Progressive loss of bone mass and strength with age in mice is associated with increased oxidative stress and expression of target genes of the FoxO transcription factors, as well as increased osteoblast and osteocyte apoptosis. In support of a mechanistic link among these phenomena,  $H_2O_2$  promotes the translocation of FoxOs into the nucleus and the transcriptional activation of pro-apoptotic genes. Albeit, FoxOs also activates the transcription of antioxidant enzymes like MnSOD and catalase, thereby mounting a defense against oxidative stress. Heretofore, the factor(s) influencing the balance between the pro-apoptotic versus pro-survival gene program activation by FoxOs remain unknown. Based on evidence that  $H_2O_2$  stimulates FoxO-mediated transcription in osteoblastic cells and induces the association of FoxOs with  $\beta$ -catenin, we investigated the relevance of the FoxO/ $\beta$ -catenin partnership to the lifespan of osteoblastic cells. Similar to the addition of  $H_2O_2$  into the culture medium, overexpression of FoxO3a in C2C12 cells increased apoptosis, as determined by the number of cells with altered nuclear morphology. A dominant negative FoxO mutant abolished the effect of  $H_2O_2$  on apoptosis; and both  $H_2O_2$  and FoxO3a increased the transcription of the pro-apoptotic gene Bim as measured by a Bim-luciferase reporter construct. Furthermore, mutation of the FoxO binding site on the Bim gene promoter abolished the effect of  $H_2O_2$  or FoxO3a, confirming the essential role of FoxO-stimulated transcription of pro-apoptotic genes in  $H_2O_2$ -induced apoptosis. Strikingly, the pro-apoptotic effect of either  $H_2O_2$  or FoxO3a was abolished in cells co-transfected with a mutant form of  $\beta$ -catenin (S33Y), which cannot be targeted for degradation. The S33Y  $\beta$ -catenin mutant also antagonized the stimulatory effect of  $H_2O_2$  or FoxO3a on Bim expression. Albeit,  $H_2O_2$  or FoxO3a also stimulated MnSOD gene expression as measured by a MnSOD-luciferase reporter construct. More strikingly,  $\beta$ -catenin S33Y upregulated the effects of  $H_2O_2$  and FoxO3a on MnSOD. Conversely, the  $\beta$ -catenin antagonist DKK-1 inhibited both basal MnSOD expression as well as the upregulation of MnSOD produced by  $H_2O_2$  or FoxO3a. We conclude that the level of active  $\beta$ -catenin in osteoblastic (and perhaps other cell types) is an important determinant of their fate by tilting the balance of FoxO-mediated transcription towards a pro-survival, as opposed to a pro-apoptotic, gene program.

**Glucose-dependent Insulinotropic Peptide Inhibits Glucose-induced Apoptosis of Bone Cells.** S. Sridhar\*<sup>1</sup>, M. Marrero\*<sup>2</sup>, X. Shi\*<sup>3</sup>, S. Sridhar\*<sup>1</sup>, Q. Mi\*<sup>3</sup>, W. B. Bollag\*<sup>1</sup>, N. Chutkan\*<sup>4</sup>, C. M. Isles\*<sup>4</sup>. <sup>1</sup>Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Pharmacology, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Pathology, Medical College of Georgia, Augusta, GA, USA, <sup>4</sup>Orthopaedic Surgery, Medical College of Georgia, Augusta, GA, USA.

We have previously demonstrated that Glucose-dependent insulinotropic peptide (GIP) receptors are present in a variety of bone cells including osteoblasts and bone marrow derived osteoprogenitor or stromal cells (BMSC). We have proposed that GIP is the hormonal link between nutrient intake and dietary-induced stimulation of bone formation. We have also shown that BMSC not only express GIP receptors but that GIP also promotes osteoblast differentiation. To further define the mechanism responsible for GIP's anabolic effect on bone we examined whether GIP might also affect apoptosis of osteoblasts and BMSC. Specifically, hyperglycemia (Diabetes Mellitus) is known to negatively impact bone formation and result in a higher number of fractures. Thus, we used high glucose as an apoptotic signal. For these experiments we used primary calvarial osteoblasts and BMSCs harvested from C57BL6 mice bone marrow and enriched for stem cells by using negative and positive selection. Cells were grown in 60 mm dishes to confluence and placed in either normal glucose (5.5 mM) or high glucose medium (25 mM) with or without increasing concentrations of GIP (0.1-10 M). Cell protein was extracted and analyzed by Western blot (n=3). We found GIP dose-dependently and very significantly inhibited high-glucose induced apoptosis as assessed by caspase 3 cleavage or Akt phosphorylation. Since GIP levels are known to decrease in diabetes mellitus we propose that loss of the anti-apoptotic effects of these hormone could contribute at least in part to diabetes related bone loss.

**Butyrate Stimulates Mineralized Nodule Formation and Osteoprotegerin Expression by Osteoblasts.** T. Kawato\*<sup>1</sup>, T. Katono\*<sup>1</sup>, N. Tanabe\*<sup>1</sup>, N. Suzuki\*<sup>2</sup>, T. Iida\*<sup>1</sup>, K. Ochiai\*<sup>3</sup>, M. Maeno\*<sup>1</sup>. <sup>1</sup>Oral Health Sciences, Nihon University School of Dentistry, Tokyo, Japan, <sup>2</sup>Biochemistry, Nihon University School of Dentistry, Tokyo, Japan, <sup>3</sup>Microbiology, Nihon University School of Dentistry, Tokyo, Japan.

**Objective:** Butyric acid (sodium butyrate; BA) is a major metabolic by-product of main periodontopathic bacteria present in subgingival plaque. In the present study, we examined the effects of BA on cell proliferation, alkaline phosphatase (ALPase) activity, mineralized nodule formation, extracellular matrix protein expression, macrophage colony-stimulating factor (M-CSF), and osteoprotegerin (OPG) in normal human osteoblasts.

**Methods:** The cells were cultured with 0,  $10^{-8}$ ,  $10^{-6}$  or  $10^{-4}$  M BA for up to 12 days. Mineralized nodule formation was detected by alizarin red staining, and the calcium content in mineralized nodules was determined using a calcium assay kit. The gene and protein expression levels for type I collagen, bone sialoprotein (BSP), osteopontin (OPN), M-CSF, and OPG were examined using real-time PCR and ELISA, respectively.

**Results:** Mineralized nodule formation and the calcium content of mineralized nodules were increased by BA in a dose-dependent manner. Cell proliferation and ALPase activity were not affected by the addition of BA. Following the addition of  $10^{-4}$  M BA, the expression levels of BSP, OPN, and OPG increased, whereas the expression levels of type I collagen and M-CSF were not markedly affected.

**Conclusion:** These results suggest that BA stimulates bone formation by increasing the production of BSP and OPN, whereas it suppresses osteoclast differentiation by increasing the production of OPG by human osteoblasts.

**OPG Serum Levels in Shaft Fractures Healing and Non-union.** C. F. Corradini<sup>\*1</sup>, D. Marchelli<sup>\*2</sup>, L. Parravicini<sup>\*1</sup>, C. Crapanzano<sup>\*3</sup>, F. M. Ulivieri<sup>\*2</sup>, C. A. Verdoia<sup>\*4</sup>. <sup>1</sup>Orthopaedic and Traumatologic Clinic, Studies University of Milan c/o G. Pini Institute, Milan, Italy, <sup>2</sup>Nuclear Medicine Unit, IRCSS Fondazione Policlinico Mangiagalli, Milan, Italy, <sup>3</sup>Clinical Pathology Unit, G. Pini Institute, Milan, Italy, <sup>4</sup>Orthopaedic and Traumatologic Clinic, Studies University of Milan c/o G.Pini Institute, Milan, Italy.

In normal bone healing, osteoblastic formation follows osteoclastic bone resorption along rhymes fracture. In non-unions no callus formation is radiologically evident. In the last years OPG/RANKL/RANK system has been recognized to play a key role in the cross-talk between osteoblasts and osteoclasts. In particular OPG has been involved in the bone repair process following fracture. But in animal model OPG treatment impairs the normal remodeling and consolidation.

The aim of this study was to verify OPG serum levels in shaft fractures healing and non-union in male adults.

To be eligible for the study, a patient with single closed shaft fracture of lower limbs had to be aged between 20 and 39 years and not under treatment with drugs interfering with bone metabolism. Patients with local or systemic severe diseases or with previous same limb segment fractures or non-union were excluded.

Sixteen male patients with atrophic non-union fractures and nineteen age-matched male with healing fractures were enrolled. Two orthopaedic surgeons reviewed all medical records pertaining to the patients and independently verified the correct synthesis and diagnosed the atrophic non-union fractures due to non infective causes.

Serum OPG, RANKL, bone alkaline phosphatase (BAP) and osteocalcin(OC) were determined.

The mean age was 28.1±5.9 for non-unions group and 29.7±6.0 for healing group. OPG was significantly higher in non-unions group (0.558±0.114 ng/ml) compared to healing group (0.425±0.110 ng/ml; p=0.0014). In the two groups RANKL was not significantly decreased even if a difference of 15% was detected. For the other bone turn-over markers mean serum levels were within normal references range and not significantly different. OC was negative correlated to OPG.

Significant high OPG serum levels in shaft fracture non-unions vs healing suggests an altered bone remodeling. The reason of no proportional OPG/RANKL balancing is unknown. Further studies are necessary to explain if OPG could be directly involved in the pathogenesis of shaft fractures non union and consequently used as predictive marker in clinical practice.

## M014

**Cardiotrophin-1 Is an Osteoclast-derived Coupling Factor Required for Normal Bone Remodeling.** E. C. Walker<sup>\*</sup>, N. E. McGregor<sup>\*</sup>, I. J. Poulton<sup>\*</sup>, S. Pompolo, E. H. Allan<sup>\*</sup>, J. M. W. Quinn, M. T. Gillespie, T. J. Martin, N. A. Sims. St. Vincent's Institute, Melbourne, Australia.

Cardiotrophin-1 (CT-1) is a cytokine that signals through gp130 and the LIF receptor (LIFR). Both receptors are expressed in osteoblasts but not in osteoclasts and deletion of either receptor results in neonatal lethality, dwarfism and osteopenia indicating a critical role in bone metabolism. We investigated the role of CT-1 in bone by immunohistochemistry, which revealed positive staining for CT-1 in active osteoclasts in mouse bone, suggesting a role in local regulation of bone metabolism. Administration of recombinant CT-1 to cultured mouse stromal cells and by calvarial injection in vivo increased osteoblast activity and mineralization. CT-1 also stimulated STAT, Erk and ATF4 phosphorylation and runx2 activation in mouse stromal cells in vitro, confirming a direct effect on osteoblast activity. In addition, CT-1 stimulated osteoclast formation from mouse bone marrow, but only in the presence of osteoblasts. Surprisingly, administration of CT-1 to mouse stromal cells did not enhance RANKL mRNA expression, but rapidly upregulated IL-6 mRNA ~8 fold, providing a putative mechanism for the pro-osteoclastogenic effect.

To determine the importance of CT-1 in vivo, we examined the phenotype of neonate CT-1 ligand null (CT-1 KO) mice, which had no survival defect and no reduction in neonatal bone size. These neonates did demonstrate a 75% reduction in BV/TV, associated with a 60% reduction in ObS/BS, and a doubling in OcS/BS. Furthermore, CT-1 KO osteoclasts were double the size of wild type osteoclasts. Despite this, the percentage of cartilage within the trabecular bone of CT-1 KO mice was doubled, suggesting impaired resorption. The similarity with the receptor knockout phenotypes suggests that CT-1 is the critical gp130:LIFR signaling cytokine required for normal trabecular development, but is not the cytokine required for normal bone size. Cultured bone marrow (BM) from CT-1 KO mice generated many oversized osteoclasts and BM mesenchymal precursors mineralized poorly when cultured under osteoblastic conditions compared to wild type BM, consistent with the in vivo phenotype. As the CT-1 KO mice aged, reduced osteoblast surface (ObS/BS) was no longer detected but impaired bone resorption continued resulting in normalization of BV/TV at 4 weeks, and an osteopetrotic phenotype in male and female mice at 10 and 26 weeks of age indicating different requirements for CT-1 during bone development and remodeling.

Taken together, these data indicate that CT-1 may now be classed as an essential osteoclast-derived coupling factor, capable of stimulating both bone formation and resorption through direct actions on the osteoblast.

**Primary Bone Cells of Pregnant Mice Exposed to Oscillatory Fluid Flow.** H. G. Lee<sup>\*</sup>, B. G. Kim<sup>\*</sup>, J. H. Kwag<sup>\*</sup>, C. H. Kim. Yonsei University, Wonju, Republic of Korea.

Mechanical loading and pregnancy are conditions that can affect the balance of bone remodeling. However, the relationship between pregnancy and loading-induced bone remodeling has not been well studied. Therefore, the aim of this study was to investigate whether bone during pregnancy responded differently to mechanical loading compared to bone during non-pregnant conditions. Bone cells were isolated from 11 week old ICR mice. The mice were either non-pregnant, 10-day pregnant, or 18-day pregnant. The long bones were harvested and removed of bone marrow and surface cells. The bones were cut in small pieces and bone cells were allowed to migrate out of the bone pieces into a culture dish. 48 hours prior to mechanical loading, cells were seeded on glass slides and treated with vitamin D3 for expression of receptor activator of NF- $\kappa$ B ligand (RANKL). Oscillatory fluid flow-induced shear stress was applied to cells at 1 Pa for 1 hr. Control cells received no flow. Immediately after end of loading, mRNA was extracted. Real-time RT-PCR was performed to quantify the following genes: core binding factor  $\alpha$ 1 (cbfa1), osteopontin (OPN), collagen I, osteoprotegerin (OPG) and RANKL. Alkaline phosphatase protein level was quantified by kinetic reaction method. Results for RANKL and OPG of non-pregnant and 18-day pregnant mice have been quantified thus far. Comparing 18-day pregnant mice to non-pregnant mice, OPG expression was significantly increased by 10-fold due to pregnancy. This resulted in a significant decrease in RANKL/OPG ratio in pregnant mice. Effects of loading was also compared in both non-pregnant and 18-day pregnant groups. Compared to the respective non-loading group, RANKL expression decreased by 40% in the non-pregnant loading group and by 60% in the 18-day pregnant loading group. OPG expression showed no difference in the non-pregnant group, but significantly increased by 2-fold when loading was applied to the 18-day pregnant group. Results suggest that pregnancy may hinder bone resorption by decreasing the RANKL/OPG ratio through significant increases in OPG level. Also, bone cells during the third trimester of pregnancy (corresponding to 18-day pregnancy) appear to be more sensitive to mechanical loading than bone cells during non-pregnant conditions. This may help pregnant women in their third trimester to effectively prevent significant bone loss through minimal exercise.

## M016

**Msx1 Homeogene Specific and Non-redundant Function in Oral Bones.** F. Méary<sup>\*</sup>, J. Nefussi<sup>\*</sup>, A. Marchadier<sup>\*</sup>, A. Berdal<sup>\*</sup>, S. Babajko<sup>\*</sup>. Centre de Recherche des Cordeliers, INSERM, Paris, France.

Msx (1 and 2) homeogenes are transcriptional regulators involved in skeleton patterning. Even if both of them are expressed during embryonic development in the craniofacial mesenchyme and in limbs, the phenotypes of Msx1 and Msx2 knock-out mice are different suggesting a non-redundant function. We have already shown that in adults, Msx1 is expressed in the dental bone and that Msx2 is involved in osteo-dental growth. In order to answer the question concerning the specific role of Msx1, we have explored Msx1 -/- mouse oral phenotype (Houzelstein et al., 1997 Mech Dev, 65, 123-133). As these mice die before birth, osteo-chondrogenic patterning was investigated by analysing gene expression by RT-Q-PCR on E18 fetal mice. Our results showed a clear and strong decrease of Msx2 expression in the mandible and maxillary bones of Msx1 -/- mice but no difference in limbs, suggesting a link between Msx1 and Msx2 in oral bones only. Moreover, osteo-chondrogenic marker expression was similar in -/- and +/- animals suggesting that Msx1 is involved in bone morphogenesis but probably not in differentiation.

We also explored Msx1 +/- adult mouse oral phenotype by scanning their heads using a 1072 Skyscan® micro CT. 3D-skyscan analysis illustrated a distinct morphological maxillar alveolar bone process in Msx1 heterozygous mice compared to control animals. The vestibular ridge appeared to be larger in its crestal part (339 ± 47 vs 269 ± 36 p<0.005) but smaller in length (117 ± 6 vs 128 ± 9 p<0.01). This dysmorphology was coincident with areas of Msx1-expressing cells evidenced by beta-galactosidase histochemistry. It was the first time that a clear phenotype was evidenced in adult Msx1 heterozygous mice which is in accordance with the situation in humans where (heterozygous) Msx1 mutations lead to oral anomalies.

In conclusion, this study showed a link between Msx1 and Msx2 specifically in maxillary and mandible bones thus explaining, at least in part, a phenotype of Msx1 -/- mice restricted to oral bones only, even if Msx1 is also expressed in limbs. Msx1 could be considered as a bone morphogenetic factor, not involved in differentiation. Moreover, the role of Msx1 homeogene in the adult dental bone morphology might contribute to the specific dental bone physiology which diverges from the rest of the skeleton.

## M017

**Regulation of Bone Formation by Osteoclasts Involves Wnt/Bmp Signaling and the Chemokine Sphingosine-1-Phosphate.** L. Pederson<sup>\*1</sup>, M. Ruan<sup>\*1</sup>, J. J. Westendorf<sup>2</sup>, S. Khosla<sup>1</sup>, M. Oursler<sup>1</sup>. <sup>1</sup>Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Orthopedic Research Unit, Mayo Clinic, Rochester, MN, USA.

Under most conditions, resorbed bone is nearly precisely replaced in location and amount by new bone. Thus, it has long been recognized that bone loss through osteoclast-mediated bone resorption, and bone replacement through osteoblast-mediated bone formation, are tightly coupled processes. Abundant data conclusively demonstrate that osteoblasts direct osteoclast differentiation. Key questions remain, however, as to how osteoblasts are recruited to the resorption site, and how the amount of bone laid down is so precisely controlled. This has led to further consideration of the role(s) that osteoclasts and/or their activity play in the promotion of bone formation.

We examined osteoclasts for influences on osteoblasts and found that conditioned medium (CM) from both primary osteoclasts and RANKL-induced RAW 264.7 cell-derived osteoclasts stimulate human mesenchymal stem (hMS) cell migration and differentiation. We sought to identify candidate osteoclast-derived coupling factors using the unbiased approach of Affymetrix microarray. Comparing pre-osteoclasts to mature osteoclasts, we observed 4-fold induction of sphingosine kinase 1 (SPHK1), which catalyzes the phosphorylation of sphingosine to form sphingosine 1-phosphate (S1P). S1P induces osteoblast precursor recruitment and promotes mature cell survival. There was also increased expression of Wnt10b (by 4-fold) and BMP6 (by 5-fold) as osteoclasts matured. As shown in the Figure, CM from mature osteoclasts (differentiated from RAW cells) increased mineralized nodule formation of hMS cells as compared to CM from RAW pre-osteoclasts. The stimulation of hMS cell nodule formation by the osteoclast CM could be at least partially inhibited by the Wnt antagonist, Dkk1, a BMP-6 neutralizing Ab, and by a S1P antagonist, demonstrating a role for Wnt/BMP signaling and S1P in osteoclast-mediated stimulation of bone formation. Further, during osteoclast differentiation, expression of Sclerostin, an inhibitor of Wnt-induced osteoblast precursor responses, was suppressed. In summary, our findings indicate that osteoclasts may recruit osteoprogenitors to the site of bone remodeling through the chemokine, S1P, and stimulate bone formation through increased signaling via the Wnt/BMP pathways.

## M018

**Proteinase-Activated Receptor (PAR)-2 Activation Induces Bone Resorption via RANKL Upregulation in Human Osteoarthritic Subchondral Bone Osteoblasts.** N. Amiable<sup>\*1</sup>, J. Martel-Pelletier<sup>\*1</sup>, S. Kwan Tat<sup>\*1</sup>, F. Mineau<sup>\*1</sup>, N. Duval<sup>\*2</sup>, J. Pelletier<sup>\*1</sup>, C. Boileau<sup>\*1</sup>. <sup>1</sup>Osteoarthritis Research Unit, University of Montreal Hospital Centre, Notre-Dame Hospital Centre, Montreal, QC, Canada, <sup>2</sup>Centre de Convalescence Pavillon des Charmilles, Vimont, QC, Canada.

In osteoarthritis (OA), subchondral bone remodelling is closely related to cartilage degradation. The former tissue has shown a remodelling process involving factors synthesized by human osteoblasts (Ob) including the OPG/RANKL system. Moreover, these factors are produced in abnormal levels by OA subchondral bone Ob. Recently our group showed that PAR-2 was implicated in catabolic and pro-inflammatory processes in human OA cartilage. Here, we investigated the presence, production, and role of PAR-2 in human OA subchondral bone Ob.

PAR-2 expression was determined by real-time PCR, PAR-2 protein by Western blot, membranous RANKL protein by flow cytometry, and OPG, MMP-9 and intracellular signalling pathways by specific ELISA assays. Bone resorption activity was measured by using a co-culture model of human PBMC and human OA subchondral bone Ob. PAR-2 expression and protein levels were markedly increased in OA Ob compared to normal (p<0.05). On OA Ob, activation of PAR-2 with a specific agonist induced a significant upregulation of the membranous RANKL (p<0.006) without affecting OPG production. Interestingly, MMP-9 levels were also significantly increased (p<0.03), as was the bone resorption activity (p<0.05). The PAR-2 effect was mediated by the activation of the MAP kinases ERK1/2 and JNK (p<0.05).

This study demonstrated, for the first time, that PAR-2 plays a role in bone resorption via an upregulation of a major bone remodelling factor, RANKL, in human OA subchondral bone Ob. These data strongly reinforce the suggestion that PAR-2 could be a potential therapeutic target for the treatment of OA, as this factor acts on catabolic processes of both cartilage and subchondral bone.

Disclosures: N. Amiable, None.

## M019

**LPS-induced Inhibition of Osteogenesis Is TNF-α Dependent.** N. Tomomatsu<sup>\*1</sup>, K. Aoki<sup>2</sup>, M. A. Hussain<sup>\*2</sup>, N. Alles<sup>\*2</sup>, H. Shimokawa<sup>2</sup>, T. Amagasa<sup>\*1</sup>, K. Ohya<sup>2</sup>. <sup>1</sup>Maxillofacial surgery, Tokyo Medical and Dental University, Bunkyo-ku Tokyo, Japan, <sup>2</sup>Hard Tissue Engineering (Pharmacology), Tokyo Medical and Dental University, Bunkyo-ku Tokyo, Japan.

**[Introduction]** Several lines of evidence show the inhibition of osteoblast differentiation by TNF-α *in vitro*. However, there are almost no reports showing the inhibitory role of TNF-α in osteogenesis *in vivo*. The purpose of this study is to investigate whether the LPS-induced inhibition of osteogenesis is TNF-α dependent or not by using tooth extraction model.

**[Materials & Methods]** Ten mg/kg LPS (Re595) was injected subcutaneously on calvariae in either wild type (WT) or TNF-α deficient (KO) mice, and the left incisor was extracted 4 days after LPS injections. Mice were sacrificed 3 days, 1 week and 3 weeks after the extraction. TNF-α and osteocalcin levels in serum were measured by ELISA. The measuring area of BMD by pQCT and histomorphometry was set in the incisor tooth socket under the mesial root of the first molar as shown in the attached figure. The mRNA levels of bone formation marker in the tooth socket of the mandibular bone on day 3 were measured using real-time RT-PCR.

**[Results]** We confirmed the significant increase of TNF-α level in serum in the LPS-injected group (LPS-G) compared to the vehicle-injected group (Vh-G). At 3 weeks after the extraction, the significant decrease of trabecular BMD and the bone volume (BV/TV) was observed in LPS-G compared to Vh-G in WT mice (P<0.05). The significant decrease of bone formation parameters (MS/BS, MAR) was appeared in LPS-G compared to Vh-G at 1 week in WT mice. The osteocalcin level in serum and the mRNA level in the mandible were significantly decreased by LPS in WT mice compared to Vh-G. However, those differences by LPS were not observed in TNF-KO mice. Since almost no osteoclasts were observed in the measuring area, LPS-induced inhibition of bone volume in WT mice would be occurred by the inhibition of bone formation, not by the increase of bone resorption.

**[Conclusions]** The present data clearly showed LPS-induced inhibition of osteogenesis was TNF-α dependent. The neutralization of TNF-α might be a useful therapeutic strategy to accelerate bone formation after the tooth extraction or the distraction in the patients suffering from inflammatory diseases.

## M020

**Bone Response to Mechanical Loads and Lrp5 Genotype.** B. T. Hackfort<sup>\*</sup>, D. A. Knierim<sup>\*</sup>, G. K. Alvarez, D. M. Cullen, M. P. Akhter. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Genetic variations in Lrp5 (low density lipoprotein like receptor protein) are associated with bone mass variations. Lrp5 is a Wnt co-receptor and when Wnt binds it activates β-catenin translocation into the nucleus and up-regulation of Wnt response genes. The Lrp5 G171V (HBM) mutation causes a gain of function in Wnt signaling and high bone mass. The Wnt pathway is important for bone adaptation to mechanical loads and data suggests that variations in Lrp5 alter bone sensitivity to loads. This study examined the dose response curve of cortical bone to loading in mice with variation in Lrp5 expression. The genotypes tested were Lrp5<sup>-/-</sup>, Lrp5<sup>+/-</sup>, WT (C57Bl6), and HBM. Right tibiae were loaded in tibial compression at 100 cycles, 2 Hz, 3d/wk, 10 sessions. The left tibiae served as a contralateral control. Adult virgin female mice within each genotype were randomized to 5

load groups ranging from 4 to 11 N to overlap strains among genotypes. Strains were calculated based upon load and average cortical area. Strains ranged from 1300 to 2600  $\mu\epsilon$  (Figure). Tibia sections 1-3 mm proximal to the TFJ were measured by histomorphometry for area (total, marrow, cortical), mineralizing surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS). Less than 3% of the tibiae had woven bone and the majority was seen in Lrp5<sup>-/-</sup> at the highest loads. Differences were significant at  $P < 0.05$ . In nonloaded legs, all genotypes were different from each other for total area and cortical area. The Lrp5<sup>-/-</sup> mice had the smallest marrow area, but there were no other difference among genotypes. There were no differences in either periosteal or endocortical bone formation rate. However, WT tibiae had the greatest endocortical MAR which tended to increase endocortical BFR ( $P=0.07$ ). The load effect was calculated as Loaded-nonLoaded within each animal. All genotypes demonstrated a dose response to loading for periosteal BFR (Figure). The periosteal bone response to increasing strain was linear in all groups except Lrp5<sup>-/-</sup>. The homozygote KO mice did not respond to strains  $<1600\mu\epsilon$  and showed a rapid response above 2000 $\mu\epsilon$ . The threshold for response was lowest in HBM mice at 1330 $\mu\epsilon$ . Endocortical BFR was not different due to strain in Lrp5<sup>+/-</sup> tibiae, but was significant in all other groups. In conclusion, gain of function in Lrp5 increases bone sensitivity to loads and total loss of Lrp5 function suppresses the bone response, but does not eliminate it.

## M021

**Acid-induced Stimulation of Bone Resorption Is Decreased in OGR1 Knockout Mouse Calvariae.** N. S. Krieger, A. C. Michalenka\*, D. A. Bushinsky. Medicine, University of Rochester, Rochester, NY, USA.

Chronic metabolic acidosis, a systemic increase in proton concentration [ $H^+$ ], stimulates net calcium (Ca) efflux from bone. This net efflux is mediated primarily through increased osteoblastic cyclooxygenase 2, leading to prostaglandin  $E_2$ -induced up-regulation of RANKL and increased osteoclastic bone resorption. We have recently found that perfusion of calvarial osteoblasts with medium simulating metabolic acidosis induces a marked, rapid, flow-independent, transient increase in intracellular Ca ( $Ca_i$ ) in individual cells. We and others have demonstrated that osteoblasts express the recently characterized  $H^+$ -sensing G-protein coupled receptor, OGR1. As activation of OGR1 results in increased inositol trisphosphate mediated  $Ca_i$  signaling, our findings suggest that OGR1 may be the  $H^+$  sensor that detects the increase in acidity during metabolic acidosis and initiates the increase in  $Ca_i$  signaling. To test the hypothesis that OGR1 is the functioning  $H^+$  sensor in osteoblasts leading to increased bone resorption, we measured net Ca efflux, as an index of bone resorption, in calvariae from mice with a genetic null mutation in OGR1 (kindly provided by Klaus Seuwen, Novartis). Neonatal mouse calvariae from OGR1 knockout (KO, -/-) or wild type (+/+) mice were incubated for 48h in physiological neutral (NTL, pH=7.41,  $HCO_3^-$ =25 mM,  $Pco_2$ =39 mmHg) or acidic (MET, pH=7.19,  $HCO_3^-$ =15 mM,  $Pco_2$ =39 mmHg) medium that was changed at 24h. At 24h, when Ca efflux occurs primarily by physicochemical dissolution, incubation in MET induces a similar, significant increase in net Ca efflux from both wild type ( $153 \pm 7\%$  increase vs wild type, NTL,  $p < 0.01$ ) and OGR1 KO calvariae ( $161 \pm 12\%$  increase vs OGR1 KO, NTL,  $p < 0.01$ ). However at 48h, when cell-mediated Ca efflux predominates, there is a significant increase in net Ca efflux in response to MET only in wild type calvariae ( $p < 0.01$ ) but not in OGR1 KO calvariae (Figure) indicating that loss of the  $H^+$  sensing receptor OGR1 eliminates acid-induced bone resorption. Thus, our results are consistent with OGR1 being the primary osteoblast  $H^+$  sensor that detects the increase in  $H^+$  during metabolic acidosis and initiates the Ca signaling cascade which results in increased acid-induced, cell-mediated bone resorption.

Disclosures: N.S. Krieger, None.

**Secretomic Analysis of Calcium Supplement-Mediated Bone Remodeling.** G. G. Xiao, Y. Zhao\*, R. Cao\*, J. Xiao\*, J. Lappe, R. Heaney, R. Recker. Osteoporosis Research Center-Medicine, Creighton University, Omaha, NE, USA.

**Introduction:** Calcium is essential for bone health. Calcium intakes in the U.S. are much lower than recommended levels. In a recent efficacy study of milk mineral in human bone health, the results suggest that calcium supplement and milk drink can improve bone quality. To understand the mechanism of the calcium supplement intake on bone remodeling, we further analyzed proteome profile in serum samples from participating postmenopausal female subjects.

**Methods and Materials:** Sample preparation: To minimize the interference with our proteomics analysis, high abundance proteins in serum samples from postmenopausal female subjects, placebo group (17), milk drink group (28), and calcium supplement intake group (30), were depleted by using YM-30 filtration with molecular cutoff 30kDa. Then, about 5  $\mu$ g of depleted serum protein was further cleaned up using C8 magnetic beads in ClinProt robot. Cleaned samples were premixed with CHCA matrix and directly spotted onto 384-well plate.

Protein pattern discovery using direct mass spectrometry (dMS): Protein profiling was carried out by using MALDI-TOF mass spectrometry with the laser power 25%-45%. Comprehensive statistical protocols were used for selection of differentially expressed protein peaks, which were identified by MALDI-TOF/TOF mass spectrometry.

**Results**

To understand the mechanism of calcium supplement intake on bone remodeling, we aim to compare secretome profiles between calcium supplement intake and milk drink in postmenopausal female subjects using functional proteomics approach. We found that intake of calcium supplement can regulate proteome expression profile in a different fashion from that milk drink does. After 6-month designated diet-stimulation, postmenopausal female subjects have shown different proteome profiles. Milk drink can suppress protein peak at 6068 m/z ( $p < 0.000001$ ) while this peak was suppressed marginally in calcium supplement group. Further identification of this peak at 6068 m/z using Ultraflex III direct TOF/TOF mass spectrometry is subject to be alpha-methylacyl-CoA racemase (AMACR). On the other hand, milk can stimulate over-expression of proteins at 3504 m/z (3-hydroxyisobutyryl-coenzyme A hydrolase,  $p < 0.0008$ ), 3768 m/z (Sal-like 4,  $p < 0.000214$ ) and 4788 m/z (F-box protein FBL5,  $p < 0.0009$ ), while these proteins seem to be suppressed by calcium induction as demonstrated in calcium supplement group. In additions, calcium supplement intake can also suppress over-expression of a protein at 5005 m/z, which is cysteine-rich motor neuron 2 protein (CRIM-2). As expected, there is no significant difference between before and after treatment in protein expression in placebo group.

### Chemical Composition and Nanoscale Structure of Risedronate-treated Mineralizing MC3T3-E1 Cells. M. E. Ruppel<sup>1</sup>, R. Phipps<sup>2</sup>, L. M. Miller<sup>3</sup>.

<sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, <sup>2</sup>Procter and Gamble Pharmaceuticals, Mason, OH, USA, <sup>3</sup>National Synchrotron Light Source, Brookhaven National Laboratory, Upton, NY, USA.

Prevention of bone loss by inhibition of osteoclast-mediated bone resorption appears to be the major mechanism for fracture risk reduction seen with bisphosphonates (BPs) in osteoporosis. Recent examination into the effects of BPs has demonstrated that under certain conditions BPs may stimulate osteoblasts or prevent osteoblast and osteocyte apoptosis, but whether they have direct effects on the quality and/or structure of newly forming bone matrix is unknown. The goal of the present study was to determine if BP-treatment alters the quality and nanostructure of newly formed tissue. 2H-risedronate-treated and untreated MC3T3-E1 mouse osteoblasts were mineralized in culture for 0, 4, 11, 21, and 28 days. 2H-risedronate was used so that the binding and distribution of the drug within the mineralized culture could be visualized using Fourier transform infrared imaging (FTIRI) since the deuterated drug has absorption features in a spectral region different from those of bone. FTIRI was used to study the chemical composition of the cells, including level of mineralization, crystallinity, collagen cross-linking, carbonate uptake and BP binding as a function of time and drug concentration. Nano-transmission x-ray microscopy was used to probe the nanoscale structure and organization of the collagen and mineral produced by the cells. Quantification of collagen production and mineral formation were measured via hydroxyproline and osteocalcin production, respectively. Thus, these studies provide an understanding of how BPs directly affect the nanostructure and composition of mineral production by osteoblasts, which will help to evaluate the long-term effects of bisphosphonate treatment on bone quality.

### Transgenic Mice Over-expressing TIEG in Osteoblasts Display a Gender Specific Bone Phenotype. M. Subramaniam<sup>1</sup>, J. R. Hawse<sup>1</sup>, F. A. Syed<sup>2</sup>, D. G. Monroe<sup>1</sup>, K. D. Peters<sup>\*1</sup>, T. C. Spelsberg<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, Mayo Clinic & Foundation, Rochester, MN, USA, <sup>2</sup>Endocrine Research Unit, Mayo Clinic & Foundation, Rochester, MN, USA.

TGF $\beta$  inducible early gene (TIEG) is a member of the zinc finger containing Kruppel-like transcription factor family which was originally cloned from human osteoblasts. TIEG plays an important role in TGF $\beta$  mediated osteoblast growth and differentiation. TIEG over-expression in human osteoblasts mimics TGF $\beta$  action by regulating the expression of osteoblast specific marker genes. Further, we and others have demonstrated that TIEG plays an important role in TGF $\beta$  mediated Smad signaling in various cell types. In order to further define the role of TIEG in bone, we developed a transgenic mouse model that over-expresses TIEG in osteoblasts under the control of the Col 3.6 promoter. Characterization of osteoblasts isolated from transgenic mice revealed a significant increase in TIEG expression. To determine if TIEG over-expression in osteoblasts has an effect on the skeleton, we analyzed the tibias of young (1 month), adult (3 months) and aging (12 months) male and female mice by pQCT. Analysis of the femoral metaphysis revealed a trabecular osteopenic phenotype in all age groups of male mice relative to wild-type controls. This phenotype was not observed in the female transgenic mice. pQCT analysis of the femoral diaphysis revealed that male adult and aging transgenic mice display significant reductions in total and cortical vBMD. Interestingly, aging females maintained cortical and total vBMD at this site compared to their wild-type littermates. Taken together, our results suggest that over-expressing TIEG in osteoblasts has distinct effects on male and female trabecular and cortical bone, with TIEG over-expression resulting in trabecular and cortical osteopenia in male mice as a function of age, whereas female mice maintain bone densities at these sites.

### Bril (Bone Restricted Ifitm-Like) Localization in Mouse and Rat Bones. P. Moffatt<sup>1</sup>, R. Wazen<sup>\*2</sup>, G. P. Thomas<sup>3</sup>, A. Nanci<sup>\*2</sup>. <sup>1</sup>Genetics Unit, Shriners Hospital for Children, Montreal, QC, Canada, <sup>2</sup>Stomatologie, Université de Montreal, Montreal, QC, Canada, <sup>3</sup>Musculoskeletal Genetics Group, Diamantina Institute for Cancer, Immunology & Metabolic Medicine, University of Queensland, Woolloongabba, Australia.

Bril is a novel osteoblast-specific membrane protein that we originally discovered in UMR106 cells. The gene encoding Bril had been previously named interferon inducible transmembrane protein (ifitm) 5, but no localization or functional studies had been undertaken on this gene. Bril encodes a 134 amino acid protein with two transmembrane domains. Our initial characterization of Bril showed it to be present in mouse and human osteoblastic cell lines, and its expression coincides with the onset of matrix formation and mineralization. Functional evidence for Bril in mineralization was demonstrated by overexpression and shRNA knockdown increasing or inhibiting mineralization respectively in vitro. The purpose of this study was to map the distribution of Bril by immunoperoxidase labeling in embryonic and adult rodent tissues. In developing mouse embryonic E14.5 bones, Bril localized exclusively to osteoblasts of both endochondral

(clavicle, mandible, calvaria) and intramembranous (humerus, vertebra, ribs) skeletal elements. Only osteoblasts forming the bony collar of the long bones and vertebrae stained highly positive for Bril. The developing growth plate chondrocytes showed no labeling. In adult rat tissues, osteoblasts on actively forming bone surfaces were positive for Bril, especially in the mandible and tibia. Osteoclasts and osteocytes were not immunoreactive. No other tissues showed appreciable expression of Bril, except for discrete portion of the gingiva. Bril localization was also examined during repair of bony defects drilled in rat mandibles. At 3 days post-surgery, new bone deposition was not yet evident and there was no obvious Bril staining in the defects. By day 5, foci of bone formation were found throughout the defects and osteoblasts covering the actively forming bone surfaces were immunostained. In summary, the data presented indicate Bril is associated with osteoblasts in regions of active bone formation and its expression is activated during repair. Therefore, Bril represents an attractive target of intervention for modulating bone formation and repair.

### Deficiency of NCK1, an Actin Cytoskeletal Modulator with SH2/SH3 Motifs, Induces Bone Loss via Suppression of Bone Formation and Induction of Biochemical High Bone Turnover State. K. Miyai<sup>1</sup>, Y. Izu<sup>1</sup>, H. Hemmi<sup>\*1</sup>, T. Hayata<sup>1</sup>, T. Nakamoto<sup>1</sup>, Y. Ezura<sup>1</sup>, T. Pawson<sup>\*2</sup>, S. Mizutani<sup>\*3</sup>, M. Noda<sup>1</sup>. <sup>1</sup>Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Department of Medical Genetics and Microbiology, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Department of Pediatrics and Developmental Biology, Tokyo Medical and Dental University, Tokyo, Japan.

NCK proteins are adapter molecules which contain a SH2 domain at C-terminal portion and three tandem repeat of SH3 domains at N-terminal portion. SH2 domain binds to phosphorylated tyrosines and SH3 domain binds to proteins which are involved in the regulation of actin cytoskeleton. Among the NCK family members, NCK1 single knockout mice have not been regarded to show any phenotype, though NCK1 function has been observed based on the defects in foot processes in podocytes as well as neurites formation in compound knockouts. To understand the role of the actin cytoskeletal modulator protein in bone, we examined the mice deficient for NCK1. In contrast to previous observations where single knockout did not show any major phenotypes, NCK1 single knockout mice did show reduction in trabecular bone volume based on 3D micro CT analysis. The deficiency of NCK1 resulted in the impairment of osteoblastic activities, which were revealed by the analyses of bone formation rate. This was due to the influence on the individual osteoblastic function as mineral apposition rate was reduced by the deficiency of NCK1. In contrast to the reduction in the histomorphometrical parameters of bone formation, bone resorption parameters such as osteoclast number, osteoclast surface as well as in vitro development of TRAP positive multinucleated cells in the cultures of bone marrow cells did not show any major alterations by the deficiency of NCK1. However, surprisingly urinary deoxypyridinoline levels were increased in KO mice. Serum alkaline phosphatase levels were enhanced in NCK1 deficient mice indicating high turnover state based on the analyses of biochemical markers. We further examined the effect of NCK1 deficiency on the cell autonomous functions of osteoblasts. The expression levels of bone phenotypic markers such as alkaline phosphatase and osteocalcin were increased in wild type cells. In contrast, NCK1 deficiency suppressed such increase in the expression of osteoblastic phenotype marker genes in the culture of the cells. In conclusion, we found that single NCK1 deficiency resulted in reduction in bone mass indicating the role of this SH2/SH3 adapter protein in the regulation of bone metabolism.

### High Bone Mass Phenotype in the Bone Specific Dlx3 Knock Out mice. M. S. Islam<sup>\*1</sup>, I. Chen<sup>\*2</sup>, D. Adams<sup>2</sup>, J. Xi<sup>2</sup>, H. Li<sup>2</sup>, M. Kronenberg<sup>2</sup>, M. Duffin<sup>\*2</sup>, M. Morasso<sup>\*3</sup>, E. Reichenberger<sup>\*2</sup>, A. C. Lichtler<sup>2</sup>. <sup>1</sup>University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>University of Connecticut, Farmington, CT, USA, <sup>3</sup>National Institute of Health, Bethesda, MD, USA.

A major goal of our research is to understand the role of *Dlx3* in bone formation and metabolism. In a previous abstract we reported our initial results using the Cre-LoxP system to generate bone specific *Dlx3* knock out mice. We used a 3.6 kb type I collagen fragment to drive *CreERT2* expression in bone and rearrange the floxed *Dlx3* gene (*FDlx3*). The bone specific *Dlx3* knock out mice were homozygous for *FDlx3* and carried one copy of *Cre* transgene (*F/F; Cre+*). A skeletal phenotype was not detectable by whole mount skeletal staining of knock out and age and sex matched control mice. However, repeated studies at multiple ages, involving quantitative measurement of long bone, vertebrae and calvaria using microCT and static histomorphometry, and Von Kossa staining of undecalcified bone sections confirmed a significant increase in bone mass in the conditional knock out mice compared to the control group. The conditional knock out mice had lower numbers of osteoblasts that was statistically significant in male knock out mice. Osteoclast surface was significantly higher in females but not males. Analysis of serum markers Trap5b and CTX were done to measure osteoclast differentiation and function respectively. No difference was observed in these studies, suggesting osteoclast differentiation and function were not affected in these mice. Bone formation rate and mineral apposition rate were not significantly different, however serum PINP, a measure of osteoblast function, was higher in 10 week old males. Gene expression was studied using RNA from cultured calvarial osteoblasts by quantitative PCR and showed changes in the

expression pattern of other *Dlx* genes and bone expressed genes including osteocalcin, bone sialoprotein, Collagen I (*Coll1a1*) and alkaline phosphatase. Von Kossa staining did not show obvious differences between wild type and knockout cells. Our results show that lack of *Dlx3* results in a higher bone mass and that *Dlx3* may be required for completely normal osteoblast function but not for mineralization.

**Towards Development of a Porous Silicon-Based Hybrid Biomaterial with Osteoconductivity and Osteoinductivity.** T. Sheu<sup>1</sup>, W. Sun<sup>\*2</sup>, X. Liu<sup>\*2</sup>, M. Chen<sup>1</sup>, P. M. Faucher<sup>\*2</sup>, E. J. Puzas<sup>1</sup>. <sup>1</sup>Orthopaedics, U of Rochester, Rochester, NY, USA, <sup>2</sup>Biomedical Engineering, U of Rochester, Rochester, NY, USA.

An ideal material for orthopaedic tissue engineering should be biocompatible, biodegradable, osteoconductive, mechanically stable, and widely available. Porous silicon (PSi), a silicon-based material fulfills these criteria. It is biocompatible and biodegradable, and supports hydroxyapatite nucleation. The micro/nano-architecture of porous silicon can regulate cell behavior. The surface chemistry of PSi is flexible so that the interfacial properties between this material and living cells can be tailored easily by chemical modifications. In our previous work, we have demonstrated that PSi can support and promote primary osteoblast growth, protein matrix synthesis, and mineralization *in vitro*. The osteoconductivity of porous silicon can be controlled by altering the micro/nano architecture of the porous interface. Macro-scale porous silicon (MacPSi), with pore openings of approximately 1  $\mu\text{m}$ , has the highest osteoconductive potential *in vitro*. In the present work, we have further developed a hybrid biomaterial by coating MacPSi with recombinant adenovirus vectors encoding bone morphogenetic proteins, and thus making the material osteoinductive both *in vitro* and *in vivo*. With this material, we are closer to an osteoconductive and osteoinductive medical device with drug delivery functions. The knowledge obtained in this study on the interaction between living cells and a semiconductor material will also be the foundation for further development of electronic and optoelectronic biointerfaced devices.

**VEGF and PTEN Regulate Bone Homeostasis via Control of Osteoblastogenesis, Osteoclastogenesis and Adipocyte Differentiation.** Y. Liu<sup>\*</sup>, B. R. Olsen<sup>\*</sup>. Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA.

We have found that conditional loss of VEGF in osteoblasts results in osteoporosis in mice. In a recent study, it was reported that mice deficient in PTEN in osteoblasts/osteocytes exhibited high bone mass because of Akt activation. To test the hypothesis that loss of PTEN in osteoblasts rescues the bone loss of VEGF conditional knockout mice, we generated VEGF /PTEN double conditional knockout mice by crossing VEGF and PTEN floxed mice with Osterix-Cre mice. The double mutant mice look normal at birth, but they are getting smaller with age compared with control littermates. Surprisingly, the double mutants had dramatically reduced bone density compared with VEGF conditional knockout mice at 2.5 months of age. Loss of PTEN in the osteoblasts therefore does not rescue the bone loss caused by loss of VEGF, but instead aggravates the bone loss. H&E of 6 weeks old double knockout mice showed abnormal amounts of woven bone in the cortices of long limb bones and a dramatic increase in adipocytes in the bone marrow. To further elucidate the underlying mechanisms, bone marrow cells from 8-12 weeks old double knockout mice and control littermates were isolated for osteoclastogenesis assay, CFU-F and CFU-A assays to determine whether the bone loss is caused by increased osteoclastogenesis, reduced osteoblastogenesis or increased adipocyte differentiation. Osteoclastogenesis assay showed a dramatic increase in osteoclast formation with bone marrow cells of double mutants compared with cells from control littermates. CFU-F and CFU-A assays showed a decreased number of osteoblast progenitors and a large increase in adipocyte formation with bone marrow cells isolated from double mutant mice. These data suggests that the reduced bone density in mice due to loss of VEGF and PTEN in osteoblasts results from decreased osteoblastogenesis and excessive osteoclastic bone resorption as well as increased adipocyte differentiation in bone marrow. Taken together, the findings demonstrate a critical role of VEGF and PTEN in regulating bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation.

**Enamel Matrix Derivative (Emdogain) Enhance Osteoblast Differentiation on Titanium Surfaces.** R. Miron<sup>\*1</sup>, M. Wieland<sup>\*2</sup>, D. Hamilton<sup>\*1</sup>. <sup>1</sup>Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada, <sup>2</sup>Institut Straumann, Zurich, Switzerland.

Osseointegration represents a dynamic structural and functional connection between living bone and the surface of a titanium implant and is critically important for the long-term success of bone-contacting devices, including titanium dental implants. Attempts to improve this functional connection between the implant and host bone tissue have focused mainly on altering the topography of the titanium implant surface. However, incorporation of bioactive proteins could also facilitate the healing of the bone around the titanium implant. Emdogain® - enamel matrix proteins derived from developing porcine teeth - has been shown to promote regeneration of the periodontal ligament *in vitro* and *in vivo*. There are few studies of the influence of Emdogain® on bone healing, but *in vivo* data suggest that Emdogain® speeds the healing of trabecular bone. The influence of Emdogain® on bone formation adjacent to titanium implants has yet to be investigated. The aim of the present study was to evaluate the effect of Emdogain® on the differentiation of osteoblasts on titanium surfaces *in vitro*. Polished titanium discs were coated with or without Emdogain®. MC3T3-E1 osteoblast-like cells were then cultured on these substrates for 0 to 4 weeks. Differentiation was assessed by staining for alkaline phosphatase activity and by quantifying osteoblast marker expression using real-time RT-PCR. At time points ranging from 0 to 4 weeks of culture, alkaline phosphatase activity was significantly increased on Emdogain®-coated titanium compared with titanium alone. Furthermore, there were significant increases in expression of bone sialoprotein, osteocalcin, osterix and collagen I in osteoblasts cultured on Emdogain®-coated titanium surfaces. We conclude that coating of titanium with Emdogain® enhances the differentiation of osteoblasts. Thus, Emdogain® may increase the speed and quality of osseointegration around bone contacting implants *in vivo*.

**Transcriptional Activation of Osteocalcin by Runx2 During Osteoblast Development Is Controlled at the Post-Translational Level.** S. Pregizer<sup>\*1</sup>, S. K. Baniwal<sup>1</sup>, X. Yan<sup>\*2</sup>, D. P. Mortlock<sup>\*3</sup>, B. Frenkel<sup>4</sup>. <sup>1</sup>Department of Biochemistry & Molecular Biology, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, <sup>2</sup>Department of Biological Sciences, College of Letters, Arts, & Sciences, University of Southern California, Los Angeles, CA, USA, <sup>3</sup>Department of Molecular Physiology & Biophysics, Vanderbilt University School of Medicine, Nashville, TN, USA, <sup>4</sup>Department of Orthopaedic Surgery, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA.

Runx2 is a potent transcriptional regulatory factor in osteoblasts and is itself subject to transcriptional, as well as post-transcriptional and post-translational regulatory mechanisms. The purpose of this study was to ascertain whether these mechanisms play a role in the stimulation of Osteocalcin (OC), a classic Runx2 target gene, during osteoblast development. OC expression increases robustly in differentiating MC3T3-E1 cells, making this a convenient system for studying the dynamics of its regulation by Runx2. We monitored Runx2 mRNA and protein levels, as well as OC promoter occupancy in this system from confluence until the time at which OC expression peaks, approximately 2 weeks later. Each type of measurement was performed on samples collected in parallel from cells plated on the same day, thus permitting a meaningful comparison between them. Surprisingly, Runx2 mRNA and protein levels both declined as the cells matured and OC expression increased. This paradoxical inverse relationship is a novel discovery that raises the interesting question of how Runx2 can stimulate OC expression under these circumstances. Accordingly, we discovered that in contrast to its expression, Runx2 occupancy of the OC promoter increased in parallel with OC mRNA levels. Thus, activation of OC by Runx2 is attributable to enhanced promoter occupancy. The discrepancy between expression levels and occupancy may reflect post-translational regulatory control of Runx2 and its critical role in the stimulation of OC expression during osteoblast differentiation. Having identified conditions under which Runx2 is maximally recruited to the OC promoter, we then searched for novel Runx2 genomic targets by ChIP-Chip, using the NimbleGen platform. We identified a total of 64 occupied sites along mouse chromosome 3, many of which were close to transcribed sequences. Thus, we identified a novel mechanism of Runx2 regulation, occurring at the level of promoter occupancy. Moreover, we employed cells in which this mechanism is maximally operative to discover novel Runx2 target genes, some of which may mediate the well-established but poorly understood role of Runx2 in osteoblast differentiation and bone formation.

**RANKL Suppression by Small Interfering RNAs in Rat Primary Osteoblasts.** F. Pei, K. Gao, Y. Hao, H. Zhang, M. Zongyu. West China Hospital of Sichuan University, Chengdu, China.

**Purpose:** The receptor activator of nuclear factor- $\kappa$ B ligand (RANKL)/RANK/osteoprotegerin(OPG) system is a crucial factor in osteoclastogenesis. RNA interference (RNAi) has promising therapeutic potential. Our studies were designed to explore the preliminary possibility of using siRNA targeting RANKL as a novel therapeutic strategy. **Experimental Design:** Four small interfering RNA (siRNA) were designed and the most effective siRNA were selected via real time RT-PCR. At a serial time points post-transfection, the RANKL/OPG protein expression was examined by Western blotting and the function of osteoblasts were investigated through cell proliferation rate and alkaline phosphatase activity.

**Results:** siRNA targeting RANKL could specifically inhibit the expression of RANKL without affecting that of OPG, but the decrease of RANKL gradually restored. Both cell proliferation rate and alkaline phosphatase activity weren't influenced by RANKL-siRNA. **Conclusions:** Through there are many obstacles to clinic application of siRNAs, these results provide strong evidence that RANKL siRNA is a promising method for osteolytic diseases.

**Disclosures:** F. Pei, None.

**Mitogen Activated Protein Kinase-dependent Inhibition of Osteocalcin Gene Expression by Transforming Growth Factor-beta.** S. Kwok<sup>\*1</sup>, N. C. Partridge<sup>1</sup>, N. Srinivasan<sup>\*2</sup>, S. K. Nair<sup>\*3</sup>, N. Selvamurugan<sup>3</sup>. <sup>1</sup>UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, <sup>2</sup>University of Madras, Chennai, India, <sup>3</sup>Centre for Nanosciences, Amrita Institute of Medical Sciences, Kochi, India.

TGF- $\beta$  (transforming growth factor-beta) plays a key role in osteoblast differentiation and bone development. While the ability of TGF- $\beta$  to inhibit the expression of osteoblast differentiation genes has been well documented, the mechanism of this inhibition is not yet completely characterized. Runx2, a transcription factor necessary for expression of osteoblast differentiation genes is a central target of inhibition by TGF- $\beta$ . In this study, we found that TGF- $\beta$ 1 inhibits expression of osteoblast differentiation genes (osteocalcin) without altering expression of Runx2. Transient transfection experiments determined that TGF- $\beta$ 1 inhibited osteocalcin promoter activity and this effect is mediated through Runx2. We further identified by Western blot, Immunofluorescence and Chromatin immunoprecipitation (ChIP) techniques that there was no change in protein expression, cellular localization, or DNA binding affinity of Runx2 after TGF- $\beta$ 1-treatment of osteoblasts. This suggested that Runx2 undergoes post-translational modifications following TGF- $\beta$ 1 treatment. Co-immunoprecipitation experiments identified increased phosphorylation of Runx2 when differentiating osteoblasts were treated with TGF- $\beta$ 1. Mitogen activated protein kinase (MAPK) inhibitors abolished Runx2 phosphorylation at threonine amino acids and relieved the TGF- $\beta$ 1-inhibitory effect on Runx2-mediated osteocalcin promoter activity. ChIP and reChIP experiments identified that there was recruitment of histone deacetylases-4 and -5 (HDAC-4, -5; co-repressors) by Runx2 on the osteocalcin promoter upon TGF- $\beta$ 1-treatment in rat differentiating osteoblasts. Thus, our results suggest that TGF- $\beta$ 1-inhibition of osteocalcin gene expression is dependent on the MAPK pathway and this effect is most likely mediated by Runx2 phosphorylation, followed by recruitment of HDACs.

**Identification and Analysis of Human LMP Gene Promoter Region.** Y. Liu, M. Vigneswarapu, S. Sangadala, M. Bargouti<sup>\*</sup>, L. Titus, S. D. Boden. Orthopaedics, Atlanta VA Medical Center, Atlanta, GA, USA.

LIM mineralization protein (LMP) is an intracellular protein that is ubiquitously expressed in tissues. It belongs to the PDZ-LIM family of proteins that are associated with the cytoskeleton. These proteins possess an N-terminal PDZ domain and one or three C-terminal LIM domains. LMP has a PDZ domain, three LIM domains and a unique region. These domains endow LMP with a variety of functions. LMP has at least 3 alternatively spliced functional isoforms which have different bone-inducing activities. Forced expression of LMP-1 induces bone formation in vitro and in vivo in rats, rabbits and non-human primates. Further studies indicate that LMP-1 is both necessary and sufficient for induction of bone formation. Thus, we are interested in understanding regulation of the expression of this important bone inducing factor.

The genomic sequence of human LMP is localized on chromosome 5. We determined that the LMP gene contains at least 14 exons and 13 introns by comparing genomic sequence of the human LMP gene with its cDNA sequence. We cloned a putative 3.0 kb promoter fragment from a human genomic DNA PAC clone by restriction digestion. Primer extension analysis and 5'-RACE indicate a single transcription start site without a TATA box. This suggests that the various isoforms of LMP are splice variants of a single transcript. Sequence analysis revealed several putative AP-1, Egr-1, C/EBP $\alpha$ , and SP-1 binding sites within this region. Deletion mutants of the promoter were prepared in order to study the importance of these transcription factor binding sites. RD (human rhabdomyosarcoma) or TE-85 (human osteoblast) cells were transfected with the LMP promoter or its deletion fragments ligated to the luciferase reporter gene. Except for the shortest 37 bp fragment, all fragments showed significant luciferase activity. Mutation

studies demonstrated that the C/EBP $\alpha$  and Egr-1 sites within the -246 to -170 fragment are critical for full promoter activity. Promoter reporter constructs with mutated C/EBP $\alpha$  or Egr-1 site showed 37% and 61% reductions in promoter activity respectively compared with the native construct. Electrophoretic Mobility Shift Assays (EMSA) confirmed that mutated C/EBP $\alpha$  and Egr-1 sites within the -246 to -170 fragment lost their binding capacities with the corresponding nuclear binding proteins.

Our results suggest that the human LMP gene is constitutively expressed but the possibility remains that there may be cell and/or tissue specific regulation.

## M035

**DNA Methylation Analysis of Osteogenic Gene Promoter Regions in Mouse Bone Marrow Stromal Cells.** H. Egusa<sup>\*</sup>, S. Ashida<sup>\*</sup>, M. Kobayashi<sup>\*</sup>, Y. Akashi<sup>\*</sup>, H. Yatani<sup>\*</sup>. Department of Fixed Prosthodontics, Osaka University Graduate School of Dentistry, Suita-city, Osaka, Japan.

Early studies proposed that DNA methylation might regulate gene expression during stem cell differentiation. However, little is known about DNA methylation during osteogenic differentiation of mesenchymal stem cells. **Objectives:** To analyze the methylation status of osteocalcin and osteopontin promoter regions in genomes of bone marrow-derived stromal cells (BMSCs) before and after osteogenic differentiation. **Methods:** Clonal cultures of C57BL/6J mouse BMSCs were established. Genomic DNA and total RNA were extracted from uninduced or osteogenically induced BMSCs, gingival fibroblasts, brain, calvaria, and C2C12 myoblasts. DNA was treated with bisulfite conversion and amplified by PCR using primer sets for osteocalcin and osteopontin promoter regions (amplified regions contained 6 and 4 CpG sites, respectively). Subsequently, PCR products were sequenced and the methylation status of the CpG sites was analyzed. Relative expression levels were determined by RT-PCR. **Results:** The overall methylation pattern in the BMSC osteocalcin promoter region did not significantly change after osteogenic differentiation. However, the fourth CpG site was methylated less frequently (<15%) in osteogenic BMSCs, C2C12, and calvaria, all of which highly expressed osteocalcin mRNA. In contrast, the frequency of methylation at this site was high (>60%) in fibroblasts and brain, which did not express osteocalcin transcripts. In the BMSC osteopontin promoter region, the frequency of methylation at the fourth CpG site was specifically decreased after osteogenic differentiation. In addition, this CpG site was hypomethylated (<30%) in osteogenic BMSCs, fibroblasts, C2C12, and calvaria, all of which highly expressed osteopontin mRNA, and hypermethylated (>60%) in uninduced BMSCs and brain, which expressed osteopontin at lower levels. **Conclusion:** These results suggest that the methylation status of specific CpG loci in mouse osteocalcin and osteopontin promoter regions vary depending on cell type and differentiation stage, and may thus be involved in the regulation of gene expression.

**Possible Physiological Function of Menin Protein as Transcriptional Factor that Modulates microRNA Expression During Osteogenesis.** E. Luzi<sup>\*</sup>, F. Marini<sup>\*</sup>, I. Tognarini<sup>\*</sup>, G. Galli<sup>\*</sup>, A. Falchetti, M. Brandi. Internal Medicine, University of Florence, Florence, Italy.

In mesenchymal stem cells that have not been yet committed to the osteoblastic lineage, menin interacts with Smad1 and Smad5, two crucial mediators of BMP-2 signaling. The disruption of this menin-Smad1/5 interaction, due to menin inactivation, antagonizes the transcriptional activity of Smad1 and Smad5, resulting in inhibition of osteoblastic differentiation.

MicroRNAs (miRNAs) are a family of naturally occurring, evolutionary conserved, small (approximately 19-23 nucleotides), non-protein-coding RNA molecules that negatively regulate post-transcriptional gene expression. miRNAs are estimated to account for >3% of all human genes and to control expression of thousands of target mRNAs, with multiple miRNAs targeting for a single mRNA.

Using osteoblast precursors obtained by subcutaneous human adipose tissue we had previously demonstrated that miR-26a level increased in differentiating osteoblasts and that miR-26a inhibition by 2'-O-methyl-antisense RNA, increased protein levels of Smad1 transcription factor in treated osteoblasts, up-regulating bone marker genes and, thus, enhancing osteoblast differentiation.

Recently, we found that siRNA silencing of *MEN1* mRNA, in human osteoblast precursors from Human Adipose Tissue-Derived Stem cells, induces a downregulation of miR-26a and thus an up-regulation of Smad1 protein. These results suggest a possible physiological function of menin protein as transcriptional factor that modulates miRNA expression during osteogenesis.

**Retinoblastoma Binding Protein-1 Is Critical For Runx2 Expression, Transcriptional Activity and Nodule Formation in Osteoblasts.** D. G. Monroe<sup>1</sup>, J. R. Hawse<sup>1</sup>, M. Subramaniam<sup>1</sup>, J. B. Lian<sup>2</sup>, G. S. Stein<sup>2</sup>, A. J. van Wijnen<sup>2</sup>, T. C. Spelsberg<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

The retinoblastoma binding protein-1 (RBP1) is a broadly expressed transcription factor involved in the suppression of cell proliferation mediated through the retinoblastoma protein (pRb), a major pathway implicated in the pathogenesis of numerous cancers including osteosarcoma. We have previously demonstrated an estrogen receptor- $\alpha$ -specific induction of RBP1 in osteoblasts, suggesting a role for RBP1 in osteoblast function. To further characterize the importance of RBP1 in the transcriptional regulation of bone marker genes, we utilized shRNAs to reduce RBP1 expression in a mouse calvarial osteoblast model. Depletion of RBP1 resulted in significant inhibition of important osteogenic regulators (Runx2, Osterix, TIEG, BMP2) and bone phenotypic genes (osteocalcin and osteopontin) as well as significantly delayed the appearance of Alizarin Red-stained bone nodules. We present evidence that RBP1 is also involved in both Runx2 expression and Runx2-dependent transcriptional activation of target genes. Therefore, RBP1 may cooperate with Runx2 to establish and sustain the osteoblast phenotype during skeletal development. Overexpression of RBP1 in U2OS osteosarcoma cells significantly enhances Runx2-dependent activation of the Runx2-dependent osteocalcin gene. This coactivation appears to be independent of pRb, as mutation of the RBP1 LxCxE motif essential for pRb binding, retains the potent co-activation of the Runx2-dependent osteocalcin promoter. Deletion analysis demonstrates that the N-terminal domain (1-235) of RBP1 is sufficient to synergize with Runx2. Furthermore, deletion analysis of the Runx2 protein demonstrates that amino acids 391-432, encompassing the Smad interaction domain (SMID) and a subnuclear targeting signal (NMTS), are critical for maximal RBP1-mediated Runx2 coactivation of the osteocalcin gene. These results suggest that RBP1 is a critical regulator of osteoblast growth and differentiation by modulating Runx2-dependent transcriptional activation.

**Depletion of the Chromosome Remodeling Subunit BRM Accelerates Differentiation of Osteoblast Precursors.** S. Flowers<sup>\*1</sup>, N. G. Nagl<sup>\*2</sup>, G. R. Beck<sup>3</sup>, E. Moran<sup>1</sup>. <sup>1</sup>Dept. of Orthopaedics and NJMS-UH Cancer Center, University of Medicine and Dentistry of New Jersey, Newark, NJ, USA, <sup>2</sup>Fels Institute for Cancer and Molecular Biology, Temple University School of Medicine, Philadelphia, PA, USA, <sup>3</sup>Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA.

ATPase-dependent chromatin-remodeling complexes such as the SWI/SNF complex are strongly conserved throughout evolution, and play coordinating roles during programmatic changes in gene expression. Mammalian cells have evolved to contain alternative versions of two subunits of this complex. These variations in complex configuration permit fine-tuned control of gene expression, and offer the possibility of selectively manipulating entire programs of gene expression. The alternative subunits include two versions of the core ATPase, either BRG1 or BRM. We have studied the individual roles of these subunits in osteoblast differentiation, using siRNA technology to deplete them selectively in an MC3T3-E1 pre-osteoblast model. This study revealed that the alternative complexes play opposing roles in the differentiation of these cells. Depletion of BRG1 leaves the cells unable to differentiate, but depletion of BRM accelerates progression to the osteoblast phenotype indicating that BRM-containing complexes play a specific role in restraining osteoblast differentiation. Multiple osteoblast differentiation markers, including the tightly regulated osteocalcin gene, are expressed constitutively in BRM-depleted cells. Chromatin immunoprecipitation (ChIP) analysis of the osteocalcin promoter shows BRM complexes present exclusively on the repressed promoter, and required for association of the transcriptional co-repressor HDAC1. Comparison with early stage markers shows that BRM complexes dissociate sequentially from these promoters, concordant with their order of activation. BRM is an attractive target for accelerating osteoblast differentiation in applications such as bone healing because it has a fundamental role in the coordination of events, and because its biological activity is enzyme-based.

**Wdr5 is Required for Chromatin Modifications at the Runx-2 Promoter.** F. Gori, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Wdr5 is developmentally expressed in osteoblasts and accelerates osteoblast differentiation in vitro and in vivo. Wdr5 is a critical component of the Set/Ash histone methyltransferase complex and is essential for histone H3 lysine 4 (H3K4) trimethylation. Posttranslational methylation, acetylation, phosphorylation and ubiquitination of histones are known to alter chromatin conformation, thereby activating/repressing gene transcription. Histone methylation at lysine 4 of H3 and acetylation of H3 are histone modifications associated with transcriptional activation of genes. Silencing of Wdr5, using plasmid-based small interfering RNAs (siRNAs), dramatically impairs the differentiation of MC3T3-E1 cells as evidenced by a significant decrease in Runx-2 and osteocalcin mRNAs and absence of mineralized matrix formation. Wdr5 suppression resulted in a significant reduction in global acetylation of H3 lysine 9-14 (H3K9ac14ac) and trimethylation of H3K4 (H3K4me3), suggesting that posttranslational acetylation and methylation are closely linked and that Wdr5 is required for these modifications. These findings also point to a critical role for Wdr5 in regulating chromatin modifications at the promoters of genes involved in osteoblast differentiation. To test this hypothesis, the effect of suppression of Wdr5 expression on H3 acetylation and methylation at the Runx-2 promoter was examined. Chromatin immunoprecipitation (ChIP) analyses were performed using chromatin isolated from cells in which Wdr5 expression was suppressed or cells stably expressing a scrambled siRNA (siRNA-S). Real time PCR was used to quantitate the presence of Wdr5, H3K9ac14ac and H3K4me3 at the Runx-2 promoter. These analyses demonstrated that Wdr5 associates with the Runx-2 promoter (-123 to +123) and that Wdr5 occupancy of the Runx-2 promoter decreased by 2.3-fold in cells with Wdr5 knockdown compared to the siRNA-S cells. A concomitant 2.4-fold reduction in H3K9ac14ac and a 3.3-fold reduction in H3K4me3 occupancy at the Runx-2 promoter were observed in the cells with Wdr5 knockdown, relative to the siRNA-S cells. These data demonstrate that reduction of a key component of the methylation complex (Wdr5) alters these histone marks at the Runx-2 promoter and correlates with a 3-fold reduction in Runx-2 mRNA levels in the cells in which Wdr5 expression is suppressed. These findings link H3K4me3, H3K9ac14ac with Wdr5 occupancy at the Runx-2 promoter and suggest that suppression of Wdr5 expression impairs the dynamic chromatin changes that accompany expression of Runx-2 as MC3T3E1 cells recapitulate the program of osteoblast differentiation.

**Expression Profiles of Wnt Signaling Pathway Components in Response to cAMP Stimulation at Different Stages of Osteoblast Maturation.** R. S. Kao, W. Lu<sup>\*</sup>, A. Louie<sup>\*</sup>, R. A. Nissenson. Endocrine Unit, VA Medical Center and University of California, San Francisco, CA, USA.

Parathyroid hormone (PTH) can exert both anabolic and catabolic effects on bone depending on the pattern and duration of circulating levels of PTH. The cAMP pathway is one of the key effector pathways mediating PTH signaling. We postulate that the paradoxical effects of PTH on bone results from cAMP signaling having different effects on osteoblasts depending on the stage of cell maturation. Since the Wnt signaling pathway has been shown to play an important role in bone cell differentiation, proliferation, and apoptosis, we sought to determine whether cAMP signaling in osteoblasts controls bone formation by regulating Wnt signaling differently at different stages of osteoblast differentiation. Utilizing a real time RT-PCR based gene expression array (SuperArray), expression of 84 genes related to Wnt-mediated signal transduction was examined in 10-day (immature) and 23-day (mature) bone marrow derived murine osteoblast cultures. Cells were exposed to cAMP treatment for either a 3- or 24-hour duration at both differentiation time points to assess immediate-early and late gene regulation by cAMP. Very little change in the expression of Wnt signaling genes was detected after 3-hours of cAMP treatment in 10-day and 23-day cultures. Treatment with cAMP for 24 hours induced changes in the expression of several Wnt signaling genes in both immature and mature osteoblasts. 24 hours of cAMP treatment down-regulated Wnt1 and Wnt11 expression by more than two-fold. Up-regulation of Wnt9a was only detected in 10-day cells, while down-regulation of Wnt2 and Wnt16 and up-regulation of Wnt4 were uniquely observed in the 23-day osteoblasts. Expression of a negative modulator of Wnt signaling, Sfrp4, was up-regulated by cAMP in 23-day osteoblasts. This gene has been implicated to be an important negative regulator of bone mass in humans. Additionally, we compared gene expression profiles of Wnt signaling components of 10-day and 23-day untreated osteoblasts to assess changes in Wnt signaling as cells differentiate. Dramatic changes in gene expression profiles were detected. Significant among these genes were Sfrp4, Wnt16, Wnt7b, and Wif1, which were up-regulated in mature cells. These results indicate that differentiation of osteoblasts is associated with increased potential to regulate Wnt signaling. The expression levels of several secreted modulators of Wnt signaling are altered as osteoblasts differentiate. On the other hand, relatively few Wnt-related genes appear to be subject to acute regulation by cAMP. Mature osteoblasts may represent an essential control point for the paracrine regulation of Wnt signaling in the bone marrow microenvironment.

**A Runx2 Threshold for the Cleidocranial Dysplasia Phenotype.** Y. Lou\*, A. Javed\*, S. Hussain\*, J. Colby\*, D. Frederick\*, J. Pratap\*, R. Xie\*, T. Gaur\*, A. J. van Wijnen, S. N. Jones\*, G. S. Stein, J. B. Lian, J. L. Stein. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

Cleidocranial dysplasia (CCD) in humans is an autosomal dominant skeletal disease which results from mutations in bone specific transcriptional factor Runx2/Cbfa1/AML3. However, several studies have reported that there is no obvious relationship between the type of Runx2 mutations and the severity of the human CCD phenotypes which have a broad range from craniofacial to limb abnormalities. Here, we used gene targeting to generate a novel, hypomorphic Runx2 mutant allele through insertion of a neomycin(*neo*) cassette into Intron 7 (Runx2<sup>neo7</sup>) that allowed us to establish the minimum requirement of functional Runx2 levels for normal bone development. In the resulting mice, the normal splicing of Runx2 was disrupted, thus permitting expression of both wild-type Runx2 and an alternative Runx2-*neo* chimeric mRNA which encodes a truncated subnuclear defective Runx2 protein. In the homozygous Runx2<sup>neo7</sup> mice, splicing of the chimeric transcripts reduces the levels of full length Runx2 mRNA to a mean value of 62% with 38% representing the non-functional mutant Runx2. The Runx2<sup>neo7</sup> mice have grossly normal skeletons, but exhibit developmental defects in calvaria and clavicle that persist through post-natal growth. These phenotypes are somewhat similar to those of the heterozygotes of Runx2 null (Mundlos et al., 1997; Komori et al., 1997) and Runx2ΔC (Choi et al., 2001) mouse model. Our hypomorphic mice have altered bone volume parameters, as observed by histology and microCT imaging. A reduction in the expression of osteoblast marker genes, Alkaline Phosphate, Osteocalcin and Osterix were found with the decreased bone volume measurement. Only in new-born mice, we observed an enhanced proliferation with increase Histone gene expression. *Ex vivo* studies of the calvarial osteoblast from the hypomorphic mouse provided an additional evidence for these changes. In the heterozygotes with 21% of total Runx2 present as a truncated Runx2 protein, a normal bone phenotype was found. The results show that there is a critical gene dosage requirement of Runx2 for normal formation of intramembranous bone tissues during embryogenesis, and that the functional Runx2 activity levels are related to extent of the CCD-like phenotype in the mouse. These findings also indicate that the bone phenotype of CCD patients is directly attributable to a reduction in the quantitative levels of Runx2 gene expression.

**Parathyroid Hormone Regulation of Osterix Transcription in Osteoblasts.** S. H. H. Hong\*<sup>1</sup>, M. S. Nanes\*<sup>2</sup>, J. Mitchell<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Department of Medicine, Emory University, Atlanta, GA, USA.

The aim of this study was to examine parathyroid hormone (PTH) regulation of the zinc finger transcription factor osterix (osx) in osteoblasts. Intermittent administration of PTH is anabolic to bone while continuous exposure of PTH is catabolic to bone indicating that a better understanding of the mechanism of PTH regulation in osteoblasts is important. Runt-related transcription factor 2 (runx2) and osx are transcription factors essential for osteoblast differentiation and bone formation. Runx2 is regulated by PTH where short term treatment enhances runx2 transactivational activity and long term treatment promotes proteosomal degradation of runx2. However, it is not clear if PTH regulates osx. As runx2 is upstream of osx and the osx promoter contains runx2 binding sites, we hypothesized that short term PTH treatment would increase osx levels and long term PTH treatment would decrease osx expression. Real-time PCR and western blotting were used to quantify osx mRNA and protein levels in rat UMR106-01 cells, E18.5 and PN4-5 mouse primary calvaria treated with PTH for various times. Signaling inhibitors and activators were used to determine signaling pathways. DRB and cycloheximide were used to determine the half-life of osx mRNA and the requirement for *de novo* protein synthesis for the effect of PTH respectively. Luciferase assays were performed to examine PTH stimulation of runx2 activity and transcriptional regulation of the osx promoter. In UMR cells, 3-24 hr of 10<sup>-8</sup>M PTH suppressed 50±7 % osx mRNA level and 6-24 hr of 10<sup>-8</sup>M PTH suppressed 55±10 % osx protein expression. In primary calvaria, 4-24 hr of 10<sup>-7</sup>M PTH suppressed 65±5 % osx mRNA level. In comparison, runx2 mRNA levels were not regulated by PTH but runx2 activity was stimulated by PTH in luciferase assays. PTH-mediated suppression of osx mRNA could be mimicked by cAMP analogues and forskolin suggesting involvement of cAMP- or PKA- dependent pathways. PTH did not alter osx mRNA stability and osx mRNA suppression did not require new protein synthesis. Luciferase assays suggested that PTH regulated osx expression by acting at the 5' flanking region 304bp to 119bp upstream from the initiation start site of osx promoter. In summary, PTH suppressed osx mRNA and protein by regulating the 5' flanking region of osx promoter. As osx is involved in bone formation, PTH-mediated suppression of osx expression probably results in a catabolic effect on bone. Although osx is characterized as downstream target for runx2, PTH regulation of osx expression occurs more rapidly than the effect of PTH on runx2 indicating a runx2-independent process in regulating osx expression.

**Runx2 and Canonical Wnt Signaling Cooperatively Regulate BMP-Induced Differentiation Pathways of Adult Dural Cells into Osteoblasts or Chondrocytes.** M. Rodova\*, B. M. Gardner\*, Q. Lu\*, J. G. Yost\*, J. Wang. Orthopedic Surgery, University of Kansas Medical Center, Kansas City, KS, USA.

While the roles of transcription factor Runx2 and canonical Wnt signaling in embryonic skeletal development have been extensively studied, their regulatory functions in postnatal skeletal regeneration remain unclear. Implantation of bone morphogenetic protein (BMP) or its raw material, demineralized bone matrix (DBM), into soft tissue sites first induces chondrocyte differentiation followed by an endochondral sequence of ossification. Interestingly, our previous studies showed that BMP/DBM-induced repair of adult rat/mouse cranial defects occurred initially by the proliferation and differentiation of dura-derived progenitor cells directly to osteoblasts that synthesized bone tissue, which was spatially distinct from the formation of cartilage near the skin flap covering the cranial defect. This study was designed to elucidate why BMP induces direct osteoblast differentiation at the dural site. Normal 3-5 months old BALB/C mice were used for analysis in this study. We isolated total RNA from the dura mater, subcutaneous tissue covering the cranial defect, and thoracic subcutaneous tissue for gene expression analysis. Genes for the potential regulators of chondrocyte and osteoblast differentiation in these tissues were detected by quantitative real-time PCR (qPCR). The expression levels of Runx2, Wnt-1, -7a, -9a, and β-catenin were significantly higher (p < 0.01) in dural cells than in cranial or thoracic subcutaneous tissue cells. In contrast, expression levels of Sox9 and AP-2α were significantly lower in dura than in cranial or thoracic subcutaneous tissues (p < 0.001). The differences in expression levels of Msx2 and Twist1 between these tissues were not statistically significant. To explore if Runx2 and/or Wnt/β-catenin signaling is the determinant for controlling the BMP-induced dural cell differentiation pathways, we conducted a loss of function experiment using Runx2 and β-catenin short interfering RNA (siRNA) delivered with lentiviral vectors in primary dural cell cultures. The results revealed that transfection with Runx2 siRNA or β-catenin siRNA alone decreased the expression of osteoblast markers, but did not increase the expression of chondrocyte markers in rhBMP-7-treated dural cell cultures, while the combination of Runx2 siRNA and β-catenin siRNA did significantly increase the expression of chondrocyte markers with a decrease in osteoblast markers. These results suggest that higher expression levels of Runx2 and Wnt/β-catenin cooperatively suppress the chondrogenic potential of BMP-treated adult dural cells, which can be reversed by knockdown of Runx2 and Wnt/β-catenin expression.

**Interaction of Ciz, a Nucleo-cytoplasmic Shuttling Transcription Factor with C-propeptides of Type I Collagen.** T. Hayata, T. Nakamoto, Y. Ezura, M. Noda. Medical Research Institute, Tokyo Medical & Dental University, Tokyo, Japan.

Ciz is a zinc finger transcription factor with nucleocytoplasmic shuttling activity. We previously showed that Ciz-deficient mice show high bone mass phenotype. As a first step to address how Ciz suppresses bone formation, we examined the binding proteins of Ciz based on a yeast two-hybrid screening. While Ciz is an intracellular protein, 47% of the positive clones were genes encoding extracellular matrix proteins, including Colla1, Colla2, Fbln2, and Rpsa. Since type I collagen is a major protein in bone tissue, we focused on type I collagen. In vitro co-immunoprecipitation experiments using in vitro translated proteins revealed direct binding of Ciz-Delta ZF (zinc finger) to C-propeptides of Colla1 and Colla2. In vivo association of the transfected Ciz and C-propeptide of Colla1 was observed in COS-7 cells based on immunoprecipitation experiments. In terms of intracellular localization, C-propeptides of Coll1 and Ciz overexpressed in MC3T3-E1 and COS-7 cells were co-localized in nuclei. These results revealed that Ciz interacts with C-propeptides of type I collagen and this association takes place in nuclei.

**Osteotropic Peptides: Anabolic and Osteogenic Effects.** V. Madhu\*, G. Beck\*, D. Huang\*, G. Balian. Orthopedic Research Laboratories, Dept of Orthop Surg and Biochem & Molec Genetics, University of Virginia, Charlottesville, VA, USA.

The objective of this study is to establish the molecular targets of bone targeting peptides that were identified from a phage display library. These peptides promote the differentiation of mesenchymal cells *in vitro* and potentiate bone repair in uncortical defects *in vivo*. Identification of the molecular targets for these osteotropic peptides will help us understand the mechanism of peptide mediated bone regeneration. Our studies demonstrated that two of the peptides, designated R1 and L7, stimulate bone regeneration *in vivo*. The two peptides have unique sequences and showed distinct properties. R1 binds to marrow mesenchymal cells *in vitro* and promotes cortical bone and marrow *in vivo*. By contrast, L7 potentiates bone repair but without marrow regeneration at 12 weeks. The differentiation of mesenchymal cells *in vitro* was shown by measuring increases in alkaline phosphatase activity and gene expression for osteocalcin, bone sialoprotein, osterix and Runx2. In addition, the OPG/RANKL ratio is greater than the RANKL/OPG ratio, which suggest that the peptides may have a direct effect on osteoblasts and regulate bone resorption. OPG expression is regulated by Wnt/ $\beta$ -catenin signaling in osteoblasts, which is the same pathway that regulates osteoblastic bone formation. Bone mass is determined by the combined influence of osteoblasts and osteoclasts, and is regulated in osteoblasts by two major signaling pathways: RANKL/RANK and Wnt/ $\beta$ -catenin. To further elucidate the signaling pathway, we have analyzed the Wnt pathway genes. The two bone tropic peptides increased the expression of Wnt receptor LRP6,  $\beta$ -catenin, Wnt10b and Wnt7a and decreased the expression of Wnt5a and Wnt antagonist DKK1. These results suggest that the peptides act through the canonical Wnt signaling pathway. We have also identified the molecular targets for these peptides in mesenchymal cells, including elongation factor, vimentin and myosin, and certain pathways in bone metabolism through which the peptides exert their osteogenic effects. Synthetic peptides may have advantages over larger molecules such as speed of preparation, molecular stability, long shelf lives and potentially therapeutic applications. Significant progress has been made in attempts to modulate bone loss and regeneration by controlling cytokines and growth factors. These osteotropic peptides may offer attractive alternatives to existing therapies that stimulate bone anabolism and bone regeneration.

**The Proinflammatory Cytokine TWEAK Induces Sclerostin Expression in Human Immature Osteoblasts in a MAPK Dependent Fashion.** G. J. Atkins<sup>1</sup>, C. Vincent<sup>1</sup>, A. R. Wijenayaka<sup>1</sup>, K. J. Welldon<sup>1</sup>, D. R. Haynes<sup>2</sup>, T. S. Zheng<sup>3</sup>, A. Evdokiou<sup>1</sup>, D. M. Findlay<sup>1</sup>. <sup>1</sup>Discipline of Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia, <sup>2</sup>Discipline of Pathology, University of Adelaide, Adelaide, Australia, <sup>3</sup>Biogen Idec, Boston, MA, USA.

We recently showed that TNF-like weak inducer of apoptosis (TWEAK), a member of the TNF superfamily is a novel mediator in a mouse model of inflammatory bone destruction.<sup>[1]</sup> We sought to investigate a role for TWEAK in human osteoblast biology, and how TWEAK might interact with TNF in this context. Human primary osteoblasts (NHBC) were found to express TWEAK and its receptor, Fn14. Both TWEAK and TNF were mitogenic for NHBC, regulated by extracellular signal-regulated kinase (ERK)1/2 phosphorylation. TWEAK dose- and time-dependently suppressed the transcription of the master osteoblast transcription factor, RUNX2. Consistent with this, TWEAK inhibited *in vitro* mineralisation, whereas TNF had a positive effect. Notably, TWEAK, alone and in conjunction with TNF, induced the expression in proliferating and therefore phenotypically immature cells, of the osteoblast differentiation inhibitor, sclerostin, in a c-Jun N-terminal kinase (JNK) and Erk1/2-dependent manner. Sclerostin expression was observed at both the mRNA and protein levels. TWEAK induction of sclerostin was sensitive to cycloheximide, implying the requirement for new protein synthesis in the sclerostin response. Exposure of NHBC to exogenous sclerostin mimicked the TWEAK and TWEAK/TNF effects on RUNX2 and osteocalcin expression. Our results suggest that TWEAK acts in part by promoting sclerostin expression, which in turn regulates the expression of key osteoblast transcription factors. Our results suggest that the persistent presence of TWEAK may be anti-anabolic, and that TWEAK and TNF need to be considered together in the aetiology of inflammatory bone remodelling. Our results also demonstrate for the first time that sclerostin, hitherto described as a product of mature osteocytes embedded in mineral, may be induced under inflammatory conditions in osteoblasts at earlier stages of their differentiation.

**Gene Expression Analysis of *In vitro*-Aged and Immortalized Human Mesenchymal Stem Cells.** P. Benisch<sup>\*1</sup>, T. Schilling<sup>\*1</sup>, L. Klein-Hitpass<sup>\*2</sup>, M. Kassem<sup>\*3</sup>, F. Jakob<sup>1</sup>, R. Ebert<sup>1</sup>. <sup>1</sup>Orthopedic Center for Musculoskeletal Research, University of Wuerzburg, Wuerzburg, Germany, <sup>2</sup>Institute of Cell Biology, University of Duisburg-Essen, Essen, Germany, <sup>3</sup>Department of Endocrinology, University of Southern Denmark, Odense, Denmark.

Differentiation of human mesenchymal stem cells (hMSC) into osteoblasts is a major step for maintaining bone homeostasis, which is disordered in patients with osteoporosis and impaired during aging. Human MSC obtained from the bone marrow stop proliferation and enter replicative senescence *in vitro* after several months in culture. Thereby they lose their potential for multilineage differentiation and self-renewal. In contrast, telomerase-immortalized hMSC (hMSC-TERT) do not age *in vitro* and were handled as a model for rejuvenation in this study.

We investigated the gene expression pattern of hMSC of early passages, senescent hMSC and hMSC-TERT to reveal new insights into the *in vitro* aging process and possibly age-related bone loss. Therefore, cultures of human hMSC from 9 different donors were maintained until cells stopped proliferation. RNA samples of the first 2 passages (n=5) and the last passages (n=5) as well as hMSC-TERT (n=3) were extracted and analysed by microarray chip hybridization. The transcribed genome of senescent hMSC and hMSC-TERT was statistically evaluated and compared to the gene expression pattern of hMSC of early passages by SAM (Significance Analysis of Microarrays) calculations.

Using SAM analysis we found reproducible differences in the gene expression patterns of our 3 groups of hMSC. In comparison to early-passage cultures of hMSC, 1515 gene products showed more than two-fold up or down regulation of gene expression in senescent hMSC and/or hMSC-TERT. One third of these mRNA species was reciprocally expressed in aged and immortalised cells. Surprisingly, compared to hMSC of early passages, about 400 gene products showed parallel expression changes in aged hMSC and hMSC-TERT with 93 up regulated and 306 down regulated gene products in both groups. This finding was unexpected, but indicates that ageing and rejuvenation might have at least some common attitudes. In addition, we found approximately 200 gene products, which are exclusively expressed in hMSC of the first passages and could not be detected in aged cells or hMSC-TERT by SAM analysis. We conclude that these gene clusters could play a major role in maintaining the characteristics of early-passage hMSC and will therefore be examined further. Functional analysis of differentially expressed genes in aged versus telomerase-immortalized cells will also give hints for molecular mechanisms involved in cellular aging and rejuvenation *in vitro*.

**FHL2 Mediates Dexamethasone-Induced Mesenchymal Stem Cell Osteogenic Differentiation by Activating Wnt/ $\beta$ -Catenin Signaling and Runx2 Expression.** Z. Hamidouche<sup>\*1</sup>, E. Hay<sup>1</sup>, P. Vaudin<sup>\*2</sup>, P. Charbord<sup>\*3</sup>, P. J. Marie<sup>1</sup>, O. Fromiguet<sup>1</sup>. <sup>1</sup>Inserm U606 and University Paris 7, Paris cedex 10, France, <sup>2</sup>University François Rabelais, Tours, France, <sup>3</sup>Inserm-ESPRI, Tours, France.

The differentiation of bone marrow mesenchymal stem cells (MSCs) into osteoblasts is a crucial step in bone formation. However, the mechanisms involved in the early stages of MSC osteogenic differentiation are not well understood. In this study, we identified FHL2, a member of the LIM-only subclass of the LIM protein superfamily, as a key factor involved in dexamethasone-induced osteogenic differentiation in MSCs. We found that FHL2 was up-regulated during early osteoblast differentiation induced by dexamethasone in murine C3H10T1/2 pluripotent MSCs, bone marrow derived osteogenic BMC10 cells and primary human bone marrow derived MSCs. Forced FHL2 expression using lentiviral vector (LV-FHL2) promoted the expression of Runx2, alkaline phosphatase, type I collagen as well as *in vitro* extracellular matrix mineralization in both murine and human MSCs. Knocking down FHL2 using sh-RNA reduced basal and dexamethasone-induced osteoblast marker gene expression as well as *in vitro* mineralization. Immunocytochemical analysis showed that FHL2 overexpression induced  $\beta$ -catenin translocation to the nucleus where the two proteins were found to be co-localized. Furthermore, a specific sh-FHL2 partially blunted  $\beta$ -catenin nuclear translocation induced by Wnt3a. Immunoprecipitation analysis confirmed that FHL2 promoted  $\beta$ -catenin nuclear translocation which was blocked by a specific sh-FHL2. We further showed that LV-FHL2 transduction led to increase TCF/LEF-dependent reporter gene activity and potentiated Wnt3a-induced TCF/LEF transactivation. Blocking Wnt/ $\beta$ -catenin signaling using DKK1 overexpression abolished the stimulatory effect of Wnt3a and FHL2 overexpression on ALP activity and Runx2 expression. Finally, transfection with a Runx2 mutant bearing a Ser191Asn mutation in the runt domain that impairs DNA binding abolished the stimulatory effect of FHL2 on ALP expression. Altogether, the present study shows that 1) the transcription cofactor FHL2 acts as an endogenous osteogenic activator in MSCs and is involved in dexamethasone-induced mesenchymal cell differentiation into osteoblasts and 2) FHL2 interaction with  $\beta$ -catenin results in increased  $\beta$ -catenin nuclear translocation which in turn potentiates TCF/LEF dependent transcription, increased Runx2 expression and osteogenic differentiation in MSCs. These findings provide evidence that FHL2 is an important mediator of osteogenic differentiation in MSCs via activation of Wnt/ $\beta$ -catenin signaling.

**GILZ (Glucocorticoid Induced Leucine Zipper) Promotes Osteoblast Development and Modulates RANKL/OPG Levels.** T. Lekva<sup>\*1</sup>, C. Kristo<sup>\*1</sup>, T. Ueland<sup>\*1</sup>, O. K. Olstad<sup>\*2</sup>, J. Bollerslev<sup>1</sup>, R. Jemtland<sup>\*1</sup>. <sup>1</sup>Rikshospitalet University Hospital, Oslo, Norway, <sup>2</sup>Ullevaal University Hospital, Oslo, Norway.

Glucocorticoid (GC)-induced bone loss is a frequent and serious complication in patients with endogenous Cushing's syndrome (CS). However, the exact mechanism(s) by which GC influences bone metabolism is still not completely understood. To identify candidate genes with putative roles in GC-induced osteoporosis (GIO), we used global profiling of bone biopsies from CS patients (n=9), before and 3 months after surgery, to screen for changes in gene expression. Out of several hundred differentially expressed genes (p<0.05), the gene encoding GC-induced leucine zipper (GILZ) was selected to further characterize its regulated expression in (proliferating and differentiated) cultured human fetal osteoblast (hFOB 1.19), with or without exposure to dexamethasone (Dex). A putative functional role of GILZ in hFOB was assessed by means of small interfering RNA (siRNA) technology in relation to changes in mRNA levels of typical osteoblastic phenotypic markers and cytokines known to influence bone resorption. Following surgery, normalization of serum cortisol was accompanied by a significant increase in serum markers of bone turnover, 11-fold (p=0.018) for osteocalcin (OC) and 2.2-fold (p=0.018) for CrossLaps (CTX). Moreover, our microarray data demonstrated a fall in levels of GILZ mRNA in bone biopsies 3 months after surgery vs. baseline (p=0.028), whereas levels for Type I collagen and OC increased (also validated using quantitative real-time RT-PCR). We further demonstrate that GILZ is expressed in cultured hFOB osteoblastic cells *in vitro*, and that it is regulated by Dex in a dose- and time-dependent fashion, with a half-maximal effective concentration (EC50) of approx. 10<sup>-9</sup> M and maximum effect of 8.9-fold at 10<sup>-8</sup> M after 4h. Silencing experiments revealed that a reduction in GILZ mRNA levels of more than 75% was associated with reduction in levels of several skeletogenic mRNAs such as ALP, OC and RUNX2, consistent with a role for GILZ in normal osteoblast development. A similar effect of siGILZ on skeletogenic mRNAs was observed also in Dex-treated hFOB. Dex (10<sup>-8</sup> M) has reciprocal effects on OPG (decreased) and RANKL (increased) in hFOB already by 6h. OPG mRNA and protein is further reduced in siGILZ-treated vs. control cells, both in the presence or absence of Dex. However, siGILZ has little or no effect on RANKL mRNA in untreated (i.e. -Dex) osteoblasts, whereas Dex-elicited augmentation of RANKL is largely blunted in siGILZ osteoblasts. Taken together, these results suggest a positive (anabolic) role for GILZ in osteoblast development, and indirectly on bone remodeling, by influencing the balance between bone resorptive and protective cytokines.

**Both the Smad and ERK MAP Kinase Pathway Play Critical Roles in BMP-2-induced Osteogenic Transcription Factors Expression.** J. Park, K. M. Woo\*, J. H. Baek\*, H. M. Ryoo\*. Seoul National University, Seoul, Republic of Korea.

Bone morphogenetic protein-2 (BMP-2) is one of the strongest osteogenic signaling molecules. The osteogenic activity induced by BMP-2 is mediated both by canonical Smad signaling and by MAP kinase activation. The canonical Smad signaling is initiated by ligand-receptor binding, subsequent heterotetramerization of BMPRII and BMPRI receptors, receptor Ser/Thr kinase activation and finally BMP specific R-Smads activation. These BMPRI-activated Smads mediates the transcriptional activation of osteogenic transcription factors, Dlx5, Runx2 and Osx. On the other hand, activation of MAP kinases also is critical for the BMP-2-induced osteogenesis. Unfortunately, however, there were a few reports that comprehensively explain both canonical Smad pathway and MAP kinases pathway. In this study, we tried to explain cross-talk between these two signaling pathway. Our previous reports indicate that Dlx5 is one of the critical target of BMP-signaling and plays a pivotal role in stimulating downstream osteogenic master transcription factor Runx2. Its expression by BMP signaling is mainly regulated by Smad-mediated canonical BMP signaling pathway. We found that BMP-2-induced osteogenic differentiation of C2C12 cell is blocked by ERK MAP kinases. ERK MAP kinase activation by BMP-2 occurred 15-30 min after BMP-2 treatment. Moreover, ERK MAP kinase blocker strongly suppressed BMP-2-induced Dlx5 mRNA level, and overexpression of constitutive active form of MEK1/2 stimulated Dlx5 mRNA level even in the absence of BMP-2 treatment. As Dlx5 expression is stimulated both by canonical Smad signaling and ERK MAP kinase signaling, we can assume that BMP specific R-Smads could be the site of both of the BMP-2 downstream signals converge.

**LMP1, Positive Regulator in Osteolineage Differentiation of Human PDL Fibroblasts.** Z. Lin\*, Q. Jin\*, J. V. Sugai\*, W. V. Giannobile\*. Department of Periodontics and Oral Medicine, University of Michigan, School of Dentistry, Ann Arbor, MI, USA.

LMP-1, a recently discovered intracellular LIM domain protein, strongly induces osteolineage differentiation in bone marrow stromal cells and accelerates posterior thoracic and lumbar spine fusion. However, little is known about the role of LMP1 in periodontal ligament (PDL) cell differentiation and alveolar bone regeneration. This study sought to determine whether LMP1 is a positive regulator in the differentiation of PDL cells *in vitro*.

Primary culture of PDL cells were observed over 10 d via inducing and in non-inducing conditions to determine expression of LMP-1 and osteoblastic-related gene expression. Full-length cDNA of human LMP1 was acquired by RT-PCR from MG-63 cells, and cloned into a pQCXIN retroviral vector and production of retrovirus via 293T cells. PDL cells were transfected by pQC-hLMP1 or control retrovirus. After Geneticin selection for 10 d, survival cells were pooled and induced to osteolineage differentiation. qRT-PCR was utilized to detect the expression of bone-specific marker genes over time. Alizarin Red staining was used to evaluate the mineralization over a course of 3w. Our result showed that LMP1 was highly expressed in the early stages of mineralization induced by PDL cells *in vitro*. LMP1 was stably overexpressed in PDL cells via retroviral transduction. LMP1-engineered stable cells possessed elevated baseline levels of BMP2 expression, compared to controls. At 7 d osteolineage promotion conditions resulted in potent increased expression (~20 fold) for osteix, an early marker of osteoblast differentiation in pQC-hLMP1 cells compared to controls, as well as other osteogenesis associated genes including osteopontin and osteocalcin. At 2w, Alizarin red staining demonstrated more mineralization nodules were found in pQC-hLMP1 cells compared to controls. The conclusion is LMP1 is involved in the osteolineage differentiation of PDL cells leading to mineralization *in vitro*. Furthermore, PDL cells driven by LMP1 over-expression displayed enhanced osteo-lineage differentiation, which may be associated with elevated BMP2 expression. These studies suggest LMP-1 may play an important role in regulating periodontal tissue homeostasis and repair.

**TIEG: A Key Regulator of Runx2 and Osterix Gene Expression and Osteoblast Differentiation.** J. R. Hawse<sup>1</sup>, M. Subramaniam<sup>1</sup>, D. G. Monroe<sup>1</sup>, E. A. Syed<sup>2</sup>, U. T. Iwaniec<sup>\*3</sup>, M. J. Oursler<sup>2</sup>, J. B. Lian<sup>4</sup>, G. S. Stein<sup>4</sup>, A. J. van Wijnen<sup>4</sup>, H. Drissi<sup>5</sup>, R. T. Turner<sup>\*3</sup>, T. C. Spelsberg<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Department of Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, <sup>4</sup>Department of Cell Biology, University of Massachusetts, Worcester, MA, USA, <sup>5</sup>Department of Orthopedics, University of Connecticut Health Center, Farmington, CT, USA.

TGFβ Inducible Early Gene-1 (TIEG/KLF10) is a highly expressed member of the Kruppel-like family of transcription factors that regulates a multitude of genes in osteoblasts (OB). We have generated TIEG-null mice that display a severe gender-specific osteopenic phenotype revealing a critical role for TIEG in bone. Female TIEG<sup>-/-</sup> mice have significant reductions in multiple bone parameters and exhibit nearly a 60% reduction in the osteoblast perimeter/bone perimeter resulting in a 42% reduction in bone formation rate. To elucidate the basis for this bone phenotype, we assessed if the loss of TIEG expression affected the commitment of mesenchymal progenitors to the OB lineage, the differentiation and mineralization of committed cells, or both. Methylene blue staining of marrow stromal cells isolated from 2-month old female TIEG<sup>-/-</sup> (n=9) and WT (n=10) mice revealed a modest, but insignificant increase in the number of colony forming units-fibroblast (CFU-F) between the two genotypes (an avg. of 17.8 vs. 14.2 per mouse respectively) suggesting that TIEG does not regulate the number of mesenchymal cells that have the potential to become OBs. However, a significant decrease in the number of CFU-OBs in marrow cultures isolated from TIEG<sup>-/-</sup> mice as determined by alizarin red staining (an avg. of 5.1 vs. 10.5 per mouse respectively) was observed. Additionally, calvarial OBs isolated from TIEG<sup>-/-</sup> mice exhibit significant defects in mineralization relative to WT controls and exhibit reduced expression levels of Runx2 and Osterix. Complementing these studies, over-expression of TIEG in U2OS cells results in increased Runx2 and Osterix expression while depletion of TIEG, using siRNA in primary calvarial OBs, reduces the levels of Runx2 and Osterix mRNA. Transient transfection and ChIP assays reveal that TIEG directly binds to, and activates, the Runx2 and Osterix promoters. Collectively, these data demonstrate that loss of TIEG expression results in decreased expression of Runx2 and Osterix and reduces the ability of marrow stromal cells to fully differentiate into mature OBs. This defect leads to a significant reduction in the number of mature OBs lining the bone surface of TIEG<sup>-/-</sup> mice contributing to the observed osteopenic phenotype.

**Serine Protease Inhibitor AEBSF Blocks Transcription of Phex by Osteoblasts.** J. P. Gorski<sup>1</sup>, N. T. Huffman<sup>\*1</sup>, S. V. Chittur<sup>\*2</sup>, S. Liu<sup>\*3</sup>, L. D. Quarles<sup>3</sup>, R. J. Midura<sup>4</sup>, N. G. Seidah<sup>\*5</sup>. <sup>1</sup>Univ. of Missouri-Kansas City, Kansas City, MO, USA, <sup>2</sup>Univ. at Albany, Rensselaer, NY, USA, <sup>3</sup>Univ. of Kansas Med. Ctr., Kansas City, KS, USA, <sup>4</sup>Cleveland Clin. and Fdn., Cleveland, OH, USA, <sup>5</sup>IRCM, Montreal, QC, Canada.

Bone mineralization has been shown to be under local osteoblastic control. We have recently demonstrated that AEBSF specifically blocks mineral nucleation within extracellular biomineralization foci (BMF) and inhibits cleavage of biomarker proteins BSP and BAG-75 in BMF isolated by laser capture microscopy. The purpose of this study was to clarify the inhibitory action(s) of AEBSF. UMR 106-01 osteoblastic cells were grown under standard conditions and cultures harvested at different times after addition of β-glycerolphosphate (BGP). Initial studies indicated that UMR 106-01 osteoblastic cells

express proprotein convertase SKI-1 (S1P) which demonstrated a well-known susceptibility to AEBSF. Specifically, assays using a non-permeant, fluorescent peptide substrate showed that intracellular SKI-1 activity became expressed extracellularly reaching a peak at the same time when mineral crystal nucleation in BMF begins. Since proprotein convertases are known to play role in proteolytic activation of transcription factors, e.g., SREBP-1 and SREBP-2, we also investigated whether exposure to a minimum dose of AEBSF had an effect on transcription by UMR osteoblastic cells. PolyA+ RNA was prepared from cultures incubated for 12 h with added  $\beta$ -glycerolphosphate with or without added AEBSF. Triplicate specimens of each condition were subjected to microarray analysis using whole genome 2.30 rat Affymetrix genechips. Interestingly, expression of *Phex* was reduced 1.7-fold by AEBSF along with about 180 other genes. In order to confirm this finding, we transfected UMR 106-01 osteoblasts with a luciferase reporter construct representing 2736 bp of the 5' flanking region of the mouse *Phex* promoter 20-24 h after plating. The 2.7 kb murine *Phex* promoter contains a consensus SREBP response element. Some cultures were also treated with  $1 \times 10^{-7}$  M dexamethasone, a known inducer of *Phex*. Following addition of BGP and AEBSF, cultures were lysed 6-12 h later and luciferase activity determined using a fluorimetric assay. As expected, dexamethasone increased *Phex* expression by several fold compared with control cultures. However, AEBSF was found to significantly reduce *Phex* promoter activity by about 50-60% in all conditions. Alizarin red S staining of parallel cultures confirmed that AEBSF blocked mineralization in these cultures. Our results demonstrate that *Phex* RNA expression can be inhibited by short-term treatment with AEBSF. A hypothetical mechanism involving proteolytic activation of transcription factors by SKI-1 is presently under investigation.

**Dlx5 Overexpression Stimulates Odontoblast Differentiation and Function.** V. L. S. Ferrer<sup>1</sup>, Y. Kawano<sup>\*2</sup>, H. Chin<sup>\*1</sup>, L. Wang<sup>\*3</sup>, H. Li<sup>\*1</sup>, A. Lichtler<sup>1</sup>. <sup>1</sup>Reconstructive Sciences and Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Division of Oral Anatomy, Niigata University, Niigata University, Japan, <sup>3</sup>Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan.

Our lab and others have shown that Dlx5 promotes differentiation in several cell types, including osteoblasts and chondrocytes. Based on similarities between osteoblasts and odontoblasts, we hypothesize that Dlx5 also promotes odontoblast differentiation. We have previously shown by histology that 3.6 kb type I collagen promoter driven Dlx5 overexpressing (Col3.6 Dlx5) mouse incisor odontoblasts differentiate closer to the apical loop than the wild type (WT); microCT showed that mineralized enamel is initiated closer to the apical loop as well. This is consistent with our hypothesis: Dlx5 overexpression early in the odontoblast lineage results in early odontoblast and ameloblast differentiation and early dentin and enamel secretion. Our current studies involving electron probe microanalysis have validated our microCT data. Dual fluorescent dye labeling using calcein as a 1st label and alizarin as a 2nd label at 5-day interval showed that the initiation of both 1st and 2nd labels are closer to the apical alveolar bone in the transgenic mice (TG) than in the WT, further confirming early mineralization in the TG. Double labeling also revealed that the distance between the initiation of the 1st and 2nd labels is shorter in the TG, suggesting a decrease in the growth rate. Direct measurement of the incisors showed a decrease in the eruption rate in the TG. The decrease in growth and eruption rates may alternatively explain the early odontoblast polarization observed in our TG, especially since the transgene is also expressed in the periodontal ligament (PDL). Published studies of other labs involving defective PDL function using mechanical and genetic techniques showed a decreased eruption rate. In particular, the models exhibited wavy odontoblast and ameloblast layers that are positioned closer to the apical loop but secreted buckled matrices. This is in contrast to our Col3.6 Dlx5 incisor: although the eruption rate was decreased, the odontoblasts and ameloblast layers were not wavy and secreted regular, unfolded dentin and enamel at the apical end. A proliferation study using BrdU showed a dramatic decrease in proliferative cells in the apical mesenchyme and apical loop of the TG incisor. We speculate that a significant number of progenitor cells have entered differentiation thus reducing the number of available progenitor cells to proliferate. Overall, our findings suggest that Col3.6 overexpression of Dlx5 directly stimulates odontoblast differentiation and function independent of any transgene effects in the PDL.

**Regulation of RUNX2 at the Nuclear Lamina.** P. M. Fonseca<sup>1</sup>, T. Yang<sup>\*1</sup>, T. Bertin<sup>\*1</sup>, B. Dawson<sup>\*1</sup>, Y. Chen<sup>\*1</sup>, G. Zhou<sup>2</sup>, B. Lee<sup>1</sup>. <sup>1</sup>Molecular Human Genetics, Baylor College of Medicine, Houston, TX, USA, <sup>2</sup>Department of Orthopedics, Case Western Reserve University, Cleveland, OH, USA.

RUNX2 is a member of the RUNT family of transcription factors that is essential for osteoblast formation and chondrocyte maturation. Loss-of-function mutations result in cleidocranial dysplasia (CCD). RIP (RUNX2-Interacting Protein) was isolated in a screen of a human osteosarcoma cDNA library using a yeast 2-hybrid approach. Two families with rearrangements involving chromosome 8q - where RIP maps - have been reported to have a CCD-like phenotype. In transient transfection experiments, RIP down-regulated the transactivation by RUNX2 in a dose-dependent manner in both 10T1/2 and ROS17/2 cells. RIP localizes in the inner nuclear membrane and it has been identified as a component of the nuclear envelope in proteomic screens. Its major components are lamins, which have

an important role in nuclear organization, cell division, apoptosis and transcriptional regulation. Mutations in A-type lamins and associated proteins result in several laminopathies. Mandibuloacral dysplasia (MAD) phenocopies CCD and includes other clinical features such as acroosteolysis and early fractures. RUNX2 function can be regulated at both transcriptional and post-translational level, but it can also be determined by its subnuclear localization. We hypothesize that the skeletal defects observed in MAD patients are due to the disruption of lamin interactions with transcriptional regulators relevant in bone formation such as RUNX2 and RIP.

GST pull-down assays showed an interaction between lamin and RIP, as well as the RUNT domain, through the tail domain, which is mutated in MAD patients. Lamin repressed RUNX2 transactivation of a reporter gene in COS7 cells. Lamin versions carrying MAD mutations seem to lose their repressive action and have altered binding properties but show similar nuclear localization as the wild-type protein. Lamin is capable of inhibiting RUNX2 binding to a double-stranded ColX probe in EMSA. RUNX2 partially co-localizes at the nuclear rim in both ROS17/2 cells and in cultured calvarial osteoblasts from mouse. Lamin is required for terminal differentiation of C2C12 cells into osteoblasts. Knockdown experiments in ROS17/2 cells down-regulate both *Runx2* and *Osterix* genes as well as downstream targets. The up-regulation of RIP in transgenic mice causes severe osteopenia. To elucidate the potential effect of lamin in osteoblast differentiation, we are currently analyzing transgenic mice over-expressing both wild-type and MAD mutant forms. Overall, these data suggest a novel mechanism for transcription regulation of skeletogenesis involving sequestration of a RUNX2 complex at the nuclear lamina.

**Comparison of Gene Expression in Osteocytes versus Osteoblasts.** E. Paic<sup>\*1</sup>, H. Wang<sup>\*2</sup>, M. S. Kronenberg<sup>\*1</sup>, L. Kuo<sup>\*3</sup>, D. Shin<sup>\*2</sup>, S. E. Harris<sup>4</sup>, I. Kalajzic<sup>\*1</sup>. <sup>1</sup>Dept. of Reconstructive Sciences, Uni. of Conn. Health Center, Farmington, CT, USA, <sup>2</sup>Dept. of Comp. Science, Uni. of Conn., Storrs, CT, USA, <sup>3</sup>Dept. of Statistics, Uni. of Conn, Storrs, CT, USA, <sup>4</sup>Dept. of Perio., Uni. of Texas, San Antonio, TX, USA.

Osteocytes represent the most abundant cellular component of mammalian bones with important function in its remodeling and turnover. However, little is known about the osteoblast-to-osteocyte transition process. We utilized visual markers to selectively identify osteocytes and osteoblasts. This was achieved by development of dual GFP reporter mice in which osteocytes are expressing GFP(green) directed by the DMP-1 promoter, while osteoblasts are identified by expression of GFP(blue) driven by 2.3kb of the Col1a1 promoter. Histological analysis of 5-day-old neonatal calvaria revealed the expression of DMP1 in osteocytes and Col2.3 in osteoblasts and osteocytes. To isolate distinct populations of cells we utilized fluorescent activated cell sorting (FACS). Cells expressing GFPgreen were sorted as osteocytes and cells expressing only GFPblue were collected as osteoblasts. Cells suspensions were subjected to RNA extraction, in vitro transcription and labeling of cDNA. Gene expression was analyzed using Illumina WG-6v1 BeadChip.

Following normalization and statistical analysis (SAM, LIMMA), 30% of genes covered with microarray oligonucleotide probes were called present. We selected 380 genes with statistically significant changes in expression from osteocytes versus osteoblasts. Among them, 230 had higher expression ( $\geq 2$  fold), and 150 genes were expressed at lower level ( $\leq 0.5$  fold) in osteocytes vs. osteoblasts. We utilized gene ontology databases to arrange related groups according to known biological functions. As expected, among genes clustered to osteogenesis and skeletal development, *Bmp3*, *Bmp4*, *Bmp8a*, *Dmp1*, *Enpp1*, *Phex* and *Ank* were highly expressed in osteocytes. Interestingly, five of six differentially expressed genes involved in Wnt signaling pathway were downregulated (*Fzd1*, *Wnt10a*, *Wnt9a*, *Sfrp2*, *Dkk3*) with an increase in *Dkk1* expression. Muscle proteins or related molecules were all (38) upregulated. Most of the transcription factors that are significantly changed were upregulated in osteocytes, including *Notch3*, *Dlx3*, *Sox11* and *Crem* while most of extracellular matrix proteins were downregulated (12/26). We also found that most of the cytoskeletal protein (38/7), genes involved in cell differentiation (25/16) cell organization and biogenesis (25/10), cell migration (12/0) and localization (11/0) were upregulated. Therefore, utilization of isolation of osteocytes and osteoblasts allowed us to identify a number or genes and pathways with potential role in osteoprogenitor lineage differentiation and function.

**Normal Human Osteoblasts Internalize Urate Crystals by Phagocytosis and Autophagy.** I. Allaey\*, A. Marceau\*, P. E. Poubelle. Medicine, Université Laval, Québec, QC, Canada.

Chronic gouty arthritis can be associated with major tissue destruction of cartilage and bone directly related to the presence of monosodium urate monohydrate crystals (MSUM). Tissue destruction associated with MSUM can be located in joint cartilage and bone structure adjacent to and far from the joints. Since osteoblasts (OB), which orchestrate bone remodeling via soluble factors and cell-to-cell interactions, have been described in contact with microcrystals, particularly in uratic foci of gout, we hypothesized that OB have the capacity to phagocytose MSUM. This phagocytosis could result in alteration of osteoblastic functions. We first determined that OB had the capacity to phagocytose MSUM. We observed in OB, after 24h incubation with MSUM, formation of multiple and large vacuoles still present after 10 days of culture. MSUM did not affect OB viability (measured by propidium iodide incorporation), but dramatically reduced OB proliferation in a dose-dependent manner. We showed that MSUM phagocytosis was dependent on PKC, Syk, ERK and PI3K. We also found by QRT-PCR that OB gene expression was modified by MSUM stimulation. Collagen I, OPG and RANKL mRNA expression was significantly modified after 48h stimulation. Furthermore, MSUM induced an autophagic response in OB. Autophagy is an intracellular bulk degradation system, through which a portion of the cytoplasm is delivered to lysosomes to be degraded. Microtubule-associated protein light chain 3 (LC3) has been used as a specific marker to monitor autophagy, and we found that MSUM dose- and time-dependently induced the cleavage of LC3-I into LC3-II. Those results suggest that human trabecular OB can ingest MSUM with major alterations of osteoblastic functions. These modifications could be associated with decrease of bone formation and could play a role in bone loss observed in chronic gouty arthritis.

**Tcf Is Required For Wnt11 Mediated Osteoblast Differentiation.** M. S. Friedman\*<sup>1</sup>, W. Luo\*<sup>2</sup>, S. M. Oyersman\*<sup>1</sup>, K. D. Hankenson<sup>3</sup>. <sup>1</sup>Thermogenesis Corporation, Ranch Cordova, CA, USA, <sup>2</sup>University of Michigan, Ann Arbor, MI, USA, <sup>3</sup>Animal Biology, University of Pennsylvania, Philadelphia, PA, USA.

Wnt proteins are traditionally divided into two subclasses, Wnt-1 (canonical) and Wnt5a (Wnt4, Wnt5a, Wnt11 - non-canonical). Depending on the developmental stage, Wnt11 can activate either the non-canonical or the canonical pathway involving beta-catenin. We previously reported that Wnt11 overexpression in pre-osteoblasts (MC3T3 E1.14) activated beta-catenin and enhanced BMP-mediated osteoblast differentiation. For the current studies, we performed microarray analysis of Wnt11 and BMP induced gene expression to determine the transcriptional targets of Wnt11 and how Wnt11 and BMP signaling coordinate to synergistically increase osteoblast differentiation. Wnt11 and GFP control cells were cultured in osteoinductive media (BGP and ascorbate), with or without BMP2. The cells were harvested for RNA at days 3, 6, and 9 post-induction and gene expression analyzed on an Affymetrix 420A 2.0 microarray chip. A number of genes were differentially expressed in both Wnt11 and BMP treated Wnt11 cells relative to GFP and BMP treated GFP controls. We performed qPCR-based validation on a select set of those genes. The extracellular matrix proteins dentin matrix protein 1 (Dmp1) and Cdrap/Otoraplin showed elevated expression in Wnt11 cells. Sprouty 1 (Spry1), an Fgf antagonist, and Rspo2, an activator of Beta-catenin, also showed elevated expression in Wnt11 cells. Interestingly, by microarray analysis Tcf7 expression showed no difference with Wnt11 overexpression, but was increased in BMP treated cells. By western blot, Tcf7 showed increased expression and nuclear localization in BMP treated cells. To evaluate if Tcf activity was required for enhanced osteoblast differentiation by Wnt11, we overexpressed a dominant/negative form of Tcf4 (dnTcf) in Wnt11 and GFP control cells. dnTcf expression inhibited mineralization in both GFP and Wnt11 overexpressing cells. We used qPCR to examine gene expression in dnTcf cells relative to controls. Expression of Rspo2, Osterix, Dmp1, Bsp, and Phex were significantly reduced in BMP treated Wnt11-dnTcf cells relative to BMP treated Wnt11 cells. However, dnTcf had no effect on gene expression in BMP-induced control cells. We conclude that BMP increases expression and nuclear localization of Tcf7. Wnt11, in turn, activates beta-catenin, resulting in nuclear accumulation. Tcf7 and beta-catenin may complex to cooperatively activate transcription of target genes, such as Dmp1, Phex, Osterix, Bsp, and Rspo2, resulting in enhanced osteoblast differentiation. Future studies will focus on the role of these target genes in Wnt11 enhanced osteoblast differentiation.

**Osteocalcin Is a Stress Hormone: Interaction with the Sympathetic Nervous System.** P. E. Patterson-Buckendahl<sup>1</sup>, A. Vitenzon\*<sup>1</sup>, A. Shah\*<sup>1</sup>, M. Shahid\*<sup>1</sup>, R. Kvetnansky\*<sup>2</sup>. <sup>1</sup>Center of Alcohol Studies, Rutgers University, Piscataway, NJ, USA, <sup>2</sup>Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia.

Interaction of the sympathetic nervous system (SNS) and bone has received increasing attention, with adrenergic as well as neuropeptide receptors identified on both osteoblasts and osteoclasts. SNS activation by emotional and physical stressors is also well known, and affects circulating levels of human, monkey and rodent osteocalcin (pOC) in ways that are stressor specific. Most dramatic is the rapid, hormone-like elevation during acute fight/flight response. A target for influence of OC was suggested by immuno-detection of OC in rat dorsal root ganglia (DRG) in cells of nociceptive and proprioceptive neurons. We previously reported altered sensory and stress responses in OC null mutant (KO) mice. We have extended those observations by subjecting male wildtype (WT) and KO mice to foot restraint immobilization (Immo) for up to 2 hours with and without supplementation with OC or synthetic uncarboxylated OC (uOC). We evaluated stress responsive hormones in plasma, adrenal gene expression for enzymes of the catecholamine synthetic pathway and NPY, a neuropeptide decreased by Immo, and localization of OC in DRG. We measured glucose, insulin, adiponectin and leptin in blood taken from 12 KO mice before and 5 and 30 min after i.p. injection of saline or 150 ng native mouse OC/g BW (6 each) and immediate Immo. As expected, glucose increased ( $p < 0.001$ ) and insulin decreased ( $p < 0.05$ ) in all mice. There was a trend for decreased adiponectin and increased leptin, but no effect of OC supplementation, suggesting that stress-induced energy needs over-ride the published effects of OC on this axis. We compared adrenal gene expression for TH, DBH, PNMT and NPY in 6 WT and 6 KO unstressed controls with 4 groups (6 each: WT and KO injected with saline, KO injected with 300 ng/g BW OC or uOC) subjected to 2 hr Immo followed by 3 hr recovery. Native, fully carboxylated OC significantly increased ( $p < 0.01$  or less) TH, DBH, and PNMT mRNA in Immo KO compared to both WT and KO controls, whereas it decreased NPY after Immo, consistent with observations in other models. By comparison, uOC administration had lesser or non-significant effects. To determine further involvement of SNS, we dissected DRG from unstressed paraformaldehyde-perfused mice. Frozen sections (8  $\mu$ m) were reacted with goat anti-mouse OC and visualized with FITC conjugated donkey anti-goat serum. OC positive staining was seen in heterozygous DRG and limb bone, but not in KO confirming presence of OC in DRG. The data confirm that OC has a hormonal influence on the adrenal possibly via uptake by DRG innervating the adrenal. Further study of both OC and uOC in stressed and non-stressed animals is warranted.

**Regulatory Signaling Pathways in BMP Mediated Osteogenesis of Adult Human Mesenchymal Stem Cell Cultures.** K. Zdunek\*<sup>1</sup>, A. Wojtowicz\*<sup>1</sup>, J. Skarzynska\*<sup>1</sup>, L. Skrzypek\*<sup>1</sup>, M. Damulewicz\*<sup>1</sup>, P. S. Leboy<sup>2</sup>, A. M. Osyczka\*<sup>1</sup>. <sup>1</sup>Cytology and Histology, Jagiellonian University, Faculty of Biology and Earth Sciences, Krakow, Poland, <sup>2</sup>Biochemistry, University of Pennsylvania, School of Dental Medicine, Philadelphia, PA, USA.

We previously reported that BMP-mediated osteogenesis of adult human MSC (ahMSC) was negatively regulated by ERK signaling and required insulin- or IGF-activated PI3-K [Endocrinology 2005, 146:3428-37]. These studies have now been extended 1) to identify which of the downstream mediators of insulin/IGF signaling are required for BMP-stimulated osteogenesis of ahMSC cultures, and 2) to define the mechanism involved in ERK inhibition of BMP stimulation.

We blocked insulin/IGF signaling using chemical inhibitors of AKT/PKB, GSK3, PKC, and p70S6K, and examined the effects on BMP-mediated osteoblast differentiation in ahMSC cultured under serum-free conditions. The PKC inhibitor GF 109 203X decreased ALP activity in BMP-treated cultures, and decreased mRNA expression of ALP, osteopontin, and osteocalcin. PKC inhibition also reduced Msx2 expression, thus demonstrating a direct effect on BMP-stimulated Smad transcriptional activity. Inhibiting AKT/PKB with ML-9 (15-30  $\mu$ M) or triciribine (10  $\mu$ M), or inhibiting p70/S6K with rapamycin also decreased BMP-stimulated ALP activity. However, the GSK3 inhibitor SB 21673 at concentrations up to 30  $\mu$ M significantly increased BMP-induced ALP activity. These results suggest that the insulin/IGF-I requirement for BMP-stimulated Smad transcriptional activity involves PKC signaling, perhaps via PKC activation of p70S6K. In contrast, GSK3 appears to negatively regulate BMP-mediated osteogenesis in adult human mesenchymal stem cells.

The negative role of ERK on BMP signaling was examined by altering the linker region of Smad1 and over-expressing the construct in ahMSC. Because serine residues within SMAD linker regions are putative ERK phosphorylation sites and ERK phosphorylation of SMADs is reported to modulate SMAD signaling, we prepared three adenoviral constructs carrying either unmodified human Smad1, Smad1 mutated in the linker region to preclude ERK phosphorylation, and control vector carrying LacZ. Non-mutant Smad1 overexpression caused only modest increases in ALP activity compared to control LacZ-infected cells, whereas expression of Smad1 mutated in the linker region markedly increased BMP stimulation of ALP. This demonstrates that phosphorylation of SMADs in the linker region is an important regulatory mechanism in BMP-mediated ahMSC osteogenesis.

**Inactivation of the Integrin-Linked Kinase (ILK) in Osteoblasts Increases Mineralization.** J. El-Hoss<sup>\*1</sup>, A. Arabian<sup>1</sup>, S. Dedhar<sup>\*2</sup>, R. St-Arnaud<sup>1</sup>. <sup>1</sup>Genetics Unit, Shriners Hospital for Children, Montreal, QC, Canada, <sup>2</sup>BC Cancer Research Centre, Vancouver, BC, Canada.

Following engagement with the extracellular matrix (ECM), integrin receptors signal via multiple downstream effectors, including the Integrin-Linked Kinase (ILK). The net effect of stimulating ILK is to modulate gene transcription: ILK-dependent phosphorylation of the cJun transcriptional coactivator,  $\alpha$ NAC, induces its nuclear accumulation and potentiates c-Jun-dependent transcription. To determine the role of ILK in osteoblasts, we inactivated ILK using siRNA in osteoblastic cells. In parallel, we engineered mice with specific ablation of ILK in osteoblasts and analyzed the phenotype of the mutant animals, as well as the behavior of primary cultures of ILK-deficient osteoblasts. MC3T3-E1 cells were stably transfected with expression vectors encoding specific ILK siRNAs or a control siRNA. ILK protein expression was inhibited in the ILK siRNA-transfected cells. ILK knockdown led to cytoplasmic retention of  $\alpha$ NAC and increased expression of the osteoblastic differentiation markers type I collagen and bone sialoprotein. ILK-deficient osteoblasts showed dramatically increased mineralization. Bone was harvested at intervals from mice with ILK-deficient osteoblasts (Col-1-Cre;ILK<sup>-/-</sup>) and analyzed using histomorphometry. Surprisingly, we did not measure any significant changes in static or dynamic histomorphometric parameter. Marker gene expression was unchanged between control and mutant mice, with the exception of reduced ILK expression in bone tissue. These results prompted us to study primary osteoblasts isolated from the osteoblast-specific ILK deficient mice. When placed in culture, ILK-deficient primary osteoblasts showed increased expression of osteoblastic differentiation markers and increased mineralization, similar to the ILK-knockdown osteoblasts. These data suggest that in vivo, redundancy of function could account for the absence of an obvious osteoblast phenotype. The main difference between the in vivo and ex vivo conditions involves the ECM, and thus we cultured the ILK-knockdown cells on either plastic or the ECM component, type I collagen. Culture on collagen reduced the exuberant mineralization of ILK-deficient osteoblasts, and this was accompanied by increased phosphorylation of Focal Adhesion Kinase (FAK). Taken together, our data suggest that the ILK cascade normally inhibits osteoblastic activity. We propose that in vivo, other signaling pathways operating downstream of ECM-engaged integrins, such as signaling through FAK, are able to compensate for the loss of ILK activity, leading to the absence of an obvious phenotype in osteoblast-specific ILK-deficient mice.

**In Vivo Demonstration that PTH Acts on Early Osteoprogenitor Cells to Enhance Bone Formation During Repair of Critical-Size Calvarial Defects.** Y. H. Wang, L. Wang<sup>\*</sup>, X. Jiang<sup>\*</sup>, S. Hong<sup>\*</sup>, D. W. Rowe. Univ Connecticut Health Center, Farmington, CT, USA.

Cellular targets within the osteogenic lineage responsible for the anabolic effect of intermittent parathyroid hormone (PTH) on bone formation are unclear. Our previous work suggests that progenitor cells prior to the preosteoblast stage of the lineage are sensitive to intermittent PTH exposure. Those studies are done on primary osteoblast cultures from either a bone marrow or calvarial source. When the early cultures are treated with PTH for 2h per day from day 3 to 7 after which no further PTH is given, a higher proportion of the progeny of these cells commit to the osteogenic lineage and acquire a higher level of differentiation than untreated cultures. To test if this in vitro anabolic effect can also be observed as enhanced bone formation in vivo, calvarial cultures from mice transgenic for pOBCol3.6-GFP (green) or pOBCol3.6-CFP (blue) were subjected to either the intermittent PTH or control protocol and subsequently used to seed a scaffold that was transplanted into critical-size calvarial defects of wild-type host. Two 3-mm diameter parietal defects per recipient were transplanted with 50%/50% mixture of cell from the green and blue culture in which one of the two colors was exposed to PTH or both were from control condition. These fluorescent reporters identify osteoblasts in vivo by their strong fluorescent intensity, relative to low intensity in fibroblastic cells, and their close association with a newly deposited mineralized matrix which is stained with xylenol orange (XO). By mixing the two colors of cells from the calvarial cultures prior to scaffold seeding and scoring the resulting repair for the percentage of XO labeled bone surface that is occupied by either the green or blue cells, the contribution from each population to bone formation can be assessed. Four weeks after transplantation, there was more bone formation in transplantation in the sites in which one cellular source had received PTH treatment. In transplant containing PTH-treated cells, the percentage of osteoblasts (either GFP or CFP) lining the XO labeled surface was greater than the transplant from untreated cells. We also observed that transplants formed from PTH-treated cells have less residual apatite-containing scaffold which is a reflection of the resorption and new bone formation associated with bone remodeling. This result is consistent with PTH having a deterministic effect on a progenitor population, long after the PTH has been discontinued, to have enhanced properties for bone formation and potentially bone remodeling. This conditioning protocol may be a useful adjunct for bioengineering an osseous lesion.

**Traf2 Regulates BMP Signaling Pathway in Osteoblastic Cells.** K. Shimada<sup>1</sup>, K. Ikeda<sup>\*1</sup>, K. Ando<sup>\*1</sup>, M. Maeno<sup>2</sup>, K. Ito<sup>\*1</sup>. <sup>1</sup>Department of Periodontology, Nihon University School of Dentistry, Tokyo, Japan, <sup>2</sup>Department of Oral Health Sciences, Nihon University School of Dentistry, Tokyo, Japan.

Bone morphogenetic proteins (BMPs) play a specific role in osteoblastic differentiation and maturation. BMPs induce receptor-regulated Smads (R-Smads). The R-Smads form complexes with the common-partner Smad, which is Smad4 in mammals. These complexes translocate and accumulate in the nucleus and regulate the transcription of various target genes. However, the function of Smad4 remains unclear. Here, we performed a yeast two-hybrid screen using Smad4 as bait and a cDNA library from human bone marrow to identify the proteins interacting with Smad4. For this screen, full-length human Smad4 was cloned in pGBKT7 vector to express it as a fusion with the GAL4-binding domain, and the cDNA library was screened. Two cDNA clones of full-length Traf2 were identified. This interaction was confirmed with GST pull-down assay in *E. coli*. To analyze the function of Traf2 in the BMP signaling pathway, endogenous Traf2 was disrupted in human osteoblastic cell line Saos-2 or rat osteoblastic cell line ROS 17/2.8 using siRNA and examined its effectiveness in silencing Traf2 expression. The expression levels of BMP-induced transcription factor genes including Runx2, Dlx5, Msx2, and Osterix, and Smad4, Smad1 and phospho-Smad1 were examined using real-time reverse-transcribed PCR or Western blotting. The efficiency of silencing Traf2 mRNA level was more than 80%. The expression of Runx2, Dlx5, Msx2, and Osterix mRNA was markedly increased when Traf2 was silenced. The protein levels of Smad4 and phospho-Smad1 increased by siRNA for Traf2. In conclusion, it is suggested that Traf2, which is related to TNF- $\alpha$  signaling pathway, might regulate negatively BMP signaling pathway because the gene expression of the transcription factors and the protein level of phospho-Smad1 increase by siRNA for Traf2.

**Conversion of Vitamin K Analogues to Menaquinone-4 in Osteoblastic Cells.** Y. Suhara, M. Kamao<sup>\*</sup>, K. Nakagawa<sup>\*</sup>, N. Tsugawa<sup>\*</sup>, T. Okano. Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

Vitamin K (VK) is an essential nutrient and a cofactor for the carboxylation of specific glutamyl residues of proteins to  $\gamma$ -glutamyl residues, which activates osteocalcin related to bone formation. Among its homologues, menaquinone-4 (MK-4) shows most potent biological activities, and up-regulates gene expression of bone markers, and thus has been clinically used in the treatment of osteoporosis in Japan. Recently, we confirmed MK-4 was biosynthesized from dietary phyloquinone (PK), and then accumulated in various tissues in a high concentration. This system should play an important role for biological functions including bone formation, however, the biosynthetic pathway of MK-4 remains unclear. Therefore, we studied the biosynthetic mechanism of MK-4 with chemical technique using deuterated VK analogues.

The proposed mechanism of MK-4 synthesis is that a side chain moiety of dietary PK is cleaved and resulting intermediate vitamin K<sub>3</sub> (menadione) is subsequently converted to MK-4 with geranylgeranylpyrophosphate (GGPP) derived from mevalonate pathway. In this study, we investigated whether MK-4 was biosynthesized by way of vitamin K<sub>3</sub> (VK<sub>3</sub>), and whether MK-4 was produced from VK<sub>3</sub> and GGPP. Deuterated VK compounds were used *in vitro* study to distinguish from native vitamin K analogues in cells. To investigate production of deuterated MK-4 (MK-4-d<sub>n</sub>), we added chemically synthesized deuterated vitamin K<sub>3</sub> (VK<sub>3</sub>-d<sub>8</sub>) and deuterated geranylgeranylpyrophosphate (GGPP-d<sub>8</sub>) to MG-63 cell culture medium. After incubation for 24 h, the concentration of MK-4-d<sub>8</sub> in cells was measured with LC-APCI-MS/MS. As a result, the amount of biosynthesized MK-4-d<sub>8</sub> increased in a dose-dependent manner. These results indicate that MK-4 was biosynthesized from VK<sub>3</sub> and GGPP in osteoblastic cells.

We further examined whether MK-4 was biosynthesized through VK hydroquinone derivative. In the process of biosynthesis route of MK-4, a side chain part would be removed after reduction of VK quinone part. However, novel evidences have not been reported so far. We therefore chemically synthesized several hydroquinone derivatives of VK<sub>3</sub>, which could be a substrate of biosynthesis of MK-4, and investigated whether geranylgeranyl side chain bind to VK<sub>3</sub> derivatives. Based on the experiment, it was revealed that a hydroxyl group of C-4 position is most important to form MK-4. A more detailed examination is currently undergoing based on these findings using other synthetic compounds.

### Activation of P2X7 Nucleotide Receptors Increases Metabolic Acid Production by Osteoblastic Cells. M. W. Grol<sup>1</sup>, I. Zelnier<sup>2</sup>, S. J. Dixon<sup>2</sup>.

<sup>1</sup>Anatomy and Cell Biology, The University of Western Ontario, London, ON, Canada, <sup>2</sup>Physiology and Pharmacology, The University of Western Ontario, London, ON, Canada.

Nucleotides such as ATP are released from cells in response to mechanical stimulation and may mediate mechanotransduction in bone. The P2X7 receptor is expressed by cells of the osteoblast lineage and forms calcium-permeable channels when stimulated with high concentrations of extracellular ATP. Targeted disruption of *P2rx7* results in decreased periosteal bone formation and impaired response to mechanical stimulation. Previous studies from our laboratory have shown that activation of P2X7 promotes osteoblast differentiation and bone formation, though the mechanisms remain to be resolved. It is known that osteoblastogenesis coincides with an elevation in aerobic respiration. Thus, the purpose of this study was to characterize the effects of P2X7 receptor activation on osteoblast metabolism. For these experiments, we employed the MC3T3-E1 osteoblast-like cell line. The P2X7 agonist 2',3'-O-(4-benzoylbenzoyl)-ATP (BzATP, 300  $\mu$ M) induced membrane blebbing and transient elevation in the concentration of cytosolic free calcium, consistent with the expression of functional P2X7 receptors. Using a Cytosensor microphysiometer to monitor metabolic acid production, we found that BzATP (300  $\mu$ M) induced a sustained increase in acid production ~75% above basal. This increase persisted for at least 60 min following removal of BzATP. Moreover, repeated applications of BzATP elicited dramatic increases in acid production reaching levels 300% above basal. High concentrations of extracellular ATP (1 mM, sufficient to activate P2X7) mimicked the effect of BzATP, whereas agonists for other P2 receptors did not. To examine the role of mitochondrial activity in this phenomenon, we used the fluorescent probe JC-1, a vital dye sensitive to mitochondrial membrane potential. BzATP induced mitochondrial hyperpolarization, consistent with increased aerobic respiration. We conclude that activation of P2X7 receptors stimulates metabolism in osteoblast-like cells through a mechanism that involves increased mitochondrial activity. Stimulation of bone formation by P2X7 receptors may be due in part to their ability to enhance osteoblast metabolism.

### Induction of CTGF by TGF- $\beta$ 1 in Osteoblasts: Independent Effects of Src and Erk on Smad Signaling. X. Zhang<sup>1</sup>, J. A. Arnott<sup>2</sup>, S. Rehman<sup>3</sup>, W. G. DeLong<sup>3</sup>, A. Sanjay<sup>1</sup>, F. F. Safadi<sup>1</sup>, S. N. Popoff<sup>1</sup>. <sup>1</sup>Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, <sup>2</sup>Basic Sciences, The Commonwealth Medical College, Scranton, PA, USA, <sup>3</sup>Orthopaedics and Sports Medicine, Temple University School of Medicine, Philadelphia, PA, USA.

Connective tissue growth factor (CTGF/CCN2) is a cysteine rich, extracellular matrix protein that acts as an anabolic growth factor to regulate osteoblast differentiation and function. In osteoblasts, CTGF is induced by transforming growth factor beta 1 (TGF- $\beta$ 1) where it acts as a downstream mediator of TGF- $\beta$ 1 induced matrix production. The molecular mechanisms that control CTGF induction by TGF- $\beta$ 1 in osteoblasts are not understood. We have previously demonstrated the requirement of Src, Erk and Smad signaling for CTGF induction by TGF- $\beta$ 1 in osteoblasts. However, the potential interaction among these signaling pathways in osteoblasts has not been examined. In this study we demonstrate that TGF- $\beta$ 1 activates Src kinase in osteoblasts (primary rat and rat osteosarcoma cell line) and that treatment with the Src family kinase inhibitor, PP2, or two independent Src kinase mutants (kinase-dead; kinase-dead and open) prevented Src activation and CTGF induction by TGF- $\beta$ 1. The inhibition of Src kinase activity prevented TGF- $\beta$ 1 induced Smad 2 & 3 activation and Smad nuclear translocation in osteoblasts as determined by immunofluorescent and Western blot analyses. In addition, inhibiting Src prevented Erk activation. MAPKs such as Erk can modulate the Smad pathway through directly mediating the phosphorylation of Smads or indirectly through activation/inactivation of required nuclear co-activators that mediate Smad DNA binding. When we treated osteoblasts with the Erk inhibitor, PD98059, it inhibited TGF- $\beta$ 1-induced CTGF promoter activity and protein expression but had no effect on Smad activation or Smad nuclear translocation. Using electro-mobility shift assays we found that treatment with PD98059 impaired transcriptional complex formation on the Smad binding element (SBE) of the CTGF promoter, demonstrating that Erk activation was required for SBE transactivation. Taken together these data demonstrate that Src is an essential upstream signaling partner of both Erk and Smads for TGF- $\beta$ 1 induction of CTGF in osteoblasts, and that Src and Erk have independent effects on Smad signaling required for the formation of a transcriptionally active complex that regulates CTGF promoter activity and expression. Future studies will focus on examining whether these interactions are unique to osteoblasts compared to other non-osteoblast cells or lines. Evaluation of the regulation of CTGF expression in osteoblasts is important to understand its effects on osteoblast differentiation and function.

### Effects of G $\alpha$ 11 Overexpression on Osteoblast Signaling and Function in Transgenic Mice. M. Mattocks<sup>\*</sup>, J. Mitchell. Pharmacology, University of Toronto, Toronto, ON, Canada.

We have created an osteoblast-specific G $\alpha$ <sub>11</sub> transgenic mouse strain in order to examine the effects of increased osteoblastic G $\alpha$ <sub>11</sub> on parathyroid hormone receptor (PTHr) signaling in bone. Our group has previously shown that dexamethasone, a potent glucocorticoid, can alter parathyroid hormone (PTH) signaling through the parathyroid hormone receptor (PTHr) in osteoblasts, by extending the half-life of the G $\alpha$  subunit G $\alpha$ <sub>11</sub>. Since overexpression of G $\alpha$ <sub>11</sub> in osteoblastic cells increases PTH signaling through the phospholipase C pathway and activation of MMP-13 this effect may contribute to glucocorticoid-induced osteoporosis.

We examined the effects of increased levels of osteoblastic G $\alpha$ <sub>11</sub> in vivo by generating a transgenic mouse model overexpressing G $\alpha$ <sub>11</sub> driven by the 3.6kb rat Col1A1 promoter fragment. This promoter fragment drives osteoblast and fibroblast specific expression of genes under its control. The effects of this increased G $\alpha$ <sub>11</sub> expression in the bones of these mice have been assayed by histomorphometry and micro CT. We have also examined the effect of the transgene in vitro, in stably transfected UMR106-01 and ROS 17/2.8 osteosarcoma lines, as well as primary transgenic osteoblast cultures, in order to understand the effects of increased PTHr signaling through G $\alpha$ <sub>11</sub> on downstream gene regulation.

Results osteoblasts in vitro show that our transgenic model increases the extent of PTH-mediated induction in MMP-13 mRNA expression, suggesting that the PTHr signaling in transgenic G $\alpha$ <sub>11</sub> overexpressing osteoblasts is more catabolic.

### Stable Expression of Constitutively Active G $\alpha$ 12 in Osteoblastic Cells Promotes Matrix Protein Expression and Alkaline Phosphatase Activity. J. Wang, T. Yoshida, P. H. Stern. Department of Mol Pharm & Biol Chem, Northwestern University, Chicago, IL, USA.

Heterotrimeric ( $\alpha\beta\gamma$ ) G proteins mediate signaling from cell surface G protein-coupled receptors (GPCRs) to downstream effector molecules. G proteins are classified into four subfamilies, based on the  $\alpha$  subunit: G $\alpha$ s, G $\alpha$ q/11, G $\alpha$ i and G $\alpha$ 12/13. The G $\alpha$ s, G $\alpha$ q/11 and G $\alpha$ i subfamilies have been associated with differentiation and signaling responses in osteoblastic cells, whereas the role of the G $\alpha$ 12/13 class in bone has not been well defined. In other cells, G $\alpha$ 12/13-mediated effects are generated largely through RhoA small G proteins and affect cytoskeletal structures and cell migration, tumor cell invasion, and cell proliferation and survival. We have found that disruption of RhoA signaling in osteoblastic cells results in loss of actin cytoskeletal elements. In order to obtain more insight into the potential role of G $\alpha$ 12/13 signaling in osteoblasts, we stably transfected UMR-106 cells with constitutively active G $\alpha$ 12Q226L (CA-G $\alpha$ 12). Genes related to osteoblast differentiation and alkaline phosphatase activity were compared in cells transfected with either CA-G $\alpha$ 12 or empty vector (pcDNA). RT-PCR revealed that in the CA-G $\alpha$ 12 cells the expression of the matrix proteins osteopontin and decorin was more than doubled, compared to cells transfected with empty vector, whereas type I collagen, Runx2, BMP2 and alkaline phosphatase gene expression were not significantly affected. However, alkaline phosphatase activity was approximately twice as high in the CA-G $\alpha$ 12 cells, compared to cells transfected with the empty vector. The results represent novel findings regarding the role of this class of G proteins and suggest that osteoblast responses mediated through G $\alpha$ 12/13 affect bone matrix proteins and may also be involved in mineralization.

### Gut-derived Serotonin Is an Inhibitor of Bone Formation. V. K. Yadav<sup>\*</sup>, J. Ryu<sup>\*</sup>, N. Suda<sup>\*</sup>, P. Ducy<sup>\*</sup>, G. Karsenty. Genetics and Development, Columbia University, New York, NY, USA.

The role, if any, of serotonin in the regulation of bone remodeling has not been studied systematically. This is a matter of great importance given the impact of serotonin reuptake inhibitors on bone health. Serotonin produced in the gut accounts for ~95% of total serotonin in the body, and does not cross the blood-brain barrier thus its function must be different from the one synthesized in the brain. The synthesis of gut-derived serotonin (GDS) is initiated by the enzyme Tph1. To determine the influence, if any, of GDS on bone remodeling we generated various mice harboring cell-specific deletion of *Tph1*. Mice lacking *Tph1* in the duodenum developed a high bone mass phenotype while *Tph1* deletion in osteoblasts does not affect bone mass. This high bone mass phenotype was secondary to an increase in osteoblast numbers and bone formation rates while bone resorption parameters were not affected. These results identify gut-derived serotonin as a bona fide hormone regulating bone formation. Serotonin mediates its action through its binding to one of the 14 receptors present on the target cells. We could detect the expression of 3 serotonin receptors in osteoblasts, Htr1b, Htr2a and Htr2b. We are currently analyzing mice lacking each of these receptors to determine which one mediates the effect of serotonin on osteoblasts. Results of this investigation will be presented at the meeting.

**Inhibition of Lamin A/C Attenuates Osteoblast Differentiation and Stimulates Osteoclastogenesis Through Enhanced RANKL Signaling.** M. Rauner<sup>\*1</sup>, U. Hempel<sup>\*1</sup>, W. Sipos<sup>\*2</sup>, A. Wutzl<sup>\*3</sup>, R. Foisner<sup>\*3</sup>, P. Pietschmann<sup>3</sup>, L. C. Hofbauer<sup>1</sup>. <sup>1</sup>Technical University of Dresden, Dresden, Germany, <sup>2</sup>University of Veterinary Medicine, Vienna, Austria, <sup>3</sup>Medical University of Vienna, Vienna, Austria.

Osteoporosis in the elderly is a condition of low bone mass and poor bone quality due to impaired osteoblastogenesis and decreased bone formation. However, the underlying molecular mechanisms are poorly defined. Recently, the Hutchinson-Gilford progeria syndrome (HGPS), a disease of accelerated aging and premature osteoporosis, has been linked to mutations in the lamin A/C gene. We tested the hypothesis that the loss of lamin A/C in osteoblasts leads to impaired osteoblast differentiation and enhanced osteoclastogenesis. Endogenous protein levels of lamin A/C were assessed in human mesenchymal stem cells undergoing osteogenic differentiation. We found that the expression of lamin A/C increased with osteoblast maturity. Next, lamin A/C was knocked-down continuously with small interfering RNAs in human mesenchymal stem cells differentiating towards osteoblasts. Lamin A/C knock-down led to an inhibition of osteoblast proliferation by 26% ( $p < 0.001$ ), and impaired osteoblast differentiation by 48% ( $p < 0.05$ ) based on mineralized matrix formation assessed with alizarin red S staining. Expression levels of runx2 and osteocalcin mRNA assessed by quantitative RT-PCR were decreased in mature lamin A/C-knock-down osteoblasts by 44% and 78% ( $p < 0.05$ ), respectively. Furthermore, Western blot analysis showed that osteoblasts with diminished levels of lamin A/C also produced less osteocalcin. The RANKL/OPG ratio was increased at the mRNA and protein level by two-fold, resulting in an increased ability to support osteoclastogenesis based on the number of TRAP-positive multinucleated cells (+34%,  $p < 0.05$ ). Our data indicate that lamin A/C is essential for proper osteoblastogenesis. Moreover, lack of lamin A/C favors enhanced osteoclastogenesis. These data provide evidence for a link between loss-of-function of lamin A/C and impaired osteoblast differentiation, as present in the progeroid syndrome HGPS.

**Chemerin and CMKLR1 Targeted Gene Delivery Identifies A Novel Molecular Switch in the Treatment of Osteoporosis.** S. Muruganandan<sup>\*</sup>, A. Roman<sup>\*</sup>, C. Sinal. Pharmacology, Dalhousie, Halifax, NS, Canada.

A common feature in the development of osteoporosis is the enhanced differentiation of adipocytes versus osteoblasts in bone marrow. Both of these cell types originate from a common mesenchymal progenitor stem cell type. Our laboratory has identified chemerin as a novel adipokine that is secreted by mature adipocytes and acts in a paracrine fashion to further drive the differentiation of immature preadipocytes into the adipocytic lineage. The interaction of secreted chemerin with its cognate receptor, CMKLR1 was also found to be essential to the adipocyte differentiation processes. Based on these earlier findings, we hypothesized that chemerin and CMKLR1 are essential for the development of adipocytes in bone marrow. In our first set of experiments we found that chemerin is secreted during adipocyte differentiation of both mouse bone marrow mesenchymal stem cell progenitors and 7F2 preosteoblast cells. To disrupt chemerin/CMKLR1 signalling in these cells, we used short hairpin loop RNAs (shRNA) targeting chemerin or CMKLR1 mRNA and delivered these using adenoviral vectors. Consistent with our previous work, chemerin and CMKLR1 knockdown abrogated both preadipocyte clonal expansion and subsequent adipocyte differentiation (arrested lipid accumulation, decreased expression of adipocyte marker genes and transcriptional factors). Interestingly, this was also associated with up regulation of osteoblast transcriptional factors. Phenotypical characterization of the knockdown cells revealed enhanced osteoblastic marker gene expression and an increased mineralization with subsequent addition of mineralization media. All these studies mark a novel therapeutic strategy for osteoporosis that 1) arrests preadipocyte clonal expansion, 2) abrogates adipocyte differentiation, and 3) drives the cells to osteoblast differentiation.

**Pulse Treatment with Zoledronic Acid Causes Sustained Commitment of Bone Marrow Derived Mesenchymal Stem Cells for Osteogenic Differentiation.** R. Ebert, S. Zeck<sup>\*</sup>, R. Krug<sup>\*</sup>, J. Meissner-Weigl<sup>\*</sup>, D. Schneider<sup>\*</sup>, L. Seefried<sup>\*</sup>, J. Eulert<sup>\*</sup>, F. Jakob<sup>\*</sup>. Orthopedic Center for Musculoskeletal Research, University of Wuerzburg, Wuerzburg, Germany.

The aminobisphosphonate zoledronic acid (ZA) is a bone-seeking specific inhibitor of the enzyme farnesyl pyrophosphate synthase, which causes inhibition of osteoclast function and apoptosis. It is widely used as an osteoclast targeted antiresorptive treatment of metastatic bone disease, Paget's disease and osteoporosis. Mesenchymal stem cells and osteoblast precursors can also be targets of bisphosphonates, but the clinical relevance of these effects is under debate.

We investigated the influence of  $\mu\text{M}$  ZA concentrations on the proliferation and apoptosis capacity of human mesenchymal stem cells (hMSC) after 24, 48 and 72 h stimulation. Additionally, we treated hMSC with  $\mu\text{M}$  concentrations of ZA for 3 and 6 h prior to a 2 to 4 weeks period of osteogenic culture. The expression of osteogenic markers as alkaline phosphatase (ALP), osteocalcin (OC), osteopontin (OP), collagen 1A2 (Col1A2) and the wnt signaling inhibitor dickkopf 1 (Dkk1) were analyzed by RT-PCR after 2 weeks, the mineralization degree was quantified after alizarin red and alkaline phosphatase staining after 4 weeks.

ZA in vitro causes inhibition of proliferation and induction of apoptosis in hMSC, when applied in concentrations of 20 and 50  $\mu\text{M}$  for more than 24 h. However, pulse stimulation for 3 and 6 h with the same concentrations and subsequent culturing for up to 2 weeks under osteogenic conditions exerts sustained regulation of osteogenic marker genes in hMSC. The effect on gene regulation translates into marked enhancement of mineralization, as shown by alizarin red and alkaline phosphatase staining after 4 weeks of osteogenic culture.

ZA, when applied as a pulse stimulus in  $\mu\text{M}$  concentrations, might therefore also stimulate osteogenic differentiation in vivo, since  $\mu\text{M}$  plasma concentrations can be achieved by intravenous application of 5 mg in patients. These data set the stage for the future dissection of the effects of ZA and other aminobisphosphonates on cells beyond osteoclasts, with respect to cell differentiation in benign metabolic and to antitumor efficacy in metastatic bone diseases, as well as adverse events due to putative substance accumulation in bone during long-term treatment.

**The Deletion of ADAM15 Decreases Osteoblast Differentiation and Bone Formation in vitro.** F. Kolb<sup>\*</sup>, B. Thuring<sup>\*</sup>, S. Barbieri<sup>\*</sup>, F. Morvan<sup>\*</sup>.

<sup>1</sup>Expertise Protease Platform, Novartis Institutes for Biomedical Research, Basel, Switzerland, <sup>2</sup>Musculoskeletal Disease Area, Novartis Institutes for Biomedical Research, Basel, Switzerland.

Bone formation involves the development of multiple cell-cell contacts and cell-matrix interactions. These interactions are mediated by proteins such as cadherins which ensure cell-cell adhesion, connexins which are involved in cell-cell communication through gap-junction and integrins involved in cell-matrix adhesion. These complex cell-cell and cell-matrix interactions are required for osteoblast adhesion, communication, and gene expression during all stages of cell differentiation. ADAM15 (named for a disintegrating and metalloprotease 15 or metargidin) is a membrane-anchored glycoprotein that has been implicated in the cleavage of cell-matrix or cell-cell interactions such as N-Cadherin. ADAM15 is widely expressed, including robust expression in the vasculature, brain and bone of mice. Mice carrying a null mutation in ADAM15 are viable and fertile without any evident pathological phenotype, probably due to redundancy of the function of the ADAMs family members. The goal of the present study was to investigate the role of ADAM15 during osteoblastogenesis. To this end we isolated cells from the calvaria of ADAM15 deficient or control mice and performed a 21 day osteoblastic differentiation assay using an osteogenic cocktail. At various time points, RNA was extracted and quantitative real time PCR was performed to verify the expression of key osteogenic genes such as Runx2. Alkaline phosphatase (ALP) expression was determined at day 5 and its activity was measured at day 14 and 21 of culture. Furthermore calcium deposition was measured at day 14 and 21 and mineralized nodules were visualized by alizarin red staining. In ADAM15 deficient osteoblastic cells, the expression of ALP was down regulated by 4-fold compared to control littermate osteoblasts at day 5. Likewise ALP activity was reduced 4-fold at day 14 and 21. Consistent with this observation Runx2, bone sialoprotein, and osteocalcin expression level were reduced 2- to 5-fold at day 14 and 21. Calcium deposition was reduced by 5-fold at day 21 compared to control cultures, whereas at day 14 no statistical difference was observed. Nodule formation by ADAM15 deficient osteoblasts appeared decreased at day 14 and 21 post-osteogenic treatment. Taken together these data suggest a novel role for ADAM15 in the regulation of osteoblastogenesis in vitro presumably by regulating osteoblast adhesion and cell-cell communication.

**Cortical Bone Acquisition in the Appendicular Skeleton of Healthy Young Females is Reciprocally Related to Marrow Adiposity.** N. Di Iorgi<sup>1</sup>, P. P. Campbell<sup>1</sup>, M. Rosol<sup>1</sup>, G. Adams<sup>2</sup>, V. Gilsanz<sup>1</sup>. <sup>1</sup>Radiology, Childrens Hospital Los Angeles, Los Angeles, CA, USA, <sup>2</sup>Center for Stem Cell and Regenerative Medicine, Keck School of Medicine, Los Angeles, CA, USA.

Osteoblasts and adipocytes share a common progenitor cell in the bone marrow capable of mutually exclusive differentiation into the cell lineages responsible for bone and fat formation. We examined whether bone acquisition in healthy young women is inversely related to changes in marrow adiposity.

Computed tomography (CT) measurements of femoral cortical bone area (CBA), cross sectional area (CSA) and fat density (FD) in the marrow, and dual energy x-ray absorptiometry (DXA) measurements of total body fat (BF) and lean mass (LM) were obtained in 39 healthy females (15-20 years of age) at baseline and 18 to 24 months later. Marrow FD was inversely related to CBA at baseline and at follow-up ( $r$ 's = 0.39 and 0.33;  $P$ 's = .015 and 0.039, respectively), but was not associated to CSA ( $r$ 's = 0.19 and 0.17;  $P$ 's = .24 and 0.32, respectively). The reciprocal association between FD and CBA persisted even after controlling for age, BMI, DXA values for BF and LM and femoral CSA (see table below).

	BASELINE		FOLLOW-UP	
	$\beta$	$P$	$\beta$	$P$
Age	-0.013	0.60	-.034	0.12
BMI	0.011	0.64	-0.005	0.79
DXA Total Body Fat	-8.794E-6	0.51	1.957E-6	0.80
DXA Total Lean Fat	7.489E-6	0.55	2.700E-6	0.79
Femoral CSA	0.516	<0.0001	0.570	<0.0001
Marrow Fat Density	3.089	0.02	2.909	0.03
$R^2$ adjusted	0.68		0.77	

Gains in CBA during the course of the study were inversely related to decreases in marrow fat ( $R^2 = 0.15$ ;  $P = .009$ ); a relation that persisted even after accounting for changes in body mass, bone size and body composition (see table below). Marrow FD was not associated to weight, BMI, or DXA values of BF.

Regression analyses for the prediction of femoral CBA gains			
Univariate Regression Analyses			
Percent changes of:	$\beta$	$P$	$R^2$
Weight	0.021	0.84	-
Height	-0.806	0.58	-
BMI	0.26	0.24	-
DXA BF	-0.007	0.88	-
DXA LM	0.215	0.15	0.04
Femoral CSA	0.853	0.001	0.47
CT Marrow FD	-1.053	0.009	0.15
Multiple Regression Analyses			
Femoral CSA	0.738	<0.0001	0.52
CT Marrow FD	-0.524	0.03	

We conclude that bone acquisition in the appendicular skeleton of healthy young females is inversely related to changes in marrow adiposity. Deciphering the mechanisms that influence the inseparable reciprocal transformation of MSCs into osteoblasts or adipocytes could lead to the development of strategies to maximize bone mass and to prevent osteoporosis.

**Fibroblast Growth Factor 1 Inhibits Adipogenic Differentiation and Transdifferentiation of Human Mesenchymal Stem Cells.** N. Schuetze<sup>1</sup>, S. Jatzke<sup>1</sup>, R. Kueffner<sup>2</sup>, L. Klein-Hitpass<sup>3</sup>, R. Zimmer<sup>2</sup>, F. Jakob<sup>1</sup>, T. Schilling<sup>1</sup>. <sup>1</sup>Orthopedic Center for Musculoskeletal Research, University of Wuerzburg, Wuerzburg, Germany, <sup>2</sup>Institute of Informatics, University of Munich, Munich, Germany, <sup>3</sup>Institute of Cell Biology, University of Duisburg-Essen, Essen, Germany.

The age-related gain of fatty tissue in human bone marrow and the simultaneous loss of bone mass could contribute to diseases like osteopenia. Acceleration of adipogenesis of mesenchymal stem cells (MSCs) or transdifferentiation of pre-osteoblasts may contribute to this degeneration. The dissection of the hitherto unknown molecular basis is a prerequisite to uncover novel targets for therapeutic interventions that inhibit adipogenesis and enhance osteogenesis. Previously, we established a cell culture system of human MSCs to monitor transdifferentiation from osteoblasts into adipocytes and vice versa. Here, we aim to identify gene products differentially regulated during transdifferentiation that could initiate this process.

To examine adipogenic transdifferentiation of committed osteoblasts as well as osteogenic transdifferentiation of adipocytes, RNA was isolated 3 h and 24 h after initiation of transdifferentiation and subjected to Affymetrix microarray analyses in duplicates. Signal log ratios and change p-values allowed for evaluation of reproducibility and distinct regulation as well as reciprocity of gene regulation between both transdifferentiation

directions. Gene regulations were confirmed by RT-PCR, adipogenesis and osteogenesis was assessed by marker analyses.

414 and 922 gene products were reproducibly regulated in adipogenic and osteogenic transdifferentiation, respectively; many showed reciprocal regulation. Further bioinformatic analyses integrated reproducibility, degree of regulation and distinct reciprocity into a new scoring scheme that ranked genes due to their potential relevance. Some of the highly ranked genes are components of signaling pathways like Wnt/ $\beta$ -catenin, IGF or FGF signaling. Functional examination of FGF1 as one of the highly ranked potential key factors confirmed its largely inhibitory effect on adipogenic differentiation and transdifferentiation of MSCs.

Our findings serve as a prerequisite for further functional examinations of promising candidates that could provoke transdifferentiation or even act as switches between the adipogenic and osteogenic lineage. The identification of FGF1 as an inhibitor of adipogenic differentiation and transdifferentiation confirmed the array data provides a proof of principle for the gene ranking procedure. Therapeutic interventions based on our findings could counteract age-related bone loss by specific enhancement of osteogenesis and inhibition of adipogenesis.

**OPG and Bisphosphonates Had Differential Effects on Osteoclast Numbers, Bone Marrow Fibrosis and Cortical Porosity in a Mouse Model of Constitutive Activation of the PTH/PTHrP Receptor.** M. Ohishi<sup>1</sup>, R. Chiusaroli<sup>1</sup>, F. Asuncion<sup>2</sup>, M. Ominsky<sup>2</sup>, P. Kostenuik<sup>2</sup>, E. Schipani<sup>1</sup>. <sup>1</sup>Endocrine unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA.

Transgenic mice expressing constitutively active PTH/PTHrP receptors in cells of the osteoblast lineage (PPR\*Tg) display augmented trabecular bone, bone marrow (BM) fibrosis, increased number of osteoclasts and severe cortical porosity. In this model, cortical porosity is characterized by the presence of stromal cells, blood vessels and osteoclasts, and it is thus similar to the histological picture of BM fibrosis in the trabecular bone areas. These phenotypes are also typical of severe hyperparathyroidism and fibrous dysplasia. We investigated whether the presence or activity of osteoclasts influences porosity or fibrosis in PPR\*Tg mice. Three-month-old wild type (WT) and PPR\*Tg mice were injected s.c. with either vehicle (Veh), the RANKL inhibitor OPG-Fc (3mg/kg, 3/week), alendronate (ALN, 500µg/kg, once/week) or zoledronate (ZOL, 100µg/kg, once/week) for 3 months. Femurs were assessed by  $\mu$ CT and tibia were assessed by histomorphometry. PPR\*Tg mouse tibiae had 2.5-fold more trabecular osteoclasts per bone area than WT controls. OPG treatment of PPR\*Tg mice reduced osteoclast numbers by 80%, whereas ALN and ZOL treatment caused no reductions. Despite differential effects on osteoclast numbers, all treatments caused similar (~2-fold) increases in trabecular bone volume, which suggests similar suppression of trabecular osteoclast activity. Veh-treated PPR\*Tg mice showed severe BM fibrosis ( $8.17 \pm 2.12\%$  of marrow volume), while no fibrosis was observed in Veh-treated WT mice. BM fibrosis was completely abrogated by OPG-Fc treatment, whereas treatment with ALN or ZOL reduced fibrosis by 54% and 55%, respectively (both  $p < 0.01$  vs Veh). MicroCT of femur diaphysis revealed a 10-fold increase in cortical porosity in PPR\*Tg mice ( $p < 0.01$  vs WT controls), and OPG-Fc treatment of PPR\*Tg mice fully prevented this cortical porosity. ALN reduced cortical porosity by 39% ( $p < 0.05$  vs Veh), while ZOL caused no significant reduction in porosity. These data suggest that BM fibrosis and cortical porosity in PPR\*Tg mice were related to both the presence and the activity of osteoclasts. While all treatments appeared to cause similar reductions in trabecular bone resorption, only OPG caused marked reductions in osteoclast numbers and total abrogation of both marrow fibrosis and cortical porosity. It will now be important to identify the molecular mechanisms underlying this dichotomy.

**Use of GFP Reporters to Assess Cell Lineage in a Murine Model of Tibial Fracture Repair.** C. Ushiku<sup>1</sup>, J. Xi<sup>2</sup>, L. Wang<sup>2</sup>, D. J. Adams<sup>1</sup>, D. W. Rowe<sup>2</sup>. <sup>1</sup>Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Reconstructive Sciences, University of Connecticut Health Center, Farmington, CT, USA.

Successful repair of a fracture requires the coordinated action of cells from a variety of the mesodermal lineage, including hematopoietic, endothelial, pericytes/vascular smooth muscular, osteogenic, chondrogenic and potentially skeletal muscle. A variety of GFP reporter mice and a new cryohistology technique for non-decalcified bone were used to identify the temporal and spatial appearance of cells within each lineage. The Col3.6GFP reporter, which identifies preosteoblast-early osteoblast cells, provided a template for interpreting the expression of other reporters. Initially, Col3.6 is weakly expressed 4 days after fracture on the periosteum at sites distant from the fracture. As this initial callus expands toward the fracture site, strongly expressed Col3.6+ cells form its base and extend over the bridging domain. The cells are followed by a zone of mineralization and subsequently by the appearance of osteocalcin (OC-GFP) positive cells. By three weeks after the fracture, most of the Col3.6+ cells have been replaced by OC+ cells. This pattern of expression reflects the initial deposition of woven bone and its eventual remodeling to lamellar bone. To characterize the initial cellular events that occur distant to the fracture site, the smooth muscle alpha actin reporter (SMAA-GFP) was combined with Col3.6.

This reporter identifies an early progenitor population with multi-lineage potential, including bone and fat. In the advancing healing cascade, the SMAA+ cells appeared at the leading front of cells, with a gradient of cells in their wake that were double positive, followed by cells that were Col3.6+ only and associated with mineralization. The SMAA+ cells were most abundant in association with small vessels, and appeared to extend into the leading edge of the advancing callus base, suggesting regions of angiogenic-osteogenic coupling. The progression and remodeling of the cartilage component of the callus was assessed by combining a Col2A1 reporter with Col3.6. Four patterns of reporter expression were observed in chondrocytic shaped cells: no GFP; Col2A1+, Col3.6+, and rarely double positive cells. Other markers of lineage and repair are being mapped to this pattern of early osteogenic, chondrogenic, and angiogenic differentiation by introducing additional reporters, immunostaining, and fluorescent in situ hybridization. These techniques are robust in cryohistology, providing an avenue for identifying which cells generate specific molecular signals that control processes of differentiation during fracture repair.

**Osteogenic Potential of Human Bone Marrow and Circulating Stro-1+/CD45<sup>low</sup> Cells.** A. H. Undale, B. Srinivasan, S. Khosla. Endocrinology, Mayo Clinic, Rochester, MN, USA.

It has been established that bone marrow contains plastic adherent cells that have osteogenic potential. Although the identification of bone marrow stromal cells based on plastic adherence has become synonymous with the bone marrow stem cell population, there is increasing evidence that non-adherent bone marrow cells also have osteogenic potential. These cells could circulate in peripheral blood due to their non-adherent properties. We have identified circulating cells in peripheral blood expressing osteogenic markers and these circulating osteogenic cells potentially could play a role in bone repair. Following *in vitro* culture, bone marrow mesenchymal stem cells (MSCs) have been shown to be CD34 and CD45 negative (CD34- and CD45-), whereas hematopoietic stem cells (HSCs) are typically CD34 and CD45 positive (CD34+ CD45+). Although *in vivo* data regarding the expression of hematopoietic markers such as CD34 and CD45 on freshly harvested, uncultured MSCs is not very clear, studies done by Deschaseaux et al, showed that freshly isolated human bone marrow mesenchymal cells were CD49a+ and had a CD45<sup>med,low</sup> phenotype (Deschaseaux et al, 2003, *Br J Haematol*). We examined the coexpression of CD45 on the Stro-1+ (mesenchymal stromal cell marker) cells by flow cytometry analysis of freshly isolated bone marrow mononuclear cells (BMMNCs) obtained from healthy human volunteers. Fluorescent-labeled anti-human Stro-1 monoclonal antibody and an anti-human CD45 monoclonal antibody were used to identify surface expression of CD45 on the Stro-1+ BMMNCs. Our data indicates that freshly isolated human bone marrow and peripheral blood cells that are Stro-1+ also express the hematopoietic marker CD45. Based on the intensity of CD45, we identified two populations of the Stro-1+ BMMNCs: CD45<sup>low</sup> and CD45<sup>hi</sup>. Moreover, the Stro-1+/CD45<sup>low</sup> BMMNCs formed mineralized nodules under osteoblastic conditions *in vitro*; by contrast, Stro-1+/CD45<sup>high</sup> cells formed rare mineralized nodules, and Stro-1+/CD45- cells were virtually all positive for the erythroid marker, glycophorin A, and did not form nodules. In summary, we have identified a novel osteoprogenitor population contained within the Stro-1+/CD45<sup>low</sup> fraction of BMMNCs and our data provide a potentially important tool for identifying bone marrow and circulating osteoprogenitors.

**Role of ATF4 in Osteoblast Proliferation and Survival.** X. Zhang<sup>\*1</sup>, S. Yu<sup>1</sup>, D. L. Galson<sup>1</sup>, M. Luo<sup>\*1</sup>, J. Fan<sup>\*2</sup>, J. Zhang<sup>1</sup>, Y. Guan<sup>\*3</sup>, G. Xiao<sup>1</sup>. <sup>1</sup>Medicine, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Surgery, University of Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>Department of Physiology and Pathophysiology, Peking (Beijing) University Health Science Center, Beijing, China.

ATF4 (activating transcription factor 4) is essential for bone formation. However, the mechanism of its actions in bone is poorly understood. The present study examined the role for ATF4 in the regulation of proliferation and survival of primary mouse bone marrow stromal cells (BMSCs) and osteoblasts. Results showed that Atf4<sup>-/-</sup> cells display a severe proliferative defect as measured by multiple cell proliferation assays. Cell cycle progression of Atf4<sup>-/-</sup> BMSCs was largely delayed with a significant G1 arrest. Expression of cyclins A1, D1, and D3 was dramatically decreased both at the mRNA and protein level. A similar proliferation defect was observed in Atf4<sup>-/-</sup> calvarial periosteal osteoblasts *in vivo*. Knocking down Atf4 mRNA by small interfering RNA in MC3T3-E1 subclone 4 preosteoblasts markedly reduced expression of the cyclins and cell proliferation. In contrast, overexpression of ATF4 increased cyclin D1 expression as well as cell proliferation. In addition, apoptosis was significantly increased in cultured Atf4<sup>-/-</sup> BMSCs and calvarial periosteal osteoblasts *in vivo* relative to wt controls. Taken together, this study demonstrates that ATF4 is a critical regulator of proliferation and survival in primary BMSCs and osteoblasts.

**The Small G-Protein Rap1 Promotes Osteoblast Differentiation.** A. Ueda<sup>1</sup>, T. Hiraga<sup>\*2</sup>, T. Yoneda<sup>1</sup>. <sup>1</sup>Biochem, Osaka Univ Grad Sch of Dent, Osaka, Japan, <sup>2</sup>Histol and Cell Biol, Matsumoto Dental Univ, Nagano, Japan.

The Small G-Protein Rap1 is a family member of Ras with high homology to Ras. Previous studies reported that Ras regulated osteoblast and osteoclast differentiation. On the other hand, the role of Rap1 in bone is still unclear. To study this, we analyzed bones of mice deficient in SPA-1, a GTPase-activating protein which selectively inactivates Rap1. Histomorphometrical examination showed significant increase in trabecular bone volume, mineral apposition rate and bone formation rate in SPA-1-deficient (SPA-1<sup>-/-</sup>) mice compared with wild-type (WT) mice. Ral-GDS pull-down assay showed that Rap1 was markedly activated in primary osteoblasts isolated from the SPA-1<sup>-/-</sup> mice. To further examine the role of Rap1 in osteoblastogenesis, we introduced a constitutive-active (Rap1V12) or a dominant-negative (Rap1N17) mutant of Rap1 into the murine multipotent mesenchymal stem cell line C3H10T1/2 using the adenovirus system. Overexpression of Rap1V12 enhanced BMP2-induced osteoblast differentiation as determined by alkaline phosphatase (ALP) activity, whereas Rap1N17 suppressed it. Moreover, osteoblast differentiation induced by constitutive-active BMPRIIs (ALK3QD and ALK6QD) was enhanced by Rap1V12. Quantitative RT-PCR analysis showed that Rap1V12 increased BMP2-induced mRNA expression of ALP, osteocalcin and bone sialoprotein. Next, we examined the relationship between Rap1 and BMP2-Smad1-Runx2/Osterix pathway. Western blot analysis showed that Rap1V12 had no effect on BMP2-induced Smad1 phosphorylation. ALP staining showed that Rap1V12 could not rescue the osteoblastogenesis suppressed by Smad6, an inhibitory Smad in the BMP2 signaling pathway. Rap1V12 enhanced Runx2-induced osteoblast differentiation. Quantitative RT-PCR analysis showed that Rap1V12 increased Runx2 mRNA expression. On the other hand, Rap1V12 had no effect on osterix-induced osteoblast differentiation despite that Rap1V12 augmented osterix mRNA expression. Finally, we examined the relationship between the BMP2 signaling pathway and Rap1 activation. Ral-GDS pull-down assay showed that Rap1 was activated by BMP2, ALK3QD and ALK6QD. Smad6 showed no effects on Rap1 activation. Western blot analysis showed that Rap1V12 enhanced ERK phosphorylation induced by BMP2, whereas Rap1N17 suppressed it. A MEK inhibitor, U0126, suppressed BMP2-induced osteoblast differentiation. Rap1V12 could not rescue osteoblastogenesis suppressed by U0126. In conclusion, our results suggest that Rap1 plays a critical role in osteoblastogenesis through an enhancement of BMP2-induced osteoblast differentiation via MEK-ERK pathway.

**Oleuropein from Olive Stimulates the Differentiation and Mineralization of Cultured Osteoblasts and Inhibits the Formation of Osteoclasts in Culture.** K. Hagiwara<sup>\*1</sup>, T. Goto<sup>\*2</sup>, H. Hagiwara<sup>2</sup>. <sup>1</sup>Dept. of Bioscience and Biotechnology, Tokyo Institute of Technology, Yokohama, Japan, <sup>2</sup>Dept. of Biomedical Engineering, Tooin University of Yokohama, Yokohama, Japan.

The polyphenol displays antioxidant and anti-inflammatory properties. In our efforts to identify factors that might cause, prevent, or treat bone metabolic diseases, we screened a numerous polyphenol for the ability to regulate the proliferation, differentiation, and mineralization of osteoblasts, and the formation of osteoclasts. To date, we reported that curcumin, which is an important constituent of rhizomes of the plant *Curcuma longa* Linn, and quercetin, which is one of the major flavonoids in onion, inhibited the proliferation and mineralization of osteoblastic cells and the formation of osteoclasts. Furthermore, both compounds inhibited ovariectomy-stimulated bone resorption in mouse. The present study was designed to evaluate the effects of oleuropein, a main polyphenol of olive, on the formation of bone using cultured osteoblasts and osteoclasts. Oleuropein did not affect the proliferation of MC3T3-E1 cells until 10<sup>-5</sup> M and showed 50% inhibition of vehicle at 10<sup>-4</sup> M with MTT assay. Oleuropein at 10<sup>-5</sup> to 10<sup>-4</sup> M also stimulated the activity of alkaline phosphatase (day 14) and the deposition of calcium (day 18) in a dose-dependent manner at the post-proliferation. By contrast, oleuropein at 10<sup>-5</sup> to 10<sup>-4</sup> M inhibited the formation of multinucleated osteoclasts in a dose-dependent manner. Osteoclasts were formed from splenic cells of 6-week old male mouse by the addition of sRANKL and M-CSF.

Our results indicate that oleuropein might accelerate the formation of bone by stimulation of the proliferation and mineralization of osteoblastic cells and inhibition of the formation of osteoclastic cells. Furthermore, our preliminary examination indicates that this compound slightly inhibits ovariectomy-stimulated bone resorption in mouse. Oleuropein can prevent bone metabolic diseases.

**Development of High-throughput Screening System for Osteogenic Drugs Using Cell-based Sensor.** H. Hojo<sup>\*1</sup>, K. Igawa<sup>1</sup>, S. Ohba<sup>1</sup>, F. Yano<sup>1</sup>, K. Nakajima<sup>\*1</sup>, Y. Komiyama<sup>\*1</sup>, T. Yonezawa<sup>\*1</sup>, J. T. Woo<sup>\*1</sup>, A. C. Lichtler<sup>\*2</sup>, D. W. Rowe<sup>\*2</sup>, T. Ikeda<sup>3</sup>, K. Nakamura<sup>3</sup>, H. Kawaguchi<sup>3</sup>, U. Chung<sup>1</sup>. The Center for Disease Biology and Integrative Medicine, University of Tokyo, Tokyo, Japan, <sup>2</sup>Department of Genetics and Developmental Biology, and Department of Orthopedics, University of Connecticut Health Center, Farmington, CT, USA, <sup>3</sup>Department of Sensory and Motor System Medicine, University of Tokyo, Tokyo, Japan.

To effectively treat osteoporosis and other bone defects, there is a need for the development of small chemical compounds that potently induces bone formation. The present study initially attempted to establish a monitoring system that could detect osteogenic differentiation in a convenient, reliable, and real-time manner. For this purpose, we established several lines of pre-osteoblastic MC3T3E1 cells stably transfected with GFP reporter gene driven by the 2.3 kb fragment of rat type I collagen promoter (Col1a1GFP-MC3T3E1). Among them, we selected a clone that fluoresced upon osteogenic stimulation by BMP-2. This cell line was confirmed to show an increase in alkaline phosphatase (ALP) staining and osteocalcin (OC) mRNA level in a dose-dependent manner. Using this system, we screened natural and synthetic compound libraries and identified an isoflavone derivative, glabrisoflavone (GI). GI induced GFP fluorescence at 7 days. Treatment with different concentration of GI revealed that GI upregulated the OC mRNA level in a dose-dependent manner; ALP staining concurred with the osteocalcin expression. We next examined the involvement of major osteogenic pathways in GI's action using luciferase reporter plasmids driven by BMP-responsive elements (12XGCCG), Runx2-responsive elements (6XOSE2), and canonical-Wnt-responsive elements (TOPFLASH). GI did not significantly alter these signaling pathways. The mRNA expression level of Id1, Runx2, and Tcf1 were also not altered by GI treatment. In conclusion, we established a high-throughput screening system for osteogenic drugs using Col1a1GFP-MC3T3E1 cells. This system may be useful for identifying novel osteogenic drugs.

**Expression of Bone-Related Genes by Peripheral Blood CD34 Cells.** U. I. L. Moedder, M. Gössl<sup>\*</sup>, A. Lerman<sup>\*</sup>, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Peripheral blood CD34+ cells, an endothelial/hematopoietic progenitor-enriched cell population, may be involved in the repair of vascular injury. In addition, these cells have been shown to possess osteogenic potential and to express osteocalcin (OCN), suggesting that they may also initiate or modulate vascular calcification. We hypothesized that increases in local calcium (Ca<sup>2+</sup>) concentrations, perhaps related to tissue injury, may induce expression of osteogenic genes by these cells. Thus, we used MACS to isolate CD34+ cells from peripheral blood of 6 normal donors and examined expression of bone-related genes in these cells compared to undifferentiated human mesenchymal stromal cells (hMSCs). We also cultured the CD34+ cells for 5 days in the presence of Ca<sup>2+</sup> (5 mM) followed by an additional 7 days in osteoblast differentiation medium. As shown in the figure, CD34+ cells expressed significantly higher levels of RUNX2 and  $\beta$ -catenin than hMSCs; additional bone-related genes (BMP-2, MSX2, Notch, and OCN) were expressed at levels similar to hMSCs. AP, osteonectin, osteopontin (OPN), MGP, Col1 $\alpha$ 1 and Col1 $\alpha$ 2 were expressed by CD34+ cells at low levels. The stem cell marker, Nanog, was expressed at significantly higher levels in CD34+ compared to hMSCs, whereas CD44, another stem cell marker, was expressed at similar levels. HIF-1 $\alpha$  and the chemokine receptor, CXCR4, both which are involved in homing of cells to ischemic tissues, were expressed at very high levels in the CD34+ cells. CD34+ cells also expressed mRNAs for CD34 and CD45.

Following culture, mRNA expression of CD34 virtually disappeared, and CD45 mRNA

was significantly decreased. Expression of OPN, a non-collagenous bone matrix protein which is known to have chemoattractant properties, increased dramatically (by 35,800-fold) following culture. Of the 6 CD34+ cell samples, the 3 with the highest expression of OCN prior to culture significantly (by 600 fold) upregulated Col1 $\alpha$ 1 expression, whereas the 3 with low OCN mRNA levels did not.

Our data indicate that human circulating CD34+ cells express a spectrum of bone-related genes. Exposure to high Ca<sup>2+</sup> concentrations and osteogenic conditions dramatically upregulates expression of the chemoattractant, OPN, to potentially recruit additional cells for tissue repair. Moreover, the level of OCN expression by CD34+ cells may be a predictor of the ability of these cells to develop an osteogenic phenotype.

**Disclosures:** U.I.L. Moedder, None.

## M084

**Mineralization Potential and Orientational Aspects of Osteogenic Cell Cultures by Raman Spectroscopy.** G. S. Mandair<sup>1</sup>, P. Steenhuis<sup>\*2</sup>, M. D. Morris<sup>1</sup>. <sup>1</sup>Department of Chemistry, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>Department of Orthodontics and Pediatric Dentistry, University of Michigan School of Dentistry, Ann Arbor, MI, USA.

The aim of this study is to determine, using Raman spectroscopy, whether mineralized bone nodules formed in osteogenic cell cultures is relevant to normal bone. It is known that culturing cells with  $\beta$ -glycerophosphate ( $\beta$ GP) can lead to formation of abiotic mineral as well as normal bone mineral. Spectroscopic procedures were devised to distinguish between bone mineral and suspected abiotic mineral. Osteoprogenitor cells obtained from fetal day 18.5 (FD18.5) mouse calvaria were plated onto fused-silica slides. Confluent cells were cultured in standard osteogenic media containing 10 mM  $\beta$ GP and 1  $\mu$ M dexamethasone for 35 days. The physicochemical composition of the mineralizing cell cultures were assessed using unpolarized Raman spectroscopy. Known spectroscopic markers for mineralization (P-O stretch/collagen amide I band area ratio), carbonation (C-O stretch/P-O stretch band area ratio), and crystallinity (P-O stretch band width) were estimated with standard deviations. Estimates for FD18.5 calvaria and 6-month old mouse tibia were also obtained. Polarized Raman spectroscopy was used to test for orientation of mineralizing bone nodules parallel to the collagen fibril axis. When 10 mM  $\beta$ GP was used, abiotic mineral appeared early in the cell cultures and that apatitic mineral formed in the collagen scaffold later. For example, mineralized bone nodules that first appeared at day 8 were found by unpolarized Raman to be highly carbonated with levels comparable to 6-month old mouse tibia (0.12  $\pm$  0.01). Similar trends were also noted for mineralization, whereas crystallinity at day 28 (17.1  $\pm$  2.1 cm<sup>-1</sup>) was lower compared to FD18.5 calvaria (13.8  $\pm$  0.2 cm<sup>-1</sup>, p  $\leq$  0.001). These results show that carbonated apatite mineral formed during the early stages of the culture period maybe abiotic. Apatitic mineral formed during the later stages appeared to resemble normal bone. However, polarized Raman spectroscopy revealed a mixture of both bone mineral and abiotic mineral phases. Collagen amide I orientation in small spherical nodules was sensitive to polarized Raman scatter and thus was found to be structurally similar to normal bone mineral, whereas collagen orientation in large irregular-shaped nodules was reduced. In conclusion, we demonstrated the feasibility of using polarized and unpolarized Raman spectroscopy to potentially classify mineralized bone nodules formed in osteogenic cell cultures as either normal or abiotic, thus enabling more detailed study of the time course of bone mineralization.

**Sirtuin 1 (SIRT1) Is a Regulator of Mesenchymal Stem Cell Lineage Allocation.** E. Cohen-Kfir<sup>\*</sup>, A. Levin<sup>\*</sup>, E. Abramovitz<sup>\*</sup>, J. Lavi<sup>\*</sup>, G. Hamdani<sup>\*</sup>, R. Dresner-Pollak. Endocrinology and Metabolism, Medicine, Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Osteoblasts originate from progenitor mesenchymal stem cells (MSCs) which can differentiate into several distinct lineages including osteoblasts and adipocytes. Lineage commitment is determined by cell-specific master transcription factors, RUNX2 in osteoblasts and PPARGamma in adipocytes. The regulatory mechanisms of these transcriptional factors are still unknown. Sirtuin 1 (SIRT1), the mammalian ortholog of yeast Sir2 (silent information regulator 2), a key NAD<sup>+</sup> dependent protein deacetylase in aging, is a PPARGamma repressor and inhibits adipogenesis in adipose tissue.

We aimed to investigate whether SIRT1 is a regulator of osteoblastogenesis and adipogenesis from their common progenitor MSC. A murine marrow-derived mesenchymal stem cell line and primary marrow stromal cell cultures obtained from SIRT1-deficient mice were used for *in-vitro* studies. Bone mass and architecture were determined in SIRT1 deficient mice.

SIRT1 in C3HT101/2 cells was modified through retroviral infection with pBABE-SIRT1 for overexpression, and a SIRT1 dominant negative mutant (SIRT1 H355Y) for downregulation. This mutation abolishes deacetylase activity. Cells were induced to differentiate into either osteoblasts or adipocytes using an osteogenic medium or an adipogenic medium, respectively. Primary bone marrow cultures were obtained from SIRT1 haploinsufficient (HET) and wild type (WT) mice. Femurs of 3-month-old female SIRT1 knock-out (KO), HET and WT were analyzed by microCT.

mRNA expression of RUNX2 and osterix was increased by 10 and 20 fold respectively in SIRT1 overexpressing cells compared to C3HT101/2 cells. In cells expressing the mutant SIRT1 a 3 and 4 fold reduction in RUNX2 and alkaline phosphatase mRNA expression compared to SIRT1 overexpressing cells was found. Increased triglyceride accumulation determined by Oil red O staining was observed in mutant SIRT1-transfected cells compared to SIRT1 overexpressing cells. RUNX2 and Osterix mRNA expression was reduced by 50% and PPARGamma was increased by 30% in primary marrow cultures

obtained from SIRT1 HET compared to WT mice. SIRT1-deficient mice were smaller than their HET and WT counterparts, which were similar in size. Trabecular BV/TV was lower by 45% and 34% in KO and HET mice respectively compared to WT mice. Trabecular thickness was reduced by 32% in KO compared to WT, and cortical thickness was reduced in KO and HET by 30% and 25% respectively. SIRT1 plays a regulatory role in osteoblastogenesis, plausibly by affecting the relationship between osteoblastogenesis and adipogenesis from their common progenitor MSC, and may be an important linkage between aging and osteoporosis.

**Ghrelin Inhibits Early Osteogenic Differentiation of C3H10T1/2 Cells by Suppressing Runx2 Expression and Enhancing PPAR $\gamma$  and C/EBP $\alpha$  Expression.** S. Kim<sup>1</sup>, O. Choi<sup>\*2</sup>, J. Yang<sup>\*3</sup>, S. Cho<sup>\*1</sup>, C. Shin<sup>1</sup>, K. Park<sup>\*1</sup>, S. Kim<sup>\*1</sup>. <sup>1</sup>Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Department of Internal Medicine, Seoul National University Boramae Hospital, Seoul, Republic of Korea, <sup>3</sup>Clinical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea.

Ghrelin is a 28-residue peptide identified in the stomach as an endogenous ligand of the growth hormone secretagogue receptor that is expressed in a variety of peripheral tissues, as well as in the brain. In previous studies, ghrelin has been shown to stimulate both adipogenic differentiation from preadipocyte and osteogenic differentiation from preosteoblasts or primary osteoblasts. This study was undertaken to investigate the direct effect of ghrelin on the lineage allocation of mesenchymal stem cells (MSCs). We identified ghrelin receptor mRNA in C3H10T1/2 cells, and we found the levels of this mRNA to be attenuated during osteogenic differentiation. Treatment of cells with ghrelin resulted in both proliferation and inhibition of caspase-3 activity. In addition, ghrelin-treated cells showed an increase in bcl-2 expression and a reduction in cytochrome c release. Moreover, ghrelin inhibited early osteogenic differentiation, as shown by alkaline phosphatase activity and staining, and inhibited osteoblast-specific gene expression by altering Runx2, PPAR $\gamma$ , and C/EBP $\alpha$  protein expression.

**The Regulation of Osteoblast Differentiation by MicroRNA.** H. Inose, A. Kimura\*, M. Iwasaki\*, K. Shinomiya\*, S. Takeda. Orthopaedic Surgery, Tokyo Medical and Dental University, Tokyo, Japan.

