Tb.Th and Conn.D and peak stresses altered by disuse (R2=0.70, 0.77 and 0.65 for HR, IR and LR respectively). This data indicate that peak stresses in healthy trabecular bone do not necessarily reflect the differences in its quantity and structure (i.e., connectedness, thickness and number). The results also demonstrate that a poor trabecular structure predisposes an individual to great tissue losses and a large increase in peak stresses upon the loss of weightbearing. Therefore, treatment of individuals with poor trabecular bone structures may also be protective against severe tissue losses caused by conditions like bedrest or space flight.

**Excessive Erythropoiesis Affects Bone Architecture.** G. Kuhn<sup>\*1</sup>, P. Schneider<sup>\*1</sup>, B. Schuler<sup>\*2</sup>, M. Meier<sup>\*1</sup>, J. Vogel<sup>\*2</sup>, R. Müller<sup>1</sup>. <sup>1</sup>Institute for Biomechanics, ETH Zurich, Zurich, Switzerland, <sup>2</sup>Institute for Veterinary Physiology, Vetsuisse-Faculty, University of Zurich, Zurich, Switzerland.

Excessive stimulation of hematopoiesis as found e.g. in polycythemia vera or erythropoietin (epo) treatment will cause an increase in space requirements and metabolic demands of red bone marrow. Expansion of hematopoietic tissue is limited by the surrounding bone. We investigated whether bone can adapt to increased marrow volume by increasing marrow spaces and to metabolic demands by allowing more vessels to penetrate the cortex.

Femur and sternum were obtained from male 12-13 week old transgenic mice (tg) that show an oxygen-independent constitutive over-expression of human epo cDNA, wild-type (B6) controls, and wild-type animals treated with the epo-analogue novel erythropoiesis stimulating protein (NESP) for 4 weeks. Hematocrit of the tg mice was 80% compared to 45% in controls and 69% in the NESP group. Synchrotron micro-computed tomography images were taken at the proximal femur, the femoral mid-diaphysis (42% femoral length) and the 3rd segment of the sternum and quantitatively analysed.

In both bones of tg animals we found either a high number of canals penetrating the cortex, or canals with very large diameters. Less and smaller canals were found in the controls. Preliminary quantitative analysis of the sternum showed a decrease in trabecular bone volume density by 40% and an increase in trabecular spacing by 50% in tg mice (Fig. 1a) compared to their wild-type control. Trabecular thickness was similar in both groups. Cortical thickness was significantly reduced in the femur shaft of tg animals. Areas of the femur shaft that were filled with trabecular bone in controls were devoid of trabeculae in tg mice (Fig. 1b). Values of the NESP-treated group were between controls and tg animals.

Our results show that chronic excessive erythropoiesis leads to an increase in marrow cavity volume with a concomitant reduction of cortical and trabecular bone as well as an increase in cortical porosity. One reason for inferior bone properties in tg animals might be increased intramedullary pressure due to the expansion of the red bone marrow. Angiogenesis might be stimulated to enable increased trafficking of erythrocytes and reticulocytes from bone marrow to peripheral circulation as well as by a high demand of protein, leading eventually to a higher vascularization of the cortex.

**Combined Effects of Irradiation and Unloading on Murine Bone.** E. R. Bandstra<sup>1</sup>, S. E. Riffle<sup>\*1</sup>, S. A. J. Lloyd<sup>\*1</sup>, J. S. Willey<sup>1</sup>, G. A. Nelson<sup>\*2</sup>, M. J. Pecaut<sup>\*2</sup>, T. A. Bateman<sup>1</sup>. <sup>1</sup>Bioengineering, Clemson University, Clemson, SC, USA, <sup>2</sup>Radiation Medicine, Loma Linda University, Loma Linda, CA, USA.

Radiation may have deleterious effects on the trabecular bone of astronauts in the spaceflight environment. Solar particle events have the ability to deliver 1 Gy of proton radiation. On long-duration missions, astronauts will be exposed to both radiation and microgravity, which is already a well-documented cause of bone atrophy. This study investigated the effects of whole body irradiation combined with skeletal unloading. Sixteen-week-old female C57BL/6 mice (n=15/group; 4 groups) were exposed to either 1 Gy of 250 MeV protons (IRR) or served as non-irradiated controls (NR). One day after exposure, half the irradiated mice and half the control mice were hindlimb suspended (HLS), with the remainder serving as normally loaded controls (LC). Mice were killed after 4 weeks of unloading. MicroCT analysis was performed on trabecular bone in the proximal tibia. Radiation treatment alone resulted in a significant loss of bone and deterioration of trabecular microarchitecture at 4 weeks (i.e., loss of vBMD). Similarly, HLS alone induced substantial deterioration of bone. HLS alone also resulted in increased circulating levels of TRAP5b at sacrifice. While IRR alone did not exhibit elevated TRAP5b at 4 weeks, HLS + IRR did result in an increase in TRAP5b relative to both non-irradiated control (P<0.01) and HLS alone (P=0.05). HLS + IRR resulted in generally lower values for BV/TV, Conn.D, vBMD, Tb.Sp, Tb.N, and SMI than both HLS and IRR independently. Overall, the combination of IRR + HLS resulted in greater bone loss and deterioration of trabecular microarchitecture than the two challenges separately. Although both skeletal challenges induced atrophy, bone loss due to HLS alone was substantially greater than IRR alone (i.e., a 90% lower vBMD relative to control for HLS vs. 16% lower vBMD for IRR). During spaceflight missions, astronauts typically lose on the order of 2.5% of trabecular bone per month. B6 are a low bone density mouse model, and thus small amounts of atrophy can be large percent bone loss. Future models of HLS + IRR would benefit from using animals with greater baseline amounts of trabecular bone. This would more appropriately model the skeletal challenges of combined microgravity and radiation experienced by astronauts in the spaceflight environment.

## 1296

**NanoCT Can be Used to Assess Mechanically Related Modelling and Remodelling in the Mouse Fibula.** L. Saxon<sup>1</sup>, P. L. Salmon<sup>2</sup>, A. Sasov<sup>\*2</sup>, L. Lanyon<sup>1</sup>. <sup>1</sup>Royal Veterinary College, London, United Kingdom, <sup>2</sup>SkyScan, Kontich, Belgium.

**Introduction:** Nondestructive imaging of bone structure at the material level including imaging of osteocyte lacunae requires submicron resolution. NanoCT is a high resolution CT imaging technique that images voxel dimensions down to less than 150 nanometers. Using this method we set out to determine whether it can detect changes in osteocyte number, the contours of bone formation/resorption surfaces, and cortical bone geometry in the externally loaded mouse fibula.

**Methods:** Female C57BL/6 mice (n=5) at 17 weeks of age underwent two weeks of mechanical loading using a non-invasive tibia/fibula loading model that has been reported previously. The right fibula was exposed daily to 10 minutes of dynamic axial loads and the left fibula served as an internal non-loaded control. At the end of the two weeks of loading, the mice were killed and the fibulae were extracted and stored in 70% alcohol. High-resolution nano-CT was used to scan a region 2-3mm distal from the tibia-fibula junction (SkyScan 2011; SkyScan, Kontich, Belgium) at 0.400 nm voxel size (emission spot size 300 nm).

**Results:** Two weeks of mechanical loading to the right fibula resulted in significant side-to-side differences in cortical bone geometry, bone remodelling and osteocyte lacunar morphometry. There was a substantial increase in fibular volume and outward expansion of the fibular periosteum. There was also a sizeable increase in medullary volume indicating endocortical resorption; the net result on cortical thickness was no change. Elevated fractal dimension (0-40 um range) in the right fibulas signified increased surface irregularity due to surface remodelling, and a sharp drop in TB.Pf to negative values indicated extensive concave surfaces associated with resorption. Extensive low-density formation sites were also visible on the surfaces of the loaded right, but not the left, fibulas. There was a doubling of the percent volume occupied by osteocyte lacunae. Osteocyte diameter increased while separation decreased. The number density of osteocyte lacunae per fibular volume increased as did the volume of individual lacunae, in the loaded compared to non loaded fibulas.

**Conclusion:** NanoCT appears to be an effective tool for quantifying osteogenic changes in response to a mechanical loading in the mouse fibula; these changes involve outward cortical expansion and an increase in osteocyte lacunar number density and size.

## 1297

**Loading Duration Influences the Degree of Inhibition of Bone Loss using Dynamic Muscle Stimulation in a Disuse Rat Model.** Y. Qin<sup>1</sup>, M. Malbani<sup>\*1</sup>, M. Shih<sup>2</sup>, W. Carroll<sup>\*2</sup>. <sup>1</sup>Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, <sup>2</sup>RS Medical, Inc., Vancouver, WA, USA.

Musculoskeletal adaptations to aging and disuse environment have significant physiological effects on skeletal health, i.e., osteopenia and bone loss. Muscle stimulation (MS) via contractions has been shown to promote blood flow to bone, possibly by creating a pressure gradient within the microvasculature. The overall hypothesis for this study is that dynamic MS can enhance anabolic activity in bone, and inhibit bone loss in a functional disuse condition. Using a hindlimb suspension (HLS) rat model, electro-induced dynamic MS was applied as replacement of the normal weight-bearing activity of the hindlimb with two skin patch electrodes at the right quadriceps muscles for total of 30 animals. The stimulus was applied at 115 mA, 71 Hz, 0.2 ms pulse with 3s on and 8s rest. The animals were divided into six groups (5 per group), including 1) baseline control, 2) age-matched control, 3) hindlimb suspended (HLS) sham control, 4) HLS+10 min MS, 5) HLS+30 min MS, 6) HLS+60 min MS, 5days per week, for a total of 4weeks. Left and right femurs were harvested for micro-computed tomography analysis. Distal metaphyseal regions and one epiphyseal region of the femurs (0.75mm per region) were scanned at 15µm resolution and evaluated to obtain bone volume fraction (BV/TV), connectivity (Conn.D), and trabecular number (Tb.N). Disuse alone generated significant bone loss (-49.03% BV/TV, p=0.007, -58.55% Conn.D, -23.74% Tb.N, comparing to the age-match control). Dynamic muscle contraction at 30 min demonstrated anabolic effects at the metaphyseal regions (52.72% BV/TV, p=0.24, 76.38% Conn.D, 11.97% Tb.N, when comparing to the average HLS sham control). MS at 10 min showed a lesser response (7.31% BV/TV, 23.89% Conn.D, 3.17% Tb.N). The most significant response occurred at 60 min MS loading [103.43% BV/TV (p=0.003, Fig. 1), 164.65% Conn.D, 22.35% Tb.N]. These results demonstrated that dynamic electro-induced muscle contraction can indeed initiate adaptive response to inhibit bone loss under functional disuse environment with a dose dependent pattern, in which 60 min low-energy contraction is able to recover 100% of bone loss induced by disuse. These preliminary data suggest that low-level bone strain and/or increased fluid pressure induced by MS may be crucial factors in musculoskeletal tissue remodeling.

## 1298

**Dependence of Endosseous Implant Anchorage on Mechanostructural Determinants of Peri-implant Bone Trabeculae.** Y. Gabet<sup>\*1</sup>, R. Voide<sup>\*2</sup>, T. L. Mueller<sup>\*2</sup>, D. Kohavi<sup>\*3</sup>, R. Müller<sup>2</sup>, I. Bab<sup>1</sup>. <sup>1</sup>Bone Laboratory, Institute for Dental Sciences, Faculty of Dental Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel, <sup>2</sup>Institute for Biomechanics, ETH Zürich, Zürich, Switzerland, <sup>3</sup>Oral Implant Center, Hebrew University-Hadassah School of Dental Medicine, Jerusalem, Israel.

Low bone mass is highly prevalent among patients receiving endosseous implants. In turn, the implantation prognosis in low density skeletal sites is poor. However, little is known about the mechanostructural determinants of the implant anchorage. Using metabolic manipulations that lead to low bone density and to its rescue, we show here critical anchorage dependence on the peri-implant bone (PIB). Titanium implants were inserted horizontally into the proximal tibial metaphysis of adult rats, 6 weeks postorchietomy (ORX) or sham-ORX. Systemic intermittent administration of parathyroid hormone iaPTH(1-34) or vehicle commenced immediately thereafter for 6 weeks. Implant anchorage was analyzed using micro-image guided failure assessment

(µIGFA) in pullout, which allows concomitant high resolution analysis of failure initiation and progression combining 3D µCT imaging and biomechanical testing. Reactive forces in the cortex were negligible. Failure of implant anchorage occurred mainly at the thinnest segment of individual trabeculae, 0.5-1.0 mm away from the implant. ORX-induced low density trabecular bone showed the poorest biomechanical properties, due mainly to decreased trabecular number. It presented the highest intratrabecular and lowest osseointegration (OI, bone-implant bonding) failure rates. Treatment with iaPTH(1-34) induced supranormal increases in bone density and biomechanical parameters. The increases in trabecular thickness (Tb.Th) and OI in these animals were of a similar magnitude and were associated with a remarkable shifting of failure to the OI. A particularly tight correlation was found between the Tb.Th and all the biomechanical parameters ( $r^2 = 0.862$ ,  $r^2 = 0.823$ ,  $r^2 = 0.737$  for ultimate force, stiffness and toughness, respectively). iaPTH(1-34) did not affect the trabecular number. These results provide a direct link between bone quality and its importance in determining implant mechanics, thus supporting a model wherein the anchorage failure involves buckling of the weakest trabeculae followed by a "domino reaction" leading to PIB collapse. iaPTH(1-34) minimizes this reaction thus portraying Tb.Th as a target for enhancing implant anchorage.

## 1299

**Microdamage Repair and Remodeling Requires Mechanical Loading.** E. I. Waldorff<sup>\*1</sup>, K. B. Christenson<sup>\*1</sup>, L. A. Tesmer<sup>\*2</sup>, S. A. Goldstein<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>Rheumatology, University of Michigan, Ann Arbor, MI, USA.

Prior work demonstrates that bone remodeling in response to fatigue microdamage is altered with age, which may increase fracture risk. Furthermore, bone loss associated with aging may result from disuse due to reductions in physical activity or infirmity. The purpose of this study was to examine the effects of disuse on bone remodeling in response to microdamage, potentially providing clinically important insight into the relationship between microdamage accumulation and increased fracture risk in the elderly.

At day 0, 120 male 6-month old Sprague Dawley rats were assigned to 1 of 2 groups: weight-bearing (WB) or hindlimb suspension (HS). Within each group, the rats were further divided into 3 subgroups (n=20), corresponding to 3 sacrificial times (day 14, 18 or 35). At day 14, animals were anesthetized and their left tibia underwent cyclic 4-point bending in order to produce fatigue-induced microdamage (7200 cycles at 2 Hz, -7000 microstrain max. at the lateral mid-diaphysis for both WB and HS). At sacrifice, right/left pairs of tibiae were assigned to 1 of 3 treatments within each subgroup: flow cytometry for HSC and monocyte markers (n=6), basic fuchsin staining for microdamage assessment (n=7), or ELF97 (TRAP) fluorescent staining (n=7). Prior to staining, morphologic analysis was conducted on the last two groups using 3D microCT.

Morphologic examinations revealed that the damage induced a stress fracture response, which at day 35 resulted in a sig. increase in woven bone apposition for both WB and HS, with the WB group being sig. greater than the HS group. At day 35, the WB group had a sig. decrease in microdamage, while the HS group showed no change in damage remaining from day 14. Flow cytometry indicated that a shift in the osteoclast lineage had occurred due to an increase of HSCs, and a decrease of monocytes in the damaged leg for WB compared to HS at day 35. HS showed no difference between contralateral tibiae for both flow cytometry markers at any time points, indicating that the histological evidence of "no damage removal" at day 35 for HS was due to a lack of osteoclast activation, and not a change in the targeting mechanisms of remodeling.

This study demonstrated that disuse alters the microdamage response through a reduction in woven bone production and the lack of resorption of microdamage. The data suggests that elderly individuals with severe activity reductions may further accumulate microdamage. Most importantly, while a variety of studies have proposed that the repair of microdamage is triggered by cell apoptosis, these results suggest this mechanism may be insufficient without the stimulus associated with mechanical usage.

**Lovastatin Best Enhances Fracture Repair When Administered One Week Post-Fracture.** G. E. Gutierrez<sup>1</sup>, J. S. Nyman<sup>2</sup>, S. A. Munoz<sup>\*1</sup>, S. B. Jadhav<sup>\*1</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Center for Bone Biology, Vanderbilt University and Medical Center, Nashville, TN, USA, <sup>2</sup>Orthopaedics, Vanderbilt University and Medical Center, Nashville, TN, USA.

Statins stimulate osteoblast differentiation by their effects on BMP2 gene transcription. Retrospective clinical studies and animal models have suggested that statins may increase bone mineral density and reduce the risk of osteoporosis and fractures (Bauer DC, 1999).

The purpose of this study was to determine whether lovastatin (LV), when administered locally and/or systemically at the time of fracture or one week later, could positively affect bone healing using a closed femoral fracture model in rats.

Methods: Femoral fractures were created, following intramedullary pinning in rats. Groups (n=12) included vehicle-treated (veh), and LV IM (1.5-1500 µg) administered once within 2 hours of fracture in a) close proximity to the fracture site (ipsilateral), b) in the contralateral limb, and c) ipsilateral one week after fracture (delayed). Radiographs were taken at day 0, 14 and 28 days after procedure. Animals were euthanized at day 28 and femora harvested for biomechanical testing and µCT.

Results: Compared to veh, radiographs showed increased bridging at the cortices with LV treatment at 2 and 4 weeks even when LV was administered in the contralateral side. By biomechanical testing, there was a dose-response increase in maximal force and stiffness (up 41% and 46% respectively when compared to veh) in bones treated with LV, and this increase was enhanced when administered one week after fracture (16% vs. 42% with 150

ug LV). There was also a positive effect when LV was injected in the contralateral side.  $\mu$ CT images showed a decrease in gaps within the bridging cortices of the callus when treated with LV (up to 26.4% improvement) and with delayed treatment (46.9% improvement) which correlated with the increases in biomechanical strength ( $r=0.56$ ). These results demonstrate that a single sustained-release injection of LV accelerates femoral fracture repair locally and systemically in rats, and that this effect is enhanced when LV is administered one week after fracture. It has been previously shown that fracture induces endogenous expression of BMP2 with maximal peak at one week. The delayed effect reported here may be due to LV inducing higher levels of BMP2 expression beyond one week with the consequent acceleration of fracture healing.

A pharmaceutical agent capable of accelerating fracture healing in patients, improve their outcome and quality of life, even when administered systemically, will be an important advance in orthopaedics and may be beneficial for other applications where BMP2 has been shown to be efficacious.

### BMP-2 Stimulates a Feedback Activation loop for Expression of NFATc1 in Osteoblasts. C. C. Mandal<sup>1</sup>, G. G. Choudhury<sup>\*2</sup>, N. Ghosh-Choudhury<sup>3</sup>.

<sup>1</sup>Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>2</sup>Medicine, Nephrology, University of Texas Health Science Center at San Antonio and South Texas Veterans Health Care System, San Antonio, TX, USA, <sup>3</sup>Pathology, University of Texas Health Science Center at San Antonio and South Texas Veterans Health Care System, San Antonio, TX, USA.

Bone remodeling is controlled by dual actions of osteoclasts and osteoblasts (OB). The calcium sensitive NFATc1 transcription factor, as an osteoclast signature gene, regulates its differentiation downstream of BMP-2-stimulated osteoblast-coded protein factors. Whether NFATc1 has any role in osteoblasts is yet to be confirmed. We showed that BMP-2, via receptor-specific Smad pathway, regulates delayed early expression of NFATc1 in osteoblasts. Under basal condition, NFATc1 is phosphorylated. Activation of NFAT requires dephosphorylation by calcium-dependent serine threonine phosphatase, calcineurin. We examined the role of calcium in BMP-2-stimulated regulation of NFATc1 in osteoblasts. BMP-2 induced calcium release from intracellular stores, as measured by Fura-2 fluorescence. BMP-2-stimulated intracellular calcium increased calcineurin phosphatase activity, which dephosphorylated NFATc1, resulting in its nuclear translocation. Since NFATc1 is expressed as a delayed early gene product in response to BMP-2, we tested the hypothesis whether a feedback loop regulates its expression. Immunosuppressant cyclosporine A (CSA), which inhibits calcineurin upstream of NFAT, blocked BMP-2-induced NFATc1 mRNA and protein expression, as determined by real time qRT-PCR and immunoblotting. Also, VIVIT peptide, an inhibitor of NFATc1, suppressed BMP-2-stimulated NFATc1 mRNA and protein expression. To directly investigate the involvement of NFATc1 in its expression, we used the NFATc1 promoter-driven luciferase reporter construct. BAPTA-AM, an inhibitor of calcium abundance blocked BMP-2-induced transcription of NFATc1. Expression of NFATc1 increased NFATc1 transcription. CSA as well as expression of VIVIT peptide inhibited transcription of NFATc1 in response to BMP-2, indicating the action of a feedback activation loop in expression of this transcription factor. Genomatix search of the 5' flanking sequence of NFATc1 revealed the presence of an NFAT binding site in its promoter. To test the function of this NFAT element, we performed electrophoretic mobility shift assay using nuclear extracts from BMP-2-treated OB in the presence of this DNA sequence. BMP-2 increased protein-DNA complex formation, which was inhibited by excess cold element, indicating specificity. Together these data for the first time demonstrate the presence of an NFATc1 autoregulatory loop in BMP-2-stimulated osteoblasts.

### GPRC6A Null Mice Exhibit Osteopenia and Feminization. M. Pi<sup>1</sup>, L. Chen<sup>\*1</sup>, M. Huang<sup>\*1</sup>, W. Zhu<sup>\*1</sup>, B. Ringhofer<sup>\*1</sup>, J. Luo<sup>\*1</sup>, L. Christenson<sup>\*1</sup>, B. Li<sup>\*1</sup>, H. Zhang<sup>2</sup>, P. D. Jackson<sup>\*3</sup>, P. Faber<sup>\*3</sup>, K. R. Brunden<sup>\*3</sup>, J. J. Harrington<sup>\*3</sup>, L. D. Quarles<sup>1</sup>.

<sup>1</sup>Kidney Institute, Department of Medicine, KUMC, Kansas City, KS, USA, <sup>2</sup>Clinical Pharmacology, Vanderbilt University, Center for Bone Biology, Nashville, TN, USA, <sup>3</sup>Athersys, Inc, Cleveland, OH, USA.

GPRC6A is a widely expressed orphan G-protein coupled receptor that senses extracellular amino acids, osteocalcin and divalent cations *in vitro*. To determine the function of this receptor *in vivo*, we characterized the phenotype of GPRC6A null (GPRC6A<sup>-/-</sup>) mice. We observed a complex phenotype in GPRC6A<sup>-/-</sup> mice involving multiple organ systems. In this regard, we observed a decrease in bone mineral density (BMD) due to decreased mineralization of extracellular matrix, decreased lean body mass. In addition, we observed feminization of male GPRC6A<sup>-/-</sup> mice in association with increased circulating levels of estradiol, and reduced levels of testosterone. The bone phenotype appears to be due, at least in part, to a primary effect of GPRC6A on osteoblasts, since bone marrow stromal cell cultures and primary osteoblasts derived from GPRC6A<sup>-/-</sup> mice displayed a marked attenuation of extracellular calcium-stimulated ERK activation, diminished alkaline phosphatase expression and impaired mineralization *ex vivo*. The absence of GPRC6A was not associated with changes in serum TRAP, FGF23, PTH, calcium, 1,25(OH)<sub>2</sub>D levels or urine Dpd/Cr ratio. These data indicate that GPRC6A participates in the regulation of osteoblast-mediated bone mineralization and steroid biosynthesis, as well as other tissue-specific functions. The overall function of this receptor may be to mediate the anabolic effects of extracellular amino acids, osteocalcin and divalent cations in multiple tissues.

## F006

### The Adipocyte-secreted Protein URB Is a Potent Stimulator of Bone Formation. F. Tremblay<sup>\*1</sup>, S. Fukayama<sup>2</sup>, C. Huard<sup>\*3</sup>, R. X. Martinez<sup>\*3</sup>, R. Gimeno<sup>\*1</sup>. <sup>1</sup>Cardiovascular and Metabolic Diseases, Wyeth Research, Cambridge, MA, USA, <sup>2</sup>Women's Health and Musculoskeletal Biology, Wyeth Research, Cambridge, MA, USA, <sup>3</sup>Biological Technologies, Wyeth Research, Cambridge, MA, USA.

Osteoblasts (OBs) and bone marrow adipocytes share common progenitor cells. Increasing evidence suggests that these cells reciprocally regulate their functions via actions of secreted factors. Adipose tissue secretes a variety of factors, collectively named "adipokines" including leptin, adiponectin, PAI-1 or TNF- $\alpha$ . For example, it has been shown that leptin plays a pivotal role in bone metabolism. Conversely, it has recently been proposed that osteocalcin, a major OB-specific secreted protein, may have regulatory roles in energy metabolism. Together, it is an area of intense investigation to identify new adipokines and to characterize their functional roles in different target tissues. Using a combination of transcriptional profiling and bioinformatic analysis, we have identified expression of Urb as a ~150 kDa secreted protein in both human and mouse adipose tissues. Temporal analysis of Urb expression in mouse-adipose-like cell line, 3T3-L1, revealed a biphasic pattern with high mRNA levels in fully differentiated adipocytes. Expression of Urb in white adipose tissue was significantly decreased upon fasting and also was decreased in ob/ob mice. Treatment of ob/ob mice with insulin sensitizing agent rosiglitazone reversed the down-regulation of Urb. Using *ex vivo* neonatal calvaria organ culture, we next examined possible functional roles for Urb in bone formation/resorption. Incubation with 1% or 5% Urb conditioned medium (CM) for 7 days resulted in significant increase in total bone area (TBA) by 50-80%. Although the number of OBs was not altered, OBs became cuboidal in shape, suggesting that they were activated. Similar osteogenic actions/activities were observed when calvaria were incubated with FLAG-purified Urb protein. Histologically, enhanced bone resorption also was evident. Adenovirus-mediated gene transfer of Urb also induced similar calvarial responses. To investigate in more detail the mechanism(s) by which Urb protein stimulates bone formation, we next performed expression profiling studies using RNA samples prepared from calvaria after incubation with Urb protein for 4 days. Over 1,700 transcripts were modulated ( $P \leq 0.01$ ). Among all, we are currently evaluating functional significance of 38 genes in the osteogenic actions/activities of Urb.

We conclude Urb protein enhances bone remodeling (both bone formation and bone resorption) in favor of bone formation. Urb protein *per se* and/or modulation of its signaling pathways should enable us design treatments for bone disorders where bone formation lags behind bone resorption such as osteoporosis.

### Osterix, a Positive Regulator in Adult Bone Formation. W. Baek<sup>\*1</sup>, M. Lee<sup>\*1</sup>, J. Oh<sup>\*1</sup>, S. Kim<sup>2</sup>, H. Akiyama<sup>\*3</sup>, B. de Crombrughe<sup>4</sup>, J. Kim<sup>1</sup>.

<sup>1</sup>Department of Molecular Medicine, CMRI, Kyungpook National University School of Medicine, Daegu, Republic of Korea, <sup>2</sup>Skeletal Diseases Genome Research Center Kyungpook National University Hospital, Daegu, Republic of Korea, <sup>3</sup>Department of Orthopaedics, Kyoto University, Kyoto, Japan, <sup>4</sup>Department of Molecular Genetics, University of Texas M. D. Anderson Cancer Center, Houston, TX, USA.

The transcription factor Osterix (Osx) is essential for osteoblast differentiation and bone formation, as mice lacking Osx die within an hour of birth with a complete absence of intramembranous and endochondral bone formation. Perinatal lethality by Osx gene disruption prevents the study for the role of Osx in bones that are growing or already formed. Here, the function of Osx was examined in developing bones at adults after bone collar formation using the time-specific and site-specific Cre/loxP system. Osx was inactivated in all osteoblasts by Col1a1-Cre with the activity of Cre recombinase under the control of 2.3-kb collagen promoter. Even though no bone defects were shown in newborn, Osx inactivation exhibited dramatically reduced bone phenotypes in growing mice. Bone mineral density and bone forming rate were decreased in vertebra lumbar of Osx-inactivated mice with Col1a1-Cre (Osx<sup>lox/+</sup>;Col1a1-Cre). Moreover, the thinner and more porous cortical bone of the diaphysis region of long bones was observed with the reduction of bone length. The increased trabecular bones were investigated but they were immature or premature. However, no functional defects were found in osteoclasts. The expression of early marker genes for osteoblast differentiation such as Runx2, osteopontin, and alkaline phosphatase (ALP) was markedly increased in Osx<sup>lox/+</sup>;Col1a1-Cre mice. On the other hand, late marker gene, osteocalcin was decreased. We propose that Osx inactivation in growing bones delayed osteoblast maturation, accumulated immature osteoblasts, and finally, reduced osteoblast function for bone formation, without apparent defects in bone resorption. Thus, these findings suggest that Osx plays a significant role in positively regulating osteoblast differentiation and bone formation in adult bone.

**Inactivation of Dlx5 Gene Results in Altered Osteoblast-osteoclast Coupling Inducing Increased Bone Resorption and Reduced Cortical Thickness in Male Mice.** N. M. Samee<sup>\*1</sup>, V. Geoffroy<sup>1</sup>, C. Marty<sup>\*1</sup>, C. Schiltz<sup>\*1</sup>, M. Vieux-Rochas<sup>\*2</sup>, G. Levi<sup>\*2</sup>, M. C. de Vernejoul<sup>1</sup>. <sup>1</sup>INSERM U606, Paris, France, <sup>2</sup>CNRS UMR5166, Paris, France.

Dlx5 is an homeodomain transcriptional factor expressed in osteoblasts. Dlx5 inactivation in mice induces perinatal lethality. We investigated its function in late osteogenesis and bone remodelling in Dlx5-null mice at the end of gestation and in Dlx5 heterozygous adult mice using *in vivo* and *in vitro* approaches. Femurs of 18.5 dpc Dlx5-null mice exhibited a reduction of the total (Total BV/TV -21.4% ;  $P < 0.05$  ,  $n = 5$ ) and trabecular bone volume associated with increased trabecular separation and reduced trabecular number. Calvaria-derived Dlx5-/- osteoblasts displayed a reduced proliferation rate, a delayed differentiation state and a severe reduction of Runx2, Osterix, Osteocalcin and Bone Sialoprotein expression. In addition to the impaired osteoblast function that was demonstrated *in vitro*, we observed that Dlx5-/- femora exhibited an increase in osteoclasts number *in vivo*. As Dlx5 is not expressed by osteoclasts, we hypothesized that its expression in osteoblast could be involved in the control of osteoblast/osteoclast coupling. Cultured Dlx5-/- osteoblasts displayed a higher RANKL/OPG mRNA ratio and co-cultured Dlx5-/- osteoblasts with normal spleen cells induced a higher number of TRAP-positive multinucleated cells with an increased resorption pits area (Dlx5-/- :  $1534 \pm 119 \mu m^2$  versus Dlx5+/+ :  $680 \pm 32 \mu m^2$ ;  $n = 4$  wells). In 10- and 20-week-old adult mice, Dlx5 was still expressed at high levels in long bones. Bone mineral density (BMD) measured at the femurs of 10-week-old mice was lower in male Dlx5+/+ mice (-7.8%;  $P < 0.05$ ;  $n = 14$ ) but not in Dlx5+/- females compared to wild-type mice.  $\mu$ CT and histomorphometry analyses showed that the cortical thickness at the midshafts of Dlx5+/- male femurs was significantly lower (-14%;  $P < 0.01$ ,  $n = 13$ ) while no modifications of the micro-architecture were observed in trabecular bone. Unexpectedly, the cortical decrease was the result of an increased marrow diameter with a significantly higher number of endosteal osteoclasts per bone surface. Furthermore, the urinary level of deoxypyridinoline confirmed an increased bone resorption in Dlx5+/- male compared to WT male ( $29.7 \pm 3.12$  nmol /v/s  $22.1 \pm 1.46$  nmol;  $P < 0.05$ ). In conclusion, we show that the total or partial inactivation of Dlx5 triggered a bone phenotype resulting from an altered osteoblast/osteoclast coupling inducing an increased resorption activity. Moreover, Dlx5 significantly interferes with long bones remodelling mainly affecting the cortical thickness in adult male mice.

**Mice Lacking NMDA Receptor Expression in Osteoblasts Have Pronounced Vertebral Bone Abnormalities.** S. Martinez-Bautista<sup>\*</sup>, N. Wang<sup>\*</sup>, G. Richards<sup>\*</sup>, T. M. Skerry<sup>\*</sup>. Clinical Sciences (South), School of Medicine and Biomedical Sciences, University of Sheffield, Sheffield, United Kingdom.

Cell-cell communication underlies the way in which populations of different cells interact in bone to regulate skeletal architecture and mass. For some years glutamate has been proposed as a signalling molecule in the skeleton because of demonstrations of expression of numerous components of glutamatergic synapses by bone cells, and effects of chemical antagonists on osteoblast and osteoclast function *in vitro*. However, the physiological role of glutamate has been hard to establish because full knockout animals have lethal phenotypes due to marked anomalies in brain function while most chemical antagonists administered *in vivo* have significant side effects because of their actions on the brain.

We obtained mice expressing the Cre recombinase under the control of the osteocalcin promoter, and others in which the obligatory NMDA type glutamate receptor subunit Grin1 had been flanked by lox-p sites. These mice were crossed to generate double heterozygotes, and then intercrossed to produce offspring with Cre<sup>+</sup>Grin1<sup>lox/lox</sup> genotypes, in which NMDA receptor expression in osteoblasts was effectively abrogated. Analysis has been performed by staining pups at term and by microCT measurements of pups and young adult skeletons ( $n = 4$  at different ages up to 4 months). Osteoblast specific deletion of a functional NMDA receptor results in mice with normal viability and size. While their long bones have slightly reduced trabecular bone mass and thickness, the most profound effects is that their lumbar vertebrae have dramatic reductions in bone volume of over 50%. Preliminary data suggests that the compressive strength of the vertebrae in mice lacking NMDA receptor expression is reduced dramatically. We interpret our current data to show that glutamate plays a significant role in vertebral bone formation in young mice. The effect of the deletion on bone at greater ages and on bone's response to challenge is yet to be determined, but this existing insight into a site specific difference between vertebral and long bone properties could be of considerable importance clinically.

**CNBP Conditional Knockout Mice Show Severe Osteoporosis-like Phenotype.** S. Yang<sup>1</sup>, W. Chen<sup>\*1</sup>, L. Chen<sup>\*2</sup>, N. Li<sup>\*2</sup>, Y. Li<sup>1</sup>. <sup>1</sup>The Forsyth Institute-Harvard School of Dental Medicine, Boston, MA, USA, <sup>2</sup>The Forsyth Institute, Boston, MA, USA.

At any particular age and phase of life, genetic factors explain about 70% of the variance in bone phenotype after adjustment for major medical and disease factors. However, the genes underlying the genetic syndromes of osteoporosis remain largely unidentified. In order to identify genes that are important for bone formation and may be related to the genetic syndromes of osteoporosis, we have cloned a number of transcription factors that are predominately expressed in osteoblasts using Rat osteoblast cDNA differential screening. One of these transcription factors is a zinc-finger protein, cellular nucleic acid binding protein (CNBP). We found that CNBP is first expressed in early osteoprogenitor cells. Subsequently, CNBP is expressed throughout the osteoblast lineage, including osteocytes. We have generated CNBP null mutant mice. However, homozygous mutants die around E10.5 with forebrain truncation, which precludes the study of CNBP function in bone formation. To study CNBP function in bone development, we have generated conditional CNBP knockout mice (CNBP<sup>CNBP/Coll 1-Cre</sup>) by using bone tissue-specific targeted disruption of the CNBP gene using Cre/loxP technology. Bone tissue-specific targeted disruption of the CNBP gene was attained using the  $\alpha 1(I)$  collagen promoter to drive Cre expression, which allows us to examine the role of CNBP in osteoblast differentiation after birth *in vivo*. CNBP<sup>CNBP/Coll 1-Cre</sup> mice are viable, but are smaller in size with severely bended vertebral bone. Histological analysis and morphological analysis of the CNBP<sup>CNBP/Coll 1-Cre</sup> mice indicate that the mutant mice have severe skeletal defects both in newborn and adult mice. X-Ray examination and Micro-CT determination show that the mutant mice have lower bone density when compared to wild-type mice, suggesting an osteoporosis-like phenotype. Our results demonstrate that CNBP is essential to bone formation and mutation or change in expression level of CNBP may contribute the genetic syndromes of osteoporosis. This knowledge may be applied towards the development of new diagnostic and therapeutic alternatives for human osteoporosis.

**Regulation of the Osteoblast-Specific Transcription Factor Osterix by NO66, a Jumonji Family Histone Demethylase.** K. M. Sinha<sup>\*1</sup>, H. Yasuda<sup>\*1</sup>, M. M. Coombes<sup>\*2</sup>, S. Y. R. Dent<sup>\*2</sup>, B. de Crombrughe<sup>1</sup>. <sup>1</sup>Molecular Genetics, M.D. Anderson Cancer Center, Houston, TX, USA, <sup>2</sup>Biochemistry and Molecular Biology, M.D. Anderson Cancer Center, Houston, TX, USA.

Osterix (Osx) is an osteoblast-specific transcription factor required for osteoblast differentiation and bone formation. Osx null mice have a normal cartilage skeleton but fail to form bone or to express osteoblast-specific marker genes. To better understand the control of transcriptional activation by Osx, we identified Osx-interacting proteins using affinity purification techniques. Here we report that a Jumonji C (JmjC)-domain containing protein, NO66, interacts with Osx in osteoblast cells. NO66 is expressed in all developing bones. Interactions between NO66 and Osx inhibit gene activation by Osx. Knockdown of NO66 in osteoblast cells triggers accelerated osteoblast differentiation and mineralization as well as a marked stimulation in expression of Osx target genes including *Coll1a1*, *Osteocalcin* and *Bone sialoprotein* (*Bsp*). NO66 exhibits a JmjC-dependent histone demethylase activity that affects both H3K4me and H3K36me *in vivo* and this activity is required for inhibition of transcriptional activation by Osx. Osx and NO66 colocalize at the *Bsp* promoter in undifferentiated preosteoblasts. BMP-2-induced differentiation of these cells causes a marked decrease in NO66 occupancy and an increase in trimethylation of H3K4 and H3K36 in the *Bsp* gene. Our results provide the first evidence that NO66 serves as a negative regulator of Osx target genes in osteoblasts by modulating histone methylation states.

**BMP2 Induces Osterix Expression through Up-regulation of Dlx5 and Its Phosphorylation by p38 MAPK.** M. J. Ortuño<sup>\*1</sup>, A. Ulsamer<sup>\*1</sup>, S. Ruiz<sup>\*1</sup>, A. R. G. Susperregui<sup>1</sup>, N. Osses<sup>\*2</sup>, J. L. Rosa<sup>\*1</sup>, F. Ventura<sup>\*1</sup>. <sup>1</sup>Barcelona University, Barcelona, Spain, <sup>2</sup>Pontificia Universidad Católica Valparaíso, Valparaíso, Chile.

Osterix (Ox) and Dlx5 are two of the osteoblast master transcription factors induced by bone morphogenetic protein-2 (BMP2) during osteoblast differentiation. Ox is a zinc-finger transcription factor specifically expressed in osteoblast and osteocytes of developing bones. Because no bone formation occurs in Ox-null mice, Ox is thought to be an essential regulator of osteoblast differentiation. Dlx5 is a homeobox-containing transcription factor expressed in developing skeletal elements. Dlx5-null mice have a delayed cranial ossification and abnormal osteogenesis, suggesting it also plays an important role in osteoblast differentiation. We report that BMP2 induces transcriptional activation of Ox through a homeobox sequence located in the proximal promoter region. Our results demonstrate that in response to BMP2, Dlx5 expression precedes Ox expression. In addition, Dlx5 binds to BMP2-responsive homeobox sequence both *in vitro* and *in vivo*. Finally, Dlx5 overexpression assays show its role in BMP2-dependent Ox expression. These data strongly suggest that Dlx5 is essential to mediate Ox expression by BMP2. Furthermore, we demonstrate that Dlx5 is a novel target of p38 MAPK, which has been shown to be relevant for osteogenic effects of BMP2. Our results show that Dlx5 is substrate for p38 both *in vitro* and *in vivo* and that Ser34 and Ser217 are the sites phosphorylated. The phosphorylation by p38 at Ser34/217 enhances Dlx5 transcriptional activity increasing Ox expression. Thus, we propose a novel activation mechanism of Dlx5 by BMP2 through p38-induced Dlx5 phosphorylation and its further transcriptional activity inducing Ox expression.

## F024

**Overexpression of Glutathione Reductase in Osteoblasts Decreases Bone Formation and Partially Prevents Ovariectomy-induced Bone Loss.** M. Almeida, E. Ambrogini, M. Martin-Milla, L. Han, A. Warren<sup>\*</sup>, R. S. Shelton<sup>\*</sup>, J. Goellner, R. S. Weinstein, R. L. Jilka, C. A. O'Brien, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Loss of bone mass in mice either with advancing age or following gonadectomy is associated with increased oxidative stress, as well as increased osteoblast and osteocyte apoptosis; and administration of the antioxidant N-acetyl-cysteine (NAC) prevents all these changes in gonadectomized animals. Moreover, H<sub>2</sub>O<sub>2</sub> stimulates osteoblastic cell apoptosis *in vitro*, suggesting a direct effect of oxidative stress in these cells. To establish that oxidative stress influences the biology of osteoblasts in a cell autonomous manner *in vivo*, we have generated mice overexpressing the human form of the peroxide scavenging enzyme glutathione reductase (GSR) gene selectively in osteoblastic cells, using the 3.6 kb sequence of the rat collagen type 1A1 promoter (3.6Col1A1). Bone specific expression of the transgene was confirmed by RT-PCR in vertebrae and femurs, as well as in osteoblasts derived by culturing bone marrow cells in the presence of ascorbic acid. In addition, GSR activity was increased in both calvaria and bone marrow derived osteoblasts from transgenic animals. Moreover, Col-GSR female mice exhibited a decrease of BMD in the spine and femur at 2, 3, 4, 5, and 6 months of age, raising the possibility that lowering ROS with the transgene attenuated osteoblastogenesis. In support of this contention, administration of NAC for 28 d to 5 month-old C57BL/6 mice decreased osteoblastogenesis, as measured by the number of colony forming units-osteoblasts in *ex vivo* bone marrow cultures. Moreover, cell proliferation of three different osteoblastic cell models (OB-6, 2T3, and MC3T3) was attenuated after 3 d of culture in the presence of 1 nM NAC as determined by BrdU incorporation. Lastly, the loss of bone following 6 wk of OVX of 6 month-old mice was partially prevented in Col-GSR mice, as compared to the wt controls, perhaps reflecting attenuation of OVX-induced osteoblast apoptosis by the transgene. In agreement with this mechanistic scenario, bone marrow stromal cells from Col-GSR mice, cultured for 15 d in the presence of ascorbic acid, where protected against H<sub>2</sub>O<sub>2</sub>-induced apoptosis, as determined by caspase 3 activity. Collectively, these findings support our working hypothesis that at low levels intracellular H<sub>2</sub>O<sub>2</sub> is an important signal for the replication of osteoblast precursors while at high levels it promotes osteoblast apoptosis, as is the case in most other cell types including stem cells (Nature Reviews, 8:722, 2007).

**Fibroblast Growth Factor 2 Signaling in Osteoblasts: Connexin43 is a Docking Platform for Protein Kinase C delta.** C. Nigier, F. Lima, J. P. Stains. Orthopaedics, University of Maryland, Baltimore, MD, USA.

Gap junctional intercellular communication (GJIC) permits the direct transfer of small molecules between adjacent cells. We have previously shown that the gap junction protein, connexin43 (Cx43), plays a role in regulating signaling and transcriptional responses in osteoblasts. Recently, we have reported that increasing GJIC through Cx43 overexpression enhances the transcription response of the osteocalcin promoter to fibroblast growth factor 2 (FGF2) treatment. Conversely, an attenuation of the transcriptional response to FGF2 is observed when endogenous Cx43 is knocked down using siRNAs. A role for Cx43 as a docking platform for signal transduction machinery has begun to emerge in many cell types. In this study, we hypothesize that Cx43 influences the FGF2 responsiveness of cells by recruiting the signaling machinery to the gap junction plaque, where it acts to amplify signals initiated in one cell into adjacent, gap junctionally coupled cells. Accordingly, we have examined the protein-protein interactions that occur between Cx43 and downstream signal transducers of the FGF response in MC3T3 cells. We reveal that the effects of Cx43 on FGF2 signaling in osteoblasts are mediated by protein kinase C delta (PKCδ), as we can abrogate the synergistic effects of FGF2 and Cx43 using the inhibitor, rottlerin, or siRNAs against PKCδ. By immunoprecipitation, we are able to pull down PKCδ with antibodies directed against Cx43. In addition, anti-PKCδ antibodies are able to specifically pull down the phosphorylated form of Cx43, which is predominantly associated with Cx43 present at the plasma membrane. Using immunoprecipitations, we show that in the basal state PKCδ associates with Cx43. However, upon FGF2 treatment, the association of Cx43 and PKCδ diminishes rapidly (~15 minutes). By immunofluorescence, we demonstrate that upon FGF2 treatment, PKCδ translocates to the nuclei. Indeed, using chromatin immunoprecipitations, western blotting and luciferase reporter assays, we have shown that PKCδ phosphorylates Runx2 and impacts its recruitment and transcriptional activity on the osteocalcin proximal promoter. We propose that upon transduction of an FGF2 induced second messenger via GJIC, PKCδ becomes activated and is mobilized from the gap junction to the nucleus where it affects gene transcription. In total, our data show that Cx43 assembles the signaling machinery required for the propagation of signals generated by the FGF2/FGF receptor complex to adjacent cells in order to coordinate and amplify the cellular response. Understanding the association and regulation of these complexes will permit us to identify the second messengers that are transmitted by gap junctions.

**Loss of Classical ERE Signaling Results in Suppression of Early Commitment of Bone Marrow Stromal Cells to Osteoblasts.** F. A. Syed, D. G. Fraser<sup>\*</sup>, M. J. Oursler, S. Khosla. Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA.

Estrogen signals either through the "classical" ERE pathway or the "non-classical", non-ERE pathway. We have previously shown that mice with a deleted ERE allele and a knock-in of a mutant ERα that cannot bind EREs on the other allele (ERα<sup>NERKI</sup>) have cortical osteopenia and decreased bone formation rates (JBMR 20:1992, 2005). We also established that these mice display a decrease in marrow fat content *in vivo*, which was in contrast to mice lacking complete ERα signaling (ERα<sup>-/-</sup>), which displayed an increase in adipocyte volume compared to their respective ERα<sup>+/-</sup> controls (JBMR 22:S109, 2006). In the present study, we have generated ERα<sup>+/-</sup>, ERα<sup>-/-</sup> and ERα<sup>NERKI</sup> mice on a C57/BL6 background and have compared the inherent potential of marrow-derived stromal cells (MSCs) obtained from three month old female mice to form early bi-potential osteoblastic/adipocytic (methylene blue positive) fibroblastic colonies (CFU-F), early committed pre-osteoblastic (alkaline phosphatase positive) colonies (CFU-AP), and fully differentiated (von kossa positive) mineralized nodule forming osteoblastic colonies (CFU-OB). MSCs derived from ERα<sup>NERKI</sup> mice exhibited a 45% reduction in CFU-F colonies and a 72% reduction in CFU-AP colonies (P<0.001) compared to ERα<sup>+/-</sup> mice. By contrast, MSCs derived from ERα<sup>-/-</sup> mice exhibited a 95% increase in CFU-F and a 173% increase in CFU-AP colonies (P<0.001) compared to ERα<sup>+/-</sup> MSCs. Interestingly, the ERα<sup>NERKI</sup> MSCs displayed a 72% and 90% reduction in their potential for CFU-F and CFU-AP colony formation, respectively, compared to ERα<sup>-/-</sup> MSCs (P<0.001). An essentially similar pattern of differentiation to mature mineralizing osteoblasts was observed in stromal cultures derived from these mice. While ERα<sup>NERKI</sup> cultures displayed a 26% reduction in total CFU-OB colonies compared to wild types, ERα<sup>-/-</sup> cultures displayed an 84% increase. When ERα<sup>NERKI</sup> and ERα<sup>-/-</sup> CFU-OBs were compared, a 60% reduction was observed in ERα<sup>NERKI</sup> cultures. These results suggest that loss of classical ER signaling has suppressive effects on commitment of early osteoblastic and adipocytic progenitors in the bone marrow stromal compartment, which results in suppression of later mineralized nodule formation *in vitro*. These results also explain our earlier observation of reduced marrow adipocyte parameters *in vivo* in ERα<sup>NERKI</sup> mice.

**hPTHrP 1-36 Stimulates PKA-Dependent Phosphorylation and Nuclear Translocation of  $\beta$ -Catenin In Neonatal Mouse Calvarial Bone Cells.** A. Bryan\*, D. Cullen, J. A. Yee. Biomedical Sciences, Creighton University, Omaha, NE, USA.

Treatment of humans or rodents with amino terminal PTH or PTHrP stimulates either bone resorption or bone formation depending on the whether administration of the peptide is continuous or intermittent. While the anabolic effect of intermittent treatment has been related to a decrease in osteoblast apoptosis and an increase in the size of the osteoblast population, the signaling pathway that mediates these changes is not well characterized. The binding of PTH or PTHrP to their receptor activates two intracellular signaling pathways, cyclic AMP/PKA and DAG/PKC. Recently, the canonical Wnt signaling pathway mediated by  $\beta$ -catenin has been associated with the elevated BMD that occurs as a consequence of the G171V mutation in the Wnt co-receptor Lrp5. As a result, it has been proposed that the canonical Wnt signaling pathway may contribute to the action of other bone anabolic factors. The purpose of this work was to test the hypothesis that PTHrP stimulation of the cyclic AMP/PKA pathway increases canonical Wnt signaling in mouse osteoblast-like cells *in vitro*. Calvarial bone cells were isolated from neonatal mice by digestion in collagenase and grown in DMEM plus 10% FBS. The effect of recombinant hWnt3a (5 ng/ml), synthetic hPTHrP 1-36 (200 ng/ml), 10 mM LiCl<sub>2</sub>, 1 mM dBcAMP, or 10  $\mu$ M forskolin (Fsk) on the cellular and nuclear levels of  $\beta$ -catenin and on PKA-dependent phosphorylation of  $\beta$ -catenin was determined by immunoblotting. Translocation of  $\beta$ -catenin to the nucleus in response to treatment was also examined by immunohistochemistry. The effect of hPTHrP 1-36 and hWnt3a on osteoblast differentiation was assessed by measuring alkaline phosphatase (AP) activity. The level of cellular and nuclear  $\beta$ -catenin was increased at 0.5, 1, and 6 hrs after exposure to hWnt 3a, LiCl<sub>2</sub>, hPTHrP 1-36, dBcAMP, and Fsk. Pre-treatment with the PKA inhibitor H89 prevented the increase in  $\beta$ -catenin observed in cells treated with hPTHrP 1-36. Immunohistochemical staining confirmed that treatment with hWnt3a, LiCl<sub>2</sub>, hPTHrP 1-36, and Fsk increased nuclear  $\beta$ -catenin. Treatment with hPTHrP 1-36 and Fsk, but not hWnt3a or LiCl<sub>2</sub>, stimulated PKA-dependent phosphorylation of  $\beta$ -catenin. Continuous exposure to hPTHrP 1-36 or Fsk for 5 days increased AP activity by 2-3 fold; however, neither hWnt3a or LiCl<sub>2</sub> affected AP activity. These results demonstrate that hPTHrP 1-36 stimulates PKA-dependent phosphorylation of  $\beta$ -catenin in calvarial bone cells. Moreover, PKA-dependent phosphorylation of  $\beta$ -catenin may be associated with its translocation into the nucleus of PTHrP target cells. We conclude that crosstalk between the cyclic AMP/PKA and canonical Wnt signaling pathways may contribute to the anabolic action of PTHrP in bone.

**The Sympathetic Tone Mediates Leptin's Inhibition of Insulin Secretion by Modulating Osteocalcin Bioactivity.** E. Hinoi<sup>1</sup>\*, N. Gao<sup>2</sup>\*, T. Yoshizawa<sup>1</sup>\*, D. Jung<sup>3</sup>\*, J. K. Kim<sup>3</sup>\*, K. H. Kaestner<sup>2</sup>\*, G. Karsenty<sup>1</sup>. <sup>1</sup>Department of Genetics and Development, Columbia University, New York, NY, USA, <sup>2</sup>Department of Genetics, University of Pennsylvania, Philadelphia, PA, USA, <sup>3</sup>Department of Cellular and Molecular Physiology, Penn State Medical Center, Hershey, PA, USA.

The emerging relationship between bone and energy metabolisms that has been demonstrated over the last few years raised the prospect that leptin and osteocalcin may cooperate in regulating some aspects of glucose metabolism. To address this question we studied young *ob/ob* mice that are neither obese nor diabetic. These young *ob/ob* mice display a hyperinsulinemia that appears perinatally and is also present in lipodystrophic mice that have no adipocytes. Hyperinsulinemia is caused, in both mouse models, by an increase in beta-cell proliferation, insulin expression and secretion. Remarkably, sympathetic stimulation reduces hyperinsulinemia by 50% in both mutant mice demonstrating that the low sympathetic tone caused by leptin deficiency contributes significantly to its development but treatment of isolated islets with a sympathomimetic does not affect insulin gene expression or beta-cell proliferation. In contrast, ablating sympathetic signaling in osteoblasts only results in leptin-dependent hyperinsulinemia. In osteoblasts, sympathetic activity stimulates expression of *Esp*, a gene inhibiting the activity of osteocalcin, a powerful insulin secretagogue. Accordingly, *Osteocalcin* deletion halves hyperinsulinemia in *ob/ob* mice while *Esp* inactivation doubles it and also delays the onset of glucose intolerance in adult *ob/ob* mice. That leptin's ability to regulate insulin secretion depends largely on the level of osteocalcin bioactivity underscores the role of skeleton in glucose homeostasis.

**Induction of Embryonic Stem Cell-Related Pluripotency Genes in Post Natal Stem Cells During Fracture Healing.** M. V. Bais\*, J. McLean\*, P. Sabastiani\*, M. Young\*, N. Wigner\*, T. Smith\*, D. N. Kotton\*, T. A. Einhorn, L. C. Gerstenfeld. Orthopaedic Research Laboratory, Boston University School of Medicine, Boston, MA, USA.

Fracture healing is defined by one round of endochondral bone formation followed by a period of coupled bone remodeling, and is generally considered to recapitulate the processes of embryological bone formation. Using Bayesian clustering of the temporal gene expression across fracture healing identified unique temporal relationships between Notch, TGF- $\beta$  and Wnt signaling pathways that could be selectively related to gene ontologies associated with skeletogenesis, vasculogenesis, neurogenesis and gametogenesis. A comparison of the ~12,000 genes showing greater than a three fold change in the fracture callus tissues from unfractured bone identified ~300 out of ~1000 expressed genes, that have been shown to be preferentially expressed in embryonic stem cells (ESC). Multiple regulators of pluripotency, self renewal, and epigenetic chromatin remodeling observed in ESCs, showed unregulated expression during fracture healing. One of the central epigenetic regulators associated with ESC self renewal that was observed during fracture healing was the homeotic gene *Nanog*. RT-PCR showed that *Nanog* was temporally induced ~30 fold between days three and five post fracture while in induced skeletal formation after surgical marrow ablation, a ~7 fold increase in *Nanog* expression was seen in the same post injury period. Marrow stromal cells (MSC) grown *ex vivo* showed that *Nanog* had a ~45 fold induction in expression relative to murine embryonic fibroblasts (MEF) at 6 days after being placed in culture. A comparison of the maximal levels of *Nanog* expression within the MSCs to those seen in induced pluripotent stem cells (IPS) showed that MSCs expressed 30 fold less *Nanog* than the IPS cells. Once the MSCs were placed in media that promoted osteogenesis, *Nanog*'s expression fell to those observed in freshly isolated marrow aspirates. Transfection of a lentiviral shRNA to *Nanog* into undifferentiated W20 murine marrow stromal cell line that has been previously used to test BMP2 induced osteogenic differentiation lead to a seven fold induction of osteocalcin expression in the absence of BMP treatment. In summary, approximately a third of the known genes that are upregulated in ESCs relative to differentiated lineages are upregulated in the stem cell populations that are recruited during fracture healing. These data for the first time suggest that one of the known epigenetic transcriptional regulators that impart stem cell maintenance of ESC, also may play a role in regulating and maintaining post-natal stem cells such as MSCs.

**Effect of Osteoblast Depletion on Hematopoietic Niches in the Bone Marrow.** K. Lamothe<sup>\*1</sup>, D. Rowe<sup>2</sup>, H. L. Aguila<sup>1</sup>. <sup>1</sup>Department of Immunology, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Center for Regenerative Medicine and Skeletal Development, University of Connecticut Health Center, Farmington, CT, USA.

Cells of the osteoblastic lineage participate actively on defining hematopoiesis in the bone marrow. We have developed a transgenic mouse model (Col2.3ΔTK) in which osteoblasts can be selectively ablated after treatment with the drug gancyclovir (Gcv). This ablation affects hematopoiesis with a rapid loss of cells whose primary development depend on the bone marrow microenvironment. These include B cell progenitors, NK cells, myeloid progenitors and ultimately early progenitors including hematopoietic stem cells. We postulate that osteoblast depletion or alterations in bone remodeling homeostasis could be used as a way to modify hematopoietic niches.

To test this hypothesis we ablated osteoblasts in transgenic mice in the C57BL/6 (B6) background by treating them with Gcv for 10 days followed by injection of a limited number of hematopoietic stem cells from B6 transgenic mice bearing a GFP transgene driven by the H-2Kb MHC Class I promoter. These transplanted mice developed hematopoietic chimerism, scored by hematopoietic cells expressing GFP, to degrees equivalent to the observed in lethally irradiated control recipient mice. The chimerism is multilineage, including donor cells of myeloid and lymphoid origin. Moreover, sequential transplants of bone marrow from these primary chimeras to lethally irradiated recipients, congenic for the CD45.1 molecule, indicates that the initial transplant engrafted long-term hematopoietic stem cells. This was scored by the presence of GFP CD45.2 positive multilineage hematopoietic cells in the host animals.

In another set of experiments we prevented osteoblastogenesis in utero, through the injection of Gcv in pregnant wild type females mated with transgenic males. After injection of Gcv at the onset of osteoblast development (10-15 days of embryonic life) a fraction of the progeny was born with a non developed cartilaginous skeleton, that progressively generate bona fide bone after birth upon release of the Gcv pressure. These mice present drastic anomalies in the dose of hematopoietic progenitors in the bone marrow, with active hematopoiesis in periphery. Interestingly, as osteoblastogenesis initiate, hematopoiesis in the bone marrow began to establish. These results emphasize the fundamental role of osteoblastogenesis on defining hematopoietic development. They clearly show that controlled alterations in bone remodeling could be used as a regime to facilitate hematopoietic engraftment after bone marrow transplantation and provide a model to study the initiation of hematopoietic niches in the bone marrow post migration of progenitors from extramedullary sites.

**Connective Tissue Progenitor Cell Contribution to Ectopic Skeletogenesis.** V. Y. Lounev<sup>\*1</sup>, E. M. Shore<sup>2</sup>, D. L. Glaser<sup>\*1</sup>, F. S. Kaplan<sup>3</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Center for Research in FOP & Related Disorders, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>2</sup>Departments of Orthopaedic Surgery and Genetics, Center for Research in FOP & Related Disorders, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>3</sup>Departments of Orthopaedic Surgery and Medicine, Center for Research in FOP & Related Disorders, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

At least two populations of progenitor cells, one of hematopoietic origin, and one of connective tissue origin are necessary to form heterotopic bone. While cells of hematopoietic origin are critical for inducing heterotopic ossification (HO), the identity of the responding connective tissue progenitor cells is unknown. We have previously shown that cells of myogenic lineage (myoD-Cre) contribute minimally to the early fibroproliferative stages of heterotopic ossification, but not to the chondrogenic or osteogenic stages, while cells of vascular smooth muscle lineage (smMHC-Cre) do not contribute at all. In order to evaluate contributions of the vascular lineage expressing the early endothelial marker Tek/Tie2 to the various stages of BMP-induced HO, we crossed floxed lacZ reporter mice to a transgenic line that over-expresses BMP4 at neuromuscular junctions (under Nse promoter), then crossed these double transgenic mice with Tek/Tie2-Cre. In response to injury, this mouse model induced heterotopic ossification with an inflammatory muscle reaction that was physiologically similar to the inductive events experienced by patients who have fibrodysplasia ossificans progressiva (FOP), the most catastrophic form of heterotopic ossification in humans. We found that cells expressing Tek/Tie2 contributed to the fibroproliferative, chondrogenic, and osteogenic stages of the evolving endochondral anlagen. Connective tissue progenitor cells of the Tek/Tie2 vascular lineage are thus sufficient to respond to injury-induced triggers and to differentiate through an endochondral pathway to form heterotopic bone. Insight into the cellular pathophysiology of HO has important implications for the development of cell-targeted therapies for FOP and other conditions of dysregulated BMP-induced heterotopic ossification.

**Diet Induced Obesity Compromises the Osteogenic Potential of the Bone Marrow.** Y. K. Luu<sup>1</sup>, J. E. Pessin<sup>\*2</sup>, S. Judex<sup>1</sup>, C. T. Rubin<sup>1</sup>. <sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, <sup>2</sup>Medicine and Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY, USA.

It is often presumed that the load bearing challenges inherent to obesity will have a beneficial impact on the skeleton. There is increasing evidence, however, that overweight individuals do not realize a proportionally greater bone mass, and thus are at a greater relative risk of fracture when falling. We hypothesized that the failure of the skeleton to keep pace of increased adiposity was not necessarily a failure of the extant bone cell population and bone remodeling, but that diet induced obesity actually hampered differentiation of osteoprogenitors, by diet-related reduction of the mesenchymal stem cell (MSC) pool available to build up the skeleton.

Starting at 7w of age, male C57BL/6J mice were maintained on either a regular chow diet (RD) or a 45 kcal% high fat diet (HFD). Following six weeks, animals were euthanized and bone marrow harvested from femurs and tibias. Relative to RD (n=8), flow cytometric analyses of the total marrow indicated that the number of stem cells present in HFD (n=8) animals was markedly suppressed, with the overall stem cell population - including both hematopoietic and MSCs - decreased by -54.8% (p<0.001), and the undifferentiated MSC population in the HFD down by -59.6% (p<0.001).

The phenotypic impact of this diminished progenitor pool was evident at 12w. While the adipose burden in HFD (n=10) was 52.8% greater than RD (n=15; p<0.001), bone volume fraction in the proximal tibia of HFD animals only increased 16.8% (p=0.03) relative to RD, and with body mass as a covariate, this increase in bone volume fraction was insignificant (p=0.51). Cortical bone volume in the mid-diaphysis was unaffected by the HFD (4.0%, p=0.11). However, the quality of the bone structure was significantly compromised in HFD animals, with a -40.0% (p<0.001) reduction in trabecular number, and -24.5% (p<0.001) decrease in trabecular thickness relative to RD. Overall, the data indicate that a high fat diet greatly disrupts the overall stem cell population, both in terms of number and differentiation patterns, providing additional insight into the interaction of adipogenesis and osteoblastogenesis, and the role that diet ultimately may have beyond "simply" caloric intake and increased adiposity. Indeed, the suppressed population of multipotent stem cells in the bone marrow of obese mice may reflect the origins of medical complications that parallel obesity, and complicate bone's responsiveness in the overweight population.

**WNT-4 Acts Through the Non-Canonical Pathways to Stimulate Osteoblast and Bone Marrow Stromal Stem Cell Differentiation.** M. K. Bergenstock<sup>\*</sup>, J. Tamasi<sup>\*</sup>, N. C. Partridge. Physiology and Biophysics, UMDNJ-RWJMS, Piscataway, NJ, USA.

Parathyroid hormone (PTH) increases bone formation by directing changes in osteoblast function and is currently the only clinically available anabolic agent for treating osteoporosis. We discovered that non-canonical *Wnt-4* is PTH-regulated and expressed by bone lining cells, osteocytes, and hypertrophic chondrocytes after PTH stimulation. Wnt proteins are essential in development and are necessary for the acquisition of high bone mass. Wnts are divided into Wnt-1 and Wnt-5a signaling classes, which activate canonical (Wnt/β-catenin) and non-canonical intracellular pathways (Wnt/Ca<sup>2+</sup> and Wnt/Planar Cell Polarity, PCP), respectively. Primary osteoblastic cells treated with WNT-4 did not increase pre-osteoblastic proliferation when compared with controls but showed greater alkaline phosphatase activity and early stimulation of osteoblast marker genes (*runx2*, *alkaline phosphatase*, *osteocalcin*, *MMP-13*, *osterix*) as well as genes of the canonical pathway (*lef-1*, *tcf-1*, *β-catenin*, *groucho*, *wif-1*, *sfrp-4*) when compared with controls. Differentiating primary osteoblastic cells had significantly greater Von Kossa staining and a 2.5 fold increase in *osteocalcin* gene expression in WNT-4 treated cells compared with controls. In a non-osteogenic environment, we also found that WNT-4 significantly increased bone marker mRNA expression. WNT-4 only minimally activated the canonical pathway. In contrast, continuous WNT-4 treatment of mineralized rat primary cells resulted in a 12-fold increase in CamkII phosphorylation (Wnt/Ca<sup>2+</sup> pathway) and a 2-fold increase in JNK phosphorylation (Wnt/PCP pathway). Differentiating rat primary cells acutely treated with WNT-4 showed a significant 5-fold increase in CamkII phosphorylation 2 and 4 h after stimulation. Acutely stimulated MC3T-E1 cells showed significant phosphorylation of JNKs 1 h after WNT-4 stimulation in all three phases of osteoblastic development. Using specific inhibitors to CamkII and JNKs we found that WNT-4 stimulates bone marker gene expression through non-canonical means. WNT-4 treatment of bone marrow stromal stem cells showed induction of osteoblastic markers and inhibition of adipocytic markers, as well as increased colony forming units and mineralized nodules. Our data support a role for non-canonical Wnts and imply that the canonical pathway is not exclusively important in bone. We hypothesize that WNT-4 acts on immature osteoblasts to accelerate their differentiation, as well as on immature stromal stem cells in the bone marrow to stimulate osteoblastogenesis, thereby preventing differentiation to adipocytes.

**F054****Deletion of *Mef2c* in Osteocytes Decreases *Sost* Expression and Increases Bone Mass.** I. Kramer<sup>\*1</sup>, O. Leupin<sup>1</sup>, S. Mundlos<sup>\*2</sup>, H. Keller<sup>1</sup>, M. Kneissel<sup>1</sup>.

<sup>1</sup>Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland, <sup>2</sup>Max Planck Institut für Molekulare Genetik, Berlin, Germany.

Expression of the osteocyte-derived bone formation inhibitor *Sost* in adult bone requires a distant enhancer. We have recently shown that myocyte enhancer 2 (*Mef2*) transcription factors are present in osteocytes and control this enhancer and thus *Sost* expression indicating a putative role for *Mef2s* in the regulation of bone mass. To test this hypothesis we deleted *Mef2c*, one of three *Mef2s* demonstrated to activate *Sost* expression, from osteocytes by crossing *Mef2c<sup>loxP/loxP</sup>* conditional knockout mice with *Dmp1-Cre* mice to generate *Mef2c<sup>loxP/loxP</sup>; Dmp1-Cre* mice. We monitored the long bone phenotype of male and female *Mef2c<sup>loxP/loxP</sup>; Dmp1-Cre* and control littermate mice during growth and ageing (1-6 months) using peripheral and micro-computed tomography (pQCT, microCT). RNA was extracted from femoral cortical bone at necropsy for *Sost* expression analysis by real-time PCR. Animals grew to skeletal maturity with normal body weight and bone length. We found that deletion of *Mef2c* in osteocytes resulted in a reduction of *Sost* expression by about 60% in both sexes. pQCT measurements demonstrated that bone mass, cortical thickness and cancellous bone mineral density were significantly increased in the distal femur metaphysis of male mice during growth and ageing compared to controls. A similar but less pronounced phenotype reaching only borderline significance was observed in the proximal tibia metaphysis. Bone diameter was significantly increased in either long bone. MicroCT measurements revealed that cancellous bone volume and trabecular thickness were increased in the tibia metaphysis. *Ex vivo* measurements in the distal femur metaphysis and lumbar vertebra L3 demonstrated robust increases in cancellous bone volume due to trabecular thickening. Interestingly, female mice displayed a similar but distinctly more moderate cortical and cancellous bone phenotype in the femur metaphysis. Consistent with this finding increases in vertebral cancellous bone volume were also smaller. No appreciable cortical or cancellous bone gain was detectable in the tibia. In summary, osteocyte specific deletion of *Mef2c* leads to increased bone mass in male mice, while its impact on female mice is more modest. The observed *Sost* down-regulation in osteocyte specific *Mef2c* deficient mice is in line with our previous *in vitro* findings. Interestingly, while *Sost* repression occurs in both sexes to a similar extent, the bone phenotype is more distinct in male mice suggesting that *Mef2c* exerts its action on bone mass in part also via regulation of other genes. In conclusion, our data indicate a novel role for *Mef2c* in adult bone homeostasis.

**F058****Evidence that Differentiated Bone Cells Display an Autophagic Response Regulated by HIF-1 $\alpha$ .** A. M. Zahm<sup>\*</sup>, V. Srinivas<sup>\*</sup>, C. S. Adams<sup>\*</sup>, I. M. Shapiro. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

It is now recognized that many cells can survive stressful conditions through the induction of autophagy, a process in which cellular components are re-utilized for maintenance of metabolic activity. We have previously shown that in the hypoxic environment of the growth plate, chondrocytes undergo autophagy prior to activation of apoptosis. The objective of the investigation was to determine if bone cells undergo autophagy, and whether the autophagic response is dependent on expression of HIF-1 $\alpha$ . Rat long bones were sectioned and stained for LC3, a microtubule-associated protein that localizes to autophagosomes. While few osteoblasts were positive for LC3, punctate LC3 staining was observed in many osteocytes, indicative of autophagic activity. To further investigate the mechanism regulating bone cell autophagy, MLO-A5 cells were maintained in culture and autophagy was evaluated by immunofluorescence and Western blot analysis. We found that LC3 II was expressed and LC3 protein was localized to discrete, punctate subcellular locations. These results and ongoing electron microscopic studies indicate that there is a baseline level of autophagy in the bone cells. To study the mechanism of autophagy, the MLO cells were treated with thapsigargin and the expression of LC3 was evaluated. As expected, this agent enhanced LC3 II expression and condensation. In addition, thapsigargin stabilized HIF-1 $\alpha$  even under normoxic conditions. To ascertain if HIF-1 was required for bone cell autophagy, we silenced this transcription factor and measured LC3 levels following thapsigargin treatment. We found that thapsigargin-induced autophagy was inhibited in the silenced MLO cells, suggesting that HIF-1 is required for induction of the autophagic state. Interestingly, treatment of the cells with 3-methyladenine, a potent inhibitor of autophagy, exerted a profound effect on the bone cells. Following treatment with this agent, there was a dramatic reduction in thapsigargin-induced HIF-1 stabilization. Together, these results suggest a complex interaction between HIF-1 and the autophagic response. A similar study was performed using MLO-Y4 preosteocytes. In contrast to the less differentiated MLO-A5 cells, these cells did not evidence stimulation of the autophagic response following thapsigargin treatment, despite exhibiting high baseline LC3 II protein levels. The results of the investigation indicate that *in vivo*, bone cells express an autophagic phenotype that is responsive to HIF-1 $\alpha$ . Based on these findings, we conclude that the autophagic response enables bone cells to differentiate and survive in a hypoxic environment.

**F062****Imaging of Mineralization Kinetics Suggests that the Transition from Osteoblast to Osteocyte Initiates Prior to Mineral Deposition.** S. L. Dallas<sup>1</sup>, Y. Lu<sup>\*1</sup>, J. L. Rosser<sup>\*1</sup>, D. W. Rowe<sup>2</sup>, I. Kalajzic<sup>2</sup>, L. F. Bonewald<sup>1</sup>, P. A. Veno<sup>\*1</sup>. <sup>1</sup>Univ. of Missouri Kansas City, Kansas City, MO, USA, <sup>2</sup>Univ. of Connecticut Health Ctr, Farmington, CT, USA.

Mineralization of osteoid matrix and differentiation of the osteoblast into an osteocyte are two processes that occur simultaneously during bone formation and are interrelated spatially and temporally. We have previously shown by live cell imaging with fluorescent lineage markers that the transition of an osteoblast towards an osteocyte begins just prior to mineralization. We have also identified a motile cell type on the bone surface that expresses *Dmp1*-GFP and *E11/gp38*, two osteocyte markers, and may represent a committed osteocyte precursor.

To further understand the dynamic process of osteoblast to osteocyte transition and its integration with mineralization, time lapse live cell imaging was performed in mineralizing primary osteoblasts and the late osteoblast/early osteocyte cell line, MLO-A5. Primary cells were isolated from mice expressing a *Dmp1*-GFP transgene as an osteocyte marker and/or a 3.6kb *Col1a1*-DsRed transgene as an osteoblast marker. Embryonic mouse calvaria were used for *in vivo* validation of *in vitro* observations. In primary osteoblasts, areas of mineral deposition, imaged vitally using alizarin red, were defined by clusters of highly motile cells switching on *Dmp1*-GFP expression, accompanied by membrane ruffling and shedding of vesicle-like structures. These cells also expressed the early osteocyte marker, *E11/gp38*. Quantitation of mineralization kinetics showed a wave of GFP induction preceding a rapid (10-14h) mineralization phase. Dual mapping of the motion trajectories and morphology of GFP+ve cells showed correlation of mineralization with transition from a motile polygonal cell to a stationary dendritic osteocyte-like morphology. Similar to the primary cells, mineralization in E15.5 mouse calvaria was exclusively associated with interconnected tracts of cells expressing *Dmp1*-GFP that preceded and patterned mineral deposition in a honeycomb-like trabecular structure. In MLO-A5, a clonal cell line representing the transitioning late osteoblast/osteocyte, mineral was deposited throughout the culture in a honeycomb-like pattern with mineralization kinetics similar to primary cells. Transfection with a *col1a2*-GFP fusion protein as a vital probe for collagen assembly, confirmed mineral deposition on collagen bundles, arranged in honeycomb structures analogous to the mineralization pattern in E15.5 calvaria. These data provide further *in vitro* and *in vivo* evidence that the transition towards an osteocyte is initiated prior to mineralization and that this transitioning cell type is responsible for triggering mineral propagation along a prepared, primed matrix.

Mutations of *PHEX* are associated with abnormalities of mineralization as well as increased expression of phosphaturic factor FGF23. However, the mechanism of hypophosphatemia-independent impairment of extracellular matrix mineralization is unknown. The purpose of these studies was to determine if a functional Phex physically localizes to initial sites of mineralization in UMR 106-01 osteoblastic cultures, termed biomineralization foci (BMF). Phex proteolytic activity was found to be 2-3 fold higher in mineralized cultures versus non-mineralized controls or cultures treated with serine protease inhibitor AEBSEF. When mineralized BMFs were isolated by laser capture microscopy and subjected to western blotting, a 60 kDa fragment of Phex was specifically enriched within these complexes, co-localizing with biomarkers BAG-75 and bone sialoprotein, but not MEPE. Interestingly, high pressure freezing electron microscopy revealed that extracellular BMF complexes contain many vesicles which appear to undergo fusion prior to mineralization. Furthermore, proteomic peptide mapping studies on isolated BMF identified a 58 kDa gel band as synaptotagmin-7, a Ca<sup>2+</sup> binding vesicular membrane protein associated with SNARE complexes. Independently, we used the PGBKT7-Phex (E581V) bait construct containing residues 46-749 of the extracellular domain of mouse Phex containing an inactivating mutation to screen a pre-transformed mouse 17-day embryo Matchmaker cDNA library. We obtained three C-terminal clones of snapin that interacted with the Phex construct. Also, we found that snapin was expressed in osteoblastic cell lines by RT-PCR and that a FLAG-tagged full-length Phex was able to co-immunoprecipitate a V5-tagged full-length snapin in co-transfection experiments. Snapin, like synaptotagmin-7, is associated with neural SNARE complexes where they control intracellular docking/fusion of transport vesicles at the plasma membrane. These results indicate that formation and mineralization within the bone extracellular microenvironment involves multi-vesicular exocytosis and fusion. Identification of two SNARE-associated proteins at sites of mineral nucleation suggests such complexes may play a new role in extracellular vesicle fusion events in bone. This potentiality is strengthened since Phex was shown to interact directly with snapin. Whether the formation of 60 kDa Phex at sites of mineral nucleation promotes subsequent growth and propagation of the mineral phase or is a mechanism to limit the function of Phex remains to be determined.

**Deletion of CYP27B1 Reverts the Premature Aging Phenotype of the Klotho-null Mice.** X. Bai<sup>1</sup>, D. Qiu<sup>\*1</sup>, D. Panda<sup>\*1</sup>, D. Goltzman<sup>2</sup>, A. C. Karaplis<sup>1</sup>. <sup>1</sup>Department of Medicine, Lady Davis Institute, Montreal, QC, Canada, <sup>2</sup>Department of Medicine, Royal Victoria Hospital, Montreal, QC, Canada.

Mice homozygous for the null Klotho allele have a short lifespan and show biochemical and morphological features consistent with premature aging-like phenotype. In this study, we have used a mouse genetic approach to investigate *in vivo* the role of Cyp27b1 in the metabolic and skeletal derangements arising in the absence of Klotho. To this end, we crossed mice heterozygous for the hypomorphic Klotho allele (Kl<sup>+/-</sup>) to mice heterozygous for the null Cyp27b1 allele and obtained mice homozygous for both the Kl-hypomorphic and the Cyp27b1-null allele (Cyp27b1<sup>-/-</sup>/Kl<sup>-/-</sup>). Mice were sacrificed and serum and tissues were procured for analysis and comparison to WT, Cyp27b1<sup>-/-</sup> and Kl<sup>-/-</sup> controls.

From 4 weeks onward, Cyp27b1<sup>-/-</sup>/Kl<sup>-/-</sup> mice were clearly distinguishable from Klotho-null mice and exhibited a striking phenotypic resemblance to the Cyp27b1<sup>-/-</sup> controls. The life span of the double mutants increased from 10 weeks to 17 weeks as did their body weight, in parallel to the Cyp27b1<sup>-/-</sup> mice. Serum analysis for calcium, phosphorus, PTH, ALP activity, and creatinine confirmed the biochemical similarity between the Cyp27b1<sup>-/-</sup>/Kl<sup>-/-</sup> and Cyp27b1<sup>-/-</sup> mice and their distinctness from the Kl<sup>-/-</sup> controls. Interestingly, the extremely high serum FGF23 levels observed in the Klotho-null mice were almost completely suppressed in the double knock-out mice, similar to the serum levels in the Cyp27b1<sup>-/-</sup> mice. The characteristic skeletal changes associated with the absence of Klotho were also dramatically converted by the concurrent deletion of Cyp27b1. Hence, wide, unmineralized growth plates and osteomalacic abnormalities were apparent in trabecular and cortical bones of the Cyp27b1<sup>-/-</sup>/Kl<sup>-/-</sup> mice as in the Cyp27b1<sup>-/-</sup> controls. Moreover, widespread soft tissue calcification characteristic of the Kl<sup>-/-</sup> mice was absent in the double mutants.

In summary, our findings substantiate *in vivo* the essential role of Cyp27b1 in the Klotho-null phenotype as its ablation fully reverts the complete spectrum of biochemical and skeletal alterations arising from lack of Klotho. In addition, the results add *in vivo* credence to the proposed role of 1,25(OH)2D as a pivotal regulator of FGF23 expression.

**Osteoclast-Independent Function of Cathepsin K: Regulation of Toll-like Receptor 9 Signaling in Autoimmunity.** K. Okamoto<sup>\*1</sup>, M. Asagiri<sup>\*1</sup>, T. Hirai<sup>\*2</sup>, T. Kunigami<sup>\*2</sup>, H. J. Gober<sup>\*1</sup>, K. Nishikawa<sup>\*1</sup>, K. Aoki<sup>\*3</sup>, K. Ohya<sup>\*3</sup>, S. Kato<sup>\*4</sup>, P. Saftig<sup>\*5</sup>, H. Takayanagi<sup>1</sup>. <sup>1</sup>Department of Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Nippon Chemiphar Co., Ltd., Saitama, Japan, <sup>3</sup>Department of Hard Tissue Engineering, Tokyo Medical and Dental University, Tokyo, Japan, <sup>4</sup>Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, <sup>5</sup>Biochemical Institute, Christian-Albrechts-University Kiel, Kiel, Germany.

Cathepsin K is a lysosomal cysteine protease that plays a pivotal role in osteoclast-mediated degradation of the bone matrices. Thus, cathepsin K has been considered as a potential therapeutic target for the treatment of bone diseases such as osteoporosis and autoimmune arthritis. Because epoxysuccinic acid derivatives such as E-64 are known to inhibit a wide range of cysteine proteases, we examined a number of newly synthesized analogous compounds in rats treated with low calcium diet to obtain an orally bioavailable bone resorption inhibitor. Through this screening, we obtained a potent cathepsin K inhibitor named NC-2300, which suppresses osteoclastic bone resorption both *in vivo* and *in vitro*. To test the effects of the inhibitor on disease model, we treated adjuvant-induced arthritis in rats with oral administration of NC-2300 and compared the results with the effects of alendronate. NC-2300, but not alendronate, markedly suppressed bone erosion at the inflamed joints, whereas both compounds had a comparable inhibitory effect on periarticular osteoporosis. Surprisingly, NC-2300 also inhibited autoimmune inflammation even when administered after the onset of disease. Furthermore, cathepsin K-deficient mice were found to be resistant to experimental autoimmune encephalomyelitis, suggesting a more general function of cathepsin K in the immune systems. We found that pharmacological inhibition or targeted disruption of cathepsin K impaired Toll-like receptor (TLR) 9 signaling in dendritic cells in response to unmethylated CpG DNA, which in turn led to incomplete induction of the inflammatory T helper 17 cell polarization. While the antigen-presenting ability in dendritic cells was unaffected by cathepsin K inhibition, TLR9-induced secretion of pro-inflammatory cytokines, IL-6, IL-12 and IL-23 was attenuated by cathepsin K inactivation. On the other hand, neither TLR2 nor TLR4 signaling depends on cathepsin K. Therefore, our study indicates that cathepsin K, which was thought to be an osteoclast-specific enzyme, also functions as a dendritic cell-specific regulator of TLR9 signaling. Cathepsin K may serve as a potential target of therapeutic intervention to control autoimmune diseases, but immunological side effects should be carefully evaluated in inhibition of this enzyme in osteoporosis.

**PIAS3 Negatively Regulated RANKL-mediated Osteoclastogenesis Directly in Osteoclast Precursors and Indirectly via Osteoblasts.** T. Hikata<sup>1</sup>, H. Takaishi<sup>1</sup>, A. Hakozaiki<sup>1</sup>, M. Furukawa<sup>1</sup>, S. Uchikawa<sup>1</sup>, J. Takito<sup>1</sup>, T. Kimura<sup>\*2</sup>, Y. Okada<sup>\*2</sup>, R. Nishimura<sup>3</sup>, S. V. Reddy<sup>4</sup>, M. Matsumoto<sup>\*5</sup>, Y. Toyama<sup>\*1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Keio University, Tokyo, Japan, <sup>2</sup>Department of Pathology, Keio University, Tokyo, Japan, <sup>3</sup>Department of Molecular and Cellular Biochemistry, Osaka University, Osaka, Japan, <sup>4</sup>Children's Research Institute, Medical University of South Carolina, Tokyo, SC, USA, <sup>5</sup>Department of Spine and Spinal Cord Disease, Keio University, Tokyo, Japan.

Protein inhibitor of activated STAT3 (PIAS3) not only inhibits the DNA binding activity of STAT3 in the JAK/STAT signaling pathway, but also interacts with MITF that is an important transcription factor for the osteoclast differentiation. Last year, we reported that PIAS3 negatively regulated RANKL-mediated osteoclastogenesis *in vitro* using gain of function and loss of function methods. Here we generated PIAS3 transgenic mice (Tg) using the tartrate-resistant acid phosphatase (TRAP) gene promoter. Two lines selected from 27 founders gave similar results. X-ray and microcomputed tomography analysis revealed an osteopetrotic bone phenotype in the 8-week-old PIAS3 Tg. Histological analysis showed that the osteoclast number was significantly reduced in the epiphyseal region and that the bone marrow was abnormally filled with trabecular bone in PIAS3 Tg. Bone histomorphometric analysis indicated an increase in bone volume associated with a reduced osteoclast number, a decrease in the indicators of osteoclastic bone resorption, and a normal level of bone formation in PIAS3 Tg. Consistently, bone marrow macrophages (BMMs) from PIAS3 Tg showed decreased *in vitro* RANKL-mediated osteoclastogenesis. Real-time RT-PCR revealed that c-Fos, NFATc1, cathepsin K, and TRAP gene expression were markedly attenuated in BMMs from PIAS3-Tg. Taken together, PIAS3 Tg mice showed an osteopetrotic phenotype due to an impairment of osteoclast differentiation. In primary osteoblasts isolated from mouse calvaria, PIAS3 overexpression downregulated the RANKL expression through inhibition of STAT3 DNA binding activity. In co-cultures with primary osteoblasts and BMMs in the presence of Oncostatin M, PIAS3-transduced osteoblasts supported less osteoclast formation than mock-transduced osteoblasts. These results suggested that PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts.

**High Dose of RANKL Rescues Integrin  $\alpha_9$ - Osteoclast Phenotype.** G. Lu<sup>1</sup>, Y. Hiram<sup>1</sup>, F. Cackowski<sup>\*1</sup>, C. Boykin<sup>\*2</sup>, K. Patrene<sup>\*1</sup>, J. L. Anderson<sup>\*1</sup>, D. Del Prete<sup>\*1</sup>, J. J. Windle<sup>2</sup>, G. D. Roodman<sup>3</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, <sup>3</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

We have previously demonstrated that integrin  $\alpha_9$  plays a critical role in osteoclast (OCL) differentiation and function. Compared to wild type mice,  $\alpha_9$ <sup>-/-</sup> bone marrow cultures formed significantly less OCLs that are smaller in size and have a markedly reduced bone resorption capacity. Further, introduction of a full length  $\alpha_9$  cDNA into  $\alpha_9$ <sup>-/-</sup> cells rescued the OCL phenotype. Since  $\alpha_9$ <sup>-/-</sup> mice survive less than 2 weeks post-partum, the role of  $\alpha_9$  in adult bone is unknown. Therefore, we generated  $\alpha_9$ <sup>-/-</sup> chimeric mice by transplanting  $\alpha_9$ <sup>-/-</sup> bone marrow cells or WT cells into lethally irradiated mice. Genotyping confirmed that  $\alpha_9$ <sup>-/-</sup> transplanted mice were chimeric, with only their hemopoietic cells lacking  $\alpha_9$ <sup>-/-</sup>. Two months post stem cell transplantation, bone marrow cultures from the  $\alpha_9$ <sup>-/-</sup> chimeric mice showed similar phenotypes as those seen in the cultures from  $\alpha_9$ <sup>-/-</sup> mice. In addition, micro-QCT scanning of the proximal tibiae of chimeric mice, showed significantly increased trabecular bone volume/total tissue volume (BV/TV), trabecular numbers (Tb.N), trabecular thickness (Tb.Th), and decreased trabecular separation (Tb.Sp) compared to WT transplanted mice (WTT). However, these changes in micro-QCT parameters began to diminish with time and were not significant after 3 to 4 months post transplantation. In addition, bone marrow cultures from older chimeric mice formed increased numbers of normal sized OCLs. RANKL treated bone marrow cultures from chimeric mice 3-4 months post-transplant showed dramatically elevated phosphorylation of p38 and p44/42 compared to WT transplants, but had similar levels of integrins  $\alpha_9$  and  $\beta_3$  mRNA. We then tested if increased RANKL levels were present in the sera of chimeric mice 3-4 months post-transplant and found that RANKL levels were progressively increased compared to WTT. Further, treatment of  $\alpha_9$ <sup>-/-</sup> marrow cultures with the high concentrations of RANKL reversed the phenotypic abnormalities in OCL formed in  $\alpha_9$ <sup>-/-</sup> marrow cultures. These results suggest that increased RANKL signaling can reverse the abnormal OCL activity in  $\alpha_9$ <sup>-/-</sup> mice.

**Tec Kinases, Therapeutic Targets for Bone Destructive Diseases.** M. Shinohara\*, T. Koga\*, K. Okamoto\*, K. Arai\*, H. Takayanagi. Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan.

Bone homeostasis depends on balanced action of bone-resorbing osteoclasts and bone-forming osteoblasts. Tipping the balance in favor of osteoclasts leads to diseases with a low bone mass such as osteoporosis as well as rheumatoid arthritis and periodontitis. Now, it is well documented that enhanced bone destruction by osteoclasts is observed in these diseases. Therefore, it is important to understand the mechanism of osteoclast differentiation. Osteoclasts are multinucleated cells that originate from bone marrow-derived monocyte/macrophage precursor cells (BMMs). The differentiation of BMMs to osteoclasts is mainly regulated by three signaling pathways activated by RANKL, M-CSF and immunoreceptor tyrosine-based activation motif (ITAM). We reported that Tec tyrosine kinases, Btk and Tec, regulate ITAM pathway in response to RANKL stimulation through PLC $\gamma$  activation in the last year's meeting. However, it remains unclear how Tec kinases link RANKL and ITAM signaling during osteoclastogenesis. To address this issue, we performed a system biology analysis and found that SLP adaptors interact with both Tec kinases and PLC $\gamma$  in an ITAM-dependent manner. *In vitro* osteoclast differentiation was severely abrogated in BMMs from mice deficient in SLP adaptors, suggesting that the crucial role of the RANKL-stimulated formation of the osteoclastogenic complex including Tec kinases, SLP adaptor proteins and PLC $\gamma$ . Furthermore, in the last year we also reported that Tec-/-Btk-/- mice are resistant to ovariectomy-induced bone loss, suggesting that Tec kinases are good therapeutic targets for bone diseases. Thus we analyzed therapeutic efficacy of Tec kinase inhibitor in bone disease models and found that Tec kinase inhibition reduced osteoclastic bone resorption in models of osteoporosis and inflammation-induced bone destruction. This study identifies the importance of osteoclastogenic complex and provides a molecular basis for a novel therapeutic strategy for bone diseases.

**The Cholesterol Sensing Receptors, Liver X Receptor  $\alpha$  and  $\beta$ , Have Novel and Distinct Roles in Osteoclast Differentiation and Activation in Bone.** K. Robertson\*<sup>1</sup>, M. Norgård\*<sup>2</sup>, S. Windahl\*<sup>3</sup>, K. Hultenby\*<sup>2</sup>, C. Ohlsson\*<sup>3</sup>, J. Gustafsson\*<sup>1</sup>, G. Andersson\*<sup>2</sup>. <sup>1</sup>Karolinska Institute, Stockholm, Sweden, <sup>2</sup>Karolinska University Hospital, Stockholm, Sweden, <sup>3</sup>Sahlgrenska University Hospital, Gothenburg, Sweden.

The Liver X Receptor ( $\alpha$ , $\beta$ ) is primarily responsible for regulating cholesterol homeostasis within cells and the whole body. However, as recent studies show that the role for this receptor is expanding we investigated whether the LXRs could be implicated in bone homeostasis and development. pQCT was performed on both males and female LXR $\alpha$ -/-, LXR $\beta$ -/-, LXR $\alpha$ -/ $\beta$ -/- and WT mice at 4 months and 1 year of age. Then 4 month female mice were additionally analyzed using qPCR, immunohistochemistry, histomorphometry, transmission electron microscopy and also serum bone turnover markers were measured. At the mRNA level, LXR $\beta$  was more highly expressed than LXR $\alpha$  in whole femur. pQCT determined adult female LXR $\alpha$ -/- mice had a significant increase in BMD due to an increase in all cortical parameters. No difference was seen on trabecular BMD. Quantitative histomorphometry showed these mice had significantly more endosteal osteoclasts in the cortical bone; however, although SEM showed no difference in the size of the OC, their ruffled border or clear zone, they appeared to be less active than normal as suggested by a significant reduction in serum levels of CTX. Conversely, the female LXR $\beta$ -/- mice exhibited no change in BMD, presumably because a significant decline in the volume of the trabecular osteoclasts was compensated by an increase in the expression of the osteoclast markers Cathepsin K and TRAP and a larger ruffled border. These mice also had an increased expression of osteoblast associated genes and an increase in serum ALP and OC, suggesting increased bone turnover. Our study shows that both LXRs have distinct roles in cellular function within the bone; LXR $\alpha$  has an impact on osteoclast activity primarily in cortical bone whereas LXR $\beta$  modulates osteoclast differentiation and bone turnover in trabecular bone. These novel findings expand the role for the LXRs away from cholesterol metabolism.

**DC-STAMP Regulates Bone Metabolism Through Cell-cell Fusion of Osteoclasts.** R. Iwasaki\*<sup>1</sup>, T. Miyamoto\*<sup>2</sup>, H. Kawana\*<sup>3</sup>, T. Nakagawa\*<sup>3</sup>, T. Suda\*<sup>4</sup>. <sup>1</sup>Department of Cell Differentiation, Dentistry and Oral Surgery, Keio University School of Medicine, Tokyo, Japan, <sup>2</sup>Department of Orthopedic Surgery, Musculoskeletal Reconstruction and Regeneration Surgery, Keio University School of Medicine, Tokyo, Japan, <sup>3</sup>Department of Dentistry and Oral Surgery, Keio University School of Medicine, Tokyo, Japan, <sup>4</sup>Department of Cell Differentiation, Keio University School of Medicine, Tokyo, Japan.

Multinucleation by cell-cell fusion is a characteristic of osteoclasts. Recently, we have isolated DC-STAMP (Dendritic Cell Specific Transmembrane Protein), a seven transmembrane protein, as an essential molecule for osteoclast cell-cell fusion, and that osteoclasts in DC-STAMP deficient mice show complete lack of cell-cell fusion (J. Exp. Med. 2005). However, it is not yet characterized the role of osteoclast cell-cell fusion via DC-STAMP in bone homeostasis. Here we generated DC-STAMP transgenic mice (Tg) under the control of an actin(CAG) promoter to express DC-STAMP ubiquitously *in vivo*. The defects of osteoclast cell-cell fusion in DC-STAMP deficient mice was rescued by crossing with DC-STAMP Tg mice *in vivo* and *in vitro*, and DC-STAMP expression in the cells derived from DC-STAMP Tg mice was significantly upregulated compared to that from wild-type mice. *In vitro* osteoclast formation assay, the number of multinuclear cells as well as the number of nuclei in each multinuclear cell were significantly upregulated in osteoclasts of Tg mice compared with that of wild-type littermates. DC-STAMP expression was detected in various tissues of DC-STAMP Tg mice such as liver, muscle and brain, all of which do not express DC-STAMP physiologically. Interestingly, ectopic cell-cell fusion was not observed in liver and muscle, and the multinucleation of myotube was not stimulated by the forced expression of DC-STAMP in Tg mice. Thus, our results suggest that DC-STAMP promotes cell-cell fusion in a tissue specific manner under a stimulation of RANKL. The cell-cell fusion was not induced even in the cells derived from Tg bone marrow in the presence of M-CSF alone, while the addition of RANKL in turn induced hyper-multinucleation of osteoclasts. Interestingly, bone parameters such as bone volume per tissue volume and trabecular number were significantly downregulated in DC-STAMP Tg mice, whereas these parameters were significantly upregulated in DC-STAMP knockout mice, suggesting that cell-cell fusion of osteoclast via DC-STAMP plays a critical role in regulating bone metabolism.

**Inpp4b as a Regulator of Bone Mass.** M. Rashed\*, M. Arsenault\*, M. Ferron\*, M. Pata\*, J. Vacher. IRCM, Montreal, QC, Canada.

Osteoclasts are unique hematopoietic cells that derive from the monocyte lineage and are responsible for bone resorption. Loss of osteoclast activity leads to malignant osteopetrosis, a genetic disease characterized by increased bone mass and severe reduction in bone marrow compartment. In mouse and human, the grey-lethal (*gl*) gene is responsible for the most severe form of recessive osteopetrosis. We have identified a novel *gl* osteopetrosis-associated gene, the Inositol polyphosphate 4-phosphatase type II (Inpp4b) that is markedly repressed in *gl/gl* osteoclasts. The mouse Inpp4b cDNA encodes a 105kDa protein including a C2 domain and a consensus C(X)<sub>2</sub>R catalytic site. The Inpp4b phosphatase was shown to hydrolyse *in vitro* the second messenger PtdIns(3,4)P<sub>2</sub> to PtdIns(3)P which have been implicated as regulators of intracellular signaling in bone cells. Normally, Inpp4b is expressed throughout the osteoclast lineage and in osteoclast maturation/activation. To study the role of Inpp4b, we used the cell-based monocytic model RAW 264.7 that can be induced to differentiate upon RANKL stimulation into the osteoclast lineage. Enhanced *ex vivo* expression of native Inpp4b in these cells caused a significant decrease in differentiation into osteoclast-like cells. In contrast, overexpression of a phosphatase inactive Inpp4b mutant promoted differentiation. Moreover, we showed that differentiation was mainly regulated by NFATc1 activation, nuclear translocation and transcription of osteoclast-specific target genes. These results indicated that Inpp4b is a negative regulator of osteoclast differentiation and is dependent on its activity. We then investigated the role of Inpp4b *in vivo* and produced TRAP-Inpp4b transgenic mice that exhibited no obvious phenotype. By contrast, TRAP-Inpp4b-*gl/gl* transgenic mice displayed an increase in bone density with reduced osteoclast population, leading to a more severe osteopetrotic phenotype than *gl/gl* mice. Based on these results, analysis of the role of Inpp4b in bone mass regulation was undertaken independently of *gl* by production of a null allele. Together our results demonstrated that the Inpp4b phosphatase, potentially through the NFATc1 pathway, is a major regulator of the osteoclast lineage.

## F091

**Regulation of Bone Mass and Osteoclastogenesis by the Carcino-Embryonic Antigen Related Cell Adhesion Molecule 1 (CEACAM1).** S. Huang\*, M. Harris\*, M. Kaw\*, M. McInerney\*, N. Ebraheim\*, S. Najjar\*, B. Lecka-Czernik. Department of Orthopaedic Surgery, Center for Diabetes and Endocrine Research, University of Toledo Medical Center, Toledo, OH, USA.

The Carcino-Embryonic Antigen Related Cell Adhesion Molecule 1 (CEACAM1) represents a transmembrane glycoprotein belonging to a subgroup of the immunoglobulin superfamily. Among other functions, CEACAM1 promotes insulin clearance in liver and decreases inflammatory responses. Upon its phosphorylation by the insulin receptor tyrosine kinase, CEACAM1 takes part of the insulin-receptor endocytosis complex to increase the rate of receptor-mediated insulin endocytosis and degradation, which constitute the basic mechanism of insulin clearance in liver. Transgenic liver-specific overexpression of the phosphorylation-defective S503A *Ceacam1* mutant under the control of the ApoA1 promoter exerts a dominant-negative effect on CEACAM1 function in L-SACCI mice. The mice develop impairment of insulin clearance and hyperinsulinemia, which results in insulin resistance and increased hepatic triglyceride synthesis and secretion. L-SACCI animals have increased fat mass, with higher number of macrophages infiltrating fat tissue. Here, we demonstrate that the bone of 5 month-old L-SACCI male mice is larger and has more mass as compared to the bone of wild type (WT) animals. Trabecular bone of the L-SACCI tibia has increased volume (54%;  $p=0.037$ ), connectivity density (76%;  $p=0.008$ ) and trabeculae number (24%;  $p=0.048$ ). In addition, total area and cortical area in midshaft tibia are increased by 20% ( $p=0.003$ ) and 10% ( $p=0.04$ ), respectively. Although larger and thicker, L-SACCI bone is not osteopetrotic and has enlarged medullary area (42%,  $p=0.002$ ). In addition, the length of L-SACCI bone is not different from that of WT. This indicates that CEACAM1 regulates bone remodeling, rather than developmental bone growth. To determine the cellular basis for the altered bone phenotype, we have compared number of osteoclast progenitors in the bone marrow of L-SACCI and WT animals. Osteoclast progenitor number and their ability to form multinucleated TRAP+ cells were assessed in co-culture of non-adherent bone marrow cells with osteoclast-supporting mesenchymal U-33/γ2 cells. We found that adult L-SACCI animals possess 20-fold lower number of osteoclast progenitors than WT. This suggests that CEACAM1 plays an important role in osteoclast differentiation. Investigations are underway to determine whether alteration in the bone phenotype of L-SACCI mice results from systemic insulin resistance and lipid abnormalities or from impaired monocyte differentiation into osteoclasts.

**CD47 (IAP) Is an Important Modulator of Osteoclast and Osteoblast Differentiation *in vitro* and *in vivo*.** V. E. DeMambro<sup>1</sup>, L. A. Maile<sup>2</sup>, E. T. Everett<sup>1</sup>, D. R. Clemmons<sup>1</sup>, W. G. Beamer<sup>1</sup>, C. J. Rosen<sup>1</sup>. <sup>1</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>2</sup>University of North Carolina, Chapel Hill, NC, USA.

CD47 (Integrin Associated Protein; IAP) and SHPS-1 are critical signaling molecules for IGF-1 activation of smooth muscle. The extracellular domains of IAP and SHPS-1 bind and this association is required for SHPS-1 phosphorylation. Also the presence of an intact IAP extracellular domain is important for macrophage differentiation. Since multiple cell types express IAP, and osteoclast-osteoblast (OC-OB) interactions are necessary for skeletal remodeling, we hypothesized that the absence of IAP would affect both OC and OB function, resulting in impaired peak bone acquisition. We raised *IAP*<sup>-/-</sup> mice on a C57BL/6J (B6) background and performed skeletal phenotyping at 16 wks. We also extracted bone marrow stromal cells (BMSCs) and evaluated their *in vitro* capacity to differentiate. *In vivo*, *IAP*<sup>-/-</sup> females were lighter, had less % fat than B6 (WT), had reduced total whole body aBMD (DXA), total femoral vBMD (pQCT) and cortical thickness (all  $p<0.01$  vs WT). MicroCT of the distal femur revealed that *IAP*<sup>-/-</sup> mice had reduced BV/TV ( $p=0.007$  vs WT) due to reduced trabecular thickness ( $p=0.02$  vs WT) but not number. *In vitro*, non-adherent BMSCs from *IAP*<sup>-/-</sup> mice were grown in 2.5% FCS with RANKL (30ng/ml); cells were counted by TRAP staining and # of nuclei per cell was assessed. Although total TRAP+ cell #'s were similar by genotype, the # of cells with >3 nuclei was reduced (WT:  $300 \pm 40$  vs *IAP*<sup>-/-</sup>:  $48 \pm 9$ ,  $p<0.01$ ). In WT cells, addition of anti-IAP antibody that disrupts IAP/SHPS-1 association reduced the # of multinucleated cells from  $402 \pm 65$  to  $137 \pm 25$ ,  $p<0.05$ . In WT cells without RANKL, IAP was completely cleaved, but this was prevented by addition of RANKL. Further, a MMP-2 inhibitor prevented IAP cleavage in WT cells, resulting in enhanced SHPS-1 phosphorylation, whereas *IAP*<sup>-/-</sup> cells showed no SHPS-1 phosphorylation. We also cultured adherent BMSCs from *IAP*<sup>-/-</sup> and WT mice in 10% FCS; at d7 *IAP*<sup>-/-</sup> BMSCs showed a significant reduction in ALP+ colonies vs WT. By d18 von Kossa staining revealed that the *IAP*<sup>-/-</sup> cultures did differentiate and mineralize though to a lesser extent than WT controls. We conclude intact IAP is required for SHPS-1 association and phosphorylation and that both events are necessary for complete osteoclastogenesis and OB recruitment. Global deletion of IAP caused impaired cortical and trabecular bone acquisition in both genders. In sum, we believe IAP may be critical for OC fusion. One mechanism whereby RANKL promotes osteoclastogenesis may be inhibition of IAP cleavage. Further studies are needed to delineate whether changes in osteoclastogenesis or OB recruitment in the *IAP*<sup>-/-</sup> mouse are the primary mechanisms for impaired peak bone acquisition.

**Mice Deficient in Pyk-2 Have Impaired Ovariectomy-Induced Bone Resorption.** E. Smith<sup>1</sup>, D. T. Crawford<sup>1</sup>, N. A. Hanson<sup>1</sup>, E. Purev<sup>2</sup>, R. Baron<sup>2</sup>, T. A. Brown<sup>1</sup>, L. Buckbinder<sup>1</sup>. <sup>1</sup>Pfizer Global R&D, Groton, CT, USA, <sup>2</sup>Harvard School of Dental Medicine, Boston, MA, USA.

Mice deficient in proline-rich tyrosine kinase 2 (Pyk2) on a C57BL/6 background have a high bone mass phenotype at 18 weeks of age characterized by increased bone formation and increased osteogenesis of marrow-derived stromal cells (Buckbinder L, et al. PNAS 104: 10619-10624, 2007). Recent evidence has also suggested that osteoclasts from 6-8 week old *Pyk2*<sup>-/-</sup> mice on a 129 background show diminished resorptive capacity due to impaired podosome formation (Gil-Henn H, et al. JCB 178: 1053-1064, 2007). Based on this, the objective of this study was to evaluate the ability of *Pyk2*<sup>-/-</sup> mice to undergo osteoclastic bone resorption stimulated by ovariectomy. Bone marrow macrophages from *Pyk2*<sup>-/-</sup> mice on a C57BL/6 background were differentiated into osteoclasts by co-culture with primary mouse calvarial osteoblasts. Consistent with cells from *Pyk2*<sup>-/-</sup> mice on a 129 background, these cells demonstrated a decrease in % area resorbed when plated on dentin slices as well as impaired podosome formation compared to cells from WT mice. Female *Pyk2*<sup>-/-</sup> and wild-type (WT) mice received ovariectomy (OVX) or sham surgery at 10 weeks of age and were euthanized after 8 weeks of bone loss. Trabecular BV/TV of lumbar vertebrae in *Pyk2*<sup>-/-</sup> mice was not significantly reduced in OVX vs. sham mice by μCT, while BV/TV in WT mice was reduced 29.6% ( $p=0.04$ ). Despite this, 2-way ANOVA did not detect a statistically significant interaction between genotype and OVX vs. sham surgery. Trabecular BV/TV in the distal femoral metaphysis was reduced by 59% in *Pyk2*<sup>-/-</sup> mice ( $p<0.0001$ ) and 74% in WT mice ( $p=0.04$ ) after ovariectomy as measured by μCT. In this case, the interaction between genotype and surgery was significant by 2-way ANOVA ( $p=0.008$ ). Serum CTx (RatLAPS, Nordic Biosciences Diagnostics) was increased 33% after OVX compared to Sham in WT mice ( $p=0.097$ ), which represented a 43% increase compared to 10 week old WT mice ( $p=0.012$ ). In contrast, serum CTx was not significantly increased after ovariectomy compared to either Sham or 10 week old animals in *Pyk2*<sup>-/-</sup> mice. Taken together, these data suggest that *Pyk2*<sup>-/-</sup> mice demonstrate reduced resorption responses when stimulated by estrogen deficiency. These data provide *in vivo* evidence that Pyk2 is involved in osteoclastic bone resorption in addition to osteoblastic bone formation and is therefore an attractive therapeutic target for osteoporosis.

**Non-enzymatic Glycation Increases Bone Fragility Through Altered Microdamage Formation & Propagation.** S. Tang<sup>1</sup>, D. Vashishth<sup>2</sup>. <sup>1</sup>Orthopedic Surgery, University of California, San Francisco, San Francisco, CA, USA, <sup>2</sup>Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, USA.

The fracture resistance of bone in part depends on its ability to optimize the formation of microdamage such as microcracks and diffuse damage. Nonenzymatic glycation (NEG) occurs w/ aging and diabetes, and adversely affects bone matrix quality and bone's fracture resistance. We hypothesized that (1) NEG-mediated stiffening of the organic matrix of cancellous bone may alter the magnitude of microdamage production during pre-yield and post-yield loading; and (2) the differences may be the result of altered microdamage morphologies. Novel methods to segment and quantify microdamage are introduced. Bone cores from the tibial plateaus of a 64yo human donor were scanned by microCT, incubated in either a NEG or a control solution, subjected to unconfined compression to either 0.6% or 1.1% apparent strains, and stained for microdamage in a lead-uranyl acetate solution. Stained samples were rescanned by microCT to determine the magnitude of load induced microdamage. The ratios of damaged volume to bone volume (DVBV), a measure of microdamage quantity, and damaged surface to damaged volume (DSDV), an indicator of microdamage morphology, were used to characterize microdamage. During pre-yield loading, the NEG group incurred a 53% increase in total damage(DVBV) than the controls ( $p<0.05$ ) but was more crack-like as indicated by the higher DSDV ( $p<0.05$ ). Post-yield loading resulted in the controls incurring 18.6% higher DVBV but was morphologically more diffuse-like than the NEG group ( $p<0.001$ ). In summary, the new microCT based technique successfully allowed to measure and segment microdamage. Consistent w/ fracture mechanisms in brittle materials, NEG reduced microdamage formation in the post-yield region and altered microdamage morphology to more crack like than diffuse damage. These results have important implications for diabetes and antiresorptive bone therapies that cause accumulation of AGEs in bone.

**Enzyme Replacement Therapy Prevents Dental Defects in the *Akp2*<sup>-/-</sup> Mouse Model of Infantile Hypophosphatasia.** M. D. McKee<sup>1</sup>, I. Lemire<sup>2</sup>, R. Heft<sup>3</sup>, P. Crine<sup>3</sup>, J. Millan<sup>4</sup>. <sup>1</sup>Faculty of Dentistry, McGill University, Montreal, QC, Canada, <sup>2</sup>Enobia Pharma, Montreal, QC, Canada, <sup>3</sup>Enobia Pharma, Montreal, QC, Canada, <sup>4</sup>Sanford Children's Research Center, Burnham Institute for Medical Research, San Diego, CA, USA.

Osteomalacia in hypophosphatasia (HPP) is attributable to loss-of-function mutations in the tissue-nonspecific alkaline phosphatase (TNALP) gene. In the absence of functional TNALP, one of its natural substrates - pyrophosphate (PPi) - accumulates extracellularly and inhibits skeletal and dental mineralization. HPP is classified according to age at diagnosis, and varies remarkably in severity, spanning (from most severe to mildest) perinatal, infantile, childhood, adult and odontohypophosphatasia forms. TNALP-null mice (*Akp2*<sup>-/-</sup>) phenocopy human infantile HPP remarkably well, as the mice are born with a normally mineralized skeleton, but develop rickets at about 1 wk of age, and die at about 2 wks of age having severe skeletal and dental hypomineralization and episodes of apnea and epileptic seizures. In the dentition of these mice, a delay in dentin mineralization and incisor eruption, and a deficiency in the amount of acellular cementum, have been documented. Following our previous work on the skeleton, here we report on the complete prevention of tooth mineralization and acellular cementogenesis abnormalities following treatment of *Akp2*<sup>-/-</sup> mice with daily subcutaneous injections of a mineral-targeting form of recombinant, secreted human TNALP (sALP-FcD10) given at a dose of 8.2 mg/kg for 15 days. Mandibles from wild type, sALP-FcD10-injected (treated) and vehicle-injected (untreated) mice were examined by radiography, micro-computed tomography, histology (including von Kossa staining for mineral) and transmission electron microscopy (TEM; including immunogold labeling for osteopontin). In addition to preventing osteomalacia in the *Akp2*<sup>-/-</sup> mice, daily sALP-FcD10 injections prevented the hypomineralization of dentin and cementum that occurs in the untreated *Akp2*<sup>-/-</sup> mice. Hypomineralized *Akp2*<sup>-/-</sup> molar root dentin and incisor root analogue dentin, which are particularly sensitive to the lack of TNALP, showed well-developed dentin and cementum structure and complete mineralization after the sALP-FcD10 injections. Ultrastructural analysis by TEM of the tooth root surfaces confirmed that the acellular cementum typically missing or reduced in *Akp2*<sup>-/-</sup> mice was restored by the sALP-FcD10 injections, and characteristic intense immunogold labeling for osteopontin was observed over the restored acellular cementum. In conclusion, a mineral-targeting, recombinant form of TNALP prevents dental hypomineralization, and restores acellular cementum, in TNALP-null mice.

**Osteopontin Deficiency Reduces Aortic Calcification and Oxidative Stress in Diabetic LDLR<sup>-/-</sup> Mice.** J. Shao, C. Lai\*, R. Cohen\*, J. Cai\*, D. Towler. Internal Medicine, Washington University in St. Louis, St. Louis, MO, USA.

Osteopontin (OPN) is a matrix cytokine that binds calcium phosphate, inhibits epitaxial mineralization, and enhances calcium egress from pre-existing calcium deposits. When cleaved by proteases, a cryptic C-terminal peptide (SVVYGLR in humans, SLAYGLR in mice) is revealed that binds alpha-4 integrins. Previously, we showed that OPN, via this peptide, stimulates vascular Nox2 expression, increases oxidative stress, and upregulates arterial MMP9. Furthermore, we showed that OPN deficiency reduces aortic MMP9 activity and oxidative stress in male LDLR<sup>-/-</sup> mice fed high fat diets (HFD) - a model of type II diabetes and aortic calcification. Since MMP9 degrades arterial elastin -- necessary for medial artery calcium deposition in vivo -- we assessed the impact of osteopontin deficiency on diabetic vascular calcification. Two month old OPN<sup>+/+</sup>;LDLR<sup>-/-</sup> and OPN<sup>-/-</sup>;LDLR<sup>-/-</sup> mice were HFD (42% of calories from fat) for 3 months, then analyzed for (a) aortic valve and medial calcium staining using an Alizarin red histochemical score; and (b) aortic tissue calcium load, using formic acid calcium solubilization and measurement with an ion-selective electrode. Diabetes and dyslipidemia were equivalent in both genotypes. However, as compared to OPN-replete cohorts, OPN-deficient mice exhibited a 50% reduction in aortic histological calcification scores (OPN<sup>+/+</sup>;LDLR<sup>-/-</sup> = 7.9 +/- 0.9 vs. OPN<sup>-/-</sup>;LDLR<sup>-/-</sup> = 3.9 +/- 0.4, p < 0.05, two-tailed Mann-Whitney U-test). Aortic calcium tissue load was decreased by 30% (OPN-replete = 0.71 +/- 0.09 ug calcium/mg of dry aorta vs. OPN-null = 0.51 +/- 0.07 ug calcium / mg of dry aorta; p = 0.065). Reductions in aortic calcification with OPN deficiency were accompanied by reductions in aortic Nox2 and CD68+ macrophage accumulation (p < 0.05). Since pulsatile teriparatide administration down-regulates aortic OPN and calcium accrual, we examined whether teriparatide impacts vascular inflammation and oxidative stress. Two-month old OPN<sup>+/+</sup>;LDLR<sup>-/-</sup> mice were fed HFD for 1 month, treated with either vehicle or teriparatide (0.4 mpk/day s.c.). Teriparatide dosing reduced aortic OPN, Nox2, and CD68+ macrophage accumulation by 60% (all p < 0.05). This was accompanied by a 25% reduction in the serum oxidative stress marker, 8-F-isoprostane (75.4 +/- 7.5 pg/ml vs. 56.6 +/- 7.3 pg/ml, p < 0.05). Thus, aortic OPN participates in the inflammatory signals and matrix remodeling events that initiate vascular calcification. Teriparatide-induced down-regulation of aortic OPN mimics key vasculotropic features of OPN deficiency. Suppression of aortic OPN gene expression by pulsatile teriparatide may mediate the beneficial effects of teriparatide on vascular inflammation and oxidative stress in diabetic LDLR<sup>-/-</sup> mice.

## F112

**Nkx3.2 Is an Important Mediator of Hypoxia-induced Chondrocytic Differentiation.** Y. Kawato\*, M. Hirao<sup>1</sup>, J. Hashimoto<sup>1</sup>, N. Tamai\*, N. Yamasaki\*, A. Nampei<sup>1</sup>, A. Myoui<sup>2</sup>, H. Yoshikawa<sup>1</sup>. <sup>1</sup>Orthopaedics, Osaka University Graduate School of Medicine, Suita, Japan, <sup>2</sup>Medical Center for Translational Research, Osaka University Hospital, Suita, Japan.

Recently, we reported that hypoxia promotes chondrocytic differentiation in mesenchymal lineage independently of Sox9 (J Biol. Chem. 281(41), 2006). Other papers also described that there is Sox9- independent pathway in hypoxia-induced chondrocytic differentiation (J Cell Biol. 177(3), 2007) (J Biol. Chem. 283(8), 2007). It is known that Nkx3.2, a novel chondrogenic transcription factor induced by Shh, suppresses Runx2 in mesenchymal lineage. Then, we hypothesized that hypoxia induces Nkx3.2 activation followed by Runx2 suppression, leading to promotion of chondrocytic differentiation, while osteoblastic differentiation is inhibited. C3H10T1/2 was cultured under normoxia (20% O<sub>2</sub>) and hypoxia (5% O<sub>2</sub>) with rh-BMP2 (300ng/ml). At first, we performed immunocytochemistry for Nkx3.2 protein using micromass culture samples. Nkx3.2 was expressed at the site of cell condensation and the number of nucleus with positive staining was increased by hypoxia. Real time RT-PCR revealed that Nkx3.2 gene expression was promoted by hypoxia from day1 to 10. On the other hand, Runx2 expression was suppressed from day3 to 7. Shh gene expression was up-regulated from 6hrs to 24hrs after hypoxic stimulation. Sox9 gene expression showed no difference between normoxia and hypoxia. Furthermore, because it is known that PTH-rP also positively regulates Nkx3.2 during endochondral ossification, we checked the gene expression of PTH-rP and found that it was promoted by hypoxia, while Ihh, a prehypertrophic chondrocyte marker, was down-regulated. From these observations, it is suggested that hypoxia up-regulates Shh and Nkx3.2 and induces subsequent Runx2 down-regulation, which in turn promotes chondrocytic commitment and inhibits chondrocyte hypertrophy during endochondral ossification. Next, we checked the specificity of Nkx3.2 in hypoxia using RNAi. Alcian blue staining showed that siRNA for Nkx3.2 abolished hypoxia-induced glycosaminoglycan (GAG) production of 10T1/2. We also confirmed that augmentation with wild-type Runx2 (WT-Runx2) completely restored suppressed alkaline phosphatase (ALP) activity by hypoxia. These results suggest that Nkx3.2 is a dominant regulator of chondrocytic differentiation induced by hypoxia, and that Runx2 down-regulation is the primary mechanism of suppression of osteoblastic differentiation. Although further confirmation on the relationship between Nkx3.2 and Runx2 in hypoxia is necessary, Nkx3.2 seems to play important roles in hypoxia-induced Runx2 down-regulation, inhibition of osteoblastic commitment and promotion of chondrocytic differentiation.

**Postnatal Deletion of PTH/PTHrP Receptor in Growth Plate Chondrocytes Leads to Growth Plate Fusion.** T. Hirai, A. S. Chagin, T. Kobayashi, S. Mackem, H. M. Kronenberg. Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

PTH/PTHrP receptor (PPR) signaling regulates development during endochondral bone formation in fetal life. The PPR, however, is also expressed in the postnatal growth plate and its role there is unknown. PPR null mice have abnormal bones, but the physiological role of PPR signaling in postnatal chondrocytes can not be determined in PTH/PTHrP receptor null mice because of the embryonic lethality. We, therefore, generated a new mouse model in which deletion of the PPR gene in chondrocytes can be induced in a temporal- and tissue- specific manner. To selectively ablate the PPR gene in chondrocytes of the postnatal skeleton, floxed PPR mice were mated with mice in which a collagen type 2 (*Col2*) promoter drove a transgene coding for a fusion protein of Cre recombinase and an estrogen receptor ligand-binding domain with a point mutation (*ER<sup>T</sup>*). This point mutation in the fusion protein (*CreER<sup>T</sup>*) allows induction of Cre recombinase by tamoxifen. Therefore, injection of tamoxifen can be used to induce ablation of the PPR gene conditionally at any time point. We generated *Col2-CreER<sup>T</sup>;floxed PPR* (*PPR<sup>fl/fl</sup>*) mice. Mice were treated with 0.5 mg tamoxifen/body at postnatal day (P)3, and the effect on bone development was analyzed at P6, P10 and 4 weeks of age. We observed a decrease in growth of long bones in post-natal deletion of PPR (*Col2-CreER<sup>T</sup>; PPR<sup>fl/fl</sup>*) mice. Histological analysis of long bones of 4-week-old mice revealed abnormalities of the skeleton in *Col2-CreER<sup>T</sup>; PPR<sup>fl/fl</sup>*. Postnatal deletion of PPR in chondrocytes resulted in premature fusion of the growth plates and permanent deformity of bone epiphyses. To determine the mechanism of disappearance of the growth plate chondrocytes, we looked at early times after tamoxifen administration. Three days after treatment of tamoxifen, the columns of chondrocytes in the growth plate were disrupted, and ectopic hypertrophic chondrocytes expressing collagen X were found in the middle of the growth plate. The domain of expression of Indian hedgehog was also enlarged. The expansion of the hypertrophic zone was accompanied by a dramatic decrease in the number of proliferating chondrocytes in the columnar zone, as determined by BrdU labeling. Moreover, histological examination at P10 showed that the premature fusion of the growth plate in *Col2-CreER<sup>T</sup>; PPR<sup>fl/fl</sup>* mice had already occurred. Thus, PPR signaling is required postnatally for maintenance of the growth plate. We speculate that these findings may explain the premature closure of growth plates seen in human Albright hereditary osteodystrophy.

**Identification of a Transcription Factor p63 for Transactivation of Wnt9a and Gdf5 Causing Joint Cartilage Formation.** A. Kan, T. Ikeda, T. Saito, K. Nakamura, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine, Tissue Engineering, University of Tokyo, Tokyo, Japan.

Joint cartilage formation is an essential step to realize a regenerative medicine against degenerative skeletal disorders like osteoarthritis. Wnt9a and Gdf5 are known to be representative crucial molecules for joint formation from mouse genetics findings. Using comparative mapping between human and mouse Wnt9a promoters within about 3 kb upstream of the transcriptional initiation site, we initially detected a highly conserved region between -158 bp and -117 bp, called Joint-Specific Enhancer (JSE). Screening from a phage display library of human tracheal cartilage by biopanning with tandem copies of the JSE construct identified a p53 family gene p63 as the most probable transcriptional factor for this region. In fact, the JSE contained a p53 family-binding motif. In both chondrogenic ATDC5 cells and non-chondrogenic HuH-7 cells transfected with luciferase-reporter gene constructs containing tandem-repeat of the JSE, the p63 overexpression stimulated the transcriptional activity depending on its repeat number, which was abrogated by site-directed mutagenesis in the binding motif above. Electrophoretic mobility shift assay (EMSA) showed binding of nuclear extracts from p63-overexpressed HuH-7 cells with the wild-type JSE oligonucleotide probe, but not with the mutated probe. The complex disappeared with an excess of unlabelled wild-type probe and underwent supershift by the p63 antibody, indicating a specific binding between JSE and p63. Overexpression of p63 was confirmed to increase the endogenous Wnt9a expression in ATDC5 and HuH-7 cells by real-time RT-PCR. Similarly, deletion, mutagenesis, and tandem-repeat analyses of the luciferase assay within the 3 kb Gdf5 promoter identified the core responsive element to p63 between the -1 bp to +63 bp region containing the binding motif. EMSA also showed the specific binding between this region and p63. Furthermore, the p63 overexpression in non-chondrogenic HeLa cells and de-differentiated mouse costal cells caused chondrogenic differentiation with induction of type II collagen (COL2) expression. In vivo expression of p63 was detected in all cartilaginous tissues of developmental limbs of mouse embryos by immunohistochemistry. When we further investigated the skeletons of p63-deficient (p63<sup>-/-</sup>) mouse embryos, they exhibited severe short limb deformities with suppressed COL2 and SOX9 expressions. Taken together, the present analyses of Wnt9a and Gdf5 promoters identified p63 as a crucial transcription factor for joint cartilage formation. Further understanding of the molecular network related to p63 and Wnt9a/Gdf5 will herald a new era of cartilage regenerative medicine.

**Brachy-syndactyly Caused by Loss of *Sfrp2* Function.** R. Morello<sup>1</sup>, T. K. Bertin<sup>\*1</sup>, S. Schlaubitz<sup>\*1</sup>, C. A. Shaw<sup>\*1</sup>, S. Kakuru<sup>\*1</sup>, E. Munivez<sup>\*1</sup>, P. Hermanns<sup>\*2</sup>, Y. Chen<sup>\*1</sup>, B. Zabel<sup>\*2</sup>, B. Lee<sup>1</sup>. <sup>1</sup>Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, <sup>2</sup>Pediatric Genetics Section, Freiburg University Hospital, Freiburg, Germany.