Osteoblastic differentiation from mesenchymal stem cell is a multistep process regulated by several factors including cytokines and hormones. Central to this regulation is the control of gene expression by transcription factors. Recent identification of non-coding small RNAs, i.e., microRNA (miRNA), revealed a novel and important regulatory mechanisms for gene expression and cell differentiation. Therefore, we tried to elucidate the role of miRNAs in osteoblastic differentiation. miRNAs that are differentially expressed upon BMP2 treatment in C2C12 cells were comprehensively analyzed by using microarray. Of the many downregulated miRNAs, we focused on microRNA 206 (miR-206). In line with its expression profile in C2C12 cells, miR-206 expression was gradually decreased along with the osteoblastic differentiation of mouse primary osteoblasts. To address the functional role of miR-206, we overexpressed miR-206 in C2C12 cells or mouse primary osteoblasts and observed a marked inhibition of osteoblastic differentiation as evident by diminished alkaline phosphatase activity and mineralization. Conversely, knockdown of miR206 by siRNA specific for miR206 resulted in an increase in osteoblastic differentiation. Successively, searching potential targets for miR-206 using the Targetscan program revealed Connexin43 (Cx43), a gap junction protein implicated in osteoblast differentiation previously, as one highly probable target. Indeed, miR-206 bound to the 3'UTR of Cx43 genome and inhibited the translation of Cx43 protein. Finally and most importantly, Cx43 overexpression rescued the inhibition of osteoblastic differentiation by miR-206. These results demonstrated that miR-206 regulates osteoblast differentiation physiologically through the modulation of Cx43 expression.

**Activation of FGF Receptors Is a Novel Mechanism by which Extracellular Calcium Stimulates the Proliferation of Osteoblasts.** J. Caverzasio. Service of Bone Diseases, Dept of Rehabilitation and Geriatrics, University of Geneva, Geneva, Switzerland.

Extracellular calcium concentration ([Ca<sup>2+</sup>]<sub>e</sub>) can regulate bone remodelling by acting on osteoclasts and osteoblasts and local changes in [Ca<sup>2+</sup>]<sub>e</sub> may serve as a key coupling factor between bone resorption and formation. The mechanisms by which osteoblasts sense [Ca<sup>2+</sup>]<sub>e</sub> are still unclear. Controversy exist concerning a role of the calcium-sensing receptor (CaR) in mediating changes in osteoblast chemotaxis and proliferation. Beside CaR, effects through autocrine growth factors have been reported but incompletely investigated.

In this study, analysis of transduction pathways involved in cell replication induced by [Ca<sup>2+</sup>]<sub>e</sub> was performed in MC3T3-E1 cells having a high replicative response to this cation. In these cells, CaCl<sub>2</sub> (3-5 mM) induced a 14-16 fold increase in 3H-thymidine uptake and a 2-3 fold increase in cell number. To assess the potential role of transduction pathways activated by growth factor receptors in cell replication induced by CaCl<sub>2</sub>, we investigated the effect of different selective receptor tyrosine kinase (RTK) inhibitors. Of several RTK (FGFR, EGFR, VEGFR, PDGFR) inhibitors tested, only the selective FGFR inhibitor, PD173074, dose-dependently and completely (0.2-1.0  $\mu$ M) blunted cell replication induced by CaCl<sub>2</sub> without influencing basal cell replication. Associated with this effect, CaCl<sub>2</sub> markedly activated FGF2 signaling pathways such as FRS2, PLC $\gamma$ , SHP2, Akt, PKC, PKD, ERK1,2 and p38 MAP kinase. Activation of these pathways by CaCl<sub>2</sub> was already maximal after 2 min incubation and were completely blunted by PD173074. Effects on cell proliferation and activation of FGF2 signaling pathways were also obtained with 0.1 mM gadolinium suggesting the implication of a cation-sensitive like mechanism. Increased cell replication induced by CaCl<sub>2</sub> and FGF2 was associated with decreased alkaline phosphatase activity (ALP), a response also completely prevented by PD173074 but not by other RTK inhibitors. Lower concentrations of CaCl<sub>2</sub> was required to reduce ALP activity compared with those for inducing cell replication suggesting different signaling pathways involved in these responses. Similar effects of the FGFR inhibitor on cell replication and ALP activity induced by CaCl<sub>2</sub> were also observed in C3H10T1/2 pluripotent mesenchymal cells.

In conclusion, results presented in this study indicate that activation of FGFRs mediates cell replication induced by [Ca<sup>2+</sup>]<sub>e</sub> in osteoblast-like cells. The molecular mechanism by which this cation stimulates FGFR signaling remains to be investigated. These data reveal a new mechanism by which [Ca<sup>2+</sup>]<sub>e</sub> may influence the activity of osteoblastic cells.

**Icariin Induces Osteogenic Differentiation *in vitro* in a BMP- and Runx2-Dependent Manner and Bone Regeneration *in vivo*.** J. Zhao<sup>\*1</sup>, S. Ohba<sup>\*2</sup>, Y. Komiyama<sup>\*2</sup>, U. Chung<sup>3</sup>, T. Nagamune<sup>\*1</sup>. <sup>1</sup>Department of Chemistry and Biotechnology, School of Engineering, University of Tokyo, Tokyo, Japan, <sup>2</sup>Center for Disease Biology and Integrated Medicine, School of Medicine, University of Tokyo, Tokyo, Japan, <sup>3</sup>Department of Bioengineering, School of Engineering, University of Tokyo, Tokyo, Japan.

To effectively treat bone diseases using bone regenerative medicine, there is an urgent need to develop safe and cheap drugs that can potently induce bone formation. Here, we demonstrate the osteogenic effect of icariin, the main active compound of *Epimedium pubescens*. Icariin induced osteogenic differentiation in pre-osteoblastic MC3T3-E1 cells and mouse primary osteoblasts. Icariin upregulated the mRNA expression levels of the osteoblast marker genes (including osteocalcin, bone sialoprotein and alkaline phosphatase), runt-related transcription factor 2 (Runx2) and inhibitor of DNA-binding 1 (Id-1). The osteogenic effect was inhibited by the introduction of Smad6 or dominant-negative Runx2, as well as Noggin treatment. Furthermore, icariin induced mRNA expression of bone morphogenetic protein (BMP)-4. These data suggest that icariin exerts its potent osteogenic effect through induction of Runx2 expression, production of BMP-4 and activation of BMP signaling. The osteogenic effect of icariin was also confirmed in mouse calvarial bone defect model. Eight-week-old male C57BL/6N mice were transplanted with icariin-calcium phosphate cement (CPC) tablets or CPC only (n=5) and bone regeneration was evaluated at 4, 6 and 8 weeks after the operation. Significant new bone formation was observed in icariin-CPC group at 4w and thickness of new bone increased at 6w and 8w. Obvious blood vessel invasion also occurred in icariin-induced new bone. We are now evaluating the effect of icariin on age-related osteoporosis. The extremely low cost of icariin and its high abundance make it appealing for bone regenerative medicine.

**A Program of MicroRNAs Control BMP2 Induced Bone Phenotype Development.** Z. Li<sup>\*1</sup>, M. Q. Hassan<sup>1</sup>, A. J. van Wijnen<sup>1</sup>, J. L. Stein<sup>\*1</sup>, C. M. Croce<sup>\*2</sup>, J. B. Lian<sup>1</sup>, G. S. Stein<sup>1</sup>. <sup>1</sup>Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, <sup>2</sup>Department of Molecular Virology, Immunology and Medical Genetics and Comprehensive Cancer Center, Ohio State University, Columbus, OH, USA.

BMPs are potent morphogens that activate transcriptional programs for lineage-specific differentiation. How BMP induction of a phenotype is coordinated with microRNAs (miRNAs) that inhibit biological pathways to control cellular processes, remains unknown. Here we show by profiling miRNAs during BMP2 induced osteogenesis of C2C12 mesenchymal cells, that 22 miRNAs (from an array of 318 miRNAs) were downregulated in response to BMP2. These miRNAs were all predicted to target osteogenic signals, including mediators of the Wnt, BMP and FGF signaling pathways (ligands and their receptors), signal transduction cascades (JAK/STAT, MAPK), as well as transcriptional regulators of osteogenesis (including Runx2, Msx2, Dlx3, Smads, TCF/Lef). Thus, BMP2 inhibition of these miRNAs resulted in induced protein levels of osteogenic factors. Two miRNAs representative of these osteogenic pathways were characterized, identifying miR-133 directly targeting *Runx2*, an early BMP response gene essential for bone formation and miR-135 directly targeting *Smad5*, a key transducer of the BMP2 osteogenic signal, controlled through their 3'UTR sequences. Both these miRNAs functionally inhibit differentiation of preosteoblasts by attenuating the Runx2 and Smad5 osteogenic pathways that synergistically contribute to bone formation. In addition our studies reveal that miR-133 which is established as essential for promoting MEF2 dependent myogenesis and proliferation of C2C12 cells, has a second complementary function by inhibiting Runx2 mediated osteogenesis. Our studies show that BMP2 controls bone cell determination by also inducing miRNAs that target muscle genes to suppress C2C12 cell myogenesis. Thus, a novel function for morphogens, as BMP2, is established to promote cell lineage determination by both suppressing alternative phenotypes but mainly by releasing from miRNA inhibition a program of target genes required for differentiation of a tissue-specific phenotype.

**The Role of FIP200 in Osteoblast Differentiation.** F. Liu<sup>1</sup>, B. Gan<sup>\*2</sup>, J. Guan<sup>\*3</sup>. <sup>1</sup>BMS department, University of Michigan, Dental School, Ann Arbor, MI, USA, <sup>2</sup>Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA, <sup>3</sup>Division of Molecular Medicine and Genetics, Department of Internal Medicine, University of Michigan, Medical School, Ann Arbor, MI, USA.

FAK-family interacting protein of 200kDa (FIP200) is a key signaling node to coordinately regulate various cellular processes. Our previous work identified FIP200 as a novel protein inhibitor for both Pyk2 and FAK. We showed that targeted deletion of FIP200 in the mouse led to embryonic death. It was reported that FIP200 expresses in musculoskeletal system and is critical for myoblast differentiation. To determine whether FIP200 plays a role in the osteoblast differentiation, bone marrow stromal cells were isolated from the femurs of 2 month old FIP200 F/F mice. The cells were treated with the recombinant adenovirus encoding Cre (Ad-Cre) to inactivate FIP200 or a control adenovirus (Ad-lacZ) along with addition of the osteogenic inducers at day 7 of culture. Ad-Cre treatment resulted in an approximately 50% of reduction in the expression of FIP200 as assessed by real time PCR. Osteoblast differentiation was then assessed by the expression of osteoblast differentiation markers (ALP, BSP, OCN) and Alizarin red staining. The expression of above osteoblast differentiation markers was decreased by about 50% in Ad-Cre treated group compared to Ad-LacZ treated group after 7 days osteogenic culture. The Alizarin red staining was decreased by over 75% in Ad-Cre treated cells at day 21. The expression of two critical osteoblast differentiation transcription factors, Runx2 and Osx, was moderately decreased in Ad-Cre treated cells. In the control cells treated with Ad-lacZ, in agreement with other report, the expression of Wnt7b, an endogenous canonical Wnt that plays important role in osteoblast differentiation, was increased at the early differentiation stage and the Dkk2, a Wnt antagonist, which may also suppress the Wnt7b expression, was not significantly upregulated before the Wnt7b expression peaked. Interestingly, in the cells treated with Ad-Cre, Dkk2 mRNA expression was 4-6 folds higher compared with the control group throughout the culture. Conversely, the Wnt7b expression was 4-6 folds lower in these cells. We further determined the role of FIP200 in Wnt signaling utilizing the mouse MEF cells. We found that the Dkk2 mRNA expression level in FIP200<sup>-/-</sup> MEF cells was increased over 20 folds compared to FIP200<sup>+/+</sup> MEF cells. Furthermore, infection of FIP200<sup>-/-</sup> MEF cells with adenovirus encoding FIP200 greatly decreased Dkk2 expression. In conclusion, our data suggests that FIP200 may play a role in osteoblast differentiation by regulating canonical Wnt signaling through the control of Dkk2 expression.

**Effect of a Novel Splice-site Mutation of PHEX Gene During Osteoblast Differentiation.** L. Masi<sup>1</sup>, A. Gozzini<sup>\*1</sup>, S. Sorace<sup>\*1</sup>, I. Tognarini<sup>\*1</sup>, G. Galli<sup>\*1</sup>, S. Parrini<sup>\*1</sup>, I. Pela<sup>\*2</sup>, A. Tanini<sup>\*1</sup>, M. L. Brandi<sup>1</sup>. <sup>1</sup>Internal Medicine, University of Florence, Florence, Italy, <sup>2</sup>Pediatric, University of Florence, Florence, Italy.

X-linked hypophosphatemia (XLH), is a dominantly inherited rickets, characterized by renal phosphate wasting, abnormal vitamin D and PTH metabolism, and defective bone mineralization. The disease is caused by mutations in the PHEX gene (phosphate-regulating gene with homologies to endopeptidases on the X-chromosome), which is located at Xp22.1 and encodes a 749-amino acid protein. PHEX is expressed in various tissues, including bones, and its pivotal role is to cleave and to inactivate phosphatonins. The absence of functional PHEX could lead to the accumulation of phosphaturic factors and/or mineralization inhibitors. We found a novel hemizygous splice-site mutation of PHEX gene in 3 years old female children referring to our Center, affected by XLH and with a negative familial history.

The aim of this study is to evaluate the effect of this kind of mutation on osteogenic differentiation of human mesenchymal stem cells obtained from this patient in order to characterize the molecular mechanisms underlying this nucleotide substitution. Two primary cultures of Human adipose tissue-derived mesenchymal stem cells (PA4 and PA9 cells) were obtained respectively from the patient carrying the mutation and from a healthy child of the same age (control). These cells were used to evaluate the role of PHEX in osteoblastogenesis. PA4 and PA9 cells were isolated from subcutaneous adipose tissue biopsies, characterized by the expression of stem cell surface markers (CD45 and CD105) and induced into the osteoblastic phenotype. After 14 days from induction ALP activity (cytochemical staining), mineralization (light microscopy and calcein staining), and the synthesis and distribution of extracellular matrix proteins (osteopontin, osteocalcin and type I collagen) were monitored. PA4 and PA9 induced cells were highly positive for ALP staining (83% and 85% of positive cells, respectively), with the capability to deposit mineralized matrix. Nevertheless, an impaired mineralization was observed in PA4 cells that compared with PA9 cells deposited an altered calcified matrix not organized into compact nodules and not adhering to the cells. LSCM analysis showed that the osteogenic induction stimulated the synthesis of extracellular type I collagen fibrils at similar level in both primary cell lines. Osteogenic induction was accompanied by an increase of osteopontin expression and by a synthesis ex novo of osteocalcin only in PA9 cells. These results indicate that alterations in the PHEX gene control bone matrix mineralization and this can happen through the regulation of bone proteins' synthesis and deposition.

**Permanent FGFR2 Activation Promotes Osteoblast Differentiation in Mesenchymal Stem Cells Through Activation of PKC Signaling.** H. Miraoui<sup>\*1</sup>, C. Dufour<sup>\*1</sup>, Y. Tanimoto<sup>\*2</sup>, K. Moriyama<sup>2</sup>, P. J. Marie<sup>1</sup>. <sup>1</sup>Inserm U606 and University Paris 7, Paris cedex 10, France, <sup>2</sup>Department of Maxillofacial Reconstruction and Function, Tokyo Medical and Dental University, Tokyo, Japan.

One important challenge in skeletal biology is to identify factors and pathways that may be used to increase mesenchymal stem cells (MSC) differentiation into mature osteoblasts. We previously showed that Fibroblast Growth Factor Receptor 2 (FGFR2) activating mutations increase osteoblast differentiation in human Apert craniosynostosis. We therefore hypothesized that permanent activation of FGFR2 may promote MSC osteogenic differentiation. To test this hypothesis, murine C3H10T1/2 cells were stably transfected with wild type (WT-FGFR2) FGFR2, a constitutively activating S252W mutation in FGFR2 (MT-FGFR2) or empty vector (EV). Western blot analysis showed that both constructs increased FGFR2 levels. However, only MT-FGFR2 increased tyrosine phosphorylated FGFR2, indicating sustained activation of the receptor. WT-FGFR2 and MT-FGFR2 slightly increased MSC proliferation but had no effect on cell survival in basal or serum-deprived conditions. WT-FGFR2 and MT-FGFR2 increased by 3-4 fold Runx2 mRNA expression, and increased by 2-fold alkaline phosphatase (ALP), type I collagen (Col1A1) and osteocalcin (Oc) expression, as shown by quantitative PCR analysis. However, MT-FGFR2 induced a more rapid increase in Runx2, ALP and Oc expression than WT-FGFR2. Consistently, MT-FGFR2 induced a greater and sooner increase in ALP staining and in vitro matrix mineralization compared to WT-FGFR2. Both WT-FGFR2 and MT-FGFR2 decreased early or late adipocyte differentiation markers (PPARgamma2, C/EBPalpha, LPL) but had no effect on adipogenesis evaluated by oil red staining at 14 days in the presence or absence of the PPARgamma agonist linoleic acid. Both WT-FGFR2 and MT-FGFR2 decreased Sox9 whereas type X collagen was increased by WT-FGFR2 but not by MT-FGFR2. Western blot analysis showed that both WT-FGFR2 and MT-FGFR2 induced sustained ERK1/2 MAPK phosphorylation, whereas JNK, PI3K or Akt signaling was not affected. Pharmacological inhibition of ERK1/2 decreased MSC proliferation induced by either WT-FGFR2 or MT-FGFR2. However, inhibition of ERK1/2 decreased Runx2, ALP and Oc mRNA expression in WT-FGFR2 but not in MT-FGFR2-transfected cells. Conversely, inhibition of protein kinase C (PKC) reduced Runx2, ALP and Col1A1 mRNA levels in MT-FGFR2, but not in WT-FGFR2 transfected cells. These results provide evidence that sustained FGFR2 activation effectively induces osteogenic differentiation in MSCs which is mainly mediated by PKC signal transduction, thus providing a new mechanism involved in osteogenic differentiation of mesenchymal stem cells.

**Heparan Sulfate Proteoglycans Modulate Osteogenic Differentiation through Heparan Sulfate Chains.** A. Kamada<sup>1</sup>, T. Ikeo<sup>1</sup>, Y. Yoshikawa<sup>1</sup>, E. Domae<sup>\*1</sup>, S. Goda<sup>\*1</sup>, I. Tamura<sup>\*1</sup>, A. Kawamoto<sup>\*1</sup>, J. Okazaki<sup>\*1</sup>, Y. Komasa<sup>\*1</sup>, Y. Takaishi<sup>1</sup>, T. Miki<sup>2</sup>, T. Fujita<sup>3</sup>. <sup>1</sup>Osaka Dental University, Osaka, Japan, <sup>2</sup>Osaka City University, Osaka, Japan, <sup>3</sup>Katsuragi Hospital, Osaka, Japan.

Bone cells are regulated by interaction with growth factors and components of the extracellular matrix. Cell surface heparan sulfate proteoglycans (HSPGs), syndecan family and glypican family, are known to bind both other extracellular matrix molecules and certain growth factors, such as fibroblast growth factor (FGF), transforming growth factor (TGF) and bone morphogenetic protein (BMP), thus playing a unique role as a regulator of growth factor behavior. In this study, we investigated the role of HSPG in osteogenic differentiation of murine pro-osteoblastic cell line MC3T3-E1 cells using the HS-degrading endoglycosidase, heparitinase.

Cells were pretreatment with heparitinase or chondroitinase ABC, and were stimulated by ascorbic acid (VC) and beta-glycerophosphate (BGP) to induce osteoblastic differentiation. Mineralization of the cell cultures was detected by von Kossa stain and by Alizarin Red. The mRNA expression level was measured using real-time quantitative RT-PCR.

Enzymatic depletion of the HS chains by heparitinase treatment enhanced the mineralization induced by VC and BGP. VC and BGP-dependent induction of osteocalcin increased significantly by heparitinase treatment compared with non-digested controls ( $p < 0.01$ ).

Heparitinase treatment also enhanced the expression of bone-specific transcription factor Runx2 induced by BMP-2 addition, but not the BMP-2 expression.

These results demonstrate that cell surface HSPGs suppress the mineralization in osteoblasts through HS side chain-mediated binding to BMP-2. Hence the control of cell surface HSPGs may be useful for modulate osteogenic differentiation of osteoblasts.

## M095

**Enhanced Osteogenic Potential of Alveolar vs. Long Bone Derived Marrow Stromal Cells.** T. Aghaloo, O. Bezouglaia<sup>\*</sup>, N. Chaichanasakul<sup>\*</sup>, B. Kang<sup>\*</sup>, R. Franco<sup>\*</sup>, E. Atti<sup>\*</sup>, S. Tetradis. UCLA School of Dentistry, LA, CA, USA.

Systemic and local factors and associated signaling cascades have distinct effects in craniofacial vs. appendicular skeleton, while conditions such as bisphosphonate related osteonecrosis of the jaws (BRONJ), affect only maxillofacial bones. Although substantial evidence suggests differences in homeostasis between alveolar vs. appendicular bone, much of our knowledge concerning alveolar bone (AB) cell function is extrapolated using cells from other skeletal sites. Here, we have established a protocol to reproducibly isolate and culture AB MSCs from the rat mandible and compared them to long bone (LB) MSCs from the same animal.

A needle was inserted into the mandibular alveolar ridge to collect the marrow. Cells were expanded to confluence and passaged for experiments. For control, tibia marrow from the same animals was handled identically. In osteogenic media, both AB and LB MSCs stained for alkaline phosphatase (ALP) and mineralized after 2-3 weeks. To confirm absence of dental pulp/odontoblast contamination, dentin sialophosphoprotein (DSPP) expression was tested, using rat incisor pulp as positive control. Pulp tissue expressed DSPP levels 42,000 fold greater than AB and LB MSC cultures, suggesting that pulp cell contamination of AB MSCs, if any, is minimal. Interestingly, ALP staining was stronger in AB MSCs from the beginning of the culture and continued for the duration of the experiment. Von Kossa staining and [<sup>45</sup>Ca] assays showed increased mineral deposition in AB vs. LB MSCs. Furthermore, AB MSCs demonstrated an 8 fold higher ALP, almost 2 fold higher Cbfa-1 and a slightly higher osteocalcin mRNA expression. Collectively, these data demonstrate that AB MSCs possess a higher osteogenic potential compared to their LB counterparts.

To examine the direct effects of the potent bisphosphonate (BP) zoledronate (ZA) on MSC differentiation, cells were grown in the presence of various ZA doses. ZA similarly affected AB and LB MSCs, where 10<sup>-5</sup> M ZA induced cell death and decreased ALP staining, while 10<sup>-6</sup>-10<sup>-9</sup> M ZA had no effect. MSC response to ZA does not appear to be the determining factor underlying jaw sensitivity to BRONJ. Surprisingly, AB MSCs expressed lower RANKL mRNA levels and a lower RANKL/OPG ratio than LB MSCs, suggesting a decreased osteoclastogenic potential of the AB marrow.

In summary, we have established a reliable and reproducible model for AB MSC isolation and culture. Our results demonstrate that AB MSCs have an increased osteogenic potential compared to their LB counterparts. Moreover, decreased baseline RANKL expression and RANKL/OPG ratio in AB MSCs, suggest lower osteoclastogenic potential. This model provides a useful tool to investigate molecular mechanisms underlying alveolar bone homeostatic mechanisms.

**The Age-Related Impairment of IGF-I Receptor Activation Is Associated with Changes in Integrin and SHP-2 Expression.** F. Lima<sup>\*1</sup>, P. Kurimoto<sup>\*2</sup>, B. Boudignon<sup>2</sup>, B. P. Halloran<sup>1</sup>. <sup>1</sup>Endocrine Unit, VA Medical Center, University of California San Francisco, San Francisco, CA, USA, <sup>2</sup>Endocrine Unit, VA Medical Center, San Francisco, CA, USA.

The loss of bone with aging is associated with declines in osteoblast number and in the rate of bone formation. These changes are attributed, in part, to alterations in recruitment, proliferation and differentiation of osteoprogenitors. Insulin-like growth factor-I (IGF-I) promotes osteoprogenitor formation, proliferation, osteoblast formation and survival, and stimulates bone formation. With aging, the anabolic response of bone to IGF-I diminishes. We have shown that the loss of responsiveness is linked to disruption of ligand-induced receptor activation. The level of receptor phosphorylation depends on integrin function and tyrosine phosphatase SHP-2 activity. Loss of function of  $\alpha\beta3$  and  $\beta1$  induced by disintegrins and disruption of SHP-2 activity impair receptor activation and downstream IGF-I signaling. To determine the roles that the integrins and SHP-2 play in the age-related loss of IGF-I receptor responsiveness to ligand we measured expression ( $\alpha\beta3$ ,  $\beta1$  and SHP-2) and association (immunoprecipitation) of the receptor with SHP-2 in bone marrow stromal cells (day 10) from 6-week- (young), 6-month (adult), and 24-month (old) mice. With aging IGF-I receptor expression increased while receptor activation, as judged by degree of phosphorylation, decreased. Expression of mRNA and protein for  $\alpha\beta3$  was lower in cells from older animals by 30-50% while  $\beta1$  expression showed little change. SHP2 expression (+40%) and the association of SHP-2 with the IGF-I receptor (+400%) increased with age. The augmented increase in SHP-2 association would be expected to increase the rate of receptor dephosphorylation and reduce the level of receptor activation. The decrease in integrin expression and the increase in both expression and association of SHP-2 with the receptor (which depends on integrin activation), suggest that the age-related loss of IGF-I receptor responsiveness may be linked to changes in integrin function directly and indirectly through regulation of SHP-2.

**Mapping the Interrelationship of the Adipogenic and Osteogenic Lineage with Visual Reporters.** M. S. Kronenberg<sup>\*1</sup>, J. R. Harrison<sup>2</sup>, D. W. Rowe<sup>1</sup>. <sup>1</sup>Reconstructive Sciences, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Craniofacial Sciences, University of Connecticut Health Center, Farmington, CT, USA.

The adipocyte and osteoblast lineages are closely related, but the branch point at which these lineages diverge from a common progenitor remains undefined. Previously we developed a series of GFP reporter mice to map osteogenic maturation from preosteoblast (Col3.6weak) to early osteoblast (Col3.6strong) to mature osteoblast (Col2.3 and OC) to osteocyte (DMP1). Here we describe a strategy to monitor the progression of the adipocyte lineage using the FABP4 (aP2) promoter driving GFP. When bone marrow stromal cells from dual Col3.6-Cyan x aP2-Topaz mice were expanded in  $\alpha$ MEM+FCS for 10 days, 17% of the cells were Cyan-positive by flow cytometry. This increased to 38% by day 17 in untreated cultures, suggesting a default differentiation toward the osteoblast lineage. In contrast, adipogenic treatment at day 10 (ADP; 0.5  $\mu$ M rosiglitazone, 1  $\mu$ M insulin) arrested the Col3.6-Cyan population (18%). Following ADP, aP2-Topaz cells appeared within 48 h, scattered between Col3.6-Cyan positive nodules. These cells developed multiple lipid vacuoles that stained with LipidTOX, a vital fluorescent dye. The aP2-Topaz population (7% of total) was equally comprised of both adipocytes and macrophages, the latter identified by CD11b or F4/80 staining. About 10% of the total macrophage population also expressed Col3.6-Cyan. However, there was no evidence for co-expression of Col3.6-Cyan and aP2-Topaz, even as early as 48 hours post-ADP, suggesting that Col3.6-Cyan cells are not adipose progenitors. To assess trans-differentiation, cultures were developed under either osteogenic or adipogenic conditions, then switched at day 17. At this time, scanning fluorescence microscopy of osteogenic cultures showed multiple Col3.6-Cyan colonies with few aP2-Topaz cells while the ADP cultures showed numerous Topaz-positive clusters with smaller interspersed Cyan colonies. When switched to ADP, osteogenic cultures supported a robust induction of aP2-Topaz cells. Cyan-positive colonies failed to expand further, but persisted and mineralized. In contrast, when the ADP culture was switched to osteogenesis, aP2-Topaz colonies faded while the Cyan-positive nodules expanded in size and mineralized. Under both condition, aP2-Topaz and 3.6-Cyan cells were distinct with no evidence of co-expression or trans-differentiation. These data suggest that our cultures support commitment of osteoblast and adipocyte progenitor cells that require additional signals for terminal differentiation. Development of reporters that focus on genes upstream of the Col3.6 and aP2 activation stages is currently underway.

**BMP/Wnt Antagonists Are Upregulated by Dexamethasone in Osteoblasts and Reversed by Alendronate and PTH: Potential Therapeutic Targets for Glucocorticoid-Induced Osteoporosis.** T. Yamaguchi, K. Hayashi\*, S. Yano, M. Yamauchi, M. Yamamoto\*, T. Sugimoto. Internal Medicine 1, Shimane University Faculty of Medicine, Izumo-shi, Shimane, Japan.

Glucocorticoid-induced osteoporosis (GIO) is known to be caused by suppression of osteoblast-mediated osteogenesis, and to be effectively treated by bisphosphonate and parathyroid hormone (PTH). However, the exact mechanisms by which glucocorticoid suppresses osteoblast function, or alendronate and PTH alleviate GIO are still unclear. We used osteoblastic MC3T3-E1 cells in order to clarify these mechanisms. Dexamethasone (Dex) (10<sup>-7</sup>M) significantly inhibited cell growth and proliferation, which were shown by cell counting and BrdU incorporation, respectively. Dex (10<sup>-9</sup>-10<sup>-7</sup> M) also strongly and dose-dependently suppressed mineralization of the cells. Dex (10<sup>-7</sup> M) reduced mRNA expression of type I collagen and osteocalcin. On the other hand, Dex (10<sup>-7</sup> M) increased mRNA expression of bone morphogenetic protein (BMP) antagonists, follistatin and Dan, and mRNA expression of a Wnt antagonist, secreted frizzled-related protein (sFRP) and a Wnt signal inhibitor, axin-2, while concomitantly decreased mRNA expression of Runx2, downstream of the BMP signal pathway. Moreover, pretreatments with alendronate (10<sup>-8</sup> M) or human PTH (1-34) (10<sup>-8</sup> M) totally or partially antagonized not only the Dex-induced enhancement in mRNA expression of follistatin/Dan and sFRP/axin-2 but also the Dex-induced reduction in Runx2 mRNA expression and mineralization. The present study shows that Dex suppresses the Wnt and BMP pathways by enhancing the expression of BMP and Wnt antagonists, suggesting that glucocorticoids can modify osteoblastic differentiation and activity through these pathways. The effect of bisphosphonate and PTH on the cancellation of these processes may partly explain their anti-GIO pharmacologic efficacy.

**Regulation of Runx2 Function in Osteoblasts by Sex Steroid Receptors.** S. K. Baniwal<sup>1</sup>, O. Khalid<sup>\*2</sup>, D. Purcell<sup>\*2</sup>, N. LeClerc<sup>\*1</sup>, Y. Gabet<sup>\*1</sup>, M. Stallcup<sup>\*2</sup>, G. Coetzee<sup>\*2</sup>, B. Frenkel<sup>1</sup>. <sup>1</sup>Institute of Genetic Medicine at Keck School of Medicine, Los Angeles, CA, USA, <sup>2</sup>Norris Cancer Center, Los Angeles, CA, USA.

Osteoblasts from either gender harbor receptors for estrogens (ER) and androgens (AR) through which sex steroids manifest their protective effects on the skeleton. We hypothesize that these beneficial effects are mediated, at least in part by directly influencing the function of Runx2, a master regulator of osteoblast differentiation. Fluorescence microscopy and co-IP experiments revealed hormone-dependent ER $\alpha$ -Runx2 and AR-Runx2 complexes in the Osteoblastic MC3T3-E1 cells. Runx2 binding was mapped to more than one domain in the ER $\alpha$  and AR by GST pull-down assays. As GST fusion baits, the DNA or ligand binding domains (LBD) of either AR or ER $\alpha$  bound *in vitro* translated Runx2; binding to LBD were correspondingly ligand dependent. Furthermore, deletion analyses of Runx2 indicated multiple contact points (in regions aa 176-303; 408-596) to bind DNA binding domains of ER $\alpha$  and AR.

As a consequence of these interactions the transactivational property of Runx2 was strongly repressed by both ER $\alpha$  and AR in transiently transfected COS7 cells and in MC3T3-E1 cells expressing them endogenously. Interestingly, in MC3T3-E1 cells the repression was only detectable during late developmental stages, when the expression of osteocalcin, a known Runx2 target gene, otherwise peaks. On the other hand, ER $\beta$  did not repress Runx2 activity despite being as active as ER $\alpha$  in transient transactivation assays. Additionally, transcriptionally inactive mutants of ER $\alpha$  and AR fully repressed Runx2 activity, indicating that the repression was not caused by proteins whose expression is ER $\alpha$  or AR dependent. Our results, and the fact that Runx2 over-expression in mice causes high-turnover osteoporosis, suggest that bone loss after sex steroid withdrawal is attributable to the unleashing of otherwise restrained Runx2 activity. Consistent with this notion, a selective estrogen receptor modulator (SERM), tamoxifen partially mimicked E2-mediated Runx2 inhibition, while a selective estrogen receptor down-regulator (SERD) ICI-182780 had the opposite effect, possibly explaining their respective influences on bone. Given the central role of ER $\alpha$ , AR and Runx proteins in osteogenesis and in cancer biology, present investigation will improve our understanding and set the stage for novel drug development to treat osteoporosis and sex hormone-driven cancers.

**The Challenge of Continuous Exogenous Glucocorticoid Administration in Mice.** M. Herrmann<sup>\*1</sup>, H. Henneicke<sup>\*1</sup>, J. Street<sup>\*1</sup>, J. Modzelewski<sup>\*1</sup>, F. Buttgerit<sup>\*2</sup>, C. R. Dunstan<sup>1</sup>, H. Zhou<sup>1</sup>, M. J. Seibel<sup>1</sup>. <sup>1</sup>Bone Research Program, ANZAC Research Institute, Concord, Australia, <sup>2</sup>Charite Universitätsmedizin, Berlin, Germany.

Experimental investigation of the effects of glucocorticosteroids on bone often requires continuous exogenous dosing to animals. However, administering steroid hormones at a constant delivery rate and thus attaining and maintaining elevated hormone levels over time can be a challenge. This study compares the efficacy of three different methods of continuous glucocorticosteroid administration in achieving sufficient and constant drug delivery. Corticosterone (CS) was administered to CD1 Swiss White mice by (i) subcutaneous injection, (ii) subcutaneous implantation of slow-release pellets (Innovative Research, nominally 21 day release), and (iii) subcutaneous implantation of micro-osmotic slow-release pumps (Alzet). Serial blood samples were taken to determine changes in plasma CS and serum osteocalcin (OC) levels; the latter are known to readily decrease in response to supra-physiological levels of CS. A single subcutaneous injection of CS at a dose of 10 mg/kg resulted in peak plasma CS levels of 1800  $\pm$  800 ng/mL after 1h. Plasma CS levels returned to baseline at 4h, while serum OC levels became suppressed within 1h and remained so for  $\geq$  12 h. In contrast, a single subcutaneous injection of 2 mg/kg had no effect on circulating CS or OC levels. The implantation of slow-release pellets (10 mg/pellet) induced a significant rise in circulating CS within 24 h. However, plasma CS levels returned to baseline within 7 days. Serum OC levels fell rapidly on day 1 and remained suppressed for the next 7 days. Replacement of pellets after 7 and 14 days restored elevated CS plasma levels and maintained suppressed serum OC concentrations. Delivery of CS through micro-osmotic pumps had no significantly effect on CS or OC plasma levels, indicating insufficient drug delivery, independent of the carrier solution (ethanol, polyethanolglycol or dimethylsulfoxide). We conclude that slow-release pellets, at a dose of 10 mg/pellet, achieve medium-term CS delivery in mice although replacement is required after 7 days to maintain elevated CS levels. None of the methods tested provided CS delivery at a constant rate and results need to be interpreted against the background of continually varying blood levels.

**Effects of Alendronate and Raloxifene on the RANKL/OPG System in Primary Cultures of Human Osteoblasts.** M. Giner<sup>\*1</sup>, M. J. Rios<sup>\*2</sup>, M. J. Montoya<sup>\*2</sup>, M. A. Vazquez<sup>\*2</sup>, L. Najj<sup>\*1</sup>, R. Pérez-Cano<sup>\*3</sup>. <sup>1</sup>Medical., University Hospital Virgen Macarena, Seville, Spain, <sup>2</sup>Medical., University Seville, Seville, Spain, <sup>3</sup>Medical., University Hospital Virgen Macarena and University Seville, Seville, Spain.

The OPG/RANKL system is considered as one of the effector ways of communication between osteoblasts (OB) and osteoclasts, modulating the process of bone remodeling. Hormones such as estrogens and vitamin D influence bone remodeling by acting through receptors in the OB.

Alendronate (ALE) and Raloxifene (RX) are anti-reabsorptive drugs which have been demonstrated to be efficient in reducing the risk of osteoporotic fractures. It is known that they reduce the activity of bone remodeling and increase BMD. However, it is not known if they can exert a direct effect in hOB on the RANKL/OPG system.

**Objective:** To evaluate the effect of ALE and RX on OPG production as well as OPG and RANKL expression in primary cultures of human osteoblasts (hOB), comparing osteoporotic patients with a control group of patients affected by arthrosis.

**M & M:** Cell cultures of hOB were obtained from bone biopsies of 33 patients who had had an arthroplasty, 17 were due to osteoporotic hip fracture (OP) and 16 due to arthrosis (AR). The levels of OPG secretion (ELISA) and OPG and RANKL expression (RT-PCR) were quantified in basal conditions, and after incubation with ALE (10<sup>-6</sup>M), RX (10<sup>-7</sup>M) or 17-beta estradiol (E) (10<sup>-7</sup>M), for 24h. The statistical significances were determined by Student's *t*-test and ANOVA.

**Results:** OPG secretion in hOB cultures was higher in patients with OP (7.5  $\pm$  5 pmol/L) than those with AR (4.1  $\pm$  3.1 pmol/L), and remained significantly higher in all conditions of the study (*p*<0.05). The treatment with E, ALE or RX did not change the secretion levels of OPG in either of the two groups studied.

The OP group was more sensitive to treatment, in this group we observed an increase in the OPG expression after being treated with RX (34%  $\pm$  18; *p* = 0.038) and E (37%  $\pm$  19; *p* = 0.019) respect basal condition and also we found an increase in the expression of RANKL with RX about 60% (*p* = 0.013) and with ALE about 118% (*p* = 0.05) respect basal condition. No significant differences were found between OP and AR group in the expression of RANKL.

The RANKL/OPG mRNA ratio was higher in OP than AR patients under all conditions studied and become significantly higher after treatment with RX (*p* = 0.02). In the OP group, the ratio RANKL/OPG was increased significantly after treatment with ALE (112%, *p* = 0.048) and after treatment with RX (60%, *p* = 0.017).

**CONCLUSIONS:** These results indicate a direct action of alendronate and raloxifene, to the concentrations used on primary hOB cultures isolated from osteoporotic patients, and said drugs are able to modulate the OPG/RANKL system. This fact can have repercussions in patients' bone remodeling.

**Glucocorticoid-Induced Bone Loss in Mice Is Dependent on Beta 2-adrenergic Signaling.** Y. Ma<sup>\*1</sup>, J. Nyman<sup>2</sup>, F. Elefteriou<sup>1</sup>. <sup>1</sup>Vanderbilt Center for Bone Biology, Dpt of Medicine, Vanderbilt University, Nashville, TN, USA, <sup>2</sup>Vanderbilt Center for Bone Biology, Dpt of Orthopaedics, Vanderbilt University, Nashville, TN, USA.

High dose glucocorticoids used as anti-inflammatory and immunosuppressive agents cause bone loss by promoting osteoclastogenesis and bone resorption and by inhibiting bone formation. Beta 2-adrenergic receptor ( $\beta$ 2AR) stimulation by norepinephrine released by nerve terminals and the non-selective  $\beta$ 1/ $\beta$ 2AR agonist isoproterenol leads to a similar outcome, i.e. increased bone resorption and decreased bone formation. Based on this observation, we hypothesized that glucocorticoid receptor and  $\beta$ 2AR signaling may share a common pathway. Using mouse calvaria primary osteoblasts, we found that dexamethasone induces a significant increase in *Adrb2* mRNA expression,  $\beta$ 2AR protein expression and isoproterenol-induced cAMP accumulation, demonstrating that dexamethasone promotes  $\beta$ 2AR signaling in osteoblasts in vitro. These findings and our previous studies thus led us to hypothesize that glucocorticoids induce bone loss by increasing the responsiveness of osteoblasts to the anti-osteogenic action of the sympathetic nervous system in vivo. If this hypothesis is correct, we reasoned that mice lacking  $\beta$ 2AR should be resistant to glucocorticoid-induced bone loss. Two month-old  $\beta$ 2AR-deficient mice and wildtype (WT) littermates were thus treated with control or prednisolone pellets (2.1 mg/kg/day) for two months and their skeletons analyzed by 3D-microtomography and histomorphometry. In this model of genetic  $\beta$ 2AR blockade, prednisolone treatment had no significant effect on bone mass, while in WT mice it induced a significant decrease in bone volume over tissue volume. These results suggest that glucocorticoid-induced bone loss is dependent on  $\beta$ 2AR signaling, and that pharmacological blockade of  $\beta$ 2AR signaling may have a protective effect on bone mass in patients taking high dose glucocorticoids.

**Cis-Regulatory Motifs and Computationally-Derived Transcriptional Networks Predict Dynamic Motions for Osteocytes.** A. K. Dean<sup>\*1</sup>, W. Yang<sup>2</sup>, M. A. Harris<sup>2</sup>, J. Gluhak-Heinrich<sup>\*3</sup>, L. F. Bonewald<sup>4</sup>, D. W. Rowe<sup>5</sup>, I. Kalajzic<sup>6</sup>, J. Ruan<sup>\*1</sup>, S. E. Harris<sup>2</sup>. <sup>1</sup>Computer Science, University of Texas at San Antonio, San Antonio, TX, USA, <sup>2</sup>Periodontics, University of Texas Health Science Center, San Antonio, TX, USA, <sup>3</sup>Orthodontics, University of Texas Health Science Center, San Antonio, TX, USA, <sup>4</sup>Oral Biology, University of Missouri at Kansas City, Kansas City, MO, USA, <sup>5</sup>University of Connecticut Health Center, Farmington, CT, USA, <sup>6</sup>University of Connecticut Health Center, Farmington, CT, USA.

Osteocytes are thought to regulate load induced new bone formation. Gene expression profiles were obtained from osteocytes purified from calvariae of 5 day mice expressing 8kbDMP1 promoter driving GFP. Comparison of the GFP+ve osteocytes with the GFP-ve cells show osteocytes express genes and transcription factors (TFs) known to control muscle differentiation. Over 12 myosin related genes are enriched in the GFP+ve osteocytes, as well as TFs, myogenin, Mef2c, and Myf5. Enrichment for muscle and contractile related genes had a  $P < 0.05$ . We determined evolutionarily conserved and enriched TF binding sites in 5Kb flanking the transcription start site of 505 genes in the GFP+ve dataset. Within this dataset, 18 TF binding sites were enriched ( $p < 0.005$ ) including muscle related cis-motifs, Ets, Smad3, and FoxO1/4 sites. Using the Q-cut clustering algorithm, 15 gene clusters were formed from 290 of the 505 genes based on presence of enriched TF binding sites. These data were used to construct a gene network of the 290 genes and their cis-regulatory motifs. Many of the muscle and contractile related genes have conserved Mef2 and myogenin/MyoD cis-motifs, as also seen in muscle regulated genes.

As Dentin Matrix Protein1/DMP1 is highly expressed in osteocytes and Sost/sclerostin is a marker for late osteocytes and as both are regulated by mechanical load (Dmp1 is increased and Sost is decreased), a focused analysis of their cis-regulatory 5Kb regions was undertaken. The DMP1 gene has a cluster of 5 CREB binding sites related to PKA signaling. Within 200bp of these CREB sites, clusters of Mef2 and MyoD, Ets and FoxO1/4 cis-elements are located in the DMP1 5Kb region. (Similar conserved Mef2, MyoD and Ets cis-element modules are in Spp1 also.) In the 5kb region of the Sost gene, a muscle related cis-element pattern was also noted. One module at the -170 to 360 region contains 5 Mef2 and 1 MyoD conserved cis-elements, and another at -1650 to -1240 contains 1 Mef2 and 4 myogenin cis-elements. This highly conserved clustering of muscle related cis-regulatory elements in osteocyte selective/specific genes support the concept that a muscle related gene network is important in osteocyte biology and may play a role in contractility and dynamic movements of the osteocyte.

**Analysis of CXCR7-Deficient Mice Reveals CXCR7 Expression in Osteocytes But No Apparent Bone Phenotype.** H. Gerrits<sup>\*</sup>, K. J. Decherer<sup>\*</sup>, N. E. C. Bakker<sup>\*</sup>, D. S. Ingen Schenau<sup>\*</sup>, M. A. M. Krajnc-Franken<sup>\*</sup>, J. A. Gossen<sup>\*</sup>. N.V. Organon, part of Schering-Plough Corporation, Oss, Netherlands.

CXCR7 is a G-protein coupled receptor that was recently de-orphanized and shown to have SDF1 and I-TAC as high affinity ligands. Microarray analysis of BMP2 induced osteogenesis in C2C12 cells revealed CXCR7 upregulation during osteoblast differentiation. Here we describe the characterization of CXCR7-deficient mice that were generated to further investigate the function of this receptor in vivo. Expression analysis using a LacZ reporter knockin revealed that postnatally *Cxcr7* was specifically expressed in osteocytes of the bone, cardiomyocytes, vascular endothelial cells of the lung and heart, and in the cerebral cortex. Adult tissues revealed high expression in osteocytes and cardiomyocytes. The observation that 70% of the *Cxcr7*<sup>-/-</sup> mice died in the first week after birth coincides with expression of *Cxcr7* in vascular endothelial cells and in cardiomyocytes. An important role of CXCR7 in the cardiovascular system was further supported by the observation that hearts of the *Cxcr7*<sup>-/-</sup> mice were enlarged, showed myocardial degeneration and fibrosis of postnatal origin, and hyperplasia of embryonic origin. Despite high expression in osteocytes no apparent bone phenotype was observed, neither in combination with ovariectomy nor orchidectomy. Although it can not be excluded that the function of CXCR7 in osteocytes is prone to redundancy or masked by compensatory mechanisms, our data indicate that CXCR7 does not seem to play an important role in bone.

**Disclosures:** H. Gerrits, None.

**SDF-1 is Expressed in Osteocytes and Periosteal Cells in Response to Mechanical Loading.** A. B. Castillo<sup>1</sup>, P. Leucht<sup>\*2</sup>, J. Tang<sup>\*3</sup>, J. A. Helms<sup>\*2</sup>, C. R. Jacobs<sup>1</sup>. <sup>1</sup>Mechanical Engineering, Stanford University, Stanford, CA, USA, <sup>2</sup>Department of Surgery, Stanford University, Stanford, CA, USA, <sup>3</sup>Bone and Joint Research and Rehabilitation Center, Veterans Affairs Medical Center, Palo Alto, CA, USA.

Bone's response to mechanical loading involves activation of bone-lining cells at the periosteal and endosteal surfaces and recruitment of multipotent mesenchymal stem cells (MSCs) in the marrow. The mechanisms by which bone cell progenitors sense and respond to mechanical loading remain largely unknown. Stromal cell-derived factor-1 (SDF-1) and its receptor, CXCR4, are important signaling molecules in MSC survival, migration and proliferation, and have been shown to play important roles in hematopoiesis, angiogenesis and stem cell mobilization. SDF-1 is a soluble factor produced by stromal cells, osteocytes and osteoblasts. CXCR4 is a seven-pass membrane bound receptor expressed in MSCs, hematopoietic stem cells, osteoblasts and osteoclasts. SDF-1 may play a role in recruitment of progenitor cells to regions of active bone remodeling in response to mechanical loading. Right ulnae in 20-wk-old C57BL/6 mice were subjected to compressive axial loading (120 cycles, 2 Hz, 3N) while left ulnae served as internal controls. Animals were sacrificed 24h post-loading, and ulnae were processed for in situ hybridization using DIG-labeled SDF-1 and CXCR4 antisense RNA probes. In addition, multipotent C3H10T1/2 cells were grown in monolayer and subjected to either oscillatory fluid flow (OFF) (10 dynes/cm<sup>2</sup>, 1 Hz) or static conditions for either 1h or 3h, and SDF-1 and CXCR4 message was quantified by qRT-PCR. In vivo mechanical loading resulted in more broadly expressed SDF-1 in the periosteum and cortical osteocytes (Fig. 1). Three hours of OFF resulted in a 20-fold increase in CXCR4 mRNA expression ( $p = 0.05$ ) in C3H10T1/2 cells by one-way ANOVA; SDF-1 mRNA expression was not significantly affected after 1h and 3h of OFF. Taken together, these data suggest that mechanical loading of bone can result in activation of the SDF-1/CXCR4 pathway, which may ultimately play a role in progenitor recruitment.

Fig. 1. In situ hybridization analysis of SDF-1 in 20-wk-old mouse ulnar cortical bone at midshaft. (A) Non-loaded control ulna showing cortical osteocytes (arrow) and the periosteal surface (dotted line). (B) Loaded ulna showing SDF-1 positive cortical osteocytes (arrow) and prominent expression in periosteal cells (purple).

**Molecular Phenotyping of Osteoblastic and Osteocytic Cell Fractions Isolated from Mouse Calvaria.** G. Guiglia\*, I. Kramer\*, M. Kneissel, C. Halleux. Novartis Institutes for BioMedical Research, Basel, Switzerland.

Osteocytes are the terminally differentiated cells of the osteoblastic lineage embedded within the mineralized bone matrix and interconnected with each other and with cells on the bone surface via an extensive canalicular network. They have been identified as critical regulators of mineral homeostasis and are thought to be the key players in mechanotransduction. Furthermore they appear to have a central role in the mediation of bone anabolism, since they secrete the potent bone formation inhibitor *Sost*. Yet, their cellular and molecular functions are poorly characterized because of the technical hurdles to isolate these cells. In the present study, we aimed at establishing a protocol for isolation of mouse primary osteocytes. To this end calvariae were isolated from 6 day-old C57BL/6J pups and subjected to sequential digestion with 0.2% collagenase type IV and 5 mM EDTA. Seven fractions were obtained and the cell number was determined in each fraction. The cell number decreased from  $1-2 \times 10^6$  cells in fraction 1 and 2 and  $3.5 \times 10^6$  cells in fraction 3 to  $2-3 \times 10^5$  cells in fraction 5 and 6. Based on the relative cell size observed during cell counting, different types of cells were found to be enriched in different digestion fractions. Fraction 1 consisted mainly of cells with a relatively small cell size, potentially fibroblastic cells, whereas larger-sized cells, putative osteoblastic and osteocytic cells, were present in later fractions. Total RNA was isolated from each fraction using TRIzol reagent (Invitrogen). Real-time PCR was performed to quantitatively determine mRNA levels for selected osteoblastic and osteocytic marker genes. The osteoblastic marker genes *bone sialoprotein*, *osteocalcin* and *procollagen type I* were highest in fraction 2 with 9-, 5-, and 2-fold increase in expression compared to fraction 1, respectively. Expression of these osteoblastic markers gradually decreased in further fractions and was at least 2-fold higher in fraction 2 than in fraction 5. Expression of the osteocytic markers *Dmp1*, *Mepe*, *PheX* and *Sost* peaked in fraction 5 with 20-, 14-, 12- and 16-fold increase in expression compared to fraction 1, respectively. In summary, different bone cell types can be isolated from mouse calvariae by sequential digestion. Cell size and osteoblast/osteocyte marker gene expression suggest that fraction 2 is highly osteoblast and fraction 5 osteocyte enriched. This simple isolation protocol allows hence for further studies of the differential gene expression profile of osteoblastic and osteocytic cells.

**Estrogen Deficiency Alters the Localized Material Properties of the Peri-Lacunar Bone Matrix in Old Rats.** D. P. Nicoletta<sup>1</sup>, W. Yao<sup>2</sup>, N. Lane<sup>2</sup>. <sup>1</sup>Materials Engineering, Southwest Research Institute, San Antonio, TX, USA, <sup>2</sup>Aging Center, Medicine and Rheumatology, University of California at Davis Medical Center, Sacramento, CA, USA.

Loading of the skeleton increases bone mass and decreases bone turnover while unloading increases bone turnover and reduces bone mass. Also, estrogen deficiency and aging increases the activation of new remodeling units, resulting in a reduction in trabecular architecture and bone mass such that bone fractures with very little trauma. Osteocytes are ideally situated to sense mechanical strain (or a lack of strain) and to translate mechanical signals into biochemical signals that regulate bone turnover. Macroscopic bone strains are amplified at the level of the osteocyte due to the strain concentrating effect of the osteocyte lacuna and the surrounding extracellular matrix [1]. The osteocyte can modify its local peri-lacunar matrix environment as a function of hormone treatment [2] and skeletal loading [3]. We have shown that the amount of mechanical strain acting on osteocytes is a function of the properties of the peri-lacunar bone matrix; decreased peri-lacunar bone matrix modulus results in increased lacuna strain while an increase in peri-lacunar bone matrix modulus results in a decrease in lacuna strain [4]. We measured the the peri-lacunar bone matrix elastic modulus associated with osteocytes within trabecular bone from 10 month old OVXed rats (110 days post-ovx, n=3) and sham-operated controls (n=3) using a nano-indenter (Triboscope, Hysitron, Inc.) operating in the modulus mapping mode (3 lacuna/rat). Using this method, an imaged derived from the mechanical properties of the bone matrix surface was generated and microstructural spatial differences in bone tissue elastic modulus were quantified in an ROI of 20 microns around the osteocyte lacunae. Elastic modulus in OVXed rats 2-3 microns from the osteocyte lacuna ( $36.0 \pm 2.8$  GPa) was increased by 35% compared to matrix more than 10 microns from the lacunae ( $26.7 \pm 1.7$  GPa) ( $p < 0.05$ ). There was no increase in the peri-lacunar bone tissue stiffness in sham operated animals ( $24.2 \pm 3.02$  vs.  $23.8 \pm 3.75$  GPa). Based on our previous work [4], this suggests that this stiff peri-lacunar bone tissue attenuates the strain signal acting on embedded osteocytes. Thus, given equal skeletal forces, osteocytes in the OVXed animals would experience less mechanical strain than osteocytes in sham operated animals, which may lead to increased bone turnover and decreased bone mass. Additional studies are needed to determine if the mechanical strain at the osteocyte is altered after treatment with bone active agents. 1. Nicoletta et al., J. Biomech., 39:9, 2006. 2. **Kinase Activation and Osteocyte Survival Promoted by Mechanical Stimulation Require LRP5/6 Signaling and Beta-catenin Accumulation, but not beta-catenin/TCF-Dependent Transcription.** M. Martin-Millan, L. I. Plotkin, K. Vyas\*, G. Frera\*, A. R. Gortazar\*, M. Almeida, S. C. Manolagas, T. M. Bellido. Department of Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Osteocyte viability is a critical determinant of bone strength and it is promoted by both mechanical stimulation and activation of the Wnt signaling pathway. Thus mechanical stimulation inhibits apoptosis of osteocytes *in vitro*. Conversely, skeletal unloading increases osteocyte apoptosis in mice. Moreover, genetic models of increased Wnt signaling (mice deficient in the Wnt antagonist secreted frizzled related protein-1 or expressing the high bone mass LRP5 mutant G171V) exhibit decreased osteocyte apoptosis; and Wnts inhibit osteoblastic cell apoptosis *in vitro*. Furthermore, activation of T-cell factor (TCF), the main transcription factor induced by Wnt/beta-catenin, in osteocytes is one of the early responses of bone to loading. Based on evidence that both mechanical stimulation and activation of the Wnt signaling pathway promote osteocyte survival by a mechanism that requires activation of ERKs, we explored here the possibility that Wnt/beta-catenin signaling is required for the transduction of mechanical forces into survival kinase signaling and anti-apoptosis in osteocytic cells. Biaxial stretching of MLO-Y4 cells at 5% elongation for 10 min (Flexercell Strain Unit FX4000) induced activation and nuclear accumulation of ERKs and prevented glucocorticoid-induced apoptosis. Stretching also induced phosphorylation, and thereby inactivation, of GSK3beta and the consequent accumulation of beta-catenin, as detected by Western blot analysis. Furthermore, overexpression of DKK1, an antagonist that blocks Wnt activation by binding to LRP5/6 Wnt co-receptors, or overexpression of axin2, a molecule that induces beta-catenin proteasomal degradation, abolished ERK nuclear translocation as well as the anti-apoptotic effect of stretching. Remarkably, however, and in contrast to Wnt-induced anti-apoptosis, overexpression of a dominant negative mutant of TCF did not alter the response to mechanical stimulation. We conclude that LRP5/6 activation and beta-catenin accumulation are essential components of the mechanotransduction apparatus that leads to ERK activation and osteocyte survival, albeit beta-catenin/TCF-mediated transcription is not required.

**Low Intensity Pulsed Ultrasound Synergistically Modulates SOST and OPG/RANKL Ratio in MLO-Y4 Osteocytes *in vitro*.** D. Liu. Orthodontics, Marquette University, Milwaukee, WI, USA.

Low intensity pulsed ultrasound (LIPUS) has been applied to enhance angiogenesis, growth and healing of bone, however its mechanisms are still unclear, especially the effect of LIPUS on osteocytes - the most abundant cells in bone. Recent studies show that osteocytes exclusively express sclerostin (SOST) protein negatively regulating bone formation, as well as produce OPG and RANKL modulating bone remodeling. We hypothesize that LIPUS induces anabolic responses in osteocytes, in turn modulates the remodeling of bone. To testify this, MLO-Y4 osteocytes were seeded on Ø35 mm Petri dishes. Upon 80% confluence, the cells were serum starved for 24 hours, then subjected to LIPUS (30mW/cm<sup>2</sup>, 1.5MHz frequency, 1kHz repetition) for either 10 minutes to test ERK1/2 activation, or 20 minutes followed by 6 hours of post-incubation to examine protein production of cyclooxygenase-2 (COX-2), sclerostin (SOST), osteoprotegerin (OPG) and receptor activator of NF- $\kappa$ B ligand (RANKL). The "LIPUS+cells" system was maintained at 37°C with 95% air-5% CO<sub>2</sub>. Controls were set under identical conditions without LIPUS application. After LIPUS application, the cells were lysed, 50 microgram of cell lysates were resolved through 5-10% SDS-PAGE, immunoblotted with the 1st antibodies against pERK1/2, ERK1/2; COX-2, SOST, OPG and RANKL. As results, 10 minutes of exposure to LIPUS significantly activated ERK1/2 (n=6, p<0.05). When the cells were subjected to LIPUS for 20 minutes followed by a post-incubation of 6 hours, COX-2 production was slightly increased but not significantly (n=4, p>0.05). SOST protein was significantly increased (n=3, p<0.05), while the OPG/RANKL ratio was significantly decreased (n=3, p<0.05). In contrast to our previous data showing that fluid shear stress reduced the level of RANKL in MLO-Y4 cells, the increased SOST and decreased OPG/RANKL ratio exhibited a catabolic (not anabolic as we expected) change in MLO-Y4 cells when subjected to LIPUS. It could be possible that LIPUS's effects in enhancing bone formation as a long process as in bone healing may be through a temporary "resorptive phase" as its initial step. Our data also suggest that the nature of action of LIPUS exerting on osteocytes is different from that of fluid shear stress; ERK1/2 activation may possibly play a common role leading to different down-stream events; the synergistic changes of SOST and OPG/RANKL ratio lead us to speculate a possible cross-talk between SOST modulation and OPG/RANKL changes in osteocytes during bone remodeling.

**Osteocytic Perilacunar Remodeling as a Significant Source of Calcium During Lactation.** H. Qing<sup>\*1</sup>, L. Ardeshipour<sup>\*2</sup>, V. Dusevich<sup>\*1</sup>, M. Dallas<sup>\*1</sup>, J. J. Wysolmerski<sup>\*2</sup>, L. F. Bonewald<sup>1</sup>. <sup>1</sup>Oral Biology UMKC Dental School, University of Missouri-Kansas City, Kansas City, MO, USA, <sup>2</sup>Yale University School of Medicine, New Haven, CT, USA.

Osteoclastic resorption of bone is thought to be the major source of calcium for milk production. Maternal bone mineral density is reduced by 30% during lactation, but this cannot be accounted for by reduced bone volume, which only declines by 20-25%. Furthermore, while treatment of lactating mice with pamidronate effectively prevents the increase in osteoclast activity, it only blunts the decline in BMD by 60%. Since the osteocyte lacuno-canalicular surface area is extensive, we hypothesized that this internal bone surface area could be a source of additional calcium during lactation. Twelve-wk-old, CD1 mice were allowed to become pregnant, deliver and lactate. Pups were removed to induce the weaning response on the 12th day of lactation. Mice were sacrificed on the 12th day of lactation (n=5) or the 7th day after weaning (n=6). Age-matched, virgin CD1 mice were used as controls (n=4). Tibiae were embedded in methyl-methacrylate, sectioned, polished, and imaged using backscatter SEM. Osteocyte lacunar area,  $\mu\text{m}^2$ , significantly increased ( $p<0.05$ ) in cortical bone during lactation ( $42.93\pm2.35^*$ ) as compared to virgin ( $38.67\pm1.23$ ) or 7 days post-lactation ( $38.36\pm3.52$ ). A similar increase was seen in trabecular bone during lactation. The same samples were acid etched and SEM was used to measure canalicular diameter. A significant increase in canalicular width was observed in lactating animals in cortical bone (virgin  $0.26\pm0.04\ \mu\text{m}$ , lactating  $0.31\pm0.04^*$ ,  $p<0.054$ ) and in trabecular bone (virgin  $0.24\pm0.03$ , lactating  $0.36\pm0.02^*$ ;  $p<0.001$ ). These data demonstrate a reversible change in lacunar and canalicular size associated with the reproductive cycle, suggesting that the osteocyte can remove mineral from its perilacunar and pericanalicular matrix during lactation. Consistent with this idea, osteocytes in bone from lactating mice expressed significant acid phosphatase activity, which was rapidly lost after weaning. This study shows that osteocytes can remove and replace their perilacunar matrix and may play a role in providing calcium to the breast for milk synthesis during lactation.

**Primary Human Bone Marrow Adipocytes Stimulate Osteoclast Differentiation.** H. Goto<sup>\*</sup>, M. Osaki<sup>\*</sup>, K. Sakamoto<sup>\*</sup>, A. Hozumi<sup>\*</sup>, H. Shindo<sup>\*</sup>. Orthopaedic Surgery, Nagasaki University School of Medicine, Nagasaki, Japan.

[Introduction] In late years it becomes clear that the subcutaneous fat and the visceral fat are not a simple spacer and energy storehouse and secrete physiologically active substance named adipokines, which is associated with hypertension or metabolic syndrome. Also, adipokines act on osteoclasts and osteoblasts and are associated with bone metabolism. On the other hand, the functions of marrow fat cells, existing in large quantities in the marrow which is a choke space, are not well known. We examined the relations between human marrow adipocytes and the bone metabolism.

[Materials and methods] We divided marrow fat cells by collagenase treatment from marrow liquid obtained at operations of total hip arthroplasty and conducted primary adipocytes culture. We examined gene expressions of the RANKL, OPG and M-CSF in human adipocytes by using Real Time RT-PCR. We also examined the gene expression changes after 24 hours treated by glucocorticoids, TNF- $\alpha$  and VitD3. We conducted co-culture of marrow adipocytes and human osteoclast progenitor cells, and examined TRAP staining.

[Results] Primary human adipocytes expressed RANKL, OPG, and M-CSF genes. The RANKL/OPG ratio was elevated with time course. The RANKL gene expressions significantly increased by glucocorticoids, TNF- $\alpha$  and VitD3 treatments. In co-culture system with marrow adipocytes and human osteoclast progenitor cells, the onset of the TRAP positive human osteoclast progenitor cells which were poly-nuclear and had ability of bone resorption, by glucocorticoids, TNF- $\alpha$  and VitD3 treatments.

[Discussion] RANKL is essential molecules for the osteoclast differentiation which is presented by osteoblasts and marrow stem cells. In this study, we demonstrated that the expressions of RANKL gene and are increases by the stimulation such as activated VitD3 or PTH. Similar to osteoblasts and other RANKL expressing cells, the human bone marrow adipocytes have ability to promote the osteoclast differentiation and activities. These results demonstrate the importance of human bone marrow adipocytes in the bone metabolism and possible participation in bone resorption induced by steroid administration, rheumatoid arthritis, and other disorders.

**Recombinant Mouse M-CSF Receptor C-fms Inhibits TNF- $\alpha$ -induced Osteoclastogenesis.** H. Kitaura, Y. Fujimura<sup>\*</sup>, M. Yoshimatsu, T. Eguchi<sup>\*</sup>, H. Kohara, Y. Morita<sup>\*</sup>, N. Yoshida<sup>\*</sup>. Division of Orthodontics and Dentofacial Orthopedics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

It is reported that TNF- $\alpha$  can induce osteoclastogenesis and has a pivotal role in many forms of inflammatory osteolysis. Understanding the mechanism by which TNF- $\alpha$  induces osteoclastogenesis is pivotal to the design of drugs to prevent such disorders. M-CSF is also essential for osteoclastogenesis. We have reported that administration of the M-CSF receptor c-fms antibody completely blocked osteoclastogenesis and bone erosion induced by TNF- $\alpha$  administration or inflammatory arthritis. The results suggested that anti-c-fms antibody is a candidate for an inhibitor of osteolysis at inflammatory sites. However, there is the problem that the cost of this antibody is high for most therapies. This study aimed to analyze the effect of recombinant mouse c-fms on TNF- $\alpha$ -induced osteoclastogenesis. Whole bone marrow cells were collected from C57/BL6 mice. Bone marrow macrophages generated from whole bone marrow cells were cultured in a medium containing M-CSF for 3 days. Total cDNA was generated from M-CSF-stimulated bone marrow macrophages. The c-fms gene was taken from total cDNA macrophages by PCR. The expression vector of c-fms was constructed from the c-fms gene. Recombinant of c-fms was expressed in *E. coli* and purified. Whole bone marrow cells collected from C57/BL6 mice were cultured in a medium containing M-CSF and TNF- $\alpha$  with or without recombinant c-fms. When bone marrow cells were cultured in the medium without recombinant c-fms, osteoclasts were formed. On the other hand, when they were cultured with recombinant c-fms, the number of osteoclast was less than in the culture without recombinant c-fms. The results suggested recombinant c-fms could inhibit TNF- $\alpha$ -induced osteoclastogenesis. In summary, we generated murine recombinant c-fms and recombinant c-fms had the ability to block osteoclast generated by TNF- $\alpha$ . It was postulated that recombinant c-fms was a candidate for a neutralizing therapy of osteolysis related to TNF- $\alpha$  at inflammatory sites.

**Multi-Walled Carbon Nanotubes Inhibit Osteoclast Differentiation by Inhibiting Nuclear Translocation of NFATc1.** N. Narita<sup>\*1</sup>, Y. Kobayashi<sup>\*2</sup>, H. Nakamura<sup>2</sup>, K. Maeda<sup>\*2</sup>, T. Mizoguchi<sup>\*2</sup>, H. Kato<sup>\*1</sup>, H. Ozawa<sup>\*2</sup>, N. Udagawa<sup>2</sup>, M. Endo<sup>\*3</sup>, N. Takahashi<sup>2</sup>, N. Saito<sup>\*4</sup>. <sup>1</sup>Department of Orthopaedic surgery, Shinshu University, Matsumoto, Japan, <sup>2</sup>Institute of Oral Science, Department of Biochemistry, Department of Oral Histology, Matsumoto Dental University, Shiojiri, Japan, <sup>3</sup>Faculty of Engineering, Shinshu University, Nagano, Japan, <sup>4</sup>Department of Applied Physical Therapy, Shinshu University, Matsumoto, Japan.

Attention has been focused on carbon nanotubes (CNTs) as new biocompatible materials for bone substitutes due to their high mechanical strength. We previously showed that implanted multi-walled CNTs (MWCNTs) exhibited high compatibility with bone tissues and accelerated bone formation. However, implanted MWCNTs never induced bone resorption in vivo. Here, we examined effects of MWCNTs on differentiation of osteoclasts in culture, in comparison with those of carbon black (CB). (1) MWCNTs but not CB added at 5  $\mu\text{g}/\text{ml}$  to the coculture of mouse osteoblasts and bone marrow cells strongly inhibited osteoclast formation induced by  $1\alpha,25(\text{OH})_2\text{D}_3$ . Expression of RANKL, OPG and M-CSF mRNAs in osteoblasts was not affected by MWCNTs or CB, suggesting that MWCNTs act on osteoclast precursors. (2) Unexpectedly, MWCNTs failed to inhibit osteoclast formation in mouse bone marrow macrophage (BMM $\phi$ ) culture, when added simultaneously with RANKL. However, pretreatment of BMM $\phi$  with MWCNTs but not CB for 24 hours strongly inhibited RANKL-induced their differentiation into osteoclasts. Electron microscopic analysis confirmed that MWCNTs and CB were similarly incorporated into BMM $\phi$  during the pre-incubation for 24 hours. These results suggest that MWCNTs incorporated into BMM $\phi$  specifically inhibit their differentiation into osteoclasts. (3) Neither MWCNTs nor CB suppressed RANKL-induced degradation of I $\kappa$ B $\alpha$ , phosphorylation of p38 MAPK and induction of NFATc1 in BMM $\phi$ . RANKL also stimulated nuclear translocation of NFATc1 in BMM $\phi$ . MWCNTs but not CB strongly suppressed the RANKL-induced nuclear translocation of NFATc1. Treatment of BMM $\phi$  with RANKL similarly induced nuclear translocation of NF- $\kappa$ B p65, which was not affected by MWCNTs at all. These results suggest that CNTs act as a specific modulator of a certain transcription factor such as NFATc1. In conclusion, our experiments provide a new inhibitory mechanism of CNTs for bone resorption when implanted into bone. MWCNTs but not CB possess many wholes in their structures, and may specifically trap NFATc1 in the cytosol of osteoclast precursors.

**Modeled Microgravity Sensitizes Osteoclast Precursors to RANKL Mediated Osteoclastogenesis by Increasing DAP12.** R. Saxena<sup>\*1</sup>, G. Pan<sup>\*2</sup>, J. M. McDonald<sup>2</sup>. <sup>1</sup>Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Mechanical forces are essential to maintain skeletal integrity, and microgravity exposure leads to bone loss. It has been well documented that the microgravity induced bone loss is due to both a decrease in osteoblastic bone formation and an increase in the osteoclastic bone resorption. However, the underlying molecular mechanisms leading to these changes remain to be fully elucidated especially the mechanisms responsible for osteoclast-mediated bone loss. Due to the infrequency of spaceflights and payload constraints, establishing *in vitro* systems that mimic microgravity conditions becomes necessary for understanding the microgravity induced bone loss. Our lab has been successful in establishing a simulated microgravity (modeled microgravity, MMG) system to study the changes induced in osteoclast precursors and to determine the molecular mechanisms responsible for increased osteoclastogenesis. We have observed that 24h of MMG incubation of RAW264.7 cells and mouse bone marrow macrophages leads to activation of ERK, p38 and c-fos. MMG was not able to induce osteoclastogenesis on its own in osteoclast precursors, however, when MMG-incubated cells were subsequently stimulated with 10ng/ml RANKL and/or M-CSF in gravity for 3-4 days, the formation of TRAP positive multinucleated osteoclasts was enhanced as compared to those formed in gravity. Specifically the number of very large osteoclasts with greater than 30 nuclei was increased nearly three fold in the osteoclasts formed from mouse bone marrow macrophages. This was accompanied by a RANKL mediated upregulation of osteoclast marker genes- TRAP and Cathepsin K. Although MMG did not induce the mRNA expression of RANK in the precursor cells, it was found that DAP12 (an ITAM-motif bearing adaptor molecule) mRNA expression was increased two fold as a result of 24h incubation in MMG. It is known that DAP12 plays a key role in the formation of multinucleated osteoclasts. Thus, MMG increases the sensitivity of osteoclast precursor cells to RANKL treatment possibly via an increase in DAP12 expression leading to increased osteoclastogenesis that contributes to bone loss.

**Duffy Antigen Receptor for Chemokines (DARC) Regulates Osteoclast Differentiation via Modulating Chemokine Effects on Migration/Fusion of Osteoclast Precursors.** B. Edderkaoui<sup>\*1</sup>, N. Popa<sup>\*2</sup>, S. Mohan<sup>1</sup>. <sup>1</sup>JLP VAMC and Loma Linda Univ, Loma Linda, CA, USA, <sup>2</sup>JLP VAMC, Loma Linda, CA, USA.

We recently showed that variations in DARC gene, a BMD QTL gene in chromosome 1, contribute to peak BMD differences between high BMD CAST and low BMD C57BL/6 strains by influencing endosteal bone resorption. Bone marrow cells (BMCs) isolated from DARC-knockout mice showed significant reduction in numbers of TRAP-positive multinucleated cells (MNCs) after treatment with RANKL and M-CSF compared to cells isolated from wild type mice. Furthermore, neutralizing DARC with its specific antibody (Ab) altered the formation TRAP-positive MNCs. To investigate the mechanism by which DARC regulates osteoclast formation, we proposed, based on the known function of DARC in regulating chemokine mediated neutrophils trafficking, the hypothesis that DARC interacts with chemokines to regulate trafficking and subsequent fusion of osteoclast precursor cells. We found that neutralization of DARC action with DARC-Ab caused a >40% reduction (P<0.01) in the number of nuclei per osteoclast in differentiating cultures of M-CSF-dependent BMCs and RAW264.7 cells compared to IgG control. Furthermore, MCP-1 and RANTES, ligands for DARC protein, have been shown to be involved in the recruitment and fusion of osteoclast precursors and, thereby facilitate RANKL-induced osteoclastogenesis. We, therefore, determined the consequence of neutralizing DARC action on the migration of RAW264.7 cells towards chemokines. We found that RANTES and MIP-1 induced chemotaxis of RAW264.7 cells using an established transmigration chamber assay which was reduced by >50% (P<0.01) upon treatment with DARC-Ab compared to control IgG. Based on our finding that the migration of Raw264.7 cells towards chemokines is dependent on DARC, we next determined if neutralization of DARC action resulted in decreased expression of cell fusion and differentiation markers. Accordingly, we found that treatment of Raw264.7 cells with RANKL led to a significant increase in the expression of CD47 and DC-Stamp, while neutralization of DARC protein led to 79 and 92% reduction (P<0.01) in the expression levels of CD47 and DC-Stamp, respectively. To determine the molecular pathway by which DARC-chemokine interaction regulates chemotaxis, we tested if MAPK pathway is activated in RAW264.7 cells based on the findings that addition of MEK inhibitor to peripheral blood mononuclear cells inhibited their fusion. We found that chemokine induced ERK1/2 phosphorylation was reduced in RAW264.7 cells upon treatment with DARC-Ab. In conclusion, our findings provide the first experimental evidence that the DARC-chemokine interaction is involved in regulating trafficking and fusion of osteoclast precursors.

**Brain-type Creatine Kinase Is Required for RANKL-induced Osteoclastogenesis.** H. Wu<sup>\*1</sup>, J. Chen<sup>\*1</sup>, M. Wang<sup>\*1</sup>, Y. Chen<sup>2</sup>. <sup>1</sup>Pediatric Dentistry, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

We compared the protein expression profile between mature osteoclasts derived from primary bone marrow macrophages (BMMs) in the presence of RANKL and M-CSF with the osteoclast precursors in the presence of M-CSF and identified a 43kDa protein that is highly expressed in the mature osteoclasts. This molecule was further identified as brain-type creatine kinase (CKb) by Mass Spectrometry. The presence of CKb in patient sera is a hallmark of osteopetrosis among sclerosing bone disorders. Elevated serum acid phosphatase activity and the appearance of circulating CKb can be used to indicate osteoclast failure. However it is unknown how the CKb is associated with osteoclast function. We found that the expression of CKb mRNA was increased by 40 fold in mature osteoclasts as determined by quantitative real-time PCR. Western blot analysis confirmed an increase in CKb proteins. By contrast, other isoenzymes of creatine kinases were not detected during osteoclastogenesis, suggesting RANKL and M-CSF uniquely induced the production of CKb during osteoclastogenesis. Cyclocreatine, a creatine analog and an inhibitor of CKb, at non-toxic concentrations, inhibited osteoclastogenesis in both BMMs and RAW cells. Furthermore, knockdown of ckb by ckb-specific shRNA delivered with lentivirus vectors inhibited osteoclastogenesis as well, whereas non-specific shRNA control did not affect osteoclastogenesis. Western blot analysis revealed that inhibition of Ckb function by CCr inhibitor or knockdown Ckb by shRNA severely impaired RANKL-mediated activation of JNK and ERK, but not NFkB, p38-MAPK. Ckb knockdown significantly inhibited NFATc1 expression and reduced intracellular calcium mobilization, concurrently with decreased ATP level and increased ADP/ATP ratio in response to RANKL. Interestingly CKb knockdown did not affect the small GTPase RhoA function. Taken together, we conclude that the CKb is required for osteoclastogenesis via its influence on Calcium-NFATc1 axis and ATP production. Further characterization of molecular mechanism involved in CKb-regulated osteoclastogenesis may shed light on new therapeutic target for osteoclast function. **All-trans-retinoic Acid (Vitamin A) Increases Expression of MafB and Inhibits Osteoclast Formation by Interfering with Differentiation of Osteoclast Progenitor Cells.** E. Persson<sup>1</sup>, H. H. Conaway<sup>2</sup>, M. Halén<sup>\*1</sup>, S. Granholm<sup>\*1</sup>, O. Svensson<sup>3</sup>, U. Pettersson<sup>4</sup>, A. Lie<sup>\*1</sup>, U. H. Lerner<sup>1</sup>. <sup>1</sup>Dept of Oral Cell Biology, Umea University, UMEÅ, Sweden, <sup>2</sup>Dept of Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>3</sup>Dept of Orthopedic Surgery, Umea University, Umea, Sweden, <sup>4</sup>Dept of Clinical Pharmacology, Umea University, Umea, Sweden.

Effects of vitamin A (retinol) derivatives are mediated by two families of nuclear receptors, the retinoic acid receptors (RARs) and the retinoid X receptors (RXRs). Each receptor family is made up of three isoforms ( $\alpha$ ,  $\beta$  and  $\gamma$ ), produced by separate genes. An isomer of retinoic acid, all-trans-retinoic acid (ATRA), is thought to mediate the physiological retinol signal by binding RAR partners of RAR/RXR heterodimers. Activated RAR/RXR heterodimers function as transcription factors, activating specific retinoic acid response elements (RAREs) for transcriptional regulation. In the present study, the effects by ATRA on osteoclast formation have been assessed in cultures of crude mouse bone marrow cells (BMC), mouse spleen cells and mouse bone marrow macrophages (BMM). ATRA inhibited osteoclast formation in 1,25(OH)<sub>2</sub>-vitamin D<sub>3</sub> and PTH stimulated BMC cultures without affecting D<sub>3</sub> or PTH induced RANKL mRNA. ATRA also inhibited osteoclast formation in RANKL stimulated spleen cell cultures and in RANKL stimulated BMM. Inhibition was observed at and above 0.1 nM of ATRA with no signs of cytotoxicity (studies on morphology, MTT) or increased apoptosis (expression of Bax, Bcl-2). Pit formation on ivory slices caused by RANKL stimulated BMM was abolished by ATRA. Inhibition of osteoclast formation was associated with decreased mRNA expression of calcitonin receptor, cathepsin K and TRAP. In BMM, ATRA inhibited RANKL induced increase of c-Fos mRNA and protein and Fra-2 mRNA, without affecting Fra-1, JunB or JunD mRNA and slightly increasing c-Jun mRNA. The increase of NFAT2 mRNA and protein caused by RANKL in BMM was abolished by ATRA. In contrast, ATRA did not affect NF- $\kappa$ B activity. Most interestingly, ATRA reversed RANKL induced decrease of MafB, a recently described negative regulator of osteoclastogenesis. Most of the BMM expressed RAR $\alpha$  and RAR $\beta$  at both mRNA and protein level, but very few expressed RAR $\gamma$ . These data show that vitamin A has the capacity to inhibit the differentiation of early osteoclast progenitor cells, an effect involving both decreased expression of the pro-osteoclastogenic transcription factors c-Fos and NFAT2, as well as increased expression of the anti-osteoclastogenic factor MafB.

**Isoform-Specific Expression of Peroxisome Proliferator-Activated Receptors (PPARs) and Gene Regulation during Osteoclastogenesis in RAW/C4 Cells.** J. Fidalgo<sup>\*1</sup>, D. Ovchinnikov<sup>\*1</sup>, B. Fletcher<sup>\*1</sup>, G. Muscat<sup>\*2</sup>, A. I. Cassidy<sup>1</sup>. <sup>1</sup>Institute for Molecular Bioscience; Co-operative Research Centre for Chronic Inflammatory Diseases, University of Queensland, The University of Queensland, Brisbane, Australia, <sup>2</sup>Institute for Molecular Bioscience, University of Queensland, The University of Queensland, Brisbane, Australia.

Peroxisome Proliferator-Activated Receptors (PPARs) are nuclear steroid hormone receptors and have three isoforms: PPAR $\alpha$ , PPAR $\gamma$  and PPAR $\delta$ , with characteristic patterns of tissue distribution and specific roles. PPARs have been demonstrated to have a role in regulating bone biology. The PPAR $\delta$  agonist, carbaprostacyclin, stimulates osteoclast (OCL) activity whereas the PPAR agonists bezafibrate, fenofibrate and the specific PPAR $\delta$  agonist L165041, repress human OCL differentiation *in vitro*. We have sought to understand the role of PPAR $\delta$  in osteoclast biology.

In this study, we investigated the expression and role of PPAR isoforms and those of its heterodimeric partner, RXR, during the differentiation of the osteoclastogenic RAW/C4 sub-clone of the RAW264.7 murine macrophage cell line. PPAR $\delta$  is the prevailing isoform in RAW/C4-derived OCL and its expression is markedly upregulated during OCL differentiation whereas expression of the other isoforms decreases. The specific PPAR $\delta$  agonist, GW501516, induces elevated expression of the typical OCL markers tartrate-resistant acid phosphatase (TRAP), cathepsin K and calcitonin receptor (CTR) but further decreases the levels of expression of all PPAR isoforms during OCL differentiation. Stable over-expression of PPAR $\delta$  in RAW/C4 cells also upregulates the expression of these genes and this effect is further stimulated by the presence of GW501516.

The expression of PPAR-responsive element (PPRE)-containing reporter gene constructs was induced by co-expression of PPAR $\delta$  in transiently transfected RAW/C4 cells. PPRE-reporter gene expression was further induced by co-expression of the transcriptional co-activator PGC-1. The PPAR $\delta$  agonist GW501516 stimulated expression of these constructs. The expression of RXR isoforms was differentially regulated during RAW/C4 osteoclastogenesis, such that the expression of RXR $\alpha$  and RXR $\gamma$  was repressed while RXR $\beta$  was induced, showing a similar expression profile to PPAR $\delta$  itself.

PPAR $\delta$  has been shown to regulate gene expression during murine osteoclast differentiation and therefore we propose that it has a significant role in bone biology.

**Downregulation of Connexin 43 Expression and Osteoclastogenesis by a Bioceramic Bone Graft Substitute.** Z. Mladenovic<sup>\*</sup>, B. Andersson<sup>\*</sup>, M. Ransjö. Odontology/Oral Cell Biology, Umeå University, Umeå, Sweden.

Biomaterials are becoming more frequent as bone graft substitutes when treating patients with bone defects. Integration of bone graft substitutes and surrounding tissues are crucial in bone reconstruction therapies. Increased knowledge of biomaterial and bone cell interactions are of importance. Gap junctional intercellular communication (GJIC) is important in osteoblast proliferation, differentiation and extra cellular matrix mineralization. Connexin 43(Cx43) is the most widely expressed Cx protein in the osteoblasts (Stains et al., 2005). Furthermore, Cx43 mRNA has been demonstrated in osteoclasts (Ransjö et al., 2003). We have also demonstrated that GJIC and Cx43 are crucial in the fusion and formation of osteoclasts (Matemba et al., 2006). One interesting group of synthetic biomaterials is the bioactive glass ceramics, containing calcium, phosphate and silica ions. It is suggested that osteoblast proliferation and differentiation is promoted when exposed to soluble ionic constituents released from bioactive glasses (Hench LL, 2006). There are a few published very interesting studies on effects of biomaterials on gap junction communication. Our aim is to investigate effects of 45S5 Bioglass on osteoclastogenesis and Cx43 expression. We used mouse bone marrow cultures and RAW 264.7 cells for this study. Bioglass dissolution medium and particles caused time and dose dependent significant inhibition in the number of TRAP positive multinucleated cells. Real-time PCR analysis supported these findings by showing decreased osteoclast phenotypic markers. Both Bioglass dissolution medium and particles dose dependently significantly decreased Cx43 mRNA expression in RANKL-stimulated RAW cells. In conclusion this study demonstrates an inhibitory action of 45S5 Bioglass on osteoclastogenesis and Cx43 expression.

**A Novel Selective P2X<sub>7</sub> Receptor Antagonist Inhibits Human Osteoclast Formation *in vitro*.** A. Gartland<sup>\*1</sup>, K. A. Buckley<sup>\*2</sup>, K. Bowers<sup>\*3</sup>, A. Gaw<sup>\*3</sup>, M. Furber<sup>\*4</sup>, J. A. Gallagher<sup>2</sup>. <sup>1</sup>Academic Unit of Bone Biology, The University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>Human Anatomy and Cell Biology, The University of Liverpool, Liverpool, United Kingdom, <sup>3</sup>Discovery BioScience, AstraZeneca R&D Charnwood, Loughborough, United Kingdom, <sup>4</sup>Medicinal Chemistry, AstraZeneca R&D Charnwood, Loughborough, United Kingdom.

The P2X<sub>7</sub> receptor (P2X<sub>7</sub>R), a unique receptor that can form pores in the cell membrane, has been implicated in the process of multinucleation and cell fusion. We have previously demonstrated that osteoclast precursors and mature osteoclasts express functional P2X<sub>7</sub>R and that blockade of P2X<sub>7</sub>R using a monoclonal antibody or oxidised ATP inhibited formation of multinucleated osteoclasts *in vitro*. Here we provide further evidence for the role of the P2X<sub>7</sub>R in the formation of functional multinucleated human osteoclasts using a small-molecule antagonist from a distinct chemical series of cyclic imides, which are potent and highly selective for the P2X<sub>7</sub>R. When added to human blood monocytes cultured in the presence of recombinant RANKL and M-CSF, compound 15d, in a concentration-dependent manner, decreased the formation of multinucleated TRAP-positive osteoclasts, the number of actively resorbing osteoclasts, and the overall area of resorption excavated on dentine discs by these cells. These data support the argument that the P2X<sub>7</sub>R is indeed directly involved in osteoclast fusion and the utility of P2X<sub>7</sub>R antagonists in the management of diseases where bone metabolism is disturbed such as rheumatoid arthritis, Pagets disease or osteoporosis.

**Nanogel Cross-linking Hydrogel as a Drug Delivery System for Tumor Necrosis Factor-alpha Antagonist.** N. Alles<sup>\*1</sup>, N. S. Soysa<sup>\*1</sup>, A. Mian<sup>\*1</sup>, N. Tomamatsu<sup>\*1</sup>, N. Morimoto<sup>\*2</sup>, U. Hasegawa<sup>\*2</sup>, S. Sawada<sup>\*2</sup>, Y. Tada<sup>\*2</sup>, K. Akiyoshi<sup>\*2</sup>, K. Ohya<sup>1</sup>, K. Aoki<sup>1</sup>. <sup>1</sup>Section of Pharmacology, Department of Hard Tissue Engineering, Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Organic Biomaterials, Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Tokyo, Japan.

Our previous studies have already shown that a TNF antagonist peptide (WP9QY/W9) is effectively inhibits RANKL-induced bone resorption in many bone resorption models (J Clin Invest. 116:1525-1534, 2006, Arthritis Rheum. 56:1164-74, 2007). Easy degradation in serum is a major drawback towards clinical application of this peptide. We have shown previously that the W9 peptide could bind with cholesterol-bearing pullulan (CHP) nanogels in preventing bone resorption in a mouse model of low Ca diet. The objective of this study is to find out the most efficient control release system for W9 peptide. In this study we used two kinds of systems namely, the injection type of CHP nanogel and the implant type of CHP nanogel cross-linking (CHP-PEG hybrid nanogels). Five week old, male C57BL/6J mice on low Ca diet were injected with vehicle (veh), CHP-nanogel, W9 or the CHP-W9 complex (W9- 24mg x2/kg/day) twice a day for 7 days. In the case of hydrogel, CHP-hydrogel-W9 (W9- 10.28mg/kg/day) was implanted on the first day of the experiment. At the end of the experiment mice were sacrificed and the long bones were subjected to bone mineral density (BMD) measurements. The BMD of low Ca group was significantly reduced compared to normal Ca-veh group (p<0.01). CHP-W9 complexes prevented the reduction in BMD compared to low Ca-veh (p< 0.01) in both types. The BMD data was further confirmed by histomorphometry and microCT data. Twice a day CHP-W9 injection and CHP-hydrogel-W9 implantation prevented the increase of number of osteoclasts significantly (p<0.001). Both CHP nanogel and CHP-hydrogel by themselves do not have any bone resorption or bone formation effects. Taken together, the implant type of nanogel cross-linking hydrogel inhibited bone resorption by a low Ca feeding at a lower dose of W9 (10.28 mg/kg/day) compared to the injection type of CHP nanogel (48 mg/kg/day), and these results suggested that the nanogel cross-linking hydrogel could be used as an effective carrier to deliver the W9 peptide.

**Acidosis Augments the Resorptive Capacity of Human Osteoclasts by Increasing Lysosomal Acidification.** K. Henriksen, V. K. Jensen\*, M. G. Sorensen\*, M. A. Karsdal. Pharmacology, Nordic Bioscience A/S, Herlev, Denmark.

Metabolic acidosis results in detrimental effects on bone health, and local acidosis as seen in metastatic bone disease leads to localized bone destruction. The mechanism underlying the increased resorption involves a combination of upregulation of RANKL expression by osteoblasts, and upregulation of the resorptive activity by the osteoclasts. To further clarify the mechanism underlying the increased resorption, we investigated the effect of acidosis on cultures of human osteoclasts.

We used CD14+ sorted monocytes cultured in the presence of RANKL and M-CSF to generate mature human osteoclasts. We seeded the mature osteoclasts on bone slices and exposed them to medium with pH values ranging from 6.5 to 8.0 and investigated bone resorption by measurement of calcium release and osteoclast number by TRACP activity after 5 days of culture. We then measured lysosomal acidification using both the acid influx assay in membranes isolated from osteoclasts exposed to pH 6.8 and 7.5, and finally we quantified lysosomal acidification in osteoclasts using acridine orange. In addition, we measured V-ATPase activity in the membrane preparations.

We found that osteoclasts exposed to low pH values resorbed 200% of the level observed in control osteoclasts at normal pH values. Furthermore, we found that the TRACP activity increased, but that the increase did not fully explain the increase in resorption. Finally, we found the low pH treatment increased acid influx by 40% and V-ATPase activity in the membrane fractions. Finally, we found that the lysosomal pH was reduced mildly by the low pH when incubating the cells at low pH for 24 hours, but not 45 minutes.

In conclusion, we found that lowering pH leads to an increase in osteoclastic resorption via increased V-ATPase activity leading to increased acidification of the lysosomes. These data for the first time show that human osteoclasts are activated by low pH, which correlates well with the findings in disorders involving both systemic and local acidosis.

## M123

**The Chloride Channel CIC-7 Mediates Acidification of the Resorption Lacuna in Osteoclasts.** K. Henriksen<sup>1</sup>, A. V. Neutsky-Wulff<sup>1</sup>, V. K. Jensen\*<sup>1</sup>, J. Bollerslev<sup>\*2</sup>, J. Gram<sup>\*3</sup>, M. A. Karsdal<sup>1</sup>. <sup>1</sup>Pharmacology, Nordic Bioscience A/S, Herlev, Denmark, <sup>2</sup>Section of Endocrinology, Dept. of Medicine, National University Hospital, Oslo, Norway, <sup>3</sup>Department of Endocrinology, Ribe County Hospital, Esbjerg, Denmark.

The chloride channel CIC-7 has been speculated to be involved in acidification of the lysosomes and the resorption lacunae in osteoclasts, however neither direct measurements of chloride transport nor acidification have been performed.

Human osteoclasts harboring a dominant negative mutation in CIC-7 (G215R) or CIC-7 deficient murine osteoclasts were isolated, and used to investigate bone resorption measured by CTX-I, calcium release and pit scoring. CIC-7 enriched membranes from the osteoclasts were isolated, and used to test acidification rates in the presence of a V-ATPase and a chloride channel inhibitor, using a H<sup>+</sup> and Cl<sup>-</sup> driven approach. Finally, acidification rates in CIC-7 enriched membranes from ADOII osteoclasts and CIC-7 deficient bones, and their corresponding controls were compared.

Resorption by the G215R osteoclasts was reduced by 60% when measured by both CTX-I, calcium release, and pit area when comparing to age and sex matched controls. In the mouse model bone resorption was completely abrogated. Furthermore, V-ATPase and chloride channel inhibitors completely abrogated the H<sup>+</sup> and Cl<sup>-</sup> driven acidification. Finally, the acid influx was reduced by maximally 50% in the ADOII membrane fractions when comparing to controls, and completely eliminated in CIC-7 deficient bone membrane vesicles.

These data for the first time demonstrate that CIC-7 is essential for bone resorption, via its role in acidification of the lysosomes and resorption lacunae in osteoclasts.

## M124

**Protein Kinase Cδ Is Important for Acidification of the Lysosomes and Resorption Lacuna in Osteoclasts.** M. G. Sorensen, K. Henriksen, M. A. Karsdal. Nordic Bioscience A/S, Herlev, Denmark.

Bone resorption is initiated by the osteoclastic acidification of the resorption lacunae. This process is mediated by secretion of protons through the V-ATPase and chloride through the chloride channel CIC-7. Since little is known about the intracellular machinery controlling extracellular acidification, we utilized a panel of kinase inhibitors to investigate the intracellular control of lysosomal acidification in human osteoclasts and osteoclastic bone resorption.

Human osteoclasts were generated from CD14+ monocytes cultured with 25ng/ml M-CSF and RANKL. The effect of different kinase inhibitors on lysosomal acidification in human osteoclasts seeded on plastic was investigated using the dye acridine orange for different incubation times (45min, 4 hours and 24 hours). The PKC inhibitors were tested in the acridine orange based acid influx assay using membranes isolated from osteoclasts. We seeded the mature osteoclasts on bone slices and investigated bone resorption by measurement of calcium release and CTX-I into the supernatants. Cell number was measured using the AlamarBlue dye.

The PKC inhibitor, GF 109203X, inhibited both the lysosomal acidification in osteoclasts

and the acid influx in membranes from osteoclasts (IC50=0.06μM), whereas the PKC inhibitors Hypericin and Ro 31-8220 only inhibited the acid influx with IC50 values of 1.8μM and 5.8μM, respectively. All three compounds inhibited bone resorption with IC50 values of 0.8μM, 0.7μM and 3.6μM, respectively. Hypericin and Ro 31-8220 showed low levels of toxicity with IC50 values of 6.9μM and 7.2μM, respectively, whereas GF 109203X was not toxic to the osteoclasts at the tested concentrations.

Rottlerin, an inhibitor of PKCδ, inhibited lysosomal acidification in human osteoclasts. The effect was not seen after short time incubation (45 minutes) but first after long time incubations (4 hours and 24 hours). Furthermore, Rottlerin inhibited the acid influx potently with an IC50 value of 0.08μM. Moreover, Rottlerin inhibited bone resorption with an IC50 value of 1.8μM, and showed low levels of toxicity (IC50=7.3μM). However, the two PKC inhibitors Sphingosine and Palmitoyl-DL-carnitine Cl did not inhibit acidification and bone resorption, potentially due to low potency in osteoclasts. Finally, HBDDE, which inhibits the PKCα and PKCγ isozymes, did not inhibit acidification and bone resorption.

In conclusion, PKC, and especially the PKCδ isoform, appears to play a role in the acidification in human osteoclasts, and through this in bone resorption. On the other hand the PKCα and PKCγ isozymes do not appear to play a role in acidification in osteoclasts, showing that this process is specifically regulated in the osteoclasts.

**Microarchitecture and Tissue Age Influence In Vivo Bone Resorption.** C. Janeiro, D. Vashishth. Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, USA.

Previously we have demonstrated that both microarchitecture and tissue age influence and direct *in vitro* bone resorption [1]. Because bone resorption *in vivo* can be influenced by osteocytes [2], here we report results of an *in vivo* study in which osteocytes can influence bone resorption and alter the interaction between tissue age, microarchitecture, and bone resorption.

Proximal sections of 16 cadaveric human tibiae (Ages 34-89, M & F) containing naturally occurring resorption pits were obtained, stained in toluidine blue and imaged. Each resorption pit was measured, and classified as Type I, II or III based on its interaction with the microarchitecture, particularly the cement line. Type I resorption pits encountered but did not cross the cement line. Type II resorption pits encountered and breached the cement line. Type III resorption pits did not interact with the cement line. The second classification of resorption pits dealt with tissue age. Each resorption pit was classified based upon its location on the bone surface as either interstitial (I) or osteonal (O).

The number of Type III resorption pits was significantly ( $p < 0.001$ ) higher than the number of Type I and II resorption pits (I = 0.0017; II = 0.0004; III = 0.0265 #/mm<sup>2</sup>). No significant difference between the number of Type I and II interactions was seen. There were also no significant differences between the average areas of the type I, II or III resorption pits (I = 88.9; II = 125.1; III = 75.1 μm<sup>2</sup>). The number of interstitial resorption pits was significantly ( $p < 0.01$ ) higher than the number of osteonal resorption pits (I = 0.029; O = 0.001 #/mm<sup>2</sup>), while no significant difference in resorption pit size was seen (I = 77.3; O = 46.6 μm<sup>2</sup>).

In conclusion this study demonstrates that both microarchitecture and tissue age influence bone resorption *in vivo*. In particular, resorption activity is localized in regions containing interstitial bone and devoid of cement lines. These results are similar to a previous *in vitro* study, showing the same trends for tissue age as well as the increases and decreases of size, number and types of resorption pits [1]. Thus the presence of osteocytes in bone does not mitigate the role of microstructure and tissue age in directing bone resorption. These findings may help explain bone turnover induced changes with aging and disease, and with the use of antiresorptive drugs and anabolic treatments [3].

**Losartan® (Cozaar) Increases Appendicular Bone Formation by Inhibiting Osteoclastogenesis.** T. Sibai\*, T. Yang\*, D. Napierala, B. Dawson\*, S. Chen\*, J. Black\*, Y. Chen\*, B. Lee. Baylor College of Medicine, Houston, TX, USA.

Losartan® (Cozaar), an FDA approved angiotensin II type 1 receptor blocker (AT1 antagonist or ARB) is primarily indicated as an antihypertensive agent. It has been found to inhibit TGF-β1 in mouse models of chronic renal insufficiency and in aortic aneurysms of Marfan mouse models. TGF-β1 plays a fundamental and complex role in bone formation. We hypothesized that Losartan can affect bone homeostasis by antagonizing TGF-β1. Histologic femoral bone analysis at 6 weeks, micro CT analysis and Von Kossa staining for femurs and lumbar vertebrae, histomorphometry for osteoclast (OC) and osteoblast (OB) parameters on toluidine blue and tartrate resistant acid phosphatase (TRAP) stained distal femoral sections were performed in C57B6 mice treated with Losartan vs. non-treated controls. In vitro splenocyte to osteoclast differentiation assays at different doses of Losartan (+/- angiotensin II) were also performed. Six-week and 3-3.5 month old postnatally treated mice were 6% heavier ( $p=0.03$ ). Micro CT analysis showed a 9% increase in femoral cortical thickness and a 29-98% improvement in trabecular bone parameters (BV/TV, trabecular thickness, number and separation) ( $p<0.01$ ). Trabecular bone formation at the L3 and L4 vertebrae and micro CT showed a similar trend that did not reach statistical significance. Von Kossa staining confirmed the trabecular phenotype in

the femurs and lumbar spine ( $p < 0.01$ ). Histomorphometric analysis revealed a decrease in OC parameters ( $p = 0.02$ ) but no difference in OB parameters. Losartan inhibited in vitro OC differentiation assays while angiotensin II increased OC counts compared to controls. The mechanism for the enhanced appendicular bone effect and the relationship between the AT1 receptor and TGF- $\beta 1$  remains to be elucidated. Antagonism of the AT1 receptor can act as a potential target in the treatment of osteoporosis and low bone mass states.

## M127

**Effects of the Cathepsin K Inhibitor Odanacatib on Osteoclast-Mediated Bone Resorption.** P. Leung<sup>\*1</sup>, Y. Zhou<sup>\*1</sup>, P. Masarachia<sup>\*1</sup>, G. A. Wesolowski<sup>1</sup>, M. Pickarski<sup>1</sup>, J. Y. Gauthier<sup>\*2</sup>, D. Percival<sup>\*2</sup>, W. C. Black<sup>\*2</sup>, L. T. Duong<sup>1</sup>. <sup>1</sup>Merck & Co., Inc, West Point, PA, USA, <sup>2</sup>Merck & Co., Inc, Montreal, QC, Canada.

Cathepsin K (Cat K) is the major collagenase responsible for degradation of demineralized matrix proteins during osteoclastic bone resorption. Odanacatib (ODN) is a selective, potent and reversible inhibitor of Cat K that has demonstrated effective inhibition of bone loss in animal models and osteoporotic women. The objectives of this study were to characterize the cellular effects of ODN in blocking bone resorption. First, localization of Cat K in osteoclasts was confirmed using electron microscopy immunolabeling in thin sections of mouse femur. Cat K is found within lysosomes, late endosomes, ruffled border and resorption lacunae. It is not detected in osteoblasts or other bone marrow cells. In vitro studies with ODN (hCat K IC<sub>50</sub> = 0.2nM) in human osteoclasts, cultured on dentin or plastic, demonstrated no effect on formation or survival of multinucleated TRAP(+) cells at 100 nM. Similarly, equivalent numbers of multinucleated osteoclasts were generated from bone marrow isolated from CatK knockout versus wild type mice. ODN dose-dependently reduced bone resorption, as evidenced by reduction in CTx (IC<sub>50</sub> = 9.4nM) and resorption area (IC<sub>50</sub> = 6.5nM), without affecting pit number. In contrast, alendronate at 5  $\mu$ M reduced TRAP(+) cell number and abolished resorption pit formation. Characterization of pit morphology by lectin-labeled peroxidase staining revealed that untreated purified human osteoclasts generate typical trail-like resorption lacunae. In contrast, cells treated with ODN form small discrete pits with intense staining and ambiguous borders, suggesting shallow pits with undigested demineralized bone matrix proteins. Lastly, a BODIPY<sup>®</sup>-labeled analog of ODN was developed as a probe for detecting the active form of Cat K. While confocal microscopy with anti-Cat K antibody confirmed expression in all osteoclasts on bone, the fluorescence probe detected active enzyme in only a subgroup of resorbing cells, in which Cat K was found to be localized to intracellular vesicles and ruffled border, suggesting another mechanism involved in regulation of Cat K activation during resorption. Probe binding to active Cat K was readily overcome by unlabeled Cat K inhibitor (100nM), confirming accessibility and reversibility of Cat K inhibition. Staining of actin rings revealed that pharmacological inhibition of Cat K had an insignificant effect on sealing zone formation in actively-resorbing osteoclasts. Taken together, our data supports a mechanism for ODN inhibition of osteoclast mediated bone resorption that includes reduction of matrix degradation without affecting osteoclast formation, survival or polarization.

## M128

**Effect of Luteolin on Bone Loss, Microarchitecture and Bone Resorption in Ovariectomized Mice.** J. Jung<sup>\*1</sup>, J. Hong<sup>\*1</sup>, T. Kim<sup>\*1</sup>, S. Lee<sup>\*1</sup>, M. Ha<sup>\*1</sup>, H. Kim<sup>\*1</sup>, E. Park<sup>2</sup>, S. Kim<sup>3</sup>. <sup>1</sup>Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, <sup>2</sup>School of Dentistry, Department of Pathology and Regenerative Medicine, Kyungpook National University, Daegu, Republic of Korea, <sup>3</sup>Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea.

Phenolic compounds including flavonoids have been implicated in suppression of osteoclast differentiation/function and prevention of bone diseases. The flavonoid luteolin has anti-inflammatory properties both in vivo and in vitro. It has been demonstrated that luteolin has an anabolic effect in osteoblastic cells. However, the impact of luteolin on experimental models of bone and osteoclastic cell remains to be elucidated. We therefore investigated the effects of luteolin on bone metabolism in an ovariectomized (OVX) mouse model, and also osteoclast differentiation and function.

C57BL/6 mice ( $n = 32$ ) were OVX or sham-operated at 9 weeks, and luteolin treatment with different concentrations (5mg and 20 mg/kg) was started immediately after surgery. The effect of luteolin on bone of the OVX mice was evaluated by  $\mu$ CT bone morphometric analysis. Data were analyzed by One-way ANOVA test. In this study, we found that luteolin markedly decreased the differentiation of both murine bone marrow mononuclear (BMM) culture models and Raw264.7 cells into osteoclasts in dose dependent manner. Also, luteolin had increased bone mineral density (BMD), bone mineral content (BMC), tissue mineral density (TMD), bone volume fraction, trabecular number, trabecular separation, cortical BMD, and cortical BMC of the distal femur compared with control OVX mice. These results suggest that the effect of luteolin is mediated by its inhibitory effects on RANKL-induced osteoclast formation, and prevent bone loss in OVX mice. Luteolin may provide more effective therapeutic implication by progressive bone loss including osteoporosis.

**Are All Anti-resorptive Treatments the Same? Lessons Learned From Inhibition of Human Osteoclastic Bone Resorption by Alternative Pathways - Inhibition of Proteolysis vs. Inhibition of Acidification.** A. V. Neutzsky-Wulff<sup>1</sup>, M. G. Sorensen, M. A. Karsdal, K. Henriksen. Nordic Bioscience, Herlev, Denmark.

Inhibition of osteoclastic bone resorption is the primary objective by anti-resorptive treatments for osteoporosis. However, the effect on human osteoclast phenotype and subsequently the effect of bone phenotype, that may be related to bone quality, remain to be carefully investigated.

Osteoclasts are responsible for degradation of both the organic and inorganic part of the bone matrix. The degradation takes place in the resorption lacuna, where acidification is responsible for dissolution of the inorganic phase. The organic phase is dissolved by proteolysis, mainly by Cathepsin K, however MMPs might play a role as a compensatory mechanism. We investigated the effect of inhibition of proteolysis and acidification on human osteoclast phenotype and bone resorption.

Human monocytes were isolated from blood and differentiated into mature osteoclasts by treatment with M-CSF and RANKL. Cells were seeded on cortical bone slices and treated with an inhibitor of proteolysis (E64) or inhibitors of acidification (bafilomycin and ethoxylzolamide). Resorption of the different types of bone matrix was measured by Ca<sup>2+</sup> (inorganic), CTX-I (organic, Cathepsin K generated) and ICTP (organic, MMP generated). Resorbed area was scored by pit staining.

Inhibitors of acidification gave rise to very similar IC<sub>50</sub> values for degradation of the organic and the inorganic bone matrix. On the contrary, the inhibitor of proteolysis, E64, did effectively inhibit resorption of the organic bone matrix (IC<sub>50</sub> < 1 $\mu$ M), whereas inhibition of dissolution of the inorganic bone matrix was not observed. Scoring of pit area, showed a massive reduction when inhibiting acidification (>80%), whereas inhibiting proteolysis did not lead to reduced pit area compared to control. In addition, ICTP release was highly increased with inhibition of proteolysis, which was not seen with inhibition of acidification.

In conclusion, inhibition of proteolysis with E64 leads to increased release of MMP generated fragments, pointing towards a compensatory resorptive activity by MMPs. The discrepancies in the IC<sub>50</sub> values of organic vs. inorganic resorption for inhibition of proteolysis, may in addition explain the somewhat lower efficacy on BMD compared to that of biochemical markers, recently observed in osteoporosis studies with Cathepsin K inhibitors. Interestingly, inhibition of osteoclastic resorption by acidification inhibitors did not display discrepancies between the IC<sub>50</sub> values.

**The Fungal Secondary Metabolites Beauvericin and Enniatin Inhibit Osteoclast Differentiation and Bone Resorption.** S. Forsdahl<sup>\*1</sup>, F. Tedjiosop-Feudjio<sup>\*2</sup>, J. Nguemo<sup>\*2</sup>, R. Lemmens-Gruber<sup>\*2</sup>, O. Hoffmann<sup>2</sup>.

<sup>1</sup>Institutt for farmasi det medisinske fakultet, Universitetet i Tromsø, Tromsø, Norway, <sup>2</sup>Pharmacology and Toxicology, University of Vienna, Vienna, Austria.

Beauvericin and enniatins are structurally related cyclohexadepsipeptides, that are produced by several strains of the fungi genus *Fusarium*, *Beauveria*, *Polyporus* and *Paecilomyces* that are known to contaminate food and feed. They are known ionophores capable of boring holes into cell membranes, allowing for the exchange of cations in cells. We have evidence that these fungal compounds may influence development and activity of osteoclasts (OC) and thus, may be useful therapeutics. To evaluate their effects on OCs, we used the following: 1.) coculture murine bone marrow cells with primary calvarial osteoblasts (OBs) to generate OC for the assessment of OC differentiation using TRAP staining, OC bone resorption on bovine bone slices, and stained cytoskeleton with phalloidin-rhodamine, 2.) OC precursor cell line RAW 264.7 for the evaluation of cell survival and viability, and 3.) RANKL-stimulated RAW 264.7 cells were used as an OC-model to study the effect of the fungal products on MAP kinase signal transduction pathways. Beauvericin and enniatin inhibited OCs in a dose-dependent fashion in all assays tested at a range between 0.1  $\mu$ M and 10  $\mu$ M. At 10  $\mu$ M, beauvericin and enniatin completely inhibited OC bone resorption, disrupted actin rings and caused apoptosis. Moreover, both influenced OC differentiation via the MAP kinase pathway. Phosphorylation of MAPKp44/42 was reduced within 15 min of treatment and stimulated after 1 - 2 h. Beauvericin and enniatin inhibited OC differentiation and function, and induced apoptosis in OCs. These fungal products inhibit motility and resorption, and increase cytotoxicity. Beauvericin is more potent than enniatin. These data suggest that beauvericin and enniatin may be a novel class of clinically relevant compounds for the treatment of osteoporosis and bone tumours.

**Nitric Oxide Has a Powerful Effect of Osteoclast Cells.** S. J. Wimalawansa\*. Endocrinology - Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Relative over-activation of osteoclast cells has been shown as one of the causes of age-associated as well as postmenopausal osteoporosis. Hence, in most cases, anti-osteoclastic agents have beneficial effects on improving bone mineral density (BMD), bone quality, as well as fracture reduction.

Others and we have demonstrated the effects of nitric oxide (NO) donor therapy as well as inhibition of NO synthase (NOS) enzymes with NOS inhibitors *in vitro* as well as *in vivo* animal studies. Here we demonstrate a dose-dependant effect of NO donor therapy as well as inhibition of NO/cGMP on the osteoclastic bone resorption activity *in vitro* cell culture system.

At very low doses or suppression of NOS activities with NOS inhibitors in culture over-activated osteoclast cells (i.e., increased bone resorption as indicated with the number of pits formed as well as the surface area/depth of pits. Whereas, adding NO donor therapies into the culture medium up to a certain levels suppressed the osteoclast-induced bone resorption and higher doses enhanced pit resorption capacity of osteoclasts. Data confirmed the previous *in vivo* data in rats that the effects of NO-cGMP on osteoclasts are biphasic and the therapeutic margin is narrow.

Our previous studies also suggested that NO donor agents (at appropriate doses have biphasic effects of the osteoblasts including cell proliferation/apoptosis as well as their activities. Figure demonstrates the proposed overall *in vivo* biphasic effects of NO donors on bone. It is important to notice that the therapeutic margin is narrow and the correct dose is necessary to obtain beneficial effects from this therapy in animals as well as in humans. Conclusion: taken together *in vitro* and *in vivo* studies suggests that at correct dose-exposure, NO donor therapies have highly beneficial effects on bone cells and hence protective effect on the skeleton in general.

**Over-expression of RAGE Prevents Ovariectomy-mediated Bone Loss in CD1 Mice.** C. Li<sup>\*1</sup>, K. Ding<sup>\*2</sup>, S. Yan<sup>\*3</sup>, B. Lee<sup>\*1</sup>, D. Meng<sup>\*1</sup>, J. Xu<sup>\*1</sup>, L. Zhou<sup>\*4</sup>, M. Hamrick<sup>\*5</sup>, C. Isales<sup>6</sup>, Q. Mi<sup>4</sup>. <sup>1</sup>Center for Biotechnology and Genomic Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Dept. of Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Dept. of Medicine, The Medical School Hospital of Qingdao University, Qingdao, China, <sup>4</sup>Dept. of Pathology, Medical College of Georgia, Augusta, GA, USA, <sup>5</sup>Dept. of Cellular Biology, Medical College of Georgia, Augusta, GA, USA, <sup>6</sup>Dept. of Orthopedic Surgery, Medical College of Georgia, Augusta, GA, USA.

It has been reported that the advanced glycation endproducts (AGEs) and receptor for AGEs (RAGEs) are involved in diabetic complications. We recently reported that RAGE knockout mice in B6 genetic background have a significantly increased bone mass and bone biomechanical strength and a decreased number of osteoclasts compared to wild-type mice in B6 genetic background. These data therefore indicate that RAGE serves as a positive factor to regulate the osteoclast formation, and document that the over-expression of RAGE may account for diabetes-associated bone loss. To further test this, we used RAGE transgenic mice in CD1 genetic background. The bone mineral content (BMC), bone mineral density (BMD), fat and lean mass were examined using dual-energy X-ray absorptiometry, and bone biomechanical properties were also evaluated using three-point bending test. Interestingly, over-expression of RAGE did not reduce bone density or bone biomechanical properties at 18-week old age. Surprisingly, over-expression of RAGE significantly inhibited bone marrow macrophage (BMM) differentiation to osteoclasts and reduced bone resorption function compared to wild-type CD1 mice. To further test the function of RAGE over-expression *in vivo*, we ovariectomized mice at 18-week old age. Strikingly, over-expression of RAGE prevented ovariectomy-mediated bone loss. Our data suggest that RAGE negatively regulates osteoclast development modulated by ovariectomy in CD1 mice, and indicate that RAGE has dual functions to regulate

osteoclast development based on the different genetic backgrounds. Our data strongly argue that AGE/RAGE pathway in osteoclast development is very complex, which may complicate the design of novel therapies targeting this pathway.

**TGF $\beta$  Inducible Early Gene-1 Knockout Mice Display Defects in the Molecular Structure of Tendon Fibers.** L. Gumez<sup>1</sup>, C. Pichon<sup>\*2</sup>, J. R. Hawse<sup>3</sup>, M. Subramaniam<sup>3</sup>, J. Doucet<sup>\*4</sup>, T. C. Spelsberg<sup>3</sup>, S. Bensamoun<sup>1</sup>.

<sup>1</sup>Biomécanique et Bioingénierie UMR CNRS 6600, Université de Technologie de Compiègne, Compiègne, France, <sup>2</sup>Centre de Biophysique Moléculaire CNRS UPR 4301, Université d'Orléans, Orléans, France, <sup>3</sup>Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, <sup>4</sup>Laboratoire de Physique des Solides UMR 8502, Université Paris-Sud, Orsay, France.

TGF $\beta$  inducible early gene-1 (TIEG1) is a member of the Krüppel-like family of transcription factors and plays an important role in Smad signaling. TIEG has also been shown to play an important role in the morphological and mechanical properties of tendons.

The purpose of this study was to characterize the effect of TIEG on the molecular structure of collagen (triple helix, intra and inter fiber structure) in tendon fibers.

Three month old female C57Black6/129 wild-type (WT) and TIEG KO mice were used. Approximately 3-4 tendon fibers were extracted from the WT and TIEG KO tails. Synchrotron X-ray microdiffraction experiments were carried out using a 13 KeV monochromatic beam (2 $\mu$ m in diameter). Each single tendon fiber (WT = 9 and TIEG\_KO = 8) was inserted into a capillary (diameter = 0.7mm) and placed vertically in the X-ray beam. Diffraction data arising from the internal supramolecular architecture of the tendon fiber were collected on a 2D detector. An X-ray pattern was obtained by scanning the fiber along the radial direction (160  $\mu$ m). The X-ray intensity along the meridional direction (fiber axis) was extracted for detailed analysis of the molecular packing.

The same patterns were observed within each of the fiber samples isolated from the same genotype (TIEG KO and WT). The X-ray diffraction patterns from TIEG KO mice revealed differences in the organization of fibril structure compared to WT controls. Figure 1 illustrates the intensity profiles along the meridian. WT tendon fibers displayed a sixth order maximal intensity peak while TIEG KO fibers were maximal at the fifth order.

These preliminary data demonstrate that the organization of tendon fiber structure is different in TIEG KO mice relative to WT mice. These results suggest that lack of TIEG expression results in a disorganization of the internal structure of tendon fibers. Further characterization of tendon fibers will allow us to better understand the influence of TIEG on the structure of the musculoskeletal system.

**Biomarker Discovery for Bone and Cartilage Based on Metabolic Reconstruction Bioinformatics.** E. Selkov<sup>\*1</sup>, G. Hawa<sup>2</sup>, R. Datema<sup>\*1</sup>, W. Woloszczuk<sup>2</sup>. <sup>1</sup>encyclopedia Genomica GmbH, Linz, Austria, <sup>2</sup>Research & Development, Biomedica, Vienna, Austria.

In recent years the palette of biomarkers to study the biological processes leading to severe bone and cartilage diseases like osteoporosis, osteoarthritis, rheumatoid arthritis has increased significantly. Recently the focus was drawn to several regulation molecules either influencing osteoclast or osteoblast proliferation. Especially the importance of molecules involved in the Wnt signalling pathway in the progression of osteoarthritis

gained much attention. Despite that progress in understanding the biology of bone turnover, more biomarkers are needed for basic research and clinical studies on bone and cartilage disease to yield a full picture.

Therefore we developed procedures for the mining of public databases containing information about gene expression in human tissues. Transcriptomes of tissues represented in databases are deemed to be of sufficient quality for analysis of tissue-selective expression of genes, if enzymes and protein isoforms are well represented in twenty metabolic domains (examples in the table). The tool used, MPW Analyzer, is a bioinformatics mining tool that uses symbols to connect entries in protein databases with gene transcripts. Protein-coding transcripts occurring with high selectivity in bone and cartilage could thus be identified, and were further ranked based on occurrence of a gene product in body fluids, occurrence of veterinary homologues, disease association, low number of interactions with ECM-proteins, and protein features considered undesirable for future assay development. Of these selected proteins, seven represent hypothetical proteins ("unknowns"), 13 are highly selective for bone, 17 for cartilage, and three for the vasculature. Of the selected proteins, nine are expressed intracellularly; the remainder are secreted and are minor components of the ECM. Some of these proteins can be characterized by circulating peptides derived from them. We present the first sets of potential new marker molecules generated by this approach.

**Human Skeletal Muscle Cells Undergo Matrix Mineralization in an Osteogenic Pellet Culture Assay.** K. A. Corsi<sup>\*1</sup>, A. Usas<sup>\*1</sup>, T. R. Payne<sup>\*2</sup>, R. J. Jankowski<sup>\*2</sup>, J. Huard<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Cook MyoSite, Inc., Pittsburgh, PA, USA.

Previous studies indicate that murine skeletal muscle cells undergo osteogenic differentiation in the presence of bone morphogenetic protein (BMP), and that this process occurs more rapidly in cells obtained from male mice than from female mice.<sup>1</sup> The ability of human skeletal muscle-derived cells (hMDCs) to undergo osteogenesis is not as widely reported. In this study, we investigated the osteogenic differentiation of male and female hMDCs in an in vitro osteogenic pellet culture assay. Cells were isolated from the skeletal muscle of 4 female (ages 22-25) and 4 male (ages 20-31) human donors. Their expression of the cell surface marker CD56 (myogenic marker) was determined by flow cytometry. For osteogenic differentiation, hMDCs were cultured as pellets in osteogenic medium (OSM) for 28 days and analyzed by  $\mu$ CT at 7, 14, 21 and 28 days for bone volume (BV) and density (BD). Gene expression for collagen type I (*Col1*) was determined by quantitative RT-PCR after 28 days in OSM. Matrix mineralization was evident in 6 of the 8 populations as early as 7 days after initiation of cultures. The female and male cell population with the lowest percentage of CD56 on their surface began displaying calcified tissue only after 14 days in culture. The mean BV and BD increased over time in all cell populations. No sex-related differences were observed at all time points tested for both BV and BD. *Col1* gene expression was increased for both male and female hMDCs after 28 days of culture in OSM, and this was significant for female hMDCs. These results suggest that by combining the pellet culture method with microCT analysis, we were able to observe the same pellet over time and determine the rate of mineralization for each cell population tested. It was shown that all hMDCs in this study undergo osteogenic differentiation as evidenced by mineralization and the expression of osteogenic genes. Unlike murine muscle cells, hMDCs underwent mineralization in OSM that did not contain BMP. As well, hMDCs did not display a significant difference between cells obtained from male and female donors, although the current study was done with a small sample size. Nevertheless, this osteogenic assay allowed us to determine that hMDCs with low CD56 expression did not mineralize as quickly as those expressing higher levels, suggesting that CD56 may be a possible marker for the osteogenic potential of hMDCs. In conclusion, hMDCs warrant further investigation, as they represent a potential cellular candidate for bone tissue engineering applications.

**Quantification of Non-mineralized Tissue via  $\mu$ CT as a Readout for Glucocorticoid Effects on Rat Growth Plate.** F. Chen<sup>\*</sup>, S. Riley<sup>\*</sup>, D. H. Euler<sup>\*</sup>, J. E. Fisher<sup>\*</sup>, P. E. Brandish<sup>\*</sup>, J. C. Hershey<sup>\*</sup>. Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA.

Glucocorticoids (GCs) inhibit chondrocyte proliferation and increase apoptosis that result in reduction of non-mineralized tissue in growth plate (GP) and thinning of GP. This study focuses on establishing a quick and reliable method to quantify GP changes related to GC treatment in rats.

Sixteen week old intact female SD rats (N=10-12/grp) were treated for 7 d with 0.1 mpk dexamethasone (DEX) (sc, qd), 1.5 mpk 6 $\alpha$ -methyl prednisolone (6-MP) or vehicle (po, bid). In a second study, SD rats were ovariectomized (OVX) at age 12 weeks, and 6-MP (0.1, 0.3, 1 and 3 mpk, po, bid) treatment was started at age 18 weeks and continued for 28 d. Left tibias were collected and stored in 70% ethanol. The proximal tibia was scanned (SCANCO microcomputed X-ray tomography ( $\mu$ CT) 40) at 20  $\mu$ m resolution. Non-mineralized area (NMA) within GP in a fixed region (2.5x2.5 mm<sup>2</sup>) located in the center of the GP was quantified via 2D analysis at a threshold of 250 on 20 consecutive  $\mu$ CT slices. The NMA (mean of 20 slices, mm<sup>2</sup>) was calculated for each bone. Average GP thickness (GPT, mm) was also obtained by hand contouring the GP area within the above fixed region on the 1<sup>st</sup> and the 20<sup>th</sup> slices and dividing each area by 1/2 of the corresponding perimeter of the contouring line.

In the 7d experiment, both DEX and 6-MP significantly reduced the NMA (mm<sup>2</sup>) with DEX 0.148  $\pm$  0.015<sup>\*\*\*</sup>, 0.204  $\pm$  0.020<sup>\*\*\*</sup> for 6-MP vs. vehicle 0.358  $\pm$  0.031. Similarly, both DEX and 6-MP also reduced GPT (mm) with DEX 0.074  $\pm$  0.004<sup>\*\*\*</sup> and 6-MP 0.093  $\pm$  0.007<sup>\*</sup> vs. 0.120  $\pm$  0.008 for vehicle. Data from the second study also showed that 0.1 mpk of 6-MP reduced the NMA from OVX vehicle 0.234  $\pm$  0.018 to 0.155  $\pm$  0.009<sup>\*\*\*</sup>. Higher doses of 6-MP further reduced the NMAs to 0.114  $\pm$  0.015<sup>\*\*\*</sup> for 0.3 mpk, 0.066  $\pm$  0.003<sup>\*\*\*</sup> for 1 mpk and 0.066  $\pm$  0.007<sup>\*\*\*</sup> for 3 mpk. GPTs also revealed a dose dependent reduction ranging from 0.106  $\pm$  0.004, 0.083  $\pm$  0.006<sup>\*\*</sup>, 0.072  $\pm$  0.004<sup>\*\*\*</sup>, 0.060  $\pm$  0.004<sup>\*\*\*</sup> to 0.059  $\pm$  0.002<sup>\*\*\*</sup> corresponding to vehicle and low to high doses of 6-MP. Correlation study between NMA and GPT from both studies showed that NMA is significantly correlated to GPT with R<sup>2</sup> ~ 0.71 (P<0.001).

In conclusion, measurement of non-mineralized tissue via  $\mu$ CT as a readout of GC effects on rat GP is a quick, reliable and user friendly approach. It generates qualitatively similar data to those obtained by measuring GPT. The method can quantify growth plate changes induced by DEX and 6-MP after 7 d treatment in 16 week old rats. It can also reveal GC-related growth plate changes in OVX rats after 28 d treatment.

<sup>\*</sup>P<0.05, <sup>\*\*</sup>P<0.01, <sup>\*\*\*</sup>P<0.001 vs. vehicle

**Bone Turnover Evaluated by a Combined Calcium Balance and <sup>45</sup>Calcium Kinetic Study, and Dynamic Histomorphometry: Effect of Ovariectomy and Sub-optimal Dietary Calcium in Rats.** M. Shahnazari<sup>\*1</sup>, W. Lee<sup>\*2</sup>, B. R. Martin<sup>\*2</sup>, C. M. Weaver<sup>2</sup>. <sup>1</sup>UC Davis Medical Center, Sacramento, CA, USA, <sup>2</sup>Purdue University, West Lafayette, IN, USA.

The gold standard approach for evaluating bone turnover responses to an intervention is dynamic histomorphometry. This is a laborious approach that is typically restricted to animal models because of the difficulties associated with taking iliac crest biopsies in humans. Calcium (Ca) tracer kinetic studies can be used to determine bone formation and bone resorption rates. The objective of this study was to validate isotopic approaches, in a rat model, against dynamic histomorphometry for establishing rapid detection methods for evaluating the effectiveness of treatments. The interventions used in our experiments included ovariectomy and sub-optimal level of dietary Ca.

Kinetic studies involved oral and intravenous administration of radioactive <sup>45</sup>Ca and monitoring of the tracer in blood, urine, feces, and bone over a 4-d period. Complete Ca balance including dietary intake as well as urinary and fecal excretion was also measured during this time. Histomorphometric indices of mineral apposition rate, mineralizing surface, and bone formation rate were obtained from tibia.

Ca tracer kinetic data showed a significant difference (p<0.001) in skeletal resorption and formation rates in response to ovariectomy (27.6 vs 13.8 mg/d for bone resorption and 42.7 vs 28 mg/d for bone formation in ovariectomized and sham rats, respectively). Highly significant correlations were found between bone deposition evaluated by kinetic data (organ level) and histomorphometric index of bone formation rate in cortical and trabecular bone (r = 0.63 and 0.76, p<0.001). Significant correlations were also demonstrated between bone resorption and formation rates at the organ level (r = 0.91, p<0.001) using Ca balance and <sup>45</sup>Ca kinetic data. Kinetic studies also showed that bone formation and bone balance were significantly lower when dietary Ca level was reduced from 0.4% to 0.2% (25.5 vs 19.7 mg/d and 11.3 vs 4.2 mg/d, respectively, p<0.001).

Our study suggested that Ca tracer kinetic data can be used reliably to rapidly detect changes in bone in response to interventions and can lower the sample size in studies by allowing a sequential testing of treatments in the same animals.

**Dynamic Histomorphometry of Mineralized Tissue Using Cryosections of Murine Bone and Teeth.** X. Jiang\*, C. Ushiku\*, H. Li\*, D. W. Rowe. Dept. of Reconstructive Sciences, School of Dental Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Dynamic histomorphometry requires the preservation of trabecular architecture and cellular detail, detection of fluorescent mineralization dyes and maintenance of enzymatic and immunoreactivity. Traditionally, embedding in plastic matrices has been employed to maintain structural integrity but at the expense of reduced biological activities. Previously we have implemented a tape transfer protocol for quality sections of frozen decalcified sections of murine bone that preserves GFP expression and immunoreactivity. Here we demonstrate a new tape protocol that provides excellent integrity of cryosections from mineralized tissues and preserves biological activities for histological detection. The mineralized matrix is detected by DIC optics. Because fluorescent reporters provide excellent signal discrimination, we have developed our histology to employ fluorescent signals that can be mapped back to the DIC image and the GFP reporters that identify specific cell types within bone. Examples of immunostaining for surface antigens (CD31, F/480), enzymatic staining for AP and TRAP, and in situ identification for BSP or Cbfa1 will show the low background and strong fluorescent signal strength that can be produced. However the most useful application of this histology may be the fluorescent mineralization labels to measure osteoid deposition. Five different colors can be detected to demonstrate the sequential deposition and removal of mineral from which the dynamic nature of a skeletal structure can be appreciated. For example the elongation rate of the dental incisor can be measured while the rapid turnover rate of trabecular bone relative to cortical bone can be observed. Not only can a matrix apposition rate be calculated, a label loss rate can be measured. We are exploring the potential of using this histology as a new standard for dynamic histomorphometry in which cells within the osteoblast lineage are identified by AP activity while their place within the lineage is identified by their association with a mineralization label. Similarly, cells within the osteoclast lineage are identified by their TRAP activity. A protocol to register the stained sections to the original DIC images has been developed so that the cellular activities can be expressed as a percentage of trabecular bone surface, an essential measurement of dynamic histomorphometry. Because the histology sections can be produced in a shorter period of time than plastic embedding/sectioning and the information obtained from the same section is extremely rich, we believe that it could become a very valuable tool for phenotyping murine models of bone disease.

**Automatic Estimation of Body Composition Using Micro-CT and a Gaussian Mixture Model.** F. J. Ayres\*, G. M. Campbell, S. K. Boyd. Mechanical and Manufacturing Engineering, University of Calgary, Calgary, AB, Canada.

The use of micro-computed tomography (micro-CT) may present an alternative method for the measurement of body composition in mice, particularly when dual-energy X-ray absorptiometry (DXA) [1] is not practical. Body composition measurement with DXA has been validated in rats and provides a basis for which to compare micro-CT based composition measurements.

The standard procedure for the estimation of body fat ratio from micro-CT images consists of determining the percentage of voxels whose CT values fall within a predetermined range, typically associated with the density of fat. This method is prone to errors since the actual CT value of a voxel within a fatty region is better modeled as a random variable, whose distribution may extend beyond the typical range of CT values for fat tissue, with decreasing probability. The same reasoning applies to other tissues: a voxel within a lean mass region may exhibit a value that is typically associated with fat tissue due to the stochastic nature of the CT values and to the occurrence of partial volume effects.

In the present work we propose a method that does not require segmentation of the micro-CT data. A Gaussian mixture model (GMM) was applied to estimate the fractional contribution of fat, lean tissue, and bone, to the body composition of rats, while accounting for the random nature of CT values within each tissue category. The GMM represents the probability distribution of CT values in the body as a weighted sum of Gaussian distributions, each Gaussian representing the probability distribution of CT values associated with each tissue. The weights in the GMM provide the fractional composition of the body in terms of the various tissue types. The weights and the statistical parameters (mean and standard deviation) of each Gaussian in the GMM are determined such that the difference between the GMM and the observed probability distribution of values in the CT volume (given by the normalized histogram) is minimized. A genetic algorithm is used to automatically fit the GMM parameters.

Validation was conducted with skeletally mature rats subjected to ovariectomy (n = 10) or sham (n = 10) surgeries that were scanned using micro-CT and DXA. The histogram of the CT values in each volume was obtained, and a GMM was fit to the histogram data. It was observed that the correlation between GMM and DXA was high ( $r^2 = 0.93$ ), with a linear coefficient of 0.87. This is an improvement over traditional segmentation methods, especially when resolution is low, in terms of determination of body composition and computational effort. Future work will improve the GMM fitting procedure by incorporation of a filtering step prior to obtaining the histogram.

**Rapid EDTA Microwave Decalcification of Rabbit Osteochondral Samples Preserves Enzyme Activity and Antigen Epitopes.** V. Lascau-Coman\*, M. D. Buschmann\*, C. D. Hoemann\*. Chemical Engineering, Ecole Polytechnique, Montreal, QC, Canada.

Decalcifying rabbit osteochondral samples with EDTA solution protects proteins from acid hydrolysis, however this is a lengthy procedure requiring 3 months to fully demineralize. It was previously shown that microwave decalcification of bone, using 10% EDTA/2% paraformaldehyde, could shorten the decalcification time. Here we report that rapid microwave decalcification of osteochondral samples with 10% EDTA/0.1% paraformaldehyde at 37°C preserves antigen epitopes and enzyme activity in osteoclasts. The goal of current study was to optimize a microwave decalcification method to conserve tartrate-resistant acid phosphatase (TRAP) activity, immunodetection of collagen II and I, and glycosaminoglycan (GAG) staining in osteochondral cryosections and paraffin sections.

Femurs from 3.5 month old rabbits were fixed in 4% paraformaldehyde/1% glutaraldehyde/0.1M sodium cacodylate for 5 days at 4°C. As our laboratory uses the rabbit knee trochlea as a cartilage repair model, each trochlea was trimmed to 12 mm length with a diamond saw and decalcified in 10% EDTA/0.1% paraformaldehyde in a Milestone microwave oven. For 6 consecutive days, samples were irradiated 9 hours per day using 3 hour cycles of 20 min/500W and 15 min/150W all at 37°C, and left each night at RT in EDTA. After decalcification, blocks were cut in half with a razor: the proximal half was embedded in OCT compound and the distal half in paraffin. 6 µm thick sections were immunostained for collagen I, and II. TRAP was detected by enzymatic stain and GAG by histostaining with Safranin O.

Complete decalcification in EDTA was obtained in 6 days using the microwave procedure versus 3 months in standard procedures. TRAP enzyme activity and immunoreactive antigens were preserved in both paraffin sections and cryosections. This method is a significant improvement over traditional methods due to the relatively short processing time and high quality of cartilage chondrocyte morphology and preservation of bone marrow.

**Effects of Platinum Group Metals Treatment on the Bone of Developing Chick Embryos.** I. E. Pavel<sup>1</sup>, Z. E. Gagnon<sup>\*2</sup>, J. Cawley<sup>\*2</sup>, D. Reens<sup>\*2</sup>.

<sup>1</sup>Department of Chemistry, Wright State University, Dayton, OH, USA, <sup>2</sup>School of Science, Marist College, Poughkeepsie, NY, USA.

Recent studies showed that platinum group metals (PGMs) such platinum (Pt), palladium (Pd), and rhodium (Rh) from automobile catalytic converters, accumulate in the tissues of a variety living organisms. However, the effect of PGMs on bone microarchitecture and development is unknown. To examine these aspects, developing chick embryos were injected at the 7<sup>th</sup> and 14<sup>th</sup> day of incubation with either 0.1, 1.0, 5, or 10 ppm solutions of Pt (<sup>IV</sup>), Rh (<sup>III</sup>), Pd (<sup>II</sup>) or with a PGMs mixture (containing an equal amount of each metal) in saline solutions. Chick organs and tibiotarsus were harvested at the 20<sup>th</sup> day of incubation and examined. 1) Treatments with PGMs concentration above 1 ppm resulted in a bone weight loss accompanied by a decrease in the bone length and diameter directly proportional to the metal concentration (in comparison with the control samples). 2) The PGMs accumulation in soft tissue and bone was followed and quantified by graphite furnace atomic absorption spectrometry (GFAAS) on finely ground powder. The highest metal bioaccumulation was recorded for Pt. It ranged from ~0.012 mg/g of liver tissue to ~0.028 mg/g of brain tissue for metal treatments of 0.1 ppm, and showed a nonlinear increase with the metal treatment concentration. Similar PGM values were found in bone samples. X-ray fluorescence (XRF) and micro-Raman spectroscopy imaging were then used to examine the microspatial distribution of PGMs and the bone demineralization in paraffin embedded bone cross-sections of 4 µm thickness. 3) Pathological changes were observed for all PGM treatments above 1ppm. The most significant changes were noticed for the Pt treatments of 5 and 10 ppm, for which the threshold level of toxicity and the embryo mortality, respectively, were reached. At the Pt exposure level of 10 ppm, apoptotic neurons were detected, eosinophilic inclusion bodies were present in the liver, and the visual appearance of the organs indicated diseased tissue. The first brain cell edemas were noticed at the lowest concentration of 0.1 ppm. Calcium deposits were detected in the brain tissue treated with Rh at a concentration of 5 ppm (Von Kossa staining). This work demonstrated for the first time the accumulation and effects of PGMs in the bone tissues of developing chick embryos.

**Specific Inhibitors of TNAP's Pyrophosphatase Activity Suppress Medial Arterial Calcification.** W. C. O'Neill<sup>\*1</sup>, K. A. Lomashvili<sup>\*1</sup>, S. Narisawa<sup>\*2</sup>, M. C. Yadav<sup>2</sup>, R. Dahl<sup>\*3</sup>, Y. Su<sup>\*3</sup>, M. F. Hoylaerts<sup>\*4</sup>, J. L. Millan<sup>2</sup>. <sup>1</sup>Renal Division, Emory University, Atlanta, GA, USA, <sup>2</sup>Sanford Children's Health Research Center, Burnham Institute for Medical Research, La Jolla, CA, USA, <sup>3</sup>San Diego Center for Chemical Genomics, Burnham Institute for Medical Research, La Jolla, CA, USA, <sup>4</sup>Center for Molecular and Vascular Biology, University of Leuven-Campus Gasthuisberg, Leuven, Belgium.

Humans and mice with low levels of extracellular inorganic pyrophosphate (ePPi), due either to deficient production (NPP1-deficiency) or transport (ANK-deficiency) develop soft-tissue calcification abnormalities, such as severe "idiopathic infantile arterial calcification" (IIAC), ectopic ossification in spinal ligaments, ankylosis and osteoarthritis. Calcification of the medial lamina of blood vessels occurs in IIAC, renal failure, obesity, diabetes, and aging, where it is thought to increase mortality through decreased arterial compliance. Using cultures of vascular smooth muscle cells (VSMC), we have established that VSMCs from Enpp1<sup>-/-</sup> and ank/ank mutant mice upregulate TNAP expression and calcify more than control cells. We have also found that TNAP is upregulated in the aortas of uremic rats. Our working model is that upregulated TNAP activity in the vasculature leads to reductions in ePPi concentrations to levels that no longer suppress calcification. In order to test the hypothesis that inhibition of TNAP's pyrophosphatase activity will prevent/reverse medial calcification we first need to develop potent, specific TNAP inhibitors. An initial screen of 53,280 compounds identified 3 novel inhibitors of TNAP's pyrophosphatase activity. We validated their usefulness kinetically, their ability to prevent calcification in primary cultures of osteoblasts and Enpp1<sup>-/-</sup> VSMCs, and their inhibition of TNAP's pyrophosphatase activity in whole rat aortas ex vivo. More recently, a screening of 66,000 additional compounds resulted in the identification of 4 new scaffolds. At present we have tested two new TNAP inhibitors active in the low  $\mu$ M range, that demonstrate good inhibition of calcification by Enpp1<sup>-/-</sup> VSMCs in vitro and also reduction of the amount of calcium deposited in ex vivo rat aortas. This increased efficiency correlates with improved docking in the TNAP active site. Initial absorption, distribution, metabolism and elimination parameters were established. Both MLS-0010847 and MLS-0038949 show good microsomal and plasma stability and high membrane permeability. We have identified MLS-0038949 as the best candidate to test in vivo and have performed initial pharmacokinetic and biodistribution studies to test the validity of using TNAP as a therapeutic target for vascular calcification.

**Role of Pyrophosphate and Inorganic Phosphate in PKA-Mediated Osteoblastic Differentiation and Mineralization of Primary Murine Aortic Cells.** A. P. Sage<sup>\*</sup>, M. S. Huang<sup>\*</sup>, J. Lu<sup>\*</sup>, L. L. Demer, Y. Tintut. Cardiology (Medicine), UCLA, Los Angeles, CA, USA.

Vascular calcification is associated with increased cardiovascular morbidity and mortality. In vitro evidence suggests that vascular calcification occurs by osteo/chondrogenic differentiation of smooth muscle cells. We have previously found that the inflammatory cytokine, TNF-alpha, induces osteogenic differentiation of smooth muscle cell via activation of the PKA pathway. Recent studies have highlighted the importance of phosphate transport and pyrophosphates in osteoblastic differentiation and mineralization. Therefore, we investigated the role of phosphate transport in PKA-induced osteoblastic differentiation and mineralization of vascular cells isolated from murine aorta. Treatment of primary murine aortic cells with forskolin, which activates adenylate cyclase and downstream PKA signaling, significantly accelerated osteoblastic differentiation, as evidenced by the increased expression of osteoblastic differentiation markers - alkaline phosphatase (ALP), bone sialoprotein and osteocalcin. Forskolin also induced expression of ectonucleotide pyrophosphatase/phosphodiesterase-1 (Enpp-1) and pyrophosphate transporter, Ank, but did not induce the expression of sodium phosphate cotransporter, Pit-1. In the presence of 5 mM beta-glycerophosphate, mineralization was significantly induced by forskolin. Levamisole (an ALP inhibitor) and phosphonoformic acid (PFA; Pit-1 inhibitor) completely abrogated mineralization but did not attenuate expression of the osteoblastic differentiation markers. Inorganic phosphate also induced mineralization of these cells but did not induce expression of the osteoblastic differentiation markers. Phosphate-induced mineralization was inhibited by PFA but not by levamisole. Probenecid (ANK inhibitor) also inhibited mineralization, but further increased forskolin-induced expression of the osteoblastic differentiation markers. These results suggest that phosphate transport and pyrophosphate are needed for mineralization of vascular cells. Pyrophosphate also modulates osteoblastic differentiation. Interestingly, phosphate transport inhibition can completely block mineralization without affecting forskolin-induced markers of osteoblastic differentiation.

## M144

**Abnormality of Bone Formation in Transgenic Mice Expressing Odd-Skipped Related 1.** M. Yamauchi<sup>1</sup>, S. Kawai<sup>2</sup>, A. Amano<sup>\*2</sup>, T. Ooshima<sup>\*1</sup>. <sup>1</sup>Department of Pediatric dentistry, Osaka university Graduate School of Dentistry, Suita-Osaka, Japan, <sup>2</sup>Department of Oral Frontier Biology, Osaka university Graduate School of Dentistry, Suita-Osaka, Japan.

Odd-skipped gene is one of the pair-rule genes which contribute to Drosophila somite formation. Two mammalian homologues, Odd-skipped related 1 (Osr1) and Osr2, are expressed in limb, branchial arches, kidney, eye, and dermis. Previous study on Osr1 deficient mice shows that Osr1 plays a critical role in the heart and urogenital development. We previously reported that Osr2 regulated osteoblast proliferation and bone formation using dominant-negative Osr2 transgenic mice, suggesting that Osr1 is involved in bone formation and osteoblast proliferation. However, the functional role of Osr1 in osteogenesis remains to be elucidated. In this study, we thus generated Osr1 transgenic mice (Osr1 Tg) which expressed full length of Osr1 gene driven by a 2.7 kb mouse Osr1 gene promoter. Genotype was determined by PCR of tail genome using transgene-specific primers. Consequently, the body length and body weight of Osr1 Tg were significantly decreased compared with those of wild type mice. RT-PCR analysis from 5 weeks old wild type mice tissues revealed endogenous Osr1 mRNA expressed in calvarial bone, femur, and tibia. Higher level of Osr1 mRNA expression was detected in those tissues of Osr1 Tg. At 5 weeks and 6 months after birth, soft X-ray analysis of Osr1 Tg revealed an increased radiolucency in cranial bone, compared with those of the wild type mice, and Osr1 Tg also had gibbosity and more round skull shape than those of wild type mice. In addition, we found that the long bones of Osr1 Tg were slightly shorter. Morphologically, calvaria, femur, and tibia of Osr1 Tg were composed of markedly thinner parietal and cortical bones, indicating delayed intramembranous ossification. Osr1 Tg newborn mice skeletons stained with alcian blue and alizarin red showed that calvarial sutural space was wider than that of wild type mice. Our data indicate that Osr1 gene has a role in osteogenesis, especially craniofacial and crural development. The abnormalities such as gibbosity and round skull were found at 5 weeks old Tg mice, however these abnormalities were not seen at newborn Tg mice. The shape of the skull may be dependent on the rate of cranial bone growth and on the timing of suture closure through postnatal growth. We previously reported that Osr1 gene expression was suppressed by Runx2 which is known as an indispensable factor in bone formation. We are investigating whether the role of Osr1 in bone formation is dependent on Runx2 with primary osteoblastic cells from Osr1 Tg and Runx2 deficient mice.

**Quantitation of Bone Marrow Fat in Long Bones of Mice Using MRI or  $\mu$ CT.** D. J. Adams<sup>1</sup>, I. Pinz<sup>\*2</sup>, M. Praeda<sup>\*2</sup>, E. Canalis<sup>3</sup>, N. Troiano<sup>\*4</sup>, M. C. Horowitz<sup>4</sup>, C. Rosen<sup>2</sup>. <sup>1</sup>UCONN Hlth Ctr, Farmington, CT, USA, <sup>2</sup>Maine Med Ctr Res Instit, Scarborough, ME, USA, <sup>3</sup>St. Francis Hospital, Hartford, CT, USA, <sup>4</sup>Yale Univ, New Haven, CT, USA.

Bone marrow fat can be assessed histologically, but has often been considered incidental. Recent reports have noted an inverse correlation between the length of the T1 weighted signal in vertebral marrow and bone density in humans. But the developmental sequence of marrow fat in mice has not been reported. In this study we used two techniques to image and quantitate marrow fat in mice: 1) in vivo MRI of the distal femur of C57BL/6J (B6), and two mutants, Alox5<sup>-/-</sup> (Lipoxygenase 5) and *small*, which carries a mutation in the IRS-1 gene; 2) ex vivo  $\mu$ CT with osmium staining. Longitudinal MRI was performed using images acquired with a RARE pulse sequence (TR 1500 ms, TE 10.39 ms, slice thickness 0.5 mm, FOV 3.5 cm, matrix 256x256, averages 20, and total scan time 16.49 min). Localized <sup>1</sup>H MR spectroscopy was performed using PRESS (point resolved spectroscopy, TR 2000 ms, TE21.44 ms, averages 800, total scan time 26.4 min) in a 1x7x1 mm voxel positioned over the marrow. B6 females were scanned at 8, 12, 26 and 30 wks. By spectroscopy marrow fat was highest in B6 at 8 wks, lower but similar at 12, 26 and 30 wks. In Alox 5<sup>-/-</sup>, marrow fat was assessed at 8, 26 and 36 wks. At 8 wks, Alox 5<sup>-/-</sup> had greater cortical thickness (cort th) vs B6 (0.045  $\pm$  0.001 mm vs. 0.035  $\pm$  0.004 mm, p<0.05), but 40% lower marrow fat. At 26 wks, cort th was higher in B6 than Alox 5<sup>-/-</sup> (0.054  $\pm$  0.004 mm vs 0.047  $\pm$  0.002 mm, p<0.05), but Alox 5<sup>-/-</sup> had 30% higher marrow fat than B6. By 36 wks, cort th in B6 had doubled (0.063 mm  $\pm$  0.003 mm) whereas Alox 5<sup>-/-</sup> showed a slight increase to 0.051  $\pm$  0.001 mm. However, marrow fat did not change between 26 and 36 wks in either strain. In *small* mice there was near total absence of marrow fat by MRI but very low BV/TV and cort th; this was confirmed by histology. An alternative approach to MRI is osmium tetroxide (OT), which specifically stains fat and we have demonstrated that OT staining can visualize and enumerate adipocytes in nondecalcified, plastic embedded bone sections. However, this approach is time consuming and limited by the field of the section. Because OT is radiopaque to X-ray, stained adipocytes can be imaged using  $\mu$ CT. Femora from Ebf1<sup>-/-</sup> mice (high marrow fat and high BV/TV) and littermate controls were fixed, decalcified, stained with OT, and imaged using  $\mu$ CT. Adipocyte density was greatest in the epiphysis and metaphysis of the distal femur, extending proximally a few millimeters in an anterolateral cluster. Adipocyte volume in Ebf1<sup>-/-</sup> mice showed a 16-fold increase vs control bone. Thus, we believe use of MRI and  $\mu$ CT to quantitate fat in bone is a major technological advance, and facilitates developmental analysis of the relationship between osteoblastogenesis and adipogenesis.

**The Effect of Lead on Bone Mineral Properties from Female Adult C57/BL6 Mice.** A. Monir<sup>\*1</sup>, S. Yagerman<sup>\*2</sup>, M. C. H. van der Meulen<sup>2</sup>, C. M. Gundberg<sup>3</sup>, A. Boskey<sup>4</sup>, T. Dowd<sup>1</sup>. <sup>1</sup>Department of Chemistry, Brooklyn College of the City University of New York, New York, NY, USA, <sup>2</sup>Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, USA, <sup>3</sup>Department of Orthopedics, Yale University School of Medicine, New Haven, CT, USA, <sup>4</sup>Musculoskeletal Integrity Program, Hospital for Special Surgery, New York, NY, USA.

Lead toxicity continues to be a major problem in the U.S. with elevated blood lead levels being highest among very young children and older adults  $\geq 50$  years old. Bone is the major reservoir of body lead and accounts for 75% in children and 90% in adults. We investigated the effect of lead accumulation on the femora from adult, 6 month old female C57/BL6 mice ( $n=10$ /group) who were administered lead in the drinking water (250 ppm, blood lead 35 $\mu$ g/dl at sacrifice) for 4 months. Bone mineral properties were examined using Fourier Transform Infrared Microscopy (FTIRM), quantitative microcomputed tomography (microCT) and biomechanical measurements. Lead significantly decreased the bone mineral density in the cortical and proximal trabecular bone, increased the marrow area in the cortical bone and increased the bone volume fraction in proximal bone with microCT. Whole bone three-point bending showed a trend of decreased maximum and failure moments in the lead treated bones compared to controls. Lead significantly decreased the mineral/matrix ratio, collagen maturity and crystallinity in the trabecular bone as measured by FTIRM. In the cortical bone lead significantly decreased collagen maturity and produced a trend showing an increased carbonate/mineral ratio by FTIRM. In contrast to cell culture studies, lead significantly increased serum osteocalcin levels ( $71 \pm 3.5$  vs.  $46 \pm 3.3$ ,  $p<.001$ ) suggesting increased bone turnover. These data show a weakening of cortical bone with lead in adult, female mice and suggest that lead may exacerbate bone loss and osteoporosis in the elderly.

## M147

**Betulin Down Regulates Interleukin-1 $\alpha$ -stimulated Aggrecanases and Matrix Metalloproteinases Gene Expression in Human Chondrocytes.** J. Huh<sup>\*</sup>, Y. Baek<sup>\*</sup>, D. Kim<sup>\*</sup>, D. Choi<sup>\*</sup>, J. Lee<sup>\*</sup>, D. Park<sup>\*</sup>. <sup>1</sup>Oriental Medicine Research Institute for Bone and Joint disease, KyungHee University, Seoul, Republic of Korea, <sup>2</sup>Department of Acupuncture & Moxibustion, College of Oriental Medicine, KyungHee University, Seoul, Republic of Korea, <sup>3</sup>Department of Nuclear Medicine, College of Medicine, KyungHee University, Seoul, Republic of Korea.

**Objects:** Interleukin-1 $\alpha$ (IL-1 $\alpha$ ) is a pro-inflammatory cytokine that causes anti-anabolic and catabolic effects on articular chondrocytes via four major signaling pathways. In this study, we investigated the role of betulin, a triterpenoid agent, on these pathways for the repression of aggrecan and type II collagen, and induction of aggrecanases and matrix metalloproteinases in human osteoarthritic chondrocytes.

**Methods:** Chondrocytes were pretreated with various dose of betulin for 24 h, followed by IL-1 $\alpha$  for 1 h. Reverse transcription-polymerase chain reaction was performed to determine mRNA levels of type II collagen and aggrecan, matrix metalloproteinases (MMP-1,13), aggrecanases (-1, -2). Activity of mitogen-activating protein kinases (MAPK) was assayed by Western blot.

**Results:** Betulin enhance the synthesis of aggrecan and type II collagen and reduce the aggrecanase-1, -2 and MMP-1, -13 synthesis. In addition, betulin effectively inhibit the IL-1 $\alpha$ -activated extracellular signal-regulated kinases (ERK1/2), c-Jun NH<sub>2</sub>-terminal kinase (JNK) and p38-MAPK activation, and the binding of NF-kappaB and AP-1 transcription factors, two key factors involved in the expression of several pro-inflammatory genes in chondrocytes.

**Conclusion:** These results suggest that use of betulin or triterpenoid compounds derived from it may be of potential benefit in inhibiting signaling events associated with cartilage degradation in osteoarthritis.

**OAH19, an Ethanol Extract from Combined Two Herbs, Inhibits Interleukin-1 Alpha-induced Expression of Matrix Metalloproteinase-1 and -13 in Osteoarthritic Human Cartilage and Synovial Fibroblast.** Y. Baek<sup>\*1</sup>, J. Huh<sup>\*2</sup>, J. Lee<sup>\*1</sup>, D. Choi<sup>\*1</sup>, D. Kim<sup>3</sup>, D. Park<sup>\*1</sup>. <sup>1</sup>Department of Acupuncture & Moxibustion, College of Oriental Medicine, KyungHee University, Seoul, Republic of Korea, <sup>2</sup>Oriental Medicine Research Center for Bone & Joint Disease, KyungHee University, Seoul, Republic of Korea, <sup>3</sup>Department of Nuclear Medicine, College of Medicine, KyungHee University, Seoul, Republic of Korea.

**Objects:** Subchondral bone sclerosis is a common feature of osteoarthritis (OA), but the mechanisms responsible for this condition remain unresolved. we investigate the effects of beta-D-glucopyranoside from *Phellodendron amurense* on the production of

inflammatory cytokines (interleukin (IL)-1 $\alpha$ , IL-6, and prostaglandin E2 (PGE<sub>2</sub>)), growth factors (vascular endothelial growth factor (VEGF) and transforming growth factor-beta (TGF- $\beta$ )), matrixmetalloproteinase (MMP)/urokinase plasminogen activator (uPA) and bone markers in human subchondral OA Ob.

**Methods:** We measured the abundance of IL-1 $\alpha$ , IL-6, PGE<sub>2</sub>, VEGF, TGF- $\beta$ , MMP-1 and uPA using very sensitive ELISA in conditioned-media of human primary subchondral Ob from normal individuals and osteoarthritic patients. beta-D-glucopyranoside or selective COX-2 inhibitor (NS398) was performed to determine its effect on inflammatory cytokines, growth factors, MMP/uPA. The expression of bone cell markers was also determined.

**Results:** OA Ob produced all these factors with greater variability than normal cells. Interestingly, the production of IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA by OA Ob separated patients into two subgroups, those whose Ob produced levels comparable to normal (low producers) and those whose Ob produced higher levels (high producers). In those cells classified as high producers, IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA levels were increased two- to three-fold and five- to six-fold, respectively, compared with normal. In contrast, we found that IL-1 $\alpha$  and TGF- $\beta$  levels were similar in normal and all osteoarthritic Ob. beta-D-glucopyranoside significantly reduced IL-6, PGE<sub>2</sub>, VEGF and MMP-1/uPA levels in all OA Ob. In contrast, using NS398 did not reduce VEGF and MMP-1/uPA levels in either group. The evaluation of alkaline phosphatase activity, osteocalcin release and collagen type I activity increased by beta-D-glucopyranoside in OA Ob regardless to which subgroup they were assigned.

**Conclusion:** These results suggest that beta-D-glucopyranoside may contribute to bone remodeling through inhibition of inflammation and MMP/uPA system in subchondral OA Ob, ultimately leading to treatment of abnormal bone sclerosis in OA.

## M149

**Effect of Bisphosphonate Treatment of Osteoarthritis in a Guinea Pig Model.** A. Brüel, T. S. Straarup<sup>\*</sup>, C. C. Danielsen<sup>\*</sup>, H. Oxlund<sup>\*</sup>, J. S. Thomsen. Institute of Anatomy, University of Aarhus, Aarhus, Denmark.

Dunkin Hartley guinea pigs spontaneously develop osteoarthritis (OA) at approximately 3 months of age. The effect of bisphosphonate (Risedronate, BP) on the development of OA in Dunkin Hartley guinea pigs was investigated. Our hypothesis is that treatment with BP would decrease bone turnover and thereby reduce formation of new subchondral bone resulting in a reduced load on the articular cartilage, thus arresting the development of OA.

Fifty-six 3-month-old male Dunkin Hartley guinea pigs were randomized into 7 groups. Three groups received Risedronate (30  $\mu$ g/kg) injections s.c. 5 times a week for 6, 12, or 24 weeks. The remaining four groups served as either baseline or controls receiving vehicle. The left hind limb was removed from the anesthetized animals before they were perfusion fixed. The right knee was embedded undecalcified in MMA and 7- $\mu$ m-thick frontal sections were cut through the central part of the condyles, where the articular cartilage is not covered by meniscus. The sections were stained with Safranin O, TRAP, or von Kossa. The OA was scored with the Osteoarthritis Research Society International (OARSI) score. The articular surface of the left proximal tibia was stained with Indian ink, and the area of the articular cartilage lesion was determined from digital images of the medial tibial plateau. Using TRAP sections, osteoclast covered surfaces were counted in the medial epiphysis with CAST grid software. Digital images of the von Kossa stained sections were obtained and combined trabecular and cortical bone volume fraction (bone density) and subchondral plate thickness were determined using custom software.

The OARSI score did not differ between the BP-treated and the control animals at any time-point. The area of the articular cartilage lesions of the BP-treated animals was significantly higher after 6 weeks, but did not differ at the later time-points. The combined OARSI and area score did not differ at any time-point. The bone density was higher for the BP-treated animals, but significant only at 6 and 12 weeks. The OARSI score was significantly correlated with the bone density when all animals were pooled. The subchondral plate was significantly thicker in BP-treated animals than in control animals at all time-points. The BP treatment significantly suppressed the fraction of osteoclast covered surfaces at all time-points.

In conclusion, treatment with Risedronate did not influence the development of OA in Dunkin Hartley guinea pigs.

**Impact of Calpain Inhibition on Chondrocyte Development.** A. Kashiwagi<sup>\*1</sup>, E. Schipani<sup>1</sup>, P. A. Greer<sup>\*2</sup>, A. P. McMahon<sup>\*3</sup>, M. Shimada<sup>1</sup>.

<sup>1</sup>Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, <sup>2</sup>Queen's University Cancer Research Institute, Kingston, ON, Canada, <sup>3</sup>Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA, USA.

We have previously demonstrated that the calpain small subunit directly binds the intracellular C-terminal tail of the PTH/PTHrP receptor (PPR) and modifies its cellular functions *in vitro*. To investigate a role of *capn4* in cells of osteoblast lineage *in vivo*, we established osteoblast-specific *capn4* knockout mice by mating mice homogenous for floxed *capn4* alleles (*Capn4*<sup>fl/fl</sup>) with mice expressing *Cre* under the control of osterix promoter (*Osx-Cre*<sup>+/+</sup>). As previously reported, *Osx-Cre*<sup>+/+</sup>*Capn4*<sup>fl/fl</sup> (mutant) mice had smaller bodies with shorter limbs, reduced trabecular bone, and decreased osteoblast number, at least in part, due to reduced proliferation of cells of the osteoblast lineage.

Interestingly, in *Osx-Cre<sup>+/+</sup>* transgenic mice, *Cre* recombinase is expressed not only in early cells of the osteoblast lineage but also in late proliferating chondrocytes. We, thus, hypothesize that the smaller size of the skeleton of mutant mouse at E14.5 and birth could be caused by abnormal growth plate development secondary to genetic ablation of *capn4* in chondrocytes. Routine histology and *in situ* hybridization analysis were performed on histological sections of hind limbs isolated from E14.5, E15.5 and E18.5 embryos, respectively. At E14.5, the expression patterns of type II collagen, *PPR*, and type X collagen (*ColX*) mRNAs were similar in *Osx-Cre<sup>+/+</sup>Capn4<sup>fl/-</sup>* (control) and mutant mice. Conversely, the domain of *OP* mRNA expression was markedly reduced and *MMP13* mRNA was virtually undetectable in mutants vs. controls. A spatially restricted expression of both *ColX* and *OP*, and a severe decrease of the *MMP13* mRNA levels were also observed in E15.5 mutants vs. controls. Thus, these data suggest that terminal differentiation of chondrocytes was delayed in mutant embryos. Consistent with this developmental delay, mutant mice displayed a shorter bone collar as indicated by von Kossa staining. Blood vessel invasion and formation of the primary ossification center were also delayed in mutant embryos as shown by histology and *in situ* hybridization analysis of type I collagen mRNA expression. We further tested calpain's role in chondrocyte proliferation and differentiation using chondrogenic progenitor cells, ATDC5. ATDC5 cells treated with calpain-specific inhibitor, ALLM, showed significantly reduced both cell mitosis and cyclin D protein accumulation, and mRNA expression of chondrocyte differentiation markers such as *ALP*, *PPR*, *ColX*, and *MMP13*. Collectively, these results suggest that calpain plays a critical role in chondrocyte proliferation and differentiation.

**Essential Hox Gene Function in Limb Skeletal and Synovial Joint Formation.** E. Koyama<sup>\*1</sup>, T. Ochiai<sup>\*1</sup>, D. Wellik<sup>\*2</sup>, M. Pacifici<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA, <sup>2</sup>Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA.

*Hox* genes are key regulators of early limb skeletal patterning, but their subsequent roles in cartilaginous anlage and synovial joint development remain largely unclear. Here we analyzed mice lacking *Hoxa10/Hoxc10/Hoxd10* or *Hoxa11/Hoxc11/Hoxd11* paralogues and focused on their hindlimbs. Newborn *Hox10* compound mutants contained a drastically shortened and abnormally shaped femoral cartilaginous anlage, while the *Hox11* mutants contained abnormal tibial and fibula anlagen. Interestingly, the latter mutant anlagen closely resembled each other, implying that the normal significant morphological difference between tibia and fibula was lost. The chondrocytes within the prospective metaphyseal and diaphyseal regions of all affected skeletal elements failed to organize in growth plates, displayed a small size and expressed markedly lower levels of genes normally associated with their maturation and hypertrophy, including Indian hedgehog and collagen X. Not surprisingly, primary spongiosa and intramembranous bone collar formation were severely delayed compared to age-matched wild type mice. Behavior and function of epiphyseal joint-associated chondrocytes were deranged as well. Normally, the knee joint involves articulation of distal femoral epiphysis with proximal tibial epiphysis without the participation of fibula. In the mutants, however, the knee joints were mis-shaped and both tibia and fibula epiphyses articulated with an enlarged femoral epiphysis, thus creating an ectopic fibula-femoral joint. In addition, articular cartilage tissue was disorganized, and the ectopic fibula-femoral joint was associated with ectopic expression of joint-associated genes such as lubricin. In sum, *Hox* genes not only direct early skeletal patterning, but have essential roles in continuation of long bone development and in synovial joint formation. Presence of an ectopic fibula-femoral joint in addition to a tibial-femoral joint indicates that fibula and tibia anlagen lose their identity and developmental distinction in the absence of *Hox10* or *Hox11* function.

**Disclosures:** E. Koyama, None.

**BT-201, a Butanol Extract of *Panax notoginseng* Inhibits Progression of Joint Degeneration in a Rat Model of Osteoarthritis.** S. Chang<sup>\*1</sup>, J. Han<sup>\*1</sup>, J. Park<sup>\*1</sup>, M. Son<sup>\*1</sup>, D. Jung<sup>\*2</sup>, B. Lee<sup>\*2</sup>, S. Shim<sup>\*2</sup>, S. Kim<sup>1</sup>, J. Ko<sup>1</sup>, K. Kim<sup>\*1</sup>. <sup>1</sup>Dept. of Pharmacology and Mechanism, Oscotec Inc., Cheonan, Republic of Korea, <sup>2</sup>Dept. of Botanical Medicine, Oscotec Inc., Cheonan, Republic of Korea.

Osteoarthritis (OA) is a degenerative joint disease in which proinflammatory cytokines such as IL-1 $\beta$  and TNF- $\alpha$  stimulate cartilage destruction. From the screening of various herbal extracts, we found that BT-201, an n-butanol extract of *Panax notoginseng* (Burk.) F. H. Chen (*P. notoginseng*) has the ability to inhibit TNF- $\alpha$  secretion and protect from the degradation of cartilage matrix. The purpose of this study has been to evaluate potential therapeutic effects of BT-201 on osteoarthritis. The cartilage protective effects of BT-201 were evaluated by measuring the production of matrix metalloproteinase (MMP-2), matrix metalloproteinase-13 (MMP-13), tissue inhibitor of matrix metalloproteinase-3 (TIMP-3) and glycosaminoglycan (GAG). BT-201 significantly inhibited the production of MMP-13 and GAG in a dose-dependent manner, but not MMP-2 *in vitro*. And BT-201 increased the production of TIMP-3 from osteosarcoma cells. In addition, oral administration of BT-201 (15 mg/kg, once a day for 21 days) to OA rat significantly reduced cartilage destruction. These results suggest that BT-201 may be used as a promising botanical drug for the treatment of osteoarthritis.

**Disclosures:** S. Chang, None.

**Overexpression of CCN2/CTGF in Cartilage Shows Prolonged Bone Length Resulting from Stimulation of Chondrogenesis, Chondrocyte Growth, Apoptosis, and Bone Mineralization During Endochondral Ossification.** N. Tomita<sup>\*1</sup>, T. Hattori<sup>\*1</sup>, S. Ito<sup>\*1</sup>, E. Aoyama<sup>\*1</sup>, M. Yao<sup>\*1</sup>, T. Yamashiro<sup>\*2</sup>, M. Takigawa<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Dentistry, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama City, Japan, <sup>2</sup>Orthodontics, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama City, Japan.

CCN2/CTGF is highly expressed in prehypertrophic chondrocytes. Our previous studies using cultured chondrocytes and the analysis of *ccn2*-deficient mice show CCN2 promotes proliferation, differentiation, and maturation of growth plate chondrocytes. However, there is no direct evidence showing that it promotes cartilage development and growth *in vivo*. Here we generated transgenic mice (tg) overexpressing the *ccn2* gene in cartilage under the control of the type II collagen (*col2a1*) promoter and show for the first time that this overexpression of CCN2 causes extended bone length. To overexpress CCN2 in cartilage, *ccn2* cDNA was inserted to downstream of the 6 kb-*Col2a1*-enhancer/promoter followed by *IRES-LacZ*. Whole mount X-gal staining showed transgene expression in all cartilage, overexpressed *ccn2* mRNA and CCN2 protein were detected in tg cartilage. Tg mice showed increased body size resulting from prolonged bones. Immunohistochemical analysis of tibia showed accumulation of proteoglycans and type II collagen in cartilage, while hypertrophic zone was shortened. The length of tibia was prolonged depending on the overexpression level of *ccn2* mRNA. Cell proliferation was accelerated in the resting zone in addition to the growth plate. TUNEL assay showed accelerated apoptosis in cartilage-bone transition. Bone density of cancellous bone and thickness of cortical bone were increased in tg mice by peripheral quantitative computed tomography (pQCT) analysis. Cultured chondrocytes isolated from tg mice showed enhanced expression of *col2a1*, *col10a1* and *aggrecan* mRNA and accumulation of proteoglycans. Furthermore, expression of vascular invasion factors such as *vegf* and *mmp9* mRNA was also enhanced. Micromass culture of limb buds from 11.5E tg embryos showed accelerated chondrogenesis.

Our findings indicate that CCN2 promotes chondrogenesis and accelerates growth of cartilage, chondrocyte death, and bone mineralization during endochondral ossification, resulting in prolonged long bones.

**Development of Osteoarthritis and Its Relationship to Meniscal Ossification in Dunkin Hartley Guinea Pigs.** J. S. Thomsen, T. S. Straarup<sup>\*</sup>, C. C. Danielsen<sup>\*</sup>, H. Oxlund<sup>\*</sup>, A. Br  l. Institute of Anatomy, University of Aarhus, Aarhus, Denmark.

Dunkin Hartley guinea pigs is a well established animal model of spontaneous development of osteoarthritis (OA). It has been observed that the menisci of these rodents ossify at a very early age and well before the OA develops. Our hypothesis is that this meniscal ossification may play a role in the pathogenesis of OA in these animals. Ten male Dunkin Hartley guinea pigs to each of the ages 2, 6, 9, and 12 months were anaesthetized and the left hind limb was removed before the animals were perfusion fixed. The meniscus of the left tibia was dissected free and embedded in MMA. Horizontal 7- $\mu$ m-thick sections were cut at every 140  $\mu$ m through the entire meniscus and stained with Goldner trichrome. For all sections the amount of fibrous cartilage, hyaline cartilage, and bone was determined using CAST grid software. The articular surface of the left proximal tibia was stained with Indian ink and the areas of the articular cartilage lesions were determined from digital images of the tibial plateaus. The right knee was embedded in MMA and 7- $\mu$ m-thick frontal sections were cut through the central part of the condyles, where the articular cartilage is not covered by meniscus, and stained with Safranin O. The degree of OA was scored using the Osteoarthritis Research Society International (OARSI) score.

At the medial condyle, no articular cartilage lesions were found in the 2-month-old animals, whereas the older animals showed increasing OA score. At the lateral condyle, early stage OA was found in five 12-month-old animals, whereas no cartilage lesions were found in the younger animals. The meniscal bone volume/total meniscal volume (ossified meniscus fraction) increased with age from 26% to 38% (medial), and from 16% to 28% (lateral). The severity of the articular lesions were significantly correlated to the medial ossified meniscus fraction ( $r^2 = 0.6$ ,  $p < 0.0001$ ).

In conclusion, the present study showed that ossification of the medial meniscus is correlated to the development and progression of OA in Dunkin Hartley guinea pigs. However, additional factors may also play a role in the pathogenesis of OA. Nevertheless, these findings may question whether the OA developed in this animal model is comparable to human primary OA, where ossification of the meniscus rarely occurs.

**PTH has Direct Anabolic Effects on Osteoarthritic Articular Cartilage *in Vitro* and *in Vivo*: Is PTH a New Treatment for Osteoarthritis?** B. C. Sondergaard<sup>\*1</sup>, S. H. Madsen<sup>\*1</sup>, A. B. Jensen<sup>\*1</sup>, N. A. Sims<sup>2</sup>, J. Gooi<sup>\*2</sup>, M. A. Karsdal<sup>1</sup>. <sup>1</sup>Pharmacology, Nordic Bioscience, Herlev, Denmark, <sup>2</sup>St. Vincent's Institute, Fitzroy, Australia.

The pathogenesis of osteoarthritis (OA) involves major changes in both the bone and cartilage compartments of the affected joints. It is well-known that PTH is bone anabolic. One signaling pathway of the PTH G-coupled receptor on osteoblasts is through cAMP. cAMP has recently shown to be of major importance for chondrocyte phenotype. We investigated whether chondrocytes, which originate from the same mesenchymal stem cell type as osteoblasts, responded anabolically to PTH treatment, and thereby whether PTH may represent a novel possible treatment opportunity for OA. We used validated human OA cartilage models and a pre-clinical model of accelerated cartilage loss for our investigations.

*In vitro*: Human chondrocytes were isolated and maintained serum-free for 1h in the presence of 100µM IBMX (PDE inhibitor), and subsequently stimulated with PTH 1nM-100nM + IBMX and the cAMP levels were quantified by ELISA. Articular cartilage explants were cultured in 6 replicates for 17 days, with or without 10nM PTH treatment, and 5µCi <sup>35</sup>Sulphate was added for the last 24h. Soluble proteoglycans were released by 4M GuHCl and incorporated sulphate was measured. Neo-epitopes of pro-peptides of collagen type II (PIINP) were quantified as a measure of formation in the conditioned medium. *In vivo*: Forty 5-month old female rats were subjected to either sham or ovariectomy (OVX), and administered either vehicle or hPTH(1-34) 30µg/kg by s.c. injection for 5 weeks, n=10. Serum samples were evaluated by osteocalcin, CTX and CTX-II ELISAs.

Accumulated intracellular cAMP levels increased dose-dependently from 1nM PTH, p=0.003, with a maximum 23-time increase at 100nM PTH, p<0.0001. In cultures of OA articular cartilage explants PIINP levels increased over 100% after PTH stimulation compared to non-stimulated cartilage explants. Additionally, 10nM PTH increased incorporation of <sup>35</sup>Sulphate by 40%, p=0.002. In the OVX animals the osteocalcin levels were significantly elevated after PTH treatment compared to sham and vehicle treated, p<0.001. Cartilage degradation measured by CTX-II in serum was decreased by 60% as well, p<0.01.

An increasing amount of attention is directed to potential treatments for OA with positive effect on calcium metabolism. The current data strongly suggest that PTH also has direct anabolic effects on chondrocytes. Furthermore, in a pre-clinical model of OA, PTH decreased cartilage degradation significantly. These data warrant further investigation of PTH as a potential as treatment for OA.

**Gene Expression Profiling within Murine Growth Plates Using DNA Microarrays.** S. Nishimori, T. Kobayashi, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital / Harvard Medical School, Boston, MA, USA.

To investigate gene expression profiling in the murine growth plates comprehensively, we took a systems-biological approach based on a high density oligonucleotide probe array (Affymetrix GeneChip<sup>®</sup>), using total RNA obtained from three anatomically and functionally distinct chondrocyte types (round cell layer (RL), flat cell layer (FL), and hypertrophic cell layer (HL)). We chose manual microdissection of fresh-frozen newborn proximal tibiae rather than Laser Capture Microdissection to obtain as much total RNA as possible, to avoid possible distortion of gene expression by multiple rounds of RNA amplification. We assessed chondrocyte layers with biological triplicate RNA samples, using Mouse Genome 430 2.0 Arrays. RT-PCR and *in situ* hybridization were used with a subset of genes to validate the microarray data.

We judged expression of a probe set positive, when Affymetrix GeneChip<sup>®</sup> Operating Software called it as "present" for all three chips from the same layer. Out of 45,037 probe sets, 18,763 (42 %), 17,749 (39 %), and 18,772 probe sets (42 %) were expressed in RL, FL, and HL, respectively. 15,744 probe sets (35 %) were expressed in all three layers, and 23,846 (53 %) were not expressed in any layer. 1281 (2.8%), 460 (1.0 %), and 1101 (2.4 %) probe sets were expressed only in RL, FL, and HL, respectively.

To analyze differentially expressed genes, we used Rosetta Resolver<sup>®</sup> software. We imported the triplicate data from 21,191 probe sets (=45,037-23,846) into Rosetta Resolver<sup>®</sup>, which then defined one normalized value for each probe. After filtering by "fold ratio≥2" in at least one ratio (R vs. F, F vs. H, H vs. R), we identified 2,683 probe sets that correspond to genes expressed differentially in various layers. Cluster analysis was then used to group these 2,683 probe sets into 9 groups with similar patterns of expression across the three types of chondrocytes.

Out of these groups, we focused on 163 probe sets that are differentially expressed in the flat cell layer (F/R≥2 and F/H≥2), because few genes have been described as unique to the flat cell layer. Interestingly, we found 60 genes identified as "muscle" genes by the Gene Ontology Database in this group. Though manual dissection might have led to muscle contamination of these chondrocytes, several genes highly expressed in muscle were not found in this group, making contamination as unlikely explanation. Since the transcription factor, MEF2C, regulates gene expression in the growth plate, we are exploring the possible roles of muscle transcription factors as potential regulators of these genes.

**Thyroid Hormone Activates Wnt Signaling Pathways in Rat Growth Plate Chondrocytes.** L. Wang<sup>\*1</sup>, Y. Y. Shao<sup>\*1</sup>, R. T. Ballock<sup>2</sup>. <sup>1</sup>Biomedical Engineering, The Cleveland Clinic Foundation, Cleveland, OH, USA, <sup>2</sup>Orthopaedic Surgery and Biomedical Engineering, The Cleveland Clinic Foundation, Cleveland, OH, USA.

Both thyroid hormone signaling and Wnt signaling pathways are involved in the regulation of skeletal maturation in the growth plate. Previously we demonstrated that thyroid hormone promotes canonical Wnt/beta-catenin signaling and terminal differentiation of growth plate chondrocytes by upregulating Wnt-4 expression, increasing the intracellular accumulation of beta-catenin, enhancing TCF/LEF transcriptional activity, and activating transcription of the Wnt target gene Runx2.

There are at least nineteen Wnt genes, ten Wnt receptor Frizzled genes, and five Wnt antagonist secreted frizzled related receptors (sFRPs) in the mouse and human genome. To increase our understanding of the interactions between thyroid hormone and Wnt signaling, we examined the expression of Wnt pathway components in the growth plate, including Wnt, Frizzled and sFRP genes, and analyzed their expression in response to thyroid hormone treatment.

RT-PCR analysis revealed that Wnt-4, Wnt-5a, Wnt-5b, Wnt-9a, and Wnt-11 genes are expressed in the rat growth plate. Likewise, Frizzled-1, Frizzled-2, Frizzled-5, and Frizzled-7 expression was detectable, as well as sFRP-1, sFRP-2, sFRP-3 and sFRP-4.

Expression of these genes was then analyzed in T3-treated cells using quantitative real-time PCR. Growth plate chondrocytes were collected from the resting zone of the distal femurs of 2-day old rats. The cells were cultured in pellets and incubated in serum-free medium. T3 was added at a concentration of 100 ng/ml. RNA was extracted at day 2, day 5 and day 7 of treatment.

The results showed that T3 increased the expression of Wnt-4, Wnt-5b, and Wnt-11 as early as day 2 of treatment, and increasing at day 5 and day 7. Wnt-9a was expressed at relatively lower levels; however, Wnt-9a was also upregulated by T3 at day 5 and day 7. All four Wnt receptors (Frizzled-1, -2, -5, and -7) were not significantly regulated by T3 treatment. Administration of sFRP1, -2 and -3 recombinant proteins all resulted in an inhibition of T3-mediated terminal differentiation, as shown by the decreases in both Col10a1 mRNA expression and alkaline phosphatase activity. sFRP1 and sFRP2 expression was down-regulated by T3 at day 2, day 5 and day 7, while sFRP3 was decreased at day 2 and day 7 only. In contrast, sFRP4 was significantly upregulated by T3 treatment from day 2 to day 7.

Together these data suggest that thyroid hormone promotes Wnt signaling in growth plate chondrocytes by activating expression of both canonical and non-canonical Wnt ligands while downregulating the expression of several Wnt antagonists.

**Regulation of Hypertrophic Chondrocyte Apoptosis.** S. U. Miedlich<sup>\*</sup>, M. B. Demay. Endocrine Unit, MGH, Boston, MA, USA.

*In vivo* studies in genetically modified (Npt2a knockout, VDR knockout and hyp) and dietary manipulated mouse models have demonstrated that hypophosphatemia leads to impaired apoptosis of hypertrophic chondrocytes in the growth plate. Treatment of wild type C57BL/6 mice with caspase 9-inhibitors prevents apoptosis of hypertrophic growth plate chondrocytes demonstrating a critical role for the mitochondrial apoptotic pathway in hypertrophic chondrocytes. Because proliferative chondrocytes are not susceptible to phosphate-mediated apoptosis we hypothesized that during maturation hypertrophic chondrocytes either increase their phosphate transport or increase their susceptibility to phosphate-induced apoptosis. Recent studies suggest a decrease in the mitochondrial membrane potential during chondrocyte maturation as a possible prerequisite to apoptosis in chicken chondrocytes.

The clonal chondrocytic cell line (RCJ3.1C5.18) recapitulates the program of chondrocytic differentiation in culture, including acquisition of markers of hypertrophic differentiation and formation of mineralized matrix nodules. These cells were used as an *in vitro* model of chondrocyte maturation and phosphate-induced apoptosis. Collagen X, a marker of hypertrophic chondrocyte differentiation, was observed in RCJ3.1C5.18 cells after 7-10 days of culture in the presence of ascorbic acid. Annexin V-PE was employed to measure plasma membrane changes associated with apoptosis. Quantification of the mitochondrial membrane potential was performed by FACS analysis of JC-1 and/or Mitotracker Orange, dyes which are used to evaluate mitochondrial depolarization. Treatment of hypertrophic chondrocytes with phosphate (7 mM) resulted in a significant increase in apoptosis within 24h of treatment and was partially (50%) inhibited by alendronate, an inhibitor of phosphate transport. In addition, a progressive decrease in the mitochondrial membrane potential was observed during chondrocyte maturation.

These findings were confirmed in primary chondrocytes isolated from costal cartilage of newborn C57BL6 mice. Treatment of hypertrophic chondrocytes with 7 mM phosphate resulted in caspase 9 activation and a significant increase in apoptotic cells within 24h. A differentiation-dependent decrease in mitochondrial membrane potential was also observed.

Characterization of the mechanisms underlying the susceptibility of hypertrophic chondrocytes to phosphate-induced apoptosis in hypertrophic chondrocytes will not only further our understanding of the development of rickets but may also provide insights into the regulation of growth plate maturation and apoptosis.

**Proinflammatory Mediators Downregulate Peroxisome Proliferator-Activated Receptor gamma1 Expression and Activity In Osteoarthritic Synovial Fibroblasts.** H. Afif\*, N. Chabane\*, N. Zayed\*, J. Martel-Pelletier\*, J. P. Pelletier\*, H. Fahmi\*. CHUM, Université de Montréal, Montreal, QC, Canada.

**Introduction:** Peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ) is a nuclear receptor involved in the regulation of many cellular processes including inflammation. We and other have previously shown that PPAR $\gamma$  activators inhibit several inflammatory and catabolic responses in synovial fibroblasts and to be protective in animal models of osteoarthritis. PPAR $\gamma$  has two isoforms, PPAR $\gamma$ 1 and PPAR $\gamma$ 2 generated by alternative promoters and differential splicing. So far, little is known about the factors and the mechanisms that regulate PPAR $\gamma$ 1 and PPAR $\gamma$ 2 expression in synovial fibroblasts.

**Aim:** In this study we investigated the effect of IL-1 $\beta$ , TNF- $\alpha$ , IL-17 and PGE2, on the expression and activity of PPAR $\gamma$ 1  $\alpha$ 8  $\gamma$ 2 in osteoarthritic synovial fibroblasts.

**Methods:** Synovial fibroblasts were treated with increasing concentrations of IL-1 $\beta$ , TNF-1, IL-17 or PGE2 for different time periods. PPAR $\gamma$ 1 and  $\gamma$ 2 mRNA and protein levels were evaluated by real-time PCR and western-blotting analysis, respectively. PPAR $\gamma$ 1 promoter activity and PPAR $\gamma$ 1 transcriptional activity were analyzed in transient transfection experiments.

**Results:** Quantification of PPAR $\gamma$ 1 and PPAR $\gamma$ 2 mRNAs revealed that PPAR $\gamma$ 1 mRNA levels were 20-fold higher than PPAR $\gamma$ 2 mRNA levels. IL-1 $\beta$ , TNF- $\alpha$ , IL-17 and PGE2 reduced the expression of PPAR $\gamma$ 1 protein in a dose-dependent manner. Similarly, these factors dose- and time-dependently inhibited the expression of PPAR $\gamma$ 1 mRNA as well as PPAR $\gamma$ 1 promoter activity, suggesting that these effects occurred at the transcriptional levels. Finally, we demonstrated that IL-1 $\beta$ , TNF- $\alpha$ , IL-17 and PGE2 dose-dependently suppressed PPAR $\gamma$ 1 transcriptional activity.

**Conclusion:** These results suggest that OA synovial fibroblasts express predominantly PPAR $\gamma$ 1 isoform, and that IL-1 $\beta$ , TNF- $\alpha$ , IL-17 and PGE2 might contribute to the pathogenesis of arthritis by downregulating the expression and activity of PPAR $\gamma$ 1.

**Reconstruction of Massive Skeletal Defects due to Osteomyelitis by Distraction Osteogenesis.** D. Peng\*<sup>1</sup>, Z. Li\*<sup>2</sup>, X. Zhang\*<sup>2</sup>, D. Liqun\*<sup>3</sup>.

<sup>1</sup>Department of Orthopaedics, The Second Xingyia Hospital of Central South University, Changsha, China, <sup>2</sup>Orthopaedics, The Second Xiangya Hospital of Central South University, Changsha, China, <sup>3</sup>Orthopaedics, Anhui Provincial Hospital, Hefei, China.

Reconstruction of large skeletal defects secondary to osteomyelitis is a challenging clinical problem. To evaluate the effectiveness of distraction osteogenesis in the treatment of massive skeletal defects following osteomyelitis, we used a combination of an intramedullary nail and a monolateral external fixator in 17 patients (11 male and 6 female, 17 to 32 years old, average age 24 years old) with massive skeletal defects of femur resulting from osteomyelitis. After a diaphyseal osteotomy of the femur, an intramedullary nail was inserted into the femur, and a monolateral external fixator was placed with a half-pin laterally to the nail. The femur lengthening was started on the seventh postoperative day at a rate of 1 mm per day. When the docking site achieved solid bone union, the monolateral external fixator was removed while the intramedullary nail remained for bone consolidation until it was completely reconstructed. The outcome was assessed clinically and radiographically at a mean of 70.3 months postoperatively. The results show that at an averaged of 70.3 months follow-up, ranging from 24 months to 8 years, the skeletal defects were filled by new bone, bone union at the docking site was achieved in the absence of bone graft, and the leg length discrepancy (LLD) was less than 2.5 cm in all 17 patients. The average gain in length was 12.9 cm (from 10.5 to 18.0 cm). According to Paley's evaluation criteria, the bone results were graded as ten excellent, five good, one fair and one poor; the functional results were graded as twelve excellent, four good, and one fair. The mean external fixation index was 18.1 days/cm, and the mean consolidation index was 35.7 days/cm. Although ten out of 17 patients had pin site infection and one patient had a recurrent deep infection, none of the patients developed neurological or vascular complications. We conclude that the distraction osteogenesis technique using the combination of an intramedullary nail and a monolateral external fixator is a reliable method for reconstruction of massive skeletal defects resulting from osteomyelitis.

## M161

**Comparison of Cyclic Parathyroid Hormone (cPTH) 1-31 to PTH 1-34 in the Enhancement of Experimental Fracture Healing.** M. L. Young\*<sup>1</sup>, R. Fontaine\*<sup>2</sup>, Z. Mason\*<sup>2</sup>, G. Bishop\*<sup>1</sup>, L. C. Gerstenfeld<sup>1</sup>, E. F. Morgan<sup>2</sup>, T. A. Einhorn<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA, <sup>2</sup>Biomedical Engineering, Boston University, Boston, MA, USA.

The purpose of this study was to compare the effects of PTH 1-34 and two doses of cPTH 1-31 on the structural and mechanical integrity of bone during experimental fracture healing. Standard closed femoral fractures were performed on 192 male Sprague Dawley rats, and each animal was randomly assigned to one of four experimental groups: control, PTH 1-34 (30 $\mu$ g/kg), or cPTH 1-31 (30 or 45  $\mu$ g/kg). Daily subcutaneous injections of

saline (control) or drug were administered for 21 or 35 days after the fracture. Following euthanasia the fractured bones and contralateral femurs were harvested and subjected to microquantitative computed tomography and mechanical torsion testing. Analysis of variance determined if treatment, time, or the cross of treatment and time had a significant effect on the outcome variables ( $p < 0.05$ ), and the Tukey method identified differences between the groups. By 21 days, all of the calluses from the active treatment animals had a significantly increased bone volume fraction (BV/TV) compared to controls ( $p < 0.0097$ ), and this effect was sustained after 35 days of fracture healing. At 35 days, the cPTH 1-31 groups demonstrated a higher BV/TV than the PTH 1-34 group, but these values did not reach statistical significance. The effect of PTH treatment alone significantly increased the BMC compared to controls ( $p < 0.0087$ ). No differences were observed between the groups across time with respect to bone mineral density (BMD), bone mineral content (BMC), and stiffness. Only the cPTH 1-31 (30 $\mu$ g/kg) group showed greater torque strength and work to failure compared to controls ( $p < 0.0245$ ) at 35 days. Evaluation of the contralateral femurs revealed a positive effect of treatment on torque strength with the high dose cPTH 1-31 group showing significant improvements over controls ( $p < 0.003$ ).