*Sfrp2* belongs to the secreted frizzled related family of proteins that share a cysteine-rich domain (CRD) with the Wnt family of receptors, called frizzled. Since Wnt molecules bind the CRD domain of the frizzled receptors, the Sfrps proteins can function as soluble receptors for Wnt thereby modulating its downstream signaling. *Sfrp2* is highly expressed during mouse embryonic development of the eye, brain, neural tube, craniofacial mesenchyme, kidney, joints, testis, pancreas and sub-epithelial structures. We found that during mouse limb bud development, *Sfrp2* is expressed in perichondrium of the digits at E13.5, in all limb joints and mesenchymal tissue surrounding them at E15.5 and then in mesenchyme lining ossified diaphyses of autopod elements. We generated *Sfrp2* knock-out mice via homologous recombination. Although *Sfrp2*<sup>-/-</sup> pups are grossly indistinguishable from their WT counterparts and thrive into adulthood they show subtle limb defects with mesomelic shortening and consistent shortening of all autopodal elements that is clinically manifested as brachydactyly. Moreover, a selective hind-limb syndactyly, involving the 3rd and 4th digit, was also observed and showed variable penetrance depending on the mouse genetic background. The brachydactyly is caused by decreased chondrocyte proliferation and delayed differentiation in distal limb chondrogenic elements. These data suggest that *Sfrp2* can regulate both chondrogenesis and regression of interdigital mesenchyme in distal limb. *Sfrp2* can also repress canonical Wnt signaling by *Wnt1*, *Wnt9a*, and *Wnt4* in vitro. *Sfrp2*<sup>-/-</sup> and TOPGAL/*Sfrp2*<sup>-/-</sup> mice have a mild increase in beta-catenin and beta-galactosidase staining, respectively, in some phalangeal elements. This however does not exclude a potential concurrent effect on non-canonical Wnt signaling in the growth plate. In combination with what is known about BMP and Wnt signaling in human brachydactyly, our data establish an important role for *Sfrp2* in proper distal limb formation and suggest *SFRP2* could be a novel candidate gene for human brachy-syndactyly defects.

**Determinants of Humeral Bone Volume in Males: A Genome-wide Analysis.** L. L. Tosi<sup>1</sup>, F. Suer<sup>\*2</sup>, B. Harmon<sup>\*2</sup>, C. Brandoli<sup>1</sup>, H. Gordish-Dressman<sup>\*2</sup>, E. Hoffman<sup>\*2</sup>, J. Devaney<sup>\*2</sup>. <sup>1</sup>Bone Health Program, Children's National Medical Center, Washington, DC, USA, <sup>2</sup>Research Center for Genetic Medicine, Children's National Medical Center, Washington, DC, USA.

**Objective:** We sought to identify genetic markers for bone volume, a polygenic trait with critical implications for bone strength and quality, in men. Previous studies have suggested that genes for bone structure may be sex-specific, thus we began by focusing on a single sex. We chose to study the humerus because we believe that it may be a particularly sensitive bone for detecting genetic predispositions in bone health for two reasons: (1) it is a single bone and thus not subject to load sharing; and (2) it is not weight-bearing and thus less affected by confounding factors such as fluctuations in weight or activity. **Methods:** We calculated total bone volume in the distal 9.6 cm of the humeral diaphysis of the non-dominant arm from magnetic resonance images (MRI) using semi-automated software from Rapidia. Subjects were 303 young adult Caucasian males (23.68 ± 5.47 years) participating in the Functional Polymorphisms Associated with Muscle Size and Strength (FMS) study, a multi-center program designed to study the influence of genetic polymorphisms on bone geometry, fat volume, and skeletal muscle size and strength. We performed genome-wide screening for the 60 subjects with the highest and lowest bone volumes in the cohort, using the Affymetrix® Genome-Wide SNP Array 6.0. Results were analyzed using the bioinformatics software package Partek GS. **Results:** We identified 138 SNPs associated with bone volume in the study cohort. Among the most significant SNPs, 121 of 138 were in five linkage disequilibrium blocks and 129 fell on the X chromosome. In all, we identified eight regions of interest, with four SNPs falling in the UTR regions of genes, and one SNP falling in the coding region of a gene. The genes KCND1, DMD, TMEM 164, CHDR1, KAL 1, GEMIN8, RPGR, and DGKK contained the most statistically significant SNPs. **Discussion:** Many whole genome scans that have attempted to study bone density (a combination of bone size and mineral properties) have shown inconsistent results. By focusing on bone volume, we believe that we may be able to identify genetic markers that are consistent across multiple populations. As next steps, we plan to (1) validate the results of the whole-genome analysis by genotyping the most statistically significant SNPs in the entire FMS population, (2) fine-map and deep sequence the identified regions, and (3) develop hypotheses as to how these genes influence bone quality.

**Expression of an Engineered G<sub>s</sub>-coupled Receptor in Osteoblasts Affects Intramembranous and Endochondral Bone Formation During Bone Repair.** E. Hsiao<sup>1</sup>, S. Lieu<sup>\*2</sup>, Y. Yu<sup>\*2</sup>, C. Manalac<sup>\*1</sup>, B. Conklin<sup>\*1</sup>, R. Nissenson<sup>3</sup>, C. Colnot<sup>2</sup>. <sup>1</sup>GICD, J. David Gladstone Institutes, San Francisco, CA, USA, <sup>2</sup>Dept. of Orthopedics, Univ. of California, San Francisco, CA, USA, <sup>3</sup>Endocrine Unit, VA Medical Center, San Francisco, CA, USA.

Activation of G-protein coupled receptors (GPCRs) in bone, such as the parathyroid hormone receptor (PTHr1) by recombinant PTH(1-34), has been associated with improved fracture healing; however, how GPCR signals regulate fracture healing is not well understood. We previously described mice expressing an engineered G<sub>s</sub>-coupled GPCR, Rs1, in maturing osteoblasts using the Collagen 1 alpha 2.3 kb promoter fragment (Coll(2.3)-tTA/TetO-Rs1 mice). Mutant mice showed dramatic skeletal expansion in both intramembranous and endochondral bones that was suppressed when Rs1 expression was delayed until after 4 wks of age. Since bone repair can recapitulate embryologic bone development, we hypothesized that Rs1 signaling in osteoblasts would accelerate and/or augment healing after bone injury. In this study, we used 14-16 wk old male Coll(2.3)-tTA/TetO-Rs1 mice where Rs1 expression was induced at 4 wks of age. A 1-mm tibia cortical defect model and a non-stabilized 3-point bending tibia fracture model were used to assess repair via intramembranous or endochondral ossification, respectively. Three mice per time point were analyzed at 7, 14, and 21 days after surgery and compared to littermate WT controls. In the cortical defect group, histomorphometry on the mutant mice showed significant increases in the total callous and trabecular bone volumes at 21 days (0.606 ± 0.159 vs. 0.262 ± 0.069 mm<sup>3</sup>, p=0.01 and 0.217 ± 0.026 vs. 0.130 ± 0.030 mm<sup>3</sup>, p=0.009) but not at 7 or 14 days after injury. These increases in trabecular bone were confirmed by microCT. In the non-stabilized fracture group, mutant mice showed a significant increase in callus volume at day 7 (41.383 ± 3.827 vs. 29.308 ± 1.963 mm<sup>3</sup>, p=0.004) but equal callous volumes at days 14 and 21 by histomorphometry. The proportion of cartilage within the callus was decreased at days 7 (0.044 ± 0.038 vs. 0.094 ± 0.025, p=0.07) and 14 (0.037 ± 0.010 vs. 0.091 ± 0.014, p=0.003) and was correlated with increased bone content within the callus at day 14 (0.499 ± 0.066 vs. 0.383 ± 0.022, p=0.02). These results show that constitutive Rs1 expression in adult osteoblasts stimulates callous and bone formation during healing of cortical defects and non-stabilized fractures, correlating with our prior results that Rs1 is anabolic in both intramembranous and endochondral ossification. Our findings also suggest that G<sub>s</sub> signals in osteoblasts may negatively regulate chondrogenesis during bone repair.

**Disclosures:** E. Hsiao, None.

**Impaired Bone Formation in Mice Lacking Lamin A/C Activation Leads to Severe Osteopenia.** D. Rivas<sup>1</sup>, W. Lee<sup>\*2</sup>, R. Akter<sup>1</sup>, J. E. Henderson<sup>2</sup>, G. Duque<sup>3</sup>. <sup>1</sup>Lady Davis Institute-McGill University, Montreal, QC, Canada, <sup>2</sup>JTN Wong Laboratories-McGill University, Montreal, QC, Canada, <sup>3</sup>Nepean Clinical School-University of Sydney, Penrith, Australia.

Nuclear lamina alterations occur in premature aging syndromes that include severe osteoporosis. The role of proteins of the nuclear lamina in bone remains to be elucidated. Our previous study demonstrated that knockdown of lamin A/C, a protein of the nuclear lamina, inhibits osteoblastogenesis and promotes adipocyte differentiation of mesenchymal stem cells (MSC) *in vitro*. In this study we used the Zmpste24-null progeroid mice, which exhibit nuclear lamina defects and lack active lamin A/C, to identify the role of lamin A/C in MSC differentiation *in vivo*. At four months of age, histological and micro computed tomography measurements of femurs in Zmpste24-null mice revealed a significant decrease in bone volume (BV/TV), trabecular number (Tb.N) and both cortical and trabecular thickness in Zmpste24-null mice compared with their wild type littermates ( $p < 0.001$ ). Osteoblasts surface and numbers are dramatically diminished by 75% in the Zmpste24-null mice. This phenotype occurred in the absence of alterations in osteoclast numbers or eroded surfaces. In contrast the number of marrow adipocytes and the amount of fat volume was significantly higher in Zmpste24-null mice compared to controls ( $p < 0.01$ ). The expression of osteoblast markers (alkaline phosphatase, osteocalcin) was found to be significantly down regulated in Zmpste24-null mice 60-70 % compared to WT littermates, and serum levels of parathyroid hormone, vitamin D and osteoclast markers remained unchanged. The differences were significantly higher in male than female Zmpste24-null mice ( $p < 0.01$ ). We also examined bone marrow stromal cells isolated from Zmpste24-null and WT mice and tested their ability to differentiate into osteoblasts. Colony forming unit-osteoblasts were significantly reduced in Zmpste24-null mice compared to WT mice. These data indicate that the presence of lamin A/C is necessary for normal osteoblast differentiation *in vivo*, possibly by preventing the differentiation of MSC into the adipocyte lineage.

**Bone Microarchitecture Is Dependent Upon Collagen  $\alpha 1(XI)$  Expression During Development.** N. J. Hoskins\*, A. Pedracini\*, L. M. Mercer\*, J. T. Oxford. Biology, Boise State University, Boise, ID, USA.

Collagen type XI is an essential component of the collagen fibrils within the developing skeleton. It is a quantitatively minor member of the fibrillar collagens that plays a regulatory role in the assembly of embryonic collagen fibrils as the diameter of collagen fibrils is dependent on the presence of Collagen  $\alpha 1(XI)$ . However, very little is known about the role of collagen type XI in bone microarchitecture formation.

In this study, skeletal mineralization was evaluated in the absence and presence of Collagen  $\alpha 1(XI)$  comparing the chondrodysplasia (*cho*) mouse embryo to wildtype. The data presented support a role for collagen type  $\alpha 1(XI)$  in skeletal development that is distinct from its function in nucleating the formation and limiting the diameter of cartilage type II collagen fibrils.

Established characteristics of the *cho* mouse were apparent in the mouse included in this study, including a shortened snout, and short, wide long-bones with flared metaphyses. The *cho* mouse humerus was 55% the length of the wildtype humerus and approximately 35% wider at the diaphysis and metaphyses.

Quantification of the differences in the humerus, vertebral column, and ribcage of the *cho* and wildtype mice was carried out using high-resolution three-dimensional models that were created from x-ray microcomputed tomography images.

Analysis revealed differences in bone density, size and microarchitecture. The differences in skeletal properties between these mice were analyzed by determining bone mineral density (BMD) calculations and three-dimensional measures of microarchitecture (BV/TV, Tb.Th, Tb.N, Tb.Sp). Results indicated that bone mineral density was increased in the absence of collagen  $\alpha 1(XI)$  in humerus, vertebrae, and the anterior rib samples of the *cho* mouse. The increase in bone density correlated with an observed increase in trabecular number, trabecular thickness, and percent bone volume, as well as a decrease in trabecular separation in the humerus, ribs, and vertebrae. In contrast, cortical bone mineral density was similar in wildtype and *cho* mice.

A function for Collagen  $\alpha 1(XI)$  in the establishment of bone microarchitecture during embryonic development is supported by this data. Future studies will focus on Collagen  $\alpha 1(XI)$  in bone formation and mineralization by osteoblasts, and new functions for Collagen  $\alpha 1(XI)$  in non-cartilaginous tissues of the skeleton.

## F141

**Nephroblastoma Overexpressed (Nov) Induces Gremlin Expression by Post Transcriptional Mechanisms.** A. Smerdel-Ramoya<sup>1</sup>, S. Zanotti<sup>1</sup>, A. N. Economides<sup>\*2</sup>, E. Canalis<sup>\*1</sup>. <sup>1</sup>Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA, <sup>2</sup>Senior Director, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA.

Nov, a member of the CCN family of proteins, inhibits osteoblastogenesis and causes osteopenia *in vivo*. Although Nov binds bone morphogenetic protein (BMP)-2/4 and decreases BMP signaling and activity, interactions of Nov with other extracellular proteins are possibly responsible for selected effects of Nov in bone. We postulated that Nov could induce the synthesis of BMP antagonists, and examined for their expression *in vitro* and *in vivo*. ST-2 stromal cells transduced with retroviral vectors to overexpress Nov under the control of the cytomegalovirus promoter (pLPCX-Nov) were compared to vector transduced cells. Gremlin mRNA levels increased in Nov overexpressing cells from *gremlin/gapdh* copy number of  $10 \pm 2$  in control to  $377 \pm 58$  in pLPCX-Nov cells. Conversely, down regulation of Nov in ST-2 cells by RNA interference (RNAi) reduced gremlin mRNA levels from  $3.4 \pm 0.6$  in control to  $1.2 \pm 0.2$  *gremlin/gapdh* copy number in Nov down regulated cells. To explore mechanisms of gremlin induction by Nov, a 2.1 kilobase fragment of the gremlin promoter was cloned and transfected into ST-2 cells overexpressing Nov (pLPCX-Nov), co-transfected with Nov expression vectors (pcDNA-Nov) or transfected into wild type ST-2 cells and treated with Nov protein. Gremlin promoter activity was not altered by Nov under any of these conditions. Furthermore, gremlin promoter activity was not changed in Nov down regulated cells. The results indicate lack of transcriptional control. To determine whether post transcriptional mechanisms were operational, ST-2 cells were transcriptionally arrested, using 5,6-dichlorobenzimidazole riboside (DRB), and the decay of gremlin transcripts determined. Gremlin mRNA half life was prolonged from ~12 h in control cultures to >48 h in pLPCX-Nov cells. Conversely, down regulation of Nov destabilized gremlin transcripts shortening the half life of gremlin mRNA from 11 h in control to 2.7 h in Nov down regulated ST-2 cells. Moreover, the half life of gremlin mRNA was shortened to ~25% in stromal cells from *nov* null mice when compared to wild type cells. The regulation of gremlin by Nov was confirmed *in vivo*, and gremlin mRNA levels in calvariae from Nov transgenic mice were 10 times higher than in wild type controls, whereas gremlin mRNA levels were reduced to 50% in *nov* null calvariae. The effect of Nov seemed to be selective to gremlin, and expression of noggin, another BMP antagonist was not modified. In conclusion, Nov induces gremlin expression in cells of the osteoblastic lineage by post-transcriptional mechanisms. This effect explains in part the inhibitory actions of Nov on osteoblastogenesis and bone formation.

**Specific Forms of DMP1 Support Attachment and Haptotactic Migration via  $\alpha V\beta 3$  but not  $\alpha V\beta 5$  Integrin.** Z. von Marschall\*, L. W. Fisher. CSDB, NIH, Bethesda, MD, USA.

Mutations in dentin matrix protein-1 (DMP1) result in human skeletal disease. While the precise function(s) of DMP1 in mineralizing and metabolically active ductal epithelial tissues remains essentially unknown, the presence of a highly conserved integrin-binding RGD motif suggests that interaction with integrins is critical. Using a panel of relevant human cell types [primary dental pulp stem cells (DPSC), a salivary intercalated duct cell-line (HSG), and osteosarcoma cells (MG63)], we compared both integrin-specific attachment and haptotactic migration on various forms of DMP1 as well as two other SIBLINGs, bone sialoprotein (BSP) and osteopontin (OPN). DPSC and MG63 cells attached and migrated onto DMP1 using  $\alpha V\beta 3$ , while cells lacking this integrin (HSG) failed to do so. Contrary to reports using other cells, the  $\alpha V\beta 5$  integrin on HSG cells also failed to support attachment to OPN. As expected, HSG did attach to the much more integrin-promiscuous BSP. *De novo* expression of  $\alpha V\beta 3$  by adenoviral gene transduction induced HSG cells to attach to as well as migrate onto both DMP1 and OPN. Using a variety of DMP1 constructs, we found that neither 1) substituting the BSP-derived conserved amino acid residues flanking the RGD in DMP1, nor 2) replacing the first four coding exons of BSP for same in DMP1, nor 3) the lack of post-translational modifications changed integrin-binding specificity of DMP1 for  $\alpha V\beta 3$  integrin. In contrast to previous studies suggesting that the proteolytic processing of DMP1 is required to generate a functional C-terminal fragment, we did not observe significant differences in cell attachment or migration between the full-length and BMP-1-processed (57 kDa) form. However, the proteoglycan form of the full-length DMP1 exhibited a dramatically lower ability to support cell attachment and those that did attach failed to spread effectively. The migration onto DMP1 was also severely inhibited by the presence of the glycosaminoglycan (GAG) chain. Both attachment and spreading were rescued after the GAG chain was eliminated by an *in situ* treatment with chondroitinase ABC. In conclusion, attachment and migration on DMP1 and OPN are mediated by  $\alpha V\beta 3$  and not  $\alpha V\beta 5$  integrins. BSP can use either receptor but substituting the BSP RGD domain or the first four coding BSP exons into DMP1 did not engender BSP-like properties. Intact, BMP-1-processed, and nonpost-translationally modified forms of DMP1 were equally efficient at these processes, but the greatly diminished activity of the proteoglycan form suggests that the GAG chain may be critical for differential functions of DMP1.

**Changes in Bone Matrix Material Properties Due to Osteopontin Deficiency.** P. J. Thurner<sup>1</sup>, C. Chen<sup>\*2</sup>, S. Ionova<sup>\*3</sup>, J. W. Ager<sup>\*3</sup>, R. O. Ritchie<sup>\*3</sup>, T. Alliston<sup>2</sup>. <sup>1</sup>School of Engineering Sciences, University of Southampton, Southampton, United Kingdom, <sup>2</sup>Orthopaedic Surgery, University of California San Francisco, San Francisco, CA, USA, <sup>3</sup>Lawrence Berkeley National Laboratories, Berkeley, CA, USA.

Bone matrix material properties reflect the ability of bone matrix to resist deformation and fracture. Using advanced mechanical testing techniques we previously identified TGF $\beta$  as one of the first known regulators of the material properties of bone matrix, through mechanisms that remain unknown. TGF $\beta$  regulates the expression of several bone matrix proteins including osteopontin (OPN). Previous work by our group and others suggests that OPN contributes to the material quality of bone matrix by direct mechanical contributions and by regulation of mineralization. Therefore, we hypothesized that OPN is required for the regulation of bone matrix material properties by TGF $\beta$ . In the present study, we aim to determine if and how OPN participates in the specification of bone matrix material properties by TGF $\beta$ .

If OPN is downstream of TGF $\beta$  in the regulation of bone matrix material properties, then OPN expression should be disrupted in transgenic mice with altered TGF $\beta$  signaling that exhibit defective bone matrix material properties and bone from OPN deficient mice (OPN<sup>-/-</sup>) should resemble bone from DNT $\beta$ R11 mice which express a dominant negative TGF $\beta$  type II receptor in osteoblasts. Although TGF $\beta$  induces OPN expression in vitro, preliminary data reveal no TGF $\beta$ -dependent differences in OPN mRNA expression in 10-day old mouse calvarial bone. To evaluate the material properties of OPN<sup>-/-</sup> bone matrix, bones were harvested from 2-month old male mice (WT and OPN<sup>-/-</sup>) on a C57/bl6 background according to approved protocols. Notched three-point bending tests of femora showed a reduced fracture toughness ( $p \leq 0.03$ ,  $N=9/9$ ) in OPN<sup>-/-</sup> mice ( $3.87 \pm 0.79$  MPa m<sup>1/2</sup>, compared to WT mice ( $5.55 \pm 1.78$ ) MPa m<sup>1/2</sup>). Small angle X-ray scattering revealed a significantly smaller mean crystal thickness ( $p \leq 0.02$ ,  $N=9/7$ ) in OPN-KO mice ( $1.93 \pm 0.7$ ) nm compared to WT mice ( $2.02 \pm 0.07$ ) nm. Consistent with previous reports, the altered material properties of OPN<sup>-/-</sup> bone result in part from altered mineral organization. To examine the possible direct mechanical role of OPN, de-mineralized femora were evaluated by tensile testing. These tests show a possible decrease in ultimate tensile strength in OPN-KO mice compared to WT mice. Nanoindentation studies are currently underway. Although preliminary data do not reveal consistent similarities between DNT $\beta$ R11 and OPN<sup>-/-</sup> bone, we find so far that OPN deficiency results in lower fracture toughness and decreased mineral crystal thickness.

**Loss of MMP-9 Results in Improved Healing, and Remodeling of Adhesions in A Murine Model of Flexor Tendon Repair.** A. E. Loisel<sup>\*</sup>, M. J. Wolenski<sup>\*</sup>, J. A. Jacobson<sup>\*</sup>, D. J. Mitten<sup>\*</sup>, E. M. Schwarz<sup>\*</sup>, H. A. Awad<sup>\*</sup>, R. J. O'Keefe. Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

In a murine model of flexor tendon healing, we have previously demonstrated that MMP-9 expression is significantly increased at seven days post repair, returning to basal levels after this time. Biomechanically, flexion of the metatarsophalangeal (MTP) joint range of motion (ROM) was limited due to fibrous adhesion formation between 14 and 21 days post-repair. To gain a better understanding of the effects of MMP-9 and collagen catabolism during flexor tendon healing, we examined tendon healing in MMP-9<sup>-/-</sup> (KO) mice. Healing was evaluated based on biomechanical properties, histological evaluation and gene expression patterns using real-time RT-PCR up to 28 days post-repair.

MMP-9<sup>-/-</sup> mice had delayed synthesis of both reparative collagen 3, and mature collagen 1. Wild type (WT) mice had peak Col3 expression at day 10, while peak expression of Col3 was delayed until day 21 in KO mice. Interestingly, histology indicated that KO mice displayed an organized arrangement of collagen fibers earlier than WT mice (day 21, compared to day 28 wild type), suggesting an earlier transition from scar tissue to mature tendon tissue. Consistent with an earlier return to normal tendon architecture, expression of GDF-5 and Smad8 was observed earlier in KO mice. Expression of these two genes that have each been shown to induce neotendon formation was elevated beginning at day 7 post-repair in KO mice, with peak GDF-5 expression occurring at day 14 and the highest Smad8 expression on day 28. In WT mice there was no significant induction of GDF-5 or Smad8 until day 28 post-repair. Biomechanically, WT and KO mice both displayed a steady increase in maximum load at failure of the repair, but loss of MMP-9 resulted in significant increases in the maximum load at failure compared to WT at all time points post repair (44% of control for KO and 27% of control for WT at day 28). To quantify adhesion formation, MTP joint ROM was measured at incrementally applied loads, and the adhesion coefficient ( $[\alpha]$ , a measure of resistance to gliding) was calculated. MMP-9<sup>-/-</sup> mice exhibited earlier and more robust adhesion formation, with the greatest resistance to MTP joint ROM occurring at 14 days post-repair. ( $[\alpha]$  KO = 139,  $[\alpha]$  WT = 57) Notably, remodeling of adhesions occurred earlier and to a greater degree in MMP-9<sup>-/-</sup> mice. By day 21, adhesions in the KO tendons were completely remodeled and no significant loss in functional ability was present.

This data suggests that despite an early lag in healing, and more robust adhesion formation, loss of MMP-9 is beneficial in the later stages of healing, resulting in the presence of adhesions for a shorter period of time, as well as increase in the overall rate of healing.

**TGF $\beta$ - and BMP-Signaling Pathways Have Antagonistic Effects During Chondrogenesis.** B. Keller<sup>\*1</sup>, Y. Chen<sup>\*1</sup>, E. Munivez<sup>\*1</sup>, T. Bertin<sup>\*1</sup>, B. Zabel<sup>\*2</sup>, B. Lee<sup>3</sup>. <sup>1</sup>Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, <sup>2</sup>Centre for Pediatrics and Adolescent Medicine, University Hospital of Freiburg, Germany, <sup>3</sup>Molecular and Human Genetics, Baylor College of Medicine, Howard Hughes Medical Institute, Houston, TX, USA.

TGF- $\beta$ /BMP signaling is essential for normal development of almost all embryonic and extraembryonic tissues. Ligands of these pathways are involved in the development of cartilage and bone at multiple stages. BMPs are important during early condensation of the cartilaginous anlagen, proliferation and hypertrophy of chondrocytes. *Smad1* and *Smad5* are two mediators of the BMP signals and they are both expressed in the growth plate. Similarly, TGF $\beta$  signaling has been shown to exhibit diverse effects both *in vitro* and *in vivo*. To compare the role of these signaling pathways in the growth plate, we generated mouse models of loss of function of BMP vs. TGF $\beta$  signaling. To down regulate BMP signaling *in vivo*, we generated chondrocyte-specific deletions of *Smad1* on either a wild type or *Smad5* heterozygous background.

Mice deficient in *Smad1* in proliferating chondrocytes show only a slight shortening of the growth plate, while mice with an additional *Smad5* heterozygous background show a more severe phenotype with shorter prehypertrophic and hypertrophic zones and a diminished proliferation rate. *Ihh* expression in these mice is down-regulated. Morphologically, the conditional *Smad1* deletion with and without *Smad5* heterozygous background mice showed craniofacial alternations characterized by agenesis of the nasal septum. Interestingly, mineralization and extracellular matrix production were not affected.

To down-regulate TGF $\beta$  signaling, we generated transgenic mice over-expressing a dominant negative form of the TGF $\beta$  receptor I ( $\Delta$ T $\beta$ RI) in proliferating chondrocytes. The transgenic mice are smaller but show histologically an elongated growth plate with enhanced *Ihh* expression and an increased proliferation rate. The production of the extracellular matrix is disturbed. Morphologically,  $\Delta$ T $\beta$ RI transgenic mice also exhibited a craniofacial phenotype; the skull is smaller with a prominent mandible. Hence, during endochondral ossification, BMP and TGF $\beta$  signaling have antagonistic effects on cell proliferation and differentiation. While disruption of BMP signaling leads to a shortening of the growth plate with fewer proliferating cells, impairment of TGF $\beta$  signaling results in an increase in the proliferation rate and thus a longer prehypertrophic and hypertrophic zone.

## F163

**Evaluation of Clinical Utility of Venous Sampling for FGF23 in Identifying and Confirming Responsible Tumors for Tumor-Induced Osteomalacia (TIO): Analysis of 15 Patients.** N. Ito, H. Suzuki<sup>\*</sup>, Y. Shimizu<sup>\*</sup>, T. Saito<sup>\*</sup>, S. Fukumoto, T. Fujita<sup>\*</sup>. Division of Nephrology & Endocrinology, Department of Medicine, University of Tokyo Hospital, Tokyo, Japan.

TIO is a paraneoplastic syndrome caused by overproduction of FGF23 by responsible tumors. This disease is completely cured by resection of responsible tumors. Therefore, the detection of responsible tumors for TIO is clinically very important. Several methods including MRI skeletal survey and Octreotide scintigraphy have been advocated for the detection of responsible tumors for TIO. However, the sensitivity of these methods is not 100%. Furthermore, even when tumors were found by these methods, none of these techniques can confirm that the detected tumors are responsible for TIO. On the other hand, venous sampling for FGF23 was reported to be useful for the detection and confirmation of responsible tumors in a few patients with TIO. Therefore, we further analyzed the clinical utility of venous sampling for FGF23 in consecutive 15 patients with typical features of TIO. Blood samples were collected either by using catheters inserted from femoral vein (average 15.5 samples/patient) or by venipuncture from the body surface (average 5.4 samples/patient), and FGF23 levels in these samples were measured by ELISA for intact FGF23 (Kainos, Japan). In 6 patients, previous imaging studies by CT or MRI had revealed suspicious tumors for TIO. In these patients, venous sampling (4 patients with catheters and 2 patients from the body surface) revealed the increase of FGF23 in the proximal regions of tumors and confirmed that the tumors are responsible for TIO in 5 patients. Resection of tumors resulted in the cure of TIO in these 5 patients. In contrast, the increase of FGF23 was not detected around the tumor in one patient and the resection of that tumor did not improve the clinical features in this patient. On the other hand, suspicious tumors had not been identified by previous studies in 9 patients. Venous sampling (4 patients with catheters and 5 patients from the body surface) indicated the increase of FGF23 in 6 of these patients and subsequent detailed imaging studies detected responsible tumors for TIO in all 6 patients. Collectively, sampling using catheters and from the body surface identified the responsible tumors in 6 out of 8 patients and 5 out of 7 patients, respectively. These results indicate that venous sampling for FGF23 is clinically useful for identifying and confirming responsible tumors for TIO.

**Intermittent Injection of Recombinant Osteocalcin Improves Glucose Tolerance and Insulin Sensitivity.** M. Ferron<sup>\*1</sup>, G. Karsenty<sup>1</sup>, P. Ducy<sup>\*2</sup>.<sup>1</sup>Genetic and development, Columbia University, New York, NY, USA, <sup>2</sup>Pathology, Columbia University, New York, NY, USA.

We recently showed that the uncarboxylated form of the osteoblast-specific secreted molecule osteocalcin functions as a hormone favoring glucose handling and increasing energy expenditure. We also demonstrated that continuous subcutaneous infusion of recombinant uncarboxylated osteocalcin can increase insulin secretion,  $\beta$ -cell proliferation and energy expenditure in wild-type (WT) mice. As a result, it could prevent the development of obesity and type 2 diabetes in hyperphagic mice or mice fed a high fat diet. In a new set of studies, we tested the effect of recombinant osteocalcin administered intermittently once a day on energy metabolism. Daily injections of osteocalcin in WT mice at both 3 and 30 ng/g/day significantly improved glucose tolerance, as assessed by glucose tolerance tests (GTT). At 30 ng/g/day this effect was already significant after 3 weeks, peaked at 6 weeks and was no longer detectable after 12 weeks of treatment. In contrast, injection of osteocalcin at 3 ng/g/day induced a significant effect on GTT only after 6 weeks but this effect kept improving overtime. Insulin sensitivity, as assayed by insulin tolerance tests (ITT), was improved after 3 weeks at both concentrations. This effect was still detectable after 12 weeks of treatment in mice injected with 3 ng/g/day. Blood glucose after feeding was significantly reduced following 5 to 10 weeks of osteocalcin injections at 30 ng/g/day. Importantly, daily injections of osteocalcin had no effect on body weight, food intake or body temperature. Experiments are in progress to determine if intermittent injection of osteocalcin can improve insulin sensitivity in a diet-induced mouse model of type 2 diabetes.

**Prostaglandin E2 as a Potential Mediator of Parathyroid Hormone (PTH)-dependent Regulation of Hematopoietic Stem Cells (HSC).** R. Porter<sup>\*</sup>, B. Frisch<sup>\*</sup>, J. Weber<sup>\*</sup>, A. Olm-Shpan<sup>\*</sup>, L. M. Calvi. Department of Medicine, University of Rochester School of Medicine, Rochester, NY, USA.

HSC are pluripotent cells responsible for the establishment and renewal of the entire hematopoietic system. We and others have established that osteoblastic cells in the bone marrow microenvironment regulate HSC cell fate decisions. Specifically, PTH expands HSC by activating osteoblasts in the HSC niche. However, the molecular mechanisms for this increase are unknown. PTH increases local production of prostaglandin E2 (PGE2) in osteoblasts by stimulating cyclooxygenase 2. We also recently found that treatment of MC3T3 cells with PTH ( $10^{-7}$  M) rapidly induces PGE2 Synthase expression, suggesting that PGE2 may be a mediator of the PTH effect on HSC. In fact, we have shown that *in vivo* PGE2 treatment increases lineage<sup>+</sup> Sca-1<sup>+</sup> c-kit<sup>+</sup> (LSK) cells within the bone marrow 2.75-fold compared with vehicle treated mice ( $p=0.0061$ ,  $n=8$ /group). This increase was specific to HSC as there was no effect on CFU-C or peripheral blood Hct, Plt or WBC counts. Bone marrow mononuclear cells (BMMC) from mice treated with PGE2 also had superior lymphomyeloid reconstitution in competitive repopulation analyses. However, this effect was specific to the short-term HSC responsible for repopulation 6-8 weeks after transplantation. To investigate the mechanism of PGE2 mediated expansion of short-term HSC, we analyzed the expression of the four PGE2 receptors, EP1-EP4, by quantitative RT-PCR. Reciprocal differential expression was found, with EP2 and EP4 transcript levels very low in long-term HSC and high in short-term HSC, and EP1 and EP3 showing the opposite pattern. These data suggest that PGE2 may act through EP2 and/or EP4 to cause expansion and increased repopulating ability of short-term HSC. It is known that HSC that reside in G<sub>0</sub> of the cell cycle have increased ability to reconstitute myeloablated recipient mice. Since PGE2 treatment resulted in superior reconstitution, we hypothesized that PGE2 may increase the percentage of HSC residing in G<sub>0</sub>. To test this hypothesis, we treated BMMC from wild type or EP2<sup>-/-</sup> mice with  $10^{-6}$  M PGE2 or vehicle for 90 minutes. The percentage of cells in G<sub>0</sub> vs. G<sub>1</sub> was determined by flow-cytometric analysis using the RNA and DNA dyes, Pyronin-Y and Hoechst 33342 respectively. PGE2 treatment increased the percentage of wild-type LSK cells in G<sub>0</sub> compared to vehicle-treated LSK cells (62% vs. 53.1%). However, this effect was not observed in the EP2<sup>-/-</sup> mice (67.2% vs. 58.1%). Taken together, these findings suggest that one mechanism of the PGE2-dependent regulation of short-term HSC activity may involve increasing the percentage of HSC that reside in G<sub>0</sub> by activation of EP2, thereby augmenting their ability to reconstitute the hematopoietic system of a myeloablated recipient.

**Craniofacial Bone Defect in Nell-1 Mutant Mice Associated with Disregulated Runx2 and Osx Expression.** X. Zhang<sup>1</sup>, T. Ko<sup>\*1</sup>, D. Pathmanathan<sup>\*1</sup>, H. Lee<sup>\*1</sup>, F. Chen<sup>\*1</sup>, C. Soo<sup>\*2</sup>, C. T. Culiat<sup>\*3</sup>, K. Ting<sup>1</sup>.<sup>1</sup>Dental and Craniofacial Research Institute, University of California, Los Angeles, Los Angeles, CA, USA, <sup>2</sup>Plastic and Reconstructive Surgery, University of Southern California, Los Angeles, CA, USA, <sup>3</sup>Life Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN, USA.

Nell-1 has been verified as a factor capable of promoting osteochondrogenic differentiation *in vitro* and *in vivo* consistently. ENU-induced *Nell-1* nonsense mutant mice died immediately post-birth and exhibited major defects in skeletal system. Current study has focused on the contributions of Runx2 and Osx to the craniofacial defects in mice with *Nell-1* deficiency since both molecules were crucial in osteochondrogenesis and linked to *Nell-1*'s function in previous studies. To further clarify the craniofacial feature of the *Nell-1* mutant mice, the quantitative Micro CT and cephalometric analyses were applied on newborn mice. To verify the defects of craniofacial bone development in *Nell-1* mutant mice, *in situ* activities of Alp and TRAP as well as protein expression of the marker genes *Opn*, *Ocn*, *Bsp*, *Col X* and *Sox9* were evaluated by histochemistry or immunohistochemistry. To address the possible mechanisms of craniofacial bone defects associated with *Nell-1* deficiency, the expression level and tissue distribution of Runx2 and Osx were investigated in context with cell proliferation and differentiation status in craniofacial tissues of mouse embryos at multiple stages in addition to newborns by real time PCR, Western Blot and immunohistochemistry. The result showed significantly increased calvarial suture width, decreased calvarial bone mineralization, decreased mandibular bone density and altered mandible angle morphology in mutant over wild type mice. Mutants also exhibited markedly reduced Alp activity in bone forming regions, while TRAP activity remained unchanged. All osteoblastic marker proteins were consistently downregulated to various degrees in the calvarial bones and craniofacial cartilages in newborn mutants. In particular, altered Runx2 and Osx expression in mesenchymal condensation, the osteogenic fronts of cranial suture, bones and cartilages in mutant over wild type mice at different developing stages suggest *Nell-1* is important for normal Runx2 and Osx expression. In conclusion, *Nell-1* deficiency induces delay and malformation of craniofacial bone and cartilage, possibly through dysregulating Runx2 and Osx expression and/or protein functionality. Combined with previous findings, we conclude that *Nell-1* plays a significant role in modifying craniofacial membranous and endochondral skeletal growth and development.

**Phospholipase C $\gamma$ 2 as a Promising Therapeutic Target in Rheumatoid Arthritis.** V. Cremasco<sup>\*</sup>, E. Benasciutti<sup>\*</sup>, D. B. Graham<sup>\*</sup>, M. Cella<sup>\*</sup>, R. Faccio. Washington University, St Louis, MO, USA.

Rheumatoid arthritis is a debilitating chronic autoimmune disease characterized by synovial inflammation of peripheral joints and progressive destruction of bone and cartilage. Thus, identifying common signaling molecules affecting the osteo-immune system is likely to lay the groundwork for future therapies.

We have shown that phospholipase C gamma 2 (PLC $\gamma$ 2) is required for osteoclast (OC) differentiation and function. To analyze the role of PLC $\gamma$ 2 in inflammatory mediated bone loss, we used an established model of LPS induced bone erosion, in which injection of LPS directly into the knee joint enhances OC formation by inducing production of proinflammatory cytokines. While WT mice exhibited profound OC activation and bone erosion, PLC $\gamma$ 2<sup>-/-</sup> mice were protected from LPS induced focal osteolysis.

These findings together with the previously reported role of PLC $\gamma$ 2 in B cells, suggested that PLC $\gamma$ 2 could be central to both the inflammatory and the osteolytic response during arthritis. We used an antigen induced arthritis model wherein WT or PLC $\gamma$ 2<sup>-/-</sup> mice were immunized with methylated bovine serum albumin (mBSA), and then challenged 21 days later by intra-knee injection with mBSA. We found that PLC $\gamma$ 2<sup>-/-</sup> mice were protected from bone loss and inflammation compared to WT mice. Despite the capacity of PLC $\gamma$ 2<sup>-/-</sup> T cells to be activated *in vitro* by PMA and ionomycin, *ex-vivo* activation of T cells, as assessed by production of TH1-TH2 cytokines, was impaired in KO animals.

To determine whether the defective B cell development may contribute to the protection from mBSA-induced arthritis, we adoptively transferred WT CD45.1 congenic B cells into PLC $\gamma$ 2<sup>-/-</sup> mice. Strikingly, despite the presence of functional B cells, PLC $\gamma$ 2<sup>-/-</sup> mice remained protected from arthritis and unable to activate T cells. Consistent with this finding, we observed that B cell deficient mice developed arthritis at similar rates as WT mice, suggesting that the diminished response observed in PLC $\gamma$ 2<sup>-/-</sup> is independent of B cells.

In the multifactorial pathogenesis of arthritis, dendritic cells (DC) play a crucial role in initiating T cell response as they are armed antigen presenting cells. To test whether PLC $\gamma$ 2<sup>-/-</sup> mice might have defective DC function, we employed a DC transfer model of arthritis, where WT mice were immunized with mBSA pulsed WT or PLC $\gamma$ 2<sup>-/-</sup> DC and then challenged by intra-knee injection with mBSA. We found that mice injected with PLC $\gamma$ 2<sup>-/-</sup> DC did not develop any signs of arthritis, while WT DCs potentially induced inflammation, bone erosion, and T cell activation.

In conclusion, our study indicates a novel role for PLC $\gamma$ 2 in inflammatory bone loss and DC induced T cell activation suggesting PLC $\gamma$ 2 as a promising target for the treatment of both inflammation and bone erosion during the arthritic disease.

**Mice Lacking the Growth Hormone Receptor (GHR) in Liver Have Normal Skeletal Growth and Bone Volume Despite Virtual Absence of Circulating IGF-1.** D. J. DiGirolamo<sup>1</sup>, M. Mavalli<sup>1\*</sup>, C. Wan<sup>1</sup>, Y. Fan<sup>2\*</sup>, M. A. Sperling<sup>3\*</sup>, T. L. Clemens<sup>1</sup>. <sup>1</sup>Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Immunology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>Children's Hospital of Pittsburgh, Pittsburgh, PA, USA.

Growth hormone (GH) is thought to exert its effects on skeletal growth and mass through production of insulin-like growth factor-1 (IGF-1) from both liver and peripheral tissues. It is currently accepted that circulating IGF-1 produced in the liver, and peripheral IGF-1 produced in bone in response to GH, both play an important role in dictating linear growth and bone mass. However, limitations of previous models confound interpretation of the contribution of circulating versus peripheral IGF-1. To further explore the specific contribution of liver-derived and peripheral IGF-1 in mediating linear skeletal growth, we developed a model of tissue-specific GH receptor (GHR) deletion using the Cre-LoxP system. Liver-specific deletion of GHR (GHR<sup>LD</sup>) via albumin-driven Cre, resulted in >90% deletion of GHR as determined by quantitative RT-PCR and immunohistochemical analyses. Compared to controls, circulating IGF-1 was suppressed by 94% ( $23.9 \pm 4.2$  ng/ml;  $n = 13$  vs  $400 \pm 33.1$  ng/ml;  $n = 15$ ); IGFBP3 was suppressed by 80% ( $220.8 \pm 23.5$  ng/ml vs  $1083.2 \pm 125.1$  ng/ml); and acid labile subunit was suppressed by 84% ( $330.2 \pm 41.8$  ng/ml vs  $1992.6 \pm 163.9$  ng/ml;  $p < 0.001$  for each). Growth hormone was elevated ~4 fold in GHR<sup>LD</sup> mice ( $33 \pm 6.3$  ng/ml vs  $9.9 \pm 0.7$  ng/ml in controls;  $p < 0.001$ ) likely due to the absence of negative feedback by IGF-1. Despite virtual absence of circulating IGF-1, total body weight ( $23.45 \pm 0.67$  gm vs  $25 \pm 0.86$  gm), total length ( $8.88 \pm 0.11$  cm vs  $9.07 \pm 0.07$  cm) and tibial length ( $1.82 \pm 0.03$  vs  $1.8 \pm 0.02$  cm) were not different in GHR<sup>LD</sup> versus controls. Additionally, preliminary uCT studies showed no difference in bone volume between control and GHR<sup>LD</sup> mice at 16 weeks. To determine if normal linear growth resulted from a compensatory increase in IGF-1 from the growth plate, real-time PCR for IGF-1 was performed on RNA extracted from the growth plates of these mice. No difference in IGF-1 expression was seen between GHR<sup>LD</sup> and control mice. In summary, linear growth and bone volume are unchanged by >90% suppression of circulating IGF-1. These results challenge the prevailing view that circulating IGF-1 is required for normal bone growth and mass.

## F186

**BMP2 Inactivates TAK1-ATF2 Signaling Pathway in Chondrocytes.** L. Gao<sup>\*</sup>, T. Li, Y. Zhang, T. Sheu<sup>\*</sup>, M. J. Zuscik, D. Chen, E. M. Schwarz, R. J. O'Keefe. Orthopaedics, University of Rochester, Rochester, NY, USA.

A concomitant increase in BMP and decrease in TGF $\beta$  signaling occurs in Smad3<sup>-/-</sup> chondrocytes and contributes to the pathogenesis of osteoarthritis in these mice. Since both TGF $\beta$  and BMP regulate the p38 MAP kinase pathway, the manner in which BMP2 modulates this pathway was investigated.

## Table of Contents

Primary sternal chondrocytes from Smad3<sup>-/-</sup>, ALK2<sup>fllox/fllox</sup>, ALK3<sup>fllox/fllox</sup> and Smad1<sup>fllox/fllox</sup> mice and C5.18 cells, C9 cells, and primary articular porcine chondrocytes were used. Transfection and luciferase reporter assays, Western blots and immunoprecipitation were performed. p38 kinase and ATF2 binding assays were performed.

TGF $\beta$  or constitutively active (ca) ALK5 enhanced while BMP2 and ca-ALK3/6 decreased ATF2 reporter activity. TGF $\beta$  and anisomycin stimulated p38 phosphorylation, an effect suppressed by BMP2. BMP2 also suppressed p38 kinase activity. Similar inhibition was also observed in porcine chondrocytes and in C9 cells that overexpress BMP2. Western blots showed that BMP2 prevented activation of TAK1, MKK3/6, p38 and ATF2, indicating inhibition of the MAPK pathway in chondrocytes at an upstream signaling event. To determine possible involvement of Smad1 and BMP type I receptors, phosphorylation of p38 was examined in Smad1, ALK2 or ALK3 deficient chondrocytes. Cre-mediated deletion of Smad1 and ALK3 completely abolished BMP2 mediated inhibition of the p38, including the ability of anisomycin and TGF $\beta$  to induce ATF2 binding to its response element. In contrast, deleting ALK2 had a minor role in the inhibitory effect of BMP2 on p38. Immunoprecipitation assays were done to determine where BMP2 inhibits the TAK1-ATF2 pathway. TAB1 formed a complex with TAK1 in anisomycin or TGF $\beta$  treated cells. BMP2 prevented formation of this complex. In the presence of BMP2, TAB1 instead formed a complex with phospho-Smad1. Subsequent experiments showed that the Smad1 linker region is responsible for interaction with TAB1. Ad-TAB1 greatly reduced, while Ad-Smad1 increased *colX* expression in mouse chondrocytes.

The findings demonstrate that BMP2 inhibits activation of TAK1-ATF2 signaling by anisomycin and TGF $\beta$ . The mechanism involves the classic ALK3-Smad1 pathway and targets the upstream signaling molecule, TAB1. In response to BMP2, phospho-Smad1 forms a complex with TAB1, and prevents interaction between TAB1 and TAK1. The findings provide novel insights regarding integration of TGF $\beta$ /BMP2 signaling and define the TAK1-ATF2 as a potential therapeutic target to modulate chondrocyte maturation in diseases such as osteoarthritis.

**TGF $\beta$ 1 Induces Migration of Sca-1 and CD29-Positive Mesenchymal Stem Cells in Coupling Bone Resorption and Formation.** Y. Tang, X. Wu<sup>\*</sup>, W. Lei<sup>\*</sup>, L. Zhao<sup>\*</sup>, W. Chao<sup>\*</sup>, Z. Shi<sup>\*</sup>, X. Feng<sup>\*</sup>, X. Peng<sup>\*</sup>, M. Wan<sup>\*</sup>, X. Cao<sup>\*</sup>. Pathology, University of Alabama at Birmingham, Vestavia Hills, AL, USA.

The recruitment of osteoprogenitors to the bone resorptive sites is the initial event for coupling of bone resorption and formation. We demonstrate that TGF $\beta$ 1 released from bone matrix during osteoclastic bone resorption induces migration of stro-1 positive primary human bone marrow mesenchymal cells (MSC). Migration of MSCs was examined in coupling with *in vitro* osteoclastic bone resorption. Osteoclastic bone resorption-conditioned medium (CM) stimulates migration of MSCs, whereas CM from monocytes/macrophage or osteoclasts without bone slices had no effect. Importantly, addition of an antibody against TGF $\beta$ 1 inhibited the migration, CM prepared from bone slices of TGF $\beta$ 1<sup>-/-</sup> mice did not induce migration of MSCs with no detectable active TGF $\beta$ 1. The results indicate that TGF $\beta$ 1 released and activated during osteoclastic bone resorption.

Bone resorption was stimulated or inhibited in mice by injection with PTH (1-34) or OPG. Immunostaining of consecutive tibia sections with antibodies against CD29 and Sca-1, the markers for MSCs with osteogenic potential, revealed that PTH treatment resulted in a significant increase in the numbers of MSCs at the bone surface, and the numbers of the Sca-1<sup>+</sup> and CD29<sup>+</sup> MSCs at the remodeling surfaces were significantly reduced in the trabecular bone of OPG injected mice. Injection of the T $\beta$ R1 inhibitor in the rat tibia reduced bone formation dose-dependently as demonstrated by X-ray,  $\mu$ CT and histomorphometry, and the numbers of the Sca-1<sup>+</sup> and CD29<sup>+</sup> MSCs at the remodeling surfaces were significantly reduced. The TGF $\beta$ 1<sup>-/-</sup> mice was crossed with immunodeficient Rag2<sup>-/-</sup> mice to prevent the early death of the TGF $\beta$ 1<sup>-/-</sup> mice due to organ failure with inflammatory disease. Immunostaining showed lack of the Sca-1<sup>+</sup> and CD29<sup>+</sup> MSCs at the remodeling surfaces. Tracking of BrdU-labeled MSCs that were injected into the femur cavities of TGF $\beta$ 1<sup>-/-</sup>Rag2<sup>-/-</sup> and TGF $\beta$ 1<sup>-/-</sup>Rag2<sup>-/-</sup> mice demonstrates that TGF $\beta$ 1 induces migration of labeled STRO-1<sup>+</sup> MSCs to the bone remodeling sites *in vivo*. Therefore, active TGF $\beta$ 1 functions as a primary factor for recruitment of MSCs to the bone remodeling surface in the coupling process.

**Halofuginone Inhibits Melanoma Bone Metastases and TGF-beta Signaling.** P. Juárez<sup>1</sup>, J. Chirgwin<sup>1</sup>, K. Mohammad<sup>1</sup>, R. McKenna<sup>1\*</sup>, H. Walton<sup>1\*</sup>, M. Niewolna<sup>1\*</sup>, D. Javelaud<sup>2\*</sup>, F. Luciani<sup>3\*</sup>, V. Delmas<sup>3\*</sup>, L. Larue<sup>3\*</sup>, A. Mauviel<sup>2\*</sup>, T. Guise<sup>1</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA, USA, <sup>2</sup>INSERM, Paris, France, <sup>3</sup>Institut Curie, Orsay, France.

TGF-beta derived from bone fuels a vicious cycle of osteolytic metastases by inducing tumor expression of prometastatic genes, whose products act on bone cells to enrich the skeletal microenvironment. The vicious cycle can be blocked with inhibitors of the TGF-beta pathway. Halofuginone (Hfg), is a plant alkaloid derivative that is orally active, extensively used in animals, and has entered Phase II clinical trials in cancer patients. It increases expression of inhibitory Smad7, decreases phosphorylation of Smads 2 and 3 and blocks TGF-beta-induced type I collagen synthesis. We tested Hfg against osteolytic bone metastases caused by melanoma and then showed that TGF-beta induction of prometastatic target genes was inhibited by Hfg in breast, prostate and melanoma cell lines.

Nude mice inoculated in the left cardiac ventricle with 1205Lu human melanoma cells developed osteolytic bone metastases in 5 weeks. Mice treated daily i.p. with 5 $\mu$ g of Hfg had significantly less osteolysis on radiographs compared with mice injected with PBS ( $0.08 \pm 0.03$  vs  $0.42 \pm 0.09$ ,  $p < 0.01$ ; lesion area (mm<sup>2</sup>) of fore- and hind-limbs;  $n = 12$ /group). In contrast, Hfg had no effect on the growth of subcutaneous 1205Lu tumors or on the capacity to invade Matrigel<sup>TM</sup> *in vitro*, suggesting that the effect of Hfg is specific to block tumor growth in the bone microenvironment.

Human 1205Lu melanoma, MDA-MB-231 breast and PC-3 prostate cancer cells (all of which cause osteolytic metastases) were treated with 5ng/ml TGF-beta1 for 24hrs +/- 4hr pretreatment with 200nM Hfg. All three cell lines showed similar responses. Hfg blocked TGF-beta activation of: a) the synthetic Smad-signaling reporter pGL3-(CAGA)<sub>3</sub> by dual luciferase assay (decreased 70-80%,  $p < 0.05$ ); b) phosphorylation of Smads 2 and 3, as measured by Western blotting (decreased 60-70%); c) transcription of Smad7 (by PCR +/- actinomycin D). It reduced mRNAs for TGF-beta1 and alpha1-collagen I 80-90% and significantly (all  $p < 0.05$ ) decreased TGF-beta induction of mRNAs encoding CXCR4, PTHrP and CTGF in MDA-MB-231 cells (5.25, 2.5, 11-fold), in PC-3 cells (5, 10, 15-fold) and in 1205Lu (3.5, 4, 15-fold) respectively. Finally, Hfg reduced TGF-beta receptor II expression, but not that of receptor I in all 3 cell lines.

Our results suggest that halofuginone may be particularly effective for treatment of TGF-beta-responsive bone metastases due to melanoma, breast and prostate cancer.

**Calcitonin Attenuates the Anabolic Effect of PTH *in vivo* and Rapidly Upregulates Sclerostin Expression.** J. H. Gooi\*, S. Pompolo\*, N. E. McGregor\*, E. Walker\*, M. T. Gillespie, J. M. W. Quinn, T. J. Martin, N. A. Sims. St. Vincent's Institute, Fitzroy, Australia.

There is increasing evidence for a role of osteoclasts in the anabolic action of PTH. To determine whether osteoclast activity contributes to PTH anabolic action, 3-week-old rats were treated with daily subcutaneous hPTH(1-34) (30ug/kg) and co-treated with 0.5ug/kg salmon calcitonin (sCT). The dose of sCT was identified by bioassay as the lowest dose required to lower serum calcium transiently ( $P < 0.01$ ), in order to inhibit osteoclast activation acutely without a prolonged effect on resorption. The anabolic effect of PTH, detected by pQCT and histomorphometry, was significantly impaired in rats co-treated with sCT ( $p < 0.05$  for both). Daily sCT alone had no effect on trabecular bone mineral density (Tb.BMD) or trabecular bone volume (BV/TV).

To identify inhibitors or stimulators of bone formation modified by sCT co-administration with PTH we examined gene expression in metaphyseal bone of 3 week old female rats treated with vehicle, 0.5ug/kg sCT, 30ug/kg hPTH(1-34) or co-administered sCT and hPTH(1-34). Bones were collected at 1.5, 4 and 6 hours after treatment and femoral metaphyseal mRNA analysed by quantitative real time PCR (qRT-PCR) and tibial sections prepared for immunohistochemistry. Several genes whose expression was affected by PTH were not modified by simultaneous sCT treatment, including RANKL, OPG, IL-6, c-fos and ephrinB2. In contrast, the reduction of mRNA for the osteocyte-derived bone formation inhibitor, sclerostin caused by PTH administration, was significantly diminished by sCT co-administration at all time points. Furthermore, sCT alone increased sclerostin mRNA at least 2.5-fold at 1.5, 4 and 6 hrs ( $p < 0.001$ ). This increase was confirmed by immunohistochemistry in samples from the same experiment: in the tibia, the number of sclerostin positive osteocytes in cortical bone was significantly increased at 4 hrs following sCT administration (vehicle:  $26\% \pm 4\%$ ; sCT:  $43\% \pm 3\%$ ,  $p < 0.01$ ). Also at 4 hrs, qRT-PCR analysis revealed that sCT reduced mRNA for other osteocytic gene products including MEPE ( $-1.4 \pm 0.06$  fold,  $p < 0.01$ ) and DMP-1 ( $-1.9 \pm 0.06$  fold,  $p < 0.001$ ).

These data indicate that calcitonin can promote sclerostin production, as well as influence production of other genes characteristic of the osteocyte, and suggest this is a pathway by which calcitonin might modify the anabolic effect of PTH. Since the only known target of CT in bone is the osteoclast, it seems likely that this effect of calcitonin on sclerostin production by osteocytes is the result of an indirect action, either through the osteoclast or through some non-skeletal site of calcitonin action, which could include the brain.

## F202

**Deprivation of Vitamin A Results in a Partial Rescue of the Mineralization Defects in Phex-Deficient Hyp Mice.** S. Seitz\*, F. Barvencik\*, M. Amling, T. Schinke. Center for Biomechanics, Experimental Trauma Surgery & Skeletal Biology, Hamburg, Germany.

Inactivation of the *Phex* gene causes severe defects of bone matrix mineralization and phosphate homeostasis in mice and humans. Although *Phex* encodes a transmembrane protein with significant homologies to endopeptidases, a physiologic substrate has not yet been identified. Moreover, *Fgf23*, the major gene regulating phosphate homeostasis downstream of *Phex*, is mostly affected at the transcriptional level, since its expression is increased in osteoblasts from *Phex*-deficient *Hyp* mice. Therefore, to analyze the possibility that changes in gene expression may be involved in the skeletal abnormalities caused by *Phex* deficiency, we compared primary osteoblasts from wildtype and *Hyp* mice using Affymetrix Gene Chip hybridization. Here we observed that the expression of about 200 genes, including *Fgf23*, *Mepe* and *Dmp1*, was more than two-fold increased in cultures from *Hyp* mice. Since several known target genes of retinoic acid signaling, but also genes involved in the uptake and intracellular processing of retinol, were also expressed at higher levels in osteoblasts from *Hyp* mice, we next asked the question, whether vitamin A-deprivation would influence their phenotype. Surprisingly, feeding a vitamin A-deficient diet until the age of 6 weeks led to an overall increased size of the *Hyp* mice, and their growth plate thickness was significantly reduced compared to *Hyp* mice on a normal diet ( $0.26 \pm 0.02$  mm vs.  $0.43 \pm 0.08$  mm) with a near absence of rachitic features. Moreover, osteoid volume and surface were significantly decreased in *Hyp* mice receiving the Vitamin A-deficient diet (OV/BV:  $20.4 \pm 5.9\%$  vs.  $42.2 \pm 8.9\%$ ), suggesting that increased retinoic acid signalling in osteoblasts contributes to the defects of bone matrix mineralization caused by *Phex*-deficiency. Interestingly, the improvement of the *Hyp* phenotype by deprivation of vitamin A occurred without normalization of phosphate homeostasis, since serum *Fgf23* and phosphate levels were not changed compared to *Hyp* mice receiving the control diet. Taken together, these data reveal a novel aspect in the pathogenesis of X-linked hypophosphatemic rickets and could help identify further molecules involved in the regulation of bone matrix mineralization.

**Disclosures:** S. Seitz, None.

## F205

**MEPE Regulates Bone Remodelling Independent of Serum Phosphate and Alters Renal Vascularisation.** V. David, A. Martin, A. M. Hedge\*, P. S. N. Rowe. Medicine, The University of Kansas Medical Center, Kansas, KS, USA.

Matrix extracellular phosphoglycoprotein (MEPE) like dentin matrix protein 1 (DMP1) is a SIBLING-protein involved in bone and phosphate mineral metabolism. In *HYP*, increased proteolysis of MEPE and DMP1 generates small protease-resistant ASARM-peptides that inhibit mineralization. Bolus or short-term infusion of MEPE and ASARM-peptides in normal mice inhibit intestinal and renal phosphate uptake. Remarkably, despite a major age-dependent low bone mass phenotype, transgenic mice over expressing MEPE (MEPE-tgn) are hyperphosphatemic with increased serum  $1,25(\text{OH})_2\text{D}_3$ . Unlike *HYP* mice, MEPE-tgn mice respond to constitutively increased levels of MEPE by markedly over expressing PHEX ( $3x$   $p < 0.01$ ) and this may contribute to the hyperphosphatemia. To clarify MEPEs role we fed MEPE-tgn mice (4 months) with a normal and low phosphate/ $1,25(\text{OH})_2\text{D}_3$  diet. The diets consisted of 1% phosphorus (1% PO4) and 2.4 IU/g  $1,25(\text{OH})_2\text{D}_3$  or 0.1% of phosphorus (0.1% PO4) and 1 IU/g  $1,25(\text{OH})_2\text{D}_3$ . As previously shown, MEPE-tgn mice were hyperphosphatemic on the 1%PO4 diet (WT:  $8.1\text{mg/dL}$  vs. MEPE-tgn:  $11.4\text{mg/dL}$ ,  $p < 0.01$ ) whereas the 0.1%PO4 diet induced a hypophosphatemia in both WT and MEPE-tgn animals (WT:  $7.3\text{mg/dL}$  vs. MEPE-tgn:  $7.4\text{mg/dL}$ ). Barium sulphate perfusion and  $\mu\text{CT}$  imaging revealed a marked increase in renal vascular number ( $+200\%$   $p < 0.03$ ) and decreased vascular diameter ( $-15\%$ ;  $p < 0.03$ ) in the MEPE-tgn mice (1%PO4 diet). This was accompanied by a 3 fold increase in bone-renal VEGF ( $p < 0.05$ ). Interestingly, by further reducing bone turnover in both WT and MEPE-tgn mice, the low 0.1% PO4 diet partially corrected the MEPE-tgn BMD defect (figure 1) and compensated for the growth delay and shorter bones. In contrast, MEPE-tgn mice still retained the cortical and trabecular bone thinning defect ( $-5\%$  Ct.Th. and  $-10\%$  Tb.Th.,  $p < 0.05$ ) and also the reduced bone remodelling (both diets). Consistent with this, serum measurements of osteocalcin ( $-40\%$  versus WT,  $p < 0.05$ ), and CTX (1% PO4:  $-40\%$ ; 0.1% PO4:  $-5\%$ , NS) were reduced. To conclude, MEPE dynamically modulates an age-dependent inverse relationship between BMD and serum phosphate. In contrast, MEPE lowers bone remodeling in a phosphate independent manner and significantly alters renal vascularisation. The altered vascularisation may contribute to the impaired renal-phosphate handling.

**MEPE C-terminal ASARM-peptide, Promotes Hypophosphatemia, Bone Defects and Increases Adiposity.** A. Martin, V. David, A. M. Hedge\*, P. S. N. Rowe. Medicine, The University of Kansas Medical Center, Kansas, KS, USA.

ASARM is a protease resistant peptide belonging to several SIBLING proteins and was first described as a C terminal MEPE fragment. Proteolytic degradation of MEPE releases protease resistant ASARM peptide into the circulation. In hypophosphatemic rickets mice (HYP), increased protease activity and MEPE expression results in increased serum ASARM levels. We tested the hypothesis *in vivo* that circulating ASARM peptides were responsible for, at least in part, the hypophosphatemia and bone disorders noted in HYP. Male mice (8 weeks, C57/Bl6, n=5) were fed *ad libitum* for 2 months either with a 1% phosphorus /2.4 IUg<sup>-1</sup> 1.25(OH)<sub>2</sub>D<sub>3</sub> diet (1% PO<sub>4</sub>) or a 0.1% of phosphorus/1 IUg<sup>-1</sup> 1.25(OH)<sub>2</sub>D<sub>3</sub> diet (0.1% PO<sub>4</sub>). During the last month, animals were also infused either with ASARM peptide (5mg/d/Kg) or vehicle (V) using Alzet osmotic pumps. ASARM treatment induced a hypophosphatemia (-20% vs. V; p=0.03) and an increased fractional excretion of phosphate (FEP) on the 1% PO<sub>4</sub> diet (+50% vs. V p=0.004). Serum PO<sub>4</sub> was decreased with both V and ASARM treated groups on the 0.1%PO<sub>4</sub> diet. The hypophosphatemia and two-fold increase in serum ASARM (p=0.002) and 1,25(OH)<sub>2</sub>D<sub>3</sub> levels (V=48 pg/mL vs. ASARM=98 pg/mL; p<0.02) occurred without significant changes in serum FGF23 or PTH (1%PO<sub>4</sub> diet). ASARM-peptide treated mice also displayed a reduced cortical thickness (-30 %, p<0.01) and bone volume (-20%, p<0.01). Accordingly, ASARM treatment significantly reduced serum osteocalcin (-30%, p<0.01), osteopontin (-25%, p<0.01) and RANKL/OPG (-30%, p<0.01). On the 0.1%PO<sub>4</sub> diet, ASARM-treated mice did not show any significant changes in bone parameters, while 1.25(OH)<sub>2</sub>D<sub>3</sub> levels were decreased. Interestingly, on this diet, ASARM-treated animals presented with a higher body weight (+10% vs. V, p<0.05) related to an increase in fat mass (+40% vs. V, p<0.05). As a consequence, serum leptin levels were increased significantly in these mice (+72%; p=0.04) and correlated significantly with ASARM serum levels (Figure 1). To conclude, ASARM peptide induces hypophosphatemia and decreases bone turnover independent of serum FGF23 levels. Thus, in HYP, increased ASARM-peptides likely play a component role in the hypophosphatemia. The peptide also induces an increase in adiposity in a phosphate dependent manner that is regulated negatively by 1.25(OH)<sub>2</sub>D<sub>3</sub>.

Disclosures: A. Martin, None.

## F210

**Transgenic ASARM-peptide Overexpression with Reduced Serum Phosphate and 1.25(OH)<sub>2</sub>D<sub>3</sub> Leads to Decreased Bone Mineral Density and Obesity.** A. Martin, V. David, A. M. Hedge\*, P. S. N. Rowe. Medicine, The University of Kansas Medical Center, Kansas, KS, USA.

ASARM is a protease resistant peptide belonging to several SIBLING proteins and first described as a C-terminal MEPE motif. Studies *in vitro* show both MEPE and ASARM peptide inhibit mineralization. In familial hypophosphatemic rickets (HYP, ARHR) or tumor-induced osteomalacia (TIO) MEPE expression is increased. We therefore used ASARM peptide over expressing transgenic mice (2.3 kb col1a1 promoter) to investigate the role of ASARM-peptides *in vivo*. Wild type (WT) and transgenic (Ap-tgn) mice (C57/Bl6 males, 4 and 8 months) were fed *ad libitum* with a 1% phosphorus/ 2.4 IUg<sup>-1</sup> 1.25(OH)<sub>2</sub>D<sub>3</sub> diet (1%PO<sub>4</sub>), or a 0.1% phosphorus/1 IUg<sup>-1</sup> 1.25(OH)<sub>2</sub>D<sub>3</sub> (0.1%PO<sub>4</sub>) diet. Ap-tgn mice on the 1%PO<sub>4</sub> diet, were hypophosphatemic (-14% vs. WT, p<0.05) and displayed a decreased cortical thickness (-5% vs. WT, p<0.05). An increased BMD also occurred in the older Ap-tgn animals (+10% vs. WT, p<0.05) with intra meta- and diaphyseal calcifications, reduced bone resorption (-50% sCTX vs. WT, p<0.005) and a marked increase in abdominal fat mass (+25% vs. WT, p<0.05). The increased fat mass was associated with increased leptin levels (+257% vs. WT, p<0.05) and unchanged body weight. When fed lower levels of phosphorus and 1.25(OH)<sub>2</sub>D<sub>3</sub>, ASARM peptide over expression induced a significant BMD decrease in 4 month-old mice (-10% vs. WT, femur and vertebrae BMD, p<0.05). Older, 0.1%PO<sub>4</sub> Ap-tgn mice displayed a higher body weight (WT: 31.4±2.9g vs. Ap-tgn: 36.3±3.0g, p<0.05), a striking increased fat mass (+70% vs. WT, p<0.05) and dramatically elevated serum leptin levels (+750% vs. WT, p<0.02). These older mice still had a very low global BMD (-10% compared to WT, p<0.05), but long bone defects were less pronounced compared to the younger Ap-tg mice (-5% vs. WT, NS). Notably, the 0.1%PO<sub>4</sub> diet Ap-tg mice sustained a major increase in leptin with a 2 fold increase apparent as early as 4 months. To conclude, ASARM peptide alters bone turnover and induces obesity when associated with low phosphate and 1.25(OH)<sub>2</sub>D<sub>3</sub>. The increased disordered body-weight/fat mass mirrors an age dependent evolution towards obesity status and central leptin resistance. This suggests non-collagenous matrix proteins actively regulate metabolism with bone functioning dynamically as an endocrine organ.

Disclosures: A. Martin, None.

## F213

**Parathyroid Hormone-related Peptide (PTHrP) Blockade Inhibits Tumor Progression in a Model of Human Breast Cancer.** D. C. Huang, X. F. Yang, R. Kremer. Department of Medicine, Center for Bone and Periodontal Research, McGill University, Montreal, QC, Canada.

Elevated production of parathyroid hormone-related peptide (PTHrP), the major mediator of malignancy-associated hypercalcemia, is usually associated with advanced metastatic breast cancer. It has been suggested that PTHrP plays a role in tumor invasion and metastasis independent of its role on tumor osteolysis. Here we analyzed the effect of PTHrP inhibition *in vitro* and *in vivo* on growth, invasion and metastasis. First, we used transient transfection of siRNA against human PTHrP designed against the N-terminal region of hPTHrP 1-7 and cloned into the pENTR<sup>TM</sup>/H1/TO vector. An 80% inhibition of PTHrP transcription and production was observed at 24 h and sustained up to 72 h in the MDA-MB 435 human breast cancer cell line. A 36% (p<0.01) inhibition of invasion through the matrigel coated filters in siRNA-treated cancer cells was observed compared with control cells. Next, we examined these effects using a monoclonal antibody (mAb) against human PTHrP. These mAbs were produced after immunization of BALB/c mice with synthetic human PTHrP (1-33). The mAb was then purified from the myeloma line FO fusion clone using protein G Sepharose columns. Specificity of the mAb was confirmed by ELISA using different fragment peptides. Addition of mAb to the cell cultures showed a significant inhibition of invasion as compared to cells treated with control mouse IgG. Next we analyzed breast tumor growth and metastasis in BALB/c nu/nu mice following injection of MDA-MB-435 cells into the mammary fat pad. Six weeks following tumor implantation and treatment with mAb (200 ug subcutaneously, every 2 days), a 60% inhibition (p<0.01) in tumor growth was observed as compared to animals injected with control IgG. Lung metastasis was also inhibited with only 33% of mAb-treated animals to 100% of control IgG-treated animals showing metastatic spread. Overall our data demonstrate that PTHrP blockade inhibits invasion *in vitro* and tumor growth and metastasis *in vitro* and *in vivo* in a model of human breast cancer. These data suggest that therapeutic strategies aimed at blocking PTHrP may be useful in the treatment of breast cancer growth and extra-skeletal metastasis.

**Suppression of Canonical wnt Signaling by Dkk1 Attenuates PTH-mediated Peritrabecular Stromal Cell Response and New Bone Formation in a Model of Secondary Hyperparathyroidism.** J. Guo, M. Liu\*, D. Yang, C. C. Thomas\*, E. Schipani, F. R. Bringhurst, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

We have previously shown that PTH suppresses Dkk1 expression and activates canonical wnt signaling in bone. Transgenic mice that overexpress Dkk1 under the control of the 2.3 Kb collagen  $\alpha 1(I)$  promoter exhibit attenuated canonical wnt signaling and low bone mass. Either continuous infusion of PTH or feeding mice a low calcium diet that induces secondary hyperparathyroidism causes extensive peritrabecular stromal cell responses and new bone formation. To determine whether the suppression of Dkk1 is required for the peritrabecular stromal cell responses to PTH, Dkk1 transgenic mice at weaning were fed a low calcium diet for three weeks, and bone was examined by histology with H&E, von Kossa and Masson-Goldner Trichrome stains, and by *in situ* hybridization analysis. As expected, wild type mice fed a low calcium diet displayed large amounts of disorganized bone and extensive peritrabecular stromal cell responses. Such stromal cells strongly express mRNAs encoding  $\alpha 1(I)$  collagen and osteopontin, and to a lesser extent osteocalcin, indicating that they are preosteoblasts. Masson-Goldner Trichrome stain

demonstrated that the disorganized bone contained a high density of osteocytes and irregularly deposited mineral, suggesting that such disorganized bone is very similar to woven bone and presumably represents poorly organized, newly formed bone. Dkk1-overexpressing mice, when fed the low calcium diet, exhibited elevated serum PTH and a rachitic expansion of hypertrophic chondrocytes like those found in the wild type mice, but also uniquely exhibited tibial fractures and failed to develop a peritrabecular stromal cell and woven bone response seen in the wild type mice. Our findings indicate that activation of canonical wnt signaling at least in part by suppression of Dkk1 is essential for PTH-mediated peritrabecular stromal cell responses and new bone formation.

### Safety and Efficacy of Long-Term Parathyroid Hormone Replacement in a Pediatric Patient with Inherited Hypoparathyroidism: Skeletal and Renal Outcomes.

T. A. Theman<sup>\*1</sup>, M. T. Collins<sup>1</sup>, D. W. Dempster<sup>2</sup>, H. Zhou<sup>2</sup>, J. C. Reynolds<sup>3</sup>, J. S. Brahimi<sup>\*4</sup>, P. Roschger<sup>5</sup>, K. Klaushofer<sup>5</sup>, K. K. Winer<sup>\*6</sup>.

<sup>1</sup>Skeletal Clinical Studies Unit, Craniofacial and Skeletal Diseases Branch, NIDCR, NIH, Bethesda, MD, USA, <sup>2</sup>Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>3</sup>Nuclear Medicine, CC, NIH, Bethesda, MD, USA, <sup>4</sup>CC, NIH, Bethesda, MD, USA, <sup>5</sup>Ludwig Boltzmann Institute of Osteology, Hanusch Hospital, Vienna, Austria, <sup>6</sup>ENGB, NICHD, NIH, Bethesda, MD, USA.

Autosomal dominant hypocalcemia (ADH) is an inherited form of hypoparathyroidism caused by activating mutations in the calcium-sensing receptor (CaR). Features include hypocalcemia, hyperphosphatemia and hypercalciuria, which can lead to nephrocalcinosis and renal insufficiency. Treatment with PTH(1-34) may be superior to conventional therapy but is contraindicated in children, and long-term effects on the skeleton are unknown.

The patient is a 20-year-old female with ADH treated with PTH continuously since age 6/12. Serum and urine mineral levels and were measured regularly. A bone biopsy was obtained at age 19 for histomorphometry and quantitative backscattered electron imaging (qBEI). Her data were compared to one age, sex, and length of hypoparathyroidism-matched control not on PTH, and two sex-matched ADH controls before and after one year of PTH.

The patient's growth was normal. Despite normal or below normal serum calcium and magnesium levels on PTH, persistent hypercalciuria and hypermagnesuria were observed. Nephrocalcinosis, without evidence of impaired renal function, developed by age 19. Cancellous bone volume was dramatically elevated in the patient as well as both ADH controls after one year of PTH. Bone mineral density distribution (BMDD) by qBEI of the patient and ADH controls was strikingly shifted towards lower mineralization compared to the non-ADH control. Moreover, the ADH controls exhibited a further reduction in mineralization after one year of PTH. These findings imply a role for CaR in bone matrix mineralization. Notably, there were no fractures or osteosarcoma.

Long-term PTH replacement in a child with ADH was safe, increased bone mass without negatively impacting mineralization, and improved serum and renal mineral control but did not prevent nephrocalcinosis. Additionally, this is the first direct evidence of a role for CaR in human bone.

## F219

### Pthrp-Induced Wnt Signaling Specifies the Mammary Mesenchyme.

M. Hiremath<sup>\*</sup>, J. J. Wysolmerski. Internal Medicine, Yale University School of Medicine, New Haven, CT, USA.

PTHrP regulates mammary morphogenesis by specifying mesenchymal cell fate during embryonic development. Disruption of the PTHrP or PTHrP genes results in a lack of mammary-specific mesenchyme and a failure of the mammary buds to give rise to the mammary ducts, while overexpression of PTHrP in the epidermis (K14-PTHrP mice) induces ectopic mammary mesenchyme under the ventral skin and causes inappropriate differentiation of the ventral epidermis into nipple skin. Previous studies demonstrated that PTHrP secreted by the mammary epithelial cells induced the expression of  $\beta$ -catenin and Lef1 in the mammary mesenchyme, suggesting that PTHrP signaling might modulate Wnt signaling in these cells. To test this hypothesis, we bred a Wnt reporter transgene, TOPGAL-C, onto the PTHrP-null and K14-PTHrP overexpressing backgrounds. As reported previously, canonical Wnt signaling was active in the mammary mesenchyme of WT mice between embryonic day 12 and 18. Overexpression of PTHrP led to the induction of ectopic Wnt signaling in the ventral mesenchyme underlying the nipple-like epidermis of K14-PTHrP mice. Interestingly, both mesenchymal and epithelial TOPGAL-C expression was abolished in PTHrP-null mammary buds. In order to determine if Wnt signaling contributed to the ability of PTHrP to specify mammary mesenchyme fate, we crossed the K14-PTHrP transgene onto a Lef1-null background. Loss of Lef1 partially reversed the nipple-like differentiation of the ventral skin usually associated with overexpression of PTHrP, suggesting that TCF/ $\beta$ -catenin signaling acts downstream of PTHrP in these cells. Taken together, our studies suggest that PTHrP regulates mammary bud development by inducing mesenchymal Wnt signaling.

## F221

### A Long-Acting PTH Ligand that Binds to a Distinct PTH Receptor Conformation (R<sup>0</sup>) Can Stimulate Increases in Markers of Both Bone Resorption and Bone Formation in Mice. M. Okazaki<sup>\*</sup>, J. T. Potts, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

The mechanisms that govern the balance between the bone-anabolic and bone-catabolic effects of PTH are not fully understood, but it is clear that the timing (periodicity /duration) of ligand exposure is a critical parameter. Thus, the paradigm, that once-daily (intermittent) PTH stimulates a net increase in bone, while continuous infusion stimulates a net bone loss. We reported last year that the modified PTH ligand, M-PTH(1-28) (M = Ala1,Aib3,Gln10,Har11,Ala12,Trp14,Arg19), binds with high affinity to a PTHR conformation, R<sup>0</sup>, which, by mechanisms still under study, results in prolonged signaling due to continued receptor occupancy. We showed that the R<sup>0</sup> analogs induce prolonged hypercalcemic and hypophosphatemic effects in mice. Such long-acting ligands might be predicted to have enhanced effects on bone resorption, relative to bone formation, even when administered intermittently. We therefore examined the effects of a long-acting PTH ligand on markers of bone metabolism in mice. We injected (i.v.) into wild-type C57/BL6 mice (age 3 months), the R<sup>0</sup>-selective ligand, M-PTH(1-34), rat PTH(1-34), or vehicle control, once daily, for 14 days, and measured parameters of bone formation and resorption. Peptides were injected at a concentration of 5 nanomole per kg body weight, which produced equivalent rises in plasma cAMP for the two peptides. Serum markers of bone formation (PINP and osteocalcin) and resorption (CTX) were measured by EIA at days 7 and 14, and areal bone mineral density at the isolated femur was measured by PIXIMUS at day 14. Maximum effects on CTX occurred at day 14: relative to vehicle, rPTH(1-34) increased CTX 1.3-fold ( $P = 0.001$ ), and M-PTH(1-34) increased CTX 2.3-fold ( $P = 0.0002$ ). The effect of M-PTH(1-34) on CTX was greater than that of PTH(1-34) ( $P = 0.001$ ). PTH(1-34) tended to increase PINP at day 7 (~1.3 fold,  $P = 0.09$ ) but not at day 14, and did not significantly change osteocalcin. In contrast, M-PTH(1-34) significantly ( $P \leq 0.0004$ ) increased PINP at day 7 (1.6-fold) and day 14 (2.6-fold), and increased osteocalcin by 2-fold at day 14 ( $P = 0.048$ ). PTH(1-34) increased total femur BMD by 3 % ( $P = 0.003$ ), while M-PTH(1-34) increased femur BMD by 11% ( $P < 0.0001$ ). These data show that a long-acting PTH analog, when administered in a once-daily regimen, can stimulate a net increase in bone mineral density in mice. The analog, as expected, strongly increases markers of bone resorption, but also increases markers of bone formation, and thus increases BMD as well as the rate of bone turn-over to greater extents than does an equal dose of PTH(1-34), at least in this mouse strain.

### Identification and Optimization of Residues in PTH and PTHrP that Determine Altered Modes of Binding to the PTH/PTHrP Receptor. M. Okazaki<sup>\*</sup>, J. T. Potts, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

PTH and PTHrP use the same G protein-coupled receptor, the PTHR, to mediate their distinct biological actions. Recent data, for example, from competition binding and FRET analyses, suggest that PTH and PTHrP bind to the PTHR via different mechanisms that involve altered selectivities for distinct PTHR conformations. Thus, PTH(1-34) has a greater capacity to bind to the G protein-uncoupled conformation (R<sup>0</sup>), than does PTHrP(1-36), whereas PTHrP(1-36) favors the G protein-coupled conformation (RG). To explore the molecular basis for this apparent differential binding and conformational selectivity, we compared the effects of substitutions in the N-terminal and C-terminal regions of PTH and PTHrP peptides on the interaction of the ligands with the PTHR. Unlike in PTH(1-14) where Ala substitutions at positions 1, 3, 10,11,12 and 14 increased cAMP activity, each Ala substitution in PTHrP(1-14) abolished activity in cells expressing PTHR. Thus, the (1-14) regions of PTH and PTHrP interact with the juxtamembrane (J) region of the PTHR differently. Both PTHrP(1-14) and PTHrP(1-36) were much less potent for cAMP activity in cells expressing a PTHR lacking the extracellular N-terminal (N) domain (delNT), as compared to their respective PTH(1-14) and PTH(1-34), counterparts. PTHrP(1-36) activity therefore depends more heavily on interactions between the C-terminal ligand region and the PTHR N domain than does PTH(1-34) activity. Ala -scan analysis of the C-terminal regions of PTH(1-28) and PTHrP(1-28) revealed for each peptide strong reductions in activity at positions Arg20, Trp/Phe23 Leu24 and Leu/Ile28, known in PTH to form the core N domain-binding motif. Enhancements in activity were found at several, but different positions in each scaffold: Leu18, Phe22, and His26 in PTHrP(1-28) and Asn16, Glu19 and Ala22 in PTH(1-28). The Ala substitutions at positions 16, 19, and 22 in PTH increased binding to delNT, whereas those at positions 18, 22, 26 in PTHrP decreased binding to delNT. The enhancing effects of the Ala substitutions at positions 16, 19, and 22 of PTH are thus mediated via the PTHR J domain, whereas, those at positions 18, 22, 26 of PTHrP require the PTHR N domain. Further type substitution analysis of positions 16, 19, 22, as well as 25 (neutral to Ala substitution) in PTHrP(1-28) resulted in the analog [Ala18,22,Leu25,Lys26]-PTHrP(1-28), which exhibits a cAMP potency and RG binding affinity that is greater than that of PTH(1-34) and among the highest of any PTH or PTHrP peptide studied so far. These data support the hypothesis that PTH and PTHrP interact with the PTHR via different mechanisms, and suggest new tactics for developing potent PTH and PTHrP ligands.

**The N-Terminally Extended XL $\alpha$ s (XXL $\alpha$ s) Acts as a Novel Heterotrimeric G Protein Subunit with an Ability to Transduce Receptor Activation into Intracellular Signaling.** C. Aydin\*, M. J. Mahon\*, M. Bastepe. Endocrine Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

*GNAS* encodes both the  $\alpha$ -subunit of the stimulatory G protein (G $\alpha$ ) and its extra-large variant XL $\alpha$ s. Disruption of XL $\alpha$ s in mice results in poor adaptation to feeding and impairs the glucose and energy metabolism. Also disrupted in the XL $\alpha$ s knockout mice is an N-terminally extended XL $\alpha$ s variant, termed XXL $\alpha$ s, which results from 5' extension of the open reading frame. Furthermore, XXL $\alpha$ s is also predicted to be disrupted by most *GNAS* mutations associated with human disease, such as progressive osseous heteroplasia, Albright's osteodystrophy, and fibrous dysplasia of bone. Thus, impaired XXL $\alpha$ s activity may contribute, at least partly, to the phenotype of XL $\alpha$ s knockout mice and the pathogenesis of diseases caused by *GNAS* mutations. Nonetheless, the cellular role of this highly conserved XL $\alpha$ s variant remains unknown. Here we engineered cDNA encoding the full-length human XXL $\alpha$ s and investigated its functional properties in cultured HEK293 cells and *Gnas*<sup>E2-/-</sup> cells, i.e. MEFs that lack endogenous XXL $\alpha$ s, XL $\alpha$ s, and G $\alpha$  due to homozygous disruption of *Gnas* exon 2. By confocal indirect immunofluorescence microscopy, native XXL $\alpha$ s, an N-terminally FLAG-tagged XXL $\alpha$ s, and an XXL $\alpha$ s mutant in which the methionine corresponding to the initiator of XL $\alpha$ s is changed to a valine (XXL $\alpha$ s-M302V) were localized to the plasma membrane of transfected HEK293 cells. Basal cAMP accumulation was markedly elevated in *Gnas*<sup>E2-/-</sup> cells transiently expressing an XXL $\alpha$ s mutant carrying an arginine-to-histidine change in its GTPase core domain (XXL $\alpha$ s-R844H). Isoproterenol (10<sup>-5</sup> M) stimulation of *Gnas*<sup>E2-/-</sup> cells transiently expressing either XXL $\alpha$ s or XXL $\alpha$ s-M302V resulted in an approximately 10-fold increase in cAMP accumulation. Sequence analysis of an Est clone derived from E18.5 whole mouse embryo showed that XXL $\alpha$ s mRNA comprises the entire open reading frame. However, 5'-RACE using total RNA from newborn mouse heart and rat INS-1 cells determined that XXL $\alpha$ s mRNA starts either 307 bp or 297 bp downstream from the first ATG of the longest open reading frame, predicting an N-terminal truncation of 48 or 101 amino acids, respectively. Our findings indicate that XXL $\alpha$ s is a plasma membrane protein with an ability to signal as a G $\alpha$ - and XL $\alpha$ s-like protein and that the N-terminus of XXL $\alpha$ s varies in a tissue-specific manner. It will be necessary to determine whether the size of the N-terminal domain affects XXL $\alpha$ s activity and whether deficiency or overactivity of this protein due to paternally inherited *GNAS* mutations is involved in disease pathogenesis.

## F228

**PTHrP Regulates Mammary Gland Ductal Elongation During Puberty.** K. Boras-Granic\*, J. J. Wysolmerski<sup>1</sup>, M. Dunbar<sup>\*2</sup>. <sup>1</sup>Endocrinology, Yale University, New Haven, CT, USA, <sup>2</sup>Biology, Penn State Berks-Lehigh Valley College, Reading, PA, USA.

Pubertal development of the mammary gland is mediated by bulbous structures known as terminal end buds (TEBs) that develop at the tips of the growing ducts. Estrogen is necessary for the formation and maintenance of TEBs and acts to cause ductal growth, in part, by upregulating amphiregulin expression and shedding by epithelial cells and causing subsequent epidermal growth factor receptor activation in stromal cells. We have previously shown that transgenic overexpression of PTHrP inhibits the effects of estrogen on ductal extension. In this study we asked if endogenous PTHrP acted to modulate ductal growth during puberty. We first examined the normal pattern of PTHrP expression in the mammary gland using a PTHrP-lacZ knockin mouse. During puberty, the PTHrP gene was expressed within cap cells of the terminal end buds (TEBs) and in myoepithelial cells of the ducts. These cell-types are located adjacent to stromal cells bearing PTH/PTHrP receptors and are the same cell-types in which PTHrP was previously overexpressed using the human keratin 14 promoter. We next used the Cre-loxP recombination system to disrupt PTHrP gene expression in the mammary gland at the onset of puberty. MMTV-Cre (line D) mice direct recombination in both luminal and myoepithelial/cap cells beginning at day 21. At 5 weeks of age, we found that PTHrP expression was reduced by 50% in MMTV-Cre/PTHrPlox/lox mice and that elongation of the ductal tree was accelerated by 20-30% in these mice as compared to littermate controls. Thus, PTHrP serves as an endogenous inhibitor of mammary ductal extension during puberty. Finally, given the importance of EGFR signaling during ductal extension, we investigated the effects of PTHrP on this signaling system. Estrogen could not stimulate proliferation or phosphorylation of the EGFR in primary cultures of either mammary epithelial cells (MECs) or stromal cells alone. However, estrogen readily induced both proliferation and EGFR phosphorylation in co-cultures of MECs and stromal cells. Co-cultures of MECs and mammary stromal cells from K14-PTHrP mice were resistant to both proliferation and EGFR activation when treated with estrogen, as were co-cultures of WT cells treated with exogenous estrogen plus PTHrP. In summary, our data suggest that endogenous PTHrP, secreted by cap and/or myoepithelial cells, acts on surrounding stromal cells to inhibit EGFR signaling, thus modulating mammary ductal growth during puberty.

## F233

**Glucocorticoid Signaling in Osteoblasts Maintains Normal Bone Structure in Mice.** R. Kalak\*, J. Street\*, R. E. Day\*, J. R. K. Modzelewski\*, P. Y. Liu\*, G. Li\*, C. R. Dunstan<sup>1</sup>, H. Zhou<sup>1</sup>, M. J. Seibel<sup>1</sup>. <sup>1</sup>Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia, <sup>2</sup>Medical Engineering & Physics, Royal Perth Hospital, Australia, <sup>3</sup>Musculoskeletal Research Unit, Queen's University Belfast, United Kingdom.

The role of endogenous glucocorticosteroids (GC) in bone development is still ill-defined. Using a transgenic (tg) mouse model of osteoblast-targeted disruption of intracellular GC signaling, we examined the role of endogenous GC in bone growth and development and its dependence on age, gender and skeletal site. Tibiae and L3 vertebrae of 3 and 7-week-old, male and female wild type (WT) mice and their tg, age and sex matched littermates (n= 10/ group; 80 in total) were analysed by micro-CT and mechanical testing. Data were analysed separately for 3 and 7-wk-old mice by 2-way ANOVA using genotype (WT or tg), gender and their interactions as factors. No interaction between genotype and gender was found for any of the analysed parameters; therefore, we only present data which was statistically pooled across gender. Tibial trabecular bone volume (BV/TV) and trabecular number (TbN) were significantly reduced by 24% and 20%, resp., and trabecular separation (TbSp) was significantly increased by 23% in 7-wk-old tg mice when compared to their WT littermates. Analogous changes were observed in the tibiae of 3-wk-old-mice and in the vertebrae of 7-wk-old mice but not in the vertebrae of 3-wk-old mice, where trabecular bone structure did not differ between tg and WT animals. Tibial length and cortical bone area were significantly decreased by 3% and 14% in 7-wk-old tg vs. WT mice and similar changes were seen in 3-wk-old mice. When compared to WT animals, tibial strength of 7-wk-old tg mice was significantly reduced with a decrease in both maximum load (-27%) and stiffness (-32%). In contrast, differences in tibial strength of 3-wk-old tg and WT mice were not statistically significant. The lack of interaction between genotype and gender indicated that the effect of disrupted GC signaling on bone structure in both sexually immature and mature mice was independent of gender. However, the effect of genotype was modulated by age for vertebral BV/TV, TbN and TbSp (p< 0.02). Correction for body weight did not affect the difference between WT and tg animals in 7-week-old mice, but in 3-wk-old mice it removed the observed effects in tibial bone parameters. We conclude that GC signaling in osteoblasts is important in maintaining normal bone volume and strength, however its effects are likely to be modulated by other factors such as age and skeletal site but not gender.

**Intestinal-Specific Vitamin D Receptor Null Mice Maintain Normal Calcemia but Display Severe Bone Loss.** L. Lieben\*, R. Masuyama, K. Moermans\*, R. Bouillon, G. Carmeliet. Experimental Medicine, KULeuven, Leuven, Belgium.

The signaling of 1,25(OH)<sub>2</sub>vitaminD<sub>3</sub> [1,25(OH)<sub>2</sub>D<sub>3</sub>] via the vitamin D receptor (VDR) is required for normal mineral and skeletal homeostasis, and its effect on intestinal calcium absorption is considered to be essential. To verify this hypothesis, intestinal-specific VDR null mice were generated by crossing VDR floxed (VDR<sup>fl</sup>) mice with mice expressing Cre recombinase driven by the Villin promoter. The VDR<sup>fl</sup>/Villin-Cre<sup>+</sup> mice (VDR<sup>int-/-</sup>) showed specific and efficient VDR inactivation in the intestine. VDR<sup>int-/-</sup> mice were born at the expected Mendelian frequency and developed normally until weaning, where after their weight gain gradually declined compared to VDR<sup>fl</sup>/Villin-Cre<sup>+</sup> mice. As expected, intestinal calcium absorption was decreased in 8-wk-old mutant mice evidenced by reduced accumulation of <sup>45</sup>Ca in serum after oral gavage (-60%) and decreased TRPV6 and calbindin-D<sub>9k</sub> mRNA expression. Surprisingly, serum calcium levels were normal suggesting compensatory mechanisms. Indeed, serum PTH and 1,25(OH)<sub>2</sub>D<sub>3</sub> levels were increased 1.8 and 6.5 fold in mutant mice. Accordingly, renal calcium reabsorption was enhanced as evidenced by decreased urinary calcium/creatinine levels (-50%) and increased TRPV5 (x1.6) and calbindin-D<sub>9k</sub> (x3.5) mRNA levels. In addition, both trabecular and cortical bone mass was manifestly reduced in mutant mice (-50%), often resulting in spontaneous bone fractures. This bone loss was associated with increased bone resorption as serum CTX levels (x3) were elevated. In particular, the number of TRAP<sup>+</sup> cells in the cortex of mutant mice was increased resulting in decreased cortical thickness and increased porosity. Moreover, serum levels and femoral mRNA expression of osteocalcin was significantly increased. Also, osteoid surface was tripled in VDR<sup>int-/-</sup> mice, indicative of enhanced bone formation and/or decreased mineralization, thereby contributing to lower mineralized bone mass. Unlike systemic VDR null mice, growth plate morphology was not altered in VDR<sup>int-/-</sup> mice. Despite high 1,25(OH)<sub>2</sub>D<sub>3</sub> levels, FGF23 serum levels were decreased in mutant mice (-40%). Treating cultured stromal cells with increasing PTH doses inhibited the 1,25(OH)<sub>2</sub>D<sub>3</sub>-induced FGF23 expression. This mechanism may have contributed to the normal renal NPT2a protein and serum phosphate levels in VDR<sup>int-/-</sup> mice. In conclusion, loss of the VDR in the intestine decreases intestinal calcium absorption even during normal calcium intake, resulting in compensatory mechanisms mediated by increased PTH, 1,25(OH)<sub>2</sub>D<sub>3</sub> and decreased FGF23 levels to maintain normal serum calcium and phosphate levels and normal growth plate structure, at the expense of severe bone loss.

**Disclosures:** L. Lieben, None.

## F240

**Evidence of a Role for the Human Vitamin D Response Element Binding Protein, Heterogeneous Nuclear Ribonucleoprotein (hnRNP) C1/C2 in Chromatin Remodeling and Transcript Splicing.** H. Chen<sup>1</sup>, M. Hewison<sup>2</sup>, M. Nanes<sup>1</sup>, J. S. Adams<sup>2</sup>. <sup>1</sup>Division of Endocrinology, Emory University School of Medicine, Atlanta, GA, USA, <sup>2</sup>Department of Orthopaedic Surgery, UCLA/Orthopaedic Hospital, Los Angeles, CA, USA.

Heterogeneous nuclear ribonucleoproteins (hnRNPs) are among the most plentiful proteins in the eukaryotic cell nucleus. Constitutive overexpression of hnRNP C1/C2 in humans results in clinical resistance to the active vitamin D metabolite, 1,25-dihydroxyvitamin D (1,25D). Resistance is legislated in part by the ability of C1/C2 to compete with the vitamin D receptor (VDR)-retinoid x receptor for occupancy of double-strand (ds), *cis*-acting, vitamin D response elements (VDREs) involved in 1,25D-directed transcriptional regulation. Because of the ability of C1/C2 to specifically interact with single-strand (ss) as well as ds nucleic acid with an AGGTCA-like motif, we theorize that C1/C2 is instrumental in marking the exposed, exterior surface of ds DNA as it wraps around the nucleosome, readying that stretch of ds DNA and its underlying histone for chromatin remodeling and transcription. In chromatin immunoprecipitation (ChIP) analysis of 1,25D-responsive cells the functional VDRE in the CYP24 proximal promoter was occupied by C1/C2 in the absence of added 1,25D. Re-ChIP assays demonstrated that: 1) chromatin assembly factor 1 (CAF1); a chaperone for histones H3/H4; 2) acetylated H4 itself; 3) the gene-silencing proteins, heterochromatin protein 1 (hp-1) and histone deacetylase (HDAC), were also associated with the C1/C2-bound VDRE. Following addition of 1,25D, C1/C2 and associated proteins were competitively displaced from the VDRE by VDR, and the RNA polymerase II (pol II) recruited. By contrast, in 1,25D-resistant cells the over-abundant C1/C2 was less readily displaced from the VDRE with concomitant dysregulation of associated proteins and pol II recruitment. These data suggest that C1/C2 tethers both chromatin assembly/remodeling and transcriptional proteins to specific *cis* elements in the CYP24 gene promoter. Furthermore, because C1/C2 also binds to an AGGUCA element in ss mRNA, we also assessed the ability of C1/C2 to affect splicing of a VDRE-driven growth hormone minigene reporter construct. 1,25D-directed minigene splicing was disrupted in a time-dependent fashion in 1,25D-resistant cells, suggesting that displacement of C1/C2 from the VDRE is also essential for subsequent processing of RNA transcripts. Collectively, these data demonstrate that C1/C2, by virtue of its ability to bind both ss and ds nucleic acid, can direct 1,25D-VDR-VDRE-directed gene expression at the level of chromatin remodeling, transcription and splicing.

**Snail Downregulates VDR Expression by Recruiting Sin3A, HDAC1 and HDAC2 to Multiple Regions of VDR Promoter and Deacetylating Histone H3/H4.** H. Wang\*, J. Shen\*, S. Park\*, A. T. M. Adesanya\*, Y. Li, S. Refetoff\*, R. E. Weiss\*, M. J. Favus. Medicine, University of Chicago, Chicago, IL, USA.

Snail is a key transcription repressor that plays important roles in epithelial to mesenchymal transitions (EMTs) during embryonic development and tumor invasion. Snail also downregulates VDR expression in human colon cancer and cell lines to block the anti-tumor action of 1,25(OH)<sub>2</sub>D<sub>3</sub> analogs. We have found elevated VDR and suppressed Snail in intestine and kidney of genetic hypercalciuric stone-forming (GHS) rats and speculate on the potential mechanisms whereby Snail downregulates VDR gene expression. In this study, we tested the hypothesis that Snail repression of VDR is the result of Snail binding to novel sites in the VDR promoter. Using cell lines that differ in their level of VDR expression, we found that higher VDR expression was associated lower Snail expression at both the mRNA and protein levels. The electrophoretic mobility shift assay (EMSA) demonstrated that Snail binds to several VDR promoter sequences containing E-box (CACCTG or CAGGTG) *in vitro*. Moreover, the chromatin immunoprecipitation (ChIP) assay demonstrated that endogenous Snail, Sin3A, HDAC1 and HDAC2 bind to multiple VDR promoter regions containing the E-box sequence. Additionally, overexpression of Snail in HEK293 (kidney) and SW480 (intestine) cells resulted in greater deacetylation of histones H3 and H4 at the VDR promoter regions. As a result, VDR gene expression was down-regulated. Immuno-staining shows that Snail, Sin3A, HDAC1 and HDAC2 co-localize with VDR in the nuclei of both HEK293 and SW480 cells. In conclusion, we demonstrated that Snail binds to novel multiple E-boxes within the VDR promoter and recruits the co-repressor Sin3A, histone deacetylase HDAC1 and HDAC2 to suppress VDR expression in kidney and colon cancer cell lines.

**Double Deletion of  $\alpha$ 2a- and  $\alpha$ 2c-adrenergic Receptors Results in a Phenotype of High Bone Mass and in Resistance to the Thyrotoxicosis-induced Osteopenia.** T. L. Fonseca\*, C. C. Costa\*, A. C. B. Moulattai\*, F. R. S. Freitas\*, P. C. Brum\*, C. H. A. Gouveia\*. <sup>1</sup>Department of Anatomy, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Physical Education and Sports School, University of Sao Paulo, Sao Paulo, Brazil.

It is well known that thyrotoxicosis induces bone loss. Recent studies demonstrated that the activation of the sympathetic nervous system (SNS) also reduces bone mass, via  $\beta$ 2 adrenergic receptors (AR). To investigate if thyroid hormone interacts with the SNS to regulate bone mass, we studied the effect of triiodothyronine (T3) on bone of mice with disruption of both  $\alpha$ 2a-AR and  $\alpha$ 2c-AR ( $\alpha$ 2a/ $\alpha$ 2c-AR<sup>-/-</sup>), which present chronically elevated sympathetic tone, with high levels of plasma noradrenaline. Forty-day-old female wild type C57BL/6J mice (WT) and  $\alpha$ 2a/ $\alpha$ 2c-AR<sup>-/-</sup> mice (KO) were treated with a supraphysiological dose of triiodothyronine (T3; 3.5 $\mu$ g/100g/BW/day) for 80 days or left untreated. Surprisingly, we found that KO mice present 15-24% ( $p < 0.01$ ) higher bone mineral density (BMD) than WT mice in all skeletal regions analyzed [tibia, femur, vertebra and hind body (lumbar spine+pelvis+hind limbs)]. As expected, T3 treatment significantly decreased BMD (11-14%,  $p < 0.01$ ) in all skeleton sites, but did not induce osteopenia in KO mice. The Three-Point Bending Test showed that the maximum load was 8% and 17% increased in the femur and tibia, respectively, of KO versus WT mice. Bone histomorphometry analysis showed that trabecular volume, thickness and number were also increased in KO versus WT mice (92, 47 and 29%, respectively;  $p < 0.01$ ). By real-time PCR analysis, we found that  $\alpha$ 2a-AR and  $\alpha$ 2c-AR mRNAs are expressed and that  $\alpha$ 2c-AR mRNA was downregulated by T3 (33%,  $p < 0.05$ ) in the tibia of WT mice. Tibial  $\beta$ 2-AR mRNA expression did not vary between mice lineages (WT vs. KO) or by T3 treatment. The mRNA of tartrate-resistant acid phosphatase and receptor activator of nuclear factor kappa B (factors positively related to osteoclastic activity) presented a 2-fold lower expression in KO versus WT mice ( $p < 0.05$ ), which suggests that bone resorption is reduced in KO mice. Finally, we found that T3 downregulates (3-fold,  $p < 0.001$ ) the mRNA of osteoprotegerin, a protein that limits osteoclastic activity, in WT but not in KO mice. In conclusion, the phenotype of high bone mass presented by  $\alpha$ 2a/ $\alpha$ 2c-AR<sup>-/-</sup> mice suggests that  $\alpha$ 2a-AR and/or  $\alpha$ 2c-AR are important to mediate the osteopenic effects of the SNS. The resistance of KO mice to the T3-induced osteopenia suggests a T3-SNS interaction, which probably depends on  $\alpha$ 2a-AR and/or  $\alpha$ 2c-AR, to regulate bone mass.

**A Key Mechanism Underlying the Immunosuppressive Effects of Vitamin D: 1,25dihydroxyvitamin D<sub>3</sub> Is a Transcriptional Modulator of IL-17.** S. Joshi\*, S. Youssef\*, S. Gaffen\*, L. Steinman\*, S. Christakos\*. <sup>1</sup>Biochemistry, UMDNJ-NJMS, Newark, NJ, USA, <sup>2</sup>Neurology, Stanford University, Stanford, CA, USA, <sup>3</sup>SUNY Buffalo School of Dental Medicine, Buffalo, NY, USA.

A new class of helper T cells producing IL-17 has recently been identified as a distinct inflammatory CD4+ helper T cell lineage (TH17). IL-17 has been reported to play a critical role in numerous inflammatory conditions and autoimmune diseases, including inflammation induced bone loss and multiple sclerosis. We report here for the first time that the active form of vitamin D, 1,25(OH)<sub>2</sub>D<sub>3</sub>, has a direct repressive effect on the expression of IL-17. 1,25(OH)<sub>2</sub>D<sub>3</sub> treatment (10<sup>-9</sup>-10<sup>-7</sup> M) for 24 - 96 h of activated mouse CD4+ T cells resulted in a dose dependent inhibition of IL-17 (maximum decrease, 66%). The murine model of multiple sclerosis, EAE, was used to test whether 1,25(OH)<sub>2</sub>D<sub>3</sub> inhibits IL-17 production *in vivo*. Treatment with 1,25(OH)<sub>2</sub>D<sub>3</sub> (50 ng/day/3 days) of mice with existing EAE (clinical score, 3.5) reversed paralysis, prevented the progression of the disease and resulted in a 50-60% decrease in the percentage of infiltrating IL-17 producing CD4+ T cells to the CNS. Correlated to the findings in mice, treatment of activated human CD4+ T cells with 1,25(OH)<sub>2</sub>D<sub>3</sub> also inhibited the production of IL-17. The mechanism of 1,25(OH)<sub>2</sub>D<sub>3</sub> mediated repression was found to be transcriptional repression mediated by VDR/RXR. When the human T cell line Jurkat was transfected with the human IL-17 promoter (-1,125/+5) and VDR and treated with PMA (10<sup>-7</sup> M) and ionomycin (200 ng/ml), there was a dose dependent inhibition of the transcriptional activation of IL-17 in the presence of 1,25(OH)<sub>2</sub>D<sub>3</sub> (activation levels were maximally reduced 70%). Deletion mutant analysis indicated that the region between -232 and -159 was required for the activation of the IL-17 promoter and for inhibition by 1,25(OH)<sub>2</sub>D<sub>3</sub>. Two NFAT sites are located within this region. Activation and inhibition by 1,25(OH)<sub>2</sub>D<sub>3</sub> were not observed using the -232/+5 construct with both NFAT sites mutated. Overexpression of NFAT was able to relieve the 1,25(OH)<sub>2</sub>D<sub>3</sub> dependent repression. EMSA showed that VDR/RXR binds to the NFAT sites and displaces NFAT from its site. ChIP analysis using the Hut 102 T cell line showed that activation by PMA/ionomycin can enhance recruitment of NFAT to the -232/-159 region of the IL-17 promoter. In the presence of 1,25(OH)<sub>2</sub>D<sub>3</sub> and VDR, recruitment of NFAT is inhibited and recruitment of VDR to this site is observed. These findings indicate that VDR mediates the suppression of IL-17 by blocking NFAT from binding to its sites on the IL-17 promoter and by associating with the NFAT element. The inhibition of IL-17 transcription by 1,25(OH)<sub>2</sub>D<sub>3</sub> may provide a key mechanistic explanation for the potent immunosuppressive action of 1,25(OH)<sub>2</sub>D<sub>3</sub>.

**Augmentation of Peak Bone Mass Occurs in Female and Male Mice without Progesterone Nuclear Receptors.** W. Yao, Z. Cheng, A. Pham\*, C. Busse\*, N. E. Lane. Center for Healthy Aging, UC Davis Medical Center, Sacramento, CA, USA.

Peak bone mass (PBM) is a strong determinant of incident osteoporotic fracture risk. We characterized skeletal acquisition and bone metabolism at the age of rapid skeletal acquisition in mice with the two nuclear progesterone receptors (PRA and PRB) rendered nonfunctional (PRKO).

**Methods.** We measured bone mass acquisition by repeated in vivo microCT scans of the distal femurs (DF) and mid-femurs in both female and male mice from all the genotypes (n=5-8/genotype: WT, PRKO +/-, PRKO -/-) from 1-9 months of age. At 2 months of age, when the rapid skeletal acquisition occurred, we characterized bone metabolism by measurement of biochemical markers of bone turnover (PINP, DPD/Cr), reproductive hormones/growth factors (FSH, Inhibin A, testosterone (T), progesterone (P), IGF1, TGFβ1), bone cell activities (primary osteoblast cultures for ALP and mineralization nodule formation; osteoclast maturation and activity by TRAP staining and dentin resorption).

**Results.** No differences were found between PRKO +/-, -/- and WT mice in body weight or femur length in both genders. PRKO -/- and +/- mice had an accelerated gain in BV/TV of the DF (between the ages of 1-3 months), greater PBM at age 3 months in both the female (+400%) and male (+95%; p < 0.05) PRKO mice compared to WT litter-mates. Mid-femur cortical thickness was greater in the PRKO -/- and +/- mice than the WT in both the males and females aged 6-9 months. At 2 months of age, FSH levels were higher in WT > PRKO +/- > -/- in both genders (p<0.05), while inhibin A levels were PRKO -/- > +/- > WT mice (p<0.05). P, T and IGF1 levels were similar among the genotypes. In the female mice, osteoblast maturation and activity (TGFβ1, PINP, in vitro ALP level and mineralization nodules) were PRKO -/- > +/- > WT mice (p<0.05); while the osteoclast maturation and activity (DPD/Cr, TRAP+ staining and dentin resorption) were similar among the genotypes. In male mice, osteoblast maturation (ALP, nodule formation) was higher in PRKO -/- > +/- = WT (p < 0.05); while osteoclast maturation and activity (DPD/Cr, TRAP+ staining, and dentin) were lower in PRKO -/- and +/- mice (p<0.05).

**Conclusions.** PRKO mice achieved a higher PBM than WT mice with females more affected than males. Elucidation of how progesterone mediates bone cell functions through its receptors may provide a novel pathway to augment PBM and reduce the burden of osteoporosis.

## F253

**Lrp6 Loss of Function Impacts Bone Homeostasis and Responds to Folate Supplementation.** B. Slowinska\*, J. Monaghan\*, M. C. H. van der Meulen<sup>2</sup>, D. Chen\*, L. Lukashova\*, M. E. Ross\*. <sup>1</sup>Laboratory of Neurogenetics and Development, Weill Medical College of Cornell University, New York, NY, USA, <sup>2</sup>Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, USA, <sup>3</sup>Musculoskeletal Repair and Regeneration Core Center, Hospital for Special Surgery, New York, NY, USA.

Human mutations in the low-density lipoprotein receptor-related protein 5 (LRP5) gene are associated with clinical disorders of high bone mass (HBM, gain of function alleles) or low bone mass (osteoporosis-pseudoglioma, OPPG, loss of function alleles). LRP5 and LRP6 both function as co-receptors with Frizzled to transduce Wnt signals in the canonical pathway. Since Lrp6 is expressed in cells important for bone formation and remodeling, we examined its role in bone homeostasis. In addition, our previous studies of an Lrp6 mutant allele revealed that this gene can contribute to neural tube birth defects that can be prevented by dietary supplementation with the vitamin, folic acid (FA). We therefore sought to determine the effect of the Lrp6 null allele with or without FA supplementation on bone morphology of the femur, measured by microcomputed tomography (micro-CT), and on whole bone strength, measured by three-point bending assays. Mice from the

Lrp6<sup>+/+</sup> line were maintained on defined diets containing either 2 ppm (mg/kg) FA or 10 ppm FA. Subjects were F2-generation or beyond, male offspring of Lrp6<sup>+/+</sup> x Lrp6<sup>+/+</sup> parents maintained on one of the two diets. In age matched adults (50 wk) fed 2 ppm FA, micro-CT revealed significant differences in several parameters in femurs including trabecular number and spacing (Tb. N., 1.16±0.5 vs 2.34±1.4 p<0.015; Tb. Sp. 1.2±0.65 vs 0.45±0.03 p<0.01) comparing heterozygous Lrp6<sup>+/+</sup> with <sup>+/+</sup> siblings, respectively. Interestingly, no statistical differences existed between genotypes maintained on the high (10 ppm) FA diet. No significant differences in these parameters were found in Lrp6<sup>+/+</sup> mice on the 2 ppm vs 10 ppm diet, while Lrp6<sup>+/+</sup> mice fed the 10 ppm diet had Tb.N. and Tb.Sp. values indistinguishable from <sup>+/+</sup> on either diet. Whole bone strength and stiffness in bending were not significantly different between genotypes or diets. We conclude that Lrp6 haploinsufficiency alters bone homeostasis in trabecular bone but does not alter cortical bone mechanics. Dietary supplementation with FA can ameliorate the effects of genotype on trabecular bone.

**Camurati-Engelmann Disease (Progressive Diaphyseal Dysplasia): A Unique Variant Featuring a Novel, Heterozygous, Leucine Repeat Mutation in TGFβ1 Together with a Novel, Homozygous, Missense Change in TNFSF11 Encoding RANKL.** M. P. Whyte<sup>1</sup>, W. Totty<sup>2</sup>, D. Novack<sup>2</sup>, D. Wenkert<sup>1</sup>, X. Zhang\*, S. Mumm<sup>1</sup>. <sup>1</sup>Shriners Hosp for Children, St. Louis, MO, USA, <sup>2</sup>Washington Univ Schl Med, St. Louis, MO, USA.

We report what seems to be a unique disorder of skeletal homeostasis affecting a mother and son. Our molecular studies indicate that the condition derives from disturbances and dosage effects in two key genes that regulate bone turnover.

A 32-year-old man was self-referred for an undiagnosed disorder causing lower limb pain beginning in childhood. As a teenager, "osteopathia striata" was diagnosed, and he grew to 6' 10" by his late 20's. He had disproportionately long lower limbs, pseudoclubbing, deafness, torus palatinus, and hypomasculinization. Karyotype was normal. Skeletal survey revealed generalized osteosclerosis, widened bones, and cortical and trabecular bone thickening most closely resembling Camurati-Engelmann disease (CED). However, the changes extended to the ends of the long bones unlike CED (Fig). BMD z-scores were +7.7 and +4.4 in spine and hip, respectively. Markers of bone turnover were elevated. Calcium homeostasis seemed normal, except for marked hypocalciuria. Non-decalcified iliac crest revealed significant osteomalacia (Fig). His asymptomatic mother was 5' 9," and had similar, but distinctly more mild, clinical, radiological, and biochemical changes.

We amplified by PCR and sequenced exon 1 of *TNFRSF11A* (RANK) as well as all coding exons and adjacent mRNA splice junctions of *TNFRSF11B* (OPG), *TNFSF11* (RANKL), *SQSTM1* (sequestosome 1), and *TGFβ1* [transforming growth factor β1].

No mutations were detected for RANK, OPG, or sequestosome 1. However, in *TGFβ1*, we found a novel 12 bp duplication in exon 1 that would insert 4 Leu residues, reminiscent of a report (Nat Genet 26:273, 2000) of a 9 bp insertion at the same site adding 3 Leu residues in a patient with CED. Additionally, in our proband we identified in *TNFSF11* a homozygous, single-base change resulting in a non-conservative amino acid change (c.107C>G, p.Pro36Arg) in RANKL that was heterozygous in his mother. This *TNFSF11* change is not found in dbSNP (SNP Database), nor reported in several association studies of RANKL polymorphisms, but was detected in 1/22 alleles tested randomly from other patients. Hence, this change may reflect the impact of a gene dosage effect of RANKL that contributes to the novel skeletal phenotype in this family.

**Geometric Property QTLs in HcB/8 x HcB/23 F2 cross.** N. Saless<sup>1</sup>, S. Litscher\*, M. J. Houlihan\*, T. K. O'Neil\*, R. S. Kattappuram\*, S. Sudhakaran\*, K. G. Abdul Raheem\*, S. Olson\*, G. Lopez Franco\*, P. Demant\*, R. D. Blank\*. <sup>1</sup>Cellular and Molecular Biology, University of Wisconsin, Madison, WI, USA, <sup>2</sup>University of Wisconsin, Madison, WI, USA, <sup>3</sup>University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Roswell Park Cancer Institute, Buffalo, NY, USA, <sup>5</sup>Endocrinology, University of Wisconsin and Madison VAMC, Madison, WI, USA.

Fractures are an important health problem with a significant genetic component. We performed a reciprocal F2 intercross of the recombinant congenic mouse strains HcB/8 and HcB/23 including 603 animals, reporting whole bone biomechanical performance-related quantitative trait loci (QTLs). To elucidate the mechanisms leading to biomechanical performance in our animals, we now report femoral geometry QTLs in the same cross. Animals were maintained to 17 weeks under standard husbandry conditions. Following

sacrifice, we subjected femora to quasi-static 3-point bend testing to failure. We acquired cross-sectional digital images of the fracture surfaces and extracted of major and minor inner and outer axes, perimeter, cortical cross-sectional area, and cross-sectional moment of inertia. Linkage analyses were performed with QTL Cartographer and R-QTL. Experiment-wide 5% and 1% significance levels for linkage were established by permutation testing.

The main results are summarized in the table. On chromosome 4 in particular, a QTL for femoral size appears to underlie the previously identified QTL for yield load, maximum load, stiffness, and BMD. It is worth noting that our chromosome 4 QTL overlaps that identified by Beamer and colleagues for bone mineral density. Subsequent work by Robling and colleagues showed that the chromosome 4 locus contributes to differences in responsiveness to mechanical loading in vivo. Our experiment allows localization of the QTL to a short chromosomal segment centered at 67 cM.

Bone geometry is a major determinant of biomechanical performance, accounting for approximately 50% of whole bone strength in multiple regression analyses performed by multiple investigative teams. In addition to its importance in fracture susceptibility, geometric phenotypes are highly reproducible, making them ideal for linkage studies. More importantly, the relationship between long bone geometry and modeling during growth makes these phenotypes amenable to investigation of the cellular-level mechanisms by which biomechanical performance is established.

Geometric Property QTLs		
Location (Chromosome, cM)	Traits	Max LOD Score
1, 52-67	Outer Minor Axis, Shape Factor	3.7, 3.1
2, 27-31	Outer Major Axis, Perimeter, Cross-Sectional Area, Shape Factor	6.5, 5.8, 3.5, 6.5
3, variable	Outer Major Axis, Cross-Sectional Area, Moment of Inertia	3.7, 3.0, 3.22

## F265

**A Recombinant Congenic Strain (B.H-6) Establishes that Trabecular Bone Mass and Bone Marrow Adiposity Are Distinct and Heritable Phenotypes.** C. Ackert-Bicknell<sup>1</sup>, G. A. Churchill<sup>1\*</sup>, K. R. Shockley<sup>2\*</sup>, M. Horowitz<sup>3</sup>, E. Canalis<sup>4</sup>, C. J. Rosen<sup>5</sup>. <sup>1</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>2</sup>The Jackson Laboratory, B, ME, USA, <sup>3</sup>Yale University, New Haven, CT, USA, <sup>4</sup>St Francis Hospital and Medical Center, Hartford, CT, USA, <sup>5</sup>Research Institute, Maine Medical Center, Scarborough, ME, USA.

We previously reported a Quantitative Trait Locus (QTL) for serum IGF-I and vBMD on mouse Chr 6. This QTL was named *Igf1s1*. The B6.C3H-6T (6T) congenic mouse was generated such that C3H/HeJ (C3H) alleles for this QTL were moved onto a C57BL/6J (B6) background. The C3H-like region of the 6T congenic extended from 48.6 to 121 Mb (NCBI Bld 36). We also generated a second congenic strain for the *Igf1s1* QTL, i.e. B.H-6. The B.H-6 congenic strain is C3H-like for the region from 89.0 Mb to 125 Mb on Chr 6 and therefore is only C3H-like for the distal two-thirds region on Chr 6 that the 6T congenic is C3H. Female B.H-6 mice had more body fat than 6T ( $p<0.05$ ), but not different from B6 mice. B.H-6 mice had significantly greater trabecular BV/TV by  $\mu$ CT, whereas femoral vBMD by pQCT did not differ from B6; in contrast, 6T mice had low vBMD and reduced trabecular BV/TV vs. B6. Both strains exhibited a marked increase in marrow adiposity. We hypothesized there was a common genetic mechanism regulating marrow adiposity in the 6T and B.H-6 strains, but that a separate genetic pathway was involved in bone acquisition. To test this hypothesis we examined gene expression in the femur of the B.H-6 and the 6T mice by Illumina microarray. A total of 41 genes were found to have significantly different expression between the 2 strains. None were located within the B.H-6 congenic region suggesting that genes found within the 6T region, but not the B.H-6 locus were responsible for differences in BV/TV between 2 strains. Osteocalcin, also known as *Gpmb*, is located at 48.9 Mb on mouse Chr 6; this gene regulates both osteoblasts and osteoclasts. The 6T strain is C3H-like for this gene whereas B.H-6 is not, and *Gpmb* had 3.3 fold lower expression in the femur of 6T vs. B.H-6 ( $q<0.00001$ ). Previously, we showed that 6T lost bone but did not increase marrow fat on a high fat diet (HFD), while B6 did not lose bone but showed increased marrow adiposity on a HFD. We then compared gene expression from femorae of 6T and B6 mice on a HFD, by Illumina micro-array, and found *Gpmb* to be significantly suppressed in 6T vs. B6 (-1.5 fold;  $p<0.04$ ). Importantly, *Gpmb* has a non-synonymous SNP in the 2<sup>nd</sup> Exon of C3H, resulting in an asparagine to aspartic acid substitution in 6T. In conclusion, we showed differential genetic regulation of marrow fat and bone mass. This would imply that marrow adiposity is a distinct and heritable phenotype, independent of BV/TV. Polymorphic differences in *Gpmb* likely contribute to the low bone mass phenotype of the 6T congenic.

## F270

**Drugs which Inhibit Osteoclast Function Suppress Tumor Growth and Alter Hematopoietic Cell Populations in Bone.** X. Li<sup>1</sup>, J. Liao<sup>1\*</sup>, A. Koh<sup>1\*</sup>, K. J. Pienta<sup>2\*</sup>, L. K. McCauley<sup>1</sup>. <sup>1</sup>Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>Medicine, University of Michigan, Ann Arbor, MI, USA.

Inhibition of bone resorption is effective in reducing tumor burden in murine models and human prostate cancer patients. However, whether drugs which inhibit osteoclast function restrict tumor growth independent of inhibition of bone resorption is unclear. It was recently reported that increased osteoclast activity resulted in mobilization of hematopoietic stem cells (HSCs). The purpose of this investigation was to determine whether drugs which inhibit osteoclast function alter tumor growth directly or indirectly, and how they impact HSCs in the marrow.

Zoledronic acid (ZA), a bisphosphonate, and recombinant OPG-Fc, a RANKL inhibitor, (provided by Amgen), were administered to mice bearing vertebral implants (vossicles) containing Ace-1 osteoblastic prostate cancer cells. Vertebrae from 11d mice or gelfoam sponges were seeded with  $5 \times 10^5$  luciferase tagged prostate carcinoma (Ace-1<sup>luc</sup>) cells subcutaneously in athymic mice (2 vossicles, 2 gelfoam implants/mouse). Mice received ZA (5 $\mu$ g/mouse, twice/week), (OPG-Fc at 10mg/kg, 3 times/week) or vehicle, and luciferase activity measured weekly. At sacrifice, bone marrow cells were harvested and HSCs evaluated by flow cytometry. Histologic analysis of the tumors, vossicles and endogenous bones and serum biochemistry were performed.

Results showed: 1) There was a significant increase in tumor luciferase activity in vossicles versus gelfoam implants. The tumor size was also significantly larger in vossicles than in gelfoam. 2) ZA (versus vehicle) significantly inhibited tumor growth in bone but not in gelfoam implants, decreased serum TRAP5b and osteoclast numbers, increased tibia and vossicle bone areas, and increased the percent of HSCs (lin<sup>-</sup>, c-kit<sup>+</sup>, sca-1<sup>+</sup> cells) in the marrow. 3) OPG-Fc (versus vehicle) significantly inhibited tumor growth in bone but not in gelfoam implants, decreased serum TRAP5b and osteoclast numbers, increased tibia and vossicle bone areas, and increased the percent of HSCs in the marrow. The ZA studies were repeated in non-tumor bearing C57B6 mice and similar significant elevations in HSCs in the bone marrow were found.

These data suggest that tumors prefer to grow in bony sites and that the effect of drugs which inhibit osteoclast function on prostate carcinoma growth and osteoblastic lesions requires the bone microenvironment. Furthermore, these data resulted in the novel findings of an association of inhibition of bone resorption with elevated marrow HSCs. These studies begin to clarify the mode of action of drugs which inhibit osteoclast function in treating skeletal metastasis and shed light on the interactions of bone resorption, tumor growth and HSCs.

## F272

**2-Methoxyestradiol Blocks Prostate Cancer Bone Metastases.** K. S. Mohammad<sup>1</sup>, L. Kingsley<sup>1</sup>, T. La Vallee<sup>2\*</sup>, T. A. Guise<sup>1</sup>, J. M. Chirgwin<sup>1</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA, USA, <sup>2</sup>EntreMed Inc., Rockville, MD, USA.

The majority of patients with hormone-refractory advanced prostate cancer develop bone metastases, where disorganized new bone formation results from paracrine stimulation of osteoblasts by tumor cells. Many secreted proteins that activate osteoblasts are regulated by the hypoxic response pathway. We hypothesized that anti-hypoxic therapy should be effective against bone metastases and tested this with 2-methoxyestradiol (2ME2), an inhibitor of microtubule polymerization and the Hif-1 pathway that is in clinical trials in cancer patients. 2ME2 was tested alone and in comparison and combination with two established treatments for bone metastases: zoledronic acid (ZA), and the endothelin A receptor antagonist, atrasentan.

Nude mice (n=15/group) received human prostate cells by intratibial injection. The LuCaP23.1 xenograft is androgen-dependent, secretes prostate specific antigen (PSA), and causes florid osteoblastic bone responses. Effects of treatments on bone and tumor burden were assessed in vehicle, 3 single-treatment groups, 3 double-treatment groups and one triple-treatment group. Atrasentan was given at 20mg/kg/d in drinking water. 2ME2 (EntreMed, Inc) was given at 150mg/kg/day by ip injection (of soluble bioactive dispersion formulation). ZA was given at 5ug/kg/3x per wk by sc injection. Mice were treated for 26 wks, while followed by X-ray, ELISA for serum PSA. No group that received 2ME2 alone or in combination showed bone lesions on X-ray, although direct effects on bone of the drugs can obscure the X-ray appearance of small tumor responses. More significantly, only one mouse out of the 60 receiving 2ME2 had detectable PSA, a surrogate marker of tumor burden secreted by prostate cancers and not present in mice. While all the mice in the other treatment groups showed a significant increase in PSA level starting at 8 weeks post-tumor inoculation.

Preliminary data suggest that 2ME2, while lacking substantial estrogenic activity, may be a moderately effective anti-androgen, consistent with loss of muscle mass seen in the 2ME2-treated mice. LuCaP23.1 xenografts are androgen-dependent; so the efficacy of 2ME2 against this tumor in bone may represent a combined anti-androgen and anti-hypoxic effect. Separating these two mechanisms, both of which would be beneficial in the clinic, requires testing 2ME2 in an androgen-independent model of prostate cancer bone metastases.

**Combined Transforming Growth Factor  $\beta$  Receptor I Kinase Inhibitor and Bisphosphonates Are Additive to Reduce Breast Cancer Bone Metastases.** K. S. Mohammad<sup>1</sup>, E. Stebbins<sup>\*2</sup>, L. Kingsley<sup>1</sup>, P. G. J. Fournier<sup>1</sup>, M. Niewolna<sup>\*1</sup>, C. R. McKenna<sup>\*1</sup>, X. Peng<sup>\*1</sup>, L. Higgins<sup>\*2</sup>, D. Wong<sup>\*2</sup>, T. A. Guise<sup>1</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA, USA, <sup>2</sup>Scios Inc., Fremont, CA, USA.

Breast cancer commonly metastasizes to and destroys bone to cause pain and fracture. Substantial data support central roles for bone-derived TGF- $\beta$  and tumor-derived osteolytic factors such as PTHrP in a vicious cycle of bone destruction. A small molecule inhibitor of TGF- $\beta$  receptor I kinase (TGF- $\beta$ RI), SD-208, inhibits signaling downstream of the TGF- $\beta$  receptor, reduced osteolytic lesion area and prolonged survival in mice. Bisphosphonates reduce skeletal morbidity in patients with bone metastases. Thus, we hypothesized that combined treatment of SD-208 and zoledronic acid (ZA) would be more effective for osteolytic bone metastases than either treatment alone.

Mice were inoculated with MDA-MB-231 breast cancer and randomized to receive the following treatments when osteolytic lesions were detected on radiographs: 1) SD-208 (60mg/kg/day); 2) ZA (5ug/kg/1/wk); 3) ZA (5ug/kg 3/wk); 4) SD-208+ZA; 5) SD-208+ZA or 6) vehicle. Osteolytic lesion area was reduced in mice treated with SD-208, ZA 1/wk ( $p<0.001$ ), ZA 3/wk ( $p<0.05$ ) vs. vehicle. Mice treated with combinations had significantly less osteolysis than vehicle or single treatment: SD-208+ZA 1/wk ( $3.11 \pm 0.091 \text{ mm}^2$ ) ( $p<0.001$ ) and SD-208+ZA 3/wk ( $2.19 \pm 0.47 \text{ mm}^2$ ) vs. vehicle ( $p<0.001$ ); Single treatment, SD-208 vs. SD-208+ZA 1/wk ( $p<0.001$ ), SD-208 vs. SD-208+ZA 3/wk ( $p<0.001$ ); ZA 1/wk vs. SD-208+ZA 1/wk ( $p<0.001$ ), ZA 3/wk vs. SD-208+ZA 3/wk ( $p<0.001$ ). Histomorphometric analysis showed a significant reduction in tumor burden and increase in total bone area with all single and combined treatment. Combined treatment with SD-208 + ZA 3/wk increased total bone area than SD-208 alone ( $p<0.01$ ) or ZA 1/wk alone ( $p<0.05$ ). This was accompanied by a reduction in osteoclast # by all single treatments. Combined treatment with SD-208 + ZA 1x/wk decreased OCL # than SD-208 alone ( $p<0.05$ ). SD-208 alone ( $p<0.01$ ) or in combination with ZA (ZA 1/wk  $p<0.05$ , ZA 3/wk  $p<0.05$ ) and not ZA alone increased osteoblast #.

To determine if the reduced osteolysis observed in mice treated with combined SD-208 and ZA was due to reduced expression of TGF- $\beta$  target genes. Quantitative RT-PCR analysis indicated that PTHrP, IL-1 and PMPA mRNA steady-state levels were decreased in response to combined SD-208+ZA more than either treatment alone. These data indicate that combination therapy with TGF- $\beta$  receptor I kinase inhibition and bisphosphonates reduce the progression of established osteolytic metastases more effectively than either therapy alone. This effect may be due to reduction in tumor factors which promote osteolysis.

**Bortezomib, a Proteasome Inhibitor, Prevents Metastatic Breast Cancer Osteolysis and Reduces Mammary Fat Pad Tumor Growth in Mice.** M. D. Jones<sup>\*1</sup>, J. C. Liu<sup>\*2</sup>, J. Schoonmaker<sup>\*3</sup>, T. K. Barthel<sup>2</sup>, S. Mulay<sup>\*3</sup>, M. L. Bouxsein<sup>\*3</sup>, G. S. Stein<sup>1</sup>, S. Mukherjee<sup>\*2</sup>, J. B. Lian<sup>1</sup>. <sup>1</sup>Department of Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester, MA, USA, <sup>2</sup>Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, <sup>3</sup>Center for Regenerative Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

The selective proteasome inhibitor bortezomib (Bzb) inhibits the proliferation of several solid tumors and can increase osteoblasts in the bone marrow. Our goal was to test the efficacy of Bzb in preventing breast cancer metastasis to bone by directly inhibiting tumor cell growth and protecting the bone from osteolysis using experimental approaches in mice appropriate for translational studies. MDA-MB-231 metastatic breast cancer cells were injected into the mammary fat pad (MFP) or the right tibia of female NCr/SCID mice that received intraperitoneal injections of Bzb 3x/week at a dose of 0.3mg/kg or PBS injections (controls) following IUCAC approved procedures. Experimental groups were: 1) Bzb treatment initiated 24 hours following MDA-MB-231 cell inoculation; 2) Bzb treatment initiated 3 weeks prior to MDA-MB-231 cell inoculation, followed by withdrawal upon MDA-MB-231 cell inoculation, to assess protective effective on the skeleton; and 3) Bzb treatment initiated upon radiographic evidence of osteolytic disease as monitored by weekly radiography. At 6 or 8 weeks, tibias with tumors were examined by histology and  $\mu$ CT (Scanco, Inc) to quantify bone parameters. Tumors developed in the MFP were significantly reduced in volume in Bzb treated mice. Intratibial tumor growth progressed and osteolysis continued until the cortical bone was lost in the control mice. In contrast, osteolysis in Bzb treated mice progressed more slowly (group 1). Bzb pretreatment (group 2) resulted in significantly less bone loss compared to controls. Tumor size and osteolytic disease were reduced in the Bzb group treated after osteolytic disease was detected (group 3) compared to controls. The  $\mu$ CT images and calcein labeled bone indicated a replacement of lost bone occurred in Bzb treated mice. Additionally, examination of the contralateral tibias showed Bzb increased skeletal bone mass in mice of each treatment group. Our studies show that in the mouse, Bzb inhibits tumor growth and osteolysis and appears to regenerate lost bone. In patients with breast cancer, Bzb has the potential to increase bone renewal following tumor irradiation and can reduce osteolytic bone disease by inducing new bone formation through recruitment of progenitor cells into the osteoblast lineage as indicated by in vitro studies.

**Ectopic Runx2 Expression Disrupts Normal Acini Structure in Mammary Epithelial Cells.** J. Pratap, K. Imbalzano<sup>\*</sup>, J. Underwood<sup>\*</sup>, N. Cohet<sup>\*</sup>, K. D. Veeraraj<sup>\*</sup>, A. J. van Wijnen, A. N. Imbalzano<sup>\*</sup>, J. L. Stein<sup>\*</sup>, J. B. Lian, J. Nickerson<sup>\*</sup>, G. S. Stein. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

The Runx2 transcription factor, essential for skeletal development, regulates mammary gland specific genes. Recent evidence shows that Runx2 is ectopically expressed in metastatic breast cancer cells and contributes to tumorigenic properties by increasing expression of VEGF and MMPs. To understand the role of Runx2 during early events of mammary gland formation, disruption of which results in a cancer cell phenotype, we utilized the three-dimensional culture system (20 days) of human MCF10-A normal mammary epithelial cells. These cells cultured on basement membrane (Matrigel) form polarized, growth-arrested acini-like spheroids that recapitulate in vitro several aspects of in vivo glandular architecture. We find low levels of Runx2 in nuclear extracts of MCF10A cells by EMSA and by in situ immunofluorescence. Here we show that ectopic expression of Runx2 by adenovirus in MCF10-A cells causes disruption of normal acini formation compared to controls. Ultrastructural analysis using electron microscopy revealed disorganized acini with absence of a lumen in the Runx2 overexpressed cells. We find that the disrupted structure is due to altered cell proliferation detected by increased Ki-67 staining and increased expression of cdc6, a cell proliferation marker and the anti-apoptotic marker Bcl-2. Interestingly, these disorganized structures do not show  $\beta$ 4-integrin staining indicating the loss of basement membrane. In complementary experiments, we depleted Runx2 in bone metastatic MDA-MB-231 breast cancer cells by lentiviral stable expression of shRNA-Runx2 and achieved more than 80% knockdown of endogenous Runx2. The parental MDA-MB-231 cells do not form organized acini when cultured in reconstituted basement membrane. Upon culture of MDA-MB-231-shRNA-Runx2 cells, we find a partial reversion to acini structures compared to the controls by 10 days of differentiation. In summary, our studies show that overexpression of Runx2 causes increased cell proliferation and decreased apoptosis of mammary epithelial cells in vitro and that depletion of Runx2 in cancer cells results in acquisition of the normal architecture of mammary glands. These novel findings provide direct evidence of the biological activity of Runx2 in early aspects of breast cancer progression, in addition to the Runx2 induction of metastatic genes in primary tumors. Together these findings suggest Runx2 as a potential therapeutic molecular target in breast cancer.

**Application of Preventive Measures Minimizes the Occurrence of Osteonecrosis of the Jaw in Patients with Bone Loss Treated with Bisphosphonates: A Single-Institution Series.** C. Ripamonti<sup>\*</sup>, M. Maniczo<sup>\*</sup>, E. Cislighi<sup>\*</sup>, T. Campa<sup>\*</sup>, E. Fagnoni<sup>\*</sup>, G. Salbene<sup>\*</sup>, C. Bareggi<sup>\*</sup>, L. Ascani<sup>\*</sup>, A. Pigni<sup>\*</sup>, C. Brunelli<sup>\*</sup>. IRCCS Foundation, National Cancer Institute of Milan, Milan, Italy.

Osteonecrosis of the jaw (ONJ) is an uncommon adverse event that has been reported in patients receiving complex cancer treatment regimens including bisphosphonates (BPs). Risk factors such as periodontal disease and dental trauma place patients at increased risk of ONJ; therefore, proactive monitoring of the oral cavity is recommended (Ruggiero et al. J Oral Maxillofac Surg. 2004;62:527-534). The occurrence rates of ONJ before and after the implementation of dental preventive measures were investigated in this study. Patients with bone loss treated with BPs and who did not receive preventive dental care ( $n = 812$ ; referred from January 1999 to February 2007; PRE group) were retrospectively compared with patients who received regular dental examinations every 6 months ( $n = 154$ ; POST group). POST-group patients received regular dental maintenance and care (dental visit  $\pm$  panoramic jaw radiograph) to assess potential dental pathologies throughout BP treatment. ONJ incidences are presented as raw percentages ([ONJ cases,  $n$ ]/[total patients,  $n$ ]  $\times$  100) and incidence rate (IR) ([ONJ cases,  $n$ ]/[monitoring time of all patients]). Differences between the PRE and POST groups were analyzed through 1-tailed Fisher's exact test and presented as IR difference (IRD) with 95% confidence interval (CI). Among 966 BP-treated patients assessed (male/female = 255/711), 73% had bone metastases from breast cancer. Patients received zoledronic acid (ZOL;  $n = 244$ ), pamidronate (PAM;  $n = 600$ ), PAM followed by ZOL ( $n = 79$ ), or clodronate (alone or with PAM;  $n = 43$ ). BPs were administered per institutional guidelines; ZOL was used per label. Overall, the observed ONJ incidence was 2.9% (ZOL/PAM + ZOL,  $n = 19$ ; PAM,  $n = 9$ ). ONJ incidence was significantly lower in the POST group ( $n = 1$ ; 0.6%) vs the PRE group ( $n = 27$ ; 3.3%) ( $P = .048$ ). Among both ZOL- and PAM + ZOL-treated patients, the incidence was significantly lower in the POST group (0.9%) vs the PRE group (8.7%) ( $P = .002$ ). For all BP-treated patients, IR of ONJ was 0.007/patient-yr for the POST group and 0.03/patient-yr for the PRE group, resulting in an IRD of 0.24 (95% CI = 0.006, 1.45). In conclusion, implementation of routine preventive measures before and during BP treatment reduced the frequency of ONJ by 76% relative to that of patients who did not receive preventive dental care. These data support the importance of preventive dental care in all patients undergoing BP treatment to maintain bone health.

## F283

**Inhibition of BMP Pathway and Osteoclast Activity in Osteoblastic Prostate Cancer Lesion in Bone.** M. S. Virk<sup>\*1</sup>, F. A. Petrigliano<sup>\*2</sup>, N. Q. Liu<sup>\*2</sup>, D. Stout<sup>\*3</sup>, A. F. Chatzioannou<sup>\*3</sup>, W. C. Dougall<sup>\*4</sup>, J. R. Lieberman<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, UCHC, Farmington, CT, USA, <sup>2</sup>Orthopaedic Surgery, UCLA, Los Angeles, CA, USA, <sup>3</sup>Pharmacology, UCLA, Los Angeles, CA, USA, <sup>4</sup>Amgen Inc., Seattle, WA, USA.

The purpose of this study was to investigate the influence of inhibition of BMP activity and osteoclast activity on the development and progression of an osteoblastic prostate cancer lesion in a murine model of bone metastasis. A total of 45 male SCID mice tibias were implanted with 200,000 human prostate cancer cells (LAPC-9) and divided into five groups. Osteoclast activity was inhibited with recombinant RANKL antagonist (RANK: Fc) and BMP inhibition was achieved by ex-vivo transduction of LAPC-9 cells with retrovirus expressing a BMP antagonist, noggin (RN). Group I: RANK: Fc treatment; Group II: Retronoggin treatment; Group III: combined treatment; Group IV: cells alone (control); Group V: empty vector control. Radiographs, hind limb measurements, micro PET-CT (<sup>18</sup>F- fluorodeoxyglucose [FDG] and <sup>18</sup>F-fluoride), and histology were performed at 2, 4 and 5 weeks. Osteoblastic lesions were present on radiographs in control groups (IV and V) & Group I tibias at 4 wks. However, blastic lesions were first detected in Group II & III tibias at 5 wks and these lesions were limited to the proximal tibia. The blastic lesions were quantified on microCT, which demonstrated a lower (p<0.001) percentage increase in bone volume in Group II & III but not in Group I tibias (p>0.05) at 4 & 5 wks compared to the controls. Micro PET with FDG, which correlates with glucose metabolism demonstrated significantly smaller signal volumes (p<0.001) in Group II & III tibias at 4 and 5 wks compared to the control animals. Hind limb measurements were smaller (p<0.001) in Group II & III tibias but not in Group I tibias (p>0.05) compared to the control group tibias at 2 and 4 wks. Serial micro PET scans with <sup>18</sup>F-fluoride tracer demonstrated a lower percentage difference in maximum fluoride signal intensity (p<0.05) in Group II & III tibias but not in Group I tibias (p>0.05) compared to the control group tibias at 2 and 4 wks. Histomorphometric analysis demonstrated a lower (p<0.001) bone area/tissue area in Group II & III tibias but not in Group I tibias (p>0.05) when compared to the control tibias. The number of osteoclasts/mm were significantly lower (p<0.001) in Group I & III tibias compared to the control group tibias. BMP inhibition by noggin delayed the development and progression of osteoblastic lesions. However, inhibiting osteoclast activity did not have a significant effect on the development or progression of osteoblastic lesion. Combined inhibition of BMPs and osteoclast activity was not superior to inhibition of BMPs alone in delaying the progression of osteoblastic prostate cancer lesions in this model.

**Novel Splicing Variants of ADAM8 Stimulate Tumor-Induced Bone Metastasis by Increasing Invasion and Osteoclastogenesis.** I. Hernández<sup>\*1</sup>, J. L. Moreno<sup>2</sup>, C. Zandueti<sup>\*1</sup>, L. Montuenga<sup>\*1</sup>, F. Lecanda<sup>1</sup>. <sup>1</sup>Division of Oncology, Center for Applied Medical Research, Pamplona, Spain, <sup>2</sup>Orthopaedics, University of Maryland School of Medicine, Baltimore, MD, USA.

ADAMs (a disintegrin and metalloprotease) are type I transmembrane proteins involved in morphogenesis, cell proliferation, differentiation, migration, adhesion, fusion, and tumorigenesis. They form a large family of cell-surface proteins, characterized by containing a disintegrin domain displaying adhesive properties and a metalloproteinase domain with proteolytic activity. ADAM8 is highly expressed in osteoclast precursors and induces leukocyte adhesion and migration. Recently it has been associated with poor prognosis of lung cancer. To gain insight in the function of ADAM8 in the context bone metastasis, we screened a panel of lung cancer cell lines by RT-PCR. ADAM8 was downregulated in lung cancer cell lines as compared to normal epithelium cells (NHBE). However, several splicing isoforms were differentially upregulated in tumor cells vs NHBE. These data were confirmed by western blot analysis in cell lysates. We cloned and sequenced several new splicing isoforms. Two of them, Δ18a and Δ14', both lacking their transmembrane and cytoplasmic domains, were present in several tumor cell lines but they were expressed at low levels in normal NHBE. Only retroviral overexpression of Δ18a in two lung cancer cell lines showed enhanced invasive activity as compared to mock cells (p<0.001). Interestingly, ADAM8-shRNA markedly decrease invasive activity as compared to mock cells (p<0.05). In conditions that mimic the bone-marrow microenvironment by coculture of lung cancer cells with ST-2 stromal cell line, expression levels of ADAM8 and Δ14' isoform were markedly increased. Moreover, addition to osteoclast cultures of cell free supernatants from Δ14' overexpressing cells only, and not Δ18a or wild type, resulted in a significant increase in the area of TRAP+ cells in vitro (p<0.01). Furthermore, in a murine model of bone metastasis, intracardiac inoculation lung cells overexpressing Δ14' induced an increase in prometastatic activity with high tumor burden as assessed by X-Ray image analysis (p<0.05) and μCT scans. These data indicate that the expression of different truncated forms of ADAM8 by lung cancer cells may result in the specific up-regulation of their invasive and osteoclastogenic activity in the bone microenvironment. These findings suggest a novel mechanism of tumor-induced osteolysis in bone metastatic colonization.

**Role of Fibroblast Activation Protein (FAP) and Dipeptidyl Peptidase (DPP4) in Myeloma Bone Disease and Tumor Growth.** A. Pennisi<sup>\*1</sup>, X. Li<sup>\*1</sup>, D. Gaddy<sup>2</sup>, N. Akel<sup>\*2</sup>, N. Aziz<sup>\*3</sup>, S. Yaccoby<sup>1</sup>. <sup>1</sup>MIRT, UAMS, Little Rock, AR, USA, <sup>2</sup>Department of Physiology and Biophysics, UAMS, Little Rock, AR, USA, <sup>3</sup>Point Therapeutics, Wellesley Hills, MA, USA.

Fibroblast activation protein (FAP) and dipeptidyl peptidase 4 (DPP4) are related serine proteases which have been implicated as tumor microenvironmental factors. We found that these proteases were not expressed by myeloma (MM) cells, however, while DPP4 was highly expressed by osteoclasts, FAP was one of few genes consistently upregulated in osteoclasts after co-culture with MM cells. Inhibition of FAP in MM-osteoclast co-cultures using siRNA attenuated osteoclast-induced MM cell survival (*Ge et al., BJH 2006*). The aim of the study was to investigate the effect of two FAP/DPP4 inhibitors, PT-100 and PT-630, on MM cell growth and osteoclastogenesis in. Ex vivo MM cells from 6 patients were co-cultured with osteoclasts and treated with PT-100 or PT-630 (0.1-100 μM) for 7 days. Whereas PT-100 inhibited MM cell growth in all tested doses by 43%-72% (p<0.002 vs. 100 μM), PT-630 inhibited MM cell growth in a dose dependent manner reaching 49% growth inhibition with 100 μM (p<0.02). These compounds had no direct effect on MM cell growth, suggesting that FAP-induced MM cell survival depends on close contact between MM cells and osteoclasts. MMP-2 and MMP-9 have been associated with tumor metastasis and FAP activity. MMP-2 but not MMP-9 was reduced in co-culture conditioned media by 44±7% (p<0.04) following treatment with PT-100 while PT-630 had no significant effect. PT-100 and PT-630 inhibited formation of multinucleated osteoclasts by 70±4% (p<0.001) and 56±6% (p<0.003) respectively, through a mechanism involving reduced p38 MAPK activity. These compounds also reduced resorption pit area by osteoclasts on dentine slices by 92% (p<0.01) and 69% (p<0.04) respectively, indicating that reduced osteoclast differentiation by these compounds was accompanied by reduced resorption activity. In vivo, SCID-hu mice engrafted with MM cells from 5 patients were treated with PT-100 and PT-630. Overall, PT-100 and PT-630 reduced MM growth by 51% (p<0.05) and 66% (p<0.05) respectively. Bone mineral density (BMD) measurements of the myelomatous bone revealed prevention of bone loss by PT-100 or PT-630 (p<0.05). These agents markedly reduced number of multinucleated osteoclasts (p<0.02) but had no effect on number of osteoblasts in myelomatous bones. We conclude that FAP/DPP4 are involved in MM osteolysis and tumor growth and thus approaches to inhibit activity of these serine proteases in myelomatous bone may help control MM and its associated bone disease.

**Identification of RhoB as a Key Target Involved in Cell Motility and Bone Metastasis.** D. Luis-Ravelo<sup>\*</sup>, I. Antón<sup>\*</sup>, S. Vicent<sup>\*</sup>, I. Hernández<sup>\*</sup>, C. Zandueti<sup>\*</sup>, J. Agorreta<sup>\*</sup>, M. J. Pajares<sup>\*</sup>, L. Montuenga<sup>\*</sup>, F. Lecanda. Division of Oncology, University of Navarra, Pamplona, Spain.

Lung cancer disseminates to a variety of organs including the skeleton. This process is associated with significant morbidity and dismal prognosis. The aim of this study was to identify and functionally characterize key target genes involved in the deleterious process of bone metastasis. Using an in vivo model of bone metastasis after intracardiac inoculation (i.c.) of a lung cancer cell line, we isolated highly metastatic subpopulations (HMS) derived from parental cells. Transcriptomic profiling and robust bioinformatics analysis identified RhoB as a significant overexpressed gene in HMS. Rho B is a membrane associated GTPase involved in cell transformation, survival, stress fiber formation and angiogenesis. RhoB was validated by real-time RT-PCR and Westernblot analysis in HMS. To delineate its functional role in bone metastasis, we lentivirally transduced lung cells with several shRNA against RhoB (shRhoB). Westernblot analysis showed abrogation of RhoB levels as compared to scramble control cells. Cell proliferation in vitro was unaffected in shRhoB and scramble transduced cells. Interestingly, chemotactic assay in Boyden chamber showed a dramatic decrease in motility of shRhoB cells as compared to control cells (p<0.001), whereas RhoB overexpressing cells showed increased motility, consistent with its role in cytoskeletal remodelling. Conditioned media of shRhoB or RhoB overexpressing cells did not show any difference in their proosteoclastogenic or metalloproteolytic activities in vitro. Interestingly, i.c. inoculation of shRhoB cells in nude mice induced a dramatic decrease in their prometastatic activity, including a severe reduction of osteolytic lesions and tumor burden (p<0.01), assessed by X-ray image analysis, bioluminescence imaging, and μCT scans, as compared to control cells. Finally, to assess the relevance of these findings, immunohistochemical analysis of RhoB in a panel of human lung tumor samples revealed significant decrease in survival by Kaplan Meier curves in patient lung cancer biopsies with high RhoB as compared to low RhoB staining (log Rank test p<0.01). Taking together these data indicate that RhoB plays a critical role in bone metastasis, by increasing motility and promoting bone colonization. These data suggest that Rho B may represent a good prognosis marker in lung cancer and a potential therapeutic target in bone metastasis progression.

**Blocking TGF $\beta$  Signaling Reduces Gammopathy and Improves Bone Volume and Strength In Vivo.** A. J. Hart\*, J. A. Fowler, S. T. Lwin\*, S. A. Munoz\*, E. C. O'Quinn\*, J. S. Nyman, C. M. Edwards, G. R. Mundy. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Bone disease caused by multiple myeloma (MM) results not only from increased osteoclast-mediated bone resorption, but also a marked impairment of bone formation by osteoblasts. Since TGF $\beta$  suppresses osteoblast differentiation in vitro, and blocking TGF $\beta$  signaling with a receptor kinase inhibitor antagonizes the inhibitory action of MM-cell conditioned media on osteoblasts, we hypothesized that inhibition of TGF $\beta$  would have beneficial effects on MM progression in vivo. To study this, we chose the 5T Radl murine model of myeloma, and the 1D11 monoclonal antibody (Genzyme) that has been shown to effectively block all three TGF $\beta$  ligands. We show that blocking TGF $\beta$  in vivo reduces MM serum paraprotein levels and significantly improves bone volume and strength. Fourteen Rag2<sup>-/-</sup> mice were injected with 1x10<sup>6</sup> 5TGM1 myeloma cells and monitored for the development of gammopathy. Starting on the day of MM cell injection, mice were injected IP every three days with 10mg/kg 1D11, or a control antibody, 13C4. At 22 days following tumor cell inoculation, there was a significant decrease in IgG2b levels in mice treated with 1D11 compared to 13C4, indicating a protective effect of anti-TGF $\beta$  treatment against MM progression. Examination of the bones by  $\mu$ CT after sacrifice showed a significant improvement in BV/TV, trabecular number, and cortical bone thickness in mice treated with 1D11 compared to 13C4. There was also a significant improvement in biomechanical parameters including stiffness, bending strength, and maximum force needed to fracture the bone when tested using three point bending. Thus, we have shown that anti-TGF $\beta$  therapy reduces paraprotein levels and improves bone volume and strength. We propose, based on these preclinical data, that anti-TGF $\beta$  therapy is worthy of evaluation in a prospective clinical trial in patients with MM.

**Effects of Odanacatib on Bone Biomarkers in Ovariectomized Non-Human Primates.** G. A. Wesolowski, M. Pickarski, L. T. Duong. Molecular Endocrinology, Merck & Co., Inc, West Point, PA, USA.

Odanacatib (ODN) is a selective and reversible inhibitor of cathepsin K (Cat K) currently being developed for the treatment of osteoporosis. Other evidence on efficacy of ODN for the prevention of bone loss in the ovariectomized (OVX) rhesus monkey study has been reported [1, 2]. Female rhesus monkeys (12-19 yr-old) were ovariectomized or left intact, and assigned into four groups: Intact, OVX, OVX+6 and 30 mg/kg ODN. ODN was dosed, orally daily, in prevention mode. At 21 months, OVX-induced loss in bone mineral density at the spine and hip were shown to be fully protective by both doses. This study monitors the changes in bone turnover markers for the duration of treatment. Serum or urine collected at baseline, 6, 15, 27, 40, 48, 59, 72 and 91 weeks are analyzed for resorption markers, C-telopeptide of Coll (sCTX), N-telopeptide (uNTX) and total deoxypyridinoline (uDPD); and formation markers N-propeptide of Coll (sP1NP) and bone specific alkaline phosphatase (sBSAP). Two exploratory markers were assayed, tartrate resistant acid phosphatase (TRAP5b) as a marker for osteoclast number, and C-terminal peptide of Coll (ICTP), a marker generated by metalloproteinases and degraded by Cat K. CTX, NTX and DPD were increased 60, 100 and 80% above baseline respectively by week 6 in OVX, and gradually returned to baseline by week 72. All resorption markers were dose dependently restored to or below sham levels by ODN. TRAP5b was increased in OVX to 220% above baseline and remained elevated throughout the study. Unlike current antiresorptive therapies, ODN did not suppress TRAP5b, similar to what was observed in Cat K knock-out mice, suggesting pharmacological inhibition of Cat K had no effect on osteoclast formation or survival. Bone formation markers responded to OVX more slowly than resorption markers, reaching significance by 15 weeks post-OVX compared to sham. P1NP and BSAP peaked by 267% and 75% respectively, above baseline; and ODN treatment restored these markers to levels consistent with sham. ICTP is normally undetectable in post-menopausal women and not responsive to bisphosphonates. In monkeys, this marker also did not respond to OVX; however, as a direct substrate of Cat K, ICTP was dose dependently increased 50 and 100% by 6 and 30 mg/kg ODN respectively versus baseline, providing evidence of ODN engagement of Cat K. Together with the reported efficacy of ODN in prevention of BMD loss in the same study [2], here we show that ODN restored markers of bone resorption and formation to normal sham levels, further demonstrating ODN is a novel antiresorptive in blocking estrogen deficiency induced bone loss with no apparent effect on osteoclast number. **The Relationship of Urinary Excretion of C-Telopeptides to Growth in Children.** F. Gossiel<sup>\*1</sup>, R. A. Hannon<sup>1</sup>, N. J. Bishop<sup>2</sup>, P. Dimitri<sup>\*2</sup>, R. Eastell<sup>1</sup>. <sup>1</sup>Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom. <sup>2</sup>Academic Unit of Child Health, University of Sheffield, Sheffield, United Kingdom.

The DG motif of the CTX epitope <sup>1207</sup>EKAHGDDR<sup>1214</sup> exists in the  $\alpha$  form in newly synthesised collagen. It undergoes non-enzymatic  $\beta$  isomerisation as collagen ages. Measurement of  $\alpha$ CTX and  $\beta$ CTX may allow us to distinguish between bone turnover in newly synthesised and mature bone.

The aims were a) to investigate the relationship between the ratio of  $\alpha$ - and  $\beta$  CTX fragments to age, and height velocity in children, b) to compare this to the ratio found in premenopausal women.

48 healthy boys and girls (mean age 10.5 years; range 4.3 to 16.6 years) were recruited. Height was measured at baseline and again 1 year later in a subset of 25 children and height velocity was calculated. 75 healthy premenopausal women (mean age 38 years; range 30 to 45 years) were also recruited. Second morning void urine samples were collected from all subjects at baseline.

$\alpha$  and  $\beta$  CTX were measured in urine (Alpha and Beta Crosslaps ELISA (Nordic Biosciences Diagnostics a/s, Copenhagen, Denmark)).

$\alpha$  and  $\beta$  CTX and  $\alpha/\beta$  CTX ratio decreased with age in children ( $\alpha$ CTX  $r = -0.46$ ,  $P < 0.001$ , 95% CI -0.66 to -0.21,  $\beta$ CTX  $r = -0.46$ ,  $P < 0.001$ , 95% CI -0.66 to -0.20;  $\alpha$ CTX /  $\beta$ CTX ratio  $r = -0.36$ ,  $P < 0.05$ , 95% CI -0.58 to -0.01).

In the subset of children  $\alpha$  and  $\beta$  CTX and  $\alpha/\beta$  CTX ratio significantly predicted height velocity, ( $\alpha$ CTX  $r = 0.68$ ,  $P < 0.001$ , 95% CI 0.36 to 0.85;  $\beta$ CTX  $r = 0.50$ ,  $P < 0.05$ , 95% CI 0.10 to 0.76;  $\alpha/\beta$  CTX ratio  $r = 0.72$ ,  $P < 0.0001$ , 95% CI 0.46 to 0.87).

	Children	Adults
$\alpha$ CTX ng/ml, median (CI)	11.5 (9.1-12.3)	0.29 (0.25-0.34)
$\beta$ CTX ng/ml median (CI)	12.2 (9.7-14.3)	1.47 (1.31-1.84)
$\alpha/\beta$ CTX ratio median (CI)	0.89 (0.80-0.96)	0.20 (0.19-0.21)

The median and 95% confidence interval (CI) of the urinary CTX measurements

We conclude  $\alpha$  and  $\beta$  CTX and the  $\alpha/\beta$  CTX ratio in the children are related to growth.  $\alpha$ CTX and the  $\alpha/\beta$  CTX ratio are more strongly associated and are better predictors of height velocity than  $\beta$ CTX, a marker of the degradation of mature collagen. The alpha/beta ratio was 4 times higher in children compared to adults, as this reflect the high level of degradation of immature collagen during growth.

## F306

**Age Is the Key to Assessing Fracture Risk: FRAX.** C. Greenbaum\*, M. Greenwald. Desert Medical Advances, Palm Desert, CA, USA.

The World Health Organization (WHO) has developed FRAX, a computer model to estimate the risk of fracture using the density measurement and 10 clinical risk factors. Ideally the radiologic technician would enter this information into the computer program and relate the risk of fracture to the patient. In practice, the radiologic tech may not have medical history, other than age and sex. In a community osteoporosis program, we evaluated consecutively 97 men and 200 women naïve to prior osteoporosis treatment, and compared the results in two formats, using BMD and age, versus FRAX with all 10 clinical risk factors.

The average age of the women was 67 (range 55-96) and the average age of the men was 73 (range 55-96) and all were Caucasian. The bone density measurement evaluated was the femoral neck and the clinical risk factors were collected by questionnaire. Diagnostic threshold and intervention threshold was based on a 4% ten year risk of hip fracture. Using this cutoff, the diagnostic agreement was very high between the two formats. In women, the concordance between the two formats was 97.5% and in men the concordance between the two formats was 92%.

	Osteoporosis Treatment Indicated		
	FRAX (BMD+age)	FRAX (BMD+10 risks)	Agreement
Women (n=200)	59	64	97.5%
Men (n=97)	23	32	92%

Of interest, using bone density alone and no risk factors (assuming a threshold of -2.5 T score for the bone density) only 31 women were identified for treatment and only 11 men. The practical conclusion to this community screening program is that bone density measurement and age will approximate the FRAX diagnosis with all 10 risk factors and that a significant percentage will be more correctly assessed at risk and identified for treatment. This finding concurs with the finding that the current standard basing treatment decisions on bone mineral density alone has proven to be specific but not sensitive for the identification of patients at high risk of fracture. In NORA, nearly 50% of postmenopausal women in the community over the age of 50 years who developed a hip fracture were not identified by the BMD test (J Bone Miner Res 2004 Aug;19(8):1215-20).

## F308

**Treatment Threshold in Men on Androgen Deprivation Therapy: T-score vs. FRAX.** R. A. Adler. Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA.

Men treated with androgen deprivation (ADT) for prostate cancer are at risk for osteoporosis and fracture. Which men should be treated with bisphosphonates? The new FRAX calculator uses secondary osteoporosis as a risk factor only if femoral neck bone density (BMD) is not available. We compared FRAX with and without femoral neck BMD in 115 consecutive men screened because of ADT (46 Caucasian, 67 African-American, 2 other). We used default settings on a Hologic Discovery densitometer (ethnicity-adjusted male database) to measure spine, hip, and forearm BMD. Using spine, total hip, and femoral neck only, 18 men had osteoporosis and 67 had osteopenia or low bone mass. Adding total forearm increased the number with osteoporosis to 39. Calculating FRAX using weight and height and checking off "secondary osteoporosis," 57 men met criteria for bisphosphonate treatment (at least 3% hip fracture or 20% osteoporotic fracture risk within 10 years). Of the 57, osteoporosis was found in 12 (spine and hip) or 29 (spine, hip,

or forearm). 8 men meeting FRAX criteria had normal BMD at all sites. We attempted to calculate FRAX with the femoral neck T-score, but FRAX uses a female normative database. Thus, to use the male database T-score, we adjusted it by 0.3 for Caucasian and 0.5 for African-American men. Calculating FRAX with the femoral neck BMD, only 12 men were recommended for treatment. Of these, only 5 had osteoporosis; the rest had osteopenia. Seven men with osteoporosis (spine and hip) and 4 men with osteoporosis (spine, hip, forearm) did not meet criteria for treatment with either FRAX calculation. Because we used an ethnicity-adjusted normative database for the T-scores, we analyzed only the white men and found similar results.

We conclude that while FRAX may turn out to be very useful for men in general, the specific group of men treated with ADT may need to be judged on clinical grounds and BMD for treatment decisions. Similar to previously reported results, adding forearm bone density increases the detection of osteoporosis in ADT patients. FRAX based on weight, height, and secondary osteoporosis may identify additional men who are at risk for fracture, despite normal BMD. Recalculating FRAX using a female database T-score (rather than the arbitrary adjustment to the male T-score we used) may improve the fracture risk prediction. Without fracture outcome studies in ADT patients, clinicians will need to use BMD, fall risk assessment, and possibly FRAX to identify those men who will likely benefit from bisphosphonate therapy.

## F310

**Bone Mineral Density Shows no Peak from Birth to Youth as Measured by Quantitative Computed Tomography.** E. M. Hauge<sup>1</sup>, J. S. Thomsen<sup>2</sup>, A. Brüel<sup>2</sup>, K. Brixen<sup>3</sup>, A. Vesterby<sup>4</sup>, F. Melsen<sup>1\*</sup>. <sup>1</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark, <sup>2</sup>Institute of Anatomy, Aarhus University, Aarhus C, Denmark, <sup>3</sup>Department of Endocrinology, Odense University Hospital, Odense, Denmark, <sup>4</sup>Institute of Forensic Medicine, Aarhus University, Aarhus C, Denmark.

Peak bone mass is a major determinant of fracture risk in senescence. Most of the growth-related increase in bone mineral density (BMD) as assessed by dual-energy X-ray absorptiometry (DXA) is due to an increase in bone size. In contrast to the area-dependent DXA-BMD, quantitative computed tomography (QCT) supplies a volumetric measurement of BMD, which is not influenced by bone size. Although DXA-BMD and QCT-BMD are correlated, data suggests that changes in QCT-BMD during growth differ from the increases seen in DXA-BMD.

We investigated the age-related changes in BMD measured in vitro by DXA and QCT using second lumbar vertebral bodies obtained during routine autopsy procedures, as approved by the regional ethical committee. The study comprised 126 individuals (53 women and 73 men) with an age range of 0.2-95 years and a median age of 60.5 years. The studied individuals had died suddenly from accidents or acute diseases. Individuals with known malignant, renal, or metabolic bone diseases were excluded as were vertebral bodies with fractures. The vertebral bodies were scanned with a Hologic Discovery A DXA-scanner and a Stratix XCT 960A pQCT scanner at a voxel size of 0.689x0.689x1 mm. Data were analyzed by linear regression, and reported as the squared Pearson correlation coefficient ( $r^2$ ) and the slope of the regression line (B) with its statistical significance (p).

Peak bone mass was reached at the age of approximately 25 years. During bone growth (0-25 years) DXA-BMD increased in both females ( $r^2$ : B, p) (0.99; 63 g/cm<sup>2</sup>/year, p<0.001) and males (0.61; 45 g/cm<sup>2</sup>/year, p<0.001). In contrast, QCT-BMD remained constant during the period from birth to peak bone mass, and was therefore not correlated with age neither in females (0.12; 0.10 mg/cm<sup>3</sup>/year, p=0.50) nor in males (0.08; -0.10 mg/cm<sup>3</sup>/year, p=0.31). After peak bone mass was reached, DXA-BMD decreased significantly with age for women (0.57; -142 g/cm<sup>2</sup>/year, p<0.001) and men (0.18; -106 g/cm<sup>2</sup>/year, p<0.01). This senescent decrease in DXA-BMD was paralleled by decreases in QCT-BMD for both women (0.63; -0.32 mg/cm<sup>3</sup>/year, p<0.001) and men (0.43; -0.38 mg/cm<sup>3</sup>/year, p<0.001). The discrepancy between BMD assessed by DXA and QCT confirms the confounding of bone geometry in DXA-scans. QCT may better reflect the mineral density of architecturally intact bone without being influenced by bone size. This is of particular importance when studying mineral density during bone growth, where the skeletal geometry changes substantially.

**Assessment of Absolute Fracture Risk and Osteoporosis in Chinese: Is There Any Difference Between the Application of Chinese Normative Database and NHANES III Caucasian Database?** E. Y. W. Chu\*, S. W. Y. Tsang\*, A. W. C. Kung. Medicine, The University of Hong Kong, Hong Kong, China.

WHO and ISCD recommend the use of a uniform Caucasian (non-race adjusted) female normative database for women of all ethnic groups as reference for BMD T-scores determination and fracture risk assessment. The objectives of the study were (1) to compare the Southern Chinese and NHANES III normative database in identifying subjects with osteoporosis and fractures in postmenopausal Southern Chinese women in Hong Kong; and (2) to examine the relation of BMD thresholds and clinical risk factors (CRF) evaluation and incident osteoporosis fracture rate and hip fracture rate. 2226 postmenopausal Hong Kong Southern Chinese women aged 45 and above were prospectively followed for incident low trauma fracture. Bone mineral density (BMD) was determined at the hip and spine by dual-energy X-ray absorptiometry (DXA). New fractures were recorded and verified by either retrieval of x-ray report or from the

computerised patient record system of the Hospital Authority of the Hong Kong Government.

The mean age at baseline was 62.1 ± 9.3 yr. After 4.3 ± 2.2 yr (range 3-12 yr) of follow-up, 137 new osteoporotic fractures were reported. Compared to Southern Chinese database, NHANES III Caucasian female database at the femoral neck overestimated the percentage of women with osteoporosis (18.2% vs 28.8%). However, the overall osteoporotic fracture rate and hip fracture rate were similar between the two reference databases. Although fracture rates were highest in women with femoral neck BMD T-score ≤ -2.5 SD, these women only experienced 56% of the osteoporotic fractures and 61% of the hip fractures. Addition of one or more CRF (>65 yr of age, BMI <19, previous fracture, 1 or more falls in the past 12 months, exercise <30min/day) improved the detection rate of osteoporotic fractures to 80% and hip fractures to 88%. Lowering the BMD T score threshold to -2.0 together with CRF further increased the detection rates to 86% and 91% respectively. The NHANES III Caucasian database can be applied to Southern Chinese for absolute fracture risk assessment. BMD T-score threshold at -2.0 together with CRF assessment could identify the majority of women at high risk of osteoporotic fracture.

**Evaluating Bone Microstructure at the Distal Tibia in Children: An X-treme CT Study.** M. Burrows<sup>1</sup>, D. Liu<sup>\*1</sup>, Y. Ahamed<sup>\*1</sup>, S. Braid<sup>1</sup>, H. A. McKay<sup>2</sup>. <sup>1</sup>Dept of Orthopaedics, University of British Columbia, Vancouver, BC, Canada, <sup>2</sup>Dept. of Orthopaedics and Family Practice, University of British Columbia, Vancouver, BC, Canada.

A high resolution pQCT system permitting in vivo assessment of bone architecture has been developed (X-tremeCT, Scanco). X-tremeCT reference data is available for adults but not for children. Our aim was to develop reference data for X-tremeCT in children. We assessed the distal tibia with the X-treme CT at the 8% site in a cross-section of 77 girls and 94 boys (14-18 years). We provide data for cortical bone density (D.Cort, mg/cm<sup>3</sup>), trabecular bone density (D.Trab, mg/cm<sup>3</sup>), cortical thickness (Cort.Th, mm), total bone volume (BV/TV, 1), trabecular number (Tb.N, 1/mm), trabecular thickness (Tb.Th, mm), trabecular separation (Tb.Sp, mm) and inhomogeneity of the network (Tb.Sp SD, mm). Means and standard deviations are provided for sex and age (Tables 1 and 2). We used two-way ANOVA to test for main effects by age group and age-by-sex interactions (p<0.05). Within sexes, D.Cort was significantly greater for girls and boys across age (p<0.01). D.Trab increased significantly for girls and boys between 14 and 17-18 yrs (p<0.01). Cort.Th did not increase significantly in girls, but was increased significantly in boys across age (p<0.01). BV/TV increased significantly for girls from age 14 to 15-16 years (p<0.05) but was stable in boys. Tb.N, Tb.Th, Tb.Sp and Tb.Sp SD did not change significantly across age in boys or girls (p>0.05). Between the sexes, D.Cort was significantly greater for girls (p<0.01) compared with boys at all ages. Cort.Th was greater for girls at ages 14 and 15-16 years, after which boy's Cort.Th was significantly greater (p<0.01). We provide novel bone microstructure data for boys and girls using X-treme CT.

**Measurement of T2\* Relaxation Time of the Trabecular Bone Network at 7T and 3T Compared to Topological and Structural Measurements from HR-pQCT.** R. Krug\*, A. J. Burghardt, A. S. Issever\*, M. Kentenich\*, G. Diederichs\*, T. M. Link, S. Majumdar. Radiology, UCSF, San Francisco, CA, USA.

In recent years, magnetic resonance imaging (MRI) has become increasingly the method of choice to assess bone architecture in vivo non-invasively and without ionizing radiation. In addition to resolve the trabecular microarchitecture directly by using high-resolution MRI, indirect methods like T2\* measurements can also be used. This method takes advantage of induced magnetism between the more diamagnetic bone and the bone marrow interface leading to signal cancellations. Thus, T2\* is expected to be very closely related to topological and structural bone properties. Previously, T2\* measurements were conducted at 1.5T of human vertebral bone specimens in vitro revealing a strong positive association between 1/T2\* and bone mineral density (BMD) measured by QCT. However, there is strong evidence that trabecular bone strength is a function of the bone's architectural make-up, rather than merely BMD. The relationship between T2\* measurements of trabecular bone and structural as well as topological parameters obtained from very high-resolution images has not yet been investigated.

In this work, we hypothesized that T2\* is more strongly related to topological and structural parameters than BMD and that new clinical ultra-high field MRI at 7T might have some advantages over lower field strength regarding T2\* measurements. To this end, we measured the T2\* relaxation time of trabecular bone at the wrist from five intact human cadaver hand specimens at both 7T and 3T MRI and compared the obtained results with structural and topological measurements using a new in vivo 3D high-resolution peripheral quantitative micro-CT (HR-pQCT) modality (isotropic voxel size of 41µm).

Highest correlations (R>0.7) were found for trabecular spacing and for the structure model index (SMI) which is a metric for topological classification. Correlations for BMD were significantly lower and very low for trabecular thickness. All correlations were significantly higher for 7T than for 3T. The correlation of T2\* between both field strengths was very high (R=0.98) and the absolute T2\* values were significantly lower at 7T. Our results indicated that T2\* measurement of bone density are well suited at ultra high field strength and correlate highly with topological and structural parameters as measured from HR-pQCT at high, isotropic resolution. The high correlations reflect the closer relationship of T2\* to bone structure than to BMD. Thus, T2\* has the ability to provide additional topological and structural information as compared to only BMD measurements.

**Osteoporosis Risk Assessment: A Composite Index Combining Clinical Risk Factors and Biophysical Parameters.** M. Rachidi\*<sup>1</sup>, F. Richard\*<sup>2</sup>, H. Bierme\*<sup>2</sup>, C. Roux\*<sup>3</sup>, P. Fardellone\*<sup>4</sup>, E. Lespessailles<sup>5</sup>, C. Chappard<sup>1</sup>, C. Benhamou<sup>1</sup>. <sup>1</sup>CHR Orleans - IPROS, INSERM Unit 658, Orleans, France, <sup>2</sup>University Paris Descartes, MAP5, CNRS UMR 8145, Paris, France, <sup>3</sup>Rheumatology Service, Cochin Hospital, Paris, France, <sup>4</sup>INSERM Unit ERI 12, Amiens, France, <sup>5</sup>Rheumatology Service, IPROS, Orleans Hospital, Orleans, France.

The objective of this work was to develop a composite index including clinical risk factors, bone mineral density (BMD) and bone micro-architecture analysis to evaluate osteoporosis fracture risk in post-menopausal women. The protocol was a multi-center cross sectional case-control study of 169 healthy postmenopausal women without fracture and 122 age-matched women with osteoporotic fractures (20 hip, 41 vertebrae, 32 wrist and 29 other fractures). BMD was measured at the lumbar spine (LS) and the total hip (TH) by DXA. Radiographs of the calcaneus were obtained with a new X-ray high-resolution digital device (BMA, D3A, France). Several mathematical estimators [1] were used to extract trabecular bone texture properties. The method is based on the analysis of directional regularity of the image line by line, and on the field projections using anisotropic fractional Brownian fields. The results showed that combining different and complementary information related to several risk factors led to an improvement of the OR of osteoporotic fractures. For hip plus vertebral fractures a higher OR was obtained when the textural parameters were added to TH-BMD T-score  $\leq -2.5$  SD than with each parameter separately. The OR was 4.7 [95% CI, 2.5-8.9] with TH-BMD, 5.5 [95% CI, 2.9-10.4] using textural parameters and 13.9 [95% CI, 7.7-25.3] with both combined. When we added the age and body mass index to BMD and micro-architecture analysis the OR increased slightly to 15.9 [95% CI, 8.7-29.4]. When including other clinical factors (family history of fracture, tobacco and chair test) the OR shifted to 23.6 [95% CI, 12.4-44.8]. For all fractures globally, the improvement is lower. The OR was 2.4 [95% CI, 1.5-3.9] when TH-BMD values were combined to texture parameters and was 2.9 [95% CI, 1.8-4.8] when the clinical factors were added. These data reflect the multifactorial nature of osteoporosis and suggest that a composite index combining BMD, bone texture analysis and clinical risk factors may constitute a relevant tool in the field of osteoporosis.

**Finite Element Analysis of Proximal Femur QCT Scans for the Assessment of Hip Fracture Risk in Older Men.** T. M. Keaveny<sup>1</sup>, L. M. Marshall<sup>2</sup>, C. M. Nielson<sup>2</sup>, S. R. Cummings<sup>3</sup>, P. F. Hoffmann\*<sup>1</sup>, D. L. Kopperdahl<sup>1</sup>, E. S. Orwoll<sup>2</sup>. <sup>1</sup>O. N. Diagnostics, Berkeley, CA, USA, <sup>2</sup>Oregon Health & Science University, Portland, OR, USA, <sup>3</sup>California Pacific Medical Center, San Francisco, CA, USA.

Finite element (FE) analysis of quantitative CT (QCT) scans provides an integrative measure of strength for the proximal femur and can be combined with estimates of the *in vivo* loads acting at the hip during a fall to calculate a load-to-strength ratio. We studied the relation of such biomechanical measures to the risk of incident hip fracture in men, alone and in combination with other fracture risk factors. A case-cohort design was used to identify a randomly selected subcohort of 225 men and 45 incident hip fracture cases from among 3549 community dwelling men (age  $\geq 65$ ) followed on average for 5.5 years after a baseline hip QCT scan. FE analyses of the QCT scans were performed (n=250 total, 40 with fractures), blinded to fracture status, to simulate a sideways fall and in vivo loads were estimated from mass and height data. Cox proportional hazards regression models were used to compute the hazard ratio (HR) per standard deviation (SD) change in FE outcome after controlling for age, study site, body mass index (BMI), and areal BMD (by DXA). The HR per SD change in FE-strength, load-to-strength ratio, and BMD were highly significant before and after adjusting for age (Table). When additionally adjusted for BMD (and study site and BMI, which had little effect), the HR for the load-to-strength ratio remained statistically significant. These results provide unique insight into hip fracture etiology and demonstrate the clinical potential of such a biomechanical approach to the assessment of hip fracture risk.

**Table:** Hazard ratio (HR) per standard deviation (SD) change\*.

VARIABLES	MODELS		
	Unadjusted	Age-adjusted	Age, BMI, Site, BMD-adjusted
FE-Strength (N)	13.1 (3.9-43.5)	8.0 (2.6-24.3)	2.7 (0.5-14.6)
Load-to-Strength Ratio	4.0 (2.7-6.0)	3.5 (2.4-5.2)	3.1 (1.6-6.1)
Total hip BMD (g/cm <sup>2</sup> )	5.1 (2.8-9.2)	4.6 (2.6-8.3)	

95% confidence interval shown in parentheses. Site - study site. \*Risk increased per SD decrease in FE-Strength and BMD, and per SD increase in Load-to-Strength Ratio.

**Towards an Understanding of The Mechanism of Femur Strength Improvement by Alendronate In Postmenopausal Women.** T. J. Beck\*<sup>1</sup>, J. Cauley\*<sup>2</sup>, H. Wang\*<sup>3</sup>, J. West<sup>3</sup>, A. DePapp\*<sup>3</sup>, K. Ensrud\*<sup>4</sup>. <sup>1</sup>Johns Hopkins Univ., Baltimore, MD, USA, <sup>2</sup>Univ. of Pittsburgh School of Public Health, Pittsburgh, PA, USA, <sup>3</sup>Merck Research Laboratories, Rahway, NJ, USA, <sup>4</sup>Minneapolis VA Medical Center, Minneapolis, MN, USA.

Alendronate (ALN) treatment reduces hip fracture rates compared to placebo among osteoporotic women, but appears unlikely to affect fall risk suggesting that ALN improves femur strength.

However, the mechanism underlying this association is uncertain. Potentially ALN may alter geometry to diminish load stresses and/or may improve tissue stress resistance. Some effect on the latter is evident from biopsy studies showing increased mean tissue mineralization in subjects treated with ALN. To examine the effect of ALN on bone geometry parameters separate from its mineralization effects, we compared differences in changes in geometric parameters with ALN treatment as defined by 2 different methods in 803 post-menopausal women with low bone mass (400 on placebo [PBO] and 403 treated with ALN 5-10 mg/d) enrolled in the FIT trial at Minneapolis and Pittsburgh sites. Method 1 derived from Hip Structure Analysis (HSA) assumed a fixed mineralization and Method 2 utilized cortical margin dimensions reliable in only thick cortex regions, but did not require a mineralization assumption.

Annual rates of change after 36 months of treatment in bone cross section analysis (CSA), section modulus, mean cortical thickness and buckling ratio for the two treatment groups by both methods are shown in the Figure. Among women taking PBO, mean rates of change in section modulus, cortical thickness and buckling ratio as defined by both methods were similar, although the increase in CSA was greater using Method 2.

Among women assigned to ALN, average rates of change in CSA were similar using both methods, but rates of change in section modulus, cortical thickness, and buckling ratio were smaller in magnitude using Method 2. Except for Method 2 CSA, differences in rates of change in parameters between ALN and PBO groups reached significance, irrespective of method (p<0.05).

Our findings suggest that ALN treatment improves femur shaft geometry independent of tissue mineralization effects, but geometric improvement is overestimated by 50-75% if mineralization effects are not taken into account. Bone strength improvement by ALN appears to combine geometric changes with greater tissue stress resistance.

### Annual rates of change in femur shaft geometry

**Frequent Apheresis for Platelet and Plasma Donations Constitutes an Independent Risk Factor for Decreased Bone Mineral Density.** K. Amrein<sup>1</sup>, C. Katschnig<sup>1</sup>, G. Lanzer<sup>1</sup>, H. Dobnig<sup>2</sup>. <sup>1</sup>Dept. of Blood Group Serology, Medical University Graz, Graz, Austria, <sup>2</sup>Div. of Endocrinology, Medical University Graz, Graz, Austria.

**BACKGROUND:** Modern medicine requires supply with single donor platelets and plasma products. Apheresis is the procedure of choice to obtain selective blood components, and citrate is used routinely for anticoagulation. In Austria, plasma and thrombocyte donations may be performed up to 50 and 26 times per year. The aim of the present study was to investigate whether frequent apheresis donations and thus substantial intermittent changes in acid-base homeostasis can be considered a safe long-term procedure for maintenance of skeletal health.

**METHODS:** We enrolled plasma and thrombocyte donors (>15 donations in the last six years) in an open, observational, single-center, cross sectional study. 70.3% of study subjects donated platelets only ("P"), 29.7 % donated both plasma and platelets ("PP"). 101 donors were included in the study group (76% m/24% f) and compared to 75 age, sex and BMI matched controls from similar socioeconomic status (74% m/26% f). The median number of donations was 51 for the entire group [(range 16 to 633), 46 for "P" and 105 for the "PP" group]. We performed bone densitometry by DEXA and measured lumbar spine and hip bone mineral density (BMD). A case report form including evaluation of calcium intake and physical activity was completed for every participant.

**RESULTS:** Statistical analysis adjusted for BMI, physical activity and daily calcium intake revealed a significantly lower BMI at the lumbar spine and femoral neck in the order of 4% at both measurement sites for the donor group (see table). Analysis of biochemical parameters relating to bone and mineral metabolism is in progress.

**CONCLUSIONS:** Regular blood donations by apheresis seem to constitute an independent risk factor for lower BMD at the lumbar spine and hip. Studies to further characterize bone turnover and calcium metabolism during and following the apheresis procedure are in progress. If results of our study can be confirmed in a prospective study design, effective strategies for prevention of detrimental long-term effects on bone mass must be formulated and/or the number of donations limited.

**Inflammatory Markers and the Risk of Hip Fracture: The Women's Health Initiative (WHI).** J. A. Cauley<sup>1</sup>, R. Boudreau<sup>1</sup>, K. Barbour<sup>1</sup>, D. C. Bauer<sup>2</sup>, J. S. Lee<sup>3</sup>, R. Jackson<sup>4</sup>, J. A. Robbins<sup>2</sup>, M. A. Allison<sup>5</sup>, N. Greep<sup>6</sup>, R. B. Wallace<sup>7</sup>, S. R. Cummings<sup>8</sup>, A. Z. LaCroix<sup>9</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of California, San Francisco, San Francisco, CA, USA, <sup>3</sup>University of California, Davis, Davis, CA, USA, <sup>4</sup>The Ohio State University, Columbus, OH, USA, <sup>5</sup>University of California, San Diego, San Diego, CA, USA, <sup>6</sup>University of California at Irvine, Orange, CA, USA, <sup>7</sup>University of Iowa, Iowa City, IA, USA, <sup>8</sup>University of California San Francisco, San Francisco, CA, USA, <sup>9</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, USA.

To test the hypothesis that inflammatory burden confers a higher risk of subsequent hip fractures (fx), we conducted a nested case control study among 400 cases of incident hip fx and 400 controls matched on age, race and date of blood draw. Hip fxs were identified over an average follow-up time of 7.1 yrs. Subjects were selected from 38,795 women enrolled in the WHI Observational Study who had no prior hip fx and were not using estrogens or other bone active agents. Baseline soluble receptors of interleukin 6 (IL6sR) and tumor necrosis factor (TNFsR1 and TNFsR2) were measured with ELISA (CV%<16%). Conditional logistic regression was used to estimate the odds ratio (OR) and 95% CI. Multivariable models (MV) included age, BMI, fx history (hx), family hx of hip fx, diabetes, smoking, alcohol, calcium intake, NSAIDS use and corticosteroid use. Inflammatory markers were higher in cases versus controls, (IL6, p=0.08; TNFsR1, p=0.018; TNFsR2, p=0.006). Women with the highest cytokines (Quartile 4) had a 47-61% higher risk of hip fx compared to Quartile 1-3, Table. Because high levels of ≥2 inflammatory markers maybe more indicative of inflammatory burden, we compared women with 0 or 1 (referent), 2, or 3 markers in the highest quartile. 13% of cases compared to 6% of controls had all 3 cytokines in the highest quartile, p=0.001. Compared to women with 0 or 1 "high" cytokine, the OR (95%CI) of hip fx in women with 2 "high" cytokines was 1.47(0.95, 2.77); and for 3 "high", 2.66(1.48, 4.78) p trend <0.001. Adjustment for frailty score, falls, or bone turnover markers had little effect. Adjustment for bioavailable estradiol tended to strengthen the association: OR=3.06(1.66, 5.64). Both estradiol and inflammatory markers were independently related to hip fx. We conclude that elevated inflammatory markers are prognostic for hip fx.

MV odds ratio (95%CI) of hip fracture by inflammatory markers: Quartile 4 vs Quartile 1, 2 and 3 combined (referent)

	OR	(95%CI)
IL6sR	1.49	(1.05, 2.13)
TNFsR1	1.47	(1.04, 2.08)
TNFsR2	1.61	1.15, 2.27)

## F335

**Low Vitamin D Levels and Risk of Death in Older Men: A Prospective Study.** S. R. Cummings<sup>1</sup>, P. M. Cawthon<sup>1</sup>, N. Parimi<sup>1</sup>, E. Barrett-Connor<sup>2</sup>, K. E. Ensrud<sup>3</sup>, A. R. Hoffman<sup>4</sup>, J. Shikany<sup>5</sup>, E. S. Orwoll<sup>6</sup>. <sup>1</sup>Research Institute, California Pacific Medical Center, San Francisco, CA, USA, <sup>2</sup>UCSD, San Diego, CA, USA, <sup>3</sup>University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Stanford University, Palo Alto, CA, USA, <sup>5</sup>University of Alabama, Birmingham, Birmingham, AL, USA, <sup>6</sup>Oregon Health and Sciences University, Portland, OR, USA.

A low level of 25(OH)D (vitamin D) have been associated with an increased risk of fracture, falls, function and some diseases, including some types of cancer, but it is not known whether vitamin D deficiency increases mortality. We tested the hypothesis that low levels of 25(OH)D are associated with increased cause-specific mortality. We measured 25(OH)D levels with LC-MS in serum archived from 1608 men randomly sampled from the Osteoporotic Fractures in Men study (MrOS), a community-based cohort of men age 65 or older recruited from 6 U.S. cities. Follow-up for vital status was 97.7% during an mean of 6.1 years. Causes of death were adjudicated from medical records and death certificates. We used proportional hazards models to test the associations between 25(OH)D levels and overall mortality (N=258), non-cancer mortality (N=169) and cancer mortality (N=89). We also specifically analyzed cardiovascular (CV) death (N=91). Results were adjusted for age, BMI, season of blood draw, clinical center and education level and race.

Compared with 25(OH)D levels >30 ng/mL, men with vitamin D deficiency (≤15ng/mL) had a 2.2-fold increased risk of death due to causes besides cancer with no significant increased mortality for those with levels of 15 ng/mL -30 ng/mL (Table). The p-value for linear trend was 0.008. This increased risk with deficiency was due to both an increased risk of CV death, (RH=2.0: 0.9-4.2) and non-CV non cancer death (RH=2.3; 1.1-5.2). There was no significant association between 25(OH)D deficiency and death due to all types of cancer combined (RH=0.6; 0.2-1.4). Results for vitamin D deficiency were similar for to results men in the lowest quartile 25 (OH)D levels (≤ 20 ng/mL) compared to men in the highest quartile.

In conclusion, vitamin D deficiency is associated with an increased risk of death besides death due to cancer. In older men, vitamin D supplementation might decrease mortality from causes besides cancer.

Table. Relative Hazard (RH, 95% CI) of death by category of Vitamin D status

Mortality	Vitamin D status			p for trend
	Deficiency (≤15 ng/mL)	Insufficiency (>15 ng/mL to <30 ng/mL)	Sufficient (≥30 ng/mL)	
Overall	1.4 (0.9, 2.2)	0.9 (0.7, 1.3)	1.0 (ref)	0.246
Non-cancer	2.2 (1.3, 3.7)	1.2 (0.8, 1.8)	1.0 (ref)	0.008
CV	2.0 (0.9, 4.2)	1.1 (0.6, 2.1)	1.0 (ref)	0.098
Non-CV, non-cancer	2.3 (1.1, 5.2)	1.2 (0.6, 2.2)	1.0 (ref)	0.046
Cancer	0.6 (0.2, 1.4)	0.7 (0.4, 1.1)	1.0 (ref)	0.12

## F337

**Lack of Seasonal Variation of Bone Resorption in Elderly Women in Relation to Periodicity of Sunlight Exposure at a Northerly Latitude (57° N).** A. Mavroei<sup>1</sup>, F. O' Neill<sup>2</sup>, A. J. Black<sup>3</sup>, W. D. Fraser<sup>4</sup>, B. L. Diffey<sup>5</sup>, D. M. Reid<sup>3</sup>, H. M. Macdonald<sup>3</sup>. <sup>1</sup>School of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>St Thomas Hospital, Twin Research & Genetic Epidemiology Unit, London, United Kingdom, <sup>3</sup>School of Medicine, University of Aberdeen, Aberdeen, United Kingdom, <sup>4</sup>Unit of Clinical Chemistry, Liverpool University, Liverpool, United Kingdom, <sup>5</sup>Institute of Cellular Medicine, Newcastle University, Newcastle, United Kingdom.

Although evidence is accumulating that vitamin D may influence many health outcomes there is still uncertainty regarding its role on bone health. It is assumed that healthy adults in the UK obtain most of their vitamin D by exposure of skin to sunlight with seasonality, latitude and lifestyle playing an important role. The aim of this study was to assess the contribution of sunlight exposure to bone resorption changes over a 15 month period.

365 Caucasian Scottish women (mean age 61.4 y ± 1.5 (SD)), participated in a 15-month longitudinal study examining the role of diet and sunlight on vitamin D status at a northern latitude of 57°. They were > 5 years postmenopausal and were not suffering from any disease or taking any medication that would affect their bone metabolism. Data were collected at 3 month intervals. The main outcome measures presented here were seasonal periodicities of ultraviolet radiation (using personal polysulphone film badges worn by the volunteers for one week every season as an objective method of measuring UV exposure), fasting serum parathyroid hormone (PTH) and fasting serum beta C-telopeptide (CTX). All data were log-transformed before General Linear Model repeated measures analysis.

	CTX (µg/L)	PTH (pmol/L)	Sunlight exposure (SED/wk)
Spring 2006 (Mar-May)	0.385 (± 0.167)	5.04 (±1.59)	4.4 (±5.0)
Summer 2006 (June-Aug)	0.382 (±0.163)	4.92 (±1.67)	7.6 (±6.2)
Fall 2006 (Sep-Nov)	0.379 (±0.161)	5.00 (±1.84)	1.3 (±2.2)
Winter 2006/07 (Dec-Feb)	0.379 (±0.162)	5.10 (±1.68)	0.4 (±0.5)
Spring 2007 (Mar-May)	0.376 (±0.155)	5.14 (±1.93)	4.1 (±4.3)

There was no significant seasonal variation in serum CTX, while periodicity in serum PTH peaked in the spring 2007 (p = 0.003). As expected, sunlight exposure was highest in the summer (p <0.001) followed by the two spring readings. When considering each season separately, sunlight exposure was a significant predictor of CTX explaining 2% of the variation during the summer period only (Beta = +0.063 P = 0.016).

These longitudinal data suggest that bone resorption is unaffected by season in postmenopausal women living in the North of the UK in spite of reduced quality of sunlight in the winter months.

**Bone Mass Recovers in Young Women with Anorexia Nervosa Who Are Both Weight and Menstrual Recovered.** E. J. Waugh<sup>1</sup>, B. Woodside<sup>2</sup>, D. E. Beaton<sup>3</sup>, P. Cote<sup>4</sup>, G. A. Hawker<sup>1</sup>. <sup>1</sup>Osteoporosis, Women's College Hospital, Toronto, ON, Canada, <sup>2</sup>Psychiatry, University Health Network, Toronto, ON, Canada, <sup>3</sup>Mobility Program, St. Michael's Hospital, Toronto, ON, Canada, <sup>4</sup>Rehabilitation Solutions, University Health Network, Toronto, ON, Canada.

We evaluated the effect of recovery from anorexia nervosa (AN) on BMD in a cohort of patients aged 17-40 yrs who had received inpatient treatment for AN over a 12-yr time period. A detailed illness history and key covariates were obtained by a Life History Calendar semi-structured interview. BMD at the lumbar spine L1-L4 (LSP), femoral neck (FN) and total body (TB) was measured by DXA. Low BMD was defined as a Z-score value ≤ -1.5 at one or more sites. Participants were considered recovered if they both achieved a BMI ≥ 18.5 kg/m<sup>2</sup> and resumed regular menstruation, for ≥ 1 year. Ill vs. recovered groups were compared by t-test or chi square; logistic regression was used to determine the odds of having low BMD adjusted for current weight, and duration and severity (lowest lifetime BMD) of illness.

We recruited 190 participants from two treatment centers: 77 were recovered, 113 were ill (91 never recovered; 22 relapsed). At interview, mean age of the participants was 27.2 ± 5.6 yrs and mean BMI was 19.4 ± 3.4 (11.1 - 35.5) kg/m<sup>2</sup>. Age at AN onset was 18.2 ± 4.2 (10-32) yrs, duration of illness was 5.9 ± 4.6 (1 - 25) yrs and lowest lifetime BMI was 13.9 ± 2.3 (7.2 - 18.0) kg/m<sup>2</sup>. Compared to ill participants, those recovered had shorter duration of illness (3.8 ± 2.7 vs 7.3 ± 5.1 yrs, p < 0.0001); only n=14 (18.9%) of those ill > 5 years were recovered. Among those recovered, mean duration of recovery was 5.1 ± 3.8 (1 - 26) yrs. Mean Z-scores were significantly higher in recovered vs ill patients at each skeletal site: LSP (0.07 ± 1.1 vs. -1.03 ± 1.2, p<0.0001), FN (0.17 ± 1.2 vs. -0.40 ± 1.2, p=0.008), TB (0.38 ± 1.0 vs. -0.13 ± 1.1, p=0.004). The prevalence of low BMD was 47.3% in ill patients who had never recovered, 27.3% in patients currently relapsed and 11.7% in recovered patients (p<0.0001, ill vs recovered). The adjusted odds of having low BMD in recovered vs ill patients was 0.22 (95% CI 0.09-0.53). Duration and severity of illness had minimal effect on the odds ratio (OR) associated with recovery status (weight only adjusted OR = 0.19). Participants who were only weight recovered (n=18) or only menstrual recovered (n=11) had similar odds of having low BMD compared to ill participants (p=0.62, p=0.58, respectively). Results indicate that significant recovery of BMD occurs in women with AN who achieve both weight and menstrual recovery. Neither duration or severity of illness appear to have a major influence on recovery of BMD; however those ill > 5 years are less likely to experience recovery from AN.

## F341

**Essential Fatty Acid and Fish Intake Is Associated with Higher BMD in Elderly Women and Men: The Framingham Study.** E. Farina<sup>1</sup>, D. P. Kiel<sup>2</sup>, R. Roubenoff<sup>3</sup>, E. J. Schaefer<sup>1</sup>, L. A. Cupples<sup>4</sup>, K. L. Tucker<sup>1</sup>. <sup>1</sup>Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA, <sup>2</sup>Institute for Aging Research, Hebrew SeniorLife, Harvard Medical School, Boston, MA, USA, <sup>3</sup>Schools of Nutrition and of Medicine, Tufts University, Boston, MA, USA, <sup>4</sup>Boston University School of Public Health, Boston, MA, USA.

Few studies have examined the relationship between essential fatty acid (EFA) intake and bone. Thus, we examined associations between both cross-sectional and longitudinal changes in hip BMD and EFA intake in the original cohort of the community-based Framingham Study. BMD was measured at the femoral neck (FN) and trochanter (TROCH) in 521 women (age 75.4 ± 4.8 y) and 334 men (age 75.3 ± 5.0 y) at baseline (exam 20) using dual-photon absorptiometry, and in 388 women and 235 men at 4-y follow-up (exam 22) using dual-energy x-ray absorptiometry (with adjustment for difference in scanners). Dietary intake was assessed by the previously-validated Willett food frequency questionnaire. EFA exposure variables consisted of α-linolenic acid (ALA,

18:3 n-3), docosahexaenoic acid (DHA, 22:6 n-3), eicosapentaenoic acid (EPA, 20:5 n-3), total n-3 fatty acids (sum of ALA + DHA + EPA + docosapentaenoic acid (22:5 n-3)), total n-6 fatty acids (sum of  $\alpha$ -linoleic acid (18:2 n-6) + arachidonic acid (20:4 n-6)), and n6:n3 ratio. BMD measures were regressed on energy adjusted quartile of EFA intake, with adjustment for age, BMI, height, dietary and supplemental intakes of calcium and vitamin D, physical activity, smoking, alcohol use, and estrogen use for women. In women, significant positive linear trends were observed with baseline BMD for total n-3 fatty acids (FN & TROCH) and total n-6 fatty acids (FN). Women with greater intakes of total n-6 fatty acids lost less BMD over 4-y (FN, P for trend=0.058) than those with lesser intakes. Women with fish intakes  $\geq$  the median (1.47 servings/week) lost less BMD over 4-y (-0.022 g/cm<sup>2</sup> vs -0.034 g/cm<sup>2</sup>) at the FN than those with lower fish intakes (P=0.024). In men, those with greater intakes of DHA as well as those with a lower n6:n3 ratio lost less BMD over 4-y than those with lesser DHA intakes and a higher n6:n3 ratio. Men with fish intakes  $\geq$  the median (1.47 servings/week) had higher mean baseline BMD (0.815 g/cm<sup>2</sup> vs 0.772 g/cm<sup>2</sup>) at the TROCH than those with lower fish intakes (P=0.005). These findings suggest a beneficial role for EFAs on skeletal health in the elderly.

## F345

**Women Who Fractured Their Hips Experience Greater Loss of Geometric Strength in the Contralateral Hip During the Year Following Fracture Compared to Age-Matched Controls.** L. Reider<sup>\*1</sup>, T. Beck<sup>1</sup>, M. Hochberg<sup>2</sup>, W. Hawkes<sup>\*2</sup>, D. Orwig<sup>\*2</sup>, J. YuYahiro<sup>\*2</sup>, R. Hebel<sup>\*2</sup>, J. Magaziner<sup>2</sup>. <sup>1</sup>Johns Hopkins University, Baltimore, MD, USA, <sup>2</sup>University of Maryland, Baltimore, MD, USA.

The majority of hip fracture research has focused on predicting fractures, interventions that reduce incidence, and the consequences on survival and quality of life. Limited attention has been given to changes in bone after a hip fracture, despite the propensity these patients have to fracture their contralateral hip. An understanding of changes in the contralateral hip after an index hip fracture is relevant to design of interventions to optimize recovery and to minimize the risk of additional fractures. This study compared femur geometry and its change over 12 months in women following hip fracture compared to women who had not sustained a hip fracture. Geometry of the contralateral hip was derived from DXA scan images obtained at baseline and 2, 6, and 12 months after fracture in 131 women 65 years and older participating in the Baltimore Hip Studies using the Hip Structural Analysis (HSA) program and compared with those from an age-matched group of 263 women enrolled in the Study of Osteoporotic Fracture (SOF) who had not suffered a hip fracture obtained a mean of 42 months apart. Multi-level mixed models were used to compare BMD, section modulus (Z), cross sectional area (CSA), outer diameter, and buckling ratio at baseline and over 12 months at the narrow neck, intertrochanteric, and shaft regions of the hip adjusted for age, height, weight, baseline value and HRT use. At baseline, wider bones and smaller CSA underlie the significantly lower BMD observed in women who fractured their hip resulting in more fragile bones expressed by a lower bone bending strength (Z) and higher buckling ratio. Relative to baseline, these women experienced a significantly greater net loss in CSA, Z and BMD and a greater increase in buckling ratio at all three regions over 12 months compared to women without a hip fracture. Not surprisingly women who have fractured a hip show much weaker geometry in the unfractured femur than in women without hip fractures but rates of further decline are considerably faster over 12 months following fracture compared to age matched controls. Results suggest little progression to an unfractured level and even greater susceptibility to a second hip fracture.

**Baseline means (SE) and annual net change in femur geometry in 131 women with hip fracture and in 263 age-matched controls**

**Timing of Repeated Bone Mineral Density Measurements: Development of an Absolute Risk-based Prognostic Model.** S. A. Frost<sup>\*</sup>, N. D. Nguyen, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Group, Garvan Institute of Medical Research, Sydney, Australia.

Osteoporosis is operationally defined in terms of bone mineral density (BMD), which is known to decline with advancing age. The present study attempted to address the following question: for an individual who is at present non-osteoporotic, given their current age and BMD level, when is the ideal time to repeat the BMD measurement?

To address the above question, data from the Dubbo Osteoporosis Epidemiological Study (DOES) were used. Non-osteoporotic women (n = 1008) and men (n = 750) over the age of 60 in 1989 were followed-up with bi-annually measurements of BMD until one of the following outcomes occurred: (1) osteoporosis at the femoral neck (T-score  $\leq$  -2.5), or (2) an incident low-trauma fracture. A modified Cox's proportional hazards model that accounted for a competing risk of death was used to estimate the probability of an outcome within 5-year and 10-year period.

At baseline (1989) there were 1008 women and 750 men whose femoral neck BMD T-scores were greater than -2.5 (non-osteoporosis). During the follow-up period (median 7.1 years), 346 women (34%) and 160 men (21%) developed osteoporosis or sustained a low-trauma fracture. As expected, the risk of either osteoporosis or fracture increased with advancing age (RR 1.3; 95%CI: 1.1 - 1.6 for women and 2.3; 95% CI: 1.7 - 2.9 for men) and lower BMD levels (RR 3.2; 95% CI 2.6 - 4.1 for women, and 2.6; 95% CI 2.0 - 3.3 for men). Using the predicted risk [of osteoporosis or fracture] of 10% as a cut-off level for repeating BMD measurement, the estimated time to reach the cut-off level varied from 1.5 years (for an 80-year old woman with a T-score of -2.2) to 10.6 years (for a 60-year old man with a T-score of 0). A nomogram was developed to facilitate the estimation of time for repeating BMD measurements.

Based on an individual's current age and BMD T-score, it is possible to estimate the average time to repeat BMD testing for the individual. The prognostic model and approach presented in this study may help improve the individualization and management of osteoporosis.

**Development a Nomogram for Individualizing the Absolute Risk and Time to Recurrent Fracture.** N. D. Nguyen, S. A. Frost, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Some, but not all, individuals with a pre-existing fracture are at increased risk of subsequent fractures. However, the identification of those high-risk individuals (of re-fracture) is a challenge. This study sought to develop a prognostic model for individualizing the risk of and time to subsequent fracture.

The model was developed from 2234 participants (1377 women) aged 60+ years as of 1989 in the Dubbo Osteoporosis Epidemiology Study, whose fracture incidence was ascertained between 1989 and 2007. Apart from anthropometric and demographic variables, femoral neck bone mineral density (BMD) was measured by DXA. A "counting process" model within the framework of the Cox's model was utilized to account for multiple fractures within an individual.

Between 1989-2007, 539 women (W) and 195 men (M) had sustained an incident fracture; among whom 193 W and 40 M sustained a recurrent fracture, 81 W and 11 M sustained 2 or more recurrent fractures. In women, advancing age (HR per SD: 1.1, 95% CI: 1.0-1.2) and low baseline BMD (1.4, 1.2-1.7) were consistently associated with an increased risk of recurrent fracture. Moreover, women with a pre-existing major clinical fracture (e.g. hip, vertebral, Colles' fracture) had a greater risk of subsequent fractures (2.0; 1.2-3.4). In men, advancing age (1.3; 1.2-1.5) and low BMD (1.5; 1.4-1.7) were independent risk factors for recurrent fractures.

For any given age and BMD, the time to reach an absolute risk of subsequent fracture was shorter than the time from fracture-free to a first fracture. For example, a 60-year old woman with BMD T-score = -2.5 was estimated to have a 17% 5-year risk of an initial fracture, but once fracture has occurred, the 5-year risk of subsequent fracture was increased to 26%. Based on age, BMD and types of fracture in women, a multivariable nomogram was developed for individualizing the absolute risk of subsequent fracture for any individual. Such a nomogram for women is illustrated in the figure below.

These results suggest that it is possible to identify men and women who are at high risk of subsequent fracture by considering their age, femoral neck BMD and fracture type in a prognostic model. The model can aid clinical decision making by estimating short-term and long-term absolute risks of re-fractures.

Figure: Nomogram for prediction of subsequent fracture risk given any first incident fracture for a woman

## F351

**SSRI Use and Risk of Fracture in Older Women.** S. Diem<sup>1</sup>, T. Blackwell<sup>2</sup>, K. Stone<sup>2</sup>, J. Cauley<sup>3</sup>, T. Hillier<sup>4</sup>, E. Haney<sup>5</sup>, K. Ensrud<sup>1</sup>. <sup>1</sup>University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>California Pacific Medical Center Research Center, San Francisco, CA, USA, <sup>3</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>Kaiser Permanente, Minneapolis, MN, USA, <sup>5</sup>Oregon Health Sciences Center, Portland, OR, USA.

The use of SSRIs has been associated with an increased risk of fractures in some studies, although most have been limited by inadequate control of potential confounding factors including depressive symptoms. To test the hypothesis that SSRI use in older women is associated with an increased risk of fracture, we assessed current use of SSRIs and incident fractures over a 10 year period in a cohort of 8045 older women in the Study of Osteoporotic Fractures. We verified current antidepressant use by inspection of medication containers and classified type of medication using a computerized medication dictionary. Users of other classes of antidepressants were excluded. We categorized women according to their SSRI use as users or non-users. SSRI use status was updated at each follow-up visit (average of 2.2, 4.5 and 9.3 yrs after initial assessment) using time-dependent methods. The hazard ratio (HR) and 95% CI for risk of fracture was calculated by category of SSRI use using Cox Proportional Hazards models. All results were adjusted for the following characteristics, which were updated at each follow-up visit: age, race,

weight, total hip BMD, health status, functional status, walking for exercise, cognitive function, estrogen use, bisphosphonate use, smoking, fall in previous 12 months, living situation, and depressive symptoms (measured by Geriatric Depression Scale). Average length of follow-up was 10.0±4.11 years.

Of the 8045 women, (average age 77.0 yrs at initial visit), 2682 (36%) women experienced > 1 non-spine, non-traumatic fracture during the follow-up period, including 914 (11.9%) with a hip fracture and 568 (7.1%) with a wrist fracture. 582 (7.2%) women were on an SSRI at at least one visit. Below are the age-adjusted and multivariable-adjusted HRs for risk of fracture for SSRI users vs. non-users.

	Age-adjusted HR (95% CI)	p-value	MV-adjusted HR (95% CI)	p-value
Any non-spine, non-trauma fracture	1.44 (1.18, 1.76)	0.0003	1.38 (1.12, 1.71)	0.003
Hip fracture	1.32 (0.95, 1.83)	0.09	1.04 (0.73, 1.47)	0.84
Non-spine, non-hip fracture	1.47 (1.17, 1.84)	0.0008	1.44 (1.13, 1.84)	0.003
Wrist fracture	1.38 (0.91, 2.11)	0.13	1.50 (0.97, 2.31)	0.07

Use of SSRIs in elderly women is associated with an increase in risk of non-spine fractures in age-adjusted models. The association between SSRI use and hip fracture appears to be largely explained by potential confounders, but there was a robust independent association between SSRI use and risk of non-spine, non-hip fractures.

## F354

**The Epidemiology of Rib Fractures in Older Men: The Osteoporotic Fractures in Men (MrOS) Study.** E. Barrett-Connor<sup>1</sup>, C. Nielsen<sup>2</sup>, E. Orwoll<sup>3</sup>, D. Bauer<sup>4</sup>, J. Cauley<sup>5</sup>. <sup>1</sup>Department of Family & Preventive Medicine, University of California, San Diego, La Jolla, CA, USA, <sup>2</sup>Bone and Mineral Unit, Oregon Health and Science University, Portland, OR, USA, <sup>3</sup>Bone and Mineral Unit, Oregon Health and Science University, Portland, OR, USA, <sup>4</sup>General Internal Medicine, University of California, San Francisco, San Francisco, CA, USA, <sup>5</sup>Department of Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Although rib fractures are common, they are barely mentioned in studies of osteoporotic fractures. We report here the first prospective study of validated rib fractures in ambulatory community-dwelling older men.

In MrOS we obtained demographic, lifestyle, and medical data and measured hip and spine BMD using DXA in 5995 men recruited from 6 U.S. sites; 99% responded to mailed queries about new fractures every four months for an average 5.1 year follow-up. Fractures were validated by physician review of radiographs or radiology reports; pathologic fractures were excluded. Baseline characteristics were compared between men who did or did not have an incident rib fracture. Cox proportional hazard ratios with 95% confidence intervals included all baseline variables with an age-adjusted p < 0.10.

24.1% of all incident non-spine fractures were rib fractures. At baseline the 126 men who had new rib fractures, compared to those without, were older, thinner, had lower BMD, and were significantly more likely to report a history of fracture and to report falling in the past year. Men with a history of rib fracture did not differ from men without in lifestyle, physical function, or family history of osteoporosis, but were more likely to have a history of cancer, stroke, or Parkinson's disease, and less likely to report arthritis. 48.4% had rib fractures after falling from ≤ a standing height. Only 2.3% of men had multiple rib fractures on the same date. In the final multiply adjusted Cox model (Table), age ≥ 80, BMD, history of rib/chest fracture, difficulty with 5 IADLs and statin use predicted an increased risk of rib fracture, while arthritis predicted a reduced risk. Most risk estimates were not materially changed when BMD was removed from the model except weight emerged as an independent risk factor and statin use was no longer significant.

Table. Multivariate-adjusted models of baseline risk factors for rib fracture with and without including BMD (HR [95% CI])

	Model 1: Including BMD	Model 2: Excluding BMD
Total hip BMD	1.44 (1.20-1.74)	—
Weight	NS	1.23 (1.01-1.49)
Age ≥ 80	1.55 (1.03-2.34)	1.56 (1.03-2.37)
Rib/chest/sternum fracture at any age	2.63 (1.81-3.82)	2.88 (1.99-4.19)
Arthritis	0.59 (0.41-0.85)	0.59 (0.41-0.85)
Difficulty with 5 IADLs (score)	1.13 (1.04-1.23)	1.15 (1.06-1.26)
Statin use	1.47 (1.01-2.13)	NS

Rib fractures are strongly associated with low BMD and future rib fractures, and should be considered when evaluating patients for treatment to prevent fracture.

## F356

**Direct Medical Costs Associated with the Treatment of Non-hip, Non-vertebral (NHNV), Hip, and Vertebral Fractures in a Managed Care Setting.** K. Foley<sup>\*1</sup>, N. Shi<sup>\*1</sup>, G. Lenhart<sup>\*1</sup>, E. Badamgarav<sup>\*2</sup>. <sup>1</sup>Thomson Healthcare, Cambridge, MA, USA, <sup>2</sup>Amgen Inc, Thousand Oaks, CA, USA.

Fracture cost burden studies in osteoporosis generally focus on hip and spine fractures. However, recent studies suggest that 60% of all fractures occur at sites other than hip and spine. Evidence characterizing the economic burden of all fractures, including NHNV, in a managed care setting is limited. This retrospective analysis examined incremental direct medical costs associated with NHNV, hip, and vertebral fractures. Fully adjudicated medical claims from a research database were used to identify patients aged  $\geq 50$  years with a closed hip, clinically evident vertebral, or NHNV fracture (distal femur, pelvic, humerus, wrist, clavicle, or leg) between 7/1/2001 and 12/2/2004. The first observed fracture became the index fracture. Patients were continuously enrolled 6 months before and 12 months after the index fracture. A 1:1 control group for each fracture category was matched on age, gender, region, and diagnostic cluster score  $\pm 3$  points. Multivariate regression modeling controlled for potential confounders. Total direct medical cost in the 12 months after the index fracture was determined. Incremental cost attributable to fractures was calculated as the difference between the costs incurred by fracture and control cohorts in the same time period. Incremental costs by fracture site and age cohorts (i.e., 50-64 and  $\geq 65$ ) were analyzed separately. Six study samples and matched controls were identified. The mean age of the 50-64-age cohort was 60 and the  $\geq 65$ -age cohort was 80. Similar to published studies, NHNV fractures were more common than hip or vertebral fractures in both age groups. The ratio of NHNV:hip fracture was 11:1 among patients aged 50-64 years and 2:1 in patients aged  $\geq 65$  years. Adjusted incremental costs and total fracture costs by fracture site and age cohort are shown in the Table.

Table: Adjusted One-Year Direct Medical Costs			
Age 50-64 yrs (N=33,233)	N	Incremental Cost (\$) (Fracture-control)	Total fracture-related cost (\$ million) (N x incremental cost)
NHNV	27,424	\$9,183	\$251.8
Hip	2,423	\$26,545	\$64.3
Vertebral	3,386	\$14,977	\$50.7
Age $\geq 65$ yrs (N=73,945)			
NHNV	40,690	\$6,106	\$248.5
Hip	21,504	\$15,196	\$326.8
Vertebral	11,751	\$6,701	\$78.7

The economic burden of all osteoporotic fractures is significant for managed care plans. Although individual NHNV fractures have a lower direct incremental cost than hip or vertebral fractures, their total cost is greater for patients aged 50-64 years because of the greater prevalence of NHNV fractures in this population.

**The 10-Year Probability of Recurrent Osteoporotic Fractures After a Primary Wrist Fracture in Postmenopausal Women Enrolled in the Canadian Multicentre Osteoporosis Study (CaMOS) Cohort.** A. Hodsman<sup>1</sup>, G. Gamble<sup>\*2</sup>, R. Adachi<sup>3</sup>, G. Ioannidis<sup>3</sup>, N. Krieger<sup>4</sup>, D. Goltzman<sup>5</sup>, A. Papaioannou<sup>3</sup>, J. Prior<sup>6</sup>, T. Anastassiades<sup>7</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada, <sup>2</sup>University of Auckland, Auckland, New Zealand, <sup>3</sup>McMaster University, Hamilton, ON, Canada, <sup>4</sup>University of Toronto, Toronto, ON, Canada, <sup>5</sup>McGill University, Montreal, QC, Canada, <sup>6</sup>University of British Columbia, Vancouver, BC, Canada, <sup>7</sup>Queen's University, Kingston, ON, Canada.

**Background:** Wrist fractures are the most prevalent of the "osteoporotic" fractures in post-menopausal women, and herald future fractures; little is known of the absolute risk of recurrent (2<sup>o</sup>) fracture after a wrist fracture, when it occurs as the first (1<sup>o</sup>) fracture event in adulthood.

**Methods:** All fractures, occurring as non-trauma events after age 50, were identified among 6053 women in the CaMOS cohort, specifically at the wrist or at other sites (clinical spine, hip, pelvis or ribs). All prevalent (historical) fractures prior to enrollment (total 257, 4.2%) and incident fractures during 7 yr. follow-up (total 323, 5.2%) were included to determine the 10 yr. probability of 2<sup>o</sup> fractures following a 1<sup>o</sup> wrist fracture. Bone mineral density (BMD) measurement at the femoral neck (FN), and x-ray evidence of morphometric vertebral fractures were obtained at enrollment. From multivariable Cox proportional hazards analysis, Hazard Ratios (HR) and 95% confidence intervals (CI) were calculated.

**Results:** Within the cohort, there were a total of 580 fractures, including 265 at the wrist (46% of all identified fractures), 84 spine, 92 hip, and 158 pelvis/rib fractures. There were 247 1<sup>o</sup> wrist fractures, which occurred at mean (SD) age 65 (10) yr. Thirty two women had 2<sup>o</sup> fractures beginning at age 73 (9) yr. The 10-yr. probability of a 2<sup>o</sup> fracture was 12% (CI 7.2-16.8), but was higher for women  $> 65$  yr. (13.0%, CI 7.4-18.6) than those  $< 65$  yr. (9.0%, CI 0.5-17.5 - n.s.). Risk factors for all incident 2<sup>o</sup> fractures post-enrollment included any 1<sup>o</sup> wrist fracture (adjusted HR 3.0, CI 1.6-5.6), age at enrollment  $> 65$  yr. (HR 2.0, CI 1.3-3.2), presence of morphometric vertebral fractures, (HR 2.0, CI 1.4-3.0), and preserved FN BMD with T-score  $> -2.5$  (HR 0.4, CI 0.3-0.6) - all p-value  $< 0.001$ .

**Conclusion:** Wrist fractures are the most common of the osteoporotic fractures. Using

Canadian guidelines, (which define a high fracture risk as  $> 20\%$  probability over 10 yr.), a 1<sup>o</sup> wrist fracture may constitute only a moderate risk for future fractures, unless there are other well-defined risks for osteoporosis, including age  $> 65$ yr and osteoporotic BMD.

## F361

**Improving the Diagnostic Yield of Bone Densitometry: Use of Age and Weight Thresholds in Postmenopausal Women.** J. D. McCrea, T. Hewer\*. Bone Densitometry, North Cumbria Acute Hospitals NHS Trust, Whitehaven, Cumbria CA28 8JG, United Kingdom.

Widespread dxa scanning of postmenopausal women to detect osteoporosis is not officially sanctioned in the UK while an opportunistic case finding strategy is endorsed. In 2002 we introduced a minimum age criterion of 65 years (in the absence of any other clinical risk factors) to referrals of postmenopausal women to improve the percentage of patients diagnosed with osteoporosis at any site from its then level of 30%. In 2005 we added a maximum weight criterion of 60 kg (along with a further restriction on age to 70 - 75 years) to patients referred under a special initiative. We have now compared the diagnostic yield of patients with osteoporosis in 317 postmenopausal women referred for a first scan during the year immediately prior to the introduction of the weight criterion with 325 patients referred immediately after the introduction of the criterion. 95% of the initiative patients weighed 59 kg or less (vs. 34% of controls), 93% were aged 70 or older (vs. 37% of controls) and 94% had an OST of -3 or less (vs. 22% of controls). Low trauma fractures were found in 131 initiative patients vs. 64 controls (p  $< 0.001$ ). Fracture site results for initiative vs. control patients were: 64 vs. 34 (distal forearm) p  $< 0.001$ , 34 vs. 3 (vertebral body) p  $< 0.001$ , 14 vs. 4 (hip) p  $< 0.05$  respectively. BMD results are given below:

		Routine patients (n=308) Mean ( $\pm$ SD)	Initiative patients (n=321) Mean ( $\pm$ SD)
TOTAL FEMUR	BMD (g/cm <sup>2</sup> )	0.854 ( $\pm$ 0.144)	0.759 ( $\pm$ 0.145) p $< 0.001$
	T - SCORE	- 1.2 ( $\pm$ 1.2)	- 2.0 ( $\pm$ 1.2) p $< 0.001$
FEMORAL NECK	BMD (g/cm <sup>2</sup> )	0.776 ( $\pm$ 0.139)	0.742 ( $\pm$ 0.121) p $< 0.001$
	T - SCORE	- 1.3 ( $\pm$ 1.1)	- 1.9 ( $\pm$ 1.0) p $< 0.001$

The proportion of patients found to be osteoporotic at any site was 63% in the initiative patients (vs. 35% of controls) p  $< 0.001$ . Overall, 79% of initiative patients (vs. 57% of controls) were recommended for treatment (p  $< 0.001$ ).

The raising of the minimum age requirement to 65 years only produced a marginal and non significant increase in diagnostic yield (from 30 to 35%) whereas the introduction of a maximum weight criterion had a more profound effect in identifying patients with osteoporosis who required treatment. It is clear that the important association between low body weight does not seem to be appreciated by our referring primary care physicians. We now propose to modify our bone density scanning referral criteria by adding a weight threshold. We also consider in the light of these results that serious consideration be given to the introduction of a policy of selective screening of all females who weigh 60 kg or less at age 70 and who have not had a dxa scan in the previous decade.

**Disclosures:** J.D. McCrea, Hoffmann La Roche (UK) Ltd 5.

## F363

**Percentage Body Fat and Risk of Prospective Hip Fracture in Older Men and Women: The EPIC-Norfolk Study.** A. Moayyeri, R. N. Luben\*, N. J. Wareham\*, S. Bingham\*, K. T. Khaw\*. Public Health and Primary Care, The University of Cambridge, Cambridge, United Kingdom.

The association between fat mass, an important component of total body weight, and osteoporosis is uncertain. There is particularly a paucity of data on the association of fat mass with prospective risk of fractures. We examined these associations in men and women in the European Prospective Investigation into Cancer (EPIC)-Norfolk who had measurements of both heel quantitative ultrasound (QUS) and percentage body fat (%BF) using a validated impedance technique between 1997 and 2000 and were followed for any incident fracture up to March 2007. From 14,789 participants (6,470 men) aged 42-82 years at baseline, 140 suffered a hip fracture during 114,371 person-years of follow-up (mean 7.7 ± 0.8 years). In sex-specific multivariate linear regression analyses, age-adjusted heel broadband ultrasound attenuation (BUA) measures were positively associated with %BF ( $\beta$  coefficient = 0.38 for women and 0.19 for men;  $P < 0.001$  for both). However, after inclusion of body mass index (BMI) in the model, the relation between BUA with %BF became significantly negative and remained significant after inclusion of other factors including waist-to-hip ratio, history of fracture, smoking and alcohol intake ( $\beta$  coefficient = -0.11 for women and -0.30 for men;  $P < 0.001$  for both). Women with incident hip fracture during follow-up ( $n=102$ ) had significantly lower %BF (36.1% vs. 39.8%) and BMI (25.6 vs. 26.5 kg/m<sup>2</sup>) compared to women without hip fracture ( $n=8,217$ ); however, there were no significant differences for %BF and BMI between men with ( $n=38$ ) and without fracture ( $n=6,432$ ). In sex-specific multivariate Cox proportional-hazard regression models, increasing %BF appeared significantly protective against hip fracture in women (hazard ratio [HR] for 10% increase = 0.55, 95% CI 0.39-0.78;  $P=0.001$ ) but not in men (HR = 0.70, 95% CI 0.26-1.83;  $P=0.46$ ). BMI became a significant risk factor for hip fracture in the model including %BF for women (HR for 4 kg/m<sup>2</sup> = 1.37, 95% CI 1.02-1.85;  $p=0.039$ ). In a multivariate model, a 10% increase of %BF on hip fracture risk was equivalent to about 1 standard deviation increase in BUA and about 7 years decrease in age in women. The interaction term between %BF and BMI included in the model was marginally significant ( $P$  value=0.09). The observed independent and protective effect of %BF against fractures and interaction between %BF and BMI for prediction of fractures warrant consideration. Understanding the complex relationships between different indices of obesity (such as %BF and BMI), BUA and fracture risk in men and women may help elucidate the metabolic and other underlying mechanisms involved in bone health and fracture risk.

## F365

**Factors Associated with Kyphosis Progression in Older Age.** D. M. Kado<sup>1</sup>, K. Prenovost\*, L. Palermo\*, K. Stone\*, S. R. Cummings\*. <sup>1</sup>Orthopaedics, University of California, Los Angeles, Los Angeles, CA, USA, <sup>2</sup>Medicine, University of California, Los Angeles, Los Angeles, CA, USA, <sup>3</sup>Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, USA, <sup>4</sup>California Pacific Medical Center, San Francisco, CA, USA.

Since only 36-38% of those with the worst thoracic hyperkyphosis have underlying vertebral fractures, there must be other important causes of age-associated thoracic postural changes. Because hyperkyphosis is associated with impaired pulmonary and physical function and increased mortality, we sought to determine other important and possibly modifiable causes. Using longitudinal data from the Study of Osteoporotic Fractures, we studied 1074 women aged 65 or older who had baseline, 3-5 year, and 15-17 year follow-up thoracic spine radiographs. From these, we calculated the Cobb angle of kyphosis (T4-T12) and measured prevalent vertebral fractures (3SD definition, from T4-L5). Participants also underwent baseline and 3.7 year follow-up calcaneal bone mineral density testing, disc height measurements (T4-T12), baseline and follow-up grip strength and walking speed testing, and answered questions regarding medical history and health behaviors. At baseline, the average kyphosis angle was 44.9 degrees (SD=12) that progressed an average of 6.7 degrees (SD= 2.5) over 15 years. Weighted multilevel models were run on Cobb angle as a function of various categories of predictors. A final combined model revealed that Cobb angle was predicted not only by age, vertebral fractures, and bone density, but also by family history of hyperkyphosis, disc height, grip strength, and walking speed. As expected, increased age, baseline and incident vertebral fractures predicted worse thoracic kyphosis. And, while low baseline heel bone density continued to predict worse kyphosis over time, the change in density did not. A family history of hyperkyphosis, decreased disc height, and low baseline grip strength predicted kyphosis progression. We also observed an interaction where a decrease in walking speed was associated with worsening kyphosis that was further accentuated in those who also experienced height loss over time. Thus, besides vertebral fractures and low bone density, a family history of hyperkyphosis, decreased disc height, low muscle strength, and decline in walking speed (indicating worse physical function) are other potential important factors that are independently associated with hyperkyphosis. Not only do predictors at a relatively early stage predict later life hyperkyphosis, some baseline effects and changes in these effects continue to affect kyphosis progression over time. Thus, development of effective treatments for thoracic hyperkyphosis should include attention to these influences.

**Low Serum 25 Hydroxyvitamin D [25(OH)D] Is Associated with Higher Rates of Hip Bone Loss in Older Men.** K. E. Ensrud<sup>1</sup>, B. C. Taylor\*, M. L. Paudel\*, J. A. Cauley<sup>3</sup>, P. M. Cawthon<sup>4</sup>, S. R. Cummings<sup>4</sup>, H. A. Fink<sup>1</sup>, E. Barrett-Connor<sup>5</sup>, J. M. Zmuda<sup>3</sup>, J. M. Shikany\*, E. S. Orwoll<sup>7</sup>. <sup>1</sup>University of Minnesota and VAMC, Minneapolis, MN, USA, <sup>2</sup>University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>California Pacific Medical Center Research Institute, San Francisco, CA, USA, <sup>5</sup>University of California - San Diego, San Diego, CA, USA, <sup>6</sup>University of Alabama, Birmingham, AL, USA, <sup>7</sup>Oregon Health & Science University, Portland, OR, USA.

While vitamin D deficiency is common among older adults, there is inconsistent evidence to support an association between serum 25(OH)D levels and change in bone mineral density (BMD) in elderly people. To test the hypothesis that lower 25(OH)D levels are associated in a graded manner with higher rates of hip bone loss among older men, we measured total 25(OH)D (in fasting serum using LC-MS) and total hip BMD (THBMD) at baseline in a randomly selected sample of 1279 community dwelling men aged ≥65 years enrolled in the Osteoporotic Fracture in Men (MrOS) Study and followed them prospectively for an average of 4.4 years for changes in THBMD. Mean (±SD) 25(OH)D was 25.6 (±7.9) ng/mL. After adjustment for age, race, site, season, body weight, and baseline THBMD (base model), lower 25(OH)D level was associated with increasing rates of loss at the total hip ( $p$  for trend=0.009) (table). The majority of effect was observed among men in the lowest quintile (<19.2 ng/mL) who experienced a 1.5-fold increase in the rate of loss ( $p=0.003$  for Q1 vs. Q2-5); rates of loss were similar among men in higher quintiles and not different from each other ( $p>0.13$  for all comparisons). A similar pattern was observed at the hip subregions ( $p$  for trend=0.03 at trochanter and 0.08 at femoral neck). Findings were unchanged after further adjustment for additional potential confounders including health status, smoking status, alcohol intake, physical activity level, and inability to rise from a chair ( $p$  for trend at TH=0.02) (table). In conclusion, our results indicate that community-dwelling older men with low 25(OH)D levels (below 19 ng/mL) are at increased risk of hip bone loss, but suggest that rates of loss are similar among men with higher levels. These findings support the view that vitamin D deficiency, but not insufficiency, is detrimental to BMD in older men.

Mean Annualized Rate of Change in THBMD (95% CI) by Quintile of Total 25(OH)D Level		
Quintile	Base Model	Final Multivariable Model
Q1 (n=257)	-0.58 (-0.69, -0.46)	-0.56 (-0.68, -0.44)
Q2 (n=253)	-0.42 (-0.53, -0.31)	-0.41 (-0.53, -0.29)
Q3 (n=258)	-0.37 (-0.49, -0.26)	-0.38 (-0.49, -0.26)
Q4 (n=256)	-0.30 (-0.41, -0.18)	-0.30 (-0.41, -0.18)
Q5 (n=255)	-0.38 (-0.49, -0.26)	-0.39 (-0.50, -0.27)
p for trend	0.009	0.02

**Prediction of Incidental Low Trauma Limb Fractures in Older Men and Women with Quantitative CT (QCT) Variables of Bone and Muscles in Mid-Thigh: The AGES-Reykjavik Study.** G. Sigurdsson<sup>1</sup>, T. Aspelund\*, K. Siggeirsdottir\*, B. Jonsson\*, B. Mogensen\*, S. Sigurdsson\*, L. Launer\*, T. B. Harris\*, T. F. Lang\*, V. Gudnason<sup>1</sup>. <sup>1</sup>Icelandic Heart Association, Kopavogur, Iceland, <sup>2</sup>Intramural Research Program, National Institute on Aging, Bethesda, MD, USA, <sup>3</sup>University of California, San-Francisco, CA, USA.

QCT permits a direct measure of bone and muscle size and assessment of bone/muscle relationship. We have studied cross-sectional QCT variables in mid-thigh as predictors of incidental limb fractures in the AGES-Reykjavik Study, a cohort of 66-96-year-old men ( $n=2160$ ) and women ( $n=2385$ ) drawn from an established population based cohort and not taking medications affecting bone metabolism. We used a 4-detector Siemens CT system, a single axial section through the right mid-thigh (10 mm slice thickness). The variables included in the Cox's proportional hazard model were: total cross-sectional cortical area (CSA), derived cortical thickness, shaft BMD, shaft bending strength index (BSI), medullary area and buckling ratio, total cross-sectional muscle and quadriceps area and bone/muscle area ratio. All low trauma limb fractures (including proximal end of femur but excluding toes, foot, hand and finger fractures) during mean 3.5 years of follow-up were validated by medical and radiological records, altogether 170 in women and 61 in men, including 87 hip fractures.

Results; with sex as a confounding variable the most significant risk factor was the buckling ratio (ratio of bone radius to cortical thickness) with more than twofold greater risk in the top compared to the lowest tertile. This variable was >90% independent of muscle area which was however a significant protective factor independent of bone variables. Bone/muscle area ratio and BSI were not significant in multivariate analysis. The area under the ROC curve, using these QCT predictors and age, was 0.70 (CI 0.66-0.73).

We conclude that buckling ratio, a parameter which depicts the decreasing cortical thickness due to medullary expansion, is a significant risk factor for limb fractures including hip fractures in old age. Better understanding of the determinants of buckling ratio might be of importance in the prevention of these fractures in the elderly.

## F371

**Loop Diuretic Use and Rates of Hip Bone Loss, and Risk of Falls and Fractures in Older Women.** L. S. Lim<sup>\*1</sup>, H. A. Fink<sup>2</sup>, T. Blackwell<sup>\*3</sup>, B. C. Taylor<sup>2</sup>, K. E. Ensrud<sup>2</sup>. <sup>1</sup>Internal and preventive medicine, Griffin Hospital, Derby, CT, USA, <sup>2</sup>VA Medical Center, Minneapolis, MN, USA, <sup>3</sup>University of California, San Francisco, San Francisco, CA, USA.

The aim of this study was to determine if loop diuretic use is associated with hip bone loss, and increased risk of falls and fractures in older women.

We conducted a prospective study of 8127 women aged 65 and older from the Study of Osteoporotic Fractures (SOF) cohort who had available medication use data at the 4<sup>th</sup> examination (V4). The following outcomes were examined (analysis cohort): 1) Change in DXA-measured hip BMD between V4 and the 6<sup>th</sup> examination (V6) (n=2980 with BMD measures at V4 and V6); 2) 2+ falls in the year after the 4<sup>th</sup> examination (n=6244); and 3) incident clinical fracture (hip, nonspine) (n=7297).

After a mean of 4.4 years (+/- 0.6) follow-up, loop diuretic users had greater loss of total hip BMD compared to nonusers (TABLE). After adjustment for multiple confounders, risk of recurrent falls was not increased among loop diuretic users compared with nonusers (multivariable OR 0.99, 95% CI 0.71-1.39). Similarly, compared with nonusers, loop diuretic users did not have an increased risk of nonspine (multivariable RR 1.04, 95% CI 0.90-1.21) or hip fracture (RR 1.03, 95% CI 0.81-1.31).

In this cohort of older women, loop diuretic use was associated with a small, but significantly higher rate of bone loss at total hip compared to nonuse. However the risk of falls or fracture did not differ between loop diuretic users and nonusers.

TABLE: Age and multivariate (MV)-adjusted mean annualized % BMD change (95% CI) from baseline as a function of loop diuretic use (bone loss cohort, n=2980)

		Loop diuretic category		P
	Model	Nonuser	User	
Total hip	Age	-0.70 (-0.75, -0.65)	-0.94 (-1.08, -0.81)	0.001
	MV†	-0.71 (-0.76, -0.66)	-0.87 (-1.01, -0.73)	0.03
Femoral neck	Age	-0.53 (-0.59, -0.47)	-0.66 (-0.82, -0.49)	0.14
	MV†	-0.53 (-0.59, -0.47)	-0.62 (-0.79, -0.44)	0.39
Trochanter	Age	-0.66 (-0.72, -0.59)	-0.86 (-1.04, -0.69)	0.03
	MV†	-0.66 (-0.73, -0.60)	-0.81 (-0.99, -0.62)	0.15

†Adjusted for age, baseline weight (kg), baseline site-specific BMD (g/cm<sup>2</sup>), impairments in instrumental activities of daily living, alcohol use (drinks/wk), total daily calcium intake (mg), physical activity (kcal/wk), self reported health status, hypertension, congestive heart failure, change in weight (kg), diabetes, smoking status, and statin use. 82 women were not included in the multivariate models due to missing covariate data.

**Timed Up and Go Test and BMD as Predictors of Fracture: A 10-year Longitudinal Study.** K. Zhu<sup>1</sup>, A. Devine<sup>\*2</sup>, R. L. Prince<sup>3</sup>. <sup>1</sup>Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Nedlands, Australia, <sup>2</sup>School of Exercise, Biomedical and Health Science, Edith Cowan University, Perth, Australia, <sup>3</sup>School of Medicine and Pharmacology, University of Western Australia, Nedlands, Australia.

The relative importance of reduced bone structure and impaired neuromuscular function to fracture risk remains uncertain.

This study examines the association between incident osteoporotic fracture, hip DXA BMD and a standardised test of neuromuscular function, the Timed Up and Go test (TUAG), in which the patient is timed while rising from a chair, walking 3m, turning, returning to sit on the chair. The study subjects were 1500 women aged 75.2 ± 2.7 years when recruited in 1998 from the population. After finishing a five year RCT of calcium supplementation (CAIFOS), they were then recruited into a five year epidemiology study, the CARE study. The TUAG was measured at baseline and the hip DXA BMD at year one. Clinical incident osteoporotic fractures, excluding face and digits were confirmed from radiographic report, 1125 women were included in this analysis.

Baseline TUAG was 9.7 ± 2.6 seconds and one year DXA hip BMD T score was -1.1 ± 1.0. Over the study, 271 subjects had incident non-vertebral fracture, 96 subjects had incident clinical vertebral fracture and 334 subjects had at least one incident fracture at any site. Cox's proportional hazards analyses adjusted for baseline age and weight, previous fracture and calcium treatment group showed that one unit decrease in hip BMD T score was associated with 33.7%, 40.6% and 36.2% increase in the risk of non-vertebral fracture, vertebral fracture and any fracture, respectively. Whereas a 1 SD (2.6 seconds) increase in TUAG was associated with a 24.0% and 16.6% increase in the risk for non-vertebral and any fracture, respectively, it was not associated with higher risk for vertebral fracture.

	Non-vertebral fracture hazard ratio (95%CI)	Vertebral fracture hazard ratio (95%CI)	All fracture hazard ratio (95%CI)
Hip BMD (T score increase)	0.663 (0.561-0.783)	0.594 (0.445-0.794)	0.638 (0.549-0.743)
TUAG (2.6 second increase)	1.240 (1.105-1.390)	NS	1.166 (1.044-1.301)

The results confirm the independent effects of measures of neuromuscular coordination and bone structure to incident fracture risk. In addition to suggesting ways of improving fracture prediction, the data confirms the suggestion that modern fracture prevention should include assessment of both neuromuscular risk and skeletal structural risk as assessed by the TUAG and DXA hip BMD. Depending on the patients deficits, management should be directed at reducing neuromuscular risk, bone structural risk or both.

**Percutaneous Injection of GEM OS2 (rhPDGF-BB and β Tricalcium Phosphate (βTCP)/Bovine Type I Collagen Matrix) Increases Vertebral Bone Mineral Density in Geriatric Female Baboons.** D. S. Perrien<sup>1</sup>, N. L. Fleming<sup>\*1</sup>, J. O. Hollinger<sup>\*1</sup>, C. Schmidt<sup>\*2</sup>, L. Condel<sup>\*2</sup>, D. F. Jimenez<sup>\*3</sup>, D. Dean<sup>\*3</sup>, J. Bradica<sup>\*5</sup>, S. E. Lynch<sup>1</sup>, C. E. Hart<sup>\*1</sup>, C. S. Young<sup>1</sup>. <sup>1</sup>BioMimetic Therapeutics, Inc., Franklin, TN, USA, <sup>2</sup>Southwest Foundation for Biological Research, San Antonio, TX, USA, <sup>3</sup>UTHSCSA, San Antonio, TX, USA, <sup>4</sup>Veterinary Imaging Center, San Antonio, TX, USA, <sup>5</sup>Kensy Nash Corporation, Exton, PA, USA.

Approximately 161,000 VCFs are treated by injection of PMMA (vertebroplasty or kyphoplasty) in the U.S. each year. This treatment may increase secondary VCFs in adjacent vertebrae creating the need for local anabolic agents to prevent these secondary VCFs. To address this need, an osteoconductive βTCP/collagen matrix combined with rhPDGF-BB (GEM OS2) was created for direct injection into vertebrae as a local anabolic agent. PDGF stimulates chemotaxis and proliferation of osteoblasts, chondrocytes, fibroblasts and vascular smooth muscle cells, while synergizing with VEGF to promote neovascularization. This study was designed to assess the safety and efficacy of percutaneous injection of GEM OS2 in vertebral bodies of aged female baboons. The T12, L2, and L4 vertebrae in 6 female baboons, 17-22 yr old, were percutaneously injected with 0.5 cc of either βTCP/collagen + 1.0 mg/ml rhPDGF-BB (PDGF, n=3) or βTCP/collagen matrix + sodium acetate buffer (Matrix, n=3). The L6 vertebra in each animal was injected with sodium acetate buffer alone (Buffer). Body weights, serum chemistry, CBC, radiographs, MRI, and CT images were obtained at 1 wk pre- and post-surgery and at 1, 3, 6, and 9 mo post surgery. Volumetric bone mineral density (vBMD) was quantified from the CT images either including or excluding the needle track. All animals exhibited normal food intake, daily clinical observations, and serum chemistry markers were in or near normal limits. All radiography demonstrated that the test material was safe through 9-mo post-surgery. vBMD in the Matrix group did not change significantly through the study. In contrast, vBMD in the PDGF group at 3-mo was significantly greater than at 1 wk post-op (2.64% +/-1.16 [1-wk] vs. 5.93% +/-1.33 [3-mo]; p=0.023) and reached a peak at 6-mo and plateau at 9-mo, when the needle track was included in the analysis. A similar and significant pattern was seen when the needle track was excluded from the analysis. These data demonstrate that percutaneous injection of GEM OS2 into primate vertebral bodies is safe up to 9-mo post surgery. The QCT analysis demonstrates that direct injection of GEM OS2 containing PDGF acts as a rapid and potent anabolic agent suggesting this is a viable therapeutic for focal treatment of osteoporosis and bone augmentation.

**Serum Estradiol and Fracture Reduction during Treatment with Hormone Therapy: The Women's Health Initiative (WHI).** J. Cauley<sup>1</sup>, A. LaCroix<sup>2</sup>, J. Robbins<sup>3</sup>, J. Larson<sup>4</sup>, J. Wactawski-Wende<sup>4</sup>, Z. Chen<sup>5</sup>, S. Cummings<sup>6</sup>, R. Jackson<sup>7</sup>. <sup>1</sup>Univ of Pittsburgh, Pgh, PA, USA, <sup>2</sup>Fred Hutchinson Cancer Research Ctr, Seattle, WA, USA, <sup>3</sup>Univ of California at Davis Med Ctr, San Francisco, CA, USA, <sup>4</sup>Univ at Buffalo, Buffalo, NY, USA, <sup>5</sup>Univ of Arizona, Tucson, AZ, USA, <sup>6</sup>California Pacific Med Ctr, San Francisco, CA, USA, <sup>7</sup>Ohio State Univ, Columbus, OH, USA.

The WHI hormone therapy (HT) trials both demonstrated significant reductions in fractures among women randomized to either estrogen plus progestin (E+P) or Estrogen alone (E) compared to placebo. Despite these reductions in fractures, recommendations about the use of HT for the treatment of osteoporosis are cautious given the lack of overall benefits and greater risks of HT. Identification of women who are most likely to benefit could improve the overall risks/benefits ratio. We tested the hypothesis that HT reduces fracture risk to a greater degree in women with lower estrogen levels. The present study is a case-control study nested within the prospective design of the WHI-HT trials. All confirmed cases of hip (n=248) and all fracture (n=2596) were identified as potential cases. Cases were matched to controls for age, ethnicity, randomization date, fracture history, and hysterectomy status. The final set included 231 hip fracture case-control pairs and a random sample of 519 all fracture case-control pairs (Total N =1500). Of these participants, 721 were randomized to HT; 779 to placebo. Fasting baseline serum samples stored at -70° until assay were used. Serum estradiol (E2) was measured by RIA following extraction and chromatography with an intra- and inter-assay coefficient variation (CV) of 8-12%. Sex hormone binding globulin (SHBG) was measured by an immunoassay, CV, 6-13%. Logistic regression was used to evaluate the relationship between HT and the biomarkers on fractures, modeling the fracture outcome as a function of biomarker quartiles, HT, and an interaction term. The average age of the women was 65 years; 90% were Caucasian. There was no evidence that the effect of HT on fracture reduction differed by baseline level of E2, Table. Across quartiles of E2, women randomized to E+P or E alone, had about a 50% lower risk of fracture compared to placebo. For SHBG, the interaction with HT was borderline significant but there was no consistent pattern of association. We conclude that the effect of HT on fracture reduction is independent of sex steroid hormone levels.

Table 1: Odds ratio (95% confidence interval) of fracture among women randomized to HT versus placebo by levels of hormones at baseline

**Strontium Ranelate Decreases Osteoblast-induced Osteoclastogenesis through the Involvement of the Calcium-Sensing Receptor.** T. C. Brennan<sup>1</sup>, M. S. Rybchyn<sup>1</sup>, A. D. Conigrave<sup>2</sup>, R. S. Mason<sup>1</sup>. <sup>1</sup>Physiology, Bosch Institute, University of Sydney, Sydney, NSW, Australia, <sup>2</sup>Molecular and Microbial Biosciences, Bosch Institute, University of Sydney, Sydney, NSW, Australia.

Strontium ranelate reduces vertebral and non-vertebral fractures in post-menopausal women. Previous studies have shown that strontium ranelate increases bone formation and decreases bone resorption. Moreover, strontium is an agonist of the calcium-sensing receptor (CaSR), a receptor involved in the strontium ranelate increase in osteoblast replication and osteoclast apoptosis. We previously showed that strontium ranelate induced replication and differentiation, as well as increasing the survival of primary human osteoblasts (HOBs) subject to stress. In the current study, we investigated the effects of strontium ranelate on osteoblast-derived osteoclastogenic signals and hypothesized that these effects could be mediated by the CaSR. After treatments as short as 24 h, strontium ranelate dose-dependently increased OPG mRNA expression (qRT-PCR), up to 1.9-fold with 2 mM strontium ranelate (p<0.001). This effect was confirmed by a strong up-

regulation of the secretion of OPG (ELISA) with 1 and 2 mM strontium ranelate (p<0.001). In parallel, RANKL mRNA expression decreased by 75% after treatment with strontium ranelate (0.1, 1 and 2 mM, p<0.01, p<0.01 and p<0.001, respectively). The expression of RANKL at the HOB surface was also strongly down-regulated after 48 h treatment with 1 mM strontium ranelate, as shown by immunoprecipitation followed by western blotting. HOBs were transfected with siRNA directed at the CaSR or scrambled sequence. Transfection occurred over 24 h and the extent of the knockdown of the CaSR in HOBs was confirmed by western blot analysis. Knocking down the CaSR had no significant effect on OPG mRNA expression in vehicle treated cells, but diminished the stimulatory effects of strontium ranelate up to 46 % (2 mM, p<0.001). In conclusion, strontium ranelate increases the production of OPG, while decreasing the production of RANKL at the osteoblast surface, thus supporting an indirect inhibitory effect on osteoclastogenesis. Previous studies have shown that the CaSR is involved in both the increase in osteoblast replication and osteoclast apoptosis induced by strontium ranelate. Our results show that the CaSR at the surface of the human osteoblasts is involved in the strontium ranelate-induced increase in OPG. This observation strengthens the proposal that the CaSR plays a key role in the dissociating effect of strontium ranelate on bone formation and bone resorption.

## F391

**Injection of Mesenchymal Stem Cells Overexpressing both CXCR4 and RANK-Fc Effectively Prevented Ovariectomy-induced Bone Loss.** S. W. Cho<sup>1</sup>, H. J. Sun<sup>1</sup>, J. Y. Yang<sup>1</sup>, H. J. Choi<sup>1</sup>, D. H. Kim<sup>2</sup>, S. W. Kim<sup>1</sup>, S. Y. Kim<sup>1</sup>, C. S. Shin<sup>1</sup>. <sup>1</sup>Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Internal Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea.

Gene transfer to mesenchymal stem cell (MSC) may be a promising tool for wide variety of degenerative diseases including osteoporosis. Previously we demonstrated that intraperitoneal injection of MSCs overexpressing receptor activator of nuclear factor-κB (RANK-Fc) could prevent ovariectomy (OVX)-induced bone loss in mice. To enhance the homing efficacy of the injected cells, we introduced CXCR4 chemokine receptor 4 (CXCR4) along with the RANK-Fc to MSCs using retrovirus and studied the effects of MSC infusion in the prevention of OVX-induced bone loss. Ten weeks old adult female C57BL/6 mice were used and repeated intravenous injection of MSCs was performed as follows: (1) Sham-operated mice treated with PBS (n = 6); (2) OVX mice treated with MSCs transduced with RANK-Fc-RFP and CXCR4-GFP virus (RANK-Fc + CXCR4; n = 6); (3) OVX mice treated with MSCs transduced with RANK-Fc-RFP and GFP virus (RANK-Fc + GFP; n = 6); (4) OVX mice treated with GFP and RFP virus (GFP + RFP; n = 8); (5) OVX mice treated with PBS (OVX + PBS; n = 6). Measurement of BMD by dual energy x-ray absorptiometry (PIXImus) revealed that RANK-Fc + CXCR4 group gained significantly greater BMD compared to RANK-Fc + GFP group (2.1% vs. -0.5% at 4 weeks and 4.4% vs. -0.1% at 8 weeks, p<0.05). GFP + RFP group also showed less bone loss compared to OVX + PBS group (-1.7% vs. -6.2% at 8 weeks, p<0.05). Homing of RANK-Fc + CXCR4 cells were identified by PCR analysis of GFP DNA fragment that was co-expressed through IRES link. Serum RANK-Fc level peaked at 2 weeks post cell infusion but the level was not significantly different between RANK-Fc + CXCR4 group and RANK-Fc + GFP group. In summary, transplantation of MSCs retrovirally transduced with both RANK-Fc and CXCR4 resulted in protection of OVX-induced bone loss in mouse model. The extent of protection by RANK-Fc and CXCR4 was greater compared to RANK-Fc alone, suggesting that co-overexpression of CXCR4 could improve the efficacy of MSCs cell therapy.

**Anti-Sclerostin Antibody Increases Bone Formation and Decreases Bone Resorption in Distal Tibial Metaphyseal Trabecular Bone in Ovariectomized Rats.** X. Li<sup>1</sup>, H. Y. Chen<sup>2</sup>, K. Warmington<sup>1</sup>, X. Q. Liu<sup>2</sup>, Q. T. Niu<sup>1</sup>, T. Thway<sup>1</sup>, B. Stouch<sup>1</sup>, M. Grisanti<sup>1</sup>, H. Tan<sup>1</sup>, W. S. Simonet<sup>1</sup>, C. Paszty<sup>1</sup>, W. S. S. Jee<sup>2</sup>, H. Z. Ke<sup>1</sup>. <sup>1</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>2</sup>University of Utah, Salt Lake City, UT, USA.

Sclerostin inhibition via an anti-sclerostin monoclonal antibody (Scl-Ab) increased bone formation, restored bone mass and bone strength in proximal tibial metaphysis and lumbar vertebral body of ovariectomized (OVX) rats with established osteopenia. In this study, we examined the effects of various Scl-Ab doses on bone mass, bone formation and bone resorption parameters on distal tibial metaphysis (DTM), a low bone turnover site, in adult OVX rats. Six-month-old female SD rats were sham-operated or OVX and left untreated for 5 months. OVX rats were then treated with vehicle or Scl-Ab at 2.5, 5, 10, 25 mg/kg (twice per week, s.c.) for 5 weeks. Calcein and tetracycline were injected s.c. 12 and 2 days before necropsy, respectively. Trabecular bone histomorphometric analysis was performed in the area between 0.8 mm to 2.8 mm from epiphysis using 20 µm thick longitudinal sections of DTM. Ovariectomy for more than 6 months did not induce significant changes in trabecular bone volume (BV/TV) and parameters of bone formation and bone resorption compared with sham controls in the DTM. This is in agreement with previous observation that OVX did not induce bone loss in this low bone turnover site in rats. Treatment with Scl-Ab in OVX rats increased BV/TV in all dose groups (+24, +52, +69, and +60% for 2.5, 5, 10 and 25 mg/kg groups, respectively; p < 0.05 for 10 and 25 mg/kg groups) compared with OVX controls. Significant increases were found in mineralizing surface (MS/BS, +141 to +293%), mineral apposition rate (MAR, +61 to

+110%) and bone formation rate (BFR/BS, +273 to +693%) in OVX rats treated with 5, 10 or 25 mg/kg as compared with OVX controls. In addition, MS/BS was significantly increased by 112% in OVX rats treated with 2.5 mg/kg of Scl-Ab compared to OVX controls. Eroded surface/ bone surface, a bone resorption index, was decreased in OVX rats treated with Scl-Ab at 5, 10 and 25 mg/kg groups (-22%, -28% and -44%, respectively; with  $p < 0.05$  for 25 mg/kg group) compared to OVX controls. These results reveal that treatment with a Scl-Ab in OVX rats increases bone mass by increasing bone formation and decreasing bone resorption in a low bone turnover site. Together with our previous finding, we conclude that inhibition of sclerostin via Scl-Ab stimulates bone formation and increases bone mass in both high and low bone turnover sites in OVX rat model of postmenopausal osteoporosis.

### One Year of Teriparatide Treatment Increases Hip Strength in Subjects with Recent History of Anti-resorptive Treatment: The OPTAMISE Study.

J. Keyak<sup>1</sup>, E. Quek<sup>\*2</sup>, P. Miller<sup>3</sup>, J. Bilezikian<sup>4</sup>, J. Stewart<sup>\*5</sup>, T. Lang<sup>2</sup>.

<sup>1</sup>Department of Orthopaedic Surgery, University of California, Irvine, CA, USA, <sup>2</sup>Department of Radiology, University of California, San Francisco, CA, USA, <sup>3</sup>Colorado Center for Bone Research, Lakewood, CO, USA, <sup>4</sup>Division of Endocrinology, Columbia University, New York, NY, USA, <sup>5</sup>Sanofi-Aventis, Laval, QC, Canada.