Summary of Bone Densitometry and Biomechanical Testing				
Day 21 Fractures	BV/TV	BMC (mg/line)	Max Torque (Nm)	Stiffness (Nmm <sup>2</sup> /rad)
Control	0.56 $\pm$ 0.06	314.5 $\pm$ 58.1	0.20 $\pm$ 0.07	33831 $\pm$ 20085
PTH 1-34 (30mg/kg)	0.69 $\pm$ 0.07	360.0 $\pm$ 45.8	0.21 $\pm$ 0.08	34746 $\pm$ 20786
PTH 1-31 (30mg/kg)	0.69 $\pm$ 0.07	353.0 $\pm$ 85.9	0.20 $\pm$ 0.09	32591 $\pm$ 16379
PTH 1-31 (45mg/kg)	0.65 $\pm$ 0.07	334.9 $\pm$ 69.1	0.18 $\pm$ 0.45	24853 $\pm$ 11486
Day 35 Fractures				
Control	0.59 $\pm$ 0.05	269.5 $\pm$ 60.9	0.37 $\pm$ 0.09	57651 $\pm$ 16600
PTH 1-34 (30mg/kg)	0.72 $\pm$ 0.05	315.2 $\pm$ 81.2	0.46 $\pm$ 0.15	61444 $\pm$ 26740
PTH 1-31 (30mg/kg)	0.75 $\pm$ 0.04	314.5 $\pm$ 70.8	0.53 $\pm$ 0.17	63659 $\pm$ 16893
PTH 1-31 (45mg/kg)	0.76 $\pm$ 0.06	336.2 $\pm$ 68.7	0.45 $\pm$ 0.15	62398 $\pm$ 19719

Daily systemic administration of cPTH 1-31 is equivalent to PTH 1-34 in enhancing fracture healing by increasing percentage of bone volume and mineral content within the callus tissue and by improving torque strength. The trends suggest treatment with cPTH 1-31 may be superior to PTH 1-34 with respect to BV/TV, BMC and torque strength during the remodeling phase as well as the torsional strength of the entire skeleton.

**Role of Galectin-3 in Osteoarthritis.** C. Boileau\*<sup>1</sup>, A. Janelle-Montcalm\*<sup>2</sup>, J. Pelletier\*<sup>2</sup>, J. Martel-Pelletier\*<sup>2</sup>, P. Reboul<sup>2</sup>. <sup>1</sup>Pharmacology, University of Montreal, Montreal, QC, Canada, <sup>2</sup>Medicine, University of Montreal, Montreal, QC, Canada.

Osteoarthritis (OA) is a chronic disease linked to aging and characterized by cartilage destruction and subchondral bone modifications. More specifically, subchondral bone presents a sclerosis and a perturbation of its mineralization in OA. During OA, some synovial membrane inflammation occurs, leading to a structure named pannus, which covers cartilage and subchondral bone. Macrophages present in the pannus can directly secrete catabolic factors (interleukin-1 $\beta$ ) as well as other proteins involved in inflammation such as galectin-3 (gal-3).

Based on results obtained by Ohshima(2003), demonstrating that gal-3 was over expressed in inflamed synovial membrane during OA, our work focused on gal-3 which, when present extracellularly, induces deleterious effects in both cartilage and subchondral bone (Janelle-Montcalm 2007). In brief, our data showed that gal-3 decreases the expression of osteocalcin in human OA subchondral bone osteoblasts whereas a truncated form of gal-3 (Trc-gal-3) although having similar binding properties as gal-3 but unable to activate second messengers, had no effect.

We have since cloned the 850 bp osteocalcin promoter into a pBasicGL3 vector and transfected human OA osteoblasts. Human OA osteoblasts were transfected with a firefly luciferase vector driven by 850 bp of the proximal osteocalcin promoter (p850-OCN-GL3) or with a vector not driven by a promoter (i.e. pBasicGL3). Without Vit D3, the p850-OCN-GL3 gave a background value equivalent to pBasicGL3. As expected, the addition of Vit D3 increased the activity of p850-OCN-GL3 (sixfold) but had no effect on pBasicGL3. When cells were incubated with both Vit D3 and gal-3, the promoter activity decreased by 40% ( $p < 0.02$ ,  $n = 8$ ) compared to Vit D3 alone. In contrast, Trc-gal-3 had no effect. These data indicate that this regulation takes place in the osteocalcin promoter.

In addition to inducing, in human OA chondrocytes, the expression of two major enzymes cleaving aggrecan, we now have results showing that extracellular gal-3 stimulates type X collagen expression twofold ( $p = 0.04$ ,  $n = 5$ ). This collagen is typically found in growth plates but also abnormally re-expressed in OA. Therefore, it is tempting to postulate that gal-3 could be involved in this process. In an in vivo model, new results show that the intra-articular injection of Trc-gal-3 does not induce OA-like lesions in WT mice, unlike gal-3.

Finally, we are able to measure gal-3 in media of synovial membrane. The incubation of synovial membrane with LPS (1  $\mu$ g/ml) increases significantly gal-3 concentration in media ( $p = 0.005$ ,  $n = 6$ ).

All of these data corroborate the concept of a deleterious effect of gal-3 when it is secreted into the joint during phases of inflammation.

**Identification and Characterization of Angiogenesis-inducing Secretory Molecules from Osteogenically Differentiated Mesenchymal Stem Cell.** J. Kim\*, J. Kim\*, Y. Kim\*, J. Choi\*, S. Ryu\*, P. Suh\*. Postech, Pohang, Republic of Korea.

The relationship between osteogenesis and angiogenesis has been examined for a long time. Despite of its importance, much of cellular and molecular communications between them have been unknown. Fracture repair process is complex step including proliferation, migration, differentiation and activation of many different cells, such as endothelial cell, osteoblast, and osteoclast. Since bone fracture is accompanied with disruption of blood vessels, the interaction between bone forming-osteoblast and vessel forming-endothelial cell is essential to bone fracture healing process. In this process, communicators between osteoblast and endothelial cell are needed. In this point of view, focusing the secretory molecules from osteoblast, we identified several molecules to modulate angiogenesis of endothelial cell. First, we conducted differentiation of human bone marrow derived-mesenchymal stem cell (MSC) into the mature osteoblast and collected conditioned medium from differentiated osteoblast and undifferentiated MSC. And then, we checked the effect of conditioned medium on endothelial cell angiogenesis including cell proliferation, migration and tube formation. As a result, conditioned medium from differentiated osteoblast showed highly increasing effect on endothelial cell migration when compared with the effect of conditioned medium from undifferentiated MSC. To identify the secretory molecules with migration-inducing activity, we used reverse phase-high performance liquid chromatography and selected fractions of chromatography with increasing activity for endothelial cell migration. We used ESI-LC-MS/MS analysis for fractions with activity and could find out several candidate proteins and peptides especially increased in differentiated osteoblast. Based on this study, identification of new molecules they have endothelial cell migration-inducing activity and elucidation of signal transduction pathways associated with that molecules will be helpful for understanding of the communications between osteoblast and endothelial cell. Furthermore, understanding of these communications can be applied to regulation of bone fracture repair process, bone development and disease treatments.

**Bone Tether Formation in Femoral and Basicranial Growth Plates Have Similar Responses to Growth Disruptions Due to Nuclear Vitamin D Receptor Genotype and Mineral Homeostasis.** C. S. D. Lee\*<sup>1</sup>, J. Chen\*<sup>2</sup>, Y. Wang\*<sup>1</sup>, J. K. Williams\*<sup>3</sup>, R. E. Guldberg\*<sup>1</sup>, Z. Schwartz\*<sup>1</sup>, B. D. Boyan\*<sup>1</sup>. <sup>1</sup>Institute of Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA, USA, <sup>2</sup>Chongqing University, Chongqing, China, <sup>3</sup>Children's Healthcare of Atlanta, Atlanta, GA, USA.

Mutations in  $1\alpha,25(\text{OH})_2\text{D}_3$  mediated signaling can cause mechanical instability in limbs and craniofacial deformities. We have shown that micro-CT imaging of distal femoral growth plates of mice can be used to quantify an accumulation of mineralized struts called "tethers" during normal growth plate closure and decreased tether formation is highly correlated with growth disruption in long bone growth plates of mice lacking functional nuclear vitamin D receptors (nVDR). Our results suggest that growth plate tethers facilitate overall skeletal structural stability during rapid bone growth, however tether formation in growth plates in other bones are currently uncharacterized and the mechanism causing tether formation is still unknown. Therefore, our goals were to verify that growth disruption is associated with tether formation in basicranial growth plates (BGP) and that tether formation in these growth plates and the femoral growth plate (FGP) is dependent on normal mineral homeostasis. FGPs in right distal femurs and BGPs next to the occipital and basisphenoid were isolated from micro-CT scans of 10 week old male and female nVDR<sup>-/-</sup> and nVDR<sup>+/+</sup> mouse littermates. Treatments included regular diet, rescue diet (includes 20% lactose, 2% Ca, 1.25% P) and rescue diet +200IU Vitamin D<sub>3</sub>/kg. Parameters of average growth plate thickness and tether volume fraction (tether volume/growth plate volume) were determined with standard morphometric software. Knocking out the nVDR increased growth plate thicknesses and decreased tether formation and rescue diets partially restored normal morphologies in both FGPs and BGPs. Tether volume fraction in nVDR<sup>-/-</sup> growth plates was 0.2-0.4% of those in nVDR<sup>+/+</sup> mice. Average growth plate thickness increased by 7.8-10 fold in nVDR<sup>-/-</sup> mice on regular diet. Rescue diets decreased nVDR<sup>-/-</sup> growth plate thicknesses by 24-27% in FGPs and BGPs and also increased tether volume fraction by ~35 fold in FGPs and by ~150 fold in BGPs. Rescue diets with or without vitamin D<sub>3</sub> were not statistically different with respect to affecting measured parameters. There was no significant difference between male and female samples with respect to diet or genotype except for nVDR<sup>+/+</sup> mice treated with a rescue diet with vitamin D. These results suggest that tether formation is conserved in growth plates throughout the skeletal system and that their development is strongly dependent on serum calcium and phosphorous concentration levels but not the nuclear effects of  $1\alpha,25(\text{OH})_2\text{D}_3$ .

**Reconstituting Marrow-derived Extracellular Matrix *Ex Vivo*: An Optimal Niche for Retaining the Properties of Human Mesenchymal Stem Cells.** Y. Lai\*, C. M. Skinner\*, Y. Sun\*, X. Chen. Restorative Dentistry, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Mesenchymal stem cells (MSCs) show great potential in cell and gene therapy applications for multiple tissue repair and regeneration in age-related diseases. However, one of the major bottlenecks in the use of MSCs has been their limited number to achieve a clinical successful result, because MSCs are extremely rare in the primary tissue and are very difficult to expand *ex vivo* without losing their properties. Recently, we reported that extracellular matrix (ECM) prepared from mouse marrow stromal cells dramatically enhanced mouse MSC proliferation, and preserved their stemness (Chen et al, JBMR. 22:1943, 2007). Encouraged by these findings in the mouse model, we attempt to study the properties of ECM to support *human* MSC behavior using a similar approach. In this study, we prepared a cell-free ECM made by human marrow stromal cells. Consistent with the mouse model, cultured human marrow stromal cells elaborated a fibrillar ECM with ~12  $\mu\text{m}$  thickness, containing at least collagen type I, fibronectin, and biglycan. Human marrow stromal cells were cultured on the ECM, or 2D culture systems comprising plastic, or plastic coated with fibronectin or type I collagen, in  $\alpha$ -MEM/15%FCS for 14 days. The proportion of human MSCs present in the cultures after 3, 7 10 and 14 days was determined by using flow cytometry to quantify SSEA-4<sup>+</sup> cells [a surface marker for MSCs (Gang et al, Blood. 109:1743, 2007)]. The results showed that the percentage of SSEA-4<sup>+</sup> cells progressively decreased (from ~60% to ~18%) during 14 days of culture maintained on the 2D culture systems. In contrast, the ECM retained 70-82% of SSEA-4<sup>+</sup> cells during the entire 14 days of culture. The number of cells in culture maintained on the 2D culture systems reached a plateau at day 10. In contrast, the number of cells in culture maintained on the ECM continued to increase during 14 days of culture. More important, the increase in the number of SSEA-4<sup>+</sup> cells was ~7-fold more when cells were cultured on the ECM than on the other substrata. Strikingly, the intracellular level of reactive oxygen species (ROS) was at least 3-fold lower in cells maintained on the ECM than in cells maintained on the other substrata. In hematopoietic stem cells, it has been reported that a high level of ROS is associated with loss of stem cell characteristics and increased differentiation as well as apoptosis (Tothova et al, Cell. 128: 325, 2007). We conclude that culture of human bone marrow cells on such ECM may produce massively amount of MSCs without needing extensively subculturing or passaging of the cells for the purpose of enriching their population.

**Studies on the Deposition of Ochronotic Pigment in Alkaptonuria Reveal Tyrosine Metabolism in Human Chondrocytes.** A. M. Taylor\*<sup>1</sup>, P. J. M. Wilson\*<sup>1</sup>, W. D. Fraser\*<sup>2</sup>, L. R. Ranganath\*<sup>2</sup>, J. A. Gallagher\*<sup>1</sup>. <sup>1</sup>Human Anatomy & Cell Biology, University of Liverpool, Liverpool, United Kingdom, <sup>2</sup>Clinical Chemistry, University of Liverpool, Liverpool, United Kingdom.

Alkaptonuria (AKU) is a genetic disorder resulting from the absence of homogentisate dioxygenase (HGO), an important enzyme in tyrosine metabolism. The lack of HGO results in a failure to breakdown homogentisic acid (HGA), which is deposited as ochronotic pigment in connective tissue, especially cartilage, and leads to severe and early onset arthropathies. Using electron microscopy, we have recently identified specific binding of ochronotic pigment to collagen fibrils *in vivo* and *in vitro*, but the mechanisms underlying the deposition of pigment has not been elucidated. It has previously been suggested that enzymatic activity, possibly by polyphenol oxidases (PPOs), is required for the polymerization of HGA and subsequent pigment formation. In this study, we have looked for the expression of candidate enzymes and we report for the first time, the detection of enzymes involved in tyrosine metabolism in primary human chondrocytes and the chondrocytic cell line C20-A4. We designed primers to tyrosinase (TYR), tyrosine hydroxylase (TH) and HGO. Using reverse transcription PCR positive signals have been identified for TYR, TH and HGO in the C20-A4 cell line. TH has also been detected in all primary cells from alkaptonuric bone, cartilage and capsule tissue. Initial experiments on the osteoblastic cells lines, SaOS-2 and MG63, were negative but the technique used may not be sensitive enough to detect low levels of expression. HGO has been previously reported only in liver and kidney, where the majority of tyrosine metabolism takes place. Our investigations point towards the presence of TYR and TH, previously not known to be present in chondrocytes, as possible candidates for polyphenol oxidases involved in ochronotic pigment formation in AKU. In the liver and kidneys, these enzymes act on their preferential substrates, such as tyrosine or L-DOPA. However, in AKU cartilage, the presence of HGA, and other environmental factors affecting substrate specificity may result in the PPOs polymerising HGA as an alternative substrate. The specific localization of pigment in tissues may depend upon the local PPO-like activity. A better understanding of the mechanism of pigment formation and deposition including a clarification of the role of the PPO-like enzymes may allow specific targets for therapy in AKU to be identified. These results also raise the more general issue of why chondrocytes express enzymes involved in tyrosine metabolism.

**(Ala-Gly)<sub>n</sub> Sequences Configured Silk Protein Scaffold Induces Osteoblast Differentiation and Bone Formation via Increased Cbfa1 and Osterix Expression.** M. Hirata, M. Kobayashi\*, A. Yoshida\*, C. Miyaura, T. Asakura\*, M. Inada. Department of Life Science and Biotechnology, Tokyo University of Agriculture and Technology, Tokyo, Japan.

**Bone formation induced by growth factors is well characterized, the ligand bind to osteoblast leads to up regulate specific transcriptional factors.** Several genes are implicated for bone formation, cbfa1 (runx2) and osterix (osx) mainly regulate activation of osteoblast functions. The other potential factors controlling osteoblast functions are the scaffolds for osteoblast. Type I collagen, a major bone ECM acts as scaffold that is consisting multiple (Gly-X-Y)<sub>n</sub> and (Arg-Gly-Asp; RGD) sequences, activation of osteoblast functions through direct or indirect manners. The other aspects of type I collagen, to form fibrous scaffold enclose osteoblasts with three-dimensional network that assumed to activate cell functions. Here we investigated osteoblast differentiation and function using silk protein scaffold configured multiple (Ala-Gly)<sub>n</sub> simple sequences. We developed silk film sheet from silkworms dissolved in 9 M LiBr solution was dialyzed in lyophilized water, and regenerated silk fibroin sheet. The experiments were performed maintaining osteoblasts on silk scaffold film (SF) or control plastic plate (PP) within the same culture well, silk scaffold film attached into center of culture well plate, comparing bone nodule formation. To quantify osteoblastic gene expression in culture, mRNA was extracted from SF or PP individually then used for RT-PCR analysis. On day 1, both runx2 and osx expression was dramatically increased in osteoblasts cultured on SF compared to PP. Type I collagen, coll1 $\alpha$ 1 expression also increased in SF about 2 times fold than PP, suggesting the transcriptional stream of runx2, osx and its target gene coll1 $\alpha$ 1 was enhanced functionally in early phase of osteoblasts culture. In long term culture of 4 weeks, expression of osteocalcin was detected, and the expression level was 2 times higher in SF than PP. To determine calcified bone nodule formation, alizarin red staining was performed. After 4 weeks, alizarin red positive calcified bone nodules were only found in SF. At 6 weeks, the area of bone nodule was expanded, and the thickness was enhanced at twice. These results clearly indicated that silk protein scaffold induced osteoblast specific genes in both early and later phase of bone formation. Multiple (Ala-Gly)<sub>n</sub> sequences formed simple structured  $\beta$ -sheet protein may apply as a supportive carrier for tissue regeneration of bone in various clinical cases.

**Histologic and Radiographic Analysis of Osteopromotive Property of Demineralized Allogenic Dentin Matrix in Parietal Bone Defects in Rabbit.** N. Bakhshalian\*, H. Azimi\*, T. Jalaier\*, B. H. Arjmandi<sup>1</sup>. <sup>1</sup>Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, <sup>2</sup>Oral and Maxillofacial Surgery, Shahed Dental School, Tehran, Iran, Islamic Republic of, <sup>3</sup>Oral and Maxillofacial Radiology, Shahed Dental School, Tehran, Iran, Islamic Republic of.

The aim of this study was to evaluate the bone forming ability of demineralized allogenic dentin matrix (DADM) using rabbit model of experimental surgical bone defect. The DADM specimens were obtained from the mandibular incisors of rabbits. DADM specimens were cut into small pieces (less than 3 mm<sup>3</sup>) and then mixed in order to make them homogenous. Surgical bone defects (6 mm in diameter) were created on the skull of 6 New Zealand white rabbits (two defects in each rabbit). Experimental defects were filled with DADM applying the guided bone regeneration technique (GBR.) with the use of Paraguide collagen membrane while control defects' inner and outer surfaces were covered by Paraguide membrane with no material in between. The rabbits were sacrificed after 15, 30, 45, 60, 75 and 90 days (one rabbit at a time) and the defects were examined radiographically and histologically. Histological data indicated that bone mass and the rate of bone formation were significantly greater in the experimental defects in comparison to control defects. Additionally, bone formation in experimental defects was seen in both center and border of the defects. By comparison, bone formation was not observed in the center of control defects. Radiographic examination showed that the experimental defects achieved radiopacity more quickly than the control defects. DADM pieces served as nuclei facilitating bone growth in and around them resulting in complete closure of bone defects with normal bone. No infection and inflammatory reaction were detected at the tissue level.

Post Surgery Period (Days)	Experimental Defects (% Osteogenesis)	Control Defects (% Osteogenesis)
15	2%	0%
30	38%	11.50%
45	19%	24.50%
60	31%	10%
75	43%	18%
90	54%	31%

**A Novel Modification of Bone Grafts Inhibits Bacterial Colonization.** C. Ketonis\*, A. Ayer\*, I. M. Shapiro<sup>1</sup>, C. S. Adams<sup>1</sup>, N. J. Hickok\*, J. Parvizi\*. <sup>1</sup>Thomas Jefferson University, Philadelphia, PA, USA, <sup>2</sup>Rothman Institute, Philadelphia, PA, USA.

Infection is the most devastating complication associated with use of allograft bone due to bacterial colonization of its surface. We developed a new method for covalently modifying allografts with an antibiotic and demonstrated long term, stable bactericidal activity with no adverse effects.

Morselized human bone was coupled with aminoethoxyethoxyacetate (AEEA) linkers (2X) and vancomycin (VAN). Surface-bound VAN was visualized by confocal laser microscopy after incubation with rabbit anti-VAN IgG (4°C, 12h) and AlexaFluor 488-coupled goat anti-rabbit IgG. To test bacterial colonization, equal dry weights of sterile control and VAN-modified bone (VAN-bone) were incubated with *S. aureus* (C=10<sup>4</sup> cfu) in trypticase soy broth (TSB), 37°C, for 2, 5, 8 and 12 hrs. Non-adherent bacteria were removed by washing and adherent bacteria stained with the Live/Dead BacLight Kit and visualized by confocal microscopy. In parallel, adherent bacteria were suspended by sonication in 0.3% Tween-80 followed by serial dilutions and plating. To determine elution kinetics, bone was modified with fluorescent dansyl-glycine modified VAN (dVAN-bone) or dVAN was adsorbed onto control unmodified bone. The adsorbed and dVAN-bone were incubated in PBS, 37°C for up to 3 weeks and eluted dVAN measured daily. Biocompatibility of the VAN-bone was assessed by seeding Human Fetal Osteoblasts (hFOB) on sterile VAN-modified and control cortical bone squares and performing a BCECF AM assay at 3 days to measure cellular attachment, and proliferation; LDH was measured to assess toxicity. Finally, adherent hFOBs were visualized using confocal microscopy and SEM.

Using anti-VAN antibodies, VAN-bone displayed a uniform, bright signal with only background fluorescence on controls, indicating good VAN coverage. By confocal microscopy, few fluorescent bacteria were observed at any time (2-12hrs) on VAN-bone, whereas abundant fluorescence was present on control bone. These observations were confirmed by direct bacterial counts. dVAN elution after adsorption to control bone occurred mainly within the first 4 days; dVAN-bone showed minimal if any release of dVAN. After 17 days, when challenged with *S. aureus*, dVAN-bone resisted bacterial colonization whereas dVAN-adsorbed bone was highly colonized. hFOBS readily proliferated on VAN-bone with similar cell numbers, toxicity and morphology to unmodified controls.

We have described a novel modification of bone grafts with antibiotics to render them bactericidal while maintaining biocompatibility. This antibiotic tethering shows clear advantages over current incorporation methods and may serve as a paradigm for development of a new generation of self-protecting bone grafts.

**Assessment of Changes in Thoracic and Lumbar Vertebrae in T-type Cav3.2 (a1H) Voltage Sensitive Calcium Channel Knock Out Mice.** A. Kronbergs<sup>1</sup>, Y. Shao<sup>1</sup>, K. P. Campbell\*, R. L. Duncan<sup>1</sup>, M. C. Farach-Carson<sup>1</sup>. <sup>1</sup>Biology, University of Delaware, Newark, DE, USA, <sup>2</sup>Howard Hughes Medical Institute, University of Iowa, Iowa City, IA, USA.

Voltage sensitive calcium channels (VSCCs) are essential to the development of skeleton. We have also shown that inhibition of the L-type VSCC's significantly reduce the response of bone to exogenous mechanical loads. However, our lab has shown that two dominant types of VSCCs are found in bone, the L-type Ca<sub>v</sub>1.2 ( $\alpha_{1C}$ ) VSCC and the T-type Ca<sub>v</sub>3.2 ( $\alpha_{1H}$ ) VSCC. These channels are differently expressed in osteoblasts and osteocytes; with preosteoblasts and osteoblasts expressing both the L- and T-type VSCC while osteocytes only express the T-type Ca<sub>v</sub>3.2 ( $\alpha_{1H}$ ) VSCC. From these observations, we postulate that the loss of L-type VSCC signaling may act as the switch to induce a more differentiated phenotype in osteocytes. Further, we predict that the T-type VSCC may play a stronger role in the differentiated osteocyte function. In the current study, we used mice with conventional knockout of the T-type Ca<sub>v</sub>3.2  $\alpha_1$  subunit to examine changes in the skeletal phenotype of thoracic and lumbar vertebrae. These mice are characterized by constitutively constricted coronary arterioles, reduced relaxation of the coronary arteries and focal myocardial fibrosis. Alcian blue & alizarin red skeletal staining previously showed that the knock out animals exhibited abnormal osteochondral junction of the ribs. Using micro-CT scanning, we demonstrated that, compared to the wild-type controls, the Ca<sub>v</sub>3.2 null mice exhibited a lower bone mineral density and the vertebral foramen appeared to be larger. Using sodium fluorescein, we are extending our studies to include the density of osteocytes and osteocytic lacunae in thoracic and lumbar vertebrae of the control and knockout animals. These data together with the previous findings on the long bones suggest that the T-type Ca<sub>v</sub>3.2 knockout results in an altered bone mineralization process. We also hypothesize that the presence of Ca<sub>v</sub>3.2 channels in osteocytes may play a significant role of these channels in bone mechanotransduction.

The extent to which bone marrow contributes to physiological cell renewal in various organs is still controversial. The current studies employs human placental alkaline phosphatase (hPLAP) as genetic marker, because this marker survives paraffin and methylmethacrylate embedding, and sets new standards in histological detection quality especially in hard tissues. Here we examined the role of bone marrow in physiological cell renewal by sequentially analyzing tissues from lethally irradiated, wild-type inbred Fischer 344 rats transplanted with bone marrow from transgenic F344 rats expressing hPLAP under the control of the ubiquitous R26 promoter. Bone marrow-transplanted rats were followed up to 6 months post-transplantation. Osteoblasts, osteocytes, and chondrocytes were exclusively of recipient origin at all time points post-transplantation. In contrast, the extent of hPLAP-labeled endothelial cells of donor origin profoundly increased with time in almost all organs. This finding was independently confirmed by a novel 5-bromo-2'-deoxyuridine (BrdU)-based method to directly assess the half life of cells. However, epithelial cells in the intestinal tract, kidney, liver, pancreas, and brain were of recipient origin at all time points. Similarly, muscle cells in skeletal muscle, heart, blood vessels or intestine were almost exclusively of recipient origin. Our analysis shows that physiological bone marrow-derived cell renewal in adult rats is restricted to endothelial cells, and casts doubt on the idea that adult bone marrow-derived precursor cells participate in physiological renewal of epithelial or mesenchymal cells.

**Cortical Bone Microstructure and Strength at the Mid-Diaphysis of Human Femurs: Influence of the Anatomical Position.** H. Beaupied<sup>\*1</sup>, A. Basillais<sup>1</sup>, J. Lepissier<sup>\*1</sup>, R. Hambli<sup>\*2</sup>, D. Soulat<sup>\*2</sup>, C. Chappard<sup>1</sup>, E. Dolléans<sup>\*1</sup>, C. Benhamou<sup>1</sup>. <sup>1</sup>Inserm U658, Orleans, France, <sup>2</sup>UMR CNRS 8106, Orleans, France.

The aim of this study was to assess the relationships between 3D microstructure and biomechanical parameters of human cortical bone in relation to their anatomical position around the medullary area.

Nine cadaveric femurs were removed from osteoporotic women at the anatomy department. Thirty six cortical bone samples were extracted from the anterior, lateral, posterior and medial mid-diaphysis of femurs. The samples were imaged by microcomputed tomography (skyscan 1072). The optical system was set to get a voxel size of 10.78  $\mu\text{m}$ . The cortical porosity (PoV/TV), the pore diameter (PoDm) and spacing (PoSp), the pore number (PoN), the pore surface (PoS) and the degree of anisotropy (DA) were calculated on these images. Compressive tests were performed on the samples in order to calculate their biomechanical properties (ultimate stress ( $\sigma_U$ ), yield stress ( $\sigma_Y$ ) and Young's modulus (E)). Spearman correlation coefficients were used to correlate the microstructure parameters with the mechanical parameters.

The linear regression analysis showed significant correlations between  $\sigma_U$  and PoV/TV ( $r = -0.84$ ), PoDm ( $r = -0.81$ ), PoN ( $r = -0.65$ ), PoSp ( $r = 0.51$ ) and DA ( $r = 0.42$ ) when the data were analyzed all together. The results showed significant correlations between  $\sigma_Y$  and PoV/TV ( $r = -0.81$ ), PoDm ( $r = -0.78$ ) and PoN ( $r = -0.63$ ) for the pooled data. The linear regression analysis showed significant correlations between E and PoV/TV ( $r = -0.85$ ), PoDm ( $r = -0.77$ ), PoN ( $r = -0.73$ ), PoSp ( $r = 0.66$ ) and DA ( $r = 0.39$ ). When the data were analyzed according to their location (anterior, posterior, medial and lateral)  $\sigma_U$ ,  $\sigma_Y$  and E were significantly correlated with PoV/TV and PoDm for the lateral, posterior and anterior positions. No correlation was significant between the biomechanical parameters and the microstructural parameters for the medial orientation. This study analyzed for the first time the correlations between the 3D structural parameters and the biomechanical parameters assessed by compressive testing of human cortical bone. Particularly, we showed that the relationships between the microstructure and the strength of cortical bone were different according to its position around the medullary area. The medial area seemed to have particular behaviour induced by a lower porosity (PoV/TV and PoDm lower than others sites).

**Low Magnitude Vibration can Inhibit Muscle Loss and Increase Mineralizing Bone Surfaces in Aging Mice.** J. Colantoni<sup>\*</sup>, D. Freeman<sup>\*</sup>, P. Arounleut<sup>\*</sup>, E. Kellum<sup>\*</sup>, K. Wenger, J. Yu<sup>\*</sup>, M. Hamrick. Medical College of Georgia, Augusta, GA, USA.

Previous studies using animal models have demonstrated that low magnitude, high frequency vibration can stimulate bone formation and increase bone mass. For example, vibration has been observed to produce a 26% increase in bone strength and a 10% increase in bone mineral content (BMC) in sheep. In a previous study we showed that C57BL/6 mice lose significant muscle mass, bone mass, and bone density between 18 and 24 months of age, suggesting that interventions aimed at preventing age-associated loss of muscle and bone strength in humans might be evaluated using this animal model. Here we test the hypothesis that vibration can increase bone formation and attenuate loss of muscle mass with aging in this mouse model. Approximately 25 mice, 18 months of age, were separated into three treatment groups: no vibration (control), low vibration (0.5 g; 31.7 Hz, 0.125 mm), or high vibration (1.5 g; 31.7 Hz, 0.375 mm). Mice exposed to either low or high vibration were vibrated for 30 min/day, 5 day/week, for 12 weeks, beginning at 18 months and finishing at 21 months. Results indicate that mice exposed to the low vibration regime showed significantly (~25%) greater cross-sectional areas for their extensor digitorum longus muscle fibers than either control mice or mice in the high vibration group. Soleus muscle fiber areas were significantly larger (~45%) in the control and low vibration groups compared to the high vibration group. Finally, calcein-labeled bone surfaces increased significantly (90%) in both the high and low vibration groups compared to controls. These findings suggest that low magnitude vibration may be effective at preserving musculoskeletal tissues with aging, and that higher magnitude vibration may actually have catabolic effects on skeletal muscle.

Funding for this research was provided in part by the National Institutes of Health (AR049717).

**Role of OPN in Beta-adrenergic Signaling Induced Bone Loss *in vivo*.** M. Nagao<sup>1</sup>, Y. Saita<sup>\*1</sup>, J. Nagata<sup>\*1</sup>, Y. Izu<sup>\*1</sup>, T. Hayata<sup>\*1</sup>, H. Hemmi<sup>\*1</sup>, Y. Ezura<sup>1</sup>, H. Kurosawa<sup>\*2</sup>, M. Noda<sup>1</sup>. <sup>1</sup>Dept Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, <sup>2</sup>Dept Orthopedic Surgery, Juntendo University School of Medicine, Bunkyo-ku Tokyo, Japan.

Bone mass is regulated under the control of sympathetic nervous system. One of the pathways to induce changes in bone based on the nervous tone is through  $\beta$ -adrenergic receptors which are expressed on osteoblastic cells. OPN expression is observed on osteoblastic cells as well as osteoclastic cells which are both under the control of sympathetic nervous tone. As for the interaction between  $\beta$ -adrenergic signaling and OPN, we observed that ISO administration reduced trabecular bone mass while OPN deficiency prevented such bone loss. This was based on the reductions in the changes in bone formation activities as well as bone resorption activities altered by ISO treatment. However, the point of action of OPN has not yet been elucidated. To understand whether OPN action is through the cell autonomous mechanism or through indirect pathway mediated by its property such as extracellular matrix protein, involvement of OPN was tested *in vitro* and *in vivo*. To examine whether ISO treatment increase cell autonomous actions of OPN, MC3T3E-1 cells were exposed to 10uM ISO. C-fos expression was induced with its peak at 1h after the treatment with ISO. In the absence of OPN, based on the treatment of the cells with siOPN, resulted in the similar patterning, ie: peak at 1h, of the expression of the c-fos mRNA. With respect to bone resorption related cytokine, RANKL expression was induced by ISO treatment with its peak at 2hrs and reduced after 4 hrs in WT and this was also observed in presence of siOPN. As possible control OPN mRNA expression levels were reduced by 40% to 70% in the presence of si. To exclude the possibility that the observed changes were due to the treatment with siOPN, Both WT and KO mouse derived calvariae osteoblasts were exposed to 10uM ISO. RANKL mRNA expression was induced by the treatment with ISO with its peak at 2 hrs and reduced after 4hrs and similar pattern was observed both WT and OPN deficiency mouse derived osteoblast cells. We also examined *in vivo* setting and injected ISO into the peritoneum of the mice for 7 days and prepared RNA from the femur to examine the levels of TRAP. ISO treatment in WT increased expression levels of TRAP and this was blocked by the absence of OPN. As control expression of OPN per se was enhanced by the ISO treatment in bone marrow microenvironment.

In conclusion, OPN modulates the action of a ISO signaling *in vivo* while its function in cell autonomous pathway may not be a major part of the function of this molecule. Thus, OPN is a key molecule in the microenvironment of bone to regulate bone formation and bone resorption under the control of sympathetic nervous tone.

**Increased Expression of Osteopontin in Peripheral Blood Mononuclear Cells is Associated with Alteration in the Fractions of Lymphocytes in Hindlimb-unloaded Mice.** Y. Ezura, J. Nagata\*, H. Hemmi\*, T. Hayata, T. Nakamoto\*, M. Noda. Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan.

Unloading induced bone loss analyzed by rodent "tail-suspension" has possible confounding factors related to sympathetic nervous tone, blood circulation, and immune function. To begin addressing with this problem, we investigated gene expression profiles and immunological lymphocyte surface markers of peripheral blood mononuclear cells in the mice subjected to 2-weeks of tail-suspension. Micro-array analysis revealed a reduced expression of B-cell specific genes in peripheral blood of tail-suspended mice, representatively indicated by Ebf1, Cd19, and Cd22. In contrast, genes characteristic for monocyte/macrophage lineage cells such as Msr2, Mrc1, C1q(s), and Itgam increased in parallel, implying proportional reduction and expansion in numbers of these leukocytes. Indeed, fluorescence activated cell sorting analysis for peripheral leukocytes revealed significant decrease of proportional numbers of B-cells and increased numbers of monocyte/macrophage lineage cells at day 3 of tail-suspension; these alterations continued until day-15 (Figure 1). However, since these fractional changes in lymphocytes remained small (less than 2-fold), we estimated the observed alterations in gene expression (greater than 2-fold) may not necessarily depend on the differences in cell numbers. Interestingly, we also observed significantly increased expression of osteopontin (also known as Spp1) in peripheral blood. Although it is not clear if the expression of osteopontin increased as a consequence of activation of peripheral blood macrophages, our data may imply that activation of peripheral blood macrophages and the increased expression of osteopontin may have some impact on bone metabolism in the hindlimb-unloaded mice.

**Cartilage Engineered with a Calcified Zone Enhances Interfacial Shear Strength to the Underlying Substrate.** J. St-Pierre\*, L. Gan\*, J. Wang\*, R. M. Pilliar\*, M. D. Grynblas, R. A. Kandel\*. University of Toronto, Toronto, ON, Canada.

The purpose of this study was to design bioengineered cartilage with improved attachment to a porous calcium polyphosphate (CPP) bone substitute by the formation of a zone of calcified cartilage (ZCC) at the cartilage-CPP interface zone. Cartilage-CPP biphasic implants were formed by seeding deep-zone chondrocytes onto the top surface of porous CPP substrates coated with a thin sol-gel-formed hydroxyapatite film. The cells were grown either in the absence or presence of  $\beta$ -glycerophosphate supplementation to induce mineralization. After 8 weeks, tissues were harvested and examined histologically, biochemically, by RT-PCR for gene expression and for the shear properties of the interface between cartilage and the substrate using a specifically designed shear test apparatus. Histological sections stained with toluidine blue and von Kossa demonstrated cartilage tissue with a thin ZCC when cultured in mineralization-inducing media. The ZCC was localized in the tissue directly above the substrate, mimicking osteochondral zonal organization. Previous work demonstrated that the mineral formed in cartilage *in vitro* under these conditions has similar composition and crystal size to that present in the ZCC of native cartilage [1]. Conversely, no calcification was observed in cartilage formed in the absence of  $\beta$ -glycerophosphate. Collagen and glycosaminoglycan contents were similar for tissues with and without a calcified zone. Expression levels of cartilage extracellular matrix genes including collagen type II and type X were not affected by the generation of a ZCC. Interestingly, the shear stiffness of the interface was increased by 2-fold in bioengineered cartilage with a ZCC compared to cartilage without a ZCC. This was associated with 240% improvement in the peak shear load and in 340% increase in energy to failure measurements. The maximal displacement prior to failure was similar in both tissues. In conclusion, this study demonstrates a significant increase in interfacial shear properties of biphasic cartilage constructs by mimicking the zonal organization of adult articular cartilage by generating a ZCC at the tissue/bone substitute interface. Generating biphasic cartilage constructs with a strong interface may be critical to the clinical success of biphasic constructs for repair of larger joint defects. [1] Tissue Eng. 5:25, 1999.

**Physiological Concentrations of Inhibin A Are Anabolic, Affecting both Trabecular and Cortical Bone in Normal Intact Mice.** K. M. Nicks, N. S. Akei\*, L. Liu\*, J. Aronson\*, L. J. Suva, D. Gaddy. Physiology and Biophysics & Orthopaedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Skeletal metabolism is regulated by many endocrine hormones, including non-steroidal hormones in the hypothalamic-pituitary-gonadal axis. We have previously demonstrated the skeletal anabolic actions of the gonadal peptide Inhibin A (InhA) in a transgenic (TG) model of systemic expression in intact mice. We have now extended our observations in the tibia and spine of Inh TG mice to demonstrate InhA affects both the trabecular and cortical compartments of the humerus in TG mice expressing 600-800 pg/ml human (h) InhA. The expression of InhA increases trabecular (Tb) bone volume (BV/TV), via increases in Tb thickness. InhA *in vivo* also altered cortical geometry, inducing increases in total and cortical cross-sectional area, medullary diameter, and both endocortical and periosteal perimeters. To determine if InhA treatment in adult wild-type outbred mice is similarly anabolic, 3 month old male Swiss-Webster mice were treated with continuous recombinant hInhA at physiological concentrations (serum levels of 30-80pg/ml) via osmotic minipump for 17d. Femoral bone marrow cultures were initiated at sacrifice for osteoblast (OB) differentiation; tibiae and humeri were used to quantify bone volume and trabecular architecture as well as all geometric indices using microCT. InhA treatment *in vivo* recruited more mesenchymal cells into the OB lineage in *ex vivo* culture (by increases in AP+ CFU-F), and increased the number of mineralized bone nodules (CFU-OB). Increases in BV/TV were observed in both the humerus and the tibia, due to increases in Tb thickness and number. Collectively, these data demonstrate that physiological concentrations of systemic hInhA (delivered either transgenically or by osmotic mini-pump) is anabolic in intact adult mice. The bone anabolism of continuous hInhA treatment in outbred mice confirms the regulation of bone metabolism by non-steroidal gonadal hormones. These observations suggest that modulation of the Inh signaling pathways may represent a new therapeutic target for the treatment of osteopenia.

**PTH and not Vitamin D Predicts Age-Related Bone Loss in the Elderly: A Prospective Population Based Study.** A. Arabi<sup>1</sup>, R. Baddoura<sup>2</sup>, G. El-Hajj Fuleihan<sup>1</sup>. <sup>1</sup>Calcium Metabolism and Osteoporosis Program, American University of Beirut, Beirut, Lebanon, <sup>2</sup>Rheumatology, Saint Joseph University, Beirut, Lebanon.

Type I involutional osteoporosis is mediated by increased sensitivity to PTH whereas type II is also induced by primary changes in calciotropic hormones. Over the years, attention has focused, amongst others, on serum 25-hydroxy vitamin D (25-OHD) rather than parathyroid hormone (PTH), although PTH is the mediator for the deleterious effect of hypovitaminosis D on bone. Moreover, scarce are the studies that prospectively evaluated the impact of calciotropic hormones on bone loss rates. We had previously shown that the negative effect of low vitamin D on bone mineral density (BMD) is mediated by PTH in the elderly. We further examined these observations in a prospective follow-up of the same cohort.

195 ambulatory subjects (65 men and 130 women), age 72.3±5.0 years, participated in a prospective population based study assessing bone mass, bone loss and fractures in the elderly Lebanese. 25-OHD, PTH levels, and BMD of the spine, hip and forearm were measured at baseline and follow up 4.2±0.3 years later. The mean values of 25 OHD and PTH (baseline and follow up) were used in the analyses.

The annualized percent changes in BMD were 0.18±2.3 at the spine, -1.0±1.7 at the hip, -0.63±2.0 at the femoral neck, -1.12±2.1 at the trochanter and -0.58±1.3 at the forearm. A significant negative correlation between changes in BMD and PTH, but not 25 OHD, was observed at all skeletal sites (p<0.05). We divided the study subjects into subgroups according to three categories: 25-OHD> 20 ng/ml, 25-OHD< 20 ng/ml and normal PTH levels, and 25-OHD<20 ng/ml and high PTH levels (Table). There were too few subjects (N=5) with 25-OHD levels > 30 ng/ml to use this cut-off for analyses. There was no difference in annualized bone loss rates between subjects with 25-OHD> 20 ng/ml and those with low 25-OHD & normal PTH levels. Conversely, the annualized bone loss was higher in subjects with low 25-OHD and high PTH levels compared to the two other groups (Table). In multivariate analyses, the negative effect of PTH persisted after adjustment for age and changes in BMI (p< 0.05) except at the forearm (p=0.07). In conclusion, PTH levels rather than vitamin D predict bone loss rates in the elderly. Aiming at normalizing PTH, as opposed to targeting specific D levels, may be the best approach to optimize skeletal health in elderly with low vitamin D levels.

Annualized percent changes in BMD by categories of mean 25-OHD (ng/ml) and PTH (pg/ml) levels

	25OHD ≥20 n=30	25OHD<20 & PTH≤76(n=141)	25OHD<20 & PTH>76 (n=19)
Spine	1.28±2.2 <sup>a</sup>	0.17±2.2	-0.94±2.6 <sup>a</sup>
Total Hip	-0.85±1.2 <sup>a</sup>	-0.93±1.8 <sup>b</sup>	-1.92±2.0 <sup>a,b</sup>
Femoral neck	0.6±2.2 <sup>a</sup>	-0.7±1.9	-1.1±2.1 <sup>a</sup>
Trochanter	-0.85±1.5 <sup>a</sup>	-1.06±2.2 <sup>b</sup>	-2.2±2.1 <sup>a,b</sup>
Forearm	-0.49±1.4	-0.56±1.3	-1.09±1.6

**The Negative Relationship between PTH and Vitamin D: Is There an Age and a Gender Effect?** A. ARABI, R. El-Rassi\*, G. El-Hajj Fuleihan. Calcium Metabolism and Osteoporosis Program, American University of Beirut, Beirut, Lebanon.

Hypovitaminosis D is prevalent worldwide and across age groups. In adults, optimal vitamin D levels are defined based on biological read outs of low vitamin D levels such as parathyroid hormone (PTH) levels. Sex steroids and aging affect calcium absorption and possibly PTH levels. Although the inverse relationship between vitamin D and PTH is well described, it is unclear whether the relationship is the same across genders and age groups. This study assessed the vitamin D-PTH relationship in 340 adolescents (age 13±3 years, mean±SD) and 443 elderly subjects (age 72±5 years) studied within the same period. Estimated calcium intake was 735±330mg in the young and 310±231 mg/day in the elderly. Female subjects consumed less calcium than male subjects in both age groups. PTH levels were measured with a second generation assay and 25 hydroxy vitamin D (25-OHD) levels with a radioimmunoassay (IDS Immunodiagnostics, Boldon, UK). Vitamin D sub-groups were created using 25-OHD levels <10 ng/ml, 10-20 ng/ml, 20-30 ng/ml, > 30 ng/ml.

In the overall group, mean 25-OHD levels were lower in the elderly compared to adolescents (11.4±4.9 vs 15.3±7.5,  $p < 0.001$ ), and in female compared to male subjects (10.9±5 vs 12.1±4 in elderly and 14.2±8 vs 16.5±6 in children,  $p < 0.05$ ). Mean PTH levels were higher in the elderly compared to adolescents (44.0±47 vs 18.4±20,  $p < 0.001$ ) but there were no gender differences in either age group. Within each vitamin D level subgroup, mean PTH levels were comparable across genders (data not shown). Within each vitamin D level subgroup, mean 25-OHD levels were comparable across age groups, but PTH levels were 1.5- two folds higher in the elderly ( $p < 0.0001$ , Figure). These age differences persisted in multivariate analyses adjusting for calcium intake.

The vitamin D-PTH relationship varies by age but not gender. For the same 25-OHD level subgroup, PTH levels are higher in elderly compared to young, possibly reflecting differences in calcium absorption and renal function. Optimal vitamin D levels derived from examining the 25-OHD-PTH relationship may differ between young and elderly subjects.

**Parathyroid Hormone Increases after Oral Peptones Administration in Obese Subjects Treated with Roux-En-Y Gastric Bypass Surgery: Role of Phosphate on the Rapid Control of Parathyroid Hormone Release.** M. Bevilacqua<sup>\*1</sup>, L. J. Dominguez<sup>\*2</sup>, V. Righini<sup>\*1</sup>, T. Vago<sup>\*1</sup>, D. Foschi<sup>\*1</sup>, E. Corsi<sup>\*1</sup>, E. Trabucchi<sup>\*1</sup>, E. Chebat<sup>\*1</sup>, E. Renesto<sup>\*1</sup>, M. Barrella<sup>\*1</sup>, M. Massarotti<sup>3</sup>, M. Barbagallo<sup>\*2</sup>. <sup>1</sup>Ospedale L. Sacco-Polo Universitario, Milan, Italy, <sup>2</sup>Internal Medicine and Geriatrics, University of Palermo, Palermo, Italy, <sup>3</sup>Rheumatology Unit, Humanitas, Milan, Italy.

**Introduction:** PTH is regulated by changes in circulating ionized calcium (iCa); its rapid regulation by P was recently demonstrated in low-P treated rats: duodenal infusion of sodium P increased PTH levels by twofold within 10 min, concomitantly with a 1 mg/dl increase of circulating P without changes of iCa. We previously demonstrated that oral peptones administration increases serum P and consequently PTH in hypophosphoremic primary hyperparathyroid patients but not in normal controls. We wonder whether the administration of peptones to patients after RYGB could be followed by a rise of PTH owing to the rapid absorption of P directly arriving into the jejunum. **Materials and Methods:** We recruited 24 obese subjects (18M/6F; 18-35 years) to study the effect of oral

peptones administration on PTH before and after 6 m of RYGB. Before and after RYGB we evaluated gastrin, P, PTH, iCa and pH before and during the oral administration of peptones (10 g Liebig meat extract in 250 ml NaCl 0.9%). **Results:** Before RYGB peptones elicited a significant increase of gastrin ( $P < 0.001$ ), and a slight increase of P, evident at 60-90 min ( $P < 0.05$ ), without changes of PTH; pH slightly increased perhaps as a mirror of the gastric acidification and iCa slightly decreased. After RYGB surgery, gastrin did not change, along with pH and iCa, maybe due to the lack of gastric remnant acidification. Serum P increased by 0.4-0.6 mg/dl in 15-30 min and remained elevated for 120 min, and PTH increased at 15 min ( $P < 0.05$ ) and remained elevated for 120 min ( $P < 0.01$ ). **Conclusions:** The marked difference in P and PTH response elicited by peptones observed in obese subjects before and after RYGB in the absence of changes of other possible regulators of PTH suggest that after RYGB there is a rapid arrive of P into the jejunum, with a rapid increase of serum P accompanied by a rapid release of PTH. Therefore we conclude that in some conditions, PTH is rapidly regulated also by P in man.

**Hematopoietic Cells in the Bone Marrow Augment Anabolic Actions of PTH.** A. J. Koh\*, T. Wang\*, R. Taichman, L. K. McCauley. POM, University of Michigan, Ann Arbor, MI, USA.

PTH has potent anabolic effects on the skeleton and previous reports suggest that a cell in the hematopoietic lineage may be a critical mediator of this effect. The purpose of this study was to determine whether the ability of PTH to increase hematopoietic stem cells (HSCs) in the bone marrow niche is linked to its anabolic actions in bone. Total body irradiation (TBI) was performed to selectively target hematopoietic cell populations in the marrow. Preliminary studies of varied irradiation doses identified 325cGy as a sub-lethal dose in neonatal C57/B6 mice. Analysis of the bone marrow hematopoietic cells determined by flow cytometry at d3 and d21 post TBI revealed a significant reduction in B220 (B cells) and CD41 (megakaryocytes). Irradiation decreased the total numbers of bone marrow cells and hematopoietic cells after 3 days; however, there was a relative increase in the percentage of HSCs (lin-sca-1+c-kit+ cells). At day 3, histologic analysis of irradiated vertebrae and tibia confirmed a severe generalized decrease in nucleated hematopoietic cells within the marrow, but cells lining the trabecular bone appeared robust and selectively protected. Analysis of the effects of PTH treatment with and without irradiation was performed after 21 days (TBI performed on d1, then PTH treatment, 50µg/kg/d on d2). Femur length and width were significantly reduced with irradiation regardless of PTH treatment. As shown previously, PTH treatment significantly increased bone area in control, non-irradiated mice. Interestingly, PTH treatment in irradiated mice increased bone area to a greater extent than in non-irradiated mice. Osteoclast activity as revealed by TRAP+ staining was increased similarly with PTH in non-irradiated and irradiated mice. Immunostain for Von Willebrand factor on histologic sections identified reduced numbers of megakaryocytes in irradiated mice but no impact of PTH treatment. An in vitro model system was utilized to test the hypothesis that increased HSC's promote osteoblast differentiation. Coculture of osteoblastic cells with whole bone marrow cells typically inhibits mineralization. Whole bone marrow from irradiated mice partially blocked this effect, resulting in more mineralization vs. non-irradiated mice, and supporting the in vivo findings of hematopoietic cells supporting osteoblast differentiation. The mechanisms of PTH anabolic action are as yet unclear and complex. Sub lethal ablation of the bone marrow may increase osteoblast exposure to its target cells (which survive) and may thus increase its anabolic action. Alternatively, irradiation may decrease cell types which are inhibitory for the anabolic actions of PTH. The technique of irradiation provides valuable information about the cell types involved in anabolic actions of PTH.

**A Novel and Sensitive Immunoassay for Parathyroid Hormone Related Protein.** L. J. Deftos<sup>1</sup>, A. Caston-Balderrama<sup>\*2</sup>, R. T. Dimayuga<sup>\*2</sup>, C. L. Chalberg<sup>\*1</sup>, K. C. Smith<sup>\*1</sup>, D. W. Burton<sup>\*1</sup>, R. E. Reitz<sup>2</sup>. <sup>1</sup>University of California, San Diego and San Diego VA Medical Center, San Diego, CA, USA, <sup>2</sup>Endocrine Division, Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, USA.

The potential of parathyroid hormone-related protein (PTHrP) as a serum biomarker for common PTHrP-expressing tumors has not been realized, especially for the differential diagnosis of hypercalcemia of malignancy. Most available assays can detect only the markedly elevated levels of this oncoprotein present in the later stages of disease, and the circulation of this polypeptide in normal subjects remains controversial. The poor diagnostic value of many PTHrP assays seems to be due to inadequate specificity and sensitivity for circulating PTHrP species, as well as poor technical performance. Through a series of in vitro and in vivo biochemical and immunochemical studies, we identified PTHrP 107-138 as a candidate for clinical assay targeting, since this domain is less affected by proteolysis and thus more stable in biological fluids. We focused on this region to develop antibodies, tracers, standards, and assay matrices that would yield a diagnostically useful assay procedure. We developed rabbit antibodies to human PTHrP 107-138 and used the same peptide as the assay standards. Chloramine T iodination of Tyr108-PTHrP 109-138 yielded a peptide of high specific activity that was further enhanced by chromatographic purification. Assay conditions were optimized to produce a one-day immunoassay with a limit of detection of 0.3 pmol/L and limit of quantitation of 0.5 pmol/L. Inter-assay and intra-assay variations of 9.8% and 4.4% were achieved by appropriate modifications of assay reagents and incubation conditions. Clinical samples were collected from 110 apparently healthy adults for reference range studies and analyses of specimen

stability, specimen type comparisons, and interfering substances. The adult reference range for plasma samples collected in sodium heparin tubes was established as 1.4-2.7 pmol/L, with no age or gender dependencies; specimen comparison studies indicated that PTHrP-cocktail tube specimens are also acceptable. Because PTHrP overexpression can be seen in a majority of patients with common malignancies, such as breast and lung cancer, this novel assay should be useful for the diagnostic application of PTHrP measurement in patients with cancer-related hypercalcemia. Furthermore, since PTHrP is overexpressed in most patients with prostate cancer, who are not usually hypercalcemic, the assay could have wider application as a serum tumor biomarker.

**Parathyroid Hormone-gene Family in the Cartilaginous Fish, *Callorhynchus milii*.** Y. Liu<sup>\*1</sup>, S. J. Richardson<sup>\*1</sup>, A. S. Ibrahim<sup>\*1</sup>, T. I. Walker<sup>\*2</sup>, J. Bell<sup>\*2</sup>, S. Brenner<sup>\*3</sup>, B. Venkatesh<sup>\*3</sup>, J. A. Danks<sup>1</sup>. <sup>1</sup>School of Medical Sciences, RMIT University, Bundoora, Australia, <sup>2</sup>Marine and Freshwater Systems, Department of Primary Industries, Queenscliff, Australia, <sup>3</sup>Institute of Molecular and Cell Biology, Biopolis, Singapore, Singapore.

Parathyroid hormone (*pth*) and parathyroid hormone-related protein (*pthrp*) genes have been isolated and cloned in a number of bony vertebrates, including teleost fishes. Cartilaginous fishes are the most ancient living jawed vertebrates. They comprise of two groups: the elasmobranchs (sharks and rays) and the holocephalans. We have identified three members of the *pth* gene family (designated *EShpth1*, *EShpth2* and *EShpthrp*) in the genome of a holocephalan cartilaginous fish, *Callorhynchus milii*, commonly known as elephant shark or elephant fish. These animals are confined to south-eastern waters of Australia and New Zealand. *C. milii* has been recently targeted for whole-genome sequencing since its genome is the smallest among cartilaginous fishes (Venkatesh et al, *Science* 314:1892, 2006 and *PLoS Biol.* 5(4): e101, 2007). Initial bioinformatic analyses suggested that the three genes isolated were *EShpth1*, *EShpth2* and *EShpthrp* and this was confirmed by testing PTH-like biological activity in UMR106 cells. The expression pattern of the three genes were analyzed by RT-PCR and one gene, *EShpth2*, appeared to be confined to the brain. Immunohistochemistry was performed and strongest EShPthrp immunostaining was in the epidermis, kidney and gill while the strongest signals for EShPth1 and 2 were in the pancreas. This study confirms that *pth 1*, *2* and *pthrp* genes are present in the most ancient jawed vertebrates suggesting that the roles played by the parathyroid hormone family are fundamental and basic.

**A Continuous Rat Parathyroid Cell Line Expressing Parathyroid Hormone.** C. Mavilia<sup>\*</sup>, C. Mazzotta<sup>\*</sup>, L. Cavalli<sup>\*</sup>, T. Cavalli<sup>\*</sup>, M. Brandi. Department of Internal Medicine, University of Florence, Florence, Italy.

Development of a clonal parathyroid cell line capable to express parathyroid hormone (PTH) would represent an extraordinary achievement in the field of parathyroid biology. A PT-r cell strain was purified by successive colony isolation in 1995. However, PT-r cells secrete only PTH-related peptide (PTHrP) and this limited the use of the cell line for studies on regulatory mechanisms that control parathyroid cell differentiation. From primary cultures of hyperplastic parathyroid tissue we selectively recloned epithelial cell lines by limiting dilution using plastic surfaces coated with antibodies to the amino-terminal extracellular domain of the rat Ca(2+) receptor. The culture medium used was Coon's modified Ham's F12 containing 1.1 mM calcium and 10% FCS. Among the selected clones that we characterized one strain expressed *PTH* mRNA and it was, therefore, named PTHc1. The PTHc1 cells showed a polygonal morphology, with a doubling time of 25 hr, that did not vary over 8 months in culture. Over eighty five percent of PTHc1 cells exhibited a diploid chromosome number (2n=42) when analyzed over 5 months of serial culture. PTHc1 cell line expression profile was evaluated by RT-PCR. Parallel RT-PCR reactions, without added reverse transcriptase, were performed to confirm that the PCR products resulted from cDNA rather than from genomic DNA. PTHc1 cells expressed *PTH*, *CaSR*, *VDR*, *FGF23r4*, *ERα*, *ERβ*, and *GH-R*. Conversely, PTHc1 cells did not express *PTHrP*, *ENDO1*, *PTHr1*, *FGF23* and *Klotho*.

In conclusion, these results describe a novel PTH-secreting cell line derived from rat hyperplastic parathyroid tissue. The PTHc1 clone is ongoing an intensive characterization for both proliferative and differentiative features. We are confident that this cellular model will represent a unique opportunity for the understanding of either parathyroid physiology or the molecular bases of parathyroid disorders.

## M185

**Functional Induction of Target Genes in Parathyroid Cell by Direct Injection Technique.** K. Shiizaki<sup>1</sup>, I. Hatamura<sup>\*2</sup>, E. Nakazawa<sup>\*1</sup>, Y. Iwazu<sup>\*1</sup>, Y. Watanabe<sup>\*1</sup>, M. Fukagawa<sup>\*3</sup>, T. Akizawa<sup>\*4</sup>, E. Kusano<sup>\*1</sup>. <sup>1</sup>Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan, <sup>2</sup>The First Department of Pathology, Wakayama Medical University, Wakayama, Japan, <sup>3</sup>Division of Nephrology & Dialysis Center, Kobe University School of Medicine, Kobe, Japan, <sup>4</sup>Department of Nephrology, Showa University School of Medicine, Tokyo, Japan.

Since there are not any available cell lines for studying parathyroid cell (PTC), it is difficult to adequately investigate the cellular effects of various factors in PTC. In the present study, the gene induction technique for PTC has been developed and this accuracy is also examined.

5/6-nephrectomized Sprague-Dawley rats were fed with a high-phosphate diet for eight weeks. LacZ-induced adenovirus (LacZ-Ad) was administered by the direct injection into parathyroid gland (PTG) (DI), the intravenously from jugular vein or directly applied on the PTG surface. The PTGs were excised at 48 hours after the treatment and were evaluated by X-Gal staining. Moreover, one of the PTGs was treated by DI of VDR- or CaSR-induced adenovirus (VDR-Ad and CaSR-Ad, respectively) and the other was treated with that of LacZ-Ad in the same rat. The VDR and CaSR expressions of PTCs at the same timing were examined immunohistochemically. Moreover, Ca-PTH response curves before and after treatment with CaSR-Ad were investigated.

Many X-gal-positive PTCs were observed in all over the PTG treated with DI of LacZ-Ad, however never in PTGs treated by the other administrations of LacZ-Ad. Marked increases in the number of both VDR- and CaSR-positive PTC were also confirmed in PTG treated by DI of VDR-Ad and CaSR-Ad, respectively. These findings were not observed in those with control treatment. The Ca-PTH response curve clearly sifted to the left side following the treatment with CaSR-Ad.

The functional gene induction in PTC of rat model with uremic secondary hyperparathyroidism has been established. This technique may make it possible to investigate the direct effects of various factors for PTC; in particular the signaling pathways and changes in cellular functions and proliferative activity in PTC.

## M186

**Selective Removal of PLC Signaling in Novel PTH(1-28) Analogs Abolishes Regulation of NaPi-IIc but not Napi-IIa.** S. Nagai, M. Mahon<sup>\*</sup>, M. Okazaki, J. T. Potts, H. Jüppner, T. Gardella. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Last year we reported that the analog M-PTH(1-28) (M = Ala1,Aib3,Gln10,Har11,Ala12,Trp14,Arg19), a potent agonist for cAMP and IP3 signaling pathways, induces, when injected into mice, prolonged hypophosphatemic and hypercalcemic effects. The analog also induced prolonged reductions in NaPi-IIa immunoreactivity at the brush border membrane and cytoplasmic compartments of renal PT cells of injected mice. To help elucidate further the signaling mechanisms by which PTH ligands regulate renal phosphate transport, we developed a derivative of M-PTH(1-28) in which PLC/PKC signaling capacity is removed, but cAMP/PKA signaling activity is potentially retained. The new analog has alanine of M-PTH(1-28) replaced by tryptophan, in accordance with findings of Ferrari et. al (JBC 1999) showing that such bulky substitutions at position one selectively impair PLC signaling. In HEK-293 cells transiently transfected with the rat PTHR, Trp1-M-PTH(1-28) was about as potent as M-PTH(1-28) for stimulating cAMP formation, but at least 100-fold less potent than the parent peptide for stimulating IP3 formation. Trp1-M-PTH(1-28) retained the capacity to produce a prolonged cAMP response in MC3T3-E1 cells after ligand wash-out, as seen with M-PTH(1-28). When injected into mice (20 nmoles/kg) Trp1-M-PTH(1-28), like M-PTH(1-28), induced prolonged suppression of plasma phosphate levels, as compared to effects of PTH(1-34): maximal suppression at 2h for each analog; recovery to vehicle control levels at 4h for PTH(1-34), and at 6h for M-PTH(1-28) and Trp1-M-PTH(1-28). Apical and cytoplasmic NaPi-IIa staining was reduced in mice treated with each peptide at 2h, staining returned to vehicle control levels at 6h with PTH(1-34), it remained reduced for at least six hours in mice treated with either M-PTH(1-28) or Trp1-M-PTH(1-28). Reduction of NaPi-IIc surface expression required the more potent, PLC-sufficient analog M-PTH(1-28), and followed a slower kinetic loss of immunoreactivity than did reduction of NaPiIIa. Thus, immunostaining of NaPiIIc was reduced in mice treated with M-PTH(1-28) over the interval 4 to 6 h, and was unchanged in mice treated with Trp1-M-PTH(1-28) or PTH(1-34). M-PTH(1-28) inhibited 32P uptake in early passage LLC-PK1 cells (NHERF-1/ezrin positive) virally transduced to express NaPi-IIc, and the rat PTHR, but Trp1-M-PTH(1-28) failed to inhibit this activity. The combined findings in vivo and in vitro with the model PT cell system thus reveal that the selective elimination of PLC stimulation in the long-acting PTH analog Trp1-M-PTH(1-28) abolishes effects on NaPiIIc internalization, and indicate the importance of this signaling pathway in control of NaPiIIc, as distinct from NaPiIIa.

**Glial Cells Missing-2 (GCM2), the Regulator of Parathyroid Cell Fate, Transactivates the Calcium-sensing Receptor Gene (CASR): Identification of GCM-response Elements in CASR Promoters P1 and P2.** L. Canaff<sup>1</sup>, X. Zhou<sup>\*1</sup>, D. E. C. Cole<sup>\*2</sup>, G. N. Hendy<sup>1</sup>. <sup>1</sup>Medicine, McGill University, Montreal, QC, Canada, <sup>2</sup>University of Toronto, Toronto, ON, Canada.

Glial cells missing-2 (GCM2) is a transcription factor expressed in the parathyroid hormone (PTH)-secreting cells of the parathyroid gland and is essential for their development. Thus far, downstream targets of GCM2 have not been identified. Here, we show that the promoters of the calcium-sensing receptor (CASR) gene, a differentiation marker for the parathyroid gland, are transactivated by wild-type GCM2. The human CASR gene has two promoters yielding transcripts with alternative 5'-untranslated regions but encoding the same receptor protein. Activities of P1 and P2 promoter-luciferase reporter constructs were stimulated ~2-3-fold over basal by cotransfection of a wild-type GCM2 expression vector in human embryonic kidney (HEK293) cells. Studies with mutated CASR promoter-reporter constructs as well as oligonucleotide precipitation assays identified GCM-response elements in CASR P1 (-451 to -441; relative to the transcription start site) and in CASR P2 (-166 to -156). Primary hypoparathyroidism is a heterogeneous group of conditions characterized by hypocalcemia and hyperphosphatemia due to deficient PTH secretion. In a few cases, homozygous or heterozygous inactivating mutations in the GCM2 gene have been implicated in familial isolated hypoparathyroidism inherited in an autosomal recessive or dominant manner, respectively. In co-transfection studies with either synthetic (3xgbs-lux; GCM-response element multimers) or natural (CASR) promoter-reporter constructs, a dominantly inherited mutant GCM2 exerted a dominant-negative effect on wild-type GCM2 activity, whereas recessively inherited mutants had little or no effect. These data support the notion that different functionality of the GCM2 mutants is sufficient to explain the different modes of inheritance. In addition, we have provided the mechanistic link for a previously noted association between GCM2 and CASR in the development of parathyroid glands of terrestrial vertebrates and evolutionarily related gills of bony fish.

**Serum Parathyroid Hormone Response to Oral Calcium Load in Asian Adolescents.** L. Wu<sup>\*1</sup>, B. Martin<sup>1</sup>, L. McCabe<sup>\*2</sup>, G. McCabe<sup>\*2</sup>, R. M. McClintock<sup>\*3</sup>, M. Peacock<sup>3</sup>, C. M. Weaver<sup>1</sup>. <sup>1</sup>Foods & Nutrition, Purdue University, West Lafayette, IN, USA, <sup>2</sup>Statistics, Purdue University, West Lafayette, IN, USA, <sup>3</sup>Indiana University School of Medicine, Indianapolis, IN, USA.

Measurement of calcium absorption is expensive and not routine. PTH suppression has been used as an indirect indicator of calcium absorption in adults, but not children. Thus, we investigated the calcium load effect on serum (s) PTH suppression in Asian adolescents. Sixteen healthy Chinese boys and girls, aged 12-15 years who had been in the USA for more than 8 months, participated in two 3-week metabolic calcium balance studies separated by a one week washout period. The subjects were randomly assigned to a pair of low (630-1008 mg/d) and high (1275-1602 mg/d) dietary calcium intakes in a cross-over design. Subjects ate a breakfast containing one-third of their daily calcium intake assignment on day 8 of each session. Blood was drawn before and at multiple times after the meal over a 5-hour period and sPTH was measured by radioimmunoassay. The sPTH nadir occurred 1.25 hours after the calcium load (Figure), earlier than the 3 hour nadir reported in adults. The high calcium load (425-534mg) led to significantly greater sPTH suppression ( $P<0.05$ ) than the low calcium load (210-336mg). The 5h sPTH 'area-under-the-curve' following the low calcium load was greater than that following the high calcium load, reflecting lesser suppression of sPTH. There was a significant calcium dose-effect on PTH suppression ( $P<0.05$ ). We also compared sPTH suppression and calcium absorption measured by the stable calcium isotope ratio method in the same subjects. The results suggest that PTH suppression reflects calcium absorption in Adolescents, but is limited to rather large calcium loads.

**Molecular Mechanisms Involved in PTH-induced Apoptosis in Caco-2 Intestinal Cells.** N. Calvo<sup>\*</sup>, R. L. Boland, A. Russo de Boland<sup>\*</sup>, C. Gentili<sup>\*</sup>. Dept. Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina.

Apoptosis, a form of programmed cell death, is a process fundamental to normal growth and development, immune response, tissue remodeling after injury or insult, and plays a critical role in maintaining homeostasis of the intestinal epithelium. Recently, it has become apparent that signaling by the PTH receptor can either promote or suppress apoptosis depending on the cellular context. In this study we show that stimulation of human colonic Caco-2 cells with PTH ( $10^{-8}$  M) results in the dephosphorylation and translocation of pro-apoptotic protein Bad from the cytosol to mitochondria and release of cytochrome c and Smac/Diablo. The hormone also triggers mitochondria cellular distribution to the perinuclear region, diminishes the number of viable cells, increases the enzymatic activity of caspase-3, that is also evidenced from the appearance of its cleaved fragments in western blot experiments, and degradation of its substrate PARP. Moreover, we found that the hormone induces disruption of actin filaments with changes of cellular shape, alteration of cell-to-cell junctions, externalization of membrane phosphatidylserine and also chromatin condensation and DNA fragmentation of the nucleus. Taken together, the present study suggests that the mitochondrial pathway may account for PTH promotion of apoptosis in Caco-2 intestinal cells.

**Influence of Primary Hypoparathyroidism (PHp) on Bone Mineral Density (BMD) and Vertebral Morphometry.** F. J. A. de Paula<sup>\*</sup>, F. A. Pereira, L. M. Monsingnore<sup>\*</sup>, S. R. Teixeira<sup>\*</sup>, M. H. Nogueira-Barbosa<sup>\*</sup>. Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.

The physiological role of PTH in the maintenance of bone mass and of the qualitative characteristics of this tissue is unknown. Our objective was to evaluate BMD and the prevalence of vertebral fractures by morphometric criteria in PHp, this being the first study evaluating vertebral morphometry in PHp. Thirty-three patients (27F:6M) with iatrogenic PHp and with a previous diagnosis of atoxic multinodular goiter were studied. Mean age was  $55.3 \pm 10.3$  years, weight =  $70.4 \pm 14.7$  kg, height =  $1.59 \pm 0.07$  m, BMI =  $25 \pm 7.4$  kg/m<sup>2</sup>, and duration of PHp  $13.3 \pm 11.8$  years. We determined calcium levels, Ca<sup>++</sup>, Pi, PTH, calciuria, BMD at L1-L4, femoral neck (FN) and hip and obtained thoracic and lumbar radiographies using rigid standardization criteria to measure the anterior (AH), middle (MH) and posterior (PH) height of each vertebral body from T4 to L4 using a digital caliper. The criteria of vertebral deformity were: 1) more than a 20% reduction between two of these measures and/or a 20% reduction in the relation between any one of these measures and the measure of the corresponding region of the vertebral body immediately superior or inferior to the vertebra analyzed, and 2) a reduction  $\geq 4$  mm in absolute value. Thus 228 measurements were made for each patient, for a total of 7980. In the diagnosis, calcium, Ca<sup>++</sup> and Pi levels were  $7.2 \pm 0.7$  mg/dl,  $0.89 \pm 0.1$  mol/l and  $5.3 \pm 0.8$  mg/dl, respectively. At last visit, the levels were: calcium =  $8.7 \pm 0.7$  mg/dl, Ca<sup>++</sup> =  $1.07 \pm 0.08$  mmol/L, Pi =  $4.4 \pm 0.9$  mg/dl, and calciuria =  $84 \pm 70$  mg/24 h. Densitometry values at L1-L4 were (BMD =  $1.138 \pm 0.3$  g/cm<sup>2</sup>; T-score =  $+0.8 \pm 2.4$  SD), FN (BMD =  $0.940 \pm 0.2$  g/cm<sup>2</sup>; T-score =  $+0.7 \pm 1.7$  SD), Hip (BMD =  $1.013 \pm 0.2$  g/cm<sup>2</sup>; T-score =  $+0.3 \pm 1.4$  SD). Seventeen patients (51%) presented at least one vertebral deformity and vertebral deformity were distributed as follows: T4 = 1, T5 = 5, T6 = 2, T7 = 7, T8 = 7, T9 = 5, T10 = 5, T11 = 9, T12 = 6, L1 = 5, L2 = 3, L3 = 2, L4 = 3, for a total of 60 vertebral deformity. Three patients had only one altered measure and 9 patients (27% of the total and 53% of the patients with vertebral deformity) had at least three deformities in different vertebral bodies. No other causes of vertebral deformity, such as neoplasias, were detected. This is the first study evaluating vertebral morphometry in PHp, showing that preservation or elevation of bone mass occurs in this condition. Nevertheless, a large number of vertebral deformity were observed in the study group, possibly indicating that the bone quality of these patients is compromised.

**Analysis of Chromosome Breaks in Osteoblasts and Non-osteoblastic Cells Treated with Intermittent PTH.** E. C. A. Oliveira<sup>\*</sup>, C. H. M. Castro<sup>\*</sup>, V. L. Szejnfeld. Rheumatology, Universidade Federal de São Paulo, São Paulo, Brazil.

Intermittent PTH has been approved for the treatment of osteoporosis as an anabolic agent. Toxicological studies have demonstrated that intermittent PTH is associated with osteosarcoma in Fischer rats. However, no solid evidence has been accumulated on the potential genotoxic and mutagenic effect of intermittent PTH and its safety remains controversial. In the present study we investigated the chromosome breaks formed by intermittent PTH on human and murine osteoblasts cells versus non-osteoblastic cells (Hep-2 and HeLa) using the Micronuclei (MN) assay. Osteoblastic cells were grown in  $\alpha$ MEM and non-osteoblastic cells in DMEM. All cell cultures were supplemented with 10% FBS, 100 IU/ml penicillin and 100  $\mu$ g/ml streptomycin. Cells were treated with PTH at 50 and 100 nM for 21 days. Cells were incubated with PTH for 6 hours a day and then were placed in new medium containing 10% FBS and antibiotics. Micronuclei assays were performed at different time points (6 hours, 7, 14 and 21 days). Non-treated cells and cultures exposed for 6 hours to methyl methane sulfonate at 0.1mg/ml were used as negative and positive controls, respectively. At the different time-points, cytochalasin B (4.5  $\mu$ g/ml) was added to the cultures

to inhibit cytokinesis at the end of mitosis. 36 hours after adding cytochalasin B, cells were fixed in methanol, stained with acridine orange and chromosome breaks were visualized by fluorescence microscopy. We observed a 2-3-fold increase in the prevalence of micronuclei in human and murine osteoblastic cells treated by PTH intermittent as compared to the controls. The effect was detectable 6 hours after PTH treatment and was more significant with the highest PTH concentration. Accordingly, the number of micronuclei increased significantly in the treated cells with time in culture and nucleoplasmic bridges were detected, suggesting that PTH treatment in osteoblastic cells induces genomic instability and can be considered clastogenic, at least *in vitro*. To non-osteoblastic cells chromosome breaks appeared only after three weeks of treatment, suggesting a delayed less potent effect in these cells. Our results demonstrate that intermittent PTH can interact with DNA, inducing chromosome breaks. The clastogenic effect is more accentuated in osteoblasts as compared to non-osteoblastic cells. These results are in agreement with our previous findings showing that intermittent PTH is also genotoxic to osteoblastic cells in an *in vivo* mice model.

**The Role of Osteoprotegerin / Receptor Activator of Nuclear Factor kappa B Ligand System for Bone Loss in Primary Hyperparathyroidism.** N. G. Mokrysheva\*, S. S. Gulyaeva\*, Y. A. Dubrovina\*, L. G. Rostomyan\*, L. Y. Rozhinskaya, A. V. Ilyin\*, G. S. Kolesnikova\*, N. I. Sazonova\*. The National Research Centre for Endocrinology, Moscow, Russian Federation.

Pathogenesis of bone mineral density (BMD) loss in primary hyperparathyroidism (PHPT) has not been fully understood. The aim was to investigate the role of osteoprotegerin (OPG) / Receptor Activator of Nuclear factor kappa B ligand (RANKL) system in primary hyperparathyroidism (PHPT). Sixty seven patients with PHPT (62 women and 5 men, mean age 58 y) and 20 generally healthy people for control group were enrolled. Forty two of this patients received surgical treatment on parathyroid glands. Biochemical parameters, BMD (DXA), the markers of bone metabolism (osteocalcin and serum CTx), OPG and RANKL were measured in all subjects before and at the 6th, 12th months after surgical treatment. OPG and RANKL levels were significantly increased in patients with PHPT ( $p < 0.05$ ). Serum OPG correlated with PTH level ( $r = 0.33$ ,  $p < 0.009$ ). RANKL level did not correlate with PTH. Predictably, OPG level correlated with age ( $r = 0.5$ ,  $p < 0.05$ ) and duration of menopause ( $r = 0.36$ ,  $p = 0.007$ ). RANKL level showed negative correlation with duration of menopause ( $r = -0.36$ ,  $p < 0.05$ ). Correlation of OPG with osteocalcin level ( $r = 0.27$ ,  $p < 0.05$ ) was found. OPG level correlated with BMD T-score in L2-L4 ( $r = -0.48$ ,  $p < 0.001$ ), total hip ( $r = -0.37$ ,  $p < 0.005$ ) and radius total ( $r = -0.26$ ,  $p = 0.043$ ). PTH, CTx, osteocalcin, calcium levels were in the reference range 6 and 12 months after surgical treatment. However, OPG and RANKL levels did not decrease significantly even 1 year after surgical treatment, though some tendency to decrease of OPG was observed. OPG/RANKL system is involved in bone loss in PHPT. However the role of OPG/RANKL system is secondary to the effects of high PTH level on bone in patients with PHPT.

**Nmp4-Knockout (KO) Mice Exhibit A Complex Phenotype.** A. G. Robling, J. Cottee\*, P. Childress\*, J. P. Bidwell. Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

The nucleocytoplasmic shuttling transcription factor Nmp4/CIZ (nuclear matrix protein 4/cas interacting zinc finger protein) is a ubiquitously expressed protein that regulates both cytoplasmic and nuclear activities in many cell types. In the nucleus, Nmp4/CIZ represses transcription of genes crucial to osteoblast differentiation (e.g., Runx2) and genes activated by a variety of anabolic stimuli, most notably PTH. We investigated the role of Nmp4/CIZ in PTH responsiveness by engineering mice with loss-of-function mutations in the Nmp4/CIZ gene, and treating those mice with intermittent PTH. Nmp4 knockout (Nmp4-KO) mice were prepared by replacing coding exons 4-7 with the Neo gene cassette. The progeny were backcrossed onto a pure C57BL/6 background (Nmp4-KO-N6) or left on a mixed B6/129 background (Nmp4-KO-F2). Bone mineral density (BMD), content (BMC), and body composition were collected by dual-energy X-ray absorptiometry (pdxMUS). To evaluate the response of Nmp4-KO-N6 mice to anabolic doses of human parathyroid hormone (hPTH 1-34), 10 wk-old female mice were injected with vehicle control or hormone at 30 µg/kg/day, 7 day/wk, for 6 wks.

The Nmp4 mutant alleles had no effect on body weight when expressed on a mixed background, but the same alleles on a pure B6 background yielded a significant, 15% increase in body weight among the KO mice, compared to their WT controls. Nmp4-KO mice exhibited significantly greater whole body, femur, and tibia BMD at 8 wks, regardless of genetic background, as compared to their WT counterparts. These differences were maintained at 16 wks, with the exception of femoral BMD, which returned to WT values in the mature skeleton.

Treatment of the backcrossed mice with PTH resulted in a significant increase in body weight among WT mice, but the same PTH regimen caused the KO mice to lose weight. PTH significantly enhanced femur BMD in both WT and Nmp4-KO-N6 animals however, the latter exhibited a significantly greater (~8%) PTH-induced gain in BMD than WT mice. These results suggest that femora from Nmp4-KO-N6 mice are more sensitive to anabolic PTH than femora from WT mice. The magnitude of PTH-response at other skeletal sites did not differ between the Nmp4-KO-N6 and WT mice.

These data suggest that Nmp4 plays a significant role in regulating tissue development, perhaps by altering differentiation of cells that contribute to lean and fat mass. Furthermore, Nmp4 appears to regulate site-specific skeletal response to PTH. The

differential effects of the Nmp4 null alleles on a pure B6 vs. mixed genetic background suggest the presence of modifier genes that alter the action of Nmp4. Nmp4 has distinct effects on the development, homeostasis, and PTH response at different skeletal sites.

**Behavior of Circulating Rat(s) PTH Molecular Forms in Secondary Hyperparathyroidism Related to Vitamin D Deficiency and Renal Failure.**

P. D'Amour<sup>1</sup>, L. Rousseau<sup>\*1</sup>, S. C. Hornyak<sup>\*2</sup>, Y. Zang<sup>\*2</sup>, T. Cantor<sup>2</sup>.

<sup>1</sup>Department of Medicine, Université de Montréal, Centre de recherche du CHUM, Hôpital Saint-Luc, Montreal, QC, Canada, <sup>2</sup>Scantibodies Laboratory Inc., Santee, CA, USA.

The behavior of circulating PTH molecular forms has been well studied under a variety of clinical conditions and their immunoreactivity in second- (Intact or Total hPTH assays) and third- (Whole PTH assay) generation PTH assays well characterized. Little is known on similarity and possible differences between species concerning PTH molecular forms. The following study was thus performed to study the behavior of circulating PTH molecular forms in normal rats (N-r) and in rats with secondary hyperparathyroidism related to vitamin D deficiency (D-r) and advanced renal failure (RFr). rPTH assays similar to human assays were developed for this study. The rWhole PTH assay reacted with rPTH(1-84) but not with rPTH(7-84), demonstrating a 1-6 epitope. The rTotal PTH assay reacted equally well with rPTH(1-84) and (7-84) and could be saturated with PTH(7-34) indicating an epitope in the region 7-34. D-r had lower ionized calcium ( $\text{Ca}^{++}$ ) ( $p < 0.05$ ), 25(OH)D levels ( $p < 0.001$ ) and a 3-fold increase in Whole ( $15 \pm 17.6$  pmol/L;  $p < 0.001$ ) and Total rPTH ( $20.8 \pm 9.9$  pmol/L;  $p < 0.001$ ). RFr had a low  $\text{Ca}^{++}$  ( $p < 0.01$ ) and a 25 to 30-fold increase in Whole ( $140 \pm 70$  pmol/L;  $p < 0.001$ ) and Total ( $147 \pm 72$ ;  $p < 0.001$ ) rPTH levels. Pools of serum coming from 25 Nr, 13 D-r and 5 RFr were submitted to HPLC separation and analyzed with the 2r assays. Three regions were identified on HPLC profiles corresponding to tubes 28-37, 38-42 and 43-49. The first corresponded to non-(1-84) PTH fragments reacting in the rTotal PTH assay, the second to an aminoterminal (N) peak of PTH reacting slightly better in the rWhole PTH assay and the third to the election position of rPTH(1-84). With the rWhole PTH assay, rPTH(1-84) was 90.4% and N-PTH (8.4%) in D-r, 86.4 and 13.6% in NR and 67.5 and 29.9% in RFr. With the rTotal PTH assay, rPTH(1-84) was 82.5%, N-PTH 6.4% and non-(1-84) PTH 11.1% in D-r, 78.9, 9.6 and 11.5% in NR and 68.3, 19.5 and 12.2% in RFr. These results indicate that in rats adjustment of circulating PTH molecular forms are mainly made through rPTH(1-84) and N-PTH and less through non-(1-84) PTH fragments, with a decreased production of N-PTH in favor of rPTH(1-84) in D-r and with the accumulation of N-PTH in renal failure.

**The N-terminal Fragment of Parathyroid Hormone-related Protein (PTHrP) Promotes the Glucocorticoid-related Deficiency of Bone Regeneration after Bone Marrow Ablation in Mice.** L. F. de Castro<sup>\*1</sup>, D. Lozano<sup>\*1</sup>, E. Gómez-Barrena<sup>\*2</sup>, S. Dapia<sup>\*3</sup>, P. Esbrit<sup>1</sup>.

<sup>1</sup>Bone and Mineral Metabolism Laboratory, Fundación Jiménez Díaz, Madrid, Spain, <sup>2</sup>Dpt. of Traumatology, Fundación Jiménez Díaz, Madrid, Spain, <sup>3</sup>Trabeculae, S.L., Orense, Spain.

Glucocorticoids (GCs) inhibit osteoblast viability and function, and decrease bone formation. Osteoblastic expression of parathyroid hormone-related protein (PTHrP), an important modulator of bone formation, decreases by GCs. We here examined the effect of the PTH-like fragment of PTHrP on bone regeneration after bone marrow ablation in GC-treated mice. We administered 3-methylprednisolone (10 mg/Kg, s.c., every other day) or vehicle to C57BL/6 mice for 16 d. Some GC-treated mice were simultaneously injected with PTHrP (1-36) (100 µg/Kg, s.c., every other day). At day 5, bone marrow ablation was performed under anaesthesia. At the end of the study, bone marrow of one tibia was cultured for up to 21 days for evaluation of the abundance of cell colonies (by crystal violet staining), alkaline phosphatase (ALP) staining, and bone nodule formation (by alizarin red staining). Total RNA was isolated from the remaining hard tissue for mRNA analysis of several osteoblast-related genes (by real-time PCR). The other tibia was fixed, decalcified and included in paraffin for histological studies. Evaluation of femoral bone structure in these mice by µCT showed a 20% decrease in cortical thickness, and a trend to an increased porosity, with no changes in trabecular parameters. GC-treated mice had a moderate but significant weight loss (5%), but this was not observed in PTHrP (1-36)-administered mice. GC-treated mice showed a 25% decrease in both osteoid surface (by Masson's staining) and osteoblast number in the metaphysis, and a 2-fold higher number of adipocytes in the distal diaphysis, in the regenerating tibia, compared to those in control mice. Moreover, GC-treated mice exhibited a decreased gene expression of several osteoblastic products: Runx2, osterix, alkaline phosphatase, osteocalcin, vascular endothelial growth factor and its 1 and 2 receptors, and the osteoprotegerin/receptor activator of NF-κB ligand mRNA ratio; associated with a lower PTHrP gene expression in the regenerating tibia. These changes were totally or partially recovered by PTHrP (1-36) treatment. In addition, *in vivo* GC treatment induced a decrease in bone marrow-derived cell colonies and ALP staining, and also in their mineralization capacity. These *ex vivo* changes were also reversed by *in vivo* PTHrP (1-36) administration. In conclusion, the N-terminal fragment of PTHrP can restore the GC-induced alteration of osteoblastic function, and thus accelerates bone regeneration in mice.

**Metabolic Alkalosis Transition in Renal Proximal Tubule Cells Facilitates an Increase in CYP27B1, While Blunting Responsiveness to PTH.** M. A. Forster<sup>\*1</sup>, S. Masilamani<sup>\*2</sup>, T. A. Reinhardt<sup>3</sup>, M. J. Beckman<sup>\*4</sup>. <sup>1</sup>Physiology and Biophysics, Virginia Commonwealth University, Richmond, VA, USA, <sup>2</sup>Internal Medicine, Nephrology, Virginia Commonwealth University, Richmond, VA, USA, <sup>3</sup>Mineral Metabolism and Mastitis, ARS USDA National Animal Disease Center, Ames, IA, USA, <sup>4</sup>Biochemistry, Virginia Commonwealth University, Richmond, VA, USA.

Parathyroid hormone (PTH) is the central activator of renal proximal 1- $\alpha$ -hydroxylase (CYP27B1), the enzyme responsible for synthesis of 1,25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>). Past studies have documented a disruption of CYP27B1 activity in chronic metabolic acidosis *in vivo*, while simulated acidosis in cultured renal cells failed to demonstrate impairment of 1,25(OH)<sub>2</sub>D<sub>3</sub> synthesis. To determine the factors involved in regulating responsiveness of CYP27B1 to PTH in renal proximal tubule cells, we developed a dietary protocol to study the transition from metabolic acidosis (diet low in potassium) to metabolic alkalosis (diet high in potassium-bicarbonate) in young adult rats, n=9. Gene expression was determined in renal proximal tubules isolated from each group using Affymetrix GeneChip<sup>®</sup> microarray, n=3. The high potassium bicarbonate diet was found to induce metabolic alkalosis (> 7.5) by day 10 as tested by urine pH. The rats being fed the control diet were maintained at a slightly acidic urine pH (< 7.4) throughout the study. Blood concentrations of phosphate, calcium and 25-OH-D<sub>3</sub> were replete under the conditions effected by both acidic and basic diets, however, blood 1,25(OH)<sub>2</sub>D<sub>3</sub> concentrations were significantly increased by the switch to the high potassium-bicarbonate alkaline diet. This was matched by an increase in gene expression of 1- $\alpha$ -hydroxylase (CYP27B1), 9kDa-CaBP and NR4A2, and a decrease in VDR following alkalosis in renal proximal tubules. The orphan nuclear receptor family 4A, member 2 (NR4A2, also known as HZF-2, NURR1) was recently identified as a positive regulator of CYP27B1 transcription in renal proximal tubule epithelial cells. In the present study, intermediate components of PTH cell signaling such as adenylate cyclase and CREB were expressed at significantly higher levels in animals fed the acidic control diet, while NR4A2 was closely associated with the regulation pattern of CYP27B1 in metabolic alkalosis. These results indicate that the important link between PTH responsiveness and renal CYP27B1 gene expression is predisposed by levels of cAMP/PKA/CREB pathway intermediates, but CYP27B1 expression requires NR4A2. In conclusion, chronic acidosis suppressed CYP27B1 gene expression in proximal tubules but maintained enhanced responsiveness to PTH. In contrast, metabolic alkalosis displayed blunted PTH responsiveness.

**Documented Response to Cinacalcet in Two Cases of Acquired Hypocalciuric Hypercalcemia.** A. Godbout<sup>\*1</sup>, G. Rondeau<sup>\*1</sup>, J. H. Brossard<sup>\*1</sup>, P. D'Amour<sup>1</sup>, R. Bélanger<sup>\*1</sup>, H. B. Lavoie<sup>\*1</sup>, G. N. Hendy<sup>2</sup>, N. Alos<sup>3</sup>, L. G. Ste-Marie<sup>1</sup>. <sup>1</sup>Endocrinology, Chum, Montreal, QC, Canada, <sup>2</sup>Department of Medicine, McGill University, Montreal, QC, Canada, <sup>3</sup>Endocrinology, Hôpital Ste-Justine, Montreal, QC, Canada.

Differential diagnosis of hypercalcemia (Hc) with inappropriately normal or elevated serum parathyroid hormone (PTH) includes primary hyperparathyroidism, rare cases of paraneoplastic PTH secretion and familial hypocalciuric hypercalcemia, which is caused by an inactivating mutation of the calcium-sensing receptor (CaSR). Only five cases of acquired hypocalciuric Hc due to CaSR autoantibodies have been reported. We present 2 cases of severe symptomatic Hc with hypocalciuria diagnosed in a girl and a man of respectively 15 and 75-year-old. Initially, they disclosed high serum Ca respectively of 3.20 and 5.10 mmol/L (N: 2.15-2.60). The teenager presented with 1 year history of weight loss. She was already treated for hypothyroidism and Myoclonic-Astatic Epilepsy. Being adopted, no information about her family was available. The old man was admitted for confusion and weight loss. His past medical history was negative. He took no medication. Family history was negative and his four daughters were normocalcemic. At presentation, both had inappropriate or elevated serum PTH (3.2 and 13.5 pmol/L N:1.4-6.8) and normal renal function. Serum phosphate (Pi) was normal for the girl but lowered in the old man. Serum 25(OH)vitamin D, 1,25(OH)<sub>2</sub>vitamin D and PTHrP were all normal. In both patients, 24h urinary Ca excretion was low at 3.7 and 2.4 mmol/d, with reduced Ca clearance to creatinine clearance ratio (CCa/CCreat) of 0.0042 and 0.0064. Mutation analysis of both patients DNA found all *CaSR* gene protein-coding exons to be normal. Serum Ca remained high despite alendronate for the girl and repeated pamidronate and zoledronic acid infusions in the man. However, after 2 weeks of prednisone (1mg/kg/d), Hc ameliorated in the first case decreasing from 3.00 to 2.71mmol/L whereas serum Ca, Pi and PTH normalized in the man but CCa/CCreat remained low in both. These responses, as previously published, suggest autoantibodies against the CaSR as the cause of the acquired hypocalciuric hypercalcemia. Prednisone was then tapered and cinacalcet, a calcimimetic, was administered and successfully controlled the Hc at a dosage of respectively 120 and 180 mg PO die. The CCa/CCreat normalized in both patients. Presence of circulating CaSR autoantibodies will now be sought. These are the first documented cases of successful control of acquired hypocalciuric hypercalcemia with cinacalcet, resulting in sustained normalization of calcemia and urinary calcium excretion. Cinacalcet should be considered as a first line treatment in acquired hypocalciuric hypercalcemia.

## M198

**Efficient Expression of the Full-Length Calcium-Sensing Receptor in Insect Cells.** Z. Ryan<sup>\*</sup>, R. Kumar. Nephrology Research, Mayo Clinic, Rochester, MN, USA.

The Calcium-Sensing Receptor (CaSR) is a 1078 amino acid cell surface G protein-coupled receptor that regulates calcium homeostasis by altering parathyroid hormone release and renal calcium transport. The receptor binds divalent and trivalent cations, amino acids, polyamines, and polycationic ligands and is involved in the sensing of serum calcium concentrations. The CaSR is localized in tissues involved in calcium homeostasis including the parathyroid gland, kidney, thyroid C-cells, bone (osteoclasts, osteoblasts), and intestine, as well as several other tissues without obvious roles in the maintenance of extracellular calcium such as nerve terminals, cardiac myocytes, and oligodendrocytes. The CaSR is composed of three domains: a large extracellular domain (ECD, amino acids 20-612), a seven-transmembrane-spanning segment (amino acids 613-867), and a cytoplasmic tail (amino acids 868-1078). The exact amino acid residues and molecular orientations which are responsible for Ca<sup>2+</sup> binding, Ca<sup>2+</sup> sensing, and signal transduction in response to changes in serum Ca<sup>2+</sup> concentrations are unknown.

In order to determine the biophysical properties of full-length CaSR, we have generated an efficient system for the expression of full-length CaSR in quantities sufficient for functional analysis and x-ray crystallography. Two CaSR constructs were created: one full length (amino acids 1-1078) and the other missing the CaSR signal sequence (amino acids 20-1078). Both constructs were cloned into a pIB/V5-His TOPO insect expression vector for transfection into the High-Five insect cell expression system (Invitrogen). The orientation of the inserts and DNA sequence were verified by DNA sequencing. *Trichoplusia ni* (High Five) cells were stably transfected with the pIB/V5-His CaSR constructs. After Blasticidin S selection for successful transfection, cells were harvested for SDS-PAGE and Western blot analysis using a V5-HRP antibody. Protein samples were made with and without DTT to determine whether the CaSR expressed by the insect cells formed dimers. Results indicate that the full-length (amino acids 1-1078) CaSR construct is highly expressed and is able to dimerize successfully. The CaSR lacking signal sequence (amino acids 20-1078) is poorly expressed and is unable to dimerize.

Conclusion: We have devised an efficient insect cell based system for the expression of the full-length CaSR which will permit the isolation of sufficient amounts of the receptor for biophysical and crystallization studies.

**Disclosures:** Z. Ryan, None.

**Dietary Normalization of Calcium Absorption in Mice Genetically Deficient in CaSR and 25-Hydroxyvitamin D-1 $\alpha$ -Hydroxylase Results in Non-Lethal, Severe Hyperparathyroidism with Reduced Osteoclastogenesis.** C. Richard<sup>1</sup>, D. Miao<sup>\*2</sup>, R. Huo<sup>\*1</sup>, G. N. Hendy<sup>1</sup>, D. Goltzman<sup>1</sup>. <sup>1</sup>Medicine Dept, Calcium Laboratory, McGill University, Royal Victoria Hospital, Montreal, QC, Canada, <sup>2</sup>Human Anatomy, Nanjing Medical University, Nanjing, China.

The calcium sensing receptor (CaSR) mediates the effect of high calcium to suppress PTH synthesis and secretion and also to promote renal calcium excretion. CaSR is also expressed in multiple bone cells, however the specific function of CaSR in bone is still controversial. These tissues are also the target sites for the action of 1,25-dihydroxyvitamin D [1,25(OH)<sub>2</sub>D]. To further delineate the specific *in vivo* interactions of CaSR and 1,25(OH)<sub>2</sub>D, we developed a mouse model in which the genes encoding CaSR and 1 $\alpha$ (OH)ase were inactivated. We investigated the effects of the combined deficiency of CaSR and 1,25(OH)<sub>2</sub>D on mice fed a diet high in lactose, calcium and phosphorus. This diet has been shown to normalize gastrointestinal calcium absorption in the absence of vitamin D. Study of genetic models showed that compared to CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup>, CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice had the lowest weight at weaning and the slowest initial growth rate but survived long-term. These mice were markedly hypercalcemic and hypophosphatemic (serum calcium and phosphorus of 5.0 mM and 0.6 mM respectively) in contrast to CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> which had normal serum calcium and phosphorus levels. Serum intact PTH levels were high in CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> (3000 pg/ml) but normal in normocalcemic CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice. Bone volume over tissue volume of CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice, and osteoid volume over bone volume, were both increased in the tibia (100%) and to a lesser extent in the lumbar spine compared to CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup>. Parathyroid gland size was clearly increased in CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> but not in CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice. Alkaline phosphatase staining of the femur revealed a large increase in osteoblast numbers in CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> compared to CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice. TRAP staining showed a decrease in osteoclasts in both CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice. Bone mineral density (BMD) of 90 day old female CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> and CaSR<sup>-/-</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice but not CaSR<sup>+/+</sup>;1 $\alpha$ (OH)ase<sup>-/-</sup> mice was higher than in male counterparts. Taken together these results suggest that CaSR activation is implicated in the control of bone resorption through osteoclastogenesis and that CaSR gene inactivation may result in a gender-specific effect on BMD.

**Calcium Sensing Receptor Mediated Signaling In Human Vascular Smooth Muscle Cells.** R. Bland<sup>1</sup>, G. Molostvov<sup>\*2</sup>, J. Bennett<sup>\*1</sup>, D. Zehnder<sup>\*2</sup>.

<sup>1</sup>Biological Sciences, University of Warwick, Coventry, United Kingdom, <sup>2</sup>Clinical Sciences Research Institute, University of Warwick, Coventry, United Kingdom.

Vascular smooth muscle cells play a pivotal role in the pathogenesis of medial calcification. We have recently demonstrated expression of the calcium sensing receptor (CaSR) in human aortic smooth muscle cells (HAoSMC) and human arteries and demonstrated a correlation between CaSR expression and medial calcification. Here we have examined downstream CaSR-mediated signaling pathways in HAoSMC and investigated the role of the CaSR in regulating HAoSMC proliferation and apoptosis.

HAoSMC were incubated with CaSR agonists (neomycin or gentamycin) alone or in the presence of specific signaling inhibitors. Activation of the MEK1/ERK1,2 pathway was assessed by Western blot analysis. HAoSMC proliferation was assessed by BrdU incorporation and apoptotic cells were identified by flow cytometry following propidium iodide staining. CaSR knock-down was performed using siRNA technology.

Incubation of HAoSMC with the CaSR agonist neomycin (300µM), resulted in a 7.5 fold increase in ERK1,2 phosphorylation (p<0.05). This induction was attenuated by pre-treatment with PD98059 (10µM) an ERK1 inhibitor (p<0.01) and U73122 (5µM) a PLC inhibitor (p<0.01) suggesting that PLC-signaling was important for MEK1/ERK1,2 activation. No changes were seen with PKC and PI3K inhibitors. Further confirming PLC activation, IP3 production was increased by neomycin (p<0.05), which was reduced in the presence of U73122 (p<0.05). To confirm ERK1,2 stimulation and PLC signaling were mediated via the CaSR, responses were assessed in HAoSMC in which CaSR expression had been knocked-down. CaSR-knockdown resulted in attenuated ERK1,2 phosphorylation in response to neomycin (>50% of neomycin induction in control cells, p<0.01) and IP3 production was almost completely abolished. Gentamycin (300 µM, 15 min) induced similar, but less pronounced, effects. CaSR activation (neomycin treatment) increased HAoSMC proliferation 3.6 fold (p<0.01). This was inhibited by PD98059 and U73122 (p<0.05). Neomycin failed to induce proliferation in CaSR-knockdown cells confirming the importance CaSR-mediated MEK/ERK1,2 and PLC signaling in HAoSMC proliferation. Apoptosis was not affected by neomycin or expression of the CaSR, but inhibition of PLC signaling (incubation with 5µM U73122) increased apoptotic cell death 3.5 fold (p<0.05), which was further increased by CaSR-knockdown (4.8 fold vs. control siRNA, p<0.05).

In conclusion, stimulation of the CaSR results in activation of the MEK1/ERK1,2 and PLC-IP3 pathways and increases proliferation in HAoSMC independently of PKC and PI3K signaling. In addition, CaSR-mediated PLC activation protects against apoptosis in HAoSMC.

Inactivating mutations of the calcium-sensing receptor (CASR) have been implicated in the genesis of different hypercalcemic syndromes, including familial hypocalciuric hypercalcemia (FHH), cases of primary hyperparathyroidism (PHPT), and familial isolated hyperparathyroidism (FIHP). However, assessment of the yield from molecular diagnostics applied to large cohorts from a single centre have not been reported. We describe our molecular findings for a series of cases with FHH (n=17), PHPT (n=173) and FIHP (n=3), and controls (n=200); all seen and prospectively evaluated at the "Casa Sollievo della Sofferenza" Hospital in southern Italy. CASR screening was conducted by denaturing high-performance liquid chromatography (dHPLC) using a fully validated series of primers to generate 12 amplicons covering the translated exons and exon/intron boundaries, with sequencing of the C-terminal amplicon to distinguish causative mutations from three common missense SNPs. Four novel missense variants were identified in the normocalcemic controls, suggesting that false positive tests will be uncommon but not rare. Mutations were identified in 2 PHPT cases - on follow-up, 1 was confirmed as PHPT, and 1 reclassified as FHH. Thus, CASR mutations are rare in PHPT. In hypocalciuric hypercalcemic probands, however, mutations were found in 8/17 (47%). With a hypercalcemic family member, mutation detection rate rose to 7/8 (87%), while only 1 of 9 sporadic cases was positive, and none of the 3 FIHP cases had detectable CASR mutations. Co-segregation of FHH and a novel intronic mutation (IVS4-19A>C) was noted in one family. A CASR fragment comprised of either mutant or wild-type IVS4, exonV and part of IVS5 was inserted into a minicassette with flanking PTHR1 and RAB1 exons and the construct expressed in HeLa cells. RT-PCR product from wild-type indicated normal splicing but the IVS4-19C mutant showed additional abnormal splicing into a cryptic site 118bp downstream of the wild-type exonV acceptor site. The importance of functional analyses for three novel missense mutations in this FHH cohort is accentuated by the identification of missense variants in the occasional control.

**Activation of the Calcium-Sensing Receptor by Beta-Aspartyl & Gamma-Glutamyl Peptides.** G. K. Broadhead<sup>\*1</sup>, S. C. Brennan<sup>\*1</sup>, H. Mun<sup>\*1</sup>, D. R. Hampson<sup>\*2</sup>, A. D. Conigrave<sup>1</sup>.

<sup>1</sup>School of Molecular and Microbial Biosciences, University of Sydney, Sydney, Australia, <sup>2</sup>Department of Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.

The extracellular Ca<sup>2+</sup>-sensing receptor (CaR) is a class 3 G-protein coupled receptor that plays a major role in the regulation of whole body calcium homeostasis. The receptor is activated not only by Ca<sup>2+</sup>, various polycations and type-II calcimimetics, such as cinacalcet, but also L-amino acids in physiological relevant concentrations (L-Phe = L-Trp > L-Ala > L-Leu). Recent work has demonstrated that the receptor's promiscuity arises from the presence of multiple activator binding sites in the extracellular and transmembrane domain regions. L-amino acids have been shown to bind in the CaR's Venus Fly Trap (VFT) domain and molecular modeling of the amino acid binding site has indicated that the side-chain binding site is large enough to accommodate larger ligands, such as short peptides, in which the free α-amino and α-carboxylate functional groups are preserved. Consistent with this idea, the gamma-glutamyl tripeptide glutathione has recently been shown to activate the receptor. We have extended this analysis to test whether the receptor is activated by a series of glutathione related peptides. HEK-CaR cells, which stably express the CaR, and human parathyroid cells, which endogenously express the CaR, were loaded with fura-2AM and then exposed to various activators in the presence of Ca<sup>2+</sup> (0.5 - 5.0 mM). β-Aspartyl and γ-Glutamyl peptides activated the receptor. The following order of potency was observed: β-Asp-His > β-Asp-Phe ≥ GSH > γ-Glu-Cys ≥ γ-Glu-His > β-Asp-Leu > L-Phe. The most potent activator, β-Asp-His, was effective in the concentration range of 0.01 - 1 µmol L<sup>-1</sup>. The finding that β-Aspartyl and γ-Glutamyl peptides activate the CaR has potential physiological and pharmacological significance.

**Molecular Basis of Primary Hyperparathyroidism: Adenomatous Parathyroid Cells Are Resistant to L-Amino Acids.** H. C. Mun<sup>\*1</sup>, S. C. Brennan<sup>\*1</sup>, L. Delbridge<sup>\*2</sup>, M. Wilkinson<sup>\*3</sup>, E. M. Brown<sup>4</sup>, A. D. Conigrave<sup>1</sup>.

<sup>1</sup>School of Molecular and Microbial Biosciences, University of Sydney, NSW, Australia, <sup>2</sup>Department of Surgery, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia, <sup>3</sup>Department of Endocrinology, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia, <sup>4</sup>Division of Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA.

Ca<sup>2+</sup>-sensing receptor (CaR) activation by L-amino acids suppresses PTH secretion and stimulates intracellular Ca<sup>2+</sup> mobilization in human parathyroid cells via enhanced sensitivity to extracellular Ca<sup>2+</sup> (Ca<sup>2+</sup><sub>o</sub>). Compared to normal cells, adenomatous cells exhibit reduced sensitivity to Ca<sup>2+</sup><sub>o</sub>, raising the possibility that impaired L-amino acid activation of the CaR disables the normal control of PTH secretion. In the current study, we compared the amino acid sensitivities of samples of normal and adenomatous human parathyroid tissue obtained under guidelines established by the Human Research Ethics Committees of Royal North Shore Hospital, St Leonards, NSW and the Mater Hospital, North Sydney, NSW, Australia. Human parathyroid cells were prepared by collagenase digestion and loaded with Fura-2 AM for analysis of intracellular Ca<sup>2+</sup> mobilization or perfused for analysis of PTH secretion as described previously (1). In normal cells (n = 9), PTH secretion was suppressed by Ca<sup>2+</sup><sub>o</sub> in the range 0.8 - 1.2 mM and the CaR-active amino acid L-Phe (5 mM) enhanced its Ca<sup>2+</sup><sub>o</sub> sensitivity such that the IC<sub>50</sub> for Ca<sup>2+</sup><sub>o</sub> fell from 1.16 ± 0.01 to 1.10 ± 0.01 mM. Adenomatous cells (n = 15), on the other hand, were unresponsive to L-Phe at Ca<sup>2+</sup><sub>o</sub> concentrations below 1.2 mM. In normal cells, L-Phe also markedly left-shifted Ca<sup>2+</sup><sub>o</sub>-dependent mobilization of intracellular Ca<sup>2+</sup> as described previously (1); however, adenomatous cells exhibited impaired amino acid sensitivity. The data support the hypothesis that impaired amino acid sensitivity in human adenomatous parathyroid cells is a significant factor in the loss of Ca<sup>2+</sup><sub>o</sub>-dependent feedback control of PTH secretion in primary hyperparathyroidism.

**Functional Characterization of Unreported Calcium Sensing Receptor in Four Italian Kindreds with Familial Hypocalciuric Hypercalcaemia.** E. Cetani<sup>\*1</sup>, S. Borsari<sup>\*2</sup>, M. Lemmi<sup>\*3</sup>, E. Pardi<sup>\*2</sup>, D. Cervia<sup>\*4</sup>, L. Cianferotti<sup>1</sup>, C. Banti<sup>\*1</sup>, E. Ambrogini<sup>\*1</sup>, E. Vignali<sup>\*1</sup>, P. Bagnoli<sup>\*5</sup>, A. Pinchera<sup>\*6</sup>, C. Marcocci<sup>6</sup>. <sup>1</sup>Endocrinology, University of Pisa, Pisa, Italy, <sup>2</sup>Endocrinology, University of Pisa, Pisa, Italy, <sup>3</sup>Endocrinology, University of Pisa, Pisa, Italy, <sup>4</sup>Biology, University of Pisa, Pisa, Italy, <sup>5</sup>Biology, University of Pisa, Pisa, Italy, <sup>6</sup>Endocrinology, University of Pisa, Pisa, Italy.

Familial hypocalciuric hypercalcaemia (FHH) is characterized by moderate and lifelong hypercalcaemia, relative hypocalciuria, and inappropriately normal serum PTH levels. Loss-of-function mutations of the CASR are responsible for this disease. We describe four unrelated FHH kindreds (A, B, C and D). Mutational analysis of the CASR gene was performed on genomic DNA of the probands. Functional studies on three mutations were performed in COS-7 cells transiently expressing the wild-type and mutant CASR. In family A, a novel heterozygous base substitution C to T was detected, determining a change of an histidine to a tyrosine at codon 595 (H595Y) of exon 7. In family B, a heterozygous mutation was found at codon 748, with a substitution of C to A in exon 7, leading to conversion of a proline to an histidine (P748H). In family C, an heterozygous C to G substitution determining a change of a cysteine to a tryptophan at codon 765 (C765W) of exon 7 was detected. In case D, direct sequencing showed a substitution of G to T in the donor splice site of intron 2 (IVS2+1G>T). The absence of these mutations in 50 unrelated healthy subjects could exclude their polymorphic nature. In fura-2-loaded COS-7 cells expressing the wild-type or mutant receptors, the P748H and H595Y mutants produced, in the cytosolic calcium response to increasing extracellular calcium concentrations, a shift to the right relative to the wild-type CASR. In contrast, the co-transfected WT/P748H and WT/H595Y had the same behaviour as the WT. The C765W mutant had a concentration-response curve shifted to the right and the co-transfected WT/C765W had the same EC<sub>50</sub> relative to that of WT. Immunofluorescence experiments revealed an equal quantity of WT, as well as mutant receptors, expressed in transfected COS-7 cells. In addition, COS-7 cells transfected with mutant CASR showed, in western blotting analysis, a response similar to the WT, with respect to intracellular signaling (MAPK activation) to increasing extracellular calcium concentrations. In conclusion, molecular analysis showed that all kindreds carried unreported CASR mutations, three of them functionally inactivate the receptor.

**Dimerization and Trafficking of the Calcium-Sensing Receptor (CaSR) to the Plasma Membrane: Biochemical and Biophysical Evaluation of COOH-terminally Truncated CaSR Mutants.** M. Grant<sup>\*1</sup>, K. Schorr<sup>\*1</sup>, U. Kumar<sup>\*2</sup>, G. N. Hendy<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada.

Calcium homeostasis is critical to survival and in the functioning of numerous bodily processes. Due to its exquisite sensitivity to minute changes in extracellular calcium levels, the calcium-sensing receptor (CaSR) is a key player in this regard. Its primary function is to regulate parathyroid hormone secretion, a critical factor in calcium homeostasis. In addition to the parathyroid gland, CaSR plays important roles in kidney, gut and bone. The CaSR is a G-protein coupled receptor (GPCR) and in humans, the monomer comprises 1078 amino acids, 612 in the extracellular domain, 250 in the transmembrane domain (TMD) and 216 residues in the cytoplasmic tail (C-tail). The CaSR functions as a dimer at the plasma membrane and constitutive dimerization that occurs in the endoplasmic reticulum (ER) is necessary but may not be sufficient for exit from the ER and trafficking to the plasma membrane via the Golgi. Several different mechanisms contribute to receptor dimerization including covalent and noncovalent interactions occurring within the extracellular domain. However, other parts of the molecule, as yet uncharacterized, in the TMD and/or C-tail are likely to be important. In addition, the sequence requirements for exit of the CaSR from the ER are unclear. To address these issues we have generated and transiently transfected HEK-293 cells with a series of COOH-terminally truncated receptors, all based upon naturally occurring mutations identified in familial hypocalciuric hypercalcaemia and/or neonatal severe hyperparathyroidism patients. Although cell-surface expression was observed for truncation mutants where all or part of the C-tail was removed, the trafficking of mutants lacking all or part of the TMD was impaired. Furthermore, CaSR mutants deleted from TM4 onwards were retained in the ER and were not present in the Golgi. By Western blot and photobleaching fluorescence resonance energy transfer (pbFRET) microscopy techniques, the dimerization properties of each mutant were assessed. PbFRET analysis indicated constitutive dimerization for all cell-surface targeted receptors but not for TMD truncation mutants lacking TM5 onwards. Hence, with this particular set of CaSR mutants, the ability to undergo constitutive dimerization is correlated with exit from the ER to the Golgi but may not be sufficient for trafficking to the cell-surface. While dimerization is important for CaSR maturation, other factors are necessary to ensure its forward trafficking.

**Skeletal Consequences of Familial Hypocalciuric Hypercalcaemia and Primary Hyperparathyroidism.** S. E. Christensen<sup>1</sup>, P. H. Nissen<sup>\*2</sup>, P. Vestergaard<sup>1</sup>, L. Heickendorff<sup>\*2</sup>, L. Rejnmark<sup>1</sup>, K. Brixen<sup>3</sup>, L. Mosekilde<sup>1</sup>. <sup>1</sup>Endocrinological Dept. C., Aarhus University Hospital, DK-8000 Aarhus C., Denmark, <sup>2</sup>Department of Clinical Biochemistry, Aarhus University Hospital, DK-8000 Aarhus C., Denmark, <sup>3</sup>Endocrinological Dept., Odense University Hospital, DK-5000 Odense C., Denmark.

Bone metabolism is well described in Primary Hyperparathyroidism (PHPT) but not in Familial Hypocalciuric Hypercalcaemia (FHH). We describe biochemical and osteodensitometric measurements in FHH and compare them with PHPT in a cross-sectional study.

We studied 66 hypercalcaemic FHH-patients with mutations in the CASR gene from 25 kindreds, 147 hypercalcaemic patients with surgically verified PHPT, and 48 controls matched to 48 of the FHH patients with respect to age (+/- 5 years), sex and season. All patients had a plasma creatinine level < 140 µmol/l. We measured plasma calcium, plasma ionized calcium, albumin, creatinine, phosphate, magnesium and intact PTH by standard laboratory methods. Plasma 25OHD and 1,25(OH)<sub>2</sub>D were measured by radio-immunoassay or enzyme-immunoassay. Plasma alkaline phosphatase (AP) was measured by the spectrophotometrical method, Aeroset. U-NTx was measured in morning spot urine by an immunometrical method and expressed as U-NTx/U-creatinine ratio (U-NTx), nmol/mmol. In FHH, all protein coding exons in the CASR were sequenced and aligned to GenBank reference sequence NM\_000388.

Osteodensitometry (DXA) was performed on the lumbar spine (L1-L4), the total hip, the forearm, and whole body using Hologic® equipment. In the PHPT, DXA was performed within the last year before surgery.

The FHH patients had normal Z-scores in all regions, and increased levels of PTH (p<0.01), AP (p<0.01) and U-NTx (p=0.02), compared to normal controls. Compared to PHPT, the FHH patients were younger, had a lower BMI, and lower levels of PTH (p<0.01), 1,25(OH)<sub>2</sub>D (p<0.01), 24h-U-calcium (p<0.01) and the calcium/creatinine clearance ratio (p<0.01). The PHPT patients exhibited lower BMD at all sites, higher plasma levels of AP (p<0.01), and U-NTx (p=0.03), compared to FHH. Plasma calcium and 25OHD did not differ between FHH and PHPT. PHPT patients had decreased Z-scores in the total hip (p=0.02), and in the forearm (p<0.01), compared to FHH, and normal controls (p<0.01, p<0.01, respectively). In FHH, increased severity of CASR mutations, as expressed by the severity of hypercalcaemia, was associated with increased BMD in the lumbar spine, but was not associated with bone markers.

FHH is not associated with increased bone loss. Inactivating CASR mutations do not cause deleterious effects on bone, as evaluated by DXA measurements, in spite of increased plasma levels of PTH, AP, and U-NTx. The levels of PTH, 1,25(OH)<sub>2</sub>D, AP, and U-NTx were significantly lower in FHH than in PHPT.

**Disclosures:** S.E. Christensen, None.

## M207

**In Vivo Longitudinal QCT Analysis PTH Efficacy in a Rat Cortical Defect Model.** D. E. Komatsu, K. A. Brune\*, A. L. Schmidt\*, H. Liu\*, B. Han\*, Y. Lu\*, M. S. Westmore\*, J. A. Wolos\*, Q. Q. Zeng\*, Y. L. Ma, M. Sato. Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN, USA.

Osteoporotic patients with fracture could possibly benefit from therapies to accelerate bone healing. PTH has been shown to enhance fracture repair in numerous animal models; however, the spatial and kinetic efficacy of PTH in the bone healing process remains to be elucidated. Therefore, we conducted a longitudinal, region-specific analysis of bone regeneration in osteopenic rats using a new cortical defect model. Sprague Dawley rats were ovariectomized at 6 months of age and allowed to lose bone for 2 months prior to the generation of 2 mm circular defects through the anterior and posterior cortices of both femoral diaphyses. The animals were then treated for 5 weeks with hPTH1-38 at doses of 0, 3, 10 or 30 µg/kg/d sc, and scanned weekly by in vivo quantitative computed tomography (QCT, GE). Longitudinal, QCT analyses showed that the posterior cortices healed significantly faster than the anterior cortices regardless of treatment. The highest dose of PTH generated significant increases of 22% in BMD after 2wk within the posterior cortex and 56% after 3wk within the anterior cortex, with steady dose dependent increases observed until study termination. Slice by slice analyses (153 µm steps) from the anterior periosteal edges, through the defects to the posterior periosteal edges, showed dose dependent enhancement of mineral apposition along the endocortical edges and within the marrow cavities that was significant by 2wk, and continued to increase through 5wk for the two highest dose groups. Whole bone analyses of transverse cross-sections at the defect sites showed dose dependent gains of 39% cortical area by 2wk, as well as 25% BMD and 29% BMC by 3wk for the highest dose, but no significant changes in periosteal mineral apposition. Histomorphometry confirmed PTH stimulation of primarily endochondral bone formation activity. Post-necropsy 3-point bending tests showed that the ultimate moment of vehicle controls was 44% that of intact, non-drilled controls and that the highest dose of PTH significantly increased this to 63% of intact. Serum biomarker analyses identified a dose dependent elevation of PINP, with an 80% increase seen for the highest PTH dose along with an unexpected 60% reduction in Trap5b levels at 3wk. In summary, longitudinal QCT analyses demonstrated that PTH dose dependently induced new bone formation within the defects, along the endocortical surfaces and within the intramedullary spaces, resulting in stronger femora and some unexpected effects on serum markers. The effects of PTH were kinetic, region-specific, and most apparent at high doses which may not be clinically relevant.

## M208

**Marrow Ablation Induces Periosteal Bone Formation and Potentiates the Effect of PTH on Endosteal Bone Formation in Rat Femurs.** Q. Zhang<sup>1</sup>, J. Carlson<sup>2</sup>, M. Kim<sup>3</sup>, H. Ke<sup>3</sup>, J. Gilligan<sup>4</sup>, N. Mehta<sup>4</sup>, A. Vignery<sup>1</sup>. <sup>1</sup>Orthopaedics, Yale School of Medicine, New Haven, CT, USA, <sup>2</sup>Comparative Medicine, Yale School of Medicine, New Haven, CT, USA, <sup>3</sup>Pfizer Global Research, Groton, CT, USA, <sup>4</sup>Unigene Laboratories, Inc., Fairfield, NJ, USA.

During development and repair of bone, two distinct yet complementary mechanisms, intramembranous and endochondral, mediate bone formation via osteoblasts. Mechanical bone marrow ablation (BMX) leads to differentiation of osteoblasts, and transient formation of new intramembranous bone in lieu of bone marrow. We initially reported that systemic administration of parathyroid hormone (PTH) promotes the formation of new bone after BMX in a rapid and site-specific manner. We demonstrated that lamellar bone progressively fills the marrow cavity of ablated femoral shafts in animals treated daily with PTH for 3 weeks and that this newly formed bone endows femoral shafts with improved biomechanical properties when compared to those of contra lateral femurs as well as left femurs from control, sham operated and vehicle-treated rats (Tissue Eng. 14:237, 2008). Here we asked whether long-term treatment with PTH could maintain the new bone formed in lieu of marrow. We subjected the left femur of rats to sham operation or BMX, and treated the operated animals daily with PBS or the PTH analog PTH(1-34)NH<sub>2</sub> for 12 weeks (n = 8). Femurs were analyzed by soft X-ray, pQCT, microCT and histology, and serum osteocalcin concentration was determined.

The amount of new lamellar bone that had filled the marrow cavity in response to BMX and daily treatment with PTH for 3 weeks was substantially less after 3 months of treatment with PTH. Instead, the femoral shafts from these PTH-treated BMX rats demonstrated a 43% increase in cortical thickness when compared with controls, and 30% when compared with BMX alone. This 43% increase resulted for the most part from a 35% reduction in endosteal circumference. Marrow ablation alone led to an 8% increase in periosteal circumference. Our results thus demonstrate that BMX induces periosteal bone formation, and potentiates endosteal bone formation induced by PTH.

The spatial and time-dependent effect of PTH that follows marrow ablation is suggestive of an adaptation of bone to injury in the context of mechanical stress. While PTH is known to augment trabecular density, and to some extent endocortical bone density, we report here that PTH synergizes with the repair mechanism that takes place after marrow ablation to augment the thickness of cortical bone to a greater degree than previously seen with PTH treatment alone. These findings might be useful for investigations on the molecular mechanisms of periosteal versus endosteal cortical bone formation, and for preferential site-directed cortical bone growth.

**A New Intact Parathyroid Hormone (PTH) Assay on the IDS Automated Analyser 3X3™.** C. Dixon\*, C. E. Wynn\*, D. Laurie\*, C. J. Fox\*, M. J. Gardner\*, A. K. Barnes\*, M. L. Garrity\*. Immunodiagnostic Systems Ltd, Boldon, United Kingdom.

Abnormalities of bone and mineral metabolism are among the main complications in the treatment of patients with end-stage renal failure. Biologically active PTH (1-84) is secreted by the parathyroid gland and degraded within minutes into smaller N- and C-terminal fragments. The predominant mechanism for excretion of these fragments is via the kidneys and as a consequence, patients with renal impairment accumulate high levels of these fragments even when parathyroid activity is normal. Furthermore, recent data suggests the presence of novel, large C-terminal PTH fragments having unique biological mechanisms in bone. Intact PTH assays are therefore an important tool in the differentiation of renal bone disease from parathyroid gland activity-dependent conditions. We have developed a new Intact PTH assay that will be part of a comprehensive panel of bone and growth tests on the new IDS Automated Analyser 3X3™. This analyser will enable clinical laboratories to determine 25-hydroxy Vit D, PTH, Calcium and Phosphorus from a single specimen tube with integrated measurement modules for simultaneous analysis of different diagnostic tests, to include immunochemistry, biochemistry and coagulation.

The measurement of Intact PTH on the analyser is performed as a two-site chemiluminescent immunoassay. Biotinylated anti-PTH allows capture of PTH analyte by binding to streptavidin-coated magnetic particles. Captured PTH is then detected by an acridinium-conjugated second anti-PTH antibody. Following a wash step the signal generated by the acridinium conjugate is measured by a high sensitivity luminometer. The amount of analyte present is directly proportional to the Relative Light Units (RLU) quantitated by the luminometer.

The Intact PTH assay has a range of 5-1800pg/mL. The analytical sensitivity for this assay is 0.81pg/mL. Correlation by linear regression with a commercially-available Intact PTH EIA (n = 108) gave an R<sup>2</sup> value of 0.965. Analysis by Passing-Bablok gave an intercept of 3.29pg/mL and a slope of 0.853. No interference by small C-terminal PTH fragments including PTH (39-84), (39-68), (44-68) and (53-84) was observed up to 100,000pg/mL. Excellent correlation to existing manual assays combined with a reportable range covering the full likely clinical range of PTH demonstrate that this assay has the potential to provide a rapid and accurate automated measurement of full-length (1-84) and large C-terminal fragment PTH. This will form part of a comprehensive bone panel essential to the clinical laboratory.

**Regulation of Nuclear Import of the Parathyroid Hormone Receptor.** E. Patterson<sup>\*1</sup>, B. Gaudet<sup>\*1</sup>, A. Hodsman<sup>1</sup>, R. Bringham<sup>2</sup>, L. Fraher<sup>1</sup>, P. H. Watson<sup>1</sup>. <sup>1</sup>Medicine, University of Western Ontario, London, ON, Canada, <sup>2</sup>Medicine, Harvard University, Boston, MA, USA.

**Introduction:** Previous studies in our lab have demonstrated that the PTH1R is able to traffic to the nucleus of expressing cells in a  $\beta$ -importin dependent manner and that it contains a bipartite type nuclear localization sequence (NLS). Our current studies revolve around determining the domains of the PTH1R which are responsible for regulating the nuclear import of the PTH1R.

**Hypothesis:** The amino acids sequence from 471-488 in the intracellular tail of the PTHR comprise a functional NLS, which can be regulated by other domains.

**Methods:** This study employed mutagenesis to produce plasmids coding for specific fragments of the C-terminal tail of the PTH1R fused to green fluorescent protein (GFP) for construct visualization. These constructs were then expressed in LLC-PK1 cells and the subcellular localization of the expressed proteins were studied by confocal microscopy. This allowed for the determination of the extent of nuclear localization via quantification of the relative fluorescent intensity in the nucleus versus cytoplasm.

**Results:** Constructs containing the NLS alone fused downstream of GFP were able to localize to the nucleus to a level of 12-fold that of the cytoplasm, compared to GFP alone (P<0.01). This capability was not seen when a mutated non-functional PTH1R NLS (i.e. K-A mutations) was fused to GFP. Sequences in the intracellular C-terminal tail of the PTH1R downstream of the NLS, when included in the construct, were shown to attenuate the nuclear localization activity of the NLS. The nuclear import of GFP was further diminished when only sequences directly adjacent to the NLS were included in the construct.

**Discussion:** The PTH1R NLS (residues 471-488) is a strong promoter of nuclear import as demonstrated by GFP fluorescence in our fusion constructs. However, this ability appears to be regulated (attenuated) by other downstream domains of the PTH1R. The amino acids directly downstream of the NLS comprise a binding site for a class of proteins known as 14-3-3 proteins, which have been shown to regulate the activity of NLSs in other proteins. Regulation of PTH1R NLS activity appears to be affected by still other, as yet undefined, domains in the distal C-terminal tail of the PTH1R.

**Relationship Between Vitamin D and PTH: Serum Calcium and Magnesium Are Major Determinants of PTH in Patients with Mild Chronic Kidney Disease.** S. Patel<sup>1</sup>, M. Mirzazadeh<sup>\*2</sup>, H. Gallagher<sup>\*3</sup>, S. Hyer<sup>\*4</sup>, W. Fraser<sup>5</sup>, T. Cantor<sup>6</sup>, J. Barron<sup>\*2</sup>. <sup>1</sup>Dept Rheumatology, St Helier University Hospital, Carshalton, United Kingdom, <sup>2</sup>Clinical Chemistry, St Helier University Hospital, Carshalton, United Kingdom, <sup>3</sup>South West Thames Renal Unit, St Helier University Hospital, Carshalton, United Kingdom, <sup>4</sup>Dept Endocrinology, St Helier University Hospital, Carshalton, United Kingdom, <sup>5</sup>Clinical Chemistry, University of Liverpool, Liverpool, United Kingdom, <sup>6</sup>R&D, Scantibodies Laboratory, Santee, CA, USA.

25-hydroxyvitamin D (25OHD) is known to be inversely related to parathyroid hormone levels (PTH). Previously we showed that estimated glomerular filtration rate (eGFR) is a major determinant of the PTH response for a given 25OHD level. In the present study we have examined this relationship in more detail using patients with varying degrees of chronic kidney disease (CKD).

We randomly recruited 165 adult patients from the Renal Unit database who were not being dialysed [CKD stage 1 (n=12), stage 2 (n=34), stage 3 (n=63), stage 4 (n=36) and stage 5 (n=20)]. PTH (1-84) and intact-PTH were measured by immunoassay (Scantibodies; California). We calculated C-PTH fragment levels by subtracting PTH (1-84) from intact-PTH. 25OHD levels were measured by HPLC-MS/MS (University of Liverpool).

No differences were found between the different PTH subtypes so data are presented only for intact-PTH. We found significant relationships between intact-PTH and eGFR (r = -0.71; p < 0.001), phosphate (r = 0.30; p < 0.001), Mg (r = 0.24; p = 0.003), age (r = 0.23; p = 0.003), albumin (r = -0.17; p = 0.03) and 25OHD (r = -0.16; p = 0.04). Multiple regression analysis showed that eGFR (r = -0.66; p < 0.001) and 25OHD (r = -0.14; p = 0.03) were determinants of intact-PTH. However for patients in the top tertile of eGFR (> 53 ml/min) we found that only Mg (r = 0.34; p = 0.01) and ionised Ca (r = -0.30; p = 0.03) were significantly associated with intact-PTH whereas only eGFR (r = -0.41; p = 0.001) and 25OHD (r = -0.31; p = 0.01) remained associated with intact-PTH for patients in the lowest tertile of eGFR (< 30ml/min).

There is a complex explanation for the PTH response for a given 25OHD level. Whilst eGFR and vitamin D are important determinants of PTH, in patients with normal eGFR or mild CKD, and therefore sufficient renal 1-alpha hydroxylase activity, serum ionised Ca and Mg have a more important role in determining PTH. Possible explanations include that in patients with adequate renal 1-alpha hydroxylase activity, PTH is able to maintain serum Ca in a tight range for cellular function through efficient 1-hydroxylation of 25OHD. Mg is essential for PTH release from chief cells hence a positive relationship with serum PTH levels. These findings need to be considered when interpreting vitamin D and PTH levels in clinical practice.

This study received funding from: Epsom & St Helier University Hospitals R&D Department.

## M212

**Circulating Concentrations of 25-Hydroxyvitamin D after a Single Oral Dose of 100,000 IU of Vitamin D2 or Vitamin D3.** E. Cavalier<sup>1</sup>, A. M. Wallace<sup>2</sup>, S. Knox<sup>2</sup>, V. I. Mistretta<sup>1</sup>, J. Chapelle<sup>1</sup>, J. Souberbielle<sup>3</sup>.

<sup>1</sup>Clinical Chemistry, University Hospital of Liege, University of Liege, Liege, Belgium, <sup>2</sup>Clinical Biochemistry, Glasgow Royal Infirmary, Glasgow, United Kingdom, <sup>3</sup>Service d'Explorations Fonctionnelles, Hôpital Necker-Enfants Malades, AP-HP, Paris, France.

The aim of our study was to compare the evolution of circulating concentrations of 25-OH vitamin D (25VTD) in healthy subjects after a single oral dose of 100,000 IU of VTD2 or VTD3.

To determine 25VTD, we used a reference method (HPLC). We studied 18 young healthy volunteers who were randomly assigned to receive VTD2 (n=11) or VTD3 (n=7). The study involved subjects living in the area of Liege, Belgium during November, a time of year when UVB radiation is too low to increase circulating concentrations of 25VTD. Blood samples were drawn before giving VTD (D0) and after 1 (D1), 7 (D7) and 28 (D28) days. The serum 25VTD concentration at D0 was not significantly different in both groups (33.0±10.1 ng/mL vs 33.9±7.0 ng/mL respectively). At D1, the increase in 25VTD concentration was greater in the D3 group (+14.6 vs +7.4 ng/mL) but the difference was not significant. 8/11 and 7/7 subjects had a 25VTD level >30 ng/mL in the VTD2 and VTD3 group respectively. At D7, the difference between the two groups approached significance (p=0.07) with no change for the D2 group (-0.4 ng/mL) and a small increase in the D3 group (+4.7 ng/mL). At D28, the D3 group had significantly higher concentrations than the D2 group (40.9±6.4 vs 31.9±9.7 ng/mL respectively, p<0.05). The concentration of 25VTD in the D2 group fell to the pre-supplementation range whereas treatment with D3 resulted in a significant increase (+7.0 ng/mL, p<0.05) of the 25VTD level compared to baseline. At D28, 7/11 and 7/7 subjects had a 25VTD level >30 ng/mL in the VTD2 and VTD3 group respectively. In conclusion, our results indicate that initially both VTD2 and VTD3 increase 25VTD concentrations to a similar extent when given as a single 100,000 UI dose. VTD3, however, seems to maintain sufficient concentrations of 25VTD for a longer period than VTD2 as, at D28, subjects supplemented with D3 were the only ones to present a 25VTD level higher than before supplementation. This should be taken in consideration when prescribing monthly doses of vitamin D.

**Disclosures:** E. Cavalier, None.

## M213

**Distinctive Anabolic Roles of 1,25-Dihydroxyvitamin D<sub>3</sub> in Teeth and Mandible versus Long Bones.** H. Liu<sup>1</sup>, J. Guo<sup>2</sup>, L. Wang<sup>1</sup>, N. Chen<sup>1</sup>, D. Goltzman<sup>3</sup>, D. S. Miao<sup>1</sup>. <sup>1</sup>Institute of Dental Research, Nanjing Medical University, Nanjing, China, <sup>2</sup>The Research Center for Bone and Stem Cells, Nanjing Medical University, Nanjing, China, <sup>3</sup>Medicine, McGill University, Montreal, QC, Canada.

Elevated PTH in the secondary hyperparathyroidism of vitamin D deficiency is believed to be anabolic for long bones. We previously compared mice with targeted disruption of the gene encoding parathyroid hormone (PTH)(PTH<sup>-/-</sup> mice) or the gene encoding 25-hydroxyvitamin D 1 $\alpha$ -hydroxylase [1 $\alpha$ (OH)ase] [1 $\alpha$ (OH)ase<sup>-/-</sup> mice] with compound mutant PTH<sup>-/-</sup>1 $\alpha$ (OH)ase<sup>-/-</sup> mice. We found that PTH plays a predominant role in appositional bone growth, whereas 1,25(OH)<sub>2</sub>D<sub>3</sub> acts predominantly on endochondral bone formation in long bones. It is unknown, however, whether 1,25(OH)<sub>2</sub>D<sub>3</sub> or PTH plays a role in dentin and dental alveolar bone formation in the mandibles as it does in long bones. To determine whether 1,25(OH)<sub>2</sub>D<sub>3</sub> plays a distinctive role in flat bones such as mandibles, we examined the effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> deficiency on dentin and dental alveolar bone formation and mineralization in the mandibles, and compared osteoblastic bone formation in the mandibles and tibiae in 1 $\alpha$ (OH)ase<sup>-/-</sup> mice. Compared to wild-type (WT) mice, the mineral density was decreased in the teeth and mandibles, and unmineralized dentin (predentin and biglycan immunopositive dentin) and unmineralized bone matrix in the dental alveolar bone were increased in 1 $\alpha$ (OH)ase<sup>-/-</sup> mice. The dental volume, reparative dentin volume and dentin sialoprotein immunopositive areas were reduced in 1 $\alpha$ (OH)ase<sup>-/-</sup> mice. The cortical thickness, dental alveolar bone volume and osteoblast numbers were all decreased significantly in the mandibles; in contrast, the osteoblast number and surface were increased in the trabecular bone of the tibiae in 1 $\alpha$ (OH)ase<sup>-/-</sup> mice consistent with their secondary hyperparathyroidism. The expression of parathyroid hormone receptor (PTHr) and insulin-like growth factor-1 (IGF-1) was reduced slightly in mandibles, but enhanced in the long bones in the 1 $\alpha$ (OH)ase<sup>-/-</sup> mice. These results indicate that 1,25(OH)<sub>2</sub>D<sub>3</sub> plays distinct roles in dentin and dental alveolar bone formation in the mandibles relative to trabecular bone formation in long bones, and suggests that 1,25(OH)<sub>2</sub>D<sub>3</sub> plays a more prominent anabolic role than does PTH in dentin and dental alveolar bone formation in mandibles.

## M214

**25-Hydroxyvitamin D Acts on Calcium and Skeletal Homeostasis Independent of 1,25-Dihydroxyvitamin D *In Vivo*.** L. Nguyen-Yamamoto, I. Bolivar\*, M. Gratton\*, R. Kremer, G. Hendy, D. Goltzman. Medicine, Royal Victoria Hospital McGill University, Montreal, QC, Canada.

Previous studies in humans have demonstrated that increases in serum 25-Hydroxyvitamin D<sub>3</sub> (25OHD<sub>3</sub>), the most abundant circulating metabolite of vitamin D, are associated with increases in calcium absorption, and reductions in elevated parathyroid hormone (PTH) concentrations. Such bioactivity of 25OHD<sub>3</sub> has been ascribed to the renal and/or local conversion of 25OHD<sub>3</sub> to the active form, 1,25 dihydroxyvitamin D<sub>3</sub> [1,25(OH)<sub>2</sub>D<sub>3</sub>]. We assessed whether 25OHD<sub>3</sub> might exert direct actions on mineral and skeletal metabolism independent of 1,25(OH)<sub>2</sub>D<sub>3</sub>. 25OHD<sub>3</sub> has been reported to bind to the vitamin D receptor (VDR) with low affinity. We therefore first examined the capacity of 25OHD<sub>3</sub> to recruit the vitamin D receptor (VDR) to the promoter regions of the target genes osteopontin, osteocalcin and 24 hydroxylase in MC3T3-E1 osteoblastic cells *in vitro* using a chromatin immunoprecipitation (ChIP) assay in which 5  $\mu$ M ketoconazole had been added to inhibit 1 $\alpha$  hydroxylation. 1,25(OH)<sub>2</sub>D<sub>3</sub> 10<sup>-8</sup>M, significantly enhanced VDR and RXR binding to these promoters whereas 25OHD<sub>3</sub> at a concentration of 10<sup>-6</sup>M, also significantly stimulated binding suggesting that 25OHD<sub>3</sub> could function independent of prior 1 $\alpha$  hydroxylation at least *in vitro*. We next examined the bioactivity of 25OHD<sub>3</sub> *in vivo* in mice expressing the null mutation for the 25OHD<sub>3</sub>-1 $\alpha$  hydroxylase enzyme (1 $\alpha$  OHase<sup>-/-</sup>). We first injected 1 $\alpha$  OHase<sup>-/-</sup> mice, after weaning, with vehicle or 50 pg/g body weight, 10 ng/g, and 100 ng/g of 25OHD<sub>3</sub> intraperitoneally 3 times per week for 1 week while they were maintained on a high calcium diet. On this diet, mean serum calcium, phosphorus (P) and PTH concentrations in vehicle treated mice were 1.32 mM, 2.44 mM and 1.6 ng/ml respectively and values were not significantly different in mice treated with 50pg/g 25OHD<sub>3</sub>. In mice treated with 10 ng/g and 100ng/g of 25OHD<sub>3</sub> serum calcium rose to means of 1.71 and 2.77mM, respectively, serum P rose to means of 2.59 and 3.97 mM, respectively, and serum PTH decreased to means of 1.35 and 0.14 ng/ml, respectively. Serum calcium, phosphorus and PTH levels comparable to those achieved with a dose of 100ng/g 25OHD<sub>3</sub> were observed with a dose of 50 pg/g of 1,25(OH)<sub>2</sub>D<sub>3</sub>. After 3 months of treatment with 75ng/g of 25OHD<sub>3</sub> from the time of weaning, growth rates and mineralization of bones were increased and serum calcium and PTH levels were within the normal range. These results show that 25OHD<sub>3</sub> can exert effects on parathyroid, mineral and skeletal homeostasis independent of conversion to 1,25(OH)<sub>2</sub>D<sub>3</sub> *in vivo*.

**Disclosures:** L. Nguyen-Yamamoto, None.

## M215

**1,25-Dihydroxyvitamin D<sub>2</sub> Is as Effective as 1,25-Dihydroxyvitamin D<sub>3</sub> in Regulating Cellular Proliferation in Cultured Normal Human Keratinocytes and Transformed Prostate Cells.** X. Hung\*, I. S. Tsai\*, K. S. Persons\*, T. C. Chen\*, M. F. Holick. Boston University School of Medicine, Boston, MA, USA.

Recently it has been reported that vitamin D<sub>2</sub> is as effective as vitamin D<sub>3</sub> in maintaining serum levels of 25-hydroxyvitamin D. However, it remains unknown whether 1,25-dihydroxyvitamin D<sub>2</sub> [1,25(OH)<sub>2</sub>D<sub>2</sub>] is as effective as 1,25-dihydroxyvitamin D<sub>3</sub> [1,25(OH)<sub>2</sub>D<sub>3</sub>] in regulating cell growth and gene expression. We evaluated the antiproliferative activity of 1,25(OH)<sub>2</sub>D<sub>2</sub> and compared it to 1,25(OH)<sub>2</sub>D<sub>3</sub> in cultured human keratinocytes and in the human prostate cells PZ-HPV-7.

**Methods** Cultured human keratinocytes from neonatal foreskins and PZ-HPV-7 cells were cultured and exposed to varying concentrations of 1,25(OH)<sub>2</sub>D<sub>2</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>. <sup>3</sup>H-thymidine incorporation and real time RT-PCR for 24-hydroxylase (24-OHase) was determined.

**Results** A dose dependent inhibition in proliferation was observed in human keratinocytes exposed to 1,25(OH)<sub>2</sub>D<sub>2</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>. When compared to the placebo controlled treated keratinocytes, 1,25(OH)<sub>2</sub>D<sub>3</sub> reduced proliferative activity by 20±3, 36±4 and 60±5% at 10<sup>-10</sup>, 10<sup>-8</sup>, 10<sup>-6</sup> M 1,25(OH)<sub>2</sub>D<sub>3</sub>. In comparison, 1,25(OH)<sub>2</sub>D<sub>2</sub> reduced proliferative activity by 15±4, 32±6 and 82±2% at 10<sup>-10</sup>, 10<sup>-8</sup>, 10<sup>-6</sup> M 1,25(OH)<sub>2</sub>D<sub>2</sub>. A similar observation was made in PZ-HPV-7 human prostate cancer cells. There was a dose dependent inhibition in cellular proliferation with a reduction of 21±5 and 64±7% at 10<sup>-9</sup> and 10<sup>-7</sup> M 1,25(OH)<sub>2</sub>D<sub>3</sub>. In comparison, 1,25(OH)<sub>2</sub>D<sub>2</sub> decreased proliferative activity by 24±4% and 74±3% at 10<sup>-9</sup> and 10<sup>-7</sup> M 1,25(OH)<sub>2</sub>D<sub>2</sub>. An evaluation for the expression of the 24-OHase was performed in DU145 prostate cancer cells revealed that 1,25(OH)<sub>2</sub>D<sub>3</sub> enhanced the expression of the 24-OHase by 178, 104 and 11 fold at 10<sup>-7</sup>, 10<sup>-8</sup> and 10<sup>-9</sup> M compared to 34, 5 and 1 fold in cells treated with 1,25(OH)<sub>2</sub>D<sub>2</sub> at 10<sup>-7</sup> and 10<sup>-8</sup> and 10<sup>-9</sup> M respectively.

**Conclusion** The results from these studies suggest that 1,25(OH)<sub>2</sub>D<sub>2</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in its antiproliferative effect in both normal cultured human keratinocytes and in transformed human prostate cells. 1,25(OH)<sub>2</sub>D<sub>3</sub> may be effective in enhancing 24-OHase expression in a human prostate cancers cell line than 1,25(OH)<sub>2</sub>D<sub>2</sub>. Thus, vitamin D<sub>2</sub> is not only able to maintain vitamin D status as well as vitamin D<sub>3</sub>, but 1,25(OH)<sub>2</sub>D<sub>2</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in inhibiting proliferation of cultured human cells.

**Disclosures:** M.F. Holick, None.

**The Mechanism of Enhanced 19-nor-2a-(3-hydroxypropyl)-1 $\alpha$ ,25-Dihydroxyvitamin D<sub>3</sub> Anti-cancer Activity in Prostate Cancer Cells.** J. N. Flanagan<sup>\*1</sup>, A. Kittaka<sup>\*2</sup>, T. Sakaki<sup>\*3</sup>, Y. F. Lee<sup>\*4</sup>, M. F. Holick<sup>5</sup>, T. C. Chen<sup>5</sup>.  
<sup>1</sup>Karolinska Institute, Stockholm, Sweden, <sup>2</sup>Teikyo University, Sagamiko, Japan, <sup>3</sup>Toyama Prefectural University, Toyama, Japan, <sup>4</sup>University of Rochester, Rochester, NY, USA, <sup>5</sup>Boston University School of Medicine, Boston, MA, USA.

It has been shown that 19-nor-vitamin D derivatives are less calcemic when administered systemically and that C2- substituted 19-nor-2 $\alpha$ -(3-hydroxypropyl)-1 $\alpha$ ,25-dihydroxyvitamin D<sub>3</sub> (MART-10) was about 500- to 1000-fold more active than 1 $\alpha$ ,25-dihydroxyvitamin D<sub>3</sub> (1,25D) in inhibiting cell growth in the immortalized PZ-HPV-7 normal prostate cells. Based on the findings, we further compared its activities to 1,25D in PC3 prostate cancer cell model by examining (1) cell proliferation, (2) cell invasion, and (3) the induction of CYP24 and MMP-9 genes. We also studied the kinetics of their 24-hydroxylation by CYP24, and their vitamin D binding protein (DBP) binding affinities in cell-free systems. We showed that (1) MART-10 was more potent than 1,25D in inhibiting cell proliferation and invasion, (2) MART-10 induced CYP24 gene expression at lower concentrations and sustained the induction longer compared to 1,25D, (3) MART-10 inhibited MMP-9, a protease involved in cell invasion, at lower concentrations compared to 1,25D, (4) MART-10 has a much lower V<sub>max</sub> and a higher K<sub>m</sub> for CYP24, and (5) MART-10 has a much lower affinity for DBP compared to 1,25D. The down-regulation of MMP-9 expression in PC3 cells may provide a mechanism of how MART-10 can influence prostate cancer cell invasion. Most importantly, the findings that MART-10 was more resistant to CYP24 hydroxylation and had lower affinity for DBP may explain why MART-10 was more potent in inhibiting cell invasion and cellular proliferation. Taken together, our data suggest that MART-10 may be an effective vitamin D analog candidate for clinical trials to treat prostate cancer.

## M217

**A Randomized Controlled Trial of Vitamin D3 Supplementation for the Prevention of Viral Upper Respiratory Tract Infections.** M. Mikhail, J. F. Aloia, S. Pollack\*, B. Cunha\*, J. Yeh\*, N. Berbari\*, M. Li-Ng\*. Winthrop University Hospital, Mineola, NY, USA.

**PURPOSE:** Vitamin D has been shown to be an important immune system regulator. Vitamin D insufficiency during the winter may cause increased susceptibility to infections, particularly viral upper respiratory tract infections (URIs). The purpose of the study is to determine whether vitamin D supplementation during the winter season prevents or decreases URI symptoms in adults.

**METHODS:** A randomized, double-blind, placebo-controlled trial was conducted in 162 adults. Participants were randomized to receive vitamin D3 50 mcg (2000 IU) daily or matching placebo for 12 weeks from December 2006 to March 2007. A biweekly questionnaire was used to record the incidence and severity of URI symptoms.

**RESULTS:** There was no difference in the incidence of URIs between the vitamin D and the placebo group (48 URIs out of 388 reports versus 50 URIs out of 363 reports respectively, p=0.57). There was no difference in the duration (or severity) of URI symptoms between the vitamin D and placebo group (5.4  $\pm$  4.8 days versus 5.3  $\pm$  3.1 days respectively, p=0.86). The mean 25-hydroxyvitamin D level at baseline was similar in both groups (64.3  $\pm$  25.4 nmol/L in the vitamin D group; 63.0  $\pm$  25.8 nmol/L in the placebo group, ns). The mean 25-OHD level increased to 88.5  $\pm$  23.2 nmol/L in the vitamin D group while remaining virtually constant in the placebo group.

**CONCLUSION:** There was no benefit of vitamin D3 supplementation in decreasing the incidence or severity of viral URI during the winter months. Further studies are needed to determine the role of vitamin D in infection.

Characteristics of URIs by group			
	VitaminD N = 78	Placebo N = 70	p-value
Reported URI, n	28 (37%)	29 (41%)	0.61
Duration of URI, days	5.4 $\pm$ 4.8	5.3 $\pm$ 3.1	0.86
Severity of URI, range 1-5 (1=healthy; 5=very ill)	2.6 $\pm$ 1.0	2.8 $\pm$ 1.2	0.4

**Disclosures:** M. Mikhail, None.

**Vitamin D and Physical Performance in African American Women.** M. Mikhail, J. F. Aloia, T. Bojadzievski\*, S. Pollack\*, J. Yeh\*, M. Li-Ng\*. Endocrinology, Winthrop University Hospital, Mineola, NY, USA.

**PURPOSE:** There is increasing evidence that vitamin D improves muscle strength in vitamin D-deficient elderly women. It also has been shown to improve body sway in ambulatory elderly women. The purpose of the study is to determine if vitamin D supplementation influences physical performance in postmenopausal African-American women.

**METHODS:** We performed a 4-month prospective cohort trial of vitamin D3 supplementation in 51 African-American postmenopausal women. Our goal in supplementation was to reach optimal levels of 25(OH)D > 75 nmol/L. Physical performance was measured by the Short Physical Performance Battery (SPPB) and grip strength. Subjects were asked to perform a balance assessment (open, semi-tandem, and tandem stance), a timed 4-meter walk, and a chair rise test (timed 5 rises). Each of these tests has a maximum score of 4 points (total SPPB maximum score is 12). Grip strength was measured using a handgrip dynamometer. The four physical tests were repeated one week later to account for any learning effect on subsequent measurements. This enabled us to measure the reliability of these four measures. Reliability ranged from 0.75 to 0.93.

**RESULTS:** A total of 48 women completed the study. The mean age of the women was 67.4 years and mean BMI was 30 kg/m<sup>2</sup>. Nine subjects were given no vitamin D3 as their baseline 25(OH)D was > 75 nmol/L, 23 subjects were given 70 mcg/day since their baseline 25(OH)D was between 45 and 75 nmol/L, and 20 subjects were given 100 mcg/day since their baseline 25(OH)D was < 45 nmol/L. Physical performance at baseline was exceptionally good in this cohort based on the four measures that we observed. Only the grip strength increased significantly. The increase was due to improvement in the subset with baseline 25(OH)D below 50 nmol/L with an increase in strength of 7%.

**CONCLUSION:** This study suggests that vitamin D benefit on physical performance was seen in grip strength in the subset with baseline 25(OH)D below 50 nmol/L. The high performance in this group on the SPPB may have precluded finding an improvement.

**Disclosures:** M. Mikhail, None.

## M219

**Effects of Alfacalcidol on Bone and Skeletal Muscle in Glucocorticoid-treated Rats.** H. Sasaki, N. Miyakoshi, Y. Kasukawa, S. Maekawa, K. Kamo, Y. Shimada. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Several recent studies have demonstrated that vitamin D prevents falls and osteoporotic fractures through its effects on bone and muscle. However, the effects of vitamin D on muscle and the mechanisms of fall-prevention have yet to be elucidated.

As glucocorticoids, which are prescribed as anti-inflammatory agents, are considered to cause secondary osteoporosis and skeletal muscle atrophy, the present study investigated whether alfacalcidol (1 $\alpha$ (OH)D<sub>3</sub>) could prevent skeletal muscle atrophy and osteoporosis induced by prednisolone (PSL).

Seven-week-old female Wistar rats were randomized into the following four groups: 1) control group, treated with vehicle of 1 $\alpha$ (OH)D<sub>3</sub> orally and daily s.c. injections of normal saline; 2) PSL group, administered PSL (10 mg/kg s.c., daily); 3) 1 $\alpha$ (OH)D<sub>3</sub> group, treated with alfacalcidol (0.1  $\mu$ g/kg/day, orally); and 4) 1 $\alpha$ (OH)D<sub>3</sub> + PSL group, treated with alfacalcidol plus PSL. After a 4-week treatment period, the left tibialis anterior (TA) muscle was removed for histological analysis and the cross sectional area (CSA) of muscle fiber was measured. In addition, the left femur was harvested in order to measure the bone mineral density (BMD) in the distal third of the femur by dual energy x-ray absorptiometry.

The CSA of the TA muscle in the PSL group was significantly smaller than that in the control group (-31%, p<0.05). However, the CSA in the 1 $\alpha$ (OH)D<sub>3</sub> and 1 $\alpha$ (OH)D<sub>3</sub> + PSL groups showed no significant difference compared to that in the control group (5% and -11%, respectively). The BMD in the PSL group was significantly lower than that in the control group (-11%, p<0.05). Furthermore, the BMD in the 1 $\alpha$ (OH)D<sub>3</sub> + PSL group was significantly higher than that in the PSL group (20%, p<0.05).

The present results suggest that in glucocorticoid-treated rats, alfacalcidol prevents not only decrease of BMD but also muscle atrophy. Therefore, administration of alfacalcidol might have positive effects on muscle in patients treated with glucocorticoids in addition to its known effects on bone metabolism.

**Expression of Vitamin D Receptor in the Developing Zebrafish Embryo.** T. Craig<sup>\*1</sup>, S. Sommer<sup>\*1</sup>, C. Sussman<sup>\*2</sup>, J. Grande<sup>\*3</sup>, R. Kumar<sup>1</sup>. <sup>1</sup>Nephrology Research, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Physiology, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Laboratory Medicine/Pathology, Mayo Clinic, Rochester, MN, USA.

The vitamin D receptor has been previously shown to be widely distributed in epithelial cells, cells of the central nervous system and skeleton of the adult zebrafish, *Danio rerio*. Little is known of the ontogeny of the VDR in the developing zebrafish embryo. We examined the distribution of the VDR in 48 h and 96 h post-fertilization zebrafish embryos. In the 48 h post-fertilization embryo, the VDR is seen in the developing brain (diencephalon) and in cells of the neural retina. The VDR immunostaining is also seen in the developing mandibular cartilage.

Figure 1A demonstrates results obtained with immune serum in 96 h post-fertilization (p.f.) embryos. VDR immunostaining is observed in the ganglion cells of the eye (E), portions of the brain (B), and the epithelium of the otic vesicle (O). Pre-immune serum does not demonstrate the presence of the VDR in these tissues (Figure 1B). A higher magnification view of the developing eye is seen in Figure 1C. Ganglion cells appear to immunostain for the VDR (G). Cells of the lens (L) do not immunostain. Rods (R) do not immunostain. Cells lining the otic vesicle (OE) immunostain for the VDR (Figure 1D). Conclusion. These data show that the VDR is expressed in the central nervous system, eye and ear of the developing zebrafish, and suggest that the receptor may play a role in the development of these organs in the zebrafish.

**High Prevalence of Vitamin D Insufficiency in a Young Adult Population.** M. Calatayud<sup>\*</sup>, R. Sánchez<sup>\*</sup>, S. Guadalix<sup>\*</sup>, E. Jódar, G. Martínez, F. Hawkins. Endocrinology, University Hospital 12 de Octubre, Madrid, Spain.

Recent studies have shown a wide range of beneficial skeletal and extra-skeletal effects of vitamin D. During the last years a high prevalence of vitamin D insufficiency (<30 ng/ml) and deficiency (<20 ng/ml) has been proved in aged and adult population. The main reasons for this high prevalence seem to be poor intake and low sun exposure. On the other hand, data related to the young adult population are scarce.

Our primary objective was to determine the prevalence of vitamin D insufficiency and deficiency in a young healthy population (physicians and nurses) and its relationship with calcium concentration, PTH, nutritional parameters and sun exposure. Data were obtained from 116 subjects (38 men and 78 women aged 26.56 ± 3.32 years), during the months of June and July in the year 2007.

Fasting blood sample was obtained and 25-hydroxyvitamin D, intact PTH, calcium, albumin and a basic biochemical study were measured. A questionnaire designed to assess sun exposure and sunshine protection during the previous 12 months was carried out. Average value of 25-hydroxyvitamin D obtained was 24.58 ± 6.98 ng/ml. Subjects were divided into three groups according to 25-hydroxyvitamin D levels: deficient, < 20 ng/ml (29.46% of the subjects); insufficient, 20 - 30 ng/ml (58.03% of the subjects) and sufficient, ≥ 30 ng/ml (16.96% of the subjects). There are no significant statistical differences between the groups and the study variables.

Our study shows a high prevalence of vitamin D insufficiency in a young healthy population without a clear relationship with sun exposure or sunshine protection. Just 1 in 6 subjects had the recommended levels of vitamin D. The lack of food fortification with vitamin D and the wide use of sunscreen could account for the low levels of vitamin D in this young population of southern of Europe.

**Impaired Fracture Healing in the Absence of the Vitamin D-24-hydroxylase, Cyp24a1.** R. P. Naja<sup>\*</sup>, A. Arabian, R. St-Arnaud. Genetics Unit, Shriners Hospital for Children, Montreal, QC, Canada.

The Cyp24a1 enzyme (25-hydroxyvitamin D-24-hydroxylase) is involved in the catabolic breakdown of 1,25(OH)<sub>2</sub>D but also synthesizes the 24,25(OH)<sub>2</sub>D metabolite. Studies in chicken showed increases in serum levels of 24,25(OH)<sub>2</sub>D and of the renal mRNA levels of cyp24a1 following fracture, suggesting a role for 24,25(OH)<sub>2</sub>D in fracture repair. We used a cyp24a1-deficient mouse strain to determine the putative role of 24-hydroxylated vitamin D metabolites during mammalian fracture repair. In wild-type mice, we measured a significant increase in local expression of cyp24a1 mRNA in the tibiae subjected to an osteotomy as compared to the unfractured contralateral tibiae. We then subjected four-month-old wild-type and cyp24a1-deficient mice to a stabilized, transverse mid-diaphyseal fracture of the tibia. Bones were collected at days 14 and 21 post-fracture and analyzed for histology and gene expression. Examination of the callus sections stained by Goldner showed that the homozygous mutant animals had delayed hard callus formation when compared to wild-type littermates. Expression profiling using RT-qPCR showed that the levels of osteocalcin and type X collagen transcripts were reduced in mutant mice at 14 and 21 days post-fracture, reflecting the delayed healing. We attempted rescue of the impaired healing by subcutaneous injection of 24,25(OH)<sub>2</sub>D<sub>3</sub> (6.7 µg/kg) or 1α,25(OH)<sub>2</sub>D<sub>3</sub> (67 ng/kg). Control groups were injected with the vehicle (propylene glycol). Treatment with 1α,25(OH)<sub>2</sub>D<sub>3</sub> had no effect on fracture repair. Daily injection with 24,25(OH)<sub>2</sub>D<sub>3</sub> normalized the histological appearance of the callus and the measured static histomorphometric index (BV/TV). The treatment with 24,25(OH)<sub>2</sub>D<sub>3</sub> also rescued and normalized type X collagen mRNA expression at all time points studied. These results show that cyp24a1 deficiency delays fracture repair and strongly suggest that vitamin D metabolites hydroxylated at position 24, such as 24,25(OH)<sub>2</sub>D<sub>3</sub>, play an important role in the mechanisms leading to normal fracture healing.

**Vitamin D Status, Bone Mass, and Bone Metabolism in Postmenopausal Women and Men Older than 50 Attended in a Primary Care Center of Spain: The Camargo Cohort Study.** J. M. Olmos<sup>1</sup>, J. L. Hernández<sup>\*1</sup>, J. Martínez<sup>\*1</sup>, J. de Juan<sup>\*2</sup>, D. Nan<sup>\*1</sup>, C. Ramos<sup>\*2</sup>, C. Valero<sup>\*1</sup>, P. García<sup>\*2</sup>, J. González-Macías<sup>1</sup>. <sup>1</sup>Medicina Interna, Hospital Universitario M. Valdecilla, Santander, Spain, <sup>2</sup>Centro de Salud "José Barros", Camargo, Spain.

The objective of the present study was to determine the prevalence of vitamin D deficiency and insufficiency in a population of postmenopausal women and men older than 50 living in the North of Spain. People studied are part of a cohort that is being set up to study the prevalence and incidence of metabolic bone diseases and disorders of mineral metabolism attended in a primary care center of our region (The Camargo cohort study). We present results from 1.159 subjects (895 women, and 264 men). Serum levels of amino terminal propeptide of type I collagen (P1NP), C-terminal telopeptide of type I collagen (β-CrossLaps, β-CTX), 25-Hydroxyvitamin D<sub>3</sub> (25OHD), and intact parathyroid hormone (iPTH) were measured by a fully automated electrochemiluminescence system (Elecys 2010, Roche). BMD at lumbar spine (LS), femoral neck (FN) and total hip (TH) was determined by DXA. Studied women and men were 63±9 and 66±8 years old, respectively. Results are shown in the table 1 and 2.

Vitamin D deficiency (25OHD < 10 ng/ml) and insufficiency (25OHD < 30 ng/ml) were present in 3% and 74% of women, and in 4% and 74% of men. Serum 25OHD concentration was correlated with BMD at FN (r: 0.064; p<0.05) and TH (r: 0.068; p<0.05), but not at LS. Vitamin D levels were also correlated with P1NP (r: 0.063; p<0.05). Conversely, an inverse correlation between iPTH and 25OHD was found (r:-0.28; p<0.001). This relationship persisted after adjustment by age and sex.

Prevalence of hypovitaminosis D among Spanish adult population is similar to that described in other countries. The percentage of people with either vitamin D deficiency or insufficiency is the same in both sexes. An inverse relationship between serum vitamin D levels and PTH was observed.

Table 1				
	25OHD(ng/ml)	iPTH(pg/ml)	P1NP(ng/ml)	β-CTX(ng/ml)
Women	26±9	54±21	37±18	0.29±0.17
Men	25±9	52±22	47±20	0.38±0.18

Table 2			
	LS (g/cm <sup>2</sup> )	FN (g/cm <sup>2</sup> )	TH (g/cm <sup>2</sup> )
Women	0.91±0.13	0.72±0.11	0.87±0.12
Men	1.03±0.15	0.79±0.11	1.00±0.13

## M224

**The Requirement of the Bone for Vitamin D for 1,25(OH)<sub>2</sub>D<sub>3</sub> Synthesis and Bone Mineralisation.** P. H. Anderson<sup>\*1</sup>, G. J. Atkins<sup>2</sup>, R. K. Sawyer<sup>\*3</sup>, D. M. Findlay<sup>2</sup>, P. D. O'Loughlin<sup>\*3</sup>, H. A. Morris<sup>3</sup>. <sup>1</sup>School of Medicine, University of Adelaide, Adelaide, Australia, <sup>2</sup>Department of Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia, <sup>3</sup>Hanson Institute, IMVS, Adelaide, Australia.

*In vitro* evidence suggests that the 1,25-dihydroxyvitamin D<sub>3</sub> (1,25D) can exert effects during both the resorptive and synthetic phases of bone remodelling. However, the question as to whether the primary action of vitamin D on bone under normal circumstances is indirect by mediating changes in ECF calcium and phosphate concentrations or whether there is also a significant direct effect of vitamin D on bone is unclear. We hypothesise that 1,25D, synthesized by osteoblasts, regulates osteoblast differentiation and osteoclast activation, independently of changes to circulating 1,25D levels. In adult animals with stable mean 25-hydroxyvitamin D<sub>3</sub> (25D) levels ranging from 20 nmol/L to 115 nmol/L, a strong positive association occurred between femoral trabecular bone volume (BV/TV) and 25D levels ( $R^2=0.57$ ,  $P<0.01$ ). Interestingly, the loss of bone volume with vitamin D-insufficiency was as a consequence of increased osteoclast numbers and activity (via increased RANKL/OPG ratio) which is dependent on serum 25D levels ( $R^2=0.60$ ,  $P<0.01$ ) and not on circulating calcium, PTH or 1,25D levels. The autocrine actions of 1,25D may help explain why osteoclastogenesis occurs without an increase in circulating 1,25D levels. When the mRNA for CYP27B1 was reduced by 80% in HOS bone cells by RNAi, the production of 1,25D was markedly reduced when treated with 25D (100 to 400nm). The decline in 1,25D production almost completely abrogated the mRNA levels for osteocalcin and CYP24. Also, when primary human bone cells were treated with 25D (100 or 200nm) the anti-proliferative effects (as measured by CFSE fluorescent labelling of cells) and stimulation of *in vitro* mineralisation were comparable to cells treated with 1,25D (100pM). This *in vitro* mineralisation of osteoblasts is associated with a decline in RANKL mRNA expression. These results suggest that locally produced 1,25D is important for an intrinsic autocrine/paracrine signalling from pro-resorptive to pro-osteogenic activity as the osteoblast matures. Ultimately, the potential benefits of maintaining a healthy vitamin D status to limit bone loss due to reduced osteoclastic activity may be to enhance the osteogenic potential of osteoblasts.

**Sunscreen Use and Vitamin D Status.** M. G. Kimlin, A. Brodie\*, C. Lang\*. Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia.

Previous research suggests that the use of sunscreen reduces the skin's capability to synthesize Vitamin D to, in some cases, zero. Sunscreen has been demonstrated to be an important tool in the prevention of non-melanoma skin cancers and potentially in melanoma. This research poses the question, "Does sunscreen use impact on Vitamin D status in a population in a sunny climate such as Australia?". In this research we interviewed 127 participants (40 males / 87 females) with a median age 35 (18-87 years). A self reported questionnaire recorded a wide variety of demographic details along with sunscreen use. A blood sample was collected to assess 25(OH)D status. The application of sunscreen was varied. 43% of the sample rarely used sunscreen, 32% "usually" or "almost always" and 26% not at all. Sunscreen with an SPF of  $\geq 30$  was used by most (82%). Those who applied sunscreen, the face was the highest compliance site and other sites less frequently. In this sample, 24% had an adequate Vitamin D (blood serum 25[OH]D) level (50-75nmol/L), and 41% were Vitamin D deficient ( $<50$ nmol/L). Data was collected at the end of winter 2006 and in summer 2007. We found no association between Vitamin D (25[OH]D) status and sunscreen use. Of the participants who usually or almost always used sunscreen, 32% had Vitamin D levels of  $>75$ nmol/L, whilst 26% of participants were within the 51-75nmol/L range. This research suggests that individuals living in a sunny climate may have sufficient Vitamin D status even with the use of sunscreen. A potential factor that have led to this finding is that perhaps the sunscreen was not applied correctly, either through volume or application technique. This data, from a 'real-world' situation presents a differing message to research conducted under controlled conditions.

**Vitamin D (Cholecalciferol) Production Does Not Increase Linearly with UV Dose: An in Vitro Model.** W. J. Olds<sup>1</sup>, M. R. Moore<sup>\*2</sup>, M. G. Kimlin<sup>1</sup>. <sup>1</sup>Australian Sun and Health Research Laboratory, Institute of Health and Biomedical Innovation, Queensland University of Technology, Kelvin Grove, Brisbane, Queensland, Australia, <sup>2</sup>National Research Centre for Environmental Toxicology (EnTox), University of Queensland, Brisbane, Queensland, Australia.

It is widely known that sun exposure initiates the synthesis of vitamin D (cholecalciferol) in human skin. The ultimate goal of current research is to arrive at a statement of what amount of time an individual should exposure himself to UV in order to receive adequate vitamin D. This is an important but complex question of public health, because excessive exposure to UV causes skin cancers and ocular conditions. It has been assumed that the amount of cholecalciferol produced will scale in proportion if the amount of exposure to UV is increased. However, we have used an *in vitro* model (Olds et al, 2008, J Photochem Photobiol B: Biol, in press) to demonstrate that, as the dose of UV radiation increases, the production of cholecalciferol actually decreases. This characteristic nonlinear dose-response relationship for cholecalciferol production will also apply to humans. Therefore, we conclude that if an individual increases his or her sun exposure, it cannot be assumed that a proportionate increase in serum vitamin D levels will result; that is, exposing oneself to twice the dose UV radiation will not produce twice the amount of cholecalciferol. Moreover, this may increase the risk of skin and eye conditions without justifiably benefiting vitamin D status. The *in vitro* model we used is a refinement of an existing model, where 7-dehydrocholesterol (the precursor to cholecalciferol) is dissolved in ethanol, placed into quartz cuvettes and exposed to UV and HPLC analysis of the photoproducts is undertaken. Our model uses a sound analytical methodology involving HPLC analysis and a computer-controlled UV dose system that is calibrated to the NIST international standard of irradiance. We discuss that this characteristic of cholecalciferol synthesis may arise because of a known reciprocity phenomenon, where additional UV actually degrades the cholecalciferol produced and creates other biologically inert photoproducts instead. This project shows that a vital key to understanding appropriate sun exposure for humans is to understand the reciprocity characteristic of cholecalciferol synthesis.

**Silencing of PDIA3 (ERp60) Reduces the Rapid Membrane Response to 1,25-Dihydroxyvitamin D<sub>3</sub> in MC3T3-E1 Osteoblast-like Cells.** J. Chen\*, Y. Wang\*, R. Olivares-Navarrete\*, Z. Schwartz, B. D. Boyan. Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

Protein disulfide isomerase A3 (PDIA3), also known as ERp60, ERp57, Grp58, and 1,25-MARRS, is a multifunctional protein that has been associated with rapid membrane-initiated signaling by 1 $\alpha$ ,25-dihydroxyvitamin D<sub>3</sub> (1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>) in several cell types. Chondrocytes and osteoblasts isolated from mice lacking functional nuclear vitamin D receptors (VDR), retain 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>-stimulated protein kinase C (PKC) activity and PKC-dependent responses to the vitamin D metabolite. To further elucidate the mechanism of PDIA3 action in the rapid response to 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>, we assessed the effect of PDIA3 knockdown in the mouse osteoblastic cell line MC3T3-E1 on 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> regulated PKC and phospholipase C (PLC) activity. The expression of PDIA3 in wild type MC3T3-E1 cells and its co-localization with caveolin-1 were detected both by immunofluorescence staining and by Western blot. The cells were then transfected with adenovirus-mediated siRNA against five different sequences of the PDIA3 gene. After selection in puromycin, silencing efficiency was evaluated at the mRNA level by RT-PCR as well as at the protein level by Western blot and flow cytometry. PKC and PLC specific activity were measured in wild type and PDIA3-silenced cells after 9 minutes treatment with different concentrations of 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>. Immunofluorescence staining demonstrated abundant expression of PDIA3 in wild type MC3T3-E1 cells, which was localized to the caveolar fraction based on Western blot. A silencing efficiency of 80% was achieved in one of the five clones as determined by RT-PCR and confirmed by Western blot and flow cytometry. Treatment with 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> for 9 minutes resulted in a dose dependent increase in PKC in wild type and silenced cells, but the effect was reduced in this clone. Furthermore, 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> failed to induce a significant increase in PLC activity in silenced cells compared to wild type cells. These results suggest that knockdown of PDIA3 could decrease cell sensitivity to 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>-regulated PKC and PLC activity. In addition, adenovirus-mediated siRNA can specifically and efficiently reduce PDIA3 expression in MC3T3-E1 cells, providing a useful model for further study on its function in caveolae and PKC-dependent responses to 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>.

## M228

**Thyroid Hormone Receptor Beta-Specific Agonist GC-1 Increases Bone Quality of Adult Female Mice.** C. C. Costa<sup>\*1</sup>, C. C. Wang<sup>\*2</sup>, K. O. Nonaka<sup>\*2</sup>, T. S. Scanlan<sup>\*3</sup>, C. H. A. Gouveia<sup>1</sup>. <sup>1</sup>Department of Anatomy, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Department of Physiological Science, University of Sao Carlos, Sao Carlos, Brazil, <sup>3</sup>Department of Physiology and Pharmacology, Oregon Health and Science University, Portland, OR, USA.

It is well known that thyroid hormone excess is a risk factor for osteoporosis and bone fractures. Bone tissue expresses three isoforms of thyroid hormone receptors: TR $\alpha$ 1, TR $\alpha$ 2 and TR $\beta$ 1. In this study, we compared the effects of triiodothyronine (T3) and GC-1, a TR $\beta$ -selective agonist on biomechanical parameters of the tibia by the three-point bending test. 130-day old female C57BL/6J mice were divided in the following groups (n=6-7/group): (i) Euthyroid (EUT), untreated animals; (ii) Hypothyroid (HYPO), treated with methimazole and sodium perchlorate (MMI+P), to inactivate the thyroid function; (iii) 10xT3, (iv) 20xT3 and (v) 40xT3, treated with 10, 20 or 40 times the physiological dose of T3 (0.35 ug/100g BW/day), respectively; (vi) 10XGC-1; (vii) 20XGC-1 and (viii) 40XGC-1, treated with GC-1 in equimolar doses of T3. Groups ii-vii were also treated with MMI+P and all treatments lasted 60 days. Serum levels of thyroxine (T4) were decreased in all MMI+P-treated groups (vs. EUT) and were not affected by T3 or GC-1 treatment. Serum levels of T3 were reduced in MMI+P-treated groups and increased in a dose-dependent fashion by T3-treatment (above the EUT levels), but were not affected by GC-1 treatment. As expected, all T3 doses promoted cardiac hypertrophy, characterized by an increase in the dry mass of the heart, while GC-1 treatment had no effect. HYPO did not affect any biomechanical parameter of the tibia, while T3 treatment reduced bone resistance in 20% (evaluated by the maximum load applied to the bone) and bone stiffness in 17%. Surprisingly, all GC-1 doses promoted significant increases in bone resistance (36-45%), stiffness (14-30%) and resilience (75-83%). These findings show that bone tissue of mice is responsive to GC-1 in vivo and that its administration improves biomechanical parameters and, therefore, bone quality. Considering the selectiveness of GC-1 for TR $\beta$  and the positive effects of this analog on biomechanical parameters of the tibia, contrasting to the deleterious effects of high doses of T3, our results suggest that TR $\beta$  mainly mediates actions of T3 that improve bone quality.

## M229

**Differential Cellular and Molecular Responses of Intestinal Epithelium to High Calcium Diet and 1,25(OH) $_2$ D $_3$ .** S. Peleg<sup>1</sup>, J. H. Sellin<sup>\*2</sup>, S. Umar<sup>\*2</sup>. <sup>1</sup>Endocrine Neoplasia & Hormonal Disorders, M. D. Anderson Cancer Center, Houston, TX, USA, <sup>2</sup>Gastroenterology & Hepatology, U. T. Medical Branch, Galveston, TX, USA.

Dietary calcium and the active metabolite of vitamin D (1,25(OH) $_2$ D $_3$ ), are essential for normal calcium homeostasis and skeletal health. While it is well established that a key component of their physiological action is adequate intestinal calcium absorption, little is known about how calcium and 1,25(OH) $_2$ D $_3$  affect the cellular dynamics in intestinal epithelium. To obtain a better understanding of epithelial responses to nutrients we used an infectious agent, *Citrobacter rodentium* (CR), which colonizes the distal colon of mice. CR infection induces a profound and sustained epithelial hyperplasia accompanied by a substantial activation of the  $\beta$ -catenin and NF- $\kappa$ B pathways. Because previous studies have shown that high calcium (hCa, 1%) diet inhibited the hyperplasia but had no effect on these pathways, we used this model to elucidate alternative molecular target/s for the protective action of hCa diet and to distinguish epithelial responses to calcium and 1,25(OH) $_2$ D $_3$ . First, we assessed the effect of infection on expression of several genes associated with calcium homeostasis in isolated colonic crypts and found a profound and sustained increase (up to 20-fold) in expression of the calcium channel TRPV6, but not in expression of TRPV5, calbindin D9K, calcium-sensing receptor, and vitamin D-metabolizing enzymes. Immunohistochemistry showed that in uninfected crypts TRPV6 was localized in the apical membrane of absorptive enterocytes, but in the infected crypts its abundance increased and its localization overlapped with the expanded proliferative zone. Expression of TRPV6 was diminished by hCa diet but increased substantially in both uninfected and infected crypts by intermittent administration of 1,25(OH) $_2$ D $_3$  (3  $\mu$ g/kg, 3 times per week). Likewise, hCa diet inhibited DNA synthesis (assessed by BrdU labeling) whereas 1,25(OH) $_2$ D $_3$  increased DNA synthesis and cellular mass in both uninfected and infected crypts. Furthermore, 1,25(OH) $_2$ D $_3$  blunted the anti-mitotic activity of hCa diet in both uninfected and infected crypts. This direct correlation between TRPV6 expression and cell proliferation in colonic crypts suggests that it promotes intestinal epithelial hyperplasia. This hypothesis was substantiated by finding that TRPV6 was over expressed in colon neoplasia. We conclude that in addition to its role in active calcium absorption, TRPV6 has the potential to regulate growth-promoting signaling in intestinal epithelium, and that intermittent 1,25(OH) $_2$ D $_3$  induces adverse cellular responses and attenuates the protective action of hCa diet in the intestine.

**Pregnancy Upregulates Duodenal Calcium-Transport Genes and Normalizes Calcium Homeostasis In *Vdr* Null Mice.** N. J. Fudge<sup>\*</sup>, A. G. Green<sup>\*</sup>, C. S. Kovacs. Memorial University, St. John's, NL, Canada.

Without vitamin D receptors (VDR), intestinal calcium absorption is reduced, leading to hypocalcemia, rickets and osteomalacia. Pregnancy imposes a substantial demand on the mother to supply calcium to her fetuses, a demand met by doubling intestinal calcium absorption. Previous work has shown that *Vdr* null mice upregulated duodenal  $^{45}$ Ca absorption to normal during pregnancy, and increased their bone mineral content (BMC) to 158% of baseline, thus equalling wild-type (WT) by end of pregnancy (EP).

We investigated the impact of pregnancy on mineral homeostasis, histomorphometry, and duodenal gene expression in *Vdr* null versus WT.

*Vdr* null and WT siblings were raised on 1% calcium chow until 10 weeks of age, in order to induce rickets and secondary hyperparathyroidism in *Vdr* nulls. Both genotypes were then switched to a 2% calcium, 20% lactose "rescue" diet to maximize fertility in *Vdr* nulls. After confirming stability of baseline BMC by DXA (Piximus), mice were mated and followed to EP. Analyses included serum Ca and PTH; urine Ca and deoxypyridinoline/creatinine (DPD/Cr); histomorphometry of toluidine blue stained undecalcified sections of tibiae; and RNA expression analysis (SuperArray) of genes relevant to calcium and bone homeostasis.

By EP, serum Ca was normal in *Vdr* nulls ( $1.2 \pm 0.2$  versus  $1.3 \pm 0.2$  in WT), while serum PTH dropped from high pre-pregnancy levels to expected low-normal WT levels at EP. Urine DPD/Cr also fell in *Vdr* null from  $42.9 \pm 4.5$  to  $12.6 \pm 5.0$ , reaching the same value as WT at EP ( $12.2 \pm 5.0$ ). Urine calcium rose in *Vdr* nulls from  $1.6 \pm 2.6$  to  $10.8 \pm 3.2$  mM and equalled WT at EP. *Vdr* null tibiae revealed rachitic growth plates, substantial fibrosis and secondary hyperparathyroidism at baseline that was unchanged at EP, despite the 158% increase in BMC. Duodenal microarray revealed significantly altered expression of genes in *Vdr* null mice at EP versus baseline, including (fold change in brackets): 1 $\alpha$ -hydroxylase (11.3), Ca $^{2+}$ -ATPase (3.1), calmodulin (4.4), calbindin9K (2.6), and FGF-23 (0.1). Compared to WT mice at EP, significantly altered expression was noted in: calbindin 28K (2.1), calmodulin (1.8) and Ca $^{2+}$ -ATPase (1.8), but the expression of other calcium-binding proteins and channels was no different between pregnant *Vdr* null and WT.

In summary, pregnancy in *Vdr* nulls was associated with improved systemic mineral homeostasis and increased renal calcium excretion. The skeleton accrued more mineral but had not repaired the rachitic phenotype. Several genes involved in calcium transport were upregulated in the duodenum.

In conclusion, *Vdr* nulls upregulate duodenal genes independently of VDR, thus upregulating  $^{45}$ Ca absorption and leading in turn to improved mineral homeostasis and skeletal mineral content.

**CYP27A1 Mutations at Phe147 Confer 25-hydroxylase Activity Towards a Vitamin D $_2$ -type Sidechain.** D. E. Prosser<sup>\*</sup>, M. Kaufmann<sup>\*</sup>, R. C. Murchie<sup>\*</sup>, K. Vong<sup>\*</sup>, G. Jones<sup>\*</sup>. Biochemistry, Queen's University, Kingston, ON, Canada.

CYP27A1 is a mitochondrial cytochrome P450 which 25-hydroxylates vitamin D $_3$  but 24-hydroxylates vitamin D $_2$ . The objective of this study was to identify substrate contact residues responsible for this regioselectivity. A detailed examination of a CYP27A1 homology model suggested that steric and electronic interactions between the aromatic bonds in Phe147 and the  $\Delta^{22-23}$  and 24-methyl moieties in the vitamin D $_2$  sidechain preferentially positions C24 for hydroxylation. We also examined the ability of Ser56, a putative substrate A-ring contact residue or access channel determinant, to regulate regioselectivity at C24. Wildtype CYP27A1 and site-directed mutants S56A, S56G, F147A, and F147L were stably transfected into V79-4 cells cultured in DMEM and incubated with 10 $\mu$ M 1 $\alpha$ -OH-D $_3$  or DHT $_2$  (dihydrocholesterol-2, a model D $_2$  sidechain-containing analog) for 24 hours in BSA-supplemented media. HPLC analysis of total lipid extracts was used to identify hydroxylated products which were confirmed by LC-MS and co-migrational analysis with authentic standards. The wildtype CYP27A1 expressed C24:C25:C27 hydroxylase activities towards 1 $\alpha$ -OH-D $_3$  in the ratio of 0.1:1:0.4. The mutants gave similar product ratios but total enzymatic activities were reduced: S56A (70% of wildtype), S56G (50%), F147A (8%), and F147L (54%). By comparison, the wildtype and Ser56 mutants displayed barely detectable 24-, 27-, and 28-hydroxylase activity (<20ng total) towards DHT $_2$  and no detectable 25-OH-DHT $_2$ . The Phe147 mutations, however, exhibited substantial activity towards the DHT $_2$  sidechain and produced unprecedented amounts of 25-OH-DHT $_2$ : F147A (780ng) and F147L (560 ng). The lack of 25-OH-DHT $_2$  production for the wildtype CYP27A1 and Ser56 mutants is consistent with the view that Phe147 directs hydroxylation of vitamin D $_2$ -type sidechains away from C25. Overall, the F147A and F147L mutations conferred substantially larger total activity and 25-hydroxylase activity towards a vitamin D $_2$ -type sidechain.

**Allele Specific Silencing of Collagen 1 Alpha Genes in Primary Human Bone Cells Using RNAi.** K. Lindahl\*, C. J. Rubin, A. Kindmark, Ö. Ljunggren. Dept. Med. Sciences, Uppsala University, Uppsala, Sweden.

Recent studies have reported successful allele specific gene silencing by RNA interference (RNAi) using small interfering RNA (siRNA) that discriminate between polymorphisms in mRNAs. These studies suggest that siRNAs may be interesting to explore as therapeutics in monogenic disorders, such as Osteogenesis Imperfecta, where the dysfunctional allele could be targeted specifically.

In the present study primary cultures of human bone derived cells were genotyped for a C/T single nucleotide polymorphism (SNP) in the coding region of COL1A2 (SNP ID rs1800222) (Allele frequencies: T=0.09 C=0.91). Heterozygous cells were transfected using the Magnet Assisted Transfection protocol (Promokine, Germany). Transfection was carried out for seven separate tiled siRNAs perfectly complementary to the T-allele of the COL1A2 mRNA (Figure 1A) and also with three separate scrambled negative control siRNAs. The transfected cells were incubated at 37°C until RNA was isolated 48h post-transfection and allele specific expression of COL1A2 mRNA was determined by cDNA-sequencing.

Cells transfected with negative control siRNA exhibited equal expression of the two alleles of rs1800222, whereas cells transfected with siRNA3 exhibited significant allelic imbalance of COL1A2, with lower relative abundance of the T-allele of rs1800222 (Figure 1B).

In conclusion: COL1A2 was silenced allele specifically in primary human bone cells using RNAi. The future aim is to design siRNAs that target mutated Collagen alleles in patients suffering from Osteogenesis Imperfecta (OI).

## M233

**Stem Cell Antigen Positive (Sca-1<sup>+</sup>) Hematopoietic Cell-based Human Growth Hormone (hGH) Gene Therapy Enhanced Endosteal Bone Resorption in Mice.** S. L. Hall\*, S. T. Chen\*, S. Mohan, J. E. Wergedal, D. D. Strong, K. H. W. Lau. Pettis Mem. VAMC, Loma Linda, CA, USA.

Because hGH and its mediator, insulin growth factor-I (IGF-I), are key bone formation (BF) stimulators, this study tested the hypothesis that increasing hGH expression levels on the endocortical bone surface would increase trabecular BF in the marrow cavity. To increase hGH expression of cells at the endocortical surface, Sca-1<sup>+</sup> hematopoietic cells were transduced *ex vivo* to express hGH and transplanted into recipient mice. Sca-1<sup>+</sup> cells were used because of their ability to engraft into the marrow cavity and because the Sca-1<sup>+</sup> cell-based gene therapy approach has successfully been used to stimulate trabecular bone formation with FGF-2. Sublethally irradiated stem cell-deficient W<sup>41</sup>/W<sup>41</sup> mice were injected IV with GFP-expressing transgenic Sca-1<sup>+</sup> cells that were transduced with HIV-based vectors expressing hGH or  $\beta$ -galactosidase ( $\beta$ -gal). Engraftment, assessed by % GFP<sup>+</sup> cells in peripheral blood of recipients at 6 months post-transplantation, was high (70-80%) and stable, with no significant difference between the two groups. Consistent with successful hGH transgene transduction, engraftment and transcription, relative hGH mRNA levels (by real-time PCR) in bone marrow cells of hGH recipient mice were increased 20,000-fold ( $p < 0.001$ ) compared to the  $\beta$ -gal group. Serum IGF-1 levels were also significantly higher in the hGH group over the  $\beta$ -gal group ( $545 \pm 71$  vs.  $382 \pm 42$  ng/ml,  $p < 0.002$ ) and positively correlated with hGH expression ( $R = 0.86$ ,  $p < 0.01$ ), thus demonstrating high functional hGH levels in the hGH group.  $\mu$ CT analyses revealed that

trabecular bone volume fraction (BV/TV) of hGH-expressing Sca-1<sup>+</sup> recipient mice not only did not increase, but was significantly decreased, compared to the  $\beta$ -gal group ( $4.7 \pm 0.9$  vs.  $7.2 \pm 1.1$  %,  $p < 0.003$ ). hGH mice also had decreased trabecular number ( $2.6 \pm 0.3$  vs.  $3.5 \pm 0.2$  mm<sup>-1</sup>,  $p < 0.0002$ ) and increased trabecular separation ( $392 \pm 38$  vs.  $284 \pm 18$   $\mu$ m,  $p < 0.0003$ ). More importantly, trabecular connectivity density was drastically decreased in the hGH group compared to the  $\beta$ -gal group ( $20.9 \pm 4.5$  vs.  $58.1 \pm 17.9$  mm<sup>-3</sup>,  $p < 0.004$ ). Based on our findings that Sca-1<sup>+</sup> cell mediated hGH gene therapy results in loss of trabecular bone and previous findings that IGF-I stimulates bone resorption, we predict that continuous overexpression of hGH in Sca-1<sup>+</sup> cells at high levels at the endosteum leads to trabecular bone destruction presumably via increased formation/activity of osteoclasts. In conclusion, while the Sca-1<sup>+</sup> cell-based *ex vivo* gene therapy strategy is a powerful tool to deliver a therapeutic gene to marrow space, the choice of an appropriate growth factor gene is critical to effectively increase endosteal BF.

## M234

**Proinflammatory Marker Values at Baseline and after a Fracture Are Distinctly Different Comparing a Mouse Model of Osteogenesis Imperfecta with Normal Controls.** A. I. Leet<sup>1</sup>, Y. Ni<sup>1,2</sup>, A. Jain<sup>1,2</sup>, T. Kazarian<sup>1</sup>, N. S. Fedarko<sup>1,2</sup>. <sup>1</sup>Orthopedic Surgery, Johns Hopkins University, Baltimore, MD, USA, <sup>2</sup>Geriatrics, Johns Hopkins University, Baltimore, MD, USA.