**Purpose:** Previous studies using QCT imaging of the hip to follow subjects being treated with teriparatide (TPTD) have shown opposing effects on cortical and trabecular bone, with loss of cortical BMD and gain in trabecular BMD. However, there is little direct information on how these compartmental changes translate to changes in strength (fracture load) of the whole proximal femur, and no information on the response of proximal femoral strength to TPTD after anti-resorptive treatment.

**Methods:** 205 subjects previously treated with alendronate (ALN, n=110) and risedronate (RIS, n=95) discontinued their bisphosphonate and were treated with TPTD (20 µg/d SQ) for 12 months. QCT images of the hip with satisfactory accuracy were obtained at baseline and 12 months. Using a previously-described method, patient-specific 3D finite element models of the hip were constructed for each time point. The mechanical properties of each element (elastic modulus and ultimate strength) were based on the BMD measured within each element. Models were evaluated under loading simulating a fall with impact on the posterolateral aspect of the greater trochanter. Percentage changes in fracture load were analyzed by ANCOVA and paired *t*-test.

**Results:** For this sample similar to the whole, analyses showed that whole-bone hip fracture load increased by  $4.3 \pm 17.5\%$ ,  $p < 0.001$  after 1 year of TPTD treatment. Percentage increase in fracture load did not differ significantly by ALN or RIS pre-treatment ( $p=0.3$ ).

**Conclusions:** One year of treatment with TPTD led to a significant increase in hip fracture load despite recent history of treatment with RIS and ALN. The extent of the increase was less than increases previously reported for vertebral strength in response to TPTD treatment. This may be explained by the opposing changes of decreasing cortical bone and increasing trabecular bone density.

## F398

### Skeletal Plasma Clearance, as Measured by Quantitative Radionuclide Studies, Is Correlated with Bone Turnover Markers at 3 Months of Teriparatide Therapy.

A. E. B. Moore<sup>\*1</sup>, G. M. Blake<sup>1</sup>, K. Taylor<sup>2</sup>, P. Chen<sup>\*2</sup>, I. Fogelman<sup>1</sup>. <sup>1</sup>King's College London, Osteoporosis Screening and Research Unit, London, United Kingdom, <sup>2</sup>Eli Lilly, Indianapolis, IN, USA.

Teriparatide (TPTD) has profound anabolic effects on the skeleton as shown by marked increases in bone mass, bone mineral density and bone strength. TPTD increases biochemical markers of bone turnover, which may estimate clinical response to therapy. Quantitative radionuclide studies reflect bone blood flow and regional osteoblast activity and may provide a more precise measure of bone metabolism. We examined the bone metabolic response to TPTD using the radiopharmaceutical <sup>99m</sup>Tc-methylene diphosphonate (<sup>99m</sup>Tc-MDP) to quantify bone plasma clearance and correlate it with changes in bone turnover markers.

Ten postmenopausal women with osteoporosis (mean age 68 yr; mean baseline lumbar spine T-score of -3.2) had bone scans at baseline and 3 months after initiating TPTD therapy (20 µg/day sc). All women received daily calcium (1000 mg) and vitamin D (400-1200 IU) supplements. Women were injected with 600 MBq <sup>99m</sup>Tc-MDP and whole body bone scan images acquired at 10 min, 1, 2, 3 and 4 h. Multiple blood samples were taken between 5 min and 4 h and free <sup>99m</sup>Tc-MDP was measured using ultrafiltration. The Patlak plot method was used to evaluate whole skeleton <sup>99m</sup>Tc-MDP plasma clearance ( $K_{bone}$ ) as well as to derive regional values of bone clearance for the skull, spine, pelvis, arms and legs using gamma camera counts for each sub-region. At baseline and 3 months, serum concentrations of bone formation markers, amino-terminal propeptide of type I collagen (PINP) and bone-specific alkaline phosphatase (BSAP), and a bone resorption marker, urinary N-terminal telopeptide (NTX) /creatinine ratio, were measured.

From baseline to 3 months of treatment, mean whole body  $K_{bone}$  increased by 25.0% ( $P = 0.004$ ).  $K_{bone}$  was also increased at the skull (64.9%;  $P = 0.004$ ), spine (16.3%;  $P = 0.04$ ), pelvis (21.5%;  $P = 0.049$ ), arms (51.8%;  $P = 0.01$ ), and legs (36.8%;  $P = 0.02$ ). Parallel increases occurred in serum BSAP (21.8%,  $P = 0.04$ ), PINP (157.3%,  $P = 0.002$ ), and in

the urinary NTX /creatinine ratio (144.5%,  $P = 0.02$ ). Increases in these bone markers at 3 months were highly correlated with increases in  $K_{bone}$  in whole body and legs (correlation coefficients between 0.68 - 0.92).

Net plasma clearance of <sup>99m</sup>Tc-MDP to bone ( $K_{bone}$ ), a measure of osteoblastic activity, was significantly increased after 3 months of TPTD therapy. This is the first study to show a direct metabolic effect of TPTD therapy on bone blood flow kinetics at several clinically important skeletal sites. These results may provide physicians with clinical insights on the anabolic effects of TPTD as measured in bone scans.

### Bone Mineral Density and Biochemical Marker Response Rates in Postmenopausal Women after Treatment with Zoledronic Acid.

P. Delmas<sup>1</sup>, I. Reid<sup>2</sup>, R. Rizzoli<sup>3</sup>, S. Adami<sup>4</sup>, P. Sambrook<sup>5</sup>, E. Eriksen<sup>6</sup>, P. Mesenbrink<sup>\*7</sup>, R. Eastell<sup>\*8</sup>. <sup>1</sup>Hôpital Edouard Herriot, Lyon, France, <sup>2</sup>University of Auckland, Auckland, New Zealand, <sup>3</sup>Geneva University Hospitals, Geneva, Switzerland, <sup>4</sup>University of Verona, Verona, Italy, <sup>5</sup>University of Sydney, Sydney, Australia, <sup>6</sup>Novartis Pharma AG, Basel, Switzerland, <sup>7</sup>Novartis Pharmaceuticals Corporation, New Jersey, NJ, USA, <sup>8</sup>University of Sheffield, Sheffield, United Kingdom.

Clinical monitoring of responses to treatment is very important, and the choice of response variable depends on the ability of that given variable to detect clinically relevant responses. In the HORIZON-Pivotal Fracture Trial, 7736 women were treated with three annual infusions of zoledronic acid 5 mg (ZOL), resulting in significant reduction of osteoporotic fractures of the spine, hip and appendicular skeleton. In this study, bone mineral density (BMD) was measured annually in all women. In a subset of women, bone turnover markers [C-telopeptides (CTX), bone alkaline phosphatase (bone ALP) (n=605) and procollagen type I intact N-terminal propeptide (PINP) (n=1248)] were measured in serum at baseline, 12, 24 and 36 months. CTX and bone ALP were also measured at 6 months. We used these measurements to assess the response rates to treatment in two ways: 1) fraction of patients showing the expected deviation from baseline and 2) fraction of patients revealing a deviation from baseline in excess of the least significant change (LSC) for the given biomarker. LSC is the least change needed to be 95% certain that a change has truly occurred. Lumbar spine BMD was more sensitive than total hip BMD exhibiting increases over baseline in 88.8%, 92.4%, 93.2%, and 94.8% of patients at 6, 12, 24, and 36 months respectively. Assuming an LSC of 3.0%, the response rates at the same time points were 50.4%, 61.9%, 83.4% and 83.6%, respectively. Among the biochemical markers serum CTX (S-CTX) was the most sensitive. The fraction of patients showing a decrease from baseline were 96.0%, 94.5%, 89%, and 86.2% at 6, 12, 24, and 36 months, respectively. Assuming an LSC for CTX of 30%, the response rates were 91.4%, 84.0%, 78.0% and 71.1%, respectively. In conclusion, assessment of S-CTX at 6 months provides excellent early monitoring of patient responses to ZOL, with 96% showing a decrease and 72.2% showing a clinically significant reduction. BMD increases in the spine were seen in 92.4% of patients at 12 and 93.2% at 24 months, while clinically significant BMD responses were seen in 61.9% at 12 months and 83.4% at 24 months. Thus, for zoledronic acid early monitoring (6-12 months) with S-CTX is more sensitive than BMD. However with increasing duration of treatment BMD becomes more sensitive.

## F403

**Effect of a Single Infusion of Zoledronic Acid 5 mg versus Oral Risedronate 5 mg on Bone Mineral Density at Lumbar Spine, Hip, Femoral Neck and Trochanter in Patients with Glucocorticoid-Induced Osteoporosis.** D. M. Reid<sup>1</sup>, J. Devogelaer<sup>2</sup>, K. Saag<sup>3</sup>, C. Roux<sup>4</sup>, C. S. Lau<sup>5</sup>, J. Reginster<sup>6</sup>, P. Papanastasiou<sup>7</sup>, A. Ferreira<sup>8</sup>, F. Hartl<sup>9</sup>, T. Fashola<sup>10</sup>, P. Mesenbrink<sup>9</sup>, P. Sambrook<sup>10</sup>. <sup>1</sup>Division of Applied Medicine, University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>Saint-Luc University Hospital, Brussels, Belgium, <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Cochin Hospital, Paris, France, <sup>5</sup>University of Dundee, Dundee, United Kingdom, <sup>6</sup>Bone and Cartilage Metabolism Unit, University of Liège, Liège, Belgium, <sup>7</sup>Novartis Pharma AG, Basel, Switzerland, <sup>8</sup>F Hoffman-LaRoche AG, Basel, Switzerland, <sup>9</sup>Novartis Pharmaceuticals Corporation, New Jersey, NJ, USA, <sup>10</sup>University of Sydney, Sydney, Australia.

The purpose of this study was to compare the safety and efficacy of intravenous zoledronic acid (ZOL) and oral risedronate (RIS) in the prevention and treatment of glucocorticoid-induced osteoporosis (GIO). A single 5 mg infusion of ZOL and oral RIS (5 mg/day) were compared in a 1-year, randomized, double-blind, double-dummy study involving 2 groups of glucocorticoid-treated patients (prevention subpopulation:  $\leq 3$  months of glucocorticoid treatment at randomization [ZOL, n=144; RIS, n=144]; treatment subpopulation:  $>3$  months of treatment at randomization [ZOL, n=272; RIS, n=273]). Within each subpopulation, the primary efficacy objective was to demonstrate non-inferiority of ZOL versus RIS, in percentage change in lumbar spine (LS) bone mineral density (BMD) between baseline and 12 months. Secondary efficacy endpoints included percentage change in LS BMD at 6 months, and in BMD of the femoral neck, total hip and trochanter at 6 and 12 months. Within each subpopulation, baseline characteristics were comparable between treatment arms.

Patients were predominantly Caucasian (94.0%) and female (68.2%). After 12 months, LS BMD had increased significantly more with ZOL than RIS in both subpopulations (treatment: ZOL, 4.1%; RIS, 2.7%;  $P=0.0001$ ; prevention: ZOL, 2.6%; RIS, 0.6%;  $P<0.0001$ ). ZOL was also significantly more effective than RIS in increasing BMD at the femoral neck, trochanter and total hip in both subpopulations at 12 months. The superior effect of ZOL on BMD was evident at 6 months (both subpopulations: LS, total hip and trochanter; prevention subpopulation only: femoral neck). In the first 3 days after treatment initiation, adverse events (AEs) were more common in ZOL-treated patients, mainly due to transient post-dose symptoms. From day 3 onwards, the 2 treatment groups had similar AE rates. Serious AE incidence was comparable between ZOL and RIS. These 1-year data indicate that a single 5 mg infusion of ZOL is significantly more effective than oral RIS (5 mg/day) in the prevention and treatment of GIO.

## F405

**Effect of Severe Suppression of Bone Turnover on Osteocyte Viability.** C. V. Odvina<sup>1</sup>, S. Qui<sup>2</sup>, S. Palnitkar<sup>2</sup>, D. S. Rao<sup>2</sup>. <sup>1</sup>Center for Mineral Metabolism, UT Southwestern Medical Center, Dallas, TX, USA, <sup>2</sup>Bone and Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA.

Recently, we discovered severe suppression of bone turnover (SSBT) in some patients with osteoporosis on long-term alendronate treatment. Bone remodeling is essential for replacing dead osteocytes with new ones. However, it remains unclear about the association between SSBT and osteocyte viability.

Iliac bone biopsies were obtained from 16 postmenopausal women. Eight were patients treated with alendronate  $>5$  years and associated with very low bone turnover rate. Another 8 age-matched healthy postmenopausal women were selected for control. All subjects underwent double tetracycline labeling before biopsy. From 5  $\mu$ m sections stained with goldner trichrome, the following osteocyte related variables were measured in cancellous bone: osteocyte density [Ot.Dn/(mm<sup>2</sup>)], empty lacunar density [EL.Dn/(mm<sup>2</sup>)], total lacunar density [TL.Dn/(mm<sup>2</sup>)] and the percent empty lacunae [EL/TL(%)]. Coefficient of variation [CV (%) = SD/mean x 100] of each variable was computed from measured areas to determine the homogeneity of osteocyte and empty lacunar distribution.

Compared to the control, SSBT patients had significantly increased EL.Dn and EL/TL, and significantly decreased Ot.Dn (Table 1). CVs for Ot.Dn and TL.Dn were significantly greater in SSBT patients than in healthy control. All the subjects in control group showed double labels in the trabecular bone, and both bone formation rate and activation frequency remained in normal range. In 8 patients with alendronate treatment, 6 did not show double labels and 2 had considerably lower bone formation rate and activation frequency compared to the normal.

Bone remodeling likely targets the area with excessive osteocyte death. Consequently, a decrease in bone remodeling would result in accumulation of bone with less viable osteocytes. This study demonstrated that SSBT not only increases loss of osteocytes but also enhances heterogeneity of osteocyte distribution. Based on our previous study, increased heterogeneity of osteocyte distribution in lower remodeled cancellous bone results from the increase in trabeculae with no osteocyte. However, because of the lack of baseline biopsy, SSBT in our patients cannot be entirely attributed to the use of alendronate. The association between bisphosphonates and SSBT and decreased osteocyte viability merits further investigation.

Comparison of mean values between postmenopausal women and patients with SSBT			
	Normal	SSBT	p
N	8	8	
Age (years)	62.6 (8.43)	62.9 (9.61)	0.957
Ot.N/(mm <sup>2</sup> )	183 (26.6)	118 (38.4)	<0.001
EL.N/(mm <sup>2</sup> )	19.4 (6.85)	62.7 (7.46)	<0.001
TL.N/(mm <sup>2</sup> )	203 (24.1)	181 (34.0)	0.124

**The Role of Active Site Threonine 201 in the Inhibition of Farnesyl Pyrophosphate Synthase by Nitrogen Containing Bisphosphonates.** J. E. Dunford<sup>1</sup>, E. Pilka<sup>2</sup>, A. Kwaasi<sup>1</sup>, A. Evdokimov<sup>3</sup>, B. L. Barnett<sup>4</sup>, U. Oppermann<sup>2</sup>, F. H. Ebetino<sup>5</sup>, R. G. G. Russell<sup>1</sup>, K. L. Kavanagh<sup>5</sup>. <sup>1</sup>Nuffield Department of Orthopaedic Surgery, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Structural Genomics Consortium, University of Oxford, Oxford, United Kingdom, <sup>3</sup>P & G Pharmaceuticals, Cincinnati, OH, USA, <sup>4</sup>Dept. of Chemistry, University of Cincinnati, Cincinnati, OH, USA, <sup>5</sup>Dept. of Chemistry and Biochemistry, University of Texas at Austin, Austin, TX, USA.

The major molecular target of nitrogen containing bisphosphonates (N-BPs) is the mevalonate pathway enzyme Farnesyl Pyrophosphate Synthase (FPPS). However the exact mechanism of inhibition has not been determined. Recent crystallographic and kinetic studies have shown that potent N-BPs inhibit the enzyme by initially competing with one of the substrates, geranyl pyrophosphate (GPP), for a binding site, followed by a slow isomerisation of the enzyme structure to form a tightly bound complex. This complex is presumably maintained by the hydrogen bonding interactions of the bisphosphonate side chain nitrogen with a threonine hydroxyl residue and also the carbonyl oxygen of the adjacent lysine residue (Lys200/Thr201) in the active site of the enzyme. We aimed to investigate the interactions of the bisphosphonate nitrogen and these highly conserved residues. We constructed a mutant of FPPS, replacing the Thr 201 with an Ala residue (T-A Mutant). The mutant had an increased affinity (Km) for GPP with 1.5 $\mu$ M for T-A compared to 2.1  $\mu$ M in the wildtype. The Km for the second substrate, Isopentenyl Pyrophosphate was increased from 1.8 $\mu$ M in the wildtype to 17.7 $\mu$ M in the TA mutant. The maximal speed of the reaction was also reduced with Kcat of 0.34S<sup>-1</sup> for T-A compared to 0.42S<sup>-1</sup> for wildtype. The TA mutant had an increased final Ki for zoledronate, from 0.07nM to 2.17nM and also a reduced isomerisation constant (ICON), a measure of the reversibility of the inhibition, from 1224 to 37.6. Conversely, the effect of this mutation on the inhibition by risedronate was to decrease the Ki from 0.34nM to 0.16nM and increase the ICON from 237 to 1000. The inhibition of FPPS by NE58022 (Ki = 302 nM), an analogue of risedronate with no sidechain nitrogen was unchanged in the T-A mutant. Similarly, the inhibition of FPPS by ibandronate, an N-BP which is not predicted to make an interaction with Thr201 was only slightly affected with the final Ki changing from 3.6nM in the wild type to 5.5nM in the T-A mutant. We show that the interaction of the N-BP sidechain nitrogen with Thr 201 is not essential for inhibition, but can be responsible for the higher potency of many analogs. It may be that the interaction of the sidechain nitrogen with the carbonyl oxygen of Lys200 is the more important of the two possible hydrogen bonding interactions with FPPS for N-BPs.

## F409

**Risk of Hip Fracture after Bisphosphonate Discontinuation: Implications for a Drug Holiday.** J. R. Curtis<sup>1</sup>, A. O. Westfall<sup>2</sup>, H. Cheng<sup>3</sup>, E. Delzell<sup>3</sup>, K. G. Saag<sup>1</sup>. <sup>1</sup>Center for Education and Research on Therapeutics (CERTS), University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>3</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA.

**Purpose:** Recent data suggests that hip fracture risk was not significantly increased among women receiving 5 years of bisphosphonate therapy who were subsequently randomized to placebo. We studied older women compliant with bisphosphonates  $\geq 2$  years to evaluate the risk of hip fracture after bisphosphonate discontinuation.

**Methods:** Using administrative databases from a large U.S. healthcare organization, we identified women initiating bisphosphonate therapy who were compliant (Medication Possession Ratio, MPR  $\geq 66\%$ ) for 2 years. We examined the rate of hip fracture among women who discontinued bisphosphonates versus those who remained on therapy.

**Results:** From the original cohort, only 46% (n = 9063) of women were compliant (MPR  $\geq 66\%$ ) at 2 years and were eligible for analysis. Hip fracture incidence among women who discontinued bisphosphonates versus those who did not was 8.43 versus 4.67 per 1000 person years (p=0.016). The adjusted hazard ratio of hip fracture per 90 days following discontinuation was 1.2 (1.1-1.3). For women with higher compliance at 2 years (MPR  $\geq 80\%$ ) or compliant for 3 years, there were no significant differences in risk associated with discontinuation.

**Conclusions:** The rate of hip fracture was increased among women compliant with bisphosphonate therapy for 2 years who subsequently discontinued, suggesting that discontinuation is not advisable under these conditions. This association was attenuated with higher compliance and a longer duration of previous bisphosphonate therapy.

## F411

**Increase in Risk of Atypical Subtrochanteric Fractures with Zoledronic Acid? Results from the HORIZON-PFT.** D. M. Black<sup>1</sup>, D. C. Bauer<sup>1</sup>, P. Mesenbrink<sup>\*2</sup>, L. Palermo<sup>\*1</sup>, S. R. Cummings<sup>3</sup>, S. Boonen<sup>4</sup>, R. Eastell<sup>5</sup>. <sup>1</sup>UCSF, San Francisco, CA, USA, <sup>2</sup>Novartis Pharma, East Hanover, NJ, USA, <sup>3</sup>CPMC Research Institute & UCSF, San Francisco, CA, USA, <sup>4</sup>Leuven Univ., Leuven, Belgium, <sup>5</sup>Univ. of Sheffield, Sheffield, United Kingdom.

Two recent clinical case series studies suggested the possibility that low-trauma, subtrochanteric hip fractures may be increased in long term users of bisphosphonates. However, both of these case-series were small, uncontrolled and were derived from clinical populations: no data from population-based epidemiologic studies or randomized trials has been reported. We examined the occurrence of subtrochanteric hip and femoral shaft fractures in the Horizon Pivotal Fracture Trial, a randomized trial comparing 3 years of zoledronic acid treatment (ZOL) to placebo in 7736 patients. Self-reported fractures required central confirmation based on an x-ray report or (in some cases) review of x-rays. Confirmed hip fractures were categorized as femoral neck, intertrochanteric, subcapital, subtrochanteric or "other" (could not be classified or region uncertain). The categorization was developed prior to the study and was not specifically targeted to define the type of subtrochanteric fractures recently reported. A total of 140 women had hip fractures, of which 6 were subtrochanteric. In addition, 11 women had femoral shaft fractures. The table shows the distribution of these and femoral shaft fractures by treatment.

Type	All	ZOL	Placebo	RH (95% CI)
All hip fractures	140	52	88	0.59 (0.42, 0.83)
-Subtrochanteric hip	6	3	3	1.0 (0.2, 5.0)
Femoral shaft	11	5	6	0.84 (0.26, 2.75)

Hip fractures classified as subtrochanteric represent about 4.3% of confirmed hip fractures. While the relative hazard for subtrochanteric fractures is 1.0, the confidence interval is wide due to the low numbers. Femoral shaft fractures also did not differ by treatment.

Our analysis is limited by the small number of subtrochanteric fractures, and the short study duration (3 years) as the association may only become evident after longer term treatment. We also did not limit to those with minimal trauma. A further review to more precisely identify fractures similar to those recently reported is underway but will have limited ability to address this question due to low numbers and need to rely on x-ray reports in most cases.

Our results do not suggest an increase in risk in subtrochanteric fracture with 3 years of treatment with ZOL, but they do demonstrate the difficulty of assessing an association with such a rare outcome in a single randomized trial.

## F413

**Intravenous Ibandronate for Prevention of Early Bone Loss after Kidney Transplantation: a Prospective Study.** I. Adamsone<sup>\*1</sup>, D. Babarykin<sup>\*2</sup>, I. Folkmane<sup>\*1</sup>, D. Amerika<sup>\*1</sup>, R. Rozental<sup>\*1</sup>. <sup>1</sup>Department of Transplantation, Riga Stradin's University, Riga, Latvia, <sup>2</sup>Department of Biology, University of Lavia, Riga, Latvia.

After kidney transplantation bone mineral density (BMD) decreases dramatically (mostly during the first 6-12 months after the grafting). This is explained by the relatively high doses of glucocorticoids used immediately after operation, by a preexisting bone abnormalities caused by renal failure and by long-term increase of bone turnover probably due to persisting secondary hyperparathyroidism and calcineurin inhibitor immunosuppression. There is some evidence for a beneficial effect on BMD of antiresorptive treatments after kidney transplantation, but fracture and safety data are scarce.

Thirty eight osteopenic and osteoporotic kidney graft recipients were included in a controlled prospective intervention trial aiming to assess the effect on BMD of a 1-year treatment of quarterly infusions of ibandronate, combined with 1 g calcium and 400 U vitamin D per day. Twenty two patients with good graft function received an injection of 2 mg of ibandronate 3 weeks after transplantation and at 4, 7, and 10 mo after transplantation. Sixteen matched patients received calcium and vitamin D alone and served as controls. Primary outcome was the change in BMD after 12 mo treatment. Secondary measures included clinical fracture rate, change of body height, metabolic data (including iPTH), graft outcome (graft function, acute rejection rate).

Changes of BMD (ibandronate versus controls) were as follows: lumbar spine, +1.5±3.8% versus -2.9±4.3% ( $P<0.01$ ); femoral neck, +0.5±2.7% versus -3.6±4.7% ( $P<0.01$ ); and trochanter, +1.2±3.9% versus -2.5±4.0% ( $P<0.05$ ). There were no clinical fractures in both groups during study. Loss of body height was -1.1±1.6 cm versus -1.4±1.6 cm in control subjects ( $P=NS$ ). Graft function (serum creatinine concentration, proteinuria rate) after 1 yr was comparable. Serum iPTH concentration fell considerably in ibandronate group from 26.2±10.2 pmol/l to 14.3±11.9 pmol/l ( $P<0.05$ ) as well as in control group from 27.2±11.2 pmol/l to 10.8±9.6 pmol/l ( $P<0.01$ ), but changes did not differ ibandronate versus controls. We did not find any difference with regard to acute rejection rate between study groups. Three patients on ibandronate reported muscle pain in temporal relation to ibandronate administration while no such side effect was seen in control group ( $P<0.05$ ).

In conclusion, a 1-year prophylactic treatment with ibandronate given every 3 months to patients with existing osteopenia and osteoporosis immediately after kidney transplantation prevented further bone loss at lumbar spine and proximal femur. There were no negative effects of ibandronate on graft outcomes and bone turnover during study.

**Disclosures:** I. Adamsone, None.

## F416

**Predictors of Patient Perceived Need for Oral Bisphosphonates to Prevent Fracture: the Role of the MD-Patient Relationship.** J. T. Schousboe<sup>1</sup>, B. Dowd<sup>\*2</sup>, M. Davison<sup>\*3</sup>, P. Johnson<sup>\*4</sup>, R. L. Kane<sup>\*2</sup>. <sup>1</sup>Park Nicollet Institute; Division of Health Policy and Management, Univ of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Division of Health Policy and Management, Univ of Minnesota, Minneapolis, MN, USA, <sup>3</sup>Department of Education Psychology, Univ of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Carlson School of Management, Univ of Minnesota, Minneapolis, MN, USA.

**Background:** Perceived need for fracture prevention therapy is a strong predictor of persistence with oral bisphosphonate therapy. Our objective was to assess the association of self-reported medication need with patient-perceived quality of the MD-patient relationship, perceived susceptibility to and severity of fractures, personal and family history of fracture, bone mineral density (BMD), income, educational status, age, and personal & family history of fracture.

**Methods:** 1179 patients prescribed an oral bisphosphonate between 1/1/2006 & 3/31/2007 were mailed a survey to assess attitudes toward osteoporosis & medication to reduce fractures. 686 (58%) returned the survey, had complete data, and had BMD test results in their medical record. Perceived medication need, the MD-patient relationship quality (trust in physician, open communication, decision making congruence), and perceived susceptibility to & severity of fractures were assessed with Likert scales, and BMD by medical record review. The association between medication need & these predictors were assessed with ordinal logit models.

**Results:** The odds ratio for an increase of a defined unit (one quartile) of perceived medication needs for each predictor are shown in the following table.

Predictor	Medication Need, OR (95% C.I.)
MD-Patient Relationship (per SD increase)	1.64 (1.38 - 1.95)
	1 <sup>st</sup> quartile: 1.0 (reference)
	2 <sup>nd</sup> quartile: 1.53 (1.06 - 2.21)
	3 <sup>rd</sup> quartile: 2.01 (1.40 - 2.89)
	4 <sup>th</sup> quartile: 4.66 (3.30 - 6.59)
Perceived Fracture Susceptibility*Severity	
Age (per 10 year increase)	0.79 (0.69 - 0.89)
	High School: 1.0 (reference)
	Some College: 0.72 (0.55 - 1.04)
	College Graduate: 0.65 (0.44 - 0.98)
	> 4 Year College: 0.78 (0.52 - 1.17)
Education Level	
T-Score ≤ -2.5 at spine or femoral neck (vs No)	1.07 (0.81 - 1.42)
Personal History of Fracture (vs None)	1.02 (0.74 - 1.40)
Family History of Spine or Hip Fracture (vs None)	0.99 (0.71 - 1.39)

**Conclusions:** Need for medication to prevent fractures is positively influenced by the quality of the MD-patient relationship, and strongly driven by perceived susceptibility to and severity of fractures. Older patients are less likely to report need for medication, even though they are at higher risk of fractures. BMD level and fracture history are not related to perceived need for medication independent of these other predictors.

## F420

**The Influence of Long-Term Hormone Replacement Therapy on Tibia Bone Mineral Mass and Mass Distribution in Postmenopausal Women.** T. M. Mikkola<sup>\*1</sup>, A. Heinonen<sup>1</sup>, V. Kovanen<sup>\*1</sup>, S. Cheng<sup>1</sup>, U. M. Kujala<sup>\*1</sup>, H. Suominen<sup>1</sup>, M. Alén<sup>\*2</sup>, J. Puolakka<sup>\*3</sup>, P. Ronkainen<sup>\*1</sup>, M. Koskenvuo<sup>\*4</sup>, J. Kaprio<sup>\*4</sup>, T. Rantanen<sup>\*1</sup>, S. Sipilä<sup>\*1</sup>. <sup>1</sup>Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, <sup>2</sup>Department of Medical Rehabilitation, Oulu University Hospital, Oulu, Finland, <sup>3</sup>Central Finland Central Hospital, Jyväskylä, Finland, <sup>4</sup>Department of Public Health, University of Helsinki, Helsinki, Finland.

In this study, case-control co-twin design was used to investigate the association of hormone replacement therapy (HRT) with bone mineral content (BMC), polar BMC distribution and radial volumetric bone mineral density (vBMD) distribution in tibial cross-sections.

Twenty-three (mean 62 years, range 54-72) monozygotic female twin pairs discordant for HRT participated in this study. Peripheral quantitative computed tomography (pQCT) was used to measure BMC, polar BMC distribution and radial vBMD distribution in the cross-section of distal tibia and tibial shaft.

The HRT users and non-users did not differ in body weight or physical activity. Mean duration of use of HRT was 8 years (range 1-25 years). In distal tibia, the HRT users had 10% (95% CI, 4-16%, paired sample t-test  $p=0.002$ ) and in the tibial shaft 11% (5-16%,  $p<0.001$ ) higher BMC than their non-HRT co-twins. The HRT users had significantly higher (4 to 16%) BMC on most of the 5 degree sectors around the center of mass in both distal tibia (Fig 1) and tibial shaft (Fig 2). Also, the HRT users had higher average vBMD throughout the bone from the center of mass to the bone's outer edge in distal tibia ( $p<0.001$  to  $p=0.08$ ) and throughout the cortex in tibial shaft ( $p<0.001$  to  $p=0.05$ ). Long-term HRT results in higher bone mineral mass in both epiphyseal and diaphyseal bone when controlled for genetic and shared childhood sources of variability. The gained BMC is distributed uniformly on the bone's cross-sections.

## F426

**Influence of Body Weight on Cost-Effectiveness of Bone Densitometry and Treatment for Osteoporosis Among Older Women and Men Without Prior Fracture.** J. T. Schousboe<sup>1</sup>, B. C. Taylor<sup>2</sup>, H. A. Fink<sup>2</sup>, R. A. Adler<sup>3</sup>, M. Gourlay<sup>4</sup>, E. S. Orwoll<sup>5</sup>, E. Barrett-Connor<sup>6</sup>, S. R. Cummings<sup>7</sup>, L. J. Melton<sup>8</sup>, K. E. Ensrud<sup>2</sup>. <sup>1</sup>Park Nicollet Clinic, Division of Health Policy and Management, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Minneapolis VAMC, University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>Richmond VAMC, Richmond, VA, USA, <sup>4</sup>University of North Carolina, Chapel Hill, NC, USA, <sup>5</sup>Oregon Health & Science University, Portland, OR, USA, <sup>6</sup>University of California at San Diego, San Diego, CA, USA, <sup>7</sup>San Francisco Coordinating Center, San Francisco, CA, USA, <sup>8</sup>Mayo Clinic, Rochester, MN, USA.

**Background:** Routine DXA bone density screening is recommended for women aged 65 years and older, and by some specialty societies, for all men aged 70 and older. Both self-reported prior fracture and low body weight increase the pre-test probability of osteoporosis on DXA. Our objective was to test for body weight thresholds below which DXA followed by therapy for osteoporosis would be cost-effective for women and men without prior fracture, assuming a societal willingness to pay of \$60,000.

**Methods:** Associations between osteoporosis prevalence and self-reported prior fracture and body weight were estimated for women and men ages 65, 70, 75, 80, and 85 using data from the Study of Osteoporotic Fractures (SOF) and the Study of Osteoporotic Fractures in Men (MrOS). Participants without prior fracture at baseline were studied. Using previously published Markov models with updated (Jan 2008) fracture and treatment costs, we determined threshold body weights at which the cost per QALY gained equaled \$60,000 for DXA followed by five years of oral bisphosphonate therapy (assuming drug cost of \$500 per year) for individuals with gender-specific femoral neck T-score  $\leq -2.5$ . Using NHANES 2005-2006 data, the proportions of women and men at each age below these weight thresholds were calculated.

**Results:** Body weight thresholds below which DXA screening is cost-effective, and proportions of Men and Women Without Prior Fracture with weights below the threshold

Age	Women		Men	
	Body Weight Threshold (lbs)	Proportion	Body Weight Threshold (lbs)	Proportion
65	199.2	72.1%	171.3	22.6%
70	205.9	92.6%	183.6	36.3%
75	224.2	99.4%	204.4	67.0%
80	227.5	99.8%	211.7	92.5%
85	228.7	99.8%	216.4	94.7%

**Conclusion:** Universal bone densitometry is cost-effective for most women age 65 and older, but not for many men without prior fracture included in current osteoporosis screening guidelines. To increase cost-effectiveness, indications for DXA should consider age, prior fracture status, and body weight.

**Disclosures:** J.T. Schousboe, Roche, Inc 2.

## F433

**Cathepsin K Inhibitor, MIV-701, Suppresses Bone Resorption Markers in Healthy PMW: Results of a Phase I Clinical Trial.** D. Böttiger<sup>\*1</sup>, B. Darpo<sup>\*1</sup>, U. Grabowska<sup>\*2</sup>, M. Shiroo<sup>\*2</sup>, T. J. Chambers<sup>3</sup>, B. Samuelsson<sup>\*1</sup>. <sup>1</sup>Medivir AB, Huddinge, Sweden, <sup>2</sup>Medivir AB, Little Chesterford, United Kingdom, <sup>3</sup>St George's, University of London, London, United Kingdom.

Cathepsin K is a lysosomal cysteine protease expressed abundantly in osteoclast cells. Numerous lines of evidence support a pivotal role for cathepsin K in bone degradation and the development of cathepsin K inhibitors is being pursued by many companies. Recently cathepsin K inhibitors have demonstrated efficacy in phase II trials, as measured by increased bone mineral density (BMD), in a dose dependent manner. Studies also show that inhibition of cathepsin K can decrease bone degradation without negatively impacting bone formation, differentiating this osteoporosis treatment from currently available anti-resorptives such as bisphosphonates. A rationale for this augmentation of bone formation may arise from a new mechanism of action wherein cathepsin K inhibitors lead to the intact release of matrix-derived growth factors and/or PTH spikes. This highlights the potential for cathepsin K inhibition as a novel therapeutic approach for bone metabolism diseases such as osteoporosis.

Medivir has now developed a series of novel, highly potent, specific and non-nitrile warhead cathepsin K inhibitors. These inhibitors were additionally selected for their high potency in inhibiting bone resorption by human osteoclasts *in-vitro*. MIV-701 ( $K_i$ : Cath K = 1.7 nM; Cath L, S, B, V & H > 1500 nM; Cath F = 675 nM for the human enzymes) was selected as a candidate drug (CD) for further preclinical and clinical development.

Initially, the pharmacodynamic effect of MIV-701 was evaluated on bone markers of bone resorption, the C-terminal telopeptides of Type I collagen (CTX-I), *in vivo* in young male cynomolgus monkeys. Oral administration of MIV-701 (16 mg/kg) resulted in a rapid reduction in CTX-I levels within 2 h to a maximum of 80 % after 4-8 hours. A multiple dose study, with once daily oral administration of MIV-701, demonstrated a similar reduction of the biomarker where this suppression of CTX-I was reversible, returning to pre-treatment levels within 48 h. This quick onset and offset of suppression of bone resorption may by perturbing PTH levels give an additional advantage over other osteoporosis treatments.

MIV-701 has subsequently progressed into the clinic and in phase I studies, MIV-701 produced a dose-dependent decrease in CTX-I from baseline. In a 14 day multiple dose study in healthy males and postmenopausal women (PMW), MIV-701 was administered once daily, 300 mg, resulting in > 50 % reduction of CTX-I biomarker at trough for both males and PMW.

## F435

**Randomized, Placebo-Controlled, Double Blind Study on High Frequency Low Intensity Vibration in Bone Mass, Muscle Strength and Quality of Life in Children with Motor Disabilities.** M. L. Reyes<sup>1</sup>, J. Holmgren<sup>\*2</sup>, M. Hernandez<sup>\*1</sup>, E. Sanhueza<sup>\*1</sup>, J. Dixon<sup>\*3</sup>, R. Escobar<sup>\*1</sup>. <sup>1</sup>Dep of Pediatrics, Pontificia Universidad Catolica de Chile, Santiago, Chile, <sup>2</sup>Instituto de Rehabilitacion Teleton, Santiago, Chile, <sup>3</sup>Faculty of Electric Engineering, Pontificia Universidad Catolica de Chile, Santiago, Chile.

**Aim:** to determine the efficacy and safety of high frequency low intensity vibration (HFLIV) in children with motor disabilities. A randomized, placebo-controlled, double blind study, factorial design (3 treatment: placebo, 60 Hz and 90 Hz and 2 diagnosis groups: cerebral palsy (CP) and neuromuscular diseases) was conducted. Subject: children 6 to 10 yrs-old, prepubertal, sitting present, IQ > 70, otherwise healthy and with medication rather than calcium and vitamin D. Primary outcome BMD (DXA, Lunar DPX) at radii and FN, secondary outcomes: BMC and bone area; grip strengths, motor function, quality of life (PedsQL), and balance assessment. Intervention: stimulation with a placebo, 60 or 90 Hz device for 5 min on each limb, during 6 mo. All patients kept on regular physiotherapy. Baseline variables were similar between groups. Compliance (number of sessions) was 34.92±32.92%, and did not affect outcomes. No side effects were reported. Percentage of changes in BMD of Radio Ultra distal (RU), Radio 33% (R33), Area-RU and R33 were negatively correlated with initial values ( $p=0.05$ ,  $p=0.0001$ ,  $p=0.0001$  and  $p=0.001$  respectively). In a mixed model the frequency of 60 Hz affected positively the increase in BMD, BMC and area;  $p<0.0001$ ; increase in area was greater in RU ( $p<$

0.0001) and CP group ( $p=0.02$ ); and left side bones showed more increment in BMD ( $p=0.023$ ) and BMC ( $p=0.03$ ). There were no significant effects in FN. There was a positive correlation between most muscle strengths and densitometric variables. In Table are shown significant change percentages in DXA and others important variables.

Item / % of change	Placebo (n=21)	60 Hz (n=20)	90 Hz (n=16)	p
BMD-RU	0.91±5.95	31.88±135.30*	5.20±9.43	0.011
BMC-RU	-0.17±18.21	-0.91±11.78	6.42±14.32*	0.035
BMC-R33	7.33±10.99	11.58±14.78	7.10±8.14	0.060
Motor function (%)	-3.25±4.80	1.41±6.10	1.03±13.78	0.078
Tinetti test (balance)	-0.59±8.59	7.98±11.50	2.92±10.53	0.082
Muscle strength upper limbs	-19.98±49.89	165.27±164.81&	99.27±194.26	0.045
Dairy activities item PedsQL	21.18±72.28	46.52±104.39*	-17.85±51.26	0.046

\*Group 60 Hz ≠ placebo and 90 Hz. # 90 Hz ≠ 60 Hz and placebo. & 60 Hz ≠ placebo.

HFLIV was more effective than physiotherapy alone in improving bone mass, muscle strength in upper limbs. Frequency of 60 Hz is more effective than 90 Hz. Consistent with literature, trabecular bone responds better. Changes in upper limbs make these children more independent as assessed by PedsQL. Due to low cost, efficacy and safety we recommended HFLIV as a part of rehabilitation of these children. This is the first RCT on HFLIV reported in children.

**Deletion of FXR Leads to an Osteopenic Phenotype in Mice.** L. Y. Tang<sup>1</sup>, Y. P. Kharode<sup>1</sup>, C. Milligan<sup>\*1</sup>, J. Pirrello<sup>\*1</sup>, S. Selim<sup>\*1</sup>, M. Sharp<sup>\*1</sup>, J. A. Robinson<sup>\*1</sup>, P. Bodine<sup>1</sup>, D. Harnish<sup>\*2</sup>. <sup>1</sup>Osteoporosis in Women's Health & Musculoskeletal Biology, Wyeth Research, Collegeville, PA, USA, <sup>2</sup>Cardiovascular Metabolic Diseases Research, Wyeth Research, Collegeville, PA, USA.

Farnesoid X receptor (FXR), a member of the nuclear receptor superfamily, plays an important role in many metabolic pathways, including bile acid, lipid, and glucose metabolism via the liver and intestine. FXR is also highly expressed in the kidney and adrenal gland but its physiological or pathological importance in these organs is not understood. Renal gene profiling showed that FXR regulates genes involved in both nitric oxide production and VitD synthesis, two pathways implicated in bone mineral metabolism. This led us to investigate whether FXR signaling plays a role in the bone.

To test the hypothesis, we examined the bone mineral density (BMD) of femurs from FXR<sup>-/-</sup> and WT mice (females and males) at age of 22 weeks by pQCT. Study data showed that deletion of FXR reduced trabecular BMD by 34% ( $p<0.001$ ), cortical BMD by 5% ( $p<0.001$ ), and total BMD by 19% ( $p<0.001$ ) in female mice; and these parameters were reduced by 21% ( $p<0.02$ ), 2% ( $p<0.05$ ), and 10% ( $p<0.01$ ) respectively in male mice. Similar results were observed in FXR<sup>-/-</sup> mice at the age of 28 and 68 weeks. No significant difference in body weight was observed between FXR<sup>-/-</sup> and WT mice. To understand the skeletal change at the histological level, histomorphometric analysis was conducted in distal femoral metaphysis of female FXR<sup>-/-</sup> and WT mice at the age of 22 weeks. A moderate decrease in trabecular bone volume (BV/TV) was observed in FXR<sup>-/-</sup> mice (-27%,  $p=0.07$ ) when compared to the WT mice. Other significant findings in FXR<sup>-/-</sup> mice included increases in eroded surface (ES/BS, +27%,  $p<0.03$ ), bone turnover rate (BFR/BV, +23%,  $p<0.03$ ), bone mineral apposition rate (MAR, +22%,  $p<0.001$ ), and bone formation rate (BFR/BS, +15%,  $p=0.07$ ). No significant change in mineralized surface (MS/BS) was observed.

In summary, deletion of FXR resulted in an osteopenic phenotype in both female and male mice at ages between 22 and 68 weeks. Histomorphometric data suggests that an increase in bone turnover might contribute to the FXR deletion-induced osteopenia in female mice. Our data demonstrated that FXR is involved in bone metabolism. Whether the effect of FXR on bone was direct or indirect are under investigation.

## F444

**Uncarboxylated Osteocalcin is an Endocrine Link between the Skeleton and the Glucose Metabolism: Clinical Evidences from Obese and Post Gastric By-pass Patients.** A. Spagnoli<sup>1</sup>, J. Chen<sup>\*2</sup>, Z. N. Pamuklar<sup>\*2</sup>, F. Granero-Molto<sup>\*1</sup>, A. Torquati<sup>\*2</sup>. <sup>1</sup>Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, <sup>2</sup>Surgery, Duke University, Durham, NC, USA.

There is an increasing body of knowledge indicating that hormones that regulate fat/glucose metabolism have effects on the skeleton and vice-versa. Most recently, Karsenty's group reported that in mice, increased levels of uncarboxylated osteocalcin (uOST) protect from type 2 diabetes regulating adiponectin secretion, while lack of osteocalcin leads to insulin resistance (Lee NG et al, Cell 2007,130:458). In obese patients with diabetes, gastric bypass surgery (GBS) through unknown mechanisms, leads to ~90% resolution of type 2 diabetes before any significant weight loss occurs. Study is designed to determine: 1) uOST levels in obese patients with and without diabetes; 2) the effect of GBS on uOST; 3) the relationship of uOST with adiponectin and in turn with insulin sensitivity. We studied: 40 obese patients (BMI: 48.5±9.7 kg/m<sup>2</sup>) of which 19 had type 2 diabetes, 12 patients that had GBS 12-24 months prior to the study (post-GBS) (BMI: 29±7 kg/m<sup>2</sup>); 16 normal weight age-matched control subjects (BMI: 25±3.3 kg/m<sup>2</sup>). We evaluated fasting glucose and insulin to determine HOMA, serum total and uncarboxylated osteocalcin,

serum HMW-adiponectin by RIA or IRMA. Data are expressed as mean±SD; statistical significance is set at  $P<0.05$ . As shown in Fig. 1A, we found that uOST levels were significantly lower in obese patients with or without diabetes compared to controls, and significantly increased and normalized post-GBS. Similar results were found for HMW-adiponectin levels (Fig. 1B). GBS also normalized levels of total osteocalcin that were significantly lower than controls in obese patients with or without diabetes ( $p=0.001$ , ANOVA). When all patients were analyzed, an inverse correlation was found between uOST and HMW-adiponectin ( $r=-0.28$   $p=0.02$ ), between uOST and HOMA ( $r=-0.33$   $p=0.006$ ) and between HMW-adiponectin and HOMA ( $r=-0.32$   $p=0.008$ ). This is the first report that in obese patients, uOST levels are decreased and, normalize post-GBS. Our data provide the first clinical evidence to support the hypothesis that uOST is a bone hormone that regulates insulin sensitivity by modulating adiponectin. We postulate that normalization of uOST is a mechanism for diabetes resolution post-GBS.

## F452

**Osteoblast-targeted Deletion of the Glucocorticoid Receptor has Little Impact on Peak Bone Mass but Attenuates Dexamethasone-induced Suppression of Bone Formation.** P. J. Bernard<sup>1</sup>, K. Ding<sup>\*2</sup>, C. Isaacs<sup>2</sup>, M. Hamrick<sup>3</sup>, L. J. Muglia<sup>\*4</sup>, S. L. Teitelbaum<sup>5</sup>. <sup>1</sup>Pediatrics, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Orthopedics, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Cell Biology and Anatomy, Medical College of Georgia, Augusta, GA, USA, <sup>4</sup>Pediatrics, Washington University, St Louis, MO, USA, <sup>5</sup>Pathology, Washington University, St Louis, MO, USA.

The pathogenesis of glucocorticoid (GC) induced osteoporosis (GIOP) is unclear. Knowing that GCs signal through the glucocorticoid receptor (GR), we generated an osteoblast specific GR knockout to define the direct effects of GCs on bone forming cells. GR was inactivated through Cre recombinase (Cre)-mediated excision of exons 1C and 2 of the GR gene. This modification deletes 50% of the mature GR protein, encompassing the translation start site and the taur1 transactivation domain, and has previously been shown to effectively disrupt GR action. Osteoblast and osteoblast precursor specific inactivation of GR was accomplished through Dermo1 promoter driven Cre expression, creating an osteoblast specific GR knockout (OB-GRKO). Once generated, 4 month old male OB-GRKO mice and control (Cre negative) littermates were randomized to receive a 14 day trial of either daily dexamethasone (Dex) (10 mg/kg) or saline IP injections. At trial completion, serum was assayed for markers of bone formation, and bones were harvested for histomorphometric, densitometric, and biomechanical analysis. In control mice, Dex exposure significantly decreased osteocalcin levels by 79% ( $p<0.001$ ,  $n=10$ ) and alkaline phosphatase levels by 30% ( $p<0.05$ ,  $n=10$ ). However, Dex treatment of OB-GRKO mice had no significant effect ( $p>0.05$ ,  $n=10$ ) on these markers. Interestingly, osteocalcin levels were 3.5 fold greater in Dex treated OB-GRKO mice than in Dex treated controls ( $p<0.05$ ,  $n=10$ ). Bone histomorphometry showed that Dex treated control mice experienced a downward, but not significant trend in mineral apposition rate (MAR) of 53% ( $p=0.07$ ,  $n=10$ ) and a significant decrease in bone formation rate/bone surface (BFR) of 80% ( $p<0.05$ ,  $n=10$ ), but Dex treated OB-GRKO mice did not. Analysis of femurs removed from untreated 4 month old (normal peak bone mass) OB-GRKO mice and control mice by PIXImus densitometry and Instron biomechanics did not reveal any significant differences. Our findings indicate disruption of GR signaling in the osteoblast reduces Dex's inhibition of bone formation at pharmacologic dosages, but does not cause abnormal bone growth when GCs are at physiologic levels. Complementing previous work that demonstrated osteoclast GR signaling modulates bone formation, we have shown that osteoblast GR signaling also plays an important role in the Dex-induced suppression of bone formation.

## F455

**Circulating DKK-1 Levels Are Reduced in Young Subjects with Low Bone Mass.** V. De Paola, L. Gennari, D. Merlotti, G. Martini, A. Avanzati\*, B. Franci\*, S. Campagna\*, B. Luciani\*, R. Nuti. Internal Medicine, Endocrine-Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy.

Primary osteoporosis predominantly affects postmenopausal women and elderly men. However, low bone mineral density also occurs in middle-aged men and premenopausal women. Even though the pathogenesis of low bone mass in these individuals may be heterogeneous, several results suggest that a low bone turnover with a possible osteoblast dysfunction may be responsible of these forms of osteoporosis in both sexes. DKK-1 is an inhibitor of the Wnt/ $\beta$ -catenin signaling pathway, which is a critical signaling pathway for osteoblast differentiation. It has been recently shown that DKK-1 protein levels are detectable in the serum and elevation in DKK1 levels have been associated with decreased osteoblastic bone formation occurring in multiple myeloma or, in vitro, during glucocorticoid treatment. In order to better characterize the structural and metabolic basis of reduced bone mass in young adults, we measured circulating DKK-1 levels (DKK-1 enzyme immunoassay, Biomedica, Wien) in adult men (n=50, mean age 46.5 $\pm$ 9.6) and premenopausal women (n=23, mean age 43.4 $\pm$ 7.1) with low bone density, in subjects with senile or postmenopausal osteoporosis (n= 60, mean age 65.3 $\pm$ 8.8) as well as in young (n= 40, mean age 45.4 $\pm$ 8.2) and elderly (n= 50, mean age 68.3 $\pm$ 10.1) controls with normal bone density. The lower limit of detection was 0.38 pmol/l. The intra-assay and inter-assay coefficients of variation were 5.7% and 9.2%, respectively. All samples were run in duplicate. In controls, DKK-1 levels decreased significantly with age ( $r = -0.42$ ;  $p < 0.05$ ), and this decrease was higher in males than in females. Moreover, in normal subjects circulating DKK-1 were positively correlated with parathyroid hormone ( $r = 0.39$ ;  $p < 0.05$ ) in both sexes and negatively correlated with bone alkaline phosphatase in women ( $r = -0.30$ ;  $p < 0.05$ ). Interestingly, an unexpected decreased concentration of DKK-1 was observed in the group of premenopausal women and young adult men with low bone density with respect to age- and sex-matched controls (17.9 $\pm$ 8.9 vs. 42.9 $\pm$ 8.1;  $p < 0.001$ ), as well as to older controls (17.9 $\pm$ 8.9 vs. 35.4 $\pm$ 12.2;  $p < 0.001$ ). No statistically significant differences in DKK-1 were observed between elderly osteoporotic and non osteoporotic subjects. Longitudinal analysis in 34 of the 60 subjects showed a significant 33% decrease in DKK-1 levels during bisphosphonate treatment. In conclusion adult males aged 50 yrs or less and premenopausal females with low bone mass show an unexpected decrease in circulating DKK-1 levels, likely representing an homeostatic counteracting mechanism to limit the reduction in osteoblast activity.

**Disclosures:** V. De Paola, None.

## F458

**Low systemic BMD Increases Implant Migration in Cementless Hip Replacement.** H. T. Aro\*, N. Moritz\*, T. J. Mäkinen\*, J. J. Alm\*, P. Lankinen\*. <sup>1</sup>Department of Orthopaedic Surgery, Turku University Central Hospital, Turku, Finland, <sup>2</sup>Orthopaedic Research Unit, University of Turku, Turku, Finland.

Initial implant stability is critical in cementless total hip arthroplasty (THA). Although the surgical technique was originally developed only for patients with normal bone quality, many postmenopausal patients undergoing the procedure have been found to have unrecognized osteoporosis. We assumed that osteoporotic women might exhibit more marked femoral stem migration than those with normal bone density after cementless THA. Thirty-nine female patients with an average age 64 years (range, 41-78 years) underwent cementless THA (ABG II, Stryker) with hydroxyapatite-coated anatomically designed femoral stem equipped with tantalum markers for radiostereometric analysis. All patients had primary hip osteoarthritis and fulfilled other strict inclusion criteria (no inflammatory arthritis, no history of metabolic bone disease or any treatments with corticosteroids, bisphosphonates or calcitonin). The patients had a Type A (n=21) or Type B (n=18) bone quality according to the Dorr classification. On preoperative DXA screening (both hips, lumbar spine and distal non-dominant forearm), BMD was normal in 11 patients (28%), osteopenia was found in 22 patients (56%) and osteoporosis in 6 patients (15%). Fifteen patients (39%) had D-vitamin deficiency (S-25(OH)D < 50 nmol/l). According to the prevailing clinical practice, the patients were instructed to partial weight-bearing for a period of 6 weeks, followed by full weight-bearing as tolerated. RSA examinations were performed after surgery (within 3-7 days) and repeated at 3, 6 and 12 months. Three-dimensional migration of the femoral stem was calculated in relation to the postoperative examination. Radiostereometric analysis revealed only minor stem migration, but the degree of axial stem migration at 12 months was significantly related to the preoperative systemic BMD ( $R^2 = 0.191$ ,  $p = 0.005$ ). Axial stem migration (mean  $\pm$  SD) was  $-0.52 \pm 0.58$  mm in patients with normal BMD,  $-1.12 \pm 1.01$  mm in osteopenic patients and  $-2.09 \pm 1.37$  mm in osteoporotic patients. This study gave a proof of radiostereometric analysis that low systemic BMD may adversely affect initial stability of cementless THA. Although evidence of implant settling was observed in the majority of patients within 3 months and there has been no loosening of the implants within a 2-year follow-up, the results urge to evaluate long-term clinical consequences of increased initial migration and the efficacy of osteoporosis treatment as an intervention.

**Diffuse Osteopenia After Tibia Fracture: Benefits of Early Mobilization and Weight Bearing.** R. Zhao<sup>1</sup>, T. Z. Guo<sup>1</sup>, I. Sabsovich<sup>1</sup>, L. Wang<sup>1</sup>, T. Wei<sup>1</sup>, W. S. Kingery<sup>2</sup>. <sup>1</sup>PM&R Service (117), VAPAHCS, Palo Alto, CA, USA, <sup>2</sup>PM&R Service (117), VAPAHCS, Palo Alto, CA, and Orthopedic Surgery, Stanford University, Stanford, CA, USA.

After tibia fracture in man there is accelerated trabecular bone loss in the proximal and distal tibia and femur, peaking at 5 months post-fracture and persisting indefinitely. There is also bone loss in the spine and contralateral leg. The etiology of fracture-induced osteopenia is unknown. It has been proposed that early weight bearing may reduce this bone loss, but there is little clinical evidence supporting this hypothesis. In the current study we used microCT scanning to examine the effects of mobilization and weight bearing on bone loss induced by tibia fracture in 9-month-old rats. Fracture rats treated by 4 weeks cast immobilization (FX + cast) developed trabecular bone loss in the lumbar and thoracic spine, bilateral distal femurs, and right proximal humerus, but had no effect on cortical bone. Fracture rats treated by intramedullary nailing and casting (FX + nail + cast) for 4 weeks exhibited a similar pattern of bone loss. Fracture rats treated by intramedullary nailing alone (FX + nail) failed to develop any trabecular bone loss. Control rats that were not fractured but underwent hindlimb cast immobilization for 4 weeks (cast) developed the same pattern of trabecular bone loss as did the FX + cast treated rats. There were minimal differences between groups in serum chemistries or nutritional status. Neither chronic propranolol treatment or capsaicin lesioning of the sensory nerves had any effect on fracture-induced bone loss. Histomorphometric analysis demonstrated a reduction in bone volume and BFR with increased osteoclastogenesis and resorption activity in the FX + nail + cast and cast only groups, effects that were not observed in the FX + nail group. Collectively, these data indicate that immobilization after fracture caused increased bone resorption and decreased bone formation, leading to diffuse osteopenia. Early mobilization prevented bone loss in the tibia fracture rat model and may have similar beneficial effects in man.

**Vitamin D Deficiency, Osteomalacia and High Bone Turnover in Patients with Neurofibromatosis 1.** S. Seitz\*, C. Schnabel\*, H. Schmidt\*, F. T. Beil\*, V. F. Mautner\*, M. Amling<sup>1</sup>. <sup>1</sup>Center for Biomechanics, Experimental Trauma Surgery & Skeletal Biology, Hamburg, Germany, <sup>2</sup>Department of Clinical Chemistry, University Medical Center Hamburg Eppendorf, Hamburg, Germany, <sup>3</sup>Center of Orthopedics Wandsbek, Hamburg, Germany, <sup>4</sup>Department of Maxillofacial Surgery, University Medical Center Hamburg Eppendorf, Hamburg, Germany.

Neurofibromatosis 1 (NF-1) is a severe inherited disease with a wide range of clinical manifestations, including decreased bone mineral density. Although it is known, that patients with NF-1 suffer from vitamin D deficiency, which might be associated with skeletal mineralization defects, histologic and histomorphometric analysis in these patients is rare. Thus, we performed a detailed clinical evaluation including DEXA osteodensitometry and laboratory parameters, as well as a histomorphometric evaluation on non-decalcified sections of iliac crest biopsies from 14 patients that were set in direct comparison to biopsies from age- and sex-matched control individuals. Patients with NF-1 had significantly lower 25-(OH)-cholecalciferol serum levels, accompanied by secondary hyperparathyroidism and decreased bone mineral density. Histomorphometric analysis revealed a decreased bone volume and trabecular thickness in NF-1 patients, as well as a more than 3-fold increase in osteoid volume (OV/BV,  $0.96 \pm 0.77$  % vs.  $3.68 \pm 2.20$  %). Moreover, both osteoblast (NOB/BPm,  $2.17 \pm 0.69$  mm<sup>3</sup> vs.  $0.50 \pm 0.26$  mm<sup>3</sup>) and osteoclast (NOC/BPm,  $0.23 \pm 0.13$  mm<sup>-1</sup> vs.  $0.02 \pm 0.02$  mm<sup>-1</sup>) numbers were about 4-fold 10-fold increased respectively, indicating a high bone turnover. To analyze, whether normalization of vitamin D serum levels can improve the clinical outcome of the patients, we re-evaluated them by DEXA osteodensitometry and serum analysis after one year of treatment with 25-(OH)-cholecalciferol. Here we observed a normalization of serum PTH levels and a significant improvement in bone mineral density, indicated by an increase of T-Scores up to one standard deviation at the lumbar spine and hip. Taken together, our data provide the first complete histomorphometric analysis of non-decalcified biopsies from NF-1 patients. Moreover, they suggest that low Vitamin D levels significantly contribute to the skeletal defects associated with the disease.

**Rare Cases of X-linked Hypophosphatemic Rickets/Osteomalacia Mimicking Autosomal Recessive Hypophosphatemic Rickets/Osteomalacia.** T. Saito\*, H. Suzuki\*, N. Ito\*, T. Igarashi\*, T. Fujita\*, S. Fukumoto\*. <sup>1</sup>Department of Pediatrics, University of Tokyo Hospital, Tokyo, Japan, <sup>2</sup>Division of Nephrology & Endocrinology, Department of Medicine, University of Tokyo Hospital, Tokyo, Japan.

X-linked hypophosphatemic rickets/osteomalacia (XLH), autosomal dominant hypophosphatemic rickets/osteomalacia (ADHR) and autosomal recessive hypophosphatemic rickets/osteomalacia (ARHR) share common clinical features such as

impaired proximal tubular phosphate reabsorption and rather low serum 1,25-dihydroxyvitamin D for hypophosphatemia. Excess actions of fibroblast growth factor (FGF)23 are believed to have important roles in the development of these diseases. The responsible genes for XLH, ADHR and ARHR are *phosphate-regulating gene with homologies to endopeptidases on the X chromosome (PHEX)*, *FGF23* and *dentine matrix protein 1 (DMP1)*, respectively. However, it remains unclear whether these diseases can be clinically distinguished. The proband is a 39-year-old sister and her 37-year-old brother shows the same clinical features. They developed bowing legs and the treatment with vitamin D metabolites started with the diagnosis of hypophosphatemic rickets. When they came to our attention, they were hypophosphatemic (sister: P 1.8 mg/dL, brother: P 1.6 mg/dL) with high FGF23 levels (sister: 542 pg/mL, brother: 96 pg/mL). Because their parents are clinically normal without any features of rickets/osteomalacia, we presumed that they have ARHR. However, sequencing analysis of all the coding exons of *DMP1* and *FGF23* gene in these patients showed no mutation. Analysis of *PHEX* gene in the sister showed no point mutation, either. In contrast, exons 1 to 3 of *PHEX* gene could not be amplified using genomic DNA from the brother. Subsequent analysis revealed that there is deletion of 52,143 bp including exons 1 to 3 in *PHEX* gene of the brother. His sister was found to be a heterozygote for the same deletion indicating that they are suffering from XLH. The same deletion was detected in genomic DNA from the mother. Comparison of wild-type and mutant *PHEX* alleles by semi-quantitative PCR indicated that there is more wild-type allele and less mutant one in genomic DNA from the mother compared to that from the sister. These results suggested that the mother is a somatic mosaicism. Actually, she was found to be a heterozygote for one single nucleotide polymorphism situated in the deleted region of *PHEX* gene indicating she has two wild-type alleles. These results indicate that genetic analyses are essential for correct diagnosis of hypophosphatemic diseases caused by excess actions of FGF23.

**The Human SLC34A3/NaPi-IIc Mutations T137M and L527del Uncouple Sodium-phosphate Co-transport.** C. Bergwitz<sup>1</sup>, G. Jaureguiberry<sup>1</sup>, B. Kremke<sup>\*2</sup>, K. Page<sup>\*3</sup>, O. Hion<sup>\*2</sup>, T. Carpenter<sup>4</sup>, K. Inosona<sup>3</sup>, S. Forman<sup>\*5</sup>, H. Jüppner<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Pädiatrische Endokrinologie und Diabetologie, Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Lübeck, Germany, <sup>3</sup>Endocrine Unit, Yale School of Medicine, New Haven, CT, USA, <sup>4</sup>Dept. of Pediatrics and Endocrine Unit, Yale School of Medicine, New Haven, CT, USA, <sup>5</sup>Dept. Anesthesiology, Massachusetts General Hospital, Boston, MA, USA.

We recently reported homozygous and compound heterozygous loss-of-function mutations in SLC34A3/NaPi-IIc as the cause for hereditary hypophosphatemic rickets with hypercalciuria (HHRH). To understand whether some of the point mutations reported by us and others (T137M, S138F, S192L, G196R, R468W, L527del, R353L, D237N and A413E) lead to renal phosphate wasting by reducing membrane expression, we generated expression plasmids encoding enhanced green-fluorescence protein (EGFP) concatenated to the N-terminus of wild-type or mutant human NaPi-IIc (EGFP-wt/NaPi-IIc or EGFP-mut/NaPi-IIc) to visualize membrane expression using confocal microscopy. Upon transient expression in Opossum kidney cells, G196R and R468W were not detected in apical patches (the renal brush border membrane equivalent of this cell line), nor were these mutants present in the plasma membranes of *Xenopus* oocytes following cRNA injection (50 ng/oocyte). For S138F, S192L, R353L, D237N and A413E oocyte membrane fluorescence was reduced to <20% compared to EGFP-wt/NaPi-IIc, as quantified by confocal microscopy. The T137M and L527del mutants were expressed in both kidney cells and oocytes, and sodium-dependent [33P]-uptake into oocytes corrected for surface expression was preserved. When further investigated, the Na:P-stoichiometry of simultaneous [33P]- and [22Na]-uptake was increased from 2.3±0.4 in wild-type to 7.1±3.6 and 23±13 for T137M and L527del, respectively. Two-electrode studies indicated that EGFP-mut/NaPi-IIc carrying these mutations remains non-electrogenic, like wild-type NaPi-IIc, but displayed a significant phosphate-independent inward-rectified sodium-leak current which appears to be insensitive to phosphonoformic acid (PFA), a known inhibitor of sodium-dependent phosphate co-transport. T137M and L527del may thus reduce the rate of phosphate uptake by uncoupling sodium-phosphate co-transport, suggesting that these amino acid residues have an important functional role in human NaPi-IIc. Interestingly, heterozygous carriers of T137M, L527del, and S138F presented with recurrent kidney stones and clinical characterization of additional heterozygous carriers may help to elucidate further the distinctive genotype-phenotype relations for these NaPi-IIc mutations.

**The Synergistic Role of Npt2a and Npt2c in Inorganic Phosphate Metabolism of Mice.** H. Segawa<sup>\*1</sup>, A. Onitsuka<sup>\*1</sup>, Y. Tomoe<sup>\*1</sup>, J. Furutani<sup>\*1</sup>, I. Kaneko<sup>\*1</sup>, F. Aranami<sup>\*1</sup>, S. Kuwahara<sup>\*1</sup>, M. Li<sup>\*2</sup>, N. Amizuka<sup>2</sup>, M. Matsumoto<sup>\*3</sup>, M. Ito<sup>\*1</sup>, K. Miyamoto<sup>1</sup>. <sup>1</sup>Deptment of Molecular Nutrition, Institution of Health Biosciences, University of Tokushima Graduate School, Tokushima, Japan, <sup>2</sup>Center for Transdisciplinary Research, Niigata University, Niigata, Japan, <sup>3</sup>Division of Molecular Immunology, Institute for Enzyme Research, University of Tokushima, Tokushima, Japan.

Primary loss of inorganic phosphate (Pi) from the kidneys results in hypophosphatemia, the severity of which is directly related to the degree of secondary bone mineralization defects. While the renal type IIa sodium-dependent Pi co-transporters (NPT2a/Npt2a) play a major role in renal Pi reabsorption, Npt2a null mice (Npt2a<sup>-/-</sup>) do not exhibit rickets/osteomalacia. Type IIc sodium-dependent Pi co-transporter (NPT2c/Npt2c) is the pathogenic protein involved in hereditary hypophosphatemic rickets with hypercalciuria (HHRH). However, Npt2c null mice exhibit hypercalcemia, hypercalciuria, elevation of plasma 1,25(OH)<sub>2</sub>D<sub>3</sub> levels, and reduction of plasma fibroblast growth factor 23 (FGF23) levels, but not hypophosphatemia, hyperphosphaturia, rickets, or osteomalacia. The goal of the present study was to characterize the role of renal Pi wasting in bone disorders by studying Npt2a/Npt2c double knock-out mice (WKO mice). WKO mice showed severe hypophosphatemia, hypercalcemia, expansion of the late hypertrophic zone of the epiphyseal plate, and markedly-reduced bone mineralization (characteristics of rickets), which is the phenotype associated with HHRH. Na-dependent Pi transport activity was significantly decreased in WKO mice when compared with other mice groups. Urinary Pi and calcium excretion were further increased in the WKO mice when compared with Npt2a<sup>-/-</sup> mice (Npt2a<sup>-/-</sup>, Npt2c<sup>+/+</sup>). Severe hypophosphatemia in WKO mice may be secondary to impaired bone mineralization. In conclusion, maintenance of plasma Pi levels via Npt2a and Npt2c may be necessary for normal skeletal development in rodents.

**Co-Expression of p62<sup>P392L</sup> and MVNP in Osteoclasts (OCL) Precursors Increases the Formation of OCL that Express a Pagetic Phenotype.** Y. Hiruma<sup>1</sup>, N. Kurihara<sup>1</sup>, H. Zhou<sup>2</sup>, M. A. Subler<sup>\*3</sup>, D. W. Dempster<sup>2</sup>, J. J. Windle<sup>3</sup>, G. D. Roodman<sup>4</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>3</sup>Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, <sup>4</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Both environmental and genetic abnormalities contribute to the development of Paget Disease (PD). We recently reported that expression of measles virus nucleocapsid protein (MVNP) in OCL in mice induces pagetic-like OCL (hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub>, hypermultinucleated, increased bone resorbing capacity/OCL) and PD-like bone lesions in 30% of mice, while expression of the p62<sup>P392L</sup> mutation, the most frequent mutation linked to PD, increases RANKL responsiveness in OCL precursors but does not induce PD in vivo. It is our hypothesis that both MVNP and p62<sup>P392L</sup> are necessary for development of PD in patients. We used the TRAP promoter to examine the effects of targeted co-expression of the MVNP gene and p62<sup>P392L</sup> in OCL precursors on the development of PD-like OCL, and their capacity to induce high levels of IL-6 as found in PD by breeding TRAP-p62<sup>P392L</sup> mice with TRAP-MVNP mice. Wild-type (WT) and TRAP-p62<sup>P392L</sup> transgenic mice were not hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub>. However, OCL precursors from both TRAP-MVNP and the double transgenic TRAPp62<sup>P392L</sup>/TRAP-MVNP mice were hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub>, and the levels of OCL formation were increased in the doubly-transgenic mice. As anticipated, TRAP-p62<sup>P392L</sup>/TRAP-MVNP-doubly-transgenic mice but not WT or TRAP-MVNP mice were hyper-responsive to RANKL. OCL formed in marrow cultures derived from both the TRAP-MVNP and the doubly-transgenic mice produced high levels of IL-6 when treated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> and secreted elevated levels of IL-6 even in the absence of 1,25-(OH)<sub>2</sub>D<sub>3</sub>. In contrast, OCL precursors from TRAP-p62<sup>P392L</sup> mice did not produce increased levels of IL-6. The doubly transgenic OCL precursors appeared to secrete more IL-6 than TRAP-MVNP mice. OCL formed in vitro in marrow cultures from TRAP-MVNP/TRAP-p62<sup>P392L</sup> doubly-transgenic mice were markedly increased in size and number and have increased numbers of nuclei per OCL. These results suggest that co-expression of p62<sup>P392L</sup> with MVNP in OCL precursors should create a more robust PD phenotype in OCL in vivo.

**High Levels of IL-6 and Hyper-responsivity to 1,25-(OH)<sub>2</sub>D<sub>3</sub> Are Both Required for Development of Pagetic Osteoclasts (PD-OCL).** Y. Hiruma<sup>1</sup>, N. Kurihara<sup>1</sup>, H. Zhou<sup>2</sup>, M. A. Subler<sup>\*3</sup>, D. W. Dempster<sup>2</sup>, J. J. Windle<sup>3</sup>, G. D. Roodman<sup>4</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>3</sup>Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, <sup>4</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Our most recent studies show that measles virus nucleocapsid protein (MVNP) can induce development of PD-OCL and pagetic lesions in vivo. MVNP induces both hyper-responsivity of OCL precursors to 1,25-(OH)<sub>2</sub>D<sub>3</sub> through increased expression of a novel VDR co-activator, TAF<sub>II</sub>-17, and high levels of IL-6 in the local bone microenvironment. Our hypothesis is that high levels of IL-6 and hyper-responsivity to 1,25-(OH)<sub>2</sub>D<sub>3</sub> are both required for development of PD-OCL. To test this hypothesis, TRAP-MVNP mice, which have MVNP targeted to the OCL lineage using the TRAP promoter and develop pagetic-like bone lesions, were mated with IL-6<sup>-/-</sup> mice to generate TRAP-MVNP/IL-6<sup>-/-</sup> mice. TRAP-TAF<sub>II</sub>-17 mice were generated to induce OCL that were hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub>. TRAP-MVNP, TRAP-MVNP/IL-6<sup>-/-</sup> and TRAP-TAF<sub>II</sub>-17 mice were then tested for their capacity to form OCL that express a pagetic phenotype in vitro. OCL precursors from TRAP-MVNP and TAF<sub>II</sub>-17 but not TRAP-MVNP/IL-6<sup>-/-</sup> mice were hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub> even though OCL precursors from MVNP/IL-6<sup>-/-</sup> mice still expressed increased levels of TAF<sub>II</sub>-17 when treated with 1,25-(OH)<sub>2</sub>D<sub>3</sub>. As expected, OCL formation in marrow cultures from both TRAP-MVNP/IL-6<sup>-/-</sup> mice, TRAP-MVNP and WT mice showed similar responses to RANKL. High levels of IL-6 were produced by OCL from TRAP-MVNP, and not by WT or TRAP-TAF<sub>II</sub>-17 mice. OCL precursors from TRAP-MVNP and TRAP-TAF<sub>II</sub>-17 mice also showed increased 24(OH)-ase activity compared to WT mice when treated with low concentrations (10<sup>-11</sup>M) of 1,25-(OH)<sub>2</sub>D<sub>3</sub>. Although OCL precursors from TRAP-TAF<sub>II</sub>-17 were hyper-responsive to 1,25-(OH)<sub>2</sub>D<sub>3</sub> and formed increased OCL numbers, they did not form PD-OCL (hyper-multinucleated, increased bone resorption capacity). In contrast, addition of high levels of IL-6 enhanced OCL formation in marrow cultures from TRAP-TAF<sub>II</sub>-17 mice, and the OCLs that formed expressed a pagetic phenotype. These data suggest that expression of TAF<sub>II</sub>-17 in the presence of IL-6 is required for hypersensitivity of OCL precursors to 1,25-(OH)<sub>2</sub>D<sub>3</sub> and that high levels of IL-6 combined with hypersensitivity of OCL precursors to 1,25-(OH)<sub>2</sub>D<sub>3</sub> may be sufficient to induce PD-OCL and pagetic bone lesions in vivo.

**FGF-2 Stimulates RANK Ligand Expression in Paget's Disease of Bone.** K. Sundaram<sup>1</sup>, J. Senn<sup>\*2</sup>, D. S. Rao<sup>3</sup>, S. V. Reddy<sup>1</sup>. <sup>1</sup>Charles P. Darby Children's Research Institute, Medical University of South Carolina, Charleston, SC, USA, <sup>2</sup>Bristol Myers Squibb Pharmaceuticals, Syracuse, NY, USA, <sup>3</sup>Henry Ford Hospital, Detroit, MI, USA.

RANK ligand (RANKL), a critical osteoclastogenic factor expressed in marrow stromal/preosteoblast cells is upregulated in Paget's disease of bone (PDB). We previously demonstrated that heat shock factor-2 (HSF-2) is a downstream target of fibroblast growth factor-2 (FGF-2) signaling to induce RANKL expression in bone marrow stromal/preosteoblast cells. In this study, we identified a 2.5-fold increase in serum FGF-2 levels in patients (n=8) with PDB compared to normal subjects (n=10). We showed that HSF-2 co-immunoprecipitates with heat shock protein-27 (HSP-27) and that FGF-2 stimulation significantly increased phospho-HSP-27 levels in marrow stromal cells. Confocal microscopy demonstrated HSF-2 co-localization with HSP-27 in unstimulated cells. Recent evidence indicates suppressors of cytokine signaling (SOCS) interact with and modulate FGF signaling. We therefore hypothesized that FGF-2 modulates SOCS levels to enhance RANKL expression in PDB. Interestingly, real-time PCR analysis demonstrated a significant increase in the levels of SOCS-1 (3.4-fold) and SOCS-3 (3.5-fold) mRNA expression in pagetic bone marrow mononuclear cells. Also, FGF-2 stimulation enhanced SOCS-1 and SOCS-3 mRNA expression 5.3 and 4.8-fold in stromal/preosteoblast cells respectively. We next examined if SOCS plays a role in FGF-2 signaling to modulate RANKL expression in PDB. Co-expression of SOCS-1/3 with hRANKL gene promoter-luciferase reporter plasmid in bone marrow stromal cells demonstrated a 3.0-fold increase in promoter activity without FGF-2 stimulation. Since signal transducers and activators of transcription (STAT) molecules are implicated in growth factor signaling and SOCS expression, we further examined participation of STAT in FGF signaling to enhance RANKL expression in marrow stromal/preosteoblast cells. FGF-2 stimulation significantly increased the levels of p-STAT-1/3 in these cells. Western blot analysis demonstrated that siRNA suppression of STAT-1/3 decreased (3.2-fold) RANKL expression in FGF-2 stimulated cells. Also, FGF-2 stimulated hRANKL gene promoter activity was significantly decreased by siRNA suppression of STAT-1/3. These results suggest STAT-1/3 are downstream effectors of FGF-2 signaling and that elevated levels of FGF-2 stimulates RANKL expression in PDB.

**A New Long-Acting PTH/PTHrP Hybrid Analog that Binds to a Distinct PTHR Conformation has Superior Efficacy in a Rat Model of Hypoparathyroidism.** M. Shimizu<sup>\*1</sup>, F. Ichikawa<sup>\*1</sup>, H. Noda<sup>\*1</sup>, M. Okazaki<sup>1</sup>, C. Nakagawa<sup>\*1</sup>, T. Tamura<sup>\*1</sup>, T. J. Gardella<sup>2</sup>, J. T. Potts<sup>2</sup>, E. Ogata<sup>3</sup>, O. Kuromaru<sup>\*1</sup>, Y. Kawabe<sup>\*1</sup>. <sup>1</sup>Pharmaceutical Research Dept.1, Chugai Pharmaceutical Co., LTD., Gotemba, Shizuoka, Japan, <sup>2</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>3</sup>Cancer Institute Hospital, Tokyo, Japan.

Conventional therapy for hypoparathyroidism (HPT) with vitamin D analogs and calcium (Ca) is often accompanied by hypercalciuria. PTH(1-34) has been used as an alternative option, but it requires frequent injections. Thus, a long-acting PTH analog that can normalize serum Ca (sCa) levels via once-daily injection would provide more convenient and efficacious therapy for HPT than PTH. We previously reported that the modified analog, M-PTH(1-28) (M = Ala1,12,Aib3,Gln10,Har11,Trp14,Arg19) binds with greater affinity to the G-protein-uncoupled receptor conformation (R<sup>1</sup>), and produces more prolonged calcemic responses in mice than does PTH(1-34). In the present study, we evaluated a new R<sup>1</sup>-selective analog, [Ala1,3,12,Gln10,Arg11,Trp14]-PTH(1-14)/PTHrP(15-36), termed super-potent PTH, or SP-PTH, that shows even longer calcemic actions in rats than does M-PTH(1-28), as a candidate treatment for HPT. Upon single injection (i.v.) into thyroparathyroidectomized (TPTX) rats, PTH(1-34) control, at a dose-range of 1.25 - 20 nmol/kg, transiently increased sCa and decreased serum phosphorus (sPi) levels at 1 hr, but not to the normal range, as levels returned to pre-injection conditions by 6 hrs. In contrast, SP-PTH, at doses of 1.25 and 5 nmol/kg, increased sCa and decreased sPi to normal levels within 6 hrs, and these levels were maintained for 24 hrs. Blood concentrations of SP-PTH and PTH(1-34) were similar at times after injection, suggesting similar PK profiles for the two peptides. The effectiveness of SP-PTH in TPTX rats was then examined by repeated treatment. Animals were treated once-daily and for 2 weeks with either SP-PTH, via s.c. injection over a dose-range of 1 to 8 nmol/kg, or 1α(OH) vitamin D<sub>3</sub>, via oral administration over a dose-range of 0.075 to 0.2 μg/kg. Both 1α(OH) vitamin D<sub>3</sub> and SP-PTH normalized sCa in dose-dependent fashion; but, where 1α(OH) vitamin D<sub>3</sub> induced hypercalciuria, SP-PTH decreased urinary Ca excretion. Both agents ameliorated hyperphosphatemia and increased urinary phosphorus excretion. Neither SP-PTH at 1 to 4 nmol/kg, nor 1α(OH) vitamin D<sub>3</sub> caused significant increases in serum CTX or urinary DPD levels after 2-weeks of treatment. The results indicate that SP-PTH can normalize hypocalcemia in TPTX rats without causing hypercalciuria and excessive bone resorption over a certain dose range, and therefore the peptide would be a convenient and efficacious treatment option for HPT with little risk of renal complications.

**PTH Increases Bone Turnover in Hypoparathyroidism.** M. R. Rubin<sup>1</sup>, S. Cremers<sup>1</sup>, D. W. Dempster<sup>2</sup>, J. Sliney<sup>\*1</sup>, D. J. McMahon<sup>1</sup>, H. Zhou<sup>2</sup>, T. Nickolas<sup>\*1</sup>, E. M. Stein<sup>1</sup>, J. P. Bilezikian<sup>1</sup>. <sup>1</sup>Columbia University, New York, NY, USA, <sup>2</sup>Helen Hayes Hospital, New York, NY, USA.

Hypoparathyroidism (HypoPT) is a disorder in which PTH is absent from the circulation. In addition to the biochemical manifestations of hypocalcemia and relative hypercalciuria, bone turnover is low. We sought to quantify bone turnover in HypoPT and to determine whether low bone turnover can be enhanced by PTH. We measured biochemical markers of bone turnover in 12 HypoPT subjects (8 women; 53 ± 9 yr) at baseline, and at monthly intervals during treatment with 100 μg of hPTH(1-84)[PTH] every other day for 2 yrs. Correlations with histomorphometric indices of bone turnover were assessed from measurements of iliac crest bone biopsy samples obtained before (n=10) and after 1 (n=3) or 2 (n=7) yrs of PTH treatment. Biochemical markers of bone turnover, measured thrice at baseline, were in the lower half of the normal reference ranges. With PTH, bone turnover markers increased significantly, peaking at 5-9 months, but fell to baseline levels by 2 yrs. Bone formation markers peaked at 6 mos with PINP (+211% from baseline to maximum level; 52 ± 127 to 162 ± 122 ng/ml; nl: 16-96); and OC (+235% from baseline to maximum level; 14 ± 41 to 47 ± 40 ng/ml; nl: 11-38); followed at 9 mos by BSAP (+47% from baseline to maximum level; 34 ± 26 to 51 ± 25 U/l; nl: 12-43). Bone resorption markers peaked at 5 mos with TRAP-5b (+84% from baseline to maximum level; 3.2 ± 3 to 6.0 ± 3 U/l; nl: 1.8-4.0); followed at 6 mos by s-CTX (+190% from baseline to maximum level; 0.4 ± 1 to 1.1 ± 1 ng/ml; nl: 0.11-1.35). Increases in bone turnover markers predicted increases in dynamic histomorphometric indices of bone remodeling: PINP predicted bone formation rate at 1 yr (R<sup>2</sup>=0.9, slope=0.01 ± 0.1, p=0.002) and at 2 yrs (R<sup>2</sup>=0.9, slope=0.01 ± 0.1, p<0.0001), osteoid perimeter at 1 yr (R<sup>2</sup>=0.9, slope=0.05 ± 0.1, p<0.0001) and mineralized perimeter at 2 yrs (R<sup>2</sup>=0.9, slope=0.04 ± 0.1, p<0.0001); BSAP predicted mineralized perimeter at 1 yr (R<sup>2</sup>=0.9, slope=0.17 ± 0.1, p<0.0001) and mineral apposition rate at 1 yr (R<sup>2</sup>=0.9, slope=0.01 ± 0.1, p=0.02); TRAP-5b predicted osteoid thickness at 1 yr (R<sup>2</sup>=0.5, slope=0.62 ± 0.2, p=0.02); s-CTX predicted mineral apposition rate at 1 yr (R<sup>2</sup>=0.9, slope=0.25 ± 0.1, p=0.04). We conclude that bone turnover is low in a state of chronic PTH deprivation and that the administration of PTH increases bone turnover in the hypoparathyroid skeleton. The dynamic changes occur within the first year of therapy, with all biochemical markers of bone remodeling returning to baseline levels by 2 yrs. Whether these changes lead to long term effects on skeletal dynamics and bone strength remains to be seen.

**Recovery from Hepatitis C-Associated Osteosclerosis (HCAO) Following Anti-viral Treatment.** R. Javier<sup>\*1</sup>, M. de Vernejoul<sup>2</sup>, N. Afif<sup>\*1</sup>, F. Habersetzer<sup>\*3</sup>, J. Kuntz<sup>\*1</sup>, J. Sibilia<sup>\*1</sup>. <sup>1</sup>Rheumatology, University Hospital, Strasbourg, France, <sup>2</sup>Inserm U606, Paris, France, <sup>3</sup>Hepatology, University Hospital, Strasbourg, France.

HCAO is characterized by a generalized increase in bone mass with a marked cortical thickening and deep bone pain and tenderness of the limbs in adults infected with hepatitis C virus (HVC). However, the pathogenesis remains imperfectly known as no direct relationship between HVC and osteosclerosis has yet been described. The purpose of this case report is to demonstrate clinically the causal relationship between HVC and bone. Case report: A 67 year-old nun was hospitalized in 1991 for ill-defined pain of the lower limbs. Compared to the normal X-rays of 1987, her radiographs revealed condensation (opacities) of all vertebrae, and thickening of femoral cortices. DEXA revealed a T-score of +7.62 at the Lumbar Spine (LS). Biochemical analysis showed: hypocalcemia 1.99 mmol/l (2.20-2.70), normal phosphorus 1.24 mmol/l and 25(OH) D 41.3 µg/l (6-30), increased PTH 177 pg/ml (10-60), increased alkaline phosphatase ALP 716 IU/l (N : 80-220), elevated γ-GT 93 U/l (11-85) with normal transaminases and negative hepatitis B, C and A serology. Undecalcified bone biopsy revealed woven bone in the trabeculae, associated with intra-cortical hyperostoidosis but with a normal mineralization rate (0.78µm/d). However, osteomalacia was evoked and vitamin D and calcium treatment was initiated. In 2000, radiographs showed an enhanced osteosclerosis, with clear thickening of cortical bones. Biochemical evaluation indicated: normal calcium, phosphorus, ALP, PTH and 25(OH) D and increased transaminases (ALAT 59 U/l and ASAT 68 U/l), positive HVC serology, weak viremia (0.28 x 105 virus particles/ml) with no co-infection with HIV. Hepatic biopsy revealed lesions of moderately active and fibrosing chronic hepatitis (Metavir index: A2 F2; Knodell score: 12). The bone marrow biopsy showed normal polymorphous marrow. DXA revealed a T-score: + 5.53 at the LS and + 15.9 at the femoral neck (FN). HCAO was diagnosed and a six-month treatment with ribavirin and interferon was undertaken, resulting in the absence of all detectable RNA following one month treatment. In June 2007, while HVC remained undetectable and transaminases normal, X-rays showed weakening of the sclerosis of the vertebrae and reduction of the width of femoral cortices. A dramatic decrease in BMD was noticed: T-score: + 0.5 at the LS and + 4.03 at the FN. Serum bone markers were in the normal range. In conclusion, we report here the first case of HCAO recovery after anti-viral treatment with clear decline in BMD and decreased trabecular and cortical radiological condensation in the absence of any specific bone treatment. This case straighten the relationship between HVC and bone sclerosis

**Increased Proinflammatory Cytokines TNF-α and IL-6 Correlate with Pathological Bone Turnover Markers in Diabetic Patients with Acute Charcot Foot.** C. Moniz<sup>1</sup>, N. Petrova<sup>\*2</sup>, R. Musto<sup>\*1</sup>, S. Thomson<sup>\*1</sup>, T. Dew<sup>\*1</sup>, M. Edmonds<sup>\*2</sup>. <sup>1</sup>Clinical Biochemistry, Kings College Hospital, UK, United Kingdom, <sup>2</sup>Diabetes Foot Clinic, Kings College Hospital, UK, United Kingdom.

The Charcot foot is characterised by acute inflammation but its role in the pathogenesis is poorly understood. This study shows that the proinflammatory cytokines, tumour necrosis factor-α (TNF-α) and interleukin-6 (IL-6), as well as high sensitive C-reactive protein (hsCRP) - an acute phase protein, are raised in acute Charcot osteoarthropathy and are significantly associated with serum C-telopeptide of type I collagen (CTX), a marker of bone resorption. We studied 3 groups of patients: 27 presenting with acute Charcot osteoarthropathy; 14 with chronic Charcot osteoarthropathy and 24 diabetic control patients. In acute Charcot patients, there was a significant increase in the serum levels of IL-6 (3.84 ± 3.55 pg/ml) compared with chronic Charcot patients (1.73 ± 1.23 pg/ml) and diabetic controls (1.86 ± 1.52 pg/ml), p=0.025. Furthermore, there was a significant rise in serum TNF-α in acute Charcot patients (1.74 ± 0.94 pg/ml) compared with chronic Charcot patients (1.25 ± 0.38) and diabetic control patients (1.12 ± 0.38 pg/ml), p=0.008. Similarly, serum levels of hsCRP were significantly increased in acute Charcot patients (10.1 ± 13.4 mg/L) compared with chronic Charcot patients (2.6 ± 2.2 mg/L) and diabetic control patients (4.8 ± 4.3 mg/L), p=0.013. Serum CTX, a breakdown product of type I collagen, was significantly raised in patients with acute Charcot foot (0.409 ± 0.395 ng/ml), compared with patients with chronic Charcot foot (0.095 ± 0.042 ng/ml) and diabetic patients (0.107 ± 0.68 ng/ml), p=0.001. Serum bone specific alkaline phosphatase (BAP), a marker of bone formation, was also significantly raised in acute Charcot patients (18.5 ± 9.2 µg/L) compared with chronic Charcot patients (12.7 ± 4.42 µg/L) and diabetic controls (14.7 ± 5.13 µg/L), p=0.041. Serum osteoprotegerin (OPG), a cytokine that modulates bone resorption and osteoclastic activity, was significantly raised in acute Charcot patients (5.52 ± 1.74 pmol/L) compared with chronic Charcot patients (4.86 ± 1.42 pmol/L) and diabetic patients (4.37 ± 1.38 pmol/L), p=0.048. Serum IL-6 (r=0.472, p<0.001) and TNF-α levels (r=0.556, p<0.001) were significantly associated with serum CTX. Similarly, serum hsCRP levels were significantly correlated with serum CTX (r=0.561, p<0.001). This study indicates that inflammation, as reflected by the proinflammatory markers TNF-α and IL-6, and hsCRP plays an important role in the pathological bone resorption of the acute Charcot foot.

**Premature Aging-Like Phenotypes in Metastasis-Associated Protein 1 (Mta1) Null Mice.** S. Takiguchi<sup>\*1</sup>, M. Yaguchi<sup>\*2</sup>, K. Ogawa<sup>\*2</sup>, Y. Wada<sup>\*2</sup>, K. Matsusue<sup>\*3</sup>, T. Ito<sup>\*4</sup>, H. Hamamoto<sup>\*4</sup>, N. Akimitsu<sup>\*4</sup>, K. Sekimizu<sup>\*4</sup>, Y. Toh<sup>\*1</sup>, H. Iguchi<sup>\*5</sup>. <sup>1</sup>National Kyushu Cancer Center, Fukuoka, Japan, <sup>2</sup>Graduate School of Pharmaceutical Sciences, Kyushu University, Fukuoka, Japan, <sup>3</sup>Faculty of Pharmaceutical Sciences, Fukuoka University, Fukuoka, Japan, <sup>4</sup>Graduate School of Pharmaceutical Sciences, University of Tokyo, Tokyo, Japan, <sup>5</sup>National Shikoku Cancer Center, Matsuyama, Japan.

The metastasis-associated gene 1 (mta1) was identified initially in rat highly metastatic cancer cell lines. The expression level of human MTA1 correlates with the metastatic potential of several human cancer cell lines and tissues. MTA1 is a component of the nucleosome remodeling and deacetylation complex (NuRD), which is associated with adenosine triphosphate (ATP)-dependent chromatin remodeling and transcriptional regulation. MTA1 also interacts with estrogen receptor alpha (ER) and represses ER transcription by recruiting histone deacetylase (HDAC) to estrogen response element (ERE)-containing target gene chromatin. To study the biological effect of Mta1, we generated mice with a null mutation in the Mta1 gene. The birth rate of Mta1-deficient (Mta1KO) mice was lower and the mice were smaller than wild-type (WT) mice. Mta1KO mice had a short life span (ca. 70% of WT) and showed numerous features consistent with premature aging-like phenotypes, including lordokyphosis, muscle wasting, osteoporosis, cataract, low fertility and atrophy of the skin, testis, ovary, liver and adrenal. To examine the type of osteoporosis, computerized tomography (CT) scanning and histomorphometric analysis were performed. The density of cortical bone and substantia spongiosa from Mta1KO mice was reduced to 40-80% of that from age-matched WT mice by CT scanning. The osteoblastic and osteoclastic surface, and the number of multinuclear osteoclasts from Mta1KO mice were considerably decreased compared with that from WT mice by histomorphometric analysis. These results suggest that osteoporosis seen in Mta1KO mice is low-turnover type, which is consistent with senile osteoporosis. Mta1KO ES cells showed aberrant expression of several genes, including estrogen-regulated genes, compared to WT ES cells at the mRNA level by DNA microarray analysis. Mouse embryonic fibroblasts (MEF) from Mta1KO mice showed greater acceleration of replicative senescence than WT MEF. Several tissues from Mta1KO mice showed a higher expression of CDK inhibitors (p16INK4a, Arf, p15INK4b, p21CIP), biomarkers of aging, than tissues from WT mice at the mRNA level by real-time PCR. In conclusion, Mta1KO mice are a novel model of premature aging with aberrant estrogen-regulated pathways.

**In utero Stem Cell Therapy as Treatment for Classical Osteogenesis Imperfecta Using the Knock In Murine Model BrtlIV.** C. Panaroni<sup>\*1</sup>, R. Gioia<sup>\*1</sup>, A. Lupi<sup>\*1</sup>, A. Farina<sup>\*2</sup>, M. Casasco<sup>\*2</sup>, E. Perilli<sup>\*3</sup>, F. Baruffaldi<sup>\*1</sup>, G. Cetta<sup>\*1</sup>, S. A. Goldstein<sup>\*4</sup>, J. Kreider<sup>\*4</sup>, I. Villa<sup>\*5</sup>, A. Rossi<sup>\*1</sup>, J. C. Marini<sup>\*6</sup>, A. Frattini<sup>\*7</sup>, P. Vezzoni<sup>\*8</sup>, A. Forlino<sup>\*1</sup>. <sup>1</sup>Department of Biochemistry, University of Pavia, Pavia, Italy, <sup>2</sup>Department of Experimental Medicine, University of Pavia, Pavia, Italy, <sup>3</sup>Laboratorio di Tecnologia Medica, Istituti Ortopedici Rizzoli, Bologna, Italy, <sup>4</sup>Orthopaedic Research Laboratories, University of Michigan, Ann Arbor, MI, USA, <sup>5</sup>Bone Metabolic Unit, San Raffaele Scientific Institute, Milan, Italy, <sup>6</sup>BEMB, NICHD, NIH, Bethesda, MD, USA, <sup>7</sup>Istituto Clinico Humanitas, Rozzano, Milano, Italy, <sup>8</sup>Istituto Clinico Rozzano, Milan, Italy.

Classical Osteogenesis Imperfecta (OI) is a genetic bone disorder characterized by skeletal fragility and deformity and caused by mutations in the type I collagen genes. BrtlIV is a knock-in murine model for OI which carries the typical glycine substitution and whose phenotype models the moderately severe Type IV OI. We developed a cell therapy treatment which employs *in utero* transplantation to avoid marrow ablation for this metabolic inborn disorder. The bone marrow cells were isolated from long bones of eGFP-CD1 mice and injected into the liver of E14.5 BrtlIV and WT embryos. Mice were analyzed at 2 m, the age corresponding to the severest BrtlIV bone phenotype compared to WT. Engraftment with a characteristic patchy distribution was detected in various tissues at sacrifice by inverted microscopy. Confocal microscopy was used to directly quantify the engraftment in long bone diaphysis (3.82 ± 5.00%). The percentage of donor cells was determined by FACS, in both bone marrow (F 1.3 ± 1.8, n=18; M 0.47 ± 0.33, n=15) and spleen (F 1.48 ± 1.88, n=18; M 1.16 ± 0.83, n=16) and by Real Time PCR in different tissues. The femur length was increased in transplanted mutant mice (p<0.005). PQCT of the distal femoral metaphysis revealed increased total bone and trabecular density in treated versus untreated mutant mice. Micro CT analysis of Brtl mid-shaft femur detected improvement in Total Mineral Content, Cortical Thickness and Cortical Area. Biomechanical studies are ongoing. The analysis of the treated mice suggested that *in utero* cell therapy is a promising treatment for classical OI in spite of a relatively low engraftment.

**Odanacatib Increases Bone Strength and Maintains Bone Quality in Estrogen Deficient Adult Rhesus Monkeys.** K. R. Scott<sup>1</sup>, B. Pennypacker<sup>1</sup>, R. Samadfan<sup>2</sup>, S. Y. Smith<sup>\*2</sup>, D. B. Kimmel<sup>1</sup>. <sup>1</sup>Molecular Endocrinology, Merck, West Point, PA, USA, <sup>2</sup>Montreal Preclinical Services, Charles River, Montreal, QC, Canada.

Odanacatib (ODN) is a selective inhibitor of Cathepsin K (CatK) in large animals and humans. Though CatK inhibition is a promising mechanism to treat osteoporosis, more bone strength/quality data in the adult skeleton during longer treatment are needed. Rhesus monkeys (aged 13-19yrs) were ovariectomized (OVX) and given ODN (0 [N=11], 6 [N=8], or 30 [N=10] mg/kg (qd, PO)) for 21 months. Quarterly bone mineral density (BMD) measurements of spine (LV), femoral neck (FN), and total hip (H) was done. At necropsy, LV4-6 and the right femur were frozen.

The mid-point of the femur (CF) was tested in three-point bending. The femoral neck (FN) was tested in shearing. The fourth vertebral body (L4) was trimmed of endplates/processes and tested in compression. Load-deformation curves were used to calculate Ultimate Load (F.U, N), Stiffness (N/mm), Toughness (N-mm) and Ductility (mm). Peripheral quantitative computed tomography (pQCT) was done (CF and L4) to derive BMC and architectural endpoints at the site of failure.

**Results:** Baseline LVBMD differed little among the groups. Final LVBMD was 11% and 17% higher; HBMD was 10% and 16% higher and FNBMD was 11% and 12% higher than OVX+0, in the ODN groups.

CFCTh was higher (16%), as were CFFU (25-32%) and CFStiffness (23-33%) with ODN than OVX+0. FNFU was 17-19% higher and L4FU was 18% higher with ODN. Toughness and ductility (L4 only), did not differ among groups. CFFU and CFStiff correlated to CFBMC ( $r=0.95$ ;  $P<0.0001$  and  $r=0.82$ ;  $P<0.0001$ ;  $N=28$ ). LV4FU and LV4Stiff correlated to LV4BMC ( $r=0.79$ ;  $P<0.0001$  and  $r=0.46$ ;  $P<0.02$ ;  $N=27$ ). CFFU and CFStiff correlated to CFCTh ( $r=0.70$ ;  $P<0.0001$  and  $r=0.46$ ;  $P<0.02$ ;  $N=28$ ).

**Summary:** ODN-treated adult non-human primates have higher bone mass in sites of osteoporotic fracture in humans. ODN-treated animals have greater bone strength and stiffness in the central femur and trends toward better bone strength at the femoral neck and spine. The relationship of bone mass to bone strength, toughness and brittleness are normal. ODN increases bone mass and strength, while maintaining normal bone quality in adult non-human primates.

Endpoint/Group	OVX+0 (N=11)	OVX+6mg/kg ODN (N=8)	OVX+30mg/kg ODN (N=9)	ANOV A (P=)
CFCTh (mm)	1.82±0.26	2.10±0.14*	2.12±0.226**	0.022

## F516

**Disuse with a Rapid Bone Loss Affects the Expression Profile of Osteoblastic and Resorption Genes.** M. Le Drévo<sup>\*</sup>, H. Libouban<sup>\*</sup>, D. Chappard. Faculty of Medicine, INSERM U922, Angers, France.

Prolongated disuse reproduces the effects of microgravity and induces a rapid bone loss due to reduced strains. It increases the risk of irreversible damage to the skeleton. Disuse of one extremity can be induced in different ways (denervation, spinal section, tenotomy...) leading to a permanent immobilization and inducing a rapid bone loss. Nonsurgical methods (casting, bandaging, tail suspension or Botulinum toxin (BTX) injection) have become more popular. Decrease in the formation rate and increase in resorption rate have been simultaneously advocated. The aim of the present study was to elucidate the molecular events that occur in the microenvironment of immobilized bone. A single BTX injection in the quadriceps was used to induce paralysis of the right hindlimb in Swiss-Webster mice; saline injection in the left side was used as control. Bone marrows from the left and right femurs were extracted after euthanasia at 0, 7, 14, 21 and 28 days post- BTX. RNAs were extracted to perform qPCR analyses. Bone loss was measured by microCT on the tibia upper extremity. On the right side, 3D measurements showed a significant decrease in bone volume as from 7 days (-31%) associated with microarchitectural changes that intensified in time (-45.9% at 21 days). However, no significant differences in cortical thickness were observed. Expression of bone formation factors was significantly reduced as from 7 days and maintained until 28 days post-BTX; among them LRP5/6, Osteopontin, TGF- $\beta$ , Oncostatin and Runx2. At the opposite, the expression of IL-1 $\beta$ , an indicator of bone resorption, was increased as from 14 days. In conclusion, a localized disuse induces rapid modifications in the gene expression profile in the bone microenvironment leading to an early decrease of bone formation factors and an increase in bone resorption.

**The Short-Term Deleterious Skeletal Response to Hindlimb Suspension Involves Multi-Faceted Compromises in Cells of the Osteogenic Lineage.** K. M. Nicks<sup>1</sup>, T. B. Palculict<sup>\*1</sup>, N. S. Ake<sup>1\*</sup>, P. M. Savage<sup>\*1</sup>, E. E. Dupont-Versteegden<sup>\*2</sup>, L. J. Suva<sup>1</sup>, D. Gaddy<sup>1</sup>. <sup>1</sup>Physiology and Biophysics & Orthopaedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>2</sup>Rehabilitation Sciences, University of Kentucky, Lexington, KY, USA.

It is well established that musculoskeletal disuse leads to a significant loss of skeletal mass and strength in the load-bearing bones of both young and old animals and humans. Using evidence obtained from a rodent model of hindlimb suspension (HS), it has been concluded that a major component of disuse-associated bone loss is related to a decrease in bone formation. Prior studies have shown that these deleterious skeletal changes can be partly attributed to decreases in proliferation and differentiation of osteoblast (OB) progenitors. We previously demonstrated that there is an increase in adipogenesis (AD) that is associated with decreases in osteoblastogenesis after 2 weeks of HS. In this study, the time course required for this HS-induced mesenchymal marrow cell fate switch was investigated. Six month old Fisher 344/Brown-Norway male rats were subjected to HS for 24, 48 or 96 hrs. At the time of sacrifice, bone marrow cultures from femurs were established to determine the capacity of cells to be recruited into the OB/AD lineage (as determined by AP+ CFU-F), or to undergo mature OB mineralization (as determined by CFU-OB). AD cultures were initiated using insulin/hydrocortisone/IBMX (IHI) adipogenic cocktail (as measured by Oil Red O+ CFU-AD). Cell recruitment into the OB lineage (AP+ CFU-F) was unaffected within 96h of HS. However, a reciprocal increase in IHI-induced CFU-AD and decrease in CFU-OB was observed in cultures from 48-96h HS rats. This decreased OB cell fate *in vitro* was associated with compromises in both OB number and activity *in vivo*. As expected, there were no significant differences in BV/TV. However, by 48h, a significant decrease was observed in the mineralizing surface (sLPM/BPM) as measured by calcein labeling injected 48h prior to sacrifice. Dynamic changes in OB number on the bone surface at the time of sacrifice via proliferation or cell death was measured by PCNA staining and BrDU incorporation, or TdT-FragEL staining respectively. OB proliferation decreased at 24h, whereas OB apoptosis increased by 96h. Wnt pathway-specific microarrays were performed on whole femoral RNA. Wnt10b and Wnt3a were suppressed by 48h of HS, consistent with early changes in Wnt signaling leading to the mesenchymal switch from OB to AD development in response to short-term HS. Collectively, these data demonstrate that there is a rapid skeletal response to HS that involves multi-faceted compromises in proliferation, differentiation, activity and survival of cells in the osteoblastic lineage.

**Load induced Changes in Trabecular and Cortical Bone are Dose Dependent in Both C57BL/6 and C3H/Hej Mice.** D. J. Webster<sup>\*1</sup>, E. Wasserman<sup>\*1</sup>, F. Weber<sup>\*2</sup>, I. Bab<sup>3</sup>, R. Mueller<sup>1</sup>. <sup>1</sup>Institute for Biomechanics, ETH Zurich Switzerland, Zurich, Switzerland, <sup>2</sup>University of Zurich, Dept. Cranio-maxillofacial Surgery, Zurich, Switzerland, <sup>3</sup>Hebrew University of Jerusalem, Bone Laboratory, Jerusalem, Israel.

Most in vivo studies addressing the skeletal responses of mice to mechanical loading have targeted cortical bone. To investigate trabecular bone responses we have developed a caudal vertebrae axial compression device (CVAD) that transmits mechanical loads to compress the fifth caudal vertebrae (C5) via stainless steel pins inserted into C4 and C6. Here we used the CVAD in C57BL/6 (B6) and C3H/Hej (C3H) mice to investigate dose-related responses of several morphometric parameters to regular bouts of mechanical stimulation. Three weeks after pinning, the 15wk-old mice were divided into 4 loading groups (N=10) for each strain, namely 0N (sham loading), 2N, 4N and 8N. Loading was applied using an acute regime of 3000 cycles at 10 Hz, 3 times weekly. The mice were sacrificed after 4-weeks of loading. Newly formed bone was double labeled with calcein administered i.p. 4 days and 1 day prior to sacrifice. Structural and functional parameters were affected only by the 8N load. Quantitative  $\mu$ CT analysis of the trabecular compartment revealed 25.9% and 14.2% increases in bone volume density in the B6 and C3H mice, respectively ( $p < 0.05$ ). In the B6 animals this increase was accompanied by 21.9% augmentation ( $p < 0.001$ ) of trabecular thickness. Histomorphometry showed respective 89.8% and 163% increases in the mineralizing perimeter (Min.Peri) ( $p < 0.05$ ), and bone formation rate (BFR) ( $p < 0.05$ ) in B6 mice and 48% ( $p < 0.05$ ) and 110% ( $p < 0.05$ ) in C3H mice. The trabecular osteoclast number was reduced by 51.7% and 77.7% in the B6 ( $p < 0.05$ ) and C3H ( $p < 0.05$ ) mice, respectively. The B6 mice showed also a nearly significant ( $P = 0.06$ ) 11% increase in cortical bone volume together with load-induced increases of 371.25% (periosteal) and 76.81% (endosteal) BFR (both at  $p < 0.05$ ). The C3H mice showed no significant cortical structural changes. However, their periosteal and endosteal BFR exhibited 371.25% and 76.81% increases, respectively. These findings demonstrate that cortical and particularly trabecular bone are mechano-sensitive in both strains in a dose dependent manner, especially in the B6 mice. The caudal vertebral loading model established here is proposed for further studies addressing load-induced changes in gene expression in both cortical and trabecular bone in addition to the effect of genetic manipulations on the response of these skeletal components to mechanical loading.

## F536

**Mediation of Bone Loss with Ultrasound Induced Dynamic Mechanical Signals in an OVX Rat Model of Osteopenia.** S. Ferreri<sup>\*1</sup>, R. J. Talish<sup>\*2</sup>, T. Trandafir<sup>\*2</sup>, Y. Qin<sup>1</sup>. <sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, <sup>2</sup>Juvent Inc., Sommerset, NJ, USA.

This study tests the hypothesis that an ultrasound generated dynamic mechanical signal can inhibit bone loss in an estrogen deficient model of osteopenia. 72, 16 w.o. Sprague-Dawley rats were divided into six groups; baseline control, age-matched control, OVX control, OVX + 5 mW/cm<sup>2</sup> ultrasound (US), OVX + 30 mW/cm<sup>2</sup> US and OVX + 100 mW/cm<sup>2</sup> US. Low intensity pulsed ultrasound (LIPUS) was delivered transdermally at the L4/L5 vertebrae, using gel-coupled plane wave US transducers (Exogen, Inc.). The signal, characterized by 200 $\mu$ s pulses of 1.5 MHz sine waves repeating at 1 kHz with intensities of 5, 30 or 100mW/cm<sup>2</sup>, was applied 20 min/day, 5 days/week for 4 weeks. A 1.5 mm thick, anterior RIO containing cancellous bone, from the center of the US radiated area was imaged using  $\mu$ CT at 15  $\mu$ m and evaluated for bone volume fraction (BVf), structural model index (SMI), trabecular number (Tb.N.) and trabecular thickness (Tb.Th.). Specimen specific, voxel based, finite element (FE) models ( $E=18\text{GPa}$  &  $\nu=0.3$ ), were generated using  $\mu$ CT image data and 1% axial compressive strain was simulated using a nonlinear FE solver (ABAQUS). OVX treatment reduced BVf and compromised microstructure at 4 weeks post surgery. LIPUS treatment, however, significantly increased BVf compared to OVX controls for the 100mW/cm<sup>2</sup> treated group. Additionally, SMI, and Tb.N showed significant improvements compared with OVX for the 100mW/cm<sup>2</sup> treated group and Tb.Th was significantly improved in the 30 and 100mW/cm<sup>2</sup> treated groups. Interestingly, the 100mW/cm<sup>2</sup> treated groups showed a significant improvement over the 5mW/cm<sup>2</sup> treated group in terms of BVf, SMI and Tb.N. Improvements in bone's microstructure with 100mW/cm<sup>2</sup> US translated into significant improvements in apparent Elastic Modulus. Mean principal compressive stress demonstrated a non-significant increasing trend for the 100mW/cm<sup>2</sup> treated group, however, significant differences were observed for the same group among peak principal compressive stresses associated with the 75<sup>th</sup> percentile. These findings support the hypothesis that LIPUS can inhibit bone loss and preserve bone strength under conditions of estrogen deficient osteopenia. This study also suggests that there exists a minimum intensity threshold below which LIPUS is less effective at maintaining bone's microstructural and mechanical characteristics.

**Peak Bone Mass Is Determined at 1 Year-Old: Evidence from Growth Charts.** S. Cheng<sup>1</sup>, Q. Wang<sup>2</sup>, A. Lyytikäinen<sup>1</sup>, L. Xu<sup>1</sup>, F. Tylavsky<sup>3</sup>, E. Seeman<sup>2</sup>, M. Alen<sup>\*1</sup>. <sup>1</sup>Health Sciences, University of Jyväskylä, Jyväskylä, Finland, <sup>2</sup>Endocrine Centre, Austin Health, University of Melbourne, Melbourne, Australia, <sup>3</sup>Preventive Medicine, University of Tennessee, Memphis, TN, USA.

A low peak bone mass (PBM) is likely to be a risk factor for fractures in adulthood. We hypothesized that the variance in bone size and mass originates in early life and that traits track in their percentile of origin. We tested this hypothesis in 150 girls aged 18.4 (17-20) yrs, their mothers (46  $\pm$  5 yr) and fathers (50  $\pm$  6 yr). Crown-heel length (CHL) of the girls at birth, 1-, 5-, 10- 14- and 18-yrs of age was documented at birth and from growth charts while DXA was used to measure bone mass (BMC) at maturity. Gestational age, CHL and weight at birth did not correlate with BMC at 18yr. However, CHL at age 1-yr and later predicted current BMC ( $r = 0.51 - 0.58$ ) as well as height at 18 yrs did ( $r = 0.59$ ) (Fisher's z-transformation, Fig). The tracking of the ratio CHL/height in it's percentile of origin was established at 1-yr of age ( $r = 0.77-0.60$ ) and remained significant after controlling for current height (partial  $r=0.21-0.25$ ,  $p < 0.05$ ). Body weight at 1yr and later also predict current BMC ( $r = r = 0.50$ ) but current weight predicted BMC more strongly ( $r = 0.79$ , Fig).

Fathers and mothers' BMC correlated with their daughters' BMC at maturity ( $r = 0.32$  and  $0.43$ , respectively,  $p < 0.01$ ) before but not after controlling for the daughter's body length or weight at 1yr. We infer the percentile or origin of a girl's PBM in the population distribution is established as early as 1 year-old and tracks during the next two decades. Hence PBM is determined early in life, whether this has a genetic basis or is the result of intra-uterine or postnatal environmental factors is yet to be determined.

**Late Pregnancy Serum Vitamin D and Longitudinal Bone Loss During Pregnancy: The Southampton Womens Survey.** M. Javai<sup>1</sup>, I. Reading<sup>\*1</sup>, N. Harvey<sup>1</sup>, P. Taylor<sup>\*2</sup>, R. Swaminathan<sup>\*3</sup>, N. Arden<sup>1</sup>, K. Godfrey<sup>\*1</sup>, C. Cooper<sup>1</sup>.

<sup>1</sup>MRC Epidemiology Resource Centre, Southampton, United Kingdom, <sup>2</sup>Southampton University Hospitals NHS Trust, Southampton, United Kingdom, <sup>3</sup>St Thomas' Hospital, London, United Kingdom.

**Purpose:** Previously, we described a seasonality in bone loss during pregnancy. We now compare bone loss, as measured by quantitative ultrasound, with late pregnancy maternal concentrations of serum 25(OH) vitamin D (25OHD).

**Methods:** We analysed a sample of term pregnancies using an established cohort of women living in Southampton, UK. During early (11 wk) and late (34 wk) pregnancy, speed of sound (SOS) and bone ultrasound attenuation (BUA) were measured at the left calcaneus using a Hologic Sahara Quantitative Ultrasound device. Late pregnancy serum 25OHD was measured using Diasorin RIA. Linear regression models for SD change in QUS were adjusted for change in ankle width, BMI and vitamin D supplement use.

**Relationship between late pregnancy serum maternal 25(OH) vitamin D concentration and SD change in calcaneal QUS during pregnancy**

Legend: Unadjusted Mean (95% CI) shown; P values from regression models adjusted change in calcaneal width, late pregnancy adiposity, as measured by mid upper arm circumference, and vitamin D supplement use

**Results:** 416 women had paired QUS during pregnancy and serum 25OHD recorded in late pregnancy. A third of women had 25OHD  $\leq 50$  nmol/l and 4.6%  $\leq 25$  nmol/l 25OHD. 23% of mothers were taking vitamin D supplements and had significantly higher 25OHD concentrations (88.6 nmol/l) than non-supplement users (61.3 nmol/l). Season of late pregnancy accounted for 30% of variance in serum 25OHD in non-supplement users. There was a weak negative association between adiposity (mid upper arm circumference) and 25OHD ( $r = -0.12$ ,  $p = 0.04$ ).

The mean loss of SOS was 0.31 SD and BUA 0.23 SD between early and late pregnancy ( $p < 0.001$ ). There was a greater reduction in both SOS ( $p = 0.02$ ) and BUA ( $p = 0.03$ ) for women with greater vitamin D concentrations at 34 weeks gestation. (Figure). This association persisted after adjusting for adiposity, vitamin D supplement use and season.

**Conclusions:** In this observational study of healthy singleton pregnancies, women with higher concentrations of serum 25(OH)D in late pregnancy had a greater reduction calcaneal QUS measurements during pregnancy. Taken together with our previous finding that greater levels of maternal 25(OH)D are associated with increased intrauterine bone mineral accrual in the offspring, these results are consistent with the hypothesis that 25OHD facilitates mineral transfer to the foetus at the expense of the maternal skeleton.

## F546

**Body Fatness Negatively Associated with BMD and Hip Geometry Indices in Adolescents. A Longitudinal Twin Study.** Y. Hsu<sup>1</sup>, X. Hong<sup>\*2</sup>, H. Terwedow<sup>\*3</sup>, S. Venners<sup>\*4</sup>, X. Xu<sup>\*2</sup>, X. Wang<sup>\*5</sup>. <sup>1</sup>Hebrew SeniorLife and Harvard Medical School, Boston, MA, USA, <sup>2</sup>Sch. Public Health, Univ. Illinois at Chicago, Chicago, IL, USA, <sup>3</sup>Harvard Sch Public Health, Boston, MA, USA, <sup>4</sup>Sch. Public Health, Univ. Illinois at Chicago, Chicago, IL, USA, <sup>5</sup>Children's Memorial Research Center, Northwestern Univ., Chicago, IL, USA.

In the last 30 years, a growing number of adolescents have developed overweight problems. Overweight and obesity is associated with an increased risk of cardiovascular and cerebrovascular diseases in their later life. Studies that investigated BMD in overweight teenagers have shown conflicting results. Rapid bone formation during growth influences bone strength including both bone mass and geometric properties. Therefore, we examined the effects of body fatness on bone strength in a large cohort of adolescent twins, and their genetic correlations.

Participants included 960 boys and 764 girls with age range 11-22 yrs. Body composition (g) and BMD (g/cm<sup>2</sup>) was assessed by DXA at the hip and whole body. Percentage of total body fat (%fat) was calculated. Hip structure analysis was used to determine cross-sectional area (compression strength), section modulus (bending strength) and subperiosteal width. Sex-specific mixed effect models were used to calculate means and assess regression coefficients in BMD and geometry values across %fat tertiles, adjusted for age, tanner stage, height and BMI. Sex-specific variance components analysis (M-plus) was performed to estimate genetic correlations ( $\rho_g$ ) between %fat and hip BMD and geometry indices.

Total body fat mass and %fat were significantly higher in girls than boys. No difference of the total body lean mass and hip BMD was found between girls and boys. %fat increased

with age in both boys and girls. However, hip BMD and geometry indices reached the peak values at tanner stage 3 in girls, and at tanner stage 5 in boys. Multivariable-adjusted mean hip BMD, BMC, and all three geometry indices significantly decreased from the lowest to the highest %fat tertile (table) in boys and girls, except for subperiosteal width in girls. Significant genetic correlations between %fat and bone measurements were found (-0.21 to -0.44 in girls; -0.31 to -0.44 in boys).

In summary, our study suggests that increased %fat may have a negative effect on bone growth in both boys and girls. Furthermore, the associations between body fatness and bone measurements are affected by shared genetic factors.

## F548

**Interaction Between the Skeletal Parameter Bone Mineral Density and Lifestyle Factors in 390 Adolescent Daughter-Mother Pairs.** H. Ohta, T. Kuroda\*, Y. Onoe, Y. Miyabara\*, R. Yoshikata\*, S. Orito, M. Sakai\*, Y. Haruna\*, K. Ishitani\*, H. Okano. Dpt. of Obstetrics and Gynecology, Tokyo Women's Medical University, Tokyo, Japan.

The purpose of this study was to clarify how genetic or environmental factors influence adolescent lumbar bone mineral density (L-BMD) among Japanese daughters and their mothers.

Healthy adolescent daughters and their mothers (n = 390 pairs) were enrolled in this cross-sectional study. L-BMD was measured in all subjects by using dual energy x-ray absorptiometry, as well as their height and body weight; and their current nutritional intake, physical activity patterns, birth weight and weeks, and age at menarche were also assessed by using questionnaires. Standard deviation transformation was performed for three parameters (L-BMD, height, and body weight) to exclude the influence of aging. Spearman's rank test was used to examine the parameters for correlation in each daughter and mother pair and to identify correlates for L-BMD in the daughter. Multiple regression analysis was used to estimate the association between selected parameters and L-BMD in the daughter as an endpoint.

In the pre-menarche daughter group (n = 49), L-BMD, height and nutrition intake were significantly correlated within the mother-daughter pairs ( $P < 0.05$ ). In the post-menarche daughter group (n = 339), L-BMD, birth weight, age at menarche, height, body weight, nutritional intake, physical activity patterns were significantly correlated within the mother-daughter pairs ( $P < 0.05$ ). By multiple regression analysis, L-BMD in the mother and height in the daughter were significantly associated with pre-menarche L-BMD in the daughter ( $P < 0.05$ ; model  $R^2 = 0.34$ ). L-BMD in the mother, height, body weight, age at menarche and intensity of exercise in the daughter were significantly associated with post-menarche L-BMD in the daughter ( $P < 0.05$ ; model  $R^2 = 0.37$ ).

The results suggest a strong hereditary association in L-BMD between daughter and mother and that greater age at menarche leads to low peak bone mass. Additionally, intensive physical activity and adequate body weight were found to have an important role in achieving maximal L-BMD in post-menarche daughters as interventional factors.

**Bone Formation in Mice with Variations in Lrp5 Expression.** S. Moen\*, B. T. Hackfort\*, G. K. Alvarez, D. M. Cullen. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Peak bone mass in adults is determined by bone acquisition during growth where genetics may play an important role. Mutations in the low-density lipoprotein receptor-related protein 5 (LRP5) directly affect peak bone mass. Specifically, the human G171V mutation has been associated with high bone mass (HBM) and inactivation of LRP5 is associated with osteoporosis-pseudoglioma syndrome. High bone mass in humans with the G171V mutation has been observed as early as age 5, but has not been assessed in younger children. The purpose of this study is to test the hypothesis that the effects of variation in Lrp5 expression on bone mass accrual will develop in mice between 2 and 6 weeks of age. Femoral shafts from mice with increasing levels of Lrp5 expression (Lrp5<sup>+/+</sup>, Lrp5<sup>+/+</sup>, Lrp5<sup>+/+</sup> wild-type, and HBM) were examined at 2, 4 and 6 weeks of age (10/grp). Fluorochrome double labels were administered and femoral midshaft processed for histomorphometry. Measurements included area (total, marrow, cortical), moment of inertia, single and double labeled surface (LS/BS, dLS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS) for periosteal and endocortical surfaces. Differences due to age and genotype were tested by GLM. At 2 weeks there were no differences in cortical area or bone formation rate among the four

genotypes. By 4 weeks of age there were distinct differences among the various genotypes and these differences were magnified by 6 weeks. The *Lrp5*<sup>-/-</sup> mice closely resembled the WT control throughout the study. By 6 weeks the cortical area and structural resistance to fracture (moment of inertia) of the *Lrp5*<sup>-/-</sup> mice was 19% and 26% lower than WT, respectively, and the HBM mice were 41% and 55% greater than WT. The bone formation rate increased 116% from 2 to 4 weeks for the HBM mice, while the WT and both knockout animals (*Lrp5*<sup>-/-</sup> or *Lrp5*<sup>+/-</sup>) increased less than 23%. Formation rates decreased 27-50% from 4 to 6 weeks for all genotypes. In conclusion, this study shows that the adult phenotypes seen in previous studies for the *Lrp5*<sup>-/-</sup> and HBM mice does not begins to develop until between 2 and 4 weeks of age. Furthermore, a single knockout of the *Lrp5* gene does not seem to affect cortical bone growth in size or structural resistance to fracture.

Figure: Femur cortical area at 2, 4, and 6 wks of age in *Lrp5*<sup>-/-</sup>, *Lrp5*<sup>+/-</sup>, *Lrp5*<sup>+/+</sup> and HBM mice.

**Arterial Compliance is Associated with Change in Bone Strength in Children: A 16-month Prospective Study.** J. M. Hughes<sup>1</sup>, M. A. Petit<sup>1</sup>, K. E. Reed<sup>2</sup>, H. M. Macdonald<sup>3</sup>, J. M. Cousins<sup>1</sup>, D. E. R. Warburton<sup>2</sup>, R. Z. Lewanczyk<sup>4</sup>, J. M. Scott<sup>2</sup>, J. M. McGavock<sup>4</sup>, M. J. Haykowsky<sup>4</sup>, H. A. McKay<sup>2</sup>. <sup>1</sup>School of Kinesiology, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada, <sup>3</sup>University of Calgary, Calgary, AB, Canada, <sup>4</sup>University of Alberta, Edmonton, AB, Canada.

Associations between cardiovascular disease and osteoporosis have been reported for adult populations. However, it is unclear whether these relationships exist in youth. Therefore, the purpose of this investigation was to evaluate the relationship between arterial compliance, a predictor of vascular disease, and bone strength in children. We used peripheral quantitative computed tomography (pQCT, Stratec XCT 2000) to assess bone geometry (total area, ToA, mm<sup>2</sup>), volumetric density (vBMD, mg/mm<sup>3</sup>), and indices of compressive bone strength (BSI) at the distal (8% site) tibia and bone geometry (cortical area, CoA, mm<sup>2</sup> and ToA), cortical density (CoBMD, mg/mm<sup>3</sup>), and bending strength (section modulus; Z, mm<sup>3</sup>) at the 66% site of the tibia in 84 children (45 boys; aged 9-11 years) at baseline and after 16 months. We used dual energy x-ray absorptiometry to assess lumbar spine and proximal femur bone mineral content (BMC, g). Large arterial compliance was assessed by applanation tonometry (HDI/Pulsewave CR2000) at one time point. We divided participants into 3 tertiles of arterial compliance (T1 (lo)-T3 (hi)). We used ANCOVA to compare arterial compliance with bone outcomes across tertiles. Baseline bone values were adjusted for age, tibia length and weight. Change data were adjusted for age, change in tibia length and change in weight. We noted trends (NS) for higher baseline ToA (+1.4%) and BSI (+3.4%) in those children with the highest arterial compliance (T3) compared with those in T1. For change, at the distal tibia BSI increased significantly more (+6.1%, p=0.04) in the T3 compared to the T1 group due to a greater increase in vBMD (+2.1%); there was no difference between groups for change in ToA. At the 66% site, there was a trend for bending strength (Z) to increase more in the T3 group (+4.5%, p=0.06) due to a greater increase in CoA (+3.6%) with no difference for change in CoBMD or ToA at that site. Children in T3 also had an 8.1% greater change in lumbar spine BMC compared to T1 (p=0.03). Overall, children with the highest arterial compliance at baseline showed a greater increase over 16 months for bone strength, vBMD, and spine BMC, particularly at highly trabecular sites of the distal tibia and lumbar spine. These data suggest a relationship between cardiovascular and bone health in youth that should be explored further.

## F554

**Comparison of the Effect of Puberty on Hip Structure in Boys and Girls.** A. Sayers<sup>\*</sup>, J. H. Tobias. Academic Rheumatology, University of Bristol, Bristol, United Kingdom.

Women are at greater risk of fragility fractures compared to men, the difference in risk largely reflects gender differences in hip structure that determine biomechanical competence. Puberty is a critical time for bone development, particularly in relation to gender differences in skeletal phenotype. To improve the understanding of the

pathogenesis of hip fracture, we compared how puberty influences hip structure and biomechanical strength in boys and girls. All children from the Avon Longitudinal Study of Parents and Children (ALSPAC), a large population-based birth cohort, were invited at age 13.8 years for total body and hip DXA scans using a GE-Lunar Prodigy. Following which indices of femoral neck (FN) structure were derived using GE-Lunar software. These comprised cross sectional moment of inertia (CSMI- an indicator of bone stiffness), minimum femoral neck width (FNW-an indicator of bone size), and bone cross sectional area (CSA-an indicator of cortical bone area). Relationships between pubertal stage, gender and FN structure were examined based on 3752 children with both structural data and puberty information derived from self-completed Tanner stage questionnaires. 612, 477 and 546 boys were in early (Tanner stages I and II), mid (Tanner stage III) and late (Tanner stages IV and V) puberty, compared with 348, 816 and 953 girls respectively.

Table 1: Geometric Properties of the Femoral Neck

FN structure	Puberty	Boys		Girls		Puberty sex interaction
		Mean	95% CI	Mean	95% CI	
CSMI (mm <sup>4</sup> )	Early	8041.4	[ 7852.9 , 8229.9 ]	6281.5	[ 6036.1 , 6526.8 ]	p < 0.0001
	Mid	8896.6	[ 8681.7 , 9111.5 ]	7169.5	[ 7003.7 , 7335.3 ]	
	Late	10924.1	[ 10719.8 , 11128.5 ]	7982.5	[ 7826.4 , 8138.6 ]	
CSA (mm <sup>2</sup> )	Early	131.3	[ 129.6 , 133.0 ]	118.8	[ 116.6 , 120.9 ]	p < 0.0001
	Mid	139.1	[ 137.2 , 141.0 ]	130.4	[ 128.9 , 131.9 ]	
	Late	154.3	[ 152.5 , 156.1 ]	140.5	[ 139.1 , 141.9 ]	
FNW (mm)	Early	28.9	[ 28.7 , 29.1 ]	26.9	[ 26.7 , 27.1 ]	p < 0.0001
	Mid	29.7	[ 29.5 , 29.9 ]	27.4	[ 27.2 , 27.6 ]	
	Late	31.4	[ 31.2 , 31.6 ]	27.8	[ 27.7 , 28.0 ]	

Means and 95% CI derived from OLS Regression controlling for age of scan, height and weight.

These results demonstrate that both sexes show similar proportional increases in biomechanical strength (CSMI) between early and mid puberty, but in late puberty, CSMI increases to a greater extent in boys compared to girls. Underlying these changes, periosteal expansion in late pubertal boys is evident from increases in both FNW and CSA. Although CSA also increased in late pubertal girls, there was little change in FNW, implying that gains at the endosteal surface had occurred, leading to an increase in cortical thickness, whereas there was only very limited periosteal expansion. We conclude that in late puberty, boys undergo FN periosteal expansion, whereas girls predominantly accrue bone at the endosteal surface. Since periosteal expansion influences CSMI to a greater extent than endosteal deposition, these differences result in greater improvements in biomechanical strength at the FN in late pubertal boys compared to girls, which is in turn likely to contribute to the higher fracture risk in women compared to men in later life.

## F557

**Suboptimal Vitamin D Status in Pregnant Adolescents is Associated with Neonatal Vitamin D Insufficiency.** K. O. O'Brien<sup>1</sup>, B. V. Essley<sup>1</sup>, E. Cooper<sup>2</sup>, A. W. McIntyre<sup>2</sup>, F. R. Witter<sup>3</sup>, Z. L. Harris<sup>3</sup>, T. Kent<sup>1</sup>, T. McNalley<sup>2</sup>. <sup>1</sup>Division of Nutritional Sciences, Cornell University, Ithaca, NY, USA, <sup>2</sup>University of Rochester School of Medicine, Rochester, NY, USA, <sup>3</sup>Johns Hopkins School of Medicine, Baltimore, MD, USA.

Pregnant adolescents may be at risk for suboptimal calcium intakes and vitamin D insufficiency. This may impact maternal and fetal bone health across pregnancy in this vulnerable age group. To assess this issue, vitamin D status was monitored in pregnant adolescents and their neonates in relation to measures of maternal and fetal bone health across gestation. Pregnant adolescents ( $\leq 18$  y of age) were recruited at or after 12 weeks of gestation and were longitudinally followed at 3 time points across pregnancy (approximately 16, 25 and 34 weeks of gestation). At each visit maternal bone health was measured using a heel ultrasound technique and data on fetal femur and humerus length were obtained by sonogram. Blood samples were collected from each adolescent at mid-gestation both maternal and cord blood were obtained in a subset of this group at parturition. To date, adolescents were  $16.9 \pm 1.1$  years of age (range 13.7 - 18.7 y, n=82) at entry into the study. Serum 25-hydroxyvitamin D (25(OH)D) concentrations were  $23.3 \pm 11.2$  ng/mL (n=82 range 5-61 ng/mL) at 25.3  $\pm$  3.5 wks gestation and these values did not statistically differ from measures obtained in a subset of these teens at delivery ( $25.1 \pm 15.7$  ng/mL; n=45, range 7-91). In this population; 48% (39/82) and 42% (19/45) of pregnant adolescents had vitamin D insufficiency (< 20 ng/mL) at mid-gestation and delivery respectively. At parturition, concentrations of 25(OH)D were significantly higher among Caucasian adolescents when compared to African American adolescents ( $31.2 \pm 18.4$  (n=17) vs.  $21.3 \pm 13.2$  (n=25), p<0.05). In the group as a whole; cord 25(OH)D concentrations ( $20.0 \pm 12.1$ , range 5-67 ng/mL) were significantly associated with maternal 25(OH)D concentrations at delivery (P<0.0001, n=45, R<sup>2</sup>=0.657). Among the neonates studied to date; 60% (24/40) had suboptimal vitamin D status (< 20 ng/mL) at birth. A net loss of bone at the calcaneus (change in BMD t-score per week) was evident across gestation ( $-0.119 \pm 0.864$ , n=27). Serum parathyroid hormone is currently being analyzed in this cohort to assess its relationship with study outcomes. Because pregnant adolescents are at high risk of vitamin D insufficiency and bone acquisition is not complete during adolescence, further studies are need to assess the impact of maternal vitamin D status on maternal and fetal bone health across pregnancy.

**Osteoprotegerin (OPG) Deficiency Mimicked by a Novel 15-Base Pair Tandem Duplication in *TNFRSF11A* Encoding RANK: Merging the Juvenile Paget's Disease and Expansile Skeletal Hyperphosphatasia Phenotypes.** S. Mumm<sup>1</sup>, C. Tau<sup>2</sup>, X. Zhang<sup>\*1</sup>, W. H. McAlister<sup>1</sup>, M. P. Whyte<sup>1</sup>.  
<sup>1</sup>Washington Univ Schl Med and Shriners Hospt Children, St. Louis, MO, USA, <sup>2</sup>Metabolismo Calcico y Oseo, Endocrinol, Hospt Pediatr J.P. Garrahan, Buenos Aires, Argentina.

Disorders of enhanced osteoclastogenesis due to genetic defects in the RANK/OPG/RANKL/NF- $\kappa$ B signaling pathway include familial expansile osteolysis (FEO), familial Paget's disease in Japan (PDB2), and expansile skeletal hyperphosphatasia (ESH) caused by 18, 27, and 15 bp tandem duplications, respectively, in exon 1 of *TNFRSF11A* (RANK). Each is an autosomal dominant trait. Juvenile Paget's disease (JPD) is an autosomal recessive disorder due to deactivating mutations in *TNFRSF11B* (OPG).

We discovered that a 5-year-old girl diagnosed with JPD carried a unique, heterozygous, 15 bp tandem duplication in exon 1 of *TNFRSF11A*. She was born to non-consanguineous Bolivian parents after an uneventful full-term pregnancy. At birth, she had a short, right femur. Subsequently, both femurs bowed. At age 1 3/4 years, she fractured a radius and cubitus. At age 2, there was bilateral deafness, but no mental retardation. Deciduous teeth were lost prematurely, with missing maxillary incisors. Radiographs at age 3 years showed cortical thickening, coarse trabeculation, and long bone widening consistent with relatively mild JPD (Fig). Some mandibular teeth, including molars, had missing roots. Vertebrae were sandwiched at age 1, but recovered. CT showed eroded cochleas with osteosclerosis. There was no ophthalmologic disease. Family history was negative for bone disease.

Markers of bone turnover were elevated, but with i.v. pamidronate they normalized except serum ALP remained elevated at 750 IU/L.

Exon 1 of *TNFRSF11A* (RANK) was amplified by PCR and sequenced in both directions, showing a heterozygous insertion/deletion in the coding sequence. The amplicons were cloned and sequenced individually to demonstrate a heterozygous, 15 bp duplication (encoding Leu-Cys-Ala-Leu-Leu) in the signal peptide of RANK. This 15 bp duplication is 3 bp displaced from the sequence repeated in the original ESH report (JBMR 17:26, 2002), but adds the same 5 amino acids. It was not detected in the mother; the father was unavailable for study. No OPG gene mutation was found.

Hence, the JPD phenotype can be recapitulated by an activating mutation in RANK, showing further "overlap" among FEO, PDB2, ESH, and JPD.

**Bisphosphonate-Induced Osteopetrosis: Novel Bone Modeling Defects, Metaphyseal Osteopenia, and Osteosclerosis Fractures After Drug Exposure Ceases.** M. P. Whyte<sup>1</sup>, W. H. McAlister<sup>\*2</sup>, D. V. Novack<sup>2</sup>, K. L. Clements<sup>\*1</sup>, P. L. Schoenecker<sup>\*1</sup>, D. Wenkert<sup>1</sup>. <sup>1</sup>Shriners Hospt Children, St. Louis, MO, USA, <sup>2</sup>Washington Univ Schl Med, St. Louis, MO, USA.

In 2003, we reported (NEJM 349:457) a 12-year-old boy who had developed osteopetrosis (OPT) while receiving pamidronate (PMD) for idiopathic bone pain and enigmatic elevation in serum bone alkaline phosphatase activity. Now age 17 years, he was reevaluated in 2007, 6 1/2 years after PMD exposure stopped. He described less bone pain, but further limb fractures. Growth plates were fused, yet hyperphosphatasemia persisted. Radiographs documented interval fractures of a metacarpal, an osteosclerotic distal radius, and a dense diaphyseal segment of an ulna where a "chalkstick" break was incompletely healed after 2 years. There was new L<sub>4</sub> spondylolysis, and previous L<sub>5</sub> spondylolysis had caused spondylolisthesis. Modeling disturbances of OPT persisted, but partial recovery was demonstrated by metaphyseal surfaces with a concave shape (Fig 1). Metaphyseal osteosclerosis had remodeled imperfectly to become focal areas of dense, diaphyseal bone. Newer metaphyseal bone was unexpectedly osteopenic, especially in his distal femurs where cortices were thin and a paucity of trabeculae was documented by CT. Femoral necks had become short and wide with an abnormal contour. A "bone-within-bone" configuration was now present throughout his skeleton. In vertebrae, endplates were thin and trabecular osteopenia was central and peripheral to the bands of osteosclerosis. BMD Z-scores assessed by DXA had decreased into the normal range in his spine, hip, and

whole body. Iliac crest biopsy revealed active bone formation, with much less accumulated primary spongiosa than during the PMD infusions. Osteoclasts that had been dysmorphic, round cells without polarization and off of bone surfaces were now unremarkable in number, location, and appearance (Fig 2). Hence, bisphosphonate toxicity during childhood can impair skeletal modeling and remodeling with structural changes that evolve and carry into adult life (JBMR, in press).

**FIGURE 2:** Osteoclasts during PMD toxicity (top, arrow) are rounded and not polarized toward bone, whereas those at followup (bottom, arrow) have a normal flat and polarized morphology.

**FIGURE 3:** Modeling and remodeling abnormalities in the lower limbs in 2007 (A) include novel shaping changes and osteopenia, especially apparent in the distal femurs and proximal tibia, that developed between 2002 (B) and 2007 (C). At the right knee, metaphyseal osteosclerosis and a fracture (B) has been repaired by osteopenia and modeling failure (C) (dotted matching arrows). Some of the original osteosclerotic metaphyseal bone persists as dense metaphyseal bone (C) once again has a concave surface.

**The Non-genomic Estrogen Receptor Gpr30 Is a Runx2 Responsive Gene that Is Required for Osteoblast Proliferation.** N. Teplyuk<sup>\*1</sup>, M. Galindo<sup>\*2</sup>, J. Pratap<sup>1</sup>, J. L. Stein<sup>1</sup>, J. B. Lian<sup>1</sup>, G. S. Stein<sup>1</sup>, A. J. van Wijnen<sup>1</sup>. <sup>1</sup>Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, <sup>2</sup>Program of Cellular and Molecular Biology, Institute of Biomedical Sciences (I.C.B.M.), University of Chile, Santiago, Chile.

Multiple target genes for the Runt-related transcription factor 2 (Runx2) support its biological functions in lineage-commitment, proliferation and anabolic functions of osteoblasts. Re-introduction of Runx2 into Runx2 null cells using adenoviral vectors attenuates cell proliferation. Affymetrix expression profiling of Runx2 responsive genes during growth suppression shows that Runx2 regulates groups of coordinately expressed genes involved in G-protein coupled receptor (GPCR) signaling (e.g., *Rgs2*, *Rgs4*, *Rgs5*, *Rgs16*, *Gpr23*, *Gpr30*, *Gpr54*, *Gpr64* and *Gna13*). As Runx2 activity is coupled to modulations in intracellular cAMP levels in osteoblasts, we examined the function of two genes known to work through cAMP signaling: *Gpr30*, the non-genomic estrogen receptor that activates cAMP production, and *Rgs2*, a G protein inhibitor that blocks cAMP production. We find that *Gpr30* is stimulated and *Rgs2* is down regulated by Runx2 in osteoblasts. Forced expression of *Rgs2* inhibits osteoblast proliferation as determined by a reduced number of cells in S-phase of the cell cycle as estimated at the single cell level by Ki67 immunostaining. Moreover, *Rgs2* knock-down by RNA interference stimulates S-phase entry as assessed by FACS analysis. This positive effect is more pronounced upon cAMP stimulation with forskolin, suggesting that *Rgs2* suppresses cAMP dependent stimulation of osteoblast growth. In contrast, RNA interference of *Gpr30* completely blocks proliferation of MC3T3 cells, indicating that *Gpr30* is required for osteoblast growth and could mediate mitogenic actions of estrogens in bone cells. Whether *Rgs2* interferes with *Gpr30* function directly or acts through different receptors remains to be established. However, our results clearly indicate that Runx2 sensitizes cAMP related GPCR signaling by activating *Gpr30* and repressing *Rgs2* gene expression in osteoblasts to increase responsiveness to mitogenic signals.

**Dependence of Post Natal Osteogenic Differentiation on BMP2: Dissection of Osteogenic Lineage Commitment by Lentivirus BMP2 shRNA *ex vivo* and *in vivo*.** M. V. Bais\*, N. Wigner\*, M. Young\*, R. Toholka\*, D. Graves\*, E. F. Morgan\*, L. C. Gerstenfeld, T. A. Einhorn. Orthopaedic Research Laboratory, Department of Orthopedic Surgery, Boston University School of Medicine, Boston, MA, 02118, Boston, MA, USA.

In order to examine if autogenous BMP-2 expression is necessary for the osteogenic differentiation of marrow stromal cells, BMP-2 expression was inhibited using lentiviral transfection of a BMP2 shRNA. Inhibition of BMP2 expression decreased the expression of markers of terminal osteoblasts (osteocalcin, Runx2, osterix, APase activity, and mineral deposition), while the expression of transcription factors (Sox 9 and Msx2) that are seen in skeletal lineage progenitors were not effected. Rescue of osteogenic differentiation by the exogenous addition of either BMP7 or BMP2 recovered the levels of expression of osterix and APase and enhanced Sox9 and Msx2. However, BMP7 did not recover the expression of Runx2 and only partially recovered mineral deposition while the exogenous addition of BMP2 recovered all of these phenotypic properties. The effect of the loss of BMP2 expression on bone formation after marrow ablation lead to 80% loss of mineralized bone formation as assayed by microCT at day seven after surgery. Assay of same set of mRNAs as examined *in vitro* showed transient ~2 fold increase of Sox9 at day three after surgery in the shRNA BMP2 samples while at day seven osterix, Runx2, osteocalcin and Sox9 all showed ~50 to ~80% inhibition compared to expression in the NT (scrambled) treated samples. Interestingly, Msx2 showed ~10 fold elevation expression at seven days post surgery. Immunohistological examination of the cell populations found in the medullary space three days after surgery with antibodies for CD146 and Sox9, showed equal numbers of cells expressing these skeletal stem markers in both control and shRNA treated specimens. These results demonstrate that: 1) BMP-2 is a central morphogenetic factor for the post natal osteogenic differentiation: 2) BMP2 does not effect the initial recruitment or expansion of skeletal stem cells *in vivo*: 3) Both BMP2 and BMP7 can both induce osterix and this transcription factor can promote osteogenic differentiation: 4) Expression of Runx2 is dependent on BMP2: 5) Both osterix and Runx2 are needed to fully promote osteogenic development.

**Clinical Application of Resorbable Polymers in Guided Bone Regeneration.** W. IP\*. Orthopaedics & Traumatology, The University of Hong Kong, Hong Kong, Hong Kong.

**INTRODUCTION:** Long segmental diaphyseal bone loss often results from high energy trauma like blast injury, osteomyelitis or wide excision of malignant conditions. Treatment of this long segmental diaphyseal defects remain a difficult clinical problem. In the literature, many authors have reported that bone loss more than 2.5 cm always require bone grafting. This is probably the critical size defect in human. Non-vascularized bone graft frequently fails if the defect is longer than 6-7 cm. 2.5 cm is probably the critical size defect in human and 7 cm is likely the critical size for non-vascularized bone graft. Various treatment methods are adopted currently to address this problem, including vascularized bone graft, distraction osteogenesis and massive allograft. However, all these methods are associated with a lot of problems.

Successful guided bone regeneration has been achieved in skull bone and jaw bone using resorbable allograft. Bone regeneration in long segmental defect and relatively small defect in tumour excision has been achieved using resorbable polylactide scaffolds.

**METHODS & MATERIALS:** 10 patients with bone defect of sizes up to 6 cm due to various causes including benign tumour, osteomyelitis & fractures were treated with resorbable polylactide scaffold impregnated with marrow blood which contains stromal cells. In cases with infection, antibiotics was also loaded into the scaffold and in this situation, the scaffold also served as a drug delivery device. The patients have assessed regularly with X rays and clinical symptoms.

**RESULTS:** Serial X ray evaluation and clinical evaluation revealed presence of bone regeneration. The limbs enjoyed satisfactory function and there was minimal donor site morbidity and major surgery can be avoided.

**DISCUSSION :** Selected cases are treated with guided bone regeneration which would be

treated otherwise by conventional technique. Vascularized bone transfer has limited supply and involves a major operation. There is always a chance of vascular complication and there is donor site morbidity. Distraction osteogenesis has a limitation of length that can be lengthened and requires a prolonged placement of external fixation. There is a high chance of traction injury to nerve and other soft tissues. Massive allograft requires a prolonged period, in terms of decades, for complete creep substitution. There is also a high incidence of disease transmission and infection. Therefore there is a constant demand for bone substitute which can bridge long segmental defect effectively with minimal morbidity and can heal in reasonable time frame. The affected limb can be rehabilitated and bear weight for functional restoration as early as possible. These early results are promising.

**CCAAT/Enhancer Binding Protein-Beta (C/EBP  $\beta$ ) Overexpression Causes Osteopenia.** S. Zanotti, A. Smerdel-Ramoya, L. Stadmeier\*, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

C/EBPs are a family of ubiquitous transcription factors involved in cell differentiation. Six different C/EBPs are known,  $\alpha$ ,  $\beta$ ,  $\delta$ ,  $\gamma$ ,  $\epsilon$  and  $\zeta$ ; and they can form homo- and heterodimers that bind to similar sequence motifs. C/EBPs are expressed by osteoblasts and adipocytes during differentiation *in vitro*, and C/EBP  $\beta$  is required for adipogenesis. However, the role of C/EBP  $\beta$  in osteoblastogenesis is less clear, and its function in the postnatal skeleton is not known. To study the function of C/EBP  $\beta$  in osteoblasts *in vivo*, we created transgenic mice expressing C/EBP  $\beta$  under the control of the 3.8 kilobase fragment of the human osteocalcin promoter. Two transgenic lines were established in an FVB genetic background, and four week old C/EBP  $\beta$  transgenic mice were compared to wild type littermates of identical sex. Both C/EBP  $\beta$  transgenic lines exhibited osteopenia with a 30 % decrease in trabecular bone volume over tissue volume, due to a decrease in trabecular number. There was a reduction in number of osteoblasts per tissue area, although the number of osteoblasts per bone perimeter was not changed. The phenotype was the same in both male and female transgenics. To examine the mechanism leading to osteopenia, bone marrow stromal cells and calvarial osteoblasts from C/EBP  $\beta$  transgenics, and ST-2 stromal cells stably transduced with a C/EBP  $\beta$  expression construct were studied. In accordance with the results observed *in vivo*, bone marrow stromal cells from C/EBP  $\beta$  transgenics showed reduced mineralization as determined by alizarin red staining, and reduced alkaline phosphatase mRNA levels. Furthermore, calvarial osteoblasts from C/EBP  $\beta$  transgenics and ST-2 stromal cells stably expressing C/EBP  $\beta$  displayed reduced alkaline phosphatase activity. In conclusion, C/EBP  $\beta$  overexpression *in vivo* causes osteopenia, possibly by impairing osteoblastic function.

**Use of GFP Reporter Mice for Assessing Osteoprogenitor Cell Activity in a Critical Size Calvarial Defect.** L. Wang, Y. Liu\*, P. Maye, D. W. Rowe. Dept. of Reconstructive Sciences, School of Dental Medicine, University of Connecticut Health Center, Farmington, CT, USA.

A successful repair strategy of a critical size defect in bone requires the interaction of cells from the endothelial/vascular, osteoprogenitor and hematopoietic lineages and a scaffold that is permissive or proactive to this process whether the cells are derived from host or implanted donor cells. Using a variety of GFP reporter mice that reflect the cellular activities of each tissue element and a new cryohistology for non-decalcified bone that preserves GFP signals, we have developed a calvarial defect model to assess the temporal and special events of a successful repair as a baseline for understanding why some strategies may fail. In two experimental designs, one assesses the host and donor contribution to a repair, host and donor express the same promoter driving distinguishable fluorescent proteins. Thus a defect that is closed with an acellular scaffold results in Col3.6green host cells streaming into the scaffold but never making a bone matrix as judged by the lack of xylenol orange (XO) staining or gross mineral deposition that is visible by DIC optics. However when donor cell derived from neonatal calvaria carrying the Col3.6blue reporter, a DIC positive matrix is produced that contains blue osteoblasts overlying the XO staining osteoid surface. The early woven bone present at 4 weeks begins the transition to remodeled bone observed when the repair is sampled at 8 weeks. Limited intermingling of host and donor osteoblasts can be observed at the margins, but no invasion of host osteoblasts within the scaffold is detected. However host derived osteoclastic cells are abundant in the repair and are recognized as weak Col3.6+ green cells that are not associated with the XO mineral label and are TRAP positive. The second design uses a nontransgenic host that receives donor cells carrying cell specific reporters expressing distinguishable colors. When the scaffold is inoculated with fresh bone marrow from a Col3.6green donor, no bone is formed and no donor cells survive. In contrast, when the

fresh marrow is mixed with neonatal calvarial cells carrying the Col3.6blue reporter, bone is formed with blue osteoblasts overlying the XO labeled matrix. Abundant green cells are present in the 8 week sample that have the signature of osteoclastic cells. However if marrow stromal cells that are double positive for BSP-green and DMP1-red are expanded in cultures and then used to seed the scaffold, abundant bone is formed that shows active green osteoblasts on the bone surface and red osteocytes within the bone matrix. Many permutations of this approach can be applied to assess the donor/scaffold/host variables that affect the repair of a bone defect.

**Bone Cell Response to Neurotransmitters and Mechanical Loading.** J. H. Kwag\*, B. G. Kim\*, H. G. Lee\*, C. H. Kim. Yonsei University, Wonju, Republic of Korea.

Mechanical loading is an important regulator of bone resorption. Also, neurotransmitters have been shown to exist in bone tissue and play a vital role in stimulating the calcium content and alkaline phosphatase level. In this study, our objective was to investigate the role of an important neurotransmitter (vasoactive intestinal peptide (VIP)) in controlling the mechanotransduction in bone cells. First, a dose study was performed. MC3T3-E1 preosteoblast cells were cultured in culture dishes with complete culture medium (CCM) for 6 days. VIP was added at either 0 (control),  $10^{-9}$ M or  $10^{-6}$ M on day 0 and day 3. mRNA was isolated on day 6 and real-time RT-PCR was performed. Second, the effect of VIP on mechanical loading was assessed. MC3T3-E1 cells were cultured in culture dishes and  $10^{-6}$ M of VIP added on day 0 and day 3. Cells were subcultured onto glass slides on day 5. Oscillatory fluid flow-induced shear stress was applied on day 6 using a custom-built loading device at 1 Pa for 1 hour. mRNA was isolated immediately after end of loading and real-time RT-PCR performed. For real time-RT-PCR, expression levels of osteoprotegerin (OPG) and receptor activator for NF- $\kappa$ B ligand (RANKL) genes were quantified. For the dose study, RANKL decreased by 40% ( $10^{-9}$ M VIP) and 60% ( $10^{-6}$ M VIP), while OPG increased by 50% ( $10^{-6}$ M VIP) compared to control. When VIP was combined with loading, RANKL decreased by over 90% and OPG increased by approximately 70% compared to control. Results suggest that VIP may have the potential to decrease osteoclastogenesis. In addition, it appears that VIP and oscillatory fluid flow-induced shear stress may have synergistic effects in controlling the bone remodeling process.

**Silencing of RhoGTPases Counteract Microgravity-induced Effects on Osteoblasts.** A. Guignandon\*, C. Faure\*, M. Linossier\*, A. Rattner\*, N. Laroche\*, L. Vico. LBTO, INSERM U890, Saint Etienne, France.

Effects of space-related conditions on osteoblastic cells are characterized by a decrease in cell adhesion, disruption of cytoskeletal integrity leading to reduced differentiation potential. These effects can be mainly explained by deregulation of p21-RhoGTPases (p21), well-known regulators of actin-cytoskeleton. We exposed MG63 osteoblastic cells to 3 days of microgravity ( $\mu$ g) during Foton M3 ESA mission and compared them to ground controls (1g) kept in similar conditions except  $\mu$ g. Specific p21 activities are altered by siRNA for RhoA, Rac1, Cdc42 and compared to Scramble (SiScr). Being dependent on p21, cell migration, stress fiber number (SF), vinculin positive contacts, fibronectin matrix deposition and VEGF synthesis and immobilization into matrix are evaluated by way of RT-PCR and image analysis. We find that migration of SiScr cells increases in  $\mu$ g (+20%,  $p < 0.05$ ) as consequence of reduced adhesion (-35%,  $p < 0.01$ ) and increased polarity. SiRhoA in 1g group recapitulates most of SiScr cells  $\mu$ g-induced effects on focal adhesion area (-30%,  $p < 0.01$ ) and migration (+25%,  $p < 0.05$ ). SiRhoA does not induce major alteration in  $\mu$ g compared to  $\mu$ g SiScr and 1g SiRhoA. Interestingly, SiRac1 and SiCdc42 in 1g are not able to significantly increase SF and focal adhesion size while they increase both parameters in  $\mu$ g. SiRac cells in  $\mu$ g present an increased SF (+20%,  $p < 0.05$ ), matrix deposition (+25%,  $p < 0.01$ ) and a reduced migration (-40%,  $p < 0.01$ ). We previously showed (ASBMR 2006, #1274) that matrix-bound VEGF (VEGFm) expression is conditioned by a mechanically-increased SF. Whatever the silencing no change in basal levels of soluble (VEGFs) or VEGFm was seen in 1g. In  $\mu$ g, we observe that VEGFs/VEGFm ratio is greatly in favor of VEGFs in SiScr. SiRac1 and SiCdc42 in  $\mu$ g reduce significantly VEGFs, correcting VEGF ratio. All together SiRac1 and SiCdc42 may have activation effects on RhoA not seen in 1g leading to increased adhesion, matrix deposition and correction of VEGF alternative splicing thus counteracting  $\mu$ g-induced effects.

**Deciphering the Cellular Defects of Osteoblasts in Microgravity.** N. Nabavi\*. University of Toronto, Toronto, ON, Canada.

Gravity has been shown to be essential for biological events occurring in organisms on earth. It is also known that major physiological changes occur in bone during space flights, however, the intracellular changes have not been analyzed in details due to the difficult nature of these studies. The goal of this project was to understand the molecular mechanisms by which bone loss occurs during space flights using an elaborate closed culture system enabling cell proliferation. In this study, we investigated the cellular mechanism of bone loss in microgravity conditions by first determining whether osteoblasts exhibit impaired differentiation and/or function in microgravity environments compared to ground controls. Mature osteoblasts grown in microgravity environments were fixed and immunostained with antibodies. Samples were analyzed post-flight using epi- and confocal microscopy in order to determine whether the actin and microtubule (MT) cytoskeletons as well as the associating regulating proteins show differential organization and stability in osteoblast cells during spaceflight compared to ground controls. Focal adhesion proteins as well as apoptosis were examined in osteoblasts grown in microgravity versus ground control. We observe a marked impairment of cytoskeletal organization and cell adhesion which correlates with increased cell death in osteoblasts grown in space. These findings may have important relevance for astronauts participating in extended flights, as well as relevance for bone-wasting disorders, including disuse osteoporosis.

**Microporosity In Beta-TCP Ceramics May Be Detrimental to Mesenchymal Stem Cell Survival and Osteoblastic Differentiation.** J. Isaac\*<sup>1</sup>, J. Hornez\*<sup>2</sup>, D. Jian\*<sup>3</sup>, M. Descamps\*<sup>2</sup>, C. Chauveau\*<sup>1</sup>, P. Hardouin<sup>1</sup>, D. Magne\*<sup>1</sup>. <sup>1</sup>Cellular and Molecular Biology EA2603, ULCO/Lille University, Boulogne/Mer, France, <sup>2</sup>LMP, Université de Valenciennes et du Hainaut Cambrésis, Maubeuge, France, <sup>3</sup>Orthopaedic Surgery, Shanghai Jiaotong University Sixth People Hospital, Shanghai, China.

Aims of the present study were to determine whether microporosity in beta-tricalcium phosphate (b-TCP) ceramics is beneficial or detrimental to human mesenchymal stem cells (MSCs), for the development of hybrid constructs for bone repair. MSCs, either purified or contained in bone marrow stromal cells, were seeded on ceramics with 0%, 25%, or 45% microporosity and cultured from 18 hours, 7 days, 14 days or 21 days, in an osteogenic medium consisting of DMEM with 10% FCS supplemented with  $10^{-8}$  M vitamin D3, 50  $\mu$ M ascorbic acid and 10 mM beta-glycerophosphate. Cell adhesion and viability were measured by cell counting, and with MTS and LDH assays. Osteoblastic differentiation was evaluated by measuring the activity of alkaline phosphatase (ALP) by the method of Lowry and by quantifying osteocalcin secretion by ELISA. Results indicated that whereas microporosity had no effect on cell adhesion, it increasingly inhibited cell viability in a rate and time-dependent manner. In addition, early and late osteoblastic differentiation appeared stimulated on non microporous b-TCP ceramics. Indeed, ALP activity and osteocalcin secretion were always decreased by the more microporous ceramics. Results of this in vitro study therefore reveal an unexpected negative role for microporosity in the osteoblastic differentiation of human mesenchymal stem cells.

**JNK Activation Is Involved in Tumor Necrosis Factor- $\alpha$ -stimulated Smurf1 Expression.** H. Lee<sup>\*1</sup>, T. Yi<sup>\*2</sup>, H. Ryoo<sup>1</sup>, K. Woo<sup>1</sup>, G. Kim<sup>\*1</sup>, J. H. Baek<sup>1</sup>. <sup>1</sup>Department of Cell and Developmental Biology, Seoul National University School of Dentistry, Seoul, Republic of Korea, <sup>2</sup>Clinical Research Center, INHA University Hospital, Incheon, Republic of Korea.

Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) is a pro-inflammatory cytokine that induces local and systemic bone loss through the stimulation of bone resorption as well as through the inhibition of bone formation. Although previous report has shown that TNF- $\alpha$  stimulated Smurf1 expression, the signal pathways involved in TNF- $\alpha$ -induced Smurf1 transcription have not been clarified yet. Therefore, we were to examine the intracellular signaling pathways involved in TNF- $\alpha$ -mediated Smurf1 expression in C2C12 cells. As reported previously, TNF- $\alpha$  stimulated Smurf1 mRNA and protein expression in C2C12 cells. Cycloheximide treatment did not exert any effects on TNF- $\alpha$ -induced Smurf1 mRNA expression, indicating that Smurf1 induction is a direct effect. Although TNF- $\alpha$ -inhibited ALP activity was partially rescued by blocking of NF- $\kappa$ B activation as well as by c-Jun N-terminal kinase (JNK) inhibition, Smurf1 induction was suppressed only by JNK inhibition but not by NF- $\kappa$ B inhibition. This result suggests that JNK activation is involved in TNF- $\alpha$ -mediated Smurf1 induction.

**TGIF Regulation of Bone Mass: Impaired Osteoblast Differentiation.** M. K. Crook<sup>1</sup>, K. Mohammad<sup>1</sup>, L. Bartholin<sup>\*2</sup>, A. Carver<sup>\*3</sup>, L. Suva<sup>3</sup>, J. Chirgwin<sup>1</sup>, D. Wotton<sup>\*2</sup>, T. Guise<sup>1</sup>. <sup>1</sup>Internal Medicine, University of Virginia, Charlottesville, VA, USA, <sup>2</sup>Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA, USA, <sup>3</sup>Orthopedics, University of Arkansas, Little Rock, AR, USA.

TG Interacting factor (TGIF) is a transcriptional corepressor of TGF-beta and retinoic acid (RA) actions. TGIF mutations occur in holoprosencephaly (HPE), a defect in craniofacial and forebrain development, also caused by mutations at three steps in the Sonic Hedgehog (SHH) pathway: SHH, Ptc-1 and Gli-2. Zebrafish lacking TGIF have low RA-activating enzyme, aldehyde dehydrogenase 1a2 (aldh1a2) and degrading enzyme cyp26a1, suggesting that TGIF may regulate RA activity gradients. Aldh1a2<sup>-/-</sup> mice have diminished SHH signaling and severe skeletal abnormalities. The SHH promoter is RA-responsive, and TGIF may act on the skeleton via altered RA activity regulating SHH expression. *Tgif*<sup>-/-</sup> mice show growth retardation, domed skulls, twisted noses, and defects in vertebrae, ribs and sternum. These mice had significantly less trabecular bone by DEXA, microCT and histomorphometry. Low bone mass was accompanied by increased osteoclast activity and reduced osteoblast number and bone formation rates. Osteoblast progenitors, CFU-OBs, were decreased in bone marrow from *Tgif*<sup>-/-</sup> compared to wild-type (WT) mice. Primary osteoblasts from *Tgif*<sup>-/-</sup> vs WT mice had increased expression of the early marker Col1a (p<0.01), and reduced expression of two late markers, osteocalcin (p<0.05) and bone sialoprotein (p<0.01), suggesting multiple effects of TGIF on the osteoblast lineage.

We previously showed that TGF-beta inhibition did not correct the low bone mass in *Tgif*<sup>-/-</sup> mice-beta. Here we focus on RA signaling. Aldh1a2 mRNA was 30% lower in *Tgif*<sup>-/-</sup> osteoblasts (p<0.05) compared to WT in an initial experiment. Cyp26a1 was increased by 30% (P<0.01), suggesting that TGIF may determine RA gradients. SHH induces osteoblastogenesis and mineralization by increasing Gli-2 expression. In one of two experiments, Gli-2 mRNA concentration was decreased in untreated *Tgif*<sup>-/-</sup> osteoblast (p=0.033) compared to WT. Diminished SHH signaling may contribute to impaired differentiation in stimulated *Tgif*<sup>-/-</sup> osteoblasts.

The actions of RA and SHH signaling are best understood during embryogenesis. The epistatic relationship of these two pathways post-developmentally and whether they act primarily on adult mesenchymal stem cell differentiation are presently unclear. TGIF may play a role in adult bone remodeling by modulating these pathways.

**Conditional Disruption of *Pkd1* in Osteoblasts Results in Osteopenia Due to Direct Impairment of Osteoblast-Mediated Bone Formation.** Z. Xiao, S. Zhang<sup>\*</sup>, L. Cao<sup>\*</sup>, R. Wu<sup>\*</sup>, L. Quarles. The Kidney Institute, Kansas University Medical Center, Kansas City, KS, USA.

Polycystin-1 (PKD1) is a highly conserved, multi-domain membrane protein widely expressed in various cell types. Mutations of human *PKD1* cause Autosomal Dominant Polycystic kidney disease, however, the biological functions of PKD1 in other tissues remain poorly defined. We recently reported that *Pkd1* is highly expressed in bone and that the *Pkd1*<sup>m1Bci</sup> mouse, which has an inactivating mutation of *Pkd1*, develops osteopenia and impaired osteoblastic differentiation. To determine whether *Pkd1* directly functions in osteoblasts to regulate bone mass, we generated mice with osteocalcin (*Oc*)-promoted selective inactivation of *Pkd1* in osteoblasts. Transgenic *Oc-Cre* mice were crossed with

*Pkd1*<sup>m1Bci/+</sup> mutant mice to create double heterozygous *Cre/+; Pkd1*<sup>m1Bci/+</sup> mice, then *Oc-Cre/+; Pkd1*<sup>m1Bci/+</sup> mice were crossed with homozygous floxed *Pkd1* (*Pkd1*<sup>lox/lox</sup>) mice to generate control mice (*Pkd1*<sup>lox/+</sup>), conditional *Pkd1* heterozygous mice (*Oc-Cre-Pkd1*<sup>lox/+</sup>), and conditional *Pkd1* null mice (*Oc-Cre-Pkd1*<sup>lox/m1Bci</sup>). Diagnostic PCR demonstrated that *Cre*-mediated recombination (*Pkd1*<sup>lox</sup>) occurred exclusively in bone, whereas non-skeletal tissues retained the floxed *Pkd1* allele (*Pkd1*<sup>lox</sup>). Compared to control mice, the conditional deletion of *Pkd1* from osteoblasts resulted in a gene-dose dependent reduction in bone mineral density (BMD; 10 versus 18%) compared to controls at 3 months-of-age. In addition,  $\mu$ CT analyses found that bone volume (BV/TV, %) and cortical thickness (Ct.Th., mm) were reduced in *Oc-Cre-Pkd1*<sup>lox/+</sup> (25.5 $\pm$ 2.5 % and 0.241 $\pm$ 0.009 mm) and *Oc-Cre-Pkd1*<sup>lox/m1Bci</sup> (18.8 $\pm$ 1.6 % and 0.211 $\pm$ 0.005 mm) compared with the age-matched control littermates (33.7 $\pm$ 2.1 % and 0.267 $\pm$ 0.005 mm). Mineral apposition rates were also reduced proportionate to *Pkd1* gene dose (1.28 $\pm$ 0.31, 0.83 $\pm$ 0.13, and 0.45 $\pm$ 0.07  $\mu$ m/day in control, *Oc-Cre-Pkd1*<sup>lox/+</sup> and *Oc-Cre-Pkd1*<sup>lox/m1Bci</sup>, respectively). Real-time RT-PCR analyses also revealed a conditional *Pkd1*-gene dosage effect on osteoblast-related genes expressions, including *Runx2-IL*, *Osteocalcin*, *Osteopontin*, and *bone sialoprotein*. Thus, the selective deletion of *Pkd1* from osteoblasts postnatally results in defective osteoblast-function and osteopenia. These findings indicate that *Pkd1* functions in osteoblasts to regulate bone formation.

**Noncanonical Wnt Signaling Is Involved mir-206 Expression in Osteoblastic Differentiation.** M. Sato<sup>\*1</sup>, M. Nashimoto<sup>\*2</sup>, D. Kanayama<sup>\*1</sup>, Y. Yawaka<sup>\*3</sup>, M. Tamura<sup>1</sup>. <sup>1</sup>Biochemisrty and Molecular Biology, Grad. Sch. Dent. Med., Hokkaido University, Sapporo, Japan, <sup>2</sup>Department of Applied Life Sciences, NUPALS, Niigata, Japan, <sup>3</sup>Dentistry for Children and Disabled Person, Grad. Sch. Dent. Med., Hokkaido University, Sapporo, Japan.

Wnt signaling plays a role in the developing skeletal system. However, the exact mechanisms by which Wnt signaling regulates bone remodeling remain to be elucidated. Our previous studies demonstrated that an interaction between  $\beta$ -catenin and Smad was crucial for Wnt-mediated regulation of BMP-2 responsive gene expression, and that BMP-2 up-regulated Wnt-induced osteoprotegerin (OPG) expression. MicroRNAs (miRNAs) are small non-coding RNAs that are emerging as important post-transcriptional gene regulators. Many miRNA are expressed in a tissue-specific manner, suggesting a role of the miRNA in the specification of the tissue during differentiation. In this study, we investigated the regulation of miRNA expression by Wnt signaling in osteoblastic differentiation. We cultured Wnt3a or Wnt5a stably over-expressing mesenchymal pluripotent C2C12 cell lines and examined levels of miR206 expression using TaqMan MicroRNA Assays. In C2C12 cells, miR-206 was expressed, while its expression was dramatically reduced in Wnt5a over-expressing C2C12 (Wnt5a-C2C12) cells. In contrast, miR-206 expression was similar in Wnt3a-C2C12 cells. These results indicated that non-canonical Wnt mediated signaling regulates miR-206 gene expression, and this is the first study linking miRNA expression to Wnt signaling. The miR-206 expression levels were also down-regulated by treatment with BMP2 in C2C12 cells. To further investigate the function of miR-206, we have examined over-expression of miR-206 or silencing of miR-206 by sgRNA (tRNaseZL-utilizing gene silencing method). Transfection of miR-206 reduced cell number in Wnt5a-C2C12 cells, indicating that miR-206 might regulate cell proliferation in these cells. RT-PCR analysis indicated that Id-1 expression was reduced by transfection of miR-206. These results show that miR-206 is a target gene for non-canonical Wnt signaling, and that its link is mediated by a novel mechanism by which miRNAs regulate cell proliferation and osteoblastic differentiation.

**Accelerated Fracture Callus Remodeling and Membranous Bone Healing in STAT1 Deficient Mice.** K. Tajima<sup>\*1</sup>, H. Takaishi<sup>1</sup>, N. Ota<sup>1</sup>, N. Kosaki<sup>1</sup>, T. Tomonda<sup>\*1</sup>, M. Yoda<sup>\*2</sup>, J. Takito<sup>\*1</sup>, M. Matsumoto<sup>\*2</sup>, Y. Toyama<sup>\*1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, <sup>2</sup>Spine and Spinal Cord Disease, Keio University School of Medicine, Tokyo, Japan.

Signal transducer and activator of transcription 1 (STAT1), originally identified as a signal transducing molecule in the interferon (IFN) pathway, participates not only in immune responses but also acts directly on osteoclast precursor cells and mesenchymal cells. Bone fracture triggers a steady inflammatory cascade of bone regeneration and this reparative process consists of a variety of molecular and cellular events. Although various growth factors and cytokines that participate in fracture healing have been identified, the precise mechanism behind these processes has not been fully understood. Here, we generated a fracture model using STAT1 knock out (KO) mice to elucidate the role of STAT1 in fracture healing.

A transverse osteotomy was performed at the middle of the tibia of 8-week-old male STAT1 KO and wild type (WT) mice. The fracture site was stabilized by inserting a inner pin of a 23-gauge spinal needle intramedullary. Soft X-ray and micro CT scanning were

performed at 1, 2, 3, 4, 6, and 10 weeks after surgery. There was no difference in the rate of callus formation and bone union between STAT1 KO and WT until post-fracture-week (PFW) 4. But the cross sectional area of the fracture site after bone union significantly decreased in KO mice ( $1.48 \pm 0.39 \text{ mm}^2$  at PFD6 and  $1.35 \pm 0.32 \text{ mm}^2$  at PFW10) compared to WT ( $2.41 \pm 0.27 \text{ mm}^2$  at PFW6 and  $2.32 \pm 0.18 \text{ mm}^2$  at PFW10), suggesting the accelerated callus resorption and bone remodeling in STAT1 KO. To examine the membranous ossification in STAT1 KO mice, we next generated a cortical defect model in tibiae. Soft X-ray and histological analysis were performed at PFW1, 2, 3, and 4. STAT1 KO mice showed the rapid recovery at PFW2 and 3. The number of stromal cells existed in the defect area was the same between WT and STAT1 KO.

It is known that the skeletal phenotype in STAT1 KO mice exhibits a high bone turnover typed osteosclerosis due to accelerated RANKL-dependent osteoclastogenesis and the enhanced calcification by osteoblasts. The enhanced calcification of STAT1 KO osteoblasts is explained by the release of inhibition of Runx2 function by STAT1. Since there was no significant difference in callus formation in two groups, we assumed that the STAT1 attenuated the callus remodeling and the membranous ossification in fracture healing. Further investigation of the STAT1 signaling *in vitro* will be presented.

**Characterization of Jun Activation-Domain Binding Protein (Jab1)-Interacting Motif in LIM Mineralization Protein-1.** S. Sangadala, Y. Liu, M. Viggewarapu, L. Titus, S. Boden. Orthopaedics, Atlanta VA Medical Center, Atlanta, GA, USA.

Members of the transforming growth factor  $\beta$  (TGF $\beta$ ) superfamily have important effects on osteoblast differentiation and bone formation. We have shown previously that LIM Mineralization Protein-1 (LMP-1) enhances the efficacy of BMP-2, a member of the TGF $\beta$  superfamily, in cultured mesenchymal stem cells by the association of LMP-1 with Smurf1. Additionally, we report here that LMP-1 associates with Jab1, a protein also involved in protein degradation pathways like Smurf1. We screened a bone marrow library using the yeast-2-hybrid system. Sequencing and database matching of positive clones identified Jun activation domain binding protein 1 (Jab1) as a candidate binding partner for LMP-1. Immunoprecipitations demonstrated that Jab1 was found in complexes with LMP-1.

Jab1 is also known as the 5<sup>th</sup> subunit of the COP signalosome exhibiting homology to the 26S proteasomal lid complex. Jab1 binds to Smad4, Smad5 and Smad7, key intracellular signaling molecules of the TGF $\beta$  superfamily, and results in ubiquitination and/or degradation of these Smads. We confirmed a direct interaction of Jab1 with LMP-1 using recombinantly expressed proteins in slot-blot binding assays. In these studies, we also identified interaction of Smad1 with Jab1, in addition to Smads4, 5, and 7 as reported in literature. We hypothesized that LMP-1 binding to Jab1 prevents the binding and subsequent degradation of these Smads causing increased accumulation of osteogenic Smads in cells. To test this hypothesis we overexpressed LMP-1 in cells, separated the nuclear proteins by SDS-PAGE, and probed blots with Smad4 specific antibody. We demonstrated a 2-fold increase in the amount of Smad4 detected in LMP-1 treated cells compared with untreated cells. The phosphorylated receptor Smads1, 5 or 8 oligomerize with Smad4, enter the nucleus and induce osteogenic genes in the BMP pathway. An increase in nuclear Smad4 is an indicator of enhancement of this pathway.

We identified a motif in LMP-1 that is predicted to interact with Jab1 based on the MAME/MAST sequence analysis of several cellular signaling molecules that are known to interact with Jab-1 such as p27 (a cyclin-dependent-kinase inhibitor), Leukocyte functional antigen-1, lutropin/choriogonadotropin receptor, c-jun, Smad4, p53 and psoriasins. We further mutated the potential key interacting residues in LMP-1 and showed loss of binding to Jab1 in binding assays *in vitro*. Further studies are underway to establish biological relevance of LMP-1 and Jab1 interaction in enhancing the levels of osteogenic Smads resulting in potentiation of signaling by members of the TGF $\beta$  superfamily.

**PTH/PTHrP Mediated Stimulation of Osteoblast Differentiation Involves Epac-Rap1 Dependent Processes.** N. S. Datta<sup>1</sup>, N. J. D'Silva<sup>\*2</sup>, L. K. McCauley<sup>2</sup>, A. B. Abou-Samra<sup>1</sup>. <sup>1</sup>Internal Medicine, Wayne State University, Detroit, MI, USA, <sup>2</sup>Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA.

The mechanisms underlying the crosstalk between the cAMP and mitogen-activated protein kinases (MAPKs or ERKs) and the involvement of the MAPK pathway in the actions of PTH and PTHrP on osteoblast differentiation and mineralization are not completely understood. Our previous studies suggested involvement of ERK and cyclin D1 in the proliferative and differentiative actions of PTH and PTHrP; expression of cyclin D1 was dependent on ERK activity in MC3T3 osteoblastic cells. The mechanisms involved in the activation or inhibition of ERK signaling by cAMP include activation of the small G protein Ras and the protein kinase Raf-1 as well as the monomeric G protein Rap1 (GTPase Rap1) which preferentially activates B-Raf. cAMP can modulate ERKs via the Epac/Rap1/B-Raf pathway in a PKA- and Ras- independent manner. Although studies *in vivo* suggest that the anabolic actions of PTH and PTHrP are mediated by cAMP it is not known if Epac,

Rap1 and B-Raf signaling pathway is involved. To examine the involvement of Rap1 signaling pathway on the growth of MC3T3-E1 osteoblastic cells, the cells were synchronized by switching them to media without serum for 36-48h to render them quiescent and then treated with or without PTHrP (100 nM) in low serum (2%) for 30 min-5h and harvested. Differentiation was induced with ascorbic acid for 7 days; and the cells were then treated with vehicle or PTHrP for 30 min-5h before harvesting. Total cellular proteins and RNA were isolated. Using a pull-down assay, active GTP bound-Rap1 was up-regulated following SDS PAGE and Western blot analyses in differentiated MC3T3-E1 osteoblastic cells. Real-time PCR analysis demonstrated induction of Rap1B transcription ( $p < 0.01$ ) in these cells following PTHrP treatment. Ectopic ossicles, an engineered bone growth model generated with bone marrow stromal cells from C57BL6 mice implanted in nude mice, showed an increase in bone formation and increased Rap1B transcription ( $p < 0.01$ ) following 2 weeks of daily PTH treatment ( $40 \mu\text{g/kg}$ ; sc) *in vivo*. These studies show that activation of the PTH/PTHrP receptor in the osteoblastic cells increase the expression of Rap1B. The increased Rap1B provides an alternate signaling mechanism for the expression of the anabolic action of PTH and PTHrP in the differentiated osteoblasts. **Ahnak Regulates Calcium Signaling and ATP Release in Osteoblasts in Response to Mechanical Stimulation.** Y. Shao, V. P. Fomin\*, M. C. Farach-Carson, R. L. Duncan. Biological Sciences, University of Delaware, Newark, DE, USA.

We have found that ahnak, a 700kDa scaffold protein, interacts with the auxiliary  $\beta$  subunit of the  $\text{Ca}_v1.2$  cardiac L-type voltage sensitive calcium channel (LVSCC) and appears to anchor these channels to the actin cytoskeleton. Western blot analysis and immunohistochemistry demonstrated that ahnak was primarily expressed at the plasma membrane of mouse osteoblasts, with relatively lower intracellular distribution. In addition to the structural function of ahnak, we postulate that ahnak can regulate LVSCC activity and, as a result, alter ATP release in osteoblasts in response to fluid shear. Using siRNA strategy directed at ahnak in MC3T3-E1 osteoblasts, we were able to suppress ahnak protein levels by approximately 80% of vector transfected controls. The intracellular  $\text{Ca}^{2+}$  increase in response to mechanical stimulation in MC3T3-E1 cells was significantly reduced by 70% in response to ahnak protein knockdown indicating a possible role of ahnak in the regulation of  $\text{Ca}^{2+}$  signaling. We have previously shown that this increase in  $\text{Ca}^{2+}$  through LVSCC activation was responsible for fluid shear-induced ATP release from MC3T3-E1 cells. Although ahnak protein knockdown had no effect on basal ATP release in static cells, fluid shear-induced ATP release was significantly attenuated in siRNA transfected cells ( $p < 0.01$ ). Interestingly, quinacrine staining indicated a marked accumulation of acidic vesicles (mostly ATP rich vesicles) in siRNA transfected cells in static conditions. While we have shown that shear induces polymerization of actin filaments, knockdown of ahnak protein with specific siRNA did not influence the structures of either actin filaments or microtubule cytoskeleton at static conditions. Microtubule filaments are disassembled in response to fluid shear untreated osteoblasts. However the microtubule structure was kept intact in ahnak siRNA transfected cells, suggesting that ahnak may participate in the microtubule-mediated vesicular ATP transportation and release. Collectively, our investigation revealed that ahnak functions in  $\text{Ca}^{2+}$  signal regulation in bone cells independently of the actin-based cytoskeleton. Ahnak protein was clearly involved in the ATP release induced by mechanical stimulation. Furthermore, Western analyses demonstrate that ahnak protein levels are rapidly reduced in MC3T3-E1 cells in response to fluid shear, suggesting that loss of this protein may be involved in the loss of mechanosensitivity in response to continued loading.

**Integrin-associated Protein Upregulates Osteogenesis-related Transcription Factors via TGF- $\beta$  and BMP Pathways.** K. Ikeda<sup>\*1</sup>, K. Shimada<sup>1</sup>, K. Kawamoto<sup>\*1</sup>, M. Maeno<sup>2</sup>, K. Ito<sup>\*1</sup>. <sup>1</sup>Department of Periodontology, Nihon University, Tokyo, Japan, <sup>2</sup>Department of Oral Health Sciences, Nihon University, Tokyo, Japan.

To understand the mechanism of developing bone leads to open new frontiers in bone regeneration. To analyze the molecular events that occur in the developing mandible, we examined the expression of 8803 genes from samples taken at different time points during rat postnatal mandible development using cDNA microarray. We demonstrated that gene expression of Integrin-associated protein (IAP, also known as CD47) changed markedly. Transforming growth factor (TGF)- $\beta$  superfamily, including bone morphogenetic proteins (BMPs), play a specific role in developing bone. TGF- $\beta$  and BMPs induce receptor-regulated Smads (R-Smads); Smad2, 3 or Smad1, 5, 8, respectively. The R-Smads form complexes with the common-partner Smad, which is Smad4 in mammals. These complexes translocate and accumulate in the nucleus and regulate the transcription of various target genes.

To analyze the function of IAP in the TGF- $\beta$  and BMP signaling pathway, endogenous IAP was disrupted in rat osteoblastic cell line ROS 17/2.8 using a 19 nucleotide siRNA and examined its effectiveness in silencing IAP expression. The gene expression of osteogenesis-related transcription factors, including Runx2, Msx2, Dlx5 and Osterix was determined by real-time reverse-transcribed PCR. Moreover, the protein levels of Smad4, Smad1, phospho-Smad1, Smad2, phospho-Smad2 were evaluated using SDS-PAGE and Western blot analysis.

The efficiency of silencing IAP mRNA level was approximately 70%. The expression of Runx2, Msx2, Dlx5 and Osterix was markedly increased when IAP was silenced. The protein levels of Smad4, phospho-Smad1, phospho-Smad2 were increased dose dependently. Our results suggest that IAP regulates osteogenesis-related transcription factors via TGF- $\beta$  and BMP pathways.

**Lithocholic Acid Downregulates the Effects of Vitamin D<sub>3</sub> on Primary Human Osteoblasts.** S. Ruiz-Gaspà<sup>\*1</sup>, A. Enjuanes<sup>\*1</sup>, P. Peris<sup>1</sup>, A. Martinez-Ferrer<sup>\*1</sup>, M. J. Martinez de Osaba<sup>\*1</sup>, L. Alvarez<sup>\*1</sup>, A. Monegal<sup>\*1</sup>, A. Combalia<sup>\*2</sup>, B. Gonzalez<sup>\*1</sup>, N. Guanabens<sup>1</sup>, A. Pares<sup>\*3</sup>. <sup>1</sup>Metabolic Bone Diseases Unit, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Spain, <sup>2</sup>Department of Orthopaedics, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Spain, <sup>3</sup>Liver Unit, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Spain.

Osteoporosis is a complication of chronic cholestasis, related to its severity and duration. Cholestasis is characterized by deficient biliary secretion of total and conjugated bilirubin and bile acids, with high circulating levels. Among bile acids, lithocholic acid has particular significance because it has potential toxic effects and on the other hand has been described as an agonist of vitamin D receptor. Therefore, this study was addressed to analyse the effect of lithocholic acid on survival and on pathways of vitamin D metabolism and cell maturation on primary human osteoblasts.

Bone cell cultures were established from trabecular bone specimens of 10 patients undergoing hip replacement for osteoarthritis. Experiments with human osteoblastic cell cultures were performed using DMEM with or without fetal bovine serum (FBS) or human albumin, and at different lithocholic acid concentrations (10<sup>-6</sup>M, 10<sup>-5</sup>M, 10<sup>-4</sup>M and 10<sup>-3</sup>M) and times (6, 24, 48 and 72 hours) with or without vitamin D<sub>3</sub> (10<sup>-7</sup>M). Cell survival was determined by cell proliferation reagent WST-1. Vitamin D 24-hydroxylase (*CYP24A*), bone gamma-carboxyglutamate protein (*BGLAP*) and osteoprotegerin (*TNFRSF11B*) gene expression were quantified by real time PCR and used as indicators of vitamin D metabolism, osteoblast maturation and osteoclast differentiation and activation, respectively.

Lithocholic acid with or without FBS or albumin at 10<sup>-3</sup>M and 10<sup>-4</sup>M, respectively had a toxic effect evidenced by a dramatic decrease in cell survival. All the following experiments were performed with lithocholic acid below these lethal concentrations. Lithocholic acid increased *CYP24A* (p=0.02) and *BGLAP* (p=0.007) mRNA expression in cell cultures with no changes on *TNFRSF11B* expression, effects which were significantly lower (*CYP24A*: - 96% and *BGLAP*: - 92%) than those observed with vitamin D<sub>3</sub>. Moreover, lithocholic acid at all time points and conditions significantly downregulated the effect of vitamin D<sub>3</sub> on *CYP24A* and *BGLAP* gene expression by -72% and -74%, respectively.

In conclusion, lithocholic acid decreases the stimulatory effect of vitamin D<sub>3</sub> on *CYP24A* and *BGLAP* expression in primary human osteoblasts. These results may explain the potential deleterious effects of retained toxic bile acids on bone formation in patients with chronic cholestasis.

**Disclosures:** S. Ruiz-Gaspà, None.

## SA031

**The Interplay Between BMP and TGF- $\beta$  Signaling in Osteoblast Differentiation.** D. J. J. de Gorter<sup>\*1</sup>, R. L. van Bezooijen<sup>\*2</sup>, C. W. G. M. Löwik<sup>\*2</sup>, P. ten Dijke<sup>\*1</sup>. <sup>1</sup>Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Endocrinology, Leiden University Medical Center, Leiden, Netherlands.

Transforming Growth Factor- $\beta$  (TGF- $\beta$ ) is a pleiotropic cytokine implicated in the control of proliferation, migration, differentiation, and survival of many different cell types. In the skeleton, TGF- $\beta$  is one of the most abundant cytokines and plays a major role in its development and maintenance by affecting both cartilage and bone metabolism. Both positive and negative effects of TGF- $\beta$  on bone formation have been reported, but the exact molecular mechanisms underlying these effects remain to be established. Among others, TGF- $\beta$  modulates signaling induced by Bone Morphogenetic Proteins (BMPs), which are required for skeletal development and maintenance of adult bone homeostasis, and play an important role in fracture healing.

Although TGF- $\beta$  is generally believed to inhibit BMP-induced osteoblast differentiation, we found that pharmacological inhibitors against the TGF- $\beta$  type I receptor ALK5 impaired BMP-induced alkaline phosphatase (ALP) activity in the murine KS483 mesenchymal and C2C12 pre-myoblast cell lines. In addition, these ALK5 inhibitors reduced BMP6 stimulated mineralization of KS483 cells. Conversely, co-stimulation with BMP6 and TGF- $\beta$ 3 further increased ALP activity and mineralization of KS483 cells compared to BMP6 alone. This was not only observed in combination with BMP6, but also with BMP2 and BMP7. In C2C12 cells, TGF- $\beta$ 3 could inhibit but also under certain conditions stimulate BMP-induced ALP activity. BMP6-induced activation of a BMP-Smad-dependent luciferase reporter was, however, always inhibited by TGF- $\beta$ 3, suggesting that the stimulatory effect of TGF- $\beta$ 3 is not due to increased BMP-Smad activity.

In conclusion, besides acting as an inhibitor, TGF- $\beta$  can also stimulate BMP-induced osteoblast differentiation. Characterization of the interplay between BMP and TGF- $\beta$  signaling and the conditions in which TGF- $\beta$  inhibits or stimulates BMP-induced osteoblastic differentiation may provide new insights into the molecular mechanisms that regulate bone formation and how this may be modulated.

**PTH Induces COX-2 in MC3T3-E1 Osteoblasts via cAMP-PKA and Calcium-Calcieneurin Pathways.** H. Huang<sup>\*1</sup>, D. Chikazu<sup>2</sup>, O. Voznesensky<sup>\*1</sup>, K. Dodge-Kafka<sup>\*3</sup>, H. Drissi<sup>4</sup>, C. Pilbeam<sup>1</sup>. <sup>1</sup>Department of Medicine, UCHC, Farmington, CT, USA, <sup>2</sup>Department of Oral and Maxillofacial Surgery, University of Tokyo, Tokyo, Japan, <sup>3</sup>Department of Cell Biology, UCHC, Farmington, CT, USA, <sup>4</sup>Department of Orthopedics, UCHC, Farmington, CT, USA.

Parathyroid hormone (PTH) is a major regulator of bone remodeling that is thought to have most of its effects via the cyclic adenosine monophosphate (cAMP)-protein kinase A (PKA) signaling pathway. PTH is also a potent inducer of cyclooxygenase-2 (COX-2) via the PKA pathway. The goal of this study was to identify cis-acting sites and trans-acting factors mediating the PTH induction of COX-2. We used osteoblastic MC3T3-E1 cells (MC-4 sub-clone) stably transfected with -371/+70 bp of the murine COX-2 promoter fused to a luciferase reporter. We made site-directed mutations in the promoter DNA in (1) the cAMP response element (CRE) at -57/-52 bp, (2) the activating protein-1 (AP-1) binding site at -68/-63 bp, (3) the nuclear factor of activated T-cells (NFAT) binding site at -77/-73 bp, and (4) both the AP-1 and NFAT sites (which comprise a consensus sequence for composite binding of NFAT and AP-1). Single mutation of the CRE, AP-1, or NFAT site decreased PTH-stimulated luciferase activity by about 60%, while mutation of the composite NFAT/AP-1 site reduced the PTH-stimulated activity by 90%. On electrophoretic mobility shift analysis (EMSA), PTH stimulated binding of phosphorylated CRE-binding protein (CREB) to an oligonucleotide spanning the CRE. PTH also increased binding of NFATc1, c-Fos and c-Jun to an oligonucleotide spanning the NFAT/AP-1 composite site. PTH did not increase binding of NFATc2, c3 or c4 to the composite site. EMSA competition experiments showed cooperative binding of NFATc1 and AP-1 proteins to the NFAT/AP-1 composite sequence, and the cooperativity depended more on NFAT than on AP-1 binding. Both PTH and forskolin, an activator of adenylyl cyclase, stimulated NFATc1 nuclear translocation. Phorbol myristate acetate, a protein kinase C (PKC) agonist, did not stimulate NFATc1 nuclear translocation. PKA inhibitors H-89 and KT-5720 inhibited PTH- or forskolin-stimulated COX-2 promoter activity 98 and 60%, respectively, while GF109203X, a specific PKC inhibitor, had no effect on either PTH- or forskolin-stimulated COX-2 promoter activity. Inhibition of the calcium-calcieneurin-NFAT pathway by chelation of calcium or by calcieneurin inhibitors reduced PTH- and forskolin-stimulated COX-2 promoter activity 60-80%. These results demonstrate a critical role for both the cAMP/PKA pathway and the calcium-calcieneurin pathway in NFAT activation and PTH signaling in osteoblasts and suggest that cross-talk between these two pathways may play a role in other important effects of PTH in osteoblasts.

**P2Y<sub>2</sub> Receptor Activation Regulates RhoA-Mediated Stress Fiber Formation in Osteoblasts.** W. D. Yang<sup>1</sup>, J. Gardinier<sup>\*2</sup>, S. Majumdar<sup>\*1</sup>, D. L. Randall<sup>1</sup>. <sup>1</sup>Biological Sciences, University of Delaware, Newark, DE, USA, <sup>2</sup>Biological Sciences, and Mechanical Engineering, University of Delaware, Newark, DE, USA.

Bone and osteoblasts rapidly lose their mechanosensitivity in response to continued loading, likely through adaption of cellular mechanism involved in the transduction of this signal. We postulate that cytoskeleton reorganization in response to load is one mechanism through which the desensitization of osteoblasts to load is incurred. Because we have shown that ATP is rapidly released from osteoblasts in response to mechanical load, we hypothesize that activation of purinergic signaling mediates the increase in actin organization. P2Y<sub>2</sub> receptor activation increases stress fibers formation in other cell types, therefore we examined the role of P2Y<sub>2</sub> in the regulation Rho-mediated stress fibers formation induced by mechanical stimulation in osteoblasts. In this study, we examined the effects of ATP and P2Y<sub>2</sub> on cytoskeleton formation, Rho activation and cell mechanical properties alterations in MC3T3-E1 cells subjected to 12 dynes/cm<sup>2</sup> fluid shear. When 100 μM ATP, ADP, BzATP or UDP were added to static cultures, ATP produced a significant change in actin stress fiber formation, mimicking the effects of shear. However, aside from a reduced effect of UDP on actin, the rest of the nucleotides tested had little effect on actin organization. Analyses of the effects of ATP and fluid shear on RhoA activation using a G-LISA kit indicated that both ATP and fluid shear increased Rho activation within minutes of stimulation, peaking at 15 min. To evaluate P2Y<sub>2</sub> function in Rho activation and stress fiber formation, MC3T3-E1 osteoblasts were transfected with P2Y<sub>2</sub> siRNA, which produced a 75% suppression of P2Y<sub>2</sub> protein 48 hours after transfection compared to vector controls. The MC3T3-E1 osteoblasts transfected with P2Y<sub>2</sub> siRNA failed to respond to ATP of fluid shear with an increase in either Rho activation or stress fiber formation. This was similar to the responses found with pretreatment of the cells with apyrase or RB-2 (P2Y<sub>2</sub> specific inhibitor). Atomic force microscopy (AFM) found that cell stiffness was significantly increased after fluid shear or ATP treatment. In contrast, P2Y<sub>2</sub> siRNA transfected cells did not increase cellular stiffness in response to these stimuli. This study suggests that P2Y<sub>2</sub> receptor activation by ATP is essential in the shear-induced, RhoA-mediated stress fiber formation, that this pathway regulates the mechanical properties of the osteoblast and that inhibition of this pathway may reduce the loss of mechanosensitivity associated with extended loads.

**Stable Isotopic Labeling of Amino Acids in Cultured Human Bone Marrow Stem Cells: Application to BMP2 Induced Wnt/β-catenin Signaling.** J. Lee<sup>\*1</sup>, B. Kim<sup>\*1</sup>, J. Ahn<sup>\*1</sup>, H. Park<sup>\*1</sup>, E. Kim<sup>\*2</sup>, S. Park<sup>\*3</sup>, J. Kim<sup>\*1</sup>, E. Park<sup>\*4</sup>, J. Yoo<sup>\*2</sup>, J. Yates III<sup>\*3</sup>, J. Cho<sup>\*1</sup>. <sup>1</sup>Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, <sup>2</sup>Mass Spectrometer Development Team, Korea Basic Science Institute, Daejeon, Republic of Korea, <sup>3</sup>Cell Biology, The Scripps Research Institute, La Jolla, CA, USA, <sup>4</sup>Pathology and Regenerative Medicine, Kyungpook National University, Daegu, Republic of Korea.

Bone morphogenetic protein-2 (BMP2) is one of the most potent bone-inducing agents and promotes differentiation of osteoblasts from bone marrow stem cells (BMSC). However the potency of BMP2 varies in a species-specific manner. Especially, BMP2 induces alkaline phosphatase activity in human BMSCs is much less than rodents, although several other genes known to be steadily induced. Thus, there has been an increasing importance of discovering the unknown mechanism of BMP2 role in human BMSC. Here, we used SILAC (Stable isotope labeling with amino acids in cell culture) in combination with LTQ-FT-mass spectrometry not only to characterize the unknown mechanisms of human BMSC differentiation by BMP2 but also to find early differentiation markers. After tandem mass spectra were interpreted by SEQUEST using DTASelect2, ion chromatograms were quantified by Census program. In this analysis, 414 proteins of total 449 uniquely identified were successfully quantified with 79.21% quantification efficiency of peptides (2762 of 3487 total peptides). Of these, 12 were found to be increased more than 1.4-fold in BMP2 stimulated cells. In addition, 18 proteins were detected only in heavy-labelled cells. Nine proteins were down-regulated less than 1.4-fold by BMP2 stimulation. Interestingly, β-catenin was only detected in heavy-labelled, BMP-2 stimulated cells. BMP2-increased β-catenin level in time-dependent and dose-dependent manner. BMP-2 stimulation also increased phospho-Gsk3β levels which are known to result in the increment of β-catenin. These results suggest that up-regulation of Wnt signaling in early time could potentiate or accelerate the capability of BMP2 induced osteoblast differentiation. In conclusion, our investigation that the SILAC combined MS-based analysis could provide the basis for the understanding of human BMSC differentiation to osteoblast mechanisms upon BMP2 stimulation.

**High Concentrations of Hydroxytyrosol and Quercetin Antioxidants Enhance Adipogenesis and Inhibit Osteoblastogenesis in Mesenchymal Stem Cells.** A. Casado-Díaz<sup>\*1</sup>, J. Anter<sup>\*2</sup>, R. Santiago-Mora<sup>\*3</sup>, L. Luque<sup>\*4</sup>, G. Dorado<sup>\*5</sup>, J. M. Quesada<sup>3</sup>. <sup>1</sup>Dpto. I+D, SANYRES XXI (Grupo PRASA), Córdoba, Spain, <sup>2</sup>Dep. Genética, Universidad de Córdoba, Córdoba, Spain, <sup>3</sup>Unidad de Metabolismo Mineral, Hospital Universitario Reina Sofía, Córdoba, Spain, <sup>4</sup>Dep. Química Analítica, Universidad de Córdoba, Córdoba, Spain, <sup>5</sup>Dep. Bioquímica y Biología Molecular, Universidad de Córdoba, Córdoba, Spain.

The increase of age-related oxidative stress is associated with aging and major chronic aging-related diseases, such as loss of bone mineral mass and osteoporosis. Therefore, natural antioxidants may be potentially useful to reduce the impact of the oxidative stress on the organism in general and the bone in particular. We have analyzed the effect of different concentrations of plant antioxidants (hydroxytyrosol and quercetin) on the differentiation of mesenchymal stem cells (MSC). Thus, MSC were induced to differentiate to osteoblasts, in the presence of 10-8 M dexamethasone, 0.2 mM ascorbic acid and 10 mM β-glycerolphosphate, or to differentiate to adipocytes, using 5 x 10<sup>-7</sup> M dexamethasone, 0.5 mM isobutylmethylxanthine and 50 μM indometacine. The cultures were supplemented with hydroxytyrosol (10<sup>-4</sup> and 10<sup>-6</sup> M) or with quercetin (10<sup>-5</sup> and 10<sup>-7</sup> M). The expression of osteoblastogenesis and adipogenesis marker genes was analyzed by quantitative real-time PCR (QRT-PCR) after seven and 14 days of treatment. The alkaline phosphatase activity was measured on the cells induced to osteoblasts, and the formation of fat vesicles was monitored after 14 days of induction to adipocytes. We found that 10<sup>-4</sup> M hydroxytyrosol and 10<sup>-5</sup> M quercetin significantly enhanced adipogenesis, increasing the number adipocytes and the expression of adipogenic marker genes (ppar-γ2 and lpl). The other tested concentrations did not affect, or increased the adipogenesis to a lesser extent. On the other hand, the higher hydroxytyrosol and quercetin concentrations tested inhibited the studied osteoblastogenesis markers, mainly after seven days of induction. These data suggest that although low concentrations of hydroxytyrosol and quercetin may enhance the bone formation, they have the opposite effect at concentrations higher than 10<sup>-5</sup> M. Such high concentrations promote the adipogenic instead of the osteoblastogenic differentiation of MSC, which may affect negatively the bone formation.

**Concentration of Connective Tissue Progenitors in Autologous Cancellous Bone Graft Enhances New Bone Formation in a Canine Femoral Defect Model.** K. Kumagai<sup>\*1</sup>, J. Otonichar<sup>\*1</sup>, R. Rozic<sup>\*1</sup>, C. Boehm<sup>\*1</sup>, K. Powell<sup>\*1</sup>, A. Vasanji<sup>\*1</sup>, T. Saito<sup>\*2</sup>, G. F. Muschler<sup>1</sup>. <sup>1</sup>Orthopaedic Research Center, The Cleveland Clinic Foundation, Cleveland, OH, USA, <sup>2</sup>Department of Orthopaedic Surgery, Yokohama City University, Yokohama, Japan.

**Objective:** Osteogenic connective tissue progenitors (CTPs) in bone marrow and cancellous bone generate progeny expressing osteoblastic markers *in vitro* and contribute to new bone tissue *in vivo*. Autologous cancellous bone (ACB) is known as one of the best bone graft materials. ACB is biocompatible and provides on osteoconductive bone matrix. ACB also contains osteogenic CTPs. The purpose of this study was to define the distribution of osteogenic CTPs in ACB and the effect of impaction grafting on their delivery and efficacy in a canine femoral defect model.

**Methods:** Four identical 1.0 cm diameter and 1.0cm deep unicortical cylindrical defects for grafting were created in unilateral femur of eight mongrel dogs. After harvest of bone marrow by aspiration and cancellous bone by curetting from proximal humerus, four defects in each femur were treated with implantation of: 1) no graft, 2) bone marrow clot (BM), 3) non-compacted autologous cancellous bone (ACB1x) and 4) compacted autologous cancellous bone (3x starting volume, ACB3x) using a Latin square design. Animals were sacrificed four weeks after implantation and graft site in femur were harvested for analysis. Bone formation within defects was assessed by quantitative micro CT analysis and histological findings.

**Results:** Seventy percent of osteogenic CTPs were located on the trabecular surface. Therefore, impaction grafting concentrated CTPs by squeezing out marrow cells having lower CTP prevalence. The mean percent of bone volume (%BV) in ACB3x (12.9) was significantly greater than that in no graft (2.9) (*p* = 0.021). Although there was no statistical difference, %BV in BM (9.5) and ACB1x (9.4) was higher than that in no graft. When each defect was radially divided into three regions composed of the central third (0-1.5mm from defect center), the middle third (1.5-3mm from defect center) and the outer third (3-4.5mm from defect center), there were significant differences of %BV between ACB3x and no graft in the middle third and the outer third (*p* = 0.022, 0.027, respectively). Better bone formation was evident in the upper half of each defect.

**Conclusions:** This study demonstrated that impaction graft of autologous cancellous bone contains a higher concentration of osteogenic CTPs and results in greater new bone formation.

**Use of  $\alpha$ -smooth Muscle actin-GFP Transgene to Identify Periodontium Derived Osteoprogenitors.** S. M. San Miguel<sup>\*1</sup>, H. Li<sup>1</sup>, J. C. Igwe<sup>\*1</sup>, V. Ferrer<sup>1</sup>, H. Aguila<sup>\*2</sup>, I. Kalajzic<sup>1</sup>. <sup>1</sup>Dept. of Reconstructive Sciences, Uni. of Conn. Health Center, Farmington, CT, USA, <sup>2</sup>Dept. of Immunology, Uni. of Conn. Health Center, Farmington, CT, USA.

Cells with osteoprogenitor potential are present within the periodontal tissues during development and in postnatal life. In previous studies we identified an  $\alpha$ -SMA-GFP expressed in mesenchymal progenitor cells within the bone marrow stromal population and in adipose tissue. The purpose of this study is to define whether the  $\alpha$ -SMA promoter would direct GFP expression to osteoprogenitor cells in the dental follicle and periodontal ligament. We have utilized a transgenic mouse model approach in which GFP expression is driven by an  $\alpha$ -SMA promoter. Epifluorescence was evaluated in histological sections of mandibles derived from neonatal and 4-6 week old mice. Alpha SMAGFP expression was detected in the dental follicle, but not in mature bone. GFP+ cells were observed in apical regions of the root, the areas rich with vascularization. In addition transgene expression was evaluated in primary cultures derived from dental follicle (mDF) and periodontal ligament (mPDL). Strong expression of  $\alpha$ -SMAGFP was observed during early stages of the culture and diminished as mineralization progressed. Observation of GFP expression was complemented with analysis of osteogenic differentiation by analysis of RNA expression of bone markers, histochemical staining for alkaline phosphatase and detection of mineralized nodules by xylene orange. An intense ALP activity and the presence of mineralized nodules followed two weeks of osteogenic induction. Expression of BSP and DMP-1 increased during osteogenic differentiation. We utilized flow cytometry (FACS) to determine the proliferative potential and cellular profile of freshly isolated or cultured  $\alpha$ -SMA positive cells. FACS analysis revealed that freshly digested mDF cells expressed the mesenchymal markers Thy1 (40%) and Scal (8.79%). In vitro expansion enriched for an  $\alpha$ -SMAGFP+ population of which 60% of cells were Thy1+ and Scal+. The  $\alpha$ -SMAGFP+ population exhibited high proliferative potential, while proliferation of  $\alpha$ -SMAGFP- population was very limited. Our data suggest that the  $\alpha$ -SMA promoter has the potential to identify a population of osteoprogenitor cells residing within the dental follicle and periodontal ligament that can differentiate into mature osteoblasts.

**Mature Human Adipocytes differentiated from Bone Marrow Derived Mesenchymal Stem Cells.** A. C. Niemeier<sup>1</sup>, J. Prawitt<sup>\*2</sup>, M. Kassem<sup>3</sup>, U. Beisiegel<sup>\*2</sup>, J. Heeren<sup>\*2</sup>. <sup>1</sup>Orthopaedics, University Hospital Hamburg-Eppendorf, Hamburg, Germany, <sup>2</sup>IMB II: Molecular Cell Biology, University Hospital Hamburg-Eppendorf, Hamburg, Germany, <sup>3</sup>Endocrinology, University Hospital Odense, Odense, Denmark.

Bone marrow adipocytes and osteoblasts share common mesenchymal precursor cells. It is a generally accepted concept that factors exist which stimulate the differentiation process in favour of either osteoblastogenesis or adipogenesis, and that these may in part be mutually exclusive. In this context, it is likely that adipocytes and osteoblasts influence each other in a paracrine fashion. In order to identify such factors, there is a demand for suitable human cell models. Most research with regard to these questions has focused on osteoblast differentiation. Here we describe the adipogenic differentiation of a bone marrow derived telomerase-immortalized human mesenchymal stem cell line (hMSC-Tert) that maintains numerous features of terminally differentiated adipocytes even after prolonged withdrawal of the peroxisome proliferator activated receptor gamma (PPARgamma) agonist rosiglitazone. Differentiated hMSC-Tert developed the characteristic monolocular phenotype of mature adipocytes. The expression of adipocyte specific markers was highly increased during differentiation. Most importantly, the presence of the PPARgamma agonist rosiglitazone was not required for the stable expression the adipocyte markers lipoprotein lipase, adipocyte fatty acid binding protein and perilipin on mRNA and protein levels. Adiponectin expression was post-transcriptionally down-regulated in the absence of rosiglitazone. Insulin sensitivity as measured by insulin-induced phosphorylation of Akt and S6 ribosomal protein was also independent of rosiglitazone. In summary, we describe a novel model for mature human adipocytes derived from bone marrow mesenchymal stem cells. This model with its unique characteristics will be a valuable tool for the in vitro identification of secreted adipocyte-specific factors which influence osteoblastogenesis.

**Enhanced Mitochondrial Biogenesis Contributes to Wnt induced Osteogenic Differentiation of C3H10T1/2 Cells.** J. H. An<sup>\*</sup>, J. Y. Yang<sup>\*</sup>, S. W. Cho, J. Y. Jung<sup>\*</sup>, H. Y. Cho, Y. M. Cho<sup>\*</sup>, S. W. Kim, C. S. Shin. Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Mitochondria play a key role in cell physiology including cell differentiation. We investigated the changes of mitochondrial biogenesis during Wnt induced osteogenic differentiation of murine mesenchymal C3H10T1/2 cells.

**Methods:** C3H10T1/2 cells were cultured in DMEM and osteogenic differentiation was induced by Wnt-3A conditioned medium (CM). Mitochondrial mass, mitochondrial membrane potential and intracellular reactive oxygen species were measured by flow cytometry analysis. Oxygen consumption rate was analyzed by high-resolution respirometry and mitochondrial (mt) DNA copy-number by real-time PCR.

**Results:** gnaling by Wnt-3A CM resulted in significant increase alkaline phosphatase (ALP) activities in C3H10T1/2 cells as expected. The increase in ALP activities were associated with significant increase in mitochondrial mass, mitochondrial membrane potential, intracellular reactive oxygen species, oxygen consumption rate and mtDNA copy number compared to the control group. Co-treatment with DKK-1 and WIF-1, both of which are Wnt inhibitors, abrogated the Wnt-3A-induced ALP activities as well as mitochondrial biogenesis markers. Moreover, inhibition of mitochondrial biogenesis by Zidovudine treatment resulted in significant inhibition of osteogenic differentiation as measured by ALP activities. Finally, removal of mitochondria from human osteosarcoma cell line (p<sub>3</sub> cells) by ethidium bromide treatment resulted lower ALP activity both in basal and Wnt-3A stimulated state compared to that in mitochondria-intact cells (p<sub>1</sub> cells).

**Conclusion:** Mitochondrial biogenesis is upregulated by Wnt signaling and this upregulation seems to contribute to the osteogenic differentiation of mouse mesenchymal C3H10T1/2 cells.

**The Comparison of the Effects of Zoledronates on the Differentiation of Human Bone Marrow and Amniotic Fluid Derived Mesenchymal Stem Cells.** J. An<sup>\*1</sup>, I. Kim<sup>\*2</sup>, Y. Kim<sup>\*2</sup>, B. Joo<sup>\*3</sup>. <sup>1</sup>Internal Medicine, Good Moonhwa Hospital, Busan, Republic of Korea, <sup>2</sup>Internal Medicine, Busan National University Hospital, Busan, Republic of Korea, <sup>3</sup>Center for Reproductive Medicine, Good Moonhwa Hospital, Busan, Republic of Korea.

**Background:** Mesenchymal stem cells (MSCs) were identified in various tissues including human bone marrow and adipose tissue. Recently it has been known that amniotic fluid is rich source of fetal MSCs. Zoledronate is the most potent amino-bisphosphonate and act primarily by inhibiting osteoclast. But many reports show that zoledronate has anabolic action by influencing osteoblast differentiation. This study was aimed to compare the effects of zoledronates on the differentiation of MSCs derived from human bone marrow and amniotic fluid into osteoblast and adipocyte.

**Method:** Amniotic fluids were collected from 5 pregnant women who underwent amniocentesis at the second trimester due to chromosomal analysis and adult male-bone marrows were obtained from 3 patients who underwent total hip arthroplasty. Zoledronate was treated to MSC derived from amniotic fluid and bone marrow to induce differentiation into osteoblast and adipocyte. Osteoblast was confirmed by alkaline phosphatase (ALP) activity assay and characteristics of adipocyte was determined by sterol regulatory element binding protein 1 (SREBP-1), fatty acid synthase (FAS), acetyl CoA carboxylase 1 (ACC1) activities.

**Result:** ALP activity tended to more prominent in MSCs derived from amniotic fluid than that of bone marrow. In osteogenic differentiation from amniotic fluid, ALP activity was positively correlated with concentration of zoledronate and it was significantly increased at 10<sup>-6</sup>M concentration of zoledronate. However, in bone marrow, ALP activity was negatively correlated with concentration of zoledronate. SREBP1 and ACC1 activities tended to be decreased but FAS activities tend to be increased in MSCs derived from both amniotic fluid and bone marrow.

**Conclusion:** These results suggest that amniotic fluid seems to be more rich source of MSCs to be differentiated into osteoblast and adipocyte than bone marrow. Zoledronates may influence differently on the differentiation of MSCs according to their origins.

## SA046

**Overexpression of Alpha-catenin in C3H10T1/2 Cells Increases Osteoblast Differentiation.** D. Kim<sup>\*1</sup>, J. Yang<sup>\*2</sup>, J. Chung<sup>\*2</sup>, S. Cho<sup>\*2</sup>, S. Kim<sup>\*2</sup>, S. Kim<sup>\*2</sup>, C. S. Shin<sup>2</sup>. <sup>1</sup>Internal Medicine, Dankook University College of Medicine, Cheon-An, Republic of Korea, <sup>2</sup>Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

Alpha- and beta-catenin link cadherins to the actin-based cytoskeleton at adherens junctions and regulate cell-cell adhesion. Beta-catenin is also an important component of Wnt signaling pathway. Although roles of cadherins and canonical Wnt signaling in osteoblastic differentiation have been extensively studied, the role of alpha-catenin is not known. Murine embryonic mesenchymal stem cells, C3H10T1/2, were transduced with retrovirus encoding alpha-catenin (MSCV-alpha-catenin-HA-IRES-GFP). Cellular alpha-catenin expression was confirmed by western blot analysis using anti-HA antibody. In the presence of osteogenic media (10 mM beta-glycerol phosphate and 50 microgm/ml ascorbic acid) or Wnt-3A-conditioned medium, cells overexpressing alpha-catenin showed enhanced osteoblastic differentiation as measured by alkaline phosphatase (ALP) staining and ALP activity assay compared to the cells transduced with empty virus (MSCV-IRES-GFP). In addition, mRNA expression of osteocalcin and Runx2 was significantly increased compared to control cells. Cell aggregation assay revealed that alpha-catenin overexpression has significantly increased cell-cell aggregation. However, cellular beta-catenin levels (total, cytoplasmic-nuclear ratio) did not change by overexpression of alpha-catenin. Moreover, transient transfection of alpha-catenin did not increase TOPflash reporter activity nor was able to augment beta-catenin-mediated reporter activity. These results suggest that alpha-catenin overexpression increases osteoblast differentiation by increasing cell-cell adhesion rather than Wnt/beta-catenin signaling.

**Aging of Human Bone Marrow Stromal Cells: Role of WNT Pathways.** L. Shen<sup>\*</sup>, S. Zhou, J. Glowacki. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Human bone marrow stromal cells (hMSCs) include a fraction of osteoblast progenitors; we showed that there is an age-dependent decrease in their proliferation and osteoblast differentiation. In other cell types, WNT signaling maintains proliferation by stimulating cell division and inhibiting differentiation and apoptosis. Thus, we tested the hypothesis that WNT signaling may be related to aging in hMSCs. The first study tested whether there is an age related difference of WNT gene expression. The second study tested whether there is an effect of age on canonical WNT signaling in response to Parathyroid Hormone (PTH).

Bone marrow samples were obtained with IRB approval as femoral tissue discarded during total hip replacement for osteoarthritis. Low-density mononuclear cells were isolated by density centrifugation on Ficoll/Histopaque 1077(Sigma, MO). Adherent hMSCs were expanded 2-4 passages for experiments.

All Passage 2 (P2) samples of hMSCs from young subjects(<50y) expressed WNT2, a canonical WNT gene (Figure). In contrast, 3 of 4 samples from older subjects (>55y) showed no or low expression of WNT2. A notable additional sample (74 years old) with Type 2 diabetes mellitus (T2DM) as a comorbidity showed the highest expression of WNT2. All samples, including those with low or no WNT2, expressed strong signals for noncanonical WNT5a, and moderate signals for canonical WNT10b. A comparison of P2 with P4 cells showed differences attributable to *in vitro* effects: WNT 2 increased and WNT10b decreased with passage in many samples. These findings emphasize that passaging hMSCs may confound interpretation of expression profiling.

We assessed the effect of age on canonical Wnt signaling by measuring the effect of 10 nM PTH(1-34) on  $\beta$ -catenin at 6 h by Western immunoblot. In hMSCs from a 74-year-old subject, PTH did not activate  $\beta$ -catenin, compared with increased  $\beta$ -catenin (450%, 187%) in hMSCs from two younger subjects (34 and 42 years).

These pilot results indicate that 1) WNTs are expressed in hMSCs, 2) WNT2 expression is decreased with age, 3) *in vitro* passaging of cells may confound *in vivo* age differences, and 4) canonical WNT signaling in response to PTH was decreased with age. In conclusion, WNT2 may play a role in effects of aging on hMSCs.

**Marked Induction of Endochondral Bone Formation by Overexpression of a Constitutively Active Gli2 in Mesenchymal Stem Cells Isolated from the Healing Site.** Q. Wang<sup>\*</sup>, C. Xie<sup>\*</sup>, M. Xue<sup>\*</sup>, X. Zhang. Orthopaedics, University of Rochester Medical Center, Rochester, NY, USA.

Hedgehog/Gli2 pathway has been critically implicated in endochondral bone formation during skeletal development. The hedgehog pathway is also activated during fracture repair, indicating a potential role of the pathway in bone repair process. Using a segmental bone graft transplantation model in mice, we have succeeded in isolation of a unique population of mesenchymal stem cells from periosteum at the early stage of healing. These cells express the typical mesenchymal stem cell markers Sca-1, SSEA4, CD105, CD29 and CD140 and demonstrated marked proliferation capacity *in vitro*. They are multipotent and capable of differentiating into osteoblasts, adipocytes and chondrocytes. Among growth factors and genes examined, we found that activation of Hedgehog signaling potentially induced osteoblastic and chondrogenic differentiation of these cells *in vitro*. Furthermore, subcutaneous implantation of the isolated periosteal cells overexpressing a constitutively active Gli2 ( $\Delta$ Ngli2), the major transcriptional activator targeted by the hedgehog signaling pathway, led to marked and robust induction of endochondral bone formation *in vivo*. To further determine the mechanisms involved in Gli2 induced endochondral bone formation, we performed pellet culture using mesenchymal stem cells isolated from the healing site. We found that Gli2 overexpression increased Col2a1 and ColX gene expression by 25-fold and 18-fold respectively. Gli2 overexpression also markedly induced OSX gene expression by 5 fold and BMP-2 gene expression by 3 fold. To further determine whether chondrogenic and osteogenic differentiation induced by  $\Delta$ Ngli2 is mediated through BMP-2, we isolated mesenchymal stem cells from BMP-2<sup>fl</sup> mice. BMP-2 was eliminated by infection of an adenovirus expressing Cre recombinase. We found that elimination of BMP-2 blocked osteogenic differentiation induced by ShhN peptide and a hedgehog agonist Purmorphamine. However, BMP-2 elimination failed to block the osteogenic differentiation induced by  $\Delta$ Ngli2, suggesting additional mechanisms involved in Gli2 induced mesenchymal cell differentiation. Taken together our current data suggest that Hh/Gli2 may function as important signals for mesenchymal stem cell differentiation during repair and overexpression of Gli2 could be used in mesenchymal stem cell therapy for enhanced bone repair and regeneration.

**Dermo1 Lineage Tracing Identifies Early Osteoprogenitor Cells in Adult Murine Bone Marrow Mesenchymal Stem Cell Cultures.** P. Maye, Y. Liu<sup>\*</sup>, L. Wang<sup>\*</sup>, M. Kronenberg<sup>\*</sup>, D. Rowe. Reconstructive Sciences, UCONN Health Center, Farmington, CT, USA.

Previous embryonic studies have shown that Twist 1 & 2 are expressed in early osteochondral progenitor cells and lie genetically upstream of Runx2 during osteogenesis. With this in mind, we hypothesized that Dermo1 (Twist 2) -Cre mice when crossed with Z/EG mice, a mouse line that ubiquitously expresses EGFP upon Cre Recombinase activity, may mark bone marrow derived osteoprogenitor cells and possibly multipotent mesenchymal stem cells in adult mice. While this approach is based on lineage tracing and results in a wide variety of mature cell types expressing EGFP, including bone cells and cartilage cells, the bone marrow compartment of F1 animals only contains a small cell population (~1%) that is EGFP positive. Preliminary attempts to FACS isolate this EGFP cell population directly from the bone marrow and test their osteogenic potential *in vitro* have proven difficult. We believe our current methodology for FACS isolation results in cell damage to the point where neither EGFP+ nor EGFP- cells attach to the culture dish. However, without FACS, standard bone marrow derived stromal cell cultures show that EGFP+ cells attach early in primary cultures. At day 3 of culture, EGFP positive cells can be observed during early colony formation. FACS isolation of EGFP positive cells from day 5 cultures reveals that these EGFP positive cells, which represent ~10% of the total cell population, when plated back into culture as a confluent spot retain very high osteogenic potential. These day 5 EGFP positive cells also have adipogenic potential and we currently are testing for their ability to differentiate into chondrocytes. To further confirm the osteogenic potential of this defined population *in vivo*, we carried out transplantation experiments where varying amounts of FACS isolated EGFP positive cells from day 5 stromal cell cultures were compared to EGFP negative cells and the matrix scaffold Helos alone in a critical size defect calvarial implant model. Quite strikingly, when 50,000 and 300,000 EGFP positive cells were loaded into the Helos scaffold, a dosage dependent increase in bone formation was observed in transplants 30 days later, while 100,000 EGFP negative cells or Helos alone resulted in no bone formation. These studies confirm that Dermo1-Cre x Z/EG leads to the identification of early osteoprogenitor cells and implicates an important role for twist genes in bone marrow derived mesenchymal stem cells.

## SA052

**In Bone, RPTP $\mu$  Is Exclusively Expressed in Osteocytes and May Affect Bone Mass.** K. E. de Rooij<sup>1</sup>, E. Waarsing<sup>\*2</sup>, E. de Wilt<sup>\*1</sup>, I. Que<sup>\*1</sup>, M. M. L. Deckers<sup>\*1</sup>, C. W. G. M. Löwik<sup>1</sup>. <sup>1</sup>Endocrinology, LUMC, Leiden, Netherlands, <sup>2</sup>Orthopaedics, Erasmus Medical Center, Rotterdam, Netherlands.

During bone formation, some osteoblasts are embedded within the newly formed matrix, where they differentiate into osteocytes. They develop long, slender cell processes, which they use to establish a three-dimensional cellular network within the mineralized matrix, analogous to the network formed by neuronal and endothelial cells. Their position within the mineralized matrix makes them very well-positioned to act as "the nerve cells of the bone". It has now been generally accepted that osteocytes act as sensors of mechanical loading of the bone.

The receptor-like protein tyrosine phosphatase  $\mu$  (RPTP $\mu$ ) belongs a subfamily of transmembrane protein tyrosine phosphatases. RPTP $\mu$  is involved in cell-cell interactions and may play a role in the formation or maintenance of the cellular network. RPTP $\mu$  is expressed in cells in which cell-cell interactions are important, such as some types of neuronal cells, lung epithelium, cardiac muscle cells and endothelial cells. Strikingly, some of these cells also form a cellular network.

Recently, RPTP $\mu$ -knock out / LacZ knock-in mice have been described, in which the expression of the LacZ gene is controlled by the promoter of the RPTP $\mu$  gene. Long bones and calvariae of these transgenic mice were isolated and analyzed for  $\beta$ -galactosidase activity by staining with X-gal. Histological analysis showed that only osteocytes exhibit  $\beta$ -galactosidase activity. The blue staining was present throughout the cells and the cellular processes could easily be distinguished.

To investigate the possibility of generating osteocytes *in vitro*, bone marrow cells of the transgenic mice were cultured under osteogenic conditions. After 21-28 days, blue stained cells could be observed associated with nodules. Using an enzymatic LacZ assay we were able to quantify the amount of osteocytes formed. The addition of BMPs to the culture medium increased the number of LacZ positive cells. Histological analysis of these cultures revealed that all positive cells were surrounded by extracellular matrix and cellular processes could be observed. Thus, RPTP $\mu$ -knock out / LacZ knock in mice provide an excellent tool for the study of compounds on osteocyte differentiation *in vitro*.

To examine if the absence of RPTP $\mu$  gene had an effect on bone mass, we have isolated tibia of wild type and knockout mice (n=6) at 5 different age groups, up to 56 weeks for  $\mu$ CT analysis. Preliminary data of tibia from 44 weeks old mice indicate that lack of RPTP $\mu$  may result in lower bone mass. We conclude that RPTP $\mu$  could play a role osteocyte function. If absence of RPTP $\mu$  indeed results in lower bone mass, stimulating RPTP $\mu$  might increase bone mass. Therefore, RPTP $\mu$  may be a target for therapy in bone disorders.

**Endothelial Progenitor Cell Mobilization During Distraction Osteogenesis in Human.** D. Lee<sup>\*1</sup>, T. Cho<sup>2</sup>, H. Lee<sup>\*2</sup>, W. Yoo<sup>\*2</sup>, I. Choi<sup>\*2</sup>. <sup>1</sup>Orthopaedic surgery, Kangwon National University, Chuncheon-city, Republic of Korea, <sup>2</sup>Orthopaedic Surgery, Seoul National University, Seoul, Republic of Korea.

**Introduction:** Distraction osteogenesis (DO) is a unique postnatal bone formation process which is characterized by profuse increment of vascularization. Recently osteoblast-lineage cells (OCs) and endothelial progenitor cells (EPCs) are reported to circulate in physiologically significant numbers and contribute to bone regeneration process. We investigated OC and EPC mobilization in patients undergoing limb lengthening.

**Materials and Methods:** Blood were drawn pre-operation, pre-distraction, and 2 weeks after the start of distraction in 25 patients undergoing limb lengthening. Peripheral blood mononuclear cells (PBMNCs) were isolated and cultured under endothelial cell growth medium. After 2 weeks, the number of EPC colonies which are stained with 1,1'-dioctadecyl-3,3,3',3'-tetramethylindocarbocyanine-conjugated acetylated-low density protein and fluorescein isothiocyanate-labeled lectin was counted. In addition, we performed fluorescence-activated cell sorting (FACS) analysis of freshly isolated PBMNCs using antibodies to bone-specific alkaline phosphatase (ALP) to identify circulating OCs and antibodies to CD34 and vasculoendothelial growth factor receptor 2 (VEGFR2) to identify circulating EPCs.

**Results:** The number of EPC colonies significantly increased during distraction period. FACS analysis demonstrated that the frequency of VEGFR2 (+) cells and CD34 (+) cells, which are EPC-enriched fractions, significantly increased post-distraction while there were no differences in AC133 (+) and ALP (+) positive cells. The number of EPC colonies was correlated with the proportion of circulating CD34 (+) cells in PBMNCs.

**Conclusions:** EPCs are mobilized during distraction osteogenesis by distraction strain while OCs are not. These data suggest that EPC mobilization enhanced by distraction strain contributes to increased vascularization during DO, but bone regeneration process during DO is not associated with systemic OC mobilization.

**Widespread Expression of Sclerostin in Adult and Embryonic Cartilage and Bone, Cells of the Developing Central Nervous System and Epithelia of the Embryonic Kidney and Intestine.** S. Sommer<sup>\*1</sup>, J. P. Grande<sup>\*2</sup>, R. Kumar<sup>1</sup>. <sup>1</sup>Nephrology Research, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Anatomic Pathology, Mayo Clinic, Rochester, MN, USA.

Sclerostin, an inhibitor of bone formation, is believed to be produced exclusively by osteocytes in adult tissues. We used a specific polyclonal antibody to examine expression of sclerostin in adult and embryonic mouse tissues. As previously reported, in adult bone, sclerostin immunostaining was detected in osteocytes and in the canalicular network of Haversian systems. We now show that at the growth plate, sclerostin immunostaining is present in dividing chondrocytes and osteoblasts of adult mouse bone. Less intense staining is seen in mature chondrocytes. Adult liver, spleen, and kidney exhibit no staining. Immunostaining with pre-immune serum is negative.

In the developing skeleton, sclerostin staining is noted in vertebrae and ribs, specifically in developing chondrocytes. Mature chondrocytes do not stain for sclerostin. Osteoblasts stain for sclerostin in the developing vertebral column. Similar patterns of staining are noted in ossification centers at the base of the skull. Immunostaining with pre-immune serum is negative.

Sclerostin immunostaining is noted in cells of the developing neural crest starting at day 8 p.c. Sclerostin immunostaining is observed in the developing dorsal root ganglia beginning at day 12 p.c. Sclerostin staining remains prominent in all developing bone tissues through the entire growth of the embryonic mouse. Sclerostin immunostaining is observed in scattered epithelial cells of the developing intestine and kidney starting at day 11 and disappearing by day 16 p.c. The sclerostin immunostaining in the kidney is most prominent in epithelial cells of the S-shaped tubules and epithelial cells of the intestine. No expression of sclerostin is noted in the developing heart, liver, muscle, or skin.

**Conclusion.** In adult bone, sclerostin is expressed not just in osteocytes but also in dividing chondrocytes and in osteoblasts found in the growth plate suggesting a function for sclerostin in the latter cells. In addition, sclerostin is prominently expressed in chondrocytes and osteoblasts of the developing mouse skeleton. Sclerostin is also expressed in the epithelium of the intestine and kidney suggesting an importance not only to bone development but also in epithelial development.

**Osteocytes can Modulate Osteoblastic Activity via NPY Signaling.** J. C. Igwe<sup>\*</sup>, S. M. San Miguel<sup>\*</sup>, F. Paic<sup>\*</sup>, H. T. Li<sup>\*</sup>, I. Kalajzic. Dept. of Reconstructive Sciences, Uni. of Conn. Health Center, Farmington, CT, USA.

Osteocytes are characterized by long neuronal-like cell processes, which may actively participate in the release of molecules that modulate the function of other surrounding bone cells. The location of osteocytes and their inherent inability to divide represents a major obstacle for studying osteocyte biology. We have previously shown that dentin matrix protein 1 (DMP1) is preferentially expressed in cells embedded within the bone matrix (osteocytes) or in partially embedded cells (preosteocytes). This was the key observation leading to generation of an osteocyte-specific GFP transgenic mouse (DMP1-GFP). To investigate the expression of regulatory molecules produced by osteocytes, we utilized dual transgenic mouse in which osteocytes are identified by DMP1-GFP(green), while osteoblasts are labeled by Col2.3GFP(blue). An *in vivo* gene expression analysis was generated by fluorescence activated sorting of neonatal calvarial cells derived from these dual transgenic mice. It was an intriguing observation that the osteocytes expressed neuropeptide Y (NPY), a gene whose role in the central control of bone mass has been well established. We confirmed this result by immunohistochemical detection of NPY in osteocytes. Furthermore, NPY mRNA expression was observed in DMP1GFP+ cells (osteocytes) and Col2.3GFP+ cells (osteoblasts/osteocytes) derived from fluorescent sorting of primary calvarial osteogenic cultures.

RNA analysis of the isolated osteocytes demonstrated increased levels of NPY mRNA transcripts in both DMP1GFP+ and Col2.3GFP+ populations. In addition, we investigated

the expression of NPY receptors in cultured osteoblast lineage cells. qPCR analysis of cultured calvarial osteoblasts demonstrated that mRNA of the NPY receptor subtypes Y1 and Y6 increased significantly between day 7 and day 14 of culture. We further investigated the effect of NPY at this stage of culture by in vitro treatment with NPY protein. Northern blot analysis of RNA from 1 nM NPY treated calvarial osteoblasts, showed a significant reduction of osteocalcin and bone sialoprotein expression at day 14 of culture. These results demonstrate the effect of NPY on mature osteoblasts, suggesting a novel, local regulation of osteoblast function by osteocytes via NPY signaling.

**Direct Correlation of Osteocyte Deformation with Calcium Influx in Response to Fluid Flow Shear Stress.** A. R. Bonivitch<sup>1</sup>, L. F. Bonewald<sup>2</sup>, J. Ling<sup>\*1</sup>, J. X. Jiang<sup>3</sup>, D. P. Nicoletta<sup>1</sup>. <sup>1</sup>Southwest Research Institute, San Antonio, TX, USA, <sup>2</sup>University of Missouri at Kansas City School of Dentistry, Kansas City, MO, USA, <sup>3</sup>University of Texas Health Science Center, San Antonio, TX, USA.

Osteocytes are generally accepted to be the mechanosensors of bone regulating both resorption and formation. Calcium signaling plays an integral role in osteocyte signaling of bone formation. These cells are highly sensitive to fluid flow derived shear stress thought to occur as bone fluid passes through the osteocyte lacuno-canalicular network. However, the resulting individual cell strain has yet to be quantified and associated with any specific individual cell biological response. We have shown previously a correlation of deformation with prostaglandin production for a population of MLO-Y4 osteocyte like cells. The purpose of this study was to directly measure individual osteocyte deformation and intracellular calcium levels in response to fluid flow. The resulting deformation of each cell was then correlated to its individual biological response.

Fluo-4, AM-loaded osteocyte-like MLO-Y4 cells were exposed to uniform laminar fluid flow of 8 dynes/cm<sup>2</sup> in a closed system. The upregulation of intracellular calcium was determined from the difference in fluorescence intensity from the cell's basal level prior to exposure to fluid flow and the level immediately following the application of fluid flow. The resulting deformation of each individual osteocyte was determined using digital image correlation.

The average strain experienced by the cells was 1.12% with a standard deviation of 0.01%. The maximum and minimum strains were 4.58% and 0.03% respectively. The average upregulation of intracellular calcium in the cells was found to be 13.99% with a standard deviation of 0.05%. The maximum and minimum increases in intracellular calcium were 22.71% and 6.45% respectively. Moreover, the MLO-Y4 cells showed an increase in intracellular calcium concentration with an increase in cell strain in response to an applied fluid flow of 8 dynes/cm<sup>2</sup> (Figure 1). Osteocytes exposed to a uniform fluid flow stimulus experienced a range of strains and individual cell deformations correlated in a dose dependent manner to increases in intracellular calcium concentrations. As mechanosensing and signaling occurs at the single osteocyte level, it is important to understand how cell deformation is translated in a wide range of osteocyte responses.

**Expression of Human Sclerostin In Heterologous Eukaryotic Insect and E. coli Expression Systems.** T. A. Craig\*, Z. Ryan\*, R. Kumar. Nephrology Research, Mayo Clinic, Rochester, MN, USA.

Sclerostin is an ~22 kDa secreted protein expressed by osteocytes which inhibits bone formation. Several sclerostin gene mutations result in a general progressive overgrowth and sclerosis of the skeleton. Sclerostin antagonizes canonical Wnt signaling pathways that control bone formation by binding to Wnt co-receptor protein, low-density lipoprotein receptor-related protein 5 and 6 (LRP5/6). High bone mass in sclerosteosis and Van Buchem disease may thus result from increased Wnt signaling due to the reduced sclerostin expression. Sclerostin mRNA has been detected in aortic tissue, in the otic vesicle and in odontoblasts suggesting that sclerostin may have functions other than bone density regulation.

In order to examine biochemical and biophysical properties of sclerostin, and its interaction with other signaling molecules, we have employed several different bacterial and insect expression systems in order to obtain soluble sclerostin. The full length cDNA for the secreted form of human sclerostin, amino acids 24-213, was expressed in the pET 28a(+) and pET 42a(+) *E. coli* expression vectors as a soluble protein with amino-terminal V5 and 6xHis tags. When sclerostin was expressed in *E. coli* using the pET 28a(+) vector nickel affinity chromatography was used for initial purification. The protein expressed in *E. coli* with the pET 42a(+) vector was a fusion protein with glutathione S-transferase (GST) and was purified using glutathione sepharose. The expression of sclerostin as a fusion protein with maltose binding protein (MBP) into the bacterial periplasmic space of BL21Star *E. coli* with the vector, pMAL-p4E, yielded, on osmotic shock of cells, some full-length 24-213 sclerostin-MBP and large amounts of MBP alone.

We used two insect expression systems for expression of sclerostin. *Trichoplusia ni* (High Five) insect cells were stably transformed with a pB/V5-His-melittin secretory signal-human 24-213 sclerostin construct. Transfected cells were selected with Blastisidin S. Secreted sclerostin was detected in the cell medium by Western blotting with anti-V5 horseradish peroxidase antibody. The cDNA for the secreted form of human sclerostin, amino acids 24-213, was also ligated in to the pTriEx-5 insect secretion vector. TriEx™ Sf9 *Spodoptera frugiperda* insect cells using GeneJuice® transfection reagent were transiently transfected in order to express sclerostin as a secreted protein.

Conclusion: Soluble sclerostin can be expressed in *E. coli* as a histidine or GST-fusion protein. Secreted, soluble sclerostin is readily expressed in insect cells using permanent and transient expression methods.

**Mechanical Perturbation of Integrin α5 with or without Association with Fibronectin Opens Connexin 43-Hemichannels in Osteocytes - a Mechanism for Release of Small Signaling Molecules in Response to Loading.** S. Burra<sup>1</sup>, A. J. Siller-Jackson<sup>\*1</sup>, M. A. Harris<sup>\*2</sup>, S. E. Harris<sup>2</sup>, G. Weber<sup>\*3</sup>, D. DeSimone<sup>\*3</sup>, L. F. Bonewald<sup>4</sup>, E. Sprague<sup>\*5</sup>, M. A. Schwartz<sup>\*6</sup>, J. X. Jiang<sup>1</sup>. <sup>1</sup>Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, <sup>2</sup>Periodontics, University of Texas Health Science Center, San Antonio, TX, USA, <sup>3</sup>Cell Biology, University of Virginia, Charlottesville, VA, USA, <sup>4</sup>Oral Biology, University of Missouri, School of Dentistry, Kansas City, MO, USA, <sup>5</sup>Radiology, University of Texas Health Science Center, San Antonio, TX, USA, <sup>6</sup>Microbiology, Biomedical Engineering and Cardiovascular Research, University of Virginia, Charlottesville, VA, USA.

Connexin 43 hemichannels are un-opposed halves of gap junctions that play a role in osteocyte viability and signaling. Mechanical stimulation in the form of fluid flow shear stress has been shown to induce the opening of hemichannels in MLO-Y4 osteocyte-like cells releasing prostaglandins, ATP and potentially other signaling molecules important for bone formation. In a search for potential mechanosensors associated with hemichannels, Cx43 was found to consistently co-localize with the α5 and β1 integrin complex on the cell but not found to co-localize with the focal adhesion proteins, vinculin or paxillin. Co-immunoprecipitation experiments validated this association between Cx43 and α5/β1 integrin.

To determine whether Cx43/integrin α5 interactions play a role in the opening of hemichannels in response to mechanical stimulation, the MLO-Y4 cell model was used. Blocking antibody to α5 integrin inhibited and α5 integrin siRNA totally abolished the opening of hemichannels and associated prostaglandin release in response to shear stress. No changes were observed in cell surface expression of Cx43. Magnetic beads coated with either anti-α5 integrin antibody or fibronectin were perturbed by a magnetic field after attachment to the cell surface. This resulted in the opening of hemichannels as visualized by dye uptake. In contrast, control beads coated with poly-lysine or anti-CD44 antibody failed to induce the opening of hemichannels when moved at the same magnitude. Similar to non-treated control, extracellular matrix substrate for α5 integrin, fibronectin, fibronectin-conjugated beads or integrin binding ligand RGD peptide did not have any effect on the opening of hemichannels by shear stress, indicating that α5 integrin, not fibronectin, is the target for opening hemichannels by shear stress. Together, these results suggest that integrin α5/β1 may serve as a mechanical tether or tensor mediating the effects of shear stress in regulating the opening of Cx43-forming hemichannels and that this novel function of integrin can be independent of its association with extracellular matrix.

**Proteoliposomes Carrying Alkaline Phosphatase and Nucleotide Pyrophosphatase/ Phosphodiesterase-1 as Matrix Vesicle Mimetics.** P. Ciancaglini<sup>\*1</sup>, A. M. S. Simao<sup>\*1</sup>, M. C. Yadav<sup>2</sup>, S. Narisawa<sup>\*2</sup>, M. F. Hoylaerts<sup>\*3</sup>, J. L. Millan<sup>2</sup>. <sup>1</sup>Departamento de Quimica, FFCLRP-USP, Ribeirao Preto, Brazil, <sup>2</sup>Sanford Children's Health Research Center, Burnham Institute for Medical Research, La Jolla, CA, USA, <sup>3</sup>Center for Molecular and Vascular Biology, University of Leuven-Campus Gasthuisberg, Leuven, Belgium.

Experimental evidence indicates that endochondral calcification is mediated by chondroblast- and osteoblast-derived matrix vesicles (MV). The primary function of tissue-nonspecific alkaline phosphatase (TNAP) is to degrade extracellular inorganic pyrophosphate (ePPi), a potent mineralization inhibitor, which is produced ectoplasmically by the enzymatic activity of nucleotide pyrophosphatase/ phosphodiesterase-1 (NPP1), restricting the concentration of ePPi, to maintain a Pi/PPi ratio permissive for normal bone mineralization. Both these enzymes act at the level of the membrane in osteoblasts and in osteoblast-derived MVs. In this study we have used a liposome system to reconstitute proteoliposomes harboring TNAP alone, NPP1 alone, or both in combination, to study the kinetic behavior of these enzymes in a lipophilic membrane environment. TNAP and NPP1 were expressed in CHO cells, solubilized with polidocanol and inserted into dipalmitoylphosphatidylcholine (DPPC) liposomes as previously standardized. Polidocanol-solubilized detergent-free TNAP and NPP1, alone or in combination showed the ability to anchor to DPPC liposomes. The enzyme activities were measured at pH 7.4, for the substrates ATP, ADP, AMP and PPi, by measuring the amount of inorganic phosphate liberated as a function of time, as previously described. Hydrolyzed ATP nucleotide intermediates were separated and quantitated by HPLC. NPP1-liposomes exclusively hydrolyzed ATP into AMP and PPi. In contrast, TNAP-liposomes, as well as TNAP+NPP1-liposomes hydrolyzed ATP, ADP, AMP and PPi. Hence, the simultaneous presence of TNAP and NPP1 on a proteoliposome membrane enables the complementary hydrolysis of natural phospho-substrates and their intermediates, leading to very efficient phosphate accumulation in the immediate microenvironment of the phospholipid membrane surface. Therefore, we conclude that the controlled reconstitution of MV-associated phosphatases and phosphodiesterases in proteoliposome membranes generates the correct microenvironment to study phospho-substrate catalysis and PPi degradation, allowing more detailed studies of those catalytic processes that initiate skeletal calcification.

**Molecular Mechanisms Underlying Matrix Vesicle-induced Mineralization During Bone Formation: An Enzyme Kinetic Approach.** P. Ciancaglini<sup>\*1</sup>, A. M. S. Simao<sup>\*1</sup>, M. C. Yadav<sup>2</sup>, S. Narisawa<sup>\*2</sup>, C. Farquharson<sup>3</sup>, M. F. Hoylaerts<sup>\*4</sup>, J. L. Millan<sup>2</sup>. <sup>1</sup>Departamento de Quimica, FFCLRP-USP, Ribeirao Preto, Brazil, <sup>2</sup>Sanford Children's Health Research Center, Burnham Institute for Medical Research, La Jolla, CA, USA, <sup>3</sup>Bone Biology Group, Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom, <sup>4</sup>Center for Molecular and Vascular Biology, University of Leuven-Campus Gasthuisberg, Leuven, Belgium.

Mineralization of cartilage and bone occurs by physico-chemical and biochemical processes that together facilitate the deposition of hydroxyapatite in specific areas of the extracellular matrix, mediated by chondroblast- and osteoblast-derived matrix vesicles (MVs). The primary function of tissue-nonspecific alkaline phosphatase (TNAP) is to degrade extracellular inorganic pyrophosphate (ePPi), a mineralization inhibitor, which is produced by nucleotide pyrophosphatase/phosphodiesterase-1 (NPP1), restricting the concentration of ePPi, to maintain a Pi/PPi ratio permissive for normal bone mineralization. We studied the efficiency of phospho-substrates catalysis by osteoblast-derived MVs, kinetically analyzing the hydrolysis of ATP, ADP and PPi by isolated native wild-type (WT), PHOSPHO1 null, TNAP null and NPP1 null MVs. The enzyme activities were determined at pH 7.4 by measuring the amount of inorganic phosphate liberated as a function of time, as previously described. Throughout catalysis, reaction nucleotide intermediates, during hydrolysis of ATP and ADP were monitored via separation and quantitation in HPLC. Comparison of the catalytic efficiencies measured for TNAP<sup>-/-</sup>, NPP1<sup>-/-</sup> and PHOSPHO1<sup>-/-</sup> MVs to those of native MVs identified ATP as the main substrate, hydrolyzed by WT MVs. Hydrolysis of ATP was significantly reduced in the absence of TNAP, but also of PHOSPHO1, implicating both enzymes in the processing of ATP by MVs. Also, we observed deficient PPi and ADP hydrolysis in TNAP-deficient MVs underscoring that, unlike for the hydrolysis of ATP, PPi is primarily processed by TNAP. The lack of NPP1 did not significantly affect the kinetic parameters of hydrolysis when compared to WT MVs, for any of the substrates. We conclude that the hydrolysis of phospho-substrates in MV membranes results from the concerted action of phospholipid-dependent NPP1, TNAP and PHOSPHO1, enabling hydroxyapatite mineralization under conditions of restricted PPi accumulation.

## SA064

**MEPE Expression Is Regulated by BMP-2 Signaling Through the Activation of Its Downstream Transcription Factors, Dlx3, Dlx5 and Runx2.** Y. Cho, J. Park<sup>\*</sup>, W. Yoon<sup>\*</sup>, K. Woo<sup>\*</sup>, J. Baek<sup>\*</sup>, H. Ryoo<sup>\*</sup>. Department of Cell and Developmental Biology, School of Dentistry and Dental Research Institute, Seoul National University, Seoul, Republic of Korea.

MEPE (Matrix Extracellular Phosphoglycoprotein), also called OF45 (osteoblast/osteocyte factor 45), is expressed in osteoblasts, osteocytes and odontoblasts during mineralization. MEPE is a 525-amino acids extracellular matrix protein, and has osteogenic activity through its centrally located GAG- and cell-attachment motif, AC-100. On the contrary, it has mineralization inhibitory activity through its C-terminal ASARM motif (minhibin). Recent reports indicated that MEPE is a standard marker of osteocytes, however, it still remained unclear how its expression is regulated by extracellular signals. In this study, we tried to illuminate upstream signals that are regulating MEPE expression. Our previously cDNA microarray analysis indicated that mRNA level of MEPE is about 27.9 folds higher in mineralizing mouse calvarial tissue than in unmineralized suture tissue. Long-term culture of MC3T3-E1 cells in osteogenic medium showed that MEPE expression is stimulated 200,000 folds at 21 day of culture (compared to 1 day). These results implicated that MEPE expression is a mineralizing tissue-specific, especially at the late mineralization stage. Our previous reports have shown that BMP-signaling is utmost important for the mineralization of the calvarial bones. In addition, its downstream transcription factors such as Dlx3, Dlx5 and Runx2 are very important modulators of calvarial bone mineralization. Thus we have tested BMP-2 effect on MEPE expression in osteogenic cells. BMP-2 (100 ng/ml) treatment to MC3T3-E1 cells strongly increased MEPE mRNA level by 25 folds. Similarly, the overexpression of BMP-2 downstream transcription factors such as Dlx3, Dlx5, and Runx2 also up-regulated MEPE mRNA expression as well as MEPE promoter activity. Moreover, co-transfection of Dlx5 and Runx2 with MEPE reporter vector showed that there was a mild synergistic effect on the promoter activation. In contrast, knock-down of Smad1/5, Dlx3/5 or Runx2 by their siRNA treatment downregulated MEPE mRNA level even in the presence of BMP-2. With a serial MEPE promoter deletion analysis, site-directed mutagenesis experiments and electrophoretic gel mobility shift assays, we specified a couple of homeodomain and Runx2 response elements, respectively, in the proximal promoter of MEPE. Taken together, MEPE expression is specific in the late mineralization stage of in vitro cell culture, and is strongly stimulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2.

**TIEG1 KO Mice Display Defects in the Bone Matrix Immediately Surrounding Osteocytes.** O. Haddad<sup>1</sup>, J. R. Hawse<sup>2</sup>, M. Subramaniam<sup>2</sup>, C. Pichon<sup>3</sup>, T. C. Spelsberg<sup>2</sup>, S. F. Bensamoun<sup>1</sup>. <sup>1</sup>UMR CNRS 6600, Biomecanique et Bioingenierie, Universite de Technologie de Compiègne, Compiègne, France, <sup>2</sup>Department of Biochemistry and Molecular Biology, Mayo Clinic College of Medicine, Rochester, MN, USA, <sup>3</sup>Cnrs upr 430, Centre de Biophysique Moléculaire, Orleans, France.

Osteocytes constitute a three-dimensional network in bone and play crucial roles in cell-cell communication and mechanotransduction. Osteocytes communicate with each other, and with cells on the bone surface, via long cytoplasmic extensions referred to as canaliculi. Through the development of TGF beta Inducible Early Gene 1 (TIEG1) KO mice, we have demonstrated that TIEG1 plays an important role in osteoblast-mediated bone mineralization [1], in bone thickness and resistance to mechanical strain as well as in osteocyte density in cortical bone [2]. In order to further examine the osteocyte phenotype observed in these animals, four femurs were extracted from female TIEG1 KO and wild-type mice. Transverse cross sections were cut in the middle of the diaphysis and sections were placed in a fixative and decalcifying solution. Thin femoral cross sections (5µm) were prepared from these samples for transmission electron microscopy. Twenty osteocytes from each TIEG1 KO and wild-type (WT) femur were observed for differences in cell morphology and the structure of the bone matrix surrounding each cell. This analysis revealed differences in the unmineralized matrix surrounding osteocytes in TIEG1 KO mice relative to wild-type controls. Figure 1 highlights the unmineralized matrix (dotted line) immediately surrounding individual osteocytes. A ratio between the cell surface and the unmineralized matrix was calculated and the results indicate that significantly less (2 fold) unmineralized matrix surrounds TIEG1 KO osteocytes relative to WT controls. Currently, little is known about the role and functions of the bone matrix immediately surrounding osteocytes. However, the present study clearly reveals differences in this bone micro-environment in TIEG1 KO mice and suggests that the bone remodeling and mechanosensing properties of these cells may be compromised in the absence of TIEG1 expression. Further investigations will be performed on cellular and molecular levels to determine precisely the impact of TIEG gene invalidation on

osteocytes biology.

**The Response of Matrix Synthesizing MLO-A5 Cells to Fluid Shear.** H. L. Morris<sup>\*1</sup>, A. Sittichokechaiwut<sup>\*1</sup>, C. R. Jacobs<sup>\*2</sup>, J. W. Haycock<sup>\*1</sup>, G. C. Reilly<sup>1</sup>. <sup>1</sup>Engineering Materials, University of Sheffield, UK, Sheffield, United Kingdom, <sup>2</sup>Mechanical Engineering, Stanford University, Stanford, CA, USA.

Bone remodels dependent on the mechanical loading it receives. For this to occur bone must be able to sense mechanical load in order to effect changes in the tissue architecture. Osteocytes are believed to be the cell type within bone which are sensitive to mechanical stimulation [1]. The interstitial fluid around osteocytes has been shown to be displaced by bone strain. Mechanosensitivity is proposed to result from the application of shear forces from fluid movement on the osteocytes. In tissue engineered bone, osteoblasts and their precursors must directly sense and respond to mechanical forces in a less constrained environment. The aim of the current work is to investigate responses to fluid flow in the cell line MLO-A5. These cells actively and rapidly synthesize bone matrix and have been reported to represent transitional cells between osteoblasts and osteocytes, also termed 'osteoid osteocytes' [2].

Intracellular calcium release in response to fluid flow was examined using the calcium indicator fluo-4. MLO-A5 cells were grown for three days in static culture on the base of a closed parallel plate flow chamber (Ibidi Integrated BioDiagnostics, GER), cells were then loaded with the indicator and subjected to pulsatile fluid flow (0.3Pa). A transitional increase in intracellular calcium was observed a few seconds after commencement of flow. Gene expression of Collagen I and Osteopontin was analysed using RT-PCR and was seen to be upregulated two fold, 24 hours after cells were subjected to a flow of 2 Pa for 2 hours. To investigate the effects of flow on the longer term response of matrix production cells were stimulated by flow for 2 hours (2Pa) on day 3 of culture and collected on day 8. An increase in collagen production was observed in cells subjected to flow compared to no flow controls as assessed by sirius red assay.

Immunofluorescence showed that MLO-A5 cells possess both a hyaluronan (HA)-rich glycocalyx and primary cilia both putative mechanosensors of fluid shear in other bone cell types. In conclusion, we have established MLO-A5s will be a good model cell type with which to study the fluid flow responses of matrix synthesising osteoblasts.

**Notch Signaling Regulates Osteoblast Maturation Transition to Mineralization Phase.** S. Gao<sup>\*</sup>, J. Hock, P. Liu. Maine Institute for Human Genetics and Health, Brewer, ME, USA.