Patients with osteogenesis imperfecta (OI) can have high fevers after fracture or general anesthesia. The etiology of this response, we hypothesized, might be from an increased inflammatory response.

In this translational study, a mouse model of osteogenesis imperfecta (OIM), carrier, and normal (NL) mice were used to measure baseline inflammatory markers including IL-1 $\beta$ , TNF $\alpha$ , INF $\gamma$ , and IL-6, IL-8, IL-10, IL-12. OIM, carrier and NL mice underwent facial bleeding for a baseline pro-inflammatory profile. Tibia fractures were created in anesthetized OIM and NL mice using a closed model with a 3 point bend applied to the midshaft, followed by splinting. At short term time intervals (.25, .5, 1, 2, 4, 6 hrs.) and long term time intervals (1, 2, 3, 6 wk) mice underwent bleeding to obtain 1 ml of blood per animal that was spun to separate the serum layer. ELISA assays were performed using a 96 well 7 chamber multiplex plate for pro-inflammatory markers in mice (MSD Inc.).

Baseline values demonstrated greater variability in the OIM samples than either the NL or the carrier mice, which is to be expected given that OIM mice have spontaneous fractures. For TNF $\alpha$  and IL-10 the mean values for the OIM mouse was greater than NL controls with the carrier phenotype having an intermediate mean value compared to NL and OIM mice. For the other interleukins the means were not statistically different.

The short term fracture data showed a diminished initial elevation in INF $\gamma$ , IL-10, IL-12 in OIM versus NL mice; however, over time the amount of these pro-inflammatory markers increased such that by 6 hours the values were significantly higher in OIM than NL. For IL-6, the values at every time course were elevated in OIM compared to NL, while TNF $\alpha$ , IL-6, and IL-8 had similar slopes for OIM and NL mice when comparing the linear regression analysis of the data which started at baseline and then increased steadily as time elapsed from the fracture. The values of the pro-inflammatory markers at long term intervals were very similar comparing OIM to NL mice and tended to hover around baseline values.

The profile of inflammatory markers are very different comparing NL and OIM mice at baseline and then in the first few hours after a fracture. A week after a fracture there is not a large pro-inflammatory response as bone healing occurs, as would be expected since the inflammatory phase is generally the first stage in fracture healing. This model allows the study of only one genotype and phenotype, thus further study is warranted to determine if the high fevers seen clinically in some patients with OI can be explained by differences in cytokine production.

**Analysis of Long Bone Fracture Nonunion by an Expression Profile of the Matrix Metalloproteinases and ADAMTS Enzyme Families.** M. Fajardo\*, K. Ego<sup>1</sup>, C. Liu. New York University, New York, NY, USA.

Skeletal tissue is one of the human tissues which can regenerate to its former biological state when injured. The ability to regenerate encompasses a complex interaction of many biological processes. When these processes are interrupted, a fracture nonunion can result. Fracture healing and osteosynthesis requires the constant remodeling of the extracellular matrix. The remodeling process is largely attributable to the matrix metalloproteinases (MMPs) and a disintegrin-like and metalloproteinase with thrombospondin type I motif (ADAMTS) enzymes. A variety of members from both these protease families have been found to be closely related to the fracture healing process. Delays in bone healing or even development of a nonunion could be related to the concentrations of these enzymes and their function. This study is aimed at defining an expression profile of most MMPs and ADAMTS enzymes and their inhibitors (TIMPs) in bone fracture nonunion tissue and correlating their expression with normal callus. Tissue samples taken from the nonunion site were prospectively collected from patients undergoing surgical treatment for an established bone fracture nonunion. Only long bone fracture nonunion tissue specimens were used. Visualized bone callus seen at the surgical site served as a control. 15 nonunion tissue samples of at least 6 months duration were compared to 15 matched site callus controls. The expression patterns of 45 different MMPs, ADAMTS, and TIMPs enzymes were determined in the nonunion/callus tissue using quantitative Real Time-PCR. The mean age of the patient cohort was 46 years (range 32-80). The anatomic sites involved included: 2 femoral shafts, 2 subtrochanteric femurs, 2 tibial shafts, 1 tibial plateau, 1 distal tibia, 2 fibular shafts, 3 mid shaft clavicles, 1 proximal humerus, and 1 ulnar shaft. Mean length of nonunion was determined to be 16 months. Comparison between both groups of tissue samples revealed significantly elevated concentrations of MMP-7, and MMP-12 in nonunion tissue when compared to normal callus ( $p < 0.01$ ). No correlation was found between the expression of these enzymes and other clinical parameters (i.e. patient smoking, use of a bone stimulator, number of previous surgeries, infection). Our findings indicate that nonunion tissue commonly expresses statistically significant levels of MMP-7 and MMP-12. The data suggests that these enzymes may play an integral role towards the development of a bone nonunion. These enzymes may likewise be used as biomarkers for the detection of a fracture nonunion in patients on one hand, and on the other hand they may be the potential therapeutic targets for development of novel treatments for bone fracture and nonunion.

## M236

**Colistin-Impregnated Bone Cement Beads Prevent Multi-Drug Resistant *Acinetobacter* Osteomyelitis.** D. P. Crane<sup>\*1</sup>, K. Gromov<sup>\*1</sup>, C. K. Murray<sup>\*2</sup>, R. J. O'Keefe<sup>1</sup>, E. M. Schwarz<sup>1</sup>. <sup>1</sup>Orthopaedics, University of Rochester, Rochester, NY, USA, <sup>2</sup>Infectious Disease, Brooke Army Medical Center, Fort Sam Houston, San Antonio, TX, USA.

Current data of military operations in Iraq and Afghanistan demonstrate that the number of serious injuries greatly exceeds fatal casualties. Among these serious injuries, war wound infection and osteomyelitis (OM) appear to be of greatest concern, including multidrug-resistant (MDR) *Acinetobacter*. While *in vitro* studies have demonstrated that most *Acinetobacter* isolates are sensitive to colistin, bone void fillers containing this antibiotic are not available, and the high doses needed to treat some of the MDR strains cannot be achieved via parenteral administration. Thus, our goal was to develop a novel quantitative model of implant-associated *Acinetobacter* OM and evaluate the efficacy of parenteral colistin vs. colistin impregnated polymethylmethacrylate (PMMA) beads.

**Methods:** Six MDR strains of *Acinetobacter* were obtained from soldiers treated for OM at Brooke Army Medical Center. Over night cultures were used to contaminate insect pins that were surgically implanted transcorically through the tibial metaphysis of 6-8-week old C57B/6 mice. OM was assessed by longitudinal x-ray, micro-CT, histology and RTQ-PCR of the *parC* gene of *Acinetobacter* standardized to mouse *beta-actin*. In the efficacy study, mice (n=8 per group) were infected with the three most virulent strains and treated with parenteral colistinmethate (0.2mg i.m./day from day0-day7) or a 5mm PMMA bead containing 0 (bead control), 1 or 2mg of colistin sulfate and sacrificed on day 19. The data from the RTQ-PCR were used to determine the percentage of mice with OM in each group and the mean bacterial load in the infected tibiae in each group.

**Results:** The parenteral colistinmethate failed to protect the mice from OM as 70.8% of the mice were infected compared to 75% in the bead control group. However, the bead containing 1mg of colistin sulfate significantly reduced the infection rate down to 33.3% ( $p=0.004$  vs bead control). We also found that the colistin sulfate has a dose dependent effect on the bacterial load of the OM, as the mice with the 1mg bead had over ten times the number of *parC* genes per tibia compared to the 2mg group (423,300 +/- 214,700 vs. 41,160 +/- 25,870;  $p=0.02$ ).

**Conclusions:** These results demonstrate that implantation of colistin sulfate impregnated PMMA beads at the surgical site of an MDR *Acinetobacter* infection significantly prevents the establishment of OM. Further studies are warranted to see if a clinically relevant product can be made to treat war wound injuries associated with war in Iraq and Afghanistan.

**Identification of a Novel Mutation (78dup27) of the *TNFRSF11A* Gene in a Chinese family with Early Onset Paget's Disease of Bone.** Z. Zhang, H. Zhang\*, W. Hu\*, J. He\*, J. Yu\*, J. Gu\*, G. Gao\*, Y. Hu\*, M. Li\*, Y. Liu\*, Y. Ke\*, W. Xiao\*, W. Fu\*. The Department of Osteoporosis, Osteoporosis Research Unit, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.

Paget's disease of bone (PDB) is rare in China. Previous study showed affected individuals of early onset PDB from Japanese descent carried a 27-bp duplication at position 75 (75dup27) in *TNFRSF11A* gene. In here, we reported that a novel mutation (78dup27) in exon 1 of *TNFRSF11A* gene was identified in a Chinese unconsanguineous family with early onset PDB. Proposita of an unconsanguineous family and 3 affected familial individuals were admitted to our hospital because of deformity affecting the lower limbs and vertebral column with pain. Early onset PDB was diagnosed based on the clinical presentation with the characteristic of osteolysis and osteosclerosis with bone enlargement and deformity in their affected bones on x-ray, and elevated serum alkaline phosphatase levels. Genomic DNA was extracted from 4 affected individuals and 6 unaffected members in a Chinese family with early onset PDB. The entire coding region of the *TNFRSF11A* and *SOST* were amplified and sequenced directly. We did not find *SOST* gene mutations in proposita and her familial members. A novel 27-bp duplication in exon 1 (78dup27) in *TNFRSF11A* was found in four affected individuals and one unaffected individual. Although same 27-bp duplication, our mutation presented at bases 78-104, and on the protein level, this 78dup27 mutation resulted in nine amino acid insertions in the RANK signal peptide. However, the duplication of nine amino acids was LLLCALLA in our patients, rather than ALLLLCALL in affected individuals of Japanese family. The mutation was not detected in genomic DNA of 100 unrelated controls and five patients with sporadic PDB. The clinical findings in affected members of our family were similar to these bone presentations of previously reported early onset PDB of Japanese family, but different features were found in our patients. We presumed that the phenotypic differences between our affected subjects and Japanese early onset PDB were due to different sequence duplication. It is to be determined if it is a new typical form of PDB which is caused by a novel 78dup27 mutation in this familial PDB of Chinese descent.

**Obesity Induced by High Dietary Fat Leads to Increased Bone Resorption Marker, TRAP, and Decreased Bone Mass in Mice.** J. J. Cao<sup>1</sup>, B. R. Gregoire<sup>\*1</sup>, H. Gao<sup>\*2</sup>. <sup>1</sup>USDA/ARS, GFHNR, Grand Forks, ND, USA, <sup>2</sup>Department of Biochemistry and Molecular Biology, University of North Dakota, Grand Forks, ND, USA.

Obesity, which is growing in prevalence, is a risk factor for such chronic health disorders as diabetes and cardiovascular diseases. However, it is thought to be a protective factor for osteoporosis and bone fractures in humans. Accumulating data in humans suggest that fat mass has a negative effect on bone when the confounding factor, mechanical loading of body weight in obesity, was removed. Furthermore, obesity is associated with the chronic up-regulation of inflammatory cytokines such as TNF- $\alpha$ , IL-1 $\beta$ , IL-6, and IL-7. These cytokines have been shown to be capable of stimulating osteoclast activity and bone resorption through regulating the RANKL/RANK/OPG pathway.

To determine how dietary fat might affect bone metabolism, we examined *in vitro* bone formation, blood markers of bone homeostasis, and bone structure in male C57BL/6 mice fed either a high-fat diet (HFD, 45% kcal as fat) or a normal fat control diet (NFD, 10%) for 14 weeks starting at 6 wk of age. Cancellous bone volume/total volume ratio decreased ( $P < 0.05$ ) in mice fed the HFD despite a greater average body weight (10 g) than those fed the NFD ( $P < 0.01$ ). Compared with mice fed the NFD, the numbers of colony forming units (CFU)-fibroblastic and CFU-alkaline phosphatase positive at d 14 and mineralization nodule at d 28 were higher in bone marrow stromal cells from mice fed the HFD. Serum osteocalcin was lower ( $P < 0.05$ ) with HFD as compared to NFD (71.2 $\pm$ 11.7 vs 53.4 $\pm$ 17.0 for NFD and HFD groups, respectively). Serum TRAP and OPG levels were higher in the HFD mice when compared to the NFD mice (TRAP: 1.74 $\pm$ 0.33 vs 2.54 $\pm$ 1.03 U/L; OPG: 1.39 $\pm$ 0.58 vs 2.81 $\pm$ 2.09 ng/ml, for NFD and HFD diet respectively). No significant differences were observed between the two groups for serum RANKL (3.07 $\pm$ 2.30 vs 3.87 $\pm$ 2.52 nmol/ml for NFD and HFD, respectively).

**Disclosures:** J.J. Cao, None.

## M239

**Bone Metabolism, Micro-architecture and Densitometric Measurement in Rat Femur after Chronic Alcohol Consumption.** D. B. Maurel<sup>\*1</sup>, G. Y. Rochefort<sup>\*1</sup>, N. Boisseau<sup>\*2</sup>, E. Lespessailles<sup>1</sup>, C. L. Benhamou<sup>1</sup>, C. Jaffre<sup>\*1</sup>.

<sup>1</sup>Rheumatology, INSERM U658, IPROS, CHR Orleans, Orleans, France, <sup>2</sup>Sport Sciences Faculty, LAPHAP, EA 3813, Poitiers, France.

It is well documented that chronic alcohol consumption weakens bone tissue, by decreasing bone density, and bone mineral content. Our objective has been to characterize bone micro architecture after alcohol consumption in rats. We have used a rat model that reproduces the human drinking pattern by separating food and beverage and by adding alcohol (20% v/v) into the drinking tap water (*ad libitum*). Forty eight male Wistar rats (8-

week-old) were randomly divided into four groups: Controls, Alcohol, Exercise and Alcohol-Exercise. Femoral bone mineral density (BMD) and content (BMC) were assessed by DXA (Discovery, Hologic, USA) at baseline and two months later. DXA has previously been validated on murine models in our lab. The femoral metaphysis micro-architecture was studied *post-mortem* by microCT (micro-scanner 1072, Skyscan, Belgium). Results are presented in table below. We observed no significant difference in BMD and BMC between groups. However, some micro architecture parameters were significantly different between groups as revealed by microCT: the Alcohol-Exercise group exhibited a lower percentage of bone in the entire sample (BV/TV) compared to both Controls and Alcohol groups. Both alcohol and exercise increased bone resorption (higher CTx concentrations vs. control), whereas exercise alone increased bone formation (higher osteocalcin concentrations in both exercise and alcohol-exercise groups vs. alcohol group). Alcohol alone decreased bone formation. In conclusion, a 20% (v/v) alcohol consumption seems to elicit a bone turnover change, with a bone resorption increase and bone formation decrease. A higher alcohol dose must be envisaged to better investigate the effects of alcohol with and without exercise.

(Mean +/- SD)	Controls (n=10)	Alcohol (n=10)	Exercise (n=8)	Alcohol-Exercise (n=10)
Weight gain (g)	249.2 +/- 24.8	183.9 +/- 37.6	208.5 +/- 40.3	211.7 +/- 31.0
Lean mass evolution (%)	40.0 +/- 6.1	29.4 +/- 6.5	38.1 +/- 6.3	38.5 +/- 6.6
BV/TV (%)	64.8 +/- 3.5	63.9 +/- 7.3	62.7 +/- 7.9	57.2 +/- 4.7
Osteocalcin (ng/mL)	1.46 +/- 0.07	1.40 +/- 0.08	1.49 +/- 0.07	1.50 +/- 0.11
CTx (ng/mL)	49.0 +/- 32.6	101.4 +/- 20.8	127.7 +/- 16.4	143.4 +/- 13.4

## M240

**A Morquio Syndrome Variant: Two siblings with Atypical Phenotype and Novel Compound Heterozygosity.** W. A. Baratela<sup>\*1</sup>, M. B. Bober<sup>2</sup>, S. Tomatsu<sup>\*3</sup>, W. Mackenzie<sup>\*4</sup>, L. Nicholson<sup>\*2</sup>, C. I. Scott<sup>\*2</sup>. <sup>1</sup>Setor de Genética Médica, Hospital das Clínicas de Ribeirão Preto - FMRP, Universidade de São Paulo, São Paulo, Brazil, <sup>2</sup>Division of Medical Genetics, AI duPont Hospital for Children, Wilmington, DE, USA, <sup>3</sup>Department of Pediatrics, St. Louis University, St. Louis, MO, USA, <sup>4</sup>Department of Orthopedics, AI duPont Hospital for Children, Wilmington, DE, USA.

Mucopolysaccharidosis type IVA (MPS IVA) or Morquio A syndrome is an autosomal recessively inherited lysosomal storage disease caused by a deficiency of the N-acetylgalactosamine-6-sulfate sulfatase (GALNS) enzyme with the resultant urinary excretion of keratan sulfate (KS). The classic form of Morquio syndrome is characterized by a progressive spondyloepiphyseal dysplasia (SED) and associated disproportionate short stature of short trunk type. Typical adult heights are 80-120 cm with the final height being reached prior to puberty. Orthopedic complications typically include odontoid hypoplasia with C1-C2 instability, genu valgus. Marked ligamentous laxity is typical as are soft tissue accumulation of GALNS substrate leading to corneal clouding and cardiac valvular disease.

We describe a brother and his younger sister born to non-consanguineous parents with compound heterozygosity for p.R61W and c.498delC mutations in the GALNS gene. Neither of these mutations had been described before. GALNS fibroblast activity from the older brother activity revealed activity 10-15% of control fibroblasts. This is substantially higher than is seen in classic Morquio patients. Clinically, the older brother was initially diagnosed with an unclassified (SED) at the 9 years of age. At that time, his height was 129.7 cm (~25th%ile), but his arm span exceeded his height by 10.5 cm. Thoraco-lumbar platyspondyly was noted as was odontoid hypoplasia without instability. Epiphyseal changes were present throughout. Genu valgus was also present. Ophthalmologic evaluation revealed corneal clouding and a storage disease was considered. Initial urine screening studies showed elevated keratan sulfate and further biochemical and molecular studies confirmed the abnormality in GALNS. Following this discovery the younger sister was studied and found to have the same Morquio variant. At the age of 8 she was 123.2 cm (~25th%ile) with an arm span of 125.6. Mild corneal clouding was seen. Growth in both of these children ceased before puberty and the final adult heights were 150.0 cm (height age 12.5 years) in the brother and 142.8 cm (height age 11years) in the sister. Neither of these children have exhibited cardiac valvular abnormalities. Both of them are obese and have had surgery to correct genu valgus. Psychiatric and learning problems are present in the brother.

**Gene Transcripts Related to T-cell Activation, Proliferation, and Cytokine Signaling Show Significant Effects on BMD Variation in Baboons.** L. M. Havill<sup>1</sup>, A. Vinson<sup>\*1</sup>, J. Blangero<sup>\*1</sup>, J. E. Curran<sup>\*1</sup>, M. P. Johnson<sup>\*1</sup>, O. S. Platt<sup>\*2</sup>, C. Brugnara<sup>\*2</sup>, M. C. Mahaney<sup>\*1</sup>. <sup>1</sup>Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, <sup>2</sup>Laboratory Medicine, Harvard University, Cambridge, MA, USA.

Interplay between the skeletal and immune systems is receiving increasing attention among researchers of bone metabolism as the extent and importance of osteoimmunological crosstalk to bone health becomes apparent. Research shows that many genes important to immune system function also play extremely influential roles in regulation of bone metabolism. Increasing evidence implicates T-cell mediated regulation of bone metabolism. The fact that activated T-cells of the express a key osteoclast

differentiation factor (TRANCE) demonstrates that normal immune cell function can affect bone homeostasis. To further characterize the nature of the relationship between T-cells and bone metabolism, we examined the effect of elements of a network of genes consisting of 57 gene transcripts related to t-cell activation, proliferation, and cytokine signaling on variation in bone mineral density (BMD). We used the Illumina Human Sentrix-6 BeadChip microarray system to measure mRNA levels in lymphocytes from 495 pedigreed baboons. Heritability of expression level was demonstrated for each of the 57 transcripts in a previous study in these baboons. We regressed forearm BMD of the radius shaft, ulna shaft, and ultradistal radius against the level of expression of each individual transcript to assess the degree to which variation in expression levels accounted for BMD variation. Five transcripts, NFKC, FYN, IRF1, IL-27R alpha, and LT alpha showed statistically significant (using a p<0.05) covariate effects on variation in forearm BMD. Each of these transcripts accounts for approximately 1% of the variation in BMD as measured at the radius shaft, ulna shaft, and ultradistal radius. The association of these transcripts related to BMD, an indicator of bone health that represents a lifetime of bone formation and resorption events, provides further support for the role of activated T-cells in bone metabolism.

**Mecp2 Null Mice Display Multiple Skeletal Abnormalities.** R. D. O'Connor<sup>1</sup>, M. Zayzafoon<sup>2</sup>, M. C. Farach-Carson<sup>1</sup>, N. C. Schanen<sup>3</sup>. <sup>1</sup>Department of Biological Sciences, University of Delaware, Newark, DE, USA, <sup>2</sup>Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>3</sup>Laboratory for Human Genetics, Nemours/A.I. duPont Hospital for Children, Wilmington, DE, USA.

Rett Syndrome (RTT), a neurodevelopmental disorder, is most often caused by inactivating mutations in the X-linked gene encoding a regulator of epigenetic gene expression, methyl CpG binding protein, MeCP2. Clinical data show that, along with neurological defects, females with RTT frequently have marked decreases in Bone Mineral Density (BMD) beyond that expected from disuse atrophy. Our work with a Mecp2 null mouse model, *Mecp2*<sup>-yBIRD</sup>, reveals a difference between the wild-type and null mice, with the *Mecp2*<sup>-yBIRD</sup> mice having significantly shorter femurs and an overall reduced skeletal size. Histological studies have highlighted a shortened growth plate as well as decreased trabecular bone in the primary spongiosum of Mecp2 null femurs by 21 days of age, prior to the onset of neurological symptoms. Additionally, the trabeculae in the primary spongiosum of 60 day old *Mecp2*<sup>-yBIRD</sup> mice were abnormally shaped and hypercellularity was noted in the marrow space. Both histological and histomorphometrical analyses have shown reductions in the cortical bone parameters of Mecp2 null mice. It does not appear that these decreases in bone are owed to a primary effect on osteoclasts, as osteoclast numbers were comparable between wild-type and null animals. Also of note, serum calcium and phosphate levels were unchanged in *Mecp2*<sup>-yBIRD</sup> mice, consistent with that seen clinically in RTT patients. We speculate that Mecp2 deficiency leads to a primary dysregulation of genes critical for regulation of bone growth, differentiation and mineral homeostasis. Several genes essential to proper bone formation and maintenance of bone and calcium homeostasis have been identified as likely targets of Mecp2 in a differentiating osteoblast cell system. Current studies are underway to determine the functional significance of Mecp2 deficiency on candidate gene expression and function in osteoblastic cells.

**Hypoxia Promotes Ligand-independent Activation of the ACVR1 (R206H) Mutant Receptor in C2C12 Cells.** H. Wang<sup>\*1</sup>, E. M. Shore<sup>1</sup>, F. S. Kaplan<sup>1</sup>, J. Groppe<sup>\*2</sup>, R. J. Pignolo<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Department of Biomedical Sciences, Texas A&M University Health Science Center, Dallas, TX, USA.

Fibrodysplasia ossificans progressiva (FOP) is a rare, autosomal dominant disorder of connective tissue that leads to progressive, disabling heterotopic ossification. A recurrent mutation in activin receptor IA/activin-like kinase 2 (ACVR1/ALK2) replaces an evolutionarily conserved arginine with histidine at residue 206 in all sporadic and familial cases of classic FOP. Protein modeling predicts that substitution with histidine, and only histidine, creates a pH-sensitive switch within the activation domain of the receptor that leads to ligand-independent activation of ACVR1. Clinically, a local hypoxic tissue microenvironment caused by trauma or minor injury could promote such signaling through the mutant ACVR1 receptor in FOP patients. Thus, we tested the hypothesis that low pO<sub>2</sub> can enhance ligand-independent activation of the mutant ACVR1 receptor. We performed transient transfections of the wild-type and mutant (FOP) ACVR1 receptor in the mouse myoblast cell line C2C12, which undergoes osteoblast differentiation in response to BMPs. We observed that ligand-independent activation of mutant ACVR1, including Smad 1/5/8 phosphorylation and inhibitor of differentiation 1 (ID1) expression, was enhanced under hypoxic conditions (1% or 5% O<sub>2</sub>) compared to ambient O<sub>2</sub> (normoxia or 21% O<sub>2</sub>). These studies provide the first evidence that hypoxia may be an important mediator of ACVR1 (R206H) activation in FOP, with important clinical implications for early lesion formation.

**Common Genetic Factors Contribute to the Relationship of Body Composition and Bone Mass in Mouse Populations.** R. Li\*, P. C. Reifsnyder\*, B. L. King\*, L. B. Donahue, E. H. Leiter\*, G. A. Churchill\*. The Jackson Lab, Bar Harbor, ME, USA.

Osteoporosis and obesity, two disorders in body components, are growing in prevalence. Genetic studies for bone mineral density (BMD) and bone geometry in humans and mice are confronted with challenges because of the influence of body composition and many other confounders such as sex, age, and diet. In this study we will introduce a new multi-gene and multi-variable analytic approach to model the relationship between body composition and bone traits. Evidence of genetic studies from two mouse populations, C57BL/6J x DBA/2J intercross and NOD x 129.H2<sup>67</sup> backcross, shows that there are common QTLs for lean mass, fat mass, and bone mineral density. The parental strains C57BL/6J and DBA/2J show remarkable differences in body composition in response to a high-fat diet. The NOD strain has fragile bones. Strain 129.H2<sup>67</sup> is an MHC (Major Histocompatibility) congenic stock with normal bones. Linkage analysis indicates that one QTL on Chr 2 (with a LOD score peak at 164 Mb) affects both subcutaneous fat pad mass and BMD in the first intercross with 111 female mice on a high-fat diet. We also identified a QTL on Chr 3 (with a peak at 140 Mb) affecting lean mass, fat mass, and BMD in the second cross with 310 female mice on a standard chow diet. In addition, the Chr 3 QTL interacts with another QTL on Chr 15 (with a peak at 96 Mb) and this interaction has a significant effect on both fat mass and plasma leptin levels. Genome-wide gene expression profiling data and protein-protein interaction databases have shown promise to help identify the underlying candidate genes involved in the muscle-fat-bone system. We plan to expand these models to additional mouse strains and intercrosses, as well as human populations.

**Key words:** body composition, bone mineral density, gene interaction

Wark<sup>6</sup>, S. Ralston<sup>9</sup>, M. A. Brown<sup>1</sup>.

<sup>1</sup>Diamantina Institute, Brisbane, Australia, <sup>2</sup>Sequenom inc., Brisbane, Australia, <sup>3</sup>University of Bristol, Bristol, United Kingdom, <sup>4</sup>Garvan Institute of Medical Research, Sydney, Australia, <sup>5</sup>Menzies Research Institute, Hobart, Australia, <sup>6</sup>University of Melbourne, Victoria, Australia, <sup>7</sup>University of Western Australia, Perth, Australia, <sup>8</sup>Erasmus MC, Rotterdam, Netherlands, <sup>9</sup>FAMOS consortium, University of Edinburgh, Edinburgh, United Kingdom.

Genomewide association studies (GWAS) are a powerful method for identifying genes of small to moderate effect involved in common heritable diseases.

A phase 1 GWAS was performed in an Australian and UK cohort of postmenopausal female probands (age 50-85 years) with extreme truncate selection for FN BMD (1.5<|z-score|<4), with 317,000 SNPs genotyped using Illumina HumanHap300 chips. 130 SNPs, selected for further study based on the initial results, were genotyped in families selected from the FAMOS cohort (proband FN or LS BMD z-score <-1, n=429 families including 1286 individuals) using Sequenom MALDI-TOF technology. PLINK was used to test association in the GWA component, and QTDT to test total association controlling for linkage in the confirmation family study. For a range of different genetic models, the phase 1 component of 140 subjects has equivalent power to a cohort study of 850-920 unselected individuals. Overall genotyping success rate was 99.6% in phase 1 and 93.1% in phase 2. No gene achieved genomewide statistical significance in the phase 1 screen (as expected due to small sample size). However, 31 markers achieved p-values of 10<sup>-5</sup> to 10<sup>-7</sup>. One SNP, rs10904952, was associated with FN BMD in both phase 1 (P=0.0021) and phase 2 (P=0.00072) studies. Combining these findings, the overall level of significance for this SNP is 4.86x10<sup>-6</sup>. This SNP lies in the gene encoding ST8 alpha-n-acetyl-neuraminide alpha-2,8-sialyltransferase 6 (ST8SIA6), a protein that interacts with fetuin-alpha, which controls apatite formation and bone and tissue mineralisation. Four other SNPs lying in ST8SIA6 were associated with FN BMD with p-values of 0.0078-0.00048 in the phase 1 study.

This study suggests that polymorphisms of ST8SIA6 influence FN BMD in the general population. Whilst the finding did not achieve genomewide significance in the discovery cohort, association was confirmed in the replication cohort, despite modest study power. A much larger cohort of cases with extreme high and low BMD is being recruited for further studies. If confirmed, ST8SIA6 represents a novel gene associated with BMD. The mechanism underlying the association and its effect on fracture risk have yet to be determined.

**Screening the PHEX Gene in a Large Cohort of Hypophosphatemic Rickets Allowed the Description of a Missense Mutation not Responsible for the Disease on a Highly Conserve Amino Acid Residue.** C. Gaucher\*, O. Walrant-Debray\*, M. Nguyen\*, M. Garabedian\*, F. Jehan. Inserm U561, Paris, France.

Mutations responsible for hypophosphatemic rickets have been mostly found in the PHEX gene and 193 different mutations have been so far described in the PHEX database (www.phexdb.mcgill.ca). We have screened the 22 exons of the PHEX gene, by PCR amplification followed by sequencing, in a large cohort of 140 hypophosphatemic patients (97 families) selected on the following criteria: rickets with bone deformities, low serum phosphate with urinary phosphate wasting, normal PTH levels and hypocalciuria. PHEX mutations were found in 79 of the 97 probands (81%), representing 76 different mutations, 43 being de novo mutations (not found in the parents' probands), and 59 mutations not being reported in the PHEX database. PHEX mutations were not found in 18 probands, including 13 sporadic cases (23 % of total sporadic cases), one of whom with oncogenic hypophosphatemia, and 5 familial cases with dominant inheritance (12 % of total familial cases), one of whom bearing an activating FGF23 mutation.

Like in the PHEX database, missense mutations were found in 20% of the probands (n=16). Interestingly, two probands bore 2 distinct mutations, the first one on different exons (a splice site mutation near exon 18, c.1899+1 g>a, and a missense mutation A653D on exon 19), the second one on the same exon (a T deletion on c.538 and a missense mutation V169M on exon 5). Clinical and genetic analysis of all healthy and affected members of the latter family (3 generations) showed segregation of the two mutations on the same allele of exon 5, the T deletion appearing at generation 2. Only the T deletion, and not the V169M mutation, was associated with hypophosphatemia.

In conclusion, PHEX mutations are found in 8 out of 10 patients with hypophosphatemic rickets, normal PTH and hypocalciuria, even in sporadic cases. Findings of missense mutations, even at a very conserved amino acid, may not cause the disease and requires complete exploration of the entire coding sequence.

Numerous quantitative trait loci (QTL) affecting bone traits have been identified in the mouse. However, few of the underlying genes have been discovered. To improve the process of transitioning from QTL to gene we describe an integrative genetics approach, which combines traditional linkage analysis, DNA microarray expression profiling and genetic association in outbred mice. In C57BL/6J and C3H/HeJ (BXH) F2 mice, QTL affecting bone mineral density (BMD) were identified using marker regression. To identify candidate genes, transcripts regulated by local expression QTL (eQTL) were identified using linkage analysis of microarray-generated gene expression profiles in individual F2 mice. Causal relationships between genes with local eQTL and BMD were predicted using network edge orienting (NEO), a recently developed R function for causality modeling. In order to fine-map QTL, regions regulating BMD in BXH mice were tested for association in outbred MF1 mice using ANOVA. Nine QTL regulating BMD were identified, three of which displayed male-biased expression. Additionally, 148 genes, located within BMD QTL support intervals, were correlated with BMD and regulated by local eQTL. Causal relationships for 18 of these genes and BMD were predicted using NEO. Integrating linkage, eQTL analysis, dense SNP maps, causality modeling and genetic association in outbred MF1 mice provided strong support for *Wnt9a*, *Rasd1* or both underlying *Bmd11*. Integration of multiple genetic and genomic data sets can substantially improve the efficiency of QTL fine-mapping and candidate gene identification.

**Craniofacial Gene Discovery in Mice.** L. Donahue, M. Curtain\*, J. Hurd\*, C. Marden\*, S. Murray\*. The Jackson Laboratory, Bar Harbor, ME, USA.

The purpose of the Craniofacial Resource (CR) at The Jackson Laboratory (TJL) is to identify and characterize craniofacial disorders in mice that are potential genetic and physiological models for human craniofacial dysmorphologies and to share these models with the scientific public. We screen for spontaneous and induced mutations resulting in abnormal clinical presentations, do comprehensive genetic and characterization studies, and

identify gene mutations by candidate gene testing and positional cloning. We provide notification of new models via our website: <http://craniofacial.jax.org/>, offer information and training via our email: [faces@jax.org](mailto:faces@jax.org), and distribute live mice to investigators worldwide. We are currently seeking collaborations to exploit the collection of mutants we are holding and welcome inquiries for mutants at all stages of development.

We have tested the heritability and penetrance of over 200 craniofacial phenodeviants and found 50 with transmissible traits of acceptable penetrance. Mutant strains carrying these abnormal craniofacial phenotypes are at various stages of genetic and phenotypic development. We have new spontaneous models for: crystallin, alpha A (*Cryaa*); sclerostin domain containing 1 (*Sostdc1*); aristaless 4 (*Alx4*), and lamin A (*Lmna*), plus 3 remutations to bone morphogenetic protein 5 (*Bmp5*). A chromosomal location has been identified for 15 additional mutant strains (Chromosomes 2, 3, 4, 5, 7, 8, 11, 12, 13, 14, 19); mapping is underway for 17 strains, and heritability testing is being done for the remaining phenodeviants. Phenotypes include: cleft lip; abnormal ear pinnae shape, size, and placement; shortened snouts; shortened, domed and asymmetrical skulls; abnormal dentition; abnormal eye morphology, and deafness. Many deviants have more than one phenotype, and are potential models of human craniofacial syndromes. Recently, we have begun to test apparently dominant phenotypes for recessive expression during embryogenesis and have discovered several extremely interesting models of cleft palate and other facial dysmorphologies. We are keenly interested in working with experts in each of these areas to take full advantage of the opportunity represented by these new models.

Craniofacial dysmorphologies represent nearly 75% of all human congenital malformations visible in newborns and are a complication in over 700 known human genetic syndromes. Gene discovery in humans is difficult due to population heterogeneity and to the diversity of interacting environmental and nutritional variables. Consequently, animal models with defined genetic backgrounds maintained in controlled environments are critical for craniofacial gene discovery.

**Bivariate Whole Genome Linkage Analysis of Femoral Bone Geometric Traits and Leg Lean Mass: the Framingham Study.** D. Karasik<sup>1</sup>, Y. Zhou<sup>\*2</sup>, L. A. Cupples<sup>\*2</sup>, D. P. Kiel<sup>1</sup>, S. Demissie<sup>\*2</sup>. <sup>1</sup>IFAR, Hebrew SeniorLife, Harvard SM, Boston, MA, USA, <sup>2</sup>Dept Biostats, BUSPH, Boston, MA, USA.

The risk of osteoporotic fracture is a function of loading conditions and the ability of the bone to withstand load. Both spatial distribution of bone tissue and applied muscle mass are important contributors to fracture risk. DXA non-invasively measures leg lean mass (LLM) as well as femoral bone geometry (BG). Both LLM and BG are known to have a substantial genetic component. Therefore, we estimated shared heritability and performed linkage analysis to identify chromosomal regions governing both LLM and BG.

A genome-wide scan (with a set of 636 genome-wide markers with an average marker spacing of 5.7 cM) was performed on 1,362 adult individuals from 321 extended families of the Framingham study. DXA was used to measure LLM; femoral neck length (FNL), neck-shaft angle (NSA), as well as subperiosteal width (Wid), cross-sectional bone area (CSA), and section modulus (Z) were measured at the narrowest section of the femoral neck (NN) and shaft (S) regions.

Variance component analysis was performed on normalized residuals (adjusted for age, age<sup>2</sup>, height, BMI, and estrogen status/menopause in women) using SOLAR. The analysis provided substantial heritability for leg lean mass ( $h^2 = 0.42 \pm 0.07$ ). Heritability was also significant for all BG traits, ranging from 0.28 (NSA) to 0.63 (S\_Wid). Phenotypic correlations between covariate-adjusted LLM and BG phenotypes ranged from low (0.038 with NSA,  $p > 0.05$ ) to substantial (0.285 with S\_Z,  $p < 0.001$ ). Genetic correlations ( $\rho_g$ ) between covariate-adjusted LLM ranged from 0.113 (NSA,  $p > 0.05$ ) to 0.603 (S\_Z,  $p < 0.001$ ). Environmental correlations ( $\rho_e$ ) between LLM and some geometric traits were lower than  $\rho_g$ . Notably, an alternative adjustment for leg fat did not change correlation estimates. Univariate linkage analysis of adjusted LLM identified no chromosomal regions with LOD scores  $\geq 2.0$ ; bivariate analysis identified two QTLs with LOD scores  $> 3.0$ , shared by LLM with S\_CSA on chr. 12p12.3-p13.2, and with NSA, on 14q21.3-q22.1.

In conclusion, we identified chromosomal regions potentially linked to both leg lean mass and femoral bone geometry. Identification and subsequent characterization of these shared loci may further elucidate the genetic contributions to both osteoporosis and sarcopenia.

## M250

**Genetic Locus on Chromosome 1q Influences Bone Loss in Young Mexican American Adults.** J. R. Shaffer<sup>1</sup>, C. M. Kammerer<sup>1</sup>, J. M. Bruder<sup>2</sup>, S. A. Cole<sup>\*3</sup>, T. D. Dyer<sup>\*3</sup>, L. Almasy<sup>\*3</sup>, J. W. MacCluer<sup>\*3</sup>, J. Blangero<sup>\*3</sup>, R. L. Bauer<sup>\*2</sup>, B. D. Mitchell<sup>4</sup>. <sup>1</sup>Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of Texas Health Science Center, San Antonio, TX, USA, <sup>3</sup>Southwest Foundation for Biomedical Research, San Antonio, TX, USA, <sup>4</sup>Division of Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, MD, USA.

Bone loss over the lifespan, eventually leading to low bone mineral density (BMD), is one of the major determinants of risk for osteoporosis. Most research has focused on BMD change in older individuals, however, substantial bone loss begins as early as the third decade and the factors affecting early adult bone loss are largely unknown. We investigated the influences of genes and environment on rate of BMD change in young adult participants of the San Antonio Family Osteoporosis Study.

Rate of BMD change, calculated from DXA measurements at two time points, 5.6 years apart, was analyzed in 300 Mexican Americans (ages 25-45 years) from 32 extended families. Family-based likelihood methods were used to estimate heritability ( $h^2$ , the proportion of trait variance due to genes) and perform genome-wide linkage analysis (using 460 genetic markers at 7.6 cM resolution) for BMD change of the proximal femur, while simultaneously adjusting for the effects of sex, baseline BMD, weight, interim change in weight, and interim menopause.

Rate of early adult BMD change was significantly heritable for the total hip ( $h^2 = 0.34$ ,  $p = 0.01$ ) and modestly heritable for the femoral neck ( $h^2 = 0.22$ ,  $p = 0.06$ ). Endogenous environmental covariates accounted for 16% and 24% of total hip and femoral neck variation, respectively. A genetic locus influencing early adult bone loss of the femoral neck was observed on chromosome 1q23 (LOD = 3.6,  $p = 0.00002$ ).

In conclusion, we observed that change in hip BMD in young adults was heritable, and performed one of the first linkage studies for BMD change. Evidence of linkage to chromosome 1q23 suggests this region may harbor one or more genes involved in regulating early bone loss of the femoral neck. Discovery of such genes could lead to new biological targets for the treatment of osteoporosis, and/or the identification of persons at risk who may benefit from preventative interventions.

**Familial Humeraloradioulnar Synostosis Maps to Chromosome 7p15.** J. Jeong<sup>\*</sup>, I. Jeon<sup>\*</sup>, S. Choi<sup>\*</sup>, H. Kim<sup>\*</sup>, M. Han<sup>\*</sup>, K. Lim<sup>\*</sup>, S. Kim, U. Kim<sup>\*</sup>, J. Choi<sup>\*</sup>. Biochemistry & Cell Biology, Skeletal Diseases Genome Research Center, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea.

Congenital bilateral humeraloradioulnar fusion of the elbow is rare. We found a rare familial humeraloradioulnar synostosis affecting the elbow and forearm among Koreans. To identify the gene causing this disorder, we have performed whole genome-wide linkage scan by 403 microsatellite markers with an average spacing of 10 cM from 16 out of 32 members in the family of whom DNA samples are available. We calculated the pairwise and multipoint LOD scores of these markers for both dominant and recessive models. The analysis with dominant model indicated LOD score of 2.3 at marker GGAA3F06 ( $\theta = 0.00$ ) on the short arm of chromosome 7. Fine mapping in the region of chromosome 7p15 with 17 microsatellite markers narrowed down the candidate region from 17 cM to 10 cM. This study provides a map location for isolation of a gene causing familial humeraloradioulnar synostosis. Also, it will aid future identification of the responsible gene, which will be useful for the understanding of the molecular mechanism of humeraloradioulnar synostosis.

**Disclosures:** J. Choi, None.

**Defining Epistasis in a Double Congenic Mouse: Implications for the Skeleton.** V. E. DeMambro, K. L. Shultz, J. A. Maynard<sup>\*</sup>, C. L. Ackert-Bicknell, W. G. Beamer, G. A. Churchill<sup>\*</sup>, C. J. Rosen. The Jackson Laboratory, Bar Harbor, ME, USA.

We have previously identified several QTLs for BMD and IGF-1 utilizing C57BL/6J X C3H/HeSnJ (B6 X C3H) F2 progeny. The strongest QTL for lowering IGF-1 was located on Chr 6 and analyses of the original cross showed an interacting locus on Chr 11. This interaction suggested that when there were fixed *c3* alleles on Chr 6 and heterozygous *c3* alleles on 11, then the lower IGF-1/BMD phenotype could be rescued. To test this interaction, we took the previously characterized B6.C3-6T mouse which has a 20% reduction in IGF-1, reduced bone mass, impaired osteoblast differentiation, and enhanced marrow and hepatic adiposity; and mated them to our B6.C3-11 congenic mouse. Once the alleles on Chr 6 were fixed for *c3* we then phenotyped and compared male mice carrying either the *b6* or *c3* alleles on Chr 11, by PIX1, pQCT, MicroCT and for serum IGF-1 levels. Mice Carrying the *c3c3* alleles on Chr 11 at 8wks of age had increased IGF-1 levels (*b6b6* =  $248 \pm 4$ , *c3c3* =  $273 \pm 7$ ;  $p = .004$ ) and increased whole body aBMD (*b6b6* =  $248 \pm 4$ , *c3c3* =  $273 \pm 7$ ;  $p = .004$ ) vs. *b6b6* mice. At 16 weeks of age *c3c3* mice had increased femur length (*b6b6* =  $15.6 \pm .05$ , *c3c3* =  $16.2 \pm .05$ ;  $p < .0001$ ), as well as increased total femur vBMD (*b6b6* =  $.592 \pm .005$ , *c3c3* =  $.612 \pm .008$ ;  $p = .02$ ) and cortical thickness (*b6b6* =  $.185 \pm .002$ , *c3c3* =  $.195 \pm .002$ ;  $p = .002$ ) as measured by pQCT. MicroCT of the distal femur revealed increased BV/TV (*b6b6* =  $.147 \pm .009$ , vs *c3c3* =  $.202 \pm .010$ ;  $p = .0007$ ) in *c3c3* mice which is attributable to increases in both trabecular # (*b6b6* =  $5.2 \pm .1$ , *c3c3* =  $5.7 \pm .1$ ;  $p = .002$ ) and thickness (*b6b6* =  $.047 \pm .001$ , *c3c3* =  $.053 \pm .002$ ;  $p = .001$ ). Thus there is an interaction between Chr 6 and 11 such that when *c3* alleles are present on the Chr 11 they rescue the 6T phenotype. Next, we looked at potential candidate genes in the Chr 11 locus using *in silico* haplotyping and gene expression. More than 50% of the SNP haplotype blocks between B6 and C3H in Chr 11 were found to be identical by descent (IBD). In previous expression data from the 6T mouse we identified 19 genes that were in the Chr 11 region that were differentially expressed and were not IBD. Two particular genes of interest *Srebp1c* (sterol regulatory element binding protein 1c: 60.01Mb on Chr 11) and *Per1* (period1: 68.92Mb, Chr 11) transcripts were two fold higher in 6T than B6 ( $p < .01$ ). Both genes are important in adipogenesis and skeletal homeostasis, particularly the former, *Srebp1c*, which is upstream of *Pparg*, the major candidate gene in our 6T mouse. *In sum*, we identified an epistatic locus on mouse Chr 11 that influences IGF-1 and bone mass in 6T. We narrowed the QTL through recombination and *in silico* mapping, and identified two potentially important candidate genes for adipogenesis and skeletal homeostasis.

**Epistasis Between QTLs for Bone Density Variation in Copenhagen X Dark Agouti F2 Rats.** D. L. Koller<sup>1</sup>, L. Liu<sup>\*1</sup>, I. Alam<sup>2</sup>, Q. Sun<sup>2</sup>, M. J. Econs<sup>3</sup>, T. Foroud<sup>\*1</sup>, C. H. Turner<sup>2</sup>. <sup>1</sup>Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Orthopedics, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>3</sup>Medicine, Indiana University School of Medicine, Indianapolis, IN, USA.

The variation in several of the risk factors for osteoporotic fracture, including bone mineral density, has been shown to be due largely to genetic differences. However, the genetic architecture of BMD is complex in both humans and in model organisms. We have previously reported QTL results for BMD from a genome screen of 828 F2 progeny of Copenhagen and dark agouti rats. These progeny also provide an excellent opportunity to search for epistatic effects, or interaction between genetic loci, that contribute to fracture risk.

Microsatellite marker data from a 20 cM genome screen was analyzed along with weight-adjusted bone density (DXA and pQCT) phenotypic data using the R/qtl software package. Genotype and phenotype data were permuted to determine a genome-wide significance threshold for the epistasis or interaction LOD score corresponding to an alpha level of 0.01.

Novel loci on chromosomes 5 and 13 demonstrated a strong epistatic effect on BMD at the femur by DEXA (LOD=5.6). A previously reported QTL on chromosome 14 was found to interact with a novel locus on chromosome 20 to affect whole BMD at the distal femur by pQCT (LOD=5.0), as well as to influence BMD at other skeletal sites. These results provide new information regarding the mode of action of previously identified rat QTL, as well as identifying novel loci that act in combination with known QTL or with other novel loci to contribute to the risk factors for osteoporotic fracture.

**Nuclear Receptor Interacting Protein 1 (NR1P1), a Novel Osteoporosis Candidate Gene Identified by Expression and Association Analyses.** D. P. Kiel<sup>1</sup>, D. Karasik<sup>1</sup>, S. Demissie<sup>2</sup>, Y. Zhou<sup>\*2</sup>, E. Bianchi<sup>\*3</sup>, K. Cho<sup>\*2</sup>, L. A. Cupples<sup>2</sup>, Y. Hsu<sup>1</sup>, J. M. Zmuda<sup>\*4</sup>, S. Ferrari<sup>\*3</sup>. <sup>1</sup>Harvard Med, Sch, HSL, IFAR, Boston, MA, USA, <sup>2</sup>Boston Univ, Boston, MA, USA, <sup>3</sup>Geneva Univ Hosp, Geneva, Switzerland, <sup>4</sup>Univ of Pitts, Pittsburgh, PA, USA.

Three mouse gene expression databases using mRNA of PTH-differentiated primary osteoblasts from neonatal calvariae, mRNA of adult femoral diaphysis and metaphysis, and in situ mRNA hybridization of skeletal embryonic tissue were used to identify NR1P1 (Chrom 21) as a potential candidate gene for osteoporosis. NR1P1 encodes a pleiotropic factor that interacts and regulates multiple members of the nuclear receptor super-family, including the estrogen receptor. Thus, to corroborate these findings in humans, we selected tag SNPs in NR1P1 including exon/missense SNPs with minor allele frequency >5%. Genotyping was performed in a subset of 1493 unrelated individuals (792 females mean age 60.6 ± 9.1 yrs and 701 males mean age 62.1 ± 9.2 yrs) from the Framingham Offspring Cohort who had DXA measurements of the hip (total hip BMD) and spine (L2-L4 BMD) and/or calcaneal broadband ultrasound attenuation (BUA) performed 1996-2001 using a Lunar DPX-L and Hologic Sahara ultrasound device. Genotyping was performed using the SNPlex™ Genotyping System and ABI Taqman. Covariate data included: age, BMI, smoking, and for women, estrogen status (premenopausal or postmenopausal on estrogen vs postmenopausal not on estrogen). Sex-specific single SNP analyses (2-df) were performed using analysis of covariance adjusting for age, BMI, height, smoking, and estrogen status. Permutation tests were performed within each gender to account for multiple testing. HWE p-values were > 0.1 for all SNPs. Of the 12 SNPs only one (rs2229742) achieved nominal significance in women for BUA p=0.033. In men four SNPs were significantly associated with either hip BMD (rs2178894, rs2249465, rs2103466), and/or spine BMD (rs13050325 and rs2249465) (all p-values<0.05). After permutation testing, two SNPs remained significant (rs13050325 and rs2249465) for spine BMD in men (permutation p<0.05). These SNPs explained 3.3% of the variance in spine BMD among men (each contributed about 2% when evaluated individually). Replication is being performed by genotyping these two SNPs in 1,800 men who participated in the Tobago Bone Health Study. Our findings suggest that NR1P1 is a widely expressed skeletal gene that is associated with BMD, mostly in men. The use of gene expression databases to identify candidate genes for osteoporosis traits may be a fruitful approach. The prominent association with BMD in men for a gene that in women has been shown by others to interact with the estrogen receptor, adds to the growing body of information supporting a role for estrogen in the male skeleton.

**Calcium-Sensing Receptor Gene "A986S" Polymorphisms: Relation to Bone Loss and Urine Calcium in a Spanish Early Postmenopausal Women Population.** J. A. Blázquez<sup>\*1</sup>, L. Navarro<sup>\*2</sup>, C. Andrés<sup>\*2</sup>, J. Ontañón<sup>\*2</sup>, J. Solera<sup>\*1</sup>, J. Del Pino<sup>\*3</sup>. <sup>1</sup>Internal Medicine, Hospital General Universitario de Albacete, Albacete, Spain, <sup>2</sup>Clinical Chemistry, Hospital General Universitario de Albacete, Albacete, Spain, <sup>3</sup>Rheumatology, Hospital Universitario, Salamanca, Spain.

**Background.** Calcium-sensing receptor (CaSR) is a candidate gene for osteoporosis susceptibility. There are not studies regarding the relationship between CaSR gene A986S polymorphism and bone loss.

**Objectives.** 1) To assess the association between CaSR gene A986S polymorphisms and postmenopausal bone loss. 2) To evaluate whether urine calcium excretion depends of CaSR gene A986S polymorphisms.

**Subjects and methods.** 153 women with natural menopause were randomly selected in the province of Albacete, Spain (mean age 53.7±1.6 yr). They did not have any diseases to affect bone metabolism. Genomic DNA was extracted from peripheral blood leukocytes by the Higuchi method. A fragment of exon 7 of CaSR gene containing the A986S polymorphism was amplified by polymerase chain reaction (PCR). After amplification, all samples were digested with Bsa H1 restriction enzymes, and the fragments were separated by agarose gel electrophoresis. Calcium was measured in a fasting 2 hr morning urine (Ca/Cr). BMD was measured at lumbar spine (L<sub>2</sub>-L<sub>4</sub>) baseline and two years later. 119 women completed the study.

**Results.** The distribution of genotype frequencies of CaSR gene A986S polymorphisms was: AA, 93 (78.2%); AS, 24 (20.2%), and SS, 2 (1.7%). The mean of annual bone loss was 2.04±1.67%. We found no association between CaSR gene A986S polymorphisms and bone loss (p>0.05), but we found an association with urine calcium. Women with the AS genotype had higher urine calcium than those with AA genotype: AS, 0.21 ± 0.09 mg/mg; AA, 0.16 ± 0.07 mg/mg (p=0.017).

**Conclusions.** 1) We found no association between postmenopausal bone loss and CaSR gene A986S polymorphisms. 2) We found an association between CaSR gene A986S polymorphisms and urine calcium.

**Association of Calcitonin Receptor Gene Polymorphisms with Bone Mineral Density and Fracture Risk in Postmenopausal Koreans.** S. H. Lee<sup>\*1</sup>, H. J. Lee<sup>\*2</sup>, S. Y. Kim<sup>\*3</sup>, Y. J. Kim<sup>\*2</sup>, B. Jung<sup>\*2</sup>, H. D. Shin<sup>\*4</sup>, B. L. Park<sup>\*4</sup>, T. H. Kim<sup>\*5</sup>, J. M. Hong<sup>\*6</sup>, E. K. Park<sup>\*5</sup>, H. L. Kim<sup>\*2</sup>, B. Oh<sup>\*2</sup>, J. M. Koh<sup>1</sup>, J. Y. Lee<sup>\*2</sup>, G. S. Kim<sup>1</sup>. <sup>1</sup>Division of Endocrinology and Metabolism, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, <sup>2</sup>The Center for Genome Science, National Institute of Health, Seoul, Republic of Korea, <sup>3</sup>Department of Orthopedic Surgery, Kyungpook National University School of Medicine, Daegu, Republic of Korea, <sup>4</sup>Department of Genetic Epidemiology, SNP Genetics, Inc., Seoul, Republic of Korea, <sup>5</sup>Department of Pathology and Regenerative Medicine, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, <sup>6</sup>Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea.

Calcitonin inhibits osteoclast-mediated bone resorption and affects calcium ion excretion in the kidney via a specific receptor, the calcitonin receptor (CTR). We investigated the association between calcitonin receptor gene (CALCR) polymorphisms and osteoporotic phenotypes in postmenopausal Korean women, to identify genetic factors that may be involved in susceptibility to osteoporosis and development of the disease phenotype. We directly sequenced the coding region, portions of the 5'-flanking and 3'-flanking sequences, and the intron-exon boundaries, of the CALCR genes from 24 individuals. We discovered nine single nucleotide polymorphisms (SNPs), and found an additional two SNPs in public databases. We investigated the potential involvement of these SNPs in osteoporosis in postmenopausal women (n = 729). The subjects carrying AA genotypes with an SNP in the CALCR promoter (-89413G > A) had higher bone mass density (BMD) values at the femoral neck (P = 0.002) and other proximal femur sites (P = 0.002-0.006). The A allele of this SNP tended to protect against vertebral fracture (OR = 0.72, 95% CI = 0.50-1.04, in the co-dominant model). In particular, functional analyses showed that the CALCR -89413G > A SNP affected expression of CALCR. These results indicate that the CALCR gene may be a key regulator of bone metabolism, and the -89413G > A SNP in the CALCR promoter may genetically modulate bone phenotype.

## M257

**Effect of Raloxifene Treatment on Bone Mineral Density Might Be Influenced by UGT1A1\*28 Polymorphism.** A. Zavratnik<sup>\*1</sup>, J. Trontelj<sup>\*2</sup>, J. Marc<sup>\*3</sup>, M. Bogataj<sup>\*2</sup>, A. Mrhar<sup>\*2</sup>. <sup>1</sup>Endocrinology, University Clinic Centre Maribor, Maribor, Slovenia, <sup>2</sup>Department of Biopharmacy and Pharmacokinetics, Faculty of Pharmacy, Ljubljana, Slovenia, <sup>3</sup>Department of Clinical chemistry, Faculty of Pharmacy, Ljubljana, Slovenia.

**Objectives:** Raloxifene concentrations were reported to approximately correlate with serum bilirubin levels. Bilirubin is typical UGT1A1 substrate. Based on these facts, we postulated a hypothesis that UGT1A1\*28 polymorphism, significantly contributes to the large pharmacokinetic variability of raloxifene and results in different bone mineral density (BMD) gain.

**Methods:** Serum samples of 47 postmenopausal osteoporotic women treated with raloxifene were assayed for the concentrations of raloxifene and its glucuronides by LC-MS-MS. The same samples were also genotyped for the presence of UGT1A1\*28 polymorphism by SSCP method. The pharmacodynamic effect was evaluated by measuring the change in BMD of femoral neck, total hip and lumbar spine after 12 months of therapy.

**Results:** Women homozygous for the \*28 allele showed a significantly, 2.2-fold higher total raloxifene concentrations compared to patients homozygous for the wild-type allele (562 +/- 116 nmol/L compared to 256 +/- 53 nmol/L, respectively,  $p=0.029$ ). Likewise, a significantly greater increase in hip BMD was observed in subjects homozygous for the \*28 allele compared to the group carrying at least one copy of the wild-type allele (4.4 +/- 2.4% compared to 0.3 +/- 1.4%,  $p=0.035$ ).

**Conclusion:** Our data have shown that the relatively common UGT1A1\*28 polymorphism strongly influences total raloxifene concentration and was clearly identified as one of the factors contributing to the large interindividual pharmacokinetic variability of raloxifene that could effect BMD gain and could be of clinical importance.

**Funding:** The authors acknowledge financial support from the state budget through the Slovenian Research Agency (project "Pharmacogenetic study of raloxifene metabolism and transport").

## M258

**Association between Polymorphisms in Tumor Necrosis Factor Receptor (TNFR) Genes and Circulating TNFR Levels, and Bone Mineral Density in Postmenopausal Korean Women.** J. Kim<sup>1</sup>, H. Kim<sup>\*1</sup>, S. Chun<sup>\*1</sup>, B. Jee<sup>\*2</sup>, C. Suh<sup>\*1</sup>, Y. Choi<sup>\*1</sup>. <sup>1</sup>Dept. of Obstetrics & Gynecology, Seoul National University Hospital, Seoul, Republic of Korea, <sup>2</sup>Dept. of Obstetrics & Gynecology, Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Tumor necrosis factor (TNF)- $\alpha$  is suggested to play a role in the increased osteoclastic bone resorption and skeletal response to TNF has been known to depend on a balance between expression and activation of the TNF receptor (TNFR)-1 and 2 gene products. We investigated the association between polymorphisms in TNFR genes and circulating soluble TNFR (sTNFR) levels, and bone mineral density (BMD) in postmenopausal Korean women

The TNFR1 A(36)G and TNFR2 T(676)G, A(1663)G, A(1668)G and C(1690)T polymorphisms were analyzed by polymerase chain reaction-restriction fragment length polymorphism or Taqman assay or DNA sequencing in 377 postmenopausal Korean women. Levels of serum sTNFR1, sTNFR2, osteocalcin, bone alkaline phosphatase, and C-telopeptide of type I collagen were measured. BMD at the lumbar spine and femoral neck was examined by dual energy X-ray absorptiometry.

TNFR2 A(1668)G polymorphism was not observed in study subjects. No significant associations were found between single genotypes of TNFR1, and TNFR2 polymorphisms and BMD of lumbar spine and femoral neck, but the prevalence of osteoporosis is significantly higher ( $p<0.05$ ) in GG genotype of TNFR2 A(1663)G polymorphism compared to other genotypes. Haplotype analysis of three TNFR2 polymorphisms did not show any significant association with BMD and the distributions of haplotype genotypes were not different among normal, osteopenic, and osteoporotic women. No significant differences in the levels of any bone turnover marker among single and haplotype genotypes of TNFR polymorphisms were found. Circulating sTNFR2 levels in TT genotype of TNFR2 T(676)G polymorphism and TT genotype of TNFR2 C(1690)T polymorphism were significantly lower compared to other genotypes, but sTNFR1 levels were not different according to TNFR1 polymorphism. The TNFR2 A(1663)G polymorphism are a genetic factor which may evaluate postmenopausal Korean women at risk of osteoporosis, and sTNFR2 level may be affected by TNFR2 T(676)G and C(1690)T polymorphisms.

## M259

**Is there any Association Between CYP 17-CYP 19 Polymorphisms and Bone Loss in Early Postmenopausal Women? Results of a Two-Years Study in a Spanish Population.** L. Navarro<sup>\*1</sup>, J. A. Blázquez<sup>\*2</sup>, C. Andrés<sup>\*1</sup>, J. Ontañón<sup>\*1</sup>, M. Cháfer<sup>\*1</sup>, M. Sosa<sup>\*3</sup>. <sup>1</sup>Clinical Chemistry, Hospital General Universitario de Albacete, Albacete, Spain, <sup>2</sup>Internal Medicine, Hospital General Universitario de Albacete, Albacete, Spain, <sup>3</sup>Internal Medicine, Hospital Universitario Insular, Las Palmas de Gran Canaria, Spain.

**Background.** Osteoporosis is a polygenic disorder resulting from the interaction of common polymorphic alleles and environmental factors. In contrast to the extensive studies on heritability of bone mass, few studies on heritability of bone loss have been reported. The CYP 17 and CYP 19 genes encode 17 $\alpha$ -hydroxylase/17,20-lyase and aromatase, respectively, both involved in androgens and estrogens synthesis, that they are important for the development and maintenance of bone mass.

**Objective.** To assess the association between CYP 17 and CYP19 polymorphisms and postmenopausal bone loss.

**Subjects and methods:** 153 women with natural menopause were randomly selected in the province of Albacete, Spain (mean age 53.7 $\pm$ 1.6 yr). They did not have any diseases to affect bone metabolism. Genomic DNA was extracted from peripheral blood leukocytes by the Higuchi method. The areas of interest were amplified with specific primers by polymerase chain reaction (PCR) technique. After amplification, all samples were digested with Msp A1 (CYP 17) and Rsa1 (CYP 19) restriction enzymes, and the fragments were separated by agarose gel electrophoresis. BMD was measured at lumbar spine (L<sub>2</sub>-L<sub>4</sub>) baseline and two years later. 119 women completed the study.

**Results.** The distribution of genotype frequencies of CYP 17 polymorphisms was: TT 45 (37.8%), TC 58 (48.7%) and CC 16 (13.4%). The distribution of genotype frequencies of CYP 19 polymorphisms was: AA 39 (38.8%), AG 61 (51.3%), GG 19 (16%). The mean of annual bone loss was 2.04 $\pm$ 1.67%. In the comparison between groups there was no difference in relation to bone loss for the CYP 17 or for the CYP19 polymorphisms ( $p>0.05$ ).

**Conclusion:** We found no association between postmenopausal bone loss and CYP 17-CYP 19 polymorphisms.

## M260

**Association of HSD11B1 Polymorphisms with Vertebral Fracture Risk and Bone Mineral Density in Postmenopausal Korean Population.** J. Hwang<sup>\*1</sup>, G. Kim<sup>\*2</sup>, M. Go<sup>\*1</sup>, Y. Kim<sup>\*1</sup>, M. Park<sup>\*1</sup>, H. Shin<sup>\*3</sup>, B. Park<sup>\*3</sup>, E. Park<sup>\*2</sup>, T. Kim<sup>\*2</sup>, J. Hong<sup>\*2</sup>, S. Lee<sup>\*2</sup>, H. Kim<sup>\*1</sup>, J. Lee<sup>\*1</sup>, S. Kim<sup>\*2</sup>, J. Koh<sup>4</sup>. <sup>1</sup>Center for Genome Science, Korean National Institute of Health, Seoul, Republic of Korea, <sup>2</sup>Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Seoul, Republic of Korea, <sup>3</sup>Department of Genetic Epidemiology, SNP Genetics, Seoul, Republic of Korea, <sup>4</sup>Division of Endocrinology and Metabolism, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

11 $\beta$ -hydroxysteroid dehydrogenase type 1 (HSD11B1) is a primary regulator that catalyze the reduction of inactive cortisone (E) to active cortisol (F). To examine the relationship between HSD11B1 polymorphism and osteoporosis, we investigated the potential involvement of five SNPs using the Illumina Golden Gate genotyping system in 729 postmenopausal women. Three SNPs, -19835G>A, +16374G>A and +27447G>C were associated with the risk of spinal fracture ( $p = 0.003$ -0.035) and vertebral fracture ( $p = 0.02$ -0.05). Two SNPs (LD) in intron 5, +16374G>A and +27447G>C were correspondently associated with bone mineral density (BMD) at the lumbar spine ( $p = 0.002$ -0.04) and femoral neck ( $p = 0.003$ -0.004). Particularly, the most significant -19835G>A (rs846908) was associated with the fracture risk on lumbar spine (OR = 2.14, 95% CI = 1.29-3.53, in the recessive model) including multiple comparison ( $p = 0.020$ ), and functionally correlated with Sox-5 (transcription factor, core matching score = 7.56). Also, +27447G>C was associated with protective effect (OR = 0.59, 95% CI = 0.41-0.86, in the dominant model) including multiple testing ( $p = 0.020$ ), and tended to be higher BMD value with independent. It suggest that the +27447G>C SNP acts as an intronic enhancer/silencer role with -19835G>A SNP in promoter sequence and genetically regulates glucocorticoid-induced osteoporosis. These results provide, for the first time, evidence supporting the association of HSD11B1 with osteoporosis in postmenopausal women.

**Disclosures:** J. Hwang, None.

## M261

**Associations of the Vitamin D Receptor and Calcitonin Receptor Genes with Bone Density, Bone Turnover Markers and Fracture Incidence with Regard to Calcium Intake Level in Slovak Postmenopausal Women.** R. Omelka<sup>1</sup>, M. Martiniakova<sup>\*1</sup>, V. Smolarikova<sup>\*1</sup>, D. Galbavy<sup>\*2</sup>, M. Bauerova<sup>\*1</sup>. <sup>1</sup>Constantine the Philosopher University, Nitra, Slovakia, <sup>2</sup>Private Orthopedic Ambulance, Nitra, Slovakia.

Osteoporosis is multifactorial in nature, and various genes, as well as insufficient diet have been reported to be involved in the pathology of the disease. The vitamin D receptor (VDR) and the calcitonin receptor (CALCR) genes code proteins that mediate an action of hormones involved in calcium homeostasis in target tissues. Therefore, genetic variability in the genes could affect the variability of bone mineral density (BMD), bone remodeling, and fracture risk.

We analyzed associations of FokI polymorphism in the VDR gene and AluI polymorphism in the CALCR gene with variability of femoral and spinal BMD, circulating alkaline phosphatase (ALP) and osteocalcin (OC; formation markers), beta-CrossLaps (CTX; resorption marker), and fracture incidence with regard to different amounts of calcium intake.

Our study involved 152 Slovak postmenopausal women (64.4±7.2 years) selected according to strict inclusion criteria. Genetic polymorphisms were detected by the PCR-RFLP method. The differences between the genotypes were analyzed by GLM procedure and covariance analysis after correction of the measurements for age and BMI. Gene-gene interactions were also evaluated within the statistical analysis. Frequencies of fractures were tested using the chi-square test. The fracture frequencies were also compared between groups with different daily calcium intake of <350 mg (group A), 350-650 mg (B), and >650 mg (C).

We found a significant effect of VDR-CALCR interaction on femoral BMD (P=0.033) and spine BMD (P<0.001). No polymorphism alone affected any of the analyzed traits significantly; however, effects of VDR gene on spine BMD (P=0.070) and ALP (P=0.086) were not far from the significance level. We did not find significant associations between the genes and OC, CTX. Comparison of fracture incidence between the genotype groups showed significant differences (P<0.05) for CALCR gene regardless of calcium intake level. The effect of the VDR gene was significant only in the C diet group (P<0.01). The ff-genotype carriers had higher frequency of fracture than the others.

The analysis of associations between candidate genes (interactions), diet, and BMD or bone turnover markers can extend our knowledge about molecular background of bone remodeling and loss. The results could be also applicable in predicting osteoporosis susceptibility. All procedures were approved by the Ethical Committee of the Specialized Hospital of St. Svorad in Nitra (Slovakia). This study was supported by the grant KEGA 3/4040/06.

## M262

**Significant Association Between Polymorphisms of CYP19A1, Fracture Incidence and Bone Mineral Density in Post-menopausal Women.** E. J. Payne<sup>\*1</sup>, S. G. Wilson<sup>1</sup>, E. Ingley<sup>\*2</sup>, R. L. Prince<sup>3</sup>. <sup>1</sup>Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia, <sup>2</sup>Cancer Medicine, Western Australian Institute for Medical Research, Perth, Australia, <sup>3</sup>Medicine and Pharmacology, University of Western Australia, Perth, Australia.

The human aromatase gene (CYP19A1) plays a major role in the biosynthesis of estrogen in a tissue specific manner. In post-menopausal women, this aromatization of adrenal androgens is the primary source of estrogen, implicating CYP19A1 in many estrogen-dependant functions such as tumour progression, obesity and bone health. Polymorphisms in CYP19A1 have been shown to alter aromatase expression furthermore we and others have shown previously that in postmenopausal women certain polymorphisms in CYP19A1 are associated with serum estradiol concentrations, bone structure and fracture risk. Thus CYP19A1 variation is a strong candidate for the known effects of heredity on osteoporosis risk in postmenopausal women.

Study subjects were members of a population-based cohort comprising of 1,257 Caucasian women aged between 70 and 85 years recruited for the Calcium Intake Fracture Outcome Study (CAIFOS). BMD at the hip site was measured by DXA (Hologic QDR 4500). Serum estradiol was measured by RIA (Orion Diagnostica, Finland). 31 tag SNPs selected to represent variation in the CYP19A1 gene were genotyped using MALDI-ToF (Sequenom Inc.). Statistical analysis was performed using SPSSv15.

Eight of the 31 tag SNPs showed significant associations with hip BMD (rs8034835 P=0.009; rs767199 P=0.039; rs3889391 P=0.045; rs17523880 P=0.005; rs16964215 P=0.028; rs12439137 P=0.048). Two SNPs showed a significant association with incident fragility fracture (rs4646 P=0.019; rs12439137 P=0.036). For SNP rs12439137, an increase in fracture rate and a decrease in BMD was observed for individuals with the rarer GG genotype. None of the SNPs analyzed were associated with detectable differences in circulating estradiol levels.

These observations indicate that genetic variation in the CYP19A1 gene contributes to variation in BMD in postmenopausal women. The lack of effect on circulating estradiol levels may be due to lack of power in the study or local tissue specific splice variant effects not reflected in circulating estradiol levels. This study confirms effects of specific variants on bone structure and supports the importance of such variation on fracture prediction. Study of the LD bins represented by these tag SNPs will allow further insights into the mechanism of the gene variation effect. These variants may be of importance given the efforts being undertaken to establish diagnostic tools and molecular targets for treatment.

## M263

**Prediction of Osteoporotic Fracture Risk by 25-hydroxyvitamin D<sub>3</sub>-1 $\alpha$ -hydroxylase (CYP27B1) Gene.** B. H. Tran<sup>1</sup>, A. Au<sup>\*2</sup>, N. D. Nguyen<sup>1</sup>, R. Clifton-Bligh<sup>2</sup>, J. R. Center<sup>1</sup>, J. A. Eisman<sup>1</sup>, T. V. Nguyen<sup>1</sup>. <sup>1</sup>Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, <sup>2</sup>Cancer Genetics Unit, Kolling Institute of Medical Research, Sydney, Australia.

Adult mice with knock-out CYP27B1 gene (which encodes the mitochondrial enzyme 1 $\alpha$ -hydroxylase) had an impairment of bone formation and bone mineralization. The present study was designed to test the hypothesis that variants within the CYP27B1 gene are associated with fracture risk.

The study was designed as a matched case-control investigation, with 295 women with fracture who were randomly matched for age with 295 women without a fracture. All women aged 60 or above as of 1989 (average age of participants was 71±7 years, mean±SD). Fracture was ascertained by X-ray reports between 1989 and 2007. Bone mineral density, lifestyle and clinical risk factors were obtained at baseline and in subsequent visits, which had taken place every two years. Genotypes of the CYP27B1 gene were determined in the promoter region (-1260 C to A) by restriction enzyme digestion. The conditional logistic regression was used to assess the association between the gene polymorphism and fracture.

Fracture cases as expected had significantly lower femoral neck BMD than controls (0.74±0.12 vs 0.8±0.12 g/cm<sup>2</sup>, p<0.001). The distribution of CYP27B1 genotypes was consistent with the Hardy Weinberg disequilibrium law: AA 18.4%, CA 38.0%, and CC 43.6%. There was no significant association between the CYP27B1 genotypes and BMD, body weight, or height. However, there was an over-representation of the heterozygous CA genotype in fracture cases (39%) compared to the non-fracture controls (32%). Thus, individuals with the CA genotype were associated with an increased risk of fracture (odds ratio [OR]: 1.35, 95%CI 1.63 - 2.40). Furthermore, after adjusting for age, BMD and lifestyle factors, individuals with polymorphic A allele was more likely to sustain a fracture than those homozygous with C allele (OR: 1.44, 95%CI 1.00 - 2.07). The CYP27B1 genotypes accounted for approximately 14% of fracture liability.

These results indicate that a common variation within the CYP27B1 gene contributes to an increased risk of fracture in the elderly independent of BMD. Genotypic information of this gene may improve the prognosis of fracture risk for an individual.

**A BMD-Associated SNP Lies in a Runx2 Binding Site of the LRP5 Promoter.** D. Grinberg<sup>\*1</sup>, L. Agueda<sup>\*1</sup>, M. Bustamante<sup>\*1</sup>, S. Jurado<sup>\*2</sup>, N. Garcia-Giralte<sup>\*2</sup>, M. Ciria<sup>\*2</sup>, G. Salo<sup>\*2</sup>, R. Carreras<sup>\*2</sup>, X. Nogues<sup>2</sup>, L. Mellibovsky<sup>\*2</sup>, A. Diez-Perez<sup>1</sup>, S. Balcells<sup>\*1</sup>. <sup>1</sup>Genetics, University of Barcelona, CIBERER, IBUB, Barcelona, Spain, <sup>2</sup>URFOA, IMIM, Hospital del Mar, Autonomous University of Barcelona, Barcelona, Spain.

LRP5 encodes the low-density lipoprotein receptor-related protein 5, one of the co-receptors involved in Wnt signalling and an important regulator of osteoblast growth and differentiation. Implication of its common variation (SNPs) in the normal spectrum of bone phenotypes has been shown by several association analyses. The purpose of the present study was to assess the functionality of SNPs found to be associated with bone phenotypes in a haplotype based association analysis.

We analysed 24 SNPs spanning the LRP5 region in a cohort of 964 Spanish women. Association with osteoporosis related phenotypes (LS BMD, FN BMD and fracture) was tested at single SNP and haplotype level. Predictive tools were employed to search for putative functional variant/s within blocks associated with bone phenotypes. Functionality of an associated promoter SNP was assessed by gel-shift assays, using SAOS-2 nuclear extracts and radiolabeled probes for both alleles.

The SNP rs312009 in the LRP5 promoter was found associated with LS-BMD [recessive model, CC/CT vs TT 0.07 (0.02-0.13) g/cm<sup>2</sup>, p=0.011]. Association analysis of the haplotype containing this SNP gave equivalent results. A consensus binding-site for the bone transcription factor Runx2 was identified at the SNP site when the T allele was present. In EMSA analyses, a band shift was produced with the T-allele probe, which was competed by increasing amounts of the cold oligonucleotide. A clear competition by the oligonucleotide containing the described OSE in the osteocalcin promoter and a supershift produced by the Runx2 antibody confirmed Runx2 involvement. Experiments using the C allele, as labelled probe or as cold competitor, produced similar results.

In conclusion, EMSA analyses showed the existence of a Runx2 binding site in the LRP5 promoter, involving rs312009. This suggests a functional role for the SNP and is the first indication of the interregulation of Runx2 and LRP5. However, the lack of differential binding by the two alleles could argue against rs312009 being the functional variant, and suggests that it might tag another unidentified causal SNP. Alternatively, limitations in gel shift experiments to detect slight differences could be the cause of the failure to find allele-specific binding affinities. Further approaches, such as competitive chromatin immunoprecipitation and gene reporter assays are currently being undertaken to assess the importance of Runx2 in LRP5 regulation.

## M265

**The -13910C>T LCT Promoter Polymorphism in the Spanish Population.** S. Balcells<sup>\*1</sup>, X. Nogues<sup>2</sup>, L. Agueda<sup>\*1</sup>, R. Urreiziti<sup>\*1</sup>, M. Bustamante<sup>\*1</sup>, S. Jurado<sup>\*2</sup>, N. Garcia-Giralte<sup>\*2</sup>, G. Yoskovitz<sup>\*2</sup>, L. Mellibovsky<sup>\*2</sup>, A. Diez-Perez<sup>2</sup>, D. Grinberg<sup>\*1</sup>. <sup>1</sup>Genetics, University of Barcelona, CIBERER, IBUB, Barcelona, Spain, <sup>2</sup>URFOA, IMIM, Hospital del Mar, Autonomous University of Barcelona, RETICEF, Barcelona, Spain.

Lactose tolerance is an autosomal dominant trait characterized by the persistence of high levels of the intestinal lactase-phlorizin hydrolase (LPH), encoded by lactase gene (*LCT*). A limited fraction of the human adult population retains LPH activity during adulthood (lactase tolerance, LT), which allows the consumption of large amounts of milk. This phenotype is especially common in Northern Europe and decreases in Southern Europe. Mutation -13910C>T at *LCT* has been previously associated with the lactase persistence trait in European population. Nevertheless, LPH persistence has been scarcely investigated in the Spanish population. Previous studies found association between lactose intolerance and bone mineral density (BMD), which might be due to reduced milk consumption and consequently reduced calcium intake.

The aim of this study was to establish the allele frequencies of the -13910C/T mutation at *LCT* gene in a Spanish population and to assess its relationship with anthropometrical markers and bone phenotypes.

The -13910C/T mutation at *LCT* gene was genotyped in 964 Spanish women (BARCOS cohort) by Taqman. Categorical parameters were analyzed by  $\chi^2$  and logistic regression. Continuous variables were analyzed by ANCOVA. The significance level was set at  $p < 0.05$ .

We found a T-allele frequency of 38.6%, which is significantly lower ( $p < 0.0001$ ) than in previously described North-European populations. No association between this polymorphism and BMD or fracture was found in our cohort. On the other hand, we found an association between it and increased body weight once adjusting for age ( $p = 0.037$ ). A stronger association was found when T-homozygotes were compared with the C-allele carriers (age-adjusted,  $p = 0.015$ ). Additionally, the T-allele carrier status was associated with higher stature (age-adjusted,  $p = 0.032$ ).

Our results confirm the previous observation of a cline in lactose tolerance across Europe, since Spanish allele frequencies are more similar to French (43.1%) or North Italian (35.7%), than to Swedish and Finnish (81.5%) or European American (77.2%). However, we have not found association between lactose tolerance and BMD.

The lack of association may be due to small effects that are below the power of this study. Alternatively, in this Spanish population, intolerant individuals may achieve equivalent calcium intake from food sources devoid of lactose. Finally, our results are in agreement with previous studies showing a tendency in milk consumers to higher stature.

**A Large Scale Candidate Gene Analysis Identifies an Association Between the Cyclin-Dependent Kinase 6 (CDK6) Locus and Trabecular Volumetric BMD at the Lumbar Spine in Older Men.** S. P. Moffett<sup>1</sup>, L. A. Yerges<sup>1</sup>, J. A. Cauley<sup>1</sup>, L. M. Marshall<sup>\*2</sup>, C. M. Kammerer<sup>\*1</sup>, R. E. Ferrell<sup>\*1</sup>, C. S. Nestlerode<sup>\*1</sup>, K. E. Ensrud<sup>\*3</sup>, A. R. Hoffman<sup>\*4</sup>, E. S. Orwoll<sup>\*2</sup>, J. M. Zmuda<sup>1</sup>.

<sup>1</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Oregon Health and Science University, Portland, OR, USA, <sup>3</sup>Veterans Affairs Medical Center, Minneapolis, MN, USA, <sup>4</sup>Stanford University, Stanford, CA, USA.

Many candidate genes have been proposed to influence bone mineral density (BMD) and osteoporosis risk; however, until recently, thorough investigations of large panels of putative candidate genes were not possible. Moreover, most studies to date have relied on DXA measures of integral areal BMD and have not been able to separately assess the possible genetic determinants of trabecular volumetric BMD (tBMD). In the current study, we investigated the association between SNPs within or flanking physiologically defined candidate genes for bone metabolism and lumbar spine tBMD measured with QCT in 882 Caucasian American men aged  $\geq 65$  years in the Osteoporotic Fractures in Men (MrOS) Study. SNPs in each candidate gene region were comprehensively interrogated by first creating a reference SNP panel spanning 30kb upstream and 10kb downstream of each gene using HapMap genotype data and then identifying tagging SNPs from the reference SNP panel with a minor allele frequency (MAF)  $\geq 5\%$  using a pairwise correlation method ( $r^2 \geq 0.80$ ). In addition, non-synonymous coding SNPs with a MAF  $\geq 1\%$  and other potentially functional SNPs with a MAF  $\geq 2\%$  were also selected for genotyping. 4,108 SNPs in 371 genes were genotyped using the Illumina GoldenGate assay, met quality control criteria and were analyzed for their association with lumbar spine tBMD. Analyses adjusted for participant age and clinic site. Principal components eigenanalysis was used to account for population substructure. Nine SNPs within 8 genes were associated with spine tBMD at  $P < 0.001$ . A SNP (MAF, 0.47) in the intronic region of the cyclin-dependent kinase 6 (CDK6) gene showed the most significant association with tBMD (additive  $p = 0.00006$ ). Men who were homozygous for the minor alleles had a mean BMD 12% higher than men who were homozygous for the major alleles. Another SNP located in the 3' untranslated region of CDK6 was also significantly associated with tBMD ( $p = 0.0002$ ). Two additional SNPs in the CDK6 gene region were associated at  $p < 0.05$ . No SNPs in the CDK gene were associated with DXA measures of the lumbar spine, highlighting the importance of examining different measures of bone density. These results require confirmation, but reveal the potential importance of the cell-cycle regulator, CDK6, in the determination of trabecular BMD variation among healthy men.

**Characterization of a Promoter Polymorphism in Frizzled Homolog 1 (FZD1): Allele-Specific Regulation by Early Growth Response Factor 1 (Egr1) in Osteoblast-like Cells.** L. Yerges, Y. Zhang<sup>\*</sup>, J. Zmuda. University of Pittsburgh, Pittsburgh, PA, USA.

WNT signaling has emerged as an important regulator of bone formation. The WNT co-receptor, Frizzled homolog 1 (FZD1), initiates WNT signal transduction and is a biological candidate gene for osteoporosis. We recently identified an association between genetic variation in the FZD1 promoter region and bone mineral density and bone structural geometry. One associated variant of interest, a common G-to-C promoter polymorphism, was associated with greater bone size and mineral content and was predicted to create an early growth factor 1 (Egr1) binding site *in silico*. To further investigate this promoter variant *in vitro*, we characterized DNA-protein binding and promoter activity. Electrophoretic mobility shift assays (EMSA) and transcription factor ELISA assays were completed to investigate allele-specific DNA-protein binding at this polymorphic site in the MG63 and SaOS-2 osteosarcoma cell lines. The C allele, which was predicted to create an Egr1 binding site, was associated with greater Egr1 binding (as evidenced by EMSA band pattern) and with a 1.5 to 1.9-fold increase ( $P < 0.05$ ) in Egr1 binding (as evidenced by transcription factor ELISA). Investigation of allele-specific promoter activity using luciferase reporter plasmids revealed a 2.3 to 3.4-fold higher FZD1 activity for reporter constructs containing the C allele as opposed to the G allele ( $P < 0.05$ ). Our results suggest that a *cis*-regulatory polymorphism in the FZD1 promoter region has a novel role in influencing Egr1 transcription factor binding and FZD1 gene expression in osteoblast-like cells. Our findings also reveal a plausible molecular mechanism for our previous genetic association and underscore the importance of combining both population-based and molecular evidence when investigating genetic polymorphisms.

**Comprehensive Genetic Analysis of Bone Volume in Men: The Osteoporotic Fractures in Men Study (MrOS).** J. M. Zmuda<sup>1</sup>, L. M. Yerges<sup>1</sup>, L. M. Marshall<sup>2</sup>, C. M. Kammerer<sup>\*3</sup>, J. A. Cauley<sup>1</sup>, K. Ensrud<sup>4</sup>, C. Nestlerode<sup>\*1</sup>, R. Ferrell<sup>\*3</sup>, A. R. Hoffman<sup>\*5</sup>, E. S. Orwoll<sup>2</sup>. <sup>1</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Oregon Health & Sciences University, Portland, OR, USA, <sup>3</sup>Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>VAMC & University of Minnesota, Minneapolis, MN, USA, <sup>5</sup>Stanford University, Stanford, CA, USA.

Bone size, an important determinant of bone strength, is a highly heritable trait. Animal and human studies suggest that the genetic determinants of bone size are to some extent distinct from those that regulate bone density. However, there is a paucity of information about the genetic factors that influence bone size in humans. Thus, we investigated the possible genetic determinants of femoral neck bone volume measured by quantitative computed tomography (QCT). To address this aim, we interrogated 371 candidate genes with 4108 tagging SNPs from HapMap Phase I and potentially functional SNPs from NCBI dbSNP in 871 men aged  $\geq 65$  years in the Osteoporotic Fractures in Men Study. Principal component eigenanalysis was used to account for population substructure. We initially adjusted for participant age and clinic site. The strongest association was with a tagging SNP (minor allele frequency=0.19) flanking the gene region encoding bone morphogenetic protein 2 inducible kinase (*BMP2K*) ( $P = 0.0001$ ), a serine/threonine protein kinase identified in 2001 as having a novel regulatory role in osteoblast differentiation. Compared to men who were homozygous for the major allele, men who were homozygous for the minor allele had 10% greater bone volume and 12% greater bone mineral content ( $P = 0.005$ ). Additional adjustments for body weight and height, to control for body size, did not alter these results. QCT volumetric and DXA areal BMD were not associated with this SNP. Three additional tagging SNPs in the *BMP2K* region were also associated with bone volume at  $P \leq 0.002$ . Our results suggest a potentially novel role of the *BMP2K* locus in the control of femoral bone size variation in men.

## M269

**Haplotype Specific Promoter Activity of the Human Frizzled 1 (FZD1) Gene.** Y. Zhang<sup>1</sup>, L. M. Yerges<sup>2</sup>, C. S. Nestlerode<sup>\*2</sup>, S. E. Hagerty<sup>\*1</sup>, J. M. Zmuda<sup>1</sup>. <sup>1</sup>Medicine, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

The Wnt signaling pathway has emerged as a therapeutic target in osteoporosis and influences human bone mass. Frizzled 1 (FZD1) is a trans-membrane receptor that mediates Wnt signaling. We have begun to characterize the human FZD1 sequence variants in the population by genetic association analysis and *in vitro* by functional analysis.

Bidirectional sequence analysis of the FZD1 promoter region identified two SNPs, a G/T and a G/C substitution, within 300 bp upstream from the translation start site in DNA from 48 men of African ancestry. These two SNPs are in high linkage disequilibrium ( $r^2=0.67$ ;  $D'=0.99$ ) and are both associated with DXA measures of BMD and cross-sectional area at the radius measured by peripheral quantitative computed tomography.

To begin to characterize the potential functional consequences of these common variants, we characterized the promoter activity associated with different haplotypes using a transient expression of a FZD1 reporter gene construct in osteoblast-like cell lines, MG63 and SaOS2. In agreement with our association study, the promoter consisting of both minor variants exhibited the highest activity while the promoter consisting of both major variants had the lowest level activity. To dissect the contribution of each polymorphism of this haplotype, we have begun to characterize allele specific promoter activities *in vitro*. We have identified Egr-1 dependent allele specific regulation of the FZD1 promoter associated with the G/C variant (see abstract by L Yerges et al at this meeting). For the G/T variant, enhanced protein binding was observed for the T allele specific DNA fragment in both MG63 and SaOS-2 cell lines using an electrophoretic mobility shift assay. *In silico* analysis of allele specific transcription factor binding revealed a high affinity consensus site for E2F1 for the minor T allele in comparison with the common G allele. The E2F family of transcription factors regulates an array of cellular functions including cell cycle progression, cell differentiation and apoptosis. E2F1, in particular, has been shown to be important in appendicular skeletal growth in transgenic mice. Thus, experimental verification of E2F1 binding to allele specific FZD1 promoter constructs is currently underway. Our results suggest that a common G/T polymorphism in the FZD1 promoter region may also contribute to the haplotype specific promoter activity of the FZD1 gene. Identification of the specific transcription factors that are responsible for this allele specific promoter regulation will be important for understanding the transcriptional regulation of FZD1 and its role in bone metabolism.

**Differential Regulation of Gene Expression by SNPs in the Osteonectin/SPARC 3' Untranslated Region (UTR): a Mechanism for Modulation of Bone Mass.** K. Kapinas<sup>1</sup>, E. S. Kurland<sup>2</sup>, C. B. Kessler<sup>\*1</sup>, A. M. Delany<sup>1</sup>. <sup>1</sup>Center for Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Division of Endocrinology, Columbia University College of Physicians & Surgeons, New York, NY, USA.

Osteonectin (ON) is a glycoprotein promoting matrix assembly, osteoblast differentiation, and survival. ON-null and -haploinsufficient mice display osteopenia and an aberrant response to intermittent PTH therapy. We reported 6 haplotypes (HAPs) consisting of 3 single nucleotide polymorphisms (SNPs) at cDNA bases 1046, 1599 and 1970 in the 3' UTR of the ON gene. The frequency of selected HAPs was associated with disease severity in Caucasian men with idiopathic osteoporosis (IOM). Here, we determined whether ON SNPs regulate gene expression, which may contribute to differences in bone density. Constitutively expressed luciferase-osteonectin 3' UTR reporter constructs were transiently transfected into the hFOB1.19 human osteoblastic cell line. The function of each HAP was assayed in the context of the entire 1.1 Kb ON 3' UTR (cDNA bases 1018-2123). The function of individual SNPs was assayed in the context of the 50 bases on either side of the SNP.

We found that HAP A (1046C\_1599G\_1970T), most frequent in severely affected IOM patients, showed the lowest level of reporter gene expression. In contrast, HAP B (1046C\_1599C\_1970T), more common in healthy controls ( $p < 0.01$ ) and associated with a higher tertile of bone density in IOM, had 2.5 fold greater gene expression compared with A ( $p < 0.01$ ). Individually, SNP 1599G, found in HAP A, repressed gene expression by 60% ( $p < 0.01$ ), whereas SNP 1599C, found in HAP B, stimulated gene expression by 50% ( $p = 0.05$ ). These data suggest that a negative regulatory element in the osteonectin 3' UTR is disrupted by a C at SNP1599.

HAP D (1046C\_1599C\_1970G) allowed slightly higher gene expression compared with HAP B (1046C\_1599C\_1970T) ( $p = \text{NS}$ ). Individually, SNP 1970T, found in HAP B, repressed gene expression by 85% ( $p < 0.01$ ), while SNP 1970G did not, suggesting that a negative regulatory element is disrupted by a G at SNP1970.

HAP E (1046G\_1599G\_1970T), associated with higher total hip density in IOM, had 3.5 fold greater gene expression than HAP A (1046C\_1599G\_1970T) ( $p < 0.01$ ). Individually, SNPs 1046C and 1046G each had modest, stimulatory effects on gene expression, suggesting that SNP1046 is not contained within an independent regulatory element. We hypothesize that it may modify the function of microRNA binding sites located 60 bases down stream in the UTR.

Overall, our data demonstrate that SNPs in the 3' UTR of the ON gene mediate differential regulation of gene expression. These findings suggest a genetic mechanism for the phenotypic association of ON 3' UTR SNP haplotypes with bone mass in IOM patients.

## M271

**Osteoprotegerin Production by Breast Cancer Cells Is Modulated by Steroid Hormones and Confers Resistance Against TRAIL-Induced Apoptosis.** T. D. Rachner<sup>\*1</sup>, M. Schoppert<sup>\*2</sup>, L. C. Hofbauer<sup>\*3</sup>. <sup>1</sup>Department of Medicine, Division of Gastroenterology and Endocrinology, Philipps-University, Marburg, Germany, <sup>2</sup>Department of Medicine, Division of Cardiology, Philipps-University, Marburg, Germany, <sup>3</sup>Department of Medicine, Division of Endocrinology and Bone Diseases, Technical University, Dresden, Germany.

Osteoprotegerin (OPG) is a secreted glycoprotein that acts as a decoy receptor for receptor activator of NF- $\kappa$ B ligand (RANKL) and TNF- $\alpha$  related apoptosis inducing ligand (TRAIL). While RANKL is an essential stimulator of osteoclastogenesis and promotes breast cancer migration into bone, TRAIL induces apoptosis of breast cancer cells. The role of the OPG/RANKL/TRAIL system for bone metabolism has been characterized in detail. However, its importance on breast cancer biology has remained elusive. First, we analyzed the expression and modulation of OPG and TRAIL by steroid hormones in estrogen receptor-positive MCF-7 cells and receptor-negative MDA-MB-231 cells using quantitative real-time polymerase chain reaction and ELISA. While pro-inflammatory cytokines IL-1 $\beta$  and TNF- $\alpha$  dose- and time-dependently increased OPG mRNA levels and protein secretion, dexamethasone suppressed OPG expression irrespective of the estrogen receptor status. 17 $\beta$ -estradiol and testosterone inhibited OPG expression in receptor-positive MCF-7 cells, but not in receptor-negative MDA-MB-231 cells. This inhibitory effect was fully reversed by the pure anti-estrogen ICI 182,780 and an aromatase inhibitor. Second, TRAIL dose-dependently activated pro-apoptotic caspases 3, 7, and poly-ADP-ribose polymerase (PARP) and decreased cell numbers of MDA-MB-231, but had no effect in MCF-7 cells. Of note, MDA-MB-231 abundantly expressed TRAIL mRNA. While the presence of IL-1 $\beta$  enhanced TRAIL mRNA expression by MDA-MB-231 cells, it was suppressed by dexamethasone. Gene silencing of OPG using siRNA resulted in a 31% higher rate of apoptosis, compared to non-target siRNA treated controls in MDA-MB-231. By contrast, TRAIL-induced apoptosis rate significantly decreased from 24.1% (in fresh medium) to 13.6% (in conditioned medium that contained OPG at 12.4 pmol/l;  $p < 0.05$ ). Furthermore, a direct correlation between cell survival and OPG levels in the supernatant of MDA-MB-231 was observed, when OPG secretion was modulated using IL-1 $\beta$  (10 ng/ml) or dexamethasone ( $10^{-8}$  M) prior to TRAIL exposure ( $p < 0.05$ ). In conclusion, OPG secretion by breast cancer cells is modulated by cytokines and steroid hormones and may represent an important mechanism conferring resistance against the autocrine pro-apoptotic effect of TRAIL. Interference with the OPG/TRAIL system could become a novel therapeutic target.

Bone is the preferential site of distant metastases in breast carcinoma (BrCa). It is possible, based on clinical features, to stratify bone metastatic breast cancer patients, in two groups: 1) patients with bone-only metastases (BO), who frequently have a better overall survival, and 2) patients with metastases in bone and visceral organs (BV), who have a worse clinical outcome. We performed a microarray analysis with the Affymetrix platform on bone metastasis samples from BO and BV patients. We evaluated the profiles obtained using an unsupervised clustering and showed that transcriptomes correlated with the clinical features, segregating BO from BV profiles. In order to obtain a BV gene signature, a statistical analysis was performed to identify the 2-fold regulated genes in BV samples relative to BO samples. This analysis revealed 100 up- and 18 down-regulated genes in BV vs. BO ( $p < 0.05$ ). However, this gene signature was validated by real time RT-PCR analysis only for 66% of the genes selected for evaluation. This result was unexpected and prompted us to perform another microarray analysis of BO and BV samples using the Agilent platform. We then matched the Affymetrix signature with the most regulated genes in the Agilent profiles and found 15 genes (13 up-, 2 down-regulated) commonly modulated in BV vs. BO in both platforms, also validated by real time RT-PCR. These genes perhaps represent the most reliable gene set segregating BV from BO. We clustered these genes by the Gene Ontology Tree Machine software, which allowed us to identify the related biological processes and molecular functions. We observed up-regulation of many processes involved in oxygen transport, plus additional processes associated with fatty acid metabolism, gametogenesis and circulation. In conclusion, this study evidenced a group of genes that are likely to characterize breast cancer patients with bone-only metastases from those who also developed multiple metastases. Our results provide a rationale for setting custom-made gene arrays for diagnostic and prognostic purposes.

**A Humanized Model of Breast Cancer Metastasis Revealing a Human-Specific Metastasis Gene Signature.** R. Goldstein<sup>\*1</sup>, K. Anderson<sup>\*2</sup>, M. Rosenblatt<sup>2</sup>. <sup>1</sup>Genetics Program, Tufts University Sackler School of Biomedical Sciences, Boston, MA, USA, <sup>2</sup>Department of Physiology, Tufts University School of Medicine, Boston, MA, USA.

The skeletal complications of malignancy represent some of the most serious complications associated with cancer, signaling the entry of the disease into an incurable phase. Despite many recent advances in cancer research and therapy, there remains a need for a better understanding of the metastatic spread of cancer from its primary location to distant "soils" within the body. Animal models are critical to the understanding of the complexities of tumor metastasis. Through creation of an animal model that is more representative of human pathophysiology, it should be possible to elucidate the genetic alterations that are required for cancer migration from orthotopic locations to distant sites. Further, clinical observations indicate that organ and stromal environments greatly influence the response of tumors to chemotherapy, suggesting that orthotopic implantation of tumor cells in animal models can recapitulate the process of cancer metastasis to bone. Currently, orthotopic implantation of cancer cells is not widely used in animal modeling. Work in our lab has developed a humanized orthotopic injection model of breast cancer metastasis. We use SUM1315 breast cancer cells injected into the murine mammary fat pad. Subsequently, metastases to subcutaneously implanted human bone cores develop. When compared to results obtained from an intracardiac injection model of cancer metastasis to murine bone, results from our gene array studies and genetic profiling have illuminated a novel metastatic gene signature. While different in specific gene identities (intracardiac signature = MMP1, IL-11, CTGF, and CXCR4; orthotopic signature = MMP13, IL-17BR, and HUNK), the two signatures contain genes of overlapping function (ie homing, invasion, angiogenesis and osteolysis). Comparison of the expression levels of the specific gene signatures across different breast cancer cell lines used in the intracardiac or the orthotopic injection models of breast cancer metastasis using qRT-PCR, provides the basis for our hypothesis, suggesting that the humanized animal model of breast cancer metastasis provides a novel, human-species specific, metastatic gene signature.

**Local Administration with Paclitaxel-loaded Hydroxyapatite-alginate Beads for Metastatic Spine Cancer in Rats.** T. Abe<sup>1</sup>, M. Sakane<sup>1</sup>, T. Ikoma<sup>\*2</sup>, M. Kobayashi<sup>\*3</sup>, N. Ochiai<sup>\*1</sup>. <sup>1</sup>Orthopedic Surgery, University of Tsukuba, Tsukuba, Japan, <sup>2</sup>National Institute for Materials Science, Tsukuba, Japan, <sup>3</sup>Innovation Satellite Ibaraki, Japan Science and Technology Agency, Tsukuba, Japan.

Breast cancer is one of the most common cancers to develop metastasis to bone. Among these patients, 5-10% did not respond to treatment and developed metastatic epidural spinal cord compression. Paralysis caused by spinal cord compression is directly associated with survival and the quality of life of breast cancer patients. Thus, local control of metastatic site is very important for metastatic spine cancer. We have shown the anti-tumor effect of 2.4wt% of paclitaxel (PTX)-loaded Hydroxyapatite (HAP)-alginate beads, previously. This study was made to clarify the effects of the 21wt% of PTX-loaded HAP-alginate beads administered therapeutically in a rat model of metastatic spine cancer. Rat's mammary adenocarcinoma (the CRL-1666 cell line) and female Fischer 344 rats (8 weeks old) weighing 130-150 grams were used. The PTX-loaded HAP-alginate beads were prepared by a spray-drying method and the gelation with alginate acid followed by drying at room temperature for 24 h. A 21 wt% of PTX was contained in each HAP-alginate bead with a diameter of approximately 1.7 mm. We performed surgery to obtain metastatic spine cancer model in rats. Twelve animals with metastatic spine cancer were divided into 2 groups. We checked hind-limb motor function and survival time using the BBB scale. The mean disease-free time (DFT) of the local-treatment group (n = 6) and the control group (n = 6) was 15.6 days and 10.8 days, respectively. The DFT in the local-treatment group was significantly longer than that in the control group. The mean survival time of the local-control group and the control group was 21.8 days and 16.0 days, respectively. The survival time in the local-treatment group was also significantly longer than that in the control group. This report documents that the local administration of the PTX-loaded HAP-alginate beads showed significant delay in the DFT and survival time. But the anti-tumor effect was not correlated with increase of the amount of PTX loaded into HAP-alginate beads. PTX loaded into HAP-alginate beads offers promise as a local treatment for patients with metastatic spine cancer to improve the quality of life. Further investigation of pharmacokinetics of the PTX-loaded HAP-alginate beads is needed.

**c-Src-regulated Osteoblast-mimicry in Breast Cancer Bone Metastasis: The Role of RAMP2 and BSP2.** B. Peruzzi<sup>\*</sup>, A. Del Fattore<sup>\*</sup>, A. Cappariello<sup>\*</sup>, M. Longo<sup>\*</sup>, N. Rucci, A. Teti. Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

Bone tissue represents the preferential target for metastatic colonization by breast cancer cells, which lead to osteolytic lesions. We compared data derived from large-scale gene expression profiles of bone versus visceral metastases of human breast ductal carcinomas, and identified two typical osteoblast genes (RAMP2 and BSP2) over-expressed in the former. Therefore we hypothesized that these genes could cause an osteoblast-mimicry of breast cancer cells. It is well known that the tyrosine-kinase c-Src plays a crucial role both in osteoblast physiology and in bone metastasis progression. Since we noted a modulation of the two genes in the transcriptomes of primary mouse calvarial osteoblasts treated with a c-Src inhibitor (PP1), we also investigated the involvement of c-Src in cancer cell osteoblast-mimicry. To this aim, we assessed expression of the two genes in highly (MDA-MB-231) and moderately (MCF-7) osteotropic human breast cancer cell lines in which c-Src was down-regulated by various treatments (PP1, small-interference RNA and transfection of a dominant negative variant). In each condition, we found modulation of the two genes in MDA but not in MCF-7 cells, indicating a c-Src regulation of osteoblast-mimicry only in tumor cells with high affinity to bone. To investigate whether the two genes were involved in typical osteoblast-like functions, we transfected MDA cells with expression vectors carrying BSP2 or RAMP2 cDNAs and found no modulation of genes involved in bone formation. However, the expression of cytokines, such as RANKL, osteoprotegerin, TNFalpha, IL6 and IL1beta, was changed in a manner favoring the osteoclastogenic process. Moreover, we treated mouse calvarial osteoblast cultures with conditioned media from transfected MDA cells and found the same pattern of modulation of osteoclastogenic cytokine expression. We then analyzed the osteoclastogenic potential in mouse bone marrow cell cultures treated with conditioned media from transfected MDA cells and found a significant increase of osteoclast number and activity in both BSP2- and RAMP2-transfected cells versus empty vector-transfected cells. Finally, we characterized the malignant phenotype of BSP2- and RAMP2-transfected MDA cells, finding no significant changes in proliferation, migration and cell survival versus empty vector-transfected MDA cells. In conclusion, we have obtained evidence of a c-Src-regulated osteoblast-mimicry in highly osteotropic breast cancer cells, in which the osteoclastogenic potential is enhanced by over-expression of RAMP2 and BSP2.

**Potential Anti-Invasion Activity of Cathepsin K Inhibitors for the Treatment of Breast Cancer-Induced Bone Metastasis.** M. Pickarski, P. Leung<sup>\*</sup>, G. A. Wesolowski, L. T. Duong. Molecular Endocrinology, Merck & Co., Inc, West Point, PA, USA.

Cathepsin K (Cat K) is highly expressed in osteoclasts and plays a critical role in bone collagen degradation. Bone metastasis is often initiated by tumor-induced bone resorption, providing a favorable environment for cancer growth. It is widely accepted that MMPs and serine proteases degrade extracellular matrices and facilitate neoplastic progression. Recent evidence supports the role of the cysteine cathepsins during pericellular proteolysis in tumor invasion. In this study, we examine the direct role of Cat K in tissue invasion by breast cancer cells. We previously reported efficacy of the Cat K inhibitor (Cat Ki) L-006235 in the prevention of osteolysis and reduction of tumor burden in the intratibial engraftment model of MDA-MB-231 breast carcinoma in nude rats. In addition, L-006235 was found to inhibit local invasion of micrometastases. Here, Cat K protein is highly expressed in breast and prostate tumors at levels comparable in osteoclasts or osteoclastomas. From a cancer tissue array study, Cat K protein is detected in ~45% of breast and >75% of prostate primary tumors. Its mRNA expression increases 3-fold in metastatic tissue as compared to pair-matched primary tumors, implicating Cat K in tumor metastasis. We show that proliferation, senescence and migration in human breast and prostate cancer cell lines are not changed by selective inhibitors of Cat K, including odanacatib (MK-0822). While stable transfection of rabbit Cat K in MDA-231 cells (MDA-CatK) results in ~1000-fold increase in mRNA, protein levels increase merely 2-fold over parental cells. Moreover, Cat K is present in the pro-form (39kDa) as undetectable, mature, active enzyme (27kDa), suggesting that additional engagement is required for activation. Using a Cat K fluorogenic substrate, MDA-CatK shows punctate staining around cell nuclei while activity in parental cells is less abundant and more diffuse. In the matrigel invasion assay, MDA-CatK shows a significant increase (89%) in basal invasion compared to parental cells. While the non-selective cathepsin inhibitor E64d inhibits MDA-231 cell invasion with IC<sub>50</sub> of 4.4μM, L-006235 and MK-0822 inhibit cell invasion with IC<sub>50</sub>s of 4nM and 11nM, respectively, which is comparable to their potencies in blocking rabbit osteoclastic bone resorption, with IC<sub>50</sub>s of 5nM and 23nM, respectively. Overall, elevated expression of Cat K in subsets of breast and prostate cancers, and its putative role in tumor cell invasion suggest that Cat Ki therapy may reduce visceral metastasis in these patients. The data also suggest that an oral, potent and reversible Cat Ki with dual antiresorptive and anti-invasive properties may present a more effective therapy for the treatment of bone metastasis.

**Opposing Effects on Bone Metastases of Tumor Adrenomedullin Expression in Breast and Prostate Cancer.** V. A. Siclari<sup>1</sup>, K. S. Mohammad<sup>2</sup>, T. A. Guise<sup>2</sup>, J. M. Chirgwin<sup>2</sup>. <sup>1</sup>Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA, USA, <sup>2</sup>Endocrinology, University of Virginia, Charlottesville, VA, USA.

Adrenomedullin (AM) is a peptide secreted by cancer cells that stimulates osteoblasts and new bone formation. AM overexpression in prostate cancer cells increased bone metastases in mice, while siRNA knockdown (k/d) of AM in lung adenocarcinoma cells decreased bone lesions. We hypothesized that decreasing AM expression in breast cancer cells would similarly suppress bone metastases.

Bone-metastatic MDA-MB-231 breast cancer cells were transfected with an AM shRNA expression vector or scrambled control. Single-cell clones were tested for AM knockdown (>90%) by real-time PCR. Clonal stability was assured by culturing in the absence of antibiotic selection for 60d. Two stable AM k/d and two control clones were injected into the left cardiac ventricle (n=12/group) and the mammary fat pad (MFP) (n=10/group) of nude mice. Bone lesions were monitored by x-ray over 5 wks. AM k/d cells caused greater osteolytic lesion area (17.9 vs 4.8 mm<sup>2</sup> at 5 wks; p<0.0001) than scrambled control cells. However, AM k/d decreased tumor take (2.5% vs 64.3%; p<0.0001) and growth (0.5 vs 126.4 mm<sup>3</sup> on d 26) when injected into the MFP. These responses are opposite to those seen in a PC-3 prostate cancer model, where AM overexpression increased osteolytic lesions and decreased growth of subcutaneous xenografts.

MDA-MB-231 clones (2) with AM k/d showed decreased IL-11 and ET-1 mRNA expression *in vitro* but no change in Cyr61, CTGF, IL-8, PTHrP, or IL-6 mRNAs compared to 2 control clones. Decreased IL-11 or ET-1 mRNAs were not rescued by exogenous AM peptide, suggesting an intracrine action of AM. No significant cell morphological differences were noted by microscopy. Osteoclast, osteoblast and CD31+ endothelial cells numbers and tumor burden will be assessed by histomorphometry.

The responses of breast cancer cells to reduction of AM expression were opposite to those found previously with A549 lung and PC-3 prostate models. In addition, the effects of changed tumor expression of AM have opposite effects on tumor burden in bone versus at soft tissue sites. This converse effect was noted in both breast and prostate models, suggesting that AM is a Jeckle & Hyde factor, whose active personality changes with both tumor type and microenvironment. AM acts on many cell types, including bone, tumor and endothelial cells, altering angiogenesis, tumor growth, apoptosis, and bone, which may account for tumor-type-specific responses to AM in bone metastasis. AM receptor antagonists are in preclinical development. They may be effective only against certain tumor types in specific locations and will need to be used with caution.

**Wnt Signaling Regulates Gli2 and PTHrP Expression in Human Breast Cancer Cells that cause Osteolysis.** R. W. Johnson<sup>\*1</sup>, J. A. Sterling<sup>1</sup>, X. Li<sup>\*2</sup>, A. Roberts<sup>\*1</sup>, N. Bhowmick<sup>\*2</sup>, G. R. Mundy<sup>1</sup>. <sup>1</sup>Center for Bone Biology, Vanderbilt University, Nashville, TN, USA, <sup>2</sup>Department of Urologic Surgery, Vanderbilt University, Nashville, TN, USA.

One of the major mediators of tumor-induced bone destruction is parathyroid hormone-related peptide, PTHrP. Our previous studies have demonstrated that tumor cells that stimulate osteoclast-mediated bone destruction and express PTHrP express the Hedgehog (Hh) signaling transcriptional activator, Gli2. However, our recent data has shown that Hh is not responsible for increasing Gli2 or PTHrP expression, indicating that Gli2 and PTHrP are regulated independently of Hh. Other laboratories have demonstrated that Gli2 expression can be regulated by Wnt signaling during development, and that Wnt signaling is important in metastasis and tumor progression. Based on these observations, we hypothesized that Wnt expression by tumor cells may regulate Gli2 expression and subsequent PTHrP expression in breast cancer cells that are associated with osteolysis. To test this hypothesis, we first examined the human metastatic breast cancer cell line, MDA-MB-231, for the effects of Wnt signaling on Gli2 and PTHrP expression. To do this, we over-expressed the downstream mediator,  $\beta$ -catenin, in the MDA-MB-231 cells and performed Real-time PCR using Gli2 specific primers to determine if Wnt signaling regulates Gli2 expression. We found that  $\beta$ -catenin expression increased Gli2 expression by 2-fold. In addition to assessing Gli2 expression, we also determined both PTHrP promoter activity and expression. We found that  $\beta$ -catenin increased PTHrP promoter activity by greater than 3.5-fold. Interestingly, ICAT expression decreased Gli2-mediated PTHrP promoter activity by 50%, suggesting that Gli2-mediated regulation of PTHrP is at least in part  $\beta$ -catenin dependent, and that  $\beta$ -catenin regulates basal PTHrP secretion by the tumor cells. Real-time PCR confirmed that  $\beta$ -catenin increased and ICAT decreased endogenous PTHrP expression. In addition, treatment with a virally expressed soluble frizzled receptor protein 2 (sFRP2) decreased PTHrP expression. Finally, we found that these cells expressed Wnt 3,3a, 5a, 7a, 7b, 10b, and 16, consistent with an autocrine role for Wnt signaling in these cells. Taken together, these studies are consistent with an important role for Wnt signaling in the regulation of Gli2 and PTHrP expression in human breast cancer cells, which in turn drives PTHrP expression and causes osteolytic bone destruction. Inhibition of Wnt signaling *in vivo* may be a rational therapeutic approach to decreasing Gli2 expression and subsequent PTHrP expression and tumor-induced osteolysis.

J. van Wijnen<sup>1</sup>, J. L. Stein<sup>\*1</sup>, G. S. Stein<sup>1</sup>, J. J. Westendorf<sup>2</sup>, J. B. Lian<sup>1</sup>. <sup>1</sup>Depts. of Cell Biology, Orthopedic Surgery and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, <sup>2</sup>Depts. of Orthopedic Surgery and Molecular Biology, Mayo Clinic, Rochester, MN, USA.

Histone deacetylase inhibitors (HDIs) suppress the expression and/or enzymatic activities of a subset of deacetylases. HDIs alter expression of genes that control cell survival, proliferation, differentiation and migration. Tumor cells with defects in the G2/M cell cycle checkpoint undergo apoptosis in response to HDIs. Vorinostat is an oral HDI with anti-tumor activity in preclinical cancer models and is in phase I and II clinical trials for hematological and solid tumors. The effects of Vorinostat on skeletal metastases and normal bone tissue have not been described. We and others previously showed that several HDIs promote *in vitro* osteoblastic differentiation. Here, we tested effects of Vorinostat on both tumor growth and osteolytic lesions formed by prostate (PC-3) and breast (MDA-MB-231) tumor cells injected into tibias of SCID mice, and on health of the normal skeleton. Tumors cells were injected into mouse tibia one week prior to administering Vorinostat (100 mg/kg, i.p., daily for three (PC3) to seven (MDA-231) weeks). Mice were sacrificed when osteolysis became severe. MRI studies showed that Vorinostat significantly reduced tumor growth within the bone by approximately 33%. Radiographs and micro-CT analysis showed that the osteolytic bone disease was also reduced in accord with lower tumor burden. These results are consistent with decreased expression of Runx2 and their metastatic target MMPs, demonstrated by *in vitro* treatment of TSA (at 50 nM) in both PC-3 and MDA-MB-231 which express high endogenous levels of Runx2 and metastatic related genes. Surprisingly, the contralateral femurs showed significant loss of bone volume density (50%) after just three weeks of Vorinostat therapy. We hypothesize that there are selective effects of HDIs on normal osteoblast lineage cells compared to metastatic cancer cells *in vitro* and within bone. Several mechanistic pathways can account for these findings that have clinical relevance in the long-term use of Vorinostat in cancer patients. For example, increased osteoclastic resorption could be related to stimulated osteoblast activity from the HDIs and/or HDIs might prevent survival or expansion of osteoblast progenitor cells. Our studies indicate that Vorinostat is effective at inhibiting cancer growth in bone and osteolytic disease. Anti-resorptive therapy could be used to prevent therapy-induced bone loss throughout the skeleton.

**Effects of Extracellular Matrix Properties and Elastic Modulus on the Expression of parathyroid hormone-related peptide (PTHrP) by Human Breast Cancer Cells.** N. S. Ruppender<sup>\*1</sup>, J. A. Sterling<sup>2</sup>, J. S. Nyman<sup>2</sup>, J. F. O'Keefe<sup>\*1</sup>, G. R. Mundy<sup>2</sup>, S. A. Guelcher<sup>\*1</sup>. <sup>1</sup>Vanderbilt University Chemical Engineering, Nashville, TN, USA, <sup>2</sup>Vanderbilt University Center for Bone Biology, Nashville, TN, USA.

When breast cancer cells metastasize to bone, they change their gene expression patterns and express PTHrP (Southby et al, 1991). The reason is unknown. We hypothesized that in the bone microenvironment, expression of osteoclastogenic factors such as PTHrP by the tumor cells is up-regulated due to the increased stiffness of the mineralized bone ECM. To test this, we created substrates to mimic the biomechanical properties of bone, and tested these for effects on PTHrP expression by the human breast cancer cell line, MDA-MB-231. Model soft and hard polyurethane (PUR) substrates were synthesized with elastic moduli of 0.05 GPa and 1.2 GPa, which mimic the estimated moduli of soft tissue (such as breast and liver) and bone, respectively. Briefly, a lysine diisocyanate prepolymer was mixed with a polyester triol or diol for 15 s, cast in the wells of a 6-well tissue culture plate, and cured at 37C for 24h. The modulus was measured by compression testing. MDA-MB-231 human breast cancer cells were cultured on the PUR substrates in 1X DMEM containing 10% heat inactivated fetal calf serum (FCS) for 48 hours. Tissue culture polystyrene (TCPS, ~2 GPa) served as a control substrate which has a modulus near the low end of the range for cortical bone. Cell morphology was observed at the 4, 24 and 48 hour time points via microscopy. Expression of PTHrP was measured by real-time PCR. Since cell attachment to substrates may also influence expression patterns, some substrates were treated with fibronectin (Fn+) prior to cell seeding. While cells seeded on TCPS (Fn+ and Fn-) and PUR substrates treated with Fn exhibited a flat morphology, cells seeded on Fn- PUR substrates were more rounded and not as well attached. For the Fn- treatment groups, expression of PTHrP for TCPS and hard PUR substrates was greater than that observed for the soft PUR substrate. For the Fn+ treatment groups, PTHrP expression was also observed to be significantly less for soft PUR substrates compared to TCPS. These data suggest that the stiffness of the substrate has a significant effect on the expression of PTHrP, either in the presence or absence of Fn. In conclusion, MDA-MB-231 human breast cancer cells respond to substrates with increasing stiffness by increasing PTHrP expression. These effects may explain in part the enhanced expression of PTHrP described in breast cancer cells that have metastasized to bone.

**A Plasma Proteomic Profile that Predicts Breast Cancer Metastasis to Bone.** S. Byrum<sup>1</sup>, K. Leitzel<sup>\*2</sup>, S. M. Ali<sup>\*2</sup>, A. Lipton<sup>\*2</sup>, L. J. Suva<sup>1</sup>.<sup>1</sup>Orthopaedic Surgery, UAMS, Little Rock, AR, USA, <sup>2</sup>Penn State/Hershey Medical Center, Hershey, PA, USA.

Bone is a common site for the spread of breast cancer. The identification of a highly discriminatory plasma protein profile could provide a tool for the early detection of bone metastasis. The purpose of this study was to identify a protein signature indicative of breast cancer metastasis to bone. Plasma was obtained from 76 breast cancer patients treated with second-line hormone therapy: 38 patients with clinical evidence of bone metastasis and high levels of the resorption marker N-Telopeptide (NTx), and 38 patients with no clinical evidence of bone metastasis and low levels of NTx. Samples were analyzed in duplicate on weak cation-exchange (CM10) arrays using surface-enhanced laser desorption ionization time-of-flight mass spectrometry (SELDI-TOF MS) in three mass ranges: low 1.5 - 10 KD, mid 7 - 30 KD, and high 25 - 150 KD. All spectra were baseline corrected, normalized to the total ion current, log<sub>2</sub> transformed, and analyzed by analysis of variance (ANOVA), principle component analysis (PCA), random forest (RF), classification and regression trees (CART), and See5. The multivariate statistical analysis and data mining procedures ultimately resulted in the detection of thirteen specific protein peaks (MW ranging from 4.1-39.1kDa) that optimally separated the two groups with a high degree of significance (p<0.05). In all, 11 peaks were increased and 2 peaks were decreased in plasma of breast cancer patients with bone metastasis compared to breast cancer patients without bone metastasis. The plasma protein profile identified was independently validated in a blinded fashion using a second set of anonymous plasma samples from 20 patients with and 20 patients without bone metastasis; 11 of the original 13 protein peaks identified were confirmed. Importantly, one protein peak found in the plasma of bone metastasis patients was identified as parathyroid hormone-related protein (PTHrP), a tumor-derived factor expressed in a majority of bone metastasis of breast cancer. SELDI-TOF MS analysis has identified and confirmed a plasma protein profile that distinguishes breast cancer patients with and without bone metastasis. Further elucidation of the identity of these proteins has value for the early diagnosis of breast cancer bone metastasis.

**Zoledronate Protects Bone but not Soft Tissue from Prostate Cancer Progression in a Nude Mouse Model.** R. L. Fitzgerald<sup>1</sup>, D. W. Burton<sup>2</sup>, T. L. Griffin<sup>\*3</sup>, D. J. Hillegonds<sup>4</sup>, D. A. Herold<sup>\*1</sup>, L. J. Deftos<sup>2</sup>. <sup>1</sup>Pathology, VA Medical Center/UCSD, San Diego, CA, USA, <sup>2</sup>Medicine, VA Medical Center/UCSD, San Diego, CA, USA, <sup>3</sup>Pathology, VA Medical Center, San Diego, CA, USA, <sup>4</sup>Center for Accelerator Mass Spectrometry, Lawrence Livermore National Laboratories, Livermore, CA, USA.

**Background:** Metastatic bone disease is one of the major causes of morbidity and mortality in prostate cancer patients. Bisphosphonates are currently used to inhibit bone resorption and reduce tumor induced skeletal complications. While widely used with good clinical efficacy, the dynamics of prostate cancer growth and progression after bisphosphonate treatment are somewhat unclear, as there are reports in animal models that indicate the bisphosphonates can increase the incidence of metastases to soft tissues.

**Methods:** Prostate tumor growth was studied using PTHrP-expressing PC-3 GFP cells that were injected into the tibiae of immunocompromised mice. The controls received saline injections and no tumor implantation (Saline/Saline, N=6). The second group received saline and tumor implantation (Saline/Tumor, N=5) and the third group of animals received zoledronate and tumor implantation (ZOL/TumorN=4). The effects of zoledronate on tumor growth in bone and outside of the bone microenvironment were evaluated fluorometrically, radiologically and histologically.

**Results:** Zoledronate protected bone from tumor mediated destruction but demonstrated a significant increase in fluorescence once the cancer expanded beyond the bone as compared to the saline treated group (see Figure below). At the end of the study, x-ray data demonstrated a significant reduction in the severity of bone lesions in the zoledronate group compared to the saline group. The histology of the tumors demonstrated more condensed nuclei in the saline group compared to the zoledronate treated group.

**Conclusions:** We showed that zoledronate was effective in reducing the severity of the bone lesions but not tumor burden outside of the bone in animals treated with PTHrP-expressing prostate cancer cells

**Figure Legend:** Prostate cancer tumor growth curves in mice implanted with PC-3-GFP cells. Fluorescent images were quantitated for GFP (sum of the pixels) as an index of tumor mass and normalized to an external fluorescent standard. The asterisks represent significant differences ( $P < 0.05$ ) between the tumor bearing mice treated with zoledronate (ZOL) vs. saline.

**Prevention of Aromatase Inhibitor-Associated Bone Loss in Women with Breast Cancer: Practical Guidance.** P. Hadji<sup>1</sup>, M. Aapro<sup>\*2</sup>, A. Brufsky<sup>\*3</sup>, M. Tubiana-Hulin<sup>\*4</sup>, T. Guise<sup>5</sup>, J. Body<sup>\*6</sup>. <sup>1</sup>Philipps-University of Marburg, Marburg, Germany, <sup>2</sup>Institut Multidisciplinaire d'Oncologie, Genolier, Switzerland, <sup>3</sup>University of Pittsburgh, Pittsburgh, OH, USA, <sup>4</sup>Centre René Huguenin, St-Cloud, France, <sup>5</sup>University of Virginia, Charlottesville, VA, USA, <sup>6</sup>Université Libre de Bruxelles, Brussels, Belgium.

American Society of Clinical Oncology guidelines recommend that women with breast cancer (BC) and osteoporosis (T-score < -2.5) be treated with bisphosphonates and that osteopenic women (T-score -1 to -2.5) receive individualized therapy. However, the majority of fractures occur in osteopenic women. Therefore, the osteoporosis (T-score < -2.5) threshold may be inadequate to avert fractures in patients with BC, particularly those being treated with aromatase inhibitors (AIs). Because bone mineral density (BMD) testing is not readily available to all patients, guidance is required to assess fracture risk and select treatment with/without BMD scores. A systematic literature review was performed to identify factors contributing to elevated fracture risk in women with BC. Risk factors were evaluated by an evidence-based medicine approach to identify patients at high risk, to determine when to initiate bisphosphonate therapy, and to identify the appropriate bisphosphonate for use.

Fracture risk factors (other than AI therapy) were identified based on their validation in large, prospective, population-based studies. Risk factors in women with BC were AI therapy, T-score 65 yr, family history of hip fracture, personal history of fragility fracture after age 50, oral corticosteroid use for > 6 mo, or body mass index < 20. Additional risk factors for which guidance could not be provided because of insufficient data included diagnosis of BC, chemotherapy, radiotherapy, low weight, and smoking. Currently available data clearly suggest that combined risk factors indicate fracture risk independent of BMD and that osteoporosis need not precede fracture. BMD measurement should therefore not be the sole criterion to assess fracture risk in women with BC. Randomized clinical trials in patients at risk for fracture support the use of zoledronic acid (4 mg every 6 mo) to prevent AI-associated bone loss when a patient is identified to be at risk. Data with other bisphosphonates are emerging.

We recommend that any patient initiating AI therapy with T-score < -2.0 should receive zoledronic acid (4 mg every 6 mo) in addition to calcium and vitamin D supplements. Zoledronic acid should also be used in patients with any 2 of the following: T-score < -1.5, age > 65 yr, family history of hip fracture, personal history of fragility fracture after age 50, and oral corticosteroid therapy > 6 mo.

**Phthalein Monophosphates Are Specific Substrates for Tartrate-Resistant Acid Phosphatase 5b.** B. Houston<sup>1</sup>, H. Ylipahkala<sup>2</sup>, J. M. Halleen<sup>3</sup>, D. Laurie<sup>1</sup>. <sup>1</sup>Immunodiagnostic Systems (IDS) Ltd, Boldon, United Kingdom, <sup>2</sup>SBA Sciences Ltd, Oulu, Finland, <sup>3</sup>Pharmatest Services Ltd, Turku, Finland.

Tartrate-resistant acid phosphatase 5b (TRACP5b) is secreted exclusively by osteoclasts. The level of TRACP5b in serum is a measure of osteoclast abundance and hence an indirect indicator of bone resorption. Measurement of TRACP5b in serum is complicated by the presence of an approximately 10-fold molar excess of TRACP5a, produced principally by macrophages and dendritic cells. An existing commercial immunoassay for TRACP5b involves the capture of TRACP5 by an immobilised antibody, followed by an activity measurement at a pH where the specific activity of TRACP5b is around 10x that of the TRACP5a. In seeking to transfer this assay onto the IDS Automated Analyser 3X3™, we encountered problems relating to the stability of the substrate pNPP. This led us to examine the utility of phthalein monophosphates (PMs) as TRACP5b substrates.

We examined the abilities of human serum-derived TRACP5a and TRACP5b (separated by chromatography on CM-Sepharose), and baculovirus-derived recombinant human TRACP5, to hydrolyse PMs. All TRACP5 preparations hydrolysed phenolphthalein monophosphate (PTMP) and thymolphthalein monophosphate (TTMP). We observed dramatic differences between the pH optima of these preparations with the PM substrates compared to those determined with pNPP. For example, using PTMP the pH optima of TRACP5a and TRACP5b were around 6.0 and 7.0 respectively. These values are markedly higher than those obtained using pNPP (4.9 and 5.9 respectively).

We next established an immunoassay for TRACP5 in which the enzyme activity was measured using PTMP at pH 7.0, and compared this with the commercial immunoassay using pNPP at pH 6.1. Typical specific activities obtained for the native TRACP5 forms were: TRACP5a (PTMP); 0.035 U/μg; TRACP5a (pNPP); 0.177 U/μg; TRACP5b (PTMP); 1.68 U/μg; TRACP5b (pNPP); 1.60 U/μg. These data indicate that while the PTMP- and pNPP-based assays detect similar amounts of TRACP5b, the PTMP-based assay detects only 20% of the TRACP5a detected by the pNPP-based assay. On a panel of 32 patient samples there was an excellent correlation between the PTMP and pNPP-based assays ( $R^2 = 0.96$ ). The values obtained with the PTMP-based assay were slightly lower than those obtained using the pNPP-based assay ( $y=1.09x-0.62$ ), consistent with the former experiencing less interference by TRACP5a.

Our results demonstrate that phthalein monophosphates are more specific substrates for TRACP5b than pNPP and related compounds, by providing an assay where the specific activity of TRACP5b approaches 50x that of TRACP5a. They also reveal that TRACP5 is not intrinsically an acid phosphatase, but that the pH optimum of the enzyme is dependent upon the substrate.

**Bone Turnover and Incident Hip Fracture Risk: The Women's Health Initiative (WHI).** D. C. Bauer<sup>1</sup>, S. Harrison<sup>2</sup>, R. Jackson<sup>3</sup>, M. LeBoff<sup>4</sup>, J. Robbins<sup>5</sup>, N. Greep<sup>6</sup>, A. LaCroix<sup>7</sup>, J. A. Cauley<sup>8</sup>. <sup>1</sup>UCSF, San Francisco, CA, USA, <sup>2</sup>CPMC, San Francisco, CA, USA, <sup>3</sup>Ohio State University, Columbus, OH, USA, <sup>4</sup>Brigham and Women's Hospital, Boston, MA, USA, <sup>5</sup>UC Davis, Sacramento, CA, USA, <sup>6</sup>UC Irving, Irving, CA, USA, <sup>7</sup>Fred Hutchinson, Seattle, WA, USA, <sup>8</sup>University of Pittsburgh, Pittsburgh, PA, USA.

Elevated bone turnover is associated with an increased risk of fracture in some, but not all, prospective studies of older women. To determine if bone turnover predicts hip fracture risk in community dwelling women, we performed a nested case-control study in the WHI Observational Study Cohort. We excluded women with previous hip fracture and those who used hormones or other osteoporosis medications. A total of 39,793 women met these criteria. We randomly chose 400 women with incident hip fractures confirmed by central review of medical records. A control was selected for each case, matched on baseline age, race/ethnicity and date of blood draw. A marker of bone resorption,  $\beta$ CTX (Roche Diagnostics), and a marker of bone formation, PINP (Roche Diagnostics), were measured in a single batch at a core laboratory (Synarc, Lyon) using archived fasting serum drawn at baseline. We used conditional logistic regression models that account for the matched case-control design to estimate the odds ratio (OR) and 95% confidence intervals (CI) per SD increase in marker, and across quintiles (defined by the distribution in controls) with p values for tests of linear trend. We adjusted for other risk factors associated with both hip fracture and bone turnover (age, BMI, smoking and corticosteroid use), but unadjusted results were similar. The mean age of cases and controls was 70.8 years; 95% were White. Mean  $\beta$ CTX levels were higher among cases than controls ( $0.446 \pm 0.206$  vs.  $0.412 \pm 0.187$  ng/ml,  $p=0.02$ ), but were similar for PINP ( $51.0 \pm 23.0$  vs.  $49.0 \pm 20.4$  ng/ml,  $p=0.2$ ). Higher quintiles of  $\beta$ CTX were associated with increased hip fracture risk ( $p$ -trend = 0.05)(Figure). Compared to women in the lower 4 quintiles of  $\beta$ CTX, hip fracture risk was elevated among those in the highest quintile ( $>0.546$  ng/ml, OR = 1.49, 95% CI: 1.04, 2.16). PINP was not associated with hip fracture risk ( $p$ -trend = 0.43). BMD was not available in the full cohort. Our results suggest that elevated  $\beta$ CTX, but not PINP, is associated with a modest increase in hip fracture risk in older women, but the relationship may be too weak to be useful as an independent clinical risk factor for hip fracture.

**Stability of TRACP 5b in Rat and Mouse Serum.** H. Ylipahkala<sup>1</sup>, L. Wahlberg<sup>2</sup>, J. M. Halleen<sup>2</sup>. <sup>1</sup>SBA Sciences Ltd, Oulu, Finland, <sup>2</sup>Pharmatest Services Ltd, Turku, Finland.

Osteoclasts secrete tartrate-resistant acid phosphatase (TRACP) 5b into the blood circulation, and serum TRACP 5b is a useful marker of osteoclast number in rat and mouse ovariectomy models. In human serum, TRACP 5b is otherwise stable enough for routine laboratory measurements, but long term storage at -20°C should be avoided. Here we have studied stability of TRACP 5b in rat and mouse serum samples. Rat and mouse serum samples were stored for up to one week at +37°C, room temperature and +4°C, and up to one month at -20°C and -70°C, and TRACP 5b activity was measured at various time points. At +37°C, TRACP 5b values decreased rapidly in both rat and mouse serum. The values decreased by 40% already after 2 hours. At room temperature, rat serum TRACP values did not change after 4 hours, but the values decreased by 40% after 8 hours. However, mouse serum TRACP 5b values did not change during 24 hours of storage at room temperature. At +4°C, rat serum TRACP values did not change during 3 days of storage, but the values were decreased by 40% after 7 days. Surprisingly, mouse serum TRACP 5b values increased by 34% after 4 hours, and stayed in the increased level for at least up to 7 days. Rat and mouse serum TRACP 5b values did not change during one month storage at -20°C and -70°C. When the samples were stored at -20°C and -70°C, after freezing and thawing, rat serum TRACP 5b values remained unchanged, but mouse serum TRACP 5b values increased by 75-85% already after 7 days. These results demonstrate that rat serum TRACP 5b is stable for 4 hours at room temperature, for 3 days at +4°C, and for up to one month when the samples are stored frozen at -20°C and -70°C both before and after freezing and thawing. Mouse serum TRACP 5b is stable at room temperature for up to 24 hours and at -20°C and -70°C for up to one month, but the values increase rapidly when the samples are stored at +4°C or frozen at -20°C and -70°C after freezing and thawing. As a conclusion, the handling and storing rat and mouse serum samples for subsequent TRACP 5b measurements should be done with care to avoid undesirable changes in the values.

**The Bone Degradation Marker CTX Shows Unique Properties in Disease Monitoring Compared to NTX, ICTP and bALP in Multiple Myeloma.** T. Lund<sup>1</sup>, J. Delaisse<sup>1</sup>, N. Abildgaard<sup>2</sup>, K. Kupisiewicz<sup>1</sup>, T. L. Andersen<sup>1</sup>, K. Soe<sup>1</sup>, T. Plesner<sup>1</sup>. <sup>1</sup>Clinical Cell Biology, Vejle Hospital, Vejle, Denmark, <sup>2</sup>Hematology, Odense University Hospital, Odense, Denmark.

Multiple myeloma (MM) is a haematological malignancy with a high degree of skeletal morbidity. 80 % of the patients present with osteolyses, pathological fractures, vertebral compression fractures and/or osteopenia on skeletal survey at diagnosis. MM causes an unbalanced bone resorption and formation as the myeloma cell induces factors stimulating osteoclast activity and inhibiting osteoblast activity. Various markers of bone turnover have been tested for prognostic value in multiple myeloma. Here we tested if consecutive measurements of bone markers could detect progressive disease (1), development of osteolysis (2) and response to treatment (3) in the individual patient. In 106 patients the bone resorption markers ICTP (CTX-MMP), NTX-I, CTX-I and bALP as well as serum M-component and serum free light kappa/lambda chains (FLC), were measured every fourth week for up to 22 months. Disease progression and response to treatment were defined according to the International Uniform Response Criteria for Multiple Myeloma 2006. In case of disease progression, bone marker values at plateau phase were compared to values when progressive disease was first detected. Development of osteolysis was evaluated by conventional radiography or computed tomography. Patients who received new treatment were divided into responders and non-responders. Bone marker values prior to treatment were compared to values when treatment was stopped or when best response during treatment was achieved.

Progressive disease was observed in 40 cases (1). Bone morbidity was evaluated in 26 patients at the time of disease progression (2). A statistically significant mean increase in

CTX-I of 44 percent was found at the time of disease progression. No deterioration in renal function was seen. No significant changes were observed in ICTP, NTX-I or bALP. Patients developing osteolysis had a statistically significant higher increase in CTX-I of 344% compared to patients who had no new osteolytic lesions. New treatment was initiated in 50 cases (3), and 33 responded. A significant decline in CTX-I of 52 percent was observed in responding patients. No significant changes in CTX-I were observed in the non-responding group. NTX-I, ICTP or bALP showed no significant changes, neither in the responding patients nor in the non-responding patients. Our data indicate that CTX-I may be a useful marker of disease progression, development of osteolysis and response to treatment in multiple myeloma. CTX-I appears to be a better marker for monitoring disease activity and bone morbidity in multiple myeloma than NTX-I, ICTP and bALP.

**Bone Resorption Markers in Saliva. Experimental Longitudinal Study.** G. G. Pellegrini<sup>\*1</sup>, M. M. Gonzales Chaves<sup>\*1</sup>, J. I. Somoza<sup>\*2</sup>, S. M. Friedman<sup>\*1</sup>, S. N. Zeni<sup>2</sup>. <sup>1</sup>Cátedra de Bioquímica General y Bucal, Facultad de Odontología, Universidad de Buenos Aires, Argentina, <sup>2</sup>Sección de Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Argentina.

Previously, we measured terminal C-telopeptide of collagen type I (CTX) in saliva. The present longitudinal experimental study sought to determine whether salivary concentrations of CTX have the same response as in serum samples under different conditions: normal, increased, and reduced bone remodeling. Thirty rats were ovariectomized (OVX) and 10 rats were SHAM operated. The rats were divided into 4 groups (G) and treated as follows for 45 days: G1 = SHAM+vehicle; G2 = OVX + 8 mg olpadronate (OPD)/100 g body weight (BW); G3 = OVX + 4 mg OPD/100 g BW ;G4 = OVX +vehicle. Saliva and serum CTX (ng/ml) were determined by ELISA (Rat Laps. Osteometer BioTech, Denmark) at baseline (t=initial), at t=10, t=20 and t=45 days of surgery. Results (mean±SD): (table 1) There were no differences in salivary CTX levels at baseline. G4 presented the highest salivary CTX levels compared to the other 3 groups throughout the experience (P <0.05). Salivary CTX values remained unchanged in G1 and G2 and decreased in G3 (P <0.01). Salivary CTX levels were similar in G1 and G2 and significantly lower in G3 (p<0.05). Conclusions: Saliva samples responded like serum samples to changes in bone turnover. Then saliva may prove to be a practical and reliable sample to evaluate changes in bone remodeling and to monitor therapy with anticatabolic drugs.

## M289

**Relationship Between Adipokines and Biochemical Bone Markers in Osteoporotic Women Before and After Growth Hormone Supplementation.** B. H. Durham<sup>1</sup>, F. Joseph<sup>\*2</sup>, R. Sodi<sup>\*1</sup>, J. P. Vora<sup>\*2</sup>, W. D. Fraser<sup>1</sup>. <sup>1</sup>Clinical Chemistry, Royal Liverpool University Hospital, Liverpool, United Kingdom, <sup>2</sup>Clinical Endocrinology, Royal Liverpool University Hospital, Liverpool, United Kingdom.

We have studied the relationship between adipokines and biochemical markers of bone formation and resorption in 14 post menopausal women with osteoporosis, average age 63.4 ± 2.1 yr, before and after 6m growth hormone supplementation [GH]. After an overnight fast, prior to and after 6m GH, serum/plasma was obtained and stored at -70C until analysed. The adipokines measured were adiponectin [Apn], ghrelin [Grn], leptin [Lpn] and the panel of bone markers were osteocalcin [OC], bone alkaline phosphatase [BoneALP], and amino terminal extension of type1 collagen [PINP] for formation and carboxy and amino telopeptides of type1 collagen [beta CTX, NTX], bone acid phosphatase [TRACP5b] and cathepsin K [CathK] for resorption. Also measured was osteoprotegerin [OPG]. All assays had CVs for the measurable range of 4-7%, correlations were calculated by Pearson's formula. There was no significant change in Lpn 28.6 ± 8.2 vs 28.4 ± 7.5 ng/mL or Grn 17.2 ± 3.7 vs 16.7 ± 4.0 ng/mL. Apn increased by 24% 9.9 ± 3.8 vs 12.3 ± 3.8ng/mL [ns]. There was no significant correlation between any of the adipokines or the change in them after 6m GH, also there was no significant correlations between the change in adipokines and that for any of the bone markers. Prior to GH there were significant negative correlations between Lpn and beta CTX, NTX, TRACP5b, CathK [p<0.05] and OC, PINP [p<0.01]; there was a significant negative correlation between Apn and OPG and beta CTX [p<0.05] but there were no significant correlations between Grn and any of the bone markers. After 6m GH only the correlations between Lpn v TRACP5b [p<0.01] and CathK [p<0.05] remained significant, also Apn v OPG [p<0.05]; significant positive correlations were found between Grn and NTX [p<0.05] and osteoclast activity [NTX/TRACP5b] [p<0.01]. The only significant correlations that were present prior to and after 6m GH were those for Lpn v TRACP5b, CathK and Apn v OPG. From this study it appears that in elderly osteoporotic women Lpn has a negative influence on bone formation and resorption; the stronger correlations were with formation markers. Grn has no effect on bone turnover whereas Apn has an inverse effect on OPG. After GH supplementation, which increases circulating IGF1 to pre-menopausal levels, the correlations between Lpn and collagen1 turnover markers disappear but the negative correlation with TRACP5b [ a marker of osteoclast number] remains. Grn has a positive influence on bone resorption whereas that of Apn is independent of IGF1 levels. The 3 adipokines studied have an inverse effect on aspects of bone turnover.

**Changes of Biochemical Resorption Markers During Fracture Healing in Osteoporosis.** C. Heiss<sup>\*</sup>. Trauma and Experimental Surgery, University Hospital of Giessen-Marburg, Giessen, Germany.

**INTRODUCTION** The aim of this study was to evaluate the development of biochemical resorption markers during the fracture healing in patients with osteoporotic fractures of the proximal femur.

### METHODS

This prospective, explorative follow-up study included 33 patients who sustained a fracture of the proximal femur and 25 control persons without a fracture. We recruited 35 patients with a fracture of the distal forearm to compare typical osteoporosis-associated fracture locations. The concentration of the resorption markers N-terminal telopeptide (NTx), Desoxypyridinoline (D-Pyr) and Pyridinoline (Pyr) were measured in the first urine spot preoperatively and at day 2, 4, 10 and 14 postoperatively. Further the Bone Mineral Density (BMD) of the lumbar spine was determined in all patients with the qCT to diagnose an osteoporosis.

**RESULTS** Among the 33 study patients with a femur fracture were 60% women and 40% men, an osteoporosis was diagnosed in 90% of all the patients, while only 10% showed a normal bone density. We found a positive correlation between age and BMD in both sexes (female p=0.002; men p=0.01). It was noticed that peritrochanteric fractures were more common with 64% than femoral neck. A statistically significant increase was found in the three measured resorption markers NTx, D-Pyr and Pyr during the observing period of 14 days of fracture healing (p<0.001). Patients suffering from osteoporosis had higher concentrations of markers than non-osteoporotic patients during the fracture healing, and female patients showed a higher increase of markers than men. Patients who sustained a peritrochanteric femur fracture had higher concentrations of markers than patients with a femoral neck fracture. Women with a femur fracture showed higher concentrations of resorption markers than women who sustained a distal forearm fracture. Higher concentrations of the resorption markers in patients were found who underwent a cemented total hip replacement than in patients with an uncemented implantation of the prosthesis.

**DISCUSSION** NTx, D-Pyr and Pyr remained unchanged during the first 2 days after operation, reflecting Phase I of fracture healing (activation), and significantly increased from day 4 to 14 reflecting Phase II (resorption). Bonemarkers showed higher concentrations in individuals with osteoporosis. This may be due to the overall increased bone resorption associated with this disease. This study described trends in the development of biochemical markers during the early period of fracture healing. If we better understand the function, the postoperative development and the meaning of bone markers during the fracture healing, it should be possible to improve the treatment of osteoporotic fractures in the future.

**The Relationship Between Biochemical Bone Markers in Osteoporotic Women Before and After 6 Months Treatment with Either Growth Hormone, Strontium Ranelate or Growth Hormone Plus Strontium.** B. H. Durham<sup>1</sup>, F. Joseph<sup>\*2</sup>, A. A. Joshi<sup>\*2</sup>, J. P. Vora<sup>\*2</sup>, W. D. Fraser<sup>1</sup>. <sup>1</sup>Clinical Chemistry, Royal Liverpool University Hospital, Liverpool, United Kingdom, <sup>2</sup>Clinical Endocrinology, Royal Liverpool University Hospital, Liverpool, United Kingdom.

We have studied the relationship between biochemical bone markers in a group of 28 osteoporotic women, age 65 ± 4y, before and after 6 m treatment with either growth hormone supplementation [GH] or 2g/d of strontium ranelate [StR] or a combination of the two [GHSr]. Fourteen received GH, 8 StR and 6 GHSr. After an overnight fast, prior to and after 6m of treatment, serum/plasma was obtained and stored at -70C until analysed. Each marker was analysed in the same run. The markers were:- for formation osteocalcin [OC], bone alkaline phosphatase [Bone ALP], amino terminal extension of type1 collagen [PINP] and for resorption carboxy and amino telopeptides of type1 collagen [beta CTX, NTX], bone acid phosphatase [TRACP5b], osteoclast activity [OcAct] was calculated as [NTX/TRACP5b]; osteoprotegerin [OPG] was also measured. The significance of the correlations was calculated using Pearson's formula. Before treatment the correlations that showed statistical significance were: OC vs PINP, beta CTX, NTX, TRACP5b [p<0.01], BoneALP [p<0.05]; PINP vs OC, BoneALP, beta CTX [p<0.01], TRACP5b [p<0.05]; BoneALP vs OC, PINP, beta CTX, NTX, TRACP5b [p<0.01]; beta CTX vs Oc, PINP, BoneALP, TRACP5b [p<0.01]; TRACP5b vs OC, BalP, beta CTX, NTX, OPG [p<0.01], PINP [p<0.05]; OcAct vs -TRACP5b [p<0.01], -OPG [p<0.05]; OPG vs TRACP5b [p<0.01], -OcAct [p<0.05]. After GH treatment most of the significant correlations disappeared, OC vs PINP [p<0.01], BoneALP vs TRACP5b [p<0.01], OcAct vs NTX [p<0.01] remained but no significance vs TRACP5b, the other component of the calculation. A similar picture was seen after StR, the remaining significant correlations were: OC vs BoneALP, beta CTX [p<0.05]; beta CTX vs OC, TRACP5b [p<0.05], OcAct vs NTX [p<0.05]. After the combination GHSr most of the significant correlations remained, the main exceptions were TRACP5b vs PINP, BoneALP, beta CTX, NTX, OPG. In all 3 treatment regimes the significance of the correlations between TRACP5b and PINP, NTX, OPG and between OPG and OcAct disappeared. Pre-treatment there were significant correlations between formation and resorption values. After 6m of GH or StR treatment the significances between formation and resorption markers disappeared; only with the combination GHSr did most of the significant correlations remain. In the 3 treatments osteoclast numbers [TRACP5b] and osteoblast activity [BoneALP] were uncoupled from other markers of resorption and formation.

**Vitamin D Insufficiency Together with High Serum Levels of Vitamin A Increase the Osteoporosis Risk in Postmenopausal Women.** J. Mata-Granados<sup>\*1</sup>, J. Cuenca-Acevedo<sup>\*2</sup>, I. Serrano-Alferez<sup>\*2</sup>, J. Caballero-Villaras<sup>\*2</sup>, M. Luque de Castro<sup>\*3</sup>, J. Quesada-Gómez<sup>\*4</sup>. <sup>1</sup>Sanyres I+D+i, Córdoba, Spain, <sup>2</sup>Mineral Metabolism Unit. Endocrinology, Hospital Reina Sofía, Córdoba, Spain, <sup>3</sup>Department of Analytical Chemistry, University of Córdoba, Córdoba, Spain, <sup>4</sup>Mineral metabolism Unit. Endocrinology, Hospital Reina Sofía, Córdoba, Spain.

Nutrition plays an important role in bone health. Hypovitaminosis D is a contributor factor both to development of osteopenia-osteoporosis and to muscle weakness and falls; therefore, vitamin D (25OHD) insufficiency is a determinant of osteoporosis fractures. An excess of vitamin A (retinol) stimulates bone resorption, inhibits bone formation, and antagonizes the ability of vitamin D to maintain normal serum calcium levels, which may also contribute to the accelerated bone loss and fracture risk.

We assessed the prevalence of low levels of 25OHD and high levels of vitamin A and their impact over the bone mineral density (BMD) in a cross-sectional study of 232 postmenopausal Spanish women referred to outpatient clinic of the Bone Mineral Metabolism Unit at the "Reina Sofía" Hospital (Córdoba, Spain) for osteoporosis screening.

Vitamin A and 25OHD were measured by a fully automated high performance liquid chromatography (HPLC) method. The BMD was measured at both the lumbar spine (LS) and the femoral neck (FN) by dual-energy X-ray absorptiometry with a Hologic QDR1000 densitometer.

The prevalence of high serum levels of vitamin A ( $\geq 2.8 \mu\text{M}$ ) was 36.4 %. Vitamin A concentration was higher in osteoporotic (3.33  $\mu\text{M}$ ) than non osteoporotic (3.04  $\mu\text{M}$ ) postmenopausal women ( $p < 0.05$ ) for bone mineral density measured in femoral neck (BMD-FN). The prevalence of vitamin D insufficiency ( $25\text{OHD}_3 < 50 \text{ nM}$ ) was 55.76%; meanwhile 14.29% showed deficiency of vitamin D ( $25\text{OHD}_3 < 25 \text{ nM}$ ) and only 29.95% postmenopausal women had normal level of vitamin D. The serum level of 25OHD<sub>3</sub> was lower in the osteoporotic group vs. non osteoporotic women, both in BMD-FN (44.92 nM vs. 51.83 nM;  $p < 0.01$ ), and BMD-LS (47.35 nM vs. 52.48;  $p < 0.05$ ). Among subjects with vitamin D below 50 nmol/L, 30.4% had high serum levels of retinol. Moreover, the group with high level of vitamin A showed low values of both BMD-FN ( $p < 0.0001$ ) and BMD-LS ( $p = 0.04$ ).

In conclusion, high levels of vitamin A, a known factor of bone loss, should be considered as a determinant factor of low BMD and bone fracture risk, mainly if it coexists with insufficiency of vitamin D. Since supplements contribute significantly to vitamin A intake, the amounts of retinol in fortified foods and vitamin supplements may need to be reassessed.

## M293

**Serum PINP is a Sensitive Marker of Bone Formation in Mouse Ovariectomy Model.** J. P. Rissanen<sup>1</sup>, Z. Peng<sup>1</sup>, M. I. Suominen<sup>1</sup>, C. Otto<sup>\*2</sup>, T. Wintermantel<sup>\*2</sup>, J. M. Halleen<sup>1</sup>. <sup>1</sup>Pharmatest Services Ltd, Turku, Finland, <sup>2</sup>Bayer Schering Pharma AG, Berlin, Germany.

We have previously shown that serum procollagen I N-terminal propeptide (PINP) is a sensitive marker of bone formation in rat ovariectomy (OVX) model. Here we have studied serum PINP as a bone formation marker in mouse OVX model. Three-month-old female mice from two different strains, C3H/HeN and C57Black/6J, were included in the study. Three study groups ( $n=12/\text{group}$ ) were included for both strains as follows: 1) Sham-operated control group receiving vehicle; 2) OVX group receiving vehicle; 3) OVX group receiving  $17\beta$ -estradiol (E2, 3  $\mu\text{g}/\text{kg}/\text{day}$  s.c.). PINP was determined as a marker of bone formation and C-terminal cross-linked telopeptides of type I collagen (CTX) as a marker of bone resorption. These two bone turnover markers were measured by immunoassays from fasting serum samples before the operations and at 2, 6, 10 and 14 days after the operations. Bone mineral density (BMD) values were determined from tibial metaphysis at 6 weeks after the operation using peripheral quantitative computed tomography (pQCT). Ovariectomized animals showed decreased uterus weight and total BMD compared to sham controls in both strains, demonstrating successful estrogen depletion and osteopenia by OVX. As expected, these effects were prevented by E2 application. Serum PINP was strongly elevated already at day 6 after OVX in both strains, and this elevation was prevented by E2. In C57Black/6J mice, CTX values showed similar changes, but not earlier than at day 14. In C3H/HeN mice, CTX values did not change as a result of OVX within 14 days after the operation. These results demonstrate that serum PINP is a sensitive marker of bone formation that describes changes in bone homeostasis in mouse OVX model. PINP values change rapidly after OVX, and short-term changes in PINP predict long-term changes in BMD in mouse OVX model.

## M294

**Vitamin D Deficiency is Highly Prevalent in Irish Hip Fracture Patients.** J. G. Browne<sup>\*</sup>, B. Brennan<sup>\*</sup>, M. Healy<sup>\*</sup>, N. Maher<sup>\*</sup>, M. C. Casey<sup>\*</sup>, J. B. Walsh. Medicine for the Elderly, St James Hospital, Dublin, Ireland.

The purpose of the study was to assess the prevalence of hypovitaminosis D in acute hip fracture patients within a Dublin hospital. It is well established that vitamin D levels are sub-optimal in the elderly and that adults with fragility fracture are more likely to have serum vitamin D levels either lower than those of control patients of similar age.

This was a retrospective review of hip fracture patients admitted to St James Hospital, Dublin (Latitude 53° 20' N), reviewing levels of serum 25-hydroxyvitamin D (Vitamin D), parathyroid hormone, markers of bone turnover (CTX, Osteocalcin, PINP) and calculated glomerular filtration rates (GFRs).

Between October 2003 to October 2006, 449 hip fracture patients were admitted with 171 hip fracture patients having a serum 25 Vitamin D available. These patients were further analysed. Mean age was 78.49 ( $\pm 9.64$ ) years, with 76% of patients being female. 13.4% were on calcium and vitamin D supplementation at the time of fracture. Mean Vitamin D was 41.86 ( $\pm 25.17$ ) nmol/L and PTH was 51.76 ( $\pm 44.39$ ) pg/mL, with 18.6% of patients having a level of PTH above 75pg/mL. 25% of patients had a calculated GFR of less than 30mls/min with a further 52% with a GFR between 30 to 60 mls/min. Vitamin D levels were subdivided into 3 categories: Severe Vitamin D deficiency (50 nmol/L). Using these criteria, 28.5% had severe vitamin D deficiency and 37.4 % had vitamin D insufficiency. Patients who had been on vitamin D supplementation at the time of fracture were excluded.

Subgroups of Patients with Categories of Vitamin D compared to Bone Markers, PTH and GFR.

	Vitamin D Deficiency <20 nmol/L (n=42)	Vitamin D Insufficiency 20-50 nmol/L (n=55)	Vitamin D Replete >50 nmol/L (n=50)
Age (Yrs)	77.84 ( $\pm 7.84$ )	79.75 ( $\pm 9.69$ )	76.58 ( $\pm 9.31$ )
PTH (pg/mL)	65.98 ( $\pm 47.92$ )	48.02 ( $\pm 46.55$ )	39.64 ( $\pm 28.23$ )
GFR (ml/min)	36.94 ( $\pm 20.37$ )	31.21 ( $\pm 19.85$ )	52.17 ( $\pm 31.45$ )
CTX	0.653 ( $\pm 0.553$ )	0.592 ( $\pm 0.357$ )	0.594 ( $\pm 0.328$ )
Osteocalcin	32.2 ( $\pm 33.62$ )	28.17 ( $\pm 34.15$ )	24.41 ( $\pm 17.51$ )
PINP	149 ( $\pm 224.3$ )	78.79 ( $\pm 60.34$ )	101.78 ( $\pm 72.15$ )

In conclusion, vitamin D deficiency is highly prevalent in Irish patients with hip fracture, with almost a third demonstrating severe vitamin D deficiency. These patients showed increased levels of PTH, reduced renal function and increased bone turnover, as compared to those that were replete. One quarter of patients showed significant renal impairment, which suggests that standard oral replacement therapy of Vitamin D may not be sufficient.

**Disclosures:** J.G. Browne, None.

## M295

**Changes in Serum PINP in Orchidectomized Osteopenic Rats Treated with PTH and Alendronate.** J. Morko<sup>1</sup>, Z. Peng<sup>1</sup>, J. P. Rissanen<sup>1</sup>, M. I. Suominen<sup>1</sup>, L. Ravanti<sup>\*2</sup>, P. J. Kallio<sup>\*2</sup>, J. M. Halleen<sup>1</sup>. <sup>1</sup>Pharmatest Services Ltd, Turku, Finland, <sup>2</sup>Orion Corporation, Turku, Finland.

Serum procollagen I N-terminal propeptide (PINP) is a sensitive marker of bone formation in rat and mouse ovariectomy (OVX) models. Here we have studied changes in serum PINP in rat orchidectomy (ORX) model. Three-month-old male rats were orchidectomized and allowed to develop osteopenia for 3 months, after which the animals were treated for 3 months with PTH (1-34) or alendronate. The following study groups were included ( $n=12/\text{group}$ ): 1) Sham-operated control group receiving vehicle; 2) ORX group receiving vehicle; 3) ORX group receiving PTH (40  $\mu\text{g}/\text{kg}/\text{day}$  s.c.); 4) ORX group receiving alendronate (10  $\mu\text{g}/\text{kg}/\text{day}$  s.c.). PINP, mid-fragment of osteocalcin (OC) and C-terminal cross-linked telopeptides of type I collagen (CTX) were determined from fasting serum samples before the start of treatment (at 3 months) and at 4 and 6 months. Trabecular bone mineral density (BMD) was determined from tibial metaphysis before the operations, before the start of treatment and at the end of the study. Static and dynamic histomorphometry were determined from tibial metaphysis at the end of the study. Prostate weight was decreased by ORX, confirming that the operations were performed successfully. Trabecular BMD was decreased by ORX at 3 months, confirming the development of osteopenia. During the treatment period, bone formation rate (BFR/BS) was increased by PTH, confirming its anabolic effects, and decreased by alendronate, confirming its anti-resorptive effects. Trabecular BMD was increased by both PTH and alendronate at the end of the study. Trabecular bone volume (BV/TV) was strongly increased by PTH, but no changes were observed with alendronate. CTX and OC did not change by ORX at 3 months, but PINP decreased strongly. OC values were elevated by PTH and decreased by alendronate at both 4 and 6 months, but CTX values showed no changes. PINP values were strongly elevated by PTH and slightly decreased by alendronate at both 4 and 6 months. These results demonstrate that PINP is a sensitive marker of bone formation in rat ORX model. PINP shows a strong response to anabolic treatment, and it can also be used for monitoring anti-resorptive treatment. OC showed less strong response to anabolic treatment and more strong response to anti-resorptive treatment than PINP, suggesting that OC may reflect both bone formation and bone resorption. The CTX assay was not sensitive enough to detect changes in bone resorption in rat ORX model.

**Validation of an Immunoassay for the Determination of PINP in Rat Serum.** T. M. Gruetzner\*, P. Oldfield\*. Immunochemistry, Charles River Laboratories PCS-MTL, Senneville, QC, Canada.

Bone formation markers in rat osteoporosis models are limited. Recently, a new immunoassay (EIA) kit was developed for the determination of the n-terminal peptide of type 1 pro-collagen (PINP) from Immuno-Diagnostic Systems. In this study, we validated this EIA kit for use as a bone formation biomarker. The kit uses an immobilized rabbit polyclonal antibody specific for a peptide region of the analyte. PINP in the sample competes for a limited number of antibody binding sites with biotinylated PINP. The biotin is visualized with a streptavidin peroxidase system. The signal is inversely proportional to the PINP concentration in the sample. Samples require a minimum 3 fold dilution.

Parameters assessed included: working calibration range (9 standard curves consisting of 9 PINP concentration ranging from 0.6 to 75.0 ng/mL in duplicate), intra- and inter-assay precision and accuracy (5 quality control levels in 6 duplicate assessments in 3 separate assays) and in-process storage stability (room temperature and 4°C for ~ 11 hours, and 3 freeze thaw cycles). Dilution linearity and spike in selectivity tests were also performed. Long term stability at -20°C is ongoing. 24 lots of normal rat serum were assessed in order to define a normal range.

A 4 parameter logistic curve fit was applied to the standard curve. 6/9 standard curves required no reprocessing (all points within +/- 20% of the theoretical concentration) and 3 standard curves required deletion of a maximum of one standard.

Table 1: Precision and accuracy of PINP in Rat Serum (n = 18, 3 different assays).

	PINP concentration on plate (after dilution) (ng/mL)	Accuracy (% from endogenous assessment)	Precision % CV
LLOQ	0.77	106.2%	16.7
QC1	1.91	100.0%	14.5
QC2	4.41	96.2%	13.0
QC3	12.89	100.0%	13.2
ULOQ	36.30	108.5 %	22.8

Note: QCs were prepared from rat serum samples with endogenous PINP levels

In process stability samples recovered +/-12 % of the untreated control samples. Dilution linearity tests of up to 100 fold yielded acceptable levels of accuracy (+/- 25% of the undiluted theoretical concentration). Selectivity experiments (standard PINP spiked into 10 individual lots of rat serum) under-recovered (mean = 35.5% of the theoretical endogenous + spiked concentration). The mean serum PINP concentration in 24 normal adult rats was 136.1 ng/mL (range 24.7 to 293.4 ng/mL and standard deviation of 72.7).

The PINP kit performs well over the concentration range found in normal rats. Under-recovery of spike-in selectivity experiments may be a result of matrix differences between the standard curve diluent and rat serum. Validation of this method against established rat bone formation biomarkers and model endpoints will determine the full utility.

**Serum Sex Hormone-Binding Globulin Level to Predict Osteoporosis Severity.** E. Hoppé\*, B. Bouvard\*, E. Legrand, R. Levasseur, C. Masson\*, M. Audran. Rheumatology, CHU, Angers, France.

**Purpose:** Sex Hormone-Binding Globulin (SHBG) is a plasma glycoprotein that binds and regulates sex steroids. Several studies have shown a relation between serum SHBG levels and bone mineral density (BMD), bone turnover markers, and fracture risk among post-menopausal women. The aim of our study was to measure serum SHBG levels among post-menopausal women, and to assess its relationship with osteoporosis severity.

**Patients and methods:** We included 184 post-menopausal women who suffered from osteoporosis (T-score < -2.5) and/or presented osteoporotic fractures. We considered physical data (age, body mass index, weight, tobacco and alcohol intake, menopause age, hormonal replacement therapy duration, corticosteroid intake), biological parameters (albumin, prealbumin, estradiol, SHBG, serum C-telopeptide of type-I collagen, osteocalcin, serum bone specific alkaline phosphatase), the presence of vertebral or peripheral fractures, and lumbar and total hip bone mineral density.

**Results:** Mean age was 76.1 (+/- 9) years-old. Mean serum SHBG level was 80.2 (+/- 43) nmol/L (range: 10-297, or -1.6 to +5.4 standard deviations (SD)). We divided this population in 4 quartiles, according to an increasing serum SHBG level (Group I, II, III and IV). Lumbar BMD was lower in group III and group IV (respectively -3.2 SD and -3.1 SD) than in group I and group II (respectively -2.0 SD and -2.3 SD) (p<0.05). Total hip BMD was lower in group III and group IV (respectively -2.8 SD and -2.9 SD) than in group I and group II (respectively -1.6 SD and -2.2 SD) (p<0.05). Mean vertebral fracture number per women was higher in group III and group IV (respectively 2.8 and 3.5) than in group I and group II (respectively 1.5 and 2) (p<0.05). The rate of women suffering from severe osteoporosis (at least 2 vertebral fractures) was higher in group III and group IV (respectively 62.8 and 70%) than in group I and group II (respectively 35.7 and 50%) (p<0.05). After adjusting for age and body mass index, logistic regression analysis showed a significant association between serum SHBG level and the presence of severe osteoporosis. The Odds Ratio of having at least 2 vertebral fractures was 2.7 (95% confidence interval: 1.24-5.99) for an increase of 1 SD for SHBG.

**Conclusion:** There is a wide range of serum SHBG level among women suffering from post-menopausal osteoporosis. The higher is the SHBG level, the lower is the BMD and the higher is the number of vertebral fractures. These data strongly suggest that measuring serum SHBG level could be a new and reliable tool to predict post-menopausal osteoporosis severity.

**Optimization of Bone Turnover Marker Measurements in a Mouse Model of Glucocorticoid-Induced Osteoporosis.** M. I. Suominen, J. P. Rissanen, Z. Peng, J. M. Halleen. Pharmatest Services Ltd, Turku, Finland.

Glucocorticoids induce osteoporosis by increasing bone resorption and decreasing bone formation. A fast and reliable animal model of glucocorticoid-induced osteoporosis (GIOP) would allow rapid determination of side-effects of new glucocorticoid analogs on bone, and effects of new osteoporosis drug candidates on GIOP. We have studied the effects of 3-week administration of prednisolone on bones in intact 13-week old BALB/c mice. The following study groups were included (n=8/group): 1) Control group receiving vehicle; 2) Oral prednisolone (10 mg/kg/day); 3) Prednisolone pellets with a release rate of 24 µg/day ("low pellet", mean dose 1.1 mg/kg/day); 4) Prednisolone pellets with a release rate of 71 µg/day ("medium pellet", mean dose 3.4 mg/kg/day); 5) Prednisolone pellets with a release rate of 238 µg/day ("high pellet", mean dose 11.4 mg/kg/day). Histomorphometric analysis and peripheral quantitative computed tomography (pQCT) were performed from proximal tibia and tibial diaphysis at the end of the study. Intact osteocalcin, procollagen I N-terminal propeptide (PINP) and C-terminal cross-linked telopeptides of type I collagen (CTX) were measured from fasting serum samples before the start of treatment and at 1, 2 and 3 weeks. Parameters of dynamic histomorphometry decreased substantially in both trabecular and cortical bone by the oral prednisolone and the high pellet. However, prednisolone had no effects on trabecular bone parameters determined by pQCT or static histomorphometry, but cortical bone mineral content and cortical thickness were decreased by the oral prednisolone and the high pellet. The medium and high pellets increased CTX values and decreased PINP and osteocalcin values at one week, indicating increased bone resorption and decreased bone formation. After the first week, the CTX values decreased and the PINP values increased towards the levels obtained before the start of treatment, but the osteocalcin values stayed low. These results demonstrate that high doses of prednisolone induce an early increase in bone resorption and decrease in bone formation, and cortical bone loss at 3 weeks, while a low dose (1.1 mg/kg/day) has no effects on bone in this study setup. Although parameters of dynamic histomorphometry reveal decreased turnover in trabecular bone at 3 weeks, a longer study period is probably required to demonstrate trabecular bone loss. An optimal timepoint for measuring bone turnover markers is at one week after start of dosing, demonstrating highly elevated bone resorption and decreased bone formation. A one-week GIOP study with bone marker measurements could be a useful tool for rapid screening of a large number of compounds.

**Clinical Significance of Undercarboxylated Osteocalcin (ucOC) in Glucocorticoid-induced Osteoporosis (GIO).** I. Tanaka<sup>1</sup>, S. Tamaki<sup>2,3</sup>, H. Oshima<sup>3</sup>, J. Ishii<sup>2,1</sup>. <sup>1</sup>Department of Laboratory Medicine, Fujita Health University School of Medicine, Toyoake, Japan, <sup>2</sup>Department of Rheumatology, National Hospital Organization, Mie Chuo Medical Center, Tsu, Japan, <sup>3</sup>Department of Rheumatology, National Hospital Organization, Tokyo Medical Center, Tokyo, Japan.

**[Objective]** In GIO, bone fractures are often seen even at high bone mineral density. This suggests bone quality is an important factor in GIO for bone strength, which is usually evaluated with bone markers on the clinical basis. In this study, we tried to clarify the clinical significance of various bone makers in predicting the bone quality in GIO.

**[Subjects & Methods]** one hundred thirty four patients (99 females and 35 males) with collagen diseases under glucocorticoid treatment were enrolled in this study. The mean of age and daily glucocorticoid dosage (prednisolone equivalent) were 52 years old and 9.0 mg/day, respectively. Serum undercarboxylated osteocalcin (ucOC) and NTX in the urine (uNTX) were measured by the ECLIA and ELISA methods, respectively. Vertebral compression fractures were evaluated with X-ray photography.

**[Results]** 1) uNTX were increased one month after the start of glucocorticoid therapy, but the ucOC decreased in that period. 2) Doses of glucocorticoids, were significantly correlated with uNTX positively and with ucOC negatively. 3) ucOC were significantly increased in patients with vertebral deformities. 4) In patients treated with menatetrenone, which is vit K analog, ucOC was lower in patients without menatetrenone. 5) uNTX seemed correlated with an incident fracture after corrected with risk factors. **[Conclusion]** It is suggested that serum ucOC levels decreased in dosage dependent manner after treatment with corticosteroids. Its shows that bone formation is inhibited by glucocorticoid in GIO.

**Uncarboxylated Osteocalcin Level in Healthy Korean Women.** B. Choi<sup>\*1</sup>, D. Lee<sup>2</sup>, Y. Lee<sup>\*1</sup>. <sup>1</sup>Cha School of Medicine, Seoul, Republic of Korea, <sup>2</sup>Rheumatology Clinic, Cha School of Medicine, Seoul, Republic of Korea.

Uncarboxylated osteocalcin(ucOC) has been recognized to evaluate vitamin K status and inversely associated with bone mineral density. We have recruited 337 healthy women age group 20, 30, 40, 50, 60, 70 years 60 women in all age groups except 37 women in 70 years old age group. All women were healthy and postmenopausal women have ever taken hormone, drugs and supplements that may influence bone metabolism or stopped taking for the last six months.

Serum uncarboxylated osteocalcin was measured from the collected fasting venous blood samples as well as alkaline phosphatase, serum calcium. Mean body mass index was lowest ( $20.3 \pm 1.9 \text{ kg/m}^2$ ) in 20 years old group and highest ( $24.8 \pm 2.6 \text{ kg/m}^2$ ) in 60 years old group. BMD of the L2-4 vertebral bodies was measured by dual-energy X-ray absorptiometry (DEXA) using a Hologic QDR 2000 densitometer (Hologic Corp., MA, USA). The coefficients of variation (CVs) of the measurement were less than 1.0% for lumbar BMD. Data for BMD are expressed as g/cm<sup>2</sup>. The serum uncarboxylated osteocalcin concentration was assayed by an enzyme-linked immunosorbent assay (ELISA) system using two monoclonal antibodies, an anti-OC (21-31) antibody and a solid-phase anti-Glu 21, 24-OC (4-5) antibody, with recombinant human uncarboxylated osteocalcin (Biotechnology Research Laboratory, Takara Shuzo Co., Otsu, Shiga, Japan. The intra- and inter-assay coefficients of variation (CVs) were 7.3% and 9.7%, respectively, and the sensitivity of the assay was 0.5 ng/ml. Spine bone mineral density was highest in age group and lowest in age group. Hip bone mineral density was highest in age group and lowest in age group.

Serum mean alkaline phosphatase was lowest ( $122 \pm 30 \text{ IU/L}$ ) in 30 years old group and highest ( $190.3 \pm 55.8 \text{ IU/L}$ ) in 60 years old group. Serum mean uncarboxylated osteocalcin levels were ( $2.6 \pm 2.0 \text{ ng/ml}$ ), ( $1.9 \pm 1.3 \text{ ng/ml}$ ), ( $1.6 \pm 1.2 \text{ ng/ml}$ ), ( $2.2 \pm 1.5 \text{ ng/ml}$ ), ( $2.1 \pm 2.3 \text{ ng/ml}$ ), ( $1.8 \pm 1.3 \text{ ng/ml}$ ) respectively. Serum ucoc was inversely associated with BMI ( $-0.12 \text{ p} < 0.02$ ) and lumbar spine BMD ( $0.13 \text{ p} < 0.01$ ) and positively associated with alkaline phosphatase ( $0.19 \text{ p} < 0.00$ ). Serum mean uncarboxylated osteocalcin was highest in 20 years old group then 50 years old group suggesting vitamin K deficiency in these age groups.

**High Level Dietary Phosphorus and Cadmium Exacerbate Ovariectomy-Induced Bone Loss.** S. Hooshmand<sup>1</sup>, N. Bakhshalian<sup>\*1</sup>, D. Y. Soung<sup>1</sup>, E. A. Lucas<sup>\*2</sup>, S. C. Chai<sup>\*1</sup>, B. H. Arjmandi<sup>1</sup>. <sup>1</sup>Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, <sup>2</sup>Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA.

Cadmium is one of the most toxic contaminants present in the natural and occupational environment and is a serious threat to living organisms. Chronic exposure to cadmium is associated with a number of disorders including kidney injury and skeletal damage. This study was designed to investigate the extent to which combination of cadmium and phosphorus exacerbates the bone loss as a result of ovariectomy. We used five groups (n=5 rats per group) of 3-month old OVX Sprague Dawley rats to examine the dose-dependent deleterious effects of cadmium (Cd) on BMD of whole body, femoral, and forth lumbar vertebrae as well as micro-structural properties of femoral necks. The treatment groups were as follows: 1) Control; 2) 50 ppm cadmium (Cd); 3) 50 ppm Cd+1.2% phosphorous (P); 4) 200 ppm Cd, and 5) 200 ppm Cd+1.2% P. Five months postovariectomy, rats were sacrificed and whole body, femoral, and forth lumbar vertebrae were scanned using DXA. Additionally, femoral necks were analyzed for microstructural properties using micro-computed tomography ( $\mu\text{CT}$  35). OVX Controls gained 3.9 and 9.8% BMD in compression with baseline BMD value after three and five months, respectively. High dose of Cd (200 ppm) completely prevented the gain in BMD. When P was added to Cd, the harmful effect of Cd on bone was pronouncedly exacerbated. In terms of femoral neck micro-structural properties, Cd decreased bone volume to total volume ratio (BV/TV), trabecular number (Tb.N) and increased structural model index (SMI) by both doses of 50 and 200 ppm. Cadmium in the context of high level of P in the diet made all these parameters worsen. Our results indicated that 200 ppm Cd+1.2% P had the most deleterious effect on BMD (7% loss) and femoral structural properties (significant differences were observed in BV/TV and Tb.N). We conclude that cadmium exposure along with high intake of phosphorus may be a public health hazard particularly in term of bone mass. The bone loss due to Cd in this study may have been confounded by OVX-induced loss of bone. Intact animals are to be used to confirm our findings.

**Comparison of 2D and 3D Subchondral Bone Texture Parameters in Severe OA Knees.** A. Wong<sup>\*1</sup>, D. Inglis<sup>\*2</sup>, K. A. Beattie<sup>\*1</sup>, P. D. Emond<sup>\*1</sup>, A. Doan<sup>\*1</sup>, J. de Beer<sup>\*3</sup>, C. E. Webber<sup>\*4</sup>, J. D. Adachi<sup>1</sup>, A. Papaioannou<sup>1</sup>.

<sup>1</sup>Department of Medicine, McMaster University, Hamilton, ON, Canada,

<sup>2</sup>Department of Civil Engineering, McMaster University, Hamilton, ON,

Canada, <sup>3</sup>Department of Orthopaedics, St. Joseph's Healthcare, Hamilton, ON,

Canada, <sup>4</sup>Department of Radiology, McMaster University, Hamilton, ON, Canada.

**Objectives:** 1) To compare apparent subchondral bone texture (BTX) parameters from radiographs with 3D parameters from bone cores using micro-computed tomography ( $\mu\text{CT}$ ) and 2) to determine the potential of 2D and 3D BTX parameters for assessing OA.

**Methods:** A cohort of male and female total knee arthroplasty (TKA) participants (N=17) had posteroanterior fixed-flexion knee radiographs of each affected knee obtained. Radiographs were digitized and analyzed for BTX parameters: bone volume fraction (BTVF), connectivity index (CX), trabecular spacing (Tr.Sp) and trabecular thickness (Tr.Th) in the centre of the tibia, 2 mm below the tibial plateau at a region of interest (ROI) 10 mm in diameter. Minimum joint space width (mJSW) was computed from digitized radiographs using a semi-automated algorithm. Cylindrical bone cores removed from the mid-tibia were imaged using a  $\mu\text{CT}$  scanner at an isotropic spatial resolution of 47  $\mu\text{m}$ . The same BTX parameters were obtained from 3D reconstructions of bone cores at 2 mm below the proximal end in cylindrical ROIs sized 1 cm<sup>3</sup>.

2D and 3D BTX parameters were correlated using a linear regression analysis. BTX parameters were correlated with mJSW to investigate the relationship between bone texture and OA severity.

**Results:** In mid-subchondral tibia, 3D BTX parameters correlated poorly with their 2D analogues. All 2D measures demonstrated significant correlations with mJSW (Table 1). Meanwhile, none of the 3D BTX parameters exhibited correlations with mJSW.

**Table 1.** Correlation coefficients of 2D BTX parameters as predictors of mJSW

2D BTX	B Coefficient	Upper CI	Lower CI	P-value
BTVF	-14.83	-4.87	-24.80	0.005
BSTV	-16.46	-0.02	-32.90	0.05
Tr.Sp	8.35	14.50	2.20	0.009
Tr.Th	-34.98	-13.50	-56.45	0.002
CX	-0.163	-0.091	-0.235	<0.001

**Conclusions:** Despite their poor construct validity, we showed that 2D BTX parameters in the mid-subchondral tibia may be predictive of OA progression. However, the same correlations were not observed with 3D analyses of bone in the mid-subchondral tibia. Our results suggest mismatch between 2D and 3D BTX parameters. Certainly, differences in spatial resolution remain a factor. Nonetheless, mid-subchondral tibia BTX measures may provide information regarding the condition of subchondral bone and remain candidates for measuring longitudinal change.

**Disclosures:** A. Wong, None.

**Trabecular 3D volumetric Density at Organ and Tissue Levels by Micro QCT Evaluation of Iliac Crest Biopsy: Relationship with Microstructure and DXA Measures.** R. Dai<sup>\*</sup>, J. Jacobson<sup>\*</sup>, J. Zhao<sup>\*</sup>, Y. Jiang. Osteoporosis and Arthritis Lab, Department of Radiology, University of Michigan, Ann Arbor, MI, USA.

QCT or DXA measures 3D or 2D bone mineral density at organ level (BMDog), calculated as amount of bone mineral content per 3D volume of interest consisting of bone and bone marrow and vascular space for QCT, or per projectional area with mixture of cortex and trabeculae (Tb) and marrow cavity and vasculature for DXA. Measurement of 3D BMD for Tb per se, or Tb 3D BMD at tissue level (BMDts) for Tb only, has not been reported. BMDts may improve our ability to understand pathophysiology and important mineralization changes underlying the mechanisms of bone fragility in osteoporosis and metabolic bone disorders, bone quality in terms of mechanical competence which is a function of bone mineral and 3D distribution, bone mineralization process as well as disorders such as hypomineralization in osteomalacia and initial administration of anabolic agents for osteoporosis, or hypermineralization in frozen bone with bisphosphonates, bony incorporation of metal, e.g., strontium, etc. We investigated the Tb 3D BMDog and BMDts and its relationship with Tb microstructure and DXA BMD.

Iliac crest bone biopsies from 35 postmenopausal women with osteoporotic vertebral fractures and the hip and lumbar DXA BMD T-score < -2.5 were scanned twice with 4-week interval using a Scanco micro CT and isotropic resolution of 20  $\mu\text{m}$ . A micro CT phantom is scanned weekly for quality control and examining conversion constants. For BMDts, partial volume effect at Tb interface with bone marrow was minimized by discarding 2 voxels on Tb surface. 3D Tb structural parameters were directly measured. The root mean square coefficient of variation (CV) as measurement error was 1.6% for BMDts and 2.7% for BMDog. Mean ( $\pm\text{SD}$ ) BMDts was 968 ( $\pm 14$ ) mg hydroxyapatite (HA)/cc, with 1.4% CV < measurement error, and could be considered constant, while BMDog was 154 ( $\pm 55$ ) mg HA/cc. BMDog is correlated with femoral neck DXA BMD ( $r = .55$ ) and lumbar spine DXA BMD ( $r = .59$ ) and with most structural parameters ( $p < .05$ ): 3D Tb bone volume fraction ( $15 \pm 6\%$ ,  $r = .98$ ), structure model index ( $1.4 \pm .5$ ,  $r = .85$ ), Tb number ( $1.1 \pm .2 / \text{mm}$ ,  $r = .66$ ), Tb thickness ( $178 \pm 46 \mu\text{m}$ ,  $r = .72$ ), Tb separation ( $887 \pm 143$

$\mu\text{m}$ ,  $r=-.79$ ), except ( $p>.05$ ) degree of anisotropy ( $1.6\pm.3$ ,  $r=.26$ ) and connectivity density ( $1.9\pm.5/\text{cm}$ ,  $r=.32$ ). BMDs was not correlated with any of them ( $r<.2$ ,  $p>.05$ ). Micro QCT can reproducibly measure iliac Tb BMDs and BMDog. BMDog is associated with microstructure and hip and lumbar DXA BMD. BMDs is constant and unassociated with other measures and may provide independent and unique information in studying bone metabolism, bone quality, metal incorporation or intoxication, mineralization process, hypo- and hyper-mineralization.

**Disclosures:** R. Dai, None.

## M304

**Femoral BMD and Femoral Structure, Assessed by DXA-Based Hip Structural Analysis, Contribute Independently to Femoral Strength.** B. J. Roberts\*, E. J. Thrall\*, J. A. Muller\*, M. L. Bouxsein. Orthopedic Surgery, Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, USA.

Measurement of areal BMD by DXA is the current gold standard for diagnosis of osteoporosis. However, aBMD has limitations with regard to fracture risk prediction, as up to half of fractures occur in individuals who are not osteoporotic by DXA-based criteria. Whole bone strength depends on bone size, macro- and microarchitecture, and the intrinsic properties of the bone matrix. Thus, we asked whether parameters of femoral structure, as assessed by DXA-based hip structural analysis (HSA), would add to aBMD in the prediction of femoral strength. We obtained 76 human cadaveric femurs (50 female and 26 male, aged  $74.2 \pm 8.7$ yr, range 55 to 98 yrs) with no evidence of prior fracture or metastatic lesions. We measured femoral neck (FN) and trochanteric (TR) aBMD, and indices of femoral structure by DXA-based HSA as implemented in the manufacturer's software (Hologic, Bedford, MA). Femora were then mechanically tested to failure in a sideways fall configuration. Bivariate and stepwise regression analyses were used to determine predictors of femoral failure load. The sample was representative of those at risk for hip fracture, as 80% of the femora had FN T-scores  $< -2.0$ . FN and TR aBMD were strong predictors of failure load ( $r = 0.84$  and  $0.86$ , respectively), as were narrow neck and intertrochanteric bone cross-sectional area (CSA) assessed by HSA ( $r=0.87$  and  $0.88$ , respectively). FN length, FN width, and intertrochanteric (IT) width were moderately correlated with failure load ( $r = 0.35$ ,  $0.37$ , and  $0.52$ , respectively). When added to FN BMD in a stepwise regression, FN width statistically significantly increased the correlation from  $r^2 = 0.70$  to  $0.75$ . Similarly, addition of IT width and avg. cortical thickness of the IT region to TR BMD statistically significantly increased  $r^2$  from  $0.74$  to  $0.80$ . Although limited by the fact that structural measures and BMD were derived from the same x-ray attenuation profile, these data show that aBMD and indices of femoral structure assessed by HSA contribute independently to femoral strength, and provide strong rationale for future studies that utilize 3D imaging to explore the contribution of femoral morphology to hip fracture risk.

## M305

**Extended Lactation Is Associated with Failure to Restore BMD 6 Months after Resumption of Menstrual Cycle.** S. A. Brown<sup>1</sup>, T. A. Guise<sup>1</sup>, A. M. Siega-Riz<sup>2</sup>, M. J. Caminiti<sup>2</sup>, C. J. Rosen<sup>3</sup>. <sup>1</sup>UVA, Charlottesville, VA, USA, <sup>2</sup>UNC, Chapel Hill, NC, USA, <sup>3</sup>Maine Medical Research Institute, Scarborough, ME, USA.

This study examined 1) IGF-I & BMD recovery after extended lactation and 2) cortical & trabecular changes by pQCT in response to lactation and weaning. This on-going prospective study enrolled women with extended lactation ( $\geq 5$  mos) and women with little to no lactation period ( $< 1$  mo). The 4 timepoints are: baseline at delivery, 3 mos postpartum, time of menstrual cycle return and 6 mos after menses return. 60 of 88 subjects enrolled completed the final visit to date. Subjects had DXA (spine, hip & whole body) and pQCT (radius & tibia) at each visit. Subjects were mean  $31.7$  yo ( $22.9-40.1$ ) with normal Z-scores at term delivery & 56% primiparous. 44 subjects had extended lactation (mean 9.8 mos), 12 had  $< 1$ mo lactation and 4 had 1-5 mos of lactation. 77% of extended lactation subjects had almost or completely weaned at the final visit.

**DXA:** The extended lactation group lost spine BMD at 3 mos postpartum ( $-6.2\%$ ,  $P<0.05$ ) which was not fully recovered by the final visit at mean 55.2 wks postpartum ( $-2.4\%$  vs. baseline,  $P<0.05$ ) with no change in the comparison group. BMD loss at the FN was greatest at the return of menses mean 29 wks postpartum ( $-5.7\%$ ,  $P<0.05$ ) and did not recover by the final visit ( $-3.5\%$ ,  $P<0.05$ ). The comparison group had FN losses of  $-2.5\%$  ( $P<0.05$ ) at the return of menses which recovered by the final visit.

**IGF-I:** Compared to baseline, IGF-I decreased at 3 mos postpartum ( $153.5$  ng/mL vs.  $172.6$ ,  $P<0.05$ ) and increased at the final visit ( $198.3$ ,  $P<0.05$ ) with extended lactation. The comparison group had no significant changes in IGF-I. IGF-I was not correlated with change in BMD by DXA.

**pQCT:** Trabecular vBMD decreased from baseline to final (radius  $4\%$ :  $204.3\pm 35.5$  mg/cm<sup>3</sup> vs.  $198.5\pm 40.0$ ,  $P<0.05$ ,  $N=19$ ) and cortical vBMD did not significantly change (tibia  $38\%$ :  $1212.8\pm 16.8$  mg/cm<sup>3</sup> vs.  $1209.9\pm 21.2$ ,  $P=0.01$ ,  $N=23$ ) with extended lactation whereas no changes occurred in the comparison group. Cortical thickness and periosteal circumference (ext. lactation:  $67.4\pm 4.3$ mm baseline vs.  $67.5\pm 4.3$  final,  $P=0.01$ ,  $N=23$ ) did not change in either group. IGF-I was correlated with cortical thickness ( $r=0.42$ ,  $P=0.05$ ), cortical area ( $r=0.53$ ,  $P=0.01$ ) and periosteal circumference ( $r=0.36$ ,  $P=0.09$ ).

These data to date suggest that spine and FN aBMD by DXA did not fully recover by 6 mos after menstrual cycle return in women with extended lactation. Trabecular vBMD but

not cortical vBMD further decreased from baseline to the final visit with no significant changes in periosteal parameters by pQCT. IGF-I decreased at 3 mos postpartum and rose above baseline at the final visit with extended lactation but were not correlated with aBMD. IGF-I was positively correlated with cortical thickness and cortical area.

**Hip Structural Analysis and Volumetric QCT in Postmenopausal Women from the PaTH Study: Mono- or Combination Therapy with Alendronate and Parathyroid Hormone.** G. J. van Londen<sup>1</sup>, L. Palermo<sup>2</sup>, T. J. Beck<sup>3</sup>, T. F. Lang<sup>2</sup>, J. M. Wagner<sup>1</sup>, D. Black<sup>2</sup>, J. P. Bilezikian<sup>4</sup>, K. E. Ensrud<sup>5</sup>, S. L. Greenspan<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of California, San Francisco, CA, USA, <sup>3</sup>John Hopkins, Baltimore, MD, USA, <sup>4</sup>Columbia University College of Physicians, New York, NY, USA, <sup>5</sup>Minneapolis Veterans Affairs, Minneapolis, MN, USA.