Notch signaling pathway is believed to control binary stem cell-fates in development. However, its precise physiological role, and temporal and spatial expression in postnatal skeletal development remains largely unknown. To address this issue, we utilized Notch GFP reporter mouse and conditionally inducible gain or loss of Notch function mouse models. To locate GFP expression as a marker for Notch activity, we used fluorescent microscopy to examine frozen bone sections from Notch GFP mice (including long bones, spines, calvarias and tails in young and adult, both sex). GFP positive cells were present on the surface of trabecular bone and within mineralized matrix. GFP expression was greatly increased in areas of high bone formation activity in the primary spongiosa underlying growth plate in young mice. To determine if this Notch expression was restricted to osteoblast lineage, mouse bone marrow stromal cells (mBMSC) from GFP mice were isolated, and induced to differentiate with osteogenic media into mature Ob. GFP expression was monitored throughout of the 21 days culture period. Although no GFP was detectable in the early stage of culture (before day 7), surprisingly strong GFP expression was observed specifically in cells at the time mineralization initiated; this expression disappeared when mineralization completed. To gain functional insight of the Notch activity in Ob lineage progression, we cultured mBMSCs from mice either with conditionally ectopic expression of active intracellular Notch domain (NICD) or mice in which Notch ligand-Jagged 1 (JAG1cKO) was knocked out. Cre was delivered to the cultures by adenovectors. Mineralization increased with increased NICD activity, but failed to occur in JAG1cKO. In the latter case, cells retained fibroblast-like morphology, and did not enter osteogenic differentiation. Collectively, these data provide new insights into the role of Notch in bone, and suggest the novel hypothesis that Notch pathway is critical in regulating progression into the mineralizing phase of Ob maturation.

**Enrichment of Type XI Collagen and 6b N-Terminal Domain at Sites of Mineral Nucleation Within Osteoblastic Cultures.** N. T. Huffman<sup>\*1</sup>, C. Chaoying<sup>\*2</sup>, S. V. Chittur<sup>\*3</sup>, J. T. Oxford<sup>4</sup>, J. A. Keightley<sup>\*1</sup>, R. J. Midura<sup>5</sup>, J. P. Gorski<sup>1</sup>. <sup>1</sup>Univ. of Missouri-Kansas City, Kansas City, MO, USA, <sup>2</sup>Tibet Univ. Med. College, Lhasa, China, <sup>3</sup>Univ. at Albany, Rensselaer, NY, USA, <sup>4</sup>Boise State Univ., Boise, ID, USA, <sup>5</sup>Cleveland Clinic, Cleveland, OH, USA.

Alternatively spliced 6b and 8 isoforms of type XI collagen are known to be associated with the process of embryonic bone formation. Type XI and I collagens co-exist in fibrils in bone and form hetero-dimeric complexes *in vitro* upon which type I fibrils can be built. Our goal was to determine when and where type XI RNA and protein were expressed during mineralization of UMR 106-01 osteoblastic cultures; nucleation of mineral occurs within extracellular biomineralization foci (BMF) in this model. Some cultures were treated with protease inhibitor AEBSF which blocks mineralization and activation of PCOLCE, an enhancer of BMP-1 processing of collagen. Type XI collagen expression increased 1.7-fold between 40 and 64 h after plating, just prior to when BMF are competent to mineralize. During this same period collagen I synthesis did not change suggesting that type XI may exhibit functions distinct from a role in type I fibrillogenesis. Cell layer fractions were also extracted sequentially with EDTA and then with 8 M urea/2% CHAPS; cell layer and media fractions were then subjected to western blotting. A 60 kDa N-terminal domain (NTD) was identified in EDTA and urea extracts using an antibody recognizing all type XI splice variants. NTDs were only detected in the media fraction in the absence of  $\beta$ -glycerol phosphate or with AEBSF. After AEBSF treatment, urea extracts contained elevated amounts of 60 kDa NTD. Both 6b and 8 splice variant forms were found to be expressed by UMR cells as 60 kDa and 110 kDa bands, respectively. Identification of alpha 1 chain 8 epitope was confirmed by mass spectral peptide mapping. However, neither 6b nor 8 isoforms were detected in the urea extract suggesting the 60 kDa NTD in AEBSF-treated cultures is composed of the 6a alternative splice form, which is not associated with mineralization. Finally, a 60 kDa NTD reactive with 6b splice variant specific antibodies was enriched preferentially in mineralized BMF, whereas the 8 splice form is not. These results indicate a clear distinction between the localization and distribution of up to three different alternatively spliced isoforms of type XI collagen. Based on extraction with EDTA and on direct isolation by laser capture microscopy, the 6b isoform NTD is enriched in extracellular BMF. When mineralization is blocked by AEBSF, NTDs apparently containing the 6a epitope become more tightly bound to the cell layer. The enrichment of a large NTD expressing 6b epitope only within BMF, sites of initial mineral nucleation, suggests a functional or structural role in this process.

**Lithium Affects Matrix Mineralization by Decreasing Tissue Non-specific Alkaline Phosphatase Levels in Osteoblasts.** J. Li<sup>\*</sup>, M. Murshed. McGill University, Montreal, QC, Canada.

Mineralization of bone extracellular matrix is achieved, at least in part, by the unique co-expression in osteoblasts of several broadly expressed genes. One of these genes *alkaline phosphatase, liver/bone/kidney (Alpl)* encodes a cell membrane-bound phosphatase, which cleaves inorganic pyrophosphate, a ubiquitously present mineralization inhibitor. We recently observed that addition of lithium ions to the cell culture medium prevented *in vitro* mineral deposition by reducing the alkaline phosphatase enzymatic activity in mouse primary osteoblasts. This reduced activity was not due to a direct inhibition of the enzyme by lithium ions as it was the case with some other magnesium-dependent phosphatases. Also, lithium treatment did not increase the release of the cell membrane-bound enzyme into the culture medium. Interestingly, we observed a decrease in alkaline phosphatase protein levels in the lithium treated cells. When added to the culture medium, recombinant bone morphogenetic protein-2 (BMP-2) reversed the effects of lithium on osteoblasts, suggesting the BMP signalling pathway a possible target for lithium action in these cells. We further investigated the mode of lithium action in pluripotent C2C12 cells stably transfected with a BMP-2 expression vector.

**Effects of Odanacatib on Bone Mass and Turnover in Estrogen Deficient Adult Rhesus Monkeys.** T. Cusick, B. Pennypacker, D. Kimmel. Molecular Endocrinology/Bone Biology, Merck & Co, West Point, PA, USA.

Odanacatib (ODN) is a selective inhibitor of Cathepsin K (CatK) in non-human primates (NHPs) and humans. Inhibition of CatK may be a promising new mechanism for treating osteoporosis. Rhesus monkeys (aged 13-19yrs) were ovariectomized (OVX), randomized by spinal bone mineral density (LVBMD), and immediately started on ODN (0 [N=11], 6 [N=8], or 30 [N=10] mg/kg, qd, PO) in 0.5% methocel for 21 months. DXA of spine (LV), femoral neck (FN), and total hip (H) (BMD, g/cm<sup>2</sup>; BMC, bone mineral content, g) was done quarterly. Pharmacokinetic studies were used to determine ODN exposure. Dual fluorochrome labeling (tetracycline PO; 20mg/kg; 15d interval) was given just before necropsy. Left femurs and the first three lumbar vertebrae (LV1-3) were fixed in 70% ethanol.

Unstained 8m parasagittal sections of LV2 (trabecular), and 100 $\mu$ m cross-sections (cortical) at 4cm from the proximal end of the femur (PF) were prepared and evaluated for double

label, single label, and distance between labels, using fluorescent microscopy. Data collection was done on coded specimens. Cortical thickness (Ct.Th) was measured (PF). Mineralizing surface (MSBS, %), mineral apposition rate (MAR,  $\mu$ m/d), and surface-based bone formation rate (BFRBS, mm<sup>3</sup>/mm/yr) were calculated.

ODN exposure was 2.2 and 3.8  $\mu$ M-24hr. Baseline LVBMD differed little among the groups. Ending LVBMD was 11% and 17% higher than OVX+0; HBMD was 10% and 16% higher in the ODN groups. FNBMD was 11% and 12% higher than OVX+0 in the ODN groups. LVBMD was not affected by 6mg/kg/d ODN, but was ~80% lower with 30mg/kg/d ODN than OVX+0, while LVMAR was unaffected. LVBFRBS was not affected by 6mg/kg ODN, but was ~75% lower with 30mg/kg ODN than in OVX+0. PFMSBS was not affected by 6mg/kg ODN, and tended to be higher with 30mg/kg ODN than in OVX+0; PFMAR was unaffected. PFBFRBS tended to be higher with 30mg/kg ODN. Ct.Th was not affected by 6mg/kg ODN and tended to be higher with 30mg/kg ODN than in OVX+0. ODN treatment at 6 and 30mg/kg/d in NHPs causes higher bone mass in osteoporotic fracture sites in humans. ODN decreases bone formation activity in vertebral body trabecular bone only at 30mg/kg/d. These data indicate that ODN increases bone mass in adult NHPs at doses where bone formation in trabecular regions appears unaffected by histomorphometric measures. ODN treatment may also be associated with increased periosteal formation rate and cortical thickness at the hip.

**Bone Effects of Odanacatib in Adult Ovariectomized Rabbits.** B. L. Pennypacker, T. E. Cusick, D. B. Kimmel. Molecular Endocrinology and Bone Biology, Merck and Co., West Point, PA, USA.

Cathepsin K (CatK), a cysteine protease highly expressed in osteoclasts, degrades type I collagen. A CatK inhibitor may be useful for treating osteoporosis. The objective was to evaluate bone mineral density (BMD) and bone turnover in surrogate osteoporotic fracture sites in ovariectomized (OVX) rabbits treated for 28 weeks with CatK inhibitor, Odanacatib (MK-0822).

New Zealand White rabbits (age 7mos) were randomized by spine BMD (DXA, Hologic QDR4500A) and body weight into five groups (N=11-13): Sham-OVX (Sh) + control diet 2031C (Harland Teklad), OVX+ control diet, OVX with 0.0016% dietary MK-0822, OVX with 0.004% dietary MK-0822, or (5) OVX + control diet, treated with alendronate (ALN, 0.3 mg/kg SC 2X/wk). ALN and special diets were started 5-7 days following OVX surgery. Pharmacokinetic studies estimated AUC at ~4 and ~9 $\mu$ m-24hr for the 0.0016% and 0.004% diets, respectively. In vivo dual calcein labeling (8 mg/kg, SC) was given on the tenth and third days before necropsy. Lumbar vertebrae (LV) 2-5 and left femurs were excised and fixed in 70% ethanol. The proximal left femur and LV3 were DXA-scanned. LV3 was embedded and sectioned parasagittally at 5 $\mu$ m and analyzed for cancellous bone volume (BV/TV), mineralizing surface, mineral apposition rate (MAR), and bone formation rate (BFR/BS). 100 $\mu$ m cross-sections of the mid-femur were analyzed for cortical thickness, endocortical (e) and periosteal (p) mineralizing surface (MS/BS), and number of double labeled Haversian systems (HS)/mm<sup>2</sup>. Significant OVX-induced BMD decline (-8.7%, p<0.05) occurred at LV3 after OVX. This BMD loss was prevented in both MK-0822 groups and by ALN. BMD was significantly higher in the total hip with MK-0822 and ALN than in OVX+0. BV/TV of LV3 was significantly higher (+13.4%, P<.05) with MK-0822 vs. OVX (P<.04). Mineralizing surface (MS/BS, %) was lower with ALN treatment vs. OVX+0, but was the same or higher than OVX with MK-0822.

These results suggest that estrogen deficiency bone loss was prevented by Cat K inhibition and ALN after seven months. However, CatK inhibition was accompanied by no suppression of bone formation, while ALN was associated with inhibition of bone formation. This may represent either transient or permanent temporal decoupling of formation from resorption in the bone remodeling process, and may differentiate the Cat K mechanism from bisphosphonates.

**Inhibition of MMP Activity Delays Bone Repair Whereas Inhibition of Osteoclast Function and Formation Does Not.** M. M. McDonald\*, K. Mikulec\*, L. Peacock\*, T. Lah\*, D. G. Little\*. Orthopaedic Research, The Children's Hospital Westmead, Sydney, Australia.

Osteoclasts are associated with all stages of bone repair, including the removal of the soft cartilaginous callus. It is unclear whether specific osteoclast mediated resorption or MMP secretion by osteoclasts and other cells are most important in this process. We designed a fracture healing experiment to dissociate osteoclastic and MMP functions during repair.

In a rat closed femoral fracture model MMI270, an MMP inhibitor was administered subcutaneously (s.c.) twice daily at 120mg/kg while Osteoprotegerin (OPG) at 10mg/kg, Clodronate (CLOD) at 45mg/kg, Zoledronic Acid (ZA) at 0.01mg/kg, or Saline were administered s.c. twice weekly. Dosing continued throughout the entire repair process. Outcomes were assessed at 2, 4 and 6 weeks post fracture. This study design dissociates osteoclast inhibition (the Bisphosphonates ZA and CLOD) from inhibition of osteoclastogenesis (OPG) and global MMP inhibition (MMI270).

MMI270 treatment led to decreased rates of radiographic union compared to Saline ( $p<0.01$ , Fishers exact test). MMI270 treatment produced a union rate of just 9% at 4 weeks and 30% at 6 weeks. In contrast, all other treatment groups showed equivalent union rates with 70-91% at 4 weeks and 100% union by 6 weeks.

QCT scans revealed a 26% reduction in fracture callus bone mineral content (BMC) and a 42% reduction in callus bone volume (volume) in MMI270 treated samples compared to Saline at 2 weeks ( $p<0.01$ ). At 4 weeks a 26% reduction in callus volume remained ( $p<0.05$ ), and by 6 weeks MMI270 had equivalent BMC and volume to Saline. Both ZA and OPG treatment showed increases in callus BMC (54-97%) and volume (44-66%) at 4 and 6 weeks post fracture ( $p<0.01$ ). CLOD produced smaller but significant increases in both BMC (30%) and volume (35%) over Saline at 4 weeks only ( $p<0.01$ ).

In conclusion, MMP inhibition led to delays in endochondral fracture union whereas OPG, ZA and CLOD did not. MMP inhibition also showed reduced callus BMC and volume, while OPG, ZA and CLOD treatment all produced significant increases in callus BMC and volume ( $p<0.01$ ).

These results suggest that MMP activity rather than osteoclast function may be crucial to achieving bony union in this rat fracture model. Osteoclast function and formation may therefore be redundant during initial endochondral bone repair.

**AP-1 and Mitf Interact with NFATc1 to Stimulate Cathepsin K Promoter Activity in Osteoclast Precursors.** M. Pang\*, W. Balkan\*, M. Rodriguez\*, M. Hernandez\*, B. R. Troen. Miami VAMC/GRECC and Geriatrics Institute, University of Miami Miller School of Medicine, Miami, FL, USA.

Cathepsin K (CTSK) is a secreted protease that plays an essential role in osteoclastic bone resorption and osteoporotic bone loss. We have previously shown that AP-1 stimulates CTSK promoter activity and that proximal NFATc1-binding sites play a major role in the stimulation of CTSK gene expression by receptor activator of NFkB ligand (RANKL). We undertook transfection analysis and nuclear factor binding studies to investigate AP-1, NFATc1, and microphthalmia-associated transcription factor (Mitf) cooperativity in the regulation of CTSK transcription. These experiments were carried out in RAW 264.7 cells, which can be readily differentiated to osteoclasts upon RANKL stimulation. Transfection of the individual factors with truncated CTSK promoter-luciferase plasmids significantly stimulated CTSK promoter activity. Cotransfection with combinations of two of the factors (AP-1+NFATc1, AP-1+Mitf, Mitf+NFATc1) dramatically enhanced CTSK promoter activity, with Mitf+NFATc1 producing the largest induction of CTSK promoter activity. Moreover, triple cotransfection of AP-1, NFATc1, and Mitf synergistically stimulated CTSK promoter activity well above levels observed with the double transfections. Cotransfections with dominant negative c-fos markedly inhibited both basal and stimulated CTSK promoter activity, suggesting that AP-1 plays an integral role in transcription of the CTSK gene. Deletion of the 4-bp core elements from three NFATc1 binding sites in the proximal CTSK promoter completely abrogated the response to NFATc1, but did not affect the stimulation by AP-1 or Mitf, either individually or together. Electrophoretic mobility shift assays and analysis of DNA-protein interactions using the Factor Finder system followed by western blots revealed that NFATc1, AP-1, and Mitf bind to similar regions of the CTSK promoter. While AP-1, Mitf, and NFATc1 can independently stimulate CTSK promoter activity, we now demonstrate that these factors cooperate intimately to regulate transcription of the CTSK gene by acting upon the proximal promoter region. Studies are under way to assess the direct DNA-protein interactions of the proximal promoter and thereby more fully elucidate the critical and multiple nuclear factor regulation of transcription of the CTSK gene.

**Identification of Osteoclast Lysosomal Proteins by Mass-Spectrometry.** H. Zhao<sup>1</sup>, R. D. LeDuc<sup>\*2</sup>, Y. Ito<sup>1</sup>, J. Chappel<sup>\*1</sup>, R. Townsend<sup>\*2</sup>, S. L. Teitelbaum<sup>1</sup>, F. P. Ross<sup>1</sup>. <sup>1</sup>Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, USA, <sup>2</sup>Proteomic Core Facility, Washington University School of Medicine, St. Louis, MO, USA.

Osteoclasts (OCs) secrete hydrochloric acid to dissolve bone mineral, a process that is mediated by a vacuolar-type proton pump and charge-coupled chloride channel, and release the lysosomal acidic hydrolase cathepsin K to digest the organic matrix of bone. Accumulating evidence indicates that OC secretion to the ruffled border is through regulated lysosomal exocytosis. Consistent with this notion, we have shown that Synaptotagmin VII, a calcium sensor protein that regulates exocytosis, is a key molecule regulating the fusion of lysosomes with the ruffled border membrane and osteoclast function. In order to understand better the molecular mechanisms governing OC lysosome biogenesis, trafficking, and secretion, we set out to identify the protein profile of OC lysosomes by mass-spectrometry (MS). Bone marrow macrophages were transduced with a retroviral vector expressing FLAG tagged lysosome membrane protein, LAMP-2. The cells were cultured with M-CSF and RANKL for 5 days to generate mature OCs. A lysosome-enriched fraction was collected from an iodoxanol density gradient ultracentrifugation. To achieve higher purity, lysosomes were immuno-purified with magnetic beads coated with anti-FLAG monoclonal antibody. By this method, intact vesicles (lysosomes) on the beads were isolated, as demonstrated by transmission electron microscopy. Western blots of bead elution showed that LAMP-2 and Cathepsin K were recovered, whereas the mitochondria proteins (cytochrome c), cytoskeletal proteins (actin and tubulin) and early endosomal proteins (EEA1), were removed. The proteins bound to the magnetic beads were then separated by SDS-PAGE and a total of 96 gel punches were trypsin digested and analyzed by MS. The raw data were searched with Mascot. More than 300 proteins have been identified, which belong to the families of small GTPases, vesicular/protein trafficking regulators, molecular channels, lysosomal membrane proteins and acidic hydrolases, molecular motors and cytoskeletal regulators. Importantly, several lysosomal proteins, functionally important for OCs, have also been identified, including cathepsin K, LAMP-1/2, a3 and v<sub>0</sub>d2 subunits of vacuolar ATPases, and rab 7. Thus, we have established an experimental system for proteomic analysis of protein profiles in OC lysosomes, providing the capacity to identify novel proteins regulating bone resorption. Further functional characterization of these novel proteins will provide new insights into the molecular mechanisms of OC secretion.

**Expression of NF-κB Ligand and Regulation of Osteoclastogenesis by Bone Marrow Adipocytes.** A. Hozumi\*. Orthopaedics, Nagasaki University, Nagasaki, Japan.

**Objective:** NF-κB Ligand (RANKL), Osteoprotegerin (OPG) and macrophage colony stimulating factor (M-CSF) are potent regulator of osteoclastogenesis. Adipocytes and osteoblasts share a common origin, and several studies reported adipokines have close relationship in the bone metabolism. Now we examined whether RANKL, OPG and M-CSF were secreted from adipocytes. This study examined the ability of bone marrow adipocytes to support osteoclast formation and function in vitro.

**Materials and Methods:** The bone marrow fluids were obtained from 10 individuals at prosthetic insertion. The mRNA expression of RANKL, OPG and M-CSF was measured by real time RT-PCR and examine the effect of glucocorticoid. Furthermore we examined osteoclastogenesis of osteoclastprecursor cell in co-culture system with bone marrow adipocytes. Osteoclast differentiation was assessed by expression of tartrate-resistant acid phosphatase (TRAP).

**Results:** RANKL, OPG and M-CSF messenger ribonucleic acid (mRNA) expression are confirmed in all individual. RANKL/OPG ratio was significantly increased treated by dexamethasone compared to the control group in bone marrow adipocytes. M-CSF expression was not significantly altered in both cell group. RANKL/OPG ratio was significant at  $10^{-7}$  mol/L dexamethasone in mRNA levels and it was time-dependent manner up to 24 hr. Osteoclast differentiation and maturation were undergone when cocultured with bone marrow adipocytes and significantly stimulated by dexamethasone ( $10^{-7}$ mol/l). **Conclusion:** Our studies demonstrated for the first time that primary bone marrow mature adipocytes can support osteoclasts-like cell formation and function in vitro.

**Expression and Function of Synoviolin in Human Osteoclastogenesis.** B. Merle<sup>\*1</sup>, P. D. Delmas<sup>1</sup>, P. Miossec<sup>\*2</sup>, M. L. Toh<sup>\*2</sup>. <sup>1</sup>INSERM U831, Université de Lyon, LYON, France, <sup>2</sup>Unité Mixte Hospices Civils de Lyon-BioMérieux, LYON, France.

Synoviolin, is an anti-apoptotic E3 ubiquitin ligase implicated in Rheumatoid arthritis (RA) synovial hyperplasia, however its role in bone destruction is less well understood. Transgenic mice overexpressing synoviolin show ubiquitous expression of synoviolin in various tissues including bone. The aim of our study was to investigate if synoviolin is expressed by human osteoclasts and implicated in their function *in vitro*.

Human osteoclasts were differentiated from human peripheral blood monocytes in the presence of RANK-L and M-CSF. Osteoclast differentiation was assessed by TRAP staining and TRAP activity in conditioned media. Synoviolin expression was measured by real-time PCR, Western Blotting and immunostaining. Synoviolin inhibition was achieved by RNA interference during osteoclastogenesis. Osteoclast function was determined by analysis of pit formation and assessment of type I collagen degradation products by ELISA.

Synoviolin was expressed in human monocytes and increased during osteoclastogenesis. Synoviolin mRNA and protein expression was 2 to 3 fold higher in mature osteoclasts compared to monocyte precursors. Immunohistochemistry staining demonstrated that synoviolin was localised to the perinuclear region in pre-osteoclasts and fully differentiated osteoclasts. Synoviolin inhibition during osteoclastogenesis dramatically reduced osteoclast formation as shown by TRAP staining and activity in the cell supernatants. In parallel, resorptive activity was reduced as measured by pit formation and the release of collagen fragments in cultured medium. Finally, synoviolin expression was inhibited by IL-4 and oestrogen during osteoclast differentiation.

In conclusion, we show that synoviolin is expressed by human osteoclasts and involved in the differentiation, survival and activity of osteoclasts *in vitro*. Overall, our findings suggest that synoviolin may be involved in the inflammatory osteoclast-mediated bone resorption observed in RA, and in the alterations of bone remodeling associated with metabolic bone diseases. In addition, oestrogen may have a protective effect on bone resorption at least in part through decreasing osteoclast survival.

**A Novel Role of L-Serine for the Activation of Receptor Activator of Nuclear Factor Kappa B Ligand (RANKL)-RANK Signaling Machinery in Osteoclastogenesis *in vitro*.** T. Ogawa, T. Sakai\*, A. Bahtiar\*, N. Ishida-Kitagawa\*, T. Takeya\*. Graduate School of Biological Sciences, Nara Institute of Science and Technology, Ikoma, Nara, Japan.

The induction of two key transcription factors, c-Fos and nuclear factor of activated T cells c1 (NFATc1/NFAT2), is known to be essential for osteoclastogenesis. We previously found, using mouse macrophage cell line RAW264 cells, that culture at high cell density blocked progression to the multinucleated cell stage induced by stimulation with receptor activator of nuclear factor kappa B ligand (RANKL). This finding eventually led us to the identification of NFATc1 as a key regulator of osteoclastogenesis. We subsequently confirmed the cell density-dependent suppression of osteoclastogenesis in a bone marrow cell system, and extended the analysis further. In comparative analysis of conditioned medium from high and low cell density cultures, we noticed the indispensability of L-serine (L-Ser), one of seven non-essential amino acids in culture medium, as a pivotal factor for the expression of NFATc1 induced by RANKL. Namely, culture at high cell density caused a depletion of L-Ser in the medium. The level of NFATc1 protein was found to be correlated with the presence of L-Ser in a concentration dependent manner. In contrast, D-Ser, an enantiomer of L-Ser, showed no NFATc1-inducing activity. We further examined the effect of L-Ser depletion on the upstream events of NFATc1 induction after RANKL stimulation. It was observed that, in the absence of L-Ser, activation of MAPK pathways and c-Fos induction triggered by RANKL stimulation were also hampered. L-Ser was subsequently found to be necessary for the expression of RANK, the receptor for RANKL. In the absence of L-Ser, the expression of RANK protein was decreased to undetectable level within 8 hours. The level of *rank* mRNA was suppressed in bone marrow cells under L-Ser depleted condition, whereas downregulation of *rank* mRNA was not evident in RAW264 cells. Furthermore, forced expression of RANK as well as NFATc1 using retrovirus vectors could compensate for the depletion of L-Ser and resume the progression to the multinucleated cell stage. These results demonstrate a novel but crucial role for L-Ser that as a prerequisite factor for RANKL-induced osteoclastogenesis *in vitro*.

**Pyrophosphates Stimulates Osteoclast Differentiation and Bone Resorption.** S. Abdelmagid\*, A. Zajac\*, I. Salhab\*, H. Nah. Plastic and Reconstructive Surgery, Children Hospital of Philadelphia, Philadelphia, PA, USA.

Cranio metaphyseal dysplasia (CMD) is a rare disease characterized by overgrowth of facial and cranial bones and abnormal flaring of metaphyses of long bones. Although the skeletal phenotype suggests that the bone remodeling process may be dysregulated in CMD, the cellular mechanisms underlying the CMD phenotype is not known. The autosomal dominant form of CMD has recently been linked to loss of function mutations in ANKH, a transmembrane protein involved in the transport of pyrophosphate (PPi). Therefore, in this study we determined the effect of PPi on bone remodeling, using *ex vivo* murine neonatal calvarial organ and bone marrow cell cultures. Our data show that exogenous PPi (0.1-1mM) stimulates a calcium release in the media of calvarial organ cultures maintained for 3 days (p<0.05) and TRAP staining of calvarial bones (p<0.01) in a dose-dependent manner, indicating that PPi stimulates bone resorption by osteoclasts. The PPi effect on bone resorption was not inhibited by either alkaline phosphatase inhibitor (Levamisole) or Pi transport inhibitor (PFA), indicating that the effect of PPi on bone resorption is not dependent on inorganic phosphates hydrolyzed from PPi. On the other hand, PPi stimulation of calcium release was abolished by an NFkB inhibitor, indicating that the PPi effect on bone resorption is NFkB-dependent. Cell culture data show that PPi also stimulates proliferation of bone marrow-derived osteoclast precursors (p<0.01) and RAW 264.7 pre-osteoclast cell line (p<0.01) in a dose-dependent manner. Nevertheless, PPi alone was not able to induce differentiation of bone marrow-derived pre-osteoclasts. Instead, pretreatment for 48 hours with PPi (0.1-1mM) accelerated differentiation of the osteoclast precursors under a differentiation permissive condition, as measured by cell TRAP activity (p<0.01), number of TRAP positive osteoclasts (p<0.05), and nuclei fusion index (p<0.05), suggesting that PPi enhances the differentiation potential of pre-osteoclasts. Taken together, our data suggest that PPi stimulation of bone resorption in calvarial organ cultures may be mediated in part by its priming effect on pre-osteoclasts for cell differentiation.

**Inhibin Directly Targets Suppression of Isolated Human Osteoclast Precursor Development and Activity.** K. M. Nicks, N. S. Akel\*, L. J. Suva, D. Gaddy. Physiology and Biophysics & Orthopaedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Serum Inhibin A (InhA) is a better predictor of bone formation and resorption markers than either follicle stimulating hormone (FSH) or bioavailable E2 in premenopausal women. Regardless of changes in sex steroids or FSH, increased bone turnover markers correlate with decreased serum InhA and InhB levels in pre-, peri-, and post-menopausal women, consistent with our *in vitro* demonstration that Inh suppresses osteoblast development of hMSCs and OCL development of human peripheral blood mononuclear cells (hPBMCs). To determine if InhA suppression of osteoclastogenesis is mediated by direct effects on OCL precursors, OCL cultures of either unselected hPBMCs, or a sub-population of OCL precursor cells (purified CD14+ hPBMCs) and treated with RANKL, mCSF +/- InhA and/or FSH were initiated. In cultured CD14+ OCL precursors, FSH significantly increased RANKL-dependent OCL differentiation whereas InhA significantly suppressed OCL differentiation. However, in heterogeneous PBMCs, RANKL-dependent OCL differentiation was significantly inhibited by either InhA or FSH. The effect of InhA was significantly more potent than FSH. In both CD14+ and PBMC cultures, RANKL-induced OCL formation in response to InhA + FSH was not significantly different from InhA alone, demonstrating the dominant effect of InhA to block any FSH effect. Since InhA was found to directly target CD14+ OCL precursor development, cells were cultured on dentine slices to measure OCL activity. InhA treatment significantly decreased bone resorption and prevented OCL migration, even in the presence of FSH. The signaling receptors mediating InhA and FSH action were determined using immunofluorescence. CD14+ OCL cultures were initiated and harvested on days 1 and 7. RANK expression was observed on both days 1 and 7, unlike the FSH receptor and the Inhibin-specific receptor, betaglycan, which were not observed on day 1 of culture but were present by day 7. Also present at day 7 were Type II receptors for BMP and Activin (BMPRII, and ActRIIA, but not ActRIIB). These data suggest that isolated OCL precursor cells become capable of responding to both InhA and FSH only after RANKL initiation of OCL development. Although FSH can enhance OCL development when CD14+ precursors are cultured, InhA dominantly suppresses. In fact, InhA suppresses OCL development, migration and bone resorption in the presence or absence of FSH. Furthermore, in heterogeneous PBMC cultures, which represent a more physiological environment in which to test the integrated role of these hormones, the effect of InhA and FSH (alone or in combination) is to suppress OCL development and activity.

**RANKL-mediated Osteoclast Lineage Commitment Dictates the Role of Lipopolysaccharides in Osteoclast Differentiation.** J. Liu<sup>\*1</sup>, S. M. Michalek<sup>\*2</sup>, X. Feng<sup>1</sup>. <sup>1</sup>Pathology, Univ. of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Microbiology, Univ. of Alabama at Birmingham, Birmingham, AL, USA.

Lipopolysaccharides (LPS), common bacteria-derived products, are recognized as a key factor implicated in periodontal bone loss. However, the role of LPS in osteoclast (OC) formation still remains controversial. The prevailing view is that LPS stimulate OC formation, which is not only supported by various contemporaneous studies, and yet consistent with the role that LPS are presumed to play in periodontal bone loss. Two groups, however, have shown that LPS play an inhibitory role in OC formation. Here, we carried out independent and thorough studies to address the controversy. We treated primary bone marrow macrophages (BMMs) from 6-week-old mice with M-CSF (44ng/ml) and different doses of LPS (5ng/ml-10ug/ml). Our data indicate that LPS and M-CSF are unable to stimulate OC formation. Next, we determined whether LPS can promote OC formation in the presence of M-CSF (44ng/ml) and RANKL (100ng/ml). In doing so, we added LPS at the beginning of the assays. We found that LPS inhibit OC formation in a dose-dependent manner (>95% at 5ng/ml) in the presence of M-CSF (44ng/ml) and RANKL (100ng/ml). However, when we treat BMMs with M-CSF (44ng/ml) and RANKL (100ng/ml) for as short as 12 hrs, LPS promoted OC formation from these committed BMMs in the presence of M-CSF and RANKL. Moreover, we found that LPS and M-CSF, without RANKL, are sufficient to promote OC formation from the RANKL-primed BMMs. Together, these findings support that RANKL-mediated OC lineage commitment dictates the role of LPS in OC formation. To further address the issue, we treated BMMs with M-CSF (44ng/ml) and RANKL (100ng/ml) for 24hrs. We then removed RANKL and cultured the cells with M-CSF alone (44ng/ml) for 12hrs, 24hrs, 2d and 3d. At each time point, BMMs were lifted and re-plated to perform OC formation assays with M-CSF, RANKL and LPS. Even 3d after the RANKL pretreatment, BMMs are still able to form OC in response to M-CSF, RANKL and LPS, revealing that the OC lineage commitment by RANKL is long-term, not transient. Finally, given that osteoblasts are indirectly involved in LPS-mediated OC formation by producing RANKL in response to LPS, we investigated the role of LPS in OC formation in co-culture system containing osteoblasts and BMMs pretreated by RANKL (100ng/ml) for 24hrs or untreated BMMs as control. The co-cultures were treated with or without LPS (10ng/ml). While the co-cultures containing committed BMMs formed OC in response to LPS, control co-cultures failed to do so. These results further support that RANKL-mediated OC lineage commitment determines the action of LPS in OC formation.

**S100 Protein Directly and Indirectly Affects RANKL-stimulated Osteoclastogenesis.** T. Yoshida, A. Flegler<sup>\*</sup>, P. H. Stern. Department of Molecular Pharmacology and Biological Chemistry, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

Diabetic osteopenia is one of the complications associated with Diabetes Mellitus, and Advanced Glycation Endproducts (AGEs) are thought to be involved in this disease. It was also reported recently that the expression of S100A4 protein, one of the ligands for receptor of AGEs (RAGE), is regulated in the course of osteoblast differentiation and this regulation is crucial for normal differentiation. However, it is still unclear how S100 protein affects bone metabolism. We were therefore interested in determining how S100 protein affects RANKL-stimulated osteoclastogenesis, either directly or indirectly through cytokines secreted from osteoblasts.

We first determined whether there was a direct effect of S100 on osteoblast proliferation and osteoclastogenesis. Studies were carried out with MC3T3-E1 pre-osteoblastic cells and RAW 264.7 mouse monocyte/macrophage lineage cells, which differentiate into multinucleated mature osteoclasts in the presence of receptor activator of nuclear factor- $\kappa$ B ligand (RANKL). MC3T3-E1 cells were incubated for 3, 7 or 14 days and proliferation rate was determined by MTT assay. S100 significantly inhibited osteoblast proliferation at day 14 but not at the shorter time points. RAW 264.7 cells were incubated for 7 days with human soluble RANKL (sRANKL) and tartrate resistant acid phosphatase (TRAP) activity and TRAP-positive multinucleated cells were measured as markers of osteoclastic differentiation. Osteoclastic differentiation was significantly inhibited by S100. Proliferation, as assessed by MTT assay, was also decreased by S100. There was a trend towards a decrease in the number of TRAP-positive multinucleated cells, but this was not statistically significant. We then determined whether S100 protein could affect osteoclastogenesis indirectly, i.e., through altering osteoblastic secretion of a stimulator of osteoclast differentiation such as RANKL, M-CSF, or the ligand of osteoclast-associated receptor (OSCAR). MC3T3-E1 cells were incubated with or without S100 for up to 15 days. Culture medium was then changed to medium without S100 and incubated with the MC3T3-E1 cells for an additional 6h. This medium was used for treatment of the RAW

cells. Unexpectedly, media from S100 treated MC3T3-E1 cells significantly promoted the proliferation of RAW cells, but no indirect effect on differentiation was seen. Thus, osteoclastogenesis could be regulated directly and indirectly by S100, possibly secreted from osteoblasts by an autocrine process to regulate osteoclastogenesis, and this regulation might be involved in the progression of diabetic osteopenia.

**Neutrophil-Like PLB-985 Cells Induce Differentiation of Human Blood Monocytic Precursors into Functional Osteoclasts via a Receptor Activator of NF $\kappa$ B ligand (RANKL)-Dependent Mechanism.** A. Chakravarti<sup>\*</sup>, P. E. Poubelle. Medicine, Université Laval, Québec, QC, Canada.

Focal bone loss in the inflammatory arthritides begins early in the disease process and can contribute to patient morbidity. This excessive bone resorption is due to increased activity of osteoclasts that require receptor activator of NF- $\kappa$ B ligand (RANKL) to function. Neutrophils are the predominant infiltrating cells at this stage. Though neutrophil presence is linked to disease severity, their role in the evolution of bony lesions is not clear. In the present study we used human myeloid cell line PLB-985, which can be induced to express a neutrophil-like phenotype, as a model for study of neutrophil-osteoclast interactions. We demonstrated that these neutrophil-like cells directly activate osteoclasts through RANKL expressed on the surface of PLB-985 cells. *In vitro* co-culture of human pre-osteoclasts, derived from circulating monocytes, with fixed PLB-985 cells induced differentiation of mononuclear osteoclast precursors into large multinucleated cells. These multinucleated cells were positive for the osteoclast specific enzymatic marker, tartrate-resistant acid phosphatase. Importantly, when co-cultures were conducted on devitalized dentine slices, well-defined bone resorption pits were observed after toluidine blue treatment. Thus, the neutrophil-like cells stimulated resorptive activity in mature osteoclasts. Gene knockdown of RANKL following nucleofection of RANKL specific siRNA in PLB-985 cells effectively diminished RANKL RNA, as seen by QRT-PCR, and surface protein expression evaluated by flowcytometric analysis. Induction of osteoclast differentiation and activity was also significantly diminished in co-culture assays of osteoclasts with transfected PLB cells, proving that PLB-derived RANKL was specifically responsible for the stimulation of osteoclasts. In conclusion, we propose that neutrophil-derived RANKL might have an important role, not only in the inflammatory component of the arthritides, but also in the early skeletal involvement that characterizes these conditions. Our work is the first to demonstrate functional interactions between the two cell types: neutrophil and the osteoclast.

**Effect of Mesenchymal Stem Cells in Coculture with Osteoclasts: A Contact Mediated and Dose-Dependent Effect?** C. Janeiro, D. Vashishth. Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, USA.

Osteoclasts, which are derived from stem cells, supply factors that positively influence the differentiation of osteoclast precursors to osteoclasts (OCLs) through signaling pathways [1]. However, the effect of mesenchymal stem cells (MSCs), which reside in bone marrow in close proximity to osteoclast precursors, has not been examined. To determine the mechanism, a set of experiments was devised to determine whether the effect is contact or signaling mediated.

Human adult osteoclast precursor cells and human mesenchymal stem cells (both from Cambrex Poietics™) were cocultured at varying densities (OCLs remained constant at 6000 cells/well, while MSCs were varied from 0-4200 cells/well) following supplier's instructions under standard cell culture conditions for up to 14 days, in standard 96 well plates (contact-mediated) and Transwell™ plates (signaling-mediated) alone and in the presence of bone slices. For each coculture variation, the number of differentiated OCLs and the resorption on the bone were analyzed. For each group, contact-mediated and signaling-mediated, the percent change in differentiated OCLs was calculated as a function of the positive control (OCL precursors only). Analysis of select cytokines was also examined.

The percent change of differentiated OCLs decreased linearly with an increase in MSCs only when the cells were allowed contact (Fig 1). For the signaling mediated group, the percentage of differentiated OCLs remained steady throughout the variation of MSC number. The only cytokine that has yielded significant results was TNF- $\alpha$ , displaying a decrease in TNF- $\alpha$  with the addition of OCLs.

These results demonstrate a clear difference between contact mediated and signaling mediated cocultures of OCLs and MSCs. The increase in the number of OCLs with a decrease in MSC number suggests that the MSCs regulate the differentiation of OCLs from hematopoietic stem cells. These findings suggest the age-related decrease in MSC as a plausible mechanism of increased OCL differentiation with increased age.

**Gastric Proton Pump Inhibitors Failed to Affect Bone Resorption and Formation.** T. Nishisho\*<sup>1</sup>, L. Wang\*<sup>1</sup>, K. Hata<sup>1</sup>, M. Nakanishi\*<sup>1</sup>, N. Yasui\*<sup>2</sup>, T. Yoneda<sup>1</sup>. <sup>1</sup>Dept Biochem, Osaka Univ Grad Sch Dent, Suita, Osaka, Japan, <sup>2</sup>Dept Orthop, Univ Tokushima Grad Sch Med, Tokushima, Japan.

Osteoclasts dissolve bone minerals by releasing protons through the vacuolar type proton pump (V-ATPase), making neighboring microenvironments acidic. Inhibitors of the V-ATPase therefore could be pharmacological agents for bone diseases associated with increased osteoclastic bone resorption. On the other hand, a gastric H<sup>+</sup>, K<sup>+</sup>-ATPase, a family member of the P-ATPase, is highly expressed in parietal cells in stomach and plays central roles in gastric acid secretion. Inhibitors of H<sup>+</sup>, K<sup>+</sup>-ATPase are the most widely used drug for the treatment of gastric ulcer, duodenal ulcer and gastroesophageal reflux disease. Of note, a recent clinical study has reported that administration of gastric H<sup>+</sup>, K<sup>+</sup>-ATPase inhibitors are associated with reduced bone mass and increased fracture rate, raising the possibility that these inhibitors promote osteopenia. However, these studies remain controversial and the effects of H<sup>+</sup>, K<sup>+</sup>-ATPase inhibitors on bone have not been fully elucidated. In the present study, we investigated the effects of the gastric H<sup>+</sup>, K<sup>+</sup>-ATPase inhibitors (PPIs) on bone resorption and formation *in vitro* and *in vivo*. To study this, we tested widely-used PPI, rabeprazole and omeprazole. As control we also examined the effects of FR167356, a specific inhibitor for the  $\alpha 3$  V-ATPase. Mouse spleen cells were cultured in the presence of M-CSF (30ng/ml) and sRANKL (100ng/ml) for 6 days together with these inhibitors. Tartrate-resistant acid phosphatase-positive multinucleated osteoclast-like cell (TRAP (+) OC) formation and pit formation on dentin slices were inhibited by FR167356 (10<sup>-8</sup>M-10<sup>-6</sup>M) in a dose-dependent manner. In contrast, rabeprazole and omeprazole (10<sup>-8</sup>M-10<sup>-6</sup>M) showed no effects on TRAP (+) OC formation and bone resorption. Histological examination revealed that rabeprazole and omeprazole failed to inhibit osteoclastic bone resorption in the calvariae in the mouse model of

lipopolysaccharide-induced bone destruction. We next examined whether these inhibitors affect bone formation. Both rabeprazole and omeprazole had no effects on BMP2-induced osteoblast differentiation in C3H10T1/2 and C2C12 cells determined by alkaline phosphatase activity. Moreover, no significant effects were observed in the mineralization of primary neonatal mouse calvarial osteoblasts. In conclusion, our results show that PPIs have little direct influences on bone and suggest that yet-unknown mechanism is involved in the pathogenesis of osteopenia in PPI-treated individuals.

**Disclosures:** T. Nishisho, None.

**Urocortin Strongly Suppresses the Formation and Function of Osteoclasts via a Novel Mechanism.** C. E. Combs\*<sup>1</sup>, K. Fuller, T. J. Chambers, K. M. Lawrence\*. Department of Histopathology, St George's Hospital Medical School, London, United Kingdom.

Urocortin (Ucn) is a 40 amino acid peptide, related to the hypothalamic corticotrophin releasing factor (CRF) family which now also includes Ucn 2 and 3. Since its discovery Ucn has been found to be widely distributed in the CNS, digestive, cardiovascular, reproductive, immune and endocrine systems. It has extremely diverse functions including reducing blood pressure in the cardiovascular system and decreasing appetite in the CNS. Recently, it has been implicated as a modulator of the immune/inflammatory system. Of particular interest, Ucn has been shown to be increased in the synovial fluid of patients with rheumatoid arthritis, and reduces inflammation and bone erosion in a mouse model of the disease. Beyond this, nothing is known of the role of Ucn in the pathobiology of bone. We therefore tested the effect of Ucn on osteoclast formation and function. Ucn showed a dose-dependent inhibition of the number of osteoclast-like cells (Ocl) formed when murine non-adherent bone marrow cells were incubated with RANKL and MCSF. We then tested the effect of Ucn on osteoclast function. To do this, *in vitro* derived Ocl were sedimented onto bone slices, and incubated with/without Ucn. We found strong suppression of bone resorption. To confirm that this was a distinct effect on osteoclastic function rather than formation, we tested the effect of Ucn on actin ring formation. Ucn similarly potently suppressed the formation of actin rings in osteoclasts, in a dose-dependent manner, with 50% inhibition of actin ring formation occurring at 5x10<sup>-9</sup>M, and almost complete inhibition at 10<sup>-7</sup>M.

It is known that activation of CRFR1 or R2 by Ucn results in elevation of either cAMP via Gs, or of IP3/diacylglycerol via Gq. We assessed expression of Ucn and its receptors in bone cells using semi-quantitative RT-PCR. We found that although osteoclasts, macrophages and osteoblasts do not express any of the known CRF receptor subtypes, osteoclasts and macrophages both express Ucn itself. The absence of known receptor types was supported by experiments in which we found that a receptor-antagonist did not block the effects of Ucn on Ocl function or formation. Furthermore, Ucn failed to generate production of either cAMP or cGMP in these cells, and selective PKA/PKC inhibitors did not suppress the anti-resorptive effect of Ucn. We did however note, using confocal microscopy, a rapid intracellular calcium transient in osteoclasts. We conclude that Ucn potently inhibits osteoclasts via a mechanism independent of known CRF receptors. Expression of Ucn by bone cells raises the possibility that it may play an autocrine/paracrine role in the pathophysiology of bone.

**TSG-6 Acts Synergistically with OPG to Inhibit Bone Resorption.** D. Mahoney\*<sup>1</sup>, C. M. Milner\*<sup>2</sup>, A. J. Day\*<sup>2</sup>, A. Sabokbar<sup>1</sup>. <sup>1</sup>Botnar Research Centre, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

TSG-6 (TNF-stimulated gene-6) is a 35-kDa protein, composed almost entirely of Link and CUB\_C domains, that is up-regulated by inflammatory mediators (e.g. TNF, IL-1). To date a wide variety of protein and glycosaminoglycan ligands (e.g. hyaluronan, heparin, bikunin, pentraxin-3 and thrombospondin-1) have been identified as associating with the Link module, whereas only fibronectin has been found to bind to the CUB\_C region. Animal models of arthritic disease have indicated that TSG-6 has anti-inflammatory and chondroprotective properties. We have recently demonstrated that recombinant TSG-6 inhibits RANKL-mediated bone resorption by osteoclasts (Mahoney *et al.*, manuscript submitted). The full-length protein had greater inhibitory activity compared to the isolated Link module and the CUB\_C domain was essentially inactive. Furthermore, binding analyses revealed that TSG-6 interacts directly with sRANKL, probably at a composite binding surface involving both the Link and CUB\_C domains. To further understand the role of TSG-6 as an inhibitor of bone resorption, we sought to (i) compare the potency of TSG-6 to that of OPG and (ii) determine whether TSG-6 can act synergistically with OPG in inhibiting RANKL-mediated osteoclastic bone resorption.

*In vitro* assays revealed that TSG-6 inhibited RANKL-induced resorption in a dose-dependent fashion, in a similar manner to that observed for OPG; the IC50 of full-length TSG-6 was 0.5nM as compared to 0.25nM for OPG. Furthermore, we have demonstrated that a combination of TSG-6 and OPG significantly inhibited the RANKL-mediated resorption compared to treatment with each protein alone.

These findings indicate that TSG-6 can act synergistically with OPG and as such TSG-6 could have therapeutic potential for the treatment of osteolytic bone disorders.

**Proteasome Inhibitors Attenuate Osteoclastogenesis and Bone Resorption via the Modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  Signaling Cascades.** E. S. Ang<sup>\*1</sup>, N. Pavlos<sup>1</sup>, T. Chai<sup>\*1</sup>, K. Yip<sup>\*1</sup>, S. Rea<sup>\*2</sup>, T. Ratajczak<sup>\*3</sup>, M. Zheng<sup>1</sup>, J. Xu<sup>1</sup>. <sup>1</sup>Centre for Orthopaedic Research, The University of Western Australia, Nedlands, WA, Australia, <sup>2</sup>Western Australia Institute for Medical Research, The University of Western Australia, Nedlands, WA, Australia, <sup>3</sup>Western Australia Institute for Medical Research, The University of Western Australia, Nedlands, WA, Australia.

Enhanced osteoclast formation and activation becomes manifest in many pathological osteolytic conditions including osteoporosis, Paget's disease and tumor metastasis to bone. Proteasome-mediated pathways regulate diverse signaling cascades that play fundamental roles in cell differentiation and apoptosis. However, the molecular mechanism(s) by which the proteasome pathway regulates osteoclast formation, bone resorption and its potential impact on RANKL-mediated signaling remains to be elucidated.

Using both primary bone marrow monocytes (BMMs) and RAW264.7 cell osteoclastogenic culture systems, we examined the effects of several proteasome inhibitors on osteoclast formation. In addition, we employed bone resorption assays and confocal microscopy to determine the effect(s) of proteasome inhibitors on the function and cytoskeletal architecture of osteoclasts. Immunoblot and immunoprecipitation analyses together with luciferase reporter gene assays and immunocytochemistry were used to dissect the molecular mechanism(s) underlying the observed effects of proteasome inhibitors on NF- $\kappa$ B, I $\kappa$ B $\alpha$ , p62 and TRAF6.

We demonstrate that proteasome inhibitors MG-132, MG-115 and Epoxomicin dose-dependently attenuate RANKL-induced osteoclastogenesis, with relative potency Epoxomicin > MG-132 > MG-115 based on the equi-molar concentrations. At high concentrations, proteasome inhibitors were found to induce cellular apoptosis and disrupt F-actin and microtubule organization in osteoclasts. Epoxomicin potently inhibited bone resorption by both BMM-derived osteoclasts and human osteoclast-like cells derived from giant cell tumors of bone. The same proteasome inhibitors were also found to effectively block RANKL-induced NF- $\kappa$ B activation, as well as prolong the proteasome-mediated degradation and targeting of I $\kappa$ B $\alpha$ , p62 and TRAF6.

Collectively, our findings demonstrate that proteasome inhibitors perturb osteoclast formation and function by influencing key RANK-mediated signaling cascades (I $\kappa$ B- $\alpha$ , p62 and TRAF6). We propose that selective proteasome inhibitors might offer potential therapeutic value for the treatment of osteoclast-mediated bone diseases.

**Resorption Mechanism of Hydroxyapatite and  $\beta$ -Tricalcium Phosphate Coating Layer.** D. Lee<sup>\*</sup>, K. Lee<sup>\*</sup>, J. Kim<sup>\*</sup>, C. Lee<sup>\*</sup>, J. Chang<sup>\*</sup>. Orthopaedic Surgery, Asan Medical Center, Seoul, Republic of Korea.

Beta-tricalcium phosphate ( $\beta$ -TCP) coating layer is known to be resorbed much faster than hydroxyapatite (HA), however, there has been no report to explain the exact reason of that to our knowledge. Therefore, we investigated whether the resorption mechanisms of these two compounds are same, if not, what is the difference. Eighty titanium discs with 12mm in diameter and 2mm in thickness were coated with HA(n=40) or  $\beta$ -TCP(n=40) by dip and spin coating method. In each group, the specimens into 2 subgroups respectively; Dissolution (D, n=20) and Osteoclast culture (C, n=20). The coated discs in D group were immersed in the cell culture media for 5 days, whereas, in C group, osteoclast-like cells ( $5 \times 10^3$  cells/500 $\mu$ l), which were isolated from human giant cell tumor, were seeded on the specimens and cultured for 5 days. Cultured cells were defined as osteoclast by the determination of osteoclast marker (tartarate-resistant acid phosphatase, TRAP). After immersion or osteoclast culture, the dissolution characteristics of coating layer surface were observed using light microscope (LM) and scanning electron microscope (SEM). In HA-C and  $\beta$ -TCP-C groups, area fraction of resorption lacunae formed by osteoclast was analysed by image analysis to evaluate the activity of osteoclastic degradation. After dissolution test,  $\beta$ -TCP coating layer showed much more cracks and denudation as compared to HA coating layer. In C group, the osteoclasts covering the coating layer were identified on LM and SEM images. Mean area fraction of resorption lacunae in HA-C group was 11.62%, which was significantly higher than that of 0.73% in  $\beta$ -TCP-C group (p=0.001). The resorption mechanisms of HA and  $\beta$ -TCP coating layers were different each other *in vitro* study. The coated  $\beta$ -TCP was degraded mainly by dissolution and separation from implant, on the other hand, the HA coating layer was resorbed by osteoclastic activity.

**Human OsteoProgenitor Cell Adhesion and Spreading on Functionalized Titanium Surfaces Followed by Quartz Crystal Resonators (QCM) and Confocal Laser Scanning Microscopy (CLSM).** D. Le Guillou-Buffello<sup>\*1</sup>, R. Bareille<sup>\*2</sup>, M. Gindre<sup>\*3</sup>, A. Sewing<sup>\*4</sup>, P. Laugier<sup>\*3</sup>, J. Amedee<sup>2</sup>. <sup>1</sup>CNRS UMR7623, Paris, France, <sup>2</sup>INSERM Unité 577, Bordeaux, France, <sup>3</sup>CNRS UMR 7623, Paris, France, <sup>4</sup>Biomat Deutschland GmbH, Berlin, Germany.

The surface characteristics of endosseous implant such as titanium-based biomaterials control considerably the cellular response and subsequently the quality and the quantity of new-formed bone around the implant. A variety of invasive methods exist for quantifying cell adhesion to a potential biomaterial surface (direct counting of labelled cells after fixing or enzymatic detachment, focal contact imaging by confocal microscopy or CLSM). The quartz crystal microbalance (QCM) technique is an attractive *in vitro* method for real-time characterization of initial cell adhesion with no need for destructive interventions.

The aim of this paper is to monitor cell adhesion under well defined conditions of medium without serum, on different titanium coatings (hydroxyapatite functionalized or not with RGD-containing peptides) on cell adhesion by QCM and to complete these data by using conventional methods such as immunolabelling of vinculin and actin.

Human OsteoProgenitor (HOP) cells were then seeded at a cell density of 12,500 cells/cm<sup>2</sup> and cultured on titanium surfaces, functionalized with hydroxyapatite (Ti-HA), type I collagen (Ti-Coll) or with RGD-containing for different times varying from 1 to 3h. Surfaces with adherent cells were then dedicated to quartz crystal resonator experiments. Impedance measurement is also expressed as a percentage of adherent cells to uncoated Ti quartz crystal resonator which was used as control. In parallel, we examine the intracellular distribution of F-actin and vinculin by CLSM for the imaging of focal contact formation. Data obtained by quartz crystal resonator technique revealed that RGD-containing peptides alone, increase HOP cell adhesion in early time period of culture. Moreover, association of RGD-containing peptides with either type I collagen or with HA layers induces an additive effect on HOP cell adhesion compared to Ti-Coll or Ti-HA. By CLSM, both the area of contact focal by cell unit and the cytoskeleton network organization, differed according to the surfaces. Interestingly, association of RGD-containing peptides with HA layers induces an additive effect on focal contact formation on HOP cells compared to Ti-HA alone. These data confirm that RGD peptide effect occurs in the early time of culture, provides a benefit for osteoblast to spread, differentiate and survive.

**In vivo Bone Matrix Density Measurements by Water and Fat Suppressed Projection MRI (WASPI).** Y. Wu<sup>1</sup>, J. L. Ackerman<sup>\*2</sup>, H. Cao<sup>\*1</sup>, T. G. Reese<sup>\*2</sup>, M. I. Hrovat<sup>\*3</sup>, M. J. Glimcher<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Children's Hospital, Boston, MA, USA, <sup>2</sup>Radiology, Massachusetts General Hospital, Boston, MA, USA, <sup>3</sup>Mirtech, Inc, Brockton, MA, USA.

Bone matrix density plays a significant role in the mechanical and physiological properties of bone substance, as exemplified by the critical role in defining the diagnosis of metabolic bone diseases.

Currently available X-ray based bone densitometry provides only bone mineral density. In conventional MRI, solid bone is not visible due to very short T2 relaxation time.

Water and fat suppressed proton projection MRI (WASPI) has been recently developed to suppress the dominating long T2 signal (water and fat) while preserving the short T2 signal of solid bone and other molecularly immobile substances of the matrix.

A volume transmit/receive MRI coil was built on a Teflon tube (to eliminate proton background signals) to image the ankle of pigs. A very fast crossed-diodes T/R switch and a receiver dead time of 10 micro-s were utilized to detect short T2 signal.

Yorkshire pigs 2-3 months old were scanned with WASPI and conventional gradient echo MRI in a Siemens Trio 3T system while under anesthesia, with the right rear foot inside the coil. Three polymer pellets of different densities were taped on the skin of the foot, serving as calibration phantoms. Fig. 1 shows a coronal view of conventional MRI with slice thickness 3 mm and in plane resolution 1 mm. The muscle, marrow and fat are clearly visible, while the bone is dark and the polymer pellets cannot be seen. Fig. 2 shows a coronal view of WASPI of the same portion of the foot with an isotropic resolution of 2.4 mm. The total 3D imaging time was 27 min. The cortical bone of phalanges and the polymer pellet are bright, while the muscle, marrow and fat signals are suppressed to background levels.

Fig 1. Conventional MRI of the foot of a 2-month-old pig. Solid bone matrix and polymer pellets of the calibration phantom do not yield MR signal.

Fig 2. WASPI of the same pig. Cortical bone tissue and the polymer pellets are visualized and the soft tissue signal is suppressed.

This study demonstrates that *in vivo* WASPI measurement is feasible. We showed in a previous *in vitro* study that the WASPI intensity correlates highly with gravimetric and amino acid analysis of matrix density. We therefore anticipate that quantitative bone matrix density measurement by WASPI will be possible.

**The Use of Endothelial Progenitor Cells to Promote Bone Healing: Preliminary Results from a Rat Model Study.** K. Atesok<sup>\*</sup>, R. Li<sup>\*</sup>, E. H. Schemitsch<sup>\*</sup>. Division of Orthopaedics, St. Michael's Hospital, Toronto, ON, Canada.

Vascular in growth is an essential and critical mechanism in fracture healing. Endothelial Progenitor Cells (EPCs) have been proven to contribute to repair of injured endothelium and formation of new blood vessels.

We hypothesize that local EPC therapy will enhance angiogenesis at the fracture site and this in turn will promote bone healing by increasing osteogenesis and callus formation.

The purpose of this study is to determine the role of EPCs in bone regeneration and to evaluate the effectiveness of local EPC therapy to accelerate fracture repair.

Rat bone marrow EPCs were isolated and cultured for 7 to 10 days. A segmental bone defect (4mm.) was created in rat femur diaphysis and stabilized with mini plate. A gelfoam carrier impregnated with a solution of EPCs ( $1 \times 10^6$ ) was placed into the fracture gap. Control animals were applied only gelfoam with saline but no cells. Ten rats were included in this pilot study. The rats were divided into two groups. Two control and 3 EPC treated rats were included in each group. Animals in Group 1 and Group 2 were sacrificed 2 weeks and 3 weeks after the procedure respectively. Plain radiographs of the operated femur were taken before sacrifice to verify callus formation and the specimens from the fracture gap were collected for histological evaluation.

Radiological evidence of bone regeneration was remarkable in EPC treated animals both in

2 weeks and 3 weeks compared to control animals where no signs of callus formation was observed at the osteotomy site (Fig. 1).

Histological evaluation revealed that the specimens from EPC treated animals had abundant osteoid islands contained predominantly osteoblasts and osteoclasts with more blood vessels in both groups. Conversely, the specimens from control animals were sparsely ossified with markedly less bone cells and vessels (Fig. 2).

We conclude that the preliminary data from this study encourages the further investigation of EPCs as a potential therapy to promote bone healing.

**Nanotechnological Scaffold with Combination of Prostaglandin E<sub>2</sub> Receptor EP4 Agonist and rhBMP2, Enhances Bone Repair in the Defect of Mouse Calvarium Bone.** P. Kamolratanakul<sup>\*1</sup>, A. Kawamata<sup>\*1</sup>, Y. Yamamoto<sup>\*2</sup>, Y. Ezura<sup>\*1</sup>, K. Akiyoshi<sup>\*2</sup>, T. Amagasa<sup>\*3</sup>, M. Noda<sup>1</sup>. <sup>1</sup>Tokyo Medical and Dental University, Molecular Pharmacology, Medical Research Institute, Tokyo, Japan, <sup>2</sup>Tokyo Medical and Dental University, Institute of Biomaterials and Bioengineering, Tokyo, Japan, <sup>3</sup>Tokyo Medical and Dental University, Maxillofacial surgery, Tokyo, Japan.

Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) is known as an anabolic action on bone formation both in Vivo and in Vitro studies; however, side effect of severe diarrhea in animal was reported. The alternative way to work through PGE<sub>2</sub> effect is PGE<sub>2</sub> receptors, which are identified into 4 subtypes. EP4 is the only PGE<sub>2</sub> receptor subtype that was determined in bone and reported to mediate PGE<sub>2</sub>-induced anabolic action on bone formation. Nanogel scaffold provides effective drug-trapping and releasing. This study examined whether EP4 with nanogel scaffold carrier, can be performed to be a supplemental treatment for bone reconstruction. In 36 mice, defects were created by implant drill 3.75mm in diameter at parietal bone of mouse calvariae in present or absent of scaffold reconstruction, then after 4 weeks, mice were sacrificed. Treatment with nanogel scaffold in addition with EP4 agonist (EP4A) 100µg and/or rhBMP-2 at low dose (0.5 µg), radiographic investigation and CT analysis revealed that treated with EP4A 100µg or BMP 0.5µg, bone formation areas were not significantly different from nanogel-treated group. On the other hand, combination treatment with EP4A 100µg and BMP 0.5µg, bone formation areas were significantly increased about 50% more than non-supplementary nanogel-treated group (p<0.01). This data demonstrated that nanogel scaffold-in supplement of EP4A and BMP-2 combination enhances bone formation at defect site of mouse calvariae.

**Calcifications in Children with Juvenile Dermatomyositis (JDM) Contain Several Bone Formation Markers.** A. L. Urganus<sup>\*</sup>, Y. Zhao, L. M. Pachman. Cellular and Molecular Pathobiology, Children's Memorial Research Center, Chicago, IL, USA.

Previous analysis of JDM calcifications confirmed the presence of osteopontin (OPN), bone sialoprotein (BSP), and osteonectin (ON) (western blot), and Fourier Transform Infrared (FTIR) spectroscopy documented a much higher mineral to matrix ratio than bone (Pachman, 2006). We hypothesize that the mechanism of JDM calcification differs from that of bone formation. The goal of this study was to determine the presence or absence of SIBLING, bone and apoptosis markers in the pathological calcifications. This study was approved by the Children's Memorial Hospital IRB, and age appropriate informed consent

was obtained. Calcification samples surgically removed from 4 different children with JDM with a long duration of JDM symptoms ( $36.9 \pm 48.3$  months) were stained for SIBLING members: OPN (full length, N- and C-terminal fragments), BSP, ON, dentin matrix protein 1 (DMP1), the dentin phosphoprotein (DPP) domain of dentin sialophosphoprotein (DSPP), matrix extracellular phosphoglycoprotein (MEPE); bone markers: osteocalcin (OCN), core binding factor alpha 1 (Cbfa1), and alkaline phosphatase (ALP); osteoclast marker: Tartrate resistant acid phosphatase (TRAP); apoptosis marker: poly(ADP-ribose) polymerase (PARP) and mineral regulator: matrix Gla protein (MGP). The following areas of the samples were examined for these markers: the center and periphery of the mineral deposits, adjacent connective tissue and vascular endothelial cells. In all 4 samples, BSP, DPP, DMP1, OPN (full length, N- and C- terminal fragments), and ALP were present within the deposits, connective tissue, and vascular endothelial cells, while MEPE was not detected in any of the samples. OCN and ON were present within mineral deposits and endothelial cells, while Cbfa1 was present in the deposits and connective tissue. PARP was observed within vascular endothelial cells and connective tissue, indicating cell death. MGP was detected in the deposits and endothelial cells. TRAP staining identified multinucleated cells, osteoclasts, which accumulated at the periphery of calcifications. In conclusion, the osteoclastic activity at the surface of calcifications appeared to represent an attempt to resolve these pathological calcifications. Cell death may contribute to the process of calcification. The calcifications share expression of BSP, DPP, DMP1, OPN, ON, OCN, ALP and Cbfa1 with bone, indicating a possible common mechanism between bone formation and calcification in JDM, despite the higher mineral to matrix ratio found in JDM calcifications.

**Novel Screening System for Bone Matrix Proteins That Control Bone Mineralization.** H. Inoue<sup>\*1</sup>, T. Nakashima<sup>\*1</sup>, A. Iwamatsu<sup>\*2</sup>, A. Suematsu<sup>\*1</sup>, A. Yamaguchi<sup>3</sup>, H. Takayanagi<sup>1</sup>. <sup>1</sup>Department of Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Protein Research Network, Inc., Yokohama, Japan, <sup>3</sup>Section of Oral Pathology, Tokyo Medical and Dental University, Tokyo, Japan.

Bone consists of many kinds of matrix proteins, which are considered to be important for bone formation and mineralization by serving as crystal nucleator and regulator of crystal growth. Although many bone matrix proteins have been identified and characterized so far, the detailed molecular function of the matrix proteins in bone mineralization is still unknown. In this study, for elucidating the molecular mechanism of bone mineralization, we have developed new method for screening bone matrix proteins responsible for the mineralization. After bone marrow and connective tissues were removed from mouse tibia and femur, bone matrix proteins were extracted with acetic acid and thereafter with guanidine chloride from these bones. After the bone matrix proteins were separated with SDS-PAGE, the gel was incubated with the phosphate buffer and thereafter with the calcium buffer for the in-gel mineralization. Some matrix proteins induced calcium phosphate formation, which was detected as red band by alizarin red staining. Dissection of the band with the strongest signal and the peptide mass fingerprinting analysis revealed that this band was identical with bone sialoprotein, which was previously reported to induce the nucleation of hydroxyapatite in vitro. This result suggests that our system is very effective for screening of the nucleators or inducers of calcium phosphate formation. Molecular mechanism of mineralization based on the functions of bone matrix proteins which are under investigation will be discussed.

**Mineralization Is Related to Collagen Cross-links in Growing Cancellous and Cortical Bone.** N. M. B. K. Willems<sup>\*1</sup>, R. A. Bank<sup>\*2</sup>, L. Mulder<sup>\*3</sup>, G. E. J. Langenbach<sup>\*3</sup>, T. Grünheid<sup>\*4</sup>, A. Zentner<sup>\*4</sup>, T. M. G. J. van Eijden<sup>\*3</sup>. <sup>1</sup>Depts. of Orthodontics and Functional Anatomy, Academic Centre for Dentistry Amsterdam (ACTA), UvA and VU, Amsterdam, Netherlands, <sup>2</sup>Dept. of Oral Cell Biology, Academic Centre for Dentistry Amsterdam (ACTA), Amsterdam/TNO Quality of Life, Leiden, Netherlands, <sup>3</sup>Dept. of Functional Anatomy, Academic Centre for Dentistry Amsterdam (ACTA), Amsterdam, Netherlands, <sup>4</sup>Dept. of Orthodontics, Academic Centre for Dentistry Amsterdam (ACTA), Amsterdam, Netherlands.

**Introduction:** An examination of the age-related changes in bone mineral and collagen including its cross-links would extend the knowledge of their concomitant development. Moreover, it might improve our understanding of the processes of modeling and remodeling. **Materials and Methods:** Thirty-five pigs, aged between 0 and 100 weeks, were used for

analysis. Cancellous and cortical bone samples were obtained from areas near the center and near the poles, respectively. The degree of mineralization of bone (DMB) was determined in cancellous and cortical bone using microcomputed tomography. The amount of collagen and its mature cross-links hydroxylslypyridinoline (HP) and lysylpyridinoline (LP) were quantified using high-performance liquid chromatography. Correlation coefficients were calculated to determine significant age-related changes. Partial correlation coefficients between collagen parameters and DMB were obtained, controlling for age.

Fig.: Schematic figure of collagen molecules and their mature cross-links HP and LP.

**Results:** DMB increased with age in cancellous and cortical bone. The amount of collagen increased in cancellous bone, whereas no changes were observed in cortical bone. Moreover, the total number of the HP and LP cross-links decreased in cancellous bone only, because of the decrease found in HP. The number of LP cross-links decreased in cancellous and cortical bone after the age of 10 weeks. DMB and LP correlated significantly in cancellous and cortical bone ( $r = -0.55$  and  $-0.60$  respectively).

**Conclusions:** Bone collagen and mineralization are related during growth. The high turnover rate in cancellous bone might be responsible for the low number of the mature cross-links HP and LP. The high number of LP cross-links observed in the first weeks suggests LP plays an important role in the onset of bone mineralization.

**AC-100 Promotes Cartilage Repair and Sub-Chondral Bone Healing In Surgically Induced Cartilage Defects.** C. A. Middleton-Hardie<sup>1</sup>, H. Aberman<sup>\*2</sup>, T. Simon<sup>\*2</sup>, R. C. Spiro<sup>3</sup>, B. Schnegelsberg<sup>1</sup>, D. M. Rosen<sup>1</sup>. <sup>1</sup>Research and Development, Acologix, Hayward, CA, USA, <sup>2</sup>Applied Biological Concepts, Los Alamitos, CA, USA, <sup>3</sup>RCS Consulting, Half Moon Bay, CA, USA.

AC-100 showed promising activity in two cartilage defect studies in goats to promote cartilage repair.

The sequence of AC-100 is derived from a central 23-amino acid region of the bone extracellular matrix protein MEPE and is one of the more conserved regions of the molecule. AC-100 has shown specific activity *in vivo* to promote tissue appropriate hard tissue deposition in teeth and in bone.

For the first study, an osteochondral defect (6mm diameter, 6mm deep) was made in the medial femoral condyle of Spanish goats. A cylindrical plug cut from a collagen sponge (CollaPlug; 6mm diameter, 6mm long) was implanted into the lesion site and saturated with the test article (saline; AC-100 2.5, 25mg/application). Post-operative treatments included intra-articular injections (0.5mL) of the appropriate test article into the operated knee joint at 1, 2 and 3 weeks post surgery. All animals were returned to full weight bearing activity post-surgery. The necropsy timepoints were at 3 and 6 months. The joints were evaluated by gross analysis and histology.

There was good correlation between the gross evaluation and the quantitative histological evaluation. Both showed the high dose AC-100 group had better healing outcomes than the saline and low-dose AC-100 groups at both timepoints.

In the second study a full-thickness cartilage defect was created in the medial femoral condyle. In half of the goats the defects underwent a microfracture procedure. The test articles (saline; AC-100 5, 25, 125mg/application) were administered by intra-articular injection (1.5mL) immediately after closing and 1, 2 and 3 weeks post-surgery. All animals were returned to full weight bearing activity post-surgery. In this study a short timeframe of 6 weeks was chosen to investigate early healing processes.

By gross evaluation the AC-100 treated defects showed significant improvements in the amount and quality of repair tissue with a dose-dependent effect ( $p=0.04 \rightarrow p=0.09$  vs. saline). Histological evaluation of the edge repair also showed a significant AC-100 effect ( $p=0.02 \rightarrow p=0.07$  vs. saline). The AC-100 treatment increased healing with and without microfracture.

As the defects were located in a major weight bearing site the observed improvements seen with AC-100 are very promising. Further studies are underway to investigate the long-term healing effects of AC-100 treated full thickness defects.

**Phosphate Induced Apoptosis in Growth Plate Chondrocytes via a Nitric Oxide and JNK-dependent Pathway.** M. Zhong\*, Z. Schwartz, B. D. Boyan. Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

Hypertrophic chondrocytes in the growth plate exit their development pathway by undergoing apoptosis, in part via the induction of high extracellular phosphate (Pi) concentration involving nitric oxide (NO) production. Recent studies show that high Pi can also initiate apoptosis in resting zone (RC) cells and NO is required. The purpose of the present study was to determine whether the c-Jun N-terminal kinase (JNK), which is associated with apoptosis in many other tissues, contributes to Pi induced apoptosis in RC cells. Rat costochondral RC cells were cultured in DMEM containing 50mM ascorbic acid and 10% FBS. Apoptosis was induced by treatment of confluent cultures with inorganic 7mM phosphate (Pi) for 24h or with the NO donor SNOG. JNK signaling was blocked by incubating the cultures with JNK inhibitor II (EMD Biosciences, Darmstadt, Germany) and NO signaling was blocked using L-NMMA. Apoptosis was assessed as a function of DNA fragmentation ([<sup>3</sup>H]-thymidine labeled DNA fragments and TUNEL staining) and cell viability using the MTT assay. NO production was determined using a DAN (2,3-diaminonaphthylene) assay. In this study, we found that Pi caused a dose-dependent increase in NO production and a corresponding increase in RC chondrocyte apoptosis, as judged by DNA fragmentation, TUNEL staining and MTT assays. Inhibition of NO production by L-NMMA blocked Pi-dependent apoptosis. Moreover, the NO donor SNOG caused a dose dependent increase in RC chondrocyte apoptosis and inhibition of JNK blocked this effect. In summary, these results show that RC chondrocytes also undergo apoptosis under the induction of Pi, and the pathway is NO-dependent and via JNK. This suggests that one mechanism for preventing premature growth plate closure may be regulation of extracellular Pi production, commensurate with low levels of alkaline phosphatase in the reserve zone.

**Targeted Expression of SOX9 in Hypertrophic Chondrocytes Leads to Enhanced Adipogenic Activity and Spontaneous Osteoarthritis in Transgenic Mice.** B. Liang<sup>1</sup>, D. Chen<sup>\*1</sup>, B. Lee<sup>2</sup>, G. Zhou<sup>1</sup>. <sup>1</sup>Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, <sup>2</sup>Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

The disturbed balance in cartilage metabolism plays an important role in the pathogenesis and progression of osteoarthritis (OA). Transcription factors are key regulators of cartilage metabolism by stimulating chondrogenesis under both physiologic and pathologic conditions. Among them, SOX9 is essential for successive steps of chondrogenesis while RUNX2 is a positive regulator of chondrocytes maturation. RUNX2 also represses adipocytes differentiation and its deficiency in chondrocytes leads to increased adipogenesis. We have previously shown that SOX9 can physically interact with RUNX2 and inhibit its transcriptional activity *in vitro*. To directly investigate SOX9 effects during chondrocyte hypertrophy, a novel *Col10a1-SOX9* transgenic mouse model was generated in which *SOX9* was specifically expressed in hypertrophic chondrocytes driven by a 10kb *Col10a1* promoter. The specific transgene expression in hypertrophic chondrocyte was confirmed by RT-PCR in rib chondrocytes of 6-day-old mice and immunostaining in 10-week-old tibia samples. In monolayer culture of rib hypertrophic chondrocytes isolated from 6-day-old mice, expression of *Col10a1*, a downstream target of Runx2, was decreased by 55% in transgenic mice by quantitative RT-PCR. In comparison with wild-type mice, *Col10a1-SOX9* hypertrophic chondrocytes culture also displayed increased adipogenesis with more lipid droplets accumulation by Oil Red-O staining and higher expression levels of adipogenic genes including *C/EBPα*, *PPARγ2*, *SCD1* and *Glut4*. Additionally, mineralized areas of hypertrophic cartilage were significantly reduced in proximal tibia in 10-week-old *Col10a1-SOX9* transgenic mice. Interestingly, 11-month-old knee joints of *Col10a1-SOX9* transgenic mice but not wild-type littermates developed spontaneous severe osteoarthritis with joint space narrowing, osteophytes formation, and subchondral sclerosis. Moreover, Safranin-O histology revealed severe degradation of articular cartilage and bony outgrowth in 11-month-old transgenic mice but not in wild-type controls. Our results suggest that defective hypertrophic cartilage could contribute to the development of an adverse biomechanical environment and enhance the progression of the articular cartilage deterioration. Therefore, our study not only confirms the direct inhibitory effect of SOX9 on chondrocyte hypertrophy during cartilage formation, it also reveals a potential novel role of SOX9 in osteoarthritis pathogenesis.

**Effects of Beta-D-glucopyranoside from *Phellodendron Amurense* on the Production of Inflammatory Cytokines, Growth Factors, Matrixmetalloproteinase, and on Bone Markers in Human Subchondral Osteoarthritic Osteoblasts.** D. Kim<sup>1</sup>, J. Huh<sup>\*2</sup>, Y. Baek<sup>\*3</sup>, D. Choi<sup>\*3</sup>, D. Park<sup>\*3</sup>, J. Lee<sup>\*3</sup>. <sup>1</sup>Internal Medicine, Kyung Hee University Hospital, SEOUL, Republic of Korea, <sup>2</sup>Oriental Medicine Research Center for Bone & Joint Disease, Kyung Hee University Hospital, Seoul, Republic of Korea, <sup>3</sup>Department of Acupuncture & Moxibustion, College of Oriental Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea.

**Objects:** Subchondral bone sclerosis is a common feature of osteoarthritis (OA), but the mechanisms responsible for this condition remain unresolved. We investigate the effects of beta-D-glucopyranoside from *Phellodendron amurense* on the production of inflammatory cytokines (interleukin (IL)-1α, IL-6, and prostaglandin E2 (PGE<sub>2</sub>)), growth factors (vascular endothelial growth factor (VEGF) and transforming growth factor-beta (TGF-β)), matrixmetalloproteinase (MMP)/urokinase plasminogen activator (uPA) and bone markers in human subchondral OA Ob.

**Methods:** We measured the abundance of IL-1α, IL-6, PGE<sub>2</sub>, VEGF, TGF-β, MMP-1 and uPA using very sensitive ELISA in conditioned-media of human primary subchondral Ob from normal individuals and osteoarthritic patients. beta-D-glucopyranoside or selective COX-2 inhibitor (NS398) was performed to determine its effect on inflammatory cytokines, growth factors, MMP/uPA. The expression of bone cell markers was also determined.

**Results:** OA Ob produced all these factors with greater variability than normal cells. Interestingly, the production of IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA by OA Ob separated patients into two subgroups, those whose Ob produced levels comparable to normal (low producers) and those whose Ob produced higher levels (high producers). In those cells classified as high producers, IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA levels were increased two- to three-fold and five- to six-fold, respectively, compared with normal. In contrast, we found that IL-1α and TGF-β levels were similar in normal and all osteoarthritic Ob. beta-D-glucopyranoside significantly reduced IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA levels in all OA Ob. In contrast, using NS398 did not reduce VEGF and MMP-1/uPA levels in either group. The evaluation of alkaline phosphatase activity, osteocalcin release and collagen type I activity increased by beta-D-glucopyranoside in OA Ob regardless to which subgroup they were assigned.

**Conclusion:** These results suggest that beta-D-glucopyranoside may contribute to bone remodeling through inhibition of inflammation and MMP/uPA system in subchondral OA Ob, ultimately leading to treatment of abnormal bone sclerosis in OA.

## SA119

**Vinculin Is Involved in Hypertrophic Differentiation Through Raf/MEK/ERK Pathway in Chondrocytic ATDC5 Cells.** T. Koshimizu<sup>\*1</sup>, K. Tachikawa<sup>\*1</sup>, K. Ozono<sup>2</sup>, T. Michigami<sup>1</sup>. <sup>1</sup>Department of Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, <sup>2</sup>Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan.

Vinculin occurs in multimolecular complexes that function in adhesion and/or signaling between the extracellular milieu and the cell, via integrins and cadherins. Although vinculin-knockout mouse was reported to exhibit impaired limb development, the roles of vinculin in chondrogenesis remain unclear. Gene-trap mutagenesis is based on the idea that the random insertion of a trapping vector may disturb the function of inserted genes. We applied this method in ATDC5, a cell model of chondrocyte differentiation, and isolated a clone where vinculin gene is trapped. In this clone named #4-17, a truncated vinculin lacking paxillin-binding domain was produced from the trapped allele. Phosphorylation of FAK and ERK1/2 induced by adhesion to extracellular cell matrix (ECM) was markedly enhanced in #4-17 compared with parental cells, which is consistent with previous reports in vinculin-null fibroblasts. The expression of vinculin in parental ATDC5 was gradually elevated during the chondrocytic differentiation, and immunostaining for vinculin of tibial growth plates from wild-type mice demonstrated the parallel results. Thus, we investigated the roles of vinculin in chondrocyte differentiation utilizing the clone #4-17. When cultured in differentiation medium, #4-17 exhibited impaired nodule formation and less accumulation of cartilaginous matrices. The expression of *Col2a1* and *PTHrP* was detected in #4-17, but was diminished earlier than the parental ATDC5 cells. The expression of *Col10a1* was also markedly reduced in #4-17. Interestingly, the expression of SOX9 was retained. Then, we examined the effect of the trapping of vinculin gene on signal transduction during the chondrocyte differentiation. Since Raf/MEK/ERK pathway is reported to play a critical role in chondrocyte differentiation, we investigated the

phosphorylation of c-Raf and ERK1/2. In parental ATDC5 cells, phosphorylation of c-Raf and ERK1/2 was increased during the chondrocytic differentiation. On the other hand, phosphorylation of c-Raf and ERK1/2 was rather declined in #4-17 when cultured in the differentiation. The result makes a striking contrast with the enhanced phosphorylation of ERK1/2 induced by adhesion to ECM. These data suggest that vinculin plays an important role in hypertrophic differentiation of chondrocytes, and that Raf/MEK/ERK pathway might be involved in the regulation of hypertrophic differentiation by vinculin.

**Mouse-to-Human Strategy to Identify Bone Strength QTL Genes.** C. L. Ackert-Bicknell<sup>1</sup>, B. Paigen<sup>\*1</sup>, W. G. Beamer<sup>1</sup>, C. J. Rosen<sup>1</sup>, S. Demissie<sup>\*2</sup>, L. A. Cupples<sup>\*2</sup>, Y. H. Hsu<sup>3</sup>, D. P. Kiel<sup>3</sup>, D. Karasik<sup>3</sup>. <sup>1</sup>The Jackson Laboratory, Bar Harbor, ME, USA, <sup>2</sup>Biostatistics, BU Sch Public Health, Boston, MA, USA, <sup>3</sup>IFAR, Hebrew SeniorLife, Boston, MA, USA.

Murine models have proven to be very useful for the identification of candidate genes underlying complex traits. A large number of resources are now available to allow for translatability of gene prediction in mice to human populations. We have identified QTLs for Bone Mineral Density (BMD) on proximal Chr 15 in mice in two separate F2 mapping crosses: B6xC3H (peak at 11.9 cM) and B6xNZW (peak at 17 cM). The 95% confidence interval (CI) for the B6xC3H QTL peak extended from 4.0 cM to 28.0 cM (10 Mb to 59.96 Mb) and encompassed the CI for the B6xNZW QTL peak. This region is predicted to contain greater than 270 genes. Using block haplotyping we identified 18 distinct haplotype blocks covering 12.4 Mb. In total 52 genes were found to be either completely or partially included in these haplotype blocks. Also, a QTL for BMD was reported in the literature in a B6xDBA cross with a peak at 10 cM. When DBA was added to the haplotype analysis, we were able to exclude 22 genes as candidates. The largest of these blocks was located immediately distal to the *Trps1* gene. This gene encodes a specific zinc finger protein that is a putative transcription factor. The human *TRPS1* gene has been shown to be involved in trichorhinophalangeal syndrome (also known as Langer-Giedion syndrome with exostoses). To translate the mouse finding to humans, we performed a genetic association study of polymorphisms (SNPs) in the vicinity of the *TRPS1* in a subset of unrelated individuals from the Framingham Offspring cohort. This cohort consisted of 793 women and 700 men (age 61.3 ± 9.1 yrs), for whom both DNA and bone phenotypes (DXA measurements of the hip and spine and/or heel QUS) were available. We genotyped 22 tagging SNPs in the region on chr. 8q24, covering 93% of the variance in *TRPS1* gene, using the SNPlex<sup>TM</sup> and ABI TaqMan platforms. We assessed the association between SNPs and bone phenotypes using sex-specific multiple linear regression, adjusted for age, BMI, height, smoking, and estrogen status (in women). To correct for the numerous statistical tests in our analysis, we performed permutation tests. After adjustment for multiple testing (permuted 10,000 times), 2 SNPs near the *TRPS1* were identified to be significantly associated (p values ≤ 0.0001) with the bone traits. One SNP (rs720928, associated with femoral BMD and heel QUS in men at p<0.0005) is located distal to the *TRPS1* gene and this finding corresponds to our haplotype analysis performed in mice. We are currently exploring other genes in this haplotype block. This comparative genomic approach using mouse models may be an efficient strategy to identify new candidate genes associated with bone phenotypes in humans.

## SA121

**Intracellular PTHR2 Alters Cell Proliferation and Pattern of Gene Expression while Antagonizing PTHR1 Signalling in Chondrocytic CFK2 Cells.** D. K. Panda<sup>\*</sup>, D. Goltzman, A. C. Karaplis. Experimental Medicine, McGill University, Montreal, QC, Canada.

TIP39 and PTHR2 are extended members of parathyroid hormone ligand and receptor family. Both the ligand (TIP39) and receptor (PTHr2) are expressed in the growth plate, the former in well differentiated hypertrophic chondrocytic cells while the latter in cells of the periaricular cartilage. This expression pattern is completely opposite to that of PTHrP and PTHR1 in the developing growth plate.

We have observed that upon TIP39 stimulation, PTHR2 expressed in CFK2 chondrocytic cells undergoes endocytosis and accumulates in the perinuclear / nuclear compartment. A bipartite nuclear localization motif is present in the C-terminal region of the receptor which also contains more than one nuclear export signature. These findings prompted us to hypothesize that PTHR2 may function intracellularly, in part at the level of the nucleus and antagonize PTHrP/PTHr1 signalling. To explore the potential for intracellular action by PTHR2, we deleted the signal sequence from the N-terminal portion of the receptor so that only the mature protein would be expressed. We then stably transfected chondrocytic CFK2 cells with this construct (ΔSSPTHr2). In the absence of TIP39, expression of ΔSSPTHr2 alone, decreased proliferation and suppressed 3H thymidine incorporation in CFK2 cells. This parallels the effects of the full length receptor on cellular proliferation following TIP39 stimulation. In addition, mRNA microarray analysis was performed to get some insight into the altered gene expression pattern between in CFK2/ΔSSPTHr2 compared to CFK2/vector cells. Expression of the transcription factor Sox9 as well as matrix proteins such as type II collagen and matrix gla protein (Mgp) were highly suppressed by ΔSSPTHr2 in CFK2 cells, as observed following treatment of full-length PTHR2 transfected CFK2 cells with TIP39. The microarray data was reconfirmed by semi-quantitative RT-PCR analysis. When 1 kb of the mouse Mgp promoter inserted in a luciferase reporter system was cotransfected with ΔSSPTHr2, the activity of the reporter plasmid was reduced three- to five-fold. Interestingly, MGP expression was up-regulated by PTHrP/PTHr1 signalling at the transcriptional level. To resolve this conundrum, we

expressed a constitutively active form of PTHR1(H410P) along with leaderless form of PTHR2. When, PTHR1(H410R) was co-expressed along with ΔSSPTHr2, Mgp expression was restored to levels comparable to vector transfected CFK2 cells. In summary our results suggest, the leaderless form of PTHR2 functioning intracellularly recapitulates the proliferative and gene expression patterns of the full length receptor following TIP39 stimulation. Moreover, PTHR1 and PTHR2 may display antagonistic signalling in chondrocytes.

**Hypothyroidism Is Not Deleterious to the Skeleton During Early Fetal Development.** L. P. Capelo<sup>\*1</sup>, E. H. Beber<sup>\*2</sup>, T. M. T. Zorn<sup>\*1</sup>, S. A. Huang<sup>\*3</sup>, A. C. Bianco<sup>\*4</sup>, C. H. A. Gouveia<sup>2</sup>. <sup>1</sup>Departamento de Cell and Developmental Biology, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Departamento de Anatomy, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>3</sup>Division of Endocrinology, Children's Hospital Boston, Boston, MA, USA, <sup>4</sup>Division of Endocrinology, Diabetes and Hypertension, Brigham and Woman's Hospital, Boston, MA, USA.

Thyroid hormone (TH) has a key role on post-natal bone development, while its relevance during fetal bone development is less clear. To investigate this, we induced a hypothyroid state and analyzed the skeleton during pre- and post-natal development of mice. We also examined the mRNA expression of the monocarboxylate transporter 8 (MCT8), a plasma membrane transporter that mediates the cellular influx and/or efflux of TH, and the expression of the iodothyronine deiodinases type II and III (D2 and D3). D2 is an activating enzyme that converts thyroxine (T4) into its active form, triiodothyronine (T3), while D3 inactivates T4 and T3. Hypothyroidism (HYPO) was induced pharmacologically during gestation and nursing. The fetuses and litters were harvested at embryonic days (E) 14.5, 16.5 and 18.5 and at post-natal days (P) 4, 7, 14, 21 and 35. Histological analysis of the distal epiphyseal growth plate (EGP) of the femur and vertebra showed that HYPO barely affected bone development up to E16.5. Only at E18.5, the length and area of the proliferative and hypertrophic zones, the number of chondrocytes per proliferative column and the number of hypertrophic chondrocytes were reduced in the EGPs of HYPO fetuses. Femoral D3 mRNA was detected at E14.5 and its expression decreased markedly (~10-fold) at E18.5, and even more at P14. In contrast, femoral D2 mRNA expression increased significantly by E18.5 and markedly (~2.5-fold) by P14. At E18.5, D2 activity was increased while D3 activity was diminished in the femur of HYPO fetuses (~2 fold). Like D3, the femoral mRNA expression of MCT8 decreased significantly from E14.5 to P35 (~5-fold) and was up-regulated in the femur of HYPO animals during post-natal development. In conclusion, the absence of a HYPO-induced bone phenotype during early fetal development suggests that TH signaling in bone is kept to a minimum at this stage. In addition, the reciprocal expression pattern of D2 and D3 during skeletal development suggests that these enzymes may be responsible for keeping low levels of TH in the bone for the proper early fetal bone development. However, the MCT8 expression suggests that a minimum TH influx may be necessary during the same period. In summary, D2 and D3 are likely to have an important role during pre-natal development of the skeleton, while MCT8 may be important to modulate TH effects on bone, mostly during post-natal development.

**Functionalization of a PLGA/PEG-PLA Composite Electrospun Scaffold with rhBMP-2 Plasmid DNA for Bone Regeneration.** X. Zhao<sup>\*1</sup>, B. Hsiao<sup>\*2</sup>, B. Chu<sup>\*2</sup>, M. Hadjiargyrou<sup>1</sup>. <sup>1</sup>Biomedical Engineering, SUNY, Stony Brook, Stony Brook, NY, USA, <sup>2</sup>Chemistry, SUNY, Stony Brook, Stony Brook, NY, USA.

Previously, our laboratory reported on the fabrication of DNA based nanofibrous and biodegradable electrospun scaffolds designed to serve as gene delivery systems for *in vivo* tissue engineering applications. In the current study, using electrospinning, we generated two scaffolds, one using a combination of 30% (w/w) poly lactide- co-glycolide (PLGA) and 3% (w/w) diblock copolymer (PEG-PLA) and by incorporating 0.025% (w/w) rhBMP2 plasmid (~1mg), and the other without any DNA. The scaffolds generated measured 15cm (width) x 30cm (length) x 100µm (thickness). Scanning electron microscopy revealed that both non-woven scaffolds looked indistinguishable and had a range of fiber diameters between 500 nm - 1.5 µm. Subsequent DNA release studies using 1.5 x 1 cm sections of the rhBMP2 DNA based scaffold showed an ~60% of DNA (in TE buffer) release in the first 24 hrs and then a steep decrease over time. Collectively, ~70% of plasmid DNA was released over 5 days, corresponding to about 2µg. Gel electrophoresis confirmed that the released plasmid was structurally intact. We are now conducting experiments in order to test the released rhBMP2 plasmid's bioactivity, by transfecting pre-osteoblastic MC3T3 cells with both the original rhBMP2 plasmid and the released DNA to see if they can enhance differentiation and mineralization. In addition, we are also carrying out *in vitro* studies with MC3T3 cells plated on top of the two types of scaffolds, again to test the effects on differentiation and mineralization. Lastly, we are now starting *in vivo* experiments using the tibial drill hole (critical size defect) model in order to assess the scaffolds capability of enhancing skeletal regeneration. Overall, we hope that the rhBMP2 plasmid DNA based scaffold will be a viable gene delivery system and have the potential to deliver therapeutic rhBMP2 plasmid DNA to stimulate tissue regeneration.

**Strong and Extensive Epistatic Interactions Affect Bone Traits in a Mouse Reciprocal Intercross of HcB/8 and HcB/23.** N. Saless<sup>1</sup>, S. J. Litscher<sup>\*1</sup>, R. S. Kattapuram<sup>\*1</sup>, M. J. Houlihan<sup>\*1</sup>, T. K. O'Neil<sup>\*1</sup>, S. Sudhakaran<sup>\*1</sup>, K. G. Abdul Raheem<sup>\*1</sup>, S. Olson<sup>\*1</sup>, P. Demant<sup>\*2</sup>, R. D. Blank<sup>1</sup>. <sup>1</sup>Medicine/Endocrinology, University of Wisconsin and Madison VAMC, Madison, WI, USA, <sup>2</sup>Genetics, Roswell Park Cancer Institute, Buffalo, NY, USA.

Linkage studies have identified quantitative trait loci (QTLs) underlying bone mineral density, bone geometry, and bone biomechanics in multiple organisms. Less progress, however, has been made in identifying the genes responsible for these QTLs. Moreover, the mapped QTLs account for only a minority of the heritable component of the measured bone properties. We hypothesize that much of the "missing" genetic contribution to bone properties arises from epistatic interactions between genes. To explore this possibility, we performed an epistasis analysis in a 603 animal, reciprocal F2 intercross of the recombinant congenic strains HcB/8 and HcB/23 that was analyzed for femoral biomechanical performance and geometry.

Animals were maintained under standard husbandry conditions and sacrificed at 17 weeks. Genotyping was done using 39 microsatellite markers spanning the approximately 300 centiMorgans over which the parental strains are known to be genetically informative. The cross includes informative regions on chromosomes 1, 2, 3, 4, 6, 9, 10, 15, 17, and 19. In single locus genome scans reported previously, we found QTLs for bone related traits on chromosomes 1, 2, 3, 4, 6, and 10. We performed the epistasis analysis with the R-QTL linkage package.

Nearly every possible pair of chromosomes yielded a significant epistatic interaction for at least 1 trait. The most striking interactions involve chromosomes 1 and 3. On chromosome 1, there are significant interactions between distinct loci on the chromosome, as well as with all the other informative chromosomes. On chromosome 3, the same pattern exists, with a significant intrachromosomal interaction as well as epistatic interactions with all the other informative chromosomes. The LOD scores for the full models, including epistasis, range from 8 to 18.

Because only approximately ¼ of the genome segregates between pairs of recombinant congenic strains, they are particularly useful for studying epistasis, as the number of potential statistical tests is reduced approximately 16-fold in comparison to an intercross between ordinary inbred strains. This increases the power to detect epistasis when present. Studying epistasis is important not only because it accounts for previously unmeasured genetic contributions to bone properties, but because interactions provide additional clues for identifying the genes underlying QTLs.

**A Bone Defect Model in Mouse Femur to Challenge Biomaterials, Cells and Molecules for Bone Repair.** J. Fricain<sup>\*1</sup>, L. Monfoulet<sup>\*1</sup>, B. Rabier<sup>\*1</sup>, L. Malaval<sup>\*2</sup>, J. Amedee<sup>1</sup>, O. Chassande<sup>\*1</sup>. <sup>1</sup>INSERM U577, Bordeaux, France, <sup>2</sup>INSERM U890, Bordeaux, France.

Bone loss treatment is still a challenge for orthopaedic and oral surgeons. Experimental models are useful to better understand natural bone repair and to investigate the function of therapeutic molecules in bone repair. Mice have been used for skeletal research and the defect models used have interested the femur diaphysis to study cortical reparation or metaphysis to study cancellous bone cicatrization. The aim of this study is to demonstrate the influence of the size of a mice femur metaphyseal defect on density and volume of cancellous and cortical newly bone formed and to create a critical size defect valuable to measure the effect of molecules or biomaterials on bone repair. Holes of 0.9 and 1.6 mm were performed respectively in the right and left femur of C57Bl6/J male mice (14 weeks old) and the femur were retrieved at 14, 28, 56 and 90 days, fixed in 4% paraformaldehyde for 24 hours at 4°C, then transferred into 70% ethanol and kept at 4°C. On one hand, femurs were scanned in a Explore Locus SP X-Ray microcomputerized tomography device (GE). On the other hand, femurs were decalcified in 0.5M EDTA for 3 days, then transferred in 70% ethanol, embedded in paraffin and 3 µm thick sections were stained with HES. Qualitative analysis of bone repair revealed that 14 days after surgery, fibrous tissue was mainly observed in 1.6mm defect while primary cancellous bone was present in the inner surface of 0.9mm defects. 28 days after surgery, 0.9 mm defects, were completely filled with trabecular bone while fibrous tissue was still present in 1.6 mm defects. The cortical edge of the 0.9 mm diameter defect was partially closed with dense mineralized tissue but remained completely opened in 1.6mm diameter defects. At 56 days, no marked evolution was observed in 0.9 mm defects as compared with 28 days. In 1.6 mm defects, fibrous tissue was still present in the external part of the lesion whereas trabecular like structures invaded most of the defect volume. Similar results were observed at 90 days. Quantitative analysis of cancellous bone formation showed that bone volume fraction (BVf) in the 0.9 mm defect was more important than in 1.6mm defect, due to more important trabecular number while thickness and density (BMD) were similar. At 28, 56 and 90 days no statistical difference was observed between the two size defects. For quantitative analysis of cortical bone formation, in 1.6 mm diameter defects cortical BVf was lower than in 0.9 mm defects at 28 days, and remained very low until 90 days, reflecting failure to close the perforation. In conclusion, the 1.6mm defect in mice is a cortical critical defect that could be used to test the action of molecules, cells or biomaterials on bone repair.

**Micro-CT Abnormalities in the th3 Mouse Model of Thalassemia Start at a Young Age and Are Associated with Decreased Bone Turnover.** M. G. Vogiatzi<sup>1</sup>, J. Tsay<sup>\*1</sup>, J. Racchumi<sup>\*1</sup>, S. Rivella<sup>\*1</sup>, R. W. Grady<sup>\*1</sup>, S. B. Doty<sup>2</sup>, P. J. Giardina<sup>\*1</sup>, A. L. Bosley<sup>2</sup>. <sup>1</sup>Pediatrics, Weill Cornell Medical College, New York, NY, USA, <sup>2</sup>Hospital for Special Surgery, New York, NY, USA.

Low bone mass and fractures occur frequently in patients with beta Thalassemia Intermedia (TI), a type of congenital hemolytic anemia characterized by decreased synthesis of the beta globin chains of hemoglobin. To better understand the bone changes in TI, we studied the th3/+ mouse model of this disease. Th3/+ mice bear a heterozygous deletion of the mouse beta globin genes and, similar to humans with TI, manifest mild to moderate anemia and iron overload as well as splenomegaly.

Th3/+ mice and age-matched WT controls (6 mice per group) were studied at age 2, 4, 6 and 9 mo by micro-CT (both femurs and vertebrae) followed by mechanical testing (three-point bending). We also performed immunostaining for procollagen I and TRAP, histomorphometry for mineral apposition rate (MAR), RT-PCR for osteoprotegerin (OPG), RANKL and cathepsin K.

Compared to WT animals: i) Micro-CT of trabecular bone (L5 vertebra) showed decreased bone volume fraction, decreased number of trabeculae and increased trabecular separation in the th3/+ mouse at all ages (p<0.05). ii) Cortical bone at femur mid-diaphysis showed increased marrow area and decreased ellipticity (Imax/Imin) of the th3/+ animals (p<0.05 at all ages). iii) Micro-CT parameters in the th3/+ mice did not worsen with age. iv) Th3/+ animals exhibited decreased MAR (1.4 ± 0.3 vs. 2 ± 0.5, th3/+ vs. WT, p=0.05, age 4mo) and decreased expression of cathepsin K, OPG and RANKL (p<0.01 at all ages). The number of osteoclasts and % bone surface covered by osteoblasts were the same in both th3/+ mice and controls. iv) Biomechanics showed reduced maximum load (20 ± 3 vs. 15.5 ± 2.6, th3/+ vs. WT, p=0.01), maximum moment (35.6 ± 5 vs. 27 ± 4.5, th3/+ vs. WT, p=0.01) and structural stiffness (106 ± 19 vs. 134 ± 23 th3/+ vs. WT, p=0.05) in the th3/+ mice.

In conclusion, the th3/+ mouse model of TI manifests changes in bone micro-architecture, geometry and mechanical properties reminiscent of those in humans. Micro-CT abnormalities are present by age 2 mo and do not worsen or improve with age, suggesting problems with both bone accrual and remodeling. In fact, bone changes in this model are associated with decreased bone turnover.

## SA129

**Longitudinal Relationships between Cartilage and Bone Turnover in Osteoarthritis.** E. B. Dam<sup>\*1</sup>, M. A. Karsdal<sup>2</sup>, I. Byrjalsen<sup>2</sup>, A. B. Jensen<sup>\*2</sup>, C. Christiansen<sup>2</sup>. <sup>1</sup>Imaging, Nordic Bioscience, Herlev, Denmark, <sup>2</sup>Nordic Bioscience, Herlev, Denmark.

**Purpose:** The pathogenesis of osteoarthritis (OA) is speculated to involve interaction patterns of bone and cartilage turnover. We investigated cross-sectional and longitudinal relationships between markers for cartilage and bone turnover in healthy subjects and subjects with OA symptoms. The focus was cartilage loss and correlations between bone and cartilage markers.

**Methods:** The 21-month study included 159 subjects prospectively selected as representative for the general population. To ensure a homogeneous population, only those over 30 years at were included, resulting in 145 subjects with age 58±13, BMI 26±4, 48% female, and 25% with OA (Kellgren and Lawrence >1). MRI scans were acquired using a Turbo 3D T1 sequence on a 0.18T Esaote scanner and total medial tibial and femoral cartilage volume was quantified automatically in a computerized framework. Bone resorption was measured by the biochemical marker serum CTX-I (C-terminal telopeptide of collagen type I) and cartilage degradation by urine CTX-II.

**Results:** At baseline (BL) CTX-I and CTX-II were linearly correlated in the healthy population ( $r=0.52$ ,  $p<0.001$ ) but only borderline for the OA subjects ( $r=0.29$ ,  $p=0.09$ ).

Inspection of the OA subjects showed that elevated CTX-II scores at BL predicted longitudinal cartilage loss. Specifically, the odds ratio (OR) for increased cartilage loss was 4.0 - comparing highest and lowest tertiles of CTX-II ( $p<0.01$ ). The same OR for CTX-I was 1.4 (not significant). There was a correlation between BL CTX-II scores and follow-up (FU) CTX-I ( $r=0.23$ ,  $p<0.01$ ). Contrarily, there was no correlation between BL CTX-I and FU CTX-II ( $r=0.08$ ,  $p=0.4$ ). All results persisted after correction for gender and age.

**Conclusion:** The results support a coupling between cartilage and bone turnover in healthy individuals that however is imbalanced in OA patients. In healthy individuals, a balanced cartilage and bone turnover may be of major importance for joint health. This emphasizes a potential need for OA treatments that restore the bone/cartilage metabolic balance. By comparison of BL and FU biomarker levels, it could be hypothesized that at least a specific stage of cartilage breakdown (elevated CTX-II at BL) is preceding bone remodeling (elevated CTX-I at FU) in OA - possibly a piece for the complex puzzle of causal relationships between cartilage and bone breakdown.

**Disclosures:** M.A. Karsdal, None.

## SA130

**Apc-mediated Control of  $\beta$ -catenin Is Essential for Both Chondrogenic and Osteogenic Differentiation of Skeletal Precursors.** R. L. Miclea<sup>\*1</sup>, E. C. Robanus-Maandag<sup>\*2</sup>, C. A. J. Bosch<sup>\*2</sup>, T. Kobayashi<sup>3</sup>, H. M. Kronenberg<sup>2</sup>, G. Rawadi<sup>\*4</sup>, C. W. G. M. Löwik<sup>5</sup>, R. Fodde<sup>\*6</sup>, J. M. Wit<sup>\*1</sup>, M. Karperien<sup>7</sup>. <sup>1</sup>Pediatrics, Leiden University Medical Centre, Leiden, Netherlands, <sup>2</sup>Human Genetics, Leiden University Medical Centre, Leiden, Netherlands, <sup>3</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>4</sup>Galapagos, Romainville, France, <sup>5</sup>Endocrinology, Leiden University Medical Centre, Leiden, Netherlands, <sup>6</sup>Pathology, Josephine Nefkens Institute, Erasmus MC, Rotterdam, Netherlands, <sup>7</sup>Tissue Regeneration, Institute for Biomedical Technology, Twente University, Enschede, Netherlands.

During endochondral bone formation, levels of transduced canonical Wnt/ $\beta$ -catenin signaling determine lineage commitment of skeletal precursor cells: high levels induce osteoblast differentiation, whereas low levels lead to chondrocyte differentiation. Whether Adenomatous polyposis coli (Apc), the key intracellular gate-keeper controlling  $\beta$ -catenin turnover, is involved in this process is currently unclear.

To better understand the mechanisms that modulate  $\beta$ -catenin levels in skeletal precursor cells we generated conditional knockout mice lacking functional Apc in Col2a1-expressing cells.

Conditional heterozygous and homozygous Apc mutants were monitored for the development of an abnormal phenotype. Heterozygous Col2a1-Cre-mediated Apc inactivation did not interfere with embryonic skeletal development, postnatal growth or bone mass acquisition up to 12 weeks of age. In marked contrast, conditional homozygous mutant Col2a1-Cre:Apc<sup>15lox/15lox</sup> mice died perinatally showing greatly impaired skeletogenesis. The skeletal defects were already present at E12.5. All endochondral bones

were misshaped and lacked structural integrity. Lack of functional Apc resulted in a pleiotropic skeletal cell phenotype. The vast majority of the skeletal precursor cells lacking Apc failed to differentiate and retained a mesenchymal-like spindle shape morphology. However, skeletal precursor cells in the proximal ribs were able to escape the noxious effect of functional loss of Apc resulting in formation of highly active osteoblasts.

Inactivation of Apc in chondrocytes was associated with dedifferentiation of these cells. We conclude that Apc plays a crucial role in modulating the  $\beta$ -catenin level during mouse skeletogenesis in a spatio-temporal regulated manner. In skeletal precursor cells, Apc is required for differentiation into both chondrocytes and osteoblasts. In chondrocytes, Apc is essential to maintain the chondrocytic phenotype and enable maturation.

**Differences in Femoral Bone Structure Between Juvenile Non-transgenic and Transgenic Rabbits with the WAP-hFVIII Gene Construct.** M. Martiniakova<sup>\*1</sup>, R. Omelka<sup>1</sup>, B. Grosskopf<sup>\*2</sup>, K. Dammers<sup>\*3</sup>, M. Bauerova<sup>\*1</sup>, P. Chrenek<sup>\*1</sup>. <sup>1</sup>Constantine the Philosopher University, Nitra, Slovakia, <sup>2</sup>Georg-August University, Göttingen, Germany, <sup>3</sup>Konyang University, Nonsan, Republic of Korea.

Transgenic rabbits represent an alternative way of producing recombinant human proteins and enzymes as well as serving as an appropriate animal model for different human diseases. Transgenic technology, however, can also produce possible changes in tissues other than target ones. In a previous study we identified a new type of bone tissue - fibrolamellar tissue - in 2.5 month-old transgenic rabbits carrying the WAP-hFVIII gene construct (AHE 35: 310-315, 2006). This tissue has not been identified in rabbits even in any ontogenetic stage up to date. In the present study femoral bone structure in younger (1 and 2 month-old) non-transgenic and transgenic rabbits were compared with the focus on finding the age at which the differences first appear. Altogether, 28 clinically healthy rabbits (14 transgenic and 14 non-transgenic) were analyzed. Femoral bone microstructure was evaluated in terms of qualitative and quantitative histological characteristics. In an effort to better understand the changes, concentrations of 9 bone-related mineral elements, solids and total mineral content in the femora, as well as a rate of aneuploidy in bone marrow cells were also analyzed. We identified fibrolamellar bone tissue again only in the transgenic rabbits (both 1 and 2 month-old ones). Measured values for area and perimeter of the Haversian canals and minimum diameter of the primary osteons' vascular canals were higher in the transgenic individuals ( $P<0.05$ ). On the other hand, minimum diameter of the secondary osteons was higher in non-transgenic rabbits ( $P<0.05$ ). We observed lower concentrations of Ca, P, K, solids and total mineral content in the femora of transgenic rabbits. A significant difference was observed for concentration of Ca ( $P<0.05$ ). A significantly higher rate of aneuploidy cells from bone marrow in the transgenic individuals was also identified ( $P<0.05$ ). Our results indicate evident changes in the structure of the femur in 1 and 2 month-old transgenic rabbits which result especially in a better blood supply and a slightly reduced mineralization process. For possible applications of the results, it is necessary to verify them in successive ontogenetic stages of rabbits (mainly in new-born non-transgenic and transgenic individuals) and to explain the findings on molecular level. In the future, a genetic analysis followed by a histological one in this unique model could reveal new information about the genetic contribution to the microstructure of analyzed bones. This study was supported by the grant KEGA 3/4032/06.

**Disclosures:** M. Martiniakova, None.

**Gender-Specific Changes in Bone Microstructure of Mice Lacking Ribosomal Protein L29/HIP: An FT-IR Imaging Analysis.** L. G. Sloofman<sup>\*1</sup>, L. Spevak<sup>\*2</sup>, A. L. Boskey<sup>2</sup>, M. C. Farach-Carson<sup>1</sup>, C. B. Kirm-Safran<sup>\*1</sup>. <sup>1</sup>Biological Sciences, University of Delaware, Newark, DE, USA, <sup>2</sup>Hospital for Special Surgery, Cornell University-Weill Medical College, New York, NY, USA.

Adult HIP/RPL29-deficient mice display a short stature phenotype and were shown recently to exhibit increased bone fragility due to altered matrix protein synthesis rates (1). The purpose of this study is to provide insights into structural molecular changes that occur in HIP/RPL29-null bones versus wild type (WT) controls. To measure differences in bone properties, we examined the Fourier transform infrared (FT-IR) spectroscopic profiles of hard resin-embedded tibia sections in null mutants and WT littermates. We found that the mineral-to-matrix ratios were increased in trabecular bone and growth plate cartilage of null male tibias compared to gender-matched WT at 12 weeks. This data is consistent with previous studies performed in 24 week-old femurs that indicated that preservation of cortical thickness is associated with increased bone mineral density only in null males (1). Although female null bones did not display significant changes in their mineral-to-matrix ratios relative to gender- and aged-matched WT, their growth plate cartilage displayed a significant decrease in carbonate-to-mineral ratio. In addition, collagen maturity was severely reduced in both growth plate cartilage and trabecular bone as shown by a decrease in collagen cross-links. In contrast, our studies did not indicate significant differences in crystal growth between null and WT in either males or females. Our findings confirmed previous data that pointed to gender-specific effect of the genotype on bone material properties. We propose that in null females, ribosomal insufficiency has more pronounced consequences on the relative distribution of organic versus inorganic phases rather than absolute quantity of mineral than in null males. Ongoing work uses the HIP/RPL29 mouse model to understand the mechanisms related to protein translation that underly gender related bone fragility and fracture risk.

**Bone Marrow Stromal Cell-derived Extracellular Matrix Promotes Mesenchymal Stem Cell Motility.** J. Ling<sup>\*1</sup>, Y. Lai<sup>\*2</sup>, C. M. Skinner<sup>\*2</sup>, X. Chen<sup>2</sup>. <sup>1</sup>Bioengineering Section, Southwest Research Institute, San Antonio, TX, USA, <sup>2</sup>Restorative Dentistry, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Mesenchymal stem cells (MSCs) of bone marrow have been proposed for the repair and regeneration of specific tissues such as bone, cartilage, muscle, marrow stroma, tendon, and other connective tissues. However, MSCs are rare in adult bone marrow. It has been difficult to expand MSCs without losing their stem cell properties, thereby impairing the investigation of their behavior and limiting their therapeutic potential. Recently, we have shown that the extracellular matrix (ECM) prepared from marrow stromal cells dramatically enhanced MSC proliferation and effectively retained their stem cell properties (Chen et al, JBMR. 22:1943, 2007). The mechanism of how the ECM positively affects MSC proliferation is unclear. Interestingly, it was observed that cells cultured on the ECM were evenly distributed, whereas cells maintained on plastic grouped into nodules. This finding implies that the ECM may facilitate MSC motion. To confirm this, we applied time-lapse microscopic imaging to track cell migration on the ECM versus that on an uncoated coverslip. In this experiment, human MSCs were first sorted by FACS using an antibody against SSEA-4 a surface marker for MSCs (Gang et al, Blood. 109:1743, 2007). The MSCs were then seeded onto coverslips either uncoated or coated with the ECM made by human marrow stromal cells, at 1400 cells/cm<sup>2</sup>, allowing 20-30 cells per viewing field. The motility of cells maintained on an uncoated coverslip or on the ECM was quantified by measuring the velocity, displacement, and frequency of cell-cell contact of migrating cells using a time-lapse individual cell migration assay. Time-lapse images revealed that MSCs cultured on the ECM moved along the direction of collagen fibers, whereas cells cultured on the uncoated coverslip moved randomly. The average velocity of cells on the ECM was 25.6±11.3 µm/hr, which was significantly (p < 0.001) higher than the 17.3±4.9 µm/hr on the uncoated coverslip. Interestingly, the average of uninterrupted cell displacement over 24 hrs was 123 µm on the ECM, while 62 µm on the uncoated coverslip. Moreover, time-lapse videos showed that cell-cell collisions occurred less frequently (6 in a 24-hr period) when cells were cultured on the ECM than cells cultured on the uncoated coverslip (27 in a 24-hr period). After 72 hrs of culture, the number of cells expanded on the ECM was at least 3-fold greater than that expanded on the uncoated coverslip. We conclude that the ECM promotes MSC motility, and directs the MSC migration, thereby preventing stem cell cell-to-cell contact inhibition, which in turn results in an increased number of stem cells.

**The Early Osteocyte Marker, E11/gp38 Is Highly Elevated in New Bone Formed in Response to Distraction as Compared to Existing Bone.** D. Pacicca<sup>1</sup>, A. Zaidi<sup>\*2</sup>, A. Shah<sup>\*3</sup>, L. Bonewald<sup>4</sup>. <sup>1</sup>Orthopaedic Surgery, Children's Mercy Hospital, Kansas City, MO, USA, <sup>2</sup>UMKC School of Medicine, Kansas City, MO, USA, <sup>3</sup>Orthopaedic Surgery, UMKC School of Medicine, Kansas City, MO, USA, <sup>4</sup>Oral Biology, University of Missouri-Kansas City, Kansas City, MO, USA.

E11/gp38 is a 40kd membrane protein expressed by cells with dendritic processes. Its expression is highly elevated in embedding osteocytes and E11 expression is also increased in response to mechanical loading. We hypothesized that E11 expression would be elevated in distraction osteogenesis due to enhanced bone formation under tension.

C57Bl/6 mice (n=20) underwent application of a distraction fixator to the right femur with midshaft osteotomy. After latency, femurs were distracted at 0.15 mm per day for 14 days. Radiographs were obtained at days 7, 14, 21 and 28. Animals were sacrificed at either 7, 14, 21 or 35 days postop and femurs were harvested. Serial frozen sections were immunostained for E11 and new bone formation in each specimen was quantified. The average number of cells expressing E11 was counted using 6-8 high power fields per section. Quantification was done for both new bone formed in the distraction site as well as the primary spongiosa. Fluorescent microscopy showed numerous E11 positive osteocytes with abundant dendritic processes in the newly formed distracted bone. In contrast, in normal trabecular bone, there were much fewer E11 positive osteocytes, and these were limited to embedding or recently embedded cells near the surface of the bone, with fewer visible dendrites. The average number of E11 positive cells per unit bone area was significantly elevated in distracted bone, compared to primary spongiosa (138±36 for distracted bone, 56±24 for primary spongiosa, p=0.0001).

These data suggest that E11 is a marker for new bone formation and for newly formed or forming osteocytes. Previously it was shown that E11 expression increases in response to mechanical stimulation *in vitro* and *vivo* (Zhang et al, 2006). Therefore, the elevated expression of E11 during distraction may be not only a reflection of the high number of embedding or recently embedded osteocytes but may also be modulated by the mechanical strains that occur within the distraction site. Further studies that compare fracture healing to distraction in mice with targeted deletion of E11 should help to determine the role of mechanical loading and E11 in new bone formation.

## SA137

**TiO<sub>2</sub>-scaffolds for Use in Bone Tissue Engineering.** R. Sabetrasekh<sup>\*</sup>, G. Fostad<sup>\*</sup>, B. Hafell<sup>\*</sup>, A. Førde<sup>\*</sup>, J. Reseland, S. Lyngstadaas<sup>\*</sup>, H. Haugen<sup>\*</sup>. University of Oslo, Faculty of Dentistry, Department of Biomaterials, Oslo, Norway.

There is an increasing demand for bone repair due to bone lost cause by tumors, infections and trauma. Traditionally, autologous and allogenic bone grafts have been utilized for bone reconstructions. However, along the past decade a paradigm shift is taking place from using tissue graft to biomaterials. In this study we have chosen titanium oxide (TiO<sub>2</sub>) as scaffold's material since it has proven to fulfil many of the demands for a scaffold material. The main goal was to improve the mechanical properties of TiO<sub>2</sub> scaffolds, in terms of making stronger, bigger-load bearing devices with the desired three-dimensional geometry for bone tissue engineering.

The polymer sponge method was chosen as method making TiO<sub>2</sub> scaffolds. Fully reticulated polyester based polyurethane foams with 60 ppi were coated with solution of H<sub>2</sub>O and TiO<sub>2</sub> powder. The TiO<sub>2</sub> scaffolds were evaluated for the mechanical strength by compression test and the pore morphology was evaluated by SEM and microCT image analysis. Statistic variations were analysed by the standard deviation of four randomised scaffolds from 16 different batches. Different data groups were compared through a two-tailed ANOVA test, where the significant level was set at 0.05. Further more the TiO<sub>2</sub> scaffolds were evaluate the for bone tissue engineering by growing the murine preosteoblasts (MC-3T3-E1) on the TiO<sub>2</sub> scaffolds. Cytotoxic effect of the TiO<sub>2</sub> scaffolds on the osteoblasts was determined by lactate dehydrogenase activity in the culture medium and cell morphology was evaluated by SEM.

The scaffolds had an average pore size of 582.07µm and a porosity of 94.3% which gives us the opportunity to further coating and improvement of strength, still maintaining optimal conditions for osseointegration and vascular growth. The BET Surface Area was found to be 5.0664 m<sup>2</sup>/g. This gives a greater attachment surface for cells compared to the other commercial scaffolds. The TiO<sub>2</sub> scaffolds had compressive strength in the range of 0.6MPa to 1.2MPa after. These scaffolds had all porosity higher than 90%. The interconnectivity was also found to be high. We observed less than 5% cytotoxic effect of the TiO<sub>2</sub> scaffolds on the osteoblasts.

Study has showed that it is possible to produce TiO<sub>2</sub> scaffolds which are both mechanical loadable, have high reproducibility and low cytotoxicity. TiO<sub>2</sub> scaffolds with porosity of 90 % had compressive strength higher than 1 MPa. Since the porosity is far above what is necessary for osseointegration, reduction of porosity to reinforce the scaffolds even further is possible.

**Bone Marrow Stromal Cells and Osterix Contributing to Osseointegration of Dental Implants.** X. Beiyun<sup>\*1</sup>, J. Zhang<sup>\*1</sup>, E. Brewer<sup>\*1</sup>, Q. Tu<sup>1</sup>, M. Wieland<sup>\*2</sup>, J. Chen<sup>1</sup>. <sup>1</sup>General Dentistry, Tufts University, School of Dental Medicine, Boston, MA, USA, <sup>2</sup>Institute Straumann AG, Basel, Switzerland.

The purpose of this study is to identify the source and potential of cells involved in the processes of osteogenesis after implantation, and to elucidate the roles of osterix (Osx) in osteogenic differentiation at the interface between host bone and titanium dental implants. BSP9.0Luc/ACTB-EGFP mice contain a luciferase reporter gene driven by BSP promoter and an enhanced green fluorescent protein (EGFP) driven by a beta-actin promoter. Bone marrow stromal cells (BMSCs) isolated from these transgenic mice were transplanted into 4-week-old nude mice through intracardiac injection. Five weeks after transplantation, titanium implants (1.05 mm in diameter) were inserted into the femurs of these nude mice. The femurs were dissected at d7 (day7) and d21 after implantation. H&E staining and immunohistochemical (IHC) staining were performed. BSP/TVA mice, in which an avian retroviral receptor gene is hooked to a mouse BSP promoter, were divided into two groups. Titanium implants were inserted into bilateral femurs after local administration of RCAS/Osx virus or empty virus as control, respectively. The femurs were dissected for microCT, RT-PCR, H&E staining and IHC staining at d7 and d14 after implantation. In BMSCs transplanted nude mice, IHC staining showed that luciferase, BSP and GFP could be detected in the newly formed bone at d7 and d21. The ratio of luciferase positive cells to GFP positive cells detected at d7 was higher than that at d21. In BSP/TVA mice, 14 days after implantation, microCT analysis showed an increased bone mineral density at the bone-to-implant interface in RCAS/Osx group compared with the control group. As shown by semiquantitative RT-PCR analysis, levels of Osx, BSP and osteocalcin (OC) were higher in RCAS/Osx group than in the control group at d7 and d14. In both groups, levels of BSP and OC were higher at d14 than at d7 after implantation. Histomorphometrical analysis demonstrated increased percentage of bone-implant contact in RCAS/Osx group compared with control group at d7 and d14. Immunohistochemical staining revealed active expression of BSP and OC in the newly formed bone in RCAS/Osx group at d7 and d14. In conclusion, exogenous BMSCs underwent osteogenic differentiation and participated in the osseointegration after implantation. Overexpression of Osx could accelerate bone regeneration process at bone-to-implant interfaces.

**Regulation of Intracellular Signaling of MC3T3-E1 Osteoblasts by the Extracellular Matrix.** P. A. Jones<sup>\*</sup>, R. L. Duncan. Department of Biological Sciences, University of Delaware, Newark, DE, USA.

Osteoblast adhesion to the extracellular bone matrix (ECM) is critical to the response of these cells to hormonal and mechanical stimuli. However, the signaling mechanisms activated by attachment and growth of osteoblasts on different ECM's are poorly understood. We postulate that direct integrin attachment to different ECM proteins will result in altered calcium signaling and cell function. Early signaling responses mediated by attachment of type I collagen and fibronectin to MC3T3-E1 osteoblastic cells were investigated using atomic force microscopy (AFM) and calcium imaging. Using AFM, we determined that the average unbinding force of fibronectin to the cell was 148.3±3.3 pN, while the average unbinding force of collagen to the cell was 97.8±4.4 pN. When the fibronectin coated tip was allowed to stay in contact with the cell for 60 seconds before measuring the force of unbinding, the measured unbinding force increased two-fold. Using calcium imaging techniques, the global intracellular calcium ([Ca<sup>2+</sup>]<sub>i</sub>) response of MC3T3-E1 cells elicited by soluble ECM proteins was determined. Addition of soluble fibronectin to MC3T3-E1 cells produced a slow, sustained increase in [Ca<sup>2+</sup>]<sub>i</sub>, whereas type I collagen and the ECM associated peptide Arg-Gly-Asp-Ser (RGDS) caused a smaller, more rapid increase in intracellular calcium. The RGDS motif is contained in the sequence of fibronectin and the failure of this motif to elicit the same response as the full length fibronectin molecule indicates that other cell binding regions of fibronectin are essential to this [Ca<sup>2+</sup>]<sub>i</sub> response. The [Ca<sup>2+</sup>]<sub>i</sub> response to soluble ECM proteins was dependent on both the entry of calcium from the extracellular environment as well as the release of calcium from intracellular stores. The binding of osteoblasts to different ECM substrates also affects growth, as MC3T3-E1 cells grown on fibronectin exhibited increased proliferation as compared to the same cells grown on type I collagen. Further, this increase in proliferation on fibronectin appeared to be mediated by the L-type voltage sensitive calcium channel (L-VSCC), since the L-VSCC inhibitor, nifedipine, reduced proliferation on fibronectin coated substrates. Addition of nifedipine to osteoblasts grown on type I collagen did not have a significant effect on proliferation. Consequently, the attachment of osteoblasts to fibronectin appears to cause an increase in cell proliferation that is calcium dependent and mediated through the L-VSCC. Elucidating the signaling mechanisms in osteoblasts that are mediated by the surrounding extracellular matrix will provide important insight into the mechanisms of bone formation and maintenance.

**DMP1 Fragments Interact Differently with Hydroxyapatite: Insights into Mechanism of Action.** A. Boskey<sup>1</sup>, C. Qin<sup>\*2</sup>, Y. Sun<sup>\*2</sup>, W. T. Butler<sup>\*2</sup>, H. Taleb<sup>\*1</sup>, D. Redfern<sup>\*3</sup>, A. Gericke<sup>\*3</sup>. <sup>1</sup>Musculoskeletal Integrity Program, Hospital for Special Surgery, New York, NY, USA, <sup>2</sup>Department of Biomedical Sciences, Baylor College of Dentistry, Texas A & M University System Health Science Center, Dallas, TX, USA, <sup>3</sup>Department of Chemistry, Kent State University, Kent, OH, USA.