Bone strength depends on bone mineral density (BMD) as well as material and structural properties. Hip Structural Analysis (HSA) and Quantitative Computed Tomography (QCT) methods provide quantitative information on bone structure. Our objectives were to 1) examine changes in HSA and QCT derived structural parameters following antiresorptive, anabolic or combination therapy and 2) correlate structural indices as assessed by HSA and QCT. In the 2 year, double-blind, placebo-controlled PaTH trial, 238 postmenopausal women (mean age 70 years) were randomized to: 1) PTH (100  $\mu\text{g}$  sc daily) in year 1 followed by ALN (10 mg po daily) in year 2 (PTH-ALN); 2) PTH in year 1 followed by placebo in year 2 (PTH-PLB); 3) PTH plus ALN in year 1 followed by alendronate in year 2 (PTH/ALN-ALN) or 4) ALN for 2 years (ALN-ALN). Outcomes included conventional BMD (bone mineral density) by DXA ( $\text{g}/\text{cm}^2$ ), HSA (DXA-derived) and volumetric QCT-derived parameters measured at the femoral neck [including cross-sectional area (CSA), buckling ratio (BR, an index of cortical instability, with a decrease suggesting improvement)]. After 2 years, femoral neck BMD, CSA and BR derived by HSA and QCT improved most in the PTH-ALN group compared to the PTH-PLB group (table,  $p<0.05$ ). Similar trends for BMD, HSA and QCT were observed for other groups. At baseline, HSA-BMD correlated with QCT-BMD ( $r=0.41$ ), HSA-CSA correlated with QCT-CSA ( $r=0.58$ ), and HSA-BR with QCT-BR ( $r=0.56$ ), all  $p<0.0001$ . We conclude that in postmenopausal women who received 1 year of PTH followed by 1 year of ALN, DXA-derived HSA and QCT-derived indices of structural geometry were significantly associated with each other at baseline and demonstrate similar improvements in CSA and stability at 2 years. HSA and QCT provide additional information on structure that may complement results from BMD changes alone.

Table: Mean (SE) percent change at 24 months

**Evaluation of Osteoporosis Vertebrae Fragility by Connecting Path Method.** N. Nango<sup>1</sup>, N. Endo<sup>\*2</sup>, T. Yamamoto<sup>\*3</sup>, H. Takahashi<sup>4</sup>, M. Machida<sup>\*5</sup>, Y. Suga<sup>\*6</sup>, T. Asai<sup>\*6</sup>. <sup>1</sup>Ratoc System Engineering Co., Ltd., Tokyo, Japan, <sup>2</sup>Niigata University, Niigata, Japan, <sup>3</sup>Niigata Bone Science Institute, Niigata, Japan, <sup>4</sup>Niigata University of Health and Welfare, Niigata, Japan, <sup>5</sup>Murayama Medecal Center, Tokyo, Japan, <sup>6</sup>Kawaguchi Municipal Medical Center, Saitama, Japan.

We suggested the Connecting Path Method (CP method) last ASBMR to quantify the fragility of human lumbar vertebrae and develop a bone morphometry index to predict stress fracture tolerance. This is done by quantifying the trabecular path, the part which transmits the load on endplates.

Presently, we have expanded the method and made it possible to quantize the fragility of vertebrae to include cortical bone. We divided the bone into a hexahedron mesh to create the network that connects the paths through the center of mass. For the elastic constant of the connecting path, we brought a Young's modulus obtained from a CT value and reflected the property on the bone. As a specimen, we analyzed a clinical CT-scanned image of the L3 vertebra taken from (A) 70-year-old woman with fractures (Sp.A) and (B) 57-year-old man without fracture (Sp.B) using 3D analytical software called TRI/3D-BON (RATOC). We extracted the bone, and calculated the apparent resistance force (app RF) generated against the outer pressure through the connecting path using the CP method. These figures show the amount of power generated by bone to counter the outer pressure. The white area indicates a large power generated, and the black area indicates less power. Counter to an external deformation, the app RF generated by Sp.A is calculated to be about 1/3 that of Sp.B. In the case of Sp.A, we can observe the bone parts around the void zone mixed together, some connecting trabecular bone generates strong app RF while others provides little. Cortical bone has strong resistance force generated in all areas. Conversely, Sp.B seems to be generating stronger app RF in the neighboring areas both above and beneath endplates while the center area is weak. The distribution of app RF within the Sp.B is likely with trabecular bone anatomy showing a three-layer zonal structure. Though, Sp.A has lost its original vertebral anatomy probably due to the trabecular bone resorption. Finally, we conclude that it is possible to analyze the strength and the change in the network and fragility of trabecular and cortical bone that is caused by osteoporosis by using this method.

**Lumbar Spine TBS Complements BMD in the Discrimination Between Vertebral Fractured and Non-Fractured Subjects Postmenopausal Women: a Retrospective Case-Control Study.** B. Rabier<sup>\*1</sup>, R. Winzenrieth<sup>\*1</sup>, A. Heraud<sup>\*2</sup>, C. Grand-Lenoir<sup>\*3</sup>, P. Carceller<sup>\*1</sup>, D. Hans<sup>4</sup>, L. Pothuaud<sup>1</sup>. <sup>1</sup>PTIB - University Hospital of Bordeaux, Med-Imaps, Pessac Cedex, France, <sup>2</sup>Robert Boulin Hospital, Hospital Center of Libourne, Libourne, France, <sup>3</sup>Center of Radiology - Clinics of Lesparre, Lesparre, France, <sup>4</sup>Center of Bone Disease, Department of Bone and Joint Disease, Lausanne University Hospital, Switzerland.

Bone Mineral Density as assessed by DXA constitutes the gold standard in osteoporosis diagnosis. However, it does not take into account the bone microarchitecture deterioration. Trabecular Bone Score (TBS), a new grey-level texture measurement, based on a reanalysis of the image of DXA examination, correlates with 3D parameters of bone microarchitecture. The aim of our study was to evaluate the ability of lumbar spine TBS to complement BMD in the discrimination between vertebral fractured subjects and age-matched controls in Caucasian postmenopausal women with T-score  $\leq -1.0$ .

Included subjects, 50 to 80 years old, from a Rheumatology Department of a Hospital or the Radiology Department of a Clinic, have been measured on Prodigy GE-Lunar system and showed a BMD measurement T-score  $\leq -1.0$  at femoral neck, total hip or lumbar spine. Fractured subjects had low-energy vertebral fractures confirmed by X-rays. Non-fractured subjects had a matched age-paired in the fractured subject group ( $\pm 3$  years). Subjects with pathology, treatment known to affect bone metabolism were excluded. DXA scan files were exported onto a dedicated workstation for TBS calculation. A central database was constructed after cross-calibration.

42 vertebral fractured subjects of  $65.6 \pm 7.8$  years and 126 age-matched non-fractured subjects of  $63.5 \pm 8.3$  years were retained. The two groups were significantly different for BMD ( $p=0.0017$ ) and TBS ( $p<0.0001$ ) and not for basic anthropomorphic parameters (age, height, weight). Odds-ratios (OR) per standard deviation decrease is 1.95 [1.34-2.84] and Area Under the ROC Curve (AUC) is 0.662 [0.585-0.733] for BMD, and OR=2.96 [1.88-4.64] and AUC=0.729 [0.655-0.794] for region of interest matched TBS, with non-significant difference of the AUCs ( $p=0.243$ ). The comparison of a model combining (TBS, BMD) to (BMD) alone showed an OR of 3.40 [2.20-5.24] and AUC of 0.776 [0.705-0.836] versus an OR of 2.00 [1.39-2.87] and an AUC of 0.662 [0.705-0.836] respectively, with a significant difference in the AUCs ( $p=0.016$ ).

Combining bone microarchitecture index, TBS and BMD derived from the same spine DXA examination improved significantly the vertebral fracture discrimination in postmenopausal women. It would be of interest to test a case finding strategy using spine BMD then TBS to identify subjects at the highest risk of fracture especially in the osteopenic zone.

**In vivo Quantification of Intra-cortical Porosity in Human Cortical Bone using HR-pQCT in Patients with type II Diabetes.** A. J. Burghardt<sup>1</sup>, K. A. Dais<sup>\*1</sup>, U. Masharani<sup>\*2</sup>, T. M. Link<sup>1</sup>, S. Majumdar<sup>1</sup>. <sup>1</sup>Radiology, University of California, San Francisco, San Francisco, CA, USA, <sup>2</sup>UCSF Diabetes Research Center, University of California, San Francisco, San Francisco, CA, USA.

Cortical bone comprises a significant portion of overall bone mass and bears the bulk of axial loads in the peripheral skeleton. That metabolic disorders, including osteoporosis and type II diabetes, affect intra-cortical porosity is an emerging concept. Quantitative cortical microstructural and biomechanical endpoints are important for understanding structure-function relations in the context of fracture risk and therapeutic efficacy. In this study, novel image processing methods and  $\mu$ FE analysis applied to HR-pQCT were used to investigate intra-cortical macro-porosity in type II diabetes patients with and without a history of atraumatic fracture (Fx).

The distal radius and tibia of patients with type II diabetes and a history of Fx ( $n=2$ ), without Fx ( $n=7$ ), and age/BMI matched controls ( $n=6$ ) were imaged using HR-pQCT (XtremeCT, Scanco Medical). Segmentation of the cortical compartment was performed using manually drawn contours at the endosteal boundary. Segmentation of intra-cortical macro-porosity was achieved using a novel automated segmentation technique based on 2D component labeling and a hysteresis region growing process. Intra-cortical pore volume fraction (PVF) and cross sectional moment of inertia (CSMI) were calculated. Mechanical properties were determined by  $\mu$ FE. A 1% uniaxial compressive strain was simulated in the complete structure using a voxel based finite element technique. Apparent and compartmental parameters were calculated.

PVF was dramatically higher in diabetic Fx patients ( $p<0.01$  vs controls) but not in diabetics without Fx. Both diabetic groups tended to have higher BV/TV and Tb.N in the trabecular compartment. Accordingly, diabetes patients without Fx tended to have higher elastic modulus, stiffness, and estimated failure load, while Fx patients were similar to controls, though the cortical compartment tended to carry less load ( $p<0.01$  for tibia). CSMI tended to be lower in Fx patients compared to non-Fx and controls.

Despite limited numbers, these results suggest that loss of bone in the cortical compartment due to intra-cortical porosity is compensated for by increased trabecular bone mass in diabetics with Fx. This normalizes bone strength for axial loads, but likely results in compromised bending strength as evidenced by a lower CSMI. Non-Fx diabetes patients tended to have minimally increased porosity and higher mechanical indices for axial and bending loads. This indicates that cortical porosity metrics may be critical for differentiating patients at risk for fracture and evaluating treatment efficacy in this population profile.

**Marked Abnormalities in Cortical and Trabecular Microarchitecture and Strength in Premenopausal Women with Idiopathic Osteoporosis: A Bone Biopsy Study.** A. Cohen<sup>1</sup>, R. R. Recker<sup>2</sup>, D. W. Dempster<sup>3</sup>, H. Zhou<sup>\*3</sup>, A. Wirth<sup>\*4</sup>, T. Kohler<sup>\*4</sup>, G. H. van Lenthe<sup>4</sup>, R. Müller<sup>4</sup>, J. LeMaster<sup>\*2</sup>, J. Lappe<sup>\*2</sup>, H. F. Eisenberg<sup>\*1</sup>, D. J. McMahon<sup>\*1</sup>, E. Shane<sup>1</sup>. <sup>1</sup>Columbia University, New York, NY, USA, <sup>2</sup>Creighton University, Omaha, NE, USA, <sup>3</sup>Helen Hayes Hospital, West Haverstraw, NY, USA, <sup>4</sup>University of Zürich, Zürich, Switzerland.

Idiopathic osteoporosis (IOP) in premenopausal women (PrM) is an uncommon and poorly understood entity in which young, otherwise healthy women present with one or more low trauma fractures (LTFX) or very low BMD. In the course of a prospective study to elucidate the cause of bone fragility in PrM with IOP, we performed transiliac crest bone biopsies (BX) in 27 normally menstruating women with LTFX (n=17) and/or low BMD (T-score  $\leq -2.5$ ; n=10) and 50 healthy PrM controls (C) with normal BMD and no history of LTFX. Secondary causes of osteoporosis were excluded by clinical and laboratory evaluation. IOP and C were of comparable age (mean  $37 \pm 8$  yrs), height, weight (mean  $68 \pm 15$  kg), serum calcium, PTH, 25-OHD, and urine calcium. BMD was significantly lower at the spine, hip and forearm in IOPs. BX were analyzed by both 2D histomorphometry (2DH) and 3D micro-computed tomography ( $\mu$ CT). In a subset (n=45; 27 Cs), we also assessed mechanical competence (strength) by finite element modeling based on  $\mu$ CT image data to calculate apparent E (in the BX direction). By 2DH, IOPs had 21% lower trabecular (Tb) bone volume fraction (BV/TV), 11% lower Tb number, 20% higher Tb separation, and a trend toward lower Tb width (by 8%). Cortical (Ct) width was 25% lower, while Ct porosity (CtPoNo/CtAr) did not differ. By  $\mu$ CT, IOPs had 23% lower BV/TV, Tb number was 21% lower and separation was 18% higher. The standard deviation (SD) of Tb separation (Tb network inhomogeneity) was 14% higher, while Tb thickness and connectivity density did not differ. Mechanical competence (E) was 33% lower in IOP (p=0.06), but quite variable. E correlated best with 2DH and  $\mu$ CT BV/TV and  $\mu$ CT Tb number (R 0.8-0.9; p<0.0001). Dynamic parameters of bone remodeling activity were variable, but did not differ significantly between IOP and C.

In summary, PrM with IOP have thinner cortices, fewer and more widely spaced trabeculae, and greater Tb network inhomogeneity than C. These structural characteristics likely account for decreased bone strength and resistance to FX. The pathogenesis of these structural differences is unknown and is the subject of ongoing investigation.

**Reproducibility of Mineral Density and Morphometric MicroCT Measurements at Different Voxel Size Scans.** K. Verdelis<sup>1</sup>, L. Lukashova<sup>\*1</sup>, E. Atti<sup>\*2</sup>, S. Tetradis<sup>\*2</sup>, A. L. Boskey<sup>1</sup>, M. C. H. van der Meulen<sup>3</sup>. <sup>1</sup>Mineralized Tissues Laboratory, Hospital for Special Surgery, New York, NY, USA, <sup>2</sup>Oral Biology, School of Dentistry, Univ. of California Los Angeles, Los Angeles, CA, USA, <sup>3</sup>Sibley School of Mechanical & Aerospace Engineering, Cornell Univ., Ithaca, NY, USA.

The purpose of this study was to examine the reproducibility of mineral density and morphometric measurements from microCT analysis of mouse femurs performed at two different voxel sizes. The distal halves of three femurs from 3 month-old normal mice were analyzed in triplicate at 12 $\mu$ m and 8 $\mu$ m voxel resolution, using three different microCT systems: eXplore Locus SP (GE Healthcare, Canada), Skyscan 1172 (Skyscan, Belgium) and Scanco mCT40 (Scanco Medical, Switzerland). The samples were scanned in alcohol and each manufacturer's recommendations were followed for KVP, uMA, binning mode conditions and scan length. The scanned volumes were reconstructed in 3D and processed for both densitometric and morphometric analyses using the respective manufacturer's software for each system. Scans at each voxel size were performed in succession, without sample repositioning so that cortical or trabecular regions of interest (ROIs) defined subsequently could be applied identically to the same voxel size and system scanned volumes. Boundaries of the cortical and trabecular ROIs for each bone were constant as possible between different voxel size and system scans. True mineral density (TMD) was calculated for cortical and trabecular bone and directly measured bone volume (BV), bone volume fraction (BV/TV), surface to volume ratio (BS/BV), trabecular thickness (Tb.Th),

trabecular number (Tb.N) and trabecular separation (Tb.Sp) were determined for trabecular bone. Coefficients of variation (%) for each parameter were calculated for each system from the results of 12 $\mu$ m or 8 $\mu$ m scans individually (COVwithin resolution=COVw) or from results of 12 $\mu$ m and 8 $\mu$ m scans combined (COVbetween resolutions=COVb). COVw values were not correlated to COVb values in any of the parameters examined. 8 $\mu$ m cortical bone TMD measurements showed the lowest COVw (0.15-0.22) and 8 $\mu$ m trabecular TMD measurements the highest COVw (0.39-1.59). Decrease of the voxel size resulted in lower COVw values for cortical TMDs, while the opposite was true for trabecular TMDs. For all the 3D analysis parameters examined, higher resolution in most systems resulted in increased COVw. For both voxel sizes, BV/TV measurements presented the lowest COVw but the highest COVb values, while for the Tb.Sp the reverse held true. Increased precision in mineral density and morphometry measurements resulting from higher resolutions used in microCT is not generally accompanied by increased reproducibility of the measurements. Supported by NIH AR 46121.

## M312

**Evaluation of the Detection Sensitivity of Simulated Trabecular Bone Loss in  $\mu$ MRI at In Vivo Resolution.** C. Q. Li<sup>\*1</sup>, J. F. Magland<sup>\*1</sup>, C. S. Rajapakse<sup>\*1</sup>, X. E. Guo<sup>\*2</sup>, X. H. Zhang<sup>\*2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Columbia University, New York City, NY, USA.

The MRI-based "virtual bone biopsy" (VBB) is a method for quantifying structural signs of disease progression or treatment effectiveness using high-resolution in vivo images of trabecular bone. To evaluate VBB's detection sensitivity we created accurate models of trabecular structure from  $\mu$ CT images of human cadaveric bone samples acquired at 21x21x22 $\mu$ m<sup>3</sup> resolution. These images were binarized and inverted to generate bone and marrow phases. To simulate bone loss, the images were eroded by randomly generating pits 60 $\mu$ m in radius on bone surfaces to reduce bone volume by 1, 2, 3, 4 and 5%. The resulting pre- and post-erosion trabecular bone models were then subjected to simulated k-space scanning, assuming marrow spaces to contain MR-active material. Subsequently, the data were low-pass filtered and Fourier reconstructed analogous to in vivo image processing to result in effective resolutions of 137x137x410 $\mu$ m<sup>3</sup> and 160x160x160 $\mu$ m<sup>3</sup>. Gaussian noise was superimposed on the complex data to result in a signal-to-noise ratio (SNR) of 12 in the magnitude images, commensurate with typical resolutions and SNR achievable in vivo. BV/TV and topological parameters (surface density, curve density, junction density, surface-to-curve ratio, erosion index and skeleton density) were calculated for the pre-erosion (control) and eroded images using VBB processing, and ANOVA performed to determine if the various levels of erosion were detectable. At SNR = 12 and 137x137x410 $\mu$ m<sup>3</sup> resolution, 6 of the 7 parameters studied changed significantly (p < .05) after reducing bone volume by 2%. Four of these parameters (SD, CD, SD, S/C) were also significantly different after a bone volume reduction of 1%. BV/TV decreased linearly with increasing bone volume reduction while the erosion index increased as expected, more significantly than BV/TV (Fig). At SNR = 12 and 160x160x160 $\mu$ m<sup>3</sup> resolution, 5 of the 7 parameters changed significantly after a 2% erosion, but only BV/TV was significantly different after 1% bone loss. The data suggest that, even at limited resolution and SNR clinically achievable, the VBB can detect changes of topology and scale of the trabecular network caused by small, possibly subclinical bone loss. The results have implications for the method's potential to study the effects of aging and response to therapeutic intervention.

**Figure.** Relative change in parameter values after varying amounts of erosion, calculated with 137x137x410 $\mu$ m<sup>3</sup> voxel size and SNR=12. Error bars indicate 95% CI from Tukey HSD tests, relative to parameters of non-eroded images.

## M313

**Evidence of Increase in Vertebral Body Dimensions in Postmenopausal Women with Osteoporosis: A Three-Year Follow-Up Study.** K. Briot<sup>1</sup>, S. Kolta<sup>1</sup>, J. Fechtenbaum<sup>1</sup>, R. Said-Nahal<sup>\*1</sup>, C. Benhamou<sup>2</sup>, C. Roux<sup>1</sup>.<sup>1</sup>Rheumatology, Cochin Hospital, Paris, France, <sup>2</sup>Rheumatology, CHR d'Orléans, Unité INSERM U 658, Orléans, France.

Bone geometry plays a prominent role in the bone strength. Cross-sectional studies have shown that advancing age is associated with increasing diameter of long bones, related to both periosteal apposition and endosteal resorption. However, there are few data provided by prospective studies, especially concerning the changes in vertebral body dimensions. The objective here is to measure the changes occurring in the vertebral body size in a prospective study of women with postmenopausal osteoporosis.

Three-year data from placebo groups of the SOTI (1) and TROPOS (2) trials, performed in women with postmenopausal osteoporosis, were used for this current study. In these trials, patients underwent lateral radiographs of the thoracic and lumbar spine at baseline and annually over three years, according to standardized procedures. Six-point digitization method was used: the four corner points of the vertebral body from T4 to L4 are marked, as well as an additional point in the middle of the upper and lower endplates. From these 6 points, the vertebral body perimeter, area and depth were measured at baseline and at three years. The analysis excluded all vertebrae with prevalent or incident fracture.

A total of 2017 postmenopausal women (mean age 73.4±6.1 years) with a mean lumbar spine T score of -3.1±1.5, and a mean femoral neck T score of -3.0±0.7 are included in the analysis. Vertebral body dimensions increased over 3 years, by 0.5±1.1 mm (mean depth ± SD), by 11.4±49.2 mm<sup>2</sup> (mean area ±SD) and by 1.1±3.4 mm (mean perimeter ±SD) at the thoracic level (T4 to T12). At the lumbar level (L1 to L4), these dimensions increased as well: 0.5±1.3 mm (mean depth ± SD), 13.9±67mm<sup>2</sup> (mean area ±SD), 0.7±3.9 mm (mean perimeter ±SD). A significant increase in vertebral body size was observed for each vertebral level from T5 to L4 for each of these parameters (p<0.01).

These prospective results demonstrate that vertebral body dimensions increase over 3 years in women with postmenopausal osteoporosis.

**Radiographic Texture Analysis (RTA) of Densitometric Calcaneal Images Differs Between Subjects with and without Glucocorticoid (GC) Use.** T. J. Vokes<sup>1</sup>, M. Chinander<sup>\*2</sup>, M. Giger<sup>\*3</sup>. <sup>1</sup>Medicine/Endocrinology, University of Chicago, Chicago, IL, USA, <sup>2</sup>Radiology, University of Chicago, Chicago, IL, USA, <sup>3</sup>Radiology, University of Chicago, Chicago, IL, USA.

RTA is a method for non-invasive assessment of bone structure through computerized analysis of the pattern of radiographic images. We have previously shown that RTA performed on densitometric calcaneal images differentiated subjects with and without vertebral fractures even when controlling for age and BMD, suggesting that RTA captures an aspect of bone fragility that is not assessed by BMD. GC-associated increase in bone fragility is not fully explained by decrease in BMD, suggesting that GC also cause deterioration of bone structure. Therefore, we examined whether RTA differs between subjects who had received pharmacologic doses of GC and those who had not.

We recruited 800 subjects (age 19-95 years, mean±SD of 62.6±13.6 years, 82 males) referred for BMD testing. We used Prodigy to image the spine for VFA and to measure BMD at the lumbar spine and proximal femur, and PIXI to measure calcaneal BMD and to generate a high resolution image for RTA. RTA was performed on a 128x128 pixel ROI in the proximal calcaneus. RTA features analyzed include RMS (root mean square variation, a measure of coarseness of radiographic texture pattern) and its standard deviation across the 24 radial slices, sdRMS, which is a measure of the anisotropy of the textural pattern.

There were 126 subjects who had received more than 2800 mg of prednisone or equivalent and 674 subjects without history of GC use. Compared to non-users, GC users had higher prevalence of vertebral fractures (31 vs. 17%, p=0.001), despite their younger age (55.9 vs. 63.8 years, p<0.0001), and higher weight (165 vs. 153lbs, p=0.0005). Although BMD T-score (the lowest of hip or spine) did not differ between GC users and non-users (-2.4 vs. -2.3, p=0.5), both RMS and sdRMS were lower in GC users (4.34 vs. 4.46, p=0.001, and 0.11 vs. 0.12, p=0.03). In a multivariate logistic regression analysis with GC use as outcome, and age, weight, BMD T-score and RTA as predictors, both BMD and RTA had a significant effect with p<0.0001 for BMD T-score, p=0.002 for RMS and p=0.03 for sdRMS, respectively. In general, subjects with vertebral fractures (VFX) had lower RTA values than those without VFX. GC users without VFX had RTA values similar to non-GC users with VFX, while GC users who also had VFX had even lower values. No such relationship was observed for BMD.

These results suggest that RTA performed on densitometric calcaneal images captures changes in bone structure associated with GC-induced increase in bone fragility.

## M315

**Regional Differences in Femoral Neck Cortical Thickness Determine Hip Fragility: An in-Vivo CT Study.** P. M. Mayhew<sup>\*1</sup>, C. M. Rose<sup>\*1</sup>, K. Brown<sup>\*2</sup>, S. K. Kaptoge<sup>\*1</sup>, N. Loveridge<sup>\*1</sup>, J. Reeve<sup>1</sup>, K. E. S. Poole<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Cambridge, CB2 2QQ, United Kingdom, <sup>2</sup>Austin, Mindways Software Inc, Texas, TX, USA.

This in vivo CT study examined the regional variability in the contra-lateral femoral neck cortical thickness (C.Th) of female patients that had fractured a hip, and an age matched group of control patients, to determine whether C.Th may be an indicator of hip fragility.

Sixteen pre-discharge patients with low/moderate trauma hip fracture (intracapsular (n=7), trochanteric (n=9) mean age 80.3 +/- 1.15) consented to a CT scan of the unfractured hip (Siemens 16, 1mm slice thickness, 0.59 mm pixel size) and analysis with Mindways software (v 4.1.3, Texas, USA). Forty eight healthy controls attending for a routine clinical CT scan of the abdomen and pelvis were also consented to hip CT (age 79.5 +/- 0.7; exclusions: malignancy, severe hip osteoarthritis, liver disease, Paget's ). Femoral neck T scores were <2.5 in 5 of the controls and 6 cases (3 intracapsular and 3 trochanteric). Six cross-sectional slices at 1mm intervals of the femoral neck were automatically extracted commencing from a reproducible mid-neck location (eccentricity/max-min ratio of 1.4) for analysis of the regional C.Th. Four anatomical quadrants for each slice were defined: supero-posterior, supero-anterior, infero-posterior and infero-anterior; using the centre of mineral mass and principal axes. There were no differences in C.Th between right and left hips in controls so mean values were used. Longitudinal drift by phantom measurement was <2%. Data was Log transformed to normalize distributions of the C.Th. A nested ANOVA with random effects was used to obtain least squares means and fracture case/control contrasts in quadrants.

Allowing for the expected effect of age (reducing cortical thickness), hip fracture cases exhibited significantly lower cortical thickness in all the quadrants, when compared to the controls: Supero-anterior 21% lower (mean 0.28mm, p=0.0007), Infero-anterior 21% (1.08mm, p=0.0008), Infero-posterior 21% (2.04mm, p=0.0007), and Supero-posterior 16% (0.18mm, p=0.0132). Although there were no statistically significant differences in C.Th estimates between the intracapsular and trochanteric fracture types (p=0.23), mean C.Th estimates were lower in the intracapsular group in all quadrants.

Technological advancements in tomography and analysis mean that cortical thickness measurements can be made at clinical CT resolution, and thus help direct appropriate therapy to those at risk of hip fracture.

**In Vivo Measurements of Vertebral Body Dimensions by 3 Dimensional X-ray Absorptiometry (3D-XA) and Their Relation with Age: A Cross-Sectional and Longitudinal Study.** S. Kerkeni<sup>\*1</sup>, S. Kolta<sup>1</sup>, L. Gossec<sup>\*1</sup>, B. Billotet<sup>\*2</sup>, E. Sapin<sup>\*2</sup>, D. Mitton<sup>\*2</sup>, W. Skalli<sup>\*2</sup>, C. Roux<sup>1</sup>. <sup>1</sup>Cochin Hospital, Paris, France, <sup>2</sup>LBM, Arts et Métiers ParisTech ENSAM, CNRS, Paris, France.

Our study aimed to assess changes in vertebral geometric parameters with age using 3D-XA method in vivo. Subjects were women participating in the European population-based Osteoporosis and Ultrasound Study (OPUS) (1). This cross-sectional and longitudinal study was conducted in 3 subgroups of women without vertebral fracture. Group 1: 20-40 years (N=27), group 2: 55-60 years (N=29) and group 3: 70-79 years (N=29). All participants had an anterior-posterior and a lateral measurement of thoracic and lumbar spine using Instant Vertebral Assessment software on a standard Hologic QDR4500A device at baseline and 6 years later. All vertebrae from T4 to L4 were studied. 3D-XA was performed according to our previously published methodology (2). Several geometric parameters of vertebral bodies were measured from the 3D-XA including anterior, middle and posterior heights (aH, mH and pH), volume, minimal cross sectional area (CSA). At baseline, without any adjustment, vertebral body heights were not significantly different between groups. Mean CSA (T4-L4) was 701.5 ± 84.7, 740.9 ± 68.8 and 739.2 ± 67.2 mm<sup>2</sup> in groups 1, 2 and 3 respectively (p = 0.09). The difference was significant in thoracic vertebrae (p=0.04) but not in lumbar vertebrae. After adjustment for body height, aH, mH, pH, CSA and vertebral body volume were significantly different between the 3 groups in the thoracic vertebrae as well as the lumbar vertebrae (p<0.0001) except for thoracic aH. Six years follow-up revealed, in the whole population, a significant increase in thoracic vertebral body volume (+ 392.3 mm<sup>3</sup>, p=0.02) and a trend to an increase in CSA of thoracic vertebrae (+18.2 mm<sup>2</sup>, p=0.09). This study shows that vertebral dimensions vary with age and that these changes can be detected by the 3D-XA method. Bone geometry is known to be an important determinant of bone strength. Combined to bone density, it could improve fracture risk prediction.

## M317

**Active Shape Modelling As a Predictor of Hip Fracture.** F. Jabbar<sup>\*1</sup>, R. J. Barr<sup>\*1</sup>, D. M. Reid<sup>1</sup>, R. M. Aspden<sup>1</sup>, I. R. Reid<sup>2</sup>, B. Mason<sup>\*2</sup>, A. N. Horne<sup>\*2</sup>, J. S. Gregory<sup>\*1</sup>. <sup>1</sup>University of Aberdeen, Aberdeen, United Kingdom, <sup>2</sup>University of Auckland, Auckland, New Zealand.

Osteoporosis (OP) is a common musculoskeletal disorder characterised by reduced Bone Mineral Density (BMD) and a disruption of bone microarchitecture, leading to an increased risk of fracture. Dual Energy Absorptiometry (DXA) is used to diagnose OP, however BMD alone has a poor efficacy in terms of hip fracture prediction. The shape of the hip is known to affect fracture risk. Active Shape Models (ASM) can quantify shape variation of the proximal femur and have been shown to relate to fracture in a cross sectional study. This study aimed to discover if the link between fracture risk and the shape of the proximal femur can be observed prospectively using ASM.

Images from DXA scans of 260 subjects from the baseline visit of 'The Auckland Calcium study', were used. All subjects were healthy postmenopausal women aged over 55 years with no major disease, or treatment for OP. The fracture group comprised 20 subjects who incurred a proximal femoral fracture during the 5 year study.

Each DXA image was processed using the 'Active Shape Modelling Toolkit' software. The shape was outlined using points at key anatomical landmarks. A 29 point model from a previous study was used to automate and train the model. Once all images had been processed a new ASM was produced which outputted 9 distinct shape modes for the dataset.

Three of the modes showed significant differences in the shape of the proximal femur in the fracture group. After adjusting for age and BMI with logistic regression, Mode 1 was no longer significant, due to a high correlation with age, Mode 4 was highly significant ( $P=0.003$ ) while Mode 9 became marginally insignificant, ( $P=0.049$  to  $P=0.066$ ) (Table). The shape changes associated with an increase in Mode 4 include an increase in neck-shaft angle and femoral neck length, which have individually been shown in geometrical studies to increase the risk of hip fracture. The odds ratio for mode 4 is 2.33 indicating that a 1 standard deviation increase from the mean will more than double the risk of hip fracture.

This study has demonstrated a link between the morphology of the proximal femur and prospective risk of hip fracture. It may be possible to improve hip fracture risk assessment by using methods such as ASM to examine the shape of the whole femur.

**Calcaneal Quantitative Ultrasound Measurement of 2323 Healthy Adults in Southwest China.** J. Yang, X. Zhao\*, J. Sun\*, J. Rong\*, C. Li\*, L. Chen. Trauma Center, Institute of Surgery Research, Daping Hospital, Chongqing, China.

**Background:** In China, especially in Southwest China, the awareness of OP is not appreciated, and DEXA is not broadly used for the evaluation of bone health. As a non-invasive, radiation-free, and portable measurement, quantitative ultrasound (QUS) assessment of bone status is a reliable, fast and low-cost approach to evaluate the bone structure and bone quality.

**Objective:** To establish the reference QUS data and investigate the correlation among age, body size and ultrasound variables in healthy southwest chinese population.

**Materials and Methods:** Ultrasound bone densitometry of the calcaneus in 2323 healthy adults in southwest china (1459 men and 864 women) aged 20-95 years was carried out using SONOST2000 (Korea) in this study. QUS parameters represented as speed of sound (SOS), broadband ultrasound attenuation (BUA) and bone quality index (BQI) were determined at the right Calcaneus.

**Results:** The SOS, BUA and BQI peaked at 20-29 years old in both genders. Compared with the 20-29 years old group, there was a significant decrease in female SOS and BQI starting from the age of 50 years. The SOS and BQI in male, and BUA in female started to fall from the age of 60 years ( $P<0.05$ ). The male SOS, BUA and BQI were higher than that in the female in all age groups, but only significantly higher in groups over 60 ( $P<0.001$ ). Pearson's correlation analysis showed a significant correlation between SOS and BUA (for male,  $r=0.658$ , for female,  $r=0.610$ ,  $P<0.001$ ), which was higher than those found by other groups in mainland chinese men and women. We also observed significant correlation between BQI and SOS, or between BQI and BUA (for male,  $r=0.895$ ,  $0.870$ ; for female,  $r=0.915$ ,  $0.883$  respectively,  $P<0.001$ ). Age had the highest correlation coefficient with SOS, BUA and BQI ( $P<0.001$ ) especially in women ( $r=-0.475$ ,  $-0.317$  and  $-0.442$  respectively). The linear regression revealed that the mean decreasing rates of the QUS parameters in men ( $0.508$  m/s per year for SOS,  $0.177$  dB/MHz per year for BUA) and women ( $0.987$  m/s per year for SOS,  $0.224$  dB/MHz per year for BUA) were faster than those reported for the mainland chinese population. In the stepwise multiple linear regression analyses, the male BMI or female weight was the secondary positive factor influencing QUS parameters, which was different from the previous report, in which weight was found to be a less important factor affecting QUS parameters in mainland Chinese of both genders.

**Conclusion:** We established the normative QUS data for the adult southwest chinese of

both genders, which will provide the reference values for the screening of osteoporosis and prediction of fracture risk in local area.

This study received "973" program of China (No.2005CB522604), and NSFC (No.30470947, 30530410).

## M319

**Assessment of Cortical Thickness and Bone Mineral Density in the Radius by Low-Frequency Guided-Wave Ultrasound.** P. Moilanen<sup>\*1</sup>, V. Kilappa<sup>\*1</sup>, T. Chen<sup>\*2</sup>, H. Ma<sup>\*2</sup>, J. Timonen<sup>\*1</sup>, S. Cheng<sup>2</sup>. <sup>1</sup>Department of Physics, University of Jyväskylä, Jyväskylä, Finland, <sup>2</sup>Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland.

Low-frequency quantitative guided-wave ultrasonics (Q-GWUS) based on the first arriving signal shows enhanced sensitivity to cortical thickness and osteoporotic changes deep in the endosteal region of cortical bone. A group of female subjects were measured on the tibia and radius shaft. Low-frequency ultrasound velocity ( $V_{LF}$ ) was recorded by a Q-GWUS device (0.4 MHz) with a bidirectional array of transducers. In addition, high-frequency ultrasound velocity ( $V_{HF}$ ) was recorded by an Omnisense® (Sunlight Medical Ltd; 1.25 MHz). Peripheral quantitative computed tomography (XCT 2000, Stratec Medizintechnik GmbH) was used to assess the volumetric bone mineral density (BMD) and cortical thickness (CTH) at the same bone locations. *In vivo* reproducibility of the Q-GWUS (RMS CV) across the subjects was 0.5% for the radius and tibia.

Preliminary results indicate that radius  $V_{LF}$  follows well the typical growth and loss curve of bone with aging, similarly as CTH and BMD (age 10-85 years;  $n=207$ ). In addition,  $V_{LF}$  appears to be more strongly correlated with CTH ( $r=0.61$ ,  $p<0.001$ ) and BMD ( $r=0.75$ ,  $p<0.001$ ) than  $V_{HF}$  (respectively:  $r=0.28$ ,  $p<0.05$ ;  $r=0.38$ ,  $p<0.01$ ) ( $n=59$  for the comparative correlations).

In conclusion, our results indicate that the low-frequency ultrasound device (Q-GWUS) had an enhanced sensitivity and yielded better prediction over that of the high-frequency device (Omnisense) with respect to changing of cortical thickness and bone mineral density with aging.

## M320

**Relationship of Quantitative Ultrasound at Phalanges with Hand and Axial BMD, Sex Hormones and Bone Turnover Markers in Elderly Women.** S. Gonnelli, C. Caffarelli\*, L. Gennari, D. Merlotti, S. Campagna\*, B. Franci\*, R. Nuti. Institute of Internal Medicine, University of Siena, Siena, Italy.

Quantitative ultrasound (QUS) has been applied to the assessment of bone status for almost two decades. Some recent studies have reported that the quantitative analysis of the graphic trace of QUS signal at phalanges could improve our ability in evaluating bone status and in distinguishing different metabolic bone diseases. The literature data on the determinants of the QUS parameters derived from graphic trace analysis are scarce.

This study aimed to investigate for any possible relationships of QUS parameters at phalanges with hand and axial BMD, sex hormones and bone turnover markers in a cohort of elderly Italian women, who were participating in a larger epidemiological study. In 763 consecutive healthy women aged 55 years or more (mean age  $62.7 \pm 6.7$  yrs), living in the area of Siena (Italy), we evaluated: QUS at phalanges (amplitude dependent speed of sound [AD-SoS], bone transmission time [BTT]; ultrasound bone profile index [UBPI]) by Bone Profiler-IGEA. BMD at right hand, at lumbar spine and at femur was also assessed (Prodigy, GE-Lunar). In all subjects we also measured serum testosterone (T), estradiol (E), sex-hormone binding globulin (SHBG), 25-hydroxyvitamin D (25OHD), bone alkaline phosphatase (B-ALP), parathyroid hormone (PTH) and carboxy-terminal telopeptide of type I collagen (CTX). Dietary calcium intake was assessed by a validated Food Frequency Questionnaire.

Both AD-SoS and UBPI were inversely associated with age ( $r=-0.39$  and  $r=-0.44$  respectively). No significant correlation was found between BTT and age. Among QUS parameters BTT showed the highest correlation with hand-BMD ( $r=0.68$ ;  $p<0.001$ ). The correlation coefficients between AD-SoS, BTT and UBPI with hand and axial BMD were all significant ( $p<0.001$ ) but low, ranging from 0.25 to 0.44. Both AD-SoS and UBPI, but not BTT, showed a significant, even though marginal, correlation ( $p<0.05$ ) with serum 25OHD. SHBG serum levels were inversely correlated with AD-SoS, BTT and UBPI ( $r=-0.17$ ,  $r=-0.11$  and  $r=-0.20$ , respectively). All QUS parameters were inversely correlated with serum B-ALP, but not with serum CTX. Multiple regression analysis showed that age, E, PTH and 25OHD were significant determinants of AD-SoS; instead, only age, PTH and E were significant determinants of UBPI.

On the basis of our results we can conclude that BTT could improve the identifying of subjects with reduced BMD both at hand and axial skeleton. However, AD-SoS and UBPI seem to better reflect the changes in bone status induced by aging, sex hormones and vitamin D levels.

**Disclosures:** S. Gonnelli, None.

**Longitudinal Analysis of Calcaneal Quantitative Ultrasound Measures During Childhood.** M. Lee<sup>1</sup>, R. W. Nahhas<sup>\*1</sup>, A. C. Choh<sup>\*1</sup>, E. W. Demerath<sup>\*2</sup>, W. C. Chumlea<sup>\*1</sup>, D. L. Duren<sup>1</sup>, R. J. Sherwood<sup>\*1</sup>, K. D. Williams<sup>\*1</sup>, B. Towne<sup>\*1</sup>, R. M. Siervogel<sup>1</sup>, S. A. Czerwinski<sup>\*1</sup>. <sup>1</sup>Community Health, Wright State University, Dayton, OH, USA, <sup>2</sup>Epidemiology, University of Minnesota, Minneapolis, MN, USA.

Accrual of peak bone mass at the end of adolescence lays the foundation for bone in adulthood to manage the various challenges to the skeleton over one's lifetime. Quantitative ultrasound (QUS) technology has been used to estimate properties of bone in children and adults with the advantages of no radiation exposure. However, there are only a few studies that have examined longitudinal changes in calcaneal QUS measures in samples of children. We examined how QUS parameters change over time by examining both chronological age and skeletal age and determined whether changes in QUS measures differ by sex. The study sample consisted of a total of 219 Caucasian children and adolescents (112 males and 107 females) participating in the Fels Longitudinal Study. A total of 610 calcaneal QUS observations were obtained using Sahara ® bone sonometer (Hologic, Inc., Waltham, MA) from children aged between 7.6 and 18 years (skeletal ages between 6.4 to 18 y.). Broadband ultrasound attenuation (BUA, dM/Hz), and speed of sound (SOS, m/s) were collected twice in the dominant heel, and the average value of each QUS parameter was used in the analysis. Using statistical methods for linear mixed effect models, the best fitting models were selected. The results for log(BUA) indicate that there is a cubic growth curve that is best described using skeletal age rather than chronological age as the timing variable, and that the growth curves differ significantly by sex ( $p < 0.0001$ ). In particular, males experience their most rapid growth in BUA in early and late adolescence, while females experience their most rapid growth in BUA in mid-adolescence (Figure 1). For SOS, the growth trend is linear with respect to skeletal age with a significantly positive slope for females only; however there is no significant difference between the trends for males and females ( $p > 0.05$ ). This study documents significant sex differences in the pattern of change in QUS measures of bone strength (particularly BUA) during childhood and adolescence, demonstrating the utility of QUS for tracking bone development.

**Figure 1. Predicted log(BUA) over time, by sex**

**Post-Fracture Osteoporosis Intervention Strategy.** V. I. M. Elliot-Gibson<sup>\*1</sup>, R. Jain<sup>\*2</sup>, D. E. Beaton<sup>1</sup>, R. Sujic<sup>\*1</sup>, F. Jiwa<sup>\*2</sup>, E. R. Bogoch<sup>3</sup>, S. Richie<sup>\*4</sup>, E. Samji<sup>\*5</sup>. <sup>1</sup>Mobility Program Clinical Research Unit, St. Michael's Hospital, Toronto, ON, Canada, <sup>2</sup>Osteoporosis Canada, Toronto, ON, Canada, <sup>3</sup>Department of Surgery, St. Michael's Hospital, Toronto, ON, Canada, <sup>4</sup>Department of Surgery, McMaster University and Brantford General Hospital and Ontario Orthopaedic Association, Hamilton, ON, Canada, <sup>5</sup>Ministry of Health and Long-Term Care, Government of Ontario, Toronto, ON, Canada.

The Ontario Osteoporosis (OP) Strategy is a multifaceted initiative mandated and funded by the Ontario Government, Ministry of Health. The Post-Fracture OP Program is one of five components and was implemented by Osteoporosis Canada (OC) on behalf of the Ministry. The goals of this program are to improve OP diagnosis and treatment in this population, prevent future fractures, and improve OP knowledge among health professionals and patients. From January 3, 2007 to January 8, 2008 OC deployed 19 OP Screening Coordinators (OSCs) in 31 medium to high volume fracture clinics in Ontario. The OSC identifies fragility fracture patients, educates them on OP and their risks, and suggest follow up with the family physician (FP) for further investigation and treatment of

their bone health. OSC's also facilitate communication between the FP and surgeon by way of a standardized form letter recommending OP assessment with their patient. Quality assurance self-report data is collected on patients able to voluntarily complete the questionnaire and includes OP risk factors, prior OP treatment and adherence, prior bone mineral density (DXA) testing, OP knowledge and beliefs and socio-demographics characteristics. Patient review is conducted at three and six months. Data collection from January, 2007 to April, 2007 was completed on paper format and starting in May, 2007 data was collected using tablet PC's. From May 2, 2007 to January 11, 2008, 97,386 fracture clinic patient visits were screened, of which 16.97% were identified for OP screening and 58.92% were seen by the OSC. Out of the 9737 identified for screening, 45.65% did not meet inclusion criteria, 50.84% completed baseline screening, 2.72% refused intervention, and 0.8% missing data. From the electronic database (January 3, 2007 to January 7, 2008) and referring to the fragility fracture (target) population ( $n = 5330$ ), follow up with the FP was suggested for 85.5% patients, with 61.7% of FP's receiving the standardized form letter. Discussion about having a bone mineral density (DXA) test completed by their FP was suggested to 75.2%. It was suggested to 97.8% of patients to take 1500 mgs of calcium and 800 IU Vitamin D daily. The most common fracture sites were the wrist, ankle, shoulder and hip. Approval from each hospital's Research Ethics Board is currently underway to use the quality assurance data collected for research purposes.

**LRP5 G171V Mutation and Tobacco Smoke Related Bone Fragility.** M. P. Akhter, A. S. Manolides<sup>\*</sup>, D. M. Cullen, R. R. Recker. Medicine, Creighton University, Omaha, NE, USA.

Tobacco smoking is a lifestyle choice that may cause bone loss and osteoporosis. In this study, we characterized bone structure and strength properties to determine if the LRP5 G171V mutation will protect against bone loss associated with tobacco smoking. Ninety adult (4 mo.) female mice representing three genotypes (all bred to C57BL/6 mice): WT (Lrp5<sup>+/+</sup>, wild type), KO (Lrp5<sup>-/-</sup> knockout), HBM (High bone mass with LRP5 G171V mutation) were randomly divided into control and tobacco exposure groups. Mice were subjected to whole body tobacco/cigarette (IR4F University of Kentucky Research) smoke at either smoke exposure of 129±38 mg/mm<sup>3</sup> (mean± SD) total suspended particulates (TSP/m<sup>3</sup>) or sham exposed (no smoke exposure, Control). A smoke exposure was for 3hrs (5 days/week) for 12 weeks. Mice were inspected daily to assure adequate food intake, and general health. Femurs were collected for biomechanical measurements. Trabecular bone structure in distal femurs was analyzed by micro-CT scans. Mid-shaft femurs were tested in 3-point bending. We used the General Linear Model for univariate analysis to test for differences due to smoking within each genotype. Bone volume fraction (BV/TV) and connectivity density (ConnD) declined in all three genotypes exposed to tobacco smoke (Table). While trabecular number (TbN) was lower in the HBM smoke exposed group as compared to their respective controls (Table). Apparent density (AppDens) was lower in the smoke exposed group for HBM and KO (Table) as compared to the controls. Smoking-related loss in trabecular structure (BV/TV) was 36%, 28% and 45% in HBM, WT and KO mice respectively. In addition, the mid shaft ultimate (ULT) load declined in the Smoke exposed group as compared to their respective controls. The trabecular bone structure (BV/TV, ConnD, TbN, AppDens) and femur strength in HBM mice remained elevated as compared to both WT and KO within each treatment group (Control & Smoke exposed). The already fragile KO had a large decrease in trabecular bone structure (45%), and the HBM losses were moderate with final bone structure and strength remaining well above that for the wild type mice. Mice with the LRP5 G171V mutation (HBM) did show a significant decline to smoke exposure demonstrating sensitivity to tobacco smoke exposure.

**High Impact Exercise May Have a Protective Effect on BMD but Moderate Impact Exercise May Have Negative Effect in Young Women with Anorexia Nervosa.** E. J. Waugh<sup>1</sup>, D. E. Beaton<sup>\*2</sup>, P. Cote<sup>\*3</sup>, B. Woodside<sup>\*4</sup>, G. A. Hawker<sup>1</sup>. <sup>1</sup>Osteoporosis, Women's College Hospital, Toronto, ON, Canada, <sup>2</sup>Mobility Program, St. Michael's Hospital, Toronto, ON, Canada, <sup>3</sup>Rehabilitation Solutions, University Health Network, Toronto, ON, Canada, <sup>4</sup>Psychiatry, University Health Network, Toronto, ON, Canada.

We investigated the effect of exercise on BMD in a retrospective cohort study of patients aged 17-40 yrs who had received inpatient treatment for AN over a 12-yr time period. A detailed illness history was obtained by a Life History Calendar semi-structured interview. Lifetime exercise history was obtained by an adapted Minnesota Leisure Time Physical Activity interview. Exercise type was categorized as non/low (NL), moderate

(MOD) or high (HI) impact. Total lifetime hours for each category was converted to a lifetime percentage based on participants' age (NL%, MOD%, HI%). BMD at the lumbar spine L1-L4 (LSP), femoral neck (FN) and total body (TB) and body composition (fat, lean mass) was measured by DXA. Low BMD was defined as a Z-score value  $\leq -1.5$  at one or more sites. Participants were considered recovered if they both achieved a BMI  $\geq 18.5$  kg/m<sup>2</sup> and resumed regular menstruation for  $\geq 1$  year. Logistic regression was used to examine the association between exercise and BMD values adjusting for recovery status (no/yes), weight, and duration and severity (lowest lifetime BMI) of illness.

We recruited 190 participants from two centers (113 ill; 77 recovered). At interview, mean age was  $27.2 \pm 5.6$  yrs, mean BMI was  $19.4$  ( $11.1 - 35.5$ ) kg/m<sup>2</sup>, % fat was  $26.2$  ( $4.3 - 49.3$ ), lean mass was  $36.0$  ( $24.9 - 55.4$ ) kg, age at AN onset was  $18.2$  ( $10-32$ ) yrs, duration of illness was  $5.9$  ( $1 - 25$ ) yrs and lowest lifetime BMI was  $13.9$  ( $7.2 - 18.0$ ) kg/m<sup>2</sup>. Mean hrs/ wk of past year exercise was  $7.2$  ( $0 - 46.3$ ). Lifetime NL% was  $0.4$  ( $0 - 4.3$ ), MOD% was  $1.0$  ( $0 - 8.3$ ), HI% was  $0.7$  ( $0 - 9.2$ ). HI% was correlated with lean mass (Spearman  $r=0.29$ ,  $p<0.0001$ ). Descriptively, participants with high MOD% ( $> 2\%$ ) typically walked for  $\geq 3$  hrs/d while ill; those with high HI% ( $> 2\%$ ) participated in dance or gymnastics at a competitive level before AN onset during childhood and early adolescence. NL% was not associated with low BMD ( $p=0.8$ ), MOD% had a negative effect (OR =  $1.5$ , 95% CI  $1.11 - 2.08$ ,  $p=0.007$ ) and HI% had a positive effect (OR =  $0.49$ , 95% CI  $0.26 - 0.83$ ,  $p=0.005$ ). Lean mass also had a positive effect (OR =  $0.89$ , 95% CI  $0.8-0.98$ ,  $p=0.03$ ).

The results suggest that HI exercise prior to AN onset may have a protective effect on BMD which may be due to the associated increase in lean mass. Excessive MOD exercise often observed in AN patients appears to have a negative effect on BMD even after adjusting for weight and illness history.

## M325

**Physical Activity, BMD and Fragility Fracture: the Canadian Multicentre Osteoporosis Study (CaMos).** C. L. Hitchcock<sup>\*1</sup>, E. J. Kingwell<sup>\*1</sup>, M. A. Petit<sup>2</sup>, K. S. Davison<sup>3</sup>, S. Forsmo<sup>4</sup>, W. Zhou<sup>\*5</sup>, N. Kreiger<sup>\*6</sup>, J. C. Prior<sup>1</sup>. <sup>1</sup>UBC, Vancouver, BC, Canada, <sup>2</sup>U MN, Minneapolis, MN, USA, <sup>3</sup>Laval, Quebec City, QC, Canada, <sup>4</sup>NTNU, Trondheim, Norway, <sup>5</sup>McGill U, Montreal, QC, Canada, <sup>6</sup>U of T, Toronto, ON, Canada.

Physical activity has the potential to optimize bone mineral density (BMD) and reduce the risk of fractures. However, few studies have explored these relationships in a population-based data set. We explored the association with physical activity, BMD and fragility fracture at baseline and over 5 years using population-based data from the 9 regional centres in the Canadian Multicentre Osteoporosis Study (CaMos). Lumbar spine (LS) and total hip (hip) BMD were assessed at baseline and after 5-y using phantom-adjusted dual energy x-ray absorptiometry (DXA). Questionnaires were used to assess self-reported physical activity (PA) and prevalent and 5-yr incident fragility fractures (FFx) at any site (defined as a Fx with a fall from less than standing height).

PA was assessed by: (1) daily metabolic equivalents (METs in MET-min/day) and (2) self-report of Regular Activity (RgA). Multiple regression analysis included potential confounders (e.g., age, BMI, reproductive history, lifestyle). Descriptive statistics and regression coefficients are reported as mean $\pm$ SE and (95% CI), respectively; METs coefficients are per 1000-MET-min/day. Women's and men's data were analyzed separately. Average age was  $63.1\pm0.2$ ,  $59.9\pm0.3$  and BMI was  $26.9\pm0.1$ ,  $27.0\pm0.1$  for women and men, respectively. The Table shows that average METs were moderate (equivalent to 1.7 per min) and about half the participants reported RgA.

	Baseline (mean $\pm$ SE)		5-y change or Incident Fx (mean $\pm$ SE)	
	Women (n=5659)	Men (n=2560)	Women (n=4335)	Men (n=1859)
BMD-LS (g/cm <sup>2</sup> )	$0.94 \pm 0.002$	$1.05 \pm 0.003$	$0.013 \pm 0.001$	$0.022 \pm 0.001$
BMD-Total Hip (g/cm <sup>2</sup> )	$0.86 \pm 0.002$	$1.01 \pm 0.003$	$-0.012 \pm 0.001$	$-0.012 \pm 0.001$
Fragility Fracture	27.5%	24.2%	9.3%	4.2%
MET-min/day	$2,510 \pm 4$	$2,500 \pm 8$		
RgA (%)	54.9%	55.6%		

Results show that, for women at baseline, PA was positively associated with hip BMD (RgA: (0.005, 0.017), MET: (0.009, 0.026)), but with neither LS BMD nor FFx. For men at baseline, RgA and METs were positively associated with hip BMD (RgA: (0.026, 0.046), MET: (0.005, 0.028)). LS BMD was associated with RgA (0.009, 0.034), but no other PA measures in men.

None of the PA measures were associated with 5-year change in BMD or FFx in either men or women with the exception of METs (-0.008, -0.001) which had an unexpectedly negative association with change in hip BMD in women.

Overall, men and women who were more active had higher hip BMD at baseline, but activity level was not positively associated with change in BMD over 5 years or with incident fracture in our population-based Canadian sample.

**Osteopenia by High Alcohol Consumption in the Absence of ALDH2 Attribute to the Disturbance of the Differentiation in Osteoblasts.** Y. Shimizu<sup>\*</sup>, K. Menuki<sup>\*</sup>, T. Mori<sup>\*</sup>, A. Sakai<sup>\*</sup>, T. Isse<sup>\*</sup>, T. Oyama<sup>\*</sup>, T. Kawamoto<sup>\*</sup>, T. Nakamura<sup>\*</sup>. Orthopedics, University of Occupational Environmental Health, Kitakyusyu, Japan.

High consumption of alcohol is a risk factor of osteoporosis. Approximately 45% of Chinese and Japanese individuals are inactive ALDH2 phenotype. The absence of the ALDH2 Glu allele was found to adversely influence the risk of osteoporosis. The aim of this study is to clarify the effect of the alcohol consumption on bone metabolism with ALDH2 knock-out mice (ALDH2KO) after ethanol drinking. 8-week-old male ALDH2 knock-out mice and wild-type were free-ingested water (groups ALDH2KO/water and Wild/water) and 5% ethanol (groups ALDH2KO/alcohol and Wild/alcohol) for 4 weeks. At the age of 12 weeks, we evaluated the bone histomorphometry in trabecular bone in distal metaphysis of left tibias. Bone marrow cells from bilateral femurs and tibias were used for mRNA expressions analysis. In histomorphometry, Bone volume (BV/TV) was significantly decreased in ALDH2KO/alcohol compared with those in ALDH2KO/water and wild/water groups. Bone formation rate (BFR/BS) was significantly decreased in ALDH2KO/alcohol compared with those in the other three groups. The value of activation frequency (Ac.f) in ALDH2KO/alcohol significantly decreased, too. Quantitative RT-PCR revealed that typeI collagen, osteonin, osteopontin and osteocalcin mRNA expressions significant decreased in ALDH2KO/Alcohol mice. Our results suggested that osteopenia caused by high alcohol consumption in the absence of ALDH2, attribute to the disturbance of the differentiation in osteoblasts.

**Advancing Maternal Age Is Associated with Lower Peak Bone Mineral Density in the Male Offspring.** R. Rudäng<sup>\*</sup>, D. Mellström, C. Ohlsson, M. Lorentzon. Internal Medicine, Center for Bone Research at the Sahlgrenska Academy (CBS), Göteborg, Sweden.

In Sweden the maternal age in both primi- and multipara mothers has steadily increased during the last three decades. It has been previously reported that advancing maternal age increases the risk of fetal death, but also of morbidity in the offspring, such as chromosome abnormalities, leukemia, diabetes mellitus type 1 and schizophrenia. Whether or not maternal age influences bone mass and the subsequent risk of osteoporosis in the offspring has not been reported. The aim of the present study was to investigate whether a high maternal age was associated with lower peak bone mass, as measured using DXA in a large cohort of male offspring (the Gothenburg Osteoporosis and Obesity Determinants study (GOOD)). Through the Swedish multi-generation register, we identified the mothers of 1009 GOOD-study subjects. From the Swedish medical birth register, maternal parameters, including detailed information about the medical circumstances at the time of child birth, including maternal and offspring anthropometrics (birth height and weight), maternal age and smoking habits, parity and length of pregnancy. Maternal age was inversely correlated to areal BMD (aBMD) at the total body ( $r=-0.07$ ,  $p=0.03$ ) and the lumbar spine ( $r=-0.09$ ,  $p<0.01$ ). Using a linear regression model (including covariates that were correlated with lumbar spine BMD: GOOD-study subject current physical activity, smoking, height, total body lean mass), we found that maternal age negatively independently predicted lumbar spine aBMD ( $\beta=-0.08$ ,  $p<0.01$ ) in the male offspring (Fig.1). This association remained significant ( $\beta=-0.08$ ,  $p=0.025$ ), also after inclusion of additional covariates including GOOD-study subject age, total body fat mass, length of pregnancy, socio-economic index (of the GOOD-subjects' mothers and fathers), parity, smoking during pregnancy and paternal age. In conclusion, our results suggest that advancing maternal age negatively affects peak bone mass and could increase the risk of subsequent osteoporosis in the male offspring.

**Calcium Release from Bone in Postmenopausal Women: Effects of Low Level Cadmium Exposure.** M. Bhattacharyya, A. Ebert-McNeill\*, S. Clark\*, P. Birdsall\*, E. Cerny\*. Argonne National Laboratory, Lemont, IL, USA.

Our studies in mice and dogs demonstrate that cadmium (Cd) causes bone loss at low exposure levels - starting at 2 ng Cd/ml blood. Isotope studies show that calcium release from bone starts early - 8 to 16 hr after a single gavage dose in mice. Regarding mechanism, Cd at 10 nM causes extensive demineralization in fetal rat limb bone cultures, demonstrating a direct effect of Cd on bone, independent of kidney damage. Finally, bone cell culture and gene expression microarray results identify osteoclast formation and activation as a potential mechanism. This project grows from the above results; it examines whether low level Cd contributes to osteoporosis in humans, particularly postmenopausal women. Cd from cigarettes is the exposure source. STUDY I characterizes exposures in smoking vs. non-smoking postmenopausal women. Biological exposure measures include Cd concentrations in blood, the blood serum compartment, and urine. Cd intake from the total particulate matter of cigarette smoke vs. diet are also determined. STUDY I is nearly complete, and early results demonstrate that Cd exposures among smokers 1) were significantly higher than in non-smokers ( $p < 0.05$ ) and 2) showed a wide range of values. For example, mean blood Cd concentrations were  $1.29 \pm 0.28$  (15) in smokers vs.  $0.33 \pm 0.06$  ng/ml (10) in non-smokers [mean  $\pm$  SE (n)]. In addition, individual values for smokers ranged from 0.53 ng/ml, similar to non-smokers, to 2.74 ng/ml, a concentration at which a bone response to cadmium starts in both mice and dogs. In contrast to Cd, urine cotinine concentrations in smokers - a measure of exposure to the nicotine component of cigarette smoke - were similarly high in all smokers. This wide range of Cd exposure levels will be utilized to evaluate whether the Cd component is a causative agent in the bone response to smoking. Analogous to our studies with laboratory animals, STUDY II will use  $^{45}\text{Ca}$  labeling of the skeletons of women in STUDY I, to determine whether a relationship exists between Cd exposure and  $^{45}\text{Ca}$  release from bone.  $^{45}\text{Ca}$  measurements will be made over a 3-week period to generate a baseline level for smokers vs. non-smokers. During a time of non-smoking, ranging from 4 days (minimum required from Ca isotope studies in dogs) to 3 weeks (depending on each smoker's experiences with smoking cessation),  $^{45}\text{Ca}$  measurements will continue for a second 3-week period. Results should provide insight into which level of Cd exposure might stimulate bone loss in humans. Work supported by Philip Morris USA Inc and Philip Morris International.

**Suppression of Bone Resorption Markers by Calcium and Vitamin D Separately and in Combination.** S. D. C. Thomas\*, A. G. Need, B. E. C. Nordin. Clinical Biochemistry, Institute of Medical and Veterinary Science and Hanson Institute, Adelaide, Australia.

This study was designed to compare the effects of calcium and vitamin D separately and together on suppression of a bone resorption marker. Nineteen healthy ambulatory women aged 59-74 years were randomised to receive either 1000IU vitamin D3 (Ostelin) daily for 7 weeks or 1000mg Ca as carbonate (Calsup) daily for 1 week. The first group then received added calcium (1000mg/d) for 1 week and the second received added vitamin D (1000IU/d) for 7 weeks. Fasting blood samples were collected for biochemistry, parathyroid hormone (PTH) and beta crosslaps at baseline, after each of the supplements alone and after the combination period. The rise in mean serum ionised calcium was not significant after calcium ( $P=0.2$ ), however it rose significantly after vitamin D ( $P=0.03$ ) and after the combination ( $P=0.004$ ). The fall in serum PTH was not significant after calcium ( $P=0.4$ ), vitamin D ( $P=0.2$ ) alone but approached significance when Ca and vitamin D were taken together ( $P=0.09$ ). The fall in crosslaps was 34%, 8% and 40% on calcium, vitamin D and the combination ( $P=0.1$ , 0.2 and 0.001) respectively. The use of calcium with vitamin D is a more significant suppressor of bone resorption markers than either supplement alone. These findings are compatible with recent evidence that combined therapy reduces fracture risk more effectively than either agent alone.

**A Rodent Model to Evaluate the Effect of Dietary Protein on Intestinal Calcium Absorption.** E. G. Stomberg\*<sup>1</sup>, B. Sun\*<sup>2</sup>, C. Simpson\*<sup>2</sup>, J. Kerstetter\*<sup>3</sup>, K. Insogna\*<sup>2</sup>. <sup>1</sup>Nutritional Sciences, UConn, Storrs, CT, USA, <sup>2</sup>Internal Medicine, Yale, New Haven, CT, USA, <sup>3</sup>Allied Health, UConn, Storrs, CT, USA.

In humans, urinary calcium (UCa) increases with increasing dietary protein. As measured by dual stable calcium (Ca) isotopes, when healthy adults ingest a high protein diet (2.1 g/kg/day), skeletal turnover tends to be reduced and Ca absorption significantly increases almost entirely accounting for the observed hypercalciuria. In contrast, a low protein diet significantly impairs intestinal Ca absorption. To explore the mechanisms underlying dietary protein-induced increases in Ca absorption, 250 g female rats were randomly fed a control (20%), low (5%), or high (40%) protein diet for 7 days. All 3 diets were isocaloric and contained 0.45% Ca, 0.35% P. Twenty-four hour urines were collected both before and after the 7-day experimental period. Serum collections were made on day 7. A Ca balance study was performed during days 4-7. Dynamic and static bone histomorphometry were performed on tibiae.

UCa was not different between the 3 groups at baseline. By day 7, UCa was more than 2-fold higher in the 40% protein vs control group (4.2 mg/d vs 1.7 mg/d,  $p < 0.05$ ). In contrast,

UCa fell significantly in the 5% protein group compared to control (0.4 mg/d vs 1.7 mg/d,  $p < 0.01$ ). At day 7, there were no differences in serum Ca, 1,25(OH)<sub>2</sub>vit D, or 25(OH)vit D between the 5% and 40% protein groups. Serum PTH tended to be higher in the 5% protein group ( $p=0.07$ ). Serum osteocalcin was lower in the 40% protein group compared to the other two groups ( $p < 0.03$ ). Rats consuming the 40% protein diet absorbed and retained more Ca compared to the 5% protein group (see table). Pre-treating animals with pamidronate did not attenuate the impact of dietary protein on UCa consistent with the idea that increased bone resorption was not the basis for the increase in UCa. Histomorphometric analyses showed that rats consuming a 40% protein diet tended to have lower bone turnover.

This animal model recapitulates the key findings in humans ingesting a high protein diet in that: 1. Animals developed hypercalciuria on the high protein diet and hypocalciuria on the low protein diet. 2. During the high protein diet, increased Ca absorption, not bone resorption, is the source of the hypercalciuria. 3. Reducing levels of dietary protein leads to Ca malabsorption. Studies are ongoing to elucidate the cellular and molecular bases for the effect of dietary protein in Ca absorption.

## M331

**OP Patients Behaviours and Understanding of the Importance of Calcium and Vitamin D Supplementation.** S. Boonen\*<sup>1</sup>, P. Fardellone\*<sup>2</sup>, J. Quesada\*<sup>3</sup>, L. Kalouche-Khalil\*<sup>4</sup>, J. Ringe\*<sup>5</sup>. <sup>1</sup>University Hospital Leuven, Leuven, Belgium, <sup>2</sup>Department of Rheumatology, CHU, Amiens, France, <sup>3</sup>Unidad de Metabolismo Mineral. Hospital Universitario Reina Sofía, Córdoba, Spain, <sup>4</sup>P & G Pharmaceuticals, Asnières, France, <sup>5</sup>Medizinische Klinik IV, Klinikum Leverkusen, Cologne, Germany.

National and international guidelines recommend the co-prescription of calcium (Ca) and vitamin D (Vit D) with osteoporosis (OP) treatment unless patients are Ca and Vit D replete. Among general practices, levels of co-prescription vary considerably. In addition, patients' compliance with Ca and Vit D supplementation may be poor.

The objective of the study was to evaluate on a pan-European basis, the treatment knowledge and behaviour of osteoporotic patients treated for OP.

A quantitative patient research survey was conducted in December 07 on women aged 50 years and older in four European countries: France, Germany, UK and Spain. All participants were post-menopausal females who have been diagnosed and treated for OP. A standardized 10 minute questionnaire was used, however, data collection methods varied across countries i.e. mail-in for France, face to face for Germany and an online interview for the UK and Spain. All patients gave consent to participate in the survey.

The survey included 383 patients equally distributed across the four countries. Main results are reported in Table 1. Further analysis showed that compared to patients who never forget taking their supplement, patients who declared missing supplements were mainly:

- those who declared not convinced of the importance of this supplementation,
- those who reported not to have detailed explanations by treating physician and,
- those who reported a need for a new tool/packaging to help taking both OP treatment and supplements.

Patients were more able to identify food sources of Ca than those of Vit D.

Patients were aware of the importance of Ca and Vit D in osteoporosis management. Continued efforts by physicians will help improve patients' understanding of the importance of Ca and Vit D supplementation.

**Table 1.** Number and percentage of patients in the different countries according to their current treatment knowledge and behaviours regarding Ca & Vit D supplementation.

	Total	FR	GE	UK	SP
<b>Number of Patients</b>	<b>383</b>	<b>97</b>	<b>98</b>	<b>94</b>	<b>94</b>
<b>Treated Patients (% of patients)</b>					
- Taking osteoporotic medication regularly and correctly	91	90	96	82	95
- Taking any supplementation	74	69	74	61	90
- Taking Ca & VitD supplements	43	46	49	37	43
<b>Patients' knowledge and behaviours regarding supplementation (% patients)</b>					
- Is part of the whole treatment regimen	81	61	94	74	95
- Has to be taken regularly	72	63	59	69	97
- Complete and detailed explanation was provided by treating physician	72	59	88	56	84

## M332

**The Effects of Agave Inulin on Calcium Metabolism in Japanese Young Adults.** T. Koike<sup>1</sup>, Y. Kojima<sup>\*2</sup>, T. Okano<sup>\*1</sup>, M. Tada<sup>\*1</sup>, A. Ichimura<sup>\*3</sup>. <sup>1</sup>Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan, <sup>2</sup>Agave Inc., Osaka, Japan, <sup>3</sup>Molecular Inorganic Chemistry, Osaka City University Molecular Materials Science, Osaka, Japan.

Absorption of an adequate amount of calcium is particularly important during early adolescence to help achieve peak bone mass. In addition to dietary intake, intestinal absorption is a key factor that controls the retention of calcium. Numerous animal studies have shown that inulin-like fructans significantly increase calcium absorption. Inulins are a group of naturally occurring polysaccharides produced by many types of plants. Plants that contain high concentrations of inulin include chicory, wild yam, elecampane and agave. Agave inulin was found to consist of a few to >150 monosaccharide residues, with very much greater solubility than other known inulins. Therefore, it is feasible to obtain products of good quality with agave inulin since the high solubility facilitates homogeneity. The aim of this study is to investigate the effects of agave inulin on calcium metabolism in young adults. Calcium metabolism in 12 Japanese young adults was studied by using metabolic balance in a randomized, 12-days controlled dietary intervention: calcium gluconate (Ca 300mg, control), calcium gluconate with agave inulin (34% of volume) (high inulin) and calcium gluconate with agave inulin (11% of volume) (low inulin). The first 9 days of 12-day intervention was a period of equilibration to the diet. Days 10-12 made up the metabolic balance period, in which all urine and feces were collected. On days 1, 9 and 12, bone metabolic markers (intact PTH, osteocalcin, urinary NTX, deoxypyridinoline) were measured. Calcium absorption was significantly greater in high inulin group than in the control group (high inulin:  $45.7 \pm 5.4$ , low inulin:  $39.4 \pm 48.9$ , control:  $19.6 \pm 5.2\%$ ,  $P < 0.05$ , repeated-measures ANOVA). There was no significant difference between the supplements in calcium retention (high inulin:  $23.3$ , low inulin:  $11.7$ , control:  $4.9\%$ ). Although intact PTH significantly decreased on day 12 compared to baseline, there was no significant differences between groups. There was no significant change on other bone metabolic markers. These findings suggest that daily consumption of high dose of agave inulin significantly increases calcium absorption and enhances bone mineralization in young adults.

## M333

**The Effect of the Dietary Ca/P Ratio on the Rate of Skeletal Accrual in Mice.** B. Sun<sup>1</sup>, C. Simpson<sup>\*1</sup>, T. Carpenter<sup>2</sup>, K. Insogna<sup>1</sup>. <sup>1</sup>Internal Medicine, Yale School of Medicine, New Haven, CT, USA, <sup>2</sup>Department of Paediatrics, Yale School of Medicine, New Haven, CT, USA.

Many studies have investigated dietary factors that affect skeletal health but the impact of the dietary calcium phosphate ratio (Ca/P) on rates of skeletal accrual has received relatively little recent attention. In many earlier studies, the appearance of secondary hyperparathyroidism represented a significant confounding variable. Since the osteocyte is known to play a key role both in regulating skeletal turnover and phosphate homeostasis, we revisited the impact of alterations in the dietary Ca/P ratio on rates of skeletal accrual in mice. Forty, 4-week old female CD-1 mice were divided into equal groups and fed one of five diets varying in Ca/P ratio. The diets were isocaloric and identical in all respects except for the amount of Ca and P and were as follows: **G1:** Ca/P= 1.5:1 (0.45% Ca/0.3% P); **G2** Ca/P= 1:1 (0.3% Ca/0.3% P); **G3** Ca/P= 2:1 (0.6% Ca/0.3% P); **G4** Ca/P= 2X 1:1; (0.6% Ca/0.6% P); **G5** Ca/P= 2X 2:1 (1.2% Ca/0.6% P). There were no inter-group differences in the rates of weight gain or food consumption after 4 weeks and 8 weeks of the diets. Although both BMD and BMC increased in each group there were significant differences observed among the five dietary groups when analyzed by one-way ANOVA at week 4. Thus, the **G5** animals, (2X 2:1), had a higher percentage increase in both femur and total BMD and BMC when compared to all other groups ( $p < 0.05$ ) except **G1** ( $p = NS$ ). This resulted in significantly higher femur and total body BMD values in **G5** compared to **G2**, (1X 1:1) and **G3** (1X 2:1) groups. Total body BMD in **G5** was also higher than the mean value in **G4**, (2X 1:1). During the second 4 weeks of the study, the rate of skeletal accrual remained higher in the femur in the **G5** group compared to **G1**, **G2** and **G4** and at 8 weeks **G5** had the highest femur BMD compared to all other groups ( $p < 0.05$ ). Serum concentrations of Ca, P, Alk Phos, and PTH were not significantly different among the groups. Interestingly, serum CTX tended to be lower, albeit not significantly so, in **G5** compared to the values in **G1**, **G2** and **G4** (10.0, vs. 12.1, 12.2 and 11.7 respectively). These data demonstrate that altering the dietary Ca/Pi ratio while keeping all other nutrients constant affects the rate of skeletal accrual in mice. This occurred without alteration in PTH activity in the **G5** group, which had the highest initial rates of skeletal accrual and had the highest mean femur BMD at study end. The molecular mechanisms that underlie these changes as well as the bases for the apparent differences in the regional skeletal response to the dietary Ca/P ratio are currently under investigation.

**Disclosures:** B. Sun, None.

## M334

**Low Dose Administration of Interferon  $\gamma$  Stimulates Osteoblastogenesis and Prevents Ovariectomy-Induced Osteoporosis in C57BL/6 Mice.** D. C. Huang<sup>1</sup>, G. Duque<sup>2</sup>, X. F. Yang<sup>1</sup>, F. T. Marino<sup>\*3</sup>, J. Barralet<sup>\*3</sup>, R. Kremer<sup>1</sup>. <sup>1</sup>Department of Medicine, Department of Medicine and Center for Bone and Periodontal Research, McGill University, Montreal, QC, Canada, <sup>2</sup>Aging Bone Research Program, Nepean Clinical School, University of Sydney, Penrith, NSW 2750, Australia, <sup>3</sup>Faculty of Dentistry, McGill University, Montreal, QC, Canada.

Interferon  $\gamma$  (IFN $\gamma$ ) exerts either an antiresorptive or pro-resorptive effect on bone *in vivo* depending on the model and dosage used. However, its effect on osteoblastogenesis and bone formation has not been reported. In this study, we administered 2000 units of recombinant IFN $\gamma$  or vehicle three times a week for 18 weeks to 10 week-old C57BL/6 ovariectomized (OVX) female mice. Ex-vivo cultures of bone marrow mesenchymal stem cells (BM-MSC) isolated from IFN $\gamma$  treated animals had an increased capacity to differentiate into osteoblasts as demonstrated by the higher number of CFU-OB stained with alkaline phosphatase or Alizarin red. In contrast, ex-vivo cultures of BM-MSC isolated from normal female C57BL/6 mice and treated with siRNA against IFN $\gamma$  had a reduced ability to form CFU-OB as compared to BM-MSC treated with control siRNA. Bone mineral density (BMD) was significantly higher in IFN $\gamma$ -treated animals as compared to control both at the lumbar spine and femur. Examination of bone microarchitecture by 3D- $\mu$ CT analysis demonstrated a significant increase in bone volume (BV/TV) ( $9.7 \pm 0.5$  vs  $7.2 \pm 0.5\%$ ,  $p < 0.01$ ), trabecular thickness ( $54 \pm 5$  vs  $49 \pm 5 \mu\text{m}$ ,  $p < 0.05$ ), trabecular number ( $3.2 \pm 0.05$  vs  $2.1 \pm 0.03 \text{ N/mm}$ ,  $p < 0.04$ ) and cortical width ( $172 \pm 6$  vs  $143 \pm 7 \mu\text{m}$ ,  $p < 0.01$ ) in IFN $\gamma$ -treated OVX animals as compared to vehicle-treated OVX animals. Furthermore, static histomorphometry showed a significant increase in osteoblast number in IFN $\gamma$ -treated mice as compared to controls. Finally, mechanical properties of bone were assessed in tibia with the three-point bending test. A significant increase in all mechanical indices was observed in IFN $\gamma$ -treated OVX animals compared to vehicle-treated OVX animals including stiffness (K) ( $53 \pm 5$  vs  $43 \pm 6 \text{ N/mm}$ ,  $p < 0.05$ ), Young's modulus (E) ( $13.2 \pm 2.1$  vs  $10.5 \pm 2.2 \text{ N/mm}^2$ ,  $p < 0.05$ ), ultimate force (N) ( $13.6 \pm 2.2$  vs  $11.9 \pm 2.3 \text{ N}$ ,  $p < 0.05$ ) and work to failure (U) ( $3.55 \pm 0.18$  vs  $3.13 \pm 0.15 \text{ mm x N}$ ,  $p < 0.01$ ). Overall, our data indicates that low dose administration of IFN $\gamma$  prevents bone loss, and restores skeletal microarchitecture and bone strength induced by estrogen deficiency.

**A Selective p38alpha Inhibitor Prevents Bone Loss Induced by Estrogen Deficiency.** J. Caverzasio<sup>1</sup>, L. Higgins<sup>\*2</sup>, P. Ammann<sup>1</sup>. <sup>1</sup>Service of Bone Diseases, Dept of Rehabilitation and Geriatrics, University of Geneva, Geneva, Switzerland, <sup>2</sup>SCIOS, Fremont, CA, USA.

Increased bone remodelling with excess bone resorption over formation is the principal mechanism of bone loss with estrogen deficiency and increased bone fractures. Different mechanisms have been described to explain the enhanced osteoclast activity with estrogen deprivation such as an increased cytokines production by stromal cells and alteration in osteoclasts apoptosis. The p38 pathway is known to be involved in controlling both cytokines effects on osteoclastogenesis and osteoclast activity. Thus, in this study we investigated the effect of a selective p38alpha inhibitor (p38Inhib), on the prevention of bone loss induced by estrogen deficiency in an adult ovariectomized (OVX) rat model. Oral administration of 15 and 45 mg/kg BW of the p38Inhib for 8 weeks dose-dependently blunted the increase in urinary deoxypyridinoline (DPD) excretion level, a marker of bone resorption, induced by OVX in adult rats ( $p < 0.0001$ ). Interestingly, the p38Inhib did not reduce but significantly enhanced (2x,  $p < 0.001$ ) the rise in osteocalcin level, a marker of bone formation, observed in OVX animals. Associated with the blunted increase in DPD excretion, the p38Inhib completely prevented the vertebral bone loss associated with estrogen deficiency. A partial preventive effect was also observed in long bones (68%) with reduction of trabecular bone loss of the tibial metaphysis and enhancement of the cross sectional area of the tibial diaphysis ( $p < 0.02$ ). Finally, prevention of trabecular bone loss and increased in the cortical cross sectional area were associated with improvement of the biomechanical resistance.

In conclusion, chronic administration of a selective p38alpha inhibitor blunted the increased bone turnover induced by estrogen deficiency and differentially affected trabecular bone resorption and cortical bone formation. This effect resulted in a complete prevention of axial trabecular bone loss and alteration of bone microarchitecture induced by OVX. These data suggest that p38alpha is a critical pathway for regulation of bone resorption in response to estrogen deficiency. Selective inhibitors of this pathway are molecules of potential interest for prevention of bone loss in postmenopausal osteoporosis.

**Effects of Different Extracts of Fructus Ligustri Lucidi on Ca Balance in Normal Female Rats.** X. Dong<sup>\*1</sup>, W. Chen<sup>\*1</sup>, C. Che<sup>\*2</sup>, M. Wong<sup>1</sup>. <sup>1</sup>Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, China, <sup>2</sup>School of Chinese Medicine, The Hong Kong Chinese University, Hong Kong, China.

Our previous studies indicated that ethanol extract of *Fructus Ligustri Lucidi* (FLL) could improve bone properties in aged rats through modulating Ca homeostasis in both ovary-intact as well as ovariectomized (OVX) aged female rats. The present study aims to search for the active fractions of FLL on Ca balance *in vivo*. The ethanol extract of FLL was separated into two fractions, the lipophilic fraction extracted with ethyl acetate (EA extract) and the hydrophilic fraction extracted with water (water extract). Four month old Sprague-Dawley female rats were orally administered with ethanol extract (700mg/kg/d), EA extract (574mg/kg/d), water extract (126mg/kg/d) or its vehicle for 12 weeks, respectively. Rat urine, feces and serum were collected every week for biochemical marker determination. Urinary Ca and Ca absorption efficiency were used as the biomarker for the identification of the active fractions in FLL. Rat kidney and intestine were collected at sacrifice for subsequent gene expression analysis by real-time PCR. Urinary Ca excretion significantly decreased from week 4 onward in young rats treated with water extract of FLL; while the suppressive effects on urinary Ca excretion by ethanol extract of FLL could only be detected by week 10. In contrast, EA extract of FLL did not suppress urinary Ca excretion in young rats. The water and ethanol extract, but not EA extract, of FLL exerted positive actions on Ca absorption efficiency in young rats from week 6 onward. Our results also showed that water extract of FLL increased duodenum Ca absorption in rats through inducing mRNA expression of the vitamin D receptor (VDR) and the enzymes involved in active epithelial transport (TRPV6 and PMCA). Rat duodenum TRPV6, PMCA, and VDR mRNA in water extract treatment group were increased by 41.8% (P<0.05), 66% (P<0.05) and 61.7% (P<0.01), respectively (vs those in vehicle treated rats). Water extract of FLL also appeared to increase renal TRPV6 and CaBP28k mRNA expression in rats (vs vehicle or EA extract treated rats). Our results indicated that the hydrophilic fraction of the ethanol extract of FLL was responsible for the active action of FLL on Ca balance.

## M337

**Bone Anabolic Effects of Icaritin and Total Flavonoid Fraction of *Herba Epimedii* in Ovariectomized Mice.** W. Chen<sup>\*1</sup>, X. Dong<sup>\*1</sup>, S. Mok<sup>\*1</sup>, X. Yao<sup>\*2</sup>, P. Leung<sup>\*3</sup>, M. Wong<sup>1</sup>. <sup>1</sup>Applied Biology and Chemical Technology, The Hongkong Polytechnic University, Hong Kong, China, <sup>2</sup>Pharmacology, Pharmacology, Shenyang Pharmaceutical University, Shenyang, China, <sup>3</sup>Orthopaedics and Traumatology, Orthopaedics and Traumatology, the Chinese University of Hong Kong, Hong Kong, China.

*Herba Epimedii* (HEP) is one of the most frequently used kidney-tonifying herbs in China over centuries. Flavonoids are considered as its active components and icaritin is a major flavonoid compound found in HEP. The present study aims to determine the osteoprotective effect of total flavonoid fraction of HEP and its active ingredient icaritin in ovariectomized (OVX) mice. Four-week-old sham-operated or OVX C57BL/6J mice were pair-fed and treated with total flavonoid fraction (TF, 100ug/g/day), icaritin (0.3 mg/g/day), or its vehicle by tube-feeding for 6 weeks. Body weight and uterus weight was recorded. Blood and urine sample were collected for Ca and P detection. BMD as well as bone microarchitecture of distal femur in mice were studied by using pQCT and microCT, respectively. The bone related gene expressions in femur were determined by real time RT-PCR. No significant changes were observed in uterus weight in TF-treated and icaritin-treated mice. TF and icaritin did not alter serum Ca and P in mice as compared with OVX mice. The increase in urinary Ca excretion by OVX was reduced in TF-treated and icaritin-treated mice (P<0.01). Ovariectomy produced bone loss and a global deterioration in trabecular 3D-microarchitecture. Treatment of OVX mice with TF or icaritin increased trabecular BMD in distal femur (P< 0.05 vs. vehicle-treated OVX mice). TF treatment prevented the decrease in trabecular thickness (Tb.Th), the increase in trabecular separation (Tb.Sp) as well as the decrease in bone volume/tissue volume (BV/TV) induced by OVX in mice. In addition, TF treatment significantly up-regulated the mRNA expression of type I collagen, osteocalcin and Cbfa1 in mice femur (P<0.05), suggesting that it might modulate osteoblastic functions *in vivo*. Both icaritin and TF increased the ratio of the mRNA expression of OPG/RANKL (P<0.05), indicating that HEP might suppress osteoclastogenesis *in vivo*. These data suggest that icaritin and TF of HEP could protect against bone loss induced by estrogen deficiency in OVX mice. Moreover, our study showed the total flavonoid fraction of HEP was more effective than icaritin alone in preserving bone in respect to its ability to improve bone microarchitecture and to induce osteoblast-related gene expressions in OVX mice.

**Green Tea Polyphenols Protects Bone Microarchitecture in Female Rats with Chronic Inflammation-Induced Bone Loss.** C. Shen<sup>1</sup>, J. K. Yeh<sup>2</sup>, B. J. Stoecker<sup>3</sup>, C. Samathanam<sup>\*1</sup>, S. Graham<sup>\*1</sup>, D. M. Dunn<sup>\*1</sup>, T. Tatum<sup>\*4</sup>, R. Dagda<sup>\*1</sup>, M. Chyu<sup>\*5</sup>, X. Q. Liu<sup>\*2</sup>, C. Tubb<sup>\*4</sup>, X. Wang<sup>\*6</sup>, J. Wang<sup>\*6</sup>. <sup>1</sup>Pathology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, <sup>2</sup>Medicine, Winthrop-University Hospital, Mienola, NY, USA, <sup>3</sup>Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, <sup>4</sup>Molecular Pathology Program, Texas Tech University Health Sciences Center, Lubbock, TX, USA, <sup>5</sup>Mechanical Engineering, Texas Tech University, Lubbock, TX, USA, <sup>6</sup>Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX, USA.

Our recent study showed that green tea polyphenols (GTP) supplementation mitigated chronic-inflammation-induced bone loss in female rats. This study explored bioavailability, molecular mechanisms, and bone microarchitecture of GTP related to preventing bone loss in rats with and without chronic inflammation. A 2 (placebo vs. lipopolysaccharide, LPS) × 2 (no GTPs vs. 0.5% GTPs in drinking water) factorial design, 12-wk experiment using 40 female rats (3-month-old) assigned to 4 groups (n=10/group): placebo (P, placebo implantation), LPS implantation (L), P+0.5% GTP (PG), and LPS+0.5% GTP (LG) was performed. Concentrations of urinary GTP ingredients and 8-hydroxydeoxyguanosine were determined by high-pressure liquid chromatography-couarray detection. Efficacy was evaluated by examining changes in tibial and femoral microarchitecture using histomorphometric and µCT analysis, respectively. mRNA gene expression was determined by real-time RT-PCR. Status of fibrosis in heart vessels was evaluated by trichrome staining. GTP supplementation in drinking water increased concentrations of epigallocatechin in urine of rats, but decreased urinary 8-hydroxydeoxyguanosine level. The results of two-way ANOVA show that LPS lowered trabecular volume fraction, number, and thickness in proximal tibia, but increased eroded surface and osteoclast number in endocortical tibial shafts. GTP supplementation also increased trabecular volume fraction and number in both femur and tibia, but decreased eroded surface and osteoclast number in endocortical tibial shafts. Compared to the other treatments, the L group had a higher degree of fibrosis in heart vessels and gene expression of cyclooxygenase-2 in spleen. Neither LPS implementation nor GTP supplementation affected serum lipid profiles. This study demonstrates that GTP administered in drinking water for 12 weeks prevents trabecular bone loss through LPS-induced higher bone turnover. Such a protective role of GTP may, in part, be attributed to a decrease in oxidative stress DNA damage and expression of cyclooxygenase-2. This study suggests a potentially significant prophylactic role of green tea in bone health of women with chronic inflammation-induced bone loss.

**Calcium Signaling Is a Major Target of OCT-1547, a Small Molecule Osteoporosis Drug Candidate.** H. Hwang<sup>\*1</sup>, H. Lee<sup>\*1</sup>, S. Kim<sup>\*1</sup>, S. Ko<sup>\*2</sup>, D. Kang<sup>\*3</sup>, S. Shim<sup>\*3</sup>, S. Kim<sup>1</sup>, J. Ko<sup>1</sup>, J. Kim<sup>\*1</sup>. <sup>1</sup>Dept. of Pharmacology and Mechanism, Oscotec Inc., Cheonan, Republic of Korea, <sup>2</sup>Dept. of Oral Biochemistry, College of Dentistry, Dankook University, Cheonan, Republic of Korea, <sup>3</sup>Dept. of Medicinal Chemistry, Oscotec Inc., Cheonan, Republic of Korea.

We have previously discovered OCT-1547, a small molecule anti-osteoporosis drug candidate, using our proprietary assay system for osteoclast activity, OAAST<sup>TM</sup>. OCT-1547 has been shown to inhibit osteoclast differentiation *in vitro* and loss of bone mineral density in ovariectomized rats. Preclinical safety evaluation for OCT-1547 was completed in Aputit (UK), and phase I clinical trial will start this year. To clarify the action mechanism of OCT-1547 in the inhibition of osteoclastogenesis, we examined the signaling pathways activated by RANK and immune receptor linked to ITAM-harboring adaptors. OCT-1547 drastically reduced the RANKL-induced expression of NFATc1, which is known to be essential for osteoclastogenesis. Importantly, RANKL-induced tyrosine phosphorylation of PLCγ2 was specifically suppressed when RAW264.7 and mouse bone marrow macrophages were treated with OCT-1547. In addition, OCT-1547 treatment resulted in moderate inhibition of IκB degradation and c-Fos induction, all of which are activated at downstream of RANK. OCT-1547 did not alter the interactions of signaling proteins at downstream of RANK including TRAF6, TRAF2, c-Src, TAB1, TAB2 and TAK1. Among the tested immune receptor-downstream signaling proteins, ZAP-70 activation was significantly inhibited by OCT-1547, suggesting that inhibition of PLCγ2 activity by OCT-1547 might be mediated through the inhibition of ZAP-70 activation. Current investigation is focused on the identification of signaling proteins whose activities are modulated by OCT-1547 and of molecular target of OCT-1547.

**Effect of Cannabinoid CB1 Receptor Ligands on Body Weight and Bone Mass in Mice.** S. Park\*, C. Hwang\*, S. Choi\*, H. Kwak\*, M. Jeong\*, Y. Kang\*, C. Yim\*, H. Yoon, K. Han\*. Kwandong University College of Medicine, Cheil General Hospital, Seoul, Republic of Korea.

The cannabinoid CB1 receptor, one of the cannabinoid receptors has been known to regulate appetite, bone remodeling and bone mass. A few researches for CB1 receptor have revealed the different skeletal phenotypes according to the mouse strain and the method of gene ablation. Sympathetic CB1 signaling was suggested to stimulate bone formation. We investigated the effects of CB1 receptor agonist and antagonist on body weight and bone mass in mice with ad libitum feeding for 8 weeks. 6-week female Balb/c mice were received noladin ether (2-arachidonylglycerol ether) known as a CB1 specific agonist with or without the CB1 antagonist SR141716A intraperitoneally and injections were performed 6 times per week. CB1 agonist treatment caused a significant increase in body weight compared to placebo as well as SR141716A treatment. But, no significant weight differences were found between placebo and SR141716A treatment. Pharmacological activity for behavioral effect was evaluated with noladin ether and SR141716A. SR141716A treatment increased intestinal motility reflected by fecal numbers and this effect was counteracted by noladin ether. However, no specific difference in other tests for locomotor activity and antinociception was shown. The analysis of bone mineral density between groups showed that there was a tendency to increase in bone mineral density in femur with noladin ether and SR141716A treatment, respectively. In conclusion, the chronic treatment with CB1 receptor ligands affected body weight change and bone mineral density. Additional bone-protective effect of CB1 receptor agonist might be related to weight enhancement effect and sympathetic activity of noladin ether, which seems to overcome SR141716A effect. Further study is needed to look for molecular mechanism to delineate the role of CB1 signaling in the regulation of bone metabolism.

## M341

**Dried Plum Alters Bone Metabolism Via a Different Mechanism than PTH.** B. J. Smith<sup>1</sup>, D. M. Cullen<sup>2</sup>, S. Y. Bu<sup>1</sup>, S. L. Clarke\*, E. Rendina\*, Y. E. Lim\*, E. A. Lucas<sup>1</sup>. <sup>1</sup>Department of Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, <sup>2</sup>Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Previous studies have demonstrated that dietary supplementation with dried plum (*Prunus domestica* L.) prevents and reverses bone loss due to gonadal hormone deficiency in male and female models of osteoporosis. Despite these positive effects on bone mass and structural properties, the alterations in bone metabolism induced by dried plum supplementation remain in question. Therefore, this study was designed to assess the dose-dependent effects of dried plum on indices of dynamic bone histomorphometry. Six-month-old female Sprague Dawley rats (n=84) were either sham-operated or ovariectomized (OVX) and randomly assigned to one of 6 treatment groups: Sham-control diet (AIN-93M), OVX-control diet, OVX-5% (w/w) dried plum, OVX-15% dried plum, OVX-25% dried plum or OVX+PTH (80 µg/kg/d x 5 days/wk) used as a positive control. Animals were maintained on control diet for 6 wks with osteopenia confirmed by whole body DXA scans prior to the initiation of treatments. At the end of the 6 wk treatment period, bone specimens were collected for assessment of bone mass, microarchitectural properties and dynamic cortical and trabecular bone histomorphometry. Whole body, femur and spine BMD was restored by all 3 doses of dried plum to the level of the sham group, although as anticipated the magnitude of the restoration was not as great as that of PTH. Analysis of the proximal tibial metaphysis and the diaphysis by micro-computed tomography (µCT40 SCANCO) indicated that cortical thickness was maintained in all dried plum treated groups comparable to the sham, and that cortical porosity tended to be decreased by the two higher doses of dried plum. Although longer duration studies have demonstrated otherwise, trabecular structural parameters including BV/TV, TbTh and TbN as assessed by µCT and histology were not restored by dried plum by the end of the 6-wk treatment period. Dynamic histomorphometry revealed that dried plum significantly reduced the OVX-induced increase in trabecular MAR (15% dose only) and trabecular BFR (all doses), and all doses resulted in MAR and BFR comparable to the sham. Endocortical MAR was increased ( $p<0.05$ ) by dried plum, but periosteal BFR was not. As expected, PTH significantly increased endocortical MAR and BFR, periosteal BFR, and trabecular MAR and BFR beyond that of the OVX. These data suggest that although both dried plum and PTH increase endocortical MAR, dried plum acts via a different mechanism than PTH on trabecular bone in that it slows the OVX-induced increase in bone turnover in osteopenic animals.

**Risk Factors for Bone Fracture, Elevated by 90-Days of Bed Rest, Are Reduced by Daily Exposure to Low Magnitude Mechanical Stimuli (LMMS).** J. W. Muir\*, S. Judex, Y. Qin\*, C. Rubin. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

Extended bed-rest causes a reduction of bone density, postural stability, and muscle strength. With increasing evidence of the anabolic effects of low magnitude mechanical stimulation (LMMS) to the musculoskeletal system, we hypothesized that these signals would serve to suppress the complications inherent to non-weight bearing, and thus contain

an aggregate increase in the risk factors for bone fracture. 29 healthy subjects underwent 90 days of 6-degree head down tilt bed-rest. Eleven subjects served as controls, 12 subjects received a daily 10 minute treatment of a 0.3g, 30 Hz LMMS, and six subjects received LMMS at 0.5g at same frequency. Performed at baseline and post bed-rest, BMD was quantified by CT scan of hip and spine, muscle strength was assessed using an isokinetic dynamometer, and postural control was evaluated through center of pressure analysis during four-minute quiet stance. Untreated controls realized significant decrements to BMD (2.1% decrease per month in the hip;  $p<0.01$ ), muscle strength (14.4% decrease in knee concentric flexion strength;  $p<0.01$ ), and postural control (66.9% per month increase in peak sway velocity;  $p<0.01$ ). While treatment did not significantly impact the loss of bone (1.4% per month decrease;  $p<0.01$ , 31% improved retention,  $p=0.08$ ), it did serve to help muscle strength (6.7% loss, 53% improved retention,  $p<0.01$ ), and postural control (9.6% per month increase, 85.6% improved retention of peak sway velocity,  $p<0.01$ , Fig. 1). No difference was seen between the 0.3 and 0.5g treatment groups, so the groups were pooled. These data provide evidence of a mechanically-based means of reducing bone fracture risk under the challenges of chronic bed rest, achieved by influencing the aggregate of distinct risk factors, and ultimately may represent a means of reducing the incidence of falls in the elderly and infirm.

Fig 1: AP sway velocity in control subjects measured from COP increased significantly after bed-rest, as did the root-mean-square of the AP velocity. High sway velocity is strongly associated with high fall risk groups, indicating that subjects undergoing long term disuse are at an increased threat of fall related injury. \* =  $p<0.05$   
\*\* =  $p<0.01$

**Efficacy of Odanacatib in the Ovariectomized Rhesus Monkey as Measured with pQCT.** P.J. McCracken\*, R. Y. Jayakar\*, L. T. Duong<sup>2</sup>, T. N. Hangartner<sup>3</sup>, D. S. Williams\*. <sup>1</sup>Imaging, Merck Research Laboratories, West Point, PA, USA, <sup>2</sup>Department of Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA, <sup>3</sup>Biomedical Imaging Laboratory, Wright State University, Dayton, OH, USA.

Preclinical evaluation of disease burden and treatment efficacy is critical to the development of new therapies for osteoporosis. Clinically translatable modalities beyond DXA, such as pQCT and hrMRI, give us the advantage of studying *in-vivo* macro- and micro-architectural parameters relevant to bone strength. We have quantified effects of the Cathepsin K inhibitor for osteoporosis, odanacatib, using pQCT endpoints in the estrogen-deficient model of the ovariectomized (OVX) rhesus monkey as compared to intact animals to examine treatment effects as well as potential technological and model-based measurement limitations. pQCT (XtremeCT, Scanco Medical) in OVX, odanacatib-treated OVX, and intact anesthetized monkeys (10/group, age 14-20 years) was performed at 12, 15 and 18 months post-OVX to assess cortical and cancellous bone. BMD was also measured using a Hologic QDR Discovery. Distal radius, distal tibia, and one-third proximal locations in each were scanned and parameters derived including Cortical Thickness (CtTh), Bone Volume Fraction (BVf), Trabecular Number (TbN), Trabecular Thickness (TbTh), Trabecular Separation (TbSp), and Total Density (D100). After precubrication and scout imaging, animals were scanned using: 9mm slice pack, 220 slices, 1500 projections, 3072 points per projection, 3000x3000 matrix, 200 ms integration time, 41 µm voxel size, 8.3 min measurement time per site. The data were reconstructed at a 100 µm voxel size and processed using the manufacturer's 'clinical' and 'research' analysis protocols. Odanacatib treatment preserved the cortical thickness which remained significantly thicker at the 1/3 radial and tibial sites than the OVX cohort. Treatment effects of odanacatib also trended towards thicker trabeculae and higher vBMD. Radial and tibial measures of BVf, TbN, TbTh, TbSp, and D100 each trend towards a OVX model effect of thinning, fewer trabeculae, increased separation, and decreased vBMD, consistent with estrogen deficiency. Significant differences from intact to OVX cohorts were found in CtTh at the 1/3 site for the radius and tibia at each time point on the order of a 30% thinner cortex in the OVX animals. The longitudinal measurements over the six month period are robust. These results show that odanacatib treatment effects on bone morphometry of the OVX rhesus can be quantified by *in-vivo* pQCT. Measurable differences in the geometry of cancellous and cortical bone between normal, treated and estrogen deficient animals were observed adding value to the development of disease-modifying therapies.

**The Safe Zone for Percutaneous Extrapedicular Surgical Approach to the Lumbar Spine.** N. Karkare, A. Steever\*, L. Bogunovic\*, R. Parker\*, P. O'Loughlin\*, J. M. Lane. Metabolic Bone Disease, HSS, New York, NY, USA.

The objective of this study was to define the zone for safe placement of the targeting device for the surgical treatment of osteoporotic vertebral compression fractures of the thoracolumbar vertebrae.

29 CT scans of patients were studied. The optimal angle was calculated as the one furthest from the medial neural and the lateral peritoneal structures. The respective distance from the skin was measured from the midline.

The mean age of the patients was 64.6±16 years. The optimal angle for placement of the needle, the optimal skin entry from the midline for the left and right side are shown in table 1 for T12, L1, L2, L3, and L4 respectively.

The distance for insertion of the needle on the skin increased from T12 to L4. Our data show that this distance is the similar for L3 and L4. Optimal angles were different on the left and right side for T12 and L3 due to differences in local anatomy. The largest safe angle for safe placement of the targeting needle was at L3 on both left and right sides. This definition of the safe zone for the targeting device in percutaneous extrapedicular and far lateral surgical approach to the lumbar spine may guide surgeons intraoperatively and prevent potential complications.

		L Optimal Angle		L Skin Dist		R Optimal angle		R Skin Dist

**Short Duration Pharmacokinetic Profile of ZT-031 (Cyclic PTH [1-31]), a Novel hPTH Analog.** D. Krause, R. Vaninwegen\*. Zelos Therapeutics, Inc, West Conshohocken, PA, USA.

Anabolic responses to human parathyroid hormone (hPTH) and hPTH analogs require intermittent, short duration stimulation of PTH receptors on osteoblasts. ZT-031 (cyclic PTH [1-31]) is a novel, cyclic 31 amino acid PTH analog in late clinical development; it has previously demonstrated clinically significant increases in bone mineral density (BMD) in a 12 month Phase 2 clinical study in postmenopausal women with low BMD.

The purpose of this analysis was to define the pharmacokinetic (PK) profile of ZT-031 in a series of clinical trials.

Samples were obtained at various time points in 4 clinical trials, including a single dose, dose rising trial in healthy adults (n=40), a multiple dose, dose rising trial in healthy adult women (n=40), a multiple dose, dose rising trial in healthy elderly women (n=18) and a Phase 2 dose-ranging parallel group trial in postmenopausal women with low BMD (subset, n=10). Doses ranging from 0 (placebo) to 160 µg, in volumes from 0.1 to 0.4 mL/dose, were administered subcutaneously once daily. Samples for PK were obtained pre-dose and at 0.25, 0.5, 1, 2, 4, hours post-dose in all trials and at various other time points up to 24 hours post-dose. Samples were analyzed by a validated ELISA with a limit of detection (LOD) of 10.0 pg/mL. Dose normalized data obtained on Day 1 and on repeat dosing (7 days or 12 weeks of dosing) are displayed in the TABLE.

	AUC <sub>(0-12h)</sub> (pg-h/mL)		AUC <sub>(0-24h)</sub> (pg-h/mL)		C <sub>max</sub> (pg/mL)		T <sub>max</sub> (h)*	T <sub>1/2</sub> (h)*	CL/F (L/h)*	Vz/F (L)*
	Day 1	Repeat	Day 1	Repeat	Day 1	Repeat				
Mean	74.0	75.0	108.0	131.0	56.8	63.5	0.40	1.02	283	412
STD	56.3	59.2	69.5	74.8	28.4	33.1	0.28	0.38	129	238
N	79	48	51	18	82	49	130	49	49	49

\* all data points combined

ZT-031 had a short duration PK profile with a T<sub>1/2</sub> of 1 hour. AUC and C<sub>max</sub> were linearly related to dose whereas T<sub>max</sub>, T<sub>1/2</sub>, CL/F and Vz/F were dose-independent. Correction of dose by patient bodyweight improved the correlation between dose and AUC and C<sub>max</sub> and explained slight gender related differences in these PK parameters.

The PK profile of ZT-031 is well suited to provide the intermittent stimulation of PTH receptors required for anabolic effects on bone. Bodyweight has a significant impact on the PK parameters for a fixed dose, suggesting that dosing strategies that limit the µg/kg dose range will improve the consistency of PK parameters in patients of different bodyweights, possibly leading to improved clinical response.

**The Effect of Bodyweight on Clinical Response to ZT-031: Development of a Simple, Improved Dosing Regimen for PTH Analogs.** B. MacDonald, J. Conlon\*, M. Stogniew\*. Zelos Therapeutics, Inc, West Conshohocken, PA, USA.

ZT-031 (Ostabolin-CTM) is a cyclic 31 an analogue of parathyroid hormone (PTH) that demonstrated rapid onset of bone formation and marked increases in bone mineral density (BMD) in a 12 month study in postmenopausal women. The BMD increase was greatest at the 45 µg/day dose (11% at lumbar spine) but the incidence of asymptomatic hypercalcemia and side effects causing discontinuation was also highest. At a lower dose (30 µg/day) tolerability concerns were minimal but efficacy was also reduced, though adequate. This raised the question of which dose was most appropriate for further study.

To address this question, we converted the daily dose for every patient to a µg/kg dose and regrouped all patients into 6 cohorts of ascending µg/kg dose. Mean change in biomarker and BMD endpoints and in serum calcium was increased with increasing µg/kg dose. Incidence of PTH class side effects (headache and nausea) and hypercalcemia >2.64 mM/L showed similar trends. Stepwise regression and backward elimination regression models confirmed that, in addition to dose, bodyweight was a highly significant predictor of change in lumbar spine BMD (P<0.0001) and that no other baseline variable (including age, height, LS-BMD, FN-BMD, creatinine, smoking and alcohol history) explained the effect of bodyweight. The optimal dose range to generate a large BMD increase while minimizing the occurrence of side effects and hypercalcemia was 0.45 to 0.65 µg/kg. With a fixed dose of PTH analog, patients at either extreme of the bodyweight range are under or over-treated, increasing the risk of treatment failure due to lack of efficacy or excessive side effects/hypercalcemia. The simplest way to maintain the administered dose within the desired µg/kg range for the maximum number of patients is to provide two or more dose strengths, each for use in patients in different bodyweight categories. A ZT-031 dose of 30 µg/day for patients weighing < 68 kg or 45 µg/day for those weighing ≥ 68 kg resulted in a profile that included high BMD responder rate (71% of patients with LS-BMD increase ≥ 5% [net of placebo]) with acceptable hypercalcemia incidence (9.1% with serum calcium >2.64 mM/L at any visit [net of placebo]).

These analyses illustrate the strong influence of bodyweight on clinical response to ZT-031. Extremes of bodyweight may lead to a suboptimal clinical profile for a fixed dose PTH analog, for example diminished BMD effects in males or troublesome side effects in women with low bodyweight. A simple, weight-based dosing regimen with two or more dose strengths can produce a consistent, optimized therapeutic effect regardless of bodyweight, reflected by a higher proportion of BMD responders without significant increase in hypercalcemia or side effect incidence.

## M347

**An Active Controlled, Non-Inferiority Study to Compare the Effect of ZT-031 with Alendronate on the Incidence of New Vertebral Fractures: The PACE (cyclic PTH and Alendronate Comparative Efficacy) Study.** B. MacDonald<sup>1</sup>, E. Vittinghoff<sup>2</sup>, S. Cummings<sup>3</sup>, D. C. Bauer<sup>2</sup>, D. Krause<sup>1</sup>. <sup>1</sup>Zelos Therapeutics, Inc, West Conshohocken, PA, USA, <sup>2</sup>UC San Francisco Med Ctr, San Francisco, CA, USA, <sup>3</sup>California Pacific Med Ctr Res Inst, UC San Francisco, San Francisco, CA, USA.

In a 12 month study in postmenopausal women ZT-031 (cyclic PTH [1-31]) produced marked increases in bone mineral density with an acceptable safety profile, justifying further clinical development for the treatment of osteoporosis. Regulatory approval of new PTH analogs is complicated by usage restrictions to patients with severe disease (≥ 1 prevalent vertebral fracture [VF]). Such patients are generally excluded from placebo (PBO) controlled studies on ethical grounds. To address this issue we have designed the first active controlled non-inferiority (NI) Phase 3 trial for an investigational osteoporosis drug. The FIT-1 trial provides a reference database for the effect of alendronate (AL) (10 mg/day) versus PBO on the incidence of new VF in the target population (62% and 47% reduction at 2 and 3 years, respectively). The FIT trial (Neer et al 2001) provides a reference database on the likely effect size of a PTH analog (65-69% reduction versus PBO). The large effect size in both reference studies enables the use of NI margins defined as a percentage of the minimum risk difference (lower 95% CI bound) between AL and PBO, that maintain assay sensitivity because a PBO effect is implausible within the NI margin. Sample size calculation used these assumptions: predicted background PBO VF rate: 11.6% (2 year PBO rate in FIT-1), anticipated AL VF rate: ≥5.2% (55% reduction), ZT-031 VF rate: ≤3.8% (67% reduction), NI margin: 30% of the minimum risk difference between AL and PBO (1.17%). Using these parameters a total sample size of 3,255 patients has 90% power to reject the null hypothesis that the effect of ZT-031 is inferior to that of AL after 2 years of treatment, assuming 15% loss to follow up. To address the concern that low VF rates could diminish the validity of an NI margin based on absolute risk difference we confirmed 1) that a sample size of 3,255 could exclude a relative risk (RR) equivalent to the largest possible RR in FIT-1, and 2) that for a range of different effect sizes of AL and ZT-031, the risk difference margin never exceeds 50%, thus preserving assay sensitivity.

This Phase 3 registration study for the treatment of osteoporosis is the first to employ an active controlled design. The comparison is enabled by the existence of robust reference databases from PBO controlled studies in the target population. Sample size feasibility is maintained by establishing NI margins based on risk difference rather than risk ratio and the anticipation that the effect of ZT-031 on VF incidence will actually be greater than that of AL.

## M348

**Bone Mineral Density Response to Treatment with Recombinant Parathyroid Hormone in Patients Previously Treated with Bisphosphonates.** S. de Bhaldrath<sup>\*</sup>, A. Pazderska<sup>\*</sup>, K. Fitzgerald<sup>\*</sup>, C. Walsh<sup>\*</sup>, J. Walsh<sup>\*</sup>, M. Casey<sup>\*</sup>. St James Hospital Dublin, Dublin, Ireland.

Parathyroid hormone is the first anabolic agent available for the treatment of severe osteoporosis. Bisphosphonates, which had previously been the mainstay of treatment, act by shutting down bone turnover. We aimed to compare the bone mineral density (BMD) benefit of PTH in treatment naïve patients and patients previously treated with bisphosphonates.

We measured hip and lumbar spine BMD, at 0 and 18 months, in 52 consecutive patients treated with teriparatide.

Mean age was 74 (SD 10.1). 48 were female and 4 were male. 20 were previously treated with bisphosphonates (for a mean of 20 months), (range 4-60months). 32 did not previously receive bisphosphonates. Baseline BMD was comparable in both groups. BMD improved in both groups, however the increase in patients' BMD was significantly greater in patients who were bisphosphonate treatment naïve. See table 1. Treatment naïve patients made highly significantly greater BMD gains than previously bisphosphonate treated patients. Patients with severe established osteoporosis should be considered for PTH therapy before starting bisphosphonates to achieve maximal BMD benefit.

Table 1

	Bisphosphonate + (n=20)	Bisphosphonate - (n=32)	p
	Mean (95%CI)	Mean (95%CI)	
Baseline Spine BMD (g/cm <sup>2</sup> )	0.729	0.742	NS
Baseline Hip BMD (g/cm <sup>2</sup> )	0.646	0.691	NS
% Increase in Spine BMD	4.0 (1.6 - 8.0)	14.6 (10.6-19.0)	0.004
% Increase in Hip BMD	1.6 (0.4-3.1)	6.4 (3.8-9.2)	0.006

**Imaging the Spatial Distribution of Proximal Femoral Response to One Year of Teriparatide Therapy: The OPTAMISE Study.** W. Li<sup>1</sup>, J. H. Keyak<sup>2</sup>, P. D. Miller<sup>3</sup>, J. P. Bilezikian<sup>4</sup>, J. A. Stewart<sup>5</sup>, T. F. Lang<sup>1</sup>. <sup>1</sup>Radiology, University of California, San Francisco, San Francisco, CA, USA, <sup>2</sup>Department of Orthopaedic Surgery, University of California, Irvine, Irvine, CA, USA, <sup>3</sup>Colorado Center for Bone Research, Lakewood, CO, USA, <sup>4</sup>College of Physicians and Surgeons, Columbia University, New York, NY, USA, <sup>5</sup>Sanofi-Aventis, Laval, QC, Canada.

**Purpose:** Previous QCT studies of the hip in patients treated with teriparatide (TPTD) have shown differential effects on cortical and trabecular bone, with loss of cortical BMD and increases in trabecular BMD. However, these measurements do not address the spatial distribution of the response within the trabecular and cortical compartments. These data could be useful in understanding the therapeutic response in relevant hip fracture regions and in optimizing image-based treatment monitoring.

**Methods:** Subjects previously treated with alendronate (ALN, n=65) and risendronate (RIS, n=56) discontinued their bisphosphonate and were treated with TPTD (20 µg/d SQ) for 12 months. QCT images of the hip were obtained at baseline and 12 months. 121 pairs of QCT images were registered with satisfactory accuracy into a single population-based statistical image model for each time point, and treatment changes were computed for each voxel. Statistical significance of per-voxel changes were computed using paired T-tests, with false discovery rate (FDR) methods to correct for multiple comparisons. The distribution of voxels showing significant changes was superimposed on the image map and the mean BMD calculated. BMD changes were analyzed by ANCOVA and paired t-test.

**Results:** For this sample similar to the whole, analyses identified a group of voxels showing negative changes clustered in the inferior cortex, and a group showing positive changes clustered in dense trabecular bone. The percentage BMD changes within the trabecular and cortical bands were  $9.9 \pm 9.0\%$  and  $-4.3 \pm 4.9\%$  respectively ( $p < 0.0001$ ). In contrast to cortical changes, trabecular changes trended ( $P = 0.07$ ) towards a difference in favor of RIS.

**Conclusions:** The results showed distinct focal responses of trabecular and cortical bone to TPTD therapy. Cortical response was distributed throughout the inferior cortex, while trabecular response was found in the lateral aspect of the femoral head and in the lesser trochanter. The focal nature of these results may influence the selection of regions of interest for monitoring response to anabolic therapies.

At the introduction of Teriparatide in 2003 a national database was established with the purpose of gaining information on the results obtained in Denmark. So far 608 patients from 17 different clinics have been included.

Compared to the inclusion criteria of the Neer-study the Danish patients chosen for PTH treatment seem have more severe osteoporosis with a lower T-score in the spine and hip, as well as a higher number of prevalent vertebral fractures. Male patients were significantly more likely to be treatment naïve, while most women had been on antiresorptive treatment before Teriparatide was instituted.

In women, treatment with Teriparatide caused a significant increase in BMDspine, reaching 8.8% at 18 months ( $p < 0.0001$ ), while BMDtotalhip did not change (0.3%, n.s.). In men BMD spine and hip increased by 9.6% /0.9%, respectively ( $p < 0.0001$ ). The increase in BMD spine and total hip in females and males was identical. The BMD response was neither influenced by age nor baseline BMD. Patients with steroid induced osteoporosis had the same BMD response as other patients. Previous bisphosphonate treatment did not blunt the BMD response. Side effects to treatment were mild.

Conclusion. Using a voluntary national database it has been possible to gain information on approximately 45% of all patients treated with Teriparatide in Denmark.

**Previous Antiresorptive Agents Use Did Not Hinder the Increase of Bone Turnover Marker in Teriparatide Use.** Y. Rhee, K. Kim<sup>\*</sup>, C. Ku<sup>\*</sup>, D. Shin<sup>\*</sup>, H. Choi<sup>\*</sup>, S. Lim. Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

**Purpose:** Parathyroid hormone (PTH) is an anabolic agent which increases bone remodeling and decrease fracture rate. Previous studies reported that in patients who have been treated previously with antiresorptive agents, the actions of PTH were delayed compared with treatment naïve patients. We compared the effects of teriparatide on bone turnover changes according to the previous treatment histories. **Method:** Patients with previous fracture or osteoporosis with high risk of fracture were included. They received subcutaneous injections of 20µg teriparatide daily. Serum levels of bone turnover markers (C-telopeptide(CTx), osteocalcin) were assessed at baseline and 3,6 months. **Result:** Total 46 osteoporosis patients were included. According to the cause, 31(67%) were postmenopausal, 8(17%) were glucocorticoid-related and 7(16%) were male with any other specific reason. Twenty seven (59%) patients were previous treated with bisphosphonate, 4(9%) with raloxifene and others were treatment-naïve patients. PTH increased CTx( $302.4 \pm 21.7\%$ ) and osteocalcin ( $133.4 \pm 5.8\%$ ). There was no significant difference among prior bisphosphonate treated, prior raloxifene treated and treatment naïve groups. **Conclusion:** Teriparatide treatment well stimulated bone turnover in all patients with osteoporosis regardless of causes. Moreover, prior treatment with antiresorptive agents did not hinder the expected short term effect of teriparatide comparable with treatment naïve patients. This early change on bone turnover suggests that teriparatide does show anabolic effect in various patients with low bone mass.

**Disclosures:** Y. Rhee, None.

## M352

**Formation of New Trabeculae in a Female Patient with Osteoporosis Treated with Teriparatide, Demonstrated with in-Vivo-Assessment of 3-Dimensional Bone Micro Architecture with HR-pQCT.** H. Radspieler<sup>1</sup>, M. A. Dambacher<sup>2</sup>, M. Neff<sup>3</sup>. <sup>1</sup>Osteoporosezentrum München, München, Germany, <sup>2</sup>ZORG International, Zürich, Switzerland, <sup>3</sup>Osteoporosezentrum Zürich, Zürich, Switzerland.

Teriparatide was the first osteoanabolic drug associated with real bone formation. This was shown in bone biopsies but as the location of bone biopsy before and after therapy differs only statistically analysis is possible. With the HR-pQCT (XtremeCT®, SCANCO Medical AG) for the first time it is possible to show 3-dimensional bone architecture and the changes in bone architecture during therapy in vivo with a very low radiation dose. Because of the high resolution of 80 µm trabecular and cortical bone micro-architecture can be visualized before and after therapy at the identical site in individuals and additionally a couple of parameters of bone-structure as number of trabeculae, trabecular thickness, trabecular separation, cortical thickness and trabecular bone volume can be measured. So this method offers quite new possibilities in diagnosis of osteoporosis and monitoring therapeutic effects.

In this case study we present a 80 years old woman with severe osteoporosis and already 4 vertebral fractures was treated with Teriparatide. Before starting therapy she showed extremely low trabecular and cortical bone densities and pronounced deterioration of trabecular and cortical bone microarchitecture. After 9 month therapy with Teriparatide trabecular bone densities and particularly number of trabeculae in the ultradistal radius and tibia not only showed a significant increase but the 3-dimensional images showed new trabeculae particularly in the inner regions where before starting therapy no more trabeculae were found.

The increase of trabecular bone density in the radius after nine month was 5,5% and 2,7% respectively in the tibia and the increase of number of trabeculae was 7,2% in the radius and 34,2% in the tibia respectively. According to these findings the decrease of the disparation distance (trabekular separation) in the radius was - 7,1% in the radius and - 25,7% in the tibia respectively.

So this is probably the first documented evidence in vivo to show the ability of Teriparatide to create new trabeculae in osteoporotic patients.

The images show the bone-microarchitecture in the tibia before and after therapy with Teriparatide. The images will show trabeculae after therapy which were not visible before therapy.

**Disclosures:** H. Radspieler, None.

**Evaluating the Effect of Soy and Isoflavones on Bone Mineral Density in Older Women; A Randomized Controlled Trial.** K. Mangano<sup>\*1</sup>, A. DiCioccio<sup>\*1</sup>, B. Ryan<sup>\*1</sup>, J. Dauz<sup>\*1</sup>, A. Kenny<sup>2</sup>, R. Abourizk<sup>\*1</sup>, R. Bruno<sup>\*3</sup>, D. Anamani<sup>\*1</sup>, P. Fall<sup>\*4</sup>, A. Kleppinger<sup>\*2</sup>, L. Kenyon Pesce<sup>\*2</sup>, S. Walsh<sup>\*5</sup>, D. Dauser<sup>\*5</sup>, K. Prestwood<sup>\*2</sup>, J. Kerstetter<sup>1</sup>, R. Lipsious<sup>\*1</sup>, S. Strand<sup>\*2</sup>. <sup>1</sup>Allied Health, University of Connecticut, Storrs, CT, USA, <sup>2</sup>Center on Aging, University of Connecticut Health Center, Farmington, CT, USA, <sup>3</sup>Nutritional Sciences, University of Connecticut, Storrs, CT, USA, <sup>4</sup>Clinical Research Center, University of Connecticut Health Center, Farmington, CT, USA, <sup>5</sup>Community Medicine and Health Care, University of Connecticut Health Center, Farmington, CT, USA.

Soy foods contain several components, such as isoflavones and a relative paucity of sulfur-containing amino acids that could potentially have positive effects on bone health. However, there are few long-term clinical trials evaluating soy's effect on bone mineral density (BMD). The purpose of this study was to provide a soy or an omnivorous protein supplement with or without added soy isoflavones to postmenopausal women  $\geq 60$  y.o. for 1 y and measure the effect on BMD. Ninety-seven women participated in this randomized, double-blind, placebo-controlled trial. Following a 1-mo adjustment period in which calcium and vitamin D intake were standardized, subjects were randomized to one of 4 intervention groups: soy protein (20 g) and isoflavone tablets (90 mg), soy protein and placebo tablets, control protein (20 g) and isoflavone tablets (90 mg), control protein and placebo tablets. The primary outcome measure was BMD (by DXA) and secondary outcome measures were changes in bone-specific alkaline phosphatase and urine N-telopeptide crosslinks of collagen. There were no significant differences in compliance between the 4 groups. There were no significant differences in change from baseline in L-spine, total femur or femoral neck BMD among the 4 groups. No statistically significant differences were seen in final BMD, or final bone marker values between the 4 groups at 12 mos. In the study group as a whole bone turnover tended to decline over the 12 mos of protein supplementation ( $p < 0.001$  for BSAP,  $p = 0.06$  for urine NTX). Among the study subjects randomized to isoflavone supplementation there was no difference in mean BMD based on whether or not individuals were equal producers. We conclude that there is no observable difference, as assessed by changes in bone mass, between supplementation with a soy vs. an omnivorous protein isolate, nor is there a discernable effect of adding isoflavones to these protein sources. The trend towards a reduced rate of bone turnover suggests that protein supplementation, at least at this level, does not increase skeletal catabolism. Future, controlled intervention trials might include a higher dose of isoflavones and/or specifically recruit women with a habitually low dietary protein intake.

## M354

**Prevention of Postmenopausal Osteoporosis Using Nitroglycerine: NOVEL Clinical Study.** S. J. Wimalawansa<sup>1</sup>, J. Grimes<sup>\*1</sup>, A. Wilson<sup>\*1</sup>, N. Cosgrove<sup>\*1</sup>, D. Hoover<sup>\*2</sup>. <sup>1</sup>Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA, <sup>2</sup>Statistics, Rutgers University, New Brunswick, NJ, USA.

Several new drugs have been recently introduced to prevent and treat osteoporosis, but these agents are expensive and some have significant adverse effects. Many women previously relied on hormone replacement therapy (HRT) after menopause to reduce osteoporosis risk. However, use of HRT declined after a Women's Health-Initiative clinical trial showed that elevated risks of some cancers with HRT. This result prompted a search for cost-effective osteoporosis prevention regimens. The beneficial effects of estrogen on bone maintenance at least in part mediated via nitric oxide (NO)/cGMP pathway. At appropriate doses, nitroglycerine as a NO donor was shown to favorably affect both osteoblasts and osteoclasts (i.e., uncoupling these two cell types).

A three-year randomized, doubled-blind, controlled clinical trial was conducted to assess the efficacy nitroglycerine in preventing bone loss in early postmenopausal women. This Nitroglycerin as an Option: Value in Early Bone Loss (NOVEL) study, was funded by NIAMS. Over 200,000 women were contacted, 1,400 were interviewed, 215 were screened, and 186 were recruited. Women were randomized to receive either nitroglycerine ointment or placebo ointment. All women received calcium and vitamin D supplementation. There were no differences in the treatment arms in key baseline characteristics including BMD, BMI, smoking status, time since menopause, etc. Taking compliance (~75%) into consideration, the dose actually used by the study participants, only ~50% of that was originally intend to use in this study.

The intent to treat analysis did not reveal differences between the two treatment groups on the primary outcome of lumbar spine BMD. Change of BMD from the baseline in each group was only -0.023 (2.1% change over the three-year study period; was not significant). Except for the increase headaches in the active arm, all other adverse events had, similar profiles compared to placebo. Some of the secondary outcomes including biochemical markers of bone turnover have not been completed.

These results suggest that nitroglycerin at the dose used in this NOVEL clinical study was not effective. However, the NOVEL study subjects used only ~half the effective dose of nitroglycerine, in preventing bone loss. Taken the narrow therapeutic margin for beneficial effects of nitroglycerin on bone, this is likely to be the main reason for not having positive outcome. Therefore, we believe that an additional study using correct dose of nitroglycerine is warranted before eliminating nitroglycerine as a novel and cost-effective therapy for osteoporosis.

**Evaluation of BMD Changes in Women with Severe Osteoporosis after Teriparatide Treatment.** N. Malavolta<sup>1</sup>, A. Buffa<sup>\*1</sup>, G. Vukatana<sup>\*1</sup>, R. Mule<sup>\*1</sup>, M. Frigato<sup>\*1</sup>, S. Migliaccio<sup>2</sup>, G. Iolascon<sup>\*3</sup>, G. Resmini<sup>\*4</sup>, C. Borghi<sup>\*1</sup>. <sup>1</sup>UOS Reumatologia-UO Medicina Interna Borghi, Azienda Ospedaliero Universitaria Sant'Orsola-Malpighi, Bologna, Italy, <sup>2</sup>Università La Sapienza, Roma, Italy, <sup>3</sup>Ortopedia/Riabilitazione, Second University, Naples, Italy, <sup>4</sup>Ortopedia/Traumatologia, Ospedale Treviglio-Caravaggio, Treviglio, Italy.

Osteoporosis is a skeletal disorder characterised by altered bone strength predisposing to increased risk of fractures. Human parathyroid hormone fragment (1-34), teriparatide, is a new therapeutic approach for postmenopausal osteoporosis.

Aim of our study was to evaluate the change in bone mineral density (BMD) at the spine and hip in women with severe osteoporosis treated with teriparatide for 18-months.

We considered 105 postmenopausal women (mean age  $70.52 \pm 8.5$ ys) with severe osteoporosis (mean vertebral Tscore -3.25) and multiple vertebral fractures (mean of number of fractures:  $3.14 \pm 2.19$ ) who received daily, self-injections of teriparatide 20 microg/day, supplemented with 500-1000 mg/d calcium and 400-800 UI/d vitamin D. All patients previously received various antiresorptive drugs. BMD was measured by dual X-ray absorptiometry (DXA) at the spine and hip regions. Vertebral radiographs and DXA were performed at baseline and at the end of treatment. Biochemical markers were assessed at baseline and after 1, 6, 12 and 18 months. Physical examination and vital signs were recorded every six months, serious and non serious adverse events were registered.

The BMD of the spine and hip increased +1.09% and +5.52% respectively. This increase was statistically significant for the spine ( $p < 0.001$ ). We recorded neither new vertebral nor nonvertebral fractures. In 21.8 % of our patients we noted an increase in height ( $2.14 \text{ cm} \pm 1.07 \text{ cm}$ ).

According with literature, in our patients teriparatide treatment determined the expected increase in BMD at the axial skeleton, no new fractures were recorded and in some patients we noted an increase of height. The increased bone strength would be explained with the improvement in trabecular bone microarchitecture. These observational data indicate that teriparatide is useful in patients with severe osteoporosis.

## M356

**Effectiveness of Bisphosphonate Therapy in a Real-World Setting.** A. C. Feldstein<sup>\*1</sup>, D. Weycker<sup>\*2</sup>, G. A. Nichols<sup>\*1</sup>, G. Oster<sup>\*2</sup>, G. Rosales<sup>\*1</sup>, N. Perrin<sup>\*1</sup>. <sup>1</sup>Center for Health Research, Kaiser Permanente Northwest, Portland, OR, USA, <sup>2</sup>Policy Analysis Inc., Brookline, MA, USA.

In randomized controlled trials, bisphosphonates--the most commonly prescribed treatment for osteoporosis--have been found to prevent fractures; it is unknown whether these agents are similarly effective in real-world clinical practice where patients may be less compliant with their treatment regimens.

To examine the effectiveness of bisphosphonate therapy in clinical practice, we employed a retrospective, matched cohort design to compare risk of clinical fracture in women with low BMD (T-score  $\leq -2.0$ ) or prior fracture who initiated such therapy versus those who did not. Data were obtained from the electronic medical records of a large US HMO. Beginning with the first month of patient accrual (7/96 through 6/06), women who initiated bisphosphonate therapy and had low BMD or clinical fracture in the prior 6 months ("treated patients") were matched (1:1 without replacement) to women with a similar clinical profile who did not initiate such therapy in that month or the next 6 months ("comparison patients"). New clinical fractures were identified from the day following therapy initiation for treated patients (and from the same date for matched comparison patients) through the end of observation; treated patients were followed for fracture irrespective of their compliance with therapy. Cox proportional hazards models were employed to estimate the hazard ratio of fracture for treated versus comparison patients, adjusting for differences in potential confounders (but not medication adherence). Mean ( $\pm$  SD) age of treated patients ( $n = 1,829$ ) and comparison patients was 72 ( $\pm 10$ ) years, 45% of each group had a prior clinical fracture, and mean BMD (for those with values) was  $-2.7 (\pm 0.5)$  and  $-2.6 (\pm 0.5)$ , respectively. Mean medication (ie, bisphosphonate) possession ratio (days of therapy  $\div$  days of follow-up) among treated patients was 0.60 ( $\pm 0.38$ ). A total of 198 (11%) treated patients experienced new clinical fracture over a mean follow-up of 2.7 ( $\pm 2.0$ ) years versus 179 (10%) comparison patients over a mean follow-up of 2.3 ( $\pm 1.8$ ) years. The adjusted hazard ratio for fracture among treated versus comparison patients was 0.91 (95% CI, 0.74 - 1.12;  $p = 0.39$ ). In this analysis of post-menopausal women with low BMD or prior clinical fracture in real-world clinical practice, risk of fracture did not differ significantly between those who began bisphosphonate therapy and those who did not. While we suspect that our findings may be attributable--at least in part--to poor drug adherence, further research in this area is warranted.

**Alendronate Treatment in Postmenopausal Romanian Women Followed by BMD- Digital X-Ray Radiogrammetry.** C. Galesanu<sup>1</sup>, M. R. Galesanu<sup>\*2</sup>. <sup>1</sup>Endocrinology, University of Medicine and Pharmacy, IASI, Romania, <sup>2</sup>Osteodensitometry, Centre of Imaging and Radiology Diagnosis, IASI, Romania.

The bisphosphonates have been shown to increase bone mineral density (BMD) and reduce bone turnover in postmenopausal osteoporotic women. Measuring BMD by Digital X-Ray Radiogrammetry was accepted for diagnosis and monitoring response to therapy. The aim of this study was to evaluate the effect of Alendronate (Fosamax®) treatment in a group of postmenopausal women, assessed by Digital X-Ray Radiogrammetry (DXR-BMD) in bone changes.

We studied 9,733 healthy women with ages between 20 and 89 years referred to our department of densitometry using DXR-BMD, 6,903 from them being in postmenopause. Using WHO - criteria for osteoporosis diagnosis, 792 from them presented osteoporosis and 1,450 osteopenia. Among 385 patients who were selected for Alendronate, 115 were under the treatment after five years or more. The patients received Alendronate 70 mg/weekly. The mean age of osteoporotic treated women was 61.3 $\pm$ 7.8 years. BMD by DXR was measured at each 12 months. Statistical analyses was "t" Test (Student - Fischer). The witness group, 35 women, received 1 mcg Alfacalcidol daily.

BMD mean changes after Alendronate was: +3.3% after one year; +4.4% after two years; +5.35% after three years; +6.3% after four years and +7.1% after five years. The BMD changes under Alfacalcidol was +1.89% after the first year and +3.2% after five years. Three patients (2.6%) suffered a fracture under the Alendronate: one hip fracture and two vertebral fractures recorded on X-Ray.

Under Alfacalcidol one patient presented a hip fracture.

We conclude that BMD increase significantly after Fosamax® treatment in postmenopausal women. Though Alendronate seemed to be good tolerated by the patients the therapy adherence after five years was only 29%. The postmenopausal osteoporosis rested untreated even if it was diagnosed. In our study, like in others, the adherence at treatment was lower.

**Disclosures:** C. Galesanu, None.

## M358

**Comparative Gastrointestinal Safety of Weekly Oral Bisphosphonates.** S. M. Cadarette, J. N. Katz\*, M. A. Brookhart\*, T. Stürmer\*, M. R. Stedman\*, D. H. Solomon. Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA.

Weekly bisphosphonates are the primary agents prescribed for osteoporosis. Prior evidence from endoscopic trials and observational studies suggests that daily risedronate has better gastrointestinal safety than daily alendronate. The purpose of our study was to compare the relative gastrointestinal safety of treatment with weekly bisphosphonates among older adults. We studied a population-based cohort of new users of weekly alendronate (70 mg) and weekly risedronate (35 mg) enrolled in the Pennsylvania Pharmaceutical Assistance Contract for the Elderly. Pharmacy and Medicare claims served as the primary data sources. Covariates included risk factors plausibly related to gastrointestinal disease and were assessed using information from the 12 months prior to bisphosphonate initiation. The primary outcome was hospitalization for upper gastrointestinal bleed. Secondary outcomes included outpatient diagnoses for upper gastrointestinal disease, symptoms, endoscopic procedures, and use of gastroprotective agents. We used Cox proportional hazard models to compare outcomes between agents within 120 days of treatment initiation, adjusting for covariates using risedronate propensity score quintiles. In sensitivity analysis, we examined composite outcomes and stratified results by gastrointestinal event history (yes or no) and age group (65-79 years or 80+ years). Alendronate was the reference group in all Cox proportional hazard models. We identified 10,420 new users of either agent who initiated treatment between June 2002 and August 2005, mean age=79 years (SD=6.9) and 95% female. We observed 31 hospitalizations for upper gastrointestinal bleed (0.91/100 person-years) within 120 days of treatment initiation. Adjusting for covariates, there was no large difference in hospitalization rates for upper gastrointestinal bleed among those treated with risedronate (HR=1.12, 95%CI=0.55-2.28) compared to alendronate. Similarly, no differences were observed for secondary or composite outcomes, or in stratified analyses. However, among those with a history of gastrointestinal disease, rates for upper gastrointestinal endoscopies were lower among risedronate (HR=0.70, 95%CI=0.49-0.99) compared with alendronate recipients. Nonetheless, when endoscopies were combined with upper gastrointestinal diseases and symptoms as the outcome, this finding was attenuated towards the null (HR=0.93; 95%CI=0.83-1.04).

In conclusion, we found no difference in hospitalizations for upper gastrointestinal bleed between weekly alendronate and weekly risedronate. Small differences between agents were observed for upper gastrointestinal endoscopy, but this is of unclear clinical importance.

## M359

**Differences in Safety and Efficacy of Generic and Original Branded once weekly Bisphosphonates.** J. D. Ringe, P. Farahmand\*. Medizinische Klinik IV (Osteology/Rheumatology), Klinikum Leverkusen, University of Cologne, Leverkusen, Germany.

**Objective:** To compare the changes on bone mineral density (BMD), the effects on persistence and adverse events (AE), in patients treated for postmenopausal osteoporosis with either generic alendronate or with branded Fosamax® or Actonel®, once weekly. **Patients and methods:** In this retrospective patient chart analysis we reviewed the one year observational treatment results of 186 women (ITT population) with postmenopausal osteoporosis. Patients from our out-patient department having started with once weekly BP therapy between 36 to at least 12 months before this chart review were included in this comparative study with three arms according to their treatment: A: Generic Alendronate 70 mg products, B: Alendronate (Fosamax®) 70 mg and C: Risedronate (Actonel®) 35 mg. All patients received basic therapy with 1200 mg calcium and 800 IU Vit. D per day. Patients' BMD at lumbar spine and total hip was below - 2.5 T-score, with and without prevalent vert. and non-vert. fractures. **Results:** Analysis of the 186 patients' results shows an average increases in LS-BMD after 12 months of 2.8%, 5.2% and 4.8% for the groups A, B and C resp. The respective mean changes at total hip were 1.5%, 2.9%, and 3.1%. At both sites, the mean increases in BMD were not different between the two groups receiving original BP (B, C) but for both were significantly higher than for the group treated with generic alendronate (A). At 12 months 68% of group A, 84% of B and 94% of C were still on BP-therapy. The persistence of patients treated with generic alendronate was significantly lower as compared to each of the two original BP treated groups. The total number of patients with gastrointestinal AEs were 32, 15 and 9 for A, B and C resp. **Conclusions:** Significantly lower increases of lumbar spine and total hip BMD with generic alendronate once weekly as compared to the two branded originals (Fosamax, Actonel) were observed. We do not know the reason for the 40-50% lower BMD increase rates of the generic compounds. At least in part the lower efficacy can be explained by a significantly lower degree of compliance with generic alendronate, which could be related to a higher incidence of GI AE's. Other reasons could be lower bioavailability or potency of generic alendronate.

**Disclosures:** J.D. Ringe, None.

## M360

**Continued Evidence for Safety and Efficacy of Risedronate in Men with Osteoporosis: Outcome of the 2-year Open-Label Extension Study of MASTER.** S. Boonen<sup>1</sup>, E. Orwoll<sup>2</sup>, D. Wenderoth<sup>3</sup>, K. Stoner<sup>\*4</sup>, R. Eusebio<sup>5</sup>, P. Delmas<sup>6</sup>. <sup>1</sup>University Hospital, Leuven, Leuven, Belgium, <sup>2</sup>Oregon Health Sciences University, Portland, OR, USA, <sup>3</sup>P & G Pharmaceuticals, Schwalbach, Germany, <sup>4</sup>P & G Pharmaceuticals, Egham, United Kingdom, <sup>5</sup>P & G Pharmaceuticals, Mason, OH, USA, <sup>6</sup>INSERM Research Unit 403, Lyon, France.

The objective of this 2-year open-label extension to the 2-year, double-blind, placebo-controlled study (MASTER) was to continue to assess the safety of 35 mg once-a-week (OAW) risedronate in men with osteoporosis. 218 of the 284 men (67 of 93 placebo group [Pla/Ris]; 151 of 191 risedronate group [Ris/Ris]) from the initial blinded study were enrolled in this extension study. Safety variables included adverse events (AEs), laboratory data, vital signs, physical examinations, and changes in lumbar spine, total proximal femur, femoral neck, and femoral trochanter BMD and bone turnover markers (BTMs) including type I collagen C-telopeptide (CTX), type I collagen N-telopeptide/creatinine (NTX/Cr), and bone-specific alkaline phosphatase (BAP). BMD was measured at Months 36 and 48 of the 2-year extension; BTMs were measured at Months 27, 30, 36 and 48 of the 2-year extension.

The mean increase from baseline at Year 4 in lumbar spine BMD for patients receiving risedronate 35 mg OAW for all 4 years (Ris/Ris group) was 7.9% (6.6-9.1, 95% CI, n=128). These Ris/Ris patients also continued to show BMD response at other skeletal sites. The mean increase from baseline at Year 4 in lumbar spine BMD for the placebo patients that received risedronate 35 mg OAW for the 2 years of the open-label extension study (Pla/Ris group) was 6.2% (4.6-7.9, 95% CI, n=54), which is similar to the response observed in risedronate-treated patients during the initial 2-year, double-blind study period (5.98% [5.22-6.73, 95% CI], n=172). Similar patterns were observed in the Pla/Ris group at other skeletal sites.

Similar reductions in NTX/Cr, CTX, and BAP were found at Years 3 & 4 between the 2 groups. In general, greater decreases in BTMs were observed in the Pla/Ris group during the open-label extension study while taking risedronate 35 mg OAW than during the double-blind study while taking placebo.

The 2 groups were similar in overall percentages of patients with AEs (68.7% Pla/Ris, 66.9% Ris/Ris), serious AEs (11.9% Pla/Ris, 13.9% Ris/Ris), upper GI AEs (10.4% Pla/Ris, 8.6% Ris/Ris), and overall musculoskeletal AEs (11.9% Pla/Ris, 13.9% Ris/Ris).

In conclusion, the Pla/Ris group in the 2-year open-label extension study showed similar safety and efficacy results compared to the Ris/Ris group in the first 2 years of the study. Patients who received risedronate for 4 years in total showed similar safety and efficacy to that observed in women with postmenopausal osteoporosis treated with risedronate for 4 years.

## M361

**Postmenopausal Women with Gastroesophageal Reflux Disease and Long Term Treatment with Bisphosphonates IV.** M. Cokolic\*. Endocrinology and Diabetology, UKC Maribor, Maribor, Slovenia.

The aim of this study was to assess the effectiveness of bisphosphonate (BP) iv (zoledronat 5 mg, pamidronate 30 mg, ibandronate 3 mg) therapy in treatment of postmenopausal osteoporosis in patients with gastroesophageal reflux disease (GERD). GERD occurs when the lower esophageal sphincter opens spontaneously, for varying periods of time, or does not close properly and stomach contents rise up into the esophagus and it can eventually lead to more serious health problems and unable take BP orally.

Fifteen women with osteoporosis (T-score at lumbar spine or hip <-2.5 SD) were enrolled in a prospective study between January 2003 and December 2007. Patients were 61 to 93 years old (mean: 72,3 years). They were treated with BP iv in combination with 500-mg elemental calcium and 800 IU vitamin D. The BMD in the lumbar spine (L1-L4) and left hip was measured in all patients using dual energy X-ray densitometry (Hologic 2000+) at the start of the treatment and at 12 to 48 months after initiation of the treatment. The serum levels of RBC, Hgb, WBC, Plt, TSH, Ca, P, Mg, Na, K, Cl, ALP, AST, ALT, BUN, creatinine, osteocalcin and  $\beta$  cross laps were measured every 12 months. Average baseline BMD was 0.698 g/cm<sup>2</sup> (n=15, range 0.602 to 0.787 g/cm<sup>2</sup>) at the lumbar spine and 0.676 g/cm<sup>2</sup> (n=15, range 0.499 to 0.862 g/cm<sup>2</sup>) at the hip.

After treating patients on average for 40 months, the average BMD was 0.722 g/cm<sup>2</sup> (n=15, range 0.600 to 0.966 g/cm<sup>2</sup>) at the lumbar spine and 0.704 g/cm<sup>2</sup> (n=15, range 0.494 to 0.901 g/cm<sup>2</sup>) at the hip. BMD thus increased on average by 3.4% at the lumbar spine and 4.1% at the hip. Serum levels remained within normal limits throughout the treatment, with no adverse events observed during the study. BP iv was well tolerated in all patients.

In our report of our on-going study we have shown that postmenopausal osteoporosis with GERD can be effectively and safely treated with BP iv in all patients for up to four years without new fractures.

## M362

**Effect of a Single 5-mg Infusion of Zoledronic Acid on Bone Turnover Markers Versus Oral Risedronate (5 mg/day) Over 1 Year in Patients with Glucocorticoid-Induced Osteoporosis.** P. Sambrook<sup>1</sup>, J. Devogelaer<sup>2</sup>, J. Reginster<sup>3</sup>, K. Saag<sup>4</sup>, C. Roux<sup>5</sup>, C. Lau<sup>\*6</sup>, P. Papanastasiou<sup>\*7</sup>, O. Schoenborn-Kellenberger<sup>\*7</sup>, K. Maylandt<sup>\*7</sup>, T. Fashola<sup>\*7</sup>, P. Mesenbrink<sup>\*8</sup>, D. Reid<sup>9</sup>. <sup>1</sup>University of Sydney, Sydney, Australia, <sup>2</sup>Universite Catholique de Louvain, Brussels, Belgium, <sup>3</sup>University of Liege, Liege, Belgium, <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL, USA, <sup>5</sup>Paris-Descartes University, Paris, France, <sup>6</sup>University of Dundee, Dundee, United Kingdom, <sup>7</sup>Novartis Pharma AG, Basel, Switzerland, <sup>8</sup>Novartis Pharmaceutical Corp., East Hanover, NJ, USA, <sup>9</sup>University of Aberdeen, Aberdeen, United Kingdom.

A single zoledronic acid (ZOL, 5 mg) infusion was compared with oral risedronate (RIS, 5 mg/d) in patients with glucocorticoid-induced osteoporosis (GIO) in a 1-yr, double-blind, double-dummy study. Randomized patients were divided into 2 subpopulations: treatment (>3 months glucocorticoid therapy [ZOL, n=272; RIS, n=273]) and prevention ( $\leq$ 3 months glucocorticoids [ZOL, n=144; RIS, n=144]). Bone mineral density (BMD) was evaluated at 6 and 12 months. Changes from baseline in fasting serum  $\beta$ -C-terminal telopeptides of type 1 collagen ( $\beta$ -CTX) and procollagen type 1 amino-terminal propeptide (PINP) were measured at 9-11 days and Months 3, 6, and 12. ZOL significantly increased lumbar spine (LS) BMD vs RIS in both the treatment (4.1% vs 2.7%; P=0.0001) and prevention (2.6% vs 0.6%; P<0.0001) subpopulations at 12 months. ZOL reduced  $\beta$ -CTX and PINP levels significantly more than RIS in the treatment (day 9-11 onwards) and prevention ( $\beta$ -CTX, day 9-11 onwards; PINP, Month 3 onwards) subpopulations (P<0.0001). There was a significant correlation between LS BMD change and some biomarkers at 12 months. In subgroups of patients with/without rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) or asthma/chronic obstructive pulmonary disease (COPD), reductions in  $\beta$ -CTX for ZOL vs RIS were significant from day 9-11 onwards in the combined treatment and prevention subpopulations (P $\leq$ 0.0004 for all). Reductions in PINP for ZOL vs RIS were significant from day 9-11 onwards in patients without RA, SLE, and asthma/COPD. In subgroups with/without concomitant use of proton pump inhibitors (PPIs), selective serotonin inhibitors (SSRIs) or anti-tumor necrosis factor (anti-TNF) at baseline there was no difference in reductions in  $\beta$ -CTX levels for ZOL vs RIS (P<0.001). PINP levels were significantly reduced for ZOL vs RIS from day 9-11 onwards, regardless of PPI use (P $\leq$ 0.0002) or anti-TNF use (P $\leq$ 0.0001), but was only significantly reduced at all timepoints in patients not taking SSRIs (P<0.001). These results indicate that a single infusion of ZOL suppresses bone turnover significantly more than daily oral RIS for up to 1 yr in different subgroups of patients with GIO.

## M363

**Effect of Zoledronic Acid (Single 5-mg Infusion) on Lumbar Spine Bone Mineral Density Versus Oral Risedronate (5 mg/day) Over 1 Year in Subgroups of Patients Receiving Glucocorticoid Therapy.** C. Roux<sup>1</sup>, D. Reid<sup>2</sup>, J. Devogelaer<sup>3</sup>, K. Saag<sup>4</sup>, C. Lau<sup>\*5</sup>, J. Reginster<sup>6</sup>, P. Papanastasiou<sup>\*7</sup>, A. Ferreira<sup>\*7</sup>, F. Hartl<sup>8</sup>, T. Fashola<sup>\*7</sup>, P. Mesenbrink<sup>\*9</sup>, P. Sambrook<sup>10</sup>. <sup>1</sup>Paris-Descartes University, Paris, France, <sup>2</sup>University of Aberdeen, Aberdeen, United Kingdom, <sup>3</sup>Universite Catholique de Louvain, Brussels, Belgium, <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL, USA, <sup>5</sup>University of Dundee, Dundee, United Kingdom, <sup>6</sup>University of Leige, Liege, Belgium, <sup>7</sup>Novartis Pharma AG, Basel, Switzerland, <sup>8</sup>F. Hoffmann-La Roche Ltd., Basel, Switzerland, <sup>9</sup>Novartis Pharmaceutical Corp., East Hanover, NJ, USA, <sup>10</sup>University of Sydney, Sydney, Australia.

The effects of intravenous zoledronic acid (ZOL, single 5-mg infusion) and oral risedronate (RIS, 5 mg/d) on lumbar spine (LS) bone mineral density (BMD) were evaluated in subgroups of glucocorticoid-treated patients in a 1-year, randomized, double-blind, double-dummy study. Patients were divided into two subpopulations according to glucocorticoid treatment duration at randomization (treatment subpopulation: >3 months [ZOL, n=272; RIS, n=273]; prevention subpopulation:  $\leq$ 3 months [ZOL, n=144; RIS, n=144]), then further divided into subgroups by gender, age (<35, 35-50, 51-64, 65-74,  $\geq$ 75 years), mean prednisone dose during the trial (<7.5,  $\geq$ 7.5 to <12,  $\geq$ 12 mg/d), and history of other medications. Increases in LS BMD from baseline to 12 months seen with ZOL were significantly greater than with RIS for: men (P<0.05) and women (P<0.01) for both treatment and prevention subpopulations; age 35-40 years (P=0.0041) and 51-64 years (P=0.0075) for the treatment subpopulation and 65-74 years (P<0.05) for both subpopulations (the difference between ZOL and RIS increased with age); mean prednisone dose  $\geq$ 7.5 to <12 mg/d (P<0.001) for both subpopulations; no history of proton pump inhibitor (PPI) (P<0.01), selective serotonin reuptake inhibitor (P<0.0001) or anti-tumor necrosis factor (TNF) therapies (P<0.01) for both subpopulations; and prior history of anti-TNF (P=0.0278) and PPI therapies (P=0.0148) for the treatment and prevention subpopulations, respectively. There was no significant difference in increase in LS BMD for ZOL vs RIS for the remaining subgroup parameters in either subpopulation. In the 3 days post treatment, AEs were more common with ZOL (mainly transient post-dose symptoms). From day 3, the 2 treatment groups had similar AE rates. These findings suggest that ZOL is effective in increasing LS BMD to a significantly greater extent than RIS in a wide range of patient subgroups.

## M364

**Acute Phase Response and Bone Metabolism Marker after Intravenous Bisphosphonate in Osteoporotic Patients with Rheumatism.** W. Park<sup>1</sup>, M. Lim<sup>\*1</sup>, S. Kwon<sup>\*1</sup>, S. Kim<sup>\*1</sup>, S. Hong<sup>2</sup>. <sup>1</sup>Medicine/Rheumatology, IN-HA University Hospital, Incheon, Republic of Korea, <sup>2</sup>Endocrinology and Metabolism, IN-HA University Hospital, Incheon, Republic of Korea.

The side effects typically associated with the intermittent large dose bisphosphonate are myalgia and transient fever. Increase of cytokines in acute phase response was reported mostly in treatment for cancer and only few studies were reported for osteoporosis. The aim of this study is to evaluate cytokine change in acute phase response and bone metabolism shortly after single dose of intravenous pamidronate.

Nineteen patients with osteoporosis and rheumatism without prior bisphosphonate or immunosuppressant use were selected. They were given 30 mg of IV pamidronate and the venous blood samples were taken before and 48 hours after the infusion. Serum level of IL-6, TNF- $\alpha$  and C-telopeptide (CTX) were measured with an immunoenzymetric assay (serum IL-6 and TNF- $\alpha$ : R&D Systems, Minneapolis, Minn., USA; serum CTX: Nordic Bioscience Diagnostics, Bolden, UK). The real-time RT-PCR quantified the expression of the interferon (IFN)- $\gamma$  from peripheral blood mononuclear cells. Leukocyte count and serum calcium level were also determined at the same time. Acute phase reactants such as erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were measured for three consecutive days.

At baseline, mean level of CRP was 0.14 mg/dL which rose to 0.30 mg/dL, 0.61 mg/dL and 1.58 mg/dL at 24hours, 48 hours and 72 hours, respectively. Their rise were all significant at all times comparing to baseline ( $p=0.049$ , 0.002, 0.004, respectively). ESR seemed to increase at 72 hours but it was not significant ( $p=0.413$ ). The WBC count and serum calcium level tend to decreased after the treatment. Serum TNF- $\alpha$  increased significantly ( $p=0.031$ ). Both serum IL-6 and IFN- $\gamma$  did not increase significantly but increment of IL-6 after treatment strongly correlated with that of CRP ( $p=0.023$ ). Serum CTX decreased markedly after the treatment ( $p=0.009$ ). The dose of bisphosphonate used in this study was smaller than previous studies. The marked decrease of serum CTX implies that osteoclastic activity is suppressed as early as 48 hours after the treatment. As inflammation occurs even with 30mg of intravenous pamidronate, we recommend smaller dose frequent therapy or slower infusion of bisphosphonate in contrary to the current trend of large dose intermittent therapy.

	Before treatment	48 hours after treatment	P value
WBC (/ $\mu$ l)	6763 $\pm$ 1778	6352 $\pm$ 2212	0.31
CRP (mg/dL)	0.14	0.61	0.002
IL-6 (pg/mL)	1.76 $\pm$ 1.03	2.54 $\pm$ 1.51	0.084
TNF- $\alpha$ (pg/mL)	1.11 $\pm$ 0.91	1.96 $\pm$ 2.11	0.031
IFN- $\gamma$	1.0 $\pm$ 0	2.23 $\pm$ 2.37	0.38
Serum CTX (ng/ml)	0.49 $\pm$ 0.40	0.14 $\pm$ 0.14	0.009

**Disclosures:** W. Park, None.

## M365

**Zoledronic Acid Prevents Accelerated Bone Loss after Discontinuation of Teriparatide.** C. Deal<sup>1</sup>, K. Tuthill<sup>\*1</sup>, A. Kriegman<sup>2</sup>. <sup>1</sup>Rheumatology, Cleveland Clinic, Cleveland, OH, USA, <sup>2</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA.

Teriparatide (TPTD) is an anabolic agent approved for daily injection over a 2 year period in patients at high risk for fracture. After discontinuation of TPTD, rapid bone loss ensues. Treatment with antiresorptive agents prevents accelerated bone loss and may therefore maintain the increased bone mass following TPTD. Zoledronic acid 5mg (ZOL) is an IV bisphosphonate approved as a once-yearly infusion for the treatment of postmenopausal osteoporosis. In order to test the ability of ZOL to maintain bone mass after treatment with TPTD, we enrolled 35 postmenopausal women in a trial evaluating the effect of ZOL 5 mg given immediately after a 2-year course of TPTD. The primary endpoint was change in bone density (grams/cm<sup>2</sup>) in the lumbar spine (LS) (L1-4) at 12 months. Secondary endpoints were change in bone density (grams/cm<sup>2</sup>) at the total hip (TH), femoral neck (FN) and total body (TB); change in serum c-telopeptide type I collagen (CTX) and serum n-propeptide type I collagen (PINP). So far, 24 patients have completed 12-months of follow-up, and here we report on changes in bone density in these patients.

The study cohort had a mean age of 68.7  $\pm$  11.4 and a mean T-score at the time of TPTD discontinuation of -2.1 for both LS and TH. Table 1 summarizes the number of patients exhibiting either maintenance/increase or a decrease in BMD at LS, TH, FN and TB. Table 1. Number of patients (bone density change from baseline to 12 months)

Bone density	LS	TH	FN	TB
Maintained/ increased	21	24	22	23
Declined	3	0	2	1

**Decline = change  $>0.03$ g/cm<sup>2</sup>**

A single infusion of Zoledronic acid 5 mg appears to be a safe and effective therapy to maintain or increase bone mass in patients after TPTD treatment. It preserves, or increases bone mass in the lumbar spine, total hip, femoral neck and total body in 88%, 100%, 92% and 96% of patients, respectively.

**Alendronate Treatment for Juvenile Osteoporosis. A Double-Blind, Randomized, Placebo-controlled Cross-Over Clinical Trial.** L. L. Key, P. Madyastha<sup>\*</sup>, W. Ries, B. Hollis, F. Reed<sup>\*</sup>. Pediatrics, Medical University of South Carolina, Charleston, SC, USA.

A phase IIb, double-blind, crossover study was designed to demonstrate the efficacy and safety of alendronate treatment in juvenile osteoporosis. Twenty two children (age 5-13 years) with two or more fractures, associated with minimal or no trauma, were enrolled with a Z-score of  $\leq -2.0$  SD based upon dual energy x-ray analysis. They were randomized using a permuted block design. In the first year (12 months), eleven children (group 1) received alendronate (35mg if patients  $<40$ kg, and 70mg if  $\geq 40$ kg) along with calcium supplementation (500mg or 1000mg daily, using the same weight cutoffs and vitamin D 800 IU ). Another 11 children (group 2) received placebo, calcium and vitamin D. In the second year (12 months), they crossed over and received placebo (group 1) and alendronate (group 2) with calcium and vitamin supplements. Bone mineral density (BMD) of lumbar spine (LS) and hip were measured every 6 months. Biochemical markers of bone turnover (bone formation, serum bone-specific alkaline phosphatase, BSAP) and resorption (N-telopeptide, NTx) were also determined. At the end of first year, the BMD of LS increased significantly (11.6-45.6%) in group 1, as compared to a minimum increase in group 2 (3.9-10%). In the second year (crossover), group 1 continued to increase (13.8-49.5%) and group 2 increased to 8.2-46.5%. Although the BMD increased in all the participants at the end of two years, the increase in %BMD (group 1) was less than that over previous measurements (18.5% (6 mo), 6.5% (12 mo), 3.7% (18 mo), 1.8% (24 mo)). This pattern was observed in group 2. Bone marker analyses correlated with the BMD increase. There was no side effects and no reduction in the rate of height growth. Children with multiple fractures and low bone density should be treated with alendronate as soon as they are diagnosed. It is possible that alendronate may inhibit the osteoclast activity for a short period of time.

**Fracture Risk in Women Aged 65 Years or Older with Once-Monthly Oral Ibandronate Compared with Weekly Bisphosphonates: Analyses From the eValuation of Ibandronate Efficacy (VIBE) Database Fracture Study.** S. L. Silverman<sup>1</sup>, W. A. Blumentals<sup>\*2</sup>, S. A. Poston<sup>\*3</sup>, S. T. Harris<sup>4</sup>. <sup>1</sup>Cedars-Sinai Medical Center/UCLA, Beverly Hills, CA, USA, <sup>2</sup>Roche, Nutley, NJ, USA, <sup>3</sup>GlaxoSmithKline, Research Triangle Park, NC, USA, <sup>4</sup>University of California, San Francisco, San Francisco, CA, USA.

The VIBE study compared fracture risk between patients treated with once-monthly and weekly oral bisphosphonates (BPs). This subanalysis focused on a higher-risk group of older women, aged  $\geq 65$  years.

Patients were newly prescribed once-monthly oral ibandronate or weekly oral alendronate or risedronate, adherent for  $\geq 90$  days, and without malignancy or Paget's disease. Data were censored at fracture, 12 months after BP initiation, end of health plan enrollment, BP brand switch, regimen switch, or treatment discontinuation. Fracture risk was compared using Cox regression models to calculate hazard ratio (HR) and adjusted for potential confounding factors (age, concomitant medications, estrogen use, outpatient visits, osteoporosis diagnosis, bone densitometry procedure, fracture history, glucocorticoid use, use of other non-estrogen osteoporosis medications). The analysis was repeated for the separate weekly alendronate or risedronate groups compared with ibandronate.

The analysis included 1,811 patients receiving once-monthly ibandronate and 14,648 patients receiving weekly BPs (alendronate 9,270, risedronate 5,378). Baseline characteristics included: mean (median) age 72.41 (72) years for ibandronate vs 72.82 (73) years for weekly BPs ( $p=0.0029$ ); pre-index fracture 6.29% for ibandronate vs 6.45% for weekly BPs ( $p=0.7979$ ); pre-index glucocorticoid use 15.52% for ibandronate vs 10.98% for weekly BPs ( $p<0.001$ ); pre-index rheumatoid arthritis diagnosis 5.36% for ibandronate vs 3.29% for weekly BPs ( $p<0.001$ ). The risks of hip fracture, and nonvertebral fracture (NVF) were not significantly different between groups (hip fracture adjusted HR 1.14,  $p=0.707$ ; NVF 0.75,  $p=0.172$ ), but the risks of vertebral fracture and all fractures were statistically lower in the ibandronate group (vertebral fracture adjusted HR 0.28,  $p=0.030$ ; all fractures 0.65,  $p=0.033$ ). Similarly, when comparing ibandronate vs individual weekly BPs, the risk of hip fracture or NVF was not significantly different from either alendronate or risedronate.

Women aged  $\geq 65$  years treated with oral once-monthly ibandronate or weekly BPs had similar risks of hip fracture or NVF. The risks of vertebral fracture and all fractures were statistically lower for ibandronate patients, though the clinical implications of these findings require further exploration and validation.

## M368

**Improving the Prediction of Medication Adherence: The Example of Bisphosphonates for Osteoporosis.** J. R. Curtis<sup>1</sup>, J. Xi<sup>\*1</sup>, A. O. Westfall<sup>\*2</sup>, H. Cheng<sup>\*3</sup>, K. Lyles<sup>\*4</sup>, K. G. Saag<sup>5</sup>, E. Delzell<sup>\*3</sup>. <sup>1</sup>Center for Education and Research on Therapeutics (CERTs), University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>3</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Department of Medicine, Duke University, Durham, NC, USA, <sup>5</sup>Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA.

**Introduction** Administrative claims data have a limited ability to identify persons with high adherence to oral bisphosphonates. We tested whether adding information on adherence with other drugs used to treat chronic, asymptomatic conditions would improve the predictive ability of administrative data to identify adherent individuals.

**Methods** Using data from a large, U.S. healthcare organization, we identified new bisphosphonate users and their 1 year adherence to oral bisphosphonates, quantified by the Medication Possession Ratio (MPR). Multivariable logistic regression models evaluated the relationship between high bisphosphonate adherence (MPR  $\geq$  80%) and patient demographics, comorbidities, and health services utilization. To these logistic regression models, we evaluated the incremental change in the area under the receiver operator curve (AUC) after adding information regarding adherence with other drug classes. These included anti-hyperlipidemics (statins), anti-hypertensives, anti-depressants, oral diabetes agents, and glaucoma medications. Results from the logistic regression models were evaluated in parallel using recursive partitioning trees with 10-fold cross-validation.

**Results** Among 101,038 new bisphosphonate users, administrative data identified numerous non-medication factors (e.g. age, gender, use of preventive services) significantly associated with high bisphosphonate adherence at 1 year. However, all these factors in aggregate had low discriminant ability to identify persons highly adherent with bisphosphonates (AUC = 0.62). For persons who were new users of  $\geq$  1 of the other asymptomatic condition drugs, MPR data on the other drugs substantially improved the prediction of high bisphosphonate adherence. The impact on prediction was largest for concomitant statin users (AUC = 0.70).

**Conclusions** Information on adherence with drugs used to treat chronic asymptomatic conditions improves the prediction of adherence with oral bisphosphonates. This may help identify persons who should receive targeted interventions to promote adherence to osteoporosis medications.

**A Post-Fracture Initiative in a Rural Ontario Community Hospital.** J. E. M. Sale<sup>\*1</sup>, D. E. Beaton<sup>1</sup>, E. R. Bogoch<sup>1</sup>, V. Elliot-Gibson<sup>\*1</sup>, K. J. Ingram<sup>\*2</sup>.

<sup>1</sup>Mobility Program Clinical Research Unit, Keenan Research Centre, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada,

<sup>2</sup>Peterborough Regional Health Centre, Peterborough, ON, Canada.

We evaluated a coordinator-based osteoporosis (OP) initiative in a regional community hospital fracture clinic in rural Ontario. A coordinator screened and identified fragility fracture patients, educated them about OP, and then referred them back to their family physician for further OP assessment and intervention. Eligible patients were males  $\geq$ 50 years and females  $\geq$  40 years presenting to an outpatient fracture clinic for follow up of a low trauma fracture of the distal radius, proximal humerus, proximal femur, or vertebrae over a 12-month period. Patients voluntarily completed a quality assurance survey with the coordinator and were contacted 6 months later for follow up. At baseline, 524 patients (mean age 74 years) met our eligibility criteria; 432 (82%) were female; 150 (29%) had a prior fracture, 205 (39%) had a previous OP diagnosis, and 120 (23%) were on first-line therapy for OP. Of these 524, 339 (65%) were successfully followed-up at 6 months. Compared with patients without follow-up data (n=185), patients with follow-up data were younger (73 vs. 76 years; t(522)=2.33, p=.02), more likely to be female (86% vs. 77%;  $\chi^2(1)=6.4$ , p=.011), more likely to report ever having a bone mineral density (BMD) test (56% vs. 35%;  $\chi^2(1)=20.7$ , p<.001), and more likely to be on first-line therapy at baseline (26% vs. 18%;  $\chi^2(1)=4.15$ , p=.042). Within 6-months of screening, 26% of follow-up patients had initiated, while 22% remained on, first-line therapy. Of those on first-line therapy at baseline, only 3% were not on therapy at follow-up. Fifty-one percent (n=174) of follow-up patients reported having a BMD in the past 6 months; the majority of these patients (n=139) had not been previously diagnosed and/or treated for OP. Approximately 20% of follow-up patients reporting a previous diagnosis and/or treatment of OP at baseline and a BMD between baseline and follow-up, did not report OP or osteopenia on their BMD at follow-up. An OP screening program with education, facilitation of testing, and communication with family doctors was associated with an increased prevalence of OP testing and care when compared to baseline prevalence of OP care. Given the risk that fracture could be perceived as treatment failure, discontinuation of therapy was low (3%). However, we need to understand why some patients previously diagnosed or treated for OP did not report OP or osteopenia on their BMD at follow-up.

**Interventions to Improve Adherence and Persistence with Osteoporosis Medications: A Systematic Literature Review.** T. Gleeson<sup>\*</sup>, M. Iversen<sup>\*</sup>, D. H. Solomon. Brigham and Women's Hospital, Boston, MA, USA.

**BACKGROUND:** Adherence (% of time taking medication) and persistence (length of time from initiation to discontinuation of medication) with pharmacologic therapy for osteoporosis is poor. Prior studies have shown that adherence and persistence with osteoporosis medications decrease significantly within one year of initiation. With a rapidly growing aged population, there is strong impetus for the improvement of adherence and persistence with osteoporosis medications.

**METHODS:** A literature search of English language articles between 1990 and March 2008 was conducted using PubMed, EMBASE, CINAHL, and Cochrane Reviews. Search terms included: osteoporosis, adherence, persistence, compliance, treatment refusal, medication, and intervention. We selected papers according to the following criteria: 1) the study was an intervention to improve adherence/persistence with osteoporosis medication and 2) statistical results of adherence and/or persistence were reported for observational and intervention cohorts. Two reviewers independently reviewed the publications using a structured data abstraction form.

**RESULTS:** We found over 300 articles and reviewed their abstracts. Four articles met the inclusion criteria. These four studies are summarized in the table below. Two interventions provided patient education and counseling. One RCT (Guilera) reported a negative result. One NRHCT (Cook) reported significantly better adherence in the intervention cohort. The remaining two interventions utilized measurements of bone turnover markers (BTMs) to provide feedback to patients based on their response to therapy. One RCT (Clowes) had two intervention arms. Arm A (attention) showed statistically significant improvement in adherence over the observational cohort (no attention), whereas Arm B (attention and BTMs feedback) did not. The other RCT (Delmas) reported no significant difference in persistence between patients receiving BTMs feedback versus controls who did not receive such feedback.

**CONCLUSION:** Despite strong evidence of poor adherence and persistence with osteoporosis medications, few high quality interventions have been conducted. While some interventions produced encouraging findings, there is a need for new intervention types and rigorously controlled randomized trials to establish best practice for improving adherence and persistence with osteoporosis medications.

**The Relative Contributions of Nonvertebral Efficacy, Vertebral Efficacy, and Persistence in Determining Cost-Effectiveness: The Case of Osteoporosis and Implications for Payers.** C. M. L. Kelton<sup>\*1</sup>, M. K. Pasquale<sup>\*2</sup>. <sup>1</sup>College of Business, University of Cincinnati, Cincinnati, OH, USA, <sup>2</sup>Epidemiology & Pharmacoeconomics, Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The cost-effectiveness literature on bisphosphonates to date has focused on the importance of improved persistence without placing its impact in the context of efficacy. The objective of this research was to determine the effects of persistence (the proportion of individuals who persist on treatment), vertebral efficacy, and nonvertebral efficacy, on incremental cost-effectiveness ratios (ICERs) for osteoporosis in order to enhance the payer's ability to evaluate the tradeoff between efficacy and persistence among competing treatments. We developed an ICER relative to Vitamin D plus calcium for postmenopausal osteoporotic women with BMD T-score  $\leq$  -2.5, completing one year of bisphosphonate treatment, and determined the relative contributions to the ICER of its inputs using a mathematical approach involving partial derivatives. Model inputs from the osteoporosis literature included fracture incidence rates for two age groups, 55-59 and 75-79, drug costs, and fracture treatment costs. Efficacy values were taken from randomized clinical trials. Outcomes were a series of effects of 1 percentage point changes in nonvertebral efficacy, vertebral efficacy, and persistence values on the ICER. The effects on the ICER of a 1 percentage point change in vertebral efficacy were 2.60 and 2.24 times the effect of a 1 percentage point change in persistence for the younger and older age groups, respectively; nonvertebral efficacy had 4.95 and 5.51 times the effect of persistence for the two groups,

respectively. As shown in Figure 1, these ratios are inversely related to the level of efficacy; however, even at 80 percent efficacy, the importance to the ICER of an increase in efficacy exceeds that of an increase in persistence. These results hold generally over a 3-year time period; for different discontinuation patterns; using cost-utility analysis; and in a generic-drug cost environment. In evaluating claims regarding enhanced persistence, formulary decision-makers need to exercise caution to ensure that efficacy, particularly nonvertebral efficacy, is not compromised.

**Preference and Satisfaction with a 6-Monthly Subcutaneous Injection Versus a Weekly Tablet for Treatment of Low Bone Mass.** D. T. Gold, R. Horne\*, J. Borenstein\*, S. Varon\*, D. Macarios\*. Amgen Inc., Thousand Oaks, CA, USA.

Preference and satisfaction are important for maintaining compliance and persistence with chronic therapies for treating bone loss. We compared subject preference and satisfaction between two bone loss agents: a subcutaneous (SC) injection of an investigational product (denosumab) administered every 6 months (Q6M) with an oral tablet (alendronate) taken weekly.

Preference and satisfaction were assessed as part of the ongoing development of a new questionnaire in a phase 3 international, randomized, double-blind, double-dummy, active-controlled study. Healthy postmenopausal women, T-score  $\leq -2.0$  (total hip or spine) were randomized 1:1 to receive: denosumab injection (SC, 60 mg Q6M) + placebo tablet (oral weekly) or placebo injection (SC Q6M) + oral alendronate (70 mg weekly). After 12 months of treatment, subjects were asked to complete a 34-item questionnaire to rate their preference for and satisfaction with each agent. Preference and satisfaction were assessed based on single items and were pre-specified endpoints. Subjects were asked to choose either: the pill, the injection, or neither, for preference ("Which do you prefer?") and satisfaction (With which frequency of administration have you been more satisfied?).

In total, 1189 subjects (594 denosumab; 595 alendronate) with a mean age of 64.4 yrs enrolled. 1100 (92.5%) subjects completed the questionnaire. Some subjects in each group did not report a preference (alendronate = 101; denosumab = 96) or satisfaction (alendronate = 123; denosumab = 125). Among those who reported a preference/satisfaction, more subjects preferred and were more satisfied with the Q6M injection over the weekly tablet (Table). Similar proportions of subjects in the alendronate group or denosumab group preferred or were more satisfied with the Q6M injection compared with the weekly tablet.

As reported by others,<sup>1,2</sup> subjects in this study preferred and were more satisfied with a therapeutic agent that was dosed less frequently. Preference for and greater satisfaction with the frequency of a subcutaneous injection given Q6M compared with current weekly oral agents for the treatment of bone loss in postmenopausal women may be an important factor in helping improve compliance and persistence with therapy.

**Patient Refill Behavior among Select Daily, Weekly, Monthly, and Annual Dosing Regimens.** D. Gold<sup>1</sup>, N. Borisov<sup>2</sup>, W. Safi<sup>2</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Patient refill behavior follows the same trend across many different therapeutic classes suggesting many factors influence the refill trend. Less frequent dosing regimens have been introduced to impact this trend. This study explored patient refill trend among daily, weekly, monthly regimens of bisphosphonate therapy and explored annual dosing proxy using two integrated administrative medical claims databases (Ingenix Lab/Rx<sup>TM</sup> and Medstat MarketScan<sup>®</sup>).

The study included women 50+ years with a new prescription fill for either daily (risedronate 5mg, alendronate 5/10 mg), weekly (risedronate 35mg, alendronate 35/70 mg), or monthly (ibandronate 150 mg) treatment between July 1, 2000 and December 31, 2005. Data for the annual osteoporosis treatment (zoledronate 5mg/100 ml) were not available in the databases at the time of the study; thus, we used annual flu shot data as a proxy for the annual treatment regimen. Discontinuation was defined as either a gap between refills longer than a predefined number of days, switching between regimens, disenrollment from a plan, or end of database. Women were followed up to 6 continuous prescriptions of each treatment to measure proportion of patients refilling each script. Effect of various length of the allowable gap between prescriptions on the refill pattern was examined.

We identified 26,228 (6%) women who initiated daily, 404,149 (89%) women initiated weekly, and 24,854 (5%) initiated monthly bisphosphonate therapy. There were 2,534,860 patients who had a first flu shot during the study period. Varying the length of the gap between scripts from 15 to 90 days increased proportion of women who refilled the second script from 10 to 12 points among regimens. Figure 1 shows refill patterns using 45-day refill gap. Women who discontinued after 2 scripts had significantly less concomitant medications, specialist visits, hospitalizations, and fractures compared to women who filled all 6 scripts of either daily or monthly therapy. No difference between these groups was observed among women on monthly therapy. In this study, dosing regimens exhibited similar refill patterns among women 50+ years. Refill trend of weekly and monthly dosing regimens was observed to be nearly identical. The highest rate of discontinuation occurs within the first 3 to 4 script refills regardless of the dosing frequency.

Figure 1. Refill patterns using 45-day gap between refills

## M374

**The Impact of Dosing Frequency in Compliance with Bisphosphonates Among Postmenopausal Japanese Women for Osteoporosis Treatment.** Y. Nomura\*. Obstetrics and Gynecology, Yokohama City University, Yokohama, Japan.

[Object] Osteoporosis is an asymptomatic disease that increases fracture risk and results in considerable morbidity, mortality, and reduced quality of life. The main aim of osteoporosis management is to prevent the occurrence of fractures. To benefit, it appears that women must remain on therapy for an extended period. Bisphosphonate provides efficacious treatment for osteoporosis. However, side effects and dosing regimens often lead to patients discontinuing this treatment. Reducing oral Bisphosphonate dosing frequency is one measure available to increase therapy. This study compared compliance with weekly and daily Bisphosphonate regimens for postmenopausal osteoporosis.

[Method] Ninety postmenopausal Japanese women diagnosed with osteoporosis or osteopenia were enrolled in this study. These postmenopausal women (aged 66.2 years old) were asked some questions about their social background and treated with Alendronate 5mg/day and Alendronate 35mg/week, respectively. This study continued for 12 weeks after starting the given prescription. Explanations of anti resorptive therapy and study were done by professionals. Compliance was measured as a Medication possession ratio, defined as the proportion of days for which patients had prescription coverage prescription. [Results] The social background of the ninety postmenopausal Japanese women is different. 12(13.3%)patients live alone, 18(20%)patients have a job, 54(60%)patients have been taking other medicine. In their various lifestyles, weekly regimens had a higher compliance than those on daily regimens. Once-weekly dosing and daily dosing were well tolerated with a similar result. With regards to esophageal events, there were fewer upper GI and a trend toward a lower incidence in the once-weekly dosing compared to the daily dosing. After this, 78(87%)postmenopausal osteoporosis women want to prescribe a weekly Bisphosphonate dose. Dosing frequency was the strongest predictor of time to discontinuation.

[Conclusion] This study suggests that less frequent dosing intervals may provide an opportunity to further improve the consistent use of Bisphosphonate therapy. Without regard to any life style, dosing convenience is a key element to enhance compliance and long-term persistence with therapy.

**Correlates of Osteoporosis Treatment Persistence For Patients New to Therapy and Patients with Recent Switches: 6-Month Results from POSSIBLE US™.** A. N. A. Tosteson<sup>1</sup>, S. Wade<sup>\*2</sup>, M. Anthony<sup>3</sup>, C. Brancato<sup>\*4</sup>, S. Nichols<sup>\*4</sup>, R. W. Downs<sup>\*5</sup>. <sup>1</sup>Dartmouth Medical School, Hanover, NH, USA, <sup>2</sup>Wade Outcomes Research and Consulting, Salt Lake City, UT, USA, <sup>3</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>4</sup>REGISTRAT, Lexington, KY, USA, <sup>5</sup>Virginia Commonwealth University, Richmond, VA, USA.

Poor osteoporosis medication adherence has been associated with increased fracture incidence, yet few studies examine treatment persistence and its correlates in primary care settings. To study osteoporosis medication use, 134 US primary care physicians enrolled postmenopausal women in the Prospective Observational Scientific Study Investigating Bone Loss Experience (POSSIBLE US™). We report 6-month treatment persistence and related factors for 1217 women who (1) initiated pharmacologic therapy within 6 months of study entry and had no therapy in the prior 12 months (new), or (2) had transitioned between pharmacologic agents within 6 months of study entry (switch).

Physician and participant-reported study entry data on age, prior fracture, BMD, demographics, lifestyle/behaviors, medication class, medication side effects (none, mild, moderate, severe), treatment satisfaction using the Treatment Satisfaction Questionnaire for Medication (TSQM-efficacy, -convenience, -global subscales), and health status using EQ-5D and OPAQ were evaluated as correlates of treatment discontinuation using multiple logistic regression. We report odds ratios (OR) and 95% confidence intervals (CI) for factors related to 6-month treatment discontinuation.

At study entry, 825 women (68% of 1217) were new to pharmacologic therapy; 392 (32%) had recently switched. Most patients reported bisphosphonate use (new: 80%; switch: 73%). At entry, new and switch patients had similar health status, race, and education; however switch patients were older (67 y vs 64 y,  $p<0.001$ ) and more often had an osteoporosis diagnosis (56% vs 40%,  $p<0.001$ ). Follow-up (6-month) was available for 1106/1217 (91%). Overall, 84% (929/1106) continued the study entry agent at 6 months. Compared to those continuing therapy, discontinuers were older (67 y vs 65 y,  $p=0.019$ ), more likely to report severe side effects (29% vs 14%,  $p=0.003$ ) and have lower TSQM-convenience (70.0 vs 76.2,  $p<0.001$ ), -efficacy (60.9 vs 64.5,  $p=0.02$ ) and -global scores (58.3 vs 64.4,  $p<0.001$ ). In adjusted analyses, significant correlates [OR (95% CI)] of discontinuation at 6 months were age [1.02 (1.00, 1.04)], side effects [mild: 1.70 (1.02, 2.85); moderate: 2.12 (1.27, 3.54); severe: 4.68 (2.50, 8.78)], TSQM convenience [0.98 (0.97, 0.99)] and being new to therapy [1.75 (1.14, 2.71)]. In this 6-month period, age, side effects, perceived convenience and efficacy, and being new to therapy were related to early discontinuation.

## M376

**Medication Switching in Postmenopausal Women on Osteoporosis Therapy: Six-Month Findings from the POSSIBLE US™ Study.** T. Do<sup>\*1</sup>, S. Wade<sup>\*2</sup>, M. Anthony<sup>3</sup>, R. B. Wagman<sup>4</sup>, R. W. Downs<sup>\*5</sup>. <sup>1</sup>Amgen Inc., Seattle, WA, USA, <sup>2</sup>Wade Outcomes Research and Consulting, Salt Lake City, UT, USA, <sup>3</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>4</sup>Amgen Inc. and Stanford University School of Medicine, San Francisco and Stanford, CA, USA, <sup>5</sup>Virginia Commonwealth University, Richmond, VA, USA.

Although research is accumulating on medication adherence in osteoporosis (OP) little is known about the occurrence and causes of medication switching.

The Prospective Observational Scientific Study Investigating Bone Loss Experience (POSSIBLE US™) follows 4994 postmenopausal US women on OP therapies for up to 3 years, with self-administered questionnaires every 6 months. From October 2005 to January 2007, 134 primary care physicians enrolled women with varying therapy history. Analysis cohorts were created for new (initiating pharmacologic therapy in last 6 months, no therapy prior 12 months), stable (at least 6 months on same pharmacologic regimen), switch (transitioned between pharmacologic agents within 6 months), augment (added a pharmacologic agent to existing regimen), or calcium/vitamin D use only. We examined the first patient-reported switch (discontinuation of agent used at entry then initiation of new agent) between study entry and first follow-up assessment (approximately 6-month), reasons for switching, and patient characteristics associated with switching.

Nearly 70% (n=3414) of patients reported OP therapy use at study entry and had follow-up data at 6 months. Most (n=1877) patients reported bisphosphonate (BP) use at entry. Three percent (n=102) of the cohort reported at least 1 switch. BP users comprised 81% of switchers and 64% (n=65) of switchers switched within the drug class reported at entry. Among BP switchers, patient-reported side effects were the most common reason for switching (40%). Women entering POSSIBLE US™ as new, switch or augment patients were somewhat more likely to switch than women on stable therapy. After adjusting for age, race, education, fracture history, report of severe side effects and number of comorbidities, the increased risk of switching persisted only for new patients (Table).

Side effects and recent therapy initiation were associated with a higher likelihood of medication switching, even during a short time window. The longitudinal data accumulating from POSSIBLE US™ will be used to further test these associations.

**Table. Hazard Ratios for Switching Pharmacologic Agents Between Study Entry and A1\***

	Unadjusted HR (95% CI)	Adjusted HR (95% CI)**
Status at study entry		
	3414 women	3331 women
	102 switchers	102 switchers
	1830.0 person-years	1783.9 person-years
Stable	1.0	1.0
New	1.66 (1.06, 2.60)	1.68 (1.07, 2.64)
Augment	2.40 (1.07, 5.39)	2.26 (1.00, 5.09)
Switch	1.37 (0.74, 2.53)	1.37 (0.74, 2.55)
Calcium/ Vitamin D	0.32 (0.11, 0.90)	0.31 (0.11, 0.89)

\*Stable patients are referent group. \*\*Adjusted for differences in age, race, education, fracture history, comorbidity, patient report of severe side effects.

**Osteoporosis Therapy following Bone Densitometry - Patient Expectations as Determinants of Drug Initiation and Persistence.** D. Brask-Rasmussen<sup>\*1</sup>, S. M. Cadarette<sup>\*2</sup>, P. Eskildsen<sup>\*1</sup>, B. Abrahamsen<sup>3</sup>. <sup>1</sup>Department of Endocrinology, Køge University Hospital, Køge, Denmark, <sup>2</sup>Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, <sup>3</sup>Department of Endocrinology, Copenhagen University Hospital, Gentofte, Denmark.

Persistence with osteoporosis therapy has been disappointingly low in the past, possibly related to poor patient perception of treatment benefits.

We assessed health beliefs among patients with osteoporosis in relation to initiation of and persistence with bisphosphonate treatment.

A mailed questionnaire was sent to 1000 consecutive patients, who had been referred to DXA-scanning in a Danish osteoporosis clinic one year earlier, to assess osteoporosis treatment, persistence and beliefs. Patients and GPs had received written information on diagnosis and treatment recommendations shortly after the DXA-exam. Of the 1000 patients, 717 responded to the questionnaire (72%).

Initiation of OT had been recommended to 146 patients with osteoporosis. Of these 83% began treatment, hereof 90% with a bisphosphonate. The self-reported persistence with bisphosphonate one year after DXA assessment was 86%.

The likelihood of initiating a recommended treatment was assessed by multivariate logistic regression demonstrating significant association with beliefs in treatment benefits (OR 1.6, 95% CI 1.2-2.2,  $p<0.01$ ) but not with treatment barrier beliefs, sex or age of the patient. No significant association with persistence and beliefs, sex or age could be established for discontinuation of treatment. Side effects were reported as the main reason for discontinuing treatment.

While the encouragingly low rate of discontinuation among respondents limited the information available on factors associated with persistence, the study suggest that initiation of bisphosphonate treatment is linked to patient perception of drug benefits. This highlights the need to improve communicative strategies, perhaps especially related to conveying the message of anti-fracture efficacy

## M378

**Predictors of Self-Reported Non-persistence with Oral Bisphosphonates Due to Perceived Side Effects or Other Reasons.** J. T. Schousboe, B. Dowd\*, M. Davison\*, P. Johnson\*, R. L. Kane\*. Univ of Minn, Minneapolis, MN, USA.

**Background:** Non-persistence with drug therapy to prevent fractures remains a major obstacle to reducing the population burden of osteoporotic fractures. Our objective was to estimate the association of attitudes to medication, the patient-perceived quality of the MD-patient relationship, medication use self-efficacy, and other predictors to self-reported non-persistence due to side effects or other reasons.

**Methods:** 1179 patients prescribed an oral bisphosphonate between 1/1/2006 & 3/31/2007 were mailed a survey to assess medication adherence and attitudes toward osteoporosis and medication to reduce fractures. 729 (63%) returned the survey and had complete data. Perceived medication need, concerns about dependence upon and long-term safety of medication, medication use self-efficacy, and medication cost concerns were assessed by Likert scales. Number of adverse drug reactions (ADRs), bone density, and use of proton pump inhibitors (PPI) (a marker of gastric acidity disorder) were extracted from the medical record. The associations of these predictors with non-persistence were assessed with logistic regression models.

**Results:** Self-reported non-persistence due to side effects were associated with perceived medication need (odds ratio (OR [95% C.I.]) of 0.20 [0.10-0.41] for the top vs bottom quartile), medication concerns (OR 1.41 [1.05-1.89] per unit increase), PPI use (OR 1.63 [1.06-2.52]),  $\geq 2$  ADRs (OR 3.24 [1.84-5.69] vs no ADRs). Non-persistence for reasons other than side effects were associated with perceived medication need (OR 0.24 [0.12-0.49] for top vs bottom quartile), with poor medication use self-efficacy (OR 1.74 [1.13-2.70] vs excellent self-efficacy) and with very high medication cost concerns (OR of 4.85 [1.96-12.0] vs no cost concerns). MD-patient relationship quality was not associated directly with non-persistence, adjusting for all of these other predictors.

**Conclusion:** Patients are less likely to stop taking medications due to side effects if they feel they need fracture prevention medication to preserve their health, do not have concerns about long-term safety or dependence on medications, have not had other adverse drug reactions, and are not on a PPI. Patients are less likely to discontinue oral bisphosphonates for reasons other than side effects if they have confidence they can execute medication use in their daily lives (medication self-efficacy), do not feel burdened by their out of pocket medication costs, and perceive need for fracture prevention therapy. These results are strongly consistent with most non-persistence with bisphosphonate medication being the result of deliberate discrete choices.

## M379

**Attitudes to Fracture Prevention in Long-term Care Facilities: A Multi-centre Study Examining the Opinions of Nursing Home Staff.** A. M. Sawka<sup>1</sup>, M. Nixon<sup>2</sup>, L. Giangregorio<sup>3</sup>, L. Thabane<sup>4</sup>, J. D. Adachi<sup>2</sup>, A. Gafni<sup>4</sup>, P. Raina<sup>4</sup>, A. Papaioannou<sup>2</sup>. <sup>1</sup>Medicine, University Health Network and University of Toronto, Toronto, ON, Canada, <sup>2</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>3</sup>Kinesiology, University of Waterloo, Waterloo, ON, Canada, <sup>4</sup>Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada.

**Objectives:** In this secondary analysis, our objective was define attitudes of staff in long-term care facilities to strategies for prevention of hip fracture in residents.

**Design, Setting, and Participants:** We conducted a cross-sectional study that collected data using a self-administered, written questionnaire. We collected data from 160 staff in five nursing homes in the region of Hamilton, Ontario, Canada. For questions on opinions on fracture prevention strategies, questions were framed on a seven point Likert scale (1=strongly disagree, 7=strongly agree), with a check box for "don't know" responses.