Dentin matrix protein 1 (DMP1) is an acidic noncollagenous protein critical for hydroxyapatite (HA) mineral deposition in bones and teeth. The purpose of this study was to elucidate the mechanism of action of this process. DMP1 is present in mineralized tissues as 3 fragments: the NH2-terminal (37 kDa) and COOH-terminal (57 kDa) portions and a proteoglycan fragment, DMP1-PG that is a chondroitin-sulfated 37-kDa DMP1 fragment. The effects of each of these fragments on HA formation were examined in a cell-free solution study, and the interaction of the fragments with HA determined by attenuated reflection infrared spectroscopy (ATR-FTIR). The ATR-FTIR experiment involved interaction of the peptide solution with HA or Ca<sup>2+</sup>, followed by the characterization of the resulting secondary structure changes based upon the analysis of the protein amide I band envelope. In solution, at 10, 12.5 and 25 ug/ml both the 37kDa and 57kDa fragments acted as HA formation nucleators; in contrast, DMP1-PG was an effective inhibitor at 10 ug/ml, but at higher concentrations had a lesser effect. The intact protein (full length DMP1) expressed in bovine marrow stromal cells was also an inhibitor. Conformational studies showed that the full length DMP1 in the presence of HA or Ca<sup>2+</sup> has a slightly increased  $\beta$ -sheet secondary structure content relative to the protein in the absence of HA or Ca<sup>2+</sup>. Dynamic Light Scattering experiments showed DMP1 aggregates in the presence of Ca<sup>2+</sup>. The 37 kDa fragment showed even greater aggregation. The 57 kDa fragment had increased  $\alpha$ -helical secondary structure in the presence of HA and Ca<sup>2+</sup>. In conclusion, these results suggest that in mineralizing tissues DMP1 fragments can have distinct regulatory effects on mineralization depending on their composition, via an interaction with HA. Thus, in the DMP1 KO where there is a decrease in mineral content, the absence of the nucleating fragments, appear to be important, while the DMP1-PG fragment may be more important for cell-matrix interactions.

**Bone Sialoprotein (BSP) Deficiency Impairs Osteoclast Differentiation and Resorption *in vitro*.** M. Boudiffa<sup>\*1</sup>, N. Wade-Gueye<sup>\*1</sup>, A. Guignandon<sup>\*1</sup>, M. Linossier<sup>\*1</sup>, A. Vanden-bossche<sup>\*1</sup>, A. Anginot<sup>2</sup>, M. Lafage-Proust<sup>1</sup>, J. Aubin<sup>3</sup>, P. Jurdic<sup>2</sup>, L. Vico<sup>1</sup>, L. Malaval<sup>1</sup>. <sup>1</sup>LBTO, INSERM 890, Saint-Etienne, France, <sup>2</sup>Umr cnrs 5161, inra 1237, ENS, Lyon, France, <sup>3</sup>Dept of Molecular Genetics, Faculty of Medicine, University of Toronto, Toronto, ON, Canada.

Like Osteopontin (OPN), Bone sialoprotein (BSP) belongs to the SIBLING (Small Integrin Binding Ligand N linked Glycoproteins) family, whose members interact with bone cells and mineral. We have previously shown that BSP knockout (KO) mice have a higher bone mass with low bone formation and reduced osteoclast (oc) surface as compared to wild type (WT) mice. Because this phenotype suggests a defect in oc recruitment and function, we studied the differentiation and activity of KO oc *in vitro*. Oc precursor-containing murine spleen cell cultures were grown in the presence of RANKL and M-CSF and analysed at day (d)2 (appearance of TRACP+ cells), d5 (onset of multinucleation) or d7 (peak number- nb- of multinucleated oc). Fixed cells and extracted RNAs were used for Tartrate Resistant Acid Phosphatase (TRACP) or immunostainings (IS) and RT-PCR, respectively. IS confirmed the strong BSP expression in WT oc and its absence in mutants. At d7, TRACP+ cell nb (1150 ± 104 vs 1486 ± 93 n=12, p<0.02) and multinucleated oc nb (≥3 nuclei) (66 ± 11 vs 447 ± 35 n=12, p<0.0001) were lower in KO than in WT. Addition of 40 nM exogenous fibronectin, 80nM BSP or >400nM recombinant OPN throughout the culture time restored multinucleated oc nb in KO to WT values. However, none of these supplements restored TRACP+ cell nb at d2 to the WT level. Thus, BSP seems to be required for oc differentiation at two levels : intracellular BSP is needed for the commitment of precursors to the oc lineage and extracellular BSP is required for multinucleation. Further, image analysis of actin-stained prefusion oc (d5) suggested a higher podosome turnover in KO with more but smaller podosomes (85 ± 51 vs 145 ± 18, n=30, p<0.05) than in WT. Oc gene expression was markedly altered in KO compared to WT cells, with expression reduced for cell adhesion genes (beta3 integrin & OPN) but increased for promigratory genes (MMP2 & 9), TRACP and cathepsin K . *In vitro* resorption assays were performed on either BSP-containing dentin slices or BSP-free mineral coated slides (Osteologic<sup>TM</sup>) in presence of RANKL and MCSF for 2 d. No difference in pit number (23 ± 4 vs 24 ± 9, n=6, p= 0.79) or pit area was seen between WT and KO on dentin slices. However, pit formation by KO oc was markedly reduced on BSP-free discs (9±1 vs 22 ± 3 , n=15, p<0.0001). In conclusion, BSP appears essential for oc formation and resorption *in vitro*, confirming our *in vivo* findings. Moreover, the down-regulation of OPN expression in KO oc suggests a physiological interplay between these two SIBLING family members which remains to be clarified.

**Sequestration, Proliferation and Differentiation of Osteoblasts in Hydrogels for Tissue Engineering Applications.** M. Dadsetan<sup>\*1</sup>, T. E. Hefferan<sup>1</sup>, A. Heine-Geldern<sup>\*1</sup>, M. Benedikt<sup>\*1</sup>, D. Gaustad<sup>\*1</sup>, J. Herrick<sup>\*1</sup>, T. C. Spelsberg<sup>2</sup>, L. Lu<sup>\*1</sup>, A. Maran<sup>1</sup>, M. J. Yaszemski<sup>1</sup>. <sup>1</sup>Orthopedic Surgery, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA.

Bone is an organ that can regenerate under normal physiological conditions; however, after trauma or surgical resection for removal of bone tumors the remaining void impedes bone regeneration. In order for bone regeneration to proceed, osteoblasts must be present and functional; therefore, under these abnormal physiological conditions implementation of tissue engineering strategies to promote bone regeneration would be beneficial to provide the necessary functional cells. The osteoblasts must arrive at the site, be viable, differentiate, and eventually form bone. Therefore, our objective was to test if osteoblasts would remain viable in a hydrogel and if these cells would be able to proliferate and differentiate.

For these studies we utilized a photocrosslinkable hydrogel, oligo-(polyethylene glycol), (OPF), to encapsulate normal human osteoblasts (hFOB). The cells were cultured under static or dynamic conditions in a rotating wall vessel bioreactor (Synthecon/ RCCS-4DQ) containing DMEM/F12, 10% FBS, 1% penicillin/streptomycin and 0.6% geneticin for 3, 7 or 14 days. Rotation was set at 0 rpm for static cultures and 25 rpm for dynamic cultures. Viability of the cells was determined by uptake of calcein from a Live/Dead Kit (Molecular Probes) and proliferation was quantified by measuring DNA content using the PicoGreen Kit (Molecular Probes). Alkaline phosphatase activity was utilized as the marker of osteoblast differentiation.

The hFOB cells demonstrated calcein uptake after encapsulation in the hydrogel and during the 14 day time course, thus indicating viability throughout the experimental period. There was a significant effect of time ( $p < 0.05$ ) on the proliferation of the osteoblasts with the greatest proliferation occurring at day 3. Interestingly, there was no significant effect of culture conditions with the cells proliferating in both the static and dynamic cultures. However, there was a significant increase ( $p < 0.001$ ) in alkaline phosphatase activity for the osteoblasts grown in dynamic culture with 1.6 fold increase between days 3 and 7, and a 1.4 fold increase between days 3 and 14.

These studies have shown that osteoblasts can be successfully encapsulated in an OPF hydrogel and maintain three functions which are crucial for tissue regeneration: viability, proliferation and differentiation. Thus, OPF hydrogels can be considered as a candidate material to sequester osteoblasts and deliver these cells to sites where bone regeneration is needed.

**Identification of Dentin Sialoprotein-Phosphophoryn Cleavage Site.** H. H. Ritchie<sup>\*</sup>. Cariology, Restorative Sciences and Endodontics, University of Michigan School of Dentistry, Ann Arbor, MI, USA.

**Introduction:** Dentin sialoprotein (DSP) and phosphophoryn (PP) are the two noncollagenous proteins classically linked to dentin mineralization, but more recently found in bone, kidney and salivary glands. Point mutations in DSP-PP gene are linked to Dentinogenesis imperfecta. These two proteins are derived from a single copy DSP-PP gene. Because native PP has a DDPN N-terminal sequence, we hypothesized that SMQG<sup>447</sup>[D<sup>448</sup>]DPN is the specific cleavage site for generating DSP<sub>430</sub> and PP<sub>240</sub><sup>\*</sup>. To test this hypothesis, our Objective was to generate DSP-PP<sub>240</sub> containing mutated G<sup>447</sup> and follow the expression and processing of this mutated precursor protein. **Methods:** To achieve this goal, we used site-mutagenesis to generate G<sup>447</sup> mutations in DSP-PP<sub>240</sub> cDNA in pGEM7Z(+), which were subsequently subcloned into pVL1392 baculovirus vector for protein expression. **Results:** Wild type and mutated DSP-PP<sub>240</sub> precursor proteins are secreted into the extracellular space in the baculovirus expression system. Using MS, MS/MS analysis on the recombinant PP sample, the N-terminal sequence was determined to be DDPN. DSP-PP<sub>240</sub> cDNA containing G<sup>447</sup> mutant yielded a DSP-PP<sub>240</sub> precursor protein, which was not further processed into DSP<sub>430</sub> and PP<sub>240</sub><sup>\*</sup>. **Conclusion:** G<sup>447</sup>[D<sup>448</sup>] is the cleavage site for generating DSP<sub>430</sub> and PP<sub>240</sub><sup>\*</sup> from the wild type precursor molecule. This work was supported by NIH DE11442-9 to HHR.

**Do Type I Collagen Homotrimers Contribute to Osteoporosis by Altering Bone Remodeling?** S. Han<sup>\*1</sup>, E. Makareeva<sup>\*1</sup>, N. V. Kuznetsova<sup>\*1</sup>, A. M. DeRidder<sup>\*1</sup>, M. B. Sutter<sup>\*1</sup>, D. J. McBride<sup>\*2</sup>, C. L. Phillips<sup>\*3</sup>, U. Schwartz<sup>\*4</sup>, J. M. Pace<sup>\*4</sup>, P. H. Byers<sup>\*4</sup>, R. Visse<sup>\*5</sup>, H. Nagase<sup>\*5</sup>, S. Leikin<sup>1</sup>. <sup>1</sup>Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA, <sup>2</sup>School of Medicine, University of Maryland, Baltimore, MD, USA, <sup>3</sup>Department of Biochemistry, University of Missouri, Columbia, MO, USA, <sup>4</sup>Department of Pathology, University of Washington, Seattle, WA, USA, <sup>5</sup>Kennedy Institute of Rheumatology, Imperial College London, London, United Kingdom.

Normal type I collagen molecules are heterotrimers of two  $\alpha 1(I)$  and one  $\alpha 2(I)$  chains, but insufficient or abnormal synthesis of the  $\alpha 2(I)$  chain can result in  $\alpha 1(I)$  homotrimers, e.g., in fetal tissues and various pathological conditions. In particular, synthesis of a small fraction of  $\alpha 1(I)$  homotrimers in individuals with a polymorphism in the SP1 binding region of COL1A1 is discussed in the literature as a factor contributing to fracture in age-related osteoporosis. It is not clear, however, how to reconcile such an effect with outcomes of complete heterotrimer replacement by  $\alpha 1(I)$  homotrimers. Severe Osteogenesis Imperfecta was reported in a patient with synthesis of nonfunctional  $\alpha 2(I)$  chains, but no dramatic bone pathology was observed in patients completely lacking the  $\alpha 2(I)$  chain synthesis. If normal bone formation is possible with the complete replacement of the heterotrimers, how can just a small fraction of the homotrimers contribute to age-related bone fragility? To address this question, we investigated murine and human  $\alpha 1(I)$  homotrimers and their mixtures with the corresponding heterotrimers. The most significant findings with potential implications to tissue pathology were: (a) the segregation of the homo- and heterotrimers at a subfibrillar level and (b) the significantly reduced susceptibility of the homotrimers to cleavage by tissue collagenases. A more detailed study with rhMMP-1 revealed that the lack of the  $\alpha 2(I)$  chain does not alter the enzyme binding but hinders opening of the triple helix necessary for presenting the unwound chains to the catalytic site. In mixtures, rhMMP-1 degraded the normal type I heterotrimers before noticeable cleavage of the homotrimers. We hypothesize that an initial deposition of  $\alpha 1(I)$  homotrimers may not reduce the bone strength. However, their subfibrillar segregation and selective proteolytic degradation of the heterotrimers may result in accumulation of defects after multiple tissue remodeling cycles, altering the bone matrix quality.

**Various Roles of Syndecan Family in Osteoblastic Cells.** T. Ikeo<sup>1</sup>, A. Kamada<sup>1</sup>, Y. Yoshikawa<sup>1</sup>, E. Domae<sup>\*1</sup>, S. Goda<sup>\*1</sup>, I. Tamura<sup>\*1</sup>, A. Kawamoto<sup>\*1</sup>, J. Okazaki<sup>\*1</sup>, Y. Komasa<sup>\*1</sup>, Y. Takaishi<sup>1</sup>, T. Miki<sup>2</sup>, T. Fujita<sup>1</sup>. <sup>1</sup>Osaka Dental University, Osaka, Japan, <sup>2</sup>Osaka City University, Osaka, Japan.

Syndecans are transmembrane heparan sulfate proteoglycans known to bind both other extracellular matrix molecules and certain growth factors, thus participating in a number of fundamental biological processes, including cell adhesion and migration, and the binding and activation of growth factors, enzymes, and inhibitors. The syndecan family in vertebrates comprises four members, syndecan-1, syndecan-2 (fibroglycan), syndecan-3 (N-syndecan), and syndecan-4 (ryudocan). Previously, we showed both protein and gene expression of syndecan-1, -2 and -4 in normal human osteoblasts. To understand the role of syndecans in osteoblasts, the effect of a bone-resorbing cytokine, IL-1 $\beta$ , and differentiation-stimulated reagent, beta-glycerophosphate (BGP), on syndecan expression were examined using human osteoblast-like cell SaOS2.

Using western blot analysis, it was found that IL-1 $\beta$  caused a marked appearance of a certain heparan sulfate proteoglycan corresponding to syndecan-4. Furthermore, the mRNA expression levels of syndecan family were measured using real-time quantitative RT-PCR technique, and demonstrated the gene expression of syndecan-1, -2 and -4 in the human osteoblast-like cells.

When cells were incubated with IL-1 $\beta$  for 24 h, there were significant decrease in mRNA levels of syndecan-1 and syndecan-2 compared with time match controls, though the expression of syndecan-4 was markedly increased. These results demonstrate that syndecan-1, -2 and -4 are synthesized in human osteoblastic cells, and syndecan-4 gene transcription is rapidly responsive to an inflammatory mediator. On the other hand, addition of BGP increased syndecan-1 and -2 expression but not syndecan-4. Hence, it is indicated that syndecan-1 and -2 may be involved with the differentiation and maturation of osteoblasts, while syndecan-4 may be important in the intracellular signal transduction.

**Immunohistochemical Localisation of Sclerostin in Human Trabecular Bone from Fragility Hip Fracture Patients.** A. Papadopoulos\*, L. Truong\*, J. S. Kuliwaba\*, N. L. Fazzalari. Bone and Joint Research Laboratory, Institute of Medical and Veterinary Science, Adelaide, South Australia, Australia.

Osteocytes, the most abundant cell type in bone, are ideally located to influence bone remodelling through their syncytial relationship with surface bone cells. The expression of osteocyte-derived factors such as sclerostin, an inhibitor of bone formation and subsequent bone mineralisation, in osteocytes imply that these bone cells may regulate mineralisation, and hence, bone material properties for bone strength. This study analysed the immuno-localisation of sclerostin in human femoral trabecular bone obtained from postmenopausal females undergoing total hip arthroplasty following a fractured neck of femur (#NOF;  $n = 10$ , mean age  $78.4 \pm 5.7$  years) and a non-fracture control (NFC) group, primary hip osteoarthritis ( $n = 8$ , mean age  $78.9 \pm 6.1$  years). Using the streptavidin biotin peroxidase method of immunohistochemistry in paraffin-embedded bone tissue, positive nuclear and cytoplasmic sclerostin immunostaining were observed specifically in the osteocytes, as well as in the canaliculi and lacunar walls, as reported in published literature. The #NOF group had significantly less bone volume fraction (BV/TV; #NOF =  $7.4 \pm 4.1\%$ , NFC =  $11.5 \pm 3.2\%$ ,  $p < 0.04$ ). No significant differences were found in the number of positive-stained and negative-stained osteocytes per bone area (N.POS.Ot/BV and N.NEG.Ot/BV, respectively), number of empty lacunae per bone area (N.Em.Lc/BV), and in the total number of lacunae per bone area (Total Lc.N/BV) observed, compared to NFC. The percentage of positive (N.POS.Ot/Total Lc.N) and negative (N.NEG.Ot/Total Lc.N) osteocytes, and percent of empty lacunae (N.Em.Lc/Total Lc.N) were similar between the two groups. Interestingly, percent positive-stained osteocytes differed significantly to negative-stained osteocytes in the #NOF group ( $28.0\%$  POS.Ot vs.  $69.3\%$  NEG.Ot,  $p < 0.009$ ), in contrast to similar percent positive-negative in the NFC group ( $47.7\%$  POS.Ot vs.  $46.3\%$  NEG.Ot). The interesting finding of decreased percent positive osteocytes in the #NOF group, compared to similar percent positive-negative osteocytes in the NFC group, may suggest bone in #NOF individuals is undermineralised, as sclerostin protein expression has been found to be expressed only in mature osteocytes in fully-mineralised bone tissue (Poole *et al.*, 2005). These results may further inform understanding the mechanism of decreased mineralisation of bone in fragility fracture patients (Sutton-Smith *et al.*, 2008). Studies of the role of osteocytes and their derived factors in normal and bone pathology will aid in furthering the understanding of the pathogenesis of fragility fractures and the efficacy of new pharmaceuticals to treat osteoporosis.

**Proteins Involved in Mineralization Expressions Perturbations in Bones and Teeth of Msx2 Mutant Mouse Mandibles.** A. Bolanos\*, D. Hotton\*, A. Agalliu\*, M. Molla\*, B. Castaneda\*, B. Robert\*, F. Lézo\*, A. Berdal\*. <sup>1</sup>Laboratoire de Physiologie Orale Moléculaire (Eq. 5), INSERM UMRS 872, Centre de Recherche des Cordeliers, Paris, France, <sup>2</sup>Pasteur Institute - URA 2578 CNRS, Paris, France.

Homeobox genes of Msx family are implicated in early craniofacial skeleton development. The part of these genes later in the biomineralization has been underestimated while their expressions were described in all mineralized tissues forming cells. In contrast to Msx1 null mutant (KO) mouse that died at birth, the Msx2 KO mouse survives allowing the analysis of the impact of Msx2 absence on the expression of proteins implicated in the biomineralization.

In the present study, using immuno-histochemistry, in situ hybridization and quantitative RT-PCR, expressions of calbindin-D28K, osteocalcin, osteopontin, bone sialoprotein, collagen type I, amelogenin and ameloblastin were analyzed in mandible bones and teeth comparatively between Msx2 KO, Msx2 heterozygous and wild type mice.

Results show that all protein expressions are perturbed in the Msx2 KO mouse either in intensity as osteocalcin, collagen type I and amelogenin or in pattern as calbindin-D28K. In the Msx2 heterozygous mouse, the expression levels of some proteins implicated in the mineralization are also perturbed but evidence an opposite modulation compared to Msx2 KO. Indeed, amelogenin expression is increased in the dental epithelium of Msx2 heterozygous similarly to osteocalcin, bone sialoprotein and osteopontin in bones of the mandible. In Msx2 heterozygous mouse, the most striking result is the perturbation of calbindin-D28K expression pattern with an important level observed in the dental pulp. To conclude, this study evidences that Msx2 genetic status (KO, heterozygous and wild type) has important repercussions on the expression (level and pattern) of proteins implicated in the mineralization, so on the mineralization rank itself.

## SA151

**Circulating Fibronectin Affects Bone Matrix.** A. Bentmann\*, N. Kawelke\*, D. Moss\*, I. Nakchbandi\*. <sup>1</sup>Max-Planck Institute for Biochemistry and University of Heidelberg, Heidelberg, Germany, <sup>2</sup>Research Center Karlsruhe (ANKA), Karlsruhe, Germany.

Targeted deletion of fibronectin production by differentiating osteoblasts affects their function, but does not result in a significant decrease in the amount of fibronectin in the bone matrix or in a change in bone matrix. The liver is a major source of fibronectin. It also produces a number of proteins that are able to infiltrate the bone such as albumin and alpha2-HS-glycoprotein. We therefore examined the role of circulating fibronectin originating from the liver in bone.

Plasma fibronectin was labeled with Oyster-500 and injected in mice intraperitoneally. Examination of bone sections revealed infiltration of labeled fibronectin throughout the bone. This was not limited to areas of active bone mineralization, determined by injecting alizarin complexone prior to injecting labeled fibronectin. We then performed matings of fibronectin floxed mice with mice carrying the Cre gene under the control of the Mx or the albumin promoters in order to delete fibronectin production by the hepatocytes. Both lines showed a decrease in circulating fibronectin by more than 95% (Circulating fibronectin in the Mx line was  $4.6 \pm 0.1$  vs.  $6.2 \pm 0.4$  mg/L in the albumin line,  $p < 0.01$ ). Fibronectin staining in the liver-specific fibronectin knockouts revealed a significant decrease in the amount of fibronectin in the bone matrix that was confirmed by Western blotting.

The deletion of fibronectin in the liver was also associated with 13% decrease in bone mineral density in the Mx-cre harboring line (conditional knockouts:  $177.9 \pm 5.4$  vs. controls:  $205.4 \pm 6.2$  mg/cm<sup>3</sup>,  $n = 24$  and  $34$ ,  $p < 0.005$ ). There were no clear changes on either dynamic or static bone histomorphometry, however. Infrared microspectroscopy was therefore performed to determine whether structural changes could be seen in the matrix itself. The ratio of mineral to matrix was significantly decreased by 12% in the conditional knockout mice compared to littermate controls (Phosphate to protein ratio in conditional knockouts:  $8.76 \pm 0.20$  vs. controls:  $9.91 \pm 0.32$ ,  $n = 6$  mice per group and 9 measurements per mouse,  $p < 0.005$ ), suggesting that the loss of fibronectin in the matrix affects its mineral content.

In summary, circulating fibronectin originating from the liver infiltrates the bone matrix, where it affects the bone mineral density and mineral content in the bone. These effects take place in the absence of clear changes in the bone forming or bone resorbing cells. Thus fibronectin originating from the liver is needed for a normal matrix mineralization. This is in contrast to the effect of the deletion of fibronectin in osteoblasts showing that its production by them is required for a normal osteoblastic function without affecting the mineralization of matrix.

**PGD2 Downregulates MMP-1 and MMP-13 Expression in Human Osteoarthritic Chondrocytes.** N. Zayed\*, H. Afif\*, N. Chabane\*, J. Martel-Pelletier\*, J. Pelletier\*, H. Fahmi\*. CHUM, Université de Montréal, Montreal, QC, Canada.

**Purpose:** Prostaglandin (PG) D<sub>2</sub>, a cyclooxygenase (COX) metabolite, has been shown to play critical roles in multiple physiological processes including inflammation. Matrix metalloproteinases (MMPs), in particular MMP-1 and MMP-13 produced by chondrocytes, are major proteases responsible for cartilage degradation during osteoarthritis. This work was designed to investigate the effects of PGD<sub>2</sub> on interleukin-1 (IL-1)-induced MMP-1 and MMP-13 expression in human chondrocytes.

**Methods:** Cultured chondrocytes were stimulated with IL-1 in the absence or presence of PGD<sub>2</sub> and MMP-1 and MMP-13 protein production was evaluated by ELISA. mRNA expression and promoter activity were analyzed by real-time RT-PCR and transient transfection experiments, respectively. The expression of PGD<sub>2</sub> receptors, DP1 and CRTH2 was investigated using RT-PCR and Western blotting.

**Results:** PGD<sub>2</sub> dose-dependently decreased IL-1-induced MMP-1 and MMP-13 protein expression. Moreover, PGD<sub>2</sub> prevented IL-1-induced MMP-1 and MMP-13 mRNA expression as well as MMP-1 and -13 promoter activation, indicating that this effect occurs at the transcriptional level. We also demonstrated that chondrocytes expressed both PGD<sub>2</sub> receptors: DP1 and CRTH2.

**Conclusions:** These data indicate that PGD<sub>2</sub> inhibits IL-1-induced MMP-1 and MMP-13 production by human chondrocytes. Therefore, PGD<sub>2</sub> may play an important role in the chondrocyte response to inflammatory stimuli and may protect cartilage integrity.

## SA154

**Cathepsin K Expression During Enamel Formation.** C. E. Tye, Y. Ding\*, Y. P. Li, J. D. Bartlett\*. Department of Cytokine Biology, Forsyth Institute, Boston, MA, USA.

Dental enamel is unique in that it starts forming as a soft, protein-rich substance and ends as a hard, almost protein-free mineral. It is well established that enamel matrix proteins are degraded during enamel formation and these degraded proteins are removed from the matrix to allow for the increase in mineral content. Proteolytic processing is critical for proper enamel formation as homozygous mutation of either of the resident enamel proteases, matrix metalloproteinase-20 (MMP-20) or kallikrein-4 (KLK-4), causes *Amelogenesis Imperfecta* where the enamel is hypomineralized and protein-rich. Our objective is to determine if in addition to KLK-4 and MMP-20, other proteases may be involved in enamel formation. Cathepsin K has been shown to be important in the degradation of the collagenous matrix during bone resorption and we therefore investigated if cathepsin K may play a role in the degradation of the enamel matrix. RNA from molars of 3-11 day-old mice (secretory to maturation stage) was collected and expression of cathepsin K was assessed and quantified by RT-PCR and qPCR. High levels of cathepsin K expression were observed across amelogenesis with highest expression in mature enamel organ (6.35-fold increase over secretory stage). Immunohistochemical (IHC) staining of wild-type mouse incisors confirmed cathepsin K expression by ameloblasts. Cathepsin K was found to rapidly degrade recombinant amelogenin *in vitro* indicating a possible role for cathepsin K in enamel protein degradation. Cathepsin K may degrade the enamel proteins within the lysosomes once peptides are removed from the matrix, and it is possible that cathepsin K is secreted into the matrix to degrade the proteins during the maturation stage of enamel development. Examination of incisors from cathepsin K-null mice however, showed no significant alteration to prism pattern as assessed by scanning electron microscopy. Microhardness testing of enamel from cathepsin K-null mice revealed that loss of cathepsin K expression did not significantly alter enamel hardness. Our results suggest that cathepsin K is expressed by ameloblasts and may be part of a redundant pathway necessary to degrade proteins that are resorbed from the enamel matrix.

**Identification of Dipeptidyl Peptidase I as a Potential Activator of Kallikrein-4.** C. E. Tye<sup>1</sup>, C. T. Pham<sup>\*2</sup>, J. D. Bartlett<sup>\*1</sup>. <sup>1</sup>Department of Cytokine Biology, Forsyth Institute, Boston, MA, USA, <sup>2</sup>Division of Rheumatology, Washington University School of Medicine, St. Louis, MO, USA.

Kallikrein-4 (KLK-4) is a serine protease expressed during the maturation stage of enamel development and proteolytic processing of the enamel matrix by KLK-4 has been found to be critical for proper enamel formation. Homozygous mutation of KLK-4 causes *Amelogenesis Imperfecta* where the enamel is hypomineralized and protein-rich. KLK-4 has also been found to be overexpressed in prostate and ovarian cancer. The family of KLKs are synthesized as prepro-enzymes that are proteolytically processed to secreted pro-forms via the removal of their signal peptide. The secreted inactive pro-KLKs are then activated extracellularly by specific release of their amino-terminal propeptide. Activation of the pro-forms of the family of KLKs has been well studied; however, identification of the activator of KLK-4 remains elusive. The tooth specific protease matrix metalloproteinase-20 (MMP-20) has been shown to activate KLK-4 *in vitro*; however, KLK-4 and MMP-20 expression overlap only briefly during enamel development suggesting another protease activates KLK-4 *in vivo*. Dipeptidyl peptidase I (DPP I) is an ubiquitously expressed aminopeptidase that sequentially removes two N-terminal amino acid residues from folded proteins and was demonstrated to activate proenzymes of several chymotrypsin-like serine proteases. In this study we sought to examine DPPI expression in mouse enamel organ and determine if DPPI could act as an activator of KLK-4. RNA from molars of 3-11 day-old mice (secretory to maturation stage) was collected and expression of DPPI was assessed and quantified by RT-PCR and qPCR. High levels of DPPI expression was observed across amelogenesis with highest expression in mature enamel organ (11.4-fold increase over secretory stage). Immunohistochemical (IHC) staining of wild-type mouse incisors confirmed DPPI expression by ameloblasts. Using a fluorogenic substrate specific for KLK-4, DPPI was found to activate pro-KLK-4 *in vitro*. Examination of incisors from DPPI-null mice by scanning electron microscopy showed an altered prism pattern and microhardness testing of enamel from DPPI-null mice revealed that loss of DPPI expression caused a decrease in enamel hardness. Our results demonstrate that DPPI is highly expressed by maturation stage ameloblasts and may be involved in the activation of KLK-4. Identification of the *in vivo* activator of KLK-4 is important not only for furthering the understanding of enamel formation but also has exciting potential as a therapeutic target for both ovarian and prostate cancer.

**Canonical Wnt Signaling Suppresses BMP4 Accumulation from C3H10T1/2 Cells Transfected with BMP4 Expression Vector.** K. N. Kishimoto, E. Itoi\*. Department of Orthopaedic Surgery, Tohoku University School of Medicine, Sendai, Japan.

Lithium chloride is known as an inhibitor of glycogen synthase kinase-3 beta (GSK-3beta). Inhibition of GSK-3beta leads to accumulation of beta-catenin and activation of canonical Wnt signaling. The purpose of this study is to analyze the effect of canonical wnt

signal on the expression of BMP4 and other related factors during chondrogenic differentiation of C3H10T1/2 induced by BMP4 gene transfer.

C3H10T1/2 cells transfected with mouse BMP4 expressing plasmid was used for experiments. Plasmid was transferred by electroporation in the 4 mm cuvette at 500 V, 2 ms and 2 pulses using T-820 electroporator (BTX). A micromass formed with a drop of 10<sup>5</sup> transfected cells was allowed to adhere for 90 min and filled with 1 ml of medium containing 1% FBS, BSA, ascorbic acid 2 and ITS+. LiCl were added at 5, 10 and 25 mM. The effect of LiCl was confirmed by luciferase activity of wnt signaling reporter construct TOPflash. For quantitative RT-PCR, total RNA was isolated from each micromass. Real-time quantitative analyses were carried out with SYBR green I dye and ABI 7700 sequence detector. The culture medium was subjected to Western-blot analysis using anti-BMP4 antibody (SantaCruz) which react with both pro-BMP4 and BMP4. Micromass on 12-well plate were fixed with cold ethanol and immuno-staining was carried out with the same anti-BMP4 antibody and anti-mouse rabbit antibody conjugated with Alexa fluor 555 (Invitrogen).

LiCl treatment increased the luciferase activity of TOP flash reporter assay in a dose-dependent manner. The expression of BMP4 mRNA was not affected by LiCl. However, marked decrease of BMP4 protein by the addition of LiCl were seen in western blotting.(Figure) Also, immuno-staining for BMP4 on micromass showed decreased accumulation of BMP4 protein by LiCl. Under the presence of LiCl, alcian blue stainings of micromass were inhibited in a dose-dependent manner. Aggrecan, col2a1 and BMP antagonist noggin were also inhibited.

These results suggest that the activation of canonical wnt signaling by LiCl suppressed BMP4 protein synthesis or degraded BMP4 and inhibited chondrogenesis. The molecular system to explain this result has not been well understood. Cathepsin H (ctsh) which is previously reported to degrade BMP4 in the developmental stage of lung. The dose-dependent upregulation of ctsh by LiCl was also seen in our RT-PCR examination.

**Disclosures:** K.N. Kishimoto, None.

## SA157

**Coordinate Regulation of PTHrP and PTH1R in the Osteoblast Differentiation of C2C12 Cells Promoted by BMP-2.** A. R. G. Susperregui<sup>1</sup>, F. Vinals<sup>\*1</sup>, P. W. M. Ho<sup>\*2</sup>, M. T. Gillespie<sup>2</sup>, T. J. Martin<sup>2</sup>, F. Ventura<sup>\*1</sup>. <sup>1</sup>Barcelona University, Barcelona, Spain, <sup>2</sup>St. Vincent's Institute of Medical Research, Fitzroy, Australia.

PTH1R expression is enhanced during osteoblast differentiation and it is accepted as an osteoblast differentiation marker. Here we report that BMP-2 early induces PTH1R mRNA in C2C12 cells, which consequently become responsive to PTHrP in terms of cAMP production. Moreover, this induction is partially dependent on p38alpha as observed in experiments using p38alpha (-/-) MEFs. Simultaneously, BMP-2 also regulates the RANKL/OPG system strongly reducing the RANKL:OPG gene expression ratio. In our model, addition of exogenous PTHrP (1-34) does not modify BMP-2 regulation of RANKL and OPG. However, PTH1R expression and function affect osteoblast differentiation of C2C12 cells since PTHrP reduces the up-regulation of osteoblast master genes such as Runx2 and Osterix. Particularly PTHrP inhibits Osterix expression by activating the PKA pathway but not deregulating the Smad signaling pathway. C2C12 cells also modulate PTHrP expression in response to BMP-2. PTHrP mRNA expression is reduced by transcriptional regulation of PTHrP promoter but not enhancing PTHrP mRNA degradation. These data support the importance of a coordinate regulation of PTHrP and its receptor during osteoblastogenesis, and suggest that BMP-2 down-regulation of PTHrP could facilitate terminal differentiation of osteoblast.

**Impaired Bone Healing in a BMP2 Knockout Mouse Model of Distraction Osteogenesis.** N. Alam<sup>\*1</sup>, T. Haque<sup>\*2</sup>, M. Kotsioprifitis<sup>\*3</sup>, D. Lauzier<sup>\*2</sup>, R. St-Arnaud<sup>\*1</sup>, R. C. Hamdy<sup>2</sup>, V. Rosen<sup>\*4</sup>. <sup>1</sup>Genetics, Shriners Hospital for Children, Montreal, QC, Canada, <sup>2</sup>Orthopaedics, Shriners Hospital for Children, Montreal, QC, Canada, <sup>3</sup>Montreal Childrens Hospital, Montreal, QC, Canada, <sup>4</sup>Developmental Biology, Harvard School of Medicine, Boston, MA, USA.

Distraction osteogenesis (DO) is a surgical technique widely used for the treatment of limb length discrepancies, limb deformities, long bone non unions as well as bone loss due to trauma, infection or malignancies. One of its limitations is the long period of time required for the bone to consolidate. Bone Morphogenetic Proteins (BMPs), are essential growth factors involved in development (pre and post natal) and fracture healing. However, its specific role in DO remains to be determined. Modulating the signaling pathway of several BMPs including BMP 2, 4, 6 and 7 may be a potential strategy for accelerating bone formation during DO. The aim of the following study was to determine the significance of BMP2 during DO.

We analyzed bone formation during DO in heterozygous conditional BMP2 knockout mice. Bone samples were analyzed using MicroCT, Histology as well as Immunohistochemistry at various time intervals during the distraction and consolidation phase. Our results revealed that early bone consolidation is not impaired in mice having a 50% reduction in BMP2. MicroCT analysis showed no significant difference in bone volume, tissue volume or trabecular structure during the distraction phase and early consolidation phases. However, MicroCT images revealed poor bone healing at the end of consolidation in the mutant mice and a statistically significant reduction in trabecular number and increase in trabecular separation was apparent. Immunohistochemistry results showed that mutants had a higher upregulation of BMP2, BMP3, BMP7 BMP1b and the activin receptor compared to the control during the distraction phase. However, during early consolidation, with the exception of BMP1b, the controls had a higher expression of these genes.

In conclusion, our results indicated that in DO, BMP2 may be essential for proper bone healing at the end of consolidation but not during early consolidation. Several factors could explain these finding which include the possibility that during early bone consolidation, the function of BMP2 may be compensated for by other growth factors triggered by the process of distraction. There may also be a reserve of BMP2 within the bone, and thereby an endogenous reduction of its expression does not affect early bone healing. Further studies are being conducted in order to understand the complete role of BMP2 during DO in the molecular level.

**Disclosures:** N. Alam, None.

## SA160

**The Expression of BMP Antagonists During Fracture Healing.** D. B. Dean<sup>\*</sup>, H. C. Peters<sup>\*</sup>, J. T. Enders<sup>\*</sup>, W. Jin<sup>\*</sup>, J. T. Watson<sup>\*</sup>, Z. Zhang<sup>\*</sup>. Saint Louis University, St. Louis, MO, USA.

The bone morphogenetic protein (BMP) signalling cascade is "fine-tuned" by a group of BMP antagonists at almost every level of the pathway. This study investigated the temporal relationship between BMPs and their antagonists in bone formation using a normal fracture healing model.

Forty-two C57BL/6 mice (male, 7-week-old, approved by Saint Louis University Animal Care Committee) underwent controlled mid-shaft femoral fracture. Fractures were assessed with weekly radiographs, and fractures were healed in 3 weeks. Sequential sacrifice and tissue sampling of fracture callus were carried out at days 1, 3, 7, 14 and 21 for RNA isolation and immunohistochemistry. The tissue blocks were centered at the fracture line and included 2 fracture ends. Femoral bone segments from mid-shaft of the same aged unfractured mice were resected for experimental control. Real time RT-PCR was performed for the expression of BMP-2, -4, -6, -7; BMPR-1A, -2; and BMP antagonists: noggin, DAN, CHRDL, BAMBI, PRODC, SOST, SMAD6, SMAD7 CERBERUS, and Grem1.

Genes of the BMP and BMP receptors: Most noticeable trend was the upregulation of the expression of BMP-2 and 7. Both were significantly increased at day 7 (3.27 and 2.83-fold, respectively), and gradually decreased in the 2<sup>nd</sup> and 3<sup>rd</sup> weeks of fracture healing. While the expression of BMP-4 was increased with no statistical significance, BMP-6 expression decreased except at day 7, when it was virtually the same as the control. BMPR-2 was statistically unchanged at most time-points. In contrast, the expression of BMPR-1A was decreased at the most time-points.

Genes of BMP antagonists: The expression of PRDC, SOST, SMAD7, GREM1 and CERBERUS was downregulated during the course of fracture healing, except that, at day 7, CERBERUS was expressed at the control level. In contrast, noggin was significantly upregulated from day 1 through day 7 and decreased its expression at days 14 and 21. Three other genes, DAN, CHRDL and BAMBI, had increased expression only after day 7. While, the increase of expression of DAN and BAMBI continued to day 21, CHRDL was downregulated at day 21.

Using a mouse fracture model, this study demonstrated the interactions between BMPs and their antagonists during the course of normal fracture healing. The alterations of gene expression during fracture healing of each of the studied BMP antagonist are evident of the participation of BMP antagonists to bone formation. The roles of BMP antagonists in fracture healing are as diverse as BMPs. Some of them are suppressed, which may facilitate releasing and activation of BMPs. Some, which are upregulated in the late stages of fracture healing, may contribute to the bone remodelling process.

**Dual Roles of Smad Proteins in the Conversion from Myoblasts to Osteoblastic Cells by BMPs.** J. Nojima<sup>1</sup>, K. Kanomata<sup>\*1</sup>, T. Fukuda<sup>1</sup>, A. Nakamura<sup>1</sup>, T. Tsukui<sup>\*2</sup>, Y. Okazaki<sup>\*3</sup>, R. Kamijo<sup>4</sup>, T. Yoda<sup>\*5</sup>, T. Katagiri<sup>1</sup>. <sup>1</sup>Division of Pathophysiology, Saitama Medical University, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan, <sup>2</sup>Division of Experimental Animal Laboratory, Saitama Medical University, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan, <sup>3</sup>Division of Functional Genomics & System Research, Saitama Medical University, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan, <sup>4</sup>Department of Biochemistry, School of Dentistry, Showa University, Sinagawa-ku, Tokyo, Japan, <sup>5</sup>Department of Oral & Maxillofacial Surgery, Saitama Medical University, Moroyama, Saitama, Japan.

(Objective) BMPs induce ectopic bone formation in muscle tissue *in vivo* and convert differentiation pathway of myoblasts to differentiate into osteoblastic cells *in vitro*. At the last ASBMR Annual Meeting, we have reported that a constitutively activated mutant Smad1, Smad1(DVD), induced ALP activity and Osterix mRNA in C2C12 myoblasts. Here, we further examined the molecular mechanisms of the conversion of myoblast differentiation by BMPs.

(Method and Result) Although wild-type or Smad1(DVD) showed minimal inhibitory effect on myogenic differentiation, co-expression of Smad4 markedly reduced number of myosin heavy chain (MHC)-positive muscle cells. We found that the inhibition of myogenic differentiation was induced by nuclear Smad4 alone. The role of Smad4 in myogenic differentiation was confirmed using mouse embryonic fibroblasts (MEFs) prepared from Smad4<sup>flxed/flxed</sup> mice. The basal transcriptional activity of MyoD was increased approximately 1.4-fold in MEFs infected with Cre-expressing virus, and this increase was not suppressed by BMP-4. A deletion analysis of Smad suggested that MH2 domain may interact with other partner(s) to suppress the myogenic differentiation. We searched a protein-protein interaction (PPI) database which was constructed based on the mammalian two-hybrid method established by the RIKEN group, and found some Smad-4 binding proteins. Among them, we focused on E4F1, which contains zinc fingers and a ubiquitin E3 ligase domain. E4F1 was expressed in nuclei. The interaction between E4F1 and Smad4 was detected in nuclear Smad4 via its MH2 domain. Over-expression of wild-type E4F1 or a mutant protein lacking E3 ligase domain suppressed myogenic differentiation in the absence of BMPs. Knockdown of endogenous E4F1 reversed the inhibition of myogenic differentiation by BMP signaling.

(Conclusion) We found that Smad4 and E4F1, a novel partner of nuclear Smad4, cooperatively regulate the inhibition of myogenic differentiation by BMP signaling. Taken together, these findings suggest that the Smad signaling pathway may play dual roles in the conversion of myoblasts to osteoblastic cells induced by BMPs.

## SA162

**Improvement of Alveolar Bone Quality by Local bFGF Injection - Histological and Cellular Biological Analysis in a Rabbit Model.** M. Oshima<sup>\*</sup>, W. Sonoyama, M. Ono<sup>\*</sup>, K. Shimono<sup>\*</sup>, T. Hikasa<sup>\*</sup>, Y. Okamoto<sup>\*</sup>, Y. Tsuchimoto<sup>\*</sup>, Y. Matsuka<sup>\*</sup>, T. Kuboki<sup>\*</sup>. Department of Oral Rehabilitation and Regenerative Medicine, Okayama University, Okayama, Japan.

Basic fibroblast growth factor (bFGF) is known to have multiple roles in bone development and regeneration. Although it is already reported that bFGF accelerates the healing of periodontal bony defect and increases the bone quantity, its effect on local bone quality is not clarified yet. In this study, recombinant human bFGF was injected into bone marrow spaces of the rabbit mandible, then bone quantity and quality was examined histologically and bone morphometric parameters were analyzed by  $\mu$ CT. In addition, bone marrow cells were isolated, and the effects of bFGF on these cells were examined *in vitro* in terms of osteogenesis and osteoclastogenesis. Ilium and tibia was used as a control against mandible.

Four weeks after injection (100  $\mu$ g of bFGF), accelerated bone formation was observed obviously in the cancellous bone area of the mandible, but not in the tibia.  $\mu$ CT analysis revealed that several parameters (i.e. bone volume/tissue volume, trabecular thickness, and trabecular number) were significantly improved only in the mandible against control (normal saline solution injected-site). Although MTS assay revealed that cell proliferation was enhanced dose-dependently by bFGF in all osteogenic cells (isolated from bone marrow of mandible, ilium, and tibia), proliferative capacity of the mandibular osteogenic cells was significantly higher than that of the iliac and tibial cells. Under an osteogenic induction condition, the tibial osteogenic cells showed higher calcified nodule formation than the others at day-7 after osteogenic induction. Osteogenesis was suppressed by bFGF in all osteogenic cells. Osteoclastogenesis, analyzed by TRAP staining, was suppressed by high-dose ( $10^{-9}$ M) bFGF, and enhanced by low-dose ( $10^{-12}$ M) bFGF in all bone marrow cells isolated from the mandible, ilium, and tibia. However, the number of mature multinucleated osteoclasts derived from the iliac and tibial bone marrow was more than that from the mandibular bone marrow. Bone resorption activity was evaluated by pit formation assay and found to be suppressed by high-dose ( $10^{-9}$ M) bFGF. Identical to the results of TRAP staining, bone resorption area made by the iliac and tibial osteoclasts was much larger than that by the mandibular osteoclasts.

These results suggest that local bFGF injection can be one of the suitable strategies to improve alveolar bone quality, possibly due to the different nature of the mandibular bone marrow.

**NARS Induced by Basic Fibroblast Growth Factor Regulates the Proliferation and Survival of Osteoblasts.** S. Park<sup>\*1</sup>, J. Byun<sup>\*2</sup>, H. Choi<sup>\*2</sup>, G. Jargalan<sup>\*1</sup>, Y. Rhee<sup>2</sup>, S. Lim<sup>2</sup>. <sup>1</sup>Brain Korea 21 Project for Medical Science, College of Medicine, Yonsei University, Seoul, Republic of Korea, <sup>2</sup>Division of Endocrinology and Endocrine Research Institute, Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.

Basic Fibroblast growth factor (bFGF), the potent bone anabolic agent, regulates bone development, growth, remodeling and fracture healing. The intracellular signaling of bFGF leads to activation of genes involved in cell proliferation, migration, differentiation and survival. However, little is known about bFGF-regulated proteins in bone. Therefore, in this study, protein profiling in bFGF-treated MC3T3-E1 preosteoblast cells was evaluated using proteomics. Asparaginyl-tRNA synthetase (NARS) was one of the proteins that up-regulated more than ten-fold in MC3T3-E1 cells after treatment of bFGF. NARS is a member of aminoacyl-tRNA synthetases (ARSs) and is responsible for catalyzing the specific aminoacylation of tRNA with asparagines. Overexpression of NARS significantly increased the level of proliferation and conferred resistance to apoptosis induced by serum deprivation in MC3T3-E1 cells and calvarial cells. In contrast, the level of proliferation was remarkably decreased and cell death was increased in siNARS-transfected cells compared to those of control siRNA-transfected cells. In conclusion, NARS induced by growth factors could be one of highly linked enzymes to the proliferation and survival of osteoblastic cells.

**Serum FGF-23 Level in Term Infants.** M. Takaiwa<sup>1</sup>, K. Aya<sup>\*2</sup>, T. Miyai<sup>\*2</sup>, B. Yuan<sup>3</sup>, M. Yokoyama<sup>\*4</sup>, M. K. Drezner<sup>3</sup>, N. Kodani<sup>\*1</sup>, T. Morishima<sup>\*2</sup>, H. Tanaka<sup>5</sup>. <sup>1</sup>Dept. of Pediatrics, Matsuyama Red Cross Hospital, Matsuyama, Japan, <sup>2</sup>Dept. of Pediatrics, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, <sup>3</sup>Dept. of Medicine, University of Wisconsin, Madison; GRECC, Wm F. Middleton VAMC, Madison, WI, USA, <sup>4</sup>Dept. of Obstetrics and Gynecology, Matsuyama Red Cross Hospital, Matsuyama, Japan, <sup>5</sup>Dept. of Pediatrics, Okayama Saiseikai General Hospital, Okayama, Japan.

Recent studies demonstrated that FGF-23 (fibroblast growth factor 23) is not only crucial in the pathogenesis of inherited and acquired hypophosphatemia, but also a physiological regulator of Ca and P homeostasis. Hence, serum FGF-23 level would be widely applied as a clinical marker for assessment of mineral metabolism. In our previous study on mouse FGF-23, we reported both serum level and mRNA expression of FGF-23 are elevated in pre-weaned mice than that of mature animals. From these results, we decided to establish the normal range of human serum FGF-23 level during neonatal period to utilize FGF-23 for assessment of mineral metabolisms during infancy. In this study, we examined serum FGF-23 level at 5 days after birth of normal term neonates (5 day-old infants, N=8). We also analyzed serum from umbilical vein (cord blood, N=6). As control, we tested serum of healthy adults (healthy adults, N=6). As known, Ca level in normal newborns falls rapidly within first 48 hours of life (early neonatal hypocalcemia) and consecutively, intact PTH (iPTH) and 1,25(OH)2D3 (1,25D) start elevating. Thus, we also measured serum Ca, P, iPTH and 1,25D level. All protocols were approved by the Matsuyama Red Cross hospital ethical committee. Informed consent was obtained from all participants or legal guardians. FGF-23 level was measured using FGF-23 ELISA kit (Kainos). Data are expressed as the mean  $\pm$  SEM and statistically analyzed by a 'Bonferroni' testing. A value of  $p < 0.05$  was considered significant. Serum FGF-23 level is significantly elevated in 5 day-old infants (65.8  $\pm$  10.1 pg/ml) than in healthy adults (32.0  $\pm$  8.0 pg/ml,  $p < 0.05$ ). On the other hand, serum FGF-23 level was not different from healthy adults in cord blood samples (22.6  $\pm$  4.9 pg/ml). Serum Ca, P, iPTH and 1,25D levels were compatible with previous reports. Considering P is a potent regulator of FGF-23 expression, and our previous study indicated that the elevated serum FGF-23 level in murine infants is due to increased FGF-23 mRNA expression, our present observations indicate that FGF-23 is induced in response to hyperphosphatemia commonly accompanied with early neonatal hypocalcemia. Although further investigations are required, our results suggested that regulatory mechanism of FGF-23 is already active, and may have considerable contribution in mineral metabolism during early infancy.

**IL-12 Induces Apoptosis in TNF- $\alpha$ -mediated Osteoclastogenesis *in vivo*.** M. Yoshimatsu, H. Kitaura, Y. Fujimura<sup>\*</sup>, T. Eguchi<sup>\*</sup>, H. Kohara, Y. Morita<sup>\*</sup>, N. Yoshida<sup>\*</sup>. Division of Orthodontics and Dentofacial Orthopedics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Recently, much importance has been placed on the relationship between cytokines and bone metabolism. We reported that IL-12 induced apoptosis in bone marrow cells treated with TNF- $\alpha$  resulted in the inhibition of osteoclastogenesis *in vitro*. This study aimed to investigate the effects of IL-12 on TNF- $\alpha$  osteoclastogenesis *in vivo*. C57BL/6J mice (8-week-old males) were classified into three groups. Each group was subjected to 5 daily supracalvarial administrations of TNF- $\alpha$  as a positive control, TNF- $\alpha$  and IL-12, or PBS as a negative control. Animals were sacrificed on day 6 and fixation and demineralization performed. Histological sections of calvariae were stained for tartrate-resistant acid phosphatase (TRAP) and TUNEL. For isolating total RNA, mice calvariae frozen in liquid nitrogen were homogenized. mRNA was isolated from homogenized samples using the TRIzol reagent. cDNA was synthesized from total RNA. The expression levels of Cathepsin K, TRAP, Fas and FasL mRNA of mice calvariae were quantified by real-time-based RT-PCR. Many osteoclasts were observed in mice administered TNF- $\alpha$ . On the other hand, the numbers of osteoclasts in mice administered TNF- $\alpha$  and IL-12 were less than those treated with TNF- $\alpha$ . The expression levels of Cathepsin K and TRAP were also reduced in mice administered TNF- $\alpha$  and IL-12 compared with mice administered TNF- $\alpha$ . The mRNA level of Fas was increased when TNF- $\alpha$  was administered and the mRNA level of FasL was increased when IL-12 was administered. The apoptotic alteration of calvarial cells in situ was recognized when TNF- $\alpha$  and IL-12 were administered. In this study, IL-12 was shown to inhibit TNF- $\alpha$ -mediated osteoclastogenesis by apoptosis *in vivo*. Apoptotic alteration might be induced by the interaction of TNF- $\alpha$ -induced Fas and IL-12-induced FasL.

**A Model of High Body Mass: Bone Mineral Density, Bone Markers and Adipocytokine Levels in High Level Male Rugby Players.** S. Breban<sup>\*</sup>, C. Chappard, C. Benhamou. CHR Orleans, INSERM Unit 658, Orleans, France.

Rugby practice offers a chance of studying very high body mass subjects and the repercussion on BMD measurements, bone metabolism and adipocytokine concentrations. Forty six men aged between 17 and 28 years participated in this study and were divided in two groups: 20 national or international ranked rugby players (aged 21.6 $\pm$ 4.6 years; 11.9 $\pm$ 2.9 hours/week) and 26 age and sex matched controls (aged 22.7 $\pm$ 4.5 years; 2.2 $\pm$ 2.0 hours/week). BMC (g) and BMD (g/cm<sup>3</sup>) were measured by DXA (Delphi, Hologic®, Waltham, MA), at whole body (WB), lumbar spine (L1-L4) and non dominant femoral neck (FN). Height, weight and body composition (whole body lean mass (kg) and fat mass (kg)) were derived from the WB DXA measurements. Circulating levels of serum leptin (ng/mL) and adiponectin (µg/mL), serum osteocalcin (ng/mL) and C-terminal telopeptides of type I collagen (Ctx) (ng/mL) were assessed by ELISA assay. Rugby players had significantly higher BMD values at WB ( $p < 0.0001$ ), L1-L4 ( $p < 0.0001$ ) and non dominant FN ( $p < 0.0001$ ) compared to controls. These differences were maintained after adjustment to height, adipocytokine concentration and bone markers concentration, but there were no more differences when BMD values were adjusted to weight and WB lean mass. Rugby players also presented significantly higher concentrations of osteocalcin ( $p < 0.001$ ) and Ctx ( $p = 0.006$ ). Leptin concentrations were significantly lower in athletes ( $p = 0.02$ ) and this persisted after adjustment to WB fat mass. However, there was no significant difference for adiponectin concentrations between athletes and controls. No significant relationships were found between leptin concentrations and any measured BMD parameters in rugby players and controls ( $p > 0.05$ ). Male rugby players seemed to present a specific bone metabolism with very high BMD and bone turnover markers values. These BMD levels were as a majority explained by a higher WB lean mass in athletes compared to controls. Our results also suggested that, high body mass was associated with lower serum leptin levels. Finally, leptin concentrations were not directly related to BMD measurements in young adults.

**Mesenchymal Stem Cells Enhance Fracture Healing: Essential Role for Cytokines in Homing and Anti-Inflammatory Response.** F. Granero-Molto<sup>1</sup>, J. A. Weis<sup>\*1</sup>, B. Landis<sup>\*2</sup>, L. Longobardi<sup>\*1</sup>, M. I. Miga<sup>\*3</sup>, A. Spagnoli<sup>1</sup>. <sup>1</sup>Pediatric Endocrinology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, <sup>2</sup>Pediatric Endocrinology, Vanderbilt University, Nashville, TN, USA, <sup>3</sup>Biomedical Engineering, Vanderbilt University, Nashville, TN, USA.

Healing failure occurs in 10-20% of the bone fractures. Limitations in adult stem cells (MSC) have been shown to be a key element in lack of healing. In this study, we determine: 1) an essential homing receptor for the migration of MSC to the fracture site; 2) the systemic anti-inflammatory effects of MSC; 3) the MSC regenerative role. MSC were

isolated from 4-6 week old syngenic FVB males mice constitutively expressing luciferase. Syngenic FVB female mice 8-10 weeks old were subjected to a three point bending stabilized fracture and injected with  $10^6$  MSC. Fractured females without transplant were used as control (NC). The anti-inflammatory effect of MSC was analyzed detecting levels of TNF $\alpha$  and IL-1 $\beta$  in the serum of MSC and NC animals at 1, 3 and 7 days post-fracture (PF). Healing was assessed by distraction biomechanical testing (BMT) at 14 days. For migration studies, MSC were selected based on the presence or absence of the surface receptor CXCR4. The *in vivo* MSC migration was detected using bioluminescence at 1, 3, 7 and 14 days PF and their influence on the callus properties analyzed by  $\mu$ CT.

BLI studies showed that MSC migrated to the fracture site and CXCR4 was essential for MSC homing. In fact, in mice transplanted with MSC lacking CXCR4, cell homing to the fracture was totally abolished. Furthermore, CXCR4 transplant produced a significant increase in the total and soft tissue volume of the callus (Fig. 1). Transplanted MSC reduced the serum levels of the pro inflammatory cytokines TNF $\alpha$  and IL-1 $\beta$  at day 1 and 3 PF.

*p<0.05 vs NC		Day 1 PF	Day 3 PF	Day 7 PF
TNF $\alpha$	NC (n=5)	89.44 $\pm$ 39.97	51.29 $\pm$ 27.19	6.69 $\pm$ 3.32
(pg/ml)	MSC (n=6)	17.68 $\pm$ 6.82*	9.57 $\pm$ 5.08*	9.13 $\pm$ 4.85
IL-1 $\beta$	NC (n=5)	84.16 $\pm$ 44.23	40.48 $\pm$ 5.03	8.25 $\pm$ 10.04
(pg/ml)	MSC (n=6)	2.88 $\pm$ 1.81*	4.62 $\pm$ 3.93*	3.58 $\pm$ 2.66

BMT analysis showed that MSC transplant improved the healing by a significant increase in the energy to failure (NC, 0.14 $\pm$ 0.05 mJ; MSC 0.49 $\pm$ 0.11 mJ, p<0.05).

In conclusion, MSC have an anti-inflammatory effect, MSC migration is dependent on CXCR4 expression and the migration is beneficial for the fracture healing process.

**Figure 1:  $\mu$ CT analysis of the callus 14 days after fracture shows increased amount of soft tissue and total callus volume in CXCR4+ transplanted animals. a, p<0.05 CXCR4+ vs CXCR4-; b, p<0.05 CXCR4+ vs NC.**

**Transient Expression of CXC Receptor 2 in Human Mesenchymal Stem Cells Stimulates Chemotaxis Toward CXC Ligand 8 and Increased Mineralization in the Presence of Osteogenic Medium.** D. S. Bischoff\*, N. S. Makhijani\*, D. T. Yamaguchi. Research Service, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA.

The potential role of CXC chemokines bearing the glu-leu-arg (ELR<sup>+</sup>) motif in bone differentiation was studied using a human mesenchymal stem cell (hMSC) model. Previously, we have shown that osteogenic differentiation of hMSCs increases expression of the ELR<sup>+</sup> CXC chemokine CXC Ligand 8 (CXCL8), also known as Interleukin-8 or IL-8. hMSCs from various donors were tested and in only one case did the addition of

exogenous CXCL8 (10 nM) induce the expression of the bone marker alkaline phosphatase (ALP). There are two ELR<sup>+</sup> CXC chemokines receptors, CXC Receptor 1 (CXCR1) and CXC Receptor 2 (CXCR2). CXCL8 binds equally well to CXCR1 and CXCR2 while the other ELR<sup>+</sup> CXC chemokines bind with much greater affinity to CXCR2. CXCR2 has been shown to be associated with the angiogenic function of the ELR<sup>+</sup> CXC chemokines. Since the levels of CXCR1 and CXCR2 vary among donors and seem to decrease with passage of the cells, we used the Amara Nucleofector Device to transiently transfect hMSCs with CXCR1 and CXCR2 expression plasmids or with the pTA vector as a negative control. Transfected cells were tested for the ability to migrate toward increasing levels of CXCL8 or CXCL1 (GRO $\alpha$ ) ranging from 0.1 to 100 nM using Transwell inserts. Non-transfected cells did not migrate even at the highest level of CXCL8 or CXCL1 (100 nM). Cells transfected with the negative control pTA did not migrate in response to 10 nM CXCL8. Those cells expressing CXCR1 had decreased levels of cell migration with a chemotaxis index (CI) value of 0.75 (ratio of migrating cells towards chemoattractant / migrating cells in negative control), and those expressing CXCR2 had increased levels of migration toward 10 nM CXCL8 with a CI value 1.9. Transfected hMSCs were also tested for the ability to induce mineral deposition by alizarin red staining. Cells expressing CXCR2 have larger mineralized nodules at 2 and 3 weeks post-transfection when grown in the presence of osteogenic medium (OGM) compared to cells transfected with either the pTA negative control or the CXCR1 expression plasmid. Expression of ALP mRNA was also induced at 7 days in the CXCR2-transfected cells in the presence of OGM. Transfection of pTA or the CXCR1 expression plasmid did not induce mineralization or ALP expression at 7 days in OGM. Cells grown in basal proliferation medium did not induce mineralization or ALP mRNA expression under any circumstances even in the presence of 10 nM CXCL8. Conclusion: 1) expression of CXCR2 in hMSC confers chemotactic ability of hMSC cells toward CXCL8 and 2) stimulates expression of ALP mRNA and mineralization in the presence of OGM.

**Transforming Growth Factor  $\beta$  Receptor I Kinase Inhibitor Increases Bone Mass in Normal Mice.** K. S. Mohammad<sup>1</sup>, G. Balooch<sup>2</sup>, C. Chen<sup>2</sup>, E. Stebbins<sup>3</sup>, D. Wong<sup>3</sup>, R. Derynck<sup>2</sup>, L. Suva<sup>4</sup>, T. A. Guise<sup>1</sup>, T. Alliston<sup>2</sup>.

<sup>1</sup>University of Virginia, Charlottesville, VA, USA, <sup>2</sup>University of California San Francisco, San Francisco, CA, USA, <sup>3</sup>Scios Inc., Fremont, CA, USA, <sup>4</sup>University of Arkansas for Medical Sciences, Little Rock, AR, USA.

TGF $\beta$  can promote and inhibit specific stages of osteoblast and osteoclast differentiation and function throughout development. Consequently, the net effect of altered TGF $\beta$  signaling on bone is difficult to predict, an uncertainty supported by the complicated bone phenotypes of mice with modified TGF $\beta$  signaling. Whether or not TGF $\beta$  can be modulated in a therapeutically beneficial way in bone remains unknown. Our recent findings show that partial inhibition of TGF $\beta$  signaling in genetically modified mice increases bone mass, bone matrix material properties such as elastic modulus and hardness, and fracture toughness. In addition, pharmacologic blockade of TGF $\beta$  signaling with SD-208, a specific inhibitor of the type I TGF $\beta$  receptor (T $\beta$ RI), increases bone mass in mammary tumor bearing mice. Therefore, we sought to determine the effect of pharmacologic T $\beta$ RI inhibition on the biological and mechanical properties of bone in normal mice.

C57/Bl6 mice were administered SD-208 (20 mg/kg or 60 mg/kg) or vehicle for 6 weeks (n=15/group). Bone mineral density (BMD) was assessed longitudinally by DXA and terminally by micro-CT and X-ray tomographic microscopy (XTM). T $\beta$ RI inhibitors significantly increase BMD in male and female mice at all sites (whole body, spine, tibia, femur). MicroCT analysis showed that, trabecular, but not cortical, bone volume is increased by SD-208. Histomorphometry and in vitro differentiation assays revealed that T $\beta$ RI inhibitors increase TBV by anabolic and anti-catabolic mechanisms. Osteoblast numbers and the bone formation rate are increased in SD-208-treated mice relative to vehicle treated controls, whereas osteoclast numbers are reduced. Likewise, bone marrow cultures from SD-208-treated mice have increased osteoblast colony forming activity, but a decreased capacity to form TRAP-positive multinucleated osteoclasts. Consistent with results in genetically modified mice, pharmacologic inhibition of TGF $\beta$  signaling increases the mineral concentration and elastic modulus of bone matrix, when measured by XTM and nanoindentation, respectively. Finally, vertebral bone from SD-208-treated mice exhibits an increased load to failure in unconfined compression tests. In conclusion, inhibition of TGF $\beta$  type I receptor function exerts both anabolic and anticatabolic effects on bone, causing a net increase in bone mass and vertebral bone load to failure. TGF $\beta$  inhibitors may have therapeutic value for treating diseases associated with low bone mass.

**IL-12 Stimulates the Osteoclast Inhibitory Peptide-1 (OIP-1) Gene Expression in CD4<sup>+</sup> T-Cells.** S. Shanmugarajan<sup>1</sup>, N. Kawanabe<sup>2</sup>, M. Koide<sup>2</sup>, J. E. Arroyo<sup>\*1</sup>, L. L. Key<sup>1</sup>, S. V. Reddy<sup>1</sup>. <sup>1</sup>Charles P. Darby Children's Research Institute, Medical University of South Carolina, Charleston, SC, USA, <sup>2</sup>Medicine-Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA, USA.

Osteoclast formation and activity is regulated by local factors produced in the bone microenvironment. Immune cell products such as IFN- $\gamma$  and IL-12 are potent inhibitors of osteoclast formation. We have previously identified and characterized the human osteoclast inhibitory peptide-1 (OIP-1/hSca), a member of Ly-6 gene family. Also, demonstrated that IFN- $\gamma$  stimulates OIP-1 promoter activity and expression in osteoclast precursor cells. However, it is unknown if IL-12 regulates OIP-1 expression in the bone microenvironment. Real-time PCR analysis demonstrated that IL-12 treatment (4 hr) significantly enhanced OIP-1 mRNA expression in normal human bone marrow derived mononuclear cells. Since IL-12 induces IFN- $\gamma$  production by T-cells, we further tested if IFN- $\gamma$  participates in IL-12 stimulation of OIP-1 expression in these cells. IL-12 treatment in the presence of a neutralizing antibody against IFN- $\gamma$  significantly increased OIP-1 mRNA expression, suggesting that IL-12 directly regulates OIP-1 gene expression. Interestingly, real-time PCR analysis demonstrated that IL-12 induces OIP-1 expression (3.2-fold) in CD4 positive T-cells; however, there was no significant change in CD8 positive T-cells. Also, IL-12 (10ng/ml) treatment of Jurkat T-cells transfected with OIP-1 gene (-1 to -1988 bp) promoter-luciferase reporter plasmid demonstrated a 5-fold and 2.7-fold increase in OIP-1 gene promoter activity in the presence and absence of antibody against IFN- $\gamma$ , respectively. We previously identified a Stat binding motif (-1629 to -1639 bp position) in the OIP-1 gene promoter region. We further show that Stat-3 inhibitor peptide treatment decreased (42.8%) IL-12 stimulated OIP-1 promoter activity. In contrast, Stat-1 inhibitor has no significant effect on OIP-1 gene promoter activity. Chromatin Immunoprecipitation (ChIP) assay confirmed Stat-3, but not Stat-1 binding to the OIP-1 gene promoter element in response to IL-12 stimulation. These results suggest that IL-12 stimulates the OIP-1 gene expression through Stat-3 signaling in CD4 positive T-cells and that OIP-1 is an important autocrine/paracrine regulator of osteoclast development and bone remodeling.

**The Mechanism of Action of Lactoferrin's Bone Anabolic Activity.** J. Cornish, A. Chhana\*, J. M. Lin\*, K. E. Callon\*, I. R. Reid, D. Naot. Medicine, University of Auckland, Auckland, New Zealand.

Lactoferrin, an 80kDa iron-binding glycoprotein present in milk and other exocrine secretions in mammals, is anabolic to bone at physiological concentrations. Lactoferrin stimulates the proliferation, differentiation and survival of the osteoblasts, as well as potentially inhibiting osteoclastogenesis in bone marrow cultures. In vivo, local injection of lactoferrin results in substantial increases in bone formation and bone area. In a critical bone defect model in vivo, lactoferrin was also seen to promote bone growth. The mitogenic effect of lactoferrin in osteoblast-like cells is mediated mainly through LRP1, a member of the low density lipoprotein receptor-related proteins that are primarily known as endocytic receptors; however another yet unidentified receptor is responsible for the anti-apoptotic actions. Lactoferrin also induces activation of multiple pathways: p42/44 MAPK signalling as well as PI3-kinase-dependent phosphorylation of Akt in osteoblasts. Recently, we have further delineated the possible mechanisms of action of lactoferrin in bone, in both osteoclasts and osteoblasts. The mouse macrophage cell line, RAW 264.7, demonstrated that lactoferrin acts directly on osteoclasts to inhibit their development independently of osteoblasts. In addition, the receptor involved is *not* LRP1. In human osteoblasts treated with lactoferrin, we identified differentially-expressing genes, using microarray analysis then validated in real time PCR significant up-regulation of IGF1 and down-regulation of DKK1. We then extended these studies looking at earlier time points in the MC3T3-E1 osteoblastic cell-line, using real-time PCR with custom-designed microfluidic cards. The cards were used to measure the relative expression levels of 48 genes including bone-specific transcription factors, matrix and inflammatory proteins. Lactoferrin induced a rapid, dose-dependent increase in the transcription levels of IL-6, IL-11, the pro-inflammatory factor prostaglandin-endoperoxide synthase 2 (COX-2) and the transcription factor nuclear factor of activated T cells-1 (NFATc1). Subsequent real-time PCR experiments in primary rat osteoblasts confirmed that IL-6, IL-11, COX-2 and NFATc1 transcription levels increase significantly and transiently within two hours of lactoferrin treatment. The role these genes play in mediating the effects of lactoferrin in osteoblasts is currently being investigated by the use of specific inhibitors. Lactoferrin is proving to be a positive regulator of bone growth potentially having a physiological role in bone growth and healing, and a therapeutic role as an anabolic factor in osteoporosis.

**Stimulation of Macrophage TNF $\alpha$  Production by Orthopaedic Wear Particles Requires Activation of the ERK1/2/Egr-1 Pathway but Is Independent of p38 and JNK.** M. A. Beidelschies\*, H. Huang\*, M. R. McMullen\*, M. V. Smith\*, A. S. Islam\*, V. M. Goldberg\*, X. Chen\*, L. E. Nagy\*, E. M. Greenfield<sup>1</sup>. <sup>1</sup>Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, <sup>2</sup>Pathobiology, Cleveland Clinic Foundation, Cleveland, OH, USA.

Bone loss that causes aseptic loosening of orthopaedic implants is initiated by pro-inflammatory cytokines produced by macrophages in response to implant-derived wear particles. MAPK signaling pathways are activated by the particles; however, it is not clear which of the MAPK pathways are important for the initial response to the wear particles and which are only involved at later steps in the process, such as osteoclast differentiation. Here, we show that the ERK1/2, p38, and JNK pathways are rapidly activated by the wear particles. However, incubation of RAW264.7 cells or bone marrow-derived macrophages with specific inhibitors and their inactive analogues showed that ERK1/2 is required for the initial responses to the wear particles (TNF $\alpha$  mRNA expression and TNF $\alpha$  protein secretion). In contrast, the p38 and JNK pathways were not required for these responses. ERK1/2 activation by wear particles is also required for increased expression of the transcription factor Egr-1 as well as for Egr-1's ability to bind to the TNF $\alpha$  promoter. Measurements of luciferase activity in RAW264.7 macrophages transfected with TNF $\alpha$  promoter-luciferase constructs containing specific deletions and mutations demonstrated that Egr-1 is also required for wear particles to increase TNF $\alpha$  transcription. These results, together with our previous studies of the PI3K/Akt pathway, demonstrate that wear particles coordinately activate multiple signaling pathways and multiple transcription factors to stimulate production of pro-inflammatory cytokines, such as TNF $\alpha$ . The current study also demonstrates that the ERK1/2/Egr-1 signaling pathway is activated to a much greater extent by wear particles with adherent endotoxin than by "endotoxin-free" wear particles. These results demonstrate that the ERK1/2/Egr-1 pathway contributes to the ability of adherent endotoxin to potentiate cytokine production, osteoclast differentiation, and bone loss induced by wear particles.

**Alterations in Bone Structure and Growth in Dwarf Rats with a Depressed Growth Hormone/IGF-I Axis.** A. C. F. Bassit, M. K. Altman\*, S. E. Franz\*, M. E. Leal, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Growth hormone (GH) is an important factor in the regulation of bone growth and the maintenance of adult bone. The majority of its skeletal effects appear to be mediated by insulin-like growth factor I (IGF-I). The dwarf rat is an animal model for studies of the effects of GH/IGF-I deficiency on bone structure and function. In these mutant rats, GH synthesis is selectively reduced to about 6% of normal in females, and serum IGF-I levels are about 10% of normal. Body growth is retarded, but the dwarf rats are healthy and skeletal malformations do not occur. The objective of this study was to use imaging (pQCT) and histomorphometric techniques to determine the skeletal consequences of GH/IGF-I deficiency in dwarf rats. Groups of normal Lewis rats (N=7) and dwarf rats (N=7) were maintained in the same nutritional and environmental conditions until 11 weeks of age. At the time of euthanasia, the mean body weight of the Lewis rats was 52.9% higher than the dwarf rats (187.6  $\pm$  10.9g vs. 122.7  $\pm$  5.6g, P<0.0001), and their left femurs were 14.8% longer. Not surprisingly, tibial longitudinal bone growth was three-fold greater in the Lewis rats compared to the dwarf rats (72.1  $\pm$  4.9  $\mu$ m/d vs. 24.5  $\pm$  10.7  $\mu$ m/d, P<0.0001). All the bone structural parameters evaluated by pQCT in the femur, including total mineral content, total mineral density, trabecular content, trabecular density, trabecular area, cortical density, cortical area, cortical content, cortical thickness, and periosteal circumference, were significantly greater in the Lewis rats compared with the dwarf rats. Cancellous bone histomorphometry was performed in the right proximal tibia. Cancellous bone volume was markedly lower in the dwarf rats than in the Lewis rats (1.2  $\pm$  1.4% vs. 18.9  $\pm$  3.3%, P<0.0001), and this cancellous osteopenia was associated with decreased trabecular number and width, and increased trabecular separation. Mean values for osteoclast surface, an index of bone resorption, were nearly identical in Lewis and dwarf rats. Although mean values for osteoblast and osteoid surfaces were not significantly different between the two groups, cancellous mineral apposition rate, an index of osteoblast activity, was significantly lower in dwarf rats compared with Lewis rats (0.9  $\pm$  0.2  $\mu$ m/d vs. 1.5  $\pm$  0.3  $\mu$ m/d, P<0.0005). These findings indicate that GH/IGF-I deficiency in dwarf rats has profound negative effects on bone growth, accumulation of bone mass, and osteoblast activity. In view of the contention that IGF-I may mediate the skeletal effects of bone anabolic agents, dwarf rats appear to be a promising animal model for studies of these interactions.

**IGF-I Secreted from Osteoblasts as a Major Chemotactic Factor for Osteoblasts.** M. Nakasaki<sup>1</sup>, K. Yoshioka<sup>\*1</sup>, H. Yoshikawa<sup>\*2</sup>, K. Itoh<sup>1</sup>. <sup>1</sup>Biology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan, <sup>2</sup>Orthopedic Surgery, Osaka University Medical School, Osaka, Japan.

Osteoblast recruitment to the site of future bone formation is essential for skeletal development, bone remodeling and fracture healing, but the mechanism of which remains to be clarified. Here, we hypothesized that osteoblasts secrete a chemoattractant(s) for osteoblast recruitment and examined the serum-free conditioned medium of mouse osteoblast-like cell line MC3T3-E1 for its ability to induce osteoblast migration. Using a modified Boyden chamber assay, we found that the medium induced MC3T3-E1 chemotaxis in a dose-dependent manner. Employing several chromatographic procedures and liquid chromatography equipped with tandem mass spectrometry analysis, we identified insulin-like growth factor-I (IGF-I) as a potent chemotactic factor from the conditioned medium. IGF-I induced cell migration of both MC3T3-E1 cells and primary mouse osteoblasts, and checkerboard analysis revealed that IGF-I induced chemotaxis and not simply chemokinesis. By neutralization of IGF-I activity with specific anti-mouse IGF-I antibody, both osteoblast monolayer wound healing and cellular polarization were impaired, whereas human IGF-I replenishment reversed these inhibitory effects. IGF-I also promoted cell spreading on fibronectin in an integrin  $\beta$ 1-dependent manner. IGF-I induced Akt and ERK phosphorylation in MC3T3-E1 cells and a PI3K inhibitor, LY294002, but not a MEK inhibitor, PD98059, inhibited IGF-I-induced cell migration and wound healing. Together, these findings suggest that IGF-I secreted from osteoblasts regulates osteoblast migration through the activation of PI3K signaling.

**Is Growth Hormone/IGF-I Mediated Mechanism Involved in Regulating Gender Differences in Bone Size?** S. Mohan, K. E. Govoni, J. E. Wergedal. JLP VA Medical Center and Loma Linda Univ, Loma Linda, CA, USA.

It is now generally well accepted that estrogen and testosterone exert opposite effects on periosteal bone expansion and that greater bone size in males is mediated via androgens acting through androgen receptors. However, the molecular pathway by which estrogens and androgens exert gender-specific effects on periosteal expansion remains to be fully elucidated. Based on the findings that growth hormone (GH)/IGF-I is a major regulator of postnatal skeletal growth, we and others have predicted that sex hormones interact with GH/IGF axis to regulate bone size. To evaluate this hypothesis, we compared femur cross sectional area (CSA) measured by pQCT in transgenic mice with disruption of GH/IGF axis. We predicted if gender differences in bone size are due to interaction between sex hormone and GH/IGF axis, then disruption of GH/IGF axis should eliminate gender differences in bone size. GH-deficient *lit/lit* mice with mutation in GH releasing hormone receptor, IGF-I total knockout (IGF-I<sup>-/-</sup>), lacks both endocrine and local IGF-I, osteoblast specific IGF-I conditional knockout (IGF-I<sup>-/-</sup>), lacks osteoblast produced local IGF-I and IGF-II null mice were evaluated at 3 and 8 weeks of age. Corresponding age-matched control littermate mice were used as wild types. As expected, at prepubertal age of 3-weeks, femur CSA was not different between male and female mice for any of the strains studied.

At post pubertal age of 8 weeks, femur CSA was significantly greater in the males compared to females for all four transgenic lines studied at 8 weeks of age. To our surprise, disruption of GH, IGF-I, osteoblast-derived IGF-I or IGF-II did not affect bone size differences between male and female mice at 8 weeks (Figure). However, femur CSA was decreased as previously reported by 39, 67, 31 and 21% respectively in mice lacking GH, total IGF-I, osteoblast-derived IGF-I or total IGF-II respectively, thus demonstrating the importance of GH/IGF axis in regulating bone size during postnatal growth. In conclusion, our data using the transgenic mouse models do not support the hypothesis that GH/IGF axis is a major player in contributing to gender specific effect on bone size and suggest that the greater bone size in male mice is due to GH/IGF-independent actions of androgen on bone.

**Insulin-Like Growth Factor Binding Protein (IGFBP)-6 Is a Negative Regulator of Osteoblast Differentiation and Bone Formation.** C. A. Strohbach<sup>1</sup>, C. H. Rundle<sup>2</sup>, J. E. Wergedal<sup>\*2</sup>, T. A. Linkhart<sup>\*2</sup>, S. Mohan<sup>2</sup>, D. D. Strong<sup>\*2</sup>. <sup>1</sup>Loma Linda University, Loma Linda, CA, USA, <sup>2</sup>MDC, J.L.P. VAMC, Loma Linda, CA, USA.

We previously reported that IGFBP-6 (BP6) is a negative regulator of osteoblast (Ob) differentiation, with BP6 retroviral overexpression inhibiting MC3T3-E1 mineralization and Ob marker gene expression possibly via an IGF-independent intracellular mechanism. To further elucidate the role of BP6 in Ob differentiation, we used siRNA to knockdown BP6 mRNA and protein in MC3T3-E1 pre-Obs and less differentiated C2C12 cells and observed an increase in Osterix, Dlx5, ALP, BSP, Osteocalcin and PheX mRNAs. While our *in vitro* studies provide compelling evidence that BP6 can play an important inhibitory role in Ob differentiation, the role of BP6 in normal skeletal development and maintenance has not been established. To address this question, transgenic (Tg) mice were generated that overexpressed BP6 in Obs. The BP6 transgene was placed under the control of an Ob lineage restricted promoter that contained the proximal Col1a2 promoter and modified Runx2 enhancer sequences. Col1a2 and Runx2 are early marker genes for Ob lineage commitment and this chimeric promoter was not suppressed by BP6 transgene overexpression. Multiple founders were identified and backcrossed two generations to reduce effects of genetic background differences and establish independent Tg lines. BP6 was expressed in bones isolated from BP6 Tg mice but not in other tissues. Skeletal parameters were studied by DEXA in BP6 Tg and wild type littermate controls at 6, 12, and 24wks. Areal BMD was significantly reduced in the femurs of male (7%,  $p < 0.03$ ,  $n=8$ ) and female mice (14%,  $p < 0.002$ ,  $n=8$ ) in two independent lines of BP6 Tg mice compared to wild-type littermate controls providing evidence that BP6 is a negative regulator of bone formation *in vivo*. However, the BP6 Tg mice did not display differences in body weight or femur length, suggesting that BP6 does not influence the growth promoting effects of the IGFs that have been observed in transgenic mice expressing other IGFBPs. In conclusion, our previous and current findings demonstrate that BP6 is an important negative regulator of Ob differentiation and bone formation and that BP6 effects on Obs involve decreased expression of transcription factors and marker genes that are critical for Ob differentiation.

**Serum IGF-1 Is a Developmental Determinant of Bone Size.** S. Yakar<sup>1</sup>, E. Canalis<sup>2</sup>, W. Mejia<sup>\*1</sup>, H. Sun<sup>\*1</sup>, Y. Wu<sup>\*1</sup>, Y. Kawashima<sup>\*1</sup>, P. Nasser<sup>\*3</sup>, V. Williams<sup>\*3</sup>, K. J. Jepsen<sup>3</sup>. <sup>1</sup>Endocrinology, Mount Sinai School of Medicine, New York, NY, USA, <sup>2</sup>St. Francis Hospital and Medical Center, Hartford, CT, USA, <sup>3</sup>Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Serum insulin-like growth factor I (IGF-I) originates mainly from the liver. Liver-specific *igf1* gene deletion (LID mouse model) causes abrogated expression of IGF-I mRNA in liver, dramatic reductions (75%) in circulating IGF-I and a 3-4 fold increase in serum GH. Here we studied developmental changes in skeletal acquisition in a state of serum IGF-I deficiency. LID mice were followed from 4 to 52 weeks of age. Histomorphometry at 4, 8 and 20 weeks of age in both control and LID mice revealed no changes in bone volume fraction (%BV/TV) and a mild increase in eroded surface at 20 weeks of age (Table 1). Flow cytometry analysis of bone marrow-derived cells revealed a significant and consistent decrease in CD11b/Mac-1+ cells in LID mice, suggesting reductions in osteoclast progenitors in marrow of LID mice. Femoral microCT analyses showed reductions in total area (TtAr), marrow area (MaAr), and cortical area (CtAr) in LID relative to control mice. No differences in matrix mineralization were noted at any age. Morphological differences were apparent at 4 weeks, but were significant at 8 and 16 weeks, indicating that the reduced serum IGF-I affected bone postnatally, at the time when serum IGF-I normally peaks. The reduced serum IGF-I thus had two primary effects on bone; (1) it resulted in slender bones and (2) it impaired structural adaptation necessary to compensate for the increased slenderness (i.e. through reduced marrow expansion and/or increased matrix mineralization). These data suggest that serum IGF-I is a developmental determinant of bone size and strength, and that compensatory increases in serum GH are insufficient for gaining structural adaptations but may account for the increased resorption at later ages.

**Endocrine IGF-1 Maintains Linear Growth in the Total Absence of Tissue IGF-1.** Y. Wu\*, S. Elis\*, H. Sun\*, Y. Kawashima\*, S. Yakar. Endocrine, Mount Sinai School of Medicine, New York, NY, USA.

Insulin-like growth factor-I (IGF-I) plays a fundamental role in growth and development, and acts in an endocrine and autocrine/paracrine fashion. A daunting challenge has been to sort out which mode of IGF-I action (i.e. endocrine or autocrine/paracrine) facilitates skeletal growth. We previously generated the liver-specific IGF-I gene deletion (LID) mouse model that demonstrated a 75% reduction in circulating IGF-I levels and exhibited mild growth abnormalities, suggesting an important role for tissue IGF-I. Here we took a reversed approach and created a mouse model with total IGF-I gene-deletion (KO), that expresses Hepatic IGF-I Transgene (HIT) under the control of the transthyretin promoter. The KO-HIT mice express solely liver-derived IGF-I, show 2fold increase in serum IGF-I levels and exhibit complete absence of tissue IGF-I. Serum levels of GH and the IGF binding proteins in KO-HIT mice are similar to controls. Furthermore, body weight of KO-HIT mice was similar to controls in both males and females from 3-16 weeks of age. We reveal that in the total absence of tissue IGF-I action, endocrine IGF-I restores femoral linear growth in both males and females. These findings call into question previous concepts about the GH/IGF-I axis and have major implications for various growth disorders and therapeutic options.

**Induction of Oxidative Stress and Diversion of  $\beta$ -catenin from TCF- to FOXO-mediated Transcription by Glucocorticoids or  $\text{TNF}\alpha$  in Osteoblastic Cells.** M. Almeida, E. Ambrogini, M. Martin-Millan, L. Han, A. Warren\*, R. S. Shelton\*, L. Plotkin, T. Bellido, C. A. O'Brien, R. L. Jilka, R. S. Weinstein, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Oxidative stress induces activation of the FoxO family of transcription factors and diverts  $\beta$ -catenin from Wnt induced TCF/Lef- transcription to FoxO-mediated transcription--thereby decreasing osteoblastogenesis. Prompted by evidence that oxidative stress is also a causal mechanism of the insulin resistance produced by glucocorticoids (GC) and the inflammatory cytokine  $\text{TNF}\alpha$  alike, we tested the hypothesis that the potent suppressive effects of GC and  $\text{TNF}\alpha$  on bone formation may be caused, at least in part, by increasing oxidative stress and antagonizing the beneficial effects of Wnt signaling on osteoblast generation and survival. We report that dexamethasone (Dex) ( $10^{-7}$  M) or  $\text{TNF}\alpha$  ( $10^{-8}$  M) increased reactive oxygen species levels in osteoblast progenitors (C2C12 cells). Moreover, Dex- or  $\text{TNF}\alpha$ -induced apoptosis in C2C12, committed osteoblasts (OB6), and osteocytes (MLO-Y4), was abolished by the antioxidant N-acetyl-L-cysteine (NAC), the glutathione peroxidase mimic ebselen, as well as catalase, the enzyme that converts  $\text{H}_2\text{O}_2$  to water. Consistent with a pro-oxidant effect, Dex or  $\text{TNF}\alpha$  increased the phosphorylation of the adapter protein  $\text{p66}^{\text{thc}}$ --a redox enzyme that generates mitochondrial  $\text{H}_2\text{O}_2$  to trigger mitochondria swelling and apoptosis. In addition,  $\text{TNF}\alpha$  or Dex, similar to  $100 \mu\text{M}$   $\text{H}_2\text{O}_2$ , increased the activity of a FoxO-luciferase reporter construct and the transcription of the pro-apoptotic gene Bim (a known FoxO target). The stimulation of  $\text{p66}^{\text{thc}}$  phosphorylation as well as the activation of FoxO-luc by Dex or  $\text{TNF}\alpha$  were abolished in cells pre-treated for 1 h with NAC. Moreover, the effect of Dex or  $\text{TNF}\alpha$  on apoptosis was prevented by a dominant negative FoxO construct. On the other hand,  $\text{TNF}\alpha$  or Dex suppressed the Wnt3a-induced activation of a TCF-reporter construct, as well as alkaline phosphatase activity. In agreement with the in vitro data, implantation of slow-release pellets containing prednisolone for 28 d in 5-month-old C57BL/6 male mice increased ROS levels in the bone marrow, as well as  $\text{p66}^{\text{thc}}$  phosphorylation and Bim gene expression in bone. All these effects were prevented by administration of NAC. We conclude that activation of FoxO transcription factors by oxidative stress represents a previously unappreciated cell-autonomous mechanism of Wnt/ $\beta$ -catenin antagonism contributing to the adverse effects of aging, GC excess and inflammatory cytokines on bone alike.

**Monoclonal Antibody to Transforming Growth Factor  $\beta$  Inhibits Tumor Burden and Osteolysis in a Pre-clinical Model of Bone Metastasis.** S. Biswas<sup>1</sup>, C. Wilburn<sup>\*2</sup>, S. A. Munoz<sup>\*2</sup>, J. A. Sterling<sup>1</sup>, S. Lonning<sup>\*3</sup>, G. R. Mundy<sup>4</sup>. <sup>1</sup>Cancer Biology, Vanderbilt University, Nashville, TN, USA, <sup>2</sup>Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA, <sup>3</sup>Genzyme Corporation, Framingham, MA, USA, <sup>4</sup>Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Breast cancer is the most common cancer and the second leading cause of cancer-related deaths for women in the United States. Breast cancer cells metastasize to bone with high affinity. Transforming growth factor  $\beta$  (TGF $\beta$ ), one of the most abundant cytokines

found in the bone matrix, is secreted in active form at the site of osteolytic bone resorption. By acting on both the bone microenvironment and cancer cells, TGF $\beta$  acts as a major driver of the vicious cycle of bone metastasis. Inhibiting TGF $\beta$  signaling in breast cancer cells by the use of dominant negative receptor constructs or the use of small molecular inhibitors of the receptor kinase have been shown to reduce tumor burden and bone lesions in preclinical breast cancer metastasis models. However, small molecule kinase inhibitors often show non-specific effects on unrelated kinases, and thus have potential for unwanted side effects. Therefore, we have taken a different approach, by which we block all three isoforms of TGF $\beta$  systemically using a pan-TGF $\beta$  antibody, 1D11(Genzyme). Using MDA-MB-231 human breast cancer cells in a cardiac injection model, we have investigated the efficacy of 1D11 on the following:

- (1) metastatic progression of breast cancer cells in bone and
- (2) modulation of bone lesions in tumor bearing mice.

We have demonstrated that, treatment with 1D11(10mg/ Kg, three times a week for two weeks) reduces the number of bone lesions (Control: 7.4, Treated: 2.3, P<0.005), area of bone lesions (control: 7535.5 cm<sup>2</sup>, treated: 865.5 cm<sup>2</sup>, P<0.001). Increases in the bone volume as measured by the ratio of BV/TV (Control: 0.093, Treatment: 0.198, P=.01) using micro-CT analysis of tibia. Mice were treated with either 1D11 or control antibody (13C4) i.p. three times every week for two weeks. Treatment was initiated two weeks after tumor inoculation. These results show that 1D11 effectively reduces tumor burden and bone lesions in this preclinical model of human breast cancer metastasis to bone.

**Tissue-Engineering and Co-culture System Based Disc Regeneration Mesenchymal Stem Cell's Role.** M. Nan<sup>\*1</sup>, S. Moon<sup>2</sup>, C. Lee<sup>\*1</sup>, J. Lee<sup>\*1</sup>, E. Kwon<sup>\*1</sup>, H. Kim<sup>\*3</sup>, K. Lee<sup>\*3</sup>, H. Lee<sup>\*2</sup>, E. Moon<sup>\*2</sup>, H. Kim<sup>\*2</sup>, H. Kim<sup>\*2</sup>, I. Kwon<sup>\*1</sup>, H. Chun<sup>\*4</sup>, S. Park<sup>5</sup>. <sup>1</sup>Yonsei University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Department of Orthopedic Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea, <sup>3</sup>Allgraft and Biotechnology, Korea Bone Bank Co.,Ltd, Seoul, Republic of Korea, <sup>4</sup>Kyung Hee University, Seoul, Republic of Korea, <sup>5</sup>Department of Orthopedic Surgery, Korea University, Seoul, Republic of Korea.

Intervertebral disc (IVD) degeneration is caused by loss of water content in nucleus pulposus (NP) which is resulted from proteoglycan and type II collagen reduction. To regenerate IVD, transforming growth factor-beta1 (TGF-beta1) and bone morphogenetic protein-2 (BMP-2) can be utilized. As a technique of tissue engineering, composite IVD implants are fabricated as novel materials for disc replacement. Mesenchymal stem cells (MSCs) are known to be multipotent in tissue regeneration. Hence, the object of this study was to examine MSC based co-cultured cells in atelocollagen type I scaffold under the influence of TGF-beta1 and BMP-2. NP cells and/or MSCs were cultured at the rate of 0:1, 1:1, 1:0 in type I atelocollagen scaffold. And culture media was added with 5% FBS including TGF-beta1 of 10ng/ml, BMP-2 of 100ng/ml respectively. [<sup>35</sup>S] Sulfur incorporation for proteoglycan synthesis and [<sup>3</sup>H]-thymidine incorporation for proliferation were measured. RT-PCR was performed to assess the aggrecan, collagen type I and II, osteocalcin mRNA expressions. As result, co-cultures of MSC and NP cells in scaffold showed significant decreases in proteoglycan synthesis compared to those of NP cells only (p<0.05). Co-cultures in scaffold with TGF-beta1 or BMP-2 demonstrated increased newly synthesized proteoglycan compared to simple co-cultures (p<0.05). NP cell culture in scaffold with TGF-beta1 or BMP-2 showed significant increase in proteoglycan synthesis compared to co-culture. Aggrecan and collagen type II mRNA expression were more pronounced in NP cell culture alone than co-cultures. Adding MSC to NP cells in atelocollagen type I scaffold did not result in increased matrix synthesis consequently and chondrogenic phenotype expression and MSC based tissue engineering for disc regeneration seems not to be effective.

**Analytical Validation of Diasorin Liaison and Roche Elecsys Methods for the Determination of Osteocalcin.** E. Cavalier\*, P. Delanaye\*, A. Carlisi\*, J. Chapelle\*. Clinical Chemistry, University Hospital of Liege, University of Liege, Liege, Belgium.

Osteocalcin (OSC) determination is not an easy task. Indeed, "intact" OSC (AA 1-49) is unstable because it is cleaved between AA 43 and 44. This generates an N-mid fragment (AA 1-43), much more stable than intact OSC. The antibodies used in the kits must thus recognize both OSC and N-mid fragment.

The aim of our study was to validate 2 automated methods (Diasorin Liaison (LIA) and Roche Elecsys (ELEC)) designed for the determination of OSC in serum.

Both methods were found to be sensible (limit of detection < 0.50 ng/mL) and reproducible (intra- and inter-assay variation respectively < 2 and < 5%).

We performed a recovery test according to the NCCLS recommendations. This showed a mean recovery of 98% for LIA and 97% for ELEC. The dilution of 3 sera containing elevated levels of OSC showed a slightly better linearity for ELEC than for LIA (mean recovery: 98 vs. 115%).

When we compared the results obtained with the 2 methods on 50 patients, the Bland-Altman test showed a mean difference of 6.9 ng/mL and a clear tendency for ELEC to give higher results than LIA in patients presenting elevated OSC levels. The results obtained with ELEC were significantly higher (31%;  $p < 0.0001$ ) than those obtained with LIA.

We studied the stability of OSC at room temperature (RT), +4°C and -20°C on 10 fresh samples. Our results showed that OSC was stable up to 3 days at RT. At 4°C, a significant ( $p < 0.05$ ) but slight increase of maximum 6% was observed after 3 days. At -20°C, we also observed a significant ( $p < 0.05$ ) increase of 8.5% after 2 days, but a decrease of 9 and 11% respectively after 15 and 30 days ( $p < 0.05$ ).

In non-menopausal women, the reference range published for ELEC is broader than LIA (< 31 ng/mL vs. < 24 ng/mL respectively) which is consistent with our observations, whereas in post-menopausal ones, LIA's reference range are surprisingly higher than ELEC (< 59 ng/mL vs. < 46 ng/mL). This discrepant observation may be attributable to the different means used by the 2 societies to establish their reference range. Indeed, Diasorin selected patients with 25-OH vitamin D levels > 20 ng/mL and estimated the higher and lower limits on a Gaussian distribution (mean  $\pm$  2 SD). On the other hand, Roche evaluated the reference range in women with no hormonal substitution treatment and took the percentiles 5 and 95 as normal limits.

In conclusion, these 2 techniques perform analytically well but they do not give comparable results. This is due, for one part, to the lack of an International standard against which the societies could calibrate their kits, and for the other part, to the possible difference in the cross reactions between the antibodies and the N-mid fragment.

## SA192

**High Bone Mass Due to Increased Bone Formation in Mice Lacking the Calcitonin Receptor.** J. H. Keller\*, A. K. Huebner, P. Catala-Lehnen, T. Schinke, M. Amling. Center for Biomechanics and Skeletal Biology, Department of Trauma, Hand, and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Although the hormone calcitonin (CT) is well known for its inhibitory effect on osteoclasts, its physiologic function in bone remodelling is still not fully clarified. This is in part due to recent findings showing that the inactivation of CT in mice does not only result in increased bone resorption, but also in increased bone formation. The latter observation was especially surprising, since the calcitonin receptor (CTR) is considered not expressed by osteoblasts. Therefore, in order to analyze, how the inhibitory effect of CT on bone formation can be explained at the cellular level, we took advantage of the Cre-Lox-technology, allowing cell-specific gene deletion in mice. Since the replacement of CTR exons 6 and 7 by a neomycin resistance gene has been described to result in lethality of homozygous embryos, but in increased bone formation of heterozygous mice, we inserted loxP sites into introns 5 and 7 of the CTR gene, allowing CTR inactivation in cells expressing the *Cre-recombinase*. As a control, mice carrying two "floxed" alleles were first crossed with transgenic mice expressing *Cre* in all cell types, including germ cells, thereby leading to the generation of CTR<sup>+/+</sup> mice with a Cre-independent heterozygous deletion of exons 6 and 7. Surprisingly, when we mated these mice, we obtained living CTR<sup>-/-</sup> offspring, displaying no obvious abnormalities. To verify the success of the approach, we first confirmed the absence of functional CTR in these mice by radioligand binding assays and immunohistochemistry. Thereafter, we embarked on a complete skeletal analysis using static and dynamic histomorphometry. At the age of 3 months we already observed a significantly increased trabecular bone volume in the CTR<sup>-/-</sup> mice, accompanied by an elevated bone formation rate. The same was observed in 6 months old mice, where the differences to wildtype littermates were even more pronounced (BV/TV: 23.0  $\pm$  3.0 % vs. 12.5  $\pm$  0.6 %, BFR/BS: 230  $\pm$  31  $\mu$ m<sup>3</sup>/μm<sup>2</sup>/y vs. 101  $\pm$  6  $\mu$ m<sup>3</sup>/μm<sup>2</sup>/y). At the age of 12 months, the bone formation rate was still two-fold higher in the CTR<sup>-/-</sup> mice, but this was accompanied by cortical porosity due to increased bone resorption. Thus, since the observed phenotype resembles the one previously described for mice lacking CT, it appears that the control of bone formation is the major function of the CTR, at least in mice. In addition, having established mice with a "floxed" CTR allele should allow answering the question, whether the effect of CT on osteoblasts is mediated indirectly through CTR expression in another cell type.

Skeletally mature Wistar rats were injected intradermally with a vehicle or 0.1ml of a suspension/rat containing 6mgM Tuberculosis antigen H37 RA (Difco) to induce inflammatory arthritis. Starting from day 0, rats were treated either with daily s.c injections of placebo, salmon calcitonin (sCT) at a dose of 1, 3.2 or 10μg/kg/day, or the reference compound dexamethasone given daily orally by gavage at a dose of 0.1mg/kg/day. Treatment was continued for the entire duration of the study which was 3 weeks. TRAP5b-activity in plasma and bone parameters were measured at 0, 2 and 3 weeks in the proximal tibia metaphysis by pQCT (XCT2000, Stratec Medizintechnik, Pforzheim, Germany) and cancellous microarchitecture by in vivo μCT (vivaCT40, SCANCO Medical, Bruettisellen, Switzerland).

In vehicle treated animals, inflammatory arthritis lead to rapid and continuous decrease in cancellous bone mineral density (CnBMD) of 12% at 3 weeks and a corresponding decrease in trabecular bone volume, resulting mostly from the thinning of trabecular elements. Cortical thickness (CtTh) decreased by 14% as a result of endocortical bone resorption while no significant changes in periosteal perimeter was observed. Dexamethasone administration fully prevented joint swelling and all bone changes resulting from inflammatory arthritis. Similarly, calcitonin dose dependently reduced bone loss in both, the cancellous and cortical compartment with the highest dose of 10 μg/kg/day offering full protection. Significant effects were already seen at the lowest dose of 1μg/kg/day sCT. Histomorphometric assessment of TRAP positive cells in the ankle joint confirmed the potent dose-dependent anti-osteoclastic effect sCT, which was in line with indications from plasma TRAP5b measurements. Inhibitory effects were seen in metaphyseal cancellous bone, subchondral bone in the epiphysis, as well as in the peri-articular area.

Studies should be undertaken to investigate the potential of oral formulations of sCT in animal models of inflammatory arthritis. Calcitonin is a potent inhibitor of bone degradation in the inflammatory joint and may be an interesting adjuvant therapy to anti-inflammatory drugs (NSAIDs, DMARDs).

**Lack of Calcitonin Accentuates Bone Loss During Lactation by Enhanced Osteoclast Formation and Reduced Osteoblast Formation.** C. S. Kovacs<sup>1</sup>, B. J. Kirby<sup>\*1</sup>, J. P. Woodrow<sup>\*1</sup>, R. F. Gagel<sup>2</sup>, N. A. Sims<sup>3</sup>. <sup>1</sup>Memorial University, St. John's, NL, Canada, <sup>2</sup>MD Anderson Cancer Center, Houston, TX, USA, <sup>3</sup>St. Vincent's Institute, Melbourne, Australia.

Lactation in mice induces substantial reductions in bone mineral content (BMC, assessed by DXA) that are reversed rapidly after weaning. *Ctgrp*-null mice, with a global deletion of the gene encoding calcitonin and calcitonin gene-related peptide, suffer a 55% reduction in BMC during lactation (versus 25% in wild type [WT] mice) followed by complete restoration post-weaning. *Ctgrp*-null mice also demonstrate upregulated mammary gland PTHrP and serum PTH during lactation, which may increase osteoclast-mediated bone resorption during lactation even further above normal. To assess this, we performed histomorphometry in WT and *Ctgrp*-null mice during lactation and weaning. Pairs of sister WT and *Ctgrp*-null mice were sacrificed at day 7 of lactation and at weaning (day 21 after parturition) and histomorphometry was carried out on toluidine blue stained undecalcified sections of vertebrae and tibiae.

During lactation, both WT and *Ctgrp*-null mice demonstrate reduced trabecular thickness and increased trabecular separation, compared to non-pregnant mice of the same genotype, as well as high osteoclast and osteoid surfaces (OcS/BS and OS/BS). In lactating *Ctgrp*-null vertebrae and tibiae, OcS/BS was more than double that of WT (vertebrae: 13.9  $\pm$  2.2 vs 4.9  $\pm$  0.6%,  $p < 0.003$ ; tibiae: 24.5  $\pm$  4.3 vs 9.6  $\pm$  0.5,  $p < 0.01$ ). In contrast, osteoblast parameters were halved in *Ctgrp*-null vertebrae and tibiae compared to WT (vertebral osteoblast surface [ObS/BS]: 10.7  $\pm$  2.0 vs 20.4  $\pm$  2.9%,  $p < 0.03$ ; OS/BS: 11.7  $\pm$  2.3 vs 21.0  $\pm$  3.0,  $p < 0.04$ ). Large osteocytic lacunae consistent with osteocytic osteolysis were evident in both genotypes.

At weaning, the very high OcS/BS persisted in *Ctgrp*-null mice. However, between day 7 and 21 ObS/BS quadrupled in *Ctgrp*-null to 40.0  $\pm$  4.8%, and doubled in WT to 46  $\pm$  2.9%; similar changes were observed in osteoblast number and OS/BS.

Thus, we have confirmed upregulated osteoclast-mediated bone resorption and osteocytic osteolysis during normal lactation. Absence of calcitonin led to a greater increase in OcS/BS, consistent with elevated circulating PTH, but also led to a milder increase in ObS/BS vs WT. The sum of these differences may explain the more substantial bone loss in lactating *Ctgrp*-null mice. Moreover, *Ctgrp*-null mice retain the ability to upregulate osteoblast generation to a maximal level at the onset of weaning. This suggests that calcitonin normally dampens the effect of lactation on osteoclasts but not on osteocytic osteolysis, yet enhances the effect of lactation on osteoblasts, and is not required for skeletal recovery after lactation.

**Calcitonin Intramuscular Administration for Treating Acute Pain of Osteoporotic Vertebral Compression Fractures: A Randomized Controlled Trial.** T. Nakano\*. Orthopaedic Surgery, Tamana Central Hospital, Tamana, Japan.

Calcitonin products have an analgesic effect and vary greatly in dosage form and dose. The most common formulation of calcitonin used in the United States and European countries, etc. is a nasal spray administered on a daily basis, whereas in Japan and other East Asian countries, calcitonin therapy usually consists of intermittent intramuscular administration at relatively low doses such as 20 IU once weekly or 10 IU twice weekly. However, to date only a few clinical investigations regarding the analgesic effect of these calcitonin preparations have been conducted.

This study was designed to assess the usefulness of elcatonin, an eel calcitonin derivative, administered at 20 IU once weekly for pain relief in patients with osteoporosis who had lumbodorsal pain due to a new vertebral compression fracture. The study subjects were 78 hospitalized patients with a diagnosis of a new vertebral fracture based on MRI scan data. They were randomized either to receive elcatonin intramuscularly at 20 IU once weekly or to receive no calcitonin treatment. In these groups, other therapies included the use of a corset from the time of admission to the hospital, and also the use of non-steroidal anti-inflammatory drugs (NSAIDs) was allowed. Each patient was questioned regarding the intensity of pain at the time of getting up from a recumbent position, and the results were assessed using the visual analog scale (VAS). The inquiry to the patient using the VAS was performed by an independent member of the nursing staff who was unaware of the study being conducted.

The results of the study showed a significant reduction of the mean VAS score in patients treated with calcitonin at Week 2 of hospitalization as compared to that determined within 2 days of admission to the hospital, and the tendency remained at Weeks 3 and 4 of hospitalization. In patients with no calcitonin treatment, it was not until Week 4 that a significant decrease in the VAS score was observed; hence improvement of pain was attained earlier in the calcitonin-treated group.

The present data suggest that the therapeutic effect on pain associated with a new vertebral fracture is increased by concomitant use of elcatonin, compared to treatment with a corset and NSAIDs alone. In fact, it has been recognized that calcitonin has a mechanism of action mediated by the central serotonergic neurons, which is different from that of NSAIDs. The results of the study supported this finding.

This study has demonstrated the clinical efficacy of calcitonin intramuscularly administered at 20 IU once weekly for pain associated with osteoporosis-induced vertebral fracture, which has been widely used in the East Asia region.

**The Calcitonin Receptor on Osteoclasts Plays a Physiological Role to Protect Against Hypercalcaemia in Mice.** A. G. Turner\*<sup>1</sup>, F. Tjahjono\*<sup>1</sup>, W. S. M. Chiu\*<sup>1</sup>, A. J. Moore\*<sup>2</sup>, D. M. Findlay\*<sup>3</sup>, H. A. Morris\*<sup>2</sup>, J. D. Zajac\*<sup>1</sup>, R. A. Davey\*<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Melbourne, Austin Health, Heidelberg, VIC, Australia, <sup>2</sup>Hanson Institute, IMVS, Adelaide, Australia, <sup>3</sup>Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia.

We have recently demonstrated using a genetically modified mouse model in which the calcitonin receptor (CTR) is globally deleted (Global CTRKO), that the CTR plays a physiological role in protecting against induced hypercalcaemia (1). The aim of the present study was to further investigate the mechanism by which the CTR exerts this protective effect. To achieve this aim, we generated mice in which the CTR is deleted specifically within osteoclasts (OCL-CTR KO) using the Cre/loxP system. At 6 weeks of age, male and female OCL-CTR KO mice were fed a low calcium diet for 2 weeks after which hypercalcaemia was induced by treatment with 0.5 µg 1,25-dihydroxyvitamin D<sub>3</sub> on 2 consecutive mornings. Total serum calcium (Ca) levels were measured immediately prior to, and 45 and 50.5 hours post-first injection. OCL-CTR KO mice display a modest bone phenotype that is currently being examined. Trabecular bone volume/tissue volume (BV/TV) in the femur of female OCL-CTRKO was decreased by 17% at 6 weeks of age compared to controls (P<0.05) while BV/TV in male OCL-CTR KO was unaffected at 6 weeks of age. Furthermore, no differences were observed in baseline serum Ca and PTH levels between control and OCL-CTR KO genotypes at baseline, consistent with our hypothesis that the CTR on osteoclasts plays a modest physiological role in regulating bone and calcium homeostasis in the basal state. Peak serum total Ca levels at 50 hours following 1,25-dihydroxyvitamin D<sub>3</sub> induced hypercalcaemia were greater in male OCL-CTR KO by 31% (0.9mM) (P<0.05) compared to controls (Table 1).

Table 1: Total serum Ca levels in OCL-CTR mice versus controls, values are mM±SEM.

		0 hrs	45 hrs	50.5 hrs
Male	Control (n=7)	1.79±/-0.06	2.62±/-0.14	2.79±/-0.24
	OCL-CTR (n=5)	1.84±/-0.03	3.23±/-0.20	3.65±/-0.10
Female	Control (n=9)	1.86±/-0.04	2.96±/-0.16	3.18±/-0.16
	OCL-CTR (n=2)	1.78±/-0.01	3.55±/-0.19	3.85±/-0.08

The data for the female OCL-CTR KO is preliminary and experiments ongoing. We are currently investigating the mechanism for this increased hypercalcaemic response by

measuring bone formation markers, osteoclast number and X-laps, as well as the renal Ca handling. In conclusion, we have demonstrated that the biological role of the CTR to protect against induced hypercalcaemia in mice is primarily mediated via its action on osteoclasts.

**Low Serum Osteocalcin Predicts Carotid Plaques and Indicators of the Metabolic Syndrome.** E. Waern\*<sup>1</sup>, C. Ohlsson\*<sup>2</sup>, J. Kindblom\*<sup>2</sup>, U. Smith\*<sup>3</sup>, U. Lerner\*<sup>4</sup>, D. Mellström\*<sup>1</sup>. <sup>1</sup>Centre for Bone research at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>2</sup>Centre for Bone Research at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>3</sup>Dept of Internal Medicine at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>4</sup>Oral Cell Biology, Umea University, Umea, Sweden.

**Introduction:** The osteoblast-derived protein osteocalcin has recently been shown to affect adiposity and glucose homeostasis in mice, suggesting that the skeleton via an endocrine mechanism influences energy metabolism (Lee et al. Cell 130:456-469, 2007). The aim of the present study was to investigate the relation between serum osteocalcin and indicators of the metabolic syndrome.

**Methods and population:** 619 randomly selected 70 years old men and women participated in a longitudinal study with examinations at age 70, 76 och 86. BMD was measured in calcaneus with dual photon absorptiometry and osteocalcin was analysed by a double-antibody radioimmuno-assay. Serum was sampled after 10 hours fasting and non-smoking in the morning. Extra- and intracranial circulation was examined by means of duplex sonography and Transcranial Doppler techniques in 142 subjects at age 78.

**Results:** Osteocalcin correlated inversely to BMD and BMI in both sexes at all ages investigated (P<0.05). Osteocalcin increased by 44 percent from 70 to 86 years of age. This increase was related to, but independent of, declining kidney function (cystatin C) and increasing PTH. Serum osteocalcin (adjusted for BMI) correlated inversely to serum insulin r = -0.11 (p<0.01) and glucose r = -0.25 (p<0.0001).

A multiple regression model (diabetes excluded) with osteocalcin as dependent variable showed that glucose, (but not insulin), waist circumference and BMD were independent indirect predictors while PTH, cystatin C and ALP were independent direct predictors of osteocalcin (p<0.001).

Serum osteocalcin was inversely related to the risk of having bilateral carotid plaques (OR per SD increase in osteocalcin 0.68 (95% confidence interval 0.47-0.97)). The risk for stroke within 15 years after the age of 70 was increased in men with low serum osteocalcin (p<0.01).

Low osteocalcin increased the risk of having high waist circumference (Men > 102 cm, women > 88 cm; OR per SD increase in osteocalcin 0.77 (0.67-0.89)). In addition, low osteocalcin predicted one or more parameters of the metabolic syndrome (high waist circumference, BMI >30, high triglycerides, hypertension and diabetes; p<0.01).

**Conclusion:** Low serum osteocalcin predicts high glucose and carotid plaques and indicators of the metabolic syndrome.

Young\*<sup>4</sup>, I. Bab\*<sup>5</sup>, L. Sun\*<sup>2</sup>, M. Zaidi\*<sup>2</sup>, A. zallone\*<sup>1</sup>. <sup>1</sup>Department of Human Anatomy and Histology, University of Bari, Bari, Italy, <sup>2</sup>Mount Sinai Bone Program, Mount Sinai School of Medicine, New York, NY, USA, <sup>3</sup>Tohoku University Graduate School of Agricultural Science, Tohoku, Japan, <sup>4</sup>Center for Behavioral Neuroscience, Department of Psychiatry, Emory University School of Medicine, Atlanta, GA, USA, <sup>5</sup>Hadassah School of Medicine, Jerusalem, Israel.

Oxytocin, a hypothalamic neuropeptide secreted from the posterior pituitary, is indispensable for lactation. Mice lacking either oxytocin or its receptor (Oxtr) are thus unable to lactate, but deliver normally. Loss-of-function studies indicate further roles of oxytocin in the regulation of social behavior, memory, and food intake. Here, we show for the first time that oxytocin directly affects both components of bone remodeling, formation and resorption, and bone mass. Daily subcutaneous injections of oxytocin increase bone mass through a direct effect on osteoblastic bone formation, and also transiently elevate osteoclastogenesis. In contrast, oxytocin and Oxtr deficiency, including haploinsufficiency, cause a dramatic reduction in bone formation resulting in low-remodeling osteopenia. We find that the action of oxytocin is exerted directly on bone cells: preliminary studies reveal no effects of intracerebroventricular oxytocin on osteoclastogenesis or osteoblastogenesis in *ex vivo* bone marrow cell cultures. Oxytocin acts on osteoblasts to stimulate mineralization by enhancing BMP-2 expression, which, in turn, enhances Schnurri-3 causing an up-regulation of the transcription regulators *Osterix* and *ATF-4*. Oxytocin also promotes the production of the osteoclastogenic cytokine RANK-L, which consequently stimulates osteoclastogenesis indirectly. Finally, oxytocin directly stimulates osteoclast formation *via* the NF-κB and MAP kinase pathways, but paradoxically inhibits the

resorptive function of mature osteoclasts through  $\text{Ca}^{2+}$  signals that stimulate nitric oxide synthase (eNOS) to enhance NO production. We propose that oxytocin has a dominant stimulatory effect on bone formation to ensure optimal bone remodeling and appears indispensable for skeletal maintenance in both sexes. In females, the same hormone that controls parturition and lactation, we believe, facilitates the mobilization of calcium from bone, while protecting overt skeletal loss *via* a powerful bone-forming action. Finally, as oxytocin enhances bone mass, we envisage a therapeutic role for the nanopeptide in human osteoporosis.

## SA200

**Evidence Supporting the Necessity of UDP-N-acetyl-alpha-D-galactosamine-polypeptide N-acetylgalactosaminyl-transferase 3 (GalNac-T3) in the Processing of Fibroblast Growth Factor 23 (FGF23) in Humans.** R. I. Gafni, N. Bhattacharyya\*, J. S. Brahim\*, C. E. Dumitrescu\*, T. A. Theman\*, M. H. Kelly\*, A. A. Molinolo\*, M. T. Collins. NIDCR, National Institutes of Health, Bethesda, MD, USA.

FGF23, a protein produced primarily in bone, regulates phosphate and vitamin D homeostasis by enhancing phosphate excretion and suppressing 25-hydroxyvitamin D-1-alpha-hydroxylase in the kidney. This molecule circulates in intact and C-terminus forms, with most of the physiologic activities attributed to the intact molecule. Based on *in vitro* and animal studies, and observations in humans, the following model has evolved: 1) secretion of intact FGF23 requires O-linked glycosylation by GalNac-T3 and 2) without glycosylation, FGF23 is degraded intracellularly to the inactive C-terminus molecule by widely expressed subtilisin-like proprotein convertase(s) (PCSKs). Genetic conditions associated with increased intact FGF23 result in hypophosphatemic rickets/osteomalacia. Rarely, mesenchymal tumors produce excess FGF23 to cause tumor-induced osteomalacia (TIO). Conversely, mutations which decrease FGF23 or GalNac-T3 expression cause hyperphosphatemic tumoral calcinosis. However, direct evidence supporting the model that GalNac-T3 is present in tissues that produce both FGF23 and PCSKs in humans is lacking. We studied 8 tumors of various cell types (3 fresh frozen, 5 paraffin-embedded) from patients with TIO for the co-production of FGF23, GalNac-T3, and PCSKs. Immunohistochemistry staining was positive for both FGF23 (Immunotopics, San Clemente, CA) and GalNac-T3 (CellMab, Sweden); immunofluorescence demonstrated that FGF23 and GalNac-T3 were frequently co-expressed within the same cell. Expression of mRNA encoding FGF23, GalNac-T3 and several subtilisin-like proprotein convertases was detected by quantitative RT-PCR. Taken together, these findings suggest that the machinery necessary for post-translational modification of FGF23 is contained within these secretory tumors. The presence of GalNac-T3 in these physiologically relevant FGF23-producing tissues, and its co-expression with cells producing FGF23, support the hypothesis that GalNac-T3 is necessary for the processing of intact FGF23.

**High Expression of the Calcium/Phosphate-Regulating Hormone Stanniocalcin 2 Is Associated with Renal Calcification in the Klotho Mutant Mice.** Y. Takei\*, H. Yamamoto, M. Masuda\*, M. Fukaya\*, T. Sato, Y. Taketani, E. Takeda. Clinical Nutrition, University of Tokushima School of Medicine, Tokushima, Japan.

Stanniocalcin (STC) has been identified firstly from the corpuscles of stannius in bony fish as calcium/phosphate-regulating hormone. Two related mammalian stanniocalcin genes, STC1 and STC2, were found to be expressed in various tissues containing intestine, kidney and bone. Klotho mutant (KL) mice as known the model of precocious aging, have hypercalcemia, hyperphosphatemia and hypervitaminosis D and exhibit ectopic calcification of vascular media, gastric wall, alveolar wall and kidney. Importantly, recent studies found that the klotho plays as the regulator of fibroblast growth factor-23 (FGF23) signaling and phosphate/calcium homeostasis. It was also previously reported that renal STC2 gene expression was increased in KL mice. However, the regulatory mechanism of STC2 expression through FGF23/Klotho signaling and the physiological role of STC2 in KL mice remains unclear. In this study, we investigated the regulation of STC2 gene expression and its localization in kidney of wild-type (WT) and KL mice. At six weeks old, Real-Time PCR analysis revealed that the mRNA levels of STC2 in kidney were significantly upregulated in KL mice compared with WT mice, while renal STC1 mRNA levels were no significant alteration. We next performed immunohistochemical analysis to clarify the localization of STC2 in kidney. The focal expression of STC2 was observed in KL mice but not WT mice. In addition, we analyzed renal calcification by von kossa stain, thus ectopic calcification of glomerulus and small artery in the renal parenchyma were detected in KL mice but not WT mice. Interestingly, high expression of STC2 was colocalized with renal calcification in KL mice. These data suggested that highly STC2 expression might be associated with renal calcification in the KL mice.

**Fibroblast Growth Factor 23 (FGF-23) in Vitamin D Deficient Older Persons.** P. Lips<sup>1</sup>, J. E. Dijkstra<sup>\*2</sup>, N. van Schoor<sup>\*3</sup>, M. Lomecky<sup>\*2</sup>, V. Chel<sup>\*3</sup>, M. Vervloet<sup>\*4</sup>, H. Dijkstra<sup>\*2</sup>. <sup>1</sup>Department of Endocrinology, VU University Medical Center, Amsterdam, Netherlands, <sup>2</sup>Department of Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands, <sup>3</sup>EMGO Institute, VU University Medical Center, Amsterdam, Netherlands, <sup>4</sup>Department of Nephrology, VU University Medical Center, Amsterdam, Netherlands.

The phosphatonin FGF-23 promotes phosphate excretion and suppresses renal 1 $\alpha$ -hydroxylase leading to low serum 1,25(OH)2D in patients with hypophosphatemic osteomalacia. FGF-23 accumulates with renal failure. The objective of this study was to investigate whether FGF-23 plays a role in the decreased conversion of 25(OH)D into 1,25(OH)2D in older persons with vitamin D deficiency and decreased renal function. Subjects were 39 nursing home residents participating in a vitamin D supplementation study, mean age (SD) 84 years (6.3). Serum 25(OH)D and 1,25(OH)2D were measured by RIA (Diasorin and IDS). C-terminal FGF-23 was measured by ELISA (Immunotopics, San Clemente, CA) interassay CV < 10%. All data are from baseline. Results were: median (25-75<sup>th</sup>) 25(OH)D 20 nmol/l (14-34), 1,25(OH)2D 50.5 pmol/l (40.3-77.1) FGF-23 60.4 RU/ml (24.0-66.4) and mean (SD) calcium 2.33 (0.11) mmol/l, phosphate 1.01 mmol/l (0.13), albumin 33.6 g/l (3.1), creatinine 99  $\mu$ mol/l (18). Significant correlations were observed between serum 25(OH)D and 1,25(OH)2D (R = 0.59, p < 0.01), serum 25(OH)D and creatinine (R = 0.42, P < 0.01) and serum 25(OH)D and albumin (R = 0.35, P < 0.05). There was no relationship between serum FGF-23 and vitamin metabolites, phosphate or creatinine. When serum 25(OH)D was dichotomized in levels < 25 and > 25 nmol/l, there was no difference in FGF-23. The low serum 1,25(OH)2D and strong relationship between serum 25(OH)D and serum 1,25(OH)2D confirms the substrate-dependent synthesis of 1,25(OH)2D in vitamin D deficient older persons. These data do not support a role for FGF-23 in the decreased renal synthesis of 1,25(OH)2D in older persons.

**Rapid Detection of Intact FGF-23 in Tumor Tissue from Patients with Oncogenic Osteomalacia.** M. Mannstadt<sup>1</sup>, C. Lorente<sup>\*2</sup>, H. Jüppner<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Dept. Oral & Maxillofacial Surgery, Massachusetts General Hospital and Harvard Vanguard Medical Associates, Boston, MA, USA.

Oncogenic osteomalacia (OOM) is a rare tumor-induced disease characterized by hypophosphatemia due to decreased renal threshold of phosphate reabsorption, low 1,25-dihydroxyvitamin D concentrations and osteomalacia. The localization of OOM tumors, which often produce excess amounts of the phosphaturic hormone fibroblast growth factor-23 (FGF-23), can be difficult and confirmation of successful tumor removal may require prolonged post-operative observation until normalization of serum parameters is documented. Here, we report the modification of a commercially available intact FGF-23 assay, which enabled us to rapidly document high FGF-23 content in OOM tumor extracts. The assay takes less than 30 minutes to complete and visual inspection of the test plate is sufficient to distinguish positive from negative samples, therefore allowing fast intra-operative assessment of FGF-23 content in OOM tumor extracts. Several tumors from patients with proven OOM and control tissue were studied. Simple aqueous extracts from small amounts of tumor tissue were prepared and FGF-23 content was evaluated using a commercially available two-site ELISA (Immunotopics) that detects intact FGF-23. The assay was performed according to the manufacturer's recommendations ("standard assay"), which takes about four hours, or with shortened incubation times ("rapid assay"), which takes 30 minutes. Extracts from bone and an ovarian tumor served as controls. When measured by the standard assay, extracts from OOM tumors, but not from control tissues, were shown to contain large amounts of intact FGF-23 (3,600 to >11,000 pg/ml). The rapid FGF-23 assay unequivocally documented high FGF-23 concentrations in all OOM tumor extracts. In summary, simple aqueous extracts from small portions of six different OOM-associated tumors revealed very high FGF-23 concentrations as assessed by the standard assay, which were also readily detectable by a modified rapid test that takes less than 30 minutes to complete. Similar to intraoperative PTH assays, this rapid assay could thus potentially be performed in or near the operating room, especially since visual inspection of the test plate was sufficient to detect FGF-23 in all six tumors tested. The assay may furthermore help define, intra-operatively, the disease-free margins of tumors located in areas that are difficult to access surgically.

**FGF23 and FGF2 Share a Common but Also Have Distinct Signaling Pathways for Negative Regulation of Bone Nodule Mineralization in Cultured Osteoblasts.** T. Minamizaki<sup>1</sup>, Y. Yoshiko<sup>1</sup>, S. Suzuki<sup>\*1</sup>, J. E. Aubin<sup>2</sup>, N. Maeda<sup>\*1</sup>. <sup>1</sup>Oral Growth & Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, <sup>2</sup>Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada.

Fibroblast growth factor 23 (FGF23) is primarily expressed in osteoblasts/osteocytes and suppresses renal phosphate reabsorption and vitamin D metabolism via the circulation. FGF23 is also targeted to the parathyroid where it suppresses PTH production. Klotho forms a complex with FGF23-FGF receptor (FGFR), which appears to be necessary for FGF23-specific signaling in both tissues. Recently, we established that adenoviral overexpression of FGF23 in the rat calvaria (RC) cell/organ culture models inhibits osteoblast differentiation and bone formation, suggesting that FGF23 acts on bone in an autocrine/paracrine manner independently of its systemic effect on phosphate homeostasis. Similarly to adenoviral overexpression of FGF23, we found that treatment of RC osteoblasts with recombinant FGF23 (rFGF23) impaired bone nodule mineralization, and recombinant (rKlotho) was required for the rFGF23 effect under serum-deprived conditions. RC osteoblasts express only very low levels of Klotho, but Klotho (the secreted membrane isoform, sKlotho) is present in FCS. Removal of sKlotho from FCS by immunoprecipitation eliminated the rFGF23 effect. Consistent with these data, Klotho was detectable by immunofluorescence in RC osteoblasts grown under serum-deprived conditions supplemented with rFGF23 in combination with rKlotho but not without rKlotho. Moreover, FGF23 and FGFR1 were co-immunoprecipitated by anti-FGFR1 and anti-Klotho respectively, only when RC osteoblasts were co-treated with rFGF23 and rKlotho under serum-deprived conditions. These results suggest that FGF23 may act on osteoblasts when circulating sKlotho is present. Not only co-treatment with rFGF23 and rKlotho, but also treatment with rFGF2 alone suppressed matrix mineralization via FGFR1 and ERK activation, and both FGF23 and FGF2 stimulated early growth response-1 mRNA expression. However, FGF23 but not FGF2 is differentially expressed during bone nodule mineralization and is directly regulated by 1,25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>)-occupied vitamin D receptor at the transcriptional level. Thus, both the non-canonical FGF23 and the canonical FGF2 may act as local factors in bone at least in part via a common ERK signaling pathway. However, activity of FGF23 but not FGF2 may be regulated by circulating sKlotho and 1,25(OH)<sub>2</sub>D<sub>3</sub>, suggesting specificity of regulatory pathways of FGF family members in bone formation and mineralization.