**Results:** The most common job descriptions of respondents were: health care aide 56.9% (91/160) and registered or practical nursing 26.9% (43/160). Approximately a third of respondents were 50 years or older in age (52/160). Responses were mixed to a question asking if we are currently doing enough to prevent fractures in long-term care facilities, mean 4.4 on a seven point Likert scale with a standard deviation (SD) 1.8. Approximately sixty-one percent of respondents (97/160) indicated that they did not know if bisphosphonates decrease the risk of hip fracture. More than half of respondents indicated that they did not know if hip protectors decrease the risk of hip fracture (86/160, 54%). For statements suggesting that it is important to provide fracture-prevention interventions to all long-term care facility residents, the respondents scores according to intervention, were as follows: calcium supplements 5.4 (SD 1.6) (n=141 agreement responses), vitamin D supplements 5.4 (SD 1.6) (n=124), hip protectors 4.3 (SD 2.1) (n=114).

**Conclusions:** Knowledge translation strategies should be developed to improve the awareness of staff working in long-term care facilities on effective fracture prevention strategies for elderly residents, in an effort to improve uptake and adherence of such strategies.

**Strategies for Hip Fracture Prevention in Long-term Care Facilities: A Survey of Canadian Geriatricians and Family Physicians.** A. M. Sawka<sup>1</sup>, L. Thabane<sup>2</sup>, J. D. Adachi<sup>3</sup>, A. Gafni<sup>4</sup>, P. Raina<sup>4</sup>, S. Straus<sup>5</sup>, A. Papaioannou<sup>3</sup>.

<sup>1</sup>Medicine, University Health Network and University of Toronto, Toronto, ON, Canada, <sup>2</sup>Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada, <sup>3</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>4</sup>Clinical Epidemiology, McMaster University, Hamilton, ON, Canada, <sup>5</sup>Medicine, University of Calgary and University of Toronto, Toronto, ON, Canada.

**Objectives:** Our primary objective is to identify strategies that Canadian physicians with expertise elder- or long-term care recommend for decreasing the risk of hip fracture in elderly in elderly nursing home residents. A secondary objective is to identify the barriers associated with the implementation of various strategies for prevention of hip fracture in elderly nursing home residents.

**Design, Setting, and Participants:** We are currently conducting a cross-sectional study, collecting data using a self-administered, written questionnaire. The written questionnaire was mailed on April 1, 2008 to more than two hundred Canadian Geriatricians in active practice as well as Ontario Family Physicians belonging to the Ontario Long-term Care Association. A case-based approach in a self-administered written questionnaire is being utilized. Anti-fracture strategies being examined include: calcium, vitamin D, other vitamin therapies, pharmacologic osteoporosis therapies, hormonal therapies, hip protectors, physical therapy, and environmental modification. The nature of barriers to implementation of such strategies in the long-term care setting will be identified.

**Results:** The final results of the survey will be presented. We hypothesize that strategies such as provision of hip protectors, bisphosphonates, vitamin D, or environmental modification may be recommended in decreasing the risk of hip fracture in elderly nursing home residents. We suspect that barriers to use of pharmacologic therapies will include side effect profiles of medications, poor compliance with proper administration of strategies, prescribing contra-indications and expense. We suspect that compliance may be a barrier for use of devices such as hip protectors.

**Disclosures:** A.M. Sawka, None.

**Medication Prescription and Adherence after Hospitalization for Osteoporotic Vertebral Fracture.** H. Leydet-Quilici, M. Luc\*, Y. Grandgeorge\*, T. Pham\*, P. Lafforgue\*. Hopital la Conception, Marseille, France.

Several studies have demonstrated the lack of secondary prevention of osteoporotic non vertebral fractures, but treatment prevention of osteoporotic vertebral fractures (VF) is little assessed. Our study goal was to assess treatment prescription when patients got out from the hospital and medication adherence at least one year after.

We studied patients hospitalized between 2005 and 2006 for osteoporotic sacral or VF, in a Rheumatology Department in a tertiary referral hospital. From Sept. to Dec. 2007, all patients were interviewed, following a standardized questionnaire on treatment adherence. Patients dead, unreachable, or who wished not to answer were excluded from the analysis. Non-adherence was defined as absence of any ongoing antiosteoporosis treatment (i.e. calcium, calcitriol, raloxifen, oral or i.v. bisphosphonates, strontium or teriperatide) at the survey time. Patients were adherent if they were still carrying on an active treatment, even if this treatment was not the one prescribed during hospitalization. Calcium and calcitriol were assessed separately from the other treatments.

On 63 screened patients, 43 were analyzed : women 86%; mean age 77 years. 86% experienced previous insufficiency fractures and only 42% were previously treated for osteoporosis. All patients received a specific anti-osteoporotic treatment and 97% calcitriol and calcium prescription at the hospital leaving time. The mean time between prescription and survey was 16.7 months. Adherence was 69.8% for calcitriol and calcium and 86% for anti-osteoporotic specific treatment. The main treatment giving up reason was a GP care instead of a rheumatologist care (p=0.01). Daily treatment (calcium and calcitriol), maybe considered as compeller, had lesser observance and adherence.

Our study showed higher prescription and adherence levels compared to those usually reported. The main reasons are : the context (symptomatic VF requiring an hospitalization versus asymptomatic VF), the situation (tertiary referral hospital) and a rheumatologist care for nearly 50% of patients. These results can not be extrapolated to all prevalent osteoporotic VF.

## M382

**The Influence of Bone Osteoporotic Fractures in the Past on the Persistence of Pharmacological Treatment in Osteoporosis. Pomost study.** J. Przedlaci, K. Ksiopolska-Orowska\*, A. Grodzki\*, T. Bartuszek\*, D. Bartuszek\*, A. Swirski\*, J. Musia\*, E. Luczak\*, E. Loth\*, P. Teter\*, A. Lasiewicki\*, A. Walkiewicz\*, I. Drozdowska-Rusinowicz\*. National Center of Osteoporosis, Warsaw, Poland.

The purpose of the study was to evaluate the influence of the past bone osteoporotic fracture on the persistence of pharmacological treatment in osteoporosis. The study, as a part of POMOST study (evaluation of different aspects of medical procedures in osteoporosis) was done in KCO with participation of 188 patients who signed informed consent (28 men and 160 women, aged 70.0±7.3 years). All patients were divided into 2 groups: 89 patients with the past bone osteoporotic fracture (spine, hip or/and forearm; no-one referred to KCO due to actual fracture) and 99 patients without fracture. Evaluation of the fracture risk, decision on the need of pharmacological treatment and the method of it, as well as the control visit after 3 months were done in KCO. Next, the follow up was done by specialists or GPs. The final evaluation of persistence of therapy after 12 months was planned in KCO. Persistence of treatment was evaluated on the basis of patients visit in KCO (after 3 and 12 months). Patients were treated with medicines of approved antifracture activity (mainly weekly oral bisphosphonates), vitamin D and calcium.

After 12 months 84 patients (68.3% of 123 patients who in accordance to visits schedule ought to finish the treatment, 58 with and 65 without fracture; NS) came to KCO. 31 patients continue the treatment (between 3. and 12. month). 50 patients (26.6% of all, 28 with and 22 without fracture; NS) stopped the treatment before 3 months. 17 patients (9.0% of all; 10 with and 7 without fracture; NS) stopped the treatment after 3. month. Adverse events were the primary reason of discontinuation of therapy in all groups. We called patients who did not visit our center after expected 12 months of treatment. Nine patients out of 14 who were reached by phone (4 with and 5 without past fracture) were still interested in the therapy and were referred to KCO once more. Next 3 consider it. The lack of easy contact with specialists and the lack of stimulation by their GPs to continue the treatment in the case of adverse events was important reason in patients opinion of discontinuation of therapy.

We conclude that, contrary to our expectations, there was not difference in persistence of pharmacological treatment in osteoporosis between patients with and without past bone osteoporotic fracture. Incidents of fractures in past, sometimes several years ago did not motivate patients to treatment. Closer contact with doctors (specialist or GPs) and referral to specialist center just after bone osteoporotic fracture could have stronger impact on persistence of the treatment.

**Disclosures:** J. Przedlaci, None.

## M383

**Ambiguity about Osteoporosis and Osteoporosis Care Exists Despite a Screening Program to Educate Fracture Patients.** J. E. M. Sale\*, D. E. Beaton, R. Sujic\*, E. R. Bogoch. Mobility Program Clinical Research Unit, Keenan Research Centre, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada.

Behaviour change models suggest that people need to have clear information about their susceptibility to disease and treatment recommendations before they will successfully change their behaviour. We conducted a qualitative study to examine fracture patients' understanding of osteoporosis (OP) and OP care after being screened for OP in an urban hospital fracture clinic. English-speaking patients who were screened for OP through the fracture clinic in the previous 3-9 months and did not demonstrate any physical or cognitive impairments that would prevent them from participating were eligible. Forty-seven patients were identified by one of two screening coordinators and 24 (18 females, 6 males) aged 47-80 years old agreed to participate in 1 of 5 focus groups. During the focus groups, participants were asked about their awareness of OP and status of BMD testing and OP treatment. Twenty participants vocalized at least one expression of ambiguity regarding OP and/or treatment recommendations conveyed by the screening program staff. Participants were ambiguous about the cause of their fracture, the BMD test process and results, and the presentation of OP. They were also ambiguous about the amount and type of medication and supplements recommended. Despite a standardized screening program in which OP was addressed in fragility fracture patients, ambiguity about diagnosis, testing, and treatment were described. Efforts to clarify information relayed to fracture patients about their condition and recommended care need to extend beyond the fracture clinic so that health care providers can promote long-term adherence to these recommendations.

## M384

**Adherence in Patients with Severe Osteoporosis Treated with Teriparatide.** V. Ziller\*, S. Zimmermann\*, P. Hadji. University Hospital Giessen and Marburg, Marburg, Germany.

Introduction: Medical interventions play a key role in the treatment of severe postmenopausal osteoporosis but patients adherence to medical therapy is essential for optimal clinical outcomes. While adherence in RCT's is usually around 70-90% we were

able to show that in clinical routine 12 months after therapy initiation only 27.8% and 46.5% of the women on oral daily vs. weekly Alendronate were still on treatment. Data on adherence with treatment of severe postmenopausal osteoporosis with subcutaneous Teriparatide (TPT) in daily clinical routine have not been published. The aim of the present analysis was to investigate adherence with TPT in women visiting our out-patient clinic.

**Material and Methods:** We investigated a sample of 50 postmenopausal women with severe postmenopausal osteoporosis on TPT in accordance to the German guidelines. Treatment was initiated at least 12-24 months before recruitment. We combined patient self report using a validated questionnaire and the medication possession ratio (MPR). To calculate MPR we performed a prescription control including all doctors who were treating the patients for any disease. Finally patients were classified adherent if self-reported adherence and a MPR of  $\geq 80\%$  was achieved.

**Results:** There were no significant differences in baseline demographics, except for age at menopause which was significantly lower in the compliant group (46.1 vs. 50.0;  $p<0.006$ ). Our results comprised that 80% of the patients treated with TPT in our clinic were compliant, while 20% were noncompliant after 12 months. A significant correlation to treatment adherence was found only for self-reported medication toleration ( $p<0.001$ ).

**Discussion:** In the past numerous studies have underlined, especially for Bisphosphonates, that an optimal compliance was necessary to ensure the therapeutic treatment effect. Concerning oral long-term treatment in postmenopausal Osteoporosis our results indicate that compliance with TPT seems to be higher than expected. Further prospective studies are needed to investigate possible factors influencing treatment adherence.

**Safety and Effectiveness Profile of Raloxifene in Long-term Prospective Observational Study; Interim Analysis.** A. Miyauchi<sup>1</sup>, E. Hamaya<sup>1</sup>, D. Tsuzuki<sup>1</sup>, H. Kishimoto<sup>1</sup>, F. Yoshiki<sup>1</sup>, H. Okada<sup>1</sup>, H. Kobayashi<sup>2</sup>, S. Yokoyama<sup>2</sup>, A. Tanaka<sup>2</sup>, H. Tara<sup>1</sup>. <sup>1</sup>Eli Lilly Japan K.K., Kobe, Japan, <sup>2</sup>Chugai Pharmaceutical Co., LTD., Tokyo, Japan.

Raloxifene (RLX) is the first launched selective estrogen receptor modulator (SERM) for the treatment of osteoporosis in Japan. This large scale post marketing surveillance of RLX was designed to assess the safety of RLX in Japanese postmenopausal osteoporosis patients in long term practical use (three years). The present interim analysis was conducted using data from 6846 patients (mean age: 70.5 years) completed for 6 months and up to 12 months survey after treatment with open-label RLX therapy. The persistence of RLX administration at 180 days after treatment was 72.9%. Overall RLX was well tolerated and exhibited a favorable safety profile. A total of 664 adverse drug reactions (ADRs) out of 561 patients (8.14%) were reported. Most frequently observed ADR was gastrointestinal disorder (201 events) including stomach discomfort. One serious and 6 non-serious events of venous thromboembolism (VTE) (total 7 cases 0.10%) were reported. All 6 cases with known outcomes have recovered. Regarding efficacy, lumbar spine bone mineral density (BMD) increased significantly ( $p<0.05$ , paired t-test) compared with baseline both at 6 (2.6%) and 12 months (2.8%), comparable to the result of the Japan registration trial (Morii H et al. (2003) Osteoporosis Int 14:793-800). Significant decreases in serum and urinary type I collagen N-terminal telopeptide (NTX), urinary deoxypyridinoline (DPD) levels from baseline were observed as early as 3 months, followed by a significant decrease of serum bone specific alkaline phosphatase (BAP) at 6 months ( $p<0.01$  for all comparisons, signed rank test), indicating typical pattern of bone marker changes by antiresorptive therapy. The incidence of any new clinical fractures within 1 year (mean administration period 274 days) was 0.4% (29 cases), possibly supporting the result from a post hoc analysis used pooled data of Japan and China registration trials (Nakamura T et al. (2006) J Bone Miner Metab 24:414-418).

In summary, from this interim analysis of a prospective large scale post marketing surveillance, no new signal in safety was observed in the daily use of RLX and the VTE observation suggests a lower incidence in Japanese than in Caucasian women. Moreover, RLX exhibited a stable antiresorptive action on bone turnover leading to BMD increases in real clinical settings.

## M386

**Effects of Arzoxifene on Bone Turnover and Safety in Postmenopausal Women with Low Bone Mass: Results from a 6-Month Phase 2 Study.** R. Downs<sup>1</sup>, A. H. Moffett<sup>2</sup>, A. Ghosh<sup>3</sup>, D. A. Cox<sup>4</sup>, K. Harper<sup>4</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, VA, USA, <sup>2</sup>OB-GYN Associates of Mid-Florida, PA, Leesburg, FL, USA, <sup>3</sup>Johnson and Johnson PRD, Raritan, NJ, USA, <sup>4</sup>Eli Lilly & Company, Indianapolis, IN, USA.

Preclinical studies suggest that arzoxifene (ARZ), a benzothioephene selective estrogen receptor modulator (SERM), has an improved bone efficacy and a similar endometrial safety profile to raloxifene (RLX) 60 mg/d. This 6-month, phase 2, multicenter, randomized, double-blind, placebo (PBO)- and active-controlled (RLX) study was designed to assess the effects of various doses of ARZ on bone turnover markers and overall safety in postmenopausal women with low bone mass.

Healthy postmenopausal women (N=219; mean age, 59 yrs) with a lumbar spine or femoral neck T-score between -1 and -2.5 were randomly assigned to ARZ 5 (N=34), 10 (N=33), 20 (N=34), or 40 mg (N=40), RLX 60 mg (N=37), or PBO (N=41). All women received daily oral calcium (400-600 mg). The primary endpoints were 6-month percent change in osteocalcin and overall safety; the primary analysis was ARZ compared with

PBO. Secondary endpoints included other bone turnover markers, BMD as an exploratory endpoint, and hot flush occurrence (assessed by electronic diary). Endometrial safety was assessed by transvaginal ultrasound and endometrial biopsy.

Baseline characteristics were similar across treatment groups. All ARZ doses significantly reduced osteocalcin levels vs PBO. At 6 months, median % changes in serum osteocalcin were -24%, -30%, -45%, -39%, -45%, and -44% in the PBO, RLX, and ARZ 5, 10, 20, and 40 mg groups, respectively. Compared with PBO, ARZ also significantly reduced serum bone specific alkaline phosphatase, CTX, and PINP at 6 months. The 6-month change in lumbar spine (LS) BMD was significantly greater with all ARZ doses vs PBO: 1.50%, 1.69%, 1.77% and 1.92% in ARZ 5, 10, 20, and 40 mg, compared to a 0.60% decrease in PBO. ARZ generally had greater effects on bone turnover and LS BMD than RLX at 6 months.

The proportion of women reporting  $\geq 1$  adverse event (AE) did not differ significantly among treatment groups. Muscle cramps were reported more frequently with ARZ vs PBO, with a similar frequency to RLX (pooled ARZ 7.1%, RLX 5.4%, PBO 0%). The frequency and severity of hot flushes did not differ significantly between ARZ and PBO, except for an increase in the ARZ 5 mg group by some measures. Change in endometrial thickness was not statistically significant for any ARZ group compared with PBO or RLX, and no cases of endometrial hyperplasia or adenocarcinoma were observed.

In postmenopausal women with low bone mass, all doses of ARZ were well tolerated, suppressed bone turnover and increased LS BMD. Within the limitations of this small Phase 2 study, the endometrial safety profile of ARZ was similar to RLX.

## M387

**Assessment of Adherence to Treatment of Osteoporosis with Raloxifene and/or Alfacalcidol in Postmenopausal Japanese Women.** I. Gorai, Y. Tanaka\*, S. Hattisutari\*. Obstetrics and Gynecology, International University of Health and Welfare Atami Hospital, Atami, Japan.

Patients who are diagnosed and beginning treatment often do not persist with their osteoporosis medication relatively early after the start of the treatment because of their poor recognition of fracture risk and asymptomatic nature of osteoporosis. We have already reported that a more bone-sparing effect could be expected when estrogen was administered concomitantly with alfacalcidol rather than when used alone in postmenopausal Japanese women with osteoporosis or osteopenia. In this study we aimed to assess the adherence to the treatment of osteoporosis or osteopenia with 60mg raloxifene (R), 1µg alfacalcidol (D) or a combination of both (R+D) for 1 yr by defining precisely persistence and compliance in postmenopausal Japanese women. We defined persistence of R and D as continuing to take tablets for more than 7 of any 14 days immediately before the 1-yr visit. A total of 130 subjects aged 49 to 81 yrs (64.9±6.8 yrs, 18.8±13.3 YSM) were randomly assigned to each treatment group. There were significant increases in L-BMD (+3.3% in 6-mon and +5.0% in 1 yr,  $P<0.01$ ) in the combination-treated group and non-significant increases (+3.3% in 6-mon and +5.0% in 1 yr) in R-treated group. The increase of the R+D group at 1 yr was significant as compared with that in D-treated group (vs.+1.1%,  $P<0.05$ ). In D group one of seven subjects with adverse events (AE) was non-persistent with therapy whereas seven of seventeen subjects with AE discontinued therapy in R group. Six of thirteen subjects with AE stopped therapy in R+D group. In addition, four subjects discontinued therapy because of hypercalciuria in D group. The most common events reported were: climacteric symptoms including hot flash (n=4) and hypercalciuria (n=4). Of four subjects who had climacteric symptoms, two subjects were prescribed R alone and the other two were a combination of R and D. All the subjects who revealed hypercalciuria were treated with D alone. There were no significant differences in the number of subjects who discontinued treatment due to AE among each group. The proportions persisting with each treatment group at 1 yr were 62.8%, 67.6%, 56.7% for D, R and D+R groups, respectively whereas the compliance rates to each therapy were 97.7%, 96.6%, 97.4%, respectively. There were no significant differences in persistence and compliance among each group. In summary, the combination therapy was well tolerated compared with raloxifene or alfacalcidol alone.

**Replacing Testosterone in Male Cardiac Transplant Patients Exerts Multiple Benefits on Bone Mass, Libido and Sexual Activity: A 5-Year Prospective Study.** A. Fahrleitner-Pammer<sup>1</sup>, B. Obermayer-Pietsch<sup>1</sup>, M. Schweiger<sup>\*2</sup>, G. Prenner<sup>\*2</sup>, K. H. Tscheliessnigg<sup>\*2</sup>, J. C. Piswanger-Sölkner<sup>1</sup>, H. P. Dimai<sup>1</sup>, H. Dobnig<sup>1</sup>. <sup>1</sup>Endocrinology, Medical University, Graz, Austria, <sup>2</sup>Transplantation Surgery, Medical University, Graz, Austria.

**Background:** Hypogonadism is frequently encountered in cardiac transplant patients (CTX) with immunosuppressive treatment regimens and exerts negative effects on bone mass, libido and quality of sex life. Aim of the study was to investigate whether testosterone replacement therapy (TRT) of hypogonadal CTX recipients on top of intravenous bisphosphonate treatment confers positive effects on bone mass and quality of sex life compared to untreated hypogonadal and eugonadal CTX patients.

**Patients and Methods:** Parenteral ibandronate (2mg every 3 months) as well as 1200mg calcium and 880IU vitamin D3 was given to all patients. Fourteen out of 31 hypogonadal patients (45%) were treated with testosterone enanthate (250mg intramuscularly every 3-5 weeks).

**Results:** At baseline 77% of the hypogonadal patients admitted loss of libido (compared to 27% of eugonadal men,  $P=0.005$ ) and reported an average  $7\pm 6$  annual sexual activities (as

compared to  $15\pm 14$  of eugonadal men,  $P=0.005$ ). Hypogonadal men at baseline had also markedly lower Z-score values at the femoral neck (-1.54 vs. 0.15), and total hip (-1.34 vs. 0.01) (all  $P=0.0001$ ) as well as a higher percentage of prevalent vertebral fractures (63.3%; vs. 13.6%;  $P=0.0003$ ). After 1 and 5 years of treatment BMD had significantly increased in hypogonadal patients with TRT (neck 12.4 and 16.4%, total hip 9.2 and 12.4%, respectively, all  $P<0.001$ ) as compared to eugonadal patients (neck 2.9 and 3.4%, total hip 3.7 and 4.4%). A similarly low BMD increase was found in unreplaced hypogonadal patients (neck 2.3 and 3%, total hip 3.2 and 4.2%). Compared to baseline annual sexual activities had increased in patients with TRT after 1 year ( $29\pm 8$ ;  $p<0.0001$ ) and 5 years ( $25\pm 9$ ;  $p<0.0005$ ) and had remained unchanged in unreplaced hypogonadal ( $5\pm 4$  after 5 years) as well as eugonadal patients ( $16\pm 9$  and  $14\pm 8$ ). At 1 and 5 years the number of annual sexual activities in replaced hypogonadal patients was also higher when compared to eugonadal CTX patients.

**Conclusion:** Intravenous IBN therapy increases hip BMD in CTX patients on continuing immunosuppressive treatment. Hypogonadal patients clearly benefit from additional TRT over at least 5 years with respect to bone mass changes and a better quality of sex life.

## M389

**The Safety Profile of Bazedoxifene in Japanese Postmenopausal Women with Osteoporosis.** T. Sugimoto<sup>1</sup>, A. Itabashi<sup>2</sup>, H. Ohta<sup>3</sup>, H. Ochi<sup>\*4</sup>, A. A. Chines<sup>5</sup>, G. Constantine<sup>\*5</sup>. <sup>1</sup>Shimane University Faculty of Medicine, Shimane, Japan, <sup>2</sup>Saitama Center for Bone Research, Saitama, Japan, <sup>3</sup>Tokyo Women's Medical University, Tokyo, Japan, <sup>4</sup>Wyeth Research, Tokyo, Japan, <sup>5</sup>Wyeth Research, Collegeville, PA, USA.

Bazedoxifene (BZA) is a novel selective estrogen receptor modulator that has demonstrated bone-sparing effects without endometrial or breast stimulation in postmenopausal women. Here we report safety findings from a randomized, double-blind, phase 2 study that evaluated the efficacy and safety of 2 doses of BZA compared with placebo in Japanese postmenopausal women with osteoporosis.

Japanese postmenopausal women (aged  $\leq 85$  years) with osteoporosis were randomly assigned to treatment with BZA 20 or 40 mg or placebo (PBO) once daily for 2 years. All subjects received a daily supplement containing elemental calcium (610 mg), vitamin D<sub>3</sub> (400 IU), and magnesium (30 mg). Safety and tolerability assessments included adverse event (AE) reporting, physical and gynecologic examinations (including pelvic and breast), and transvaginal ultrasonography (TVU).

A total of 423 subjects (mean age, 63.7 years) receiving  $\geq 1$  dose of the study drug were included in analyses of safety data. No deaths occurred during the study. Overall, the incidence of AEs and serious AEs with BZA 20 or 40 mg was not significantly different from that with PBO. There were no reports of myocardial infarction, coronary occlusion, or venous thromboembolic events in any treatment group. As shown in the table below, the incidence of selected cardiac/cerebrovascular and gynecologic/breast-related AEs was low and similarly distributed among BZA- and PBO-treated subjects. There were 2 reports of cerebral infarction (1 each with BZA 20 and 40 mg), which were found incidentally on brain imaging; however, they were not considered drug related by the investigator. The incidence of hot flushes and muscle spasm was low among all treatment groups, but higher in the BZA 20-mg group.

AE, n (%)	Incidence of Selected AEs		
	BZA 20 mg (n = 143)	BZA 40 mg (n = 140)	PBO (n = 140)
Angina pectoris	1 (0.7)	1 (0.7)	1 (0.7)
Cerebral infarction	1 (0.7)	1 (0.7)	0
Carotid artery thrombosis	0	1 (0.7)	0
Hot flushes	6 (4.2)	0	2 (1.4)
Muscle spasm	8 (5.6)	5 (3.6)	2 (1.4)
Endometrial hypertrophy	1 (0.7)	0	0
Ovarian cyst	1 (0.7)	0	0
Uterine polyp	1 (0.7)	0	0
Breast cancer	1 (0.7)	0	1 (0.7)
Breast pain	0	2 (1.4)	1 (0.7)

TVU results demonstrated no differences in the change from baseline in endometrial thickness among treatment groups. No major changes in ovarian volume were observed in any treatment group.

In conclusion, BZA 20 or 40 mg was well tolerated and demonstrated a favorable safety profile that was overall similar to that of PBO in Japanese postmenopausal women with osteoporosis.

**Efficacy of Bazedoxifene In Reducing the Incidence of Nonvertebral Fractures in Postmenopausal Osteoporotic Women at Higher Fracture Risk.** S. L. Silverman<sup>1</sup>, C. Christiansen<sup>2</sup>, H. K. Genant<sup>3</sup>, J. R. Zanchetta<sup>4</sup>, S. Vukicevic<sup>5</sup>, I. Valter<sup>6</sup>, T. J. de Villiers<sup>7</sup>, M. Ciesielska<sup>8</sup>, A. A. Chines<sup>8</sup>. <sup>1</sup>Cedars-Sinai Medical Center and UCLA, Los Angeles, CA, USA, <sup>2</sup>Center for Clinical and Basic Research (CCBR), Ballerup, Denmark, <sup>3</sup>UCSF, and Synarc Inc, San Francisco, CA, USA, <sup>4</sup>Univ. of El Salvador, Metabolic Research Institute, Buenos Aires, Argentina, <sup>5</sup>Univ. of Zagreb School of Medicine, Zagreb, Croatia, <sup>6</sup>CCBR, Tallinn, Estonia, <sup>7</sup>Panorama MediClinic and Univ. of Stellenbosch, Cape Town, South Africa, <sup>8</sup>Wyeth Research, Collegeville, PA, USA.

In a recent phase 3 trial, treatment with bazedoxifene for 3 years effectively reduced the risk of new vertebral fracture relative to placebo in postmenopausal women with osteoporosis. Here we report the results of post hoc analyses of nonvertebral fracture (NVF) incidence among women at higher risk for fracture in that study.

Generally healthy postmenopausal women (N = 7,492; mean age, 66.4 y) with osteoporosis were randomized to daily therapy with bazedoxifene 20 or 40 mg, raloxifene 60 mg, or placebo; all subjects received supplemental elemental calcium (1,000-1,200 mg/d) and vitamin D (400-800 IU/d). Kaplan-Meier estimates of the incidence of NVFs at 36 months were evaluated for the overall population and for subgroups of women at higher fracture risk, based on known skeletal risk factors (low femoral neck [FN] T-score and/or prevalent vertebral fracture).

The overall incidence of NVFs was similar among groups. In a subgroup of women at higher risk for fracture (FN T-score  $\leq -3.0$  and/or  $\geq 2$  mild vertebral fractures; n = 1,772), NVF rates were 4.9%, 6.5%, 8.4%, and 9.1% with bazedoxifene 20 and 40 mg, raloxifene 60 mg, and placebo, respectively. Bazedoxifene 20 mg significantly reduced NVF incidence relative to placebo and raloxifene 60 mg (50% and 44%, respectively;  $P < 0.05$ ); a similar reduction was observed when NVF data for bazedoxifene 20 and 40 mg were combined (40% relative to placebo;  $P = 0.03$ ). Conversely, there were no significant between-group differences in NVF rates in the lower-risk subgroup (n = 5,710). Further evaluation of NVF incidence in subjects with FN T-scores  $\leq -2.5$  or  $\leq -2.0$  and/or  $\geq 1$  moderate or  $\geq 2$  mild vertebral fractures showed a trend toward NVF risk reduction with bazedoxifene treatment, supporting the robustness of the results. The selection of subjects at higher fracture risk was also supported by Cox regression analyses indicating a significant treatment by risk category interaction with bazedoxifene 20 mg ( $P = 0.025$ ) and of borderline significance with bazedoxifene 20 and 40 mg combined ( $P = 0.052$ ).

In conclusion, treatment with bazedoxifene significantly reduced the risk of NVF in postmenopausal osteoporotic women at higher risk for fracture.

## M391

**A Double-blind, Placebo-controlled, Dose-response Study of Bazedoxifene in Japanese Postmenopausal Women with Osteoporosis.** A. Itabashi<sup>1</sup>, H. Ohta<sup>2</sup>, B. Ebende<sup>3</sup>, G. Constantine<sup>3</sup>, A. A. Chines<sup>3</sup>. <sup>1</sup>Saitama Center for Bone Research, Saitama, Japan, <sup>2</sup>Tokyo Women's Medical University, Tokyo, Japan, <sup>3</sup>Wyeth Research, Collegeville, PA, USA.

Bazedoxifene (BZA) is a novel selective estrogen receptor modulator under clinical development for the prevention and treatment of postmenopausal osteoporosis. This randomized, double-blind, placebo-controlled, dose-response phase 2 study evaluated the efficacy and safety of BZA in postmenopausal women with osteoporosis.

Japanese postmenopausal women (aged  $\leq 85$  y) with osteoporosis were randomized to treatment with daily oral doses of BZA 20 or 40 mg or placebo (PBO) for 2 years; all subjects were supplemented daily with elemental calcium (610 mg), vitamin D (400 IU), and magnesium (30 mg). The primary endpoint was the percent change from baseline in bone mineral density (BMD) at the lumbar spine (L1-L4) at 2 years. Secondary endpoints included BMD response at other skeletal sites, changes in serum bone marker levels, incidence of vertebral and nonvertebral fractures, and lipid parameters.

Of 429 subjects who were randomized to therapy, a total of 387 subjects (mean age, 63.5 y) were evaluable for primary efficacy analyses. At 2 years, the mean percent changes from baseline in lumbar spine BMD were significantly greater with BZA 20 and 40 mg (2.43% and 2.74%, respectively) than with PBO (-0.65%;  $P < 0.001$  for both). There was no difference in lumbar spine BMD response between BZA 20 and 40 mg. Treatment with BZA 20 and 40 mg was associated with increased lumbar spine BMD relative to baseline as early as 24 weeks ( $P < 0.001$  vs PBO), which was sustained through study end. Similarly, the mean percent changes in BMD of the total hip, femoral neck, and greater trochanter from baseline to 2 years were significantly greater with BZA 20 and 40 mg versus PBO ( $P < 0.001$  for all), with no differences between BZA 20 and 40 mg. Relative to PBO, treatment with BZA 20 and 40 mg conferred significantly greater reductions in levels of bone turnover markers (serum CTx, NTx, OC and urinary NTx) as early as 12 weeks ( $P < 0.05$  vs baseline for all), which were sustained through study end. The incidence of new vertebral fractures with BZA 20 and 40 mg and PBO was 3.8%, 2.4%, and 4.7%, respectively. The incidence of nonvertebral fractures was 3.8%, 2.4%, and 3.1% with BZA 20 and 40 mg and PBO, respectively. BZA 20 and 40 mg demonstrated significant decreases from baseline in total cholesterol ( $P < 0.001$ ) and LDL cholesterol ( $P < 0.05$ ). HDL cholesterol levels were increased from baseline with BZA 20 mg; no clear trend with BZA 40 mg or PBO was observed. In conclusion, BZA significantly improved BMD, reduced bone turnover, and had favorable effects on the lipid profile in Japanese postmenopausal women with osteoporosis.

**The Effects of Estrogen Therapy and Flucalcic Effervescent on the Bone Mineral Densities and Bone Metabolism of Surgical Menopause Women with Osteopenia.** H. Kim<sup>\*1</sup>, H. Choi<sup>\*2</sup>, H. Park<sup>\*3</sup>, T. Kim<sup>\*4</sup>, H. Jung<sup>\*5</sup>, D. Lee<sup>\*6</sup>. <sup>1</sup>Dept. of OB & GYN, College of Medicine, Kosin University, Busan, Republic of Korea, <sup>2</sup>Dept. of OB & GYN, College of Medicine, Inje University, Seoul, Republic of Korea, <sup>3</sup>Dept. of OB & GYN, College of Medicine, Chungang University, Seoul, Republic of Korea, <sup>4</sup>Dept. of OB & GYN, College of Medicine, Korea University, Seoul, Republic of Korea, <sup>5</sup>Dept. of OB & GYN, College of Medicine, Chosun University, Kwangju, Republic of Korea, <sup>6</sup>Dept. of OB & GYN, National Cancer Center, Koyang, Republic of Korea.

Introduction: Hormon therapy results in only modest increase in bone mineral density. Sodium fluoride stimulate bone formation and has been used to treat osteopenia for decades despite debate about the antifracture efficacy. However, for women with low bone mass, the ideal therapy should not only inhibit bone resorption but simultaneously stimulate bone formation to increase bone mass above the fracture threshold.

Objective: To evaluate the effects of estrogen therapy and flucalcic on the bone mineral density and bone metabolism in the surgically menopause women with osteopenia.

Methods: This prospective randomized clinical trial examined the effects of conjugated equine estrogen and flucalcic in combination and separately, on BMD and biochemical markers of bone turnover in 200 women with low bone mass. Treatment included 0.3mg CEE (group I, n=50), 0.625 CEE (group II, n=50), 0.3mg CEE plus flucalcic (group III, n=50), and 0.625mg CEE plus flucalcic (group IV, n=50) for 12 months. Bone density measurements were performed at months 6 and 12 months at the lumbar spine and femur neck. Biochemical markers of bone turnover were also measured every six months.

Results: BMD of lumbar spine, it increased significantly during the treatment in Group III and Group IV ( $p < 0.05$ ). As for BMD of femur neck, it increased slightly during the treatment in all Groups, but not significantly, and urinary deoxypyridinoline in Group III and Group IV decreased significantly at 12 months of treatment ( $p < 0.005$ ). But serum osteocalcin and total alkaline phosphatase decreased slightly during the treatment in all groups but not significance: \*  $p < 0.05$

Conclusion: The combined treatment with Conjugated equine estrogen and flucalcic is more effective in surgical menopause women with osteopenia by decreasing bone biochemical markers, by increasing the BMD and induces a synergistic effect on bone mass.

**The Effects of Low Dose Estrogen Therapy on the Bone Mineral Densities and Bone Metabolism of Menopausal Women.** H. Kim<sup>\*1</sup>, H. Park<sup>\*2</sup>, H. Choi<sup>\*3</sup>, H. Jung<sup>\*4</sup>, T. Kim<sup>\*5</sup>. <sup>1</sup>Dept. of OB & GYN, College of Medicine, Kosin University, Busan, Republic of Korea, <sup>2</sup>Dept. of OB & GYN, College of Medicine, Chungang University, Seoul, Republic of Korea, <sup>3</sup>Dept. of OB & GYN, College of Medicine, Inje University, Seoul, Republic of Korea, <sup>4</sup>Dept. of OB & GYN, College of Medicine, Chosun University, Kwangju, Republic of Korea, <sup>5</sup>Dept. of OB & GYN, College of Medicine, Korea University, Seoul, Republic of Korea.

Introduction : Estrogen therapy(ET) is well established as an effective treatment of menopausal bone loss. There is less confidence about the minimum dose of estrogen required to prevent bone loss. Daily dosage in excess of 0.3mg conjugated equine estrogen prevents bone loss at the radius and at the spine as measured by computed tomography. Prospective studies have shown that doses equivalent to conjugated equine estrogens of 0.625mg/day are needed to produce a significant increase in bone mineral density of the lumbar spine. Safety concerns associating long-term use with endometrial and breast cancer, have prompted the search for the lowest effective dose for each indication of estrogen therapy.

Objective: To evaluate the effects of low dose estrogen therapy on the bone mineral densities and bone metabolism in the menopausal women.

Methods: This prospective randomized clinical trial examined the effects of low dose conjugated equine estrogen on BMD and biochemical markers of bone turnover in 140 women with low bone mass. Treatment included 0.625mg conjugated equine estrogen (group I, n=50) or 0.3mg conjugated equine estrogen (group II, n=50) for 12 months. Bone density measurements were performed at months 6 and 12 months at the lumbar spine and femur neck. Biochemical markers of bone turnover were also measured every six months.

Results: BMD of lumbar spine, it increased significantly during the treatment in Group I and Group II ( $p < 0.05$ ). As for BMD of femur neck, it increased slightly during the treatment in Group I and Group II, but not significantly. Urinary deoxypyridinoline in Group I and Group II decreased significantly at 12 months of treatment ( $p < 0.05$ ). But serum osteocalcin decreased during the treatment in but not significantly.

Conclusion: The low dose conjugated equine estrogen is also positive changes on bone densities and bone metabolism of menopausal women.

### An Assessment of Serum Calcium and Bone Resorption Markers in Patients Transitioned from Alendronate to Denosumab. D. Padhi<sup>\*1</sup>, A. Kivitz<sup>\*2</sup>, T. J. Weber<sup>3</sup>, K. Lyles<sup>4</sup>, E. Lee<sup>\*1</sup>, B. Cooke<sup>\*1</sup>, H. Deng<sup>\*1</sup>, E. Posvar<sup>\*1</sup>.

<sup>1</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>2</sup>Altoona Arthritis and Osteoporosis Center, Duncansville, PA, USA, <sup>3</sup>Duke Univ Med Ctr, Durham, NC, USA, <sup>4</sup>Duke Univ Med Ctr and VA Med Ctr, Durham, NC, USA.

Denosumab, a fully human mAb with a high affinity and specificity for RANKL, neutralizes the activity of human RANKL and blocks osteoclastic bone resorption. The objective of this study was to evaluate changes in serum calcium and bone resorption markers in patients transitioned from alendronate to denosumab to aid in the design of an international, double-blind, active-controlled, double-dummy, parallel group study in postmenopausal women with low bone mineral density (BMD).

In this open-label, single-dose phase 1 study, 20 postmenopausal women with low BMD (t-score between -4 and -1) who were receiving alendronate therapy (70 mg weekly or equivalent) for at least 1 year were randomized to receive a single subcutaneous (SC) dose of denosumab (n=15) or to continue with their alendronate regimen (n=5). The first 3 subjects randomized to denosumab received a SC dose of 15 mg, and the remaining 12 subjects received 60 mg SC. Blood samples were collected at baseline and for up to 107 days for determination of serum calcium, serum CTx, and denosumab concentrations.

Although small transient decreases in calcium occurred in all treatment groups, mean total and ionized calcium concentrations remained within normal limits for all groups throughout the study. The maximum mean decrease from baseline in total serum calcium for the 15 and 60 mg denosumab groups and alendronate group was 11%, 9%, and 6% and for ionized calcium was 5%, 6%, and 5%, respectively.

Fourteen days after dosing, the mean percent change from baseline in sCTx was approximately -60% and -73% for subjects in the 15 mg and 60 mg denosumab groups, respectively. These changes were generally maintained from study day 14 through 84. The mean percent change from baseline for sCTx for subjects who continued on alendronate treatment ranged from approximately -40% to +20%, with no changes on average at study day 107.

Serum denosumab concentrations were within the ranges observed in previous studies in bisphosphonate-naïve subjects. Therefore, dose adjustments of denosumab are not required in patients previously treated with alendronate.

In conclusion, there were no notable differences between the serum (total and ionized) calcium profiles after subjects were transitioned from alendronate to denosumab. Denosumab serum concentrations were consistent with those from previous denosumab studies, indicating that prior treatment with alendronate did not alter the pharmacokinetics of denosumab. Transitioning postmenopausal patients from alendronate to denosumab resulted in further reductions in sCTx levels.

### Effects of Denosumab vs Alendronate on Bone Mineral Density (BMD), Bone Turnover Markers (BTM), and Safety in Women Previously Treated with Alendronate. D. L. Kendler<sup>1</sup>, C. L. Benhamou<sup>2</sup>, J. P. Brown<sup>3</sup>, M. Lillestol<sup>\*4</sup>, C. Roux<sup>5</sup>, H. S. Man<sup>\*6</sup>, S. Siddhanti<sup>6</sup>, J. San Martin<sup>6</sup>, H. G. Bone<sup>7</sup>.

<sup>1</sup>Clinical Research Centre, Vancouver, BC, Canada, <sup>2</sup>Centre Hospitalier, Orleans, France, <sup>3</sup>CHUQ, Laval University, Quebec, QC, Canada, <sup>4</sup>Internal Medicine Associates, Fargo, ND, USA, <sup>5</sup>Hopital Cochin, Paris, France, <sup>6</sup>Amgen Inc., Thousand Oaks, CA, USA, <sup>7</sup>Michigan Bone and Mineral Clinic, Detroit, MI, USA.

Denosumab is a RANKL inhibitor in late-stage clinical development as a therapy for postmenopausal bone loss. Because many patients with osteoporosis are currently treated with bisphosphonates (BPs), it is important to understand the safety and efficacy of transitioning patients from BPs to denosumab. Cynomolgus monkeys treated with alendronate (ALN) followed by denosumab had significant reductions in BTMs and maintenance of BMD compared with monkeys remaining on ALN. In a phase 1 study in subjects who had received prior ALN therapy, serum calcium remained in the normal range following subcutaneous (SC) denosumab administration, while serum CTX decreased more than in subjects continuing to receive ALN. This phase 3 study in women previously treated with ALN was conducted to evaluate the effects of denosumab on BMD and BTM changes and safety compared with continuation of brand ALN therapy.

In this international, double-blind, active-controlled, double-dummy study, the primary efficacy endpoint was the percent change in total hip BMD from baseline to 12 mos. Secondary endpoints included percent changes in serum CTX at 3 mos and lumbar spine BMD at 12 mos. The study design allowed testing of the primary endpoint for superiority if non-inferiority was demonstrated.

Postmenopausal women  $\geq 55$  years old with a BMD measurement corresponding to a T-score of  $\leq -2.0$  and  $\geq -4.0$  at the lumbar spine or total hip who had received ALN therapy equivalent to 70 mg/week (QW) for  $\geq 6$  mos were eligible. After enrollment, all subjects received open-label ALN 70 mg QW for 1 mo, then subjects were randomized to continue receiving ALN 70 mg QW or to receive SC denosumab 60 mg Q6M. Randomization was stratified by length of prior ALN therapy. All subjects were given daily supplements of calcium (1000 mg) and vitamin D ( $\geq 400$  IU). Adverse events, serum calcium levels, and serum chemistry and hematology were evaluated to monitor safety.

A total of 504 women were enrolled from 46 study centers. The mean  $\pm$  SD age was 68  $\pm$  8 yrs, and the mean  $\pm$  SD length of prior BP therapy was 44  $\pm$  33 mos. The last subject visit occurred in March 2008, and the study remains blinded. The changes in BMD and BTM

observed in this study in subjects transitioning from ALN to denosumab may provide insights into the significance of the different mechanisms of action between denosumab, a RANKL inhibitor, and ALN, a BP.

## M396

### The Efficacy of Whole-Body Vibration in Reducing Bone Loss in Postmenopausal Women: A Meta-Analysis. L. Slatkowska<sup>1</sup>, S. M. H. Alibhai<sup>\*2</sup>, J. Beyene<sup>\*2</sup>, A. M. Cheung<sup>2</sup>. <sup>1</sup>Institute of Medical Science, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Department of Medicine, University of Toronto, Toronto, ON, Canada.

Whole-body vibration (WBV) has received attention recently due to its potential to improve bone mineral density (BMD). Animal models have shown anabolic bone effects of WBV, but small clinical trials in humans have produced variable results. Thus, we conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) examining the effects of WBV on BMD in postmenopausal women. Eligible RCTs included randomized or quasi-randomized trials, with a minimum follow-up of six months, examining WBV effects on BMD in postmenopausal women without secondary osteoporosis. Blinding of patients and researchers was not a requirement. WBV therapy was defined as mechanical vibration, performed erect, with no restriction on the amount and magnitude of WBV. Control interventions included no treatment, anti-osteoporotic drugs (matched between groups), and physical activity. The effect measure was a weighted mean difference in absolute pre-post change in the areal BMD in the spine and hip (as measured by dual-energy x-ray absorptiometry), and in the volumetric tibial trabecular BMD (as measured by computed tomography). Intention-to-treat data were analyzed preferentially. Fixed versus random effect models were reported, unless significant heterogeneity was found. Subgroup analysis was performed to examine whether WBV magnitude and amount, and control intervention type modify WBV effects. From 1257 identified titles, five RCTs were included with a total of 209 patients. Study population consisted primarily of healthy osteopenic women of Caucasian and Southeast Asian origin, 47-88 years of age, and with low to moderate physical activity levels. Four RCTs obtained areal BMD measurements (spine, 4 RCTs; hip, 3 RCTs), and one trial obtained volumetric BMD measurements. No significant effect of WBV on spine BMD was found (-3.39 mg-cm<sup>2</sup>; 95% CI, -12.01, 5.24; n = 181). Decline in hip BMD was found to be significantly smaller in the WBV versus control group (14.32 mg-cm<sup>2</sup>; 95% CI, 6.69, 21.95; n = 131). No change in volumetric tibial trabecular BMD was found in one trial (-2.20 mg-cm<sup>3</sup>; 95% CI, -6.14, 1.74; n = 29). In subgroup analysis, only WBV magnitude was found to significantly modify the effect of WBV on hip BMD. However, this involved a comparison of two high-magnitude WBV trials (n = 98) with only one low-magnitude WBV trial (n = 33). In conclusion, WBV appeared to be efficacious in attenuating postmenopausal decline in hip but not spine BMD, suggesting that this therapy is a promising new candidate for prevention of bone loss in postmenopausal women. Larger trials will need to be conducted to examine whether WBV affects bone structure or fracture risk.

Rubin<sup>9</sup>. <sup>1</sup>IFAR, Hebrew Rehab Center, Boston, MA, USA, <sup>2</sup>Maryland Med Res Inst, Baltimore, MA, USA, <sup>3</sup>Radiology, UCSF, San Francisco, CA, USA, <sup>4</sup>Ortho Biomech Lab, BIDMC, Boston, MA, USA, <sup>5</sup>Medicine, Columbia Univ, New York, NY, USA, <sup>6</sup>Epidemiol & Prev Med, Univ MD, Baltimore, MD, USA, <sup>7</sup>Cecil G. Sheps Center for Health Services Research, UNC, Chapel Hill, NC, USA, <sup>8</sup>NIA, Washington, DC, USA, <sup>9</sup>Biomed Engin, SUNY Stony Brook, Stony Brook, NY, USA.

Treatment options for osteoporosis in older persons are primarily limited to pharmacologic therapy. The VIBES trial is evaluating the efficacy of a unique, biomechanically based treatment for bone loss and possibly for sarcopenia: low magnitude mechanical stimulations (LMMS) with the use of vibrating platforms that meet ISO safety standards for vibration exposure. To extend previous findings that LMMS improves BMD in young women, disabled children and postmenopausal women, VIBES is a 2 yr, double-blind, randomized, placebo-controlled trial of LMMS in 200 women and men  $\geq 60$  yrs of age, with T-scores at the hip or spine = -1 and -2.49. Investigators at Hebrew SeniorLife (Boston) are recruiting subjects from independent living settings and data are being managed by a Maryland Medical Research Institute. Following a multi-stage screening process, eligible participants are randomized to either daily exposure to LMMS on an active vibrating platform (10 min/d of 0.3g @ 30Hz; 1g = 9.8 m/s<sup>2</sup>) or a placebo platform that is located in a common area of the independent living setting, and is activated by a radiofrequency identification card provided to all randomized participants. Subjects are receiving 1000 mg calcium and 800 IU of vitamin D/day. The primary endpoints are changes in volumetric trabecular BMD of the spine and hip by QCT. Secondary outcomes are change in biochemical markers of bone formation (Procollagen type 1 N-terminal peptide and Bone Specific Alkaline Phosphatase) and resorption (C-terminal Telopeptide of type I collagen), change in muscle strength, balance, muscle cross sectional area, and falls. Adverse events are monitored. Adherence is obtained electronically from the platforms. As of April 1, 2008, 194 subjects had been screened, and 40 participants (28 females, 12 males) randomized. Major reasons for exclusion were low BMD and current use of osteoporosis medications. The mean age of participants is  $82 \pm 8$  yrs, the mean femoral neck T-score is -1.89, and the mean vitamin D concentration is  $29 \pm 7$  ng/ml. There have been no withdrawals and few adverse events attributable to the treatment. Adherence is currently 85%. This study will provide new and important information about the role of high frequency LMMS on the skeleton, muscle mass and balance in independently living seniors.

## M398

**Optimizing Bioavailability of Oral Administration of Small Peptides through Pharmacokinetic and Pharmacodynamic Parameters: The Effect of Water and Timing of Meal Intake on Oral Delivery of Salmon Calcitonin.** M. A. Karsdal, I. Byrjalsen, B. Riis\*, C. Christiansen. Nordic Bioscience, Herlev, Denmark.

**Purpose:** Oral delivery of peptides is hampered by an array of obstacles, including but not limited to proteolytic degradation in the gastrointestinal tract and uptake in the intestine. We investigated the influence of water intake and dose timing on the pharmacokinetic and pharmacodynamic parameters of an oral formulation of salmon calcitonin (sCT).

**Methods:** The study was a randomized, partially-blind, placebo-controlled, single dose, exploratory crossover phase I study of oral sCT. 56 healthy postmenopausal women, 56 to 70 years old were randomly assigned to receive five treatments according to pre-defined sequences. The treatments comprised a combination of study medication 0.8 mg sCT + 200 mg 5-CNAC, placebo, or 200 IU Miacalcic® NS nasal spray, water volume given with the tablet (50 or 200 ml water), and time between dosing and meal (10, 30, or 60 minutes pre-meal. Plasma sCT levels and changes in the bone resorption (C-terminal telopeptide of collagen type I) was investigated.

**Results:** Oral delivery of 0.8 mg of sCT with 50 ml of water resulted in a two-fold increase in maximum concentration ( $C_{max}$  and  $AUC_{0-4}$ ) of plasma sCT when compared to 200 ml water, but comparable time to reach maximum concentration ( $T_{max}$ ). The sCT  $AUC_{0-4}$  when SMC021 was given with 50 ml of water was 4-fold higher than that obtained with nasal calcitonin, as illustrated in the figure. The increased absorption of sCT resulted in increased suppression of the serum CTX-I levels calculated as AUC of the relative change of measured in the 6 hours following drug intake. A trend towards increased efficacy when dosing 30 minutes or 1 hour before meal intake was observed when comparing to dosing 10 minutes before meal.

**Conclusion:** 0.8 mg sCT with 50 ml of water taken 30 and 60 minutes prior to meal time resulted in optimal pharmacodynamic and pharmacokinetic parameters. These results appeared to be superior to those of the currently used Miacalcic® 200IU nasal spray calcitonin, although the study was not planned nor powered to compare the two sCT formulations. The data suggest that this novel oral formulation may have improved absorption and reduction of serum CTX-I over 24 hours compared to that of the nasal form.

AUC<sub>0-4 hrs</sub> of plasma CT

## M399

**GLP-2 Acutely Uncouples Bone Resorption and Bone Formation in Postmenopausal Women.** D. B. Henriksen<sup>1</sup>, P. Alexandersen<sup>1</sup>, B. Hartmann<sup>1</sup>, C. Christiansen<sup>3</sup>. <sup>1</sup>Sanos Bioscience, Copenhagen, Denmark, <sup>2</sup>Center for Clinical and Basic Research, Ballerup, Denmark, <sup>3</sup>Nordic Bioscience, Herlev, Denmark.

We have previously shown that treatment with GLP-2 for 120 days results in a dose dependent and statistically significant increase in total hip BMD from baseline as compared to placebo.

We now report on the overall bone turnover marker response as well as TRAP-5b over the entire treatment period of 120 days. The study was a randomized, placebo-controlled 120-day trial including 160 postmenopausal women. The study subjects were osteopenic (BMD T-score,  $-2.5 < T \leq -1.0$ ) at one or more of the regions: lumbar spine, femoral neck, or total hip. Subjects received daily bedtime injections of 0.4, 1.6, or 3.2 mg GLP-2, or placebo. All subjects received supplements of calcium and vitamin D. Injection of 0.4, 1.6 and 3.2 mg GLP-2 resulted in acute and sustained reductions, of the nocturnal rise in s-CTX compared to placebo, at day 1 and day 120. At day 1 this effect was statistically significant compared to placebo for the 1.6 and 3.2 mg GLP-2 groups at all time points, but not for the 0.4 mg group. At day 120 all GLP-2 treatment groups had statistical significant and comparable reduction in s-CTX at all time points. S-osteocalcin levels were unaffected in the 10 hours following injection of GLP-2 at day 1 and day 120. There was an overall reduction in bone turnover following daily injections of 1.6 and 3.2 mg GLP-2 over the 120 days treatment period as assessed in morning fasting samples collected at day 2, 15, 30, 60, 90 and 121. This reduction resulted in a statistical significant decrease in s-CTX and s-osteocalcin between day 2 and day 121 for the 1.6 and 3.2 mg GLP-2 doses of 10-20% as compared to placebo. No reduction in s-CTX or s-osteocalcin was seen in the 0.4 mg GLP-2 group over the 120 days treatment period. TRAP-5b, which has been proposed as a biomarker for osteoclast number, showed a trend towards a decrease over the 120 days of treatment. The decrease was 10-15% compared to placebo for the 1.6 and 3.2 mg groups, whereas treatment with 0.4 mg GLP-2 did not result in any change of osteoclast number.

In conclusion, these results suggest that treatment with GLP-2 acutely uncouples the two processes of bone remodeling and thereby increases the bone calcium (ossification) balance particular at the hip. The decrease in TRAP-5b over the 120 day for the 1.6 and 3.2 mg groups suggests a reduction in osteoclast number and this might explain the overall reduction of 10-20% seen in bone turnover markers. This reduction in bone turnover markers was, however fully expressed during the first two week of treatment. An overall reduction in bone turnover markers during the 120 days treatment was not observed for the 0.4 mg GLP-2 group, whereas the acute effect on bone resorption on day 120 was identical for the three GLP-2 groups.

## M400

**Vitamin D Supplementation Intake Among Osteoporosis Patients Aged 50 Years and Older at Various 25(OH)D Levels In the US.** D. T. Gold<sup>1</sup>, T. Fan<sup>2</sup>, S. G. Sajjan<sup>2</sup>, S. S. Sen<sup>2</sup>. <sup>1</sup>Departments of Psychiatry & Behavioral Science, Sociology, & Psychology, Duke Medical Center, Durham, NC, USA, <sup>2</sup>Merck & Co., Inc, Whitehouse Station, NJ, USA.

To assess the adequacy of the vitamin D supplement use and describe the characteristics of osteoporosis patients in a US national representative population from year 2001 - 2004, a cross-sectional analysis was conducted on combined data from the National Health and Nutrition Examination Survey (NHANES) 2001 - 2002 and NHANES 2003 - 2004. Descriptive analysis and multiple regression analyses were used to estimate the prevalence of vitamin D supplements intake and characteristics of osteoporosis patients with various 25(OH)D concentrations. Detailed vitamin, dietary supplements and multi-vitamin use were also collected in the surveys. A total of 3,002 subjects aged 50 years and older (mean age =  $64.2 \pm 0.29$ ) were included in the analysis. Self-reported prevalence of osteoporosis in the US was 7.1% (SD=0.01) from 2001-2004. Overall, the prevalence of vitamin D use did not differ between patients with osteoporosis and without osteoporosis (26.4% v.s.22.4%, P=0.297). Of 202 patients with self-reported osteoporosis, 22.5% reported taking vitamin D supplements. Vitamin D supplement rate was significantly higher for

patients aged 50-66 (16.1%) than those over 65 (31.0%,  $P=0.02$ ) but there were no gender differences (male=21.0%; female=23.7%,  $P=0.69$ ). Among osteoporosis patients in the US, 21.8% had serum 25(OH)D lower than 30ng/ml. The prevalence of vitamin D supplements use was 30.6% among osteoporotic patients with vitamin D insufficiency, and 19.9% among those patients whose serum 25(OH)D was at least 30 ng/ml ( $P=0.19$ ). In the logistic regression analysis, likelihood of taking vitamin D supplements was higher among Mexican American (OR=1.83 versus whites, 95% CI = 1.29 - 7.98) and increased with age (OR=1.03, 95% CI = 1.00 - 1.05). Patients with vitamin D insufficiency did not have significantly higher vitamin D supplements intake (OR=1.83, 95% CI = 0.74 - 4.52) when other factors were controlled. The most recent US national data revealed that vitamin D supplement intake was not higher among patients with osteoporosis than in the general population and was inadequate even among patients with insufficient serum vitamin D concentrations. Comprehensive strategies should target the improvement of overall vitamin D intake for patients with osteoporosis.

## M401

**Assessment of a Provincial Strategy for Osteoporosis Best Practices: Fracture Fighters - The Ontario Osteoporosis Strategy for Inpatient Rehabilitation.** S. B. Jaglal<sup>1</sup>, S. E. Munce<sup>\*2</sup>, V. Quan<sup>\*3</sup>, C. Evans<sup>\*3</sup>, V. Bansod<sup>\*2</sup>, G. Hawker<sup>2</sup>. <sup>1</sup>Rehabilitation Science, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Physical Therapy, University of Toronto, Toronto, ON, Canada.

**Purpose:** To assess the change in practices of osteoporosis care for fracture patients in 36 inpatient rehabilitation units across Ontario, Canada using a clinical coach intervention. **Methods:** Hospitals with inpatient rehabilitation units that treated at least 40 hip fractures per year were eligible for inclusion. Two clinical coaches (nurse and rehabilitation therapist) were identified from each unit and attended a one-day training session which included education on osteoporosis best practices, change management strategies, and the distribution of resource materials. Prior to implementation, a baseline survey was conducted on existing practices related to osteoporosis, including provision of education, recommendation of calcium and vitamin D supplements, prescription of medications, referral for bone mineral density (BMD) testing, and referral to a general practitioner for follow-up. Sites were asked to complete 10 audit checklists on fracture patients and complete a 6 month follow-up telephone survey to assess changes in osteoporosis practices. **Results:** Improvement in osteoporosis best practices was observed across all dimensions in 67% of the units. The areas of greatest improvement were provision of osteoporosis education (23% of sites at baseline vs. 77% of sites after training), recommendation of calcium and/or vitamin D supplements (17% of sites at baseline vs. 50% of sites after training), referral for BMD testing (9% of sites at baseline vs. 25% of sites after training), and referral to a general practitioner for osteoporosis follow-up (0% of sites at baseline vs. 42% of sites after training). Fourteen sites completed audit checklists on 165 fracture patients. Sixty-four percent had a hip fracture; 70% were female, with 43% older than 80 years of age. At the time of admission to the rehabilitation unit, 27% had had a previous fracture, 29% had a diagnosis of osteoporosis, 32% were already taking some type of bisphosphonate, and 37% were taking a calcium and/or vitamin D supplement. **Conclusions:** This strategy produced significant changes to post-fracture care in inpatient rehabilitation units across Ontario. Particular improvement was noted in referrals to general practitioners for osteoporosis follow-up. The clinical coach model (Fracture Fighters), can have a significant impact on the post-fracture care provided by inpatient rehabilitation units, and may help health care professionals make the link between fractures and osteoporosis.

## M402

**Possible Increased Risk of Fracture among South Florida White Hispanic Women \_ Characteristics of Women Screened for the Soy Phytoestrogen as Replacement Estrogen (SPARE) Study.** S. Levis<sup>1</sup>, N. Strickman-Stein<sup>\*2</sup>, A. Barrera<sup>\*2</sup>, O. Gomez-Marin<sup>\*3</sup>. <sup>1</sup>Medicine, Geriatric Research, Education, and Clinical Center, Miami VA Healthcare System, and Geriatrics Institute, University of Miami Miller School of Medicine, Miami, FL, USA, <sup>2</sup>University of Miami Miller School of Medicine, Miami, FL, USA, <sup>3</sup>Geriatric Research, Education, and Clinical Center, Miami VA Healthcare System, and Geriatrics Institute, University of Miami Miller School of Medicine, Miami, FL, USA.

The SPARE study is a 5-year trial to test the effectiveness of purified soy isoflavone tablets in preventing rapid bone loss and improving health-related quality of life and emotional health of women in the initial menopausal years. In this ongoing, randomized, double-blind, placebo-controlled clinical trial, subjects were randomized (50/50) to receive soy isoflavones 200 mg/day or placebo. Each participant is being followed for 2 years, undergoing serial measurements of spine and hip bone mineral density (BMD), thyroid function, and vaginal cytology and serial quality-of-life assessments. We here describe the characteristics of women screened for the study according to race and ethnicity. Potential study candidates were pre-screened by telephone, and those <45 or >60 years of age, or with BMI >32, or with known diagnosis of osteoporosis were excluded from further participation. Screening visits were performed in 524 women from the south Florida area; 283 met eligibility criteria and were enrolled into the study.

Mean age ( $\pm$  SD) of the 524 women screened was  $52.3 \pm 3.4$  years; there were no differences among ethnic / racial groups. Of those screened, 69% were white Hispanics

(WH), 20% white non-Hispanics (WNH), 8% African-American (AA), and 2% other race / ethnicity. At screening, 39% of WH had normal BMD, compared to 49% of WNH and 79% of AA; 54% of WH had osteopenia, compared to 41% WNH and 17% AA. Osteoporosis was diagnosed in 6% of WH compared to 9% WNH and 5% AA. WH had lower BMD in the spine compared to WNH and AA. The mean body mass index (BMI) for the entire screened population was  $26.2 (\pm 3.5)$ . AA women had significantly higher BMI than WH or WNH ( $p = 0.01$ ), and WH had significantly higher BMI than WNH women ( $p < 0.001$ ). Mean waist-hip ratio was significantly higher in WH (0.82) and AA (0.82) than in WNH (0.79) ( $p \leq 0.002$ ). The women screened for this study are representative of the general south Florida female population. AA and WH had significantly higher BMI than WNH. In spite of having higher BMI and waist-hip ratio, the WH women screened had the highest proportion of osteopenia and the lowest spine BMD. Due to behavioral, environmental, or genetic factors, WH women might be in a higher inflammatory state that could place them at higher risk of fractures and other comorbidities than their WNH and AA counterparts.

## M403

**Cissus quadrangularis Attenuates Ovariectomy Induced Bone Loss in Mice.** J. Banu, R. Soomro<sup>\*</sup>, N. Kazi<sup>\*</sup>, G. Fernandes<sup>\*</sup>. Med/Clinical Immunology & Rheumatology, UT Health Science Center at San Antonio, San Antonio, TX, USA.

Bone loss during aging leads to osteoporosis, a disease characterized by low bone mass which increases the risk of fractures from minor trauma. Although both women and men are loose bone while aging, women lose bone drastically during and after menopause. Treatments for bone loss have been focused on hormone replacement therapy and other agents that can reduce bone resorption. However, all existing drugs have severe side-effects, therefore, the focus has turned towards identifying alternative medicines which can prevent and treat osteoporosis with minimal or no side-effects. *Cissus quadrangularis* (CQ) a medicinal herb used for bone fracture healing has shown bone forming properties. We studied the effects of CQ on bone loss after ovariectomy in young female C57Bl/6 mice.

Eight weeks old female C57Bl/6 mice were divided into the following groups: Group 1. Lab chow sham (LC S); Group 2. Lab chow ovariectomy (LC O); Group 3 CQ (500mg/kg b wt) sham (CQ S); and Group 4 CQ (500mg/kg b wt) ovariectomy (CQ O). One month after surgery mice were fed the respective diets for 11 weeks. After which the mice were sacrificed. Serum PINP and Trap5b were assayed. Femur and tibia were analyzed using pQCT densitometry.

Serum PINP decreased in LC O group, when compared to that of LC S group. There were no significant differences between CQ S and CQ O groups. No significant differences were seen in Trap5b levels in any of the groups studied.

In the distal femoral metaphysis (DFM), cancellous (Cn) BMC and BMD, cortical (Ct) BMC and BMD and cortical thickness (Ct Th) were significantly reduced in the LC O groups, when compared to that of the LC S groups. In the CQ O group, there were no significant differences in the Cn and Ct parameters studied, when compared to those of the CQ S group. In the FD, there were significant decreases in the Ct BMC and Ct Th in the LC O group, when compared to those of the LC S group while there were no significant differences between the CQ fed groups. In the proximal tibial metaphysis (PTM), Cn BMC, Cn BMD and Ct BMC decreased significantly in the LC O group when compared to those of LC S group. In the CQ O group, except for Ct BMC, there were no significant decreases in any of the parameters studied, when compared to that of the CQ S group. There were no significant differences in the tibia fibular junction between the shams and ovariectomized mice.

We conclude that CQ effectively attenuated ovariectomy induced bone loss in the cancellous and cortical bones of DFM and PTM as well as cortical bone of FD in young female mice mainly by increasing bone formation.

**Genome-Wide Copy Number Variation Study Identified a Novel Susceptibility Gene *UGT2B17* for Osteoporosis.** T. L. Yang<sup>\*1</sup>, S. F. Lei<sup>\*2</sup>, Y. Guo<sup>\*1</sup>, F. Pan<sup>\*1</sup>, Q. Zhou<sup>\*1</sup>, Z. X. Zhang<sup>\*1</sup>, S. S. Dong<sup>\*1</sup>, X. H. Xu<sup>\*1</sup>, X. G. Liu<sup>\*1</sup>, H. Yan<sup>\*1</sup>, B. Drees<sup>\*2</sup>, J. Hamilton<sup>\*2</sup>, C. J. Papasian<sup>\*2</sup>, R. R. Recker<sup>3</sup>, H. W. Deng<sup>2</sup>. <sup>1</sup>School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, China, <sup>2</sup>School of Medicine, University of Missouri - Kansas City, Kansas City, MO, USA, <sup>3</sup>Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

DNA copy number variation (CNV) is a rich and important source of genetic diversity for human diseases. We conducted the first case-controlled, genome-wide CNV analyses for osteoporosis in 700 elderly Chinese Han subjects comprising 350 case subjects with a history of osteoporotic hip fractures (OF) and 350 matched healthy controls, using Affymetrix 500K array set. For the significant CNVs identified for OF, we further examined their relevance with hip BMD and bone geometry, in both Chinese (310 subjects) and Caucasian (1000 subjects) unrelated random samples. We constructed a genomic map containing 727 CNV regions (CNVR) covering 8.5% (254 Mb) of the human genome in Chinese. We found that CNV 4q13.2 duplication was strongly associated with OF ( $P < 0.001$ , Bonferroni corrected  $P = 0.041$ , odds ratio = 1.78). Real time PCR further identified that copy number change of *UGT2B17* located in 4q13.2 was associated with OF. Interestingly, *UGT2B17* gene duplication was also significantly associated with BMD and femoral neck bone geometry parameters (CT: cortical thickness; BR: buckling ratio) in Chinese, which were further confirmed in Caucasians. The contributions of this CNV to BMD, CT, BR variations in the Chinese and Caucasian were 1.91%, 1.50%, 1.47% and 0.63%, 0.65%, 0.84%, respectively. The phenotypic differences of subjects with various CNVs vary from 1.4%-7.0%. Our findings suggested that dosage of *UGT2B17* gene (via copy number variation), probably through affecting the extent of steroid hormone synthesis and metabolism, may be a novel genomic mechanism for etiology of osteoporosis.

**Effect of Three Different Doses of Vitamin D<sub>2</sub> (Ergocalciferol) on Muscle Function and Strength in Women >65 years: A Preliminary Study.** S. R. Mastaglia<sup>\*</sup>, M. Seijo<sup>\*</sup>, D. Muzio<sup>\*</sup>, J. Somoza<sup>\*</sup>, B. Oliveri. Sección Osteopatías Médicas, Hospital de Clínica. Universidad de Buenos Aires, Buenos Aires, Argentina.

Vitamin D insufficiency is frequently observed in subjects aged  $\geq 65$  years. Serum levels of 25-hydroxyvitamin D (25OHD) $>20$ ng/ml would seem optimum for adequate muscle function and strength. In a previous study (*JBM 22: Suppl.1;2007*) we evaluated 40 postmenopausal women; 20 had mean 25OHD levels ( $X \pm DS$ ) at  $31.8 \pm 6$  ng/ml and exhibited improved muscle function compared to those with average 25OHD levels at  $12.9 \pm 3$  ng/ml ( $7.3 \pm 1$  vs.  $6.7 \pm 2$  scores;  $p < 0.02$ ). The aim of this study was to evaluate the effect of 3 different doses of vitamin D<sub>2</sub> administered for 6 months, on muscle function and strength in the group of women with levels of 25OHD $<20$ ng/ml. Twenty postmenopausal women from Buenos Aires (34°S), mean age ( $X \pm DS$ )  $70.5 \pm 4$  were randomly assigned to one of the following three groups (G) to receive: 800IU/day G 1 ( $n=6$ ); 5,000IU/day G2 ( $n=6$ ); and 10,000IU/day G3 ( $n=8$ ). All the subjects received calcium carbonate supplementation (500mg/day). Serum calcium, phosphate, 25OHD, bone alkaline phosphatase (BAP), and crosslaps (CTX) were determined, as well as 24-hours urine calciuria/creatininuria. Muscle function was assessed in terms of gait speed, balance, and stand-and-sit-test. Muscle strength of lower limbs was evaluated using a manual dynamometer. All determinations were performed at baseline and at 6 months. G2 and G3 were analyzed as a whole. Average baseline 25OHD of the whole group was 13 ng/ml. At 6 months, 25OHD levels reached  $18.4 \pm 2.5$  ng/ml in G1 and  $29.2 \pm 11.4$  ng/ml in G2+G3; G2 and G3 showed an improvement in their gait speed test (baseline:  $3.2 \pm 0.9$  vs. 6 months:  $3.6 \pm 0.9$  score;  $p < 0.05$ ) at 6 months. No significant changes in muscle strength were observed in any of the groups at the end of the study. Serum and urinary levels of calcium remained within reference values; no significant changes in BAP or CTX were observed. The dose of vitamin D supplementation for subjects in the age group at risk of suffering falls and osteoporotic fractures should be higher than the currently recommended dose.

## M406

**Circulating Osteoprotegerin and Its Ligand in Post Operative Biliary Atresia: Relationship with Metabolic Bone Disease.** S. Honsawek<sup>\*1</sup>, T. Chaiwatanarat<sup>\*2</sup>, P. Vejchapipat<sup>\*3</sup>, L. Wolfinbarger<sup>4</sup>, Y. Poovorawan<sup>\*5</sup>. <sup>1</sup>Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, <sup>2</sup>Radiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, <sup>3</sup>Surgery, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, <sup>4</sup>Research and Development, LifeNet, Virginia Beach, VA, USA, <sup>5</sup>Pediatric, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.

Osteodystrophy is a well-recognized complication of chronic liver disease. Biliary atresia (BA) is one of the typical cholestatic disorders that lead to end-stage liver disease in

children and severe cholestatic jaundice of BA is associated with a high prevalence of osteoporosis. Osteoprotegerin (OPG) and receptor activator of nuclear factor- $\kappa$ B ligand (RANKL) are proteins recently identified to play an essential role in the regulation of osteoclastogenesis. The purpose of this study has been to evaluate the relationships between circulating OPG and RANKL levels, bone mineral density (BMD), and clinical outcome in patients with BA.

We have investigated 50 patients with BA and 13 healthy controls. The mean age of BA patients and controls was  $7.3 \pm 0.6$  and  $8.0 \pm 1.1$  years. The study has been approved by the ethics committee on human research. Serum levels of OPG and RANKL were measured by sandwich enzyme-linked immunosorbent assay. BMD of the lumbar spine was determined by dual energy X-ray absorptiometry.

The results showed that BA patients had significantly elevated serum OPG levels compared with controls ( $4.0 \pm 0.3$  vs  $3.0 \pm 0.3$  pmol/l,  $P < 0.02$ ) and serum OPG levels in BA patients with jaundice were higher than in those without jaundice ( $4.6 \pm 0.4$  vs  $3.6 \pm 0.4$  pmol/l,  $P < 0.04$ ). Likewise, serum RANKL levels were significantly higher in BA patients than in controls ( $2.9 \pm 0.2$  vs  $1.2 \pm 0.7$  pmol/l,  $P < 0.001$ ). In addition, serum RANKL levels were increased in BA patients with jaundice compared to those without jaundice, but this difference was not statistically significant ( $3.2 \pm 0.3$  vs  $2.7 \pm 0.2$  pmol/l,  $P = 0.2$ ). Subgroup analysis in BA patients with normal BMD (Z score  $\geq -1.0$ ), with osteopenia ( $-2.5 < Z$  score  $< -1.0$ ), and with osteoporosis (Z score  $\leq -2.5$ ) revealed a gradual increase in OPG serum levels, with a significant increase observed in osteoporotic patients ( $P < 0.05$ ). There was an inverse correlation between OPG and BMD ( $R = -0.32$ ,  $P = 0.01$ ). Furthermore, there was a negative correlation between serum RANKL levels and BMD ( $R = -0.25$ ,  $P = 0.04$ ).

The present study showed significant differences in circulating OPG and RANKL levels between children with BA and healthy controls. High serum OPG and RANKL levels are associated with the severity of BA. The increase of serum OPG in BA patients with severe disease could reflect a compensatory response to bone loss.

Chung<sup>4</sup>. <sup>1</sup>Biochemistry and Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>2</sup>Biochemistry, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>3</sup>Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>4</sup>Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea.

Adipose tissue expresses chemotactic cytokine, monocyte chemoattractant protein-1 (MCP-1). MCP-1 has been known as adipocytokine initiating macrophage infiltration of the adipose tissue and inducing systemic insulin resistance. MCP-1 expression in adipose tissue and circulating MCP-1 levels have been known to have a positive correlation with the degree of obesity. In the field of bone and mineral research, previous studies have shown that parathyroid hormone or low-intensity pulsed ultrasound stimulates MCP-1 expression in osteoblast, receptor activator of NF kappa B ligand stimulates MCP-1 expression in human osteoclasts, and MCP-1 promotes osteoclast differentiation. However, there were no studies about the relationship of circulating MCP-1 levels with bone mineral density (BMD) in human, until now. In this study, we assessed the relationship of circulating MCP-1 levels with lumbar BMD in Korean pre- and post-menopausal women. 155 Korean women (109, premenopausal women; 46, postmenopausal women) who had no confounding diseases were recruited at the Eulji University Hospital, South Korea. We performed several anthropometric measurements and measured serum MCP-1 levels, various blood parameters, and lumbar spine L<sub>1</sub>-L<sub>4</sub> BMD using DXA. There were significant differences in age ( $39 \pm 6$  vs  $60 \pm 6$  years), body weight ( $55.5 \pm 7.0$  vs  $58.9 \pm 9.5$  kg), abdominal circumference ( $73 \pm 7$  vs  $84 \pm 8$  cm), percentage of body fat ( $28 \pm 5$  vs  $32 \pm 5$  %), BMI ( $22.2 \pm 2.7$  vs  $25.3 \pm 3.7$  kg/m<sup>2</sup>), systolic ( $116 \pm 13$  vs  $141 \pm 22$  mmHg) and diastolic ( $69 \pm 9$  vs  $79 \pm 13$  mmHg) blood pressure, serum total cholesterol ( $182 \pm 31$  vs  $215 \pm 42$  mg/dL), triglyceride ( $95 \pm 68$  vs  $119 \pm 48$  mg/dL), LDL-cholesterol ( $109 \pm 28$  vs  $137 \pm 40$  mg/dL), fasting glucose ( $83 \pm 8$  vs  $90 \pm 11$  mg/dL), MCP-1 ( $245.9 \pm 73.5$  vs  $336.5 \pm 101.7$  pg/mL) levels, and lumbar BMD ( $0.992 \pm 0.114$  vs  $0.772 \pm 0.113$  g/cm<sup>2</sup>) between pre- and post-menopausal women. Circulating MCP-1 levels increased and lumbar BMD decreased after menopause. However, circulating MCP-1 levels had no correlation with any anthropometric data, blood parameters and lumbar BMD in pre- or post-menopausal women. In conclusion, circulating MCP-1 levels had no association with lumbar BMD in Korean pre- or post-menopausal women, most of whom were not obese. Prospective studies in various populations, and involving a large number of obese subjects are required to reveal the association of circulating MCP-1 levels with BMD.

## M408

**Bone Density Changes at the Non-operated Hip Following Total Hip Arthroplasty.** S. Ortolani<sup>1</sup>, G. Bianchi<sup>2</sup>, R. Cherubini<sup>\*1</sup>, C. Trevisan<sup>\*3</sup>, G. Isaia<sup>4</sup>, L. Massari<sup>\*5</sup>, D. Dallari<sup>\*6</sup>, P. Romano<sup>\*7</sup>. <sup>1</sup>Centre for Metabolic Bone Disease, Istituto Auxologico Italiano, Milan, Italy, <sup>2</sup>Department of Rheumatology, Ospedale La Colletta, Arenzano (GE), Italy, <sup>3</sup>Department of Orthopaedics, University of Milano-Bicocca, Milan, Italy, <sup>4</sup>Department of Internal Medicine, University of Turin, Turin, Italy, <sup>5</sup>Department of Orthopaedics, University of Ferrara, Ferrara, Italy, <sup>6</sup>VII Orthopaedic Division, Rizzoli Orthopaedic Institute, Bologna, Italy, <sup>7</sup>Medical Department, SPA-Società Prodotti Antibiotici, Milan, Italy.

As part of a multicentre randomized controlled study on bone density changes after total hip arthroplasty (THA), we measured the bone mineral density (BMD) of the contralateral (non-operated) hip using DXA. Forty-one patients (mean age 65.6±6.4 (SD), 24 male and 17 female) undergoing THA operation for severe osteoarthritis of the hip were enrolled in the untreated control group of the study. Baseline assessment was obtained no later than 2 weeks after the operation and 41, 36 and 26 patients respectively completed the follow-up with DXA measurements repeated at 3, 6 and 12 months.

Total hip and greater trochanter BMD of the non operated hip showed significant decreases at 3, 6 and 12-month follow-up (total hip BMD at 12 months -1.2%, p=0.05; greater trochanter at 12 months -1.6%, p<0.05). Intertrochanteric and femoral neck regions showed significant BMD reductions only at some of the time-points. When analyzing the data according to sex, only women showed significant hip bone loss (total hip BMD at 12 months -2.4%, p<0.05; femoral neck BMD at 12 months -4.5%, p<0.05; greater trochanter at 12 months -3.1%, p<0.05), while no changes were observed in men.

The observed bone loss at the non operated hip of patients undergoing THA for severe osteoarthritis may be a consequence of reduced mechanical load, or relative disuse, contrasting with an increased load prior to THA to compensate for the reduced joint function of the affected side. However, the gender difference may indicate that postmenopausal and age related bone loss, that is more pronounced in women, is also contributing to the observed BMD decreases.

Following THA, a significant bone loss in women at the non operated hip should be interpreted with caution in clinical practice and not necessarily indicates systemic bone loss.

## M409

**Effect of Metabolic Acidosis on Bone Mineral Density and Bone Microarchitecture in Normal and Ovariectomized Rats.** R. Krapf<sup>1</sup>, J. A. Gasser<sup>2</sup>. <sup>1</sup>Medicine, Kantonsspital Bruderholz, Bruderholz/Basel, Switzerland, <sup>2</sup>Musculoskeletal Diseases, Novartis Institute for Biomedical Research, Basel, Switzerland.

Metabolic acidosis (MA) in vitro increases osteoclast, but decreases osteoblast activity and impairs bone matrix protein synthesis as well as bone mineralization. The dietary-induced MA typical of the Western diet may contribute to the current osteoporosis epidemic. We, therefore, wished to characterize the effects of MA on bone mass and microarchitecture in vivo in rats.

MA was induced in normal and ovariectomized (OVX) virgin Wistar rats by feeding 30 mEq/kg bw of NH<sub>4</sub>Cl. Rats were analysed at baseline and at weeks 6 and 10 using in vivo pQCT and in vivo uCT in proximal tibia metaphysis.

NH<sub>4</sub>Cl feeding resulted in MA of comparable severity in both groups, characterised by significant falls in the plasma [HCO<sub>3</sub><sup>-</sup>] and stable increases in urinary ammonium excretion.

Difference in % change of various bone parameters at week 10 compared to non-acidotic normal or non-acidotic ovx rats respectively

		Total BMD	Cortical thickness	Endosteal surface	BV/TV	TbN	Connectivity density
Normal NH <sub>4</sub> Cl	+	-5.7% *	-4.1%	+14.1% *	11.7%	-24.7% *	-24.4% *
OVX + NH <sub>4</sub> Cl		-5.7% *	-4.8%	+6.3%	-7.1%	-7.4%	-5.6%

\* denotes p at least < 0.5 by Dunnett

The table illustrates that MA significantly decreased total BMD and reduced cortical thickness in both normal and OVX rats at 10 weeks. Cortical thinning resulted from endosteal resorption without any change in periosteal circumference. MA also significantly diminished trabecular number (TbN) without any change in trabecular thickness (TbTh), and as a consequence, increased trabecular separation in normal rats. In addition, MA decreased connectivity density. In OVX rats, MA induced similar changes but most of the effects did not reach statistical significance. Increases in the structure model index (SMI) were seen in normal rats with MA at week 10, indicating progressive conversion of plate like structures into more rod like structures. MA also increased TRAP5b activity without any significant change in osteocalcin in the two groups.

MA significantly changes bone parameters in both, OVX and estrogen replete rats, primarily by a) increasing endosteal bone resorption and b) decreasing TbN. MA apparently increases endosteal bone resorption and induces impaired bone microarchitecture in rats in vivo.

**Therapeutic Effects of One-year Alendronate Treatment in Three Cases of Osteoporosis with Parietal Thinning.** S. Takata<sup>1</sup>, N. Yasui<sup>1</sup>, S. Takao<sup>\*2</sup>, S. Yoshida<sup>\*2</sup>. <sup>1</sup>Orthopedics, Institute of Health Biosciences, The University of Tokushima Graduate School, Tokushima, Japan, <sup>2</sup>Radiology, The University of Tokushima, Tokushima, Japan.

Parietal thinning is defined as external thinning of the parietal bone of the skull. External thinning of the posteromedial part of the bilateral parietal bones is a morphological characteristic of the skulls of osteoporotic patients with parietal thinning. There are two types of parietal thinning of the skull, flat and grooved and most cases of parietal thinning are of the flat type. At this time, the reasons for excessive bone resorption in the skull, especially in the posteromedial part of the parietal bone in osteoporotic patients, as well as the reasons for enhanced external lamina bone resorption remain unclear.

We studied the therapeutic effects of one-year alendronate treatment in three cases (two males and one female) of osteoporosis with parietal thinning of skull. Plain radiography and three dimensional computed tomography revealed asymmetric external thinning of the posteromedial part of the bilateral parietal bones. Parietal thinning of our three cases was of the flat type.

Technetium-99m methylenediphosphate bone scintigraphy did not show any changes in these three cases. Pretreatment levels of urinary type I collagen cross-linked N-telopeptides (NTX) in all three cases were high compared to the normal range. Pretreatment levels of serum bone-specific alkaline phosphatase (BAP) in the two male patients were high in contrast to the normal values in the female patient. Pretreatment mean bone mineral density (BMD) values of the 2nd to 4th lumbar vertebrae (L2-4BMD), head BMD, femoral neck BMD, and whole body BMD of all three patients were low compared with the respective normal ranges.

One-year alendronate treatment increased the whole body BMD in all three cases, the L2-4BMD of the female patient, the femoral neck BMD of the female patient and one male patient, and the head BMD of the female patient when compared to pretreatment levels. This treatment decreased both urinary NTX and serum BAP in all three cases to normal values.

**Different Influence of the Clinical Condition, Degree of Cholestasis, Alcohol Abuse and Serum Calcium on the Musculoskeletal System in Chronic Cirrhotics.** S. E. Ferretti<sup>\*1</sup>, R. F. Capozza<sup>\*2</sup>, G. R. Cointny<sup>\*2</sup>, S. Feldman<sup>\*2</sup>, M. R. Ulla<sup>2</sup>, H. Tanno<sup>\*2</sup>, J. L. Ferretti<sup>2</sup>. <sup>1</sup>Service of Gastroenterology & Hepatology, Univ Hospital, Faculty of Medicine, National University of Rosario, Rosario, Argentina, <sup>2</sup>CEMFOC, Faculty of Medicine, National University of Rosario, Rosario, Argentina.

This study analyzed the associations between indicators of the clinical condition (Child-Pugh Score -CPS, capturing bilirubinemia, albuminemia, prothrombin time, ascitis and encephalopathy-), degree of cholestasis (total bilirubinemia, plasma alkaline phosphatase -BRB, APase-), alcohol abuse, serum Ca and other biochemical variables, and tomographic (pQCT) indicators of bone mass (cortical CSA and BMC -CtA, CtC-, trabecular BMC and vBMD -TbC, vTbD-), cortical tissue mineralization (cortical vBMD -vCtD-), diaphyseal design (cross-sectional area moments of inertia -CSMI's-) and torsion strength (*Stress-Strain Index* -SSI-) and muscle mass (height-adjusted muscle CSA -mCSA-) of the radii (4% and 66% sites) and tibiae (4%, 14%, 38% & 66% sites) of 43 chronic cirrhotics (18 men) of alcoholic, viral, cryptogenetic, autoimmune or cholestatic etiology, aged 18-69 yr. Bone and muscle pQCT data were expressed as Z-scores calculated for every patient taking those of healthy men (60) and women (200) of comparable age as a control reference.

The cirrhotic sample showed reduced TbC, vTbD and mCSA, while CtA, CtC, vCtD, CSMI's and SSI were unaffected. The proportion between cortical bone mass (tibia + fibula CtA) and muscle CSA at the 66% site of the leg (calf) was reduced. Trabecular bone loss correlated with CPS (especially with its component, albuminemia) and with the degree of cholestasis only when alcohol abusers were excluded from the analyses. Muscle loss correlated with CPS but not with the degree of cholestasis. Alcohol abusers showed always these alterations, regardless of CPS and degree of cholestasis. Serum Ca did not correlate with any other indicator. No differences were detected in those analyses between forearm and leg pQCT data. The chronic cirrhosis condition reduced trabecular mass (and obviously the compressive strength of the trabecular network) in correlation with the severity of the disease and cholestasis, with little or no affection of cortical mass, design, or strength. It reduced also correlatively muscle mass, regardless of the degree of cholestasis. However, the metabolic disturbance seemed to have reduced the impact of muscle-bone interactions in terms of bone mass (not material quality, design, or strength) related to muscle mass in the studied sample. The generally negative impact of alcohol abuse on all those properties was unrelated to any other influence.

**Detrimental Effects of Abdominal Irradiation on the Skeleton in Growing Mice.** D. Jia<sup>1</sup>, R. J. Griffin<sup>\*1</sup>, R. Halakatti<sup>\*1</sup>, L. J. Suva<sup>2</sup>, D. Gaddy<sup>3</sup>, N. S. Ake<sup>1\*3</sup>, C. Jackson<sup>\*1</sup>, C. Thompson<sup>\*4</sup>, P. M. Corry<sup>\*1</sup>. <sup>1</sup>Department of Radiation Oncology, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>2</sup>Department of Orthopedics, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>3</sup>Department of Physiology, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>4</sup>U Arkansas at Little Rock, Little Rock, AR, USA.

Partial abdominal ionizing irradiation (AI) is a common clinical anti-tumor modality. AI can induce responses in distant organs presumably through systemic mechanisms. The effects of AI on the skeleton of 10-week-old male C57BL/6 mice was evaluated following a single dose of 0 or 20 Gy x-ray irradiation to the abdomen, with the skeleton shielded. The mice were monitored daily for 8 days. Blood was collected at day 8 for measurement of bone turnover markers; bone marrow collected from tibiae and femora for *ex vivo* bone cell differentiation and stromal cell colony assay; lumbar vertebrae, femora and tibiae assessed by DEXA for baseline and final bone mineral content and density (BMC and BMD). The tibiae were analyzed by microCT to determine architectural properties of cancellous bone in the proximal metaphysis as well as cortical geometry in the mid-diaphysis. DEXA scanning of the proximal one-third of the tibia revealed a decrease in BMD in the irradiated mice, compared with an increase in the controls (-5.3% vs 7.9%, *p* < 0.001). This was accompanied by changes in BMC (-7.9% vs. 9.9%, *p* < 0.001). Similar effects on BMD and BMC in the distal femora, but not the lumbar vertebrae, were observed. MicroCT assessment of the proximal tibia revealed significantly lower BV/TV and Tb.Th in irradiated mice than in the controls (0.137 vs. 0.110, and 0.053 mm vs. 0.048 mm, respectively, *p* < 0.01). Decreased BMD and BMC in the tibial midshaft, but not femoral midshaft, were also detected by DEXA in the irradiated mice, compared with increased parameters in the controls (-1.79% vs 8.52%, -7.56% vs 13.85%, respectively, *p* < 0.001). Tibial midshaft geometry, assessed by microCT, showed no difference between the two groups. Serum TRAP5b increased while osteocalcin decreased in irradiated mice as compared with the controls (*p* < 0.05). *Ex vivo* bone marrow osteoblast differentiation and stromal cell colony formation were suppressed following AI (*p* < 0.01). By contrast, bone marrow osteoclast formation was similar between the two groups, suggesting differential cell responses to AI. Our data demonstrate that AI has adverse abscopal effects on both cancellous and cortical bone in growing mice in a site-specific manner. The effects are manifested by altered activity of mature osteoblasts and osteoclasts. The cellular effects may result from direct responses to AI-induced signals, or be mediated by osteoblast progenitors/stroma-derived molecules.

**Mechanisms of Endplate Failure in the Human Vertebral Body.** A. J. Fields\*, T. M. Keaveny. Mechanical Engineering, University of California, Berkeley, Berkeley, CA, USA.

Understanding the failure mechanisms associated with vertebral fracture is important for assessing fracture risk and may provide insight into fracture etiology. Recent work suggests that the cortical endplates should play a role in the clinical diagnosis of these fractures, and thus, this study focused on the biomechanical behavior of endplate tissue. Using micro-CT-based finite element analysis of 22 human T9 whole vertebral bodies (age range: 53-97 years, 81.5±9.6 years), we sought to quantify the amount of endplate tissue at high risk of failure during compressive loading and to identify the regions where this high-risk tissue occurs. Each model (posterior elements removed) was loaded through a simulated intervertebral disc. To isolate the cause of the high-risk tissue, we performed a second set of analyses in which we removed the ability of the disc to bulge when compressed. Results indicated that the high-risk endplate tissue was strained almost exclusively in tension, indicating a unique failure mechanism of the endplates since the high-risk tissue in the cortical shell and trabecular compartments was strained proportionately more in compression. Within both endplates, the largest concentrations of high-risk tissue were in the mid-sagittal and mid-frontal regions--the locations where the endplates are thinnest. The amount of high-risk tissue comprised 20.8±6.6% of the inferior endplate bony tissue and 27.8±7.7% of the superior endplate (*p*=0.002, paired t-test) tissue, representing 8.9±2.4% and 10.2±2.1% of the total amount of high-risk bone in the vertebrae, respectively. When the disc bulging effect was removed from the models, the amount of high-risk endplate tissue decreased by over 70% and was largely due to a reduction in tensile strains in the endplates (Figure). We conclude that the endplate tissue at high risk of initial failure is primarily loaded in tension and that the development of such tensile strains is associated with bulging of the intervertebral disc.

**Acute Chronic Obstructive Pulmonary Disease (COPD) Exacerbations Are Associated with Uncoupling of Bone Resorption from Bone Formation.** A. Hutchinson<sup>\*1</sup>, M. Thompson<sup>\*1</sup>, D. Smallwood<sup>\*1</sup>, S. Bozinovski<sup>\*2</sup>, G. P. Anderson<sup>\*2</sup>, L. Irving<sup>\*1</sup>, P. R. Ebeling<sup>3</sup>. <sup>1</sup>Depts. Respiratory Medicine, CEHSEU and CCRED, The Royal Melbourne Hospital, Parkville, Australia, <sup>2</sup>Pharmacology Department, CRCID, University of Melbourne, Western Hospital, Footscray, Australia, <sup>3</sup>Dept. of Medicine (RMH/WH), University of Melbourne, Western Hospital, Footscray, Australia.

COPD is an independent risk factor for minimal trauma fractures and osteoporosis. Inhaled corticosteroids (ICS) reduce bone formation markers, while acute exacerbations (AECOPD) increase inflammatory markers. We first compared biochemical bone turnover markers in 61 patients with stable COPD on high-dose ICS with 58 sex-matched, healthy controls. Second, we measured acute changes in bone turnover markers, highly sensitive C-reactive protein (hsCRP), and insulin-like growth factor-1 (IGF-1) during AECOPD. Early morning, fasting samples were obtained during stable COPD and Day 1 to 7 after AECOPD onset. To assess the affect of maintenance ICS on bone turnover, we compared serum  $\beta$  C-telopeptide ( $\beta$ -CTX) and type 1 procollagen N-terminal propeptide (PINP) in stable COPD patients with sex-matched, healthy controls. Bone formation markers, serum osteocalcin and PINP; the bone resorption marker,  $\beta$ -CTX; hsCRP and IGF-1 were measured in AECOPD. In stable COPD, mean PINP (in men and women) and  $\beta$ -CTX levels (in men) were significantly lower than controls. For PINP: In men with COPD vs. controls 38 vs. 67 ng/mL, (*p* < 0.001); and in women with COPD vs. controls 33 vs. 51 ng/mL, (*p* < 0.002). For  $\beta$ -CTX: In men with COPD vs. controls 0.43 vs. 0.55 ng/mL, (*p*=0.03); and in women with COPD vs. controls 0.29 vs. 0.33 ng/mL (*p* = 0.52). At AECOPD onset (*n* = 17), there were significant acute decreases in both serum osteocalcin (-25%) and PINP (-32%) on day-3, after commencing high-dose systemic or oral corticosteroids. Significant increases in  $\beta$ -CTX (+24%; day-3; *p* < 0.01) and hsCRP (+30%; day-1; *p* < 0.01) occurred, the latter correlating with a decrease in bone formation, as measured by PINP. Uncoupling of bone formation from bone resorption occurs in stable COPD. In AECOPD bone formation decreases further, increasing the risk of bone loss and osteoporosis. This acute decrease in bone formation in AECOPD may be related to either inflammation or high-dose corticosteroids.

Table (n=17)				
% Change Median (range)	Day-1	Day-3	Day-5	Day-7
PINP	-41% (-78 to +267%)	-32% (-72% to 122%)	-30% (-72% to 62%)	-33% (-66% to 48%)
$\beta$ -CTX	+12.1% (-70% to 265%)	+24% (-63% to +200%)	+24% (-47% to +188%)	+50% (-100% to 236%)
IGF-1	-4.4 (-100 to +23%)	+40% (-100% to +44%)	-30% (-30% to +47%)	-30% (-34% to +72%)
Osteocalcin	-29% (-65 to 52)	-25% (-63% to 76%)	-67% (-100% to 44%)	-29% (-70% to +100%)
hsCRP	+30% (-70% to +3632%)	-8% (-100% to +2504)	-9% (-100 to +1012%)	+5% (-100% to +404%)

Disclosures: P.R. Ebeling, None.

**Impact of Adjuvant Hormonal Therapy on Bone Loss Depending on Initial Adjuvant Chemotherapy and Menstrual Status.** F. A. Tremollieres<sup>1</sup>, C. Frayssinet<sup>\*1</sup>, P. Leguevague<sup>\*2</sup>, J. M. Pouilles<sup>\*1</sup>, J. Hoff<sup>\*2</sup>, C. Ribot<sup>1</sup>. <sup>1</sup>Menopause Center, Hôpital Paule de Viguier, Toulouse, France, <sup>2</sup>Department of General and Gynaecological Surgery, CHU Rangueil, Toulouse, France.

In intermediate or high risk hormone receptor-positive (HR+) breast cancer (BC) women, adjuvant chemotherapy is standard treatment and usually followed by hormonal therapy. Tamoxifen (Tam) and aromatase inhibitors have been shown to have opposite effects on bone remodeling and the risk of fracture. However, it is not clear whether their

respective effect on bone might be influenced by initial chemotherapy (CT) and/or changes in menstrual status. We thus conducted a prospective study to determine whether the effect of adjuvant tamoxifen vs anastrozole (Ana) on bone loss was influenced by initial CT and menstrual status changes in early stage BC women.

One hundred and twelve women with early stage BC were followed over an average 28.8 month-period of time. 97 women with HR+ BC received either adjuvant Tam (n=55) or Ana (n=42) therapy. Of these women, 60 had received adjuvant CT prior to the beginning of hormonal treatment. The remaining 15 women with HR- BC received adjuvant CT only. The effect of menstrual status on BMD was further studied.

A significantly higher rate of vertebral bone loss was noted in women who received initial adjuvant CT as compared to those who did not, irrespective of the type of further adjuvant hormonal treatment (-2.5% vs -1.4%,  $p=0.0205$ ). However, such effect appeared mainly the consequence of premature ovarian failure. In postmenopausal women, Ana was associated with a significantly greater rate of femoral and total body bone loss compared to Tam. Accordingly, opposite effects of biochemical markers of bone turnover were found with a significant increase in osteocalcin levels and a significant reduction in serum CTX levels from baseline in Ana-treated women and those who received Tam, respectively. On the other hand, in pre-menopausal women who developed amenorrhea (n=19), Tam had no effect in preventing bone loss at all bone sites while a protective effect was observed in initially postmenopausal women who were further treated with Tam (n=20) (lumbar spine: -3.4% vs -0.64%,  $p=0.0002$ ; femoral neck: -1.6% vs +0.3%,  $p=0.037$ ; total body: -0.82% vs +0.003%,  $p=0.02$ ). In initially postmenopausal women, Tam induced a significantly greater decrease in serum osteocalcin and CTX levels compared to that in women who developed amenorrhea throughout follow-up. In conclusion, the impact of CT and the apparent lack of prevention of Tam on ovarian failure-induced bone loss in premenopausal women must be considered in the long-term preventive strategy of the risk of fracture in BC women. An evaluation of the risk of fracture should be recommended in all women from the beginning of therapy.

**Disclosures:** F.A. Tremollieres, None.

### Sex Steroids Have Site Specific Effects on Muscle and Bone Geometry in Young Adult Males. L. Edwards<sup>1</sup>, J. E. Adams<sup>1</sup>, P. L. Selby<sup>2</sup>, K. A. Ward<sup>1</sup>.

<sup>1</sup>Imaging Science and Biomedical Engineering, University of Manchester, Manchester, United Kingdom, <sup>2</sup>Medicine, Central Manchester and Manchester Childrens University Hospital NHS Trust, Manchester, United Kingdom.

Sex steroids are essential for skeletal development and the maintenance of bone health. The current study aimed to establish whether there were relationships between sex hormones and bone mineral density (BMD) and the geometric properties of the peripheral bones of young adult males (YM).

European Caucasian YM (18-24 years) were recruited (n=95). Fasting venous blood samples were taken for analysis of serum sex steroids. Peripheral quantitative computed tomography (pQCT) measurements were taken at the 4 and 50% non-dominant radius and 65% tibia. Dependent variables (DV) at the 4% radius included: Total and trabecular BMD (TotBMD and TrabBMD respectively mg/cm<sup>3</sup>) and total area (TA mm<sup>2</sup>). DV at the 50% radius / 65% tibia included: radius / tibia area (RA / TibA mm<sup>2</sup>) muscle cross sectional area (MCSA mm<sup>2</sup>), cortical bone mineral content (CBMC mg/mm), cortical BMD (CBMD mg/cm<sup>3</sup>), cortical thickness (CT mm), stress strain index (SSI mm<sup>3</sup>) and medullary area (MA mm<sup>2</sup>). Serum DV included: total testosterone (T<sub>t</sub> nmol/L) Total estrogen (E<sub>t</sub> pmol/L) sex hormone binding globulin (SHBG nmol/L) and albumin (Al g/L). Bioavailable estrogen (BE pmol/L) bioavailable testosterone (BT nmol/L), free estrogen (FE pmol/L) and free testosterone (FT nmol/L) were calculated from serum measured variables using standard calculations.

The influence of sex hormones upon bone variables was tested using ANCOVA controlling for height (cm), weight (Kg). There were no significant findings for the sex hormones at the 4% radius. SHBG was significant for TA ( $p=0.022$ ) and TrabBMD ( $p=0.022$ ). At the 50% radius: T<sub>t</sub> was significant for MCSA ( $p=0.017$ ), RA ( $p=0.011$ ), SSI ( $p=0.027$ ) and MA ( $p=0.024$ ); SHBG was significant for RA ( $p=0.013$ ), MCSA ( $p=0.003$ ) CBMD ( $p=0.005$ ), SSI ( $p=0.013$ ) and MA (0.032). At the 65% tibia: E<sub>t</sub> was significant for CBMC ( $p=0.028$ ) and CT ( $p=0.026$ ); SHBG and T<sub>t</sub> were significant for MCSA ( $p=0.029$  and 0.010 respectively); bioavailable oestrogen and free oestrogen were significant for CT ( $p=0.049$  and 0.040 respectively). Bioavailable and free testosterone were not significant at any of the skeletal sites.

These data suggest that there are site specific differences in the effect of sex hormones and SHBG on bone. In the radius, total testosterone and SHBG are important in determining bone geometric parameters and MCSA. In the tibia, bone geometry and BMD are influenced by total, bioavailable and free estrogen; total testosterone and SHBG also have an effect on muscle. In conclusion, in young adult males an important determinant of the geometric properties of the radius is testosterone and for the tibia, estrogen.

### Homocysteine Accumulates in Bone Tissue by Collagen Binding and Adversely Affects Bone. M. Herrmann<sup>\*1</sup>, A. Tami<sup>\*2</sup>, B. Wildemann<sup>\*3</sup>, M. Wolny<sup>\*3</sup>, A. Wagner<sup>\*4</sup>, H. Schorr<sup>\*4</sup>, O. Taban-Shomal<sup>\*4</sup>, N. Umanskaya<sup>\*5</sup>, S. Ross<sup>\*5</sup>, P. Garcia<sup>\*4</sup>, U. Huebner<sup>\*4</sup>, W. Herrmann<sup>\*5</sup>. <sup>1</sup>Bone Research Program, ANZAC Research Institute, Concord, Australia, <sup>2</sup>AO Foundation, Davos, Switzerland, <sup>3</sup>Charite Universitaetsmedizin, Berlin, Germany, <sup>4</sup>University Hospital of Saarland, Homburg, Germany, <sup>5</sup>Bone Research Program, University Hospital of Saarland, Homburg, Germany.

Recently, hyperhomocysteinemia (HHCY) has been suggested to have adverse effects on bone. This study investigated if an experimental hyperhomocysteinemia (HHCY) in rats induces an accumulation of HCY in bone tissue that is accompanied by a reduced bone quality. HHCY was induced in healthy rats by either a methionine (Meth)- or a homocystine (Homo)-enriched diet and compared with controls. Tissue and plasma concentrations of homocysteine (HCY), S-adenosylhomocysteine (SAH) and S-adenosylmethionine (SAM) were measured. Bone quality was assessed by biomechanical testing, histomorphometry,  $\mu$ CT and the measurement of biochemical bone turnover markers in plasma. Meth and Homo animals developed a significant HHCY that was accompanied by a tissue specific accumulation of HCY (1300 to 2000% vs. controls). 65% of HCY in bone was bound to collagen of the extracellular matrix. The SAH / SAM-ratio in bone and plasma of Meth and Homo animals exhibited a tissue specific increase indicating a reduced methylation capacity. Accumulation of HCY in bone was characterized by a distinct reduction of trabecular bone (proximal femur: -25 to -35%; distal femur -56 to -58%, proximal tibia: -28 to -43%). Accordingly, bone strength was significantly reduced (-9 to -12%). A tissue specific accumulation of HCY in bone may be a promising mechanism explaining adverse effects of HHCY on bone. A reduced methylation capacity of bone cells might be another relevant pathomechanism.

### Central Control of Bone Remodeling: The Neurohypophysial Hormone Oxytocin Is Decreased In Severe Post-menopausal Osteoporosis. V. Breuil<sup>1</sup>,

E. Amri<sup>\*2</sup>, J. Testa<sup>\*3</sup>, C. H. Roux<sup>\*1</sup>, P. Ferrari<sup>\*4</sup>, C. Albert-Sabonnadière<sup>\*1</sup>, C. Elabd<sup>\*2</sup>, G. Ailhaud<sup>\*2</sup>, C. Dani<sup>\*2</sup>, G. f. Carle<sup>5</sup>, L. Euler-Ziegler<sup>\*1</sup>. <sup>1</sup>Rheumatology, CHU de Nice, Nice, France, <sup>2</sup>ISBDC - Université Sophia-Antipolis, CNRS, Nice, France, <sup>3</sup>Statistics & Epidemiology, CHU de Nice, Nice, France, <sup>4</sup>Laboratory of Hormonology, CHU de Nice, Nice, France, <sup>5</sup>GEPITOS - Université Sophia-Antipolis, CNRS, Nice, France.

Oxytocin (OT) is a neurohypophysial hormone; its receptor is expressed on bone cells. In a study, we demonstrated in rodents that OT negatively modulates adipogenesis while promoting osteogenesis; in ovariectomized mice, OT serum levels were decreased and subcutaneous OT injection reversed bone loss.

**In this study** we measured OT serum levels in post-menopausal OP and its relationships with body composition and hormonal factors.

**Subjects and Methods** We measured serum levels of OT, high sensitive estradiol, testosterone, FSH, LH, SHBG, TSH, osteocalcin, crosslaps, leptin and body composition by DEXA in post-menopausal women with severe OP compared to non OP women.

**Results** Main results are presented in the following table as means  $\pm$  SEM.

group	age (years)	weight (kg)	fat mass (kg)	BMI (kg/m <sup>2</sup> )	OT pg/ml	leptin ng/ml	estradiol pg/ml	BMD femoral neck (T-score SD)
control (n=16)	67.31 $\pm$ 6.19	75.8 $\pm$ 17.5	31.8 $\pm$ 10.7	30.35 $\pm$ 6.58	110.64 $\pm$ 79.12	6.20 $\pm$ 2.70	21.51 $\pm$ 11.23	-0.069 $\pm$ 0.677
OP (n=20)	73.25 $\pm$ 9.17	61.1 $\pm$ 9.5	23.9 $\pm$ 7.1	26.24 $\pm$ 4.33	50.22 $\pm$ 39.16	3.71 $\pm$ 1.42	24.47 $\pm$ 7.68	-1.948 $\pm$ 0.748
p	0.04	0.002	0.03	0.08	<b>0.0001</b>	<b>0.002</b>	ns	<0.001

In OP women, fat mass and lean mass were significantly decreased in absolute values. OT serum level was significantly correlated to BMD (spine,  $r=0.64$  and hip,  $r=0.55$ ) but not to all others measured parameters. Leptin was significantly correlated to BMI ( $r=0.74$ ), fat mass ( $r=0.67$ ), lean mass ( $r=0.52$ ) and BMD (spine,  $r=0.48$ ) and hip  $r=0.55$ ). In logistic regression analysis, OP remains significantly correlated to OT ( $p<0.05$ ) and leptin levels ( $p<0.05$ ) regardless of age.

**Conclusion:** OT serum level is significantly decreased in OP, independently of leptin and estradiol, that are known to modulate OT secretion. Thus, OT appears as a new interesting factor in the OP pathophysiology.

**Bridging Vascular Calcification and Osteoporosis: The Function of Receptor Activator of Nuclear Factor  $\kappa$ B.** C. Byon<sup>\*1</sup>, J. Chen<sup>\*2</sup>, J. McDonald<sup>2</sup>, Y. Chen<sup>2</sup>. <sup>1</sup>Cell Biology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Clinical studies support an association between atherosclerosis/vascular calcification and osteoporosis, suggesting possible common pathophysiological mechanisms. Oxidative stress has been linked to both bone loss and vascular calcification. Our previous studies have demonstrated that hydrogen peroxide ( $H_2O_2$ ), at non-toxic concentrations, induces oxidative stress and promotes osteogenic differentiation and calcification of vascular smooth muscle cells (VSMC). Multinucleated tartrate-resistant acid phosphatase (TRAP)-positive osteoclast-like cells have been identified in calcified atherosclerotic lesions. Therefore, we sought to determine whether  $H_2O_2$ -induced VSMC calcification contributes to osteoclastogenesis.

We found a 33-fold increase in the transcripts of receptor activator of nuclear factor  $\kappa$ B (RANKL), as determined by real-time PCR, during  $H_2O_2$ -induced VSMC calcification. Further, increased expression of RANKL protein in VSMC under oxidative stress was demonstrated by ELISA and flow cytometry analysis. With the use of a series of deletion constructs of the murine RANKL promoter-driven luciferase reporter, we determined that  $H_2O_2$  responsive region is located between -200 to -400 in the 5'-flanking regions of RANKL gene. Analyses of the sequence of this region identified multiple binding sites of the key osteogenic transcript factor, Runx2, which we have reported to be essential for  $H_2O_2$ -induced VSMC calcification.  $H_2O_2$ -induced RANKL expression was blocked in VSMC with Runx2 knockdown by lentivirus-carrying shRNA for Runx2.

To determine whether  $H_2O_2$ -induced RANKL in VSMC is functionally active, we determined the effects of  $H_2O_2$ -induced RANKL in VSMC on osteoclastogenesis of bone marrow macrophages (BMM) in a co-culture system. After exposure to  $H_2O_2$  for two weeks, VSMC (wild-type) induced the differentiation of BMM into multinucleated TRAP-positive cells. Addition of osteoprotegerin (OPG) inhibited osteoclastogenesis of BMM when co-cultured with VSMC. By contrast, VSMC from RANKL deficient mice failed to induce differentiation of BMM into TRAP-positive multinucleated cells, which was restored when recombinant RANKL protein was added in culture media.

We have demonstrated that  $H_2O_2$  up-regulates the expression of RANKL during VSMC calcification and it is dependent upon the expression of Runx2. VSMC-derived RANKL induces osteoclastogenesis of BMM, which may contribute to the genesis of TRAP-positive multinucleated cells in atherosclerotic lesions and may provide a mechanism for oxidative stress-induced bone loss attributed to increased osteoclastogenesis.

**Effect of Risedronate on Osteocyte Viability in Paired Biopsies from Early Postmenopausal Women.** S. Qiu<sup>1</sup>, R. Phipps<sup>2</sup>, S. Palnitkar<sup>\*1</sup>, D. Rao<sup>1</sup>. <sup>1</sup>Bone and Mineral, Henry Ford Hospital, Detroit, MI, USA, <sup>2</sup>Procter & Gamble, Mason, OH, USA.

There is strong evidence that estrogen deficiency can accelerate osteocyte death by apoptosis. Increased osteocyte apoptosis may compromise bone quality for postmenopausal women. The purpose of this analysis was to determine whether 1 year risedronate treatment affected osteocyte viability in early postmenopausal women (within 1-5 years postmenopause).

Paired iliac bone biopsies were obtained from 19 postmenopausal women at baseline and after 1 year of treatment with placebo (n = 8; Age:  $52.9 \pm 3.44$  years) or risedronate (n = 11; Age:  $52.5 \pm 3.36$ ). From 5  $\mu$ m sections stained with goldner trichrome, we measured the following osteocyte related variables in trabecular bone: osteocyte density (Ot.Dn), empty lacunar density (EL.Dn), total lacunar density (TL.Dn) and the percent empty lacunae (EL/TL). Coefficient of variation [CV (%) = SD/mean \* 100] of each variable was computed from ten measured areas to determine the homogeneity of osteocyte and empty lacunar distribution. The difference in each variable between baseline and 1-year biopsies was compared for each group using paired t-test. ANCOVA was used to compare the difference in each variable between 1-year biopsies with placebo and risedronate treatment by adjusting for the corresponding variable from baseline biopsies.

In both placebo and risedronate groups, EL.Dn and EL/TL were significantly lower at 1 year compared to baseline, but there was no significant difference in TL.Dn and CV for each variable between baseline and 1 year (Table 1). In addition, there was no significant difference in any variable between placebo and risedronate treatment at 1 year.

In conclusion, the present study suggests that while risedronate effectively inhibits bone remodeling (data not shown), at least in early postmenopausal women it does not influence osteocyte death or impair osteocyte distribution. An unexpected observation was that the empty lacunae were significantly decreased at 1 year in the placebo treated group. Although a site-specific difference cannot be excluded (baseline and 1-year biopsies were obtained from right and left iliac crests), a possible explanation is that osteocyte apoptosis is a short-term, transient phenomenon after estrogen depletion.

Variables	Placebo (n = 8)		Risedronate (n = 11)	
	Baseline	1-Year	Baseline	1-Year
Ot.Dn (#/mm <sup>2</sup> )	134 (13.2)	162 (43.1)*	154 (31.3)	179 (28.9)
EL.Dn (#/mm <sup>2</sup> )	48.1 (13.2)	27.2 (9.31)**	39.0 (8.07)	27.9 (8.17)*
TL.Dn (#/mm <sup>2</sup> )	183 (22.0)	189 (48.4)	193 (28.4)	207 (27.1)
EL/TL.N (%)	26.6 (5.14)	14.9 (3.21)**	21.2 (6.17)	14.0 (5.37)*

**Serum Level of  $\gamma$ -glutamyltransferase (sGGT) Is One of the Factors That Determines the Response to Alendronate Treatment in Osteoporotic Women.** Y. Sakamoto<sup>\*1</sup>, M. Ishijima<sup>1</sup>, M. Yamanaka<sup>\*1</sup>, K. Kitahara<sup>\*1</sup>, A. Tokita<sup>\*2</sup>, H. Kurosawa<sup>\*1</sup>. <sup>1</sup>Orthopaedics, Juntendo University School of Medicine, Tokyo, Japan, <sup>2</sup>Pediatrics, Juntendo University School of Medicine, Tokyo, Japan.

Serum level of  $\gamma$ -glutamyltransferase ( $\gamma$ -GTP/GGT) is known as a marker for alcohol consumption, liver dysfunction and biliary tract disorders. Recently, GGT is reported to act as a bone-resorbing factor that stimulates osteoclast formation by animal studies. However, it is still remained obscure whether GGT regulates bone metabolism in human. The present study examined to determine whether sGGT is involved in the effect of alendronate (ALN) to increase in lumbar bone mineral density (L-BMD) in osteoporosis. A total of fifty-five postmenopausal women (age 58 to 86) with primary osteoporosis enrolled in this prospective study. All the patients of this study took 5mg of ALN daily for twelve months. L-BMD was measured at baseline and six and twelve months of the treatment. Serum levels of bone specific alkaline phosphatase (BAP), calcium, phosphate, creatinine, total protein (TP), lactate dehydrogenase, aminotransferases, GGT, intact-parathyroid hormone, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D and urinary N-terminal telopeptides of type I collagen (NTX) and deoxypyridinoline (DPD) were also measured. Multiple regression analysis was conducted to investigate the associations between the biochemical markers at six months and their percent change (%change) for six months as potential predictor variables listed above with the %change in L-BMD for twelve months as outcome variable. A p value less than 0.05 was considered to be statistically significant. Multiple regression analysis showed that, in addition to %change of NTX ( $\beta = -0.48$ ) and basal level of TP ( $\beta = -0.27$ ), basal level of sGGT ( $\beta = -0.33$ ) was one of the factors that determines the increase in L-BMD by ALN ( $R^2 = 0.35$ ,  $p < 0.05$ ). %change of sGGT for twelve months showed positive correlation with %change in BMD ( $r = 0.33$ ,  $p < 0.05$ ) and negative correlation with %changes of BAP and DPD for twelve months ( $r = -0.45$ ,  $p < 0.01$  and  $r = -0.39$ ,  $p < 0.01$ , respectively). Bisphosphonate is reported to increase bone mass via activation of OPG expression (Osteoporos Int 06). GGT stimulates RANKL expression and bone resorption (J Biol Chem 04). Combined with all these data and our result, GGT is speculated to activate bone resorption by stimulating RANK-RANKL-OPG system via unique pathway independent from that of bisphosphonate. This is a first report to suggest that sGGT is involved in bone metabolism in human and, furthermore, may be able to shed light on an unknown mechanism of bone resorption. In conclusion, basal level of sGGT was independent predictor of the increase in L-BMD by the ALN treatment.

**Solid-State <sup>31</sup>P MRI Quantifies Mineralization Changes in OVX Rat Bone.** S. Anumula<sup>1</sup>, D. Horng<sup>\*1</sup>, S. L. Wehrli<sup>\*2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>Radiology, University of Pennsylvania Medical Center, Philadelphia, PA, USA, <sup>2</sup>NMR Core Facility, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Postmenopausal osteoporosis is characterized by lower bone volume fraction and reduced degree of mineralization of bone (DMB) resulting in an imbalance between bone formation and resorption. There is currently no noninvasive technique for measuring DMB. Here we examined the hypothesis that 3D <sup>31</sup>P solid-state magnetic resonance imaging (<sup>31</sup>P MRI) is able to detect the increase in mineralization upon treatment with alendronate (ALN) in the ovariectomized (OVX) rat. The study involved nine OVX rats (four month old) treated with ALN (5 $\mu$ g/kg/day) compared to eleven sham-operated rats (NO) and eleven OVX rats of the same age. All animals received standard chow and water *ad libitum* for 50 days at which time they were euthanized and cortical bones extracted from the right and left femurs. <sup>31</sup>P MRI was performed at 9.4 Tesla field strength on a vertical bore superconducting system (DMX-400, Bruker Instruments, USA) in conjunction with a home-built solenoid coil using a previously developed 3D radial imaging sequence. The specimens were co-imaged with a reference phantom of 2M  $K_2HPO_4$  in order to quantify mineral <sup>31</sup>P concentration. The k-space data were reconstructed off-line yielding an isotropic resolution of 157  $\mu$ m. MRI results were compared with ash weight and ultimate strength (US) derived from three-point bending. Phosphorus concentration obtained by <sup>31</sup>P MRI was found to return toward normal levels in ALN treated bones (Fig. 1). This result was paralleled by increased ash weight and US although the latter was not significant (Table 1).

**Fig. 1 Phosphorus concentration indicating recovery of OVX bone after treatment with ALN.**

**Table 1 Measures of DMB and ultimate strength quantified by different modalities in NO, OVX and ALN groups (mean $\pm$  SD)**

Group	$^{31}\text{P MRI}$ (wt %)	Ash (wt %)	US (N/mm $^2$ )
NO	8.2 $\pm$ 0.6 <sup>a</sup>	65.4 $\pm$ 1.1 <sup>a</sup>	147.2 $\pm$ 17.6 <sup>b</sup>
OVX	7.1 $\pm$ 0.4	65.2 $\pm$ 1.2	137.9 $\pm$ 12.3
ALN	7.6 $\pm$ 0.5 <sup>a</sup>	66.5 $\pm$ 1.1 <sup>a</sup>	147.5 $\pm$ 15.5 <sup>b</sup>

<sup>a,b</sup>ALN, NO versus OVX ( $p \leq 0.01$ ;  $p > 0.05$ , respectively)

In conclusion, our data suggest that  $^{31}\text{P MRI}$  may have potential for noninvasive monitoring of the changes in mineral metabolism in response to hormonal changes and treatment

**Psychotropic Drugs Have Contrasting Skeletal Effects that Are Independent of Their Negative Effects On Activity Levels.** S. J. Warden<sup>1</sup>, S. M. Hassett<sup>1</sup>, J. L. Bond<sup>1</sup>, J. Rydberg<sup>1</sup>, J. D. Grogg<sup>1</sup>, E. L. Hilles<sup>1</sup>, R. K. Fuchs<sup>1</sup>, M. M. Bliziotis<sup>2</sup>, C. H. Turner<sup>3</sup>. <sup>1</sup>Department of Physical Therapy, Indiana University, Indianapolis, IN, USA, <sup>2</sup>Oregon Health and Science University, Portland, OR, USA, <sup>3</sup>Department of Biomedical Engineering, Indiana University-Purdue University, Indianapolis, IN, USA.

Psychotropic drugs (incl. selective serotonin reuptake inhibitors [SSRIs], tricyclic antidepressants [TCAs] and lithium) are prescribed to treat depression and other affective disorders. Preclinical studies have shown negative skeletal effects of psychotropic drugs; however, it is unclear whether these changes resulted from drug effects on animal physical activity levels. Psychotropic drugs act on the central nervous system and induce a hypoactive (skeletal unloading) phenotype in mice. This study removed this potential confounder by investigating psychotropic drug effects in animals with complete unloading. Eighty female Swiss-Webster mice were purchased at 4 wk of age and randomly divided into two activity groups: 1) cage control (ACTIVE), and; 2) tail suspended (INACTIVE). Animals within each activity group were randomly divided into four drug groups: 1) vehicle treated (VEH); 2) fluoxetine hydrochloride (20 mg/kg) treated (SSRI); 3) desipramine hydrochloride (20 mg/kg) treated (TCA), and; 4) lithium chloride (200 mg/kg) treated (LICL). *In vivo* assessments of hindlimb areal (aBMD) and proximal tibia volumetric (vBMD) BMD were performed at baseline and following 4 wk of intervention. Femurs and lumbar vertebrae were subsequently removed and assessed *ex vivo* for aBMD and vBMD, as well as trabecular bone architecture (bone volume fraction [BV/TV]). Drug reduced activity levels in ACTIVE, with LICL traveling half the total distance of VEH, SSRI and TCA. There were no differences in distance traveled between VEH, SSRI and TCA. There were no activity and drug interactions on skeletal measures indicating that their effects were independent. There were drug effects for most outcomes, with SSRI and LICL having inferior and superior bone properties than all other groups, respectively. For instance, SSRI gained 9.0% less proximal tibia vBMD and

had 3.1% less lumbar vertebrae BV/TV than VEH, whereas LICL gained 6.7% more proximal tibia vBMD than VEH. There were limited differences between TCA and VEH. These data indicate that psychotropic drugs have contrasting skeletal effects that are independent of any physical inactivity induced by these drugs. Of particular note is the inferior bone properties observed with SSRI. This observation is consistent with the recent findings of functional serotonin pathways in bone and clinical studies demonstrating accelerated bone loss with SSRIs.

**Osteogenic Action of Exendin-4 in Normal and Insulin-Resistant State.** B. Nuche-Berenguer<sup>1</sup>, P. Moreno<sup>1</sup>, L. Arnés<sup>1</sup>, S. Dapía<sup>2</sup>, P. Esbrit<sup>3</sup>, M. Villanueva-Peñacarrillo<sup>1</sup>. <sup>1</sup>Metabolism, Nutrition & Hormones, Fundación Jiménez Díaz, Madrid, Spain, <sup>2</sup>Trabeculae, Orense, Spain, <sup>3</sup>Bone & Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

**Background and Aims:** A role of incretins in changes in bone turnover, occurring after meals, was suggested. Exendin-4 (Ex-4) mimics GLP-1 (glucagon-like peptide 1) action on glucose metabolism in extrapancreatic tissues, is agonist of its specific receptors, and also has insulinotropic, antidiabetic and anorectic effects. We explored the possible *in vivo* effect of Ex-4 upon bone turnover markers in normal rats (N) and in an insulin-resistant model (IR).

**Materials and Methods:** IR was induced in adult Wistar rats by 8 weeks feeding with standard chow plus 20% D-fructose in the drinking water. N (n=21) and IR (n=20) were treated -osmotic pump- with saline (control) or Ex-4 (0.1 nmol/kg/h). In fed conditions, blood samples were taken before (basal) and by ending the treatment; femurs and tibiae were collected. Measurements: *in plasma*, osteocalcin (OC), tartrate-resistant acid phosphatase (TRAP) -ELISA-, insulin -RIA- and glucose. *In tibia*, osteocalcin, osteoprotegerin (OPG) and RANK ligand (RANKL) mRNA -rt-PCR-. Femoral bone structure was evaluated by  $\mu\text{CT}$  (n=3 rats/group).

**Results:** *In plasma* (n=10-15): Ex-4 did not modify basal OC in N (406.24 $\pm$ 16.6 ng/ml) or IR group (271.0 $\pm$ 12.3 ng/ml,  $p < 0.0001$  vs N); N basal TRAP (2.25 $\pm$ 0.23 U/l) was not modified by Ex-4, while in IR, with lower than N ( $p < 0.016$ ) value (1.50 $\pm$ 0.15 U/l), it reduced it (-33.5 $\pm$ 10.7%  $\Delta$  of basal,  $p < 0.05$ ); basal insulin and glucose were similar in all groups at any condition. *In tibia* (n=7-11): OC mRNA level in IR was 0.49 $\pm$ 0.09 times N ( $p < 0.001$ ), and Ex-4 increased it in N (1.7 $\pm$ 0.1 times control,  $p < 0.02$ ) and IR (3.6 $\pm$ 0.3 times control,  $p < 0.05$ , and  $p < 0.05$  vs N Ex-4-treated); OPG mRNA in IR was 0.66 $\pm$ 0.12 times that in N ( $p < 0.02$ ), and Ex-4 increased it in N (2.36 $\pm$ 0.20 times control,  $p < 0.001$ ), and even more in IR (4.76 $\pm$ 0.43 times control,  $p < 0.001$ ); RANKL mRNA was lower ( $p < 0.001$ ) in IR (0.56 $\pm$ 0.08 times N), and Ex-4 decreased the value in N (0.63 $\pm$ 0.07 times control,  $p < 0.01$ ), but stimulated it in IR (2.73 $\pm$ 0.49 times control,  $p < 0.02$ , and  $p < 0.0001$  vs N Ex-4-treated). In IR, OPG/RANKL mRNA ratio was 1.18-fold N, and Ex-4 increased it to 3.76 in N and to 1.74-fold in IR. *In femur*, trabecular thickness and anisotropy in IR were higher and lower, respectively, than in N, and no changes were observed after Ex-4; yet, both cortical thickness and momentum of inertia, higher than in N, were increased even further by Ex-4 treatment.

**Conclusion:** Several changes in bone markers and structure suggest a low bone turnover rate in this insulin-resistant model, and the results suggest that this situation can be ameliorated by an apparent osteogenic action of Ex-4.

## M425

**Positive Effect of GLP-1 upon Bone Formation and Resistance in Insulin-Resistant Rats.** P. Moreno<sup>\*1</sup>, B. Nuche-Berenguer<sup>1</sup>, S. Dapia<sup>\*2</sup>, P. Esbrit<sup>3</sup>, M. Villanueva-Peñacarrillo<sup>\*1</sup>. <sup>1</sup>Metabolism, Nutrition & Hormones, Fundación Jiménez Díaz, Madrid, Spain, <sup>2</sup>Metabolism, Nutrition & Hormones, Trabeculae, Orense, Spain, <sup>3</sup>Bone & Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

**Introduction:** The insulin-independent antidiabetic action of GLP-1 (Glucagon-like-peptide 1), insulinotropic and positive effect upon glucose metabolism in liver, muscle and fat, and neurotrophic and anorectic properties, are documented. It was proposed that incretins could participate in bone remodelling changes occurring after nutrients absorption. We searched for the possible *in vivo* modulating effect of GLP-1 upon bone turnover markers, in insulin-resistant rats (IR) compared to normal (N).

**Materials & Methods:** IR was induced in adult Wistar rats by 8 weeks feeding with standard chow plus 20% D-fructose in the drinking water. N (n=20 rats) and IR (n=20) were treated 3 days -osmotic pump- with saline (control) or GLP-1 (0.86 nmol/kg/h). In fed conditions, blood was taken before (basal) and by ending the treatment; femurs and tibiae were collected. Measurements: in plasma, osteocalcin (OC), tartrate-resistant acid phosphatase (TRAP) -ELISA-, insulin -RIA- and glucose; in tibia, OC, osteoprotegerin (OPG) and RANK ligand (RANKL) mRNA -rtPCR-. In femur: bone structure -μCT- (n=3 rats/group).

**Results:** In plasma: GLP-1 did not change the basal OC in N ( $407.9 \pm 16.1$  ng/ml, n=15) but decreased it in IR ( $-22.2 \pm 4\%$  Δ of basal,  $p < 0.03$ ), which was initially lower ( $p < 0.0001$ ) than N ( $289.40 \pm 16.64$  ng/ml, n= 15); N-basal TRAP ( $2.26 \pm 0.20$  U/l, n= 16) was not modified by GLP-1, while in IR, with lower than N ( $p < 0.0001$ ) basal value ( $1.14 \pm 0.16$  U/l, n= 15) GLP-1 normalized it ( $48.3 \pm 20.3\%$  Δ basal); basal insulin and glucose were similar in all groups at any condition. In tibia (n=7-11): control OC mRNA in IR was  $0.49 \pm 0.09$  times that in N ( $p < 0.001$ ), in which GLP-1 increased  $4.22 \pm 0.83$  times its control value ( $p < 0.01$ ), as it did, but less ( $p < 0.05$  vs N) in IR ( $1.82 \pm 0.18$  times control,  $p < 0.01$ ); control OPG mRNA in IR was lower than N ( $0.66 \pm 0.12$  times,  $p < 0.02$ ), and GLP-1 raised it in N ( $2.29 \pm 0.23$  times control,  $p < 0.01$ ) and also in IR ( $2.84 \pm 0.46$  times control,  $p < 0.01$ ); control RANKL mRNA was lower ( $p < 0.001$ ) in IR ( $0.56 \pm 0.09$  times N), and GLP-1 increased it only slightly in N and IR. In IR, OPG/RANKL mRNA ratio was 1.2 fold of N, and GLP-1 raised it in both (1.8 in N and 1.6 fold in IR). Femur trabecular thickness and anisotropy in IR were higher and lower, respectively, than in N, with no apparent changes after GLP-1; both femoral cortical thickness and momentum of inertia in IR were higher than in N, and further increased after GLP-1.

**Conclusion:** The insulin-resistance of this experimental model is associated to a low bone remodelling rate and in this state, GLP-1 treatment seems to favour both bone formation and resistance.

**Does Dietary Phosphorus Influence FGF-23 Concentrations in Fibrous Dysplasia Patients?** C. Marotte<sup>\*</sup>, L. Guerrero<sup>\*</sup>, A. L. Sánchez<sup>\*</sup>, J. Somoza<sup>\*</sup>, A. Bagur<sup>\*</sup>, B. Oliveri<sup>\*</sup>, M. S. Parisi<sup>\*</sup>. Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina.

High levels of fibroblast growth factor 23 (FGF-23) have been reported in Fibrous Dysplasia (FD) patients. However, whether or not phosphate physiological regulation mechanisms are maintained is unknown.

**Objective:** to determine whether serum FGF-23 concentrations are regulated by dietary phosphorus (P) in FD patients.

We studied 6 polyostotic FD patients (2M, 4W) aged  $31.5 \pm 11.2$  y (X±SD) (r: 20-50), and 6 healthy controls (1M, 5W) aged  $33.4 \pm 15.5$  y (r: 20-57).

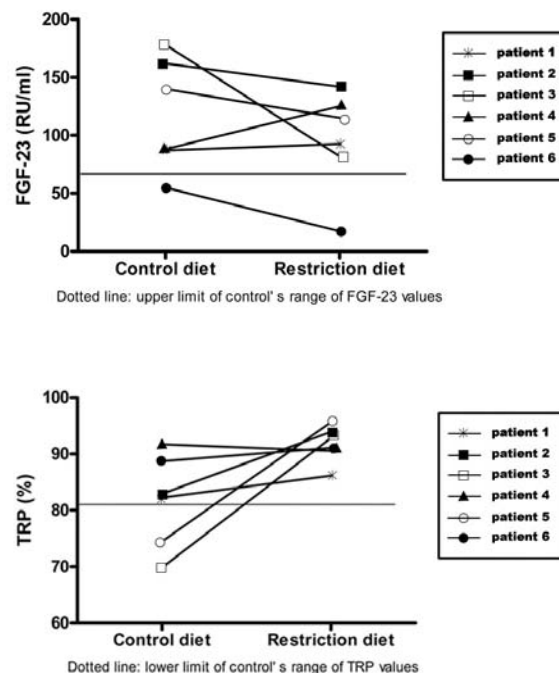

Patients and controls performed a 5 days control diet with 1500mg/d of P. After a free diet period (3-27d), FD patients performed a 5 days restriction diet with 625mg/d of P. All the subjects filled a daily meals record. P and calcium total intakes were calculated. Lab tests after each diet: serum FGF-23 (C-terminal, Inmutopics), 1,25(OH)2D, P, Ca, iPTH, and creatinine; and urinary P, Ca, and creatinine. Tubular reabsorption of P (TRP) was calculated.

After the control diet, P intakes were:  $1145 \pm 116$ mg/d in patients, and  $917 \pm 250$ mg/d in controls (ns). After the restriction diet, in FD patients, P intake was:  $712 \pm 67$ mg/d ( $p < 0.05$  vs control diet).

After control diet: FGF-23 levels were higher in FD patients ( $118.3 \pm 48.7$  vs  $40.0 \pm 25.6$  RU/ml,  $p < 0.02$ ). Only patient 6 had levels in the control's range (17.5 to 68 RU/ml). Mean TRP was lower in FD patients ( $81.7 \pm 8.3\%$ ) vs controls ( $86.7 \pm 5.6\%$ ) (ns). No differences were observed in the other studied parameters.

After the restriction diet, mean FGF-23 levels dropped to  $95.7 \pm 44.0$  RU/ml, (ns). FGF-23 values of 5 patients persisted above the control's range upper limit (fig 1). TRP values increased ( $92.2 \pm 3.4\%$ ,  $p < 0.05$ ). All patients had TRP >80% (fig 2). 1,25(OH)2D and iPTH did not correlate with FGF-23 or TRP levels.

Our observations may suggest that physiological mechanisms involved in P homeostasis could be preserved in some, but not all, FD patients. These results are in accordance with the wide clinical expression of FD. Further studies should be conducted to confirm these results.

**Association of Familial Hypocalciuric Hypercalcemia and Mandible Lesions in Two Kindreds.** M. V. Pedroni<sup>\*1</sup>, P. T. Gonçalves<sup>\*2</sup>, G. Guerra<sup>\*3</sup>, M. T. M. Baptista<sup>\*2</sup>, S. H. V. Lemos-Marini<sup>\*2</sup>, L. F. R. De Souza-Li<sup>3</sup>. <sup>1</sup>Center for Investigation in Pediatrics, State University of Campinas, Campinas, Brazil, <sup>2</sup>Pediatrics, State University of Campinas, Campinas, Brazil, <sup>3</sup>Pediatrics and Center for Investigation in Pediatrics, State University of Campinas, Campinas, Brazil.

Familial hypocalciuric hypercalcemia (FHH) is characterized by high normal serum calcium, low calcium clearance to creatinine clearance ratio ( $\text{Ca}^{++}/\text{Cr}$  ratio) and normal but not suppressed PTH. FHH is a benign disease with very few complications described. Unspecific symptoms such as fatigue, muscle pain, headache are found in some affected members. We report two families with FHH where lesions in mandible lead to their investigation. IDSS, female, 10 years old, was referred to the Pediatric Endocrinology unit due to recurrent episodes of swelling in the central part of mandible, looseness of lower central incisors and fever lasting 4 days followed spontaneous remission. After 1 year she had another episode with gingival bleeding requiring antibiotics and fixation of the loosened teeth. X-ray showed destruction of alveolar bone of the four inferior incisors. She referred Legg-Calvé-Perthes at 5 years old with persistent pain on the right leg. Her biochemical profile showed ionized calcium  $1.19$  mmol/L (reference values  $1.12-1.32$ ), serum calcium  $9.9$  mg/dL ( $8.6-10.0$ ), PTH  $30.66$  pg/mL ( $15-65$ ), Pi  $4.9$  mg/dL ( $2.7-4.5$ ) and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.0037$ . Bone scanning showed increase uptake in mandible and decrease uptake in right femoral epiphysis. Her mother had a serum calcium of  $9.1$  mg/dL, PTH  $49.1$  pg/mL and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.01$ , while her father presented with serum calcium of  $10.2$  mg/dL, PTH  $55.34$  pg/mL and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.13$ . WHG, male, 11 years old, had a history of a mass in central mandible, dislocating the lower central incisors, which was removed and the pathology revealed giant cell granuloma. The mass recurred, being excised again after 2 years. Investigation after the third recurrence of the expansive lesion, showed increase ionized calcium of  $1.43$  mmol/L, total serum calcium  $10.8$  mg/dL, PTH  $51.3$  pg/mL, Pi  $4.3$  mg/dL and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.019$ . He had a normal abdominal ultrasound, and a cranial CT scan showed an expansive lesion of soft tissue with bone involvement in anterior left mandible. His mother showed total serum calcium of  $10.9$  mg/dL, Pi  $2.2$  mg/dL, PTH  $99.3$  pg/mL and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.0089$ . His father had a normal serum calcium ( $8.9$  mg/dL), Pi  $4.1$  mg/dL, and  $\text{Ca}^{++}/\text{Cr}$  ratio of  $0.012$ . Molecular genetics analyses of the patients have been pursued. Mandible is a sensitive target to PTH and bisphosphonates action. However, it has not been described mandible lesions associated with FHH. Whether this is a casual coincidence or a rare complication of the disease is unclear.

### Bisphosphate Protect Cartilage by Reducing Chondrocyte Apoptosis and Reduce Bone Lose by Suppressing Osteoclast in Adjuvant Arthritis. C. Yongping\*. Orthopedic Surgery, Peking University, First Hospital, Beijing, China.

**Objective** To investigate the effects of bisphosphate on joint cartilage in rat adjuvant arthritis. **Method** 160 seven-week-old female Lewis rats were randomly allocated into 4 groups: normal group(NV), arthritic group(SV), low dose group(SI-10), and high dose group(SI-100). Except the normal control, the other groups were injected with Freund's complete adjuvant into the tail base. Immediately after sensitization, the rats were treated with vehicle or incadronate at 10 or 100µg/kg/d subcutaneously, three times per week. The animals were killed at 2, 4, 6 and 10 weeks after sensitization. The hind-paw and fore-paw joints were evaluated. Results At 4 weeks after sensitization, articular cartilage destruction and subchondral bone loss of the hind-paws were found in the SV group. But SI-10 and SI-100 groups showed less destruction in cartilage. The number of osteoclast and the serum IL-6, sialic acid levels obviously decreased. 2 weeks later, all groups had ruined hind-paws, even in the SI-100 group. In the fore-paw study, at 6 weeks, most severe articular cartilage destruction and subchondral bone loss were found in the SV group. The most apoptotic chondrocytes were found in the SV group when compare with others. And the SV group was significant difference with the NV, SI-100 groups ( $P < 0.05$ ), so did the SI-10 group. There was no significant difference ( $P > 0.05$ ) between the NV and the SI-100 groups. At 10 weeks, more severe articular cartilage destruction was detected in the arthritic control group than others. The apoptotic chondrocyte number in the SV group was still significant higher ( $P < 0.05$ ) than the other three groups. But among the NV, SI-10 and SI-100 groups, there was no significant difference ( $P > 0.05$ ). **Conclusion** Bisphosphates could not only inhibit osteoclast function to protect subchondral bone, but also decrease the serum inflammatory factors levels, chondrocyte apoptosis and cartilage matrix loss to protect articular cartilage in adjuvant arthritis.

### Bisphosphonates in Children with Hypercalciuria and Reduced Bone Mineral Density. U. S. Alon<sup>1</sup>, M. Freundlich<sup>2</sup>. <sup>1</sup>Nephrology, Bone and Mineral Disorders Clinic, Children's Mercy Hospital, Kansas City, MO, USA, <sup>2</sup>Pediatric Nephrology, University of Miami, Miami, FL, USA.

Previous studies have demonstrated reduced bone mineral density (BMD) and biochemical changes of excessive bone resorption in some patients with idiopathic hypercalciuria (IH). Consequently, bisphosphonates have been successfully employed in research animals and adults with IH and reduced BMD. We evaluated the effect of treatment with bisphosphonates in 7 patients, ages 10-16 years, with persistent IH and reduced BMD. In 5 children, preceding traditional therapy failed. All children received oral alendronate and one also IV Zoledronic acid, for 6-18 months (median 9.0, mean 10.7 months). With treatment, BMD Z-scores in the lumbar spine improved from  $-2.0 \pm 0.3$  to  $-0.8 \pm 0.8$  ( $p = 0.002$ ) and in the femoral neck from  $-1.8 \pm 0.4$  to  $-0.7 \pm 0.9$  ( $p = 0.01$ ); urine N-telopeptides/creatinine decreased from  $372 \pm 289$  to  $72 \pm 39$  nmol/mmol ( $p = 0.05$ ) and calcium/creatinine from  $0.29 \pm 0.12$  to  $0.13 \pm 0.06$  mg/mg ( $p = 0.009$ ). Height Z scores, normal at baseline in all, have remained unaffected, and no new stones or fractures were documented throughout the treatment period. Serum creatinine, electrolytes, Ca, P and PTH remained normal as well. In summary, in children with IH and decreased BMD, treatment with bisphosphonates normalized urine calcium excretion, eliminated urinary symptoms, and significantly improved reduced BMD. These beneficial effects indicate the need for larger prospective studies on the potential of bisphosphonates to serve as a new tool in treating children with IH and reduced BMD.

### Renal Leak Hypercalciuria: A Potential Cause of Tertiary Hyperparathyroidism. P. Tondapu\*, C. V. Odvina. Charles and Jane Pak Center for Mineral Metabolism, UT Southwestern Medical Center, Dallas, TX, USA.

Tertiary hyperparathyroidism is commonly seen in chronic renal failure, after kidney transplant, hyperphosphatemia or during long-term oral phosphate therapy, and chronic vitamin D deficiency. It has also been reported in patients with renal leak hypercalciuria although not very common. In renal leak hypercalciuria, impaired renal tubular reabsorption of calcium is the primary abnormality. Serum PTH concentration is either high or high normal because of preexisting negative calcium balance. Chronic stimulation of parathyroid gland could lead to hyperplasia (secondary hyperparathyroidism). Eventually, the hyperplastic parathyroid gland could become autonomous leading to tertiary hyperparathyroidism. Regardless of the cause, the physiological sequelae are similar, with hypercalcemia coexisting with a raised PTH. This report is a retrospective analysis of data on three patients; 2 with nephrolithiasis and one with osteoporosis. All three patients had normal serum calcium, high or high normal serum PTH and increased urinary calcium (figure 1). Administration of thiazide diuretic to control urinary calcium loss resulted in slight decline in urinary calcium but patients became hypercalcemic with non-suppressed PTH. All three patients underwent parathyroidectomy. However, despite lower serum calcium after surgery, they remained hypercalciuric (figure 1)

When compared to patients with primary hyperparathyroidism, patients with renal leak hypercalciuria had significantly higher urinary calcium excretion postoperatively. These findings suggest that renal leak hypercalciuria is the primary problem which led to the hyperparathyroidism. This has previously been described in detail by Bordier et al. in 1977. To the best of our knowledge, after the publication of the study mentioned above and 1 case report in 1980, there has not been any published cases since. Our findings emphasize the need for continued follow up of these patients. Patients with tertiary hyperparathyroidism due to renal leak should receive thiazides postoperatively to decrease the possibility of recurrence. In addition, early diagnosis and treatment with thiazides before they develop tertiary hyperparathyroidism may alleviate the need for surgery.

### Prevalence and Demographics of Asymptomatic Normocalcemic Hyperparathyroidism in the United States. B. Misra, S. J. Silverberg, J. P. Bilezikian. College of Physicians and Surgeons, Columbia University, New York, NY, USA.

Normocalcemic primary hyperparathyroidism (NPHPT) is a disorder characterized by normal serum calcium concentration and elevated PTH in the absence of known secondary causes for hyperparathyroidism (HPT). Typically these patients are identified in referral centers when they are being evaluated for low bone density, kidney stones, or other target organ complications. These patients, therefore, do not necessarily reflect a variant of asymptomatic primary hyperparathyroidism (PHPT) but rather PHPT with symptoms. This led to the hypothesis that in order to identify asymptomatic NPHPT, one would have to screen a population of healthy individuals who have not been referred to a specialty center. To gain information on the putative incidence of asymptomatic NPHPT, therefore, we obtained data from the 2003-2004 National Health and Nutrition Examination Survey (NHANES) survey, in which parathyroid hormone (PTH), calcium, 25-hydroxyvitamin D [25(OH)D] levels and renal function were measured in over 6000 individuals. Weighting allowed calculations of national estimates. We sampled 1909 individuals from this NHANES database >45 years old with a creatinine clearance of  $\geq 60$  cc/min (to eliminate those with renal-based secondary elevations in PTH), in whom the corrected serum calcium was in the mid-normal range (9-10 mg/dL) and the 25(OH)D was  $\geq 30$  ng/dL. Using these criteria, we found that 1% of the population had PTH levels  $\geq 65$  pg/mL (mean PTH level of  $81 \pm 14$  pg/mL). The group with NPHPT was 65% female, 89% Caucasian, and 48% were between the ages 45-54. The estimated prevalence of NPHPT in this sample is similar to a reported incidence of 1.2% of parathyroid adenomas discovered incidentally during neck surgery for reasons other than PHPT. Although all secondary causes of HPT have not been ruled-out, these data suggest that in a free-living unscreened population, there is an appreciable incidence of NPHPT. These individuals may be the earliest forerunners of asymptomatic PHPT. Future prospective studies should permit direct estimates of the incidence of NPHPT as well as identification of predictors of disease progression to the hypercalcemic asymptomatic variant of PHPT.

**Immunohistochemical and Genetic Characterization of the Atypical Parathyroid Adenoma.** A. Scillitani<sup>\*1</sup>, V. Guarnieri<sup>\*2</sup>, M. Bisceglia<sup>\*3</sup>, C. Battista<sup>\*1</sup>, S. Minisola<sup>\*4</sup>, I. Chiodini<sup>\*5</sup>, L. A. Muscarella<sup>\*2</sup>, C. Vainicher-  
Eller<sup>\*5</sup>, D. E. C. Cole<sup>6</sup>. <sup>1</sup>U.O. of Endocrinology, IRCCS "Casa Sollievo della Sofferenza" Hospital, San Giovanni Rotondo, Italy, <sup>2</sup>Medical Genetics Service, IRCCS "Casa Sollievo della Sofferenza" Hospital, San Giovanni Rotondo, Italy, <sup>3</sup>U.O. of Pathology, IRCCS "Casa Sollievo della Sofferenza" Hospital, San Giovanni Rotondo, Italy, <sup>4</sup>Department of Clinical Sciences, "La Sapienza" University, Rome, Italy, <sup>5</sup>Department of Medical Sciences, University of Milan, Milan, Italy, <sup>6</sup>Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.

Molecular studies of non-malignant parathyroid tumours suggest that the atypical parathyroid adenoma (AA) may be an intermediate stage of progression to parathyroid carcinoma. Various investigators have suggested that HRPT2 mutations may be found in this sub-type of adenoma, but systematic immunohistochemical and molecular study of a single cohort has not been reported. Although parafibromin immunostaining has been proposed as an adjunct tool for the diagnosis of parathyroid carcinoma, its usefulness in AA has not yet been defined. From our centre, eleven cases of AA were available for study (5 women; 6 men; age 53 +/- 17 years). The criteria for AA classification were: (i) presence of fibrous bands and/or (ii) necrosis, and/or (iii) excess mitoses, and/or (iv) capsular invasion. Screening of exons and exon-intron boundaries for germline mutations in genomic DNA from peripheral blood showed: 2/11 patients with germline truncating mutations (c.679\_680delAG; c.685\_688delAGAG). Tumor tissue was subjected to LOH analysis and mutation screening of exons 1, 2 and 7, encompassing 85% of point mutations. One somatic mutation (c.231C>G) was identified in the patient with c.679\_680delAG and LOH was observed in another. Thus, in total, at least three of the 11 patients showed genetic alterations. Parafibromin immunoreactivity, assessed in 10/11 tumours, showed: complete (~100%) expression in 3; partial but diffuse expression in 3; patchy expression in 2; and none in 2. Although the loss of parafibromin immunostaining was prevalent in atypical adenomas, it was not clearly associated with the presence of genetic mutation, suggesting that immunohistochemistry cannot substitute for molecular analysis. Studies on larger case series will better define the place of this technique in AA assessment and help identify patients needing closer clinical follow-up.

**Body Composition Changes after Radioiodine Treatment of Hyperthyroidism.** H. Xu<sup>\*1</sup>, J. Wang<sup>\*1</sup>, Q. Wu<sup>\*1</sup>, H. S. Barden<sup>2</sup>, Q. Zhou<sup>3</sup>. <sup>1</sup>Department of Nuclear Medicine, The First Affiliated Hospital, Jinan University, Guangzhou, China, <sup>2</sup>GE Healthcare, Madison, WI, USA, <sup>3</sup>GE Healthcare, Shanghai, China.

Patients treated for thyrotoxicosis often complain of increases in body weight after radioiodine <sup>131</sup>I treatment of their thyroid disorder. The objective of this study was to estimate changes in body weight and composition following treatment of hyperthyroidism with radioiodine <sup>131</sup>I. Body composition (fat mass, lean mass, and bone mineral content), was determined by dual energy X-ray absorptiometry (DXA), (GE Healthcare, Prodigy) at baseline and 3 mo after radioiodine treatment in 92 previously untreated subjects with hyperthyroidism (59 women and 33 men, age 37±9 yrs). Suppressed serum TSH and high free serum thyroxine levels were found in all patients. All patients received radioiodine <sup>131</sup>I therapy. Sixty patients achieved a euthyroid status after 3 mo of radioiodine <sup>131</sup>I therapy, while 32 patients developed a hypothyroid status. DXA total body short-term precision was good (BMC 0.7%, fat mass 1.5%, and lean mass 0.7% and BMD ranged from 0.7% to 2.1%). Body composition results by DXA before and after radioiodine <sup>131</sup>I treatment in patients with hyperthyroidism are shown in following table. Results suggest that the body weight increase in hyperthyroid patients who achieved a euthyroid status after 3 mo of radioiodine <sup>131</sup>I therapy was mainly the result of their lean mass increase, while the body weight increase in subjects who became hypothyroid after treatment was due to increases in both lean mass and fat mass.

**Changes in Cardiovascular Function after Parathyroidectomy in Mild Primary Hyperparathyroidism.** M. D. Walker<sup>1</sup>, J. Fleischer<sup>1</sup>, S. Homma<sup>\*1</sup>, T. Rundek<sup>\*2</sup>, D. J. McMahon<sup>1</sup>, A. Tineo<sup>\*1</sup>, W. B. Inabnet<sup>\*1</sup>, J. Lee<sup>\*1</sup>, J. Udesky<sup>\*1</sup>, R. Lui<sup>\*1</sup>, R. Sacco<sup>\*2</sup>, S. J. Silverberg<sup>1</sup>. <sup>1</sup>College of Physicians and Surgeons, Columbia University, New York, NY, USA, <sup>2</sup>University of Miami, Miami, FL, USA.

Severe primary hyperparathyroidism (PHPT) is associated with cardiovascular (CV) calcification and increased CV mortality. This study is designed to determine whether subclinical cardiovascular abnormalities are present in mild PHPT and reversible with surgical correction (PTX).

Patients with PHPT, who had elected to have PTX, were evaluated with structural and functional cardiovascular tests pre-PTX and for 2-yr post-PTX. Patients (N=50) were typical of those with mild PHPT: 84% female, age ± SD 62 ± 8 yrs, serum calcium 10.5 ± 0.5 mg/dl, PTH 116 ± 50 pg/ml. In the total group (n=50), carotid intimal medial thickness (IMT) and carotid stiffness, an indicator of vascular stiffness were abnormal at baseline. In the subset of patients who completed 12 months of follow-up thus far (n=20), mean values for blood pressure, left ventricular (LV) mass, endothelial reactivity (FMD), vascular compliance and diastolic dysfunction were normal at baseline. After parathyroidectomy, some measures of diastolic dysfunction (deceleration time and tissue doppler E' velocity) improved, while others worsened (isovolumic relaxation time IVRT) within the normal range. Carotid intima-medial thickness (IMT) increased post-PTX.

CV Test	Baseline Mean ± SD	12 month Mean ± SD	Normal Range	p- value*
Blood pressure (mmHg)	121 ± 18/76 ± 11	131 ± 21/78 ± 11	≤140/90	NS
Heart Rate	71 ± 9	76 ± 8	60-99	NS
LV mass (g/m <sup>2</sup> )	98 ± 26	101 ± 25	43-115	NS
Mitral Pulse Wave E/A	1.2 ± .3	1.0 ± .3	.75-1.5	NS
Deceleration Time (DT) (msec)	165 ± 27	180 ± 32	>140	0.02
IVRT (msec)	79 ± 19	94 ± 15	50-102	0.02
Tissue Doppler E' Velocity (cm/sec)	11.7 ± 1.5	10 ± 2.1	<15	0.05
FMD (%)	5.9 ± 3.5	5.8 ± 5.1	3-7%	NS
IMT (mm)	0.938 ± 0.078	1.075 ± 0.336	0.7-0.9	0.04
Carotid STRAIN (%)	10 ± 0.0	10 ± 0.0	6-12%	NS
Carotid STIFFNESS	4.3 ± 0.9	7.7 ± 3.4	< 6	NS

\*Baseline vs. 12 months

The subset of patients who had abnormal baseline measures of diastolic function (DT:120 ± 29 msec; n = 10; and tissue doppler E' velocity: 16.1 ± 1.2 cm/sec; n = 8) had normalization of those parameters post-PTX (203 ± 53 msec and 9.1 ± 3.3 respectively, p<.003). Improvement in tissue doppler E' velocity strongly correlated with the change in PTH (r = 0.8, p < 0.0001) and calcium (r = 0.4, p = 0.001) levels.

In summary, in patients with mild PHPT, improvement in structural and functional CV measures post-PTX was inconsistent. However, in patients with evidence of diastolic dysfunction at the time of diagnosis, PTX may lead to improvement. In these patients, normalization of indices of diastolic function was associated with the extent of decline in serum calcium and PTH levels. Further studies are necessary to confirm these findings.

**Clinical Implications of Commercial Biotin-Based Detection Systems in PTH Assays.** S. M. Jan de Beur<sup>1</sup>, D. Meany<sup>\*2</sup>, L. Sokoll<sup>\*2</sup>. <sup>1</sup>Medicine, Johns Hopkins Medical Institute, Baltimore, MD, USA, <sup>2</sup>Pathology, Johns Hopkins Medical Institute, Baltimore, MD, USA.

Accurate measurement of serum parathyroid hormone (PTH) in patients with end-stage renal disease (ESRD) is critical for the proper management of the aberrant bone and mineral metabolism characteristic of renal failure. Adynamic bone disease (ABD) was suspected in a 63 year old female with ESRD because of low normal serum PTH levels, high normal serum calcium and severe osteoporosis. However, her mildly elevated serum alkaline phosphatase level was inconsistent with the low bone turnover observed in ABD. This discrepant clinical profile prompted investigation into the clinical PTH assay used at our institution which utilizes biotin-streptavidin detection. Simultaneous serum samples for PTH were analyzed on the Roche Elecsys 2010 at Johns Hopkins and on the Siemens Immulite 2000 analyzer at Quest Diagnostics, discrepant values of 48 pg/mL and 786 pg/mL were obtained respectively. Heterophile antibodies were eliminated as a cause of the inconsistency. Further review of the patient's medical history revealed that she was ingesting biotin 10 mg/day for restless leg syndrome. Biotin is recognized by the assay manufacturer as a potential interferent and it is recommended that samples be collected at least 8 hours after biotin administration. We hypothesized that serum biotin was competitively inhibiting the biotinylated anti-PTH antibody in the Roche assay thus preventing the binding of the sandwich complex to the streptavidin-coated microparticles yielding falsely low PTH results. Therefore, we 1) measured patient serum biotin levels, 2) performed serial serum dilutions and 3) pre-cleared the serum with streptavidin microparticles before measuring PTH. In support of our hypothesis, the patient's serum contained high levels of biotin [4784 pg/mL (200-500 pg/mL)]. Twenty-fold dilution of the serum sample yielded PTH values of 567 pg/mL and 465 pg/mL that were concordant with those obtained from Quest. Moreover, by pre-clearing with streptavidin microparticles, we obtained results similar to the Quest assay which is not based on streptavidin-biotin chemistry (PTH: 32 pg/mL pre-treatment vs. 419 pg/mL post-treatment).

Thus, biotin molecules present in specimens from patients taking high-dose biotin will interfere with the Roche PTH assay and provide falsely low results. In addition, excessive serum biotin may interfere with a wide range of immunoassays that are based on streptavidin-biotin chemistry. As in the case of this patient, the delay in initiating appropriate therapy for severe secondary hyperparathyroidism in ESRD has significant clinical consequences that can include tertiary hyperparathyroidism and progressive hyperparathyroid bone disease.

**Mutational Analysis of Beta-catenin Exon 3 in Benign and Malignant Parathyroid Tumors.** C. Banti\*, F. Cetani\*, E. Pardi\*, S. Borsari\*, F. Saponaro\*, E. Vignali\*, G. Viccica\*, L. Cianferotti, E. Ambrogini\*, A. Pinchera\*, C. Marocci. Endocrinology, University of Pisa, Pisa, Italy.

Single benign adenoma is responsible for 80-85% of primary hyperparathyroidism (PHPT), while carcinoma accounts for 1% of all sporadic cases. In addition, tumours with histological aspects of carcinoma, but without distant metastasis, are defined atypical adenomas. Wnt signaling pathway abnormalities have been described in many human tumours and, recently, alterations and cytoplasmic accumulation of  $\beta$ -catenin, a key signal mediator of the Wnt signaling pathway, have been reported in a subset of sporadic parathyroid adenomas. The exon 3 of *CTNNB1* gene, encoding  $\beta$ -catenin, can be considered a "hotspot" for mutational activation of  $\beta$ -catenin in many human tumours, because it contains serine-threonine aminoacids, potential targets for GSK-3 $\beta$  phosphorylation.

The aim of the study was to investigate abnormalities of the regulation of  $\beta$ -catenin in parathyroid tumorigenesis. Genomic DNA from thirty sporadic parathyroid adenomas, 21 carcinomas and 6 atypical adenomas was extracted and the exon 3 of the *CTNNB1* gene was PCR-amplified and direct sequencing was performed using ABI Prism 310 sequencer. Potential mutations of target residues prevent degradation of  $\beta$ -catenin. Direct sequencing of exon 3 of the *CTNNB1* gene showed absence of stabilizing mutations in any pathologic specimens.

Our results suggest and confirm that Wnt/ $\beta$ -catenin signaling pathway abnormalities are rarely, if at all, involved in the development of sporadic benign as well as malignant parathyroid tumours.

**A Clinically Useful Paradigm for Interpretation of Serum 25-hydroxyvitamin D (25-OHD) Levels with Simultaneously Measured PTH Levels.** D. Rao, S. Qiu, N. Parikh. Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA.

The prevailing practice is to measure serum 25-OHD, the best available index, to assess vitamin D nutritional status. However, single 25-OHD level alone does not give information either about the duration of vitamin D depletion or appropriate replacement strategy in patients with low 25-OHD. Accordingly, we analyzed simultaneously measured 25-OHD & PTH levels in all patients >50y of age seeking advice on osteoporosis in 2007. We excluded patients with hypercalcemia (Ca >10.2 mg/dl), renal dysfunction (Cr >1.5 mg/dl) or with known causes of vitamin D depletion.

There were 486 patients, 434 women and 52 men; mean age  $67 \pm 10$ y. The mean serum 25-OHD was  $26.6 \pm 11.7$  ng/ml and PTH  $66.0 \pm 47.6$  pg/ml with the expected inverse relationship between the two. However, there was no regression of PTH or 25-OHD on age or Cr (data not shown).

When the patients were classified based on low or normal 25-OHD (defined as < or > 30 ng/ml; a value now considered optimal), with or without high PTH (defined as < or > 75 pg/ml), 4 groups emerged that suggested different pathophysiologic basis (Table).

Group-1 had normal 25-OHD (>30 ng/ml) and PTH (<75 pg/ml) and Group-2 had normal 25-OHD but high PTH (>75 pg/ml) with no relationship between these two variables in either group. However, in the other 2 groups with low 25-OHD (<30 ng/ml) and either high (Group-3) or normal (Group-4) PTH, there was an inverse relationship between these 2 variables. Furthermore, the slope of regression, after "normalizing" the data for each group, was significantly steeper in Group-3 with high PTH compared to Group-4 with normal PTH ( $p < 0.001$ ). This suggests that vitamin D depletion may have been of longer duration in Group-3 compared to Group-4 and thus may require aggressive (? urgent) pharmacologic therapy. The Group-4 patients with low 25-OHD and normal PTH may represent seasonal variation, short duration vitamin D depletion or abnormal PTH response. Finally, Group-2 with normal 25-OHD and high PTH may represent patients with low calcium intake or incipient primary hyperparathyroidism and thus require further evaluation.

Conclusion: Simultaneously measured 25-OHD and PTH is useful to optimize proper interpretation of vitamin D nutritional status. This strategy offers a clinically useful tool to look for other causes of high PTH in those with normal 25-OHD and explore reasons for lack of PTH response in those with low 25-OHD and normal PTH.

Relationship Between 25-OHD & PTH				
Category	n (%)	Slope	r <sup>2</sup>	p value
Group-1	160 (33)	-0.153	0.011	NS
Group-2	26 (5)	0.596	0.035	NS
Group-3	87 (18)	-3.563	0.104	<0.001
Group-4	213 (44)	-0.368	0.032	0.022
Total	486 (100)	-1.227	0.091	<0.001

## M438

**Increased Risk of Morphometric Vertebral Fracture in Postmenopausal Women with Primary Hyperparathyroidism.** G. Viccica\*, E. Vignali\*, L. Cianferotti\*, E. Ambrogini\*, F. Cetani\*, S. Chiavistelli\*, D. Diacinti\*, A. Pinchera\*, C. Marocci\*. <sup>1</sup>Endocrinology, University of Pisa, Pisa, Italy, <sup>2</sup>Clinical Sciences, University of Roma, Pisa, Italy.

An increased risk of vertebral fracture (VF) compared to general population has been reported in patients with primary hyperparathyroidism (pHPT), but the available data is still controversial. The aim of the present study was to prospectively evaluate the presence of VFs in a series of consecutive Caucasian postmenopausal women with sporadic PHPT referred to our outpatient clinic for management advice, and to compare its rate with that of a control group (C). One hundred and fifty patients underwent a standard clinical, biochemical and densitometric (DXA) evaluation. Patients were classified as symptomatic (n=21) or asymptomatic according to the presence or absence of HPT related symptoms. The latter were further grouped according to whether the met (non-mild, n=84) or not (mild, n=45) the criteria for surgery established by 2002 Workshop on Asymptomatic Primary Hyperparathyroidism. Morphometric X-ray absorptiometry (MXA) was used to assess the presence of a VF, classified by semiquantitative Genant's method. Each patient was compared with two age ( $\pm 2$ ) and menopausal age ( $\pm 5$ ) matched controls. There was no statistically significant difference in age, menopausal age, years since menopause. Vertebral fractures were detected 37 out of 150 patients (24.6%) and 12 out of 300 (4.0%) controls [ $\chi^2=44.0$ ,  $p < 0.01$ ; OR = 7.86; (95% CI, 3.96-15.61)]. The majority of VF were classified as mild. VF distribution was evaluated according to quartiles of BMD of lumbar spine (LS-BMD). Patients had an increased risk of VF in all quartiles even if VF risk decreased at increasing LS-BMD values. Stepwise multiple logistic regression analysis showed that BMD of lumbar spine ( $\beta$ -coefficient = -5.2311, SE ( $\beta$ ) 1.8382 and  $p=0.004$ ) was the only variable independently associated with the risk of VFs. The rate of VF was higher in all subgroups of patients compared to the controls: 27.6% ( $p > 0.01$ ; OR 14.7) in patients with symptomatic pHPT, 22.5% ( $p < 0.01$ ; OR 6.96) in asymptomatic ones, asymptomatic non-mild (28.6%;  $p < 0.01$ , OR 9.6) and asymptomatic mild (11.1%;  $p=NS$ , OR 3.0). In conclusion our study shows an increased rate of VF in postmenopausal women with PHPT compared to controls. Patients with asymptomatic pHPT have an increased risk of VF, even those without criteria for surgery. We suggest that an evaluation of VF should be included in the workout of postmenopausal women with pHPT.

## M439

**Serum Cathepsin K Levels in Ankylosing Spondylitis.** D. Wendling, J. Cedoz\*, E. Racador\*. Rheumatology, University Teaching Hospital, Besançon, France.

Ankylosing spondylitis (AS) is a chronic inflammatory disease associated with a reduction of BMD correlated with systemic inflammation, and reversible under anti TNF therapy. Cathepsin K is a recognized mediator of bone resorption.

The aim of this study was to evaluate serum levels of Cathepsin K levels in AS patients compared to controls, and their evolution under anti TNF treatment.

Methods: This prospective study included AS patients (modified New York criteria) and healthy volunteers as controls. Age, disease duration, BASDAI, ESR and CRP were recorded. Cathepsin K (Biomedica, France) were assessed by duplicate ELISA, as well as MMP-3 (Quantikine MMP-3, R&D Systems) and IL-17 (Quantikine IL-17, R&D). Patients treated with anti TNF were evaluated again after 10 weeks of therapy. Statistical analysis used Mann-Whitney test for comparisons between groups, Wilcoxon test for evaluation under treatment, and correlation test for correlations. Significance threshold was  $p$  less than 0.05.

Results: 23 ambulatory AS patients and 21 controls were included, mean age 39.9 and 41.2 years (ns). AS duration was 10.1 years, AS was mainly axial (n=21) and HLA-B27 positive (n=19). At inclusion, BASDAI was 44.1 (4.1), CRP 22.3 mg/l (4.7). In AS patients, serum levels of Cathepsin K (6.4 vs 3.6 pg/ml, ns), of MMP-3 (4.71 vs 2.79 ng/ml,  $p=0.04$ ) and of IL-17 (60.4 vs 32 pg/ml, ns) were higher compared to controls. No positive correlation was found between the several parameters assessed, except between ESR and CRP ( $p=0.0002$ ). 13 of the AS patients were evaluated after anti TNF (adalimumab: 7; etanercept: 4; infliximab: 2). A significative reduction of ESR, CRP, BASDAI ( $p=0.002$ ) and of MMP-3 ( $p=0.04$ ) was observed, but Cathepsin K showed tendency of increase ( $p=0.07$ ).

Conclusion: Serum Cathepsin K does not seem to be a good candidate for evaluation of bone resorption in AS.

**Bone Fragility Is Increased in the MKR Type 2 Diabetic Mouse.** S. Epstein, Y. Kawashima\*, C. Fritton\*, K. Inagaki\*, H. Sun\*, K. Jepsen\*, S. Yakar\*, M. Schaffer, D. LeRoith\*. Mt Sinai School of Medicine, New York, NY, USA.

Both Type 1 and Type 2 diabetes patients may demonstrate changes in bone morphology. While Type 1 patients may develop osteoporosis when they age, Type 2 diabetic patients often demonstrate increased bone fragility leading to fractures. The latter effects may be worsened with the use of thiazolidinedione therapy for the diabetic state. The mechanisms involved in these changes are as yet undefined.

We have created a mouse model of Type 2 diabetes (called the MKR mice) and studied the effect of this model on bone morphogenesis. Compared to control mice, MKR diabetic mice demonstrate increased periosteal and endosteal bone resorption during ontogeny that correlates with increased osteoclastic activity. Because MKR diabetic mice show minor changes in longitudinal bone growth, the increased osteoclastic activity and the lack of a compensatory increase in periosteal bone formation during growth resulted in a 28% reduction ( $p < 0.001$ , t-test) in total cross-sectional area of the femoral mid-shaft (a measure of periosteal expansion) by 16 weeks of age. This reduced radial expansion of the mid-shaft led to a 24% increase ( $p < 0.001$ ) in slenderness (i.e., width relative to length) of adult femora. Trabecular bone mass decreased and spacing was also increased, consistent with greater osteoclastic activity. Overall, femora from adult MKR diabetic mice are more fragile, as measured by a 30% reduction ( $p < 0.001$ ) in whole bone stiffness and strength relative to femora from control mice. Marrow-derived osteoclast cultures revealed an increase in the number of differentiated osteoclasts in response to M-CSF and RANK-L. Additionally, marrow derived non-adherent cells treated with increasing concentrations of insulin, in the presence of M-CSF and RANK-L revealed an increased number of differentiated osteoclasts in vitro. Taken together, the MKR mouse model suggests that skeletal fragility may arise from the hyperinsulinemia that leads to increased osteoclastogenesis and likely uncoupling of bone resorption and formation.

**The Effect of Aquatic Exercise and Education on Improving Indices of Fall Risk in Older Adults with Hip Osteoarthritis: A Randomized Controlled Clinical Trial.** C. M. Arnold\*, R. A. Faulkner<sup>2</sup>. <sup>1</sup>Kinesiology, Physical Therapy, University of Saskatchewan, Saskatoon, SK, Canada, <sup>2</sup>Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

The purpose of this study was to evaluate the effect of aquatic exercise and aquatic exercise combined with an education group program on fall risk factors in adults aged 65 years or older with hip osteoarthritis (OA). Individuals with hip OA present with an increased risk of falls and the ideal type of intervention to decrease fall risk in this population is unknown. Seventy-nine older adults with hip OA and at least 1 fall risk factor were randomly assigned to one of three groups: Aquatic-Education, Aquatic or Control. Exercise interventions were twice per week for 11 weeks with Aquatic-Education receiving an additional one half hour education class once per week. Fall risk outcomes included primary and secondary measures of balance, falls-efficacy, lower body strength, walking endurance, dual task function, and mobility. The mean age was 74 years of age (range 65 - 88 years) with 71% of the sample female and 49% reported one or more falls in the past year. An intention to treat analysis was used. There was a significant group by time interaction for primary fall risk factors (repeated measures MANCOVA;  $p = 0.038$ ), using baseline measures as co-variables, where Aquatic-Education had a 8% improvement in balance confidence compared to a 4% decrease in Control and a 20% improvement in lower body strength and mobility (chair stands) compared to an 8% improvement in Aquatic and Control. Falls-efficacy specific to daily fall-related tasks was also significantly improved in Aquatic-Education compared to both Aquatic and Control (16% improvement compared to a 2% improvement and no change respectively). General health status was also significantly improved in Aquatic-Education compared to Control. The greatest benefit in reducing fall risk factors was realized for those who entered the Aquatic-Education program with lower levels of falls-efficacy. There were no significant differences in fall risk factors comparing Aquatic to Control. In conclusion, the addition of land-based education to reinforce fall prevention strategies, teach movement control and the purpose of exercise resulted in improvements in falls-efficacy and functional strength in conjunction with an aquatic exercise program for older adults with hip OA. Aquatic exercise on its own was not sufficient to decrease fall risk in this population. Intervention programs for older adults already at risk for falls due to conditions such as arthritis should include both exercise and education programs.

**Fracture Risk in Primary Biliary Cirrhosis: Role of Osteopenia and Severity of Cholestasis.** N. Guanabens<sup>1</sup>, D. Cerda<sup>\*1</sup>, A. Monegal<sup>\*1</sup>, F. Pons<sup>\*1</sup>, L. Caballeria<sup>\*2</sup>, P. Peris<sup>1</sup>, A. Pares<sup>\*3</sup>. <sup>1</sup>Metabolic Bone Diseases Unit, Hospital Clinic, IDIBAPS, Barcelona, Spain, <sup>2</sup>Liver Unit, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Spain, <sup>3</sup>Liver Unit, CIBEREHD, Hospital Clinic, IDIBAPS, Barcelona, Spain.

**Background and aims:** Osteoporosis, a frequent complication in patients with primary biliary cirrhosis (PBC) with severe and prolonged cholestasis, may result in a higher risk of vertebral and non vertebral fractures. However, the influence of osteoporosis and severity of liver disease on fracture risk in PBC are not well characterized and therefore, we have studied a large series of women with PBC with the aim of assessing the prevalence of fractures and their association with osteoporosis and the degree and duration of liver damage.

**Patients and methods:** 185 female patients with PBC (age  $55.7 \pm 0.7$  years, range: 28-79). Age, duration of PBC, menopausal status, histological stage and severity of liver disease were assessed in all the patients. Vertebral fractures were recorded by X-ray of spine in 170 patients while non vertebral fractures were recorded in 172 patients. Diagnosis of osteoporosis and osteopenia were established by densitometric criteria at the lumbar spine (180 patients) and femoral neck (140 patients).

**Results:** The prevalence of vertebral, nonvertebral and overall fractures were 11.2%, 12.2% y 20.8%, respectively. Osteoporosis was significantly higher in PBC than in normal Spanish women at the lumbar spine (30.6% vs 11.2%,  $p < 0.001$ ) and femoral neck (12.9 vs 4.3%,  $p < 0.001$ ). Osteoporosis was associated with age, weight, height, histological stage, and severity and duration of liver damage, while fractures were associated with osteoporosis, menopausal status, age, height but not with severity of liver disease. Osteoporosis was a risk factor for vertebral fracture (OR: 8.48, 95% CI: 2.67-26.95). Lumbar osteopenia with a T-score  $< -1.5$  (OR: 8.50, 95% CI 1.89-38.09 and femoral neck osteopenia with a T-score  $< -1.5$  (OR: 6.83, 95% CI: 1.48-31.63) were already significant risk factors for vertebral fracture. Thus 17 of the 19 patients (89.5%) with vertebral fracture had a lumbar T-score lower than -1.5, and 15 patients (86.7%) a femoral neck T-score lower than -1.5.

**Conclusions:** Fractures, particularly vertebral fractures, are associated with osteoporosis and osteopenia with a T-score lower than -1.5, whereas osteoporosis and osteopenia are associated with the severity of liver damage. The clear-cut correlation between vertebral fracture and a T-score  $< -1.5$ , may indicate that this densitometric measurement is a useful criteria for prescribing agents to prevent further loss of bone mass and development of new fractures in patients with PBC.

**Serum Undercarboxylated Osteocalcin Concentration are Related to Renal Function in Type 2 Diabetes Patients.** M. Shibata, S. Sekiguchi, Y. Umetani\*, S. Asano, T. Hara\*, H. Kakizawa\*, N. Hayakawa\*, N. Oda\*, A. Suzuki, M. Itoh\*. Div. Endocrinology, Dept of Internal Medicine, Fujita Health University, Aichi, Japan.

Vitamin K contributes to bone health, probably through its role as co-factor for the gamma-carboxylation of vitamin K-dependent proteins such as osteocalcin. Undercarboxylated osteocalcin (ucOC) is considered to be an "inactive" form osteocalcin, and does not contribute to bone formation. UcOC is a sensitive marker of vitamin K status, resulting in low bone formation. The patients with high ucOC levels have been reported to have higher risk for osteoporotic fracture. Type 2 diabetes mellitus is another risk factor of osteoporosis with low bone turn over, especially for the patients with renal dysfunction due to diabetic nephropathy. In the present study, we investigated serum ucOC concentrations in type 2 diabetes patients and its association with renal function estimated by new formula of glomerular filtration rate (GFR) for Japanese population. Serum ucOC, total homocysteine and bone-specific alkaline phosphatase (BAP) concentrations were measured by ELISA, HPLC and EIA, respectively. Subjects were outpatients with type 2 diabetes mellitus ( $n=56$ , M/F = 28/28, Age  $66.1 \pm 10.3$ ). Mean blood HbA1c levels were  $6.9 \pm 1.1\%$ . Subjects were divided into 4 groups according to estimated GFR (eGFR) by MDRD formula by Japanese Society of Nephrology. Serum ucOC and homocysteine concentrations were negatively associated with eGFR, while BAP was positively associated with eGFR in type 2 diabetes patients. On the contrary, HbA1c levels were not related to these bone markers. Serum ucOC levels higher than 4.5 ng/ml was defined as cut-off value for vitamin K deficiency. The patients with eGFR under 60 ml/min/1.73m<sup>2</sup> were defined as chronic kidney disease (CKD), and they have higher incidence of vitamin K deficiency (6/27) compared with the population without CKD (1/29). In summary, vitamin K deficiency seems to be an additional risk factor for osteoporotic fracture in type 2 diabetes patients especially for the subjects with renal dysfunction such as CKD.

**Stress Fracture and Vertebral Osteosclerosis Related to Fluorosis Induced by Excessive Gingival Topical Fluoride Application.** E. Toussiot<sup>\*1</sup>, P. Ornetti<sup>\*2</sup>, D. Wendling<sup>\*1</sup>, C. Tavernier<sup>\*2</sup>. <sup>1</sup>Rheumatology, University Hospital, Besancon, France, <sup>2</sup>Rheumatology, University Hospital, Dijon, France.

Fluorosis may induce ligamentous ossifications, osteosclerosis and bone fractures. It is reported in fluoridated area (endemic skeletal fluorosis) or caused by industrial water fluorification.

We report here one case of stress fracture and another case of vertebral osteosclerosis related to fluorosis which was explained by repeated fluoride gingival application. These patients lived in Franche-Comté and Bourgogne, 2 regions from France which are not endemic for fluorosis.

**Case 1:** A 49-year old premenopausal woman, without medical history complained of mechanical pain of her left foot. Physical examination showed swelling, warmth and tenderness of the dorsal region of her foot around the second metatarsus. X-rays revealed a fracture located at the second metatarsus and technetium bone scan an increased uptake at the same level. Serum calcemia, phosphate, alkaline phosphatases, Vitamine D levels, PTH and osteocalcin were normal. Bone densitometry (Lunar DPX-IQ) showed high BMD at the spine (T score = + 2.1) with normal values at the femoral neck (T score = 0). The patient reported that she had been receiving topical fluoride applications for 10 years for periodontal disease. Serum and urinary fluoride concentrations were found elevated (35 µg/L [N<29] and 1230 µg /24H [N<950]). A bone biopsy was not performed.

**Case 2:** a 54 year old man had had for pertinent medical history a cancer of the larynx treated by radiotherapy. During this treatment, he had received prophylactic treatment for dental caries using topical fluoride application. Thirteen years later, he was referred in rheumatology for mechanical low back pain with vertebral osteosclerosis on dorso-lumbar spine X-rays. Laboratory parameters of calcium homeostasis were normal and bone scintigraphy showed increased uptake of the spine. A bone biopsy did not show any neoplastic infiltrate while the histomorphometric analysis revealed osteomalacia. Serum and urinary fluor levels were increased (5.8 µm/L [N<1.5] and 91.7 µm/L (N< 26)) as well as fluor concentrations in calcined bone specimen (0.686 % N< 0.10). The patient reported that he had been continuing gingival fluoride application since the diagnosis of cancer.

**Conclusion:** Beside the classical causes (endemic or industrial fluorosis), fluorosis may be induced by certain mineral water or ice tea beverages. Fluoride ingestion from toothpaste leading to osteosclerosis has been exceptionally reported. Our two cases suggest that repeated or excessive gingival fluoride application for periodontal disease or for the prevention of dental caries in patients with a larynx cancer may also be an etiological factor for fluorosis.

## M445

**Recombinant Human Bone Morphogenic Protein-2 (rhBMP-2) Accelerates Segmental Defect Healing in Diabetic Rats.** E. A. Breitbart<sup>\*1</sup>, V. Azad<sup>\*1</sup>, S. Yeh<sup>\*1</sup>, L. Al-Zube<sup>\*1</sup>, J. P. O'Connor<sup>\*2</sup>, S. S. Lin<sup>\*1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Medicine and Dentistry of New Jersey: New Jersey Medical School, Newark, NJ, USA, <sup>2</sup>Department of Biochemistry and Molecular Biology, University of Medicine and Dentistry of New Jersey: New Jersey Medical School, Newark, NJ, USA.

This study was designed to determine the bone healing capacity of rhBMP-2 in a non-critical size femoral defect in both healthy rats and rats with diabetes mellitus (DM). It was hypothesized that DM would result in impaired bone regeneration in this defect model due to reduced bone formation, and furthermore, that local delivery of rhBMP-2 would accelerate non-DM healing and normalize impaired bone healing in DM rats to the levels of Non-DM bone healing.

A total of 80 BB Wistar rats were used in the project. A 3mm defect was created during surgery and stabilized with a polyimide plate. Either a 0.05cc/11µg dose of rhBMP-2 or buffer in a collagen sponge was implanted into the defect at the time of surgery. Serial microradiographs were taken biweekly up to the day of sacrifice and processing of samples for PECAM-1 immunohistochemistry, histomorphometry, and mechanical testing was performed.

Both Non-DM and DM groups treated with rhBMP-2 demonstrated significantly higher radiographic scoring and total new bone formation (Table 1), and blood vessel quantification and mechanical testing parameters (Table 2) compared to those treated with buffer at all timepoints with the exception of 3 week radiographic scoring in the DM group and maximum shear stress. Moreover, no significance was noted between Non-DM and DM groups treated with rhBMP-2 in any of the above parameters.

In summary, decreased quantity and quality of new bone formation was seen in DM animals compared to Non-DM animals, showing the detrimental effects of DM upon bone healing. A single application of rhBMP-2 resulted in new bone formation in DM animals similar to Non-DM animals, suggesting a critical role for rhBMP-2 in ameliorating the deleterious effects of DM on bone regeneration and formation.

Radiographic scoring and total bone formation in DM and non-DM rats treated with rhBMP-2 / Buffer				
	Non-DM+Buffer	Non-DM + rhBMP-2 (p-value vs. Non-DM+Buffer)	DM+Buffer	DM + rhBMP-2 (p-value vs. DM+Buffer)
Sample Size (3 weeks/6 weeks)	5/6	6/6	6/6	6/6
3 weeks Radiographic Score (0-5)	1.3 ± 1.0	3.16 ± 0.68 p=0.006	1.5 ± 1.18	2.33 ± 0.4 p=0.134
6 weeks Radiographic Score (0-5)	1.75 ± 1.17	4.0 ± 0.35 p<0.001	1.16 ± 1.29	4.21 ± 0.9 p<0.001
3 weeks Total New Bone Formation (mm2)	2.07 ± 0.66	6.91 ± 1.42 p<0.001	0.84 ± 0.39	7.89 ± 1.0 p<0.001
6 weeks Total New Bone Formation (mm2)	3.22 ± 1.24	7.38 ± 0.86 p<0.001	3.01 ± 2.06	7.16 ± 2.44 p=0.006

Mechanical Testing Data and Blood Vessel Quantification in DM rats treated with rhBMP-2 vs. Buffer		
	DM+Buffer	DM+rhBMP-2
Sample Size (mechanical testing/BV quantification)	4/3	4/4
Torque to Failure (Nm)	0	393.57±233.3 p=0.03
Torsional Rigidity (Nm/rad)	0	29,711±6,224 p=0.002
Shear Modulus	0	1,978±1,467 p=0.05
Maximum Shear Stress (MPa)	0	89.6±94.9
Blood Vessel Density (BV/mm2)	4.50 ± 5.45	12.76 ± 1.90 p=0.034

**Deficiency of the Nucleocytoplasmic Shuttling Protein CIZ Suppresses K/BxN Serum-Induced Model of Rheumatoid Arthritis.** T. Nakamoto<sup>1</sup>, E. Mizoguchi<sup>1</sup>, Y. Izu<sup>1</sup>, T. Hayata<sup>1</sup>, Y. Ezura<sup>1</sup>, D. Mathis<sup>\*2</sup>, C. Benoist<sup>\*2</sup>, N. Miyasaka<sup>\*3</sup>, M. Noda<sup>1</sup>. <sup>1</sup>Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Joslin Diabetes Center, Boston, MA, USA, <sup>3</sup>Medicine and Rheumatology, Tokyo Medical and Dental University, Tokyo, Japan.

CIZ (Cas interacting zinc finger protein) is a nucleocytoplasmic shuttling protein and regulates the transcription from the collagen type I alpha1 promoter and several matrix metalloproteinase promoters. It is also known as Nmp4 (Nuclear matrix protein 4) or Zfp384 (Zinc finger protein 384), and was first identified by binding to p130<sup>cas</sup>, a docking protein involved in integrin signaling. Overexpression of CIZ suppresses BMP-induced osteoblastic differentiation *in vitro*. CIZ-deficient mice show hyper-responsiveness of osteoblasts to BMP stimulation, increased bone mass, enhanced recovery from bone marrow ablation, and resistance to unloading-induced bone loss. These observations suggest that CIZ plays a pivotal role in the skeletal system. To further examine the possible pathological features of CIZ function in skeletal system, we applied the inflammatory arthritis model to CIZ-deficient mice. Sera from spontaneously arthritic K/BxN mice were transferred to CIZ-deficient- and wild-type mice (Background C57BL/6) to elicit serum-induced arthritis.

CIZ deficiency reduced arthritis severity in both ankle swelling and a clinical score by 50%. Histological analysis showed that CIZ deficiency reduced less severe invasion of inflammatory cells in periarticular tissues. Cartilage destruction levels were also reduced by CIZ deficiency. CIZ deficiency suppressed the arthritis-induced increase in the number of osteoclasts at the interface between bone and pannus at the joint. Systemic parameters such as accelerated levels of deoxypyridinoline were also reduced by CIZ deficiency.

Arthritis-induced increase in the levels of mRNA expression of MMP-3, IL-1beta, RANKL, Adams4 and CXCL16 was decreased by CIZ deficiency.

Thus CIZ plays a key role in the arthritis in this K/BxN model.

**Disclosures:** T. Nakamoto, None.

**Prevalence and Factors Associated to the Presence of Vertebral Fractures in Patients with Type 2 Diabetes Mellitus.** P. Rozas-Moreno<sup>\*1</sup>, M. Muñoz-Torres<sup>2</sup>, G. Alonso<sup>\*1</sup>, P. Muñoz-Rueda<sup>\*1</sup>, R. Reyes-García<sup>\*1</sup>, M. Varsavsky<sup>\*1</sup>, J. Jiménez-Moleón<sup>\*3</sup>. <sup>1</sup>Endocrinology, Bone Metabolic Unit - Hospital Universitario San Cecilio, Granada, Spain, <sup>2</sup>Endocrinology, Bone Metabolic Unit - Hospital Universitario San Cecilio, Granada, Spain, <sup>3</sup>University of Granada, Department of Preventive Medicine and Public Health. RETICEF, Granada, Spain.

**Aim:** To analyse the prevalence and factors related to non-traumatic vertebral fractures (VF) in patients with type 2 diabetes mellitus (T2DM)

**Patients and methods:** Case-Control study including 118 subjects, 72 patients with T2DM and 46 healthy controls. The presence of prevalent VF was evaluated in lateral-view conventional X-Rays of the thoracic and lumbar spine (T4-L5). The severity of vertebral deformities was graded according to Genant's criteria. The relationship between the main risk factors of VF in general population (age, gender, bone mineral density, previous fragility fracture, smoking, body mass index) and the observed prevalent VF was determined. Likewise, the association between the presence of VF and the main cardiovascular risk factors linked to T2DM (arterial hypertension, dyslipidemia, abdominal obesity, diabetic retinopathy, ischemic heart disease, pathologic carotid intima-media thickness) was analyzed. Lumbar spine and femoral BMD were measured by dual X-Ray absorptiometry (Hologic QDR 4500).

**Results:** Mean age was 56.7± 6.8 yr (57.8± 6.4 and 55.1± 7.1 in T2DM and control group respectively; p=0.024). Among the T2DM patients (n=72), 47.2% were females (n=34) and 52.8% males (n=38). In the control group 56.5% were females (n=26) and 43.5% males (n=20). Prevalent VF were detected in 27.7% of T2DM group and 22.2% of controls (p=0.46). In the T2DM group prevalent VF were significantly related to the presence of diabetic retinopathy ( $\chi^2$  4.09; p=0.043) and ischemic heart disease ( $\chi^2$  5.02; p=0.025). The waist circumference was significantly greater in T2DM patients with VF compared to T2DM patients without VF (110.8 ± 11.76 vs 103.9 ± 11.18 cm respectively; p=0.024). No significant relationship was observed between the other analyzed variables and the presence of VF (age, gender, BMD, previous fragility fracture, smoking, body mass index, arterial hypertension, dyslipidemia, pathologic carotid intima-media thickness).

**Conclusions:** In patients with type 2 diabetes mellitus the presence of vascular complications was associated to increased risk of vertebral fractures. The classic vertebral fracture risk factors were not predictive of the presence of vertebral fractures in this group of patients.

## M448

**Vitamin D Insufficiency is Common in Racially Diverse Postmenopausal Women with Human Immunodeficiency Virus (HIV).** E. M. Stein<sup>1</sup>, M. Yin<sup>1</sup>, A. Shu<sup>1</sup>, D. J. McMahon<sup>1</sup>, V. Thomas<sup>\*1</sup>, D. Ferris<sup>\*2</sup>, J. Laurence<sup>\*3</sup>, E. Shane<sup>1</sup>. <sup>1</sup>Columbia University, New York, NY, USA, <sup>2</sup>Bronx Lebanon Hospital Center, New York, NY, USA, <sup>3</sup>Weill Cornell Medical College, New York, NY, USA.

Postmenopausal minority women constitute a growing segment of the HIV positive (HIV+) population in the United States (US). We hypothesized that postmenopausal HIV+ women may be at risk for abnormal bone and mineral metabolism, because of older age, estrogen deficiency, and effects of HIV infection and antiretroviral therapy (ART) upon bone. As part of a longitudinal study of bone metabolism in HIV+ Hispanic and African American (AA) postmenopausal women in the northeastern US, we assessed the prevalence and effects of vitamin D insufficiency.

Of 203 women enrolled (101 HIV+ and 102 HIV- controls, mean age 58; range 43-78 years), 32% were AA and 68% were Hispanic. Hispanic subjects were predominantly from the Dominican Republic (59%) and Puerto Rico (22%). At baseline, 19% of HIV+ subjects were ART-naïve and 81% were receiving various ART regimens. Mean CD4 count was 509 ± 305 (range 67-1550) and 37% had a viral load < 50K.

We found sub-optimal serum 25OHD levels (<30 ng/ml) in the majority of HIV+ (69%) and HIV- (74%) women. Severe vitamin D deficiency (<10 ng/ml) was present in 10% of subjects in both groups. Among HIV+ women, serum 25OHD was significantly lower in AA than Hispanic subjects (21 ± 12 vs. 27 ± 15 ng/ml respectively; p<0.04). Use of calcium supplements (r=0.20, p<0.05) and multivitamins (MVI; r=0.19; p<0.06) were positively associated with serum 25OHD. In HIV- women, 25OHD was similarly associated with race and supplement use. Serum 1,25(OH)<sub>2</sub>D did not differ between groups. In HIV+ women, no relationship was found between serum 25OHD or 1,25(OH)<sub>2</sub>D and nadir CD4 count, history of AIDS defining illness, viral load, or protease inhibitor use.

Serum 25OHD and parathyroid hormone (PTH) levels were inversely associated (r=-0.33; p<0.001), regardless of HIV status. In HIV+ women, NTx was significantly greater than in HIV- women (21 ± 11 vs. 17 ± 6 nM BCE/l; p<0.0001) and was associated with higher PTH and lower estrone levels. In a multivariate regression model, PTH and estrone accounted for 16% of the variance in NTx (p overall model <0.001). This relationship was not observed among HIV- women.

In conclusion, vitamin D insufficiency is common and comparably prevalent among HIV+ and HIV- Hispanic and AA postmenopausal women living in the northeastern US. Lower serum 25OHD is associated with higher PTH levels, and in HIV+ women, is also associated with biochemical evidence of increased bone resorption. Whether these effects are associated with higher rates of bone loss remains to be determined.

**Advanced Hip Assessment and Bone Mineral Density in Japanese Women with Osteoarthritis.** M. Takakuwa<sup>\*1</sup>, K. Ohtsuka<sup>\*1</sup>, M. Konishi<sup>\*2</sup>, W. Wacker<sup>\*3</sup>, H. S. Barden<sup>3</sup>, Q. Zhou<sup>2</sup>. <sup>1</sup>Takakuwa Orthopedic Nagayama Clinic, Asahikawa City, Hokkaido, Japan, <sup>2</sup>GE Healthcare, Shanghai, China, <sup>3</sup>GE Healthcare, Madison, WI, USA.

Osteoarthritis (OA) and osteoporosis (OP) are common, age-related, musculoskeletal diseases with complex, interrelated associations with bone mineral density (BMD) and fracture risk. Measurement of BMD with dual-energy X-ray absorptiometry (DXA) is an accepted method for diagnosing osteoporosis and assessing fracture risk. Femoral strength is a function of bone mass and its spatial distribution, which are incorporated in several Advanced Hip Assessment (AHA) structural variables, including: Hip Axis Length (HAL), Cross-Sectional Moment of Inertia (CSMI), Cross Sectional Area (CSA), and femur Strength Index (SI), a measure of the ability of the hip to withstand a fall on the greater trochanter. We measured BMD and AHA variables in 30 women with OA and 1291 controls, using Lunar Prodigy Advance (GE Healthcare). Controls and OA subjects were of similar age (70.0 vs. 69.2 yrs), height (148.7 vs. 147.7 cm) and weight (53.4 vs. 55.8 kg). Appropriate age-adjusted regression models for BMD and AHA variables were selected using TableCurve 2D. Minitab two-sample t-tests identified significant variation of mean values between subject groups. Age-related changes of AHA variables and femur neck BMD were strongly correlated. OA means were lower than controls for all variables except HAL. For OA subjects, age-adjusted femur neck and total femur BMD, and HAL and SI were significantly different from controls. Low SI and longer HAL, even after adjustment for femur neck BMD, were associated significantly with OA. We conclude that low SI and longer HAL appear to be predictors for OA, even after adjustment for femur neck BMD.

Femur BMD and Advanced Hip Assessment in Japanese Women with Osteoarthritis				
	Control Mean (SD)	OA Mean (SD)	p (Not Adjusted)	p (Adjusted for Neck BMD)

**Effects of Serum Factors During Osteoblast Differentiation - Implication for the Pathogenesis of Osteoporosis in Crohn's Disease.** M. Blaschke<sup>\*1</sup>, A. Hell<sup>\*2</sup>, R. Koepf<sup>\*1</sup>, D. Raddatz<sup>1</sup>, N. Schuetz<sup>3</sup>, N. Miosge<sup>\*4</sup>, G. Salinas-Riester<sup>\*5</sup>, H. Siggelkow<sup>1</sup>. <sup>1</sup>Gastroenterology and Endocrinology, University Medicine of Goettingen, Goettingen, Germany, <sup>2</sup>Orthopedics, University Medicine of Goettingen, Goettingen, Germany, <sup>3</sup>Orthopaedic Center for Musculoskeletal Research, University of Wuerzburg, Wuezburg, Germany, <sup>4</sup>University Medicine of Goettingen, Goettingen, Germany, <sup>5</sup>Molecular Cell Biology, University Medicine of Goettingen, Goettingen, Germany.

Crohn's disease (CD) is associated with a higher prevalence of osteoporosis, a complication, which is increasingly recognized as a significant source of morbidity also in these patients. The pathogenesis is still controversial, yet disease activity is thought to be one of the main contributing factors. We used primary human mesenchymal progenitor cells directed to the osteoblastic phenotype to investigate the effect of serum of seven patients during the active phase in CD on expression of osteoblast related genes. Four of the investigated patients had osteoporosis or osteopenia (CD-OPO+), three showed no obvious bone disease (CD-OPO-).

Mesenchymal progenitor cells obtained from a healthy patient grown in regular media were used in first passage at confluence. Cells were switched to 1% human serum and stimulated with 10 mM beta-glycerol-phosphate and 10 µM ascorbic acid. After 24 h human serum was changed to eight different CD sera (four CD-OPO+, three CD-OPO-) and cells were analyzed at days 3 and 14. Global gene expression analysis was applied using the human 4x44k design array from Agilent Technologies. A subset of regulated genes were reevaluated at all time points by real-time PCR.

The quantitative changes in significantly altered genes were listed using different criteria using the principal component analysis (PCA). A group of 38 genes was identified showing a contrast of 2 for CD-OPO+ versus CD-OPO-. A second list including 236 genes could be generated showing a contrast of 1.5 between the two groups. Regulated genes participate in the actin cytoskeleton, many of them associated with cell adhesion and extra cellular matrix. In addition, we identified regulation of genes associated with bone diseases and repression of the Wnt and TGF-beta pathways. Genes coding for proteins involved in the lipid and fatty acid metabolism were strongly increased in CD-OPO+ treated samples. Serum from CD patients with osteoporosis compared to serum from CD patients with healthy bone induced a different set of genes, including multiple involved in bone differentiation and disease. Our results suggest, that serum factors contribute decisively to bone disease in CD patients probably mediated by mesenchymal progenitor cells

**Interactions between Obesity, Cardiovascular Disease and Bone Formation.** J. L. Stevens-Smith<sup>\*1</sup>, A. Scutt<sup>\*2</sup>, G. Reilly<sup>1</sup>. <sup>1</sup>Engineering Materials, University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>Musculoskeletal Science Medical School, University of Sheffield, Sheffield, United Kingdom.

Cardiovascular and bone diseases are of great physiological and economic importance. Cardiovascular disease causes 17.5million deaths globally per annum. Osteoporosis is a metabolic bone disease characterised by a low bone mineral density (BMD). Obesity is a well known risk factor for cardiovascular disease but it is not generally associated with osteoporosis. Recent research, however, has suggested a link between osteoporosis and levels of adipocytokines and labelled osteoporosis the 'obesity of bone'. In this study we investigate the effect soluble products of adipose tissue on markers of bone formation. The effects of a cardiovascular disease on bone strength and density were investigated in a mouse model of cardiovascular disease.

Tibiae were isolated from a mouse model of cardiovascular disease (via a high fat Paigen diet<sup>1</sup>) and controls. The bone mineral density and structure were analysed by micro-CT and OCT (Optical Coherence Tomography). Bone strength was measured using the three-point bending test in an Electroforce 3200 (Bose) testing system. Mesenchymal Stem Cells (MSCs) were isolated from rat bone marrow and resuspended in 10ml cell culture medium. Fat from the abdomen, epididymus and kidneys was dissected from the same rats and 1.2g of fat was placed in 50mls of culture medium for 24 hrs in standard incubator conditions, the media was filtered and used as 'fat conditioned medium'. 2ml of fat conditioned medium was added to the cells' standard medium on day two of culture and on each subsequent media change. Cultures were stopped after 14 days and stained for alkaline phosphatase, Alizarin red (calcium), Sirius red (collagen), and methylene blue.

In the mouse model there were no differences in trabecular bone mineral density between mice on standard diets and mice fed the high cholesterol diet. However mechanical testing demonstrated a lower ultimate strength and Young's modulus of tibiae from the cardiovascular diseased mice. OCT demonstrated a corresponding decrease in optical scattering in the cortical bone. In the MSC cultures, alkaline phosphatase activity was 70% higher in the groups treated with abdominal and epididymal fat conditioned medium, compared to controls. Collagen and calcium deposition was also higher as was total colony number. These data suggest that higher body fat deposition associated with obesity and cardiovascular disease has strong effects on mesenchymal stem cell differentiation and whole bone properties.

**Diffuse Sclerosing Osteomyelitis of the Mandible: Case Report and Literature Review.** A. L. Schafer, R. Silva\*, M. Yafai\*, D. Shoback. San Francisco VA Medical Center and University of California, San Francisco, San Francisco, CA, USA.

Osteonecrosis of the jaw is a serious complication of bisphosphonate therapy and highlights the need for greater understanding of bisphosphonate effects on oral bone. We evaluated a patient with diffuse sclerosing osteomyelitis of the mandible (DSOM), for which there are reported dramatic improvements after IV bisphosphonate therapy. DSOM is a chronic inflammatory condition with intermittent, acute flares of pain and swelling in the absence of pus or fistulae. Response to conventional treatment with antibiotics is transient. Frequent flares lead to pain and progressive loss of oral function.

A 51 year-old man presented to the Oral and Maxillofacial Surgery Department with 3 years of recurrent pain and swelling of the left mandible. Repeated biopsies, debridements, and cultures failed to isolate a causative organism, although he had a modest clinical response to clindamycin. He had no history of endocrine or metabolic bone disorder. Examination showed diffuse left facial swelling, redness, warmth, and tenderness and marked trismus. CT showed cortical irregularity, destruction, and sclerosis of the left mandible. Technetium scan showed marked uptake in the left mandible. ESR and high-sensitivity CRP were elevated at 31 mm/hr (nl 0-15) and 41.9 mg/L (nl 0.2-7.5), respectively. Clindamycin and analgesics were increased, but symptoms continued unabated, and eventually he was admitted to the hospital for IV pain management. After literature review disclosed potential benefit from IV bisphosphonates, he received pamidronate 60mg IV. In 2 days, jaw swelling and pain decreased markedly. After 5 days, he had complete resolution of symptoms and remains without recurrence 3 months later.

There are 7 reports of DSO treated with IV or oral bisphosphonates, 6 of them cases of DSOM (3 children, 3 adults), and one trial with 10 patients. There are 3 cases of DSO of the femur and/or tibia. The 2 adults and 2 of the 3 children who received IV bisphosphonates for DSOM had resolution and lasting remissions. The third child developed mouth ulcers and increased pain and swelling. In the randomized trial of IV clodronate vs. placebo for DSOM, there was no difference in immediate pain relief between the 2 groups, but there was statistically significant decreased pain intensity 6 months after clodronate therapy (vs. placebo), without adverse events. Our patient with DSOM had a dramatic response to pamidronate, similar to patients in the literature. This case highlights the importance of accurate oral pathologic diagnosis and the need for greater understanding of mandibular bone disorders, especially the role of suppressing bone turnover in controlling inflammation and sclerosis in DSOM.

**Discordance in Femoral Neck Bone Density in Subjects with Osteoarthritis.** M. Tuteja<sup>\*1</sup>, J. Glowacki<sup>2</sup>, S. Hurwitz<sup>\*3</sup>, T. S. Thornhill<sup>\*2</sup>, M. S. LeBoff<sup>1</sup>. <sup>1</sup>Endocrine, Diabetes, and Hypertension Division, Brigham and Women's Hospital, Boston, MA, USA, <sup>2</sup>Department of Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, <sup>3</sup>Biostatistics, Brigham and Women's Hospital, Boston, MA, USA.

Osteoarthritis (OA) is a common disease that increases with age and currently affects an estimated 27 million Americans. Although previous studies suggest that subjects with OA have elevated bone density, we found low bone mass in a subgroup of hip OA subjects<sup>1</sup>. In non-OA women, bilateral hip bone density measurements may show a discordance in the hip BMD that may result in differences in treatment classification and fracture risk assessments<sup>2</sup>. To determine whether site-specific hip BMD measures are confounded by the presence of OA, we measured BMD in 26 subjects who were scheduled for hip replacement for confirmed advanced OA and with no comorbidities or medications affecting bone. BMD was measured by dual X-ray absorptiometry (Hologic, Discovery) on the surgical (Surg) and non-surgical (Non-Surg) hip. There were 14 (54%) women. The mean age  $\pm$ SD of the subjects was 66.1  $\pm$  10.1 years. The median BMI was 25.9 (range 19.8 to 42.6). The mean 25-hydroxyvitamin D level  $\pm$ SD was 32.3  $\pm$  9.3 ng/ml (n=22). Vitamin D insufficiency (defined as a 25(OH) D level  $\leq$ 32 ng/mL) was present in 50% of subjects. Compared with the FN BMD on Surg hip with advanced OA (mean BMD 0.819  $\pm$  0.141 gm/cm<sup>2</sup>), FN BMD on the Non-Surg hip (0.756  $\pm$  0.139 gm/cm<sup>2</sup>) was lower by 8% (p=0.010), without differences in the TH measurements (p= 0.99). Osteopenia at the FN site (BMD, T-score between -1.0 and -2.5) was present in 35% of the Surg hips versus 50% of the Non-Surg hips. These data suggest that advanced OA can be associated with a higher bone density at the femoral neck but not the TH. Because the risks of OA and of low bone mass both increase with age, discrepancies in the femoral neck BMD, which is used for fracture risk assessment, may have an impact on patient treatment decisions.

**Unsymmetrical Beam Theory and Finite Element Method: Analysis of Murine Cortical Bone based on microCT Imaging.** T. Kummer<sup>\*1</sup>, N. Götzen<sup>\*2</sup>, M. M. Morlock<sup>\*2</sup>, M. Amling<sup>3</sup>. <sup>1</sup>Department of Emergency Medicine, Brown University School of Medicine, Providence, RI, USA, <sup>2</sup>Biomechanics Institute, Hamburg University of Technology, Hamburg, Germany, <sup>3</sup>Center for Biomechanics & Skeletal Biology, University Medical Center Hamburg Eppendorf, Hamburg, Germany.

We compared two methods for the numerical analysis of the murine femur. Our goal is to develop a tool that allows the routine calculation and visualization of important biomechanical parameters without the difficulties and time constraints of the more sophisticated FE analysis.

Femora of 19 10-week old female C57BL/6 mice were scanned using a  $\mu$ CT 40. MATLAB was used for the morphometrical analysis of the mid-diaphysis. To compensate for skewed bending, the principal moments of Inertia  $I_1$  and  $I_2$  were calculated. Ultimate load and displacement were recorded during a three-point bending test and the extrinsic stiffness of the bone was calculated from the slope of the load-displacement curve.

The surface stress was calculated using the beam theory for unsymmetrical bending and the results were mapped onto a polygonal surface. FE analysis based on a linear-elastic simulation with an iterative solver (Ansys, USA) and conventional meshing technique was used to calculate and visualize the surface stress. Standard approaches for both methods were used to determine Young's modulus.

Maximal tensile stresses were not significantly different using the Beam Theory and FE method ( $75.82 \pm 2.37$  vs.  $77.67 \pm 2.35$  MPa,  $p=0.58$ ), while FE analysis resulted in higher peak compressive surface stresses ( $-78.81 \pm 2.77$  vs.  $-98.23 \pm 2.84$  MPa,  $p<0.01$ ). Figure 1 and 2 show the mapped surface stress and the stress distribution along the midshaft. The Young's Moduli were not significantly different ( $3166 \pm 747$  vs.  $3326 \pm 755$  MPa,  $p=0.51$ ).

In conclusion, we found that the ultimate tensile stresses, which are crucial for fracture initiation, as well as the Young's moduli were calculated and displayed correctly compared to the FE analysis. The peak compressive stresses were underestimated by an average of 20%.

**Contributions of Trabecular and Cortical components to Biomechanical Properties of Human Vertebrae.** J. P. Roux<sup>\*1</sup>, J. Wegrzyn<sup>\*1</sup>, M. E. Arlot<sup>1</sup>, Z. Merabet<sup>\*1</sup>, M. L. Bouxsein<sup>2</sup>, P. D. Delmas<sup>1</sup>. <sup>1</sup>INSERM unit 831, Université de Lyon, Lyon, France, <sup>2</sup>Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA.

Vertebral fractures are common in elderly persons, yet the mechanisms of injury underlying these fractures remain obscure. Whereas there is clear evidence for a strong influence of the quantity of bone (i.e., bone mass or BMD) on the mechanical behavior of vertebrae, there are less data addressing the relative influence of cortical and trabecular microarchitecture. Thus, the aim of this study was to determine the relative contributions of bone mass, trabecular microarchitecture and cortical thickness and curvature to the mechanical behavior of human lumbar vertebrae. We obtained 31 L3 vertebrae (16 men and 15 women, aged respectively  $75 \pm 10$  yrs and  $76 \pm 10$  yrs), and assessed BMD ( $\text{g}/\text{cm}^3$ ) of the vertebral body by lateral DXA; vBMD ( $\text{g}/\text{cm}^3$ , as BMC / directly measured vertebral body volume); 3D trabecular microarchitecture (BV/TV, trabecular thickness (Tb.Th), degree of anisotropy (DA), and structure model index (SMI)); thickness and curvature of the anterior cortex by  $\mu$ CT ( $35 \mu\text{m}$  voxel size, Skyscan1076). Then, compressive stiffness and failure load were measured on the whole vertebral body. No difference was found between sex, except for BMC, which was higher in men than women ( $5.99 \pm 1.25$  vs  $7.18 \pm 1.88$ , T-test  $p=0.05$ ). BMD was strongly correlated to compressive stiffness ( $r=0.60$ ) and failure load ( $r=0.70$ ). Except for DA, all trabecular parameters ( $r=0.36-0.58$ ,  $p=0.05-0.001$ ) and anterior cortex thickness or curvature ( $r=0.36-0.61$ ,  $p=0.05-0.0001$ ) were correlated with mechanical behavior. Stepwise and Multiple regression analyses indicated that the combination of BMD, SMI and Tb.Th was the best predictor of failure load ( $R=0.80$ ); BMD, Tb.Th and curvature of the anterior cortex were the best predictor of stiffness ( $R=0.82$ ) and anterior cortical thickness and BMD were the best predictor of work to failure (i.e. ability to absorb energy) ( $R=0.68$ ). Our data imply that measurements of cortical thickness and curvature may enhance predictions of vertebral fragility, and that therapies which improve both vertebral cortical as well as trabecular bone properties may provide a greater reduction in fracture risk.

**Murine Bone Mechanics Is Determined by the Ultrastructural Canal Network in a Sex- and Strain-Specific Manner.** P. Schneider<sup>\*1</sup>, R. Voide<sup>\*1</sup>, L. R. Donahue<sup>2</sup>, R. Müller<sup>1</sup>. <sup>1</sup>Institute for Biomechanics, ETH Zurich, Zurich, Switzerland, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME, USA.

Previous results from our group revealed that the canal network is a major contributor to cortical tissue porosity on an ultrastructural level, and thus, may be linked to bone mechanics. Therefore, the goal of this study was to quantify the contribution of the canal network to murine bone mechanics. To this end, we designed a mouse model including strains derived from C57BL/6J (B6) and C3H/HeJ (C3H) mice characterizing low and high bone mass phenotypes, respectively, with physiological (*lit*+) and absent (*lit*lit) growth hormone (GH) levels. Femoral mid-diaphyses of the four resulting mouse strains B6-*lit*+, C3.B6-*lit*+, B6-*lit*lit, and C3.B6-*lit*lit (N=12 each, 4-mo-old) were scanned using synchrotron radiation-based micro-computed tomography at a nominal resolution of  $3.5 \mu\text{m}$ . For quantitative analysis, morphometric indices characterizing the macroscopic cortical bone compartment and the canal network were derived. For mechanical testing, three-point bending tests were performed and ultimate force ( $F_u$ ) was determined. Multiple linear regression models were built to explain the variation in  $F_u$  in terms of the morphometric indices. For both *lit*lit strains the absence of GH removed sex differences for bone size still present in the *lit*lit strains. However, sex differences in bone strength characterized by  $F_u$  were removed only in B6-*lit*lit. These differences in the mechanical properties could only be explained by sex differences in cannular morphometry found in the same animals. From this, we hypothesized that cannular parameters accounted for the variance in  $F_u$  unexplained by bone size alone. We verified this hypothesis for *lit*lit strains, which covered a broad range in bone strength. Multiple linear regression showed that bone size predicted bone strength to a great extent for C3.B6-*lit*lit ( $R^2_{adj} = 0.90$ ) but only moderately for B6-*lit*lit ( $R^2_{adj} = 0.51$ ). Moreover, bone strength prediction was increased by 6% and 75% for C3.B6-*lit*lit ( $R^2_{adj} = 0.95$ ) and B6-*lit*lit ( $R^2_{adj} = 0.89$ ), respectively, when including cannular parameters like canal volume density, canal spacing or mean canal length in addition to bone size. We consequently provided strong evidence for a significant influence of the canal network on murine bone mechanics in a sex- and strain-specific manner. The larger increase in the power to predict bone strength for low bone mass B6-*lit*lit (75%) compared to high bone mass C3.B6-*lit*lit (6%) was due to strong coupling of the canal network with bone size for C3.B6-*lit*lit, which was absent for B6-*lit*lit. Finally, we believe that morphometric analysis of ultrastructural phenotypes will give new insights in the assessment of bone quality and the mechanical competence of bone.

**Optimization of Failure Load Estimation using Radiographs of Human Cadaveric Femur.** C. D. Arnaud<sup>1</sup>, S. Liew<sup>\*1</sup>, E. Thrall<sup>\*2</sup>, B. Roberts<sup>\*2</sup>, R. Vargas-Voracek<sup>\*1</sup>, P. Hess<sup>\*1</sup>, M. L. Bouxsein<sup>2</sup>. <sup>1</sup>Imaging Therapeutics Inc., Redwood City, CA, USA, <sup>2</sup>Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA.

Measurement of BMD by DXA is the current gold standard for diagnosis of osteoporosis. However, several studies have been critical of BMD for not fully accounting for changes in hip fracture rate in osteoporosis therapies. Bone geometry and trabecular architecture have been proposed as factors that contribute to bone strength. In this study we tested the ability of an optimization approach using radiograph-based trabecular pattern and geometric parameters to predict femoral strength.

Human-cadaver femora from 51 donors (34 female, 17 male) 55 to 98 years old were selected as representative of the target population of individuals likely to suffer a hip fracture. DXA BMD and x-ray images were obtained on all femora following a predefined imaging and positioning protocol. Femoral strength was assessed in a sideways fall configuration simulating impact to the greater trochanter. X-Ray images were analyzed to obtain femoral geometry and trabecular micro-architecture measurements. Combinations of measurements that were most robust in estimating failure load were identified using stepwise linear regressions and cross-validation. The ability of x-ray based measurements to complement DXA-BMD for prediction of femoral strength was also investigated.

A combination of five radiograph-based measurements were strongly correlated to femoral failure load ( $r=0.87$ ). Cross-validation using repeated random selections of 34 cases for optimization and 27 for validation provided an average correlation value of  $r=0.85$ . DXA total hip BMD by itself correlated strongly with failure load ( $r=0.84$ ), but the association was significantly improved to  $r=0.93$  with the addition of 5 radiographic structural measurements.

Altogether, these results indicate that radiograph-based measurement of femoral geometry and projected trabecular bone micro-architecture has the potential of providing an alternative, non-invasive and widely accessible approach to the estimation of femoral strength and possibly hip fracture risk. The follow-on blinded validation phase of the study will provide further insights on the generalizability of this method, and its relative performance with other imaging modalities.

Method	Correlation with failure load, $r$ ( $r^2$ )
DXA BMD	0.84 (0.71)
Radiographic measurements	0.87 (0.76)
DXA BMD + radiographic measurements	0.93 (0.86)

**Overweight Children Are More at Risk to Sustain a Forearm Fracture due to Poor Bone Strength Relative to Body Weight.** G. Ducher<sup>1</sup>, R. Daly<sup>2</sup>, G. Naughton<sup>\*3</sup>, P. Eser<sup>\*4</sup>, R. English<sup>\*1</sup>, A. Patchett<sup>\*1</sup>, K. Gravenmaker<sup>\*5</sup>, M. Seibel<sup>6</sup>, A. Javai<sup>\*5</sup>, R. Telford<sup>\*7</sup>, S. Bass<sup>1</sup>. <sup>1</sup>Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia, <sup>2</sup>Department of Medicine, Western Hospital, The University of Melbourne, Melbourne, Australia, <sup>3</sup>Australian Catholic University, Melbourne, Australia, <sup>4</sup>Division of Clinical Epidemiology & Biostatistics, University of Bern, Bern, Switzerland, <sup>5</sup>The Canberra Hospital, Canberra, Australia, <sup>6</sup>ANZAC Research Institute, Sydney, Australia, <sup>7</sup>Australian National University, and The Commonwealth Institute (UK and Australia), Canberra, Australia.

Comparison of bone strength between overweight and normal-weight children using 3D imaging techniques has been conducted at the femur and tibia, but not the forearm, a site prone to fracture in children. The aim of this study was to investigate forearm bone strength in prepubertal children of different adiposity levels.

Bone mass (BMC), geometry (total area, ToA) and trabecular volumetric density (TrD) were measured by pQCT at the nondominant radius (4% and 66%; TrD: 4%) in 511 children (253 boys), mean age  $8.3 \pm 0.4$  years. Two bone strength indices combining bone size and volumetric density were calculated: BSI (ToA\*ToD<sup>2</sup>) at the 4% site and polar SSI at the 66% site. The ratio between fat and muscle cross-sectional areas (66% radius) was used as an indicator of adiposity. A total of 111 children (22%) were classified as overweight (BMI>equivalent to 25 kg/m<sup>2</sup> in adults). As expected, overweight children were heavier (+3SD) and fatter (adiposity +2SD), but were also taller (+0.7SD), had larger muscle CSA (+1.2SD) and greater values for all bone parameters than normal-weight peers (Z-scores +0.5 to +0.9SD,  $p < 0.0001$ ). Age was not different between the two groups. Compared to height or weight, muscle CSA was a better predictor of BMC, ToA, BSI and SSI ( $r=0.58-0.68$ ,  $p < 0.0001$ ) and TrD ( $r=0.2$ ,  $p < 0.0001$ ). The differences in BMC, ToA, BSI and SSI remained significant after adjustment for height (except for ToA at 4%). After adjustment for muscle CSA, these differences disappeared except for ToA at 4% that became lower in overweight children ( $p=0.035$ ). TrD was greater in overweight children before (+0.6 SD,  $p < 0.0001$ ) and after adjustment for muscle CSA. Adiposity (fat CSA/muscle CSA) was negatively correlated with BMC, ToA and BSI at the radius 4% only ( $r=-0.1$ ,  $p < 0.06$ ). After controlling for body weight, these correlations were stronger and significant for all bone parameters at both sites ( $r=-0.36$  to  $-0.55$ ,  $p < 0.0001$ ), except for TrD.

Overweight children have stronger bones due largely to greater muscle size. However, high adiposity is associated with lower bone mass, size and strength relative to body weight, placing overweight children at higher risk for forearm fracture.

**Temporal Trends in Vertebral Size and Shape from Medieval to Modern-Day.** J. A. Junno<sup>\*1</sup>, M. Nieminen<sup>\*2</sup>, M. Niskanen<sup>\*3</sup>, J. Tuukkanen<sup>1</sup>. <sup>1</sup>Anatomy and Cell Biology, University of Oulu, Oulu, Finland, <sup>2</sup>Radiology, University of Oulu, Oulu, Finland, <sup>3</sup>Anthropology, University of Oulu, Oulu, Finland.

Human lumbar vertebrae support the weight of upper body and loads lifted and carried by upper extremities causing significant loading stress to vertebral bodies. It is well known that trauma based vertebral fractures are common especially among elderly people. The aim of this study was to determine the factors that could have affected to the prevalence of trauma based vertebral fractures from medieval to present. According to this study there seems to be morphological change in size and shape of vertebral body from medieval period to modern days. In this study the vertebral size and shape was measured from the 4<sup>th</sup> lumbar vertebra in chronologically differentiating samples using magnetic resonance imaging (MRI) and standard measuring calipers. Densitometric analyses were performed using pQCT and uCT. Modern sample consisted of modern Finns and archaeological samples of medieval Swedes and Britons. This survey revealed that the shape and size of the 4<sup>th</sup> lumbar vertebra has changed significantly from medieval times affecting greatly to the biomechanical characteristics of the lumbar vertebra. These changes have possibly affected to the appearance of trauma based spine fractures in modern times.

**Degradation of Allograft Bone Quality by Gamma Irradiation is Not Explained By Altered Enzymatic or Non-Enzymatic Cross-Links.** H. Nguyen<sup>\*1</sup>, E. Gyneys<sup>\*2</sup>, A. C. K. Wu<sup>1</sup>, A. I. Cassady<sup>2</sup>, M. B. Bennett<sup>\*1</sup>, D. A. F. Morgan<sup>\*4</sup>, P. D. Delmas<sup>2</sup>, M. R. Forwood<sup>1</sup>. <sup>1</sup>School of Biomedical Sciences, The University of Queensland, Brisbane, Australia, <sup>2</sup>INSERM Unit 831, University of Lyon, Lyon, France, <sup>3</sup>Institute of Molecular Biosciences, The University of Queensland, Brisbane, Australia, <sup>4</sup>Queensland Bone Bank, Brisbane Private Hospital, Brisbane, Australia.

Gamma irradiation is commonly used to sterilise bone allografts, with 25 kGy accepted as the Australian standard dose. Radiation causes dose-related degradation in mechanical properties of allograft bone, but it is not known if it affects allograft biocompatibility or enzymatic and non-enzymatic cross-links of collagen. Our aim was to investigate the mechanical properties of bone allografts irradiated at 25, 20, 15, 10, and 5 kGy; and to determine the activity of osteoblasts, osteoclasts and macrophages seeded onto this bone, and the content of pyridinoline (PYD), deoxypyridinoline (DPD) and pentosidine (PEN) in the bone samples. Sixteen femoral shafts from eight human donors were sectioned into six cortical bone beams (40x4x2mm) and irradiated at 0, 5, 10, 15, 20, and 25 kGy for three-point bending tests. 100µm-thick cortical bone slices were used for *in vitro* determination of macrophage activation (RAW264.7/ELAM-GFP cells), osteoblast (MC3T3E1 cells) proliferation and attachment assays, and osteoclast (Balb/c BMCs) formation and fusion assays. Samples of 0.3g of bone samples were hydrolysed for determination of PYD, DPD and PEN by HPLC. Irradiation up to 25 kGy did not affect the elastic properties of cortical bone, but the modulus of toughness was decreased from 87% to 74% ( $p < 0.05$ ) compared with controls from 15 to 25 kGy. Macrophage activation was not increased, and the proliferation and attachment of osteoblastic cells on irradiated bone was not affected. However, osteoclast formation and fusion were less than 40% of controls when cultured on bone irradiated at 25 kGy, and 80% at 15 kGy ( $p < 0.05$ ). Irradiation did not significantly alter the content of PYD, DPD or PEN. These data demonstrate that standard irradiation is not proinflammatory, but increases fragility of cortical allografts at doses above 15 kGy. Decreased osteoclast viability at these doses suggests a reduction in the capacity for remodelling of allograft bone. These changes cannot be explained by alterations in the enzymatic or non-enzymatic cross-links of collagen.

**The Effect of Collagen Degradation on the Fatigue Behaviour of Emu Bone.** C. A. Wynnyckyj<sup>1</sup>, S. Omelon<sup>2</sup>, J. Wang<sup>2</sup>, T. L. Willett<sup>2</sup>, M. D. Grynpas<sup>2</sup>. <sup>1</sup>Materials Science Engineering, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Mount Sinai Hospital, Samuel Lunenfeld Research Institute, Toronto, ON, Canada.

We recently conducted a pilot study using an ex-vivo emu model to investigate the ability of the Mechanical Response Tissue Analyzer (MRTA) in detecting changes in the collagen matrix of emu bone and to evaluate the differences between male and female emu bone. The emu tibia was chosen due to its size and approximate cylindrical shape, making it ideal for devices designed to accommodate human long bones. Male and female emu tibiae were endocortically treated with 1 M potassium hydroxide (KOH) for 1-14 days, resulting in negligible mass loss (0.5 %), collagen loss (0.05 %) and a significant reduction in modulus (18%). The MRTA detected this change however, the change in bone quality measured after KOH treatment by conventional clinical tools such as DXA and QUS varied by less than 2%. Male emu tibiae had significantly decreased failure stress and increased failure strain and toughness compared to female tibiae with increasing KOH treatment time. This was a surprising result since a minimal amount of collagen was removed. We hypothesize that the significant changes in bone mechanical properties may be due to partial debonding between the mineral and organic matrix or *in situ* collagen degradation.

To further determine the contribution of collagen on the mechanical properties of bone, we investigated the effects of KOH treatment on the fatigue resistance of female emu bone. Five groups (n=10) of mature female emu tibiae were endocortically treated with 1M KOH for 0, 1, 3, 7 and 14 days and then subsequently fatigued as controlled cyclic loading of bone is known to result in accumulation of microdamage and significantly reduce bone stiffness. Emu tibiae were fatigued at a frequency of 2 Hz under load control, corresponding to a set of initial strains ranging from 2000 µε to 6000 µε peak-to-peak. Strain was measured directly using strain gauges. The strain versus number of cycles to failure (S/N) was determined for each group and we found that the 14-day KOH treated specimens appear to resist less cycles at low strain fatigue. This difference in fatigue life could be due to collagen mineral interface alterations or changes in the collagen matrix itself caused by KOH treatment.

**Non-invasive Detection of Bone Microdamage by Light Scattering.** J. H. Cole<sup>1</sup>, E. I. Waldorff<sup>2</sup>, M. V. Schulmerich<sup>1</sup>, K. A. Dooley<sup>1</sup>, S. A. Goldstein<sup>2</sup>, M. D. Morris<sup>1</sup>. <sup>1</sup>Department of Chemistry, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>Department of Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA.

Microcracks develop in bone when loading rates, magnitudes, and/or cycles exceed the load-bearing capacity of the tissue. With increased loading (e.g., in athletes and military recruits) or degraded tissue properties (e.g., with osteoporosis), the repair mechanisms of bone may become insufficient, leading to microcrack accumulation and fracture. Current *in vivo* imaging tools cannot examine microdamage in bone tissue. Previous studies reported the use of optical techniques to assess bone demineralization and microdamage in excised bone tissue, as well as bone mineral and lipid content *in vivo* using idealized models. We recently developed a simple, non-invasive light scattering probe that allows us to detect microdamage in cortical bone tissue of excised limbs. Microcracks scatter light more than the undamaged native bone tissue, providing a direct means to evaluate the extent of damage. The objective of our study was to optimize probe sensitivity for detecting damage and to explore its capability for *in vivo* use. Here we report the probe's potential to assess aspects of bone quality. By using concentric paths to deliver light to the specimens (in a ring) and collect light scattered by the specimens (in a disk inside the ring), and by varying the separation between the ring and disk, we can examine tissue properties below the surface. This technique exploits the difference in tissue scattering properties between bone tissue and overlying skin, connective tissues, and the serum-based fluid between the microcracks. Using phantoms, we have tested the ability of the ring/disk light scattering probe to find boundaries between materials with different scattering properties, similar to what occurs *in vivo* with bone and surrounding soft tissues. These phantoms, which are widely used in tissue optics studies, include: a) layered composites made of engineering

polymers and b) excised murine cortical bone placed at known depths in an Intralipid® suspension. For these phantoms, an abrupt change in scattering behavior was observed, corresponding to the boundary between the dissimilar materials. For further analysis and development of the light scattering probe, we plan to take transcutaneous bone measurements in murine limbs both with and without microdamage and to compare those with exposed bone measurements. Because skin, connective tissue, and bone have different scattering properties, we can distinguish between the different scattering signals arising from these tissues. This non-invasive probe has great potential as an inexpensive and portable diagnostic tool.

**Characterization and Genetic Mapping of Bone Size Phenotypes in GK and F344 Rats Using a New 3D CT Method.** S. Lagerholm, H. Luthman\*, M. Nilsson\*, K. Åkesson. Dept of Clinical Sciences, Malmö University Hospital, Lund University, Malmö, Sweden.

Evaluation of bone phenotypes requires methods with high resolution and precision, particularly when determining bone parameters in animal models. The aim of this study was to test reproducibility and precision of a new 3D CT method measuring bone size parameters in rats and identify quantitative trait loci (QTLs) regulating bone size phenotypes.

Tibia and femur from male and female diabetic GK and non-diabetic F344 rats, representing the parental (n= 39), F1 (n=37) and F2 (n=206) generations were examined with CT (Somatom Sensation 64, Siemens, Erlangen, Germany) and analyzed using Analyze® software version 5.0 for the parameters: Total and cortical volume (mm<sup>3</sup>), total and cortical BMC (mg/cm<sup>3</sup>), straight and curved length (mm), peri- and endosteal area at mid-shaft (mm<sup>2</sup>). CVs were calculated based on repeated measurements and repeated analyses. The F2 progeny (108 male and 98 female) were genotyped for 192 genome-wide microsatellite markers at an average distance of 10 cM. Genetic maps were generated using Mapmaker/EXP and QTLs were identified in MapManager/QTx.

The repeated measurement CV (%) was parameter dependent; total and cortical volume 0.0-0.0, length 1.8-5.9, mid-shaft peri- and endosteal area 2.9-4.5 and BMC (total and cortical) 0.0-0.0. Intra-observer analysis yielded variation between 0.4-9.2. The cross-sectional areal measurements had the largest variation due to small size and subsequent few pixels, nevertheless area and periosteal circumference were highly correlated (r=0.997). All bone size parameters were significantly lower in the F344 females (Table 1). In males, the findings were similar except for bone length, total volume and BMC. Several QTLs were identified in both males and females some of which were reciprocal-cross or sex specific; LOD scores >4.0 on Chr 1, 3, 4, 9, 10, 17.

We show that this new 3D CT analysis provides high precision measurements of bone size parameters in rat bone, improving the available methods for determining bone phenotypes. Observed differences in bone size and bone mineral content between GK and F344 strains, make these rats ideally suited for studying genetic regulation of skeletal phenotypes. Several unique QTLs linked to bone size were identified, many overlapping previously identified QTLs in rats and homologous with regions found in humans.

Table 1.

CT results	Female (Tibia/Femur)		P-value
	GK (n=10)	F344 (n=10)	
Bodyweight (g)	250±20	192±12	<10 <sup>-4</sup>
Total volume (mm <sup>3</sup> )	371±19 / 430±18	285±14 / 337±29	<10 <sup>-4</sup> / <10 <sup>-4</sup>

**The Correlation between DXA Femur Strength Index and QUS Heel Stiffness Index in Chinese Women.** H. Xu<sup>1</sup>, J. Li<sup>1</sup>, Q. Wu<sup>2</sup>, H. S. Barden<sup>3</sup>, Q. Zhou<sup>4</sup>. <sup>1</sup>Department of Nuclear Medicine, The First Affiliated Hospital, Jinan University, Guangzhou, China, <sup>2</sup>Medical College, Jinan University, Guangzhou, China, <sup>3</sup>GE Healthcare, Madison, WI, USA, <sup>4</sup>GE Healthcare, Shanghai, China.

Hip strength analysis (HSA) is the new application for dual-energy X-ray absorptiometry (DXA) that allows the measurement of geometric contributions to bone strength in the proximal femur. The femur strength index (FSI) assessed by DXA may be an independent predictor of hip fracture risk. Quantitative ultrasound (QUS) bone measurement is a promising new technology for the screening diagnosis of osteoporosis. This study was aimed at assessing the correlations between the FSI calculated by DXA and SI of the heel calculated by QUS in Chinese women. We measured the bone mineral density (BMD) of the bilateral proximal femurs (i.e., total hip, femoral neck, Ward's

triangular area and trochanter) using DXA, and speed of sound (SOS), broadband ultrasound attenuation (BUA), and a calculated strength index (SI) of the left calcis in 90 Chinese females aged from 20-80 years. With HSA, a series of structural variables such as the femoral neck cross-sectional moment of inertia (CMSI), section modulus (Z), cross-sectional area (CSA), femoral neck shaft angle, and hip axis length (HAL) were assessed automatically. The BMD precision for bilateral proximal femur was 0.7-2.2%, depending on ROI. The precision for FSI was 2.6% for left side and 1.9% for right. The precision of SI, SOS and BUA was 1.8%, 0.4% and 2.9%, respectively. No significant differences ( $p>0.05$ ) in bilateral femoral BMDs (total hip, femoral neck, Ward's triangular area and trochanter) and FSI (left FSI  $1.69\pm0.45$  vs right FSI  $1.69\pm0.41$ ) were found. There were significant correlations ( $p<0.001$ ) for heel SI and femoral BMDs ( $r=0.44-0.61$ ), heel BUA and femoral BMDs ( $r=0.34-0.52$ ), and heel SOS and femoral BMDs ( $r=0.42-0.59$ ). Heel SI correlated significantly ( $p<0.001$ ) with CSA ( $r=0.52$ ), CSMI ( $r=0.36$ ), and Z ( $r=0.42$ ) for all subjects. The correlation between FSI assessed by DXA and heel SI calculated by QUS ( $r=0.18$ ) was not significant. The difference of the alignment of trabeculae in the stress orientation between femur neck and calcaneal bone may be one of reasons for no significant correlation between FSI and heel QUS. Understanding the reason for this lack of association requires further study.

**Cost-Effective Rack and Pinion System for Torsion Testing of Rodent Bones.** M. Saunders. Center for Biomedical Engineering, University of Kentucky, Lexington, KY, USA.

Thorough mechanical testing of rodent bones requires an understanding of bone behavior in a variety of loading modes including tension, compression, bending and shear. While these tests are easily conducted with single axis mechanical testing machines, it may also be desirable to determine torsional properties of bone. Although higher end biaxial materials testing machines will enable torsional and/or rotational testing, simpler, less expensive systems rarely offer these capabilities. This work illustrates the development of a torsion system that uses a simple rack and pinion concept to deliver a rotary motion to bones given the linear motion of a testing machine. While mechanical and biomechanical engineers may have high end equipment, as the bone field becomes more interdisciplinary more and more biologists will need cost-effective mechanical testing capabilities and this torsion system has proven to be more than adequate for our mechanical testing needs. Furthermore, given the small-scale size of the rodent long bones, a series of potting and testing fixtures that enable preparation and handling of the specimens without incurring damage to the bone shafts was also fabricated. Bones were potted in the testing fixtures using bone cement and kept hydrated with saline at all times during potting and testing. While the concept can be used to adapt to any linear loading system, the torsion system here was developed for a loading platform we developed in-house. A 25 in-oz torque cell and 25 mm displacement sensor were outfitted to the system to record torque-twist data with real-time data acquisition. Using simple geometry and a dial caliper, the rack and pinion was calibrated to convert linear motion of the slide to rotary motion (twist) experienced by the specimen. Once calibrated the system was used to destructively test four, three month old mice humeri and quantify torsional properties. Bones were tested to failure under displacement control at a constant linear rate of 2mm/sec (6.5 deg/sec). From destructive testing on the four bones, mean  $\pm$  standard deviations for stiffness, failure torque and failure twist were:  $8.24 \pm 3.7$  (Nmm/deg);  $12.00 \pm 5.1$  (Nmm); and,  $12.01 \pm 2.8$  (deg), respectively. Results are acceptable in comparison to published studies. Similar agreement was found for femurs tested to failure in torsion. The development of this simple rack and pinion torsion fixture enabled successful torsion testing of rodent limbs and the potting system enabled the bones to be aligned and tested along their neutral axis to guarantee pure torsion and increase testing accuracy and precision. As such, the system developed offers a cost-effective solution to adapt any axial testing machine to torsion testing.

**Comparison of HR-pQCT to DXA & QUS for the Assessment of Ex-Vivo Bone Strength.** I. Ally, J. Lau\*, C. Chan\*, A. M. Cheung. University Health Network, Toronto, ON, Canada.

Proper assessment of fracture risk depends on the ability to obtain a measure of the mechanical competence of bone, or bone strength. Current tools used to assess fracture risk, such as DXA and QUS, do not directly measure bone mechanical properties. Instead, they offer surrogate measures of bone strength based primarily on the bones' material properties (bone mineral content), and to some extent bone size. We conducted an ex-vivo emu study to examine how parameters measured by HR-pQCT, DXA, and QUS correlate with true bone mechanical properties. Forty emu tibiae were used for this study. Bone mineral content (BMC) and areal bone mineral density (aBMD) were measured by DXA, and the speed of sound through the bone (SOS) was measured by QUS. HR-pQCT was used to determine total volumetric density (TvBMD), cortical volumetric density (CvBMD), cortical thickness (CTh), total cross-sectional area (tCSA), and cortical cross-sectional area (cCSA). A bone strength index (BSI = CvBMD  $\times$  cCSA) was also calculated. To obtain the bones' mechanical properties, four-point bending tests were performed, and ultimate load, flexural cross-sectional bending stiffness (EI-4pt), and bone toughness were determined. We used Pearson correlations to examine the relationships between measures from mechanical bending tests and measures obtained from DXA, QUS, and HR-pQCT. Additionally, linear regression modeling was used to predict the mechanical properties of bone from parameters obtained

from DXA, QUS, and HR-pQCT measures. Results are shown in Table 1. We found that ultimate load correlates well with aBMD, BMC, CTh, and moderately with cCSA. Toughness correlates moderately with aBMD, CTh, and BMC. EI-4pt correlates strongly with BSI, BMC, cCSA, tCSA, and aBMD, and moderately with CvBMD and CTh. Measures of SOS had no significant relationship to any of the measures of bone mechanical competence. We also found that EI-4pt is best predicted by parameters obtained from HR-pQCT: cCSA, CvBMD, and CTh (adjusted  $r^2=0.83$ ,  $p<0.001$ ). Parameters obtained from HR-pQCT could not predict ultimate load better than DXA-based aBMD. Our results suggest that ultimate load and toughness are best predicted by aBMD. However, parameters measured by HR-pQCT are better able to predict true cross-sectional flexural stiffness than conventional measures obtained by DXA or QUS. HR-pQCT, then, provides unique information about bone mechanical competence that cannot be obtained by DXA or QUS.

Results are Pearson correlations (R <sup>2</sup> values followed by p-values in parentheses)				
		Ultimate Load	Toughness	EI-4pt

**Generating 3D Finite Element Models of a Human Proximal Femur from 2D DXA Data.** T. L. Bredbenner, D. P. Nicoletta. Materials Engineering, Southwest Research Institute, San Antonio, TX, USA.

The clinical standard for assessing an individual's risk of fracture is based on using a population-level statistical correlation to interpret clinical DXA data; however, these methods have been proven to be non-specific in assessing bone strength. Although engineering models based on clinical (QCT) imaging data improve the prediction of fracture load by providing a physics-based approach rather than a correlative approach, QCT is not widely available and biomechanical models that accurately represent the complex morphology of a human skeletal structure are time-consuming to create. In previous work, statistical shape and density modeling methods were used to develop and implement a parametric description of the complex geometry and bone mineral density (BMD) distribution based on clinical (QCT) imaging data for a set of 6 human female proximal femurs [1,2]. In the present study, a high fidelity 3D finite element (FE) model of a previously unseen (not included in the parametric model) individual human proximal femur was generated from clinical DXA data using the parametric model of the human proximal femur. The "unknown" target femur geometry and BMD distribution were determined from QCT data and the corresponding DXA data was simulated by projecting the target femur geometry and BMD distribution onto the coronal plane. The geometry and BMD of the target femur were quantified from the DXA data using standard descriptors [3,4]. The parametric model was then optimized to match the DXA data for the unknown femur, thus determining the "most probable" FE model that matches the target model. Error between the optimized models and the target femur were quantified using Euclidean distance, Mahalanobis distance, and maximum Hausdorff distance. Quantitative comparison demonstrated that the most probable FE model was capable of matching the target femur and predictive success was generally related to the number of descriptors used to drive the optimization process. The results demonstrate that a high fidelity 3D geometry and density-based FE model of an individual proximal femur can be efficiently reconstructed from 2D data using our existing parametric Statistical Shape and Density FE model. The resulting engineering models can then be used to assess the structural strength of an individual's femur, allowing a sophisticated interpretation of widely available clinical DXA scans for application to a variety of aging and disease-related conditions. **Do Racial Differences Exist in Cortical and Trabecular Bone? A pQCT Study in Young Adult Females.** N. K. Pollock<sup>1</sup>, E. M. Laing<sup>1</sup>, R. G. Taylor<sup>\*1</sup>, M. W. Hamrick<sup>2</sup>, C. A. Baile<sup>1</sup>, R. D. Lewis<sup>1</sup>. <sup>1</sup>Foods and Nutrition, The University of Georgia, Athens, GA, USA, <sup>2</sup>Cellular Biology and Anatomy, The Medical College of Georgia, Augusta, GA, USA.

Most reports examining the racial differences in bone have used DXA and found that areal BMD (aBMD) and/or bone mineral content (BMC) is higher in blacks than whites, although many of the reports do not take into account bone and body size. Few studies have investigated racial differences in the structural indices of bone using 3-dimensional imaging. The purpose of this investigation was to determine whether there are racial differences in BMC, bone geometry and BMD at the tibia and radius in black (n=48) and white (n=98) females, using peripheral quantitative computed tomography (pQCT). Female college freshman, 18 to 19 years of age, participated in this cross-sectional study. Because of the importance of body size on bone, 25 whites and 25 blacks were individually matched on age (2%), height (1%), fat-free soft tissue mass (FFST; 2%), and weight (7%). Body composition [FFST, fat mass (FM) and %fat] was measured using DXA. Tibial and radial bone measurements were assessed at the 4%, 20% and 66% sites from the distal metaphyses, which reflect trabecular bone, cortical bone and muscle cross-sectional area (MCSA), respectively. Limb lengths were also measured at the tibia and radius. Given that racial differences in muscle size and body segment lengths can result in over- or under-estimates depending on which skeletal regions and races are compared, the data were adjusted for differences in MCSA and limb length at each respective bone site. Data were analyzed using independent samples t-tests and ANCOVA. Blacks vs. whites had greater tibial and radial length. MCSA differences were not observed between groups at the radius; however, at the tibia, blacks vs. whites had smaller MCSA. In the unadjusted data, blacks vs. whites had higher total volumetric BMD (tibia and radius), cortical BMD (Cort BMD; tibia only), cortical cross sectional area (tibia only), cortical BMC (tibia only), cortical thickness (tibia only), and lower trabecular BMD (tibia only), total cross sectional area (tibia and radius at 4% site only), and Cort BMD (radius only). After adjustment for MCSA and limb length, similar results were found within the unadjusted matched sample, except blacks vs. whites had higher polar strength-strain index at the tibia. Collectively, these results create a bone strength profile reflecting a stronger bone at the radius and tibia in young adult black vs. white females, possibly accounting for the lower fracture rates in older black females.

**Combined Cs-137 Gamma Irradiation and Hindlimb Unloading Rapidly Decreased Cancellous Bone Volume Fraction in the Mouse Lumbar Vertebrae.** J. S. Alwood<sup>\*1</sup>, K. Yumoto<sup>\*2</sup>, H. Kondo<sup>\*2</sup>, R. Mojarrah<sup>\*2</sup>, D. P. Lindsey<sup>\*3</sup>, G. S. Beaupre<sup>3</sup>, C. L. Limoli<sup>\*4</sup>, E. A. C. Almeida<sup>\*2</sup>, N. D. Searby<sup>\*2</sup>, R. K. Globus<sup>2</sup>. <sup>1</sup>Stanford University, Stanford, CA, USA, <sup>2</sup>NASA Ames Research Center, Moffett Field, CA, USA, <sup>3</sup>Bone and Joint Center of Excellence, VA Palo Alto Healthcare System, Palo Alto, CA, USA, <sup>4</sup>University of California Irvine, Irvine, CA, USA.

Spaceflight poses a risk to the skeletal system due to musculoskeletal unloading in microgravity and increased radiation exposure. As separate stimuli, unloading and irradiation each can reduce bone density and increase fracture risk, but combined effects have not been investigated. We hypothesize that skeletal integrity is further compromised when unloading and irradiation are combined. Sixteen-week old C57Bl6/J male mice were continuously hindlimb unloaded (HU) or normally loaded (NL) and either irradiated (IR) with gamma rays (Cs-137, ~1Gy/min) or sham irradiated. In the first experiment, NL and HU mice were irradiated (2 Gy) 3 days before tissue harvest on day 7. A longer duration experiment was carried out to test mechanical properties; NL and HU mice were irradiated (1 Gy) 10 days before tissue harvest on day 14. Cancellous tissue in tibiae and vertebrae were analyzed by microcomputed tomography and ultimate force determined by axial compression of the lumbar vertebral bodies (L1 and L3). Statistical significance was determined via 1-way ANOVA with Tukey-Kramer post-hoc comparison, with  $p < 0.05$ . In lumbar vertebrae, combined HU and IR caused a significant 13-15% decline in cancellous BV/TV compared to controls, a greater decrement than either HU or IR alone. However, in the tibiae, HU and IR alone and in combination caused a 14-22% decline in cancellous BV/TV. Lumbar BV/TV values strongly correlated with tibial BV/TV ( $r = 0.63 - 0.72$ ), although lumbar vertebrae displayed a more plate-like cancellous structure ( $SMI < 1.0$ ) than tibiae ( $SMI > 1.5$ ). In preliminary mechanical tests, combined HU and IR caused a 30% decrease in ultimate compressive force of L3 compared to controls, an effect greater than either HU or IR alone. However, L1 did not show such a large effect. In summary, HU and IR together caused a rapid decrease in cancellous BV/TV in lumbar vertebrae, which may reduce compressive strength. The more plate-like structure of cancellous tissue in lumbar vertebrae compared to the tibiae may account for the observed differences in sensitivity to HU and IR. We speculate microgravity together with radiation may increase fracture risk of the spine.

**Proton NMR Study of Transverse Relaxation in Rabbit and Rat Cortical Bone.** H. H. Ong<sup>\*1</sup>, S. L. Wehrli<sup>\*2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>Radiology, Laboratory for Structural NMR Imaging, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, <sup>2</sup>NMR Core Facility, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

The NMR signal of bone is comprised of collagen matrix protons, collagen fibril bound water, and water in the Haversian canals and lacuno-canalicular system. Proton NMR relaxometry has the potential to provide nondestructively insight into cortical bone porosity due to its known dependence on pore size. Here, we quantified relaxation time constants  $T_1$  and  $T_2$  of rabbit and rat tibia cortical bone specimens from free induction decay (FID) and Carr-Purcell-Meiboom-Gill (CPMG) signals. Sections of cortical bone ( $10 \times 4 \times 1 \text{ mm}^3$ ) were harvested from demarrowed tibia mid-shafts of healthy 20 week-old New Zealand white rabbits (N=5). Whole tibia mid-shafts were harvested and demarrowed from healthy 16 week-old Sprague-Dawley rats (N=4). CPMG and FID experiments were performed on a vertical-bore 9.4T spectrometer (DMX-400, Bruker Instr.). Normalized CPMG signal decays and FIDs were fitted to the bi-exponential curve  $M_1 \exp(-t/T_1) + M_2 \exp(-t/T_2)$  (Levenberg-Marquadt algorithm in Matlab), where  $t$  is either TE or FID time axis,  $M_1$  and  $M_2$  are the magnitudes of the two components, and  $T_1$  and  $T_2$  represent either  $T_1$  or  $T_2$  (Figure 1). The short  $T_2$  represents protons in collagen.  $D_2O$  exchange experiments that removed unbound water indicate that the majority of the FID signal (65%) is from water (Table 1). The major difference in relaxation behavior between rat and rabbit specimens was an increased fraction of the short  $T_2$  component for rat bone. From the dependence of  $T_2$  on pore size, short and long  $T_2$  components likely originate from water in the lacunae and Haversian canals, respectively. Therefore, our results suggest a lower fraction of Haversian canals in rat. Previous studies have indicated a greater porosity in rabbit bone. In conclusion, our results suggest transverse relaxation properties provide insight into the bone NMR signal and can detect inter-species differences between rabbit and rat cortical bone porosity

**Characterization of the Osteotomy Callus Using Fourier Transfer Infrared (FTIR) Imaging in a Rabbit Ulnar Model.** P. F. O'Loughlin<sup>\*</sup>, N. Karkare<sup>\*</sup>, J. B. Toro-Arbelaez<sup>\*</sup>, K. Voellmicke<sup>\*</sup>, E. Tomin<sup>\*</sup>, B. Shore<sup>\*</sup>, L. Spevak<sup>\*</sup>, A. L. Boskey, J. M. Lane. Orthopedic Surgery, Hospital for Special Surgery, New York, NY, USA.

The purpose of the present study was to test the hypothesis that the woven bone formed in four different models of fracture repair in the rabbit would have different matrix characteristics, based on Fourier transform infrared (FTIR) imaging. Non-unions account for greater than 10% of fracture complications encountered in the clinical setting. To prevent such complications, it is necessary to understand the biology of the processes involved. The process of mineralization is different in primary and secondary fracture healing due to the inherent rigidity of plate fixation as opposed to unfixed natural bone healing. The authors had previously demonstrated that fracture fixation accelerated the rate at which endochondral ossification progressed in terms of changes in matrix composition. A previously established rabbit ulnar fracture model was used. There were four groups each consisting of 21 mature male New Zealand white rabbits (6 mo. old). In an IACUC-approved study, both forelimbs were fractured in each rabbit, with limbs randomly assigned to each group. The groups were organized as follows: Group 1: uniplated 3mm gap, Group 2 - uniplated 1mm gap, Group 3 - plated 1mm gap, Group 4 - compression plate, no gap. Ulnae were harvested at 2, 4 and 8 weeks post-fracture and analyzed via histology and FTIR.

At 2 weeks and 4 weeks (see figure), mineral to matrix ratio, crystallinity and collagen cross-linking were not significantly different in lamellar or woven bone when comparing the four treatment groups, however the distribution of parameters did differ. At 8 weeks, a statistical difference in mineral quality was not found between the groups. Despite the mode of healing at 2, 4 and 8 weeks the mineral to matrix ratio, crystallinity and collagen cross-linking was not significantly different in either lamellar or woven bone. This study demonstrates that regardless of the mode of repair, there is no significant difference in the matrix characteristics of woven or lamellar bone whether produced by endochondral or intramembranous processes.

**Non-Steroidal Anti-Inflammatory Use and the Response of Bone to Exercise.** D. W. Barry<sup>1</sup>, R. E. Van Pelt<sup>2</sup>, C. M. Jankowski<sup>2</sup>, P. Wolfe<sup>3</sup>, W. M. Kohrt<sup>2</sup>. <sup>1</sup>General Internal Medicine, University of Colorado Denver, Aurora, CO, USA, <sup>2</sup>Geriatric Medicine, University of Colorado Denver, Aurora, CO, USA, <sup>3</sup>Preventive Medicine and Biometrics, University of Colorado Denver, Aurora, CO, USA.

The bone response to exercise is a prostaglandin-dependent process. Non-steroidal anti-inflammatory drugs (NSAIDs) inhibit prostaglandin synthesis and may affect the adaptation of bone to mechanical loading, particularly when administered before loading. The purpose of this study was to examine whether taking ibuprofen before or after exercise sessions influences the bone mineral density (BMD) response of premenopausal women to a 9-month bone-loading exercise program. We hypothesized that ibuprofen before exercise would diminish the BMD response more than ibuprofen use after exercise, and that the placebo group would exhibit the most robust response to exercise. Women were randomized (n=102) to 3 arms that took 2 study pills on exercise days as follows: 1) 400 mg ibuprofen before and placebo after exercise (ibuprofen/placebo), 2) placebo before and 400 mg ibuprofen after (placebo/ibuprofen), and 3) placebo before and after (placebo/placebo). The exercise program included progressive high-intensity resistance exercises, endurance exercises (primarily walking, running), and jumping/stepping exercises. DXA was used to measure BMD of the whole body, lumbar spine and proximal femur (total and subregions) at baseline and 9 months. Fifty-three percent of participants (n=54) exercised at 80% of the prescribed frequency ( $\geq 2.4$  times/wk); only data from these subjects were included in this analysis. The average age was  $32.1 \pm 5.5$  years. Relative changes from baseline BMD and bone mineral content (BMC) values are shown in Table 1. Contrary to our hypothesis, the placebo/placebo group did not have the largest increases in BMD; this may have been related to use of non-study NSAIDs. Rather, the most robust increases in BMD occurred in the placebo/ibuprofen group. It is possible that taking ibuprofen after exercise permits the activation of bone formation during exercise, but attenuates increases in pro-resorptive cytokines. Because this is the first study of the effects of NSAIDs on the adaptation of bone to exercise, findings should be considered preliminary. Further research is needed to confirm whether taking NSAIDs after exercise enhances the BMD response.

Table 1: Relative changes in BMD and BMC from baseline

		Percent change from baseline (mean $\pm$ SD)		
		Placebo/placebo (n=23)	Ibuprofen/placebo (n=17)	Placebo/ibuprofen (n=14)
Lumbar spine BMD		$0.3 \pm 2.1$	$-0.3 \pm 1.8$	$1.0 \pm 2.0$
Total hip BMD		$0.2 \pm 1.9$	$-0.2 \pm 1.3$	$2.1 \pm 1.7^{\dagger\dagger**}$
Femoral neck BMD		$-0.5 \pm 2.5$	$-0.4 \pm 1.9$	$1.6 \pm 2.9^{\dagger*}$
Trochanter BMD		$0.2 \pm 2.2$	$0.3 \pm 1.7$	$1.9 \pm 2.0^{\dagger*}$
Shaft BMD		$0.4 \pm 2.7$	$-0.4 \pm 2.0$	$2.1 \pm 1.6^{\dagger**}$
Total body BMC		$-0.4 \pm 1.4^*$	$0.2 \pm 1.5^{\dagger}$	$1.5 \pm 2.1^{\dagger\dagger}$

<sup>†</sup>Different from placebo/placebo at the 0.05 level <sup>††</sup>Different from placebo/placebo at the 0.01 level

<sup>\*</sup>Different from ibuprofen/placebo at the 0.05 level <sup>\*\*</sup>Different from ibuprofen/placebo at the 0.01 level

**An Effective Progressive Resistive Exercise Program from Prone Position for Paravertebral Muscles to Reduce Risk of Vertebral Fractures.** M. Sinaki<sup>1</sup>, M. J. Borgo<sup>2</sup>, E. Itoi<sup>3</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Mayo Clinic College of Medicine; Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Mayo Medical School, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Department of Orthopaedic Surgery, Tohoku University School of Medicine, Sendai, Japan.

In a previous communication, it was hypothesized that back strengthening from prone, rather than vertical position, can decrease the risk of vertebral fracture due to improvement of horizontal trabecular connections. In this communication, we discuss the method of a specific progressive resistive exercise (PRE) program that had been implemented in a two-year study to decrease the risk of vertebral fractures. Therefore, it is of great interest that we describe our methodology since we did not induce any vertebral fractures with this exercise program.

Sixty-seven Caucasian women ranging from age 49 to 65 (mean of 56 years) were randomly assigned to a control group (n=33) or an exercise group (n=34). All subjects were instructed in proper dynamic and static posture principles. The level of physical activity and back extensor strength was evaluated every four weeks for a period of two years. The study group performed PRE from the prone position against measured and progressively increasing resistance, up to four sessions a week; the control group did not. The isometric strength of the back extensor muscles was measured with a strain-gauge dynamometer. Thirty percent of the subject's maximum back extensor strength was prescribed for strengthening exercises.

A statistical analysis demonstrated significant increase in the strength of back extensors in the exercise group as compared with the control group. The participants in the exercise group experienced a 100 percent greater increase in the strength of the back extensors (mean increase of 18.5 kg) when compared with the control group (mean increase of 9.5 kg).

This method of PRE of the back extensors was effective in decreasing the risk of vertebral fractures.

**Mechanical Loading Prevents Bone Loss due to Hormone-Deficiency in Female Mice.** M. E. Lynch<sup>1</sup>, R. P. Main<sup>1</sup>, T. M. Wright<sup>2</sup>, M. C. H. van der Meulen<sup>1</sup>. <sup>1</sup>Cornell, Ithaca, NY, USA, <sup>2</sup>Hospital for Special Surgery, New York, NY, USA.

Cancellous bone adaptation to mechanical loading is poorly understood. Dynamic loading stimulates adaptation in healthy mice and prevents bone loss in hormone-compromised male mice at cancellous sites. We investigated the effects of loading on cancellous bone in hormone-compromised female mice. Twenty 10 week-old C57Bl/6 mice underwent ovariectomy (OVX) or sham surgery (n=10/group). Following surgery, cyclic compression was applied to the left tibia. The right tibia served as the unloaded control. Each cycle consisted of a triangle wave with a peak load of -11.5N followed by a static dwell of -2.3N. 1200 cycles were applied 5 days/week at 4 Hz for 2 weeks. Following euthanasia, all tibiae were scanned using quantitative microcomputed tomography with a 15  $\mu$ m voxel resolution. Cancellous bone from the proximal metaphysis was analyzed for bone volume fraction (BV/TV), tissue mineral density (tBMD), and trabecular thickness and separation (Tb.Th, Tb.Sp). OVX significantly reduced BV/TV and increased Tb.Th. Loading significantly affected both sham and OVX groups (Table 1). In sham mice, tBMD (+16%), BV/TV (+57%), and Tb.Th (+4%) were greater in loaded tibiae relative to controls (Fig. 1). Similarly in OVX mice, tBMD (+16%), BV/TV (+68%), and Tb.Th (+14%) were greater in loaded tibiae relative to controls. Tb.Sp decreased with loading in both groups. The response to loading was similar in OVX and sham groups. Mechanical loading prevented bone loss due to hormone-deficiency and in fact cancellous parameters in the loaded OVX mouse tibiae were increased relative to the unloaded sham tibiae. Our results show that mechanical loading is an anabolic stimulus in cancellous bone independent of estrogen status. This work was supported by NIH AG53571 and AR46121.

**Aged and Young Adult BALB/c Male Mice Respond Similarly to In Vivo Tibial Compression.** M. D. Brodt<sup>1</sup>, R. Civitelli<sup>2</sup>, M. J. Silva<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Washington University, St. Louis, MO, USA, <sup>2</sup>Division of Bone and Mineral Diseases, Washington University, St. Louis, MO, USA.

A decline in mechanoresponsiveness with aging may contribute to diminished rates of bone formation in senile osteoporosis. Recently, we established that "aged" 22-month male BALB/c mice are osteoporotic compared to "young adult" 7-month mice, as evidenced by increased tibial medullary area, and decreased cortical thickness, trabecular bone volume and endosteal bone formation. Our goal in the current study was to compare the response of 22 and 7 mo. mice to in vivo tibial compression, a non-invasive loading method that applies force across the knee and foot (along the tibial axis). Prior to in vivo loading, we determined the force-strain relationships using a combination of strain gage measurements, microCT imaging and beam theory. Because moments of inertia were not significantly different

between 22 and 7 mo. tibiae, the force-strain relationships were similar, with differences of ~10% for the peak endocortical strain at 12 N compression. We then performed in vivo tibial compression on 60 mice at 22 (n = 28) or 7 (n = 32) mos. age. Under anesthesia, the right legs were loaded to a peak force of 8, 10 or 12 N; 60 cycles/day (rest-inserted waveform) for 5 days; left legs were not loaded (control). Mice were injected with fluorochromes on days 4 and 9, and euthanized on day 11. Tibias were embedded in plastic, sectioned and histomorphometric analysis performed at the midshaft (site of peak bone strain). Data from non-loaded controls confirmed that marrow area was greater in 22 vs. 7 mo. tibiae ( $0.52 \pm 0.07$  vs.  $0.39 \pm 0.06$  mm<sup>2</sup>), while bone area ( $0.59 \pm 0.07$  vs.  $0.72 \pm 0.07$  mm<sup>2</sup>) and cortical thickness ( $0.15 \pm 0.02$  vs.  $0.20 \pm 0.01$  mm) were less ( $p < 0.001$ ). Analysis of relative differences between loaded and control tibiae revealed that, contrary to our hypothesis, aged mice did not exhibit diminished responsiveness to loading. On the endocortical surface, the increases in mineralizing surface ( $p < 0.001$ ), mineral apposition rate ( $p = 0.06$ ) and bone formation rate (BFR/BS,  $p < 0.001$ ; Figure) were actually greater in 22 mo. mice than in 7 mo. mice (two-way ANOVA). On the periosteal surface, there were no differences between the responses of 22 and 7 mo. mice ( $p > 0.05$ ). In conclusion, we found no deficit in the ability of aged mice to form bone in response to tibial compression, indicating that the aged skeleton can respond to mechanical stimuli with increased bone formation.

**Bone Length Was Differentially Promoted in the Left/Right Hindlimbs with Knee Loading and Administration of IGF2.** P. Zhang, H. Yokota. Biomedical Engineering, and Anatomy & Cell Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA.

Treatment of limb length discrepancy requires differential bone lengthening. In order to seek for its potential therapeutic strategy, we addressed a pair of questions: Does knee loading or local injection of IGF2 increase bone length in the treated hindlimb more than the contralateral hindlimb? If so, is their growth promotion identical in the femur and the tibia? Usage of C57BL/6 mice (~8 wks) was approved by the IACUC. In knee loading (21 mice), the left hindlimb was given 5-min bouts at 0.5 N, while the right hindlimb was used as contralateral control. Age matched controls were included. In IGF2 injection (30 mice), 5  $\mu$ l of PBS containing IGF2 was injected into the distal epiphysis of the left femur at 100  $\mu$ g/kg/day, while the right hindlimb was treated as contralateral control. Vehicle controls received an equal volume of PBS. Bone length was measured with a digital caliper, and BMD and BMC were determined with a PIXImus densitometer. First, knee loading lengthened both the femur and the tibia, but IGF2 injection was effective only in the femur. BMD and BMC were increased in the femur and the tibia with knee loading, while with IGF2 injection they were unchanged in the tibia. Second, the total increase in the length of the hindlimb was significantly higher with knee loading than IGF2 injection (femora with  $p < 0.05$  and tibiae with  $p < 0.001$ ). Third, in knee loading the measured values in Table for contralateral controls were closer to those for the loaded hindlimb than those for the age-matched controls, suggesting a possibility that knee loading on one hindlimb could affect on the other hindlimb. Fourth, an increase in body weight was elevated for mice with IGF2 injection compared to mice with vehicle injection ( $p < 0.001$ ).

We demonstrate herein enhancement of bone length by both knee loading and local administration of IGF2. The effects of knee loading are observed in the femur and the tibia. The IGF2 effects were localized in the femur, and a possibility of increasing body weight was identified. Further studies are necessary to examine efficacy of treatment conditions including magnitude/dosages and durations of applications.

**Positive Influence of Physical Activity on BMD Measurements and Hip Geometry Parameters in Young Adults: a 2-year Prospective Study.** S. Breban\*, C. Chappard, C. Benhamou. IPROS - CHR Orleans, INSERM Unit 658, Orleans, France.

Weight-bearing physical activity induces higher BMD values and higher bone geometry parameters. The Hip Structural Analysis (HSA) software on DXA images has been poorly used in young athlete women. The aim of this work was to analyze in a prospective study, the effects of weight-bearing sports on BMD measurements, hip structure and peak bone geometry in young adult women. 70 women between 17 and 29 years participated in this 2-year prospective study. The sample included 40 athlete women participating in various weight-bearing sports ( $10.2 \pm 2.2$  hours/week of training) and 30 age matched control women. Each group was divided in 4 age-groups (18-20 years, 21-23 years, 24-26 years and 27-29 years). BMD ( $\text{g}/\text{cm}^2$ ) was measured by DXA (Delphi, Hologic ®), at whole body (WB), lumbar spine (L1-L4) and non dominant femoral neck (FN). The HSA software was applied to evaluate BMC, BMD, cross-sectional area (CSA), cross-sectional moment of inertia (CSMI), section modulus (Z) and cortical thickness of the FN. Age of menarche was similar in athletes and controls. BMD values were significantly higher in athletes compared to controls, at all bone sites. Moreover, bone gain was significantly greater in athletes compared to controls at LS and FN but not at WB ( $p > 0.05$ ). All the geometry parameters were significantly higher ( $p < 0.05$ ) in athletes compared to controls, at baseline and after one year. Maximal bone gain, for all geometry parameters, was observed for the 21-23 years age-group in athlete women and for the 18-20 years age-group in control women. The gain was significantly higher in athletes compared to controls for CSA ( $0.02 \pm 0.04 / -0.03 \pm 0.08 \text{ cm}^2$ ,  $p = 0.02$ ), CSMI ( $0.06 \pm 0.04 / -0.20 \pm 0.34 \text{ cm}^4$ ,  $p = 0.01$ ), Z ( $0.002 \pm 0.08 / -0.05 \pm 0.09 \text{ cm}^3$ ,  $p = 0.03$ ) but not for Cortical Thickness ( $0.003 \pm 0.002 / 0.001 \pm 0.020 \text{ cm}$ ,  $p = \text{NS}$ ). Intense weight-bearing sport induces a prolonged bone gain associated to a higher and later peak bone geometry in women. Athletes continue to optimize their femur macro architecture properties and their BMD peak whereas controls have already reached their maximal potential.

**Mechanical Underloading of the Sheep Calcaneus: A Model for Hip Fracture.** N. Loveridge\*, J. Power\*, E. Draper\*, M. Warren\*, J. Reeve\*, A. Goodship\*. <sup>1</sup>Medicine, University of Cambridge, Cambridge, United Kingdom, <sup>2</sup>Royal Veterinary College, London, United Kingdom.

The aetiology of hip fracture is associated with an age-related loss of cancellous bone, cortical thinning and an increase in cortical porosity through the formation of large pores, changes which indicate that mechanical underloading plays an important role. Currently there is no model of underloading in animals that undergo haversian remodelling in a manner similar to that in human bone. The artiodactyl calcaneus, like the human femoral neck is loaded in bending, so using fixators we have underloaded the left calcaneus of adult female sheep and analysed changes in cortical and cancellous bone after 2, 4, 8 & 16 weeks (n=6 in each group) using the contra-lateral bone as a control.

Fixing the calcaneus resulted in a significant reduction in maximum local loads as measured using surface mounted strain gauges (free:  $95.9 \mu\epsilon \pm 24.4 \text{ SD}$ ; fixed:  $48.0 \mu\epsilon \pm 9.9 \text{ S.D.}$ ) Left and right calcanei showed marked evidence of individual patterning that was unaffected by underloading (Fig). Analysis of cancellous bone (Densiscan XTREME) showed a significant loss in BV/TV at 8 (diff  $-0.043 \pm 0.011$   $p = 0.011$ ) and 16 (diff  $-0.77 \pm 0.01$ ;  $p = 0.001$ ) weeks. Histological analysis of cortical bone showed a marked increase in the mean area of canals in the fixated calcaneus at 16 weeks (diff  $-62.5 \pm 15$ ;  $p = 0.02$ ) while the number of pores showed no change.

In conclusion, underloading of the sheep calcaneus results in the anticipated loss of cancellous bone and changes in cortical bone analogous to that seen in hip fracture suggesting that this will prove to be a suitable model for the studying the aetiology of intracapsular hip fracture.

**Flexible Tibia Model Predicts Bone Strains During Walking.** A. Heinonen<sup>1</sup>, R. Al Nazer<sup>2</sup>, A. Klodowski<sup>2</sup>, T. Rantalainen<sup>3</sup>, H. Sievänen<sup>4</sup>, A. Mikkola<sup>2</sup>. <sup>1</sup>Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, <sup>2</sup>Department of Mechanical Engineering, Lappeenranta University of Technology, Lappeenranta, Finland, <sup>3</sup>Neuromuscular Research Center, Department of Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland, <sup>4</sup>Bone Research Group, UKK Institute, Tampere, Finland.

In vivo strain measurements requires invasive methodology which is challenging and limited to certain regions of superficial bones only such as the anterior surface of the tibia. Based on our previous study (Al Nazer R et al. J Biomech 2008), an alternative numerical approach to analyse in vivo strains based on the flexible multibody simulation approach was proposed. The purpose of this study was to use the flexible multibody approach in the analysis of bone strains during physical activity through integrating the MRI technique within the framework. A healthy male volunteer (28 years, 177 cm, 80 kg) served as a subject. The model was used in a forward dynamics simulation in order to predict the tibial strains during walking. The flexible tibial model was developed using the actual geometry of human tibia, which was obtained from 3-dimensional reconstruction of MRI. The walking test was recorded using four digital video cameras. The motion capture data obtained from walking at constant velocity was used to drive the model during the inverse dynamics simulation in order to teach the muscles to reproduce the motion in the forward dynamics simulation. Fig 1 shows the simulated maximum and minimum principal and maximum shear strains for four walking cycles (bolded line corresponds for one walking cycle). Fig 2 shows the simulated axial strain profiles at the middle of the tibia in four locations. Based on the agreement between the literature-based in vivo strain measurements and the simulated strain results, it can be concluded that the flexible multibody approach enables reasonable predictions of bone strain in response to dynamic loading.

**Osteoporosis in a Murine Model of Hemophilia A.** C. Vanek, D. Greenberg\*, E. Larson\*. Endocrinology, Oregon Health & Science University, Portland, OR, USA.

There is clinical evidence that patients with hemophilia A have reduced bone mineral density. This is a risk factor for osteoporosis and fragility fractures. Hemophilia A is a genetic disorder of coagulation due to a deficiency of factor VIII. Many patients with hemophilia A have multiple co-morbid conditions that could potentially adversely affect skeletal health: reduced physical activity, joint hemorrhage, HIV, and hepatitis C infection. It is therefore difficult to determine if the genetic defect in hemophilia A is the direct cause of decreased bone mass *per se* without also accounting for co-morbid health factors. To better explore this issue, we have examined factor VIII knockout mice (FVIII-KO) that mimic human hemophilia A. We assessed the skeletal phenotype of 11 female FVIII-KO and 8 female wild-type mice of the same genetic background (C57BL/6) at 20-22 weeks of age, when skeletal maturity has been achieved. Bone mineral density (BMD) was measured by dual energy x-ray absorptiometry (pisiMUS) and bone geometry was measured by desktop x-ray microtomographic CT (SkyScan model 1074). Femoral breaking strength (failure load) was measured by three-point bending until failure on a high resolution materials test apparatus (model 4442, Instron Corp.)

	L5 BMD (mg/cm <sup>3</sup> )	Femoral BMD (mg/cm <sup>2</sup> )	Cortical Area (mm <sup>2</sup> )	Femoral Failure Load(Newtons)
<b>FVIII-KO (11)</b>	39.6 +/- 1.2	49.2 +/- 1.2	0.664 +/- 0.01	16.35 +/- 0.61
<b>Wild-Type (8)</b>	44.0 +/- 1.8	53.1 +/- 1.5	0.709 +/- 0.02	19.29 +/- 0.82
<b>P Value</b>	<b>0.048</b>	<b>0.050</b>	0.056	<b>0.009</b>

The results show that FVIII-KO mice have reduced BMD, bone size, and femoral breaking strength compared to wild-type. Under these controlled conditions, the data indicates that factor VIII participates in normal skeletal development. Factor VIII deficiency is known to decrease thrombin generation. Thrombin receptors are present on osteoblasts and may play a role in skeletal development. Thus hemophilia A, through effects on thrombin generation, may directly impact skeletal integrity.

**Effects of Exercise Intensity on the Bone Metabolic Response to Running.** J. P. R. Scott\*<sup>1</sup>, J. P. Greeves<sup>1</sup>, C. Sale<sup>2</sup>, A. Casey\*<sup>1</sup>, J. Dutton\*<sup>3</sup>, W. D. Fraser<sup>3</sup>. <sup>1</sup>Human Protection and Performance Enhancement, QinetiQ, Farnborough, United Kingdom, <sup>2</sup>Sport, Exercise and Health Sciences, Nottingham Trent University, Nottingham, United Kingdom, <sup>3</sup>Department of Clinical Biochemistry, University of Liverpool, Liverpool, United Kingdom.

The aerobic fitness of recruits entering UK Army Phase 1 training varies considerably, and so, during standardised activities, training is conducted across a range of relative exercise intensities. Since low aerobic fitness is a risk factor for stress fracture injury, we examined the effect of different exercise intensities (EI) on the bone metabolic response to running. Eight physically-active men (mean (1SD) age 28 (3) y; maximal rate of oxygen uptake (VO<sub>2max</sub>) 55.7 (7.4) ml·min<sup>-1</sup>·kg<sup>-1</sup>) completed three, 8-day trials. On days 1 to 3 and 5 to 8, subjects consumed a prescribed diet and performed no exercise. On day 4, subjects completed 60 min of treadmill running at 55% (LOW), 65% (MOD) or 75% (HIGH) VO<sub>2max</sub>. Fasting blood and second void urine were obtained prior to exercise (BASE) and on four consecutive recovery days (R1 to R4). Serum was analysed for markers of bone resorption (β-CTX) and formation (PINP, OC, Bone-ALP). Urine samples were also analysed for pyridinolines (UfPYD and UfDPD), markers of bone resorption, which were corrected for creatinine concentration (Cr). There were no significant differences in the response of bone resorption or bone formation markers to different EI. Main effects of time from BASE were observed for UfDPD/Cr (P<0.001) and UfPYD/Cr (P<0.05), but not β-CTX, OC, PINP or Bone-ALP (P>0.05). Mean (1SD) values of pyridinolines are shown in Table 1. Both UfDPD/Cr (P<0.01) and UfPYD/Cr (P<0.05) increased significantly at R3 compared with BASE. UfDPD/Cr increased by 4(9)%, 10(9)%, and 10(18)%, and UfPYD/Cr increased by 4(11)%, 16(18)% and 7(18)% in LOW, MOD and HIGH.

Mean (1SD) UfDPD/Cr and UfPYD/Cr between different exercise intensities over time.					
	BASE	R1	R2	R3	R4
<b>DPD (μmol·mol<sup>-1</sup>/Cr)</b>					
LOW	4.5 (0.6)	4.2 (0.5)	4.6 (0.7)	4.7 (0.7)	4.4 (0.4)
MOD	4.4 (0.6)	4.3 (0.9)	4.7 (1.0)	4.9 (0.7)	4.4 (0.9)
HIGH	4.1 (0.7)	4.3 (0.8)	4.1 (0.7)	4.4 (0.5)	4.0 (0.7)
Mean (All Conditions)	4.3 (0.6)	4.3 (0.7)	4.4 (0.8)	4.7 (0.7)†	4.3 (0.7)
<b>PYD (μmol·mol<sup>-1</sup>/Cr)</b>					
LOW	16.2 (1.7)	14.3 (1.2)	17.6 (2.2)	16.7 (2.4)	16.7 (1.8)
MOD	15.9 (2.0)	16.1 (3.8)	18.2 (3.9)	18.5 (4.0)	16.2 (3.4)
HIGH	15.4 (2.2)	14.8 (3.4)	14.7 (3.0)	16.3 (2.9)	14.9 (2.9)
Mean (All Conditions)	15.8 (1.9)	15.0 (3.0)	16.8 (3.3)	17.2 (3.2)*	15.9 (2.8)

\* (P<0.05); † (P<0.01) significant increase from BASE. There was no effect of exercise intensity on the bone metabolic responses to 60 min of treadmill running. The increase in

pyridinolines but not in β-CTX during recovery suggests an increase in type I collagen metabolism, and not bone resorption, with exercise. Acute exercise of different intensity did not invoke a concomitant change in bone formation as indicated by OC, PINP and Bone-ALP.

**Bone Strength In Overweight Children Is Adapted to Mechanical Loads From Walking, But Is Low For Higher Loading Activities.** S. A. Novotny\*<sup>1</sup>, R. J. Wetzsteon<sup>2</sup>, K. A. Pickett\*<sup>1</sup>, J. M. Hughes<sup>1</sup>, J. M. Cousins\*<sup>1</sup>, M. A. Petit<sup>1</sup>. <sup>1</sup>Kinesiology, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Areal bone mineral density (aBMD) assessed by DXA is typically higher in overweight than healthy-weight children, however it is not clear if bone strength is adequate for higher loads incurred during physical activity by overweight children. The purpose of the present study was to assess bone strength relative to mechanical load during physical activity in overweight and healthy-weight children. We measured bone geometry (Total Area, ToA, mm<sup>2</sup>), cortical volumetric density (vBMD, mg/mm<sup>3</sup>) and estimated bone bending strength (SSI<sub>p</sub>, mm<sup>3</sup>) by peripheral quantitative computed tomography (pQCT, Orthometrix XCT 3000) at 66% of tibia length in overweight (BMI ≥ 85th percentile, n = 22) and healthy-weight (BMI < 85th percentile, n = 37) children (8-15yr). Peak ground reaction force (GRF) was assessed with Pedar insoles during 5 activities, including a walk, active video game (Dance Dance Revolution, DDR), run, tuck jump and jump from a 30cm box. Height, tibia length and weight were measured by standard procedures. Relative bone strength [(SSI<sub>p</sub>/(tibia length\*0.66))/GRF] was calculated for each activity. We used ANCOVA adjusting for tibia length and sex to compare absolute bone outcomes, and independent t-tests to compare relative bone strength for each activity between groups. Compared to the healthy-weight group, overweight children had greater ToA (+23%, p < 0.001) and SSI<sub>p</sub> (+27%, p = 0.001), but similar cortical vBMD. Peak GRF were higher in overweight children for all activities (+37-60%, p < 0.05 for all). Relative bone strength was not different between groups for DDR (p = 0.113) or walking (p=0.235). However, relative bone strength from running (-17%, p = 0.010), tuck jump (-27%, p < 0.001) and box jump (-24%, p = 0.003) were all significantly lower in overweight children. Overall, bone strength in overweight children was high and appropriately adapted to loads from normal activities such as walking. However bone strength was low in overweight children for higher impact activities such as running and jumping, suggesting that excess body weight may not have a protective effect on bone as has been previously implied.

**Intermittent, Short Duration Cyclic Loading Attenuates Disuse Osteoporosis Without Affecting Resorption.** R. K. Long\*, B. M. Boudignon\*, D. D. Bikle. Endocrine Unit, University of California, San Francisco, San Francisco, CA, USA.

Hindlimb unloading (HU) by tail suspension (a model of disuse osteoporosis) causes a rapid and profound loss of bone in the tibia and femur due to reduction in bone formation and enhanced bone resorption. On the other hand, mechanical loading of the tibia with intermittent cyclic loads stimulates bone formation. The purpose of this study is to determine whether intermittent cyclic axial compressive loading applied to the tibia concurrent with HU will prevent disuse osteoporosis, and if so, by what mechanism. Twelve-week-old male Sprague Dawley rats were subjected to a two-week period of HU or normal ambulation (controls). Concurrently, the right tibia of each animal was cyclically loaded, the left tibia served as non-loaded control. Cyclic loading with an Enduratec ELF3200 was achieved by the application of 40 trapezoidal loading cycles with a peak axial compressive load of 30 N, determined by load-strain calibrations to achieve ~2500 microstrain, each over 0.5 second with a 10 second rest inserted after each load. Six loading episodes were distributed equally over 2 weeks, totaling 42 minutes of cyclic load. Both tibiae were harvested for trabecular microCT and histomorphometric analysis, osteoclast activity and periosteal bone formation. MicroCT analysis of the proximal tibia revealed that 2 weeks of skeletal unloading caused a 54% decrease in BV/TV relative to controls (p < 0.001). These unloaded bones were more responsive to cyclic loading with a 62% increase in BV/TV (p < 0.01) relative to only a 15% increase seen in those from the controls (p < 0.05). Changes in connectivity density parallel those seen with BV/TV. Analysis of trabecular indices revealed a significant unloading induced decrease in number and thickness that normalized with cyclic loading. No cyclic loading induced trabecular changes were noted in the tibiae from controls. Resorption surfaces increased by 40% in the secondary spongiosa of unloaded bones as compared to those from controls and was unaffected by cyclic loading. However, the 25% reduction in periosteal bone formation induced by HU was mostly reversed by cyclic loading (p < 0.05). These results demonstrate that intermittent short duration cyclic loading totaling only 42 minutes over 2 weeks significantly blunts unloading induced trabecular bone loss. The mechanism of the enhanced response of the unloaded bones to cyclic loading is due to augmentation of bone formation rather than reduction in osteoclast activity. The threshold for mechanical stimulation induced bone formation in the unloaded state is lower than that required to prevent unloading induced osteoclast mediated bone loss.

**M484****The Effect of Exercise on Geometric Bone Structure and Bone Strength in Postmenopausal Women - A Systematic Review and Meta-Analysis of Randomized Controlled Trials.** I. Polidoulis<sup>1</sup>, J. Beyene<sup>2\*</sup>, A. Cheung<sup>3</sup>.<sup>1</sup>Family and Community Medicine, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Biostatistics, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Osteoporosis, University Health Network, Toronto, ON, Canada.

Current literature suggests that exercise in postmenopausal women can at best only slow bone mineral density loss by about 1% per year. Although randomized controlled trials have examined the effects of exercise on bone structure, most studies are small with variable results. Thus, we conducted a systematic review and meta-analysis of randomized controlled trials that examined effects of exercise on geometric structure of bone in postmenopausal women.

We systematically searched Medline, Pubmed, and Embase from 1950 to March 2008 using the following search terms: exercise, exercise movement techniques, motor activity, physical activity, sports, bone, microarchitecture, bone geometry or structure or histomorphometry, quantitative computed tomography. We limited to human studies and included only prospective randomized controlled trials that examined the effects of exercise on bone geometry in post-menopausal women. We excluded studies in children, men and secondary osteoporosis patients. Outcome variables were total volumetric BMD (Tv BMD), cortical volumetric BMD (Cv BMD), trabecular volumetric BMD (Trv BMD), total BMC, cortical BMC, Total Bone Area, cortical Area, Polar Stress Strain Index (PSSI), and Bone Strength Index (BSI), as measured by pQCT at the distal radius, radial shaft, distal tibia, and tibial shaft. Additional outcomes were three bone parameters as measured by DXA, including areal BMD, BMC and Section Modulus (Z), at the femoral neck, trochanter and lumbar spine.

A total of six studies satisfied inclusion and exclusion criteria with a total of 358 subjects in the exercise group and 279 in the control group. Average age was 65 years. Average duration of the exercise program was 8.8 months (range: 5-12 months). Lower extremity exercises resulted in small but significant improvements in Trv BMD of the distal tibia (0.87%, 95%CI: 0.37%-1.37%) and in Cv BMD of the tibial shaft (0.89%; 95%CI: 0.37%-1.41%). Site-specific exercises also resulted in a trend towards improvements in Tv BMD at the distal radius (1.7%; 95%CI: 0.63%-4.02%) and cortical area at the radial shaft (0.95%, 95%CI: 0.14%-2.03%). None of the other parameters had significant differences between exercise and non-exercise groups, although the number of studies and total number of subjects included are small.

Based on our data, we conclude that exercise in postmenopausal women can decrease bone loss by maintaining cortical and trabecular volumetric BMD. To better understand the effect of exercise on bone structure and strength, more and larger studies are needed.

**M485****Femur from C57BL/6 and DBA/2 Inbred Mice Display a Strain Dependent Response to Treadmill Running and Tower Climbing Exercise in Cortical and Trabecular Bone Architecture.** D. H. Lang, H. M. Preston\*, A. C. Henry\*, N. A. Sharkey. Kinesiology, Pennsylvania State University, University Park, PA, USA.

This study was designed to increase our understanding of the genetic architecture responsible for the maintenance of bone quality. By focusing efforts on defining interactions between genes and environmental loading, therapeutic interventions may someday be designed to target specific genotypes where differential responses are anticipated. We hypothesize that treadmill running and tower climbing exercise will produce a differential skeletal response as a function of inbred mouse strain.

B6 and D2 inbred female mice were subjected to treadmill running and tower climbing at 180 days of age. Ninety mice were used in a 2 x 3 experimental design with strain (B6 vs. D2), and treatment (treadmill running vs. tower climbing vs. control) as independent factors resulting in six groups with fifteen mice per group. The entire femur underwent micro-computed tomography (Scanco Medical, Zürich, Switzerland) using a 15.4µm voxel size. Separate evaluations were conducted for trabecular bone in the distal metaphysis, cortical bone at the mid-shaft and the whole bone. Strain and exercise group differences and interactions were evaluated using a three-way ANOVA.

Many of the skeletal measures had significant strain main effects. Of primary interest were those skeletal measures that displayed an exercise treatment main effect or an interaction effect with exercise treatment. Treadmill running produced thicker more closely spaced trabeculae in the distal femoral metaphysis compared to controls (Table 1). Tower climbers were intermediate to treadmill runners and controls. Several strain by treatment interactions were also identified. In general, D2 femurs were more responsive to treadmill running than B6 femur. Mid-shaft cortical BV/TV and density were greater in D2 treadmills compared to tower climbers and controls. However, no differences were identified in B6 femur. These results indicate that both strain and exercise are very important predictors of skeletal health. These data emphasize the importance of gene by environment interactions leading to future research that could provide the foundation on which to build effective means of assessing fracture risk due to osteoporosis and thereby enable early intervention.

Means and tukey pairwise comparisons. Levels not connected by same letter are significant.

	Main Effects	Treadmill Runners	Tower Climbers	Controls
Trabecular Thickness	Mean:	0.223 (A)	0.219 (A, B)	0.217 (B)
Trabecular Spacing	Mean:	0.604 (B)	0.713 (A, B)	0.797 (A)

**M486****The Osteogenic Potential of Bone Marrow, Compromised by Disuse, is Normalized by Brief Exposure to a Low-Level Mechanical Signal.** E. Ozcivici, Y. K. Luu, C. T. Rubin, S. Judex. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

Loss of functional weight bearing has devastating consequences for trabecular bone. Perhaps even worse, the lost skeletal tissue may never be fully recovered during reambulation. Here, it was hypothesized that disuse induces a reduction in the number of osteogenic cells within the bone marrow and that a high-frequency mechanical stimulus is able to rescue the cellular and morphological phenotype. Hindlimb unloaded male C57BL/6J either received a high-frequency mechanical stimulus (90Hz, 0.2g) induced by whole body vibration (WBV, n=12) for 15min/d, sham stimulation by allowing to bear weight for 15min/d (SHAM, n=12), or no stimulus at all (DC, n=12). An additional group of mice was not hindlimb suspended and served as normal age matched controls (AC, n=12). Three weeks into the protocol, half of the mice in each group were sacrificed while the remaining mice were allowed to ambulate freely for an additional 3wk. Upon sacrifice, bone marrow from each right hindlimb was extracted for fluorescence activated cell sorting (FACS) to identify cells with osteogenic potential as indicated by their positive expression of SCA-1 and CD90.2 surface antigens. Left hindlimbs were scanned by microCT. After 3wk of disuse, mice had 59% less BV/TV than age matched controls in the proximal tibia (p<0.05). Neither sham nor WBV loading was able to alleviate this loss during disuse. In contrast, FACS analysis demonstrated that AC, DC and SHAM groups had a similar percentage of total osteogenic cells while mice receiving the low-level mechanical signal had more osteogenic cells than DC (30%), SHAM (22%) and AC (30%, all p<0.05). The number of committed osteoprogenitors, a big and granulated sub-population of osteogenic cells that are SCA-1 positive, was 14% and 18% greater in AC than in SHAM and WBV mice and 55% greater than in DC mice (p<0.05). After reambulation, there were no significant differences in the number of osteogenic cells between groups. Nevertheless, trabecular BV/TV was greater (p<0.05) in WBV mice than in SHAM (18%) or DC (46%) mice but did not regain the levels of AC mice (-18%, p<0.05). These data showed that the hindlimbs of mice that received mechanical signals either by WBV or weightbearing during disuse, were able to preserve the number of osteoprogenitors, while only mice that received WBV also increased the number of cells that have the potential to commit to the osteogenic lineage. As the greater increase in BV/TV in WBV than in SHAM mice during reambulation may reflect the differences in their cell populations caused by disuse, the low-level mechanical signal may have provided long-term benefits in the absence of immediate tissue-level effects.

**Disclosures:** E. Ozcivici, None.

**M487****Bone Geometry and Bone Strength Are Compromised in Patients with Anterior Cruciate Ligament Reconstruction.** M. A. Petit<sup>1</sup>, S. L. Peart<sup>1\*</sup>, R. J. Wetzsteon<sup>2</sup>, T. J. Gaddie<sup>1</sup>, J. Rittweger<sup>3</sup>, S. D. Stovitz<sup>4\*</sup>, C. M. Larson<sup>4\*</sup>.<sup>1</sup>University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Children's Hospital of Philadelphia, Philadelphia, PA, USA, <sup>3</sup>Manchester Metropolitan University, Cheshire, United Kingdom, <sup>4</sup>Minnesota Sports Medicine, Minneapolis, MN, USA.

Loss of bone mineral content (BMC) and areal bone mineral density (aBMD), measured by dual energy x-ray absorptiometry, has been demonstrated following anterior cruciate ligament (ACL) reconstruction. However, due to the planar nature of aBMD and BMC measurements, it remains unclear whether ACL reconstruction results in alterations in volumetric bone mineral density, bone geometry and strength. Therefore, the purpose of this study was to assess leg side-to-side differences in bone volumetric density, bone geometry and bone strength in patients with a history of ACL reconstruction in the past 10 years. We used peripheral quantitative computed tomography (pQCT, Orthometrix XCT 3000) to assess bone geometry (total area, ToA, mm<sup>2</sup>), volumetric density (vBMD, mg/mm<sup>3</sup>), and an index of compressive bone strength (BSI) at trabecular sites close to the injury (patella and 4% distal femur). We assessed bone geometry (ToA and cortical area, CoA, mm<sup>2</sup>), vBMD, and an index of bone bending strength (polar strength strain index, SSIP, mm<sup>3</sup>) at the patella, 66% and 86% sites of the tibia, and at 20% of the femur. Muscle cross-sectional area (muscle CSA) was assessed at 66% tibia and 20% femur sites. We calculated differences in the surgical vs. non-surgical leg in 64 patients (41% male) aged 18-63 years (28.1±10.6yr) who had undergone a single-side ACL reconstruction in the past 1-10 years (mean 4.5yrs) and present data as mean difference (95% confidence intervals) between limbs. Bone strength (SSIP) was significantly lower in the surgical leg, particularly at sites closest to the injury from -12% (-17.4, -6.7) at the patella to -3% at 86% tibia (-5.2, -0.4) and 20% femur (-4.4, -1.3). There was no difference in bending strength at the 66% tibia site. BSI was also significantly lower at the patella (-10%; -4.4, -1.3) due largely to a significantly lower vBMD (-8.3%; -10.3, -6.4). Side-to-side muscle CSA was similar at both the tibia and femur. Further, side-to-side differences in bone strength were not associated with muscle CSA, time since surgery, surgical type, age or gender. These data suggest ACL reconstruction influences bone geometry and strength at sites closest to the injury and long-term bone deficits may exist despite post-surgical return of muscle mass.

## M488

**Can Impact Exercise Mitigate the Adverse Effects of Oral Contraceptives on Bone?** J. M. Welch<sup>1</sup>, N. C. Laroche<sup>\*1</sup>, S. M. Kaiser<sup>2</sup>. <sup>1</sup>Kinesiology, Dalhousie University, Halifax, NS, Canada, <sup>2</sup>Endocrinology and Metabolism, Dalhousie University, Halifax, NS, Canada.

Oral contraceptive (OC) use may adversely affect bone status but whether exercise can mitigate this effect is unknown. We hypothesized that young women who habitually participate in impact exercise would not differ in bone status by OC use, while non-impact exercisers who take OCs would be disadvantaged. Two cross-sectional studies were conducted. In a pilot study, Study 1, 30 women 18-25 years old were recruited. Their use of OCs, exercise history, and factors such as smoking, diet and past medical problems were collected by questionnaire. Subjects were classified into four groups: OC use plus impact exercise (OC+I), OC use without impact exercise (OC+NI), no OC use plus impact exercise (NOC+I) or no OC use plus no impact exercise (NOC+NI). A Lunar Achilles InSight bone ultrasonometer was used to measure Stiffness Index (SI) at the calcaneus, in duplicate. Women in the OC+NI group had lower SI than those in other groups but 43% of them smoked compared to 0-17% in the other groups. Therefore, we undertook Study 2, in which smokers were excluded. 39 non-smoking women, aged 18-25 were recruited. They were placed into three of the previous categories: OC+I, OC+NI, and NOC+I. Women in the NOC+I group had the best bone status (SI=119±10), those in the OC+NI group had the poorest (SI=102±21), while women in the OC+I group were intermediate (SI=109±15). The results of both studies suggest that the repressive effect of oral contraceptives on skeletal health may be mitigated to some extent by habitual participation in impact exercise. If a larger study corroborates these results, then impact exercise should be recommended concomitantly with the prescription of oral contraceptives.

**Contribution of Local Buckling to Femoral Neck Failure in Stance and Fall Mode Simulations: an Advanced FEA Analysis of Elderly Cadaver Femur Data.** A. Khaled<sup>\*1</sup>, B. Schafer<sup>\*2</sup>, J. Brown<sup>3</sup>, F. Eckstein<sup>4</sup>, V. Kuhn<sup>\*5</sup>, T. M. Link<sup>6</sup>, T. J. Beck<sup>1</sup>. <sup>1</sup>Department of Radiology and Radiological Sciences, Johns Hopkins School of Medicine, Baltimore, MD, USA, <sup>2</sup>Civil Engineering, Whiting School of Engineering, Baltimore, MD, USA, <sup>3</sup>Mindways Software Inc., Austin, TX, USA, <sup>4</sup>Institute of Anatomy and Musculoskeletal Research, Paracetus Private Medical University, Salzburg, Austria, <sup>5</sup>Medizinische Universität Innsbruck, Universitätsklinik für Unfallchirurgie und Sporttraumatologie, Innsbruck, Austria, <sup>6</sup>Department of Radiology, University of California San Francisco, San Francisco, CA, USA.

Results of several studies suggest that the mechanism underlying the ability of DXA BMD to predict hip fracture is local buckling failure but theoretical verification using continuum FEA methods are problematic since continuum methods do not accommodate local buckling failure. A specialized version of FEA called Finite Strip Method (FSM) was designed to evaluate failure in pure elastic buckling in thin-walled structures. We have developed a reliable method for deriving a smooth, geometrically accurate FSM model of the femoral neck cortex using CT scan data, without the necessity of employing the density modulus relationship. **Methods:** Six cadaver femurs from German subjects including 3 males aged 52, 66 and 93, and 3 females aged 65, 81 and 85 were scanned in a water bath using a 16 slice Siemens CT scanner with a slice spacing of 0.5 mm. Specialized software was used to extract the cross-section at the minimum neck diameter and FSM models of the cortex were derived and evaluated in the plane of the neck-shaft angle. Physiologic loads were simulated in a static one-legged stance including abductor forces acting on the outer margin of the greater trochanter. The fall mode was simulated without muscle forces and with impact on the greater trochanter, with the shaft at a fixed 10° angle from the impact surface. **Results:** In the stance mode, local buckling did not contribute to femoral neck failure in any model but it reduced strength in the fall mode in all models from 13% to 40%. **Conclusions:** The results of this preliminary analysis support the view that elderly femurs remain well adapted to physiologic loads but that the adaptation results in strength loss due to local buckling when subjected to unaccustomed loading conditions.

**The Loaded Distal Radius: Gymnastic-related Cross-sectional Asymmetry.** J. N. Dowthwaite, R. M. Hickman<sup>\*</sup>, J. A. Spadaro, T. A. Scerpella. Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY, USA.

Mechanical loading during human growth generates adaptations in areal bone mineral density; these adaptations appear to occur via enlarged total bone and cortical dimensions, elevating theoretical bone strength. Few studies have assessed whether human bone adapts to mechanical loading symmetrically. The non-dominant radius is both a specific barometer of weight-bearing impact loading via gymnastics and a suitable site for pQCT evaluation of bone architecture. Therefore, we evaluated the non-dominant radius in post-menarcheal gymnasts and non-gymnasts, hypothesizing that the radius adapts asymmetrically to gymnastic loading during growth, with greater periosteal expansion in the medial-lateral plane than the antero-posterior plane. To test this hypothesis, we used pQCT to measure aspect ratios and bone widths from a cross-section of the radial diaphysis (33% region of interest, X plane= medial-lateral, Y plane= anteroposterior), comparing

output for post-menarcheal non-gymnasts versus girls exposed to gymnastic loading during growth.

Forearm pQCT scans were performed upon 48 post-menarcheal girls at the 33% distal radius. Maximum X (medial-lateral) and Y (anteroposterior) plane bone widths were measured using the XCT 2000 ruler function. Aspect ratios were calculated with X-plane width in the numerator and Y-plane width in the denominator. Girls were classed as gymnasts (n=27)(current or ex- gymnasts) or non-gymnasts (n=21) based upon childhood exposure to gymnastic loading. Height was measured using wall-mounted rulers. ANOVA compared aspect ratios for gymnasts versus non-gymnasts. ANCOVA compared X and Y plane widths, adjusting for gynecological age and height.

Subjects averaged 17.0 years old (gynecological age 3.9 years) and 162.0 cm tall. Girls exposed to gymnastics during growth exhibited 14% higher X-axis diameters than non-gymnasts, after adjustment for gynecological age and height (gymnasts= 14.6 mm; non-gymnasts=12.8 mm (ANCOVA p<0.02)). Although an 11% difference was found between gymnast and non-gymnast Y-axis diameters, this was not statistically significant after adjustment (gymnasts= 12.1 mm; non-gymnasts= 10.9 mm (ANCOVA p= 0.16). Similarly, the 3% gymnast versus non-gymnast aspect ratio difference was not statistically significant (gymnasts= 1.21; non-gymnasts= 1.17 (ANOVA p=0.10).

Exposure to weight-bearing impact loading during growth appears to yield larger periosteal dimensions along both medial-lateral and anteroposterior axes. Examination of aspect ratios is suggestive of loading-induced asymmetry; however aspect ratio differences did not achieve statistical significance in this limited sample.

**Prevention of Nutritional Rickets in Nigerian Children with Dietary Calcium Supplementation.** T. D. Thacher<sup>1</sup>, P. R. Fischer<sup>\*2</sup>, C. O. Isichei<sup>\*3</sup>, J. M. Pettifor<sup>4</sup>. <sup>1</sup>Family Medicine, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Pediatric and Adolescent Medicine, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Chemical Pathology, University of Jos, Jos, Nigeria, <sup>4</sup>Paediatrics, University of the Witwatersrand, Johannesburg, South Africa.

Most nutritional rickets in Nigerian children result from dietary calcium insufficiency. Typical dietary calcium intakes in African children are about 200 mg daily. We sought to determine if rickets could be prevented with supplemental calcium in at risk populations. We enrolled children ages 12 to 18 months from three urban Nigerian communities. Two communities were assigned to receive 400 mg calcium (Ca), either as calcium carbonate or ground dried fish daily, while children in all three communities received vitamin A (2500 IU) daily as a placebo. Serum markers of mineral homeostasis and forearm bone mass (pDXA) were measured and radiographs obtained at entry into the study and at the end of 18 months of supplementation.

The overall prevalence of radiographic rickets at baseline was 1.2 percent. Of 647 children enrolled, 387 (60%) completed the 18-month follow-up. Rickets developed in 1, 1, and 2 children assigned to the calcium tablet, ground fish, and control groups, respectively. Children who developed rickets in the calcium-supplemented groups had less than 50% adherence (P=0.04 for developing rickets with adherence less than 50%). Serum Ca did not differ between the children from the three groups at the end of the study (P=0.70). Final height was related positively to milk intake (P<0.01) and negatively to alkaline phosphatase (P<0.01) but not to supplemental calcium intake (P=0.89). At enrollment, serum calcium and weight independently predicted forearm bone mass. When adjusted for baseline bone mass and bone area, calcium supplementation did not have a significant effect on the increase in bone mass over time of either the proximal (P=0.88) or distal (P=0.18) forearm. Serum alkaline phosphatase values were negatively related to bone mass at 18 months (P<0.01). The relative risk of alkaline phosphatase >350 U/L was unaffected by supplemental calcium (RR=0.81, 95%CI 0.58-1.1). The change in 25OHD values did not differ between children who did and did not receive supplemental calcium (P=0.53). Overall, 5.4% (95%CI 3.8-7.7%) and 7.1% (95%CI 4.8-10%) had 25OHD values below 12 ng/mL at baseline and 18 months, respectively.

Adherence to calcium supplementation appeared to prevent rickets in Nigerian children. Calcium supplementation did not lead to greater bone mineral content or altered mineral homeostasis in young Nigerian children.

**Contribution of Birth Status, Age at Menarche and Lifestyle Factors to Skeletal Formation in Junior and Senior High School Students.** Y. Onoe, T. Kuroda<sup>\*</sup>, Y. Miyabara<sup>\*</sup>, S. Orito, R. Yoshikata<sup>\*</sup>, M. Sakai<sup>\*</sup>, Y. Haruna<sup>\*</sup>, K. Ishitani<sup>\*</sup>, H. Okano, H. Ohta. Dpt. of Obstetrics and Gynecology, Tokyo Women's Medical University, Tokyo, Japan.

We investigated how birth status, age at menarche and lifestyle factors contributed to skeletal formation and bone mineral density (BMD) as skeletal indices in junior and senior high school students who were in growth and developmental stages.

The study enrolled 631 female students who were 12 to 18 years old and were attending junior and senior high school. We investigated birth-related data and age at menarche in these subjects. Height, body weight, and lumbar vertebra BMD were measured as skeletal indices. The total energy intake and intake of each nutrient were converted from answers to diet history-related questions in the DHQ, and current physical activity was investigated by using the JALS-PAQ. The skeletal indices were evaluated as z-scores as they reflected the influence of age and then were analyzed by using ANOVA and multivariate analysis.

The mean age of the subjects was  $14.4 \pm 1.7$  years old, and no significant correlation was found for birth-related data, presence of menarche, and time from menarche. A significant ( $P < 0.001$ ) correlation was seen between current height and boy weight, and gestational age showed a significant correlation with body weight and lumbar vertebra BMD ( $P = 0.012$ ,  $P = 0.031$ , respectively). Again, age at menarche showed a significant ( $P < 0.0001$ ) correlation with body weight and lumbar vertebra BMD. A significant ( $P = 0.023$ ) correlation was seen between calcium intake as a lifestyle factor and lumbar vertebra BMD. Lumbar vertebra BMD was shown to be significantly ( $P = 0.016$ ) higher in those who reported exercise ( $n = 370$ ) compared to those who reported no exercise ( $n = 261$ ). Moreover, lumbar vertebra BMD showed a significant ( $P = 0.0057$ ) positive correlation with time spent on exercise.

It was found that birth-related data and age at menarche independently influenced the skeletal indices, physique and lumbar vertebra BMD. It was also suggested that calcium intake, exercise and exercise time influenced lumbar vertebra BMD and that these lifestyle factors contribute markedly to BMD acquisition in adolescent girls who are in growth and developmental stages.

**Both Excess and Restricted Energy Availability Negatively Influence Acquisition of Trabecular Bone Mass and Microarchitecture During Growth.** M. J. Devlin<sup>\*1</sup>, D. Panus<sup>\*1</sup>, C. J. Rosen<sup>2</sup>, M. L. Bouxsein<sup>1</sup>. <sup>1</sup>Orthopedic Surgery, Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, USA, <sup>2</sup>Maine Medical Center Research Institute, Scarborough, ME, USA.

This study tested the hypothesis that energy availability during the period of rapid skeletal growth affects bone mass and microarchitecture. At 3 wks of age we weaned male C57Bl/6J mice ( $N=4$  per group) onto normal (N, 10% calories/fat), 30% caloric restriction (CR, 10% calories/fat), or high fat diet (HF, 45% calories/fat). At 6 wks of age, we measured body weight, femoral length, serum IGF-1, total body BMD (TBBMD, g/cm<sup>3</sup>) using PIXImus, and trabecular bone architecture at the distal femur and cortical bone morphology at the femoral midshaft using  $\mu$ CT. CR mice were 54% lighter than N ( $p<0.0001$ ), had 12% shorter femurs and 18% lower TBBMD ( $p<0.0001$ ). Body mass, femur length, and BMD did not differ significantly between HF and N. Compared to N, both CR and HF diets were associated with lower distal femur trabecular bone volume (BV/TV) and thickness (Tb.Th, see Figure): BV/TV and Tb.Th were 14% lower in CR ( $p<0.03$  and  $p<0.0001$ ), and 11-12% lower in HF ( $p=0.057$  and  $p=0.0006$ ). In keeping with their lower body mass and shorter femurs, CR mice had 28-67% lower femoral cross-sectional area, cortical bone area, BA/TA, and cortical thickness ( $p<0.0001$ ), and 98-129% lower area moments of inertia ( $p<0.0001$ ), but HF and N did not differ. Serum IGF-1 was 14% lower in CR and 26% higher in HF vs. N ( $p<0.01$  for both). These results support the hypothesis that energy availability during growth affects cortical and trabecular bone mass and architecture, in some instances independently of effects on body mass. Young mice fed either HF or CR diet for a short period during growth had decreased trabecular bone volume and thickness but body mass-appropriate cortical bone parameters, suggesting cortical bone properties are driven primarily by body mass, but trabecular bone is more susceptible to metabolic disturbances.

**Maternal Nutrient Restriction During Pregnancy Results in Significant Alterations in Fetal Skeletal Development in the Baboon.** L. M. Havill<sup>1</sup>, M. R. Allen<sup>2</sup>, P. B. Higgins<sup>\*1</sup>, S. Amugongo<sup>\*3</sup>, J. A. K. Harris<sup>\*1</sup>, J. Mayeux<sup>\*1</sup>, N. E. Schlambitz-Loutsevitch<sup>\*4</sup>, P. W. Nathanielsz<sup>\*4</sup>, M. C. Mahaney<sup>\*1</sup>. <sup>1</sup>Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, <sup>2</sup>Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>3</sup>Dept. of Integrative Biology, University of California at Berkeley, Berkeley, CA, USA, <sup>4</sup>Dept. of Obstetrics and Gynecology, University of Texas Health Science Center San Antonio, San Antonio, TX, USA.

Bone development begins in utero and continues through the middle of the third decade of life in humans. Osteoporosis risk later in life is closely related to peak bone mineral density (BMD) attained at the end of this period of bone acquisition. Compromised nutrition in utero may effect changes in fetal skeletal development - e.g., alterations in the number and function of cells of the musculoskeletal system and/or expression of genes that regulate bone metabolism - that have long term consequences for skeletal growth, development, aging, resulting in increased risk of osteoporosis in adulthood. We assessed the effects of moderate global nutrient restriction in pregnant baboons, and hence fetal nutrient restriction, on fetal bone growth and development at 90% gestation (165 days). Nutrient-restricted (NR) mothers ate 70% of the amount of food eaten by ad lib controls. Whole body bone mineral density (BMD) was assessed for 6 NR fetuses and 8 control fetuses using DXA. NR fetuses showed significantly lower BMD than controls ( $p=0.02$ ). Proximal tibiae from all animals and a femurs from 4 NR fetuses and 4 controls were imaged using microCT. NR fetuses show a 26% reduction ( $p=0.007$ ) in amount of bone, which appears to be due to both thinner and fewer trabeculae. The femoral midshaft in NR fetuses is also smaller in size (smaller total and bone volume, cross-sectional area, and periosteal perimeter) and shows a lower cross-sectional moment of inertia, suggesting lower bending strength. Interestingly, however, the density of the bone tissue (pixels), specifically, in the NR cases is higher. While there is less bone, it is more highly mineralized, suggesting a compensatory mechanism in these animals. Nutrient restriction appears to result in an overall reduction in BMD and also an alteration in the localized tissue geometry and mineral density properties.

**Increased Maternal Fat Intake Increases Skeletal Mass in Congenic Mice.** L. M. Cote<sup>\*1</sup>, H. F. Coombs<sup>\*2</sup>, C. J. Rosen<sup>2</sup>, J. M. Hock<sup>1</sup>, W. G. Beamer<sup>2</sup>, C. L. Ackert-Bicknell<sup>2</sup>. <sup>1</sup>Maine Institute for Human Genetics and Health, Brewer, ME, USA, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME, USA.

There is accumulating evidence that maternal environment has a significant impact upon the physiology of the progeny. In this study, we examined the effect of maternal dietary fat intake on the peak bone mass of the offspring. We chose the B6.C3H-6T congenic mouse strain for these studies as this strain is an excellent model of age related bone loss and we have previously used this strain to study the influence of dietary fat on peak bone mass. Mice were placed on either a high fat (HF, 60% KJ from fat) or a low fat (LF, 11% KJ from fat) diet when breeder pairs were established and the dams were maintained on that diet for the duration of pregnancy and lactation. When the offspring reached weaning age, they were either placed on the same diet as the mother or on the diet opposite that of the mother. At 16 weeks of age, the age of peak bone mass, whole body areal BMD (aBMD), volumetric density of the femur (vBMD) and femur size were assessed in the offspring. Stepwise ANCOVA analyses were performed to determine statistical significance. Body weight, femur length, maternal diet, wean diet and the interaction factor (maternal diet X wean diet) were considered as covariates in the statistical model. The covariates of body weight and femur length were not found to be significant for any of the phenotypes analyzed. For the phenotypes of total femoral mineral (Femoral BMC), total femoral volume and periosteal circumference the covariates maternal diet, wean diet and the interaction term: maternal diet X wean diet were found to be significant ( $p<0.05$ ) for both males and females. No effect of maternal diet was found for either femoral vBMD or whole body aBMD for females, but a significant effect was found for males. This data demonstrates a definite link between maternal dietary fat intake and bone physiology. It would be interesting to determine if the effects on bone mass were a consequence of the maternal environment during fetal development, or occurred postnatally due to transmission of key factors in breast milk.

**Disclosures:** L.M. Cote, None.

**M496****Elevated Systolic Blood Pressure is Positively Related to Bone Mass Measurements in Overweight Pre-pubertal and Pubertal Children.** F. A. Tylavsky<sup>1</sup>, M. Hare<sup>\*1</sup>, P. Richey<sup>\*1</sup>, P. Velasquez<sup>\*2</sup>, P. Cowan<sup>\*3</sup>, G. Somes<sup>\*1</sup>.

<sup>1</sup>Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN, USA, <sup>2</sup>Pediatrics, University of Tennessee Health Science Center, Memphis, TN, USA, <sup>3</sup>Nursing, University of Tennessee Health Science Center, Memphis, TN, USA.

Human and animal studies have shown that total body sodium in excess of chloride is highly correlated with total body calcium, implicating a role for incorporating sodium in bones crystalline structure. In obesity induced hypertension, there is an increase of sodium retention due to concomitant reabsorption of calcium and sodium in the proximal tubule of the nephron. This results in a positive sodium and calcium balance leading to increases in extra cellular fluid and increases of calcium and sodium available for mineralizing the growing skeleton. We investigated the relationship between systolic (sys) blood pressure (BP) and bone area (BA), bone mineral content (BMC) and bone mineral density (BMD) in pre-pubertal (4-7 years, N=93, 96% African-American(AA)) and pubertal (11-18 years, N=48,72% AA) children. All participants were classified as at risk of or overweight as indicated by a BMI greater than 85<sup>th</sup> percentile for age and gender. BA, BMC and BMD of the whole body was determined by DXA (Hologic,Inc) using a standardized protocol. After sitting quietly for 5 minutes, sysBP were measured using a conventional mercury sphygmomanometer for the pre-pubertal children and dinamap for the pubertal children. Individuals were classified as having elevated BP if sysBP was greater than the 95<sup>th</sup> percentile for age, height and gender with the remaining being classified as normal. The average weight was 40.0± 11.6 and 98.2 ± 22 kg, and BMI was 25.7± 4.8 and 36.3± 7.7 kg/m<sup>2</sup> for pre-pubertal and pubertal participants respectively. SysBP had a moderate positive correlation to BA, BMC and BMD in both pre-pubertal and pubertal children  $r = 0.33-0.34$  and  $r = 0.59-0.66$ , respectively ( $p < 0.0001$ ). Pre-pubertal children with elevated sysBP had 4.1 % higher BA ( $p = 0.28$ ), 6.1% higher BMC ( $p = 0.27$ ), 2.6% higher BMD ( $p = 0.12$ ) while pubertal children with elevated sysBP had 10.3 % higher BA ( $p < 0.01$ ); 16.9% higher BMC, ( $p < 0.02$ ) and 6.9% higher BMD ( $p = 0.07$ ) than those with normal BP. Pubertal children with elevated sysBP also had higher lean body mass (58.2±2.1 kg) than those with normal sysBP (49.9±2.7 kg) ( $p < 0.02$ ) but similar fat and total mass. In pre-pubertal children similar but non-significant results were obtained for body composition. Our findings suggest that associations between elevated sysBP and BA, BMC and BMD in overweight children are evident in early childhood and magnify in puberty. How the skeleton is affected by elevated BP in overweight children as they mature and the mechanism behinds this warrants further investigation.

**M497****Tracking of Femur Length during Intrauterine Growth.** A. Bjornerem<sup>\*1</sup>, T. Wilsgaard<sup>\*1</sup>, T. Kiserud<sup>\*2</sup>, E. Seeman<sup>3</sup>, S. L. Johnsen<sup>\*4</sup>. <sup>1</sup>Institute of Community Medicine, University of Tromso, Tromso, Norway, <sup>2</sup>Division of Obstetrics and Gynaecology, Department of Clinical Medicine, University of Bergen, Bergen, Norway, <sup>3</sup>Department of Medicine and Endocrinology, Austin Hospital and University of Melbourne, Melbourne, Australia, <sup>4</sup>Department of Obstetrics and Gynaecology, Haukeland University Hospital, Bergen, Norway.

The magnitude of the variance in traits such as bone size, mass and density is established in prepubertal life (Loro et al 2000). In addition, traits track in their percentile of origin during growth in most individuals. The aims of this study were (1) to determine whether the magnitude of variance in growth and adulthood is fully expressed in utero, (2) to determine whether individuals' traits grow at different rates establishing this variance or whether growth rate is similar from individual to individual - an observation supporting very early establishment of variance, and (3) determine whether traits track in their percentile of origin. We measured femur length (FL) in 650 low-risk pregnancies in Bergen, Norway using 2D ultrasound an average of 2.6 times (range 1-5) during weeks 10-41 gestational. The first measurement correlated the 2nd ( $r = 0.67$ ), 3rd ( $r = 0.53$ ) and the 4th ( $r = 0.26$ ) (all  $P < 0.001$ ), but not with the 5th ( $r = 0.05$ ). 42.8% of fetuses remained in the same FL quartile from the 1st to 2nd scan, 35.7% did so from 1st to the 3rd, and 33.5% from the 1st to 4th scan. Only 23.1% tracked from the 1st to 5th scan. Maternal height correlated weakly with FL at the 4th scan ( $r = 0.13$ ,  $P = 0.002$ ) and not at all with scans 1, 2 and 3. The variance in FL increased 2-3 fold in absolute terms as gestational age advanced but the standard deviation relative to age-specific mean (SD/mean) decreased as gestational age increased to 20 weeks and then remained constant and no different to their mothers SD/mean in height. We infer that variance is established in intrauterine life and tracking does occur but shifting between quartiles is more common than tracking and occurred in 77% of fetuses so that the tracking observed during postnatal growth may be set during the first years of life. The intrauterine, maternal or paternal factors operating before and shortly after birth that influence trait variance and tracking or change of tracking are unknown.

**M498****Birth Weight Predicts Bone Size, Adult Weight Predicts BMC and BMD In Young Gambian Adults.** S. de Bono<sup>\*1</sup>, I. Schoenmakers<sup>\*1</sup>, M. Ceesay<sup>\*2</sup>, M. Mendy<sup>\*2</sup>, M. Laskey<sup>\*1</sup>, T. Cole<sup>\*3</sup>, A. Prentice<sup>1</sup>. <sup>1</sup>Nutrition and Bone Health, MRC Human Nutrition Research, Cambridge, United Kingdom, <sup>2</sup>MRC, Keneba, Gambia, <sup>3</sup>UCL Institute of Child Health, MRC Centre of Epidemiology of Child Health, London, United Kingdom.

Fracture risk is determined by bone mass, size and architecture. Birth weight is reported to predict adult bone mass and density. Early life environment may therefore be a determinant of fracture risk in later life. However this evidence was obtained using dual-energy X-ray absorptiometry (DXA), which is known to be dependent on bone size. In this study we used peripheral quantitative computed tomography (pQCT) to investigate birth weight as a determinant of adult bone size, bone mineral content (BMC) and volumetric bone mineral density (vBMD) at trabecular and cortical sites, independent of adult weight, height and age. The results were compared to BMC and areal BMD (aBMD) measured by DXA. The study population had a high prevalence of factors likely to influence growth and skeletal development (poor nutrition, low calcium intake, delayed puberty and high physical activity).

Bone cross-sectional area, BMC and BMD were measured using pQCT (Stratec 2000; at 4 and 66% of the radius; 4 and 50% of the tibia length) and DXA (Lunar DPX; spine, hip, forearm and whole body) in 68 men and 52 nulliparous women aged 17.4 to 20.8 years from the rural village of Keneba, The Gambia. We used sequential univariable (influence of birth weight on each bone variable) and multivariable linear regression analyses (influence of birth weight on each bone variable after adjusting for adult height, weight and age) to investigate the independent effects of birth weight and adult size on adult skeletal status. Preliminary analyses showed significant interactions between birth weight by gender and bone variables. Therefore analyses were performed separately for both sexes. Birth weight was a significant positive predictor of total cross-sectional bone area (pQCT) at trabecular sites in females (total area radius:  $p = 0.003$ ; tibia:  $p = 0.05$ ) and cortical sites in males (total area radius:  $p = 0.01$ ; tibia:  $p = 0.005$ ), after adjustment for adult height, weight and age. Birth weight was not consistently related to BMC, vBMD or aBMD as measured by pQCT or DXA. Adult weight was a positive predictor of pQCT and DXA derived BMC and aBMD and adult height predicted aBMD at most sites in both males and females. In summary, birth weight significantly predicted adult bone size at trabecular sites in females, and cortical sites in males. Adult weight was a positive predictor of adult BMC and aBMD in both sexes. In conclusion, birth weight and hence prenatal factors affecting fetal growth may influence long-term bone health and fracture risk through their associations with adult skeletal size, independent of postnatal factors.

**M499****Effects of Diet and Menstrual Cyclicity on Bone Mass Accumulation in Pubertal Monkeys.** C. J. Lees, M. Cline<sup>\*</sup>. Wake Forest University School of Medicine, Winston-Salem, NC, USA.

By end of puberty 80-90% of total adult bone mass is present. Anything that affects bone mass accumulation (such as diet) during this time period may have long term repercussions on skeletal health.

We examined the effects of dietary soy on bone mass accumulation during puberty in *Macaca fascicularis*. Twenty-nine 1.5 kg females were imported from Indonesia. The animals were divided into two groups that were fed a diet differing only in protein source (soy {n=17} vs. casein {n=12}). Vaginal swabs were performed daily to determine onset of menses and regularity of menstrual cycle. Whole body bone mineral content (WBBMC) and vertebral bone mineral density (LV24BMD) were determined by dual X-ray absorptiometry (DEXA) at baseline and then every 6 months for a total of 5 scans. Repeated measures analysis of variance showed no overall dietary effect on either WBBMC or LV24BMD. However, at scan time point 2, menstrual cyclicity had an impact on bone mass accumulation and this impact was dependent on diet. Within the soy group, cycling vs. non-cycling females did not differ in WBBMC or LV24BMD whereas in the casein fed group, cycling animals had higher WBBMC and LV24BMD compared to non-cycling females (see table below). The animals fed soy, regardless of cycling, did not acquire as much WBBMC or LV24BMD during this period compare to cycling casein animals. A similar trend was seen at the third scan.

Diet (D)	Soy		Casein		p-Values D/C/D*C
	Yes (N=11)	No (N=6)	Yes (N=6)	No (N=6)	
Cycling (C)					
WBBMC2	79 ± 5	78 ± 4	97 ± 7	69 ± 6	ns/0.02/0.03
LV24BMD2	0.460 ± 0.013	0.457 ± 0.012	0.520 ± 0.027	0.457 ± 0.014	ns/0.06/0.09

The groups are quite small in this study, especially when divided into cycling vs. non-cycling. However, it appears that soy may have differing effects on pubertal bone mass accumulation that is dependent on menstrual cyclicity.

**Is Increased Bone Fragility During Adolescence a Result of Delayed Development in Bone Bending Strength?** S. A. Jackowski\*, R. A. Faulkner, A. Baxter-Jones. Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

**Purpose:** The objective of this study was to investigate the sequential timing between the age of peak height velocity (APHV) and age of peak section modulus velocity (APZV) at the narrow neck and femoral shaft during the adolescent growth period.

**Methods:** 41 males and 42 females aged 8-18 years were selected from the Saskatchewan Pediatric Bone Mineral Accrual Study (1991-2005). Participants height and section modulus (Z) at the proximal femur were assessed annually using a wall-mounted stadiometer and hip structural analysis (HSA) program, respectively. Height and Z values were converted into whole year velocities and the maturational age of peak tissue velocities was determined using a cubic spline curve fitting procedure. Differences in APHV and APZV at the narrow neck and femoral shaft were compared using multiple t-tests with significance set at  $p < 0.05$ .

**Results:** APHV (males,  $13.15 \pm 0.89y$ ; females,  $11.70 \pm 0.98y$ ) preceded the APZV at the narrow neck ( $13.71 \pm 1.01y$ ;  $12.39 \pm 1.15y$ ) and femoral shaft ( $13.70 \pm 1.46y$ ;  $12.28 \pm 1.04y$ ) for both males and females ( $p < 0.05$ ).

**Discussion:** The timing of APHV and Z are in agreement with previous studies showing a sequential timing between APHV and bone mineral accrual. Thus these findings support in the conjecture that during adolescence there is a period of relative skeletal fragility that may partially explain the increased risk of fracture rate at this time of life.

**Environmental Perturbations during Puberty and Bone strength.** R. N. Joshi, V. Yingling. Kinesiology, Temple University, Philadelphia, PA, USA.

Studies have reported bone densities in young athletic women similar to 51-year-old women. Fracture risk in the elderly has its origins during growth and development; both genetic and environmental factors (including secondary amenorrhea disordered eating and delayed pubertal development) have been found to correlate with low bone mass in young women. Pubertal timing is considered to be one of the key factors that predicts peak bone mass. Delayed puberty is observed in females with hypothalamic amenorrhea and energy deficiency. The purpose of this study was to determine the effect of delayed puberty on bone strength through two different physiological mechanisms. At 23 days of age, 16 female Sprague Dawley rats (Charles River) were randomly assigned into three groups: Aged match control group (C, n=4), Gonadotropin releasing hormone-antagonist (GnRH-a group, n=6), and Energy Restriction (ER, n=6). The animals in the GnRH-a group received daily injections (Antide, Bachem) at a dose of 2.5 mg/kg for 28 days. The animals in the ER group received 0.7 g for each 1 g of food consumed by control animals (Research Diets). All the animals were sacrificed on day 51. Vaginal opening (VO) was documented and considered to be the day of pubertal onset. After sacrifice, body weight, uterine weights and muscle weights were measured in all groups. Mechanical strength was measured using a 3-point bending test to failure at a loading rate of 0.05 mm/s. Differences were detected using a One-way ANOVA. Puberty was completely suppressed in the GnRH-a model as evidenced by a cessation of VO and suppressed uterine development however this group had similar body weights at sacrifice as control. The ER model had a moderate delay in puberty based on day of VO with no change in uterine development. ER resulted in a lower body weight at sacrifice and decreased muscle weight. However, there was a significant decrease in mechanical strength in the GnRH-a group and a trend towards decreased strength in the ER group. These results suggest that two physiologically different mechanisms during the pubertal period have a negative impact on bone strength.

Table 1. Outcome measures. Mean (SD) \*  $p < 0.05$

Parameters	C	GnRH-a	ER
Peak Moment Femur (Nmm)	202.9 (23.2)	156.8 (16.8)*	185.2 (18.6)
Peak Moment Tibia (Nmm)	163.1 (15.4)	133.7 (8.6)*	142.8 (14.7)

**Ethnicity-specific Bone Changes During Adolescent Growth: pQCT Analysis of the Tibia.** S. Braid<sup>1</sup>, M. Burrows<sup>1</sup>, Y. Ahamed\*<sup>1</sup>, H. McKay<sup>2</sup>.

<sup>1</sup>Department of Orthopaedics; Centre for Hip Health and Musculoskeletal Research, University of British Columbia, Vancouver, BC, Canada,

<sup>2</sup>Department of Orthopaedics and Family Practice; Centre for Hip Health and Musculoskeletal Research, Vancouver Coastal Health Research Institute, Vancouver, BC, Canada.

Ethnicity, body habitus and lifestyle including physical activity (PA) and dietary calcium (Ca2+) are among the key determinants of peak bone mass. However, little is known about ethnic differences related to the development of bone strength in growing children. Thus, we used pQCT (Stratec XCT 2000) to assess the ethnicity-specific variation in bone total area (ToA, mm<sup>2</sup>), cortical density (CoD, mg/mm<sup>3</sup>), and SSI (mm<sup>3</sup>) at the 50% site of the tibia in 142 Asian (A) and Caucasian (C) girls (F) and boys (M) over 52-months (37AF, 22CF, 45AM, 38CM). Ages (SD) were 10.4 (0.6) and 14.7yrs (0.6) at baseline (T1) and final (T2), respectively. We evaluated a 2.5mm mid-diaphyseal slice of the tibia using pQCT. Height (Ht, cm) and weight (Wt, kg) were assessed using standard protocol and tibial length (TL, cm) was the distance from the tibial plateau to the medial malleolus. PA and Ca2+ were assessed by questionnaire. Ht, Wt and TL did not differ between AM and CM at T1 {141.1cm (7.3); 36.5kg (9.5); 32.7cm (2.4)} or T2 {167.5cm (8.7), 58.0kg (13.7), 40.8cm (2.6)}. AF were shorter and weighed less than CF at T1 and T2 ( $p < 0.05$  both). T1 values (AF v CF) were: Ht 139.0 (6.9) v 143.3cm (7.6); Wt 34.1 (7.1) v 38.0kg (10.2); and TL 32.0 (2.0) v 33.1cm (2.3). T2 values (AF v CF) were: Ht 157.6 (5.7) v 164.3cm (6.2); Wt 49.9 (7.6) v 57.4kg (12.0); and TL 36.9 (1.7) v 38.9cm (2.0). No significance (NS) indicated for PA between ethnicities (F: 3.8 (3.7) and M: 6.3 load hrs/wk (5.2)). At T1 Ca2+ was 781.8 (379.9) v 1009.8kcal (397.2) for AF and CF, respectively. For M, T1 Ca2+ was 895.3 (91.9) v 1111.46kcal (98.9) for AM and CM, respectively ( $p < 0.05$ ). All bone outcomes increased with age in A and C ( $p < 0.05$ ). ANCOVA was used to assess change in bone outcomes (covariates: TL, Wt and Ca2+). At T1, CF had greater ToA 303.2 (55.4) v 279.0mm<sup>2</sup> (43.0), CoD 1052.1 (23.7) v 1061.6mg/mm<sup>3</sup> (35.9) and SSI 1006.9 (260.2) v 893.3mm<sup>3</sup> (200.6) compared with AF ( $p < 0.05$ ). T2 values (CF v AF) were: ToA 394.6 (63.4) v 361.3mm<sup>2</sup> (47.2); CoD 1126.8 (23.8) v 1136.0mg/mm<sup>3</sup> (20.9) and SSI 1601.3 (375.6) v 1414.9mm<sup>3</sup> (256.6). However, these differences were explained by size and were NS once covariates introduced. For boys, A had greater ( $p < 0.05$ ) CoD only at T1 and T2, respectively [1051.8 (27.7) and 1078.2 (31.6)] compared with C [1052.7 (36.7) and 1053.7 (44.9)]. No other differences were noted between AM and CM. Although there were some differences in lifestyle factors (Ca2+) known to effect bone, A and C girls changed similarly as they matured. However, the difference in CoD between boys is notable and should be explored further.

## M503

**Early Exposure to Soy Isoflavones Modulates Bone Mineral, Strength and Microarchitecture in CD-1 Mice.** J. Kaludjerovic\*, W. E. Ward. Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

Neonatal exposure to the soy isoflavone genistein (GEN), at levels similar to that of infants consuming soy protein-based infant formula, favourably modulates bone mineral and bone strength in mice. The objective of this study was to determine if early exposure to a combination of soy isoflavones, daidzein (DAI) and GEN, results in greater benefits to bone at adulthood than either treatment alone. Male and female CD-1 mice (n = 8-16 pups/group/gender) were randomized to subcutaneous injections of DAI (2 µg/d), GEN (5 µg/d), DAI+GEN (7 µg/d), diethylstilbestrol (DES, positive control) (2 µg/d), or corn oil (CON) from postnatal day (PND) 1 to 5, and were followed to young adulthood (4 months old). Serum isoflavones were measured at PND 5, while bone mineral, strength and microarchitecture were analyzed at 4 months of age. Females treated with DAI, GEN, DAI+GEN or DES had higher ( $p < 0.001$ ) femur and lumbar vertebrae (LV1-3) BMD compared to the CON group, which translated into stronger ( $p < 0.010$ ) bones that were more resistant to fracture. Microstructural analysis demonstrated that females treated with DAI, GEN, DAI+GEN or DES had greater ( $p < 0.001$ ) cortical area at the femur midpoint compared to the CON group, with DAI providing added benefits. At the lumbar spine, females treated with DAI and DAI+GEN had higher ( $p < 0.001$ ) trabecular number and lower ( $p < 0.001$ ) trabecular separation compared to CON, suggesting that DAI alone or in combination with GEN improves the interconnectivity of trabecular bone. Females treated with GEN had higher ( $p = 0.031$ ) trabecular thickness at the lumbar spine compared to the CON group. Effects in males were modest, with DAI or DAI+GEN resulting in higher yield load ( $p = 0.030$ ) at the femur neck compared to the CON group. In conclusion, neonatal exposure to DAI and/or GEN had a positive effect on the skeleton of female mice but compared to individual treatments, DAI+GEN did not have a greater benefit to bone in females or males. Future research should determine if these positive effects protect against deterioration of bone tissue during aging.

## M504

**Heel Ultrasound and Consolidation of Peak Bone Mass in Young Women - Bath Cohort Study.** S. Venkatachalam<sup>1</sup>, I. Reading<sup>\*2</sup>, C. Cooper<sup>2</sup>, D. Elvins<sup>\*3</sup>, A. Bhalla<sup>3</sup>. <sup>1</sup>Rheumatology, Cannock Chase Hospital, Cannock, United Kingdom, <sup>2</sup>MRC Environmental Epidemiology Unit, Southampton, United Kingdom, <sup>3</sup>Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom.

We had earlier identified that infant growth and physical activity in childhood are important determinants of peak bone mass in women at the age of 21 years, in a cohort of young women from Bath, UK born in 1968-69. Our longitudinal study showed continuing gain in BMD in the third decade at both the lumbar spine and the total hip in young women on DXA. Their weight at the age of 21 years was the only significant determinant of consolidation of peak bone mass. We explored the relationship of bone quality measured by heel ultrasound with consolidation of peak bone mass in these young women at the age of 31 years.

We traced 90 of 153 women from the initial cohort and 87 had heel ultrasound (Sahara) at 31 years of age. We ascertained lifestyle factors like calcium intake, physical activity, smoking and alcohol consumption by questionnaire. Data were analysed by multiple regression with changes in heel BMD, BUA (Bone Ultrasound Attenuation) and SOS (Speed of Sound) as dependent variables.

Significant determinants of heel BUA were weight at 21 years of age ( $\beta = 0.355$ ,  $p = 0.018$ ) and walking ( $\beta = 2.826$ ,  $p = 0.037$ ). Heel BMD was associated only with walking ( $\beta = 0.02$ ,  $p = 0.047$ ) while Heel SOS was not associated with any of the measures. Only weight at birth negatively predicted Heel SOS and BMD, but not BUA at age 31 years ( $p = 0.012$ ,  $p = 0.025$ ). The conditional weights at 1 year, 5, 10 or 21 years and life style factors did not predict bone quality on ultrasound in the women.

Walking is known to increase the impact on heel bone quality and is associated with consolidation of heel bone mass. Weight at 21 years of age not only determines consolidation of hip and spine BMD but also bone quality measured as heel BUA.

**Vitamin K Intake Is Positively Related to Trabecular Bone Microarchitecture in Children.** C. M. Modlesky<sup>1</sup>, J. T. Kirby<sup>\*1</sup>, S. Kanoff<sup>†\*1</sup>, F. Miller<sup>\*2</sup>. <sup>1</sup>Health, Nutrition and Exercise Sciences, University of Delaware, Newark, DE, USA, <sup>2</sup>Orthopaedics, AI duPont Hospital for Children, Wilmington, DE, USA.

Vitamin K seems to play an important role in the development and maintenance of the skeleton. This idea is supported by studies reporting an inverse relationship between vitamin K intake and fracture. Interestingly, vitamin K status is not consistently related to areal bone mineral density (aBMD). The discordant relationship suggests that vitamin K is more closely connected to skeletal features not captured by aBMD, such as the trabecular microarchitecture and the geometric structure of bone. The purpose of this study was to determine if vitamin K intake is related to measures of trabecular bone microarchitecture and cortical bone geometry in the femur of children. Fifteen boys and 15 girls (Caucasian; 6 to 12 y) participated in the study. Pubertal development was determined using Tanner staging. Vitamin K and calcium intake were determined using 3-day diet records and the USDA Food and Nutrient Database for Dietary Studies (v.1.0). Physical activity was assessed using accelerometry (Actical; MiniMitter Co.). Magnetic resonance imaging (GE 1.5 T) was used to collect images of the distal femur and images of the thigh. Distal femur images were used to assess trabecular bone microarchitecture [i.e., apparent trabecular bone volume to total volume (appBV/TV), trabecular number (appTb.N), trabecular thickness (appTb.Th) and trabecular spacing (appTb.Sp)] in the lateral half of the bone. Thigh images were used to assess measures of cortical bone geometry (i.e., cortical volume, polar moment of inertia and section modulus) and muscle mass at the level of the middle-third of the femur. All images were processed using software created with Interactive Data Language (Research Systems, Inc). The relationships between vitamin K and measures of trabecular bone microarchitecture and cortical bone geometry were determined using linear regression analysis, with midthigh muscle mass, calcium intake and physical activity counts as covariates. Twenty five children were prepubertal (Tanner stage I) and 5 children were early pubertal (Tanner stage II). Vitamin K intake was not significantly related to any measure of cortical bone geometry in the middle-third of the femur ( $p > 0.05$ ); however, vitamin K intake was positively related to appBV/TV (partial  $r = 0.501$ ,  $p = 0.008$ ) and appTb.Th (partial  $r = 0.468$ ,  $p = 0.014$ ) and inversely related to appTb.Sp (partial  $r = -0.351$ ,  $p = 0.072$ ) in the distal femur. The findings suggest that vitamin K may be an important contributor to the development of trabecular bone microarchitecture in children.

**A Protocol for Pediatric Proximal Femur DXA Analysis.** J. Eichenberger Gilmore<sup>\*1</sup>, C. A. Pauley<sup>\*2</sup>, T. L. Burns<sup>\*3</sup>, J. C. Torner<sup>\*3</sup>, E. M. Letuchy<sup>\*3</sup>, K. F. Janz<sup>\*4</sup>, M. C. Willing<sup>5</sup>, S. M. Levy<sup>1</sup>. <sup>1</sup>Preventive and Community Dentistry, University of Iowa, Iowa City, IA, USA, <sup>2</sup>Food and Nutrition, University of Iowa, Iowa City, IA, USA, <sup>3</sup>Epidemiology, University of Iowa, Iowa City, IA, USA, <sup>4</sup>Sports and Health Studies, University of Iowa, Iowa City, IA, USA, <sup>5</sup>Pediatrics, University of Iowa, Iowa City, IA, USA.

Pediatric proximal femur DXA scans present analytic challenges for both cross-sectional and longitudinal research due to lack of fully developed anatomical landmarks in the growing skeleton. The Iowa Bone Development Study (IBDS) developed a modified pediatric-specific proximal femur analysis protocol using Hologic software. Serial DXA measurements were obtained for 214 children at approximate ages 5, 8, 11, and 13 years (Waves 1 - 4). Standard analysis procedures as described by the manufacturer (Hologic Default) were compared to the IBDS protocol. The IBDS protocol yielded lower but more stable results for bone area (BA), bone mineral content (BMC) and bone mineral density (BMD) for total hip, femoral neck (FN), trochanter, and intertrochanter as a result of more precisely controlling the regions of interest (ROIs). Linear regression models with body size, age and gender as predictors were developed to examine variation in measurements. Coefficients of variation ( $R^2$ ) with the IBDS protocol were greater for each time point, demonstrating that the modified protocol was better aligned with body size (Table). Similarly, Spearman correlation coefficients between total hip and hip sub-regions were consistently higher for BMC and BA with the IBDS protocol with differences more notable among younger children (Figure). The IBDS protocol provides a reproducible method for evaluating pediatric proximal femur DXA scans during growth.

Table. Coefficients of Determination ( $R^2$ ) for Hip BMC (Hologic Default and IBDS Protocols) with Body Size (Height and Weight), Age, and Gender as Predictors.

	Protocol	Wave 1	Wave 2	Wave 3	Wave 4
Hip BMC	Default	0.57	0.68	0.67	0.63
	IBDS	0.62	0.72	0.70	0.67
Femoral Neck BMC	Default	0.41	0.50	0.64	0.61
	IBDS	0.58	0.63	0.68	0.66
Trochanter BMC	Default	0.33	0.51	0.49	0.53
	IBDS	0.54	0.66	0.66	0.62

**A Randomised Double Blinded Controlled Trial of Individual Response in Biochemical Markers of Bone Turnover to Lasofoxifene Therapy.** S. J. Glover, A. Rogers, F. Gossiel\*, R. Eastell. Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, UK, United Kingdom.

Biochemical markers of bone turnover (BTMs) may be used to monitor the response to anti-resorptive therapy. It has been proposed that to be effective in the prevention of fracture, the goals of therapy in the individual are a decrease in BTMs > the least significant change (LSC), and to within the lower half of the reference interval (RI) for healthy, young pre-menopausal women.

The aim of this study was to evaluate the use of BTMs in monitoring the response to lasofoxifene (laso) therapy after 6 months by determining the % of women: a) with a decrease in BTMs >LSC b) with BTMs in the lower half of the RI for young pre-menopausal women.

51 postmenopausal osteopenic women, ages 55 to 77 (mean 63.7) years were randomized to receive either laso (0.25 mg/day) or placebo. 47 women (completed 6 months of therapy. All women received calcium and vitamin D throughout the study. We measured serum bone alkaline phosphatase (bone ALP), procollagen type I propeptide (PINP), serum beta crosslinked C-telopeptides of type I collagen (S-bCTX) and urinary crosslinked N-telopeptides of type I collagen (NTX) at weeks -1, 0 (baseline), 4, 8, 12, 24 and 25 (6 months) using standard techniques. BTMs were also measured at a single time point in 145 healthy pre-menopausal women ages 35 to 45 years. LSC was calculated from baseline duplicate measurements using the ISCD calculator (<http://www.iscd.org/visitors/resources/calc.cfm>). T scores for the patient population were calculated from the mean and SD of the log transformed reference data.

We observed a significant decrease in all BTMs in response to laso (p<0.0001 by ANOVA). For all BTMs the change from baseline was significant by 4 weeks post laso (p<0.0001) with the largest reduction observed at 6 months. The LSC for each marker was as follows; bone ALP, 14.14%, PINP 25.10%, S-bCTX 27.67 % and NTX 36.79%. The values for mean % change in BTMs in the laso (placebo) groups at 6 months were: bone ALP -26.6(-6.5) %, PINP -44.0(-8.6) %, S-bCTX -44.1(-3.5) % and NTX -29.1(-6.3) %. The number (%) of responders and women in the lower half of the RI at 6 months are shown below (table).

We conclude that almost all patients responded to laso therapy based on the values for LSC in the serum based BTMs. BTMs were reduced to the lower half of the RI in a large % of women suggesting that laso may be a useful therapy in the prevention of osteoporotic fracture.

	Laso	Placebo	Laso	Laso
	% Responders	% Responders	% Lower Half RI	% Lower Half RI
bone ALP	88	33	48	18
PINP	92	29	76	9
S-bCTX	92	4	52	9
NTX/Cr	39	9	36	27

## MUSCLE AND BONE WORKING GROUP

### WG1

**The Effect of Non-Ambulation on Bone Strength in Boys with Duchenne Muscular Dystrophy (DMD).** Crabtree NJ<sup>1</sup>, Ward KA<sup>2</sup>, Roper H<sup>3</sup>, Mughal Z<sup>4</sup>  
<sup>1</sup>Shaw, NJ <sup>1</sup>Birmingham Children's Hospital, <sup>2</sup>University of Manchester, <sup>3</sup>Heartlands Hospital, Birmingham, & <sup>4</sup>St Mary's Hospital for Women and Children, Manchester, UK

DMD is the most common childhood neuromuscular disorder causing loss of ambulation in early life. Steroids are currently used to improve muscle strength and prolong ambulation although the effect on bone health in this group of children is still unclear. The aim of this study was to compare bone strength in healthy children to bone strength in children with DMD and investigate the interaction between high dose oral steroids and diminished muscle function.

Forty-seven children were studied, 18 healthy boys (mean age 9.0±1.5 years) and 29 boys with DMD (mean age 9.1±2.5 years). Of the 29 boys with DMD 9 were ambulant and had not started on steroids, 14 were ambulant and had taken steroids for at least 12 months (mean 25.4 ±11.0 months) and 6 were no longer ambulant and had taken steroids for between 14 and 45 months (mean 37.2 ±11.7 months). Peripheral quantitative computed tomography was used to measure bone geometry, density and muscle mass of the non-dominant tibia. Measurements were made at the distal metaphysis and mid diaphysis sites taken as 4 & 66% of the tibial length, respectively. Data were adjusted for age & height and differences between the four groups evaluated.

In general, at the distal metaphysis, healthy boys had larger bones (21.3%, p<0.001) which were more dense (18.4%, p<0.001) than the boys with DMD. The greatest differences were observed between healthy and non-ambulant DMD boys, where bone area and bone density were reduced by 41.6% and 32.0%, respectively. No significant differences were observed between ambulant steroid and non steroid DMD boys, for these parameters. At the mid diaphysis, cross-sectional tibial area, cortical area, cortical bone mass and the stress-strain index (a surrogate measure for bone strength) were all reduced in DMD boys by 40.0%, 29.2%, 22.4% & 31.5%, respectively (p<0.001). Once again this effect was most striking in the boys who had lost ambulation, with no differences detected between ambulant steroid and non steroid DMD boys. In contrast, DMD boys had significantly greater muscle mass (48.4%, p<0.001) but with greatly diminished function. In addition, there were no significant differences in cortical density.

In summary, this data suggests that ambulation and hence muscle function & gravitational load has the greatest effect on bone strength and density in boys with DMD. In contrast, whilst they remain ambulant the effect of the relatively high dose steroids appears to be negligible. This information is likely to be useful when considering potential interventions for maximising bone strength as these boys go through puberty in to young adulthood.

### WG2

**Shared Genetics Within the Musculoskeletal System: A Pleiotropic Approach to Osteoporosis and Sarcopenia.** D. Karasik. IFAR Hebrew SeniorLife and Harvard Medical School, Boston, MA, USA

Osteoporotic fracture can be viewed as an outcome of loading conditions and the ability of the bone to withstand the load. Muscle action is the major mediator of skeletal load. Aging-related change in the musculoskeletal system manifests as bone loss (osteoporosis) and muscle wasting (sarcopenia). Recently, it has become clear that bone and muscle share genetic determinants (pleiotropy), which may be pertinent to etiology of osteoporosis and sarcopenia.

This report provides evidence of accumulating data for a shared genetic influence on bone and muscle. Thus, genetic correlations between lean mass (LM) and femoral geometry ranged from 0.28 to 0.69 (Deng et al JBMR 2007) and between LM and BMD from 0.30 - 0.41 (Videman et al JBMR 2007). Animal studies (in mouse intercrosses, sheep, and beef cattle) confirm the above observations. Our recent genome-wide studies in the Framingham study provide an important insight on the pleiotropy, as well as sex-specificity of the genetic associations. Several candidate genetic mechanisms, including *ESR1* and *IGF1* pathways, show sex-specific association with bone and muscle strength phenotypes.

Physical exercise produces larger effects on the adult skeleton (beyond puberty) in men compared to women. It is not obvious whether or not sex-specific genetic associations may be attributed to the modifying effects of sex chromosomes or other differences between the genders, such as the level of sex hormones and/or physical exercise. Therefore, we considered several related questions such as (a) what genetic factors modulate varying responses to the exercise in men and women, and (b) whether there is a sex-specific genetic predisposition, or (c) whether the environment/ hormonal milieu differs by sex. Finally, some insights and recommendations as to the value of studying shared genetic factors, and possible directions for future research, will be offered and explored.

We believe that further progress in understanding the shared genetic etiology of osteoporosis and sarcopenia will provide valuable insight into important biological underpinnings for both osteoporosis and sarcopenia. For example, selective androgen receptor modulators (SARMs) and low magnitude strains (vibration) are characterized by the anabolic activity on both muscles and bones. Knowledge of the general paradigm of bone responses to mechanical loading may translate into targeted new approaches to reduce the burden of both conditions affecting elderly women and men.

## ADULT BONE AND MINERAL WORKING GROUP

### WG24

**A case presentation: Bisphosphonate induced Osteonecrosis of the Jaw in Pagetic Jaw Bone.** M. Adams<sup>1</sup>, K. Adams<sup>1</sup>, A. Freemont<sup>2</sup>. <sup>1</sup>Bolton NHS Primary Care Trust, Bolton, UK, <sup>2</sup>The University of Manchester, Manchester UK

Bisphosphonate induced Osteonecrosis of Jaw in is a rare condition in patients except for those who are on high doses in the treatment of malignancy. We would like to report what appears to be the first case of Bisphosphonate induced Osteonecrosis of Jaw in Pagetic bone. The patient was an 86-year-old lady who had been treated for pain related to Paget's disease of the bone. An isotope bone scan had shown polyostotic Paget's disease including involvement of the whole of the maxilla. She was treated with oral Risedronate 30 mg daily but had to stop after 6 weeks because of gastrointestinal adverse effects. She was then treated with IV Pamidronate but because of difficult venous access only two infusions of 60 mg were administered. A few months later she had difficulty removing a partial upper right denture, which was finally removed after 3 days. Shortly after, pieces of the upper jawbone began to come loose and fall out - two pieces with a tooth attached. (photograph). She also noted food appearing in the back of her nose. The patient attended the Department of Rheumatology at Bolton in 2006 when she produced the jaw fragments asking for someone to dispose of them. Histology of these dry fragments showed evidence of Paget's disease of bone. (photomicrograph). She refused any debridement there being visible loose bone in the gum. No further bisphosphonates were given and the maxillary defect slowly healed although a piece of jaw bone fell out about 2 years later. The defect to the palate closed and the patient has remained well now being able to eat comfortably although she cannot be fitted with any denture.

### WG25

**Diffuse Sclerosing Osteomyelitis of the Mandible: Case Report and Literature Review.** A. L. Schafer, R. Silva<sup>\*</sup>, M. Yafai<sup>\*</sup>, D. Shoback. San Francisco VA Medical Center and University of California, San Francisco, San Francisco, CA, USA.

Osteonecrosis of the jaw is a serious complication of bisphosphonate therapy and highlights the need for greater understanding of bisphosphonate effects on oral bone. We evaluated a patient with diffuse sclerosing osteomyelitis of the mandible (DSOM), for which there are reported dramatic improvements after IV bisphosphonate therapy. DSOM is a chronic inflammatory condition with intermittent, acute flares of pain and swelling in the absence of pus or fistulae. Response to conventional treatment with antibiotics is transient. Frequent flares lead to pain and progressive loss of oral function. A 51 year-old man presented to the Oral and Maxillofacial Surgery Department with 3 years of recurrent pain and swelling of the left mandible. Repeated biopsies, debridements, and cultures failed to isolate a causative organism, although he had a modest clinical response to clindamycin. He had no history of endocrine or metabolic bone disorder. Examination showed diffuse left facial swelling, redness, warmth, and tenderness and marked trismus. CT showed cortical irregularity, destruction, and sclerosis of the left mandible. Technetium scan showed marked uptake in the left mandible. ESR and high-sensitivity CRP were elevated at 31 mm/hr (nl 0-15) and 41.9 mg/L (nl 0.2-7.5), respectively. Clindamycin and analgesics were increased, but symptoms continued unabated, and eventually he was admitted to the hospital for IV pain management. After literature review disclosed potential benefit from IV bisphosphonates, he received pamidronate 60mg IV. In 2 days, jaw swelling and pain decreased markedly. After 5 days, he had complete resolution of symptoms and remains without recurrence 3 months later. There are 7 reports of DSO treated with IV or oral bisphosphonates, 6 of them cases of DSOM (3 children, 3 adults), and one trial with 10 patients. There are 3 cases of DSO of the femur and/or tibia. The 2 adults and 2 of the 3 children who received IV bisphosphonates for DSOM had resolution and lasting remissions. The third child developed mouth ulcers and increased pain and swelling. In the randomized trial of IV clodronate vs. placebo for DSOM, there was no difference in immediate pain relief between the 2 groups, but there was statistically significant decreased pain intensity 6 months after clodronate therapy (vs. placebo), without adverse events. Our patient with DSOM had a dramatic response to pamidronate, similar to patients in the literature. This case highlights the importance of accurate oral pathologic diagnosis and the need for greater understanding of mandibular bone disorders, especially the role of suppressing bone turnover in controlling inflammation and sclerosis in DSOM.

## WG26

**Bisphosphonate-associated Femoral Fracture: Implications for Management.** N Napoli, R Armamento-Villareal Div. of Bone and Mineral Diseases, Washington University Sch. Of Med.

Recent reports of femoral shaft fractures in patients on long-term bisphosphonates (BPs) with biopsy evidence of severely suppressed bone turnover raised important concerns on the safety for this class of drugs. Patients with malignant skeletal conditions, such as multiple myeloma are potentially especially at risk for this complication considering the dose and the duration of treatment with BPs that these patients are subjected to. In this report we describe the case of 56 year-old woman who was referred for evaluation at the Bone Clinic of Washington University because of a recent left femoral shaft fracture. Her history revealed that she had a stem cell transplant in Nov. 1999 for multiple myeloma. After the transplant, she was put on high dose steroids and pamidronate infusions at 30 mg monthly for 2 years followed by zoledronate infusions at 4 mg monthly for 4 years. This was discontinued because of concerns for osteonecrosis of the jaw and increasing serum creatinine. One and a half years later, she developed a left femoral shaft fracture (Figure 1A) while trying to get up from a squatting position. She underwent an intramedullary fixation of the left femur but insertion of the rod literally resulted in "splitting" of the fractured bone (Figure 1B). Follow-up x-rays showed poor healing and non-union of the fractured bones even at 6 months after surgery. Serum calcium, alkaline phosphatase, 25-hydroxyvitamin D, and thyroid stimulating hormone were normal. Serum creatinine was elevated at 1.9 ng/ml. Bone mineral density was normal in the femur and mildly low in the lumbar spine. An attempt to do a bone biopsy was unsuccessful due of the inability of the biopsy needle to penetrate the "rock-hard" iliac crest.

The above case illustrates a potential problem in the management of patients with skeletal fragility fractures from prolonged BPs. Bone X-rays from these patients may appear normal, as shown in our patients x-ray, but these bones appear to be biomechanically compromised. Our patient had a non-traumatic fracture of the left femur which was complicated by shattering of the fractured bones during surgical repair. Paradoxically, despite the apparent bone fragility, her bones were hard and impenetrable to a needle bone biopsy suggesting the likelihood of hypermineralized bone matrix perhaps superimposed on an inactive bone turnover as a possible etiology of this complication.

## WG27

**Mathematical Model of Remodelling Cycles with Feedback Mechanism for Maintaining the Balance between Bone Resorption and Formation.** D. Putra<sup>a</sup>, R.J. Patton<sup>b</sup>, P.G. Genever<sup>c</sup>, and M.J. Fagan<sup>a</sup> <sup>a</sup> Centre for Medical Engineering and Technology, University of Hull, Hull HU6 7RX, UK. <sup>b</sup> Department of Engineering, University of Hull, Hull HU6 7RX, UK. <sup>c</sup> Department of Biology, University of York, York YO10 5YW, UK.

Since Eriksen et. al.<sup>1</sup> published reconstructed curves of the remodelling process (RP) in trabecular bone of normal human adults, similar reconstructed remodelling curves have been made available for cortical bone and for some types of pathological conditions. Some dynamic interactions between osteoblasts and osteoclasts in RP have also been reported<sup>2</sup>. In this paper we describe the development of a new mathematical model that can replicate these reconstructed remodelling curves and the observed dynamic interaction between osteoclasts and osteoblasts in RP. This will facilitate our understanding of RP and provide insights into alternative therapeutics to treat bone loss diseases. The proposed RP model is given by equations (1-3), where  $\dot{x}_i = \frac{dx_i}{dt}$ ,  $x_{oc}$  and  $x_{ob}$  are the population of the osteoclasts and osteoblasts, respectively,  $x_b$  and  $\bar{x}_b$  are the bone thickness and its reference value, respectively, while  $a, b, c, d, e, f, K_{oc}$  and  $K_{ob}$  are positive scalar parameters.  $\bar{x}_b$  is the bone thickness at the end of modelling process or the one required to withstand the mechanical loads and serves as the initial value of  $x_b$ . The term  $\bar{x}_b - x_b$  in (3) represents the feedback mechanism responsible for maintaining bone thickness at  $\bar{x}_b$  at the end of normal RP. The dynamics interaction between  $x_{oc}$  and  $x_{ob}$  given by (1-2) belongs to the Gause-type predator-prey system<sup>3</sup>. Hence, this work introduces the link between bone cell dynamics and the ecological predator-prey systems. Kuang<sup>3</sup> proved that every trajectory of the subsystem (1-2) starting at positive values of  $x_{oc}$  and  $x_{ob}$  is a periodic orbit, except its unique positive equilibrium point. Hence, the cyclic coupling between osteoclastic and osteoblastic activities is preserved. The parameter values of the model have been estimated to match the reconstructed normal trabecular bone remodelling curve<sup>1</sup> and the response of the model is shown in Figure 1. The model is also able to replicate the reconstructed remodelling cycles in hyper- and hypothyroidism, primary hyperthyroidism and in normal cortical bone by altering the model parameter values. Currently, the link between the model parameters and the biochemical processes involved in the remodelling process are being established.

Figure 1 Remodelling cycles generated by the model

## WG28

**Non Steroid Responsive Hypercalcemia associated with Sarcoidosis- A Rapid Response to Hydroxychloroquine.** Sameera Daud MD, Sirinart Sirinvaravong MD, Angelo Licata MD

**INTRODUCTION:** Hypercalcemia is common in granulomatous disorders. About 10-20% of patients with sarcoidosis are hypercalcemic. Overproduction of 1,25-dihydroxyvitamin D [1,25(OH)<sub>2</sub>D<sub>3</sub>] by activated macrophages in the granulomas plays an important pathological role in hypercalcemia. The conventional treatment is corticosteroid therapy for a variable period of time. However, in the acute situation neither corticosteroid nor bisphosphonates work quickly enough to control the problem. Hydroxychloroquine/chloroquine (4- amino quinolone derivative), however has rapid onset as our case shows. **CASE:** 61 years old Caucasian female was transferred to The Cleveland Clinic with 3 week history of dyspnea and long standing polydipsia and polyuria. There was no significant past medical history. Physical examination was benign. Initial tests revealed Corrected calcium: 12.4 (8.5-10.5mg/dL), albumin 3.3 (3.5-5.0g/dL), creatinine 2.8 (0.7-1.4 mg/dL). Further investigations showed intact PTH <4 (10-60 pg/mL), PTH-rP <0.2, 25(OH) vitamin D 13.7 (31-80 pg/mL) and 1,25(OH)<sub>2</sub>D<sub>3</sub> 72 (22-67 pg/ml). CT chest showed extensive mediastinal and hilar lymphadenopathy with calcium deposition and scattered lung nodules (calcified nodes). Mediastinoscopy and hilar lymph node biopsy was performed. The pathology report revealed non-necrotizing granulomas, suggestive of sarcoidosis. The patient received pamidronate 60 mg intravenously on admission. Four days later prednisone (40 mg) was started. After 8 days no improvement in calcium occurred. The patient started hydroxychloroquine 100 mg to 200mg/day. After 2 days of hydroxychloroquine, calcium level decreased to 10.3 mg/dL and 1,25(OH)<sub>2</sub>D<sub>3</sub> to 60 pg/ml. The patient has reported symptomatic improvement in polyuria and polydipsia. **DISCUSSION:** We present a case of steroid nonresponsive hypercalcemia in a patient with sarcoidosis, who responded to low dose of hydroxychloroquine. The mechanism of action is not clear, but one proposed mechanism is the inhibition of ornithine decarboxylase that antagonizes the action of 1,25(OH)<sub>2</sub>D<sub>3</sub> in fusion of mononuclear cells to multinucleated giant cells. This results in impairment of granuloma formation. Regardless of mechanism of action, hydroxychloroquine has been reported to decrease the 1,25(OH)<sub>2</sub>D<sub>3</sub> levels. **SUMMARY:** The rapid response of hydroxychloroquine in these patients makes this a first line consideration since it antagonizes production of activated vitamin D, the underlying cause of the problem.

## WG29

**Hypoparathyroidism and Renal Insufficiency.** G. Palmieri<sup>1,2</sup>, T. Hodgkiss<sup>4,1</sup>, H. Williams<sup>3</sup>, J. Ahmed<sup>2,2</sup>. The West Clinic<sup>1</sup>, Endocrinology, University of Tennessee<sup>2</sup>, Methodist Hospital<sup>3</sup>, Memphis, TN, USA.

The skeletal and vascular effects of renal insufficiency in longstanding, preexisting, hypoparathyroidism (HpoP) are not well known. A 36 year (y) old African-American woman with diagnoses of primary hyperparathyroidism, diabetes mellitus, arterial hypertension and dyslipidemia developed HpoP after surgical removal of a parathyroid adenoma. The serum calcium (Ca) was 7.4 mg/dl (8.6 - 10.6) (normal ranges in parentheses), phosphorus (P) 5.9 mg/dl (2.5 - 4.5), creatinine (Creat) 0.8 mg/dl (0.8 - 1.4) and the Creat clearance 122 ml/min (91 - 130). For 14y she took ergocalciferol, calcitriol and Ca for control of paresthesias and cramps without strict medical supervision. At age 50y she was admitted with lethargy. Serum Ca was 18 mg/dl, P 4.1 mg/dl and Creat 11.6 mg/dl. She received hemodialysis resulting in some improvement of renal function. At the time of discharge, off dialysis, the serum Creat was 5.3 mg/dl and Ca 9.1 mg/dl. During the next 7y the Creat clearance ranged between 20-40 ml/min. At age 57y (Feb 2008) she was asymptomatic, her weight was 119 kg, the BMI was 45 and blood pressure 141/88. Medications: diuretics, phosphate binders, oral hypoglycemic agents, ergocalciferol 50,000 U/ month, calcitriol 0.25 mcg/bid and Ca 1,000 mg/bid. Serum electrolytes were normal, glucose was 195 mg/dl (65-110), Creat 4.4 mg/dl, ionized Ca 4.6 mg/dl (4.5-5.3), P 4 mg/dl, parathyroid hormone (PTH) <2 pg/ml (10-65), bone alkaline phosphatase 14 U/l (14-42.7), 25-hydroxyvitamin D 71 ng/ml (32-100), and urine N-telopeptide (NTX) 13 nM BCE/mM Creat (26-124). These results are compatible with a rather low degree of bone turnover. There is no history of fractures and the DXA bone densitometry was normal. A computerized tomography (CT) scan of the abdomen and pelvis showed no lithiasis or nephrocalcinosis. No calcifications were observed in the arteries of the abdomen and pelvis. Standard x-rays and CT scans of both forearms and hands showed normal bones and no evidence of Ca deposits in the arteries. Based on the known cellular Ca agonist effect of PTH, (Rasmussen et al. Ionic control of metabolism. Handbook of Physiology, section 7, vol VII: 225, 1976), which affects heart cells in uremia (Bogin et al. J Clin. Invest 67: 1215, 1981), we propose that the absence of the expected skeletal and vascular abnormalities in a patient with renal insufficiency and multiple risk factors for osteoporosis and arteriosclerosis was probably due to HpoP.

## WG30

**The potential role of Fibroblast Growth Factor -23 (FGF-23) in Chronic Kidney Disease-Mineral Bone Disorder (CKD-MBD).** P. Manghat<sup>1</sup>, J. Cheung<sup>1</sup>, D. MacDonald<sup>1</sup>, D.J.A. Goldsmith<sup>2</sup>, I. Fogelman<sup>3</sup>, A.S. Weirzbicki<sup>1</sup>, G. Hampson<sup>1</sup> <sup>1</sup> Chemical Pathology, St. Thomas' Hospital, London, <sup>2</sup> Renal Unit, Guy's Hospital, London, <sup>3</sup> Nuclear Medicine, Guy's Hospital, London, UK.

CKD-MBD is a clinical syndrome that develops as a systemic disorder of mineral and bone metabolism in CKD. FGF-23 is markedly elevated in CKD, although the driving stimulus for the increase in FGF-23 remains unclear. It is postulated that FGF-23 may play a central role in the regulation of phosphate and bone metabolism in CKD. The aim of this study was to assess firstly the predictors of circulating FGF-23 in early stage and pre-dialysis CKD and secondly the relationship between FGF-23 and bone metabolism. We studied 145 ambulant patients (85 M and 60 F) (age mean [SD] 53 [14] years). Forty one patients had CKD 1,2 (eGFR >60 ml/min; mean [SD] 78 [14]), 59 patients had CKD 3 (eGFR 30-59 ml/min; mean [SD] 45 [8]) and 45 patients had CKD 4 (eGFR <30 ml/min; mean [SD] 21[4]). Bone Mineral Density (BMD) and Bone Mineral Content (BMC) were measured at the lumbar spine (LS), femoral neck (FN), forearm (FA) and total hip (TH) by DXA. Serum PTH, FGF-23, 25 (OH) vitamin D, Bone Alkaline Phosphatase (BAP), Tartrate- Resistant Acid Phosphatase (TRAP), high sensitivity CRP (hs-CRP) were determined. Calcium Phosphate Product (CPP) was derived. Univariate analyses and multiple linear regression models were used. Non-parametric data were log-transformed. In the whole population, univariate analysis showed significant relationship between FGF-23 and CPP ( $r = 0.31$ ,  $p = 0.0002$ ), hs-CRP ( $r = 0.21$ ,  $p < 0.02$ ), Serum phosphate ( $r = 0.34$ ,  $p < 0.0001$ ), fractional excretion of phosphate ( $r = 0.29$ ,  $p = 0.0005$ ), eGFR ( $r = -0.40$ ,  $p < 0.0001$ ) and haemoglobin ( $r = -0.35$ ,  $p < 0.0001$ ). There was no significant correlation between PTH and FGF-23 ( $r = 0.15$ ,  $p = 0.08$ ). Following correction for confounders in a multivariate model, age ( $p < 0.05$ ), eGFR ( $p = 0.001$ ), CPP ( $p < 0.0001$ ) and hs-CRP ( $p < 0.0001$ ) remained significant independent predictors of FGF-23 and explained 45% of the variance in the circulating levels. Patients with CKD 3 and 4 had significantly higher FGF-23 ( $p < 0.002$ ), PTH ( $p < 0.0001$ ), BAP ( $p < 0.05$ ) and TRAP ( $p < 0.005$ ) compared to CKD 1 and 2. Univariate analysis between FGF-23 and bone metabolism showed significant negative association with BMD ( $r = -0.28$ ,  $p < 0.005$ ) and BMC ( $r = -0.24$ ,  $p = 0.008$ ) of the hip. No correlation was found between FGF-23 and the bone turnover markers. Significant correlations were observed between PTH and BAP ( $r = 0.45$ ,  $p < 0.0001$ ) and TRAP ( $r = 0.37$ ,  $p < 0.0001$ ). Multivariate analysis showed that FGF-23 ( $p < 0.05$ ) and TRAP ( $p = 0.057$ ) were associated with hip BMC.

In summary, circulating FGF-23 is significantly associated with the CPP and hip BMC in patients with CKD. FGF-23 may play a role in the pathogenesis of CKD-MBD.

## WG31

**Late Presentation of Autosomal Dominant Hypophosphatemic Rickets.** Nelson B. Watts<sup>1</sup>, Erik A. Imel<sup>2</sup>, Michael J. Econs<sup>2</sup> <sup>1</sup>Bone Health and Osteoporosis Center, Cincinnati, OH, USA, <sup>2</sup>Indiana University School of Medicine, Indianapolis, IN, USA.

A 34-year-old woman, previously healthy, complains of muscle and joint pain (8 on a scale of 10) and fatigue that began about 6 months ago. She is a member of large, previously published kindred with autosomal dominant hypophosphatemic rickets (ADHR), and her sister is affected. In 1994, this patient's serum phosphate was 2.6 mg/dL with tubular maximum reabsorption of phosphate per deciliter glomerular filtrate (TmP/GFR) 2.8 mg/dL. In 2002, she participated in continued evaluation of this kindred. She had grown normally without leg deformities (height was 63.5 inches). On a questionnaire, she reported a past history of tooth abscesses, root canal and chronic bone and joint pain. At that time her serum phosphorus was normal (2.8 mg/dL), (TmP/GFR) 2.5 mg/dL, alkaline phosphatase 81 U/L, C-terminal FGF23 97 RU/mL (normal <149 RU/mL), and intact FGF23 was 51 pg/mL (normal <71 pg/mL). Mutation detection indicated an FGF23 mutation resulting in an amino acid change, R176Q. She was not on treatment for ADHR. On current exam she appeared depressed and had mild proximal muscle weakness. Laboratory results revealed serum calcium 8.8 mg/dL, parathyroid hormone 79 pg/mL, serum magnesium 1.9 mg/dL, serum phosphorus 1.3 mg/dL, TmP/GFR 0.9 mg/dL, 25-hydroxyvitamin D 23 ng/mL, 1,25-dihydroxyvitamin D 19 pg/mL. During hypophosphatemia, intact FGF23 concentration was elevated at 117 pg/mL.

Treatment was started with calcitriol, ergocalciferol and phosphorus supplements. Within a month her serum phosphorus was normal but her symptoms were worse. Doses of calcitriol and phosphorus were increased. Within three months her serum phosphorus remained normal and her symptoms had completely resolved.

This case illustrates the variable nature of ADHR, with initial features sometimes occurring in childhood or adulthood. The biochemical and clinical phenotype appear to wax and wane, and may resolve completely for years. The clinical course of presentation is likely determined by the FGF23 concentrations at that particular time. The mechanism for alteration in FGF23 concentrations is unclear. Since the FGF23 mutation induces resistance to cleavage, the likely mechanism for the observed change in levels is altered gene expression or translation. One would therefore expect that all subjects would be able to down regulate FGF23 and avoid clinical disease. Since this is clearly not the case, there may be additional factors influencing the ability to

control FGF23 concentrations in this population.

A nuclear medicine bone scan, ordered by her rheumatologist, demonstrated multiple areas of increased uptake thought to be consistent with metastatic carcinoma, which caused considerable anxiety for the patient. Without a family history of ADHR, this patient's presentation might suggest tumor induced osteomalacia; however, considering FGF23 mutations in adult patients with hypophosphatemia and renal phosphate wasting may avoid a costly search for tumors.

## WG32

**Opioid-induced Osteoporosis: Delayed Bone Healing and Compression Fractures in a Man with Chronic Narcotic Use.** Rose Christian, MD, Endocrine Unit, University of Vermont College of Medicine, Burlington, VT.

History: Orthopedic surgery requested an endocrine consultation on a 60 yo white man with non-union after vertebral fusion surgery and vertebral compression fractures of T11 and T12 detected on CT scan performed post-operatively to assess integrity of hardware. The patient complained of back pain, depressed mood, low libido, fatigue and muscle weakness that had progressed in severity for one year prior to admission. He was unemployed due to disability, and ambulatory but sedentary. He had no history of height loss, falls, fractures or kidney stones. He took morphine sulfate and oxycodone daily for back pain, but denied alcohol or tobacco use. He denied past or present use of oral, iv, inhaled or intrathecal glucocorticoids. He had no history of malnutrition, malabsorption, malignancy, HIV infection, renal, pituitary or testicular disorders. His past medical history was notable for stable coronary disease post-CABG, obesity, hypertension and depression. Laboratory (serum, fasting morning values): Total T 56 ng/mL, LH 1.0 mIU/mL, FSH <0.3 mIU/mL, prolactin 10.6 ng/mL, total 25-OH- vitamin D 12 ng/mL, calcium 9.7 mg/dL, phosphorus 3.3 mg/dL, magnesium 2.3 mg/dL, creatinine 0.9 mg/dL, cortisol 24 mcg/dL, iPTH 57 pg/mL. Discussion: Hypogonadism in men is associated with low bone density and sarcopenia and is a risk factor for both falls and fractures. Hypogonadotropic hypogonadism is a recently recognized complication of chronic opioid use in both men and women (1, 2). Low bone density was detected in 83% of methadone users (3), and fracture risk was increased in a case-control study of oral narcotic users (4). Opioid-induced hypogonadotropic hypogonadism may contribute to poor bone quality and should be suspected in opioid-dependent patients with fracture non-union or bone graft failure.

## WG33

**Calciophylaxis in a patient with hypoparathyroidism and normal kidney function.** Leonardo P. J. Oliveira MD, Sameera Daud MD, Leann Olansky MD, Angelo Licata, MD, PhD

Introduction: Calciophylaxis (CP) has been known as a medical entity related to renal replacement therapy and hypercalcemic states. Recent reports demonstrate that poor kidney function and calcium abnormalities are not a requirement. Other reported etiologies include malignancy, alcoholic disease, and warfarin therapy. We wish to report a case of a 76 year old white female with type 2 diabetes (DM), post surgical hypothyroidism, coronary artery disease (CAD), atrial fibrillation (AF) on oral anticoagulation, transferred to our institution with a 3 month history of a painful ulcerative lesion in her left lower extremity. Patient (pt) was on warfarin, calcitriol, calcium carbonate, gemfibrozil, levothyroxine and insulin. Skin biopsy revealed extensive fat necrosis and calcium deposits in subcutaneous vessels compatible with CP. Laboratory tests revealed corrected calcium of 8.35 mg/dL (8.5-10.), phosphate 3.9 mg/dL (2.5-4.5), PTH 5 mg/dL (10-60), creatinine 1.1 mg/dL (0.7-1.4), PTH-rp < 0.2, 25(OH) vitamin D 57.3 pg/mL (31-80) and 1,25(OH)2D3 18 pg/mL (22-67), complement levels and rheumatologic workup was normal but homocysteine 22 umol/L (3.4-12.9), CRP 10.4 mg/dL (0 - 2), uric acid 11 mg/dL (2 - 7.0) and factor VIII assay 223% (49 - 134%) were elevated while Protein C was 66% (76-147%) although the patient was on coumadin. A CT of the abdomen revealed non-obstructing renal calculi and a CT of the brain demonstrated a small left parietal cortical infarct in addition to multiple paraneural calcifications. The pt was started on phosphate binders to reduce phosphate levels, Vit B and folic acid supplements to lower homocysteine and allopurinol for the elevated uric acid. Discussion: We present a case of rare disease in a unique context. This is the first case report of a patient with hypoparathyroidism and CP. Hypocalcemia, low calcium X phosphorus product, absence of rheumatological disease and malignancy, raises the question of the etiology of CP. Warfarin use could be a potential etiology however the prolonged use makes coumadin-induced skin necrosis unlikely. Despite a normal kidney function, elevated homocysteine and uric acid levels have been linked to arterial calcifications.

In summary: Calciophylaxis is an aggressive necrotic ulceration which may be related to novel factors such as hyperuricemia and homocysteinemia. Further studies are required to evaluate if therapy against directed against these metabolites will be beneficial.

**Multiple WNT Signaling Antagonists Are Differentially Expressed Over Time In Inflammatory Arthritis.** N.C. Walsh, C.A. Manning, S. Reinwald<sup>\*</sup>, K.W. Condon<sup>\*</sup>, S. Karmakar, D.B. Burr<sup>\*</sup>, E.M. Gravalles. Department of Medicine, University of Massachusetts Medical School, Worcester, MA 01605; <sup>\*</sup>Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN 46202

Rheumatoid Arthritis (RA) is characterized by inflammation of the joint lining (synovium) resulting in destruction of bone. Despite treatment, most RA patients do not repair erosive lesions. We have used the K/BxN serum transfer arthritis (STA) model to investigate the hypothesis: cells present within arthritic soft tissues produce factors that impact osteoblast differentiation and/or function, contributing to net bone loss. We have shown that formation of mineralized bone is reduced at bone surfaces adjacent to inflammation compared to bone surfaces adjacent to normal bone marrow, indicating that inflammation affects osteoblast capacity to form mineralized bone. Active WNT signaling is requisite for osteoblast differentiation and function. Recently, blockade of the WNT signaling antagonist DKK1 in mouse models of inflammatory arthritis resulted in protection from erosion<sup>1</sup>. We have previously shown that the WNT signaling antagonist sFRP1 is upregulated in arthritic soft tissues. We now demonstrate that additional WNT signaling antagonists are differentially expressed over time within arthritic soft tissues in STA. Expression of mRNAs for WNT signaling antagonists (assessed by quantitative RT-PCR) in arthritic soft tissues was compared to expression in tissues isolated from the same sites in non-arthritic mice. DKK1, DKK3, sFRP1, and sFRP2 mRNA expression was elevated in arthritic tissues. sFRP1 and sFRP2 mRNA expression was highest (20 fold, sFRP1; 35 fold, sFRP2) at days 7 and 8 post initial serum injection, corresponding to increasing inflammation and the onset of focal bone erosion within nearby bones. DKK1 mRNA expression peaked later in the time course of arthritis, with highest expression occurring around day 12 when inflammation and focal bone erosion is typically at its peak. DKK3 mRNA expression was elevated throughout the time course of arthritis. Interestingly, expression of mRNA for sFRP4, a WNT signaling antagonist that has been implicated in the inhibition of mineralization, was dramatically upregulated late in the time course of arthritis in tissues isolated from focal bone erosion sites. These studies demonstrate the expression of multiple WNT signaling antagonists within arthritic tissues over the course of STA. Thus inhibitors of the WNT signaling pathway are candidate factors for modulating osteoblast capacity to form mineralized bone, potentially limiting repair of focal bone erosions in RA.