**Significance of O-linked Glycosylation of FGF23 Protein.** H. Suzuki<sup>\*</sup>, N. Ito, S. Fukumoto, T. Fujita<sup>\*</sup>. Division of Nephrology & Endocrinology, Department of Medicine, University of Tokyo Hospital, Tokyo, Japan.

FGF23 is a physiological humoral factor regulating phosphate and vitamin D metabolism. Previous studies indicated that a part of FGF23 protein is proteolytically cleaved between <sup>179</sup>Arg and <sup>180</sup>Ser into inactive fragments by an enzyme that recognize <sup>176</sup>Arg-X-X-<sup>179</sup>Arg motif. In addition, FGF23 protein has three O-glycan chains at <sup>171</sup>Thr, <sup>178</sup>Thr and <sup>200</sup>Thr. We have shown that these three O-glycans are serially attached to FGF23 protein, first at <sup>200</sup>Thr, then at <sup>171</sup>Thr and finally at <sup>178</sup>Thr. The attachment of the O-glycan chain to <sup>178</sup>Thr was shown to prevent the processing of FGF23 protein. However, the significance of O-glycan chains at <sup>171</sup>Thr and <sup>200</sup>Thr remains unclear. Therefore, we analyzed the mutant FGF23 proteins which lack O-glycan chains at <sup>171</sup>Thr and <sup>200</sup>Thr in this study. FGF23(Arg176Gln, Arg179Gln) protein is resistant to the processing. Introduction of Thr178Ala mutation into this FGF23(Arg176Gln, Arg179Gln) did not change the presence of FGF23 protein with O-glycan at <sup>171</sup>Thr analyzed by Western blotting. In contrast, the FGF23 protein with O-glycan at <sup>178</sup>Thr disappeared by the introduction of Thr171Ala mutation. Therefore, O-glycosylation at <sup>171</sup>Thr seems to be necessary for the attachment of O-glycan at <sup>178</sup>Thr and thereby preventing the processing of full-length FGF23. The introduction of Thr200Ala mutation did not modify FGF23 proteins with O-glycans at <sup>171</sup>Thr and <sup>178</sup>Thr indicating that the O-glycan at <sup>200</sup>Thr does not affect O-glycosylation at <sup>171</sup>Thr and <sup>178</sup>Thr. Therefore, we then analyzed biological activity of the mutant FGF23 protein by reporter assay of early growth response-1 (Egr-1) gene in cells expressing Klotho. FGF23 without O-glycan at <sup>200</sup>Thr showed less activity compared to that of wild-type FGF23 suggesting that O-glycosylation at <sup>200</sup>Thr enhances the receptor activation by full-length FGF23. Collectively, these results indicate that O-glycans of FGF23 protein contribute to the increased activity of FGF23 either by preventing proteolytic processing or by enhancing the ability of full-length FGF23 to induce intracellular signaling.

## SA209

**The Effect of Treating Vitamin D Deficiency on FGF23 Levels in Humans.** S. M. Burnett-Bowie, B. Z. Leder, M. P. Henao<sup>\*</sup>, N. T. Mendoza<sup>\*</sup>, J. S. Finkelstein. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

**Background:** Fibroblast growth factor 23 (FGF23) is a phosphate (PO<sub>4</sub>)-regulating hormone that promotes renal PO<sub>4</sub> wasting and suppresses 1,25-dihydroxyvitamin D (1,25(OH)<sub>2</sub>D) production. Dietary PO<sub>4</sub>, serum PO<sub>4</sub>, and 1,25(OH)<sub>2</sub>D appear to regulate FGF23 secretion. Specifically, 1,25(OH)<sub>2</sub>D stimulates FGF23 production. It is not known, however, if FGF23 is regulated by 25-hydroxyvitamin D (25OHD), the more stable metabolite of vitamin D. Furthermore, the impact of treating vitamin D deficiency on circulating FGF23 is unknown.

**Methods:** 90 healthy men and women aged 18-45, with 25OHD ≤ 20 ng/mL and normal serum calcium (Ca) were randomized to ergocalciferol 50,000 international units or matching placebo (PBO) weekly for 12 weeks. Subjects consumed 1000-1500 mg of Ca daily. FGF23 (Kainos, Tokyo, Japan), 25OHD, 1,25(OH)<sub>2</sub>D, serum and urinary PO<sub>4</sub>, serum and urinary Ca, and PTH were measured at weeks 0, 4, 8 and 12. The primary endpoint was the change in FGF23 between groups. Data are presented as mean±SE in the figure and mean±SD in text.

**Results:** Subjects were well matched at baseline. 25OHD levels increased from 14±3 ng/mL at baseline to 46±17 ng/mL at week 12 with treatment but were unchanged with PBO (15±4 ng/mL at baseline to 18±10 ng/mL at week 12) (p<0.001). Urinary PO<sub>4</sub> excretion increased from 11±5 % at baseline to 13±6 % at week 12 (p=0.04) with treatment but was unchanged with PBO. Serum PO<sub>4</sub> and Ca, however, did not change with the intervention. Serum FGF23 increased significantly with treatment from 49±14 pg/mL at baseline to 83±35 pg/mL at week 12 but was unchanged with PBO (43±33 pg/mL at baseline to 43±26 pg/mL at week 12) (p<0.001). 1,25(OH)<sub>2</sub>D, PTH and urinary Ca will be presented.

**Conclusions:** Correction of vitamin D deficiency with high dose ergocalciferol significantly increases circulating serum FGF23, in the absence of any change in serum PO<sub>4</sub>. The observed increase in FGF23 is associated with an increase in urinary PO<sub>4</sub> excretion. While dietary PO<sub>4</sub> is generally well absorbed, the observed increase in urinary PO<sub>4</sub> excretion may be a result of increased dietary PO<sub>4</sub> absorption from the correction of vitamin D deficiency. Moreover, these data suggest that 25OHD, or one of its metabolites, has a direct stimulatory effect on circulating FGF23 that is independent of serum PO<sub>4</sub>. Future measurement of 1,25(OH)<sub>2</sub>D levels will help differentiate the effects of 25OHD from 1,25(OH)<sub>2</sub>D on circulating FGF23.

**Regulation of Renal Klotho: The Importance of ER $\alpha$ .** O. K. Oz<sup>1</sup>, A. Hajibeigi<sup>\*1</sup>, K. Korach<sup>\*2</sup>, P. Chambon<sup>\*3</sup>, J. Zerwekh<sup>4</sup>. <sup>1</sup>Radiology, UT Southwestern Medical Center at Dallas, Dallas, TX, USA, <sup>2</sup>Environmental Disease Medicine Program, NIEHS/NIH, Research Triangle Park, NC, USA, <sup>3</sup>Physiological Genetic, Inserm, U-596 / CNRS, UMR7104 / Universit  Louis Pasteur, Illkirch, Strasbourg, France, <sup>4</sup>Internal Medicine, UT Southwestern Medical Center at Dallas, Dallas, TX, USA.

The klotho gene was initially identified in mice harboring a mutation that was associated with several ageing phenotypes including shortened life span, sterility, arteriosclerosis, skin atrophy, muscle atrophy, osteoporosis and abnormal calcium re-absorption. The klotho gene encodes two forms of protein, a type I single transmembrane 130Kda glycoprotein with  $\beta$ -glycosidase activity and a splice variant lacking the transmembrane domain. Full-length klotho is predominantly expressed in tissues involved in calcium homeostasis, such as kidney, parathyroid glands and choroids plexus in the brain while the secreted form is found in the blood and cerebrospinal fluid. In a recently published study, we showed that the expression of klotho in the kidney of aromatase deficient (ArKO) mice was up-regulated both at the mRNA and protein levels when compared to wild type (WT) animals. Treatment with estradiol lowered klotho levels to WT levels. In the present study we further examined estrogen regulation of renal klotho in both in vitro and in vivo models. In vitro a mouse DCT cell line was grown in FBS or charcoal stripped FBS without or with estrogen as a model of estrogen deficiency or repletion. In vivo we used mutant mice lines (n=3-6 per group) lacking estrogen action through the AF-1 domain of the ER $\alpha$  (ERKO $\alpha$ AF-1/-) or completely lacking estrogen action through ER $\alpha$  knockout (ERKO $\alpha$ ). Finally, we compared the expression of renal klotho between male and female wild-type mice. Klotho expression in kidney homogenates or cell lysates was determined by western blot. The expression of klotho in the DCT cell lysates was increased in cells grown in 10%csFBS compared to FBS. Addition of estrogen to the csFBS decreased klotho levels. In both mutant mouse lines renal klotho expression was significantly higher than wild type. Interestingly, the male WT mice had higher klotho levels than female WT mice. In conclusion our results clearly indicate that in the kidney or a DCT cell line, estrogen down-regulates the expression of klotho. Since the complete and the AF-1 domain ER $\alpha$  knockout are estrogen replete and both show elevated klotho, the data suggest that the AF-1 domain is important for estrogen mediated down regulation of renal klotho.

**Parathyroidectomy Improves Quality of Life in Hemodialysis Patients with Severe Secondary Hyperparathyroidism.** P. G. S. Lacativa<sup>\*1</sup>, F. M. Franco<sup>\*1</sup>, C. H. Torres<sup>\*1</sup>, P. J. M. Patricio Filho<sup>\*2</sup>, M. D. C. Goncalves<sup>\*3</sup>, M. L. F. Farias<sup>1</sup>. <sup>1</sup>Endocrinology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, <sup>2</sup>Nephrology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, <sup>3</sup>Surgery, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Severe secondary hyperparathyroidism (HPT2) associated with end-stage renal disease (ESRD) leads to several complications that can affect quality of life. Total parathyroidectomy with autologous transplantation (PTX) is an alternative to revert hyperparathyroidism in those patients not submitted to renal transplantation. The aim of this study was to quantify the impact of the severe hyperparathyroidism and of PTX on quality of life. Nineteen patients with severe HPT2, age 42  $\pm$  15 years, were studied before (pre-PTX, mean serum PTH 2434  $\pm$  1821 pg/ml) and one year after parathyroidectomy (post-PTX, mean serum PTH 73  $\pm$  67 pg/ml) and compared with thirty-eight age-matched ESRD patients whose mean PTH was 108  $\pm$  86 pg/ml (control). All patients were maintained on chronic hemodialysis throughout the study. SF-36 questionnaires were used to evaluate quality of life. Pre-PTX patients had significantly lower functional status scores than control patients concerning physical function (30.8  $\pm$  28 vs. 54.6  $\pm$  26.6), physical role limitations (14.5  $\pm$  26.7 vs. 42.8  $\pm$  40), bodily pain (36.3  $\pm$  30.2 vs. 58.7  $\pm$  26.8), vitality (37.6  $\pm$  25.6 vs. 58  $\pm$  21.2) and emotional role limitations (26.3  $\pm$  41 vs. 55.3  $\pm$  44). Refractory bone pain was the only symptom related to the functional status deficits in multivariate regression analysis. Parathyroidectomy had a great impact in symptoms relief, especially bone pain, and improved all functional status deficits scores to the levels found in control patients. We conclude that severe HPT2 causes functional status deficits in daily physical activities, vitality and emotional problems, which are closely related to refractory bone pain. The surgical cure of hyperparathyroidism is effective in reverting pain and therefore has a great and positive impact in health status, allowing patients to recover the expected quality of life of ESRD individuals.

**Effects of Intermittent Human Parathyroid Hormone Administration on Bone Union with Hydroxyapatite Blocks at the Site of Cancellous Bone Osteotomy in Ovariectomized Rats.** K. Kamo, N. Miyakoshi, Y. Kasukawa, K. Nozaka<sup>\*</sup>, H. Sasaki, Y. Shimada<sup>\*</sup>. Akita University School of Medicine, Akita, Japan.

Although hydroxyapatite (HA) blocks have been widely used for reconstruction of bone defects, bone union with HA blocks is often delayed in osteoporotic patients. Intermittent administration of human parathyroid hormone (h-PHT) accelerates fracture healing by increasing callus formation at cortical bone and enhances bone union at the site of cancellous bone osteotomy in ovariectomized (OVX) rats. However, little is known about the effects of hPTH on bone union with HA blocks. The aim of this study was to evaluate whether h-PTH enhances bone union with HA blocks at the site of cancellous bone osteotomy in OVX rats. Following sham or OVX operation in 7-month-old female Sprague-Dawley rats, complete mid-sagittal osteotomy from the knee joint to the tibial diaphysis was performed. An HA block was then placed into the osteotomy site and fixed with cerclage wiring. Postoperatively, hPTH (100  $\mu$ g/kg) or vehicle only was administered subcutaneously once a week for 8 weeks (n=3-6 per group). Tibiae were harvested 1 week after last injection and bone histomorphometry at the site of osteotomy with HA blocks was performed to evaluate bone volume (BV/TV), osteoid surface (OS/BS), eroded surface (ES/BS), mineral apposition rate (MAR), bone formation rate (BFR/BS) and percentage of bone union with HA block. PTH treatment significantly increased BV/TV (107%, p<0.01), MAR (72%, p<0.01) and BFR (115%, p<0.05) in OVX rats compared to vehicle-treated controls. PTH did not significantly increase bone union with HA blocks in sham-operated rats. The percentage of bone union with HA blocks in OVX rats was increased (79%) by PTH treatment compared to vehicle-treated controls, but not significantly. Intermittent administration of hPTH stimulated bone formation and increased bone volume at the cancellous osteotomy site placed with HA blocks. Treatment with hPTH tended to stimulate bone union with HA blocks in OVX rats.

**PTHrP Is Processed by Skin Keratinocytes and Has Immunomodulation Properties.** L. Deftos<sup>1</sup>, D. Burton<sup>1</sup>, C. Chalberg<sup>\*1</sup>, K. Smith<sup>\*1</sup>, S. Tu<sup>\*1</sup>, R. Dorschner<sup>\*2</sup>, R. Gallo<sup>\*2</sup>. <sup>1</sup>Medicine, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, <sup>2</sup>Dermatology, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA.

Our recent appreciation of the immunomodulatory effects of PTHrP in keratinocytes sheds new light on the biology of this polypeptide. It is our overall hypothesis that the robust expression of PTHrP in keratinocytes is accompanied by processing of its three polypeptide isoforms into tissue-specific peptides with distinct biological effects that regulate the innate immune system.

In this study, we used an immortalized human keratinocyte cell line (HaCaT) to investigate the processing of PTHrP. Through size exclusion chromatography, westerns, and the use of multiple PTHrP antibodies, we showed the immunochemical and size heterogeneity of PTHrP in HaCaT keratinocytes, providing evidence for its processing in this cell. To further characterize the processed forms, we immunoprecipitated HaCaT conditioned media with N-terminal PTHrP antibody (1A5) coated beads followed by MALDI-TOF of the eluted fractions. We demonstrated several novel keratinocyte PTHrP species, consistent in masses with human PTHrP 3-30, 3-35, 9-39, and 10-36. We previously showed the biological effects of PTHrP in skin include upregulation of the antimicrobial peptide, cathelicidin, made by keratinocytes. To determine if PTHrP can act directly as an antimicrobial, we evaluated synthetic PTHrP peptides for direct antimicrobial effects on *Staphylococcus aureus* growth. While each of the peptides demonstrated some activity, PTHrP140-173 was the most potent and even more potent than the cathelicidin peptide, LL-37.

In summary, these data identify a novel role for keratinocyte-derived PTHrP in the immune defense of skin. The biological studies of PTHrP peptides and the known interactions of PTHrP with vitamin D indicate that PTHrP has a role in the innate defense system of skin against microbes and other invading agents. Our overall aim is to elucidate the molecular products and pathways of PTHrP processing and to identify the biological effects of these cellular mechanisms in keratinocyte immune function in vitro and in vivo.

**At Similar Plasma 25-hydroxyvitamin D Levels, Fat Mass Influence PTH Levels in the State of Vitamin D Insufficiency.** L. Rejnmark, P. Vestergaard, L. Mosekilde. Dept. of Endocrinology and Metabolism C, Aarhus University Hospital, Aarhus, Denmark.

A relationship may exist between bone and fat metabolism. Adiposity is associated with increased PTH levels, which have been attributed to secondary hyperparathyroidism due to low plasma 25-hydroxyvitamin D (25OHD) levels. In order to further characterise this relationship, we studied PTH levels stratified by vitamin D status and body mass index (BMI).

In a cross-sectional design, we studied 1097 recent postmenopausal women recruited from the local background population. Subjects were divided into tertiles of 25OHD levels and within each vitamin D tertile we studied whether PTH levels differ according to tertiles of BMI. Results were adjusted for age, daily calcium intake, and smoking. We also determined body composition by DXA.

Within each 25OHD tertile, mean 25OHD levels did not differ according to BMI tertiles. PTH decreased with increased 25OHD levels. In the lowest vitamin D tertile (25OHD < 47nmol/l) PTH levels were significantly higher (4.3 pmol/l) than in the mid (4.0 pmol/l) and in the highest (3.7 pmol/l) 25OHD tertile. Within each vitamin D tertile, PTH levels increased significantly with increased BMI i.e., in the lowest 25OHD tertile those in the highest BMI tertile (>26kg/m<sup>2</sup>) had significantly higher PTH levels (4.3 pmol/l) than those with a BMI in the mid (4.1 pmol/l), or in the lowest (3.9 pmol/l) BMI tertile. Similarly, in the mid 25OHD tertile (25OHD 47-73nmol/l) PTH levels were 4.4, 3.9, and 3.7 pmol/l in the highest, mid and lowest BMI tertile, respectively. A similar relationship existed in the highest 25OHD tertile. However, after adjustments the significant relationship only remained within the lowest and mid 25OHD tertile, whereas BMI did not affect PTH levels in subjects with 25OHD levels above 73 nmol/l. Performing the analyses with tertiles of total fat mass instead of BMI revealed similar results, whereas lean tissue mass did not affect PTH levels. Accordingly, in vitamin D insufficiency (in this setting at 25OHD levels < 73 nM) PTH levels are - at similar 25OHD levels - influenced by the size of the total fat mass, whereas no such relationship seems to exist in the state of a sufficient vitamin D status. Further studies are needed to determine the mechanism of action by which fat tissue increases PTH levels or whether PTH by itself may increase fat mass.

**Role of the Transcription Factor SOX4 in the Skeletal Response to Intermittent PTH.** D. D. Pierroz<sup>1</sup>, L. S. Nissen-Meyer<sup>2</sup>, S. L. Ferrari<sup>1</sup>. <sup>1</sup>Div of Bone Diseases, Geneva University Hospital and Faculty of Medicine, Geneva, Switzerland, <sup>2</sup>The Biotechnology Centre, University of Oslo, Oslo, Norway.

SOX4 is a transcription factor that is also expressed in the embryonic growth plate and in osteoblast-like cells. Homozygous mice die in utero from cardiac failure. We previously reported that heterozygous SOX4<sup>+/-</sup> mice have decreased BMD, cancellous and cortical microarchitecture and mineral apposition rate (1). Furthermore, bone biopsies from patients with primary hyperparathyroidism show increased SOX4 mRNA expression compared to parathyroidectomized patients, whereas PTH treatment of osteoblastic cells increases SOX4 mRNA. This led us to hypothesize that SOX4 is involved in the bone anabolic response to PTH. For this purpose, 12-week-old female wild type (WT) and Sox4<sup>+/-</sup> mice were treated with hPTH 1-34 (40 ug/kg/d) for 6 weeks or vehicle (veh) (n=9-12mice/goup). Bone mineral density and vertebral and femoral microarchitecture were evaluated by DXA and micro-CT, respectively, and bone turnover by serum biochemical markers.

In WT, PTH treatment significantly increased BMD at total body (TB) (+6.5%), spine (Sp) (+2.4%), and midshaft femur (Fem) (+8.6%) compared to veh (p<0.05). Similar BMD gains were observed in SOX4<sup>+/-</sup> mice (TB:+7.3%, Sp:+12.1%, Fem:+8.3%, p<0.05). Femur cortical thickness (CTh) and bone area (BA) were also similarly increased by PTH in WT and Sox4<sup>+/-</sup> (CTh:+7.2% and +7.6%, respectively; BA:+7.3% and +10.9%, respectively, compared to vehicle, p<0.05). Moreover, no differences were observed between WT and SOX4<sup>+/-</sup> mice on vertebral and distal femur trabecular bone volume fraction (BV/TV), connectivity-density, and trabecular thickness (TbTh) in response to PTH. PTH treatment significantly increased osteocalcin levels (+30%, p<0.006) in both genotypes, whereas CTX levels decreased similarly in SOX4<sup>+/-</sup> and WT, independent of PTH.

Thus, haploinsufficient SOX4<sup>+/-</sup> adult mice have a low bone mass and microarchitecture but responded adequately to intermittent PTH. Taken together with the evidence that PTH upregulates SOX4 expression in vivo and in vitro, these observations suggest that the level of SOX4 expression achieved in these mice was sufficient to maintain PTH activity on osteoblasts.

**Dominant Tissue Accumulation of MIBI in Parathyroid Glands in Uremic Rats.** Y. Imanishi<sup>1</sup>, H. Sano<sup>\*1</sup>, H. Hasegawa<sup>\*2</sup>, Y. Funase<sup>\*2</sup>, H. Kasahara<sup>\*2</sup>, T. Minamizawa<sup>\*2</sup>, M. Inaba<sup>1</sup>, T. Miki<sup>3</sup>, Y. Nishizawa<sup>1</sup>. <sup>1</sup>Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, <sup>2</sup>FUJIFILM RI Pharma Co., LTD., Tiba, Japan, <sup>3</sup>Geriatrics and Neurology, Osaka City University Graduate School of Medicine, Osaka, Japan.

Little is known about the mechanisms of parathyroid imaging by <sup>99m</sup>Tc sestamibi or MIBI, although MIBI is one of the most useful image analyses of enlarged parathyroid glands. MIBI accumulation in parathyroid tissue was investigated in 5/6-nephrectomized uremic rats, exhibiting secondary hyperparathyroidism. 5MBq of MIBI was administered to the rats from tail vein, followed by sacrifices of the rats and corrections the tissues such as parathyroid, thyroid, neck muscle tissues and blood in 2 hours. The <sup>99m</sup>Tc radioactivity of parathyroid glands of uremic rats was significantly 2.2-fold higher than that of sham-operated rats. The radioactivity in parathyroid glands of uremic rats was almost same as that of sham rats, when compared with the radioactivity per parathyroid gland weight, suggesting that <sup>99m</sup>Tc accumulation in parathyroid cells was not affected by uremia and secondary hyperparathyroidism. The radioactive ratio of parathyroid glands to thyroid glands increased 1.2-fold in uremic rats compared to sham rats. These finding suggested that the mechanisms of parathyroid imaging by MIBI in uremia were partly by increased parathyroid gland volume and the enhanced contrast of radioactivity to thyroid glands.

**The C-terminal Fragment of Parathyroid Hormone-Related Protein, PTHrP (107-139), Exerts Osteogenic Features in Both Regenerating and Nonregenerating Bone in Mice with Diabetes-Related Osteopenia.** D. Lozano<sup>\*1</sup>, L. F. de Castro<sup>\*1</sup>, E. Gómez-Barrena<sup>\*2</sup>, S. Dapia<sup>\*3</sup>, F. Manzarbeitia<sup>\*4</sup>, P. Esbrit<sup>1</sup>. <sup>1</sup>Bone and Mineral Metabolism Laboratory, Fundación Jiménez Díaz, Madrid, Spain, <sup>2</sup>Dpt. of Traumatology, Fundación Jiménez Díaz, Madrid, Spain, <sup>3</sup>Trabeculae (R), S.L., Parque Tecnológico de Galicia, Orense, Spain, <sup>4</sup>Pathology Dept., Fundación Jiménez Díaz, Madrid, Spain.

Type 1 diabetes mellitus (DM) is associated with bone loss. Osteoblastic expression of parathyroid hormone-related protein (PTHrP) -an important modulator of osteoblast differentiation- decreases in age-related osteopenia. The role of C-terminal PTHrP -unrelated to PTH- on bone is currently controversial. We here examined the putative osteogenic effects of PTHrP (107-139) in a mouse model of streptozotocin (STZ)-induced diabetes. In STZ-DM and control mice, bone regeneration was induced by marrow ablation in both tibiae. The intact femurs were used as nonregenerating bone controls. Some diabetic mice were treated with PTHrP (107-139) (100 µg/Kg/every other day, s.c.) for one week before and 6 days after marrow ablation, and then sacrificed. One tibia was decalcified and included in paraffin for histological evaluation. MC3T3-E1 cells were grown in differentiation medium (a-MEM; 50 µg/ml ascorbic acid, 10 mM β-glycerolphosphate, 10% FBS), with or without high glucose (HG) (25 mM) (or mannitol, osmotic control), supplemented (or not) with 100 nM PTHrP (107-139). Gene expression was analyzed by real-time PCR after total RNA isolation. STZ-DM mice had weight loss (15%). Evaluation of femoral bone structure in these mice by µCT demonstrated a 40% decrease in trabecular number and BV/TV and a 20% increase in trabecular SMI, and no cortical changes, compared to those in control mice. This was associated with a decrease (50-80%) in the gene expression of PTHrP and vascular endothelial growth factor (VEGF), and the RANKL/OPG ratio. In the the regenerating tibia, STZ-DM mice showed a dramatic increase in adipocyte number (10-fold over control), and a 30% decrease in osteoblast number and osteoid surface at the metaphysis. This was related to a decrease (20-40%) in the expression of the aforementioned genes, and also in that of runx2, osterix, osteocalcin, and the PTH1 receptor, and an increase in PPAR-γ2. All of these effects were reversed by PTHrP (107-139) treatment at both bone sites. In vitro, either HG- or mannitol-containing medium induced similar changes in gene expression of the aforementioned factors; all which were also reversed by PTHrP (107-139) in the culture medium. In conclusion, PTHrP (107-139) can induce osteogenic effects in a mouse model of STZ-induced diabetes. These in vitro findings further support that this PTHrP fragment has potential anabolic effects in osteoblastic cells

**Dominant-negative GCMB Mutants Causing Autosomal-Dominant Hypoparathyroidism - Protein Expression and Cellular Localization.** M. Mannstadt<sup>1</sup>, S. R. Pulusani<sup>\*1</sup>, C. Silve<sup>2</sup>, H. Jüppner<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Inserm u561, Hôpital Saint Vincent de Paul, Université Paris 5, UFR Médicale, Paris, France.

Hypoparathyroidism (HP) is characterized by levels of parathyroid hormone (PTH) insufficient to maintain normal serum calcium concentrations. HP occurs as a sporadic disease or as a familial disorder, and may present as a familial isolated form. Autosomal dominant HP (AD-HP) can be caused by heterozygous activating mutations in the genes encoding PTH or glial cells missing B (GCMB), a transcription factor specific for the parathyroid gland. Homozygous loss-of-function mutations of GCMB in humans and null mutations in mice lead to AR-HP; heterozygous carriers appear to be healthy.

We recently identified two different heterozygous, single nucleotide deletions in GCMB in genomic DNA of the affected members of two families with AD-HP. Both mutations (mutA and mutB) are located in GCMB exon 5 and both lead to a shift in the open reading frame and replace the putative second transactivation domain located within the carboxyl-terminal region of GCMB with unrelated amino acid sequence. Consistent with the mode of inheritance, mutant proteins exhibited dominant-negative properties in luciferase assays *in vitro*, while two previously reported GCMB mutations (R47L and G63S) that are the cause of AR-HP did not affect function of wild-type (WT) GCMB.

We now generated three GCMB-specific antibodies in rabbits against peptides corresponding to residues 111-130 (N1), 225-245 (C1) and 481-500 (C2). Western blot analysis of WT GCMB expressed in fibroblast DF-1 cells using antibodies N1 and C1 revealed a protein band of the expected size of about 60 kDa. As expected, lysates from cells expressing mutA and mutB showed a protein band that was slightly larger than WT protein. Antibody C2, which is directed against the portion of the protein that is replaced in mutA and mutB, also revealed the expected protein band in lysates from cells transfected with WT, but not from cells transfected with mutA or mutB. We also generated plasmids encoding WT or mutant GCMB tagged with GFP at the amino-terminus. In transiently transfected chicken fibroblast DF-1 cells using these constructs, WT or mutant proteins demonstrated normal nuclear localization.

We conclude that the identified GCMB mutations do not impair protein expression or nuclear localization, yet exert a dominant negative effect on the WT transcription factor. The mutant GCMB proteins and the anti-GCMB antibodies will help in the analysis of GCMB functions in adult parathyroid glands.

**A Possible Pathogenic Role of Aberrant Klotho Expression in Primary and Secondary Hyperparathyroidism.** T. Krajisnik<sup>1</sup>, P. Björklund<sup>\*2</sup>, G. Åkerström<sup>\*2</sup>, G. Westin<sup>\*2</sup>, T. Larsson<sup>1</sup>. <sup>1</sup>Medical Sciences, Institution of Medical Sciences, Uppsala, Sweden, <sup>2</sup>Surgical Sciences, Institution of Surgical Sciences, Uppsala, Sweden.

Klotho was recently shown to directly mediate PTH secretion in parathyroid cells in response to low extracellular calcium. In contrast, Klotho inhibits PTH secretion indirectly through the action of FGF23. Abnormal Klotho expression in parathyroid disorders remains to be determined. Herein, we explored parathyroid Klotho expression in patients with primary (pHPT) and secondary hyperparathyroidism (sHPT). Informed consent and approval by institutional ethical committee were obtained. Surgically removed parathyroid glands from patients with pHPT (n=40) and sHPT (n=25) and 4 normal parathyroid tissue specimens were analyzed for Klotho mRNA and protein levels by quantitative real-time quantitative PCR and immunohistochemistry.

In pHPT, Klotho mRNA levels were significantly decreased (n=23) or undetectable (n=17) compared to normal tissues (p<0.001). Reduced Klotho protein expression was confirmed by immunohistochemistry. Importantly, Klotho mRNA levels were significantly and inversely correlated with serum calcium (r=-0.97; p<0.0001), however, no correlation with serum PTH or adenoma weight was observed. In agreement, calcium, but not PTH, dose-dependently decreased bovine parathyroid Klotho expression *in vitro* (p<0.01). We also confirmed decreased expression of the vitamin D receptor (VDR) mRNA levels in pHPT subjects (p<0.01).

In sHPT, there was a trend of decreased Klotho mRNA expression in a majority of subjects, although not statistically significant compared to normal controls. Since all sHPT patients were on calcitriol treatment, we explored the effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> on Klotho expression. Importantly, 1,25(OH)<sub>2</sub>D<sub>3</sub> dose-dependently increased Klotho expression in bovine parathyroid cells *in vitro* (p<0.01).

In conclusion, serum calcium is a major determinant of parathyroid Klotho expression, which may play a significant role in the pathogenesis of pHPT. Suppressed Klotho and VDR mRNA levels in parathyroid adenomas indicate that both FGF23/Klotho- and vitamin D/VDR-dependent inhibitory mechanisms are perturbed and unable to diminish the uncontrolled PTH secretion. Finally, since Klotho expression is induced by vitamin D treatment, the beneficial effect of vitamin D treatment in chronic kidney disease may, in part, be ascribed to enhanced FGF23/Klotho-mediated reduction of PTH secretion.

**Anabolic Parathyroid Hormone Treatment Mobilizes Bone Marrow Stromal Stem Cells and Osteoprogenitors Towards Bone Surfaces: Role for the Epidermal Growth Factor Receptor Pathway.** J. Zhu, N. C. Partridge, L. Qin. Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

Intermittent injection of PTH dramatically increases bone mass and is one of the most effective treatments for osteoporosis. However, the detailed mechanisms are still largely unknown. Recently, we found that conditioned medium (CM) from PTH-treated UMR 106-01 osteoblastic cells contains factors which are chemotactic for bone marrow stromal stem cells (BMSSCs). In this assay, BMSSCs were seeded in the upper wells of chemotaxis chambers and the lower wells contained CM. We observed a 2-fold increase in the number of BMSSCs migrating toward the lower wells with PTH-treated CM compared with control CM. PTH itself has no chemotactic effect on BMSSCs. Time course experiments indicated that UMR 106-01 cells released chemoattractants within 30 min of PTH treatment and this was maximal at 4 h. Moreover, PTH stimulates MC3T3-E1 and primary calvarial osteoblastic cells to release factors chemotactic for BMSSCs. The migration of BMSSCs in these experiments is not due to random movement (chemokinesis) since there was no increase in the number of migrated cells if BMSSCs were in the upper wells in PTH-treated CM and the lower wells contained control CM. Using the protein synthesis inhibitor, cycloheximide, we demonstrated that PTH-treated osteoblastic cells must synthesize new protein(s) to exhibit chemotactic activity. Interestingly, this chemotactic activity was partially abolished by adding an epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor to the chemotactic assay. Previously, we have demonstrated that the expression of amphiregulin, an EGF-like ligand that signals through the EGFR, is rapidly and transiently stimulated by PTH in osteoblastic cells. Activation of the EGFR pathway stimulates the proliferation of BMSSCs and osteoprogenitors but suppresses their differentiation into mature osteoblasts. *In vitro* assays showed that all EGF-like ligands are chemotactic for BMSSCs. *In vivo*, we found that 1 h after the last of 12 days of intermittent PTH injections of adult rats the numbers of CFU-F extractable from bone marrow were decreased. Thus, PTH appears to cause the migration of BMSSCs or osteoprogenitors from bone marrow toward bone surfaces lined with osteoblasts and therefore decreases the numbers of CFU-Fs in the flushed bone marrow. Taken together, our results suggest a novel mechanism for PTH's anabolic actions that PTH stimulates bone lining osteoblasts to produce chemotactic factors, including amphiregulin, which mobilize BMSSCs and osteoprogenitors toward bone surfaces for future proliferation and differentiation into mature osteoblasts.

**Inhibition of the Mevalonate Pathway Rescues the Dexamethasone-induced Suppression of the Mineralization of Osteoblastic Cells.** I. Kanazawa, T. Yamaguchi, S. Yano, K. Hayashi<sup>\*</sup>, M. Yamauchi, T. Sugimoto. Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

AMP-activated protein kinase (AMPK) is known to be expressed ubiquitously including osteoblasts and modulate the mevalonate pathway by inhibiting HMG-CoA reductase. In this study, to clarify a physiological role of the mevalonate pathway in glucocorticoid-induced osteoporosis (GIO), we investigated the effects of 5-aminimidazole-4-carboxamide-1-β-D-ribose nucleoside (AICAR) (an AMPK activator) and fasudil hydrochloride (FH) [a specific inhibitor of Rho-kinase (ROK), downstream of HMG-CoA reductase] as well as statins (simvastatin and pitavastatin) (HMG-CoA reductase inhibitors) on dexamethasone (DEX)-induced suppression of the mineralization of osteoblastic MC3T3-E1 cells. Either AICAR (up to 0.5 mM) or FH (up to 10<sup>-4</sup> M) stimulated bone morphogenetic protein-2 (BMP-2) and osteocalcin (OC) mRNA expression by real-time PCR and mineralization by von Kossa and Alizarin red stainings until 21 days in time- and dose-dependent fashions. Simultaneous addition of either 1 mM mevalonate or 5 μM geranyl-geranyl pyrophosphate (GGPP), which also comprise the mevalonate pathway and act in the downstream of HMG-CoA reductase, antagonized BMP-2 and OC mRNA expression as well as mineralization enhanced by AICAR. On the other hand, DEX (10<sup>-8</sup> M) increased the expression of BMP-2 antagonists, Follistatin and Dan, and inhibited the mineralization of MC3T3-E1 cells. Under DEX treatments, either AICAR (0.1 mM), FH (10<sup>-5</sup> M), or statins (10<sup>-6</sup> M) still stimulated BMP-2 mRNA expression of the cells. Moreover, each agent addition reversed the DEX-induced increase in the expression of Follistatin and Dan as well as the DEX-induced suppression of mineralization of the cells. These findings showed that inhibition of the mevalonate pathway by AICAR, FH, or statins rescued the DEX-induced suppression of mineralization of osteoblastic MC3T3-E1 cells via enhancing BMP-2 expression while reducing its antagonists expression. Thus, the mevalonate pathway seems to be involved in the pathogenesis of GIO, and agents that are capable of inhibiting the pathway may be candidate drugs for the treatment of GIO by augmenting BMP-2 action.

**Proteasome Inhibition Counteracts the Negative Effect of Glucocorticoid Treatment on Bone Metabolism by Stimulating Osteoblasts and Inhibiting Osteoclasts in Vitro.** K. Søre\*, T. L. Andersen\*, T. Lund\*, T. Plesner\*, J. Delaissé. Clinical Cell Biology and Hematology, Vejle Hospital, IRS/CSFU, Southern Denmark University, Vejle, Denmark.

We have studied if simultaneous treatment with a proteasome inhibitor may neutralize the strong side effects glucocorticoids (GC) have on bone metabolism. The proteasome inhibitor bortezomib (Bz) is used to treat multiple myeloma, and it is reported to have beneficial effects on the bone resorption/formation balance and to partly rescue ovariectomy-induced bone loss in mice. We show here in an in vitro study that combining proteasome inhibition with GC treatment overcomes the inhibitory effect of prednisolone on osteoblasts, pre-osteoblasts and human mesenchymal stem cells (hMSC), and also blocks the stimulatory effect of GC on osteoclasts.

The following osteoblast/stem cell models were used: murine calvarial osteoblast cell line (MC3T3), hMSC (Tert4) and human adipose derived stem cells (hADSC). Pre-osteoblasts were defined as hMSC or hADSC differentiated in vitro with cytokines. Endpoints were metabolic activity, alkaline phosphatase activity and Q-PCR. Osteoclasts were differentiated from CD14+ cells derived from human blood donations by culturing them with MCSF and RANKL. Endpoints were metabolic, TRACP and resorptive activity. The experimental setup was adapted to the pharmacodynamics of both prednisolone and bortezomib. We used prednisolone concentrations equivalent to a daily dose of approximately 40 to 125 mg for 24 to 72 hrs, and Bz as a 3 hrs pulse corresponding to the levels reached in patients treated with 1 to 1.3 mg/m<sup>2</sup>.

The in vitro prednisolone treatment proved toxic against osteoblasts but not against pre-osteoblasts and stem cells. However, pre-treating osteoblasts with Bz protected them from toxicity. Furthermore, Bz pre-treatment of pre-osteoblasts and osteoblasts enhanced significantly the expression of key genes such as osteocalcin, osteopontin, collagen type 1 and OPG, compared to treatment with GC alone. In osteoblasts, combined treatment also enhanced Vitamin D receptor expression. In addition, hMSC displayed a significant increase in early marker genes such as ALP activity and expression as well as the expression of osteopontin in response to the combination. Finally, prednisolone rendered osteoclast resorption more aggressive but bortezomib could completely prevent this effect. Thus, we reproduce in vitro the detrimental effects of GC on OB and OC activity and show that proteasome inhibition can overcome them. We expect therefore that a possible way to prevent the induction of GC-induced osteoporosis may be through inhibition of the proteasome or the pathways that the proteasome controls.

**Effect of a Dissociating Glucocorticoid Receptor Modulator on Bone Cells.** K. Nelo\*, E. Kiiskilä\*, E. Kallio\*, J. Ilvesaro\*, H. M. Surcel\*, J. Risteli\*, M. Nissinen\*, A. Nilsen\*, H. A. Järveläinen\*, T. S. Scanlan\*, J. Tuukkanen\*. <sup>1</sup>Anatomy and Cell Biology, University of Oulu, Oulu, Finland, <sup>2</sup>National Public Health Institute, Oulu, Finland, <sup>3</sup>Clinical Chemistry, University of Oulu, Oulu, Finland, <sup>4</sup>Department of Physiology and Pharmacology, Oregon Health and Science University, Portland, OR, USA, <sup>5</sup>Global Safety Assessment, Astra Zeneca R&D, Montreal, QC, Canada.

Corticosteroid therapy is known to induce side effects like bone loss and osteoporosis. Glucocorticoid receptor modulators may have the potential for a more selective anti-inflammatory profile with fewer side effects compared with traditional corticosteroids. To define the effect of a novel non-steroidal selective glucocorticoid receptor modulator (SGRM), we studied osteoblast proliferation, matrix mineralization and osteoclastogenesis.

The anti-inflammatory effect of a arylpyrazole SGRM and dexamethasone was evaluated by analyzing *in vitro* secretion of interleukin-6 (IL-6) cytokine from lipopolysaccharide (LPS) -stimulated murine macrophage-like RAW 264.7 cells and the morphological changes of the RAW cells. The dissociative effect of the SGRM on MC3T3-E1 pre-osteoblast proliferation was studied with a WST-1 assay, mineralization by using Alizarin red S staining, and type I collagen synthesis by measuring procollagen type I N-terminal propeptide. In addition, common osteoclastogenesis markers RANKL and OPG were analyzed from MC3T3-E1 cells with quantitative RT-PCR. Bone resorption was evaluated using mouse bone marrow hematopoietic stem cells.

The anti-inflammatory effect of 10<sup>-7</sup> M SGRM was 32% and 69% of the effect of dexamethasone in IL-6 secretion and in the cell size respectively. Dexamethasone decreased osteoblast proliferation on days 3, 7, 10 and 14 and mineralization on day 14, compared with a basal control, whereas the SGRM had no effect. The 10<sup>-7</sup> M SGRM was also less potent in stimulating RANKL mRNA expression and in inhibiting OPG mRNA expression than was dexamethasone in MC3T3-E1 cells (on day 10). An osteoclastogenesis assay didn't detect any differences between these two compounds. However, the effect of 10<sup>-7</sup> M SGRM on bone resorption was significantly lower when compared with the effect of dexamethasone.

Our findings indicate that a dissociation effect was detected in osteoblast proliferation and matrix mineralization and partially in osteoclast differentiation and bone resorption. The *in vitro* separation of adverse bone effects from anti-inflammatory effects suggests a possibility of developing glucocorticoids with a more selective anti-inflammatory effect.

**Normal Intramembranous Fracture Healing in Mice with Transgenic Osteoblast-targeted Disruption of Glucocorticoid Signalling: Analysis by Microcomputed Tomography.** A. J. Weber\*, G. Li<sup>2</sup>, R. Kalak\*, J. Street\*, C. R. Dunstan<sup>3</sup>, F. Buttgeriet\*, H. Zhou<sup>3</sup>, M. J. Seibel<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany, <sup>2</sup>Musculoskeletal Education & Research Unit, Queen's University Belfast, Belfast, United Kingdom, <sup>3</sup>Bone Research Program, ANZAC Research Institute, The University of Sydney, Sydney, Australia.

The role of endogenous glucocorticoids (GC) in osteoblast differentiation and function is not well understood. Using a transgenic (tg) mouse model of osteoblast-targeted disruption of intracellular GC signalling, we examined whether endogenous GC, or the lack thereof, affect intramembranous fracture healing.

Uncortical bone defects (Ø 0.8mm) were created in tg mice (n= 36) and their wild-type (WT) littermates (n=34) using a drill on the anteromedial aspect of the left tibia. Fracture healing was assessed by X-ray (FAXITRON) and micro-CT analysis at 1, 2, and 3 weeks post-fracture. Micro-CT images were analysed for a Region of Interest covering the immediate defect site to measure the volume of new bone and its mean density.

At week 1 post-fracture, micro-CT imaging of the fracture site demonstrated formation of mineralized bone, which increased in volume and density by week 2. At week 3, healing of the defect was nearly completed in all animals.

One week post-fracture, the amount of newly formed bone (BV/TV) was similar in WT (25%) and tg (30%) animals (p=0.28). At week 2, BV/TV was 33% in WT mice as compared to 31% in tg animals (p=0.77). Mean bone densities of the newly formed bone in the WT and tg groups did not differ significantly at week 1 and week 2.

These preliminary results suggest that disrupting endogenous GC signalling in osteoblasts does not affect direct tibia bone healing as assessed by micro-CT. However, it remains to be shown whether glucocorticoid signalling affects other aspects of fracture healing such as collagen synthesis and structure, bone composition or bone turnover and remodelling.

## SA235

**Expression of 11β-Hydroxysteroid Dehydrogenase During Murine Osteoclast Formation.** M. Yang\*, J. R. Harrison<sup>2</sup>, B. E. Kream<sup>1</sup>. <sup>1</sup>Medicine, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Craniofacial Sciences, University of Connecticut Health Center, Farmington, CT, USA.

Glucocorticoids exhibit complex regulatory effects on bone remodeling, affecting cells of both the osteoblast and osteoclast lineages. Glucocorticoids have been shown to signal directly in osteoclasts to increase their longevity and suppress their activity. 11β-hydroxysteroid dehydrogenase (11β-HSD1) converts the inactive glucocorticoids cortisone and 11-dehydrocorticosterone to their biologically active forms, cortisol and corticosterone, respectively. While 11β-HSD1 is expressed by many cell types to provide a source of locally-acting glucocorticoids, only one previous study has shown 11β-HSD1 expression in osteoclasts (human). The goal of the present study was to determine whether murine osteoclast lineage cells express 11β-HSD1. Bone marrow monocytes (BMMs) were prepared from 7-week-old CD-1 mice and cultured with 30 ng/ml each of M-CSF and RANKL for 4 days to induce osteoclast formation (TRAP-positive cells with >3 nuclei). Freshly isolated BMMs expressed 11β-HSD1 mRNA as detected by real time quantitative PCR (qRT-PCR) and 11β-HSD1 protein as assessed by western blotting with a polyclonal rat 11β-HSD1 antibody (RAH113). 11β-HSD1 mRNA levels decreased more than 200-fold during osteoclast formation in BMM cultures. To assess whether the reduction of 11β-HSD1 expression occurred during the expansion of osteoclast precursors, BMMs were treated with 3 and 30 ng/ml M-CSF for up to 4 days. M-CSF caused a time- and dose-dependent reduction of 11β-HSD1 mRNA, with the greatest reduction after only one day of M-CSF treatment. To assess whether a reduction of 11β-HSD1 expression occurred during the differentiation of pre-osteoclasts to mature osteoclasts, the monocytic cell line RAW264.7 was treated with or without 30 ng/ml RANKL. 11β-HSD1 was expressed in vehicle-treated RAW264.7 cells and its expression decreased 2-fold in RANKL-induced cultures containing osteoclasts. To determine whether 11β-HSD1 was functional, BMMs were treated with M-CSF and RANKL in the presence or absence of corticosterone and its inactive metabolite 11-dehydrocorticosterone for up to 5 days. Both steroids caused a dose and time-dependent suppression of osteoclast formation, indicating that 11β-HSD1 was active. These data show that BMMs express 11β-HSD1 as a means of generating locally active glucocorticoids and that this system declines during osteoclast formation in vitro.

**Human Osteoblasts Synthesize VEGF In Response to ACTH.** H. C. Blair<sup>1</sup>, B. B. Yaroslavskiy<sup>\*1</sup>, L. Guo<sup>\*1</sup>, L. Liu<sup>\*1</sup>, M. Zaidi<sup>2</sup>, C. M. Isles<sup>3</sup>. <sup>1</sup>Pathology and Cell Biology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Medicine, Mount Sinai, New York, NY, USA, <sup>3</sup>Medicine, Medical College of Georgia, Augusta, GA, USA.

High-dose glucocorticoids cause bone mineral loss and regional osteonecrosis. Osteonecrosis is an important problem in high-turnover bone such as the femoral head and calcaneus. In the adrenal, adrenocorticotrophic hormone (ACTH) maintains corticosteroid production via vascular endothelial growth factor (VEGF) production in stromal cells; a consequence of glucocorticoid treatment is reduced systemic ACTH and adrenal cortical involution. Recently, ACTH receptors were discovered in osteoblasts, and are expressed at high levels in trabecular bone. Further, VEGF is required for bone formation. There are major species differences in glucocorticoid response; rodent bone mass increases with glucocorticoids and osteonecrosis does not occur. Thus, we studied VEGF expression in human osteoblasts in vitro. We confirmed the presence of the ACTH receptor in these cells; ACTH receptors were not present in significant amounts in mesenchymal stem cells or in fibroblasts. In early mineralising human osteoblasts, real time RT-PCR showed that VEGF mRNA was present in very low levels in untreated cells. ACTH, 100 ng/ml, induced VEGF mRNA several log orders, reaching 10% of GAPDH control concentration at 3 hours. It then declined to baseline (near zero) at 18 hours. Immune precipitation showed that VEGF protein accumulates in supernatants of osteoblasts treated with ACTH with or without 100 nM dexamethasone. In all media supporting osteoblast differentiation, without added ACTH, low but detectable levels of VEGF were found in culture supernatants. In keeping with the time course of VEGF mRNA expression, withdrawing ACTH for two days reduced VEGF protein to basal levels. It is likely that ACTH is also produced within bone: its precursor, POMC, is a regulated product of macrophages. In keeping, coculture of human monocytes with osteoblasts greatly increased VEGF production in the absence of added ACTH, although twice-higher levels of VEGF occurred in supernatants with both 100 ng/ml ACTH and 100,000 CD14 cells per cm<sup>2</sup> cultured with confluent osteoblasts. Monocytes were not a significant source of VEGF. Interestingly, in monocyte-osteoblast cocultures, dexamethasone reduced VEGF nearly to levels of unstimulated osteoblasts alone, suggesting that ACTH (or possibly other VEGF-stimulating products of monocytic cells in peripheral tissues) may be inhibited by glucocorticoids, in addition to inhibiting pituitary ACTH. Our results indicate that bone pathology, including osteonecrosis, secondary to glucocorticoid administration may reflect, in major part, interference with ACTH-dependent VEGF production that promotes osteoblast growth and survival.

**Expression of 1 $\alpha$ -hydroxylase (CYP27B1) in Human Marrow Stromal Cells: Correlations with Clinical Status.** J. Glowacki<sup>1</sup>, S. Zhou<sup>1</sup>, M. S. LeBoff<sup>2</sup>. <sup>1</sup>Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, <sup>2</sup>Endocrinology, Brigham and Women's Hospital, Boston, MA, USA.

1,25-dihydroxyvitamin D [1,25(OH)<sub>2</sub>D] is important for bone and mineral homeostasis. Recent data show that extrarenal conversion of 25-hydroxyvitamin D (25OHD) to 1,25(OH)<sub>2</sub>D occurs in several cell types by 25OHD-1 $\alpha$  hydroxylase (CYP27B1), but little is known about its expression or regulation in bone. We examined 1) whether osteoblast differentiation in human marrow stromal cells (MSCs) responds to 25OHD; 2) whether MSCs express D-related genes; and 3) whether they are regulated. Marrow discarded during orthopedic surgery was obtained from subjects with no comorbidities/medications affecting bone metabolism; 25OHD (Diasorin RIA), 1,25(OH)<sub>2</sub>D, and PTH were obtained prior to surgery. Low-density marrow mononuclear cells were isolated by density centrifugation to enrich for undifferentiated cells including a fraction capable of adherence and osteoblastic differentiation. Adherent MSCs were cultured in osteogenic supplements  $\pm$  1,25(OH)<sub>2</sub>D or 25OHD. AlkP activity was measured colorimetrically after 6d. Gene expression was evaluated by semi-quantitative RT-PCR in MSCs obtained from 14 women (W) and 14 men (M). Level of expression was analyzed with respect to clinical parameters.

1,25(OH)<sub>2</sub>D<sub>3</sub> stimulated osteoblast differentiation in 94% samples, with peak stimulation between 1 and 10 nM. Two-thirds of the samples were also stimulated by 25OHD<sub>3</sub> (10 nM). This suggests that some marrow may synthesize 1,25(OH)<sub>2</sub>D<sub>3</sub>. In the second study, 28% of subjects were vitamin D-deficient (25OHD < 20 ng/mL); 9% had elevated PTH; and 10% had elevated 1,25(OH)<sub>2</sub>D. There was a wide range of expression of CYP27B1, with no differences between genders or with age (64.8 years  $\pm$  11.0). There was lower expression of CYP27B1 in hMSCs from subjects with serum PTH >43 pg/mL (p=0.002) and in subjects with serum 1,25(OH)<sub>2</sub>D > 50 pg/mL (p=0.0014). There were trends for lower expression of CYP27B1 in MSCs from W and M with serum 25OHD <20 ng/mL, and lower expression in M with serum 25OHD  $\geq$ 34 ng/mL (Figure). In addition, there was a negative correlation between CYP27A1 and serum 25OHD (p=0.028).

This study indicates correlations between CYP27B1 expression in human marrow stroma and serum 25OHD, 1,25(OH)<sub>2</sub>D, and PTH. These data suggest that 25OHD and local production of 1,25(OH)<sub>2</sub>D may play roles in regulation of osteoblast differentiation and function.

**Vitamin D Insufficiency in Obesity.** E. R. Grethen<sup>\*1</sup>, R. V. Considine<sup>\*1</sup>, R. McClintock<sup>1</sup>, C. E. Gupta<sup>\*2</sup>, R. Jones<sup>\*2</sup>, B. M. Cacucci<sup>\*2</sup>, D. Diaz<sup>\*2</sup>, A. D. Fulford<sup>\*1</sup>, S. M. Perkins<sup>\*1</sup>, M. Peacock<sup>1</sup>. <sup>1</sup>Medicine/Endocrinology, Indiana University, Indianapolis, IN, USA, <sup>2</sup>Surgery, St. Vincent's Hospital, Carmel, IN, USA.

Obesity is a major health risk and its incidence in the USA is increasing. There are conflicting reports that serum 25-hydroxyvitamin D (s25D) levels are low in obesity. The aim of this study was to measure s25D in obese and control women and to determine if there was evidence of vitamin D insufficiency as assessed by serum PTH (sPTH). Fasting blood was obtained from obese white women prior to bariatric surgery and from healthy white women matched for age and season. Height and weight were recorded and s25D and sPTH measured by radioimmunoassay. Data were analyzed by SAS. Mean BMI and sPTH were higher and s25D was lower in obese women (Table).

		Obese women (n = 50)	Control women (n = 50)	P-value
BMI (kg/m <sup>2</sup> )	Mean (SD)	52.4 (12.4)	28.1 (5.9)	<0.001
	range	35.0- 90.2	16.7- 43.0	
s25D (ng/ml)	Mean (SD)	16.0 (8.3)	23.3 (9.8)	<0.001
	range	3.0- 41.5	8.0- 58.4	
sPTH (pg/ml)	Mean (SD)	45.2 (33.9)	25.6 (9.1)	<0.001
	range	11.5- 215*	10.2- 54.1	

\*Data were analyzed with and without the outlier PTH=215; significance was not affected. s25D was inversely related to BMI, and sPTH was inversely related to s25D (Figure).

R<sup>2</sup> of s25D vs. BMI was 0.25 (p <0.001); R<sup>2</sup> of sPTH vs. s25D was 0.10 (p <0.01). It is concluded that s25D is low in obesity and that vitamin D insufficiency is present among obese white women.

**Platelet Vitamin D Receptor Levels Are Reduced in Osteoporotic Patients.**

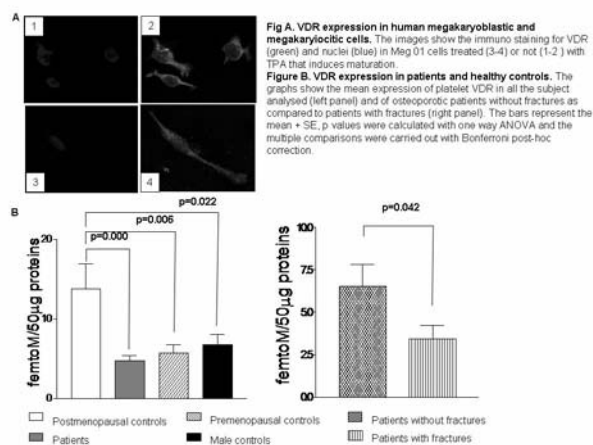

**P. D'Amelio<sup>1</sup>, M. A. Cristofaro<sup>\*1</sup>, M. Ravazzoli<sup>\*1</sup>, S. Di Bella<sup>\*1</sup>, G. P. Pescarmona<sup>\*2</sup>, G. Isaia<sup>1</sup>.** <sup>1</sup>Department of Internal Medicine, University of Torino, Torino, Italy, <sup>2</sup>Department of Biochemistry, Genetic and Biology, University of Torino, Torino, Italy.

Several findings suggest that rapid responses to the action of vitamin D are mediated by a vitamin D receptor (VDR) located in the cytosol. It has been shown that a human megakaryoblastic leukemia cell line expresses a functionally active VDR and that VDR is involved in the control of platelet (PLT) aggregation in the mouse. In the present study, we looked to see whether human PLTs express VDR, and whether its expression is different in osteoporotic as opposed to healthy subjects.

In order support to the analysis of PLT VDR we analyse the VDR expression in megakaryoblasts and megakaryocytes by immunofluorescence (Fig A). We enrolled in the study 77 women with postmenopausal osteoporosis, 33 healthy women of childbearing age, 49 healthy men, and 11 healthy women matched with patients for age and postmenopausal period. Thirty-nine patients had had one femoral fracture occurred after the age of fifty and attributable to primary osteoporosis. Bone mineral density (BMD), markers of bone metabolism and VDR levels by western blot were measured in all the subjects.

We demonstrated that VDR is expressed in the cytoplasm and the nucleus of megakaryoblasts and megakaryocytes, this lends support to the subsequent analysis of PLT VDR. After the menopause, VDR levels increase with respect to the young controls in the healthy women, but not in the osteoporotic ones. Patients with femoral fractures display fewer VDR than those without (Fig B). VDR may thus be supposed to be involved in the control of BMD and the gravity of osteoporosis. There are no marked gender-related differences in VDR expression among the healthy subjects. VDR is directly correlated with lumbar ( $r=0.4$ ,  $p=0.04$ ) and femoral ( $r=0.52$ ,  $p=0.009$ ) BMD, even after correction for age, time since menopause, BMD, PTH, 25OHvitamin D and BMI. There are no significant correlations between VDR, age and bone metabolism parameters after correction for BMD.

Our data suggest an important role for the VDR in determining bone density, the lower VDR expression in osteoporotic indicate a lower ability to react at circulating vitamin D, and could be the explanation of the increase in the PTH and decrease in the phosphorus levels in patients with respect to controls without difference in circulating vitamin D levels and in the dietary calcium intake.

**Involvement of Caveolae in  $1\alpha,25(\text{OH})_2\text{D}_3$ -dependent Activation of MAPKs in Skeletal Muscle Cells.** C. Buitrago\*, R. L. Boland. Dept. Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina.

$1\alpha,25(\text{OH})_2\text{D}_3$  is a steroid hormone that induces non-transcriptional events modulating components of signal transduction pathways in various cell types. The ERK1/2 and p38 members of the MAPK family are signaling pathways which mediate rapid responses to extracellular stimuli. Although there are data indicating that  $1\alpha,25(\text{OH})_2\text{D}_3$  regulates MAPK cascades in skeletal muscle cells, the role of plasma membrane components in the fast effects of the hormone in this tissue have not been investigated. In the present work, using the skeletal muscle cell line C2C12 as experimental model, we demonstrate by Western blot analysis with phosphospecific antibodies that  $1\alpha,25(\text{OH})_2\text{D}_3$ -dependent ERK1/2 and p38 MAPK phosphorylation are suppressed by disassembling caveolae with methyl-beta cyclodextrin (M $\beta$ CD). Moreover, c-Src activation by the hormone was abolished by exposure of C2C12 cells to M $\beta$ CD. One of the main molecules of caveolae

expressed in this cellular type is caveolin-1 (cav-1). Therefore, we investigated the relationship between cav-1 and c-Src. Confocal microscopy images of immunocytochemical assays of control C2C12 cells showed that cav-1 and c-Src colocalize at the plasma membrane. Cell treatment with  $1\alpha,25(\text{OH})_2\text{D}_3$  abolished colocalization of cav-1 and c-Src. These results were corroborated by experiments showing that  $1\alpha,25(\text{OH})_2\text{D}_3$  blocks coimmunoprecipitation of cav-1 and c-Src observed under control conditions. Localization of the vitamin D receptor (VDR) in C2C12 cells was investigated. Congruent with previous results, translocation of the VDR to the plasma membrane occurs in cells treated with  $1\alpha,25(\text{OH})_2\text{D}_3$ . In cells exposed to M $\beta$ CD the VDR is present only in the nucleus. These data suggest that caveolae are involved in c-Src-dependent MAPK activation by  $1\alpha,25(\text{OH})_2\text{D}_3$  through the VDR in skeletal muscle cells.

**Effect of  $1\alpha,25$ -Dihydroxy Vitamin D3 on Proliferation and Differentiation of C2C12 Myoblast.**

H. Okuno\*, K. N. Kishimoto, M. Hatori\*, E. Itoi\*. Department of Orthopaedic Surgery, Tohoku University School of Medicine, Sendai, Japan.

Vitamin D plays a major role in the regulation of calcium homeostasis. Recently many reports have demonstrated that  $1\alpha,25$ -dihydroxy vitamin D3 (VD3) supplementation reduced the risk of falls and osteoporosis related fractures of older individuals. An enhancement of the muscle strength and reduction of the body sway are possible mechanisms. However, in vitro effect of VD3 on skeletal muscle has not been well understood. In this study, we examined the effect of VD3 on proliferating, differentiating and differentiated phases of C2C12 myoblasts, mouse skeletal muscle cell line.

C2C12 myoblasts proliferate without fusion and differentiation when grown in 10% fetal bovine serum (FBS). Cell counting and WST-1 cell proliferation assay revealed that supplementation of VD3 under 10% FBS inhibited their proliferation and viability in a dose-dependent manner of VD3. Flow cytometric analysis showed that VD3 increased the percentage of cells in the G0/G1 phase dose-dependently. Cells cultured with VD3 exhibited larger cell size than control under the cytologic observations.

C2C12 cells start fusion and differentiation into myotubes when culture medium is changed to 2% horse serum (HS). VD3 treatment in differentiating phase was defined as starting VD3 supplementation when the medium was changed to HS. VD3 treatment in differentiated phase was defined as starting VD3 supplementation after 8 days culture in HS. VD3 treatment in differentiating phase inhibited the formation of myotube and the expression of total MHC in both mRNA and protein levels. VD3 treatment in differentiated phase did not show significant difference in amount of total MHC using western blot analysis with MF20 antibody (DSHB). However significant larger expression of fast MHC confirmed by Western blot analysis with MY-32 (Sigma) was found in the 1nM of VD3 than in the control.

Our findings indicated that VD3 inhibited proliferation of myoblasts during proliferating and differentiating phases. In the differentiated phase, 1 nM of VD3, a little higher concentration than physiological level, increased the expression of fast MHC. Our result suggested that VD3 might have anabolic effect on skeletal muscle in adequate concentration.

**The Spectrum of Osteogenesis Imperfecta Mutations in Sweden - A Study of 26 Families.** K. M. Lindahl\*, C. Rubin\*, A. Kindmark, Ö. Ljunggren. Medical Sciences, Uppsala, Sweden.

**Background/Aim:** Osteogenesis imperfecta (OI) is a heterogeneous disease of connective tissue with an incidence of approximately 1/15 000. More than 90% of OI is caused by a dominant mutation in the genes coding for collagen I, COL1A1 and COL1A2. The cardinal sign of OI is fragile bones with multiple fractures, but the disease can affect many other tissues with symptoms such as blue sclera, excessive bleeding, hyper mobile joints, dentinogenesis imperfecta and deafness. The severity of OI ranges from a mild disease with an average life expectancy to death perinatally. A mild phenotype is often due to a quantitative collagen defect, while patients with more severe forms generally have a mutation leading to a qualitative collagen defect.

Over 800 mutations causing OI have been described in collagen I. As COL1A1 and COL1A2 are large genes, there are still many blank spaces where no mutations have been found and positions where only a few of the possible substitutions have been reported. Approximately 80% of structurally abnormal collagen in OI is the result of a glycine mutation. At present only 11% of possible glycine substitutions in COL1A1 and 10% in COL1A2 have been described.

The mutation spectrum causing OI in Sweden has not been investigated previously. Here the collagen I genes of 26 unrelated patients with OI from all parts of Sweden were studied. Method: DNA was extracted from whole blood using a commercially available kit. Exons and flanking intron sequences of COL1A1 and COL1A2 were sequenced using standardised sequencing with ABI3130XL using 110 primer pairs.

**Results:** In 20 of the 26 families a mutation was found: 12 of these were known to cause OI while 8 were not previously reported.

12 mutations were located in COL1A1 and 8 in COL1A2. 11 patients had a glycine substitution, while 7 mutations were insertions, deletions or mutations leading to a premature stop codon. Surprisingly there were 2 non-glycine amino acid substitutions suspected to cause an OI-phenotype and 2 families were carriers of 2 separate mutations. In the latter cases only one of the mutations were of a typical OI-type.

**Conclusion:** The spectrum of mutations causing OI described in this Swedish cohort are of the expected type with the exception of 2 mutations that cause non-glycine substitutions. In 2 patients 2 separate mutations were found. It is presently unclear if both of these influence the patient's phenotype, but further investigations are planned.

Mutation type and location in cohort of Swedish OI-patients

	COL1A1	COL1A2
Mutations	12	8
Glycine substitutions	4	7
Insertions/deletions/stop codons	7	0
Non-glycine aa substitutions	1	1
> 1 mutation	1	1

**Disclosures:** K.M. Lindahl, None.

## SA248

**Dynamic Morphological Changes in the Skulls of Mice Mimicking Human Apert Syndrome Resulting From Gain-of-function Mutation of FGFR2 (P253R).** X. Du\*, X. Zhao\*, Z. Chen\*, X. Lu\*, N. Su\*, Q. Sun\*, Q. He\*, L. Zhao\*, L. Chen. Trauma Center, Daping Hospital, Chongqing, China.

The main distinctive craniofacial manifestations of Apert syndrome (AS) include shallow orbits with proptosis, and midface hypoplasia. We have generated a mouse model (Fgfr2+/P253R) mimicking human AS resulting from FGFR2 P253R mutation. Although, in general, this mouse model shows skull phenotypes similar to human AS, the detailed morphometric, especially the dynamic measurement of the skulls of this model was absent. To see if there are precise parallels between phenotypes in Fgfr2+/P253R mouse and human with AS, we measured, using EDMA approach, the skull morphology of this model and their wild-type controls (WT) at 4W and 8W stages. It was found by FDM (form difference matrix) analysis that there were significant differences in the overall skull shapes and subsets of anatomic structures between mutants and wt at both 4w and 8w of age. In both stages, compared with WT, the mutants exhibited obviously shortened skulls along the anteroposterior (AP) axis. The anterior portion of the mutant skulls was more severely shortened. In contrast, the mutant skulls were broadened along the mediolateral axis in their frontal regions, while the parietal parts were heightened. The 8w old mutants, however, showed alleviated severity of the shortened anterior portion of the skulls. Of the 351 linear distances constructed from the 27 cranial landmarks, 94% were affected in 4w old mutants, but there were only 76% linear distances showed changes in 8w old mutants. In 8w stage, the mutant skulls had more areas broadened mediolaterally. The percentage of the elongated linear distances in mutant skulls over their littermate WT was increased from 2% in 4w to 5% in 8w. The enlarged distances in 4w old mutants included height of the parietal bones, interorbital distance, maxillary width. In 8w, the width of the frontal bones, breadth of palates and zygomatic bones were also increased. GDM (growth difference matrix) analysis showed that the most significantly increased linear distances were mainly concentrated in the orbit region and anterior portion of the skulls roughly along the AP axis.

Since the skulls of Fgfr2+/P253R developed faster than that in WT mice during the stage between 4w and 8w, it's indicated that there was a "catch-up" growth in the mutant skulls, especially along the anteroposterior axis, to compensate the retarded development occurred during the early stages. Our data, from cephalometric aspect, further validate the use of the Fgfr2+/P253R mouse model to analyze the pathogenesis of human AS, and develop therapeutic measures for AS.

This study received the "973" program of China (No.2005CB522604), and the NSFC (No.30470947, 30425023).

**Characterisation Through Computer-Assisted Microtomography of the Bone Phenotype of Mice Showing Impaired Gait and Motor Skills.** C. Martineau\*, L. Brissette\*, R. Moreau\*. Sciences Biologiques, Université du Québec à Montréal, Montréal, QC, Canada.

Osteoarthritis (OA) designates a group of diseases characterised by stiffness of the joints and ectopic calcification, ultimately leading to erosion of the articular surfaces and consequent movement impairment. Bone architecture alterations for some OA syndromes have been thoroughly documented, such as chondrocalcinosis (CC), craniometaphyseal dysplasia (CMD) and progressive ankylosis, all of which may result from a mutation of the *Ank* gene. This gene encodes a transmembrane channel carrying inorganic pyrophosphate (PPi) to the extracellular environment, preventing excessive calcification. Though CC, CMD and progressive ankylosis show similar symptoms, they are the result of modifications in the N-terminal segment of ANK protein with a gain of function, in the case of CC, and in the C-terminal portion of ANK protein, leading to a loss of function in the case of CMD and progressive ankylosis. Indeed, excessive extracellular PPi results in calcium pyrophosphate dihydrate (CPPD) deposition as seen in CC, while low extracellular PPi leads to hydroxyapatite (HA) formation as observed in the two latter syndromes. In a C57Bl/6 mice colony, 5 individuals of a 6-month-old litter of 9 mice showed abnormal stature and severe locomotor deficiency due, at a first glance, to joint stiffness. The litter was euthanised and the tibiae, femora and lumbar vertebrae were harvested for X-ray microtomography (microCT) analysis. Results confirmed that the articular stiffness was due to excessive ectopic calcification of the toes, knees and spine. Further analysis showed signs of osteoporosis with reduced trabecular tissues, as well as lower bone mineral density (BMD) in tibiae, femora and vertebrae. Alizarin Red S staining of whole mounted legs should discriminate between CPPD and HA formation in the joints, pointing to CC or CMD/progressive ankylosis respectively. Livers harvested and cryopreserved from some individuals will be used for genomic DNA analysis to establish the presence of mutations in the *Ank* gene.

**Genome-Wide Pleiotropic Associations of Bone Phenotypes: The Framingham SHARE Project.** D. Karasik<sup>1</sup>, Y. H. Hsu<sup>1</sup>, Y. Zhou<sup>\*2</sup>, L. A. Cupples<sup>\*2</sup>, D. P. Kiel<sup>1</sup>, S. Demissie<sup>\*2</sup>. <sup>1</sup>IFAR, Hebrew SeniorLife, Boston, MA, USA, <sup>2</sup>Biostatistics, BU Sch Public Health, Boston, MA, USA.

Genome-wide association studies (GWAS) using high-density genotyping platforms offer an unbiased approach to identify new candidate genes for osteoporosis. There are multiple osteoporosis-related measurements, such as DXA BMD at different skeletal sites. Previously, using a 100K SNP marker set in the Framingham Heart Study (FHS) sample, we (ASBMR 2007) reported that associations with single nucleotide polymorphisms (SNPs) were often shared among multiple bone traits. Here we report results from our FHS SHARE project, with as many as 5 times more SNPs and twice as large sample size.

We used the Affymetrix 500K+50K SNP GeneChip marker set to examine genetic associations with BMD (FN and LS), QUS (BUA and SOS), DXA-derived geometric indices of the hip, and x-ray-derived metacarpal indices, in two cohorts from the FHS. We evaluated 432,159 SNPs with genotypic call rates  $\geq 95\%$ , HWE  $p \geq 10^{-6}$ , and MAF  $\geq 1\%$  in 1554 men and 2073 women (mean age 65 yrs) with individual level call rate  $\geq 97\%$ . Linear mixed effects models (LME) were used to test associations between SNPs and multivariable-adjusted residual trait values. Variance components analysis (SOLAR) was performed to estimate genetic correlations ( $\rho_g$ ) among these traits. We compared  $\rho_g$  among each pair of traits with the proportion of SNPs associated with both of these traits. We found that at a pre-specified significance threshold  $\alpha$ , LS and FN BMD in females share only 2.5% associated SNPs at  $\alpha = 0.001$  (5.6% at 0.01 level), despite a high  $\rho_g = 0.67$  between them. Similarly, femoral neck length and width, whose  $\rho_g = 0.48$  in females, share as much as 1.1% (2.4% at 0.01 level). There are virtually no SNPs that share associations with both BMD and geometric traits (femoral neck and shaft width, neck-shaft angle, and neck length);  $\rho_g$  among these geometric traits ranges from -0.20 to +0.48.

In conclusion, GWAS offers a hypothesis-free strategy to identify new associations and may be used to examine pleiotropic relationships between osteoporosis-related traits. Despite some statistical reservations (such as unknown false-positive rate), this strategy may prove helpful to define the best combination of phenotypes to be utilized in genetic studies of pleiotropy in osteoporosis.

## SA252

**Age-Associated Changes in the Material Properties of the G610C (Amish) OI Mouse Model.** E. L. H. Daley<sup>\*1</sup>, D. J. McBride<sup>2</sup>, T. E. Uveges<sup>\*3</sup>, N. V. Kuznetsova<sup>\*3</sup>, S. Leikin<sup>\*3</sup>, J. C. Marini<sup>3</sup>, S. A. Goldstein<sup>1</sup>. <sup>1</sup>University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>University of Maryland, Baltimore, MD, USA, <sup>3</sup>National Institutes of Health, Bethesda, MD, USA.

The Amish OI knock-in mouse was designed to replicate a COL1A2 G610C mutation associated with OI in an Amish kindred. The mutation has been stably inherited for 6 generations, is found in over 60 individuals, and exhibits a mild, but variable phenotype. The Amish OI mouse expresses mutant type I collagen mRNA and protein. Its mean dermal collagen fibril diameter is reduced compared to WT littermates. Here, we report the first assessment of the G610C mutation on femur geometric and mechanical properties. Femurs from male 2 month old (WT=9; G610C=9) and 6 month old (WT=9; G610C=6) mice were scanned via  $\mu$ CT to quantify femur morphology and mineralization (GE Medical Systems, London, ON). Cortical regions of interest (ROI) consisted of 3 mm segments of the mid-diaphyses while trabecular ROI were chosen from volumes within the distal femoral metaphyses proximal to the growth plates. Mechanical testing of the femurs was done via 4-point bending conducted with a servo-hydraulic testing system. Predicted material properties were calculated using classical beam theory. One-way ANOVA with *post-hoc* Tukey Test was used to compare group means with a P-value  $\leq 0.05$  considered significant (SPSS, Chicago, IL).

G610C femurs were shorter, had smaller radii, and had greater volumetric cortical mineral density, but did not differ in cortical thickness compared to age-matched controls. Though cortical morphologies of the mutant genotype were not qualitatively different, voxel-by-voxel image analysis revealed divergent patterns of mineralization in the G610C. Six-month G610C trabecular thickness and mineral density were similar to 6-month controls, but trabecular number was reduced. Two-month G610C yielded and failed at lower loads than the other groups, yet by six-months G610C femurs and controls withstood similar loads. There were no significant differences in yield stress at both ages, but at 6 months failure stress was greater in G610C than control. Though G610C and age-matched controls had similar whole bone stiffness, the G610C mutants had a significantly greater Young's Modulus.

The results demonstrate that G610C has significant phenotypic alterations in bone properties compared to WT. Moreover, G610C femoral material properties appear to alter over time in a way that brings whole-bone strength on par with WT by six months of age, perhaps as part of a mechanism that compensates for the smaller size of the mutant femurs. Interestingly, this compensatory mechanism is remarkably similar to the adaptation observed in Brtl IV mice, suggesting a shared skeletal response for glycine substitutions in either type I collagen chain.

**Characterization of the Enthesopathy of X-linked Hypophosphatemia in the Hyp Mouse.** C. M. Macica<sup>\*1</sup>, G. Liang<sup>\*1</sup>, L. D. Katz<sup>\*2</sup>, K. L. Insogna<sup>1</sup>, T. O. Carpenter<sup>3</sup>. <sup>1</sup>Internal Medicine, Yale University, New Haven, CT, USA, <sup>2</sup>Diagnostic Radiology, Yale University, New Haven, CT, USA, <sup>3</sup>Pediatrics, Yale University, New Haven, CT, USA.

Despite the characteristic osteomalacia seen in X-linked hypophosphatemia (XLH), paradoxical calcification occurs at tendon and ligament insertion sites, as described over 20 years ago (Polisson, 1985). We confirmed a generalized enthesopathy/osteophytopathy in a clinical survey of over 30 patients affected with XLH; calcaneal spurs and Achilles enthesopathy are often affected earlier than other sites. As previously suggested, enthesopathy does not appear to be determined by phosphate/calcitriol treatment, and is likely intrinsic to the basic disease process. Nevertheless, as no studies to date have examined the progression or pathogenesis underlying mineralization of insertion sites in XLH, we examined several fibrocartilagenous insertion sites in the murine model of XLH, the Hyp (Phex deletion) mouse, including that of the Achilles tendon. Enthesis fibrocartilage (FC) was established by cellular phenotype (small, rounded cells aligned in rows between collagen fibrils) and expression of type II collagen. In contrast to aged-matched control mice (7 mos), the enthesis FC was highly cellular and dramatically thickened, extending well into both the sesamoid and calcaneal FC. The expansion of FC also extended far into the medial process of the calcaneal tuberosity. This was accompanied by a 5-fold increase in expression of type II collagen. In addition, alkaline phosphatase (AP) activity, a general marker of cartilage and bone mineralization, was minimal in the enthesis of control mice, localized only to the enthesis tide-mark. In contrast, a dramatic 20-fold increase in AP activity was observed in Hyp mice and was associated with the expanded FC. It thus appears that the Hyp mouse phenocopies the human syndrome quite precisely and will form the basis our studies characterizing the signaling molecules involved in this process.

**Possible Central Function of the Calcitonin Receptor on Bone Mass.** C. B. Confavreux<sup>1</sup>, C. Settembre<sup>\*1</sup>, F. Oury<sup>\*1</sup>, R. A. Davey<sup>2</sup>, J. D. Zajac<sup>2</sup>, G. Karsenty<sup>1</sup>. <sup>1</sup>Genetics and Development Department, Columbia University, New York, NY, USA, <sup>2</sup>Department of Medicine, Austin Health, University of Melbourne, Heidelberg, Victoria, Australia.

Calcitonin, a hormone able to lower serum calcium level, mediates its signal through calcitonin receptor (Calcr), a member of the seven trans-membrane domains G protein coupled receptor family. Since *Calcr* is expressed in osteoclasts, it is generally assumed that calcitonin is a regulator of bone resorption. However, mice lacking one copy of *calcitonin receptor* displayed an increase in bone mass due to an increase in bone formation whereas bone resorption was normal. These *in vivo* data raise the hypothesis that calcitonin may be a regulator of bone formation, a function that may not be explained by the expression of *Calcr* in osteoclasts. To address this conundrum, we first analyzed *Calcr* expression pattern. Besides osteoclasts, *Calcr* is expressed in neurons of the arcuate nucleus and the paraventricular hypothalamic nucleus (PVH), two hypothalamic nuclei implicated in the control of bone mass. Interestingly, *Calcr* expression in these neurons was markedly stronger than in osteoclasts. This pattern of expression along with the phenotype of *Calcitonin receptor* deficient heterozygous mice raises the prospect that this receptor regulates bone formation through its expression in brain. In an effort to perform a thorough analysis of the function of calcitonin receptor in the different cell types where it is expressed, we used a *Cre-loxP* strategy to generate mice lacking *Calcr* in either all cells (*Calcr<sup>-/-</sup>*), osteoclasts only through the use of *CathepsinK-Cre* mice (*Calcr<sup>osc/-</sup>*) or in neurons through the use of *SynapsinI-Cre* mice (*Calcr<sup>neurons/-</sup>*). As expected, *Calcr<sup>-/-</sup>* mice displayed an increased bone mass due to an increase in osteoblast number. Remarkably there was no change in bone resorption parameters. Surprisingly, while mice lacking *Calcr* in osteoclasts only lived normally, the brain specific deletion of *Calcr* was lethal, most likely during embryogenesis. We are currently investigating the cause of death in *Calcr<sup>neurons/-</sup>* mice as well as studying the bone phenotype of the *Calcr<sup>neurons+/-</sup>* and *Calcr<sup>osc/-</sup>* mice. Results of this analysis will be presented at the meeting.

**An Investigation into the Impact of Osteoarthritic Changes on Bone Mineral Density Measurements in Patients with High Bone Mass.** C. L. Gregson<sup>\*1</sup>, S. Steel<sup>\*2</sup>, K. Yoshida<sup>\*3</sup>, D. M. Reid<sup>\*3</sup>, J. H. Tobias<sup>1</sup>. <sup>1</sup>Bristol University, Bristol, United Kingdom, <sup>2</sup>Royal Infirmary, Hull, United Kingdom, <sup>3</sup>Aberdeen University, Aberdeen, United Kingdom.

High Bone Mass (HBM) is of increasing interest, but so far cases have only been reported sporadically. To identify further HBM cases, we screened 7 Dual Energy X-ray Absorptiometry (DXA) databases in the UK (5 Lunar, 2 Hologic) for T or Z score of  $\geq +4$  at the lumbar spine or hip. A problem we have met is that since osteoarthritis (OA) can artefactually raise bone mineral density (BMD), and HBM may itself be associated with OA, a method is required to identify HBM cases with or without co-morbid OA, while excluding those with OA alone. To develop this, DXA images from HBM 'cases' identified in this way were graded for OA severity using the Kellgren & Lawrence (KL) score [mild (0-2), moderate (3), severe (4)] and related to BMD results. 562 out of 197,953 scans had a T or Z score of  $\geq +4$  at the lumbar spine or hip. 77% were women. Mean age 63 years, weight 81.7kg, height 164.6cm. Mean total L1-L4 Z score was 5.09 (3.65-6.55), L1 Z score 3.40 (3.24-3.56), total hip Z score 2.11 (1.97-2.25), KL score 3.36 (3.30-3.46). Subjects with scoliosis (65), ankylosing spondylitis (9), orthopaedic metalwork (8) and other known causes of raised BMD (17) were excluded. In the remaining 463, KL score was compared with BMD using linear regression. Total L1-L4 Z score was strongly correlated with increasing KL score (1.01; 0.54, 1.48;  $p < 0.001$ ); whereas, L1 Z score was not (0.04; -0.53, 0.60;  $p = 0.89$ ). Total hip Z score was negatively correlated with KL score (-0.85; -1.33, -0.38;  $p < 0.001$ ). Total L1-L4, affected most by OA, was thus not appropriate to differentiate HBM from OA; L1 Z score was affected least, reflecting the recognized pattern of progressive OA changes seen in descending sequential lumbar vertebrae. If anything, high hip BMD was negatively associated with spondylosis. Hence a new definition of HBM was developed as a) L1 Z score of  $\geq +3.5$  plus total hip Z score  $\geq +1.2$ , or b) total hip Z score  $\geq +3.5$ . Using this definition, 179/463 (38.7%) of cases originally identified, after exclusion of other HBM causes, were defined as having HBM  $\pm$  co-morbid OA, of whom 40.2% had severe and 46.4% moderate OA. In contrast, of the remaining subjects re-classified as non-HBM, 44.8% had severe OA and 45.8% moderate OA ( $p = 0.016$ ). Furthermore, when applying this definition, HBM subjects were much heavier than non-HBM subjects (86.0 [83.4, 88.6] vs 78.2 [76.2, 80.2] kg respectively), whilst height and age were similar, providing further evidence that our revised definition was effective at distinguishing between subjects with or without HBM. In conclusion, L1 and total hip Z scores are useful in identifying HBM ( $\pm$  co-morbid OA), filtering out those with OA alone as an artefactual cause of high BMD.

**PTHRI Mutations Associated with Ollier Disease Result in Receptor Loss of Function.** A. Couvineau<sup>\*1</sup>, V. Wouters<sup>\*2</sup>, G. Bertrand<sup>\*3</sup>, C. Rouyer<sup>\*1</sup>, B. Gérard<sup>\*3</sup>, L. Boon<sup>\*4</sup>, B. Grandchamp<sup>\*3</sup>, M. Vikkula<sup>\*2</sup>, C. Silve<sup>\*5</sup>. <sup>1</sup>Faculté Bichat, INSERM U773, Paris, France, <sup>2</sup>Université Catholique de Louvain, Laboratory of Human Molecular Genetics, Brussels, Belgium, <sup>3</sup>AP-HP, Hôpital Bichat, Service de Biochimie Hormonale et Génétique, Paris, France, <sup>4</sup>Cliniques Universitaires St Luc, Center for Vascular Anomalies, Brussels, Belgium, <sup>5</sup>AP-HP, Hôpital Bichat, INSERM U561 et Service de Biochimie Hormonale et Génétique, Paris, France.

The PTHRI signalling pathway is critical for the regulation of endochondral ossification. Thus, abnormalities in genes belonging to this pathway could potentially participate in the pathogenesis of Ollier disease / Maffucci's syndrome, two developmental disorder defined by the presence of multiple enchondromas. In agreement, a functionally deleterious mutation in PTHRI (p.R150C) was identified in enchondromas from two of six unrelated patients with enchondromatosis. However, neither the p.R150C mutation (26 tumors) nor any other mutation in the *PTHRI* gene (11 patients) could be identified in another study. To further define the role of PTHRI signalling pathway in Ollier disease and Maffucci syndrome, we have analysed the coding sequences of four genes (*PTHRI*, *IHH*, *PTHrP* and *GNAS1*) in leucocyte and/or tumor DNA from 57 and 23 patients affected with Ollier disease or Maffucci syndrome respectively. We identified three previously undescribed missense mutations in PTHRI in patients with Ollier disease at the heterozygous state. Two of these mutations (p.G121E, p.A122T) were present only in enchondromas, and one (p.R255H) in both enchondroma and leukocyte DNA. The assessment of receptor function demonstrated that these three mutations impair PTHRI function, either by reducing the affinity of the receptor for PTH or reducing receptor expression at the cell surface. These mutations have not been found in DNA from 222 control patients. The PTHRI mutations identified in Ollier disease (p.G121E, p.A122T, p.R150C) and Blomstrand chondrodysplasia (p.P132L) all lie within the structured core of the PTH-PTHrP extracellular domain complex in the crystal structure described by Pioszak and Xu (PNAS 2008), a location compatible with a functionally deleterious effect. Including our data, PTHRI functionally deleterious mutations have now been identified in 5/31 enchondromas from Ollier patients. These findings provide further support for the idea that heterozygous mutations in PTHRI that impair receptor function may participate in the pathogenesis of Ollier disease in some patients.

## SA259

**Hypothyroidism and Autism Combined with Pseudohypoparathyroidism in the Absence of Albright's Hereditary Osteodystrophy and GNAS Imprinting Changes: A Novel Clinical Syndrome?** L. M. Ward<sup>1</sup>, T. Pinto<sup>\*1</sup>, S. Lawrence<sup>\*1</sup>, M. Lawson<sup>\*1</sup>, M. Bastepe<sup>2</sup>, H. Jüppner<sup>2</sup>, F. Rauch<sup>3</sup>. <sup>1</sup>Div. of Endocrinology, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, <sup>2</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>3</sup>Genetics Unit, Shriners Hospital for Children, Montréal, QC, Canada.

**Introduction and Aim:** Pseudohypoparathyroidism (PHP) typically arises from defects in *GNAS* (20q13.3), an imprinted gene locus with multiple transcriptional units. Recent studies have shown that the mutations responsible for the PHP-Ib form affect control elements regulating the imprinting of *GNAS*. The purpose of this report was to describe an apparently novel form of PHP-Ib in two brothers with unique clinical features.

**Clinical Report:** The male proband presented at 12 years with increasing seizure frequency and autism. Investigations suggested PHP: (Ca<sup>2+</sup> 0.9 mmol/L, N: 1.1-1.3; PO<sub>4</sub> 1.8 mmol/L, N: 1.0-1.7; PTH 54 pmol/L, N: 1.1-6.8). A PTH infusion test (Parathar 3 units/kg) demonstrated only a 6-fold increase in cAMP (N: >10-fold increase) and a 2.5% reduction in percent tubular reabsorption of phosphate (N: 5-16% reduction). A trans-iliac bone biopsy revealed increased cancellous bone volume (38% above the average) with a 4-fold elevation in bone formation rate. These results confirmed renal resistance to PTH with bone tissue responsiveness. TSH resistance was also suspected: TSH 6.7 mU/L; FT4 <5 pmol/L. TRH stimulation consistent with primary hypothyroidism, negative anti-thyroid antibodies and lack of a goiter. An older brother also manifested autism, PTH resistance and primary hypothyroidism in the absence of positive anti-thyroid antibodies; however, a large goiter was present. Southern blot analyses using gDNA from the proband and methylation sensitive restriction enzymes showed no evidence of a methylation defect in *GNAS* exon A/B. Analysis of genomic DNA from the affected children and their parents through microsatellite markers located centromeric and telomeric of *GNAS*, and through single nucleotide polymorphisms within the *GNAS* locus showed that the two affected individuals inherited different maternal and paternal alleles.

**Conclusions:** We describe two brothers with autism, primary hypothyroidism and PHP, where the genetic and epigenetic findings suggest that *GNAS* is not linked to this form of PHP-Ib. This constellation of features may represent a novel clinical syndrome.

**Genomic Expression Analysis of Rat Chromosome 4 for Skeletal Traits at Femoral Neck.** I. Alam<sup>1</sup>, Q. Sun<sup>1</sup>, L. Liu<sup>\*2</sup>, D. L. Koller<sup>2</sup>, Y. Liu<sup>\*3</sup>, H. J. Edenberg<sup>\*4</sup>, M. J. Econs<sup>3</sup>, T. Foroud<sup>2</sup>, C. H. Turner<sup>1</sup>. <sup>1</sup>Biomedical Engineering, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>3</sup>Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>4</sup>Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Hip fracture is the most devastating osteoporotic fracture type with significant morbidity and mortality. The primary skeletal determinants of hip fracture risk are bone mineral density, structure and strength. Several studies have demonstrated that there is a substantial genetic component to hip fragility. Thus, finding the genetic basis underlying variation in skeletal traits in femoral neck will facilitate our understanding to prevent and/or treat hip fracture successfully. Genetic linkage studies in humans and animal models identified chromosomal regions linked to hip size and bone mass. Previously, we identified that the region of 4q21-q41 on chromosome (Chr) 4 uniquely harbors multiple femoral neck quantitative trait loci (QTLs) in inbred Fischer 344 (F344) and Lewis (LEW) rats. The purpose of this study is to identify the candidate genes for femoral neck density and structure by correlating gene expression in the proximal femur with the femoral neck phenotypes linked to the QTLs on Chr 4. RNA was extracted from proximal femora of 4-week-old rats from F344, LEW and two other strains (n=4 per strain). Microarray analysis was performed using Affymetrix Rat Genome 230 2.0 arrays. A total of 104 genes in the 4q21-q41 region were differentially expressed (p<0.05) among all strains of rats with a false discovery rate (FDR) less than 10%. These 104 genes were then ranked based on the proportion of variation in femoral neck phenotypes in F2 animals homozygous for a particular strain's allele at the Chr 4 QTL explained by the expression level of the gene in that strain. A total of 37 genes, including 21 candidate genes and 16 predicted genes, were strongly correlated (r<sup>2</sup>>0.50) with different femoral neck phenotypes and prioritized for further analysis. Analysis of the related pathways among prioritized candidate genes based on their molecular function, biological process and cellular component of the gene product by Ingenuity pathway analysis revealed several direct or indirect relationships among the candidate genes related to bone metabolism including pathways related to beta-estradiol, interleukin 6, insulin growth factor 2, androgen receptor and tumor necrosis factor. This study may provide a basis for identifying the genetic determinants of skeletal traits at the hip and may lead to novel approaches to prevent and treatment of hip fracture.

**Recurring Mutation Causing Severe/Lethal Recessive Type VIII Osteogenesis Imperfecta in African-Americans Originated in West Africa More than 300 Years Ago.** W. A. Cabral<sup>\*1</sup>, A. M. Barnes<sup>\*1</sup>, C. N. Rotimi<sup>\*2</sup>, F. D. Porter<sup>\*3</sup>, J. Bailey-Wilson<sup>\*4</sup>, L. Brody<sup>\*5</sup>, J. C. Marini<sup>1</sup>. <sup>1</sup>Bone & Extracellular Matrix Branch/NICHD/NIH, Bethesda, MD, USA, <sup>2</sup>Inherited Disease Research Branch/NHGRI/NIH, Bethesda, MD, USA, <sup>3</sup>Heritable Disorders Branch/NICHD/NIH, Bethesda, MD, USA, <sup>4</sup>Inherited Disease Research Branch/NHGRI/NIH, Baltimore, MD, USA, <sup>5</sup>Genome Technology Branch/NHGRI/NIH, Bethesda, MD, USA.

Recessive Osteogenesis imperfecta (OI) is caused by defects in the genes encoding cartilage-associated protein (*CRTAP*) or prolyl 3-hydroxylase 1 (*LEPRE1*) and accounts for approximately 5% of OI cases in North America. Patients deficient in prolyl 3-hydroxylase 1 have severe to lethal bone dysplasia characterized by white sclerae and extreme osteopenia, with DEXA z-scores below -6. Although recessive OI accounts for only a small percentage of OI cases, we have identified a recurring mutation in the *LEPRE1* gene, IVS5+1G>T (Nat Genet 39:359-365, 2007). The common mutation occurs in a compound heterozygous or homozygous state in 6 of 9 probands (9 of 18 alleles) with recessive type VIII OI (OMIM #610915). All six probands with this mutation were born to carrier parents of West-African (Nigerian or Ghanaian) or African-American descent, suggesting the existence of a stable mutant allele in this population. In order to determine the carrier frequency of this mutation in African-Americans, we screened genomic DNA from unrelated African-American newborns from Pennsylvania (n=1429) and Washington, D.C. (n=588). We identified 5 carriers from Pennsylvania and 5 carriers from the District of Columbia, predicting a carrier frequency of 1 in 118-286 African-American newborns (0.35-0.85%). Our results predict a 1 in 55,000-330,000 rate of occurrence of lethal type VIII OI in African-Americans due to homozygosity for *LEPRE1* IVS5+1G>T. To verify the origin of the mutation, genomic DNA from 1097 contemporary West Africans was screened using a custom SNP assay, followed by PCR confirmation of positive samples. Fifteen of 1097 unrelated individuals (1.37%) from Nigeria and Ghana were heterozygous for *LEPRE1* IVS5+1G>T, two-thirds of whom are from the Yoruba or Ibo tribes of Nigeria. This high carrier frequency suggests that the incidence of recessive type VIII OI in West Africa from this founder mutation alone is 1 in 21,000 individuals, which is equivalent to the incidence of dominant OI in North America. Screening of microsatellites covering a 4.2Mb region surrounding the *LEPRE1* gene on chromosome 1p33-34.3 revealed a conserved haplotype of less than 500Kb in probands and carriers. These data support the occurrence of a common founder mutation over 300 years ago, consistent with our hypothesis that this West African allele was transported to the Americas via the colonial slave trade.

**Background:** Osteoporosis is diagnosed by the measurement of bone mineral density (BMD)-a highly heritable and multifactorial trait. We undertook a genome-wide association (GWA) study for BMD.

**Methods:** Using 314,075 single nucleotide polymorphisms (SNPs) we identified the most promising SNPs in 2,094 women from the United Kingdom (TwinsUK discovery cohort). These were then tested for replication in 6,463 individuals from three cohorts (the Rotterdam study, the Chingford study and TwinsUK replication cohort). We also investigated allelic expression levels in lymphoblast cell lines (LCLs). Replicated SNPs were tested for their association with osteoporotic fracture in the Chingford study (n = 718) and the Rotterdam study (n = 5921).

**Findings:** A non-synonymous SNP in the LRP5 gene was associated with decreased BMD (rs3736228: P =  $6.3 \times 10^{-12}$  for lumbar spine (LS) and  $1.9 \times 10^{-4}$  for femoral neck (FN)) and an increased risk of both osteoporotic fracture (odds ratio (OR) = 1.3, P =  $2.0 \times 10^{-3}$ ) and osteoporosis (OR = 1.3, P =  $8.0 \times 10^{-3}$ ). Three SNPs near the TNFRSF11B (osteoprotegerin) gene, were associated with decreased BMD (top SNP, rs4355801: P =  $7.6 \times 10^{-10}$ , P =  $3.3 \times 10^{-8}$  for LS and FN, respectively) and increased risk of osteoporosis (OR = 1.2, P = 0.038). The risk allele at rs4355801 was associated with a 2-fold decreased expression of TNFRSF11B in LCLs (P =  $3.0 \times 10^{-6}$ ). 22% of the entire population was at least heterozygous for both risk alleles and these alleles had a cumulative association with BMD (P for trend =  $2.5 \times 10^{-17}$ ). The presence of both risk alleles increased the risk of osteoporotic fracture (OR = 1.3, P =  $6.0 \times 10^{-3}$ ) and this effect was independent of BMD.

**Interpretation**

This first comprehensive interrogation of common genetic variants influencing BMD, in 8,557 individuals, has identified two gene variants of key biologic proteins which increase the risk of osteoporosis and osteoporotic fracture. These risk alleles, whose combined effect on fracture is similar to that of most well-replicated environmental risk factors, are present in more than one in five Caucasians.

**Polymorphisms in the Wnt Inhibitory Factor 1 Gene (WIF1) Are Associated with BMD in Elderly Swedish Women.** C. J. Rubin<sup>1</sup>, K. Michaelsson<sup>\*2</sup>, H. Melhus<sup>\*1</sup>, Ö. Ljunggren<sup>1</sup>, L. Lind<sup>\*1</sup>, A. Kindmark<sup>1</sup>. <sup>1</sup>Dept. Med. Sciences, Uppsala University, Uppsala, Sweden, <sup>2</sup>Dept. Surgical Sciences, Uppsala University, Uppsala, Sweden.

Canonical wnt-signaling promotes bone accrual and perturbations in the wnt signaling pathway can cause osteopetrosis as well as osteoporosis (LRP5 mutations). Wnt Inhibitory Factor 1 (WIF1) is a secreted protein that inhibits wnt-proteins from binding to their receptors. In prior studies of an intercross between domestic and wild-type chicken we have observed differential expression of WIF1 between chicken with high and low BMD and have also identified a Quantitative Trait Locus (QTL) for BMD in the region where WIF1 is located.

Altogether, the data from the chicken studies and the importance of wnt-signaling in bone metabolism makes WIF1 an interesting candidate gene to explore in relation to inter-individual variation in bone traits. In the present study we genotyped 24 common single nucleotide polymorphisms (SNPs) located downstream, within and upstream of the human WIF1 gene and tested if any of these were associated with bone traits. The analyzed population-based cohort (the PIVUS study) comprises 1000 men and women, phenotyped by DXA at approximately 70 years of age.

Female-specific analysis with body mass index (BMI) and age included as covariates revealed associations between BMD (total body and total hip) and genotypes of two SNPs (Figure 1). These two SNPs (rs7309476 and rs10878228) had minor allele frequencies of 0.42 and female C-allele carriers had 6% higher total hip BMD and 3% higher total body BMD compared to female A-allele homozygotes. In addition to these, several other SNPs obtained P-values < 0.05 and may also be interesting to study in follow up studies in other cohorts.

## SA266

**Polymorphisms in CYP24A1, the Gene Encoding 25-hydroxyvitamin D-24-hydroxylase Are Associated with BMD.** E. A. Streeten, J. Liu<sup>\*</sup>, X. Shi<sup>\*</sup>, K. Ryan<sup>\*</sup>, D. McBride<sup>\*</sup>, B. Mitchell, A. R. Shuldiner<sup>\*</sup>. Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, MD, USA.

Vitamin D deficiency is an important contributor to reduced bone mineral density (BMD). We and others have found that serum level of 25(OH)D is hereditary. Since the main source of vitamin D is endogenous production, we hypothesized that variants in the genes encoding the vitamin D synthetic (*CYP2R1*, *CYP27B1*) and inactivating enzymes (*CYP24A1*) are associated with BMD. The purpose of this study was to perform association studies between SNPs of these 3 genes and BMD.

Healthy Amish participants (n=1467), including 643 men and 843 women, mean ( $\pm$ SD) age of  $55.4 \pm 14.7$  were studied at the Amish Research Clinic in Lancaster, PA. DXA was performed (Hologic 4500) of the spine (L1-4), hip (total, TH; femoral neck, FN) and distal radius (mid, MRad; total, TRad; ultradistal, UD). Lab studies included serum calcium, PTH and 25(OH)D. Association studies were done between BMD and SNPs on 500K genome-wide association (GWAS) chips for the 3 enzymes and also between BMD and 21 haplotype-tagging SNPs from *CYP24A1*.

Results showed T-scores: L1-4  $-1.13 \pm 1.38$ ; TH  $-0.24 \pm 1.07$ ; FN  $-0.54 \pm 1.15$ , and mean 25(OH)D  $22.8 \pm 7.6$ . From GWAS 500K chips, genotypes of 4 of 6 SNPs of *CYP24A1* were associated with BMD in 634 participants, best for SNP rs1570669 for TH (p=0.005). One SNP of *CYP2R1*, A2293926 was associated with UD BMD (p=0.007) and two SNPs of *CYP27B1* were associated with TRad (best p=0.024 for A 2216496). Findings in *CYP24A1* were replicated in an additional sample of 833 Amish (total n=1467). Genotyping of 21 additional SNPs to cover the *CYP24A1* gene in 634 subjects revealed significant associations between 13 SNPs and BMD, with best associations seen in those over age 50 (below). Serum 25(OH)D, PTH, and calcium (n=993) were not associated with genotype for SNPs of *CYP24A1*.

We conclude that variants of *CYP24A1*, the gene for 24-hydroxylase, which catabolizes 25(OH)D into inactive 24,25(OH)<sub>2</sub>D, are associated with BMD in men and women, most strongly in those over age 50. Only minimal association was seen in those under age 50. We speculate that with reduced endogenous skin production of D<sub>3</sub> that occurs with aging, the relative activity of the catabolic 24-hydroxylase enzyme may become more important to maintain optimal calcitriol levels and bone health.

SNP rs3787555 (left) SNP rs1570669 (from GWAS) (right)

**Genome-wide Association Study Identified Novel Susceptibility Loci for Osteoporosis.** Y. Guo<sup>\*1</sup>, J. T. Wang<sup>\*1</sup>, T. L. Yang<sup>\*1</sup>, F. Pan<sup>\*1</sup>, F. Zhang<sup>\*1</sup>, Z. X. Zhang<sup>\*1</sup>, X. G. Liu<sup>\*1</sup>, Q. Zhou<sup>\*1</sup>, B. Drees<sup>\*2</sup>, J. Hamilton<sup>\*2</sup>, C. J. Papasian<sup>\*2</sup>, R. R. Recker<sup>3</sup>, H. W. Deng<sup>2</sup>. <sup>1</sup>School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, China, <sup>2</sup>School of Medicine, University of Missouri - Kansas City, Kansas City, MO, USA, <sup>3</sup>Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Osteoporosis is a major public health problem. It is mainly characterized by low bone mineral density (BMD) and/or low-trauma osteoporotic fractures (OF), both of which have strong genetic determination, but specific genes are largely unknown. Using the Affymetrix 500K array set, we performed a case-control genome-wide association study in 700 elderly Chinese Han subjects (350 with osteoporotic hip fractures and 350 healthy matched controls). For the significant SNPs identified for OF, we further examined their relevance with hip BMD in both Chinese and Caucasian populations involving an addition 7,009 individuals. We found three novel loci highly significantly associated with OF, including rs13182402 within *ALDH7A1* ( $P = 3.09 \times 10^{-9}$ , odds ratio = 2.92), rs6711417 near *UBR3* ( $P = 4.61 \times 10^{-6}$ , odds ratio = 0.58), and rs6064822 within *PHACTR3* ( $P = 2.36 \times 10^{-5}$ , odds ratio = 0.55). Especially, these three loci were unequivocally confirmed as significantly associated with hip BMD even across ethnic boundary, in both Chinese and Caucasians (rs13182402: combined  $P = 8.18 \times 10^{-5}$ ; rs6711417: combined  $P = 3.60 \times 10^{-5}$ ; rs6064822: combined  $P = 3.80 \times 10^{-4}$ ), further attesting to their importance in osteoporosis. *ALDH7A1* gene degrades and detoxifies acetaldehyde, which inhibits the osteoblast proliferation and result in the decreased bone formation. *UBR3* encodes E3 ubiquitin ligase, which plays a specific role in osteoblast differentiation. *PHACTR3* is involved in protein phosphatase pathway regulating diverse cellular processes. Our findings provide a new insight into the pathogenesis of osteoporosis, which warrant further studies to explore generality in other populations, their biological effects and functional mechanisms.

**A Common Single Nucleotide Polymorphism in the High Mobility Group AT-hook 2 (HMGA2) Gene Is Associated with Bone Mass in Men.** A. L. Kuipers<sup>1</sup>, J. A. Cauley<sup>1</sup>, K. Ensrud<sup>2</sup>, C. L. Gordon<sup>3</sup>, D. Ingilis<sup>3</sup>, V. W. Wheeler<sup>4</sup>, A. L. Patrick<sup>4</sup>, C. H. Bunker<sup>\*1</sup>, C. S. Nestlerode<sup>\*1</sup>, A. R. Hoffman<sup>\*5</sup>, E. S. Orwoll<sup>6</sup>, J. M. Zmuda<sup>1</sup>. <sup>1</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>VA Medical Center and University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>McMaster University, Hamilton, ON, Canada, <sup>4</sup>Tobago Health Studies Office, Sarborough, Trinidad and Tobago, <sup>5</sup>VA Palo Alto Health Care System and Stanford University Medical Center, Palo Alto, CA, USA, <sup>6</sup>Oregon Health and Science University, Portland, OR, USA.

*HMGA2* encodes a non-histone, chromosome protein belonging to the high mobility group (HMG) family that regulates transcription of target genes. Knockout mouse experiments and a case report of a boy with a constitutional chromosomal rearrangement suggest that *HMGA2* plays a role in growth regulation. Moreover, a recent genome-wide analysis (GWA) identified a novel association of the *HMGA2* gene with human stature. To further evaluate this gene and skeletal measures, we genotyped a C-T polymorphism in the 3' UTR of *HMGA2* identified from the GWA of short stature, and conducted genetic association analysis with body size and bone mass in an initial discovery population consisting of 1,813 men of African ancestry and in a validation sample of 979 Caucasian American men. The mean age of these men were  $58.9 \pm 10.4$  years and  $73.7 \pm 5.8$  years, respectively. Skeletal measurements were obtained with peripheral quantitative computed tomography (pQCT). Specialized segmentation and analysis software (pQCT Pro) was also used to assess apparent trabecular architecture in the African ancestry men. The minor T allele frequency was 0.34 in African and 0.49 in Caucasian men. There was no significant association with height or body weight in either ethnic group. However, there was an additive association with BMD where the T allele was associated with lower trabecular volumetric BMD at the tibia ( $P=0.002$  in Caucasians;  $P=0.007$  in Africans). For example, African ancestry men with the T/T genotype had 4% lower trabecular BMD compared to men with the C/C genotype ( $231 \pm 2$  vs  $221 \pm 3$  mg/cm<sup>3</sup>), whereas, the heterozygotes had intermediate values ( $227 \pm 2$  mg/cm<sup>3</sup>). Apparent trabecular thickness was 9% less ( $P=0.005$ ) and apparent trabecular number was 15% greater ( $P=0.01$ ) among African ancestry men with the T/T than C/C genotypes. Our analysis suggests a novel association between a common *HMGA2* genetic variant and trabecular bone mass and structure in older men.

**Osteosclerotic Prostate Cancer Metastasis to Murine Bone: Enhanced with Increased Bone Turnover.** P. C. Buttker<sup>\*1</sup>, E. M. Paul<sup>\*1</sup>, R. A. Sikes<sup>\*2</sup>, R. R. Gomes, Jr<sup>1</sup>. <sup>1</sup>Orthopaedics and Rehabilitation, H089, Penn State College of Medicine, Hershey, PA, USA, <sup>2</sup>Biological Sciences, University of Delaware, Newark, DE, USA.

Spontaneous development of osteoblastic lesions of prostate cancer (PCa) in mice is modeled by orthotopic (prostatic) deposition of neoplastic cells followed by an extremely long latency with associated low incidence of bone metastasis. Intracardial injection results in overt bone metastases only with osteoclastic PCa cells (i.e., PC-3). Herein, we report that androgen independent osteoblastic PCa cells will readily colonize bone when it is in a high remodeling state. SCID/bg mice were subjected to periods of intermittent parathyroid hormone (PTH) exposure, followed by an intracardiac infusion of C4-2 PCa cells. Analysis of bone turnover markers in serum from mice treated intermittently with PTH revealed significant increases in osteocalcin ( $55.06 \pm 7.5$  vs  $74.01 \pm 18.5$  ng/ml) and TRACP-5b ( $3.3 \pm 0.6$  vs  $4.81 \pm 0.8$  U/L), but no change in type I collagen CTX levels relative to control mice. Subsequent MicroCT analysis of femurs revealed significant increases in bone mineral density, trabecular thickness ( $0.056 \pm 0.002$  vs  $0.062 \pm 0.001$   $\mu$ m) and porosity but significant decreases in connectivity density and trabecular number ( $5.756 \pm 0.17$  vs  $5.02 \pm 0.20$  mm<sup>-1</sup>) in mice treated with PTH relative to controls. By eight weeks post-PCa-injection 70% of mice, pre-treated with PTH, demonstrated detectable serum prostate specific antigens (PSAs). Immunohistochemical labeling of femurs for PSA and pan-Cytokeratin revealed the presence of tumor cell nests, as opposed to single cells, in marrow and trabecular spaces. These results suggest that 1) mouse bone physiology is an important factor for developing osteoblastic/sclerotic PCa bone metastases in murine hosts; 2) the establishment of osteosclerotic prostate cancer bone metastases in mice is enhanced by alterations in bone turnover, and 3) regimens of PTH administration for osteoporosis may require caution and/or enhanced monitoring of cancer patients at risk for developing bone metastases.

**Strength Training Prevents Bone Loss at the Spine in Older Breast Cancer Survivors: Preliminary Findings from an RCT.** K. M. Winters-Stone<sup>\*1</sup>, J. A. Bennett<sup>\*1</sup>, A. Reiner<sup>\*1</sup>, J. Dobek<sup>\*1</sup>, A. Schwartz<sup>\*2</sup>, L. Nail<sup>\*1</sup>. <sup>1</sup>School of Nursing, Oregon Health & Science University, Portland, OR, USA, <sup>2</sup>School of Nursing, Arizona State University, Tempe, AZ, USA.

Approximately 85% of women who receive a first diagnosis of breast cancer are aged 50 and over, thus the combined effect of aging, menopause and breast cancer treatment may threaten bone health in these women. Yet, few studies have focused on evaluating how exercise interventions, particularly resistance training, benefit older breast cancer survivors. PURPOSE: The purpose of this report is to present preliminary findings for an on-going resistance training study in older breast cancer survivors. METHODS: We are conducting a 12-month randomized controlled trial of resistance (strength) training (STR) versus a control group of flexibility (FLEX) training in early-stage, older BCS (mean age: 63.7 yrs) who are > 1 year past radiation and/or chemotherapy. To date, 31 women (STR n=20, FLEX n=11) have completed 12 months of exercise training and interim testing. Interim findings for bone mineral density of the total hip and lumbar spine assessed by DXA are presented. Within group changes were determined by paired t-tests and between group changes were determined by repeated measures ANOVA. RESULTS: After 12 months of exercise, spine and hip BMD was maintained in STR (0.3% and -0.8%, respectively) compared to significant decreases at both sites in FLEX (-1.7% and -1.6%, respectively). Between group changes were only significant for spine BMD ( $p<.03$ ). CONCLUSIONS: These preliminary data show trends that resistance exercise maintains BMD at the spine compared to a control program of flexibility exercise in older breast cancer survivors. Definitive conclusions must await completion of the full trial.

**TGF- $\beta$  Activates Prostate Cancer Bone Metastases, Pro-Osteolytic Gene Expression and the New TGF- $\beta$  Signaling Regulator PMEPA1.** P. G. J. Fournier, G. A. Clines, J. M. Chirgwin, T. A. Guise. Endocrinology, University of Virginia, Charlottesville, VA, USA.

Transforming growth factor- $\beta$  (TGF- $\beta$ ) increases breast cancer and melanoma bone metastases by activating pro-osteolytic genes (PTHrP, IL-11 or CTGF). We hypothesized that TGF- $\beta$  would also promote prostate cancer bone metastases.

A specific inhibitor of the TGF- $\beta$  type I receptor kinase, SD-208, decreased Smad2 phosphorylation induced by TGF- $\beta$  in PC-3 human prostate cancer cells. Osteolytic bone metastases were caused by inoculating PC-3 cells in the left cardiac ventricle of athymic mice. SD-208 (50mg/kg/d po) begun at the time of tumor inoculation decreased osteolytic bone metastases (56% decrease,  $P < 0.05$ ) and increased survival (57 to 69 days median survival,  $P < 0.05$ ). When treatment began after osteolytic lesions were detected, SD-208 decreased bone destruction (47% decrease,  $P < 0.05$ ) without significantly improving survival (51 to 55 days,  $P > 0.1$ ).

We analyzed PC-3 cells treated  $\pm$  TGF- $\beta$  (5ng/mL) by Affimetrix gene array and sqRT-PCR. Significantly up-regulated genes included PTHrP, IL-11, CTGF and ADAM19, which can increase bone resorption, as well as MMP-13 and thrombospondin-1, two activators of TGF- $\beta$ .

The most increased gene was PMEPA1 ( $>20x$ ), a protein highly expressed in breast, colon and prostate cancers. sqRT-PCR of mRNA from PC-3 cells treated  $\pm$  TGF- $\beta$  and  $\pm$  cycloheximide or  $\pm$  actinomycin-D showed that TGF- $\beta$  directly controls PMEPA1 transcription. Dual-luciferase experiments showed that a 3.7kb fragment of PMEPA1 promoter is activated by TGF- $\beta$ . This fragment contains 5 consensus Smad binding elements, but mutagenesis showed that they are not involved in TGF- $\beta$  induction. Analysis of promoter deletion constructs and overexpression of Smad2, 3 and 4 demonstrate that TGF- $\beta$  induction of PMEPA1 promoter is mediated by a 1.2kb proximal fragment through both Smad and non-Smad mechanisms.

Western blotting confirmed that TGF- $\beta$  quickly and dose-dependently increased the cytosolic isoform of PMEPA1 in PC-3 cells. PMEPA1 proteins contain 2 PPxY domains that can interact with Smurf ubiquitin ligases (which can regulate degradation of Smads and type I TGF- $\beta$  receptor) and a Smad-interaction motif (found in DNA binding co-factors that control the affinity of Smads for DNA), suggesting that PMEPA1 regulates TGF- $\beta$  signaling. shRNA knockdown of PMEPA1 significantly decreased TGF- $\beta$  activation of the Smad reporter (CAGA)<sub>3</sub>. PMEPA1 induced by bone-derived TGF- $\beta$  could potentiate TGF- $\beta$  signaling in cancer cells.

Our results show that TGF- $\beta$  can promote PC-3 bone metastases through a transcriptional program that increases bone resorption and potentiates TGF- $\beta$  signaling.

**TGF- $\beta$  Blockade Inhibits Osteolytic but not Osteoblastic Prostate Cancer Metastases.** P. G. J. Fournier, K. S. Mohammad, C. R. McKenna\*, X. Peng\*, J. M. Chirgwin, T. A. Guise. Endocrinology, University of Virginia, Charlottesville, VA, USA.

Prostate cancer cells frequently metastasize to bone causing bone destruction and/or formation. Bone-derived transforming growth factor- $\beta$  (TGF- $\beta$ ) enhances osteolytic metastases. Inhibition of TGF- $\beta$  signaling with SD-208, a kinase inhibitor of the TGF- $\beta$  type I receptor, decreased osteolytic metastases in breast cancer and melanoma models. The drug also increased bone mineral density by stimulating osteoblastic bone formation and inhibiting osteoclastic bone resorption, suggesting that it might be unsuitable against osteoblastic metastases, which are common in prostate cancer. Here we report the effects of SD-208 in mouse models of osteolytic and osteoblastic prostate cancer bone metastases.

Male nude mice were inoculated in the left cardiac ventricle with osteolytic PC-3 cells ( $10^5$  cells,  $n=11-14$ /group). Immunostaining of sections of PC-3 bone metastases showed nuclear localization of phosphorylated Smad2, a marker of activated TGF- $\beta$  signaling. Mice were treated with SD-208 (50mg/kg/d po) or vehicle and followed by x-ray. SD-208 did not decrease bone metastasis number compared to vehicle (vehicle 10/11 vs SD-208 12/14) but did decrease bone lesion area measured by x-ray compared to vehicle ( $6.7 \pm 3.3 \text{ mm}^2$  vs  $15.3 \pm 2.8 \text{ mm}^2$ ,  $P < 0.05$ ) and increased mouse median survival (57 to 69 days,  $P < 0.05$ ).

In a pilot experiment, we inoculated cells from the LuCaP 23.1 human prostate cancer osteoblastic xenograft into the tibias of nude mice ( $2 \times 10^5$  cells,  $n=3-5$ /group). Nuclear immunostaining of phosphorylated Smad2 demonstrated active TGF- $\beta$  signaling in tumor cells at sites of bone metastases. However, SD-208 treatment decreased neither incidence of metastases nor skeletal tumor burden, measured by histomorphometry compared to vehicle-treated mice. New bone formation in the tibias containing tumor was not augmented by SD-208 treatment, while trabecular bone measured in vertebrae free of tumor cells was increased by SD-208 (BV/TV 270% vs vehicle,  $P < 0.01$ ).

Our results show that blockade of TGF- $\beta$  signaling with SD-208 increases bone formation, while the drug does not enhance skeletal lesions in a model of osteoblastic prostate bone metastases. SD-208 does inhibit osteolytic metastases from prostate cancer cells. Overall, TGF- $\beta$  blockade should be an efficient therapy against bone metastases with osteolytic and mixed bone responses to tumor but less so against purely osteoblastic lesions.

**Breast Cancer Cell Conditioned Media Stimulates Osteoblastic Cells to Attract Breast Cancer Cells.** K. P. Chin-quee\*, H. J. Donahue. Department of Orthopaedics and Rehabilitation, Penn State College of Medicine, Hershey, PA, USA.

Breast cancer owes most of its mortality and morbidity to its metastasis to distant sites, especially bone. While a better understanding of what cancer cells do when they colonize bone is emerging (i.e. the "vicious cycle"), there is relatively little known as to why breast cancer cells preferentially metastasize to bone. To address this issue, we examined the hypothesis that secreted factors from breast cancer cells induce changes in osteoblastic cells, which cause them to attract metastasizing breast cancer cells. We focused on MDA-MET, a breast cancer cell line derived from MDA-MB-231, created by an *in vivo* selection process leading to a highly bone specific metastasis, and hFOB 1.19, a human fetal osteoblastic cell line. hFOB 1.19 cells were incubated for 24hr in conditioned media from MDA-MET cells (group 1), HTERT-HME1 cells (normal breast epithelial; group 2), or hFOB 1.19 cells (group 3). After this incubation, treatment media was removed from the hFOB 1.19 cells, the cells were washed with PBS and serum free media added. At the end of 12hr, this serum-free media, from all three groups was collected. The control group (group 4) consisted of serum-free media unexposed to any cells. To test the chemoattractant ability of the collected media from these four groups, we used a transwell cell migration assay, where migratory cells are placed in removable transwell inserts, the bottom of which consists of porous membranes (pore size 8 $\mu$ m), in direct contact with the test media in the lower well. The ability of media from each group to attract the MDA-MET cells, causing them to migrate to the other side of the membrane, was examined. The number of migratory cells was quantified by fluorescent labeling of the lysed cells, given in fluorescent units. Data are represented as mean fluorescence  $\pm$  SEM. We found a greater migration of breast cancer cells toward media from group 1 than toward either group 2 or group 3 ( $1533 \pm 58.2$  vs  $957 \pm 140$  vs  $983 \pm 51.4$ ), respectively;  $p < 0.01$ ), but no difference between migration towards group 2 (treated by HTERT-HME1) and group 3 (untreated) media. In addition, Group 3 media from untreated hFOB 1.19 cells caused a greater migration of cells than group 4, serum -free media alone ( $983 \pm 51.4$  vs  $653 \pm 56.1$ ;  $p < 0.01$ ). Our results suggest that factors constitutively secreted by bone cells attract breast cancer cells. More importantly, metastatic breast cancer cells (MDA-MET) but not normal breast epithelial cells (HTERT-HME1), secrete factors, which in turn increase the ability of osteoblastic cells to attract breast cancer cells.

**Osteoclast Precursors Play a Role in Recruiting Breast Cancer Cells and Osteoblasts onto the Bone in Vitro.** Z. Shi\*, X. Feng. Pathology, Univ. of Alabama at Birmingham, Birmingham, AL, USA.

Breast cancer (BC)-induced osteolysis is not only a consequence but, more devastatingly, also a cause of BC skeletal metastasis. Three key players, osteoclasts (OC), BC cells, and osteoblasts (OB), are involved in BC-induced osteolysis. Indeed, BC cells express PTHrP, which stimulates the production of RANKL by OB. The produced RANKL promotes the differentiation of OC precursors into mature OC to resorb bone, resulting in the release and activation of TGF- $\beta$  embedded in the bone matrix. The released TGF- $\beta$  further stimulates the expression of PTHrP. As such, BC-induced osteolysis is a vicious cycle. Although this mode of the action is well documented, it is unclear how BC cells and OB are brought to the scene to act. Specifically, in tumor-induced-osteolysis, before the onset of bone resorption, OB and BC cells must be recruited to bone surface to produce RANKL, which is required for OC formation. However, based on the current models, these cells are attracted by factors released from bone matrix by OC, but how OC formed in the first place is unknown. In this study, we propose a new hypothesis that OC precursors play a key role in OB and BC recruitment to bone. We performed chemotaxis assays with the following conditioned media (CM): CM1 - from OC precursors cultured in Teflon beaker, CM2 - from the OC precursors cultured in tissue culture plates without bones slices and CM3 - from the OC precursors cultured in tissue culture plates with bones slices. CM were all prepared using MEM containing 0.2 % FBS. The control medium is MEM containing 0.2% FBS. 600ul CM was added to one well in Transwell. BC cells (MDA-MB-231) or OB ( $2 \times 10^5$ /ml) were in MEM with 0.2% FBS. Transwell were inserted into well and 100ul cells ( $2 \times 10^5$  each insert) were added to the inside compartment. Transwell were cultured for 4 hours at 37°C and 5% CO<sub>2</sub>. After 4 hours, cells were fixed for 30 seconds. Cells were stained for one hour with Crystal Blue and then counted. The results indicate that all three CM (CM 1, CM2 and CM3) exhibited chemotaxis on MDA-MB-231 cells compared with control medium. More importantly, CM3 demonstrated a higher capacity in inducing chemotaxis on MDA-MB-231 cells than CM1 and CM2. Moreover, all three CM (CM 1, CM2 and CM3) exerted higher chemotaxis on OB compared to control medium. These data indicate that OC precursors can exert chemotactic effects on BC cells and OB, suggesting that OC precursors play a key role in BC bone metastasis by recruiting OB and BC cells to the active bone remodeling sites. These studies have not only deepened our understanding of the mechanisms underlying BC cells/OB recruitment to bone but also opened new directions for future investigation of the mechanism underlying BC bone metastasis.

**Effects of Androgen Deprivation Therapy on Bone Health in Prostate Cancer.** A. K. McDonough<sup>1</sup>, G. G. Teng<sup>2</sup>, J. Abbott<sup>1</sup>, R. Nair<sup>1</sup>, C. Amling<sup>3</sup>, J. Colli<sup>4</sup>, J. B. Fiveash<sup>5</sup>, R. Lopez<sup>6</sup>, D. Urban<sup>3</sup>, J. R. Curtis<sup>1</sup>, K. Saag<sup>1</sup>.

<sup>1</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Division of Rheumatology, National University Hospital, Singapore, Singapore, <sup>3</sup>Division of Urology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Birmingham VA Medical Center, Birmingham, AL, USA, <sup>5</sup>Department of Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>6</sup>Department of Radiology, University of Alabama at Birmingham, Birmingham, AL, USA.

Androgen deprivation therapy (ADT) can cause bone loss in men but it is uncertain how rapidly this develops and if its bone effects differ by race/ethnicity. We examine whether short-term ADT leads to significant increases in bone turnover markers (BTM) or a decline in BMD over 6 months. We also determined the sensitivity of QCT compared with DXA for identifying early BMD change.

Men > 40 yrs with M0 prostate cancer were enrolled within 1 month of ADT initiation and seen at baseline, 3, and 6 mos. Patients with other causes of metabolic bone disease or on anti-osteoporotic meds were excluded. Descriptive analyses examined trends in osteocalcin, urine NTX, and BMD. We also analyzed factors associated with BTM change and BMD loss.

Patients (n = 30) were 40% African American (AA), had mean age 69.5 ± 8.9 yrs and mean BMI 27.6 ± 4.3. We found significant increases in BTM (p = 0.001) as early as 3 months into ADT.

Non-statistically significant trends in BMD suggest more bone loss among Caucasians by QCT and DXA. No significant association with BMD or BTM was seen with alcohol intake, smoking, BMI, testosterone levels, or caffeine. QCT and DXA BMD of the hip (r = 0.71) and spine (r = 0.87) highly correlated.

In summary, ADT significantly increased BTM within 6 months of initiating therapy. Trends in BMD decline were notable in Caucasian, but not African Americans. QCT appears more sensitive than DXA to identify need for early intervention for men who are may have accelerated ADT-associated bone loss.