- Deficiency of the nucleocytoplasmic shuttling protein CIZ suppresses K/BxN serum-induced model of RA, M446
- Determinants of low BMD in HIV infected postmenopausal women, SU455
- Different influence of the clinical condition, degree of cholestasis, alcohol abuse and serum Ca on the musculoskeletal system in chronic cirrhotics, M411
- Diffuse sclerosing osteomyelitis of the mandible, WG25, M452
- Discordance in femoral neck bone density in subjects with OA, M453
- Does dietary P influence FGF-23 concentrations in FD patients?, M426
- Effect of aquatic exercise and education on improving indices of fall risk in older adults with hip OA, M441
- Effect of exercise on geometric bone structure and bone strength in postmenopausal women, M484
- Effects of 50,000 IU of Vitamin D $_2$  twice per month on circulating 25(OH)D and Ca levels, SU426

## Key Word Index

## ASBMR 30th Annual Meeting

- Effects of ADT on bone health in prostate cancer, SA280
- Effects of aromatase inhibitor therapy on BMD in hypogonadal elderly men, 1135
- Efficacy and safety of intravenous ZOL in the treatment of patients with resistant PDB, SA479
- Elevated SIF levels in post-menopausal women is due to the enhanced release of fluoride from bone, SA490
- Endogenous GC are critical for the development of skeletal fragility with aging in mice, 1250
- Evaluation of clinical utility of venous sampling for FGF-23 in identifying and confirming responsible tumors for TIO, F163
- Evidence of increase in vertebral body dimensions in postmenopausal women with osteoporosis, M313
- Femoral strength, bone density, and aging in women and men, 1165
- Fracture risk in primary biliary cirrhosis: role of osteopenia and severity of cholestasis, M442
- Glomerular filtration rate and physical function in community-dwelling Japanese frail elders, SA332
- Hemodialysis patients rapidly lose their bone minerals after 60 years of age, SU438
- Histomorphometric evaluation in an experimental model of hepatic osteodystrophy, M480
- Hormonal influences on volumetric bone density and geometric properties in obesity, SU367
- Improved forearm BMD after treatment with Vitamin D<sub>3</sub> in a patient 30 years after bariatric surgery, SA492
- Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184
- Increased proinflammatory cytokines TNF $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491
- Increased risk of morphometric vertebral fracture in postmenopausal women with PHPT, M438
- Influence of hip flexor or knee extensor muscle strength on spinal sagittal alignment or falls, SU454
- Interactions between obesity, CVD and bone formation, M451
- Interventions to prevent falls in the community-dwelling elderly, SU313
- Jumping mechanography safely evaluates muscle performance in older adults, SA535
- Kidney disease is associated with abnormal cortical geometry independent of age and gender, SU441
- Kidney dysfunction disturbs collagen maturation in ABD as assessed by confocal laser Raman spectroscopy, SU439
- Late presentation of ADHR, WG31
- Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, 1247
- MACD index is a strong predictor of cardiovascular death and include the predictive power of BMD, SU463
- Marked Vitamin D deficiency in recent heart and liver transplant recipients, SA501
- Mechanism of action of the anti-aging agent resveratrol on bone, 1136
- Muscle power and tibial bone strength in older women, SU362
- New data on the impact of renal function on the relationship between 25(OH)D and PTH, 1031
- Novel hypothesis explains the syndrome of chronic musculoskeletal pain and comorbid painful healed fracture sites in Vitamin D deficiency, SA474
- Osteopenia by high alcohol consumption in the absence of ALDH2 attribute to the disturbance of the differentiation in osteoblasts, M326
- Osteopenia in CKD: effects of Ca overload, SU449
- Osteoporosis in the aging males after hip fracture, SU436
- Osteoporosis in the old old: review of the evidence, SA437
- Overexpression of GSR in osteoblasts decreases bone formation and partially prevents OVX-induced bone loss, F024
- Patients with CKD and low 1/3 radius and femoral neck BMD have markedly abnormal cortical and trabecular microstructure by HR-pQCT, 1033
- PDB: a histologic and histomorphometric analysis of bone biopsies from 754 patients, 1133
- Plasma osteocalcin is inversely related to fat mass and plasma glucose in elderly Swedish men, SU459
- Possible role for the T<sub>H</sub>17 system in a mouse model of AS, SU460
- Postprandial hyperphosphatemia is a novel risk factor for CVD by involving endothelial dysfunction, SU443
- Premature aging-like phenotypes in Mta1 null mice, F494
- Pretransplant parathyroid function predicts laboratory and BMD changes after kidney and kidney/pancreas transplantation, 1032
- Prevalence and demographics of asymptomatic NPHPT in the United States, M431
- Prevalence and factors associated to the presence of vertebral fractures in patients with type 2 diabetes mellitus, M447
- Prevalence of Vitamin D deficiency among surgical orthopedic patients, SU205
- PTH increases bone turnover in HPT, F485
- PTH reverses abnormal bone remodeling and structure in HPT, 1036
- Randomized dose comparison of pamidronate in children with types III and IV OI, SU496
- Rare cases of XLH rickets/osteomalacia mimicking ARHR/osteomalacia, F469
- Recovery from HCAO following anti-viral treatment, F488
- Reduced serum osteocalcin and sex hormone binding globulin in men with type II diabetes, SU461
- Regional thinning of the femoral neck cortex with advancing age predisposes to hip fracture, SU275
- Rehabilitation after clinically-diagnosed osteoporotic vertebral fracture, SU411
- Relationship among nutritional status, oxidative stress and bone density in institutionalized elderly, SU310
- Relationship between low bone mass and aortic valve sclerosis in Korean men and women, SU452
- Renal leak hypercalciuria: a potential cause of tertiary hyperparathyroidism, M430
- rhBMP-2 accelerates segmental defect healing in diabetic rats, M445
- Risk factors for bone loss in the hip in 70-year-old women, SA374
- Scl-Ab increases bone mass by stimulating bone formation and inhibiting bone resorption in a hindlimb-immobilization rat model, 1138
- Serum 25(OH)D measurement and histomorphometric analysis of iliac crest biopsies from 1180 patients reveals a high prevalence of Vitamin D-dependent osteomalacia, 1134
- Serum Cathepsin K levels in AS, M439
- Serum uOC concentration are related to renal function in type 2 diabetes patients, M443
- Short-term deleterious skeletal response to hindlimb suspension involves multifaceted compromises in cells of the osteogenic lineage, F523
- SIF levels among hemodialysis patients are positively associated with levels of serum phosphate and intact PTH, SU440
- Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, 1137
- Stress fracture and vertebral osteosclerosis related to fluorosis induced by excessive gingival topical fluoride application, M444
- Therapy with ALF leads to a significant increase in muscle power and balance, SU444
- TPTD treatment in a young man with IJO diagnosis, SU499
- Vitamin D deficiency is associated with diminished quality of life based on Qualeffo-41 questionnaire analysis, SU424
- Vitamin D deficiency, osteomalacia and high bone turnover in patients with NF-1, F465
- Vitamin D insufficiency is common in racially diverse postmenopausal women with HIV, M448
- Vitamin D status and bone remodeling marker CTx-I in patients with early RA: association with disease activity and joint damage, SA496
- Vitamin D status in severely obese individuals can be predicted by demographic and lifestyle factors, SU201
- Vitamin D toxicity due to a commonly available remedy from the Dominican Republic, SU195
- Ahnak**  
Ahnak regulates Ca signaling and ATP release in osteoblasts in response to mechanical stimulation, SA027
- Akp2-/-**  
Enzyme replacement therapy prevents dental defects in the Akp2-/- mouse model of infantile HPP, F107  
Relative efficacy of "treating" versus "preventing" infantile HPP in Akp2-/- mice by enzyme replacement therapy, 1054
- AKT**  
Adiponectin inhibits osteoclast formation via AKT signaling pathway, SU110
- Akt**  
AG490, a Jak2 specific inhibitor, induces osteoclast survival by activating Akt and ERK signaling pathway, SU108  
Akt regulates skeletal development through GSK3, mTOR, and FoxOs, 1151  
BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/ Akt regulates NFATc1 expression and its nuclear translocation, 1081
- (Ala-Gly)n**  
(Ala-Gly)<sub>n</sub> sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167
- Ala459Pro**  
Functional polymorphism in COL1A2 (Ala459Pro) that is associated with intracranial aneurysms, shows heterozygous disadvantage concerning BMD and stroke in elderly men, SU219
- Albright's hereditary osteodystrophy**  
Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and GNAS imprinting changes, SA259
- Albuminuria**  
Albuminuria, 25(OH)D, 1,25(OH)<sub>2</sub>D, and intact PTH in older adults, SU442
- Alcohol**  
Bone metabolism, microarchitecture and densitometric measurement in rat femur after chronic alcohol consumption, M239  
Different influence of the clinical condition, degree of cholestasis, alcohol abuse and serum Ca on the musculoskeletal system in chronic cirrhotics, M411  
Osteopenia by high alcohol consumption in the absence of ALDH2 attribute to the disturbance of the differentiation in osteoblasts, M326
- ALDH2**

Osteopenia by high alcohol consumption in the absence of ALDH2 attribute to the disturbance of the differentiation in osteoblasts, M326

#### **Alendronate (ALN)**

Active controlled, non-inferiority study to compare the effect of ZT-031 with ALN on the incidence of new vertebral fractures, M347

ALN affects cross-talk of osteoclasts and osteoblasts in vivo, SU392

ALN transiently impairs removal of alveolar bone and healing of the root socket after tooth extraction in rats, 1275

ALN treatment for juvenile osteoporosis, M366

ALN treatment in postmenopausal Romanian women followed by BMD-digital x-ray radiogrammetry, M357

Assessment of serum Ca and bone resorption markers in patients transitioned from ALN to DMAB, M394

Atypical osteoclast phenotype after long-term ALN therapy for osteoporosis, SU399

BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

Changes in serum PINP in orchidectomized osteopenic rats treated with PTH and ALN, M295

Continuous local infusion of ALN prevents osteopenia of the lengthened segment during distraction osteogenesis, SU001

Cost-effectiveness of RIS vs. generic ALN, SA423

Does ALN use prevent kyphosis progression in older women?, SA410

Effect of DMAB vs ALN on bone turnover markers and BMD changes at 12 months based on baseline bone turnover level, 1285

Effects of ALN and RLX on the RANKL/OPG system in primary cultures of human osteoblasts, M101

Effects of ALN or DMAB on cortical and trabecular bone mass, bone strength, and bone mass-strength relationships in mice, 1139

Effects of co-treatment with an Scl-Ab and ALN in OVX rats, 1213

Effects of DMAB vs ALN on BMD, bone turnover markers, and safety in women previously treated with ALN, M395

Fracture reduction during two years of treatment with RIS or ALN, SA404

Hip structural analysis and volumetric QCT in postmenopausal women from the PaTH Study: mono- or combination therapy with ALN and PTH, M306

Histomorphometric changes by TPTD in ALN pre-treated women with osteoporosis, 1019

Increased non-enzymatic glycation of cancellous bone due to decrease in remodeling during ALN therapy of osteoporotic women, 1071

Monthly intravenous ZOL suppresses tissue-level remodeling significantly more than daily oral ALN in the mandible and rib of skeletally mature female dogs, SU388

Prevention of GC-induced osteoporosis with ALN or ALF in patients with ophthalmologic diseases, SA450

Reduced osteoclastogenesis and RANKL expression in marrow from women taking ALN, SU400

RIS has a more rapid onset of remodeling suppression than ALN in rabbit vertebral trabecular bone, SU387

sGGT is one of the factors that determines the response to ALN treatment in osteoporotic women, M421

Sites of femoral fractures in the Fracture Intervention Trial (FIT) of ALN and its Long-term Extension (FLEX), SU389

Subtrochanteric and diaphyseal femur fractures in patients treated with ALN, 1026

Therapeutic effects of one-year ALN treatment in three cases of osteoporosis with parietal thinning, M410

Towards an understanding of the mechanism of femur strength improvement by ALN in postmenopausal women, F323

TPTD versus ALN for treatment of GIO, 1171

Transition from ALN to DMAB in OVX cynomolgus monkeys maintained or improved cortical and trabecular bone mass, without altering the linear relationship between bone mass and bone strength, 1072

Transition from ALN to DMAB resulted in further reductions in local and systemic bone turnover parameters and reduced cortical porosity in OVX cynomolgus monkeys, 1216

Treatment discontinuation due to gastrointestinal adverse events and decreased BMD in patients switched from branded ALN to generic ALN, SA414

Use of bone biomarkers as an endpoint in a pediatric study of ALN, SU488

#### **ALERT System**

Electronic medical record based "ALERT System" improved diagnosis and treatment of osteoporosis in orthopaedic out-patient clinic, SU416

#### **Alfacalcidol (ALF)**

ALF ameliorates bone dynamics in senescence-accelerated SAMP6 mice and in fracture repair rat model, SU394

ALF prevents aromatase inhibitor (letrozole)-induced bone mineral loss in young growing female rats, SA570

Assessment of adherence to treatment of osteoporosis with RLX and/or ALF in postmenopausal Japanese women, M387

Effect of RLX and ALF on bone and joint pain assessed by fall of skin impedance (electroalgotometry), SA384

Effects of ALF on bone and skeletal muscle in GC-treated rats, M219

Prevention of GC-induced osteoporosis with ALN or ALF in patients with ophthalmologic diseases, SA450

Superiority of ALF over plain Vitamin D in men with osteoporosis, SU421

Therapy with ALF leads to a significant increase in muscle power and balance, SU444

#### **Alkaline phosphatase (ALP)**

C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292

Development of a bone specific ALP assay on the IDS Automated Analyser 3x3™, SA302

Li affects matrix mineralization by decreasing tissue non-specific ALP levels in osteoblasts, SA071

Prostaglandins enhance extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity in osteoblast-like cells, SU031

Proteoliposomes carrying ALP and NPP1 as matrix vesicle mimetics, SA061

SOST blocks GSK3-beta inhibitor-induced ALP activity, SU036

Stable expression of constitutively active Ga12 in osteoblastic cells promotes matrix protein expression and ALP activity, M068

TNF $\alpha$  and IL-1 $\beta$  stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

#### **Alkaline phosphatase, tissue-nonspecific (TNSALP)**

Altered TNSALP expression and phosphate regulation contribute to reduced mineralization in mice lacking androgen receptor, SU181

c.1250A>G, p.N417S is a common American TNSALP mutation involved in all clinical forms of HPP, including pseudo-HPP, SA566

Ca intake and serum bone formation markers are associated with the functional single nucleotide polymorphism in the TNSALP gene, SU308

Specific inhibitors of TNSAP's pyrophosphatase activity suppress medial arterial calcification, M142

#### **Alkalosis**

Metabolic alkalosis transition in renal proximal tubule cells facilitates an increase in CYP27B1, while blunting responsiveness to PTH, M196

#### **Alkaptonuria (AKU)**

Studies on the deposition of ochronotic pigment in AKU reveal tyrosine metabolism in human chondrocytes, M166

#### **All-trans-retinoic acid. See also Vitamin A**

All-trans-retinoic acid (Vitamin A) increases expression of MafB and inhibits osteoclast formation by interfering with differentiation of osteoclast progenitor cells, M117

#### **Allergies, nutritional**

Bone health impairment in children with chronic Ca and Vitamin D deficiency due to nutritional allergies, SU503

#### **ALOX12**

Polymorphisms of the ALOX12 gene are associated with increased risk of osteoporotic fracture, SU220

#### **Alternative medicine**

Use of alternative medicine for treating osteoporosis in Korea, SA390

#### **Alveolar bone**

ALN transiently impairs removal of alveolar bone and healing of the root socket after tooth extraction in rats, 1275

Enhanced osteogenic potential of alveolar vs. long bone derived BMSC, M095

Improvement of alveolar bone quality by local bFGF injection—histological and cellular biological analysis in a rabbit model, SA162

Isolation and characterization of osteoblasts from alveolar bones of aged donors, SU049

#### **Amenorrhea, hypothalamic**

Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184

#### **Amino acids**

Screening the PHEX gene in a large cohort of hypophosphatemic rickets allowed the description of a missense mutation not responsible for the disease on a highly conserve amino acid residue, M246

Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036

#### **AMP-activated protein kinase (AMPK)**

Neuroendocrine activation of AMPK in osteoblasts, SU037

Regulation of autophagy in the epiphyseal growth plate by AMPK and mTOR requires HIF-1, SU134

#### **Androgen deprivation therapy (ADT)**

C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292

Effects of ADT on bone health in prostate cancer, SA280

#### **Androgen receptor**

Altered TNSALP expression and phosphate regulation contribute to reduced mineralization in mice lacking androgen receptor, SU181

Androgen receptor disruption increases the osteogenic response to mechanical loading in male mice, 1140

Crosstalk between androgen receptor and Wnt signaling mediates sexual dimorphism during bone mass accrual, 1121

Osteoblastic androgen receptor regulates cortical BMD, 1122

## Key Word Index

## ASBMR 30th Annual Meeting

Overexpression of androgen receptor in mature osteoblasts and osteocytes inhibits osteoblast differentiation, SU192

**Androgens**

Elevated androgens are associated with increased bone formation in premenopausal exercising oligomenorrheic women, SU191  
PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299  
Treatment threshold in men on androgen deprivation therapy: T-score vs. FRAX, F308

**Angiogenesis**

Angiogenic potential of osteoclasts, SU075  
Identification and characterization of angiogenesis-inducing secretory molecules from osteogenically differentiated MSC, M163  
Impaired angiogenesis and compromised fluid volume accompanies increased osteoblast and osteocyte apoptosis with GC excess, SA453  
Inhibition of MM growth and preservation of bone with combined radiotherapy and anti-angiogenic agent, SA285  
Osteogenic cell lineages show differential responsiveness to angiogenic signals, SU061  
Overexpression of the transcriptional cofactor Lbh impairs angiogenesis and endochondral bone formation during fetal bone development in chickens, SU004  
Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, I082

**Angiopoietin-1 (Ang-1)**

Ang-1 enhanced BMP-2 induced osteoblast differentiation, SU035

**Angiotensin II**

Angiotensin II type 2 receptor blockade increases bone mass, SU007

**ANKH**

ANKH mutation causing CMD inhibits osteoclast differentiation, SU214

**Ankylosing spondylitis (AS)**

Possible role for the T<sub>H</sub>17 system in a mouse model of AS, SU460  
Serum Cathepsin K levels in AS, M439

**Annexin II (AXII)**

Role of AXII and AXIIR in homing MM cells in the bone marrow, SA287

**Annexin II receptor (AXIIR)**

Role of AXII and AXIIR in homing MM cells in the bone marrow, SA287

**Anorexia nervosa**

BMD changes over time associated with illness and recovery in young women with anorexia nervosa, SA558  
Bone mass recovers in young women with anorexia nervosa who are both weight and menstrual recovered, F339  
Effect of bed rest on bone turnover in adolescents hospitalized for anorexia nervosa, SA559  
High impact exercise may have a protective effect on BMD but moderate impact exercise may have negative effect in young women with anorexia nervosa, M324

**Anterior cruciate ligament (ACL). See Ligament****Anti-resorptive treatment**

One year of TPTD treatment increases hip strength in subjects with recent history of anti-resorptive treatment, F396

**Anti-sclerostin monoclonal antibody (Scl-Ab)**

Effects of co-treatment with an Scl-Ab and ALN in OVX rats, I213  
Increases in BMD observed with Scl-Ab treatment are reversible, I211  
Scl-Ab increases bone formation and decreases bone resorption in distal tibial metaphyseal trabecular bone in OVX rats, F394  
Short treatment with Scl-ab can inhibit bone loss in an ongoing model of colitis, I212

**Antiaromatase therapy**

BMD and vertebral fracture in women with breast cancer and antiaromatase therapy, SA400

**Antioxidants**

Antioxidants (phytoestrogens and quercetin) are potentials agents against RA, SA487

**Antiresorptive agents**

Association between BMD change, use of antiresorptive agents and fragility fracture in women and men, SA364  
Previous antiresorptive agents use did not hinder the increase of bone turnover marker in TPTD use, M351

**Antiresorptive treatment**

Biomechanical and geometrical property changes in rat tibias with tumor-induced osteolysis after anti-resorptive or anti-cancer treatments, SU236

**AOD9604**

Anabolic skeletal effects of a GH-derived peptide (AOD9604) in the OVX rat model of osteoporosis, SU373

**Aortic calcification**

Association between several factors affecting aortic calcification and BMD in postmenopausal women, SA489

**AP-1**

AP-1 and Mitf interact with NFATc1 to stimulate Cat K promoter activity in osteoclast precursors, SA076

**aP2**

Tracking adipose differentiation in vitro with aP2-GFP reporters and flow cytometry: lipid staining and macrophage mimicry, SU057

**Apert Syndrome**

Dynamic morphological changes in the skulls of mice mimicking human Apert Syndrome resulting from gain-of-function mutation of FGFR2 (P253R), SA248

**Apheresis**

Frequent apheresis for platelet and plasma donations constitutes an independent risk factor for decreased BMD, F327

**Apoptosis**

bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043  
Bisphosphonate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428  
Conditional knockout of the CaSR in osteoblasts alters regulators of Wnt signaling, delays cell differentiation, and promotes apoptosis in bone, I156  
Fat suppresses osteoblast differentiation by soluble factors that induce apoptosis, M003  
GIP inhibits glucose-induced apoptosis of bone cells, M011  
Impaired angiogenesis and compromised fluid volume accompanies increased osteoblast and osteocyte apoptosis with GC excess, SA453  
Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009  
Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, I247  
LPA enhances the viability of rat growth plate chondrocytes through the inhibition apoptosis and the promotion of cellular maturation, SU156  
Molecular mechanisms involved in PTH-induced apoptosis in Caco-2 intestinal cells, M189  
Osteoblasts apoptosis is mediated through GSK3 $\beta$ , M005  
Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

Phosphate induced apoptosis in growth plate chondrocytes via a NO and JNK-dependent pat, SA113

Phosphate regulates chondrocyte differentiation, proliferation and apoptosis in a model of embryonic endochondral bone formation, SU124

Regulation of hypertrophic chondrocyte apoptosis, M158

Sr ranelate protects osteoblasts from apoptosis independently of the CaSR, M007

TGF $\beta$ 1 induces human osteoclast apoptosis, SU078

**Aromatase inhibitors**

A allele at Valine80 of the CYP19 gene is a risk factor for aromatase inhibitors associated bone loss, I021  
Effect of tamoxifen and aromatase inhibitors on the risk of fractures in women with breast cancer, SU227  
Effects of aromatase inhibitor therapy on BMD in hypogonadal elderly men, I135  
Prevention of aromatase inhibitor-associated bone loss in women with breast cancer, M283

 **$\beta$ -arrestin**

Association between Cx43 and  $\beta$ -arrestin is required for cAMP-dependent osteoblast survival induced by PTH, I227  
PTHr1 stimulates bone formation through a distinct  $\beta$ -arrestin dependent pathway independent of G protein activation, I226

**Arthritis**

In the absence of NF- $\kappa$ B, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, I009  
Subcutaneous administration of salmon calcitonin: bone protective effect in adjuvant arthritis prevention model in rats, SA193

**Arthritis, adjuvant**

Bisphosphonate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428

**Arthritis, collagen-induced (CIA)**

Grape seed extract suppresses IL-23/Th17 inflammatory pathways and bone destruction in CIA, SU093

**Arthritis, inflammatory**

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

Multiple WNT signaling antagonists are differentially expressed over time in inflammatory arthritis, WG41

**Arthritis, psoriatic**

BMD and body composition in postmenopausal women with psoriasis and psoriatic arthritis, SU337

**Arthritis, rheumatoid (RA)**

Antioxidants (phytoestrogens and quercetin) are potentials agents against RA, SA487  
Deficiency of the nucleocytoplasmic shuttling protein CIZ suppresses K/BxN serum-induced model of RA, M446  
H4R is expressed by both OA and RA human tissues, SU159  
PLC $\gamma$ 2 as a promising therapeutic target in RA, F176  
Reduction of BMD in the patients with RA is more remarkable at proximal femur than at lumbar spine, SU451  
Relationship between focal erosions and generalized osteoporosis in postmenopausal women with RA, SA370  
Vitamin D status and bone remodeling marker CTx-I in patients with early RA: association with disease activity and joint damage, SA496

**Arthroplasty, total hip**

Bone density changes at the non-operated hip following total hip arthroplasty, M408

**Arthroplasty, total knee (TKA)**

Evaluation of tibial bone density surrounding Ta tibial implants in TKA, SU266

#### Arzoxifene (ARZ)

ARZ in postmenopausal women with normal or low bone mass, SA421

Effects of ARZ on bone turnover and safety in postmenopausal women with low bone mass, M386

#### Ascorbic acid

Osteoblast differentiation induced by Shh-expressing prostate cancer cells is enhanced by ascorbic acid, SA284

#### ASK-1

Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185

#### ATDC5

bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043

TGF $\beta$  and Smad3-dependent repression of Runx2 function in ATDC5 chondrocytes, SU122

Vinculin is involved in hypertrophic differentiation through Raf/MEK/ERK pathway in chondrocytic ATDC5 cells, SA119

#### ATF2

BMP-2 inactivates TAK1-ATF2 signaling pathway in chondrocytes, F186

#### Atherosclerosis, carotid

Higher BMD is associated with increased odds of carotid atherosclerosis in postmenopausal women not currently using estrogen therapy, 1206

#### ATP

Ahnak regulates Ca signaling and ATP release in osteoblasts in response to mechanical stimulation, SA027

Role of cell surface ATP synthase in fluid shear stress induced ATP release in osteoblasts, SU039

#### Atresia, biliary

Circulating OPG and its ligand in post operative biliary atresia: relationship with metabolic bone disease, M406

#### Atypical parathyroid adenoma. See Adenoma

#### Autism

Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259

#### Autophagy

Normal human osteoblasts internalize MSUM by phagocytosis and autophagy, M057

Regulation of autophagy in the epiphyseal growth plate by AMPK and mTOR requires HIF-1, SU134

#### Autosomal recessive hypophosphatemic rickets. See Rickets

## B

#### B cells

In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154

#### B.H-6

Recombinant congenic strain (B.H-6) establishes that trabecular bone mass and bone marrow adiposity are distinct and heritable phenotypes, F265

#### b2

Aging dependent and independent effects of b2 adrenergic receptor signaling on bone formation induced by intermittent PTH treatment in female mice, SA378

#### BAC

Engineering mice with multiple BAC fluorescent protein reporter gene elements, SU028

#### BALB/c

Aged and young adult BALB/c male mice respond similarly to in vivo tibial compression, M475

#### bALP

Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287

#### Baltimore Hip Studies

Serum Vitamin D levels do not modify the response to an exercise program following hip fracture, SA346

#### Bax

DEX triggers mitochondrial apoptosis through Bax in proliferative growth plate chondrocytes causing growth retardation, 1188

#### Bazedoxifene (BZA)

BZA in combination with conjugated estrogens improves bone mass and strength in the OVX rat, SA385

Double-blind, placebo-controlled, dose-response study of BZA in Japanese postmenopausal women with osteoporosis, M391

Efficacy of BZA in reducing the incidence of nonvertebral fractures in postmenopausal osteoporotic women at higher fracture risk, M390

Safety profile of BZA in Japanese postmenopausal women with osteoporosis, M389

#### BBB Study

TPTD in bisphosphonate-resistant osteoporosis—clinical and  $\mu$ CT data, 1172

#### Bcl-2

bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043

#### bcl-2-/-

Loss of a single bim allele recovers the defective osteoclast function in bcl-2-/- mice but does not restore the anabolic action of PTH, 1217

#### Beam theory, unsymmetrical

Unsymmetrical beam theory and finite element method: analysis of murine cortical bone based on  $\mu$ CT imaging, M454

#### Beauvericin

Fungal secondary metabolites beauvericin and enniatin inhibit osteoclast differentiation and bone resorption, M130

#### Beta-adrenergic receptor

Beta-adrenergic receptor agonist administration during hindlimb unloading effectively mitigates reductions in cancellous bone formation, SA514

Low bone mass and decreased biomechanical response in beta 1 adrenergic receptor KO but not in beta 2 adrenergic receptor KO mice, 1141

Role of OPN in beta-adrenergic signaling induced bone loss in vivo, M174

#### Beta-aspartyl peptides

Activation of the CaSR by beta-aspartyl and gamma-glutamyl peptides, M202

#### beta-D-glucopyranoside

Effects of beta-D-glucopyranoside from *Phellodendron Amurense* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117

#### Beta-tricalcium phosphate (b-TCP)

Microporosity in b-TCP ceramics may be detrimental to MSC survival and osteoblastic differentiation, SA015

#### Betulin

Betulin down regulates IL-1 $\alpha$ -stimulated aggrecanases and MMP gene expression in human chondrocytes, M147

#### bFGF. See Fibroblast growth factor

#### bim

Loss of a single bim allele recovers the defective osteoclast function in bcl-2-/- mice but does not restore the anabolic action of PTH, 1217

#### Biomechanics

Alteration of trabecular bone architecture following sciatic denervation and subsequent reinnervation in rat proximal tibiae, SA513

Anabolic response to skeletal loading in mice with targeted disruption of PTN gene, 1142

Androgen receptor disruption increases the osteogenic response to mechanical loading in male mice, 1140

Association between femoral neck BMD and the factor-of-risk for hip fracture derived from direct measurements of strength in human cadaveric femora, 1070

Bone density comparisons in young male rock climbers, weight lifters and sedentary controls, SA534

Bone geometry and bone strength are compromised in patients with ACL reconstruction, M487

Bone geometry, strength, and muscle mass in female distance runners with a history of stress fracture, SA540

Bone length was differentially promoted in the left/right hindlimbs with knee loading and administration of IGF-2, M476

Bone strength in overweight children is adapted to mechanical loads from walking, but is low for higher loading activities, M482

Bone strength measurement: new approach, SU249

Bone tissue quality is differently altered by PTH, bisphosphonates and SERMs, SA510

Bone volumetric density, geometry and strength in male and female collegiate runners, SA539

Can impact exercise mitigate the adverse effects of oral contraceptives on bone?, M488

Cartilage engineered with a calcified zone enhances interfacial shear strength to the underlying substrate, M176

Changes in bone matrix material properties due to OPN deficiency, F149

Combined effects of irradiation and unloading on murine bone, 1295

Comparison of HR-pQCT to DXA and QUS for the assessment of ex-vivo bone strength, M466

Comparison of voxel-based and smooth FEA to predict damage accumulation in vertebral bodies, SU474

Concentration of IGF-I in human cortex bone is highly correlated with fracture toughness of the bone, 1069

Contribution of local buckling to femoral neck failure in stance and fall mode simulations: an advanced FEA analysis of elderly cadaver femur data, M489

Contributions of trabecular and cortical components to biomechanical properties of human vertebrae, M455

Cost-effective rack and pinion system for torsion testing of rodent bones, M465

Degradation of allograft bone quality by gamma irradiation is not explained by altered enzymatic or non-enzymatic cross-links, M460

Dependence of endosseous implant anchorage on mechanostuctural determinants of peri-implant bone trabeculae, 1298

Development of empirical model using  $^{45}\text{Ca}$  for the study of bone remodeling in human, SA454

Disuse with a rapid bone loss affects the expression profile of osteoblastic and resorption genes, F516

Does adiposity affect bone strength indices in young adult black females?, SU318

Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503

Effect of collagen degradation on the fatigue behaviour of emu bone, M461

Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505

Effects of a high g environment on BMD in UK fast-jet trainee pilots, SU473

Effects of ALN or DMAb on cortical and trabecular bone mass, bone strength, and bone mass-strength relationships in mice, 1139

Effects of obesity on cortical bone, SA342

## Key Word Index

## ASBMR 30th Annual Meeting

- Effects of resorption cavities on strength of trabecular bone, SA512
- Effects of running exercise on bone quality after immobilization, SA518
- Effects of simulated resistive exercise on cortical bone in the tibia mid-diaphysis of hindlimb unloaded rats, SA521
- Efficacy of single-level instrumented posterolateral (intertransverse) lumbar spinal fusion in baboons with BMP-7 putty, SU146
- Environmental perturbations during puberty and bone strength, M501
- Estimation of relative stiffness contributions of cortical and trabecular compartments by MRI-based FEA, SU481
- Excessive erythropoiesis affects bone architecture, 1294
- FEA performed on radius and tibia HR-pQCT images provides new insights for fracture status assessment, 1067
- Feasibility and reproducibility of in-vivo assessment of trabecular bone architecture using  $\mu$ MRI-based method at multiple study centers, SA314
- Femoral BMD and femoral structure, assessed by DXA-based hip structural analysis, contribute independently to femoral strength, M304
- Femur from C57BL/6 and DBA/2 inbred mice display a strain dependent response to treadmill running and tower climbing exercise in cortical and trabecular bone architecture, M485
- First clinical application of electric stimulation on human distracted bone, SA568
- Flexible tibia model predicts bone strains during walking, M479
- Formation of new trabeculae in a female patient with osteoporosis treated with TPTD, demonstrated with in-vivo-assessment of 3D bone microarchitecture with HR-pQCT, M352
- Generating 3D finite element models of a human proximal femur from 2D DXA data, M467
- Geometric evidence of a modeling defect in type 2 diabetic women enrolled in the WHI as a potential explanation for increased fracture risk, 1068
- Geometric property QTLs in HcB/8 x HcB/23 F2 cross, F260
- Grayscale MRI based finite element mechanical modeling of trabecular bone at in vivo resolution, SU277
- Hip structural analysis and volumetric QCT in postmenopausal women from the PaTH Study: mono- or combination therapy with ALN and PTH, M306
- HSA and physical activity in boys and girls during puberty, SA538
- Implications of resolution isotropy on apparent topology of trabecular bone architecture in MRI, SU280
- Increased non-enzymatic glycation of cancellous bone due to decrease in remodeling during ALN therapy of osteoporotic women, 1071
- Inhibition of bone biomechanical response to physical activity and loading in mice lacking periostin, 1143
- Interfacial tissue response is influenced by local strain created during implant micromotion, SA531
- Investigation of the fatigue behaviour of rabbit tibiae: effects of sex and age, SU470
- Is increased bone fragility during adolescence a result of delayed development in bone bending strength?, M500
- Load induced changes in trabecular and cortical bone are dose dependent in both C57BL/6 and C3H/HeJ mice, F527
- Loading duration influences the degree of inhibition of bone loss using dynamic muscle stimulation in a disuse rat model, 1297
- Low bone mass and decreased biomechanical response in beta 1 adrenergic receptor KO but not in beta 2 adrenergic receptor KO mice, 1141
- Low systemic BMD increases implant migration in cementless hip replacement, F458
- LRP5 G171V mutation and tobacco smoke related bone fragility, M323
- LV best enhances fracture repair when administered one week post-fracture, 1300
- Marked abnormalities in cortical and trabecular microarchitecture and strength in premenopausal women with idiopathic osteoporosis, M310
- Measurement of T2\* relaxation time of the trabecular bone network at 7T and 3T compared to topological and structural measurements from HR-pQCT, F317
- Mechanical unloading of the sheep calcaneus: a model for hip fracture, M478
- Mediation of bone loss with ultrasound induced dynamic mechanical signals in an OVX rat model of osteopenia, F536
- Microdamage repair and remodeling requires mechanical loading, 1299
- Microstructural changes at the ultradistal radius in MGUS, SU238
- Murine bone mechanics is determined by the ultrastructural canal network in a sex- and strain-specific manner, M456
- NanoCT can be used to assess mechanically related modeling and remodeling in the mouse fibula, 1296
- NEG alters collagen fibrillar structure and energy dissipation characteristics, SU478
- New link between trabecular properties and T-score at the human femur, SU281
- Non-enzymatic glycation increases bone fragility through altered microdamage formation and propagation, F103
- Non-invasive detection of bone microdamage by light scattering, M462
- Non-invasive in vivo Raman spectroscopy in mice, SU480
- Non-steroidal anti-inflammatory use and the response of bone to exercise, M472
- ODN increases bone strength and maintains bone quality in estrogen deficient adult rhesus monkeys, F508
- Optimization of failure load estimation using radiographs of human cadaveric femur, M457
- Oral Sr ranelate treatment markedly improves implant osseointegration, SA506
- Positive influence of physical activity on BMD measurements and hip geometry parameters in young adults, M477
- Prediction of trabecular level microdamage and bone fracture through local strain, SU467
- Previous sport activity during childhood and adolescence is associated with bone geometry in young adult men, SA541
- Proton NMR study of transverse relaxation in rabbit and rat cortical bone, M470
- Reduction of MRI processing time for assessment of trabecular bone microarchitecture, SU282
- Regulation of parameters of bone quality by MMP-2 and MMP-9, 1144
- Reproducibility of mineral density and morphometric  $\mu$ CT measurements at different voxel size scans, M311
- Response of matrix synthesizing MLO-A5 cells to fluid shear, SA067
- RTA of densitometric calcaneal images differs between subjects with and without GC use, M314
- Sex steroids have site specific effects on muscle and bone geometry in young adult males, M416
- Subject-specific mechanical properties of trabecular bone using a low-dose imaging, SU471
- Targeted exercise against hip fragility, SA533
- Thermoreversible Pluronic F108 gel as a universal tissue immobilization material for  $\mu$ CT analyses, SU468
- Trabecular 3D volumetric density at organ and tissue levels by  $\mu$ QCT evaluation of iliac crest biopsy, M303
- Trabecular risk of fracture, caused by disuse, is strongly influenced by baseline morphology, 1293
- Transition from ALN to DMAb in OVX cynomolgus monkeys maintained or improved cortical and trabecular bone mass, without altering the linear relationship between bone mass and bone strength, 1072
- Transmenopausal changes in the trabecular bone intrinsic properties, SU479
- Unsymmetrical beam theory and finite element method: analysis of murine cortical bone based on  $\mu$ CT imaging, M454
- In vivo assessment of 3D bone microarchitecture with HR-pQCT in patients with and without fractures, SU276
- In vivo quantification of intra-cortical porosity in human cortical bone using HR-pQCT in patients with type II diabetes, M309
- Biotin**
- Clinical implications of commercial biotin-based detection systems in PTH assays, M435
- Birth weight**
- Born small is not bad for bone, SA551
- Preterm birth and BMD in young adulthood, 1103
- Self-reported weight at birth predicts measures of femoral size but not volumetric BMD in elderly men, SU338
- Bisphenol-A-diglycidyl ether (BADGE)**
- Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374
- Bisphosphates**
- Bisphosphate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428
- Bisphosphonate-related osteonecrosis of the jaw (BRONJ)**
- Usefulness of alveolar bone density measurement in risk assessment for BRONJ, SA305
- Bisphosphonates**
- 1-year analysis of adherence with bisphosphonate treatments in osteoporotic patients, SA415
- Acute phase response and bone metabolism marker after intravenous bisphosphonate in osteoporotic patients with rheumatism, M364
- Application of a treatment algorithm to avoid BMD loss and limit bisphosphonate use after kidney and kidney/pancreas transplantation, SA497
- Application of preventive measures minimizes the occurrence of ONJ in patients with bone loss treated with bisphosphonates, F281
- Bisphosphonate, pamidronate, suppresses the pro-inflammatory response in a mouse model of OI as well as normal littermates, SU386
- Bisphosphonate-associated femoral fracture: implications for management, WG26
- Bisphosphonate-associated ONJ cases in South Korea, SA412
- Bisphosphonate-induced osteopetrosis: novel bone modeling defects, metaphyseal osteopenia, and osteosclerosis fractures after drug exposure ceases, F569
- Bisphosphonates and osteoporotic fractures in highly compliant/persistent postmenopausal women, 1025
- Bisphosphonates in children with hypercalciuria and reduced BMD, M429
- BMD response to treatment with rhPTH in patients previously treated with bisphosphonates, M348
- Bone tissue quality is differently altered by PTH, bisphosphonates and SERMs, SA510

Case presentation: bisphosphonate induced ONJ in Pagetic jaw bone, WG24

Combined TGF $\beta$  receptor I kinase inhibitor and bisphosphonates are additive to reduce breast cancer bone metastases, F275

Comparative antifracture efficacy of N-containing bisphosphonates, SU397

Comparative gastrointestinal safety of weekly oral bisphosphonates, M358

Development of an animal model of bisphosphonate-induced severe suppression of bone turnover, SA511

Differences in safety and efficacy of generic and original branded once weekly bisphosphonates, M359

Dkk-1 predicts the gain of BMD in osteoporotic women on bisphosphonates, SA300

Effect of 10-year fracture risk tool results on likelihood of bisphosphonate prescribing, SU402

Effect of bisphosphonate treatment of OA in a guinea pig model, M149

Effectiveness of bisphosphonate therapy in a real-world setting, M356

Fracture risk in women aged 65 years or older with once-monthly oral IBN compared with weekly bisphosphonates, M367

Fracture risk with once-monthly oral IBN compared with weekly bisphosphonates, SU408

Homocystinuria associated bone disease: effect of long term bisphosphonate treatment, SA406

Impact of dosing frequency in compliance with bisphosphonates among postmenopausal Japanese women for osteoporosis treatment, M374

Improving the prediction of medication adherence: example of bisphosphonates for osteoporosis, M368

Induction of Runx2 and Osx by bisphosphonate promote osteogenic differentiation, SU062

Long-term treatment with oral bisphosphonates in postmenopausal women: effects on the degree of mineralization and microhardness of bone, 1029

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

Patient persistence with weekly bisphosphonates for two years after initiation of therapy, SA418

Patients desire of administration form and dose interval in bisphosphonate therapy of osteoporosis, SA408

Postmenopausal women with GERD and long term treatment with bisphosphonates IV, M361

Predictors of patient perceived need for oral bisphosphonates to prevent fracture: the role of the MD-patient relationship, F416

Predictors of self-reported non-persistence with oral bisphosphonates due to perceived side effects or other reasons, M378

Premenopausal reference ranges of bone turnover markers and the effect of bisphosphonates in Korean postmenopausal women, SU406

Risk of hip fracture after bisphosphonate discontinuation, F409

Studying cellular uptake and distribution of bisphosphonate in vivo using fluorescently-labelled analogues of RIS, 1065

TPTD in bisphosphonate-resistant osteoporosis—clinical and  $\mu$ CT data, 1172

**Bisphosphonates, nitrogen containing (NBP)**

Role of active site Thr201 in the inhibition of farnesyl pyrophosphate synthase by NBPs, F407

**BL6**

Effect of Pb on bone mineral properties from female adult C57/BL6 mice, M146

**Bladder cancer.** See *Cancer*

**Blood donors**

Prevalence and incidence of viral infections among musculoskeletal tissue donors and first-time blood donors, SA549

**Blood pressure.** See also *Hypertension*

Elevated systolic blood pressure is positively related to bone mass measurements in overweight pre-pubertal and pubertal children, M496

**Bmi-1**

Defects in MSC self-renewal lead to an osteopenic phenotype in *Bmi-1* null mice, 1050

**BMP and activin membrane-bound inhibitor (BAMBI)**

BAMBI gene is epigenetically silenced in a subset of high-grade bladder cancer, SU245

**BMPR2**

BMPR2 is dispensable for formation of the limb skeleton, SU145

**Body composition**

Automatic estimation of body composition using  $\mu$ CT and a Gaussian mixture model, M139

BMD is associated with lean mass and not fat mass, SU273

Body composition changes after radioiodine treatment of hyperthyroidism, M433

Body fatness negatively associated with BMD and hip geometry indices in adolescents, F546

Bone size, volumetric bone density in relation to fat mass in healthy young men at age of PBM, SU477

Establishing healthy body composition values with DXA, SU366

How does body fat influence bone health in childhood? A Mendelian randomisation approach, 1175

Increased maternal fat intake increases skeletal mass in congenic mice, M495

Percentage body fat and risk of prospective hip fracture in older men and women, F363

Plasma osteocalcin is inversely related to fat mass and plasma glucose in elderly Swedish men, SU459

At similar plasma 25(OH)D levels, fat mass influence PTH levels in the state of Vitamin D insufficiency, SA218

Variation in the osteocalcin gene: association study of BMD, fracture and changes in body fat mass in elderly women, SU225

Vertebral fracture in men: level of trauma, BMD and lean body mass, SU360

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

**Body mass index (BMI).** See also *Obesity; Weight*

Dietary patterns in Canadian men and women ages 25 and older: relationship to BMI and BMD, SU309

Model of high body mass: BMD, bone markers and adipocytokine levels in high level male rugby players, SA167

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

Weight and BMI predict BMD and fractures in women 40 to 59 years, SA438

**Bone acquisition.** See also *Pediatric bone disease*

Accuracy of Cobb angle measurement with iDXA, SU484

ALF prevents aromatase inhibitor (letrozole)-induced bone mineral loss in young growing female rats, SA570

Autosomal recessive HPP manifesting in utero with long bone deformity but showing spontaneous postnatal improvement, SA562

Bisphosphonate-induced osteopetrosis: novel bone modeling defects, metaphyseal osteopenia, and osteosclerosis fractures after drug exposure ceases, F569

Bone formation in mice with variations in Lrp5 expression, F550

Bone size, volumetric bone density in relation to fat mass in healthy young men at age of PBM, SU477

Contribution of the vertebral posterior elements in anterior-posterior DXA scans, 1180

Cortical bone acquisition in the appendicular skeleton of healthy young females is reciprocally related to marrow adiposity, M074

Determinants of humeral bone volume in males, F122

Effects of diet and menstrual cyclicity on bone mass accumulation in pubertal monkeys, M499

Effects of GH on bone micro-architecture by in vivo  $\mu$ CT, SA547

Effects of long-term administration of high-dose GH on body composition and bone mineralization, SA571

Extracellular matrix protein periostin regulates periosteal apposition, 1178

Forearm pQCT measurements in males with DMD, SU492

Kenney-Caffey syndrome in a Caucasian man, SA464

Loaded distal radius: gymnastic-related cross-sectional asymmetry, M490

PBM is determined at 1 year-old: evidence from growth charts, F542

Prevalence and incidence of viral infections among musculoskeletal tissue donors and first-time blood donors, SA549

Transcriptional silencing of Frzb/sFRP3 by promoter methylation in osteogenic sarcoma, SU231

Valproate: a model for adverse psychoactive drug effects on BMD, SA556

**Bone architecture**

Alteration of trabecular bone architecture following sciatic denervation and subsequent reinnervation in rat proximal tibiae, SA513

Bone metabolism, microarchitecture and densitometric measurement in rat femur after chronic alcohol consumption, M239

Bone microarchitecture is dependent upon collagen  $\alpha 1$ (XI) expression during development, F135

Both excess and restricted energy availability negatively influence acquisition of trabecular bone mass and microarchitecture during growth, M493

Cortical and trabecular microarchitecture in HIV-infected postmenopausal women, SU458

Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503

Effect of luteolin on bone loss, microarchitecture and bone resorption in OVX mice, M128

Effect of metabolic acidosis on BMD and bone microarchitecture in normal and OVX rats, M409

Effects of GH on bone micro-architecture by in vivo  $\mu$ CT, SA547

Excessive erythropoiesis affects bone architecture, 1294

Feasibility and reproducibility of in-vivo assessment of trabecular bone architecture using  $\mu$ MRI-based method at multiple study centers, SA314

Femur from C57BL/6 and DBA/2 inbred mice display a strain dependent response to treadmill running and tower climbing exercise in cortical and trabecular bone architecture, M485

Formation of new trabeculae in a female patient with osteoporosis treated with TPTD, demonstrated with in-vivo-assessment of 3D bone microarchitecture with HR-pQCT, M352

Green tea polyphenols protect bone microarchitecture in female rats with chronic inflammation-induced bone loss, M338

Implications of resolution isotropy on apparent topology of trabecular bone architecture in MRI, SU280

- GWAS identified novel susceptibility loci for osteoporosis, SA267
- Haplotype specific promoter activity of the human *FZD1* gene, M269
- High levels of IL-6 and hyper-responsivity to 1,25(OH)<sub>2</sub>D<sub>3</sub> are both required for development of Pagetic osteoclasts, F478
- High-fat diet negatively regulates bone development in growing mice, SA441
- Homozygous threonine to methionine substitution in FGF-23 gene is associated with tumoral calcinosis in a 12 year-old girl, SU171
- Hotspot splicing mutation in *LEPRE1* affects P3H1 and causes recessive OI, SU215
- Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471
- Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SOSTM1* (sequestosome 1), SU210
- Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259
- Hypoxia promotes ligand-independent activation of the ACVR1 (R206H) mutant receptor in C2C12 cells, M243
- Identification of a novel mutation (78dup27) of the *TNFRSF11A* gene in a Chinese family with early onset PDB, M237
- Identification of skin abnormalities in OI patients by MRI, SA561
- Impairment of osteoblast lineage differentiation leads to increased osteoclastogenesis in OI murine, 1202
- Immunohistochemical and genetic characterization of the atypical parathyroid adenoma, M432

- Immunohistochemical localisation of SCT in human trabecular bone from fragility hip fracture patients, SA148
- Impaired oxidative stress defense mechanism may reduce bone stiffness in diabetic Charcot neuroarthropathy, M002
- Integrative genetics approach to identify candidate genes regulating bone density: combining linkage, gene expression and association, M247
- Investigation into the impact of OA changes on BMD measurements in patients with high bone mass, SA257
- Is there any association between CYP 17-CYP 19 polymorphisms and bone loss in early postmenopausal women?, M259
- Large collaborative study on geographic variation of *SQSTM1* mutations in PDB in Italy, SA475
- Large osteoclasts in pediatric OI patients receiving intravenous pamidronate, SU497
- Loss of function polymorphisms in the P2X<sub>7</sub> receptor gene are associated with accelerated lumbar spine bone loss in postmenopausal women, SU224
- Lrp6 loss of function impacts bone homeostasis and responds to folate supplementation, F253
- Mecp2 null mice display multiple skeletal abnormalities, M242
- Molecular consequences of a mutant Dlx3 affecting bone homeostasis in TDO, 1272
- Molecular diagnostic strategies for mutations of the CaSR gene, M201
- Morquio Syndrome variant: two siblings with atypical phenotype and novel compound heterozygosity, M240
- Mouse with a Ser1386Pro mutation in the C-propeptide domain of *col2a1* provides a model for SEDC, 1269
- Mutational analysis of  $\beta$ -catenin Exon 3 in benign and malignant parathyroid tumors, M436
- Nonsteroid responsive HCa associated with sarcoidosis—a rapid response to hydroxychloroquine, WG28
- NR1P1*, a novel osteoporosis candidate gene identified by expression and association analyses, M254
- Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238
- OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563
- OPG serum levels in shaft fractures healing and non-union, M013
- OPN deficiency reduces aortic calcification and oxidative stress in diabetic LDLR<sup>-/-</sup> mice, F109
- Osteoblast and osteoclast involvement in the pathogenesis of a mouse model for CMD, 1204
- Osteoporosis in a murine model of hemophilia A, M480
- Over-expression of CNP enhances the formation of long bone exostoses in *Ext1*<sup>+/-</sup> mice, SU130
- Oxytocin inhibits bone formation through the activation of the sympathetic tone, 1200
- P3H1 and CRTAP are mutually stabilizing in the endoplasmic reticulum collagen prolyl 3-hydroxylation complex, 1049
- Phased GWAS identifies probable new gene affecting BMD, M245
- PHEX cleavage of SIBLING-ASARM peptides as a mechanism underlying osteomalacia in XLH, 1199
- Polymorphisms in *CYP24A1*, the gene encoding 25(OH)D-24-hydroxylase, are associated with BMD, SA266
- Polymorphisms in the WIF1 gene are associated with BMD in elderly Swedish women, SA264
- Polymorphisms of the ALOX12 gene are associated with increased risk of osteoporotic fracture, SU220
- Polyostotic form of FD in a 13 year old Colombian girl exhibiting clinical and biochemical response to neridronate intravenous therapy, SU211
- Possible central function of the calcitonin receptor on bone mass, SA255
- Prediction of fracture risk by LRP5 gene haplotype, SU222
- Prediction of osteoporotic fracture risk by 25(OH)D3-1 $\alpha$ -hydroxylase (CYP27B1) gene, M263
- Proinflammatory marker values at baseline and after a fracture are distinctly different comparing a mouse model of OI with normal controls, M234
- Protective actions of Vitamin D analogs in the vascular calcification of CKD, SU450
- Proteins involved in mineralization expressions perturbations in bones and teeth of *Msx2* mutant mouse mandibles, SA150
- Quantitative  $\mu$ CT imaging of adipocyte volume in bone marrow of mice with high and low bone mass, SU250
- Rachitic defects in *tcirg1*-dependent osteopetrosis are caused by impaired gastric acidification, 1201
- Recalculation of genome scans on a common genetic map enhances our ability to identify common bone density QTL in new and historical data, 1276
- Recurring mutation causing severe/lethal recessive type VIII OI in African-Americans originated in West Africa more than 300 years ago, SA262
- Relative efficacy of “treating” versus “preventing” infantile HPP in *Akp2*<sup>-/-</sup> mice by enzyme replacement therapy, 1054
- Role of *Ostm1* in bone, hematopoiesis and neuronal development, 1271
- RsaI* polymorphism in *ESR2* is associated with postmenopausal fracture risk, SU221
- Safety and efficacy of long-term PTH replacement in a pediatric patient with inherited HPT, F217
- Screening the PHEX gene in a large cohort of hypophosphatemic rickets allowed the description of a missense mutation not responsible for the disease on a highly conserve amino acid residue, M246
- Serum FGF-23 level in term infants, SA165
- Significant association between polymorphisms of *CYP19A1*, fracture incidence and BMD in post-menopausal women, M262
- Significant trabecular bone degradation occurs within five days of muscle paralysis, SA515
- Single nucleotide polymorphisms in the P2X<sub>7</sub> receptor gene are associated with increased postmenopausal bone loss and fracture incidence, SU223
- Skeletal consequences of FHH and PHPT, M206
- Specific inhibitors of TNSAP's pyrophosphatase activity suppress medial arterial calcification, M142
- Spectrum of OI mutations in Sweden, SA247
- Strong and extensive epistatic interactions affect bone traits in a mouse reciprocal intercross of HcB/8 and HcB/23, SA125
- T $\beta$ RI inhibitor rescues uncoupled bone remodeling in two different animal disease models, 1273
- Three unrelated patients with a unique spondylo-epi-metaphyseal dysplasia, SU494
- Twist1 haploinsufficiency is associated with reduced IGF-1 levels and an osteoporotic phenotype, SU029
- Two novel *SQSTM1* mutations in American patients with PDB, SU216
- ucOC is an endocrine link between the skeleton and the glucose metabolism, F444
- Usefulness of *HRPT2* gene and parafibromin studies in two patients with PHPT and uncertain pathological assessment, SA482
- In utero stem cell therapy as treatment for classical OI using the knock in murine model *BrtlIV*, F500
- Variation in the osteocalcin gene: association study of BMD, fracture and changes in body fat mass in elderly women, SU225
- ### Bone formation
- (Ala-Gly)<sub>n</sub> sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased *Cbfa1* and *Osx* expression, M167
- Ablation of IGF-I signaling in osteoprogenitors decreases bone formation and blunts the skeletal response to PTH, 1193
- Abnormality of bone formation in transgenic mice expressing *Osr1*, M144
- Acute change in iCa directly affects bone formation independent of PTH action during hemodialysis, SU437
- Acute COPD exacerbations are associated with uncoupling of bone resorption from bone formation, M414
- Adipocyte-secreted protein URB is a potent stimulator of bone formation, F006
- Aging dependent and independent effects of b2 adrenergic receptor signaling on bone formation induced by intermittent PTH treatment in female mice, SA378
- BMSC aging directly alters bone formation, 1252
- Bone formation in mice with variations in *Lrp5* expression, F550
- Bone tether formation in femoral and basicranial growth plates have similar responses to growth disruptions due to nuclear VDR genotype and mineral homeostasis, M164
- Ca intake and serum bone formation markers are associated with the functional single nucleotide polymorphism in the *TNSALP* gene, SU308
- Calcifications in children with JDM contain several bone formation markers, SA106
- Catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation, SU137
- CFTR regulates osteoblast bone formation independent of chloride conductance, 1274
- Concentration of connective tissue progenitors in autologous cancellous bone graft enhances new bone formation in a canine femoral defect model, SA039
- Conditional disruption of *Pkd1* in osteoblasts results in osteopenia due to direct impairment of osteoblast-mediated bone formation, SA019
- Decreased bone formation, increased bone resorption, and osteopenia in mice lacking SP, SU160
- Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026
- Deletion of the *Dkk-1* *Krm-1* and *Krm-2* in mice leads to increased bone formation and bone mass, 1004
- Deletion of the Wnt signaling antagonist sRFP4 in mice induces opposite bone formation phenotypes in trabecular and cortical bone, 1005
- Dlk1*/*FA1* is a novel factor enhancing osteoclastogenesis and inhibiting bone formation in vitro and in vivo, 1007
- Early osteocyte marker, *E11/gp38* is highly elevated in new bone formed in response to distraction as compared to existing bone, SA136
- Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385
- Elevated androgens are associated with increased bone formation in premenopausal exercising oligomenorrheic women, SU191
- Ephrin B1 reverse signaling regulates bone formation via influencing osteoblast activity in mice, 1194
- Fluoride effects on bone formation, mineralization and mechanical properties are influenced by genetics, SU465

## Key Word Index

## ASBMR 30th Annual Meeting

Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214

Gastric proton pump inhibitors failed to affect bone resorption and formation, SA095

GLP-2 acutely uncouples bone resorption and bone formation in postmenopausal women, M399

Gut-derived serotonin is an inhibitor of bone formation, M069

High bone mass due to increased bone formation in mice lacking the CTR, SA192

Histomorphometric and biochemical bone formation responses to first and second cycles of TPTD treatment, 1169

IGFBP6 Is a negative regulator of osteoblast differentiation and bone formation, SA182

Impaired bone formation in mice lacking lamin A/C activation leads to severe osteopenia, F131

Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184

Interaction of combined intervention of PTH and GH on trabecular and cortical bone formation and resorption in the hypophysectomized rats, SU502

Interactions between obesity, CVD and bone formation, M451

Long-acting PTH ligand that binds to a distinct PTH receptor conformation (R0) can stimulate increases in markers of both bone resorption and bone formation in mice, F221

Losartan<sup>®</sup> (Cozaar) increases appendicular bone formation by inhibiting osteoclastogenesis, M126

Marrow ablation induces periosteal bone formation and potentiates the effect of PTH on endosteal bone formation in rat femurs, M208

Mathematical model of remodeling cycles with feedback mechanism for maintaining the balance between bone resorption and formation, WG27

Mice lacking the Wnt receptor Frizzled-9 display osteopenia caused by decreased bone formation, 1006

Molecular mechanisms underlying matrix vesicle-induced mineralization during bone formation, SA063

Osteoblast-targeted deletion of the GC receptor has little impact on PBM but attenuates DEX-induced suppression of bone formation, F452

Osx, a positive regulator in adult bone formation, F008

Overexpression of GSR in osteoblasts decreases bone formation and partially prevents OVX-induced bone loss, F024

Overexpression of sFRP1 inhibits bone formation and attenuates PTH bone anabolic effects, 1100

Oxytocin inhibits bone formation through the activation of the sympathetic tone, 1200

PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299

Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, 1082

Positive effect of GLP-1 upon bone formation and resistance in insulin-resistant rats, M425

PTHr1 stimulates bone formation through a distinct  $\beta$ -arrestin dependent pathway independent of G protein activation, 1226

Rapid optical imaging of bone formation responses in the rodent skeleton, SU379

Regulation of bone formation by osteoclasts involves Wnt/BMP signaling and the chemokine S1P, M017

Ronacaleret, a novel CaSR antagonist, demonstrates potential as an oral bone-forming therapy in healthy postmenopausal women, 1174

Scl-Ab increases bone formation and decreases bone resorption in distal tibial metaphyseal trabecular bone in OVX rats, F394

Scl-Ab increases bone mass by stimulating bone formation and inhibiting bone resorption in a hindlimb-immobilization rat model, 1138

Serum PINP is a sensitive marker of bone formation in mouse OVX model, M293

Soluble activin receptor type IIA fusion protein, ACE-011, increases bone mass by stimulating bone formation and inhibiting bone resorption in cynomolgus monkeys, SU376

TGF $\beta$ 1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

Transgenic overexpression of the Wnt antagonist Krm-2 in osteoblasts leads to severe impairment of bone formation and increased bone resorption, 1003

In vivo demonstration that PTH acts on early osteoprogenitor cells to enhance bone formation during repair of critical-size calvarial defects, M062

**Bone formation, cortical**

Endogenous G $_i$  signaling in osteoblasts negatively regulates cortical bone formation, 1255

**Bone formation, endochondral**

Expression of an engineered G $_i$ -coupled receptor in osteoblasts affects intramembranous and endochondral bone formation during bone repair, F127

Marked induction of endochondral bone formation by overexpression of a constitutively active Gli2 in MSCs isolated from the healing site, SA049

Overexpression of the transcriptional cofactor Lbh impairs angiogenesis and endochondral bone formation during fetal bone development in chickens, SU004

Phosphate regulates chondrocyte differentiation, proliferation and apoptosis in a model of embryonic endochondral bone formation, SU124

Role of Wdr5 in endochondral bone formation during chicken limb development, SU121

Trps1 represses Runx2 during endochondral bone formation, SU126

**Bone formation, trabecular**

Ligand activation of the engineered G $_i$ -coupled receptor Rs1 in osteoblasts promotes trabecular bone formation, 1076

**Bone fragility**

Bone fragility is increased in the MKR type 2 diabetic mouse, M440

Is increased bone fragility during adolescence a result of delayed development in bone bending strength?, M500

Non-enzymatic glycation increases bone fragility through altered microdamage formation and propagation, F103

**Bone geometry**

Bivariate whole genome linkage analysis of femoral bone geometric traits and leg lean mass, M249

Bone geometry and bone strength are compromised in patients with ACL reconstruction, M487

Bone geometry, strength, and muscle mass in female distance runners with a history of stress fracture, SA540

Bone volumetric density, geometry and strength in male and female collegiate runners, SA539

Changes in marrow cell dynamics and bone geometry with aging in TSP-2 null mice, 1249

Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244

Previous sport activity during childhood and adolescence is associated with bone geometry in young adult men, SA541

Sex steroids have site specific effects on muscle and bone geometry in young adult males, M416

**Bone grafts**

Concentration of connective tissue progenitors in autologous cancellous bone graft enhances new bone formation in a canine femoral defect model, SA039

Downregulation of Cx43 expression and osteoclastogenesis by a bioceramic bone graft substitute, M119

Novel modification of bone grafts inhibits bacterial colonization, M169

**Bone growth**

Soy-based formula promotes bone growth in neonatal piglets by inducing osteoprogenitors to differentiate into osteoblasts via enhanced BMP-2 signaling, SA336

**Bone healing**

AC-100 promotes cartilage repair and subchondral bone healing in surgically induced cartilage defects, SA111

Accelerated fracture callus remodeling and membranous bone healing in STAT1 deficient mice, SA022

Impaired bone healing in a BMP-2 KO mouse model of DO, SA159

Opioid-induced osteoporosis: delayed bone healing and compression fractures in a man with chronic narcotic use, WG32

Roles of ZOL in bone healing and osteoblast functions, 1064

Use of endothelial progenitor cells to promote bone healing, SA104

**Bone homeostasis**

Lrp6 loss of function impacts bone homeostasis and responds to folate supplementation, F253

Molecular consequences of a mutant Dlx3 affecting bone homeostasis in TDO, 1272

Osx is required for skeletal growth and bone homeostasis after birth, 1074

Oxytocin directly regulates skeletal homeostasis, SA199

VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029

**Bone length**

Bone length was differentially promoted in the left/right hindlimbs with knee loading and administration of IGF-2, M476

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

**Bone loss**

(22-52) ADM prevents systemic bone loss related to inflammation in mice, SA493

A allele at Valine80 of the CYP19 gene is a risk factor for aromatase inhibitors associated bone loss, 1021

Age-related bone loss in mice associated with ubiquitin ligase Smurf1 degradation of JunB protein and reduced osteoblast proliferation, 1113

ALF prevents aromatase inhibitor (letrozole)-induced bone mineral loss in young growing female rats, SA570

Application of preventive measures minimizes the occurrence of ONJ in patients with bone loss treated with bisphosphonates, F281

Association of urine measures of diet-derived acid excretion with bone loss and fractures, SU283

Bisphosphate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428

Bone loss with smoke exposure and Lrp5 expression, SA459

Calorie restriction prevents age-related trabecular bone loss via SIRT-1, 1251

Cannabinoid receptor ligands rescue bone loss and stimulate fracture healing, SU375

CaSR gene A986S polymorphisms: relation to bone loss and urine Ca in a Spanish early postmenopausal women population, M255

*Cissus quadrangularis* attenuates OVX induced bone loss in mice, M403

Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026

DHT administration is effective for the prevention of hypogonadal bone loss, SU193

Disuse with a rapid bone loss affects the expression profile of osteoblastic and resorption genes, F516

Effect of luteolin on bone loss, microarchitecture and bone resorption in OVX mice, M128

Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505

Efficacy of whole-body vibration in reducing bone loss in postmenopausal women, M396

Evaluation of the detection sensitivity of simulated trabecular bone loss in  $\mu$ MRI at in vivo resolution, M312

Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214

GC-induced bone loss in mice is dependent on beta 2-adrenergic signaling, M102

Genetic locus on chromosome 1q influences bone loss in young Mexican American adults, M250

Gondanotropins, bone loss and fracture in men, 1278

Green tea polyphenols protect bone microarchitecture in female rats with chronic inflammation-induced bone loss, M338

High level dietary P and Cd exacerbate OVX-induced bone loss, M301

IGFBP2 and bone loss in aging women and men, 1284

Impact of adjuvant hormonal therapy on bone loss depending on initial adjuvant chemotherapy and menstrual status, M415

Inhibition of bone loss and muscle atrophy by DHT in a mouse hindlimb disuse model, SU377

Injection of MSCs overexpressing both CXCR4 and RANK-Fc effectively prevented OVX-induced bone loss, F391

Intestinal-specific VDR null mice maintain normal calcemia but display severe bone loss, F238

Intravenous IBN for prevention of early bone loss after kidney transplantation, F413

Is there any association between CYP 17-CYP 19 polymorphisms and bone loss in early postmenopausal women?, M259

Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194

Late pregnancy serum Vitamin D and longitudinal bone loss during pregnancy, F544

Loading duration influences the degree of inhibition of bone loss using dynamic muscle stimulation in a disuse rat model, 1297

Loop diuretic use and rates of hip bone loss, and risk of falls and fractures in older women, F371

Loss of function polymorphisms in the P2X<sub>7</sub> receptor gene are associated with accelerated lumbar spine bone loss in postmenopausal women, SU224

Low serum 25(OH)D is associated with higher rates of hip bone loss in older men, F367

Mechanical loading prevents bone loss due to hormone-deficiency in female mice, M474

Mediation of bone loss with ultrasound induced dynamic mechanical signals in an OVX rat model of osteopenia, F536

Melanoma-induced bone loss is mediated by the rapid recruitment of osteoclasts, SU233

Modeling pathways for bone loss in childhood malignancies, SU237

Neglected role of intracortical remodeling in age-related bone loss, 1101

Obesity is associated with higher BMD, lower bone resorption and slower hip bone loss: are these associations mediated by adipokines?, SU369

Overexpression of GSR in osteoblasts decreases bone formation and partially prevents OVX-induced bone loss, F024

Prevention of aromatase inhibitor-associated bone loss in women with breast cancer, M283

PTH and not Vitamin D predicts age-related bone loss in the elderly, M178

R-spondin 1 reduces bone loss in human TNF transgenic and OVX mice, 1215

Radiation-induced bone loss: description of dose, time course, age, strain and sex variables, SU368

Rate of bone loss is greater in young adult men than women, SU297

Reduced renal function is associated with increased rates of bone loss at the hip and spine, SU357

RIS prevents early radiation-induced bone loss at multiple skeletal sites, 1066

Risk factors for bone loss in the hip in 70-year-old women, SA374

Role of OPG/RANKL system for bone loss in PHPT, M192

Role of OPN in beta-adrenergic signaling induced bone loss in vivo, M174

Selective p38 $\alpha$  inhibitor prevents bone loss induced by estrogen deficiency, M335

Short treatment with Scl-ab can inhibit bone loss in an ongoing model of colitis, 1212

Single nucleotide polymorphisms in the P2X<sub>7</sub> receptor gene are associated with increased postmenopausal bone loss and fracture incidence, SU223

Strength training prevents bone loss at the spine in older breast cancer survivors, SA271

Trabecular bone loss in response to transient muscle paralysis is not gender dependent, SA462

ZOL prevents accelerated bone loss after discontinuation of TPTD, M365

#### Bone marrow

Bone marrow cells participate in normal endothelial, but not epithelial or mesenchymal cell renewal in adult rats, M171

*Ccrn4l*, a peripheral clock gene, influences stromal cell allocation, bone mass, and marrow adiposity in mice and humans, 1073

Changes in marrow cell dynamics and bone geometry with aging in TSP-2 null mice, 1249

Comparison of the effects of zoledronates on the differentiation of human bone marrow and amniotic fluid derived MSCs, SA045

Cortical bone acquisition in the appendicular skeleton of healthy young females is reciprocally related to marrow adiposity, M074

Diet induced obesity compromises the osteogenic potential of the bone marrow, F047

Effect of bone marrow transplantation in a child with malignant IO, SU498

Effect of osteoblast depletion on hematopoietic niches in the bone marrow, F041

Effect of vertebral marrow fat content on the diagnosis of osteoporosis, SA309

Hematopoietic cells in the bone marrow augment anabolic actions of PTH, M181

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

Osteogenic potential of bone marrow, compromised by disuse, is normalized by brief exposure to a low-level mechanical signal, M486

Osteogenic potential of human bone marrow and circulating Stro-1+/CD45<sup>low</sup> cells, M078

Primary human bone marrow adipocytes stimulate osteoclast differentiation, M111

Quantitation of bone marrow fat in long bones of mice using MRI or  $\mu$ CT, M145

Reciprocal relation between MR measures of marrow adiposity and cortical bone in the appendicular skeleton of healthy adults, SU042

Recombinant congenic strain (B.H-6) establishes that trabecular bone mass and bone marrow adiposity are distinct and heritable phenotypes, F265

Reconstituting marrow-derived extracellular matrix ex vivo: an optimal niche for retaining the properties of human MSCs, M165

Role of AXII and AXIIR in homing MM cells in the bone marrow, SA287

Selective retention of bone marrow cells in repair of canine femoral defect with polycaprolactone-tricalcium phosphate scaffolds, SU005

#### Bone marrow ablation

N-terminal fragment of PTHrP promotes the GC-related deficiency of bone regeneration after bone marrow ablation in mice, M195

#### Bone marrow stromal cells (BMSC)

Aging of human BMSC: role of WNT pathways, SA048

Anabolic PTH treatment mobilizes BMSC and osteoprogenitors towards bone surfaces, SA229

BMSC aging directly alters bone formation, 1252

BMSC and Osx contributing to osseointegration of dental implants, SA138

BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242

BMSC-derived extracellular matrix promotes MSC motility, SA134

Different osteogenic properties of human BMSC from different skeletal site origin, SU055

Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060

DNA methylation analysis of osteogenic gene promoter regions in mouse BMSC, M035

Effect of resveratrol and flax oil on MC3T3-L1 pre-adipocyte and ST2 BMSC proliferation and differentiation, SU059

Enhanced osteogenic potential of alveolar vs. long bone derived BMSC, M095

Expression of 1 $\alpha$ -hydroxylase (CYP27B1) in BMSC, SA237

Loss of classical ERE signaling results in suppression of early commitment of BMSC to osteoblasts, F029

Mature human adipocytes differentiated from BMSCs, SA042

MKP-1 is an endogenous negative regulator of pro-inflammatory cytokines in BMSC, SU013

SP stimulates BMSC osteogenic activity and osteoclast differentiation and function in vitro, SU032

Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036

WNT-4 acts through the non-canonical pathways to stimulate osteoblast and BMSC differentiation, F050

#### Bone mass

Angiotensin II type 2 receptor blockade increases bone mass, SU007

## Key Word Index

## ASBMR 30th Annual Meeting

ARZ in postmenopausal women with normal or low bone mass, SA421

Bone mass recovers in young women with anorexia nervosa who are both weight and menstrual recovered, F339

In bone, RPTP $\alpha$  is exclusively expressed in osteocytes and may affect bone mass, SA052

Both excess and restricted energy availability negatively influence acquisition of trabecular bone mass and microarchitecture during growth, M493

Brain-derived serotonin positively regulates bone mass accrual, SA463

BZA in combination with conjugated estrogens improves bone mass and strength in the OVX rat, SA385

Cannabinoid receptor GPR55 affects osteoclast function in vitro and bone mass in vivo, 1221

CCR2 receptor signaling is involved in bone mass regulation and mediates the response to anabolic but not catabolic regimens of PTH(1-34), SU158

*Ccrn4l*, a peripheral clock gene, influences stromal cell allocation, bone mass, and marrow adiposity in mice and humans, 1073

Central and peripheral leptin treatment produce similar increase in cortical and trabecular bone mass in ob/ob mice, SU164

Circulating DKK1 levels are reduced in young subjects with low bone mass, F455

Common genetic factors contribute to the relationship of body composition and bone mass in mouse populations, M244

Common single nucleotide polymorphism in the *HMGA2* gene is associated with bone mass in men, SA268

Cortical bone mass and structure in older Afro-Caribbean and Caucasian men, SU300

Critical role of Cx43 in postnatal skeletal growth and bone mass acquisition, 1257

Crosstalk between androgen receptor and Wnt signaling mediates sexual dimorphism during bone mass accrual, 1121

Deletion of *Mef2c* in osteocytes decreases *Sost* expression and increases bone mass, F054

Deletion of the *Dkk-1* *Krm-1* and *Krm-2* in mice leads to increased bone formation and bone mass, 1004

Double deletion of  $\alpha 2a$ - and  $\alpha 2c$ -adrenergic receptors results in a phenotype of high bone mass and in resistance to the thyrotoxicosis-induced osteopenia, F244

Effect of 12 months gymnastics participation on bone mass accrual in 4 to 7 year olds, SA555

Effect of cannabinoid CB1 receptor ligands on body weight and bone mass in mice, M340

Effect of RIS in liver transplantation patients with low bone mass, SA503

Effects of ALN or DMAb on cortical and trabecular bone mass, bone strength, and bone mass-strength relationships in mice, 1139

Effects of diet and menstrual cyclicity on bone mass accumulation in pubertal monkeys, M499

Effects of ODN on bone mass and turnover in estrogen deficient adult rhesus monkeys, SA072

Elevated systolic blood pressure is positively related to bone mass measurements in overweight pre-pubertal and pubertal children, M496

FOXO1 signaling in the control of bone mass, 1112

G171V and A214V *Lrp5* knock-in mice have increased bone mass and strength, and can help precisely define the in vivo functions of *Lrp5* during bone growth and homeostasis, 1002

High bone mass due to increased bone formation in mice lacking the CTR, SA192

High bone mass phenotype in the bone specific *Dlx3* KO mice, M027

IC162, a new flavonoid, preserves bone mass and microarchitecture without affecting uterine weight in OVX rats, SA386

Improved bone mass after co-administration of Sr ranelate and RIS in a rat model of osteoporosis using "in-vivo"  $\mu$ CT, SU393

Influence of long-term hormone replacement therapy on tibia bone mineral mass and mass distribution in postmenopausal women, F420

Influence of muscle size and strength on changes in bone mass and size during growth and in response to exercise, SA537

Inpp4b as a regulator of bone mass, F089

Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380

Investigation into the impact of OA changes on BMD measurements in patients with high bone mass, SA257

Low bone mass and decreased biomechanical response in beta 1 adrenergic receptor KO but not in beta 2 adrenergic receptor KO mice, 1141

MKP-1 protects bone mass via negative regulation of osteoclast differentiation and activation, 1219

Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238

Overexpression of Lef-1 $\delta$ N increases bone mass in mice, 1258

Possible central function of the calcitonin receptor on bone mass, SA255

Preference and satisfaction with a 6-monthly subcutaneous injection versus a weekly tablet for treatment of low bone mass, M372

PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038

PTH-induced bone mass gain is blunted but not abolished in *SOST* overexpressing and deficient mice, 1039

Quantitative  $\mu$ CT imaging of adipocyte volume in bone marrow of mice with high and low bone mass, SU250

Randomized, placebo-controlled, double blind study on high frequency, low intensity vibration in bone mass, muscle strength and quality of life in children with motor disabilities, F435

Recombinant congenic strain (B.H-6) establishes that trabecular bone mass and bone marrow adiposity are distinct and heritable phenotypes, F265

Recovery of bone architecture after RANKL administration in rats is characterized by increased bone mass on existing trabeculae assessed by in vivo  $\mu$ CT, SU076

Regulation of bone mass and osteoclastogenesis by the CEACAM1, F091

Relationship between low bone mass and aortic valve sclerosis in Korean men and women, SU452

Replacing testosterone in male cardiac transplant patients exerts multiple benefits on bone mass, libido and sexual activity, M388

Scl-Ab increases bone mass by stimulating bone formation and inhibiting bone resorption in a hindlimb-immobilization rat model, 1138

Soluble activin receptor type IIA fusion protein, ACE-011, increases bone mass by stimulating bone formation and inhibiting bone resorption in cynomolgus monkeys, SU376

Telomerase deficiency leads to decrease bone mass and impaired MSCs functions in telomerase deficient (TERC<sup>-/-</sup>) mice, 1147

TGF $\beta$  receptor I kinase inhibitor increases bone mass in normal mice, SA172

TGIF regulation of bone mass: impaired osteoblast differentiation, SA018

Transition from ALN to DMAb in OVX cynomolgus monkeys maintained or improved cortical and trabecular bone mass, without altering the linear relationship between bone mass and bone strength, 1072

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

Vitamin D status, bone mass, and bone metabolism in postmenopausal women and men older than 50 attended in a primary care center of Spain, M223

Weight reduction is not deleterious for bone mass or strength in obese women, SA338

**Bone mass, peak (PBM)**

Augmentation of PBM occurs in female and male mice without progesterone nuclear receptors, F249

Bone size, volumetric bone density in relation to fat mass in healthy young men at age of PBM, SU477

Heel ultrasound and consolidation of PBM in young women, M504

Osteoblast-targeted deletion of the GC receptor has little impact on PBM but attenuates DEX-induced suppression of bone formation, F452

PBM is determined at 1 year-old: evidence from growth charts, F542

Volumetric bone parameters in relation to fracture history in healthy men at the age of PBM, SU302

**Bone mechanics**

Murine bone mechanics is determined by the ultrastructural canal network in a sex- and strain-specific manner, M456

**Bone metabolism**

Acute phase response and bone metabolism marker after intravenous bisphosphonate in osteoporotic patients with rheumatism, M364

Bone metabolism in long-term kidney transplantation recipients, SA499

Bone metabolism, microarchitecture and densitometric measurement in rat femur after chronic alcohol consumption, M239

Changes of bone metabolism in immunosuppressant, FK506 treated rats, SU383

DC-STAMP regulates bone metabolism through cell-cell fusion of osteoclasts, F087

Dried plum alters bone metabolism via a different mechanism than PTH, M341

Effect of a one year exercise program on markers of bone metabolism after hip fracture, SA432

Effects of *Acanthopanax senticosus* extract on bone metabolism in Korean postmenopausal women, SA431

Effects of estrogen therapy and fluocalcic effervescent on the BMD and bone metabolism of surgical menopause women with osteopenia, M392

Effects of exercise intensity on the bone metabolic response to running, M481

Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

Effects of low dose estrogen therapy on the BMD and bone metabolism of menopausal women, M393

FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177

New automated multiplex assay for simultaneous measurements of four serum biochemical markers of bone metabolism in osteoporosis, SA295

Proteasome inhibition counteracts the negative effect of GC treatment on bone metabolism by stimulating osteoblasts and inhibiting osteoclasts in vitro, SA231

Vitamin D status, bone mass, and bone metabolism in postmenopausal women and men older than 50 attended in a primary care center of Spain, M223

**Bone mineral content (BMC)**

- Birth weight predicts bone size, adult weight predicts BMC and BMD in young Gambian adults, M498
- Differences in BMC at the lumbar spine and proximal femur in South American children of different ethnic groups, SU490
- Bone mineral density (BMD)**
- “Vibes” Trial: LMMs to improve BMD, M397
- 30IT/C of SCT modulates BMD by Wnt and estrogen signaling pathways, 1270
- 6819 analysis on measurement of BMD of phalanges by radiographic absorptiometry in Beijing, SA313
- Advanced hip assessment and BMD in Japanese women with OA, M449
- Advancing maternal age is associated with lower peak BMD in the male offspring, M327
- Age-related changes in BMD, cross-sectional area and the strength of rat femur; an involvement of suppression of GH-IGF-1 signaling, SA467
- ALN treatment in postmenopausal Romanian women followed by BMD-digital x-ray radiogrammetry, M357
- Application of a treatment algorithm to avoid BMD loss and limit bisphosphonate use after kidney and kidney/pancreas transplantation, SA497
- Are there any ethnic differences in BMD in a lupus cohort?, SU358
- Assessment of cortical thickness and BMD in the radius by low-frequency Q-GWUS, M319
- Assessment of fracture risk and treatment of osteoporosis in postmenopausal women: bone density vs. Bone DESTINY, SU251
- Assessment of the 10-year risk of fracture in Italian postmenopausal women using BMD and clinical risk factors, SU348
- Association between BMD change, use of antiresorptive agents and fragility fracture in women and men, SA364
- Association between femoral neck BMD and the factor-of-risk for hip fracture derived from direct measurements of strength in human cadaveric femora, 1070
- Association between polymorphisms in TNFR genes and circulating TNFR levels, and BMD in postmenopausal Korean women, M258
- Association between several factors affecting aortic calcification and BMD in postmenopausal women, SA489
- Association between vascular calcification and low total femur BMD in elderly people community-dwelling, SU453
- Association of CTR gene polymorphisms with BMD and fracture risk in postmenopausal Koreans, M256
- Association of *HSD11B1* polymorphisms with vertebral fracture risk and BMD in postmenopausal Korean population, M260
- Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261
- Bilateral bone density loss after unilateral disuse in the forearm, SA519
- Birth weight predicts bone size, adult weight predicts BMC and BMD in young Gambian adults, M498
- Bisphosphonates in children with hypercalciuria and reduced BMD, M429
- BMD and biochemical marker response rates in postmenopausal women after treatment with ZOL, F401
- BMD and body composition in postmenopausal women with psoriasis and psoriatic arthritis, SU337
- BMD and vertebral fracture in women with breast cancer and antiaromatase therapy, SA400
- BMD changes over time associated with illness and recovery in young women with anorexia nervosa, SA558
- BMD in children and adolescents with sickle cell disease, SU217
- BMD is associated with lean mass and not fat mass, SU273
- BMD measurement by DXA after a fragility fracture increases the likelihood of subsequent osteoporosis treatment, SU296
- BMD measurement: an independent risk factor of breast cancer recurrence?, SU265
- BMD response to treatment with rPTH in patients previously treated with bisphosphonates, M348
- BMD shows no peak from birth to youth as measured by QCT, F310
- BMD, fracture and survival in women in nursing/residential care, SA340
- BMD-associated SNP lies in a Runx2 binding site of the LRP5 promoter, M264
- Body fatness negatively associated with BMD and hip geometry indices in adolescents, F546
- Bone density changes at the non-operated hip following total hip arthroplasty, M408
- Bone density comparisons in young male rock climbers, weight lifters and sedentary controls, SA534
- Bone fragility beyond BMD: a French prospective experience, SU288
- Bone size, volumetric bone density in relation to fat mass in healthy young men at age of PBM, SU477
- Bone volumetric density, geometry and strength in male and female collegiate runners, SA539
- Carotid plaque causes low spinal BMD in Korean postmenopausal women with diabetes, SU359
- Changes in volumetric bone density and bone strength at the tibial midshaft in boys and girls 12-17 years of age, SU469
- Clinical prediction rule to identify women for BMD testing at menopause, SU271
- Clinical tool for adjusting BMD Z-scores for body size in growing children, 1105
- Comparison of the effects of IBN alone with IBN in combination with SNAC on bone density and bone strength in OVX rats, SU391
- Correlation of hip geometry and bone density with fragility fracture in Japanese postmenopausal women, SU466
- Correlations between panoramic radiomorphometric indices and BMD in postmenopausal women, SA311
- Deformity of the distal radius fractures resulting from falls in Japanese women over 50 years of age is closely associated with BMD of the lumbar spine, SU286
- Determinants of low BMD in HIV infected postmenopausal women, SU455
- Determinants of trabecular and cortical volumetric BMD differ in men of African ancestry, SU299
- Dietary patterns in Canadian men and women ages 25 and older: relationship to BMI and BMD, SU309
- Dkk-1 predicts the gain of BMD in osteoporotic women on bisphosphonates, SA300
- Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503
- Effect of a single infusion of ZOL 5 mg versus oral RIS 5 mg on BMD at lumbar spine, hip, femoral neck and trochanter in patients with GIO, F403
- Effect of DMAB vs ALN on bone turnover markers and BMD changes at 12 months based on baseline bone turnover level, 1285
- Effect of metabolic acidosis on BMD and bone microarchitecture in normal and OVX rats, M409
- Effect of once-yearly ZOL on integral BMD of the spine, SU405
- Effect of parity on BMD in premenopausal women, SA325
- Effect of RIS on bone density in HSC transplant patients, SU407
- Effect of RLX treatment on BMD might be influenced by UGT1A1\*28 polymorphism, M257
- Effect of ZOL (single 5-mg infusion) on lumbar spine BMD versus oral RIS (5 mg/day) over 1 year in subgroups of patients receiving GC therapy, M363
- Effects of a high g environment on BMD in UK fast-jet trainee pilots, SU473
- Effects of aromatase inhibitor therapy on BMD in hypogonadal elderly men, 1135
- Effects of diacylglycerol oil on body composition, BMD and bone strength in mice, SA442
- Effects of DMAB vs ALN on BMD, bone turnover markers, and safety in women previously treated with ALN, M395
- Effects of estrogen therapy and fluocalcic effervescent on the BMD and bone metabolism of surgical menopause women with osteopenia, M392
- Effects of low dose estrogen therapy on the BMD and bone metabolism of menopausal women, M393
- Effects of neurological impairment and functional mobility on BMD following stroke, SU364
- Efficacy and safety of monthly oral IBN in postmenopausal women with low bone density, SU384
- Epistasis between QTLs for bone density variation in Copenhagen X Dark Agouti F2 rats, M253
- Essential fatty acid and fish intake is associated with higher BMD in elderly women and men, F341
- Evaluating the effect of soy and isoflavones on BMD in older women, M353
- Evaluation of BMD changes in women with severe osteoporosis after TPTD treatment, M355
- Evaluation of BMD following an education intervention on osteoporosis offered to women after a fragility fracture, SU330
- Evaluation of tibial bone density surrounding Ta tibial implants in TKA, SU266
- Extended lactation is associated with failure to restore BMD 6 months after resumption of menstrual cycle, M305
- Femoral BMD and femoral structure, assessed by DXA-based hip structural analysis, contribute independently to femoral strength, M304
- Femoral strength, bone density, and aging in women and men, 1165
- FRAX™ and the assessment of ten-year fracture probability in Hong Kong Southern Chinese according to age and BMD femoral neck T-scores, SU264
- Frequent apheresis for platelet and plasma donations constitutes an independent risk factor for decreased BMD, F327
- Functional polymorphism in COL1A2 (Ala459Pro) that is associated with intracranial aneurysms, shows heterozygous disadvantage concerning BMD and stroke in elderly men, SU219
- Functionality outcomes including brisk walking speed are associated with BMD in postmenopausal women, SU418
- Gene transcripts related to T-cell activation, proliferation, and cytokine signaling show significant effects on BMD variation in baboons, M241
- GWAS of BMD and hip geometry indices, 1092
- GWAS reveals genetic variants associated with BMD, osteoporosis and osteoporotic fractures, SA263
- Hemodialysis patients rapidly lose their bone minerals after 60 years of age, SU438
- High impact exercise may have a protective effect on BMD but moderate impact exercise may have negative effect in young women with anorexia nervosa, M324
- High-fat diet facilitated decreases in BMD of OVX mice and suppressed the anabolic effects of PTH on bone, SA448
- Higher BMD is associated with increased odds of carotid atherosclerosis in postmenopausal women not currently using estrogen therapy, 1206

## Key Word Index

## ASBMR 30th Annual Meeting

Higher BMD loss in older men with diabetes, 1209

Hormonal influences on volumetric bone density and geometric properties in obesity, SU367

Impact of varying BMD resources on prediction of hip fracture using FRAX™, SU257

Impaired methylation capacity is associated with low BMD, SU317

Improved forearm BMD after treatment with Vitamin D<sub>3</sub> in a patient 30 years after bariatric surgery, SA492

Increases in BMD observed with Scl-Ab treatment are reversible, 1211

Influence of PHP on BMD and vertebral morphometry, M190

Influence of sex hormones on BMD in middle aged and elderly men, SU335

Integrative genetics approach to identify candidate genes regulating bone density: combining linkage, gene expression and association, M247

Interaction between the skeletal parameter BMD and lifestyle factors in 390 adolescent daughter-mother pairs, F548

Investigation into the impact of OA changes on BMD measurements in patients with high bone mass, SA257

Lack of correlation between glycemic control and BMD in type 2 diabetic women, SU255

Large scale candidate gene analysis identifies an association between the CDK6 locus and trabecular volumetric BMD at the lumbar spine in older men, M266

Lean body mass is a better predictor of BMD than leg power or grip strength in healthy caucasian adults, SU290

Linkage and association study of chromosome 1p36 with BMD in southern Chinese, SU295

Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, 1247

Low calcaneal BMD estimated by a periferal DXA heel scanner is associated with a high risk to have had a distal radius fracture, SU262

Low systemic BMD increases implant migration in cementless hip replacement, F458

Lumbar spine TBS complements BMD in the discrimination between vertebral fractured and non-fractured subject, M308

MACD index is a strong predictor of cardiovascular death and include the predictive power of BMD, SU463

Model of high body mass: BMD, bone markers and adipocytokine levels in high level male rugby players, SA167

Negative association between the metabolic syndrome and BMD in Korean adults, SU304

Obesity is associated with higher BMD, lower bone resorption and slower hip bone loss: are these associations mediated by adipokines?, SU369

Osteoblastic androgen receptor regulates cortical BMD, 1122

Patients with CKD and low 1/3 radius and femoral neck BMD have markedly abnormal cortical and trabecular microstructure by HR-pQCT, 1033

Patients with fragility fracture assessed by BMD, Bone DESTINY and osteoporosis Canada guidelines, SA343

Percutaneous injection of GEM OS2 increases vertebral BMD in geriatric female baboons, F376

Phased GWAS identifies probable new gene affecting BMD, M245

Physical activity, BMD and fragility fracture, M325

Physician practices in bone density testing among Medicare patients, SA428

Polymorphisms in *CYP24A1*, the gene encoding 25(OH)D-24-hydroxylase, are associated with BMD, SA266

Polymorphisms in the WIF1 gene are associated with BMD in elderly Swedish women, SA264

Poor peripheral nerve function is related to lower BMD, SA328

Positive Celiac disease serology and BMD in adult women, SA366

Positive influence of physical activity on BMD measurements and hip geometry parameters in young adults, M477

Post-fracture mortality in men: contributions of sex hormones and BMD as risk factors, 1280

Predictive validity of the WHO FRAX model, BMD and prevalent vertebral fracture for incident radiographic vertebral fractures, 1127

Preterm birth and BMD in young adulthood, 1103

Pretransplant parathyroid function predicts laboratory and BMD changes after kidney and kidney/pancreas transplantation, 1032

QUS, BMD and QCT in women with established osteoporosis treated with TPTD, SA393

Randomized, double-blind, placebo-controlled study of ODN (MK-822) in the treatment of postmenopausal women with low BMD, 1291

Recalculation of genome scans on a common genetic map enhances our ability to identify common bone density QTL in new and historical data, 1276

Reduction of BMD in the patients with RA is more remarkable at proximal femur than at lumbar spine, SU451

Regional differences of femoral BMD changes after one year once-monthly IBN as measured by 3D QCT, SU260

Reimbursement for BMD testing among US Medicare beneficiaries, SA326

Relationship among nutritional status, oxidative stress and bone density in institutionalized elderly, SU310

Relationship between BMD of the lumbar spine and knee OA in South Korean, SU298

Relationship between clinical risk factors for osteoporosis and BMD in women aged less than 50 years, SU355

Relationship between the metabolic syndrome and BMD in Korean middle-aged women, SU291

Relationship of bone turnover marker (PINP) and changes in femoral neck BMD to fracture risk in women with postmenopausal osteoporosis treated with once-yearly ZOL 5 mg, 1027

Relationship of QUS at phalanges with hand and axial BMD, sex hormones and bone turnover markers in elderly women, M320

Reproducibility of mineral density and morphometric  $\mu$ CT measurements at different voxel size scans, M311

Retrospective study evaluating the relationship of Vitamin D 25 OH and free testosterone levels with changes in hip bone density after liver transplantation, SA502

Risk factors for low BMD in healthy men age 50 years or older, SU341

Rosiglitazone-induced change in BMD among African Americans with type 2 diabetes mellitus or impaired glucose tolerance, SU315

Self-reported weight at birth predicts measures of femoral size but not volumetric BMD in elderly men, SU338

Significant association between polymorphisms of *CYP19A1*, fracture incidence and BMD in post-menopausal women, M262

Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349

Socioeconomic status, BMD testing and hip fracture rates in a universal health-care system, SU293

Study about the association of circulating MCP-1 levels with lumbar BMD in Korean women, M407

Ten-year change in BMD in a representative sample of Japanese women, SA330

Three year school-curriculum-based exercise program in prepubertal children increases bone mineral accrual and bone size but do not influence femoral neck structure, 1107

Timed Up and Go test and BMD as predictors of fracture, F373

Timing of repeated BMD measurements: development of an absolute risk-based prognostic model, F347

Transgenic ASARM-peptide overexpression with reduced serum phosphate and 1,25(OH)2D3 leads to decreased BMD and obesity, F210

Treatment discontinuation due to gastrointestinal adverse events and decreased BMD in patients switched from branded ALN to generic ALN, SA414

Type 1 diabetes is associated with lower BMD in premenopausal women but not in middle-aged men, SU456

Usefulness of alveolar bone density measurement in risk assessment for BRONJ, SA305

Validation of bone mineral measurements on the new Norland Model XR-600 and XR-800 using the BMIL QA/QC Phantom, SU252

Valproate: a model for adverse psychoactive drug effects on BMD, SA556

Variation in the osteocalcin gene: association study of BMD, fracture and changes in body fat mass in elderly women, SU225

Vertebral fracture in men: level of trauma, BMD and lean body mass, SU360

In vivo bone matrix density measurements by water and fat suppressed projection MRI (WASPI), SA102

In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154

Weight and BMI predict BMD and fractures in women 40 to 59 years, SA438

**Bone mineral density (BMD), volumetric**

Areal BMD by DXA may predict similar risk of fracture in elderly women and men due to offsetting effects of bone size and true volumetric BMD, SU267

Compartment specific genetic analysis of trabecular and cortical volumetric BMD in men, SU284

**Bone mineralization**

Aberrant *Phex* function in osteocytes has limited effects on bone mineralization in XLH, 1051

Altered TNSALP expression and phosphate regulation contribute to reduced mineralization in mice lacking androgen receptor, SU181

Deletion of the oxygen-sensor PHD2 in chondrocytes results in increased cartilage and bone mineralization, 1153

Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109

Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505

Effects of long-term administration of high-dose GH on body composition and bone mineralization, SA571

FGF-23 and FGF-2 share a common but also have distinct signaling pathways for negative regulation of bone nodule mineralization in cultured osteoblasts, SA206

Fluoride effects on bone formation, mineralization and mechanical properties are influenced by genetics, SU465

Human skeletal muscle cells undergo matrix mineralization in an osteogenic pellet culture assay, M135

Imaging of mineralization kinetics suggests that the transition from osteoblast to osteocyte initiates prior to mineral deposition, F062

Inactivation of the ILK in osteoblasts increases mineralization, M061

Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374

Inhibition of the mevalonate pathway rescues the DEX-induced suppression of the mineralization of osteoblastic cells, SA230

Li affects matrix mineralization by decreasing tissue non-specific ALP levels in osteoblasts, SA071

Long-term treatment with oral bisphosphonates in postmenopausal women: effects on the degree of mineralization and microhardness of bone, 1029

Low magnitude vibration can inhibit muscle loss and increase mineralizing bone surfaces in aging mice, M173

Mineralization is related to collagen cross-links in growing cancellous and cortical bone, SA110

Mineralization potential and orientational aspects of osteogenic cell cultures by Raman spectroscopy, M084

Molecular mechanisms underlying matrix vesicle-induced mineralization during bone formation, SA063

Notch signaling regulates osteoblast maturation transition to mineralization phase, SA068

Novel screening system for bone matrix proteins that control bone mineralization, SA108

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

Phex binds to SNARE-associated protein snapin and co-localizes in vesicle-enriched, extracellular matrix micro-environment mediating mineral crystal nucleation, F066

Prostaglandins enhance extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity in osteoblast-like cells, SU031

Proteins involved in mineralization expressions perturbations in bones and teeth of Msx2 mutant mouse mandibles, SA150

Requirement of the bone for Vitamin D for 1,25(OH) $_2$ D $_3$  synthesis and bone mineralization, M224

Solid-state  $^{31}$ P MRI quantifies mineralization changes in OVX rat bone, M422

**Bone morphogenetic protein (BMP)**

BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

Catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation, SU137

Dual roles of Smad proteins in the conversion from myoblasts to osteoblastic cells by BMPs, SA161

Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

Expression of BMP antagonists during fracture healing, SA160

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

Inhibition of BMP pathway and osteoclast activity in osteoblastic prostate cancer lesion in bone, F283

Integrin-associated protein upregulates osteogenesis-related transcription factors via TGF $\beta$  and BMP pathways, SA028

Interplay between BMP and TGF $\beta$  signaling in osteoblast differentiation, SA031

Negative regulation of Tcf/Lef-dependent transcription by the BMP/Smad4 signaling axis, SU144

Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, 1082

Regulation of bone formation by osteoclasts involves Wnt/BMP signaling and the chemokine S1P, M017

Regulation of chondrogenesis and bone development by neogenin via BMP pathway, SU127

Regulatory signaling pathways in BMP mediated osteogenesis of adult human MSC cultures, M060

Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043

TGF $\beta$  inhibits BMP signaling and osteogenesis through the TGF $\beta$  and BMP R-Smad direct interaction, 1080

TGF $\beta$ -and BMP-signaling pathways have antagonistic effects during chondrogenesis, F158

Traf2 regulates BMP signaling pathway in osteoblastic cells, M063

Transcription factor NFATp regulates BMP-induced chondrocyte differentiation in a tissue-specific manner, SU020

Wnt pathway regulation by demineralized bone requires TGF $\beta$ /BMP signaling, SU138

**Bone morphogenetic protein-1 (BMP-1)**

Circulating BMP-1 isoforms: novel diagnostic and therapeutic challenges for bone fracture repair, SU142

**Bone morphogenetic protein-2 (BMP-2)**

Ang-1 enhanced BMP-2 induced osteoblast differentiation, SU035

BMP-2 inactivates TAK1-ATF2 signaling pathway in chondrocytes, F186

BMP-2 induces Osx expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020

BMP-2 stimulates a feedback activation loop for expression of NFATc1 in osteoblasts, F002

BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/Akt regulates NFATc1 expression and its nuclear translocation, 1081

Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050

Conditional deletion of BMP-2 gene in early osteoblasts leads to reduction in the total bone marrow MSCs and their capacity to form osteoblast precursors, 1114

Coordinate regulation of PTHrP and PTHR1 in the osteoblast differentiation of C2C12 cells promoted by BMP-2, SA157

Dependence of post natal osteogenic differentiation on BMP-2, SA001

Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060

Effects of statins on eNOS and BMP-2 in osteoblasts, SU378

Identification of IRX3 a novel transcription factor during BMP-2 mediated osteoblast differentiation, SU024

Impaired bone healing in a BMP-2 KO mouse model of DO, SA159

INF $\gamma$  attenuates BMP-2 signaling via Stat-1 binding of Smad4 in the cytoplasm, SU139

Lxn is a novel effector of BMP-2 signaling in modulation of chondrocyte differentiation, SU117

Mechanism of BMP-2 enhancement of PGE $_2$  stimulated osteoclastogenesis, SU085

MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2, SA064

Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135

PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027

Program of miRNAs control BMP-2 induced bone phenotype development, M090

Regulation of the BMP-2 distant osteoblast enhancer by FGF-2, SU150

Soy-based formula promotes bone growth in neonatal piglets by inducing osteo-progenitors to differentiate into osteoblasts via enhanced BMP-2 signaling, SA336

Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036

**Bone morphogenetic protein-2, recombinant human (rhBMP-2)**

Functionalization of a PLGA/PEG-PLA composite electrospun scaffold with rhBMP-2 plasmid DNA for bone regeneration, SA124

rhBMP-2 accelerates segmental defect healing in diabetic rats, M445

**Bone morphogenetic protein-3 (BMP-3)**

BMP-3-null aged mice display increased trabecular bone volume and reduced cross sectional area at the mid-femoral diaphysis, SU143

**Bone morphogenetic protein-4 (BMP-4)**

Canonical Wnt signaling suppresses BMP-4 accumulation from C3H10T1/2 cells transfected with BMP-4 expression vector, SA156

**Bone morphogenetic protein-6 (BMP-6)**

BMP-6 from bone regulates serum glucose via IGF-1 released from pancreas, SU141

BMP-6 stimulated osteogenesis of HOB cultures is associated with suppression of PYK2, SU048

**Bone morphogenetic protein-7 (BMP-7)**

BMP-7 is not required for fracture healing, SU148

Efficacy of single-level instrumented posterolateral (intertransverse) lumbar spinal fusion in baboons with BMP-7 putty, SU146

Safety and efficacy of BMP-7 putty in a rabbit model of posterolateral vertebral lumbar fusion, SU149

**Bone quality**

Bone quality in Chinese-American and Caucasian women, SU464

Degradation of allograft bone quality by gamma irradiation is not explained by altered enzymatic or non-enzymatic cross-links, M460

Effects of running exercise on bone quality after immobilization, SA518

ODN increases bone strength and maintains bone quality in estrogen deficient adult rhesus monkeys, F508

QCT and FEA assessment of proximal femur bone quality and strength in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA509

Regulation of parameters of bone quality by MMP-2 and MMP-9, 1144

TR $\beta$ -specific agonist GC-1 increases bone quality of adult female mice, M228

**Bone regeneration**

Clinical application of resorbable polymers in guided bone regeneration, SA003

Functionalization of a PLGA/PEG-PLA composite electrospun scaffold with rhBMP-2 plasmid DNA for bone regeneration, SA124

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

N-terminal fragment of PTHrP promotes the GC-related deficiency of bone regeneration after bone marrow ablation in mice, M195

## Key Word Index

## ASBMR 30th Annual Meeting

SATB2 overexpression promotes osteoblast differentiation and enhances regeneration of bone defects, SU058

**Bone remodeling**

Central control of bone remodeling: neurohypophyseal hormone oxytocin is decreased in severe postmenopausal osteoporosis, M418

CT-1 is an osteoclast-derived coupling factor required for normal bone remodeling, M014

Development of empirical model using  $^{41}\text{Ca}$  for the study of bone remodeling in human, SA454

Do type I collagen homotrimers contribute to osteoporosis by altering bone remodeling?, SA146

Increased non-enzymatic glycation of cancellous bone due to decrease in remodeling during ALN therapy of osteoporotic women, 1071

Influence of IM on bone remodeling in juvenile mice, SA292

Mathematical model of remodeling cycles with feedback mechanism for maintaining the balance between bone resorption and formation, WG27

MEPE regulates bone remodelling independent of serum phosphate and alters renal vascularization, F205

Mice deficient in BSP display impaired modeling and remodeling and respond to ovariectomy but not to the cortical anabolic effect of PTH, 1191

Mice lacking the novel transmembrane protein Opt develop catastrophic defects in bone modeling, 1075

Microdamage repair and remodeling requires mechanical loading, 1299

NanoCT can be used to assess mechanically related modeling and remodeling in the mouse fibula, 1296

Neglected role of intracortical remodeling in age-related bone loss, 1101

PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038

PTH reverses abnormal bone remodeling and structure in HPT, 1036

Role of LIMK1 in osteoclast cytoskeletal remodeling and bone resorption, 1116

Secretomic analysis of Ca supplement-mediated bone remodeling, M022

T $\beta$ RI inhibitor rescues uncoupled bone remodeling in two different animal disease models, 1273

Vitamin D status and bone remodeling marker CTx-I in patients with early RA: association with disease activity and joint damage, SA496

**Bone repair**

Bone defect model in mouse femur to challenge biomaterials, cells and molecules for bone repair, SA126

Expression of an engineered G $_i$ -coupled receptor in osteoblasts affects intramembranous and endochondral bone formation during bone repair, F127

Inhibition of MMP activity delays bone repair whereas inhibition of osteoclast function and formation does not, SA075

**Bone resorption**

Acid-induced stimulation of bone resorption is decreased in OGR1 KO mouse calvariae, M021

Acute COPD exacerbations are associated with uncoupling of bone resorption from bone formation, M414

Are all anti-resorptive treatments the same? Lessons learned from inhibition of human osteoclastic bone resorption by alternative pathways, M129

Assessment of serum Ca and bone resorption markers in patients transitioned from ALN to DMAB, M394

Bone resorption and articular cartilage degenerative changes following performance of high repetition high force tasks are attenuated by secondary ibuprofen treatment, SA532

Bone resorption markers in saliva, M288

Cat K inhibitor, MIV-701, suppresses bone resorption markers in healthy postmenopausal women, F433

Changes of biochemical resorption markers during fracture healing in osteoporosis, M290

Decreased bone formation, increased bone resorption, and osteopenia in mice lacking SP, SU160

Disuse with a rapid bone loss affects the expression profile of osteoblastic and resorption genes, F516

Dock5, an essential Rac exchange factor in osteoclasts that controls adhesion structure organization and bone resorbing activity, SU064

Effect of luteolin on bone loss, microarchitecture and bone resorption in OVX mice, M128

Effects of resorption cavities on strength of trabecular bone, SA512

Effects of the Cat K inhibitor ODN on osteoclast-mediated bone resorption, M127

Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385

Exploring the effect of food intake on bone resorption for optimal drug delivery and efficacy in osteoporosis with oral calcitonin, SA436

Formation of podosome belts by osteoclasts on plastic correlates with resorptive activity, SU068

Fungal secondary metabolites beauvericin and enniatin inhibit osteoclast differentiation and bone resorption, M130

Gastric proton pump inhibitors failed to affect bone resorption and formation, SA095

GLP-2 acutely uncouples bone resorption and bone formation in postmenopausal women, M399

Identification of the regulatory mechanism(s) of PTP-PEST associating with the sealing ring formation and bone resorption in osteoclasts, SU065

Inactivation of *Dlx5* gene results in altered osteoblast-osteoclast coupling inducing increased bone resorption and reduced cortical thickness in male mice, F010

Increased osteoclast differentiation and bone resorption during spaceflight, SU094

Interaction of combined intervention of PTH and GH on trabecular and cortical bone formation and resorption in the hypophysectomized rats, SU502

Intermittent, short duration cyclic loading attenuates disuse osteoporosis without affecting resorption, M483

Lack of seasonal variation of bone resorption in elderly women in relation to periodicity of sunlight exposure at a northerly latitude, F337

Long-acting PTH ligand that binds to a distinct PTH receptor conformation (R0) can stimulate increases in markers of both bone resorption and bone formation in mice, F221

Mathematical model of remodeling cycles with feedback mechanism for maintaining the balance between bone resorption and formation, WG27

Menopausal and postmenopausal women have significantly higher bone resorption and oxidative stress parameters than premenopausal women, SU336

Mice deficient in *Pyk-2* have impaired OVX-induced bone resorption, F098

Microarchitecture and tissue age influence in vivo bone resorption, M125

Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238

Obesity is associated with higher BMD, lower bone resorption and slower hip bone loss: are these associations mediated by adipokines?, SU369

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

Pyrophosphates stimulates osteoclast differentiation and bone resorption, SA084

Resorption mechanism of HA and  $\beta$ TCP coating layer, SA100

Role of LIMK1 in osteoclast cytoskeletal remodeling and bone resorption, 1116

Sca-1 $^{+}$  HSC-based hGH gene therapy enhanced endosteal bone resorption in mice, M233

Scl-Ab increases bone formation and decreases bone resorption in distal tibial metaphyseal trabecular bone in OVX rats, F394

Scl-Ab increases bone mass by stimulating bone formation and inhibiting bone resorption in a hindlimb-immobilization rat model, 1138

SHBG levels in older patients with acute hip fracture are correlated with worse function and increased bone resorption, SU363

Soluble activin receptor type IIA fusion protein, ACE-011, increases bone mass by stimulating bone formation and inhibiting bone resorption in cynomolgus monkeys, SU376

Suppression of bone resorption markers by Ca and Vitamin D separately and in combination, M329

Systemic IL-8 increases bone resorption in vivo, 1234

TGF $\beta$ 1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

TOR inhibits osteoclast activity in vitro and prevents orchietomy-induced bone resorption in male rats, SA381

Toward a physiologically-based definition of hypogonadism in men: dose-response relationship between testosterone and bone resorption, 1102

Transgenic overexpression of the Wnt antagonist Krm-2 in osteoblasts leads to severe impairment of bone formation and increased bone resorption, 1003

TSG-6 acts synergistically with OPG to inhibit bone resorption, SA097

**Bone restricted ifitm-like (Bril)**

Bril localization in mouse and rat bones, M025

**Bone sialoprotein (BSP)**

BSP deficiency impairs osteoclast differentiation and resorption in vitro, SA142

Mice deficient in BSP display impaired modeling and remodeling and respond to ovariectomy but not to the cortical anabolic effect of PTH, 1191

**Bone sialoprotein 2 (BSP2)**

c-Src-regulated osteoblast-mimicry in breast cancer bone metastasis: the role of RAMP2 and BSP2, M275

**Bone size**

Areal BMD by DXA may predict similar risk of fracture in elderly women and men due to offsetting effects of bone size and true volumetric BMD, SU267

Birth weight predicts bone size, adult weight predicts BMC and BMD in young Gambian adults, M498

Bone size, volumetric bone density in relation to fat mass in healthy young men at age of PBM, SU477

Characterization and genetic mapping of bone size phenotypes in GK and F344 rats using a new 3D CT method, M463

Is GH/IGF-I mediated mechanism involved in regulating gender differences in bone size?, SA180

Serum IGF-1 is a developmental determinant of bone size, SA183

Targeted disruption of Nrf1 in osteoblasts leads to reduced bone size and dramatic alterations in trabecular bone microstructure in mice, 1190

Three year school-curriculum-based exercise program in prepubertal children increases bone mineral accrual and bone size but do not influence femoral neck structure, 1107

**Bone strength**

12 months of TPTD therapy increases ultradistal radius bone strength in severely osteoporotic postmenopausal women, SA504

Age at menarche associated with bone strength in girls, SU493

Arterial compliance is associated with change in bone strength in children, F552

Blocking TGF $\beta$  signaling reduces gammopathy and improves bone volume and strength in vivo, F293

Bone geometry and bone strength are compromised in patients with ACL reconstruction, M487

Bone geometry, strength, and muscle mass in female distance runners with a history of stress fracture, SA540

Bone strength in overweight children is adapted to mechanical loads from walking, but is low for higher loading activities, M482

Bone strength measurement: new approach, SU249

Bone volumetric density, geometry and strength in male and female collegiate runners, SA539

BZA in combination with conjugated estrogens improves bone mass and strength in the OVX rat, SA385

Changes in volumetric bone density and bone strength at the tibial midshaft in boys and girls 12-17 years of age, SU469

Comparison of HR-pQCT to DXA and QUS for the assessment of ex-vivo bone strength, M466

Comparison of the effects of IBN alone with IBN in combination with SNAC on bone density and bone strength in OVX rats, SU391

Does adiposity affect bone strength indices in young adult black females?, SU318

Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503

Effect of 1,25(OH) $_2$ D $_3$  and 25(OH)D $_3$  on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207

Effect of exercise on geometric bone structure and bone strength in postmenopausal women, M484

Effect of non-ambulation on bone strength in boys with DMD, WG1

Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505

Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244

Effects of ALN or DMAB on cortical and trabecular bone mass, bone strength, and bone mass-strength relationships in mice, 1139

Effects of diacylglycerol oil on body composition, BMD and bone strength in mice, SA442

Environmental perturbations during puberty and bone strength, M501

Femoral BMD and femoral structure, assessed by DXA-based hip structural analysis, contribute independently to femoral strength, M304

G171V and A214V Lrp5 knock-in mice have increased bone mass and strength, and can help precisely define the in vivo functions of Lrp5 during bone growth and homeostasis, 1002

GWAS identified RTP3 as a novel gene for bone strength, SU331

Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380

Is increased bone fragility during adolescence a result of delayed development in bone bending strength?, M500

Mouse-to-human strategy to identify bone strength QTL genes, SA120

Muscle power and tibial bone strength in older women, SU362

ODN increases bone strength and maintains bone quality in estrogen deficient adult rhesus monkeys, F508

Overweight children are more at risk to sustain a forearm fracture due to poor bone strength relative to body weight, M458

OVX-induced hyperphagia does not modulate bone mineral or bone strength in female Sprague-Dawley rats, SA447

QCT and FEA assessment of proximal femur bone quality and strength in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA509

Transition from ALN to DMAB in OVX cynomolgus monkeys maintained or improved cortical and trabecular bone mass, without altering the linear relationship between bone mass and bone strength, 1072

Women who fractured their hips experience greater loss of geometric strength in the contralateral hip during the year following fracture compared to age-matched controls, F345

#### Bone structure

Alterations in bone structure and growth in dwarf rats with a depressed GH/IGF-I axis, SA178

Cortical bone mass and structure in older Afro-Caribbean and Caucasian men, SU300

Deleterious effect of late menarcheal age on bone microstructure in both distal radius and tibia, 1239

Effect of exercise on geometric bone structure and bone strength in postmenopausal women, M484

Evaluating bone microstructure at the distal tibia in children, F315

GC signaling in osteoblasts maintains normal bone structure in mice, F233

Gender-specific changes in bone microstructure of mice lacking ribosomal protein L29/HIP, SA133

Non-invasive detection of bone microdamage by light scattering, M462

PTH reverses abnormal bone remodeling and structure in HPT, 1036

Target ablation of PPR in osteocytes induces hypocalcemia and impairs bone structure, 1158

#### Bone turnover

$\mu$ CT abnormalities in the th3 mouse model of thalassemia start at a young age and are associated with decreased bone turnover, SA128

Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261

Bone turnover and incident hip fracture risk, M285

Bone turnover evaluated by a combined Ca balance and  $^{45}$ Ca kinetic study, and dynamic histomorphometry, M137

Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026

Development of an animal model of bisphosphonate-induced severe suppression of bone turnover, SA511

Effect of a single 5-mg infusion of ZOL on bone turnover markers versus oral RIS (5 mg/day) over 1 year in patients with GIO, M362

Effect of bed rest on bone turnover in adolescents hospitalized for anorexia nervosa, SA559

Effect of DMAB vs ALN on bone turnover markers and BMD changes at 12 months based on baseline bone turnover level, 1285

Effects of ARZ on bone turnover and safety in postmenopausal women with low bone mass, M386

Effects of DMAB vs ALN on BMD, bone turnover markers, and safety in women previously treated with ALN, M395

Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

Effects of LASO on bone turnover markers, 1287

Effects of ODN on bone mass and turnover in estrogen deficient adult rhesus monkeys, SA072

High bone turnover in mice lacking the growth factor Mdk, 1198

Impact of physical inactivity (10 days bed rest) on markers of bone turnover in young men with low and normal birth weight, SA456

Increased proinflammatory cytokines TNF- $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

Influence of markers of bone turnover on calcaneal QUS, SA457

Longitudinal relationships between cartilage and bone turnover in OA, SA129

Optimization of bone turnover marker measurements in a mouse model of GC-induced osteoporosis, M298

Osteosclerotic prostate cancer metastasis to murine bone: enhanced with increased bone turnover, SA269

Predictive capacity of biochemical markers of bone turnover and endogenous hormones for osteoporosis in men, SU334

Premenopausal reference ranges of bone turnover markers and the effect of bisphosphonates in Korean postmenopausal women, SU406

Previous antiresorptive agents use did not hinder the increase of bone turnover marker in TPTD use, M351

PTH increases bone turnover in HPT, F485

Randomized double blinded controlled trial of individual response in biochemical markers of bone turnover to LASO therapy, M507

Relationship between serum levels of inflammatory cytokines and bone turnover markers in the year following hip fracture, SU073

Relationship of bone turnover marker (PINP) and changes in femoral neck BMD to fracture risk in women with postmenopausal osteoporosis treated with once-yearly ZOL 5 mg, 1027

Relationship of QUS at phalanges with hand and axial BMD, sex hormones and bone turnover markers in elderly women, M320

Skeletal plasma clearance, as measured by quantitative radionuclide studies, is correlated with bone turnover markers at 3 months of TPTD therapy, F398

Transition from ALN to DMAB resulted in further reductions in local and systemic bone turnover parameters and reduced cortical porosity in OVX cynomolgus monkeys, 1216

Vitamin D deficiency, osteomalacia and high bone turnover in patients with NF-1, F465

Wintertime Vitamin D supplementation inhibits seasonal variation of calcitropic hormones and maintains bone turnover in healthy men, SU433

**Bone turnover, severe suppression of (SSBT)**

Effect of SSBT on osteocyte viability, F405

## Key Word Index

## ASBMR 30th Annual Meeting

**Bone volume**

- Abrogation of Cbl-PI3K interaction in mice results in increased bone volume and osteoblast proliferation, 1150
- Blocking TGF $\beta$  signaling reduces gammopathy and improves bone volume and strength in vivo, F293
- BMP-3-null aged mice display increased trabecular bone volume and reduced cross sectional area at the mid-femoral diaphysis, SU143
- Comprehensive genetic analysis of bone volume in men, M268
- Determinants of humeral bone volume in males, F122
- HDI, Vorinostat, blocks growth and associated osteolysis of cancer cells within bone, but reduces bone volume in non-tumor bearing bones in mice, M279
- Increased bone volume and correction of HYP mouse hypophosphatemia in the Klotho/HYP Mouse, 1017
- Mice lacking the GH receptor in liver have normal skeletal growth and bone volume despite virtual absence of circulating IGF-1, F181

**Boron (B)**

- Carborane BE360, one of the carbon-containing polyhedral boron-cluster compounds, is a new type of selective estrogen receptor modulator., SU187

**Bortezomib (Bzb)**

- Bzb, a proteasome inhibitor, prevents metastatic breast cancer osteolysis and reduces mammary fat pad tumor growth in mice, F277

**Brachy-syndactyly**

- Brachy-syndactyly caused by loss of *Sfrp2* function, F118

**Breast cancer. See Cancer****Breastfeeding**

- Vitamin D supplementation in breast fed infants, SU500

**BRM**

- Depletion of the chromosome remodeling subunit BRM accelerates differentiation of osteoblast precursors, M038

**BrtlIV**

- In utero stem cell therapy as treatment for classical OI using the knock in murine model BrtlIV, F500

**BT-201**

- BT-201, a butanol extract of *Panax notoginseng* inhibits progression of joint degeneration in a rat model of OA, M152

**Butanol**

- BT-201, a butanol extract of *Panax notoginseng* inhibits progression of joint degeneration in a rat model of OA, M152

**Butyrate**

- Butyrate stimulates mineralized nodule formation and OPG expression by osteoblasts, M012

**C****C-fms**

- Recombinant mouse M-CSF receptor C-fms inhibits TNF $\alpha$ -induced osteoclastogenesis, M112

**c-Fms**

- Vimentin binds c-Fms in an M-CSF dependent manner and regulates osteoclast differentiation, SU097

**c-Fos**

- c-Fos is associated with renal FGF-23-mediated signaling, SU173

**c-Jun N-terminal kinase (JNK)**

- JNK activation is involved in TNF $\alpha$ -stimulated Smurf1 expression, SA016
- Phosphate induced apoptosis in growth plate chondrocytes via a NO and JNK-dependent pat, SA113

- Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177

**C-propeptides**

- Interaction of Ciz, a nucleocytoplasmic shuttling transcription factor with C-propeptides of type I collagen, M044
- Mouse with a Ser1386Pro mutation in the C-propeptide domain of *col2a1* provides a model for SEDC, 1269

**c-Src**

- c-Src-regulated osteoblast-mimicry in breast cancer bone metastasis: the role of RAMP2 and BSP2, M275
- Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119

**C-telopeptides**

- C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292
- Relationship of urinary excretion of C-telopeptides to growth in children, F301

**C-terminus**

- C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223
- MEPE C-terminal ASARM-peptide, promotes hypophosphatemia, bone defects and increases adiposity, F207
- PTHrP nuclear localization sequence and C-terminus regulate craniofacial development, 1264

**C/EBP $\alpha$** 

- Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

**C/EBP $\beta$** 

- Transactivation of RANKL by C/EBP $\beta$  and C/EBP $\delta$  in adipocyte lineage cells, SU092

**C/EBP $\delta$** 

- Transactivation of RANKL by C/EBP $\beta$  and C/EBP $\delta$  in adipocyte lineage cells, SU092

**c.1250A>G**

- c.1250A>G, p.N417S is a common American TNSALP mutation involved in all clinical forms of HPP, including pseudo-HPP, SA566

**C1**

- Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240

**C2**

- Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240

**C2C12**

- Coordinate regulation of PTHrP and PTHR1 in the osteoblast differentiation of C2C12 cells promoted by BMP-2, SA157
- Effect of 1 $\alpha$ ,25-dihydroxy Vitamin D3 on proliferation and differentiation of C2C12 myoblast, SA245
- Hypoxia promotes ligand-independent activation of the ACVR1 (R206H) mutant receptor in C2C12 cells, M243

**C3H/Hej**

- Load induced changes in trabecular and cortical bone are dose dependent in both C57BL/6 and C3H/Hej mice, F527

**C3H10T1/2**

- Canonical Wnt signaling suppresses BMP-4 accumulation from C3H10T1/2 cells transfected with BMP-4 expression vector, SA156
- Enhanced mitochondrial biogenesis contributes to Wnt induced osteogenic differentiation of C3H10T1/2 cells, SA043
- Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

- Overexpression of  $\alpha$ -catenin in C3H10T1/2 cells increases osteoblast differentiation, SA046

**C4**

- Isoform-specific expression of PPARs and gene regulation during osteoclastogenesis in RAW/C4 cells, M118

**C57**

- Effect of Pb on bone mineral properties from female adult C57/BL6 mice, M146

**C57BL/6**

- Femur from C57BL/6 and DBA/2 inbred mice display a strain dependent response to treadmill running and tower climbing exercise in cortical and trabecular bone architecture, M485
- Load induced changes in trabecular and cortical bone are dose dependent in both C57BL/6 and C3H/Hej mice, F527
- Low dose administration of INF $\gamma$  stimulates osteoblastogenesis and prevents ovariectomy-induced osteoporosis in C57BL/6 mice, M334

**Caco-2**

- Molecular mechanisms involved in PTH-induced apoptosis in Caco-2 intestinal cells, M189

**Cadmium (Cd)**

- Ca release from bone in postmenopausal women: effects of low level Cd exposure, M328
- High level dietary P and Cd exacerbate OVX-induced bone loss, M301

**Calcaneus**

- Calcaneal QUS measurement of 2323 healthy adults in southwest China, M318
- Longitudinal analysis of calcaneal QUS measures during childhood, M321
- Mechanical unloading of the sheep calcaneus: a model for hip fracture, M478
- Normal reference values for QUS bone densitometry of the calcaneus in Chinese children and adolescents, SU489
- RTA of densitometric calcaneal images differs between subjects with and without GC use, M314

**Calcein**

- Intestinal-specific VDR null mice maintain normal calcein but display severe bone loss, F238

**Calciol**

- Decreasing calciol (25OHD3) in serum is related to impaired function and increased mortality in the elderly, SU204
- Differential effects of GH and 1  $\alpha$  calciol on cancellous and cortical bone in hypophysectomized rats, SU501

**Calcification**

- Calcifications in children with JDM contain several bone formation markers, SA106
- Cartilage engineered with a calcified zone enhances interfacial shear strength to the underlying substrate, M176
- Strain-induced fluid flow in a 3D porous matrix promotes osteoblastic calcification in vitro, SA525

**Calcification, arterial**

- OPN deficiency reduces aortic calcification and oxidative stress in diabetic LDLR $^{-/-}$  mice, F109
- Specific inhibitors of TNSAP's pyrophosphatase activity suppress medial arterial calcification, M142

**Calcification, coronary artery**

- Ca intake is not associated with increased coronary artery calcification, 1207

**Calcification, renal**

- High expression of the Ca/phosphate-regulating hormone STC2 is associated with renal calcification in the Klotho mutant mice, SA201

**Calcification, vascular**

- Association between vascular calcification and low total femur BMD in elderly people community-dwelling, SU453
- Bridging vascular calcification and osteoporosis: the function of receptor activator of nuclear factor  $\kappa$ B, M419

Protective actions of Vitamin D analogs in the vascular calcification of CKD, SU450

**Calcineurin**

Nicotine induces chondrogenesis via calcineurin/NFAT, SU133

PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calcineurin pathways, SA033

**Calcinosis, tumoral**

Homozygous threonine to methionine substitution in FGF-23 gene is associated with tumoral calcinosis in a 12 year-old girl, SU171

**Calciophylaxis**

Calciophylaxis in a patient with HPT and normal kidney function, WG33

**Calcitonin**

Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261

Calcitonin attenuates the anabolic effect of PTH in vivo and rapidly upregulates SCT expression, F195

Calcitonin intramuscular administration for treating acute pain of osteoporotic vertebral compression fractures, SA196

Calcitonin receptor on osteoclasts plays a physiological role to protect against HCa in mice, SA197

Exploring the effect of food intake on bone resorption for optimal drug delivery and efficacy in osteoporosis with oral calcitonin, SA436

Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194

Possible central function of the calcitonin receptor on bone mass, SA255

Subcutaneous administration of salmon calcitonin: bone protective effect in adjuvant arthritis prevention model in rats, SA193

**Calcitonin receptor (CTR)**

Association of CTR gene polymorphisms with BMD and fracture risk in postmenopausal Koreans, M256

High bone mass due to increased bone formation in mice lacking the CTR, SA192

**Calcitonin-gene related peptide (CGRP)**

CGRP stimulates osteogenesis and inhibits osteoclastogenesis in vitro, SU033

**Calcitriol**

Comparison of 1,25(OH)<sub>2</sub>D<sub>2</sub> and calcitriol effects in an adenine-induced model of CKD reveals differential control over serum Ca and phosphate, SU448

**Calcium (Ca)**

25(OH)D acts on Ca and skeletal homeostasis independent of 1,25(OH)<sub>2</sub>D in vivo, M214

Activation of FGF receptors is a novel mechanism by which extracellular Ca stimulates the proliferation of osteoblasts, M088

Ahnak regulates Ca signaling and ATP release in osteoblasts in response to mechanical stimulation, SA027

Alpha-Ca/CaMKII controls osteosarcoma cell migration, SU234

Assessment of serum Ca and bone resorption markers in patients transitioned from ALN to DMAB, M394

Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261

Bone health impairment in children with chronic Ca and Vitamin D deficiency due to nutritional allergies, SU503

Bone turnover evaluated by a combined Ca balance and <sup>45</sup>Ca kinetic study, and dynamic histomorphometry, M137

Ca intake and serum bone formation markers are associated with the functional single nucleotide polymorphism in the TNSALP gene, SU308

Ca intake is not associated with increased coronary artery calcification, 1207

Ca release from bone in postmenopausal women: effects of low level Cd exposure, M328

Ca signaling is a major target of OCT-1547, a small molecule osteoporosis drug candidate, M339

Comparison of 1,25(OH)<sub>2</sub>D<sub>2</sub> and calcitriol effects in an adenine-induced model of CKD reveals differential control over serum Ca and phosphate, SU448

Controlled drug release from Ca phosphate-based orthopaedic implants, SU235

Development of empirical model using <sup>41</sup>Ca for the study of bone remodeling in human, SA454

Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

Different influence of the clinical condition, degree of cholestasis, alcohol abuse and serum Ca on the musculoskeletal system in chronic cirrhotics, M411

Differential cellular and molecular responses of intestinal epithelium to high Ca diet and 1,25(OH)<sub>2</sub>D<sub>3</sub>, M229

Direct correlation of osteocyte deformation with Ca influx in response to fluid flow shear stress, SA057

Effect of particle size of Ca carbonate supplement on Ca retention in adolescent girls, SA545

Effect of the dietary Ca/P ratio on the rate of skeletal accrual in mice, M333

Effect of Vitamin D<sub>3</sub> and Vitamin D<sub>2</sub> on intestinal Ca absorption in Nigerian children with rickets, SA560

Effects of 50,000 IU of Vitamin D<sub>2</sub> twice per month on circulating 25(OH)D and Ca levels, SU426

Effects of agave inulin on Ca metabolism in Japanese young adults, M332

Effects of different extracts of *Fructus ligustri lucidi* on Ca balance in normal female rats, M336

Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

Endocytotic processes underlying Ca-induced inhibition of plasma membrane V-ATPase in murine osteoclasts, SU101

Evidence for a role of prolactin in Ca homeostasis: regulation of intestinal TRPV6 and intestinal Ca absorption by prolactin, 1223

FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177

Goettingen minipigs—a model for Ca/Vitamin D-deficiency osteomalacia and steroid-induced osteoporosis, SA445

High expression of the Ca/phosphate-regulating hormone STC2 is associated with renal calcification in the Klotho mutant mice, SA201

Impact of dietary protein on Ca homeostasis and nitrogen excretion in the presence and absence of KHCO<sub>3</sub>, SU305

Infantile HCa: relationship of dietary intake of Ca and Vitamin D to serum and urine levels, SU491

Is it time to update normative values for ionized Ca and urine Ca? Creatinine ratios in healthy Canadian infants, SU487

Medullary carcinoma of the thyroid and anomalies of the Ca metabolism, SU246

Osteocytic perilacunar remodeling as a significant source of Ca during lactation, M110

Osteofornin increases the levels of intracellular Ca of human preosteoblast cells in culture, SU051

Osteopenia in CKD: effects of Ca overload, SU449

Osteoporosis patients behaviours and understanding of the importance of Ca and Vitamin D supplementation, M331

Pediatric Crohn's Disease is associated with negative Ca balance and increased renal losses of Ca, SA565

Pregnancy upregulates duodenal Ca-transport genes and normalizes Ca homeostasis in *Vdr* null mice, M230

Prevention of nutritional rickets in Nigerian children with dietary Ca supplementation, M491

PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calcineurin pathways, SA033

RANKL induces Ca channel activation in human osteoclasts, SU107

Relationship between physical fitness and bone and physical activity and Ca retention in adolescent girls, SA553

Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211

Rodent model to evaluate the effect of dietary protein on intestinal Ca absorption, M330

Secretomic analysis of Ca supplement-mediated bone remodeling, M022

Serum PTH response to oral Ca load in Asian adolescents, M188

Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, 1089

Suppression of bone resorption markers by Ca and Vitamin D separately and in combination, M329

**Calcium channels, voltage sensitive (VSCC)**

Assessment of changes in thoracic and lumbar vertebrae in T-type Ca<sub>v</sub>3.2 (a1H) VSCC KO mice, M170

**Calcium, serum ionized (iCa)**

Acute change in iCa directly affects bone formation independent of PTH action during hemodialysis, SU437

**Calcium-sensing receptor (CaSR)**

Activation of the CaSR by beta-aspartyl and gamma-glutamyl peptides, M202

Bone-building effects of the oral CaSR antagonist, ronacaleret, in OVX rats, SU372

CaSR gene A986S polymorphisms: relation to bone loss and urine Ca in a Spanish early postmenopausal women population, M255

CaSR mediated signaling in human vascular smooth muscle cells, M200

Conditional knockout of the CaSR in osteoblasts alters regulators of Wnt signaling, delays cell differentiation, and promotes apoptosis in bone, 1156

Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

Dimerization and trafficking of the CaSR to the plasma membrane, M205

Efficient expression of the full-length CaSR in insect cells, M198

Functional characterization of unreported CaSR in four Italian kindreds with FHH, M204

GCM2, the regulator of parathyroid cell fate, transactivates the CaSR gene, M187

Molecular diagnostic strategies for mutations of the CaSR gene, M201

Novel CaSR antagonist leads to dose-dependent transient release of PTH after oral administration to healthy volunteers, 1173

Ronacaleret, a novel CaSR antagonist, demonstrates potential as an oral bone-forming therapy in healthy postmenopausal women, 1174

Sr ranelate decreases osteoblast-induced osteoclastogenesis through the involvement of the CaSR, F389

Sr ranelate protects osteoblasts from apoptosis independently of the CaSR, M007

## Key Word Index

## ASBMR 30th Annual Meeting

Tissue-specific KO of the CaSR in chondrocytes inhibits IGF-1 signaling and delays differentiation in the growth plate, 1261

***Callorhinchus milii***  
PTH-gene family in the cartilaginous fish, *Callorhinchus milii*, M183

**Calmodulin 3 (CALM3)**  
In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154

**Calmodulin dependent kinase II (CaMKII)**  
Alpha-Ca/CaMKII controls osteosarcoma cell migration, SU234

**Calpain**  
Impact of calpain inhibition on chondrocyte development, M150

**Camargo Cohort Study**  
Vitamin D status, bone mass, and bone metabolism in postmenopausal women and men older than 50 attended in a primary care center of Spain, M223

**CaMOS Study**. See *Canadian Multicentre Osteoporosis Study*

**cAMP**. See *Adenosine monophosphate, cyclic*

**cAMP response element binding (CREB) protein**  
Cloning and functional analysis of human Nurrl (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161

**Camurati-Engelmann disease (CED)**  
CED: a unique variant featuring a novel, heterozygous, leucine repeat mutation in *TGFβ1* together with a novel, homozygous, missense change in *TNFSF11* encoding RANKL, F256

**Canadian Multicentre Osteoporosis (CaMOS) Study**  
10-year probability of recurrent osteoporotic fractures after a primary wrist fracture in postmenopausal women enrolled in the CaMOS cohort, F358  
Association of urine measures of diet-derived acid excretion with bone loss and fractures, SU283  
Fractures of the spine and hip increase the risk of death in Canadians, SU351  
Normative Z-scores from the CaMOS youth cohort, SU292  
Physical activity, BMD and fragility fracture, M325  
Population burden of first and repeat low-trauma fractures, 1056  
Reduced renal function is associated with increased rates of bone loss at the hip and spine, SU357

**Canadian Quality Circle (CQC) National Project**  
Family physician characteristics that predict appropriate x-ray ordering, SA359

**Cancellous bone**  
Beta-adrenergic receptor agonist administration during hindlimb unloading effectively mitigates reductions in cancellous bone formation, SA514  
Combined Cs-137 gamma irradiation and hindlimb unloading rapidly decreased cancellous bone volume fraction in the mouse lumbar vertebrae, M469  
Differential effects of GH and 1 alpha calcidol on cancellous and cortical bone in hypophysectomized rats, SU501  
Effects of intermittent human PTH administration on bone union with hydroxyapatite blocks at the site of cancellous bone osteotomy in OVX rats, SA214  
Increased non-enzymatic glycation of cancellous bone due to decrease in remodeling during ALN therapy of osteoporotic women, 1071  
Mineralization is related to collagen cross-links in growing cancellous and cortical bone, SA110

Treadmill exercise provides only short-term protection against cancellous bone loss with reduced dietary energy intake: endocrine mechanisms, SA449

**Cancer**  
2ME2 alters eIF4E activity and causes protein synthesis inhibition in osteosarcoma cells, SU240  
Activin A mediates MM bone disease which is reversed by RAP-011, a soluble activin receptor, 1231  
Alpha-Ca/CaMKII controls osteosarcoma cell migration, SU234  
Biomechanical and geometrical property changes in rat tibias with tumor-induced osteolysis after anti-resorptive or anti-cancer treatments, SU236  
Blocking TGFβ signaling reduces gammopathy and improves bone volume and strength in vivo, F293  
BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242  
Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287  
CXCL12 expression is regulated by HIF-2α in MM plasma cells, SU080  
CXCL13 stimulates RANK ligand expression in SCC, SU247  
Disruption of the syndecan-1/integrin axis is a novel target for myeloma therapy, 1229  
DKK1 is regulated by mRNA stability and epigenetic mechanisms in bone metastasis, 1090  
Drugs which inhibit osteoclast function suppress tumor growth and alter hematopoietic cell populations in bone, F270  
EphB4 expression in osteoblasts is regulated by myeloma cells and the Wnt signaling pathway, SU232  
FGFR signaling in the pathogenesis of osteosarcoma, 1233  
Fracture risk in patients with different types of cancer, SA290  
HDI, Vorinostat, blocks growth and associated osteolysis of cancer cells within bone, but reduces bone volume in non-tumor bearing bones in mice, M279  
Hedgehog pathway is activated in osteosarcoma and cyclopamine prevents osteosarcoma growth by cell cycle regulation, SU241  
Hfg inhibits melanoma bone metastases and TGFβ signaling, F190  
Host bone marrow-derived stromal cells promote myeloma initiation and development of osteolysis, 1088  
Identification of RhoB as a key target involved in cell motility and bone metastasis, F291  
Important contribution of the immune system in regulating the tumor/bone vicious cycle independent from osteoclasts, 1086  
Increased signaling through p62 in the MM microenvironment increases myeloma cell growth and osteoclast formation, SA289  
Influence of IM on bone remodeling in juvenile mice, SA292  
Inhibition of HIF-1α alone or combined with TGFβ blockade prevents breast cancer bone metastases, 1085  
Inhibition of MM growth and preservation of bone with combined radiotherapy and anti-angiogenic agent, SA285  
Melanoma-induced bone loss is mediated by the rapid recruitment of osteoclasts, SU233  
Microarray analysis of human bone metastases evidenced a set of genes that segregates patients with metastases only in bone from patients with metastases also in visceral organs, M272  
Monoclonal antibody to TGFβ inhibits tumor burden and osteolysis in a pre-clinical model of bone metastasis, SA187  
Monthly intravenous ZOL suppresses tissue-level remodeling significantly more than daily oral ALN in the mandible and rib of skeletally mature female dogs, SU388

Notch pathway is activated in osteosarcoma and inhibitors of γ-secretase inhibit osteosarcoma growth by cell cycle regulation, SU229  
Novel splicing variants of ADAM8 stimulate tumor-induced bone metastasis by increasing invasion and osteoclastogenesis, F286  
Opposing effects on bone metastases of tumor ADM expression in breast and prostate cancer, M277  
PGE receptor EP4 antagonist attenuates growth and metastases of cancer, 1230  
Platelets contribute to circulating levels of Dkk-1: clinical implications in MM, SU228  
Preclinical validation of a novel Dkk1 neutralizing antibody for the treatment of MM related bone disease, SU239  
Role of AXII and AXIIR in homing MM cells in the bone marrow, SA287  
Role of FAP and DPP4 in myeloma bone disease and tumor growth, F288  
Systemic IL-8 increases bone resorption in vivo, 1234  
TGFβ suppresses adipocytic differentiation and enhances accumulation of stromal cells in myeloma bone lesions, SA294  
TSP-1 and CD47 regulate osteoclastogenesis but have distinct effects on bone metastasis, 1232  
Wnt/β-catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243  
ZOL inhibits the capacity of myeloid-immune suppressor cells in myeloma to form osteoclasts, SU230

**Cancer, bladder**  
BAMBI gene is epigenetically silenced in a subset of high-grade bladder cancer, SU245

**Cancer, breast**  
BMD and vertebral fracture in women with breast cancer and antiaromatase therapy, SA400  
BMD measurement: an independent risk factor of breast cancer recurrence?, SU265  
Breast cancer cell conditioned media stimulates osteoblastic cells to attract breast cancer cells, SA276  
Breast cancer derived factors synergize with TGFβ to induce phosphorylation of ERK1/2 and to stimulate osteoclastogenesis, SU115  
Bzb, a proteasome inhibitor, prevents metastatic breast cancer osteolysis and reduces mammary fat pad tumor growth in mice, F277  
c-Src-regulated osteoblast-mimicry in breast cancer bone metastasis: the role of RAMP2 and BSP2, M275  
Combined TGFβ receptor I kinase inhibitor and bisphosphonates are additive to reduce breast cancer bone metastases, F275  
Ectopic Runx2 expression disrupts normal acini structure in mammary epithelial cells, F279  
Effect of tamoxifen and aromatase inhibitors on the risk of fractures in women with breast cancer, SU227  
Effects of extracellular matrix properties and elastic modulus on the expression of PTHrP by human breast cancer cells, M280  
Effects of LASO on fractures and breast cancer, 1288  
Humanized model of breast cancer metastasis revealing a human-specific metastasis gene signature, M273  
Inhibition of HIF-1α alone or combined with TGFβ blockade prevents breast cancer bone metastases, 1085  
KO of the PTHrP gene in breast cancer cells inhibits tumor progression and metastatic spread in vivo, 1016  
Low plasma 25(OH)D and VDR polymorphisms are associated with increased breast cancer risk, SU202

OPG production by breast cancer cells is modulated by steroid hormones and confers resistance against TRAIL-induced apoptosis, M271

Osteoclast precursors play a role in recruiting breast cancer cells and osteoblasts onto the bone in vitro, SA278

Plasma proteomic profile that predicts breast cancer metastasis to bone, M281

Potential anti-invasion activity of Cat K inhibitors for the treatment of breast cancer-induced bone metastasis, M276

Prevention of aromatase inhibitor-associated bone loss in women with breast cancer, M283

PTHrP blockade inhibits tumor progression in a model of human breast cancer, F213

Quantitative image analysis method for measuring whole-body tumor burden in a mouse model of breast cancer bone metastasis, SA282

Strength training prevents bone loss at the spine in older breast cancer survivors, SA271

Vitamin D delays breast cancer progression in the PyVMT transgenic mouse model, 1185

Wnt signaling regulates Gli2 and PTHrP expression in human breast cancer cells that cause osteolysis, M278

**Cancer, prostate**

2ME2 blocks prostate cancer bone metastases, F272

Effects of ADT on bone health in prostate cancer, SA280

Inhibition of BMP pathway and osteoclast activity in osteoblastic prostate cancer lesion in bone, F283

Mechanism of enhanced 19-nor-2a-(3-hydroxypropyl)-1a,25-(OH)<sub>2</sub>D<sub>3</sub> anti-cancer activity in prostate cancer cells, M216

Osteoblast differentiation induced by Shh-expressing prostate cancer cells is enhanced by ascorbic acid, SA284

Osteosclerotic prostate cancer metastasis to murine bone: enhanced with increased bone turnover, SA269

Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, 1089

TGF $\beta$  activates prostate cancer bone metastases, pro-osteolytic gene expression and the new TGF $\beta$  signaling regulator PMEPA1, SA273

TGF $\beta$  blockade inhibits osteolytic but not osteoblastic prostate cancer metastases, SA274

TGF $\beta$  signaling in stromal cells facilitates osteoblastic lesions in prostate cancer, 1087

Zoledronate protects bone but not soft tissue from prostate cancer progression in a nude mouse model, M282

**Cancer, spine**

Local administration with PTX-loaded HA-alginate beads for metastatic spine cancer in rats, M274

**Cancer, thyroid**

Medullar carcinoma of the thyroid and anomalies of the Ca metabolism, SU246

**Cannabinoid receptors**

Cannabinoid receptor ligands rescue bone loss and stimulate fracture healing, SU375

**Cannabinoids**

Cannabinoid receptor GPR55 affects osteoclast function in vitro and bone mass in vivo, 1221

Effect of cannabinoid CB1 receptor ligands on body weight and bone mass in mice, M340

**Carbon nanotubes.** See *Nanotechnology*

**Carborane BE360**

Carborane BE360, one of the carbon-containing polyhedral boron-cluster compounds, is a new type of selective estrogen receptor modulator., SU187

**Carcino-embryonic antigen related cell adhesion molecule 1 (CEACAM1)**

Regulation of bone mass and osteoclastogenesis by the CEACAM1, F091

**Carcinoma, medullar**

Medullar carcinoma of the thyroid and anomalies of the Ca metabolism, SU246

**Carcinoma, squamous cell (SCC)**

CXCL13 stimulates RANK ligand expression in SCC, SU247

**Cardiac transplantation**

Replacing testosterone in male cardiac transplant patients exerts multiple benefits on bone mass, libido and sexual activity, M388

**Cardiolipin**

Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009

**Cardiotrophin-1 (CT-1)**

CT-1 is an osteoclast-derived coupling factor required for normal bone remodeling, M014

**Cardiovascular disease (CVD)**

CVD as forecasters of hip fracture: a nationwide cohort study in twins, 1205

Postprandial hyperphosphatemia is a novel risk factor for CVD by involving endothelial dysfunction, SU443

**Cardiovascular Health Study**

Subclinical thyroid disease predicts risk of hip fracture, 1208

**Cardiovascular system**

Arterial compliance is associated with change in bone strength in children, F552

Cardiovascular manifestations of mild PHPT, 1034

Changes in cardiovascular function after parathyroidectomy in mild PHPT, M434

MACD index is a strong predictor of cardiovascular death and include the predictive power of BMD, SU463

**Cartilage**

AC-100 promotes cartilage repair and subchondral bone healing in surgically induced cartilage defects, SA111

Biomarker discovery for bone and cartilage based on metabolic reconstruction bioinformatics, M134

Bone resorption and articular cartilage degenerative changes following performance of high repetition high force tasks are attenuated by secondary ibuprofen treatment, SA532

Cartilage engineered with a calcified zone enhances interfacial shear strength to the underlying substrate, M176

Continuous culture of tissue engineered cartilage, SU131

Deletion of the oxygen-sensor PHD2 in chondrocytes results in increased cartilage and bone mineralization, 1153

Identification of a transcription factor p63 for transactivation of Wnt9a and Gdf5 causing joint cartilage formation, F116

Longitudinal relationships between cartilage and bone turnover in OA, SA129

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

PTH has direct anabolic effects on OA articular cartilage in vitro and in vivo, M155

PTH-gene family in the cartilaginous fish, *Callorhynchus milii*, M183

In vivo knockdown of GEP, a novel growth factor in cartilage, led to defects in cartilage and OA, 1048

Widespread expression of SCT in adult and embryonic cartilage and bone, cells of the developing central nervous system and epithelia of the embryonic kidney and intestine, SA055

**Cartilage associated protein (CRTAP)**

P3H1 and CRTAP are mutually stabilizing in the endoplasmic reticulum collagen prolyl 3-hydroxylation complex, 1049

**Cartoid plague**

Carotid plague causes low spinal BMD in Korean postmenopausal women with diabetes, SU359

**Cas interacting zinc finger protein (CIZ)**

Deficiency of the nucleocytoplasmic shuttling protein CIZ suppresses K/BxN serum-induced model of RA, M446

**Catecholamines**

Catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation, SU137

**$\alpha$ -catenin**

Overexpression of  $\alpha$ -catenin in C3H10T1/2 cells increases osteoblast differentiation, SA046

**$\beta$ -catenin**

Activation of  $\beta$ -catenin signaling in articular chondrocytes leads to OA-like phenotype in adult  $\beta$ -catenin conditional activation mice, 1047

Apc-mediated control of  $\beta$ -catenin is essential for both chondrogenic and osteogenic differentiation of skeletal precursors, SA130

Availability of cytoplasmic  $\beta$ -catenin impacts mechanical signaling in osteoblasts, 1253

$\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, 1013

$\beta$ -catenin protects osteoblasts from oxidative stress by co-activating the expression of pro-survival, but not pro-apoptotic, target genes of the FoxO transcription factors, M010

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

hPTHrP 1-36 stimulates PKA-dependent phosphorylation and nuclear translocation of  $\beta$ -catenin in neonatal mouse calvarial bone cells, F032

Induction of oxidative stress and diversion of  $\beta$ -catenin from TCF- to FOXO-mediated transcription by GCs or TNF $\alpha$  in osteoblastic cells, SA185

Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108

Mechanical strain prevents adipogenesis in MSC by stimulating a durable  $\beta$ -catenin signal, SA522

Mutational analysis of  $\beta$ -catenin Exon 3 in benign and malignant parathyroid tumors, M436

Oxidative stress stimulates the synthesis of PPAR $\gamma$ 2, and ligand-activated PPAR $\gamma$ 2 sequesters  $\beta$ -catenin leading to suppression of TCF-mediated transcription, 1099

PPAR $\gamma$ 2-mediated proteolytic degradation of  $\beta$ -catenin determines an anti-osteoblastic effect of anti-diabetic TZDs, SU023

Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036

Transcriptional regulation of Cx43 by  $\beta$ -catenin, a pathway activated by PGE<sub>2</sub>-PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

In vivo load activated propagation of  $\beta$ -catenin signaling in osteocytes through coordinated downregulation of inhibitors of Lrp, 1041

Wnt/ $\beta$ -catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243

**Cathepsin K (Cat K)**

AP-1 and Mitf interact with NFATc1 to stimulate Cat K promoter activity in osteoclast precursors, SA076

## Key Word Index

## ASBMR 30th Annual Meeting

Cat K expression during enamel formation, SA154

Cat K inhibitor, MIV-701, suppresses bone resorption markers in healthy postmenopausal women, F433

Effects of the Cat K inhibitor ODN on osteoclast-mediated bone resorption, M127

Osteoclast-independent function of Cat K: regulation of TLR-9 signaling in autoimmunity, F074

Potential anti-invasion activity of Cat K inhibitors for the treatment of breast cancer-induced bone metastasis, M276

Serum Cathepsin K levels in AS, M439

**Ca<sub>3.2</sub>, T-type**

Assessment of changes in thoracic and lumbar vertebrae in T-type Ca<sub>3.2</sub> (a1H) VSCC KO mice, M170

**Caveolae**

Congenetic mouse models provide novel evidence of caveolae-1 $\alpha$  domain regulation of osteoblast differentiation, SU147

Involvement of caveolae in 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>-dependent activation of MAPKs in skeletal muscle cells, SA243

**CB1**

Effect of cannabinoid CB1 receptor ligands on body weight and bone mass in mice, M340

**Cbfa1**

(Ala-Gly)<sub>n</sub> sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167

**Cbl-PI3K**

Abrogation of Cbl-PI3K interaction in mice results in increased bone volume and osteoblast proliferation, I150

Cbl-PI3K interaction regulates osteoclast function, differentiation and survival, I011

**CCAAT/enhancer binding protein  $\beta$  (C/EBP $\beta$ )**

C/EBP $\beta$  overexpression causes osteopenia, SA005

C/EBP $\beta$ /p57<sup>Kip2</sup> signaling maintains transition from proliferation to hypertrophic differentiation of chondrocytes during skeletal growth, I187

**CCN2**

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

**CCR2**

CCR2 receptor signaling is involved in bone mass regulation and mediates the response to anabolic but not catabolic regimens of PTH(1-34), SU158

**Ccrn4l**

*Ccrn4l*, a peripheral clock gene, influences stromal cell allocation, bone mass, and marrow adiposity in mice and humans, I073

**CD1**

Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503

Over-expression of RAGE prevents OVX-mediated bone loss in CD1 mice, M132

**CD4<sup>+</sup>**

IL-12 stimulates the OIP-1 gene expression in CD4<sup>+</sup> T-cells, SA173

**CD29**

TGF $\beta$ 1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

**CD34**

Expression of bone-related genes by peripheral blood CD34 cells, M083

**CD45<sup>low</sup>**

Osteogenic potential of human bone marrow and circulating Stro-1+/CD45<sup>low</sup> cells, M078

**CD47**

CD47 (IAP) is an important modulator of osteoclast and osteoblast differentiation in vitro and in vivo, F093

TSP-1 and CD47 regulate osteoclastogenesis but have distinct effects on bone metastasis, I232

**Celiac disease**

Positive Celiac disease serology and BMD in adult women, SA366

**Cellular nucleic acid binding protein (CNBP)**

CNBP conditional KO mice show severe osteoporosis-like phenotype, F014

**Cerebral palsy**

Is Vitamin D deficiency more common in children with cerebral palsy than in healthy children?, SU194

**Cesium (Cs)**

Combined Cs-137 gamma irradiation and hindlimb unloading rapidly decreased cancellous bone volume fraction in the mouse lumbar vertebrae, M469

**CFK2**

Intracellular PTHR2 alters cell proliferation and pattern of gene expression while antagonizing PTHR1 signaling in chondrocytic CFK2 cells, SA121

**Charcot foot**

Increased proinflammatory cytokines TNF- $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

**Charcot neuroarthropathy**

Impaired oxidative stress defense mechanism may reduce bone stiffness in diabetic Charcot neuroarthropathy, M002

**Chemerin**

Chemerin and CMKLR1 expression and function in human bone marrow MSC adipogenesis, SU165

Chemerin and CMKLR1 targeted gene delivery identifies a novel molecular switch in the treatment of osteoporosis, M071

**Chemokines**

DARC regulates osteoclast differentiation via modulating chemokine effects on migration/fusion of osteoclast precursors, M115

**Chemotherapy**

Impact of adjuvant hormonal therapy on bone loss depending on initial adjuvant chemotherapy and menstrual status, M415

**Chloride**

CFTR regulates osteoblast bone formation independent of chloride conductance, I274

Chloride channel CIC-7 mediates acidification of the resorption lacuna in osteoclasts, M123

**Cholecalciferol**. See also *Vitamin D*

Efficacy and safety of short term treatment with different doses of cholecalciferol on 25(OH)D levels in postmenopausal females with osteoporosis, SU434

Ergocalciferol is not bioequivalent to cholecalciferol in Vitamin D insufficient hip fracture cases, I289

Vitamin D (cholecalciferol) production does not increase linearly with UV dose, M226

**Cholestasis**

Different influence of the clinical condition, degree of cholestasis, alcohol abuse and serum Ca on the musculoskeletal system in chronic cirrhotics, M411

Fracture risk in primary biliary cirrhosis: role of osteopenia and severity of cholestasis, M442

**Cholesterol**

Low density lipoprotein-cholesterol levels affect vertebral fracture risk in female patients with PHPT, SA484

**Chondrocytes**

Activation of  $\beta$ -catenin signaling in articular chondrocytes leads to OA-like phenotype in adult  $\beta$ -catenin conditional activation mice, I047

Betulin down regulates IL-1 $\alpha$ -stimulated aggrecanases and MMP gene expression in human chondrocytes, M147

Bisphosphate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428

BMP-2 inactivates TAK1-ATF2 signaling pathway in chondrocytes, F186

C/EBP $\beta$ /p57<sup>Kip2</sup> signaling maintains transition from proliferation to hypertrophic differentiation of chondrocytes during skeletal growth, I187

$\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, I013

Chondrocyte differentiation is differentially affected by COX-2 and 5-LO during fracture healing, SU123

Chondrocyte-derived Ihh is required for osteoblast differentiation despite reconstitution of a normal growth plate, I154

Deletion of the oxygen-sensor PHD2 in chondrocytes results in increased cartilage and bone mineralization, I153

DEX triggers mitochondrial apoptosis through Bax in proliferative growth plate chondrocytes causing growth retardation, I188

HDAC inhibitors suppress IL-1 $\beta$ -induced NO and PGE<sub>2</sub> production in human chondrocytes, SU116

Hedgehog signaling regulates growth plate chondrocyte proliferation and growth factor expression, SU161

Impact of calpain inhibition on chondrocyte development, M150

Intracellular PTHR2 alters cell proliferation and pattern of gene expression while antagonizing PTHR1 signaling in chondrocytic CFK2 cells, SA121

LPA enhances the viability of rat growth plate chondrocytes through the inhibition of apoptosis and the promotion of cellular maturation, SU156

Lxn is a novel effector of BMP-2 signaling in modulation of chondrocyte differentiation, SU117

Nkx3.2 is an important mediator of hypoxia-induced chondrocytic differentiation, F112

Notch signaling inhibits chondrogenesis and subsequently promotes chondrocyte maturation, I268

Overcoming the zone of chondrocyte death associated with osteochondral harvest by sequential treatment with collagenase and IGF-1, SU129

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

PGD2 downregulates MMP-1 and MMP-13 expression in human OA chondrocytes, SA152

Phosphate induced apoptosis in growth plate chondrocytes via a NO and JNK-dependent path, SA113

Phosphate regulates chondrocyte differentiation, proliferation and apoptosis in a model of embryonic endochondral bone formation, SU124

Postnatal deletion of PTH/PTHrP receptor in growth plate chondrocytes leads to growth plate fusion, F114

Protein sulfation is required to prevent chondrocytes autophagy and growth factor signaling during endochondral ossification, SU119

PTHrP prevents chondrocyte premature hypertrophy by inducing cyclin D1-dependent Runx2 and 3 phosphorylation and degradation, I044

Regulation of hypertrophic chondrocyte apoptosis, M158

Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043

Studies on the deposition of ochronotic pigment in AKU reveal tyrosine metabolism in human chondrocytes, M166

- Targeted expression of SOX9 in hypertrophic chondrocytes leads to enhanced adipogenic activity and spontaneous OA in transgenic mice, SA115
- TGF $\beta$  and Smad3-dependent repression of Runx2 function in ATDC5 chondrocytes, SU122
- Thyroid hormone activates Wnt signaling pathways in rat growth plate chondrocytes, M157
- Tissue-specific KO of the CaSR in chondrocytes inhibits IGF-1 signaling and delays differentiation in the growth plate, 1261
- Transcription factor NFATp regulates BMP-induced chondrocyte differentiation in a tissue-specific manner, SU020
- Transcription factor Znf219 regulates chondrocyte differentiation through forming transcription factory complex with Sox9, 1265
- Chondrodysplasia**
- Reduced cell proliferation and chondrodysplasia in mice lacking the mitotic protein NuSAP, SU120
- Chondrogenesis**
- ADAMTS-7, a direct targeting molecule of PTHrP, is a novel potent mediator of chondrogenesis, 1262
- Apc-mediated control of  $\beta$ -catenin is essential for both chondrogenic and osteogenic differentiation of skeletal precursors, SA130
- MIA3, a novel secreted factor, regulates chondrogenic differentiation in the developing mouse embryo, 1043
- Nicotine induces chondrogenesis via calcineurin/NFAT, SU133
- Notch signaling inhibits chondrogenesis and subsequently promotes chondrocyte maturation, 1268
- Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153
- Regulation of chondrogenesis and bone development by neogenin via BMP pathway, SU127
- TGF $\beta$ - and BMP-signaling pathways have antagonistic effects during chondrogenesis, F158
- Wnt target gene Twist1 inhibits Sox9, the master regulator of chondrogenesis, 1266
- Chondroprogenitor cells**
- bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043
- Chromatin**
- Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240

- Effects of serum factors during osteoblast differentiation—implication for the pathogenesis of osteoporosis in Crohn's Disease, M450
- Pediatric Crohn's Disease is associated with negative Ca balance and increased renal losses of Ca, SA565
- CTX**
- Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287
- CTx-I**
- Vitamin D status and bone remodeling marker CTx-I in patients with early RA: association with disease activity and joint damage, SA496
- CXC**
- Transient expression of CXC receptor 2 in human MSC stimulates chemotaxis toward CXC ligand 8 and increased mineralization in the presence of osteogenic medium, SA170
- Cxcl2**
- Roles of Cxcl2 in osteoclast precursor cells, SU086
- CXCL12**
- CXCL12 expression is regulated by HIF-2 $\alpha$  in MM plasma cells, SU080
- Elevated serum levels of CXCL12 is associated with increased osteoclast activity and osteolytic bone disease in MM patients, SU079
- CXCL13**
- CXCL13 stimulates RANK ligand expression in SCC, SU247
- CXCR4**
- Injection of MSCs overexpressing both CXCR4 and RANK-Fc effectively prevented OVX-induced bone loss, F391
- CXCR7**
- Analysis of CXCR7-deficient mice reveals CXCR7 expression in osteocytes but no apparent bone phenotype, M104
- Cyclin D1**
- PTHrP prevents chondrocyte premature hypertrophy by inducing cyclin D1-dependent Runx2 and 3 phosphorylation and degradation, 1044
- Cyclin-dependent kinase 6 (CDK6)**
- Large scale candidate gene analysis identifies an association between the CDK6 locus and trabecular volumetric BMD at the lumbar spine in older men, M266
- Cyclooxygenase-2 (COX-2)**
- Chondrocyte differentiation is differentially affected by COX-2 and 5-LO during fracture healing, SU123
- Effect of MKP-1 deletion on the fluid shear stress induction of COX-2 expression in osteoblasts, SA529
- Mechanical loading upregulates expression of the transcription factor EGR2/Krox-20 by a COX-2-mediated mechanism, SA526
- PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calceineurin pathways, SA033
- Cyclopamine**
- Hedgehog pathway is activated in osteosarcoma and cyclopamine prevents osteosarcoma growth by cell cycle regulation, SU241
- CYP17**
- Is there any association between CYP 17-CYP 19 polymorphisms and bone loss in early postmenopausal women?, M259
- CYP19**
- A allele at Valine80 of the CYP19 gene is a risk factor for aromatase inhibitors associated bone loss, 1021
- Is there any association between CYP 17-CYP 19 polymorphisms and bone loss in early postmenopausal women?, M259
- CYP19A1**
- Significant association between polymorphisms of CYP19A1, fracture incidence and BMD in post-menopausal women, M262
- CYP24A1**
- 25(OH)D $_3$ -24-hydroxylase (CYP24A1): mutagenesis and activity studies reveal important residues involved in regioselectivity and substrate access, SU199
- Impaired fracture healing in the absence of the Vitamin D-24-hydroxylase, Cyp24a1, M222
- Polymorphisms in *CYP24A1*, the gene encoding 25(OH)D-24-hydroxylase, are associated with BMD, SA266
- CYP27A1**
- CYP27A1 mutations at Phe147 confer 25-hydroxylase activity towards a Vitamin D $_2$ -type sidechain, M231
- CYP27B1**
- Cloning and functional analysis of human Nurrl (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161
- Deletion of CYP27B1 reverts the premature aging phenotype of the Klotho-null mice, F069
- Expression of 1 $\alpha$ hydroxylase (CYP27B1) in BMSC, SA237

Metabolic alkalosis transition in renal proximal tubule cells facilitates an increase in CYP27B1, while blunting responsiveness to PTH, M196

Prediction of osteoporotic fracture risk by 25(OH)D3-1 $\alpha$ -hydroxylase (CYP27B1) gene, M263

**Cystic fibrosis (CF)**  
Bone status evaluation in pre-pubertal children with CF, SU486

**Cystic fibrosis transmembrane regulator (CFTR)**  
CFTR regulates osteoblast bone formation independent of chloride conductance, 1274

**Cytokines**  
Comparison of direct osteoclastogenic potential on osteoclast precursor cells among proinflammatory cytokines, SU077

Effects of beta-D-glucopyranoside from *Phellodendron Amurense* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117

Gene transcripts related to T-cell activation, proliferation, and cytokine signaling show significant effects on BMD variation in baboons, M241

Increased proinflammatory cytokines TNF- $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

MKP-1 is an endogenous negative regulator of pro-inflammatory cytokines in BMSC, SU013

MSC enhance fracture healing: essential role for cytokines in homing and anti-inflammatory response, SA169

Proinflammatory cytokine TWEAK induces SCT expression in human immature osteoblasts in a MAPK dependent fashion, M046

Relationship between serum levels of inflammatory cytokines and bone turnover markers in the year following hip fracture, SU073

Suppression of TREM-2 expression and TREM-2-mediated costimulation of RANK signaling by cytokines that inhibit human osteoclast differentiation, SU114

**D**

**DANCE.** See *Direct Assessment of Non-vertebral Fracture in Community Experience*

**DAP12**  
Modeled microgravity sensitizes osteoclast precursors to RANKL mediated osteoclastogenesis by increasing DAP12, M114

**Dasatinib**  
Tyrosine kinase inhibitor dasatinib decreases osteoclast formation and activity in vitro, SU074

**DBA/2**  
Femur from C57BL/6 and DBA/2 inbred mice display a strain dependent response to treadmill running and tower climbing exercise in cortical and trabecular bone architecture, M485

**DBP**  
Vitamin D deficiency in inner city infants: impact of DBP genotype, SA472

**DC-STAMP**  
DC-STAMP regulates bone metabolism through cell-cell fusion of osteoclasts, F087

**Decalcification, microwave**  
Rapid EDTA microwave decalcification of rabbit osteochondral samples preserves enzyme activity and antigen epitopes, M140

**Deminerlized bone matrix (DBM)**  
Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135

**Denosumab (DMab)**

Assessment of serum Ca and bone resorption markers in patients transitioned from ALN to DMab, M394

Effect of DMab vs ALN on bone turnover markers and BMD changes at 12 months based on baseline bone turnover level, 1285

Effects of ALN or DMab on cortical and trabecular bone mass, bone strength, and bone mass-strength relationships in mice, 1139

Effects of DMab vs ALN on BMD, bone turnover markers, and safety in women previously treated with ALN, M395

Phase III study of the effects of DMab on vertebral, nonvertebral, and hip fracture in women with osteoporosis, 1286

Transition from ALN to DMab in OVX cynomolgus monkeys maintained or improved cortical and trabecular bone mass, without altering the linear relationship between bone mass and bone strength, 1072

Transition from ALN to DMab resulted in further reductions in local and systemic bone turnover parameters and reduced cortical porosity in OVX cynomolgus monkeys, 1216

**Densitometry**  
Bone metabolism, microarchitecture and densitometric measurement in rat femur after chronic alcohol consumption, M239

Densitometric vertebral fracture assessment in postmenopausal women, SU254

Do different densitometers, or use of T-score vs. Z-score, affect fracture risk estimation?, SU258

Improving the diagnostic yield of bone densitometry, F361

Influence of body weight on cost-effectiveness of bone densitometry and treatment for osteoporosis among older women and men without prior fracture, F426

Normal reference values for QUS bone densitometry of the calcaneus in Chinese children and adolescents, SU489

Osteoporosis therapy following bone densitometry—patient expectations as determinants of drug initiation and persistence, M377

RTA of densitometric calcaneal images differs between subjects with and without GC use, M314

**Dentin matrix**  
Histologic and radiographic analysis of osteopromotive property of demineralized allogenic dentin matrix in parietal bone defects in rabbit, M168

**Dentin matrix protein-1 (DMP1)**  
DMP1 fragments interact differently with HA: insights into mechanism of action, SA140

Specific forms of DMP1 support attachment and haptotactic migration via  $\alpha$ V $\beta$ 3 but not  $\alpha$ V $\beta$ 5 integrin, F145

**Dentin sialoprotein (DSP)**  
Identification of DSP-phosphophoryn cleavage site, SA144

**Deoxyribonucleic acid (DNA)**  
DNA demethylation for hormone-induced transcriptional derepression, 1182

DNA methylation analysis of osteogenic gene promoter regions in mouse BMSC, M035

Functionalization of a PLGA/PEG-PLA composite electrospun scaffold with rhBMP-2 plasmid DNA for bone regeneration, SA124

Gene expression profiling within murine growth plates using DNA microarrays, M156

**Derepression**  
DNA demethylation for hormone-induced transcriptional derepression, 1182

**Dermatomyositis, juvenile (JDM)**  
Calcifications in children with JDM contain several bone formation markers, SA106

**Dermo1**  
Dermo1 lineage tracing identifies early osteoprogenitor cells in adult murine bone marrow MSC cultures, SA051

**DESTINY.** See *Bone DESTINY*

**Dexamethasone (DEX)**  
BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

DEX triggers mitochondrial apoptosis through Bax in proliferative growth plate chondrocytes causing growth retardation, 1188

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

Inhibition of the mevalonate pathway rescues the DEX-induced suppression of the mineralization of osteoblastic cells, SA230

Osteoblast-targeted deletion of the GC receptor has little impact on PBM but attenuates DEX-induced suppression of bone formation, F452

**DHCR24**  
DHCR24 gene is mandatory for the proper growth of long bone, SU118

**Diabetes mellitus**  
C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223

Carotid plaque causes low spinal BMD in Korean postmenopausal women with diabetes, SU359

Impaired oxidative stress defense mechanism may reduce bone stiffness in diabetic Charcot neuroarthropathy, M002

Increased proinflammatory cytokines TNF- $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

OPN deficiency reduces aortic calcification and oxidative stress in diabetic LDLR-/- mice, F109

rhBMP-2 accelerates segmental defect healing in diabetic rats, M445

Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, 1137

**Diabetes mellitus, type 1**  
Type 1 diabetes is associated with lower BMD in premenopausal women but not in middle-aged men, SU456

**Diabetes mellitus, type 2**  
Bone fragility is increased in the MKR type 2 diabetic mouse, M440

Geometric evidence of a modeling defect in type 2 diabetic women enrolled in the WHI as a potential explanation for increased fracture risk, 1068

Lack of correlation between glycemic control and BMD in type 2 diabetic women, SU255

Prevalence and factors associated to the presence of vertebral fractures in patients with type 2 diabetes mellitus, M447

Reduced serum osteocalcin and sex hormone binding globulin in men with type II diabetes, SU461

Rosiglitazone-induced change in BMD among African Americans with type 2 diabetes mellitus or impaired glucose tolerance, SU315

Serum ucOC concentration are related to renal function in type 2 diabetes patients, M443

In vivo quantification of intra-cortical porosity in human cortical bone using HR-pQCT in patients with type II diabetes, M309

**Diacylglycerol oil**  
Effects of diacylglycerol oil on body composition, BMD and bone strength in mice, SA442

**Diasorin Liaison (LIA)**  
Analytical validation of LIA and ELEC methods for the determination of osteocalcin, SA191

**Dickkopf-1 (DKK-1)**  
Circulating DKK1 levels are reduced in young subjects with low bone mass, F455

## Key Word Index

## ASBMR 30th Annual Meeting

Deletion of the Dkk-1 Krm-1 and Krm-2 in mice leads to increased bone formation and bone mass, 1004

Dkk-1 predicts the gain of BMD in osteoporotic women on bisphosphonates, SA300

DKK1 is regulated by mRNA stability and epigenetic mechanisms in bone metastasis, 1090

Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214

Increased circulating DKK1 in acute coronary syndrome—association with platelet release and endothelial inflammatory response, SU167

Platelets contribute to circulating levels of Dkk-1: clinical implications in MM, SU228

Preclinical validation of a novel Dkk1 neutralizing antibody for the treatment of MM related bone disease, SU239

Regulation of Dkk-1 and Dkk-2 is needed for osteoblast terminal differentiation on microstructured Ti surfaces, SU006

Suppression of canonical wnt signaling by Dkk1 attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215

**Dickkopf-2 (DKK-2)**

Regulation of Dkk-1 and Dkk-2 is needed for osteoblast terminal differentiation on microstructured Ti surfaces, SU006

**Diet**

Association of the marker of ABD with malnutrition-inflammation complex in hemodialysis patients, SU446

Bone health impairment in children with chronic Ca and Vitamin D deficiency due to nutritional allergies, SU503

Calorie restriction prevents age-related trabecular bone loss via SIRT-1, 1251

Diet induced obesity compromises the osteogenic potential of the bone marrow, F047

Dietary patterns in Canadian men and women ages 25 and older: relationship to BMI and BMD, SU309

Dietary Sr in a model of established osteopenic rats reduce the levels of 25(OH)D, SA377

Differential cellular and molecular responses of intestinal epithelium to high Ca diet and 1,25(OH)<sub>2</sub>D<sub>3</sub>, M229

Does dietary protein reduce hip fracture risk in elderly men and women?, SU319

Dried plum alters bone metabolism via a different mechanism than PTH, M341

Effect of hypercalciuria and diet on bone in genetic hypercalciuric stone-forming rats, SU213

Effect of the dietary Ca/P ratio on the rate of skeletal accrual in mice, M333

Effects of diacylglycerol oil on body composition, BMD and bone strength in mice, SA442

Effects of diet and menstrual cyclicity on bone mass accumulation in pubertal monkeys, M499

Effects of exercise and milk intake on bone in adolescents, SU301

Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

Essential fatty acid and fish intake is associated with higher BMD in elderly women and men, F341

Evaluating the effect of soy and isoflavones on BMD in older women, M353

Exploring the effect of food intake on bone resorption for optimal drug delivery and efficacy in osteoporosis with oral calcitonin, SA436

Green tea polyphenols protect bone microarchitecture in female rats with chronic inflammation-induced bone loss, M338

High level dietary P and Cd exacerbate OVX-induced bone loss, M301

High-fat diet facilitated decreases in BMD of OVX mice and suppressed the anabolic effects of PTH on bone, SA448

High-fat diet negatively regulates bone development in growing mice, SA441

Impact of dietary protein on Ca homeostasis and nitrogen excretion in the presence and absence of KHCO<sub>3</sub>, SU305

Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184

Infantile HCa: relationship of dietary intake of Ca and Vitamin D to serum and urine levels, SU491

Maternal nutrient restriction during pregnancy results in significant alterations in fetal skeletal development in the baboon, M494

Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238

Prevention of the metabolic syndrome together with osteoporosis in young men, SU314

Relationship among nutritional status, oxidative stress and bone density in institutionalized elderly, SU310

Rodent model to evaluate the effect of dietary protein on intestinal Ca absorption, M330

Treadmill exercise provides only short-term protection against cancellous bone loss with reduced dietary energy intake: endocrine mechanisms, SA449

**Dihydrotestosterone (DHT)**

DHT administration is effective for the prevention of hypogonadal bone loss, SU193

Inhibition of bone loss and muscle atrophy by DHT in a mouse hindlimb disuse model, SU377

**1,25-dihydroxyvitamin D (1,25(OH)<sub>2</sub>D)**

25(OH)D acts on Ca and skeletal homeostasis independent of 1,25(OH)<sub>2</sub>D in vivo, M214

Albuminuria, 25(OH)D, 1,25(OH)<sub>2</sub>D, and intact PTH in older adults, SU442

Effects of hPTH(1-34) infusion on circulating serum phosphate, 1,25(OH)<sub>2</sub>D and FGF-23 levels in healthy men, SU169

Genetic model to study 1,25(OH)<sub>2</sub>D action in classical and non-classical target tissues, 1184

**1,25-dihydroxyvitamin D<sub>2</sub> (1,25(OH)<sub>2</sub>D<sub>2</sub>)**

1,25(OH)<sub>2</sub>D<sub>2</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in regulating cellular proliferation in cultured normal human keratinocytes and transformed prostate cells, M215

Comparison of 1,25(OH)<sub>2</sub>D<sub>2</sub> and calcitriol effects in an adenine-induced model of CKD reveals differential control over serum Ca and phosphate, SU448

Effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> and 25(OH)D<sub>3</sub> on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207

**1,25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>)**

1,25(OH)<sub>2</sub>D<sub>3</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>2</sub> in regulating cellular proliferation in cultured normal human keratinocytes and transformed prostate cells, M215

1,25(OH)<sub>2</sub>D<sub>3</sub> can directly induce osteoclast formation in osteoclast precursors in the absence of RANKL, SU070

1,25(OH)<sub>2</sub>D<sub>3</sub> regulates collagen maturation in osteoblastic cell culture system, SU208

Differential cellular and molecular responses of intestinal epithelium to high Ca diet and 1,25(OH)<sub>2</sub>D<sub>3</sub>, M229

Distinctive anabolic roles of 1,25(OH)<sub>2</sub>D<sub>3</sub> in teeth and mandible versus long bones, M213

High levels of IL-6 and hyper-responsivity to 1,25(OH)<sub>2</sub>D<sub>3</sub> are both required for development of Pagetic osteoclasts, F478

Key mechanism underlying the immunosuppressive effects of Vitamin D: 1,25(OH)<sub>2</sub>D<sub>3</sub> is a transcriptional modulator of IL-17, F246

Rapid-nontranscriptional action of 1,25(OH)<sub>2</sub>D<sub>3</sub> induces IL-6 production in osteoclast precursors expressing MVNP, 1186

Requirement of the bone for Vitamin D for 1,25(OH)<sub>2</sub>D<sub>3</sub> synthesis and bone mineralization, M224

Silencing of PDIA3 (ERp60) reduces the rapid membrane response to 1,25(OH)<sub>2</sub>D<sub>3</sub> in MC3T3-E1 osteoblast-like cells, M227

Transgenic ASARM-peptide overexpression with reduced serum phosphate and 1,25(OH)<sub>2</sub>D<sub>3</sub> leads to decreased BMD and obesity, F210

**1α,25-dihydroxyvitamin D<sub>3</sub> (1α,25(OH)<sub>2</sub>D<sub>3</sub>)**

IFN-β is a key molecule in inhibition of human osteoclast differentiation by 1α,25-dihydroxyvitamin D<sub>3</sub>, SU090

Involvement of caveolae in 1α,25(OH)<sub>2</sub>D<sub>3</sub>-dependent activation of MAPKs in skeletal muscle cells, SA243

**DIOS Study**

Type 1 diabetes is associated with lower BMD in premenopausal women but not in middle-aged men, SU456

**Dipeptidyl peptidase 4 (DPP4)**

Role of FAP and DPP4 in myeloma bone disease and tumor growth, F288

**Dipeptidyl peptidase I (DPP-I)**

Identification of DPP-I as a potential activator of KLK-4, SA155

**Direct Assessment of Non-vertebral Fracture in Community Experience (DANCE)**

TPTD therapy in a community setting: persistence and use of other osteoporosis medications in DANCE, SA395

**Direct injection**

Functional induction of target genes in parathyroid cell by direct injection technique, M185

**Disabilities, motor**

Randomized, placebo-controlled, double blind study on high frequency, low intensity vibration in bone mass, muscle strength and quality of life in children with motor disabilities, F435

**Disc regeneration**

Tissue-engineering and co-culture system based disc regeneration MSC's role, SA189

**Distal radius**

Loaded distal radius: gymnastic-related cross-sectional asymmetry, M490

**Distraction osteogenesis (DO). See Osteogenesis**

**Diuretics**

Loop diuretic use and rates of hip bone loss, and risk of falls and fractures in older women, F371

**Dlk1**

Dlk1/FA1 is a novel factor enhancing osteoclastogenesis and inhibiting bone formation in vitro and in vivo, 1007

**Dlx3**

High bone mass phenotype in the bone specific Dlx3 KO mice, M027

MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2, SA064

Molecular consequences of a mutant Dlx3 affecting bone homeostasis in TDO, 1272

**Dlx5**

BMP-2 induces Osx expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020

Dlx5 overexpression stimulates odontoblast differentiation and function, M054

Inactivation of Dlx5 gene results in altered osteoblast-osteoclast coupling inducing increased bone resorption and reduced cortical thickness in male mice, F010

MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2, SA064

**Dmp1**

Local osteocyte defect in *Dmp1* null mice causes overproduction of FGF-23, 1225

- Mechanical unloading partially rescues hypophosphatemic rickets in *Dmp1*-null mice, 1162
- DMP1**  
7B2 protein mediated inhibition of DMP1 cleavage in osteoblasts enhances FGF-23 production in *Hyp*-mice, 1053
- Dmrt2**  
Transcription factor Dmrt2 controls endochondral ossification through regulating type 10 collagen (*Col10a1*) gene expression, 1045
- DNA**. See *Deoxyribonucleic acid*
- Dock5**  
Dock5, an essential Rac exchange factor in osteoclasts that controls adhesion structure organization and bone resorbing activity, SU064
- Dual energy x-ray absorptiometry (DXA)**. See *Absorptiometry*
- Duchenne muscular dystrophy (DMD)**. See *Muscular dystrophy*
- Duffy antigen receptor for chemokines (DARC)**  
DARC regulates osteoclast differentiation via modulating chemokine effects on migration/fusion of osteoclast precursors, M115
- Dwarfism**  
Dwarfism and osteopenia in mice with inactivated HRE in the VEGF gene promoter, 1152
- Dynorphin**  
Endorphins regulate bone material properties by actions through dynorphin, 1195
- Dysosteosclerosis**  
Dysosteosclerosis in a 2-year-old girl: investigation of a rare, sclerosing bone disorder, SA567
- Dysplasia, cleidocranial (CCD)**  
Runx2 threshold for the CCD phenotype, M041
- Dysplasia, craniometaphyseal (CMD)**  
ANKH mutation causing CMD inhibits osteoclast differentiation, SU214  
Osteoblast and osteoclast involvement in the pathogenesis of a mouse model for CMD, 1204
- Dysplasia, fibrous (FD)**  
Does dietary P influence FGF-23 concentrations in FD patients?, M426  
Polyostotic form of FD in a 13 year old Colombian girl exhibiting clinical and biochemical response to neridronate intravenous therapy, SU211
- Dysplasia, progressive diaphyseal**. See *Camurati-Engelmann disease*
- Dysplasia, spondylo-epi-metaphyseal**  
Three unrelated patients with a unique spondylo-epi-metaphyseal dysplasia, SU494

- E. coli***  
Expression of human SCT in heterologous eukaryotic insect and *E. coli* expression systems, SA059
- E11**  
Early osteocyte marker, E11/gp38 is highly elevated in new bone formed in response to distraction as compared to existing bone, SA136
- Early growth response factor 1 (EGR-1)**  
Characterization of a promoter polymorphism in FZD1: allele-specific regulation by Egr-1 in osteoblast-like cells, M267  
Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177
- Early growth response factor 2 (EGR2)**  
Mechanical loading upregulates expression of the transcription factor EGR2/Krox-20 by a COX-2-mediated mechanism, SA526
- Ebf1**  
Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109
- EDTA**  
Rapid EDTA microwave decalcification of rabbit osteochondral samples preserves enzyme activity and antigen epitopes, M140
- eIF3i**  
TRIP-1 is eIF3i: a key regulator of osteoblast activity, 1259
- eIF4E**  
2ME2 alters eIF4E activity and causes protein synthesis inhibition in osteosarcoma cells, SU240
- ELEC**. See *Roche Elecsys*
- Electroalgotomy**  
Effect of RLX and ALF on bone and joint pain assessed by fall of skin impedance (electroalgotomy), SA384
- Electromagnetism**  
Brief pulsing electromagnetic field exposure differentially effects cell cycle in proliferating and confluent osteoblasts, M004
- Embryonic stem cells (ESC)**. See *Stem cells*
- Emdogain**  
Enamel matrix derivative (emdogain) enhance osteoblast differentiation on Ti surfaces, M030
- Enamel**  
Cat K expression during enamel formation, SA154
- Endofin**  
Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, 1082
- Endorphins**  
Endorphins regulate bone material properties by actions through dynorphin, 1195
- Endothelial cells**  
Postprandial hyperphosphatemia is a novel risk factor for CVD by involving endothelial dysfunction, SU443
- Endothelial nitric oxide synthase (eNOS)**. See *Nitric oxide synthase*
- Enniatin**  
Fungal secondary metabolites beauvericin and enniatin inhibit osteoclast differentiation and bone resorption, M130
- Enzyme replacement therapy**  
Enzyme replacement therapy prevents dental defects in the *Akp2*<sup>-/-</sup> mouse model of infantile HPP, F107  
Relative efficacy of "treating" versus "preventing" infantile HPP in *Akp2*<sup>-/-</sup> mice by enzyme replacement therapy, 1054
- EP4**  
Nanotechnological scaffold with combination of PGE<sub>2</sub> receptor EP4 agonist and rhBMP2, enhances bone repair in the defect of mouse calvarium bone, SA105  
PGE receptor EP4 antagonist attenuates growth and metastases of cancer, 1230
- Epac**  
PTH/PTHrP mediated stimulation of osteoblast differentiation involves Epac-Rap1 dependent processes, SA025
- EphB4**  
Blockade of Ephrin/EphB4 signaling within the osteoblast lineage reduces osteoblast differentiation and mineralization, SU046  
EphB4 expression in osteoblasts is regulated by myeloma cells and the Wnt signaling pathway, SU232  
Inhibition of major bone catabolic mediators in human subchondral bone osteoblasts upon EphB4 receptor activation by Ephrin-B2 ligand, SU003
- Ephrin**  
Blockade of Ephrin/EphB4 signaling within the osteoblast lineage reduces osteoblast differentiation and mineralization, SU046
- Ephrin B1 reverse signaling regulates bone formation via influencing osteoblast activity in mice, 1194
- EPIC-Norfolk Study**. See *European Prospective Investigation into Cancer-Norfolk Study*
- Epidermal growth factor receptor (EGFR)**  
In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154
- Epigenetics**  
DKK1 is regulated by mRNA stability and epigenetic mechanisms in bone metastasis, 1090
- Epistasis**  
Defining epistasis in a double congenic mouse: implications for the skeleton, M252
- ERE**  
Loss of classical ERE signaling results in suppression of early commitment of BMSC to osteoblasts, F029
- Ergocalciferol**. See also *Vitamin D<sub>2</sub>*  
Effect of three different doses of Vitamin D<sub>2</sub> (ergocalciferol) on muscle function and strength in women > 65 years, M405  
Ergocalciferol is not bioequivalent to cholecalciferol in Vitamin D insufficient hip fracture cases, 1289
- ERK**. See *Extracellular-regulated protein kinase*
- ERp60**  
Silencing of PDIA3 (ERp60) reduces the rapid membrane response to 1,25(OH)<sub>2</sub>D<sub>3</sub> in MC3T3-E1 osteoblast-like cells, M227
- Erythropoiesis**  
Excessive erythropoiesis affects bone architecture, 1294
- ESR2**  
RsaI polymorphism in ESR2 is associated with postmenopausal fracture risk, SU221
- Estradiol**  
Ethanol alters estrogen receptor signaling and activates senescence pathways in osteoblasts while estradiol attenuates ethanol effects, SU182  
Older men with low serum estradiol and high serum SHBG have an increased risk of fractures, 1279  
Serum estradiol and fracture reduction during treatment with hormone therapy, F383
- 17 $\beta$ -estradiol (E<sub>2</sub>)**  
Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185  
ER $\alpha$  deletion in cells of the monocyte/macrophage lineage increases osteoclastogenesis and abrogates the pro-apoptotic effect of E<sub>2</sub> on osteoclasts, 1097
- Estrogen**  
30IT/C of SCT modulates BMD by Wnt and estrogen signaling pathways, 1270  
BZA in combination with conjugated estrogens improves bone mass and strength in the OVX rat, SA385  
Cell type specific regulation of transcription by estrogen, SU180  
Combination of flaxseed and estrogen benefits bone health in the OVX rat model of postmenopausal osteoporosis, SU381  
Effects of exercise and estrogen on OPG in premenopausal women, SU166  
ER $\alpha$  expression in mesenchymal cells is crucial for the bone protective effects of estrogen, 1123  
Estrogen suppresses RANKL-induced osteoclastic differentiation of human monocytes via an ER $\alpha$  associated cytoplasmic signaling complex, but ER $\alpha$  is downregulated during osteoclastic differentiation, 1125  
Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

## Key Word Index

## ASBMR 30th Annual Meeting

Ethanol alters estrogen receptor signaling and activates senescence pathways in osteoblasts while estradiol attenuates ethanol effects, SU182

Genetic variations in sex steroid-related genes as predictors of serum estrogen levels in men, SU183

Role of GPR30 in effects of estrogen in OVX mice, SU179

**Estrogen deficiency**

Effects of ODN on bone mass and turnover in estrogen deficient adult rhesus monkeys, SA072

Estrogen deficiency alters the localized material properties of the peri-lacunar bone matrix in old rats, M107

Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214

Low serum IGF-I alters the cortical bone response to estrogen deficiency, SU190

ODN increases bone strength and maintains bone quality in estrogen deficient adult rhesus monkeys, F508

Selective p38 $\alpha$  inhibitor prevents bone loss induced by estrogen deficiency, M335

**Estrogen receptor**

Carborane BE360, one of the carbon-containing polyhedral boron-cluster compounds, is a new type of selective estrogen receptor modulator., SU187

Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

**Estrogen receptor- $\alpha$  (ER $\alpha$ )**

Biochemical characterization of ER $\alpha$  co-regulators in multinucleated mature osteoclasts, 1126

ER $\alpha$  deletion in cells of the monocyte/macrophage lineage increases osteoclastogenesis and abrogates the pro-apoptotic effect of E $_2$  on osteoclasts, 1097

ER $\alpha$  expression in mesenchymal cells is crucial for the bone protective effects of estrogen, 1123

Estrogen suppresses RANKL-induced osteoclastic differentiation of human monocytes via an ER $\alpha$  associated cytoplasmic signaling complex, but ER $\alpha$  is downregulated during osteoclastic differentiation, 1125

Multinuclear expression of ER $\alpha$  in mature osteoclasts, SU186

Novel ER $\alpha$  variant signals rapidly from the caveolae of traditional ER $\alpha$ -negative cells, 1124

Regulation of renal Klotho: the importance of ER $\alpha$ , SA211

Specific inactivation of AF-1 in ER $\alpha$  results in growth plate closure while total inactivation of ER $\alpha$  results in increased growth plate width in elderly female mice, 1181

**Estrogen therapy**

Effects of estrogen therapy and fluocalcic effervescent on the BMD and bone metabolism of surgical menopause women with osteopenia, M392

Effects of low dose estrogen therapy on the BMD and bone metabolism of menopausal women, M393

Higher BMD is associated with increased odds of carotid atherosclerosis in postmenopausal women not currently using estrogen therapy, 1206

**Ethanol**

Ethanol alters estrogen receptor signaling and activates senescence pathways in osteoblasts while estradiol attenuates ethanol effects, SU182

OAH19, an ethanol extract from combined two herbs, inhibits IL-1 $\alpha$ -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148

**European Forsteo Observational Study (EFOS)**

Back pain is reduced in postmenopausal women with severe osteoporosis treated with rhPTH(1-34) regardless of incident fractures, SU413

Women with severe osteoporosis treated with rhPTH(1-34) improve quality of life regardless of incident fractures, SU412

**European Male Ageing Study (EMAS)**

Influence of markers of bone turnover on calcaneal QUS, SA457

**European Prospective Investigation into Cancer (EPIC)-Norfolk Study**

Percentage body fat and risk of prospective hip fracture in older men and women, F363

Performance of QUS in comparison to DXA for prediction of prospective fractures among older men and women, 1240

**EUROQOL (EQ-5)**

Quality of life in Mexican hip fractures patients using EUROQOL (EQ-5) after discharge from hip fracture and 6 months of followup, SU419

**eValuation of IBN Efficacy (VIBE) Database Fracture Study**

"Vibes" Trial: LMMS to improve BMD, M397

Fracture risk in women aged 65 years or older with once-monthly oral IBN compared with weekly bisphosphonates, M367

Fracture risk with once-monthly oral IBN compared with weekly bisphosphonates, SU408

**Exendin-4 (Ex-4)**

Osteogenic action of Ex-4 in normal and insulin-resistant state, M424

**Exercise**

Bone density comparisons in young male rock climbers, weight lifters and sedentary controls, SA534

Bone geometry, strength, and muscle mass in female distance runners with a history of stress fracture, SA540

Bone volumetric density, geometry and strength in male and female collegiate runners, SA539

Can impact exercise mitigate the adverse effects of oral contraceptives on bone?, M488

Effect of 12 months gymnastics participation on bone mass accrual in 4 to 7 year olds, SA555

Effect of a one year exercise program on markers of bone metabolism after hip fracture, SA432

Effect of aquatic exercise and education on improving indices of fall risk in older adults with hip OA, M441

Effect of exercise on geometric bone structure and bone strength in postmenopausal women, M484

Effective progressive resistive exercise program from prone position for paravertebral muscles to reduce risk of vertebral fractures, M473

Effects of exercise and estrogen on OPG in premenopausal women, SU166

Effects of exercise and milk intake on bone in adolescents, SU301

Effects of exercise intensity on the bone metabolic response to running, M481

Effects of running exercise on bone quality after immobilization, SA518

Effects of simulated resistive exercise on cortical bone in the tibia mid-diaphysis of hindlimb unloaded rats, SA521

Femur from C57BL/6 and DBA/2 inbred mice display a strain dependent response to treadmill running and tower climbing exercise in cortical and trabecular bone architecture, M485

Flexible tibia model predicts bone strains during walking, M479

Functionality outcomes including brisk walking speed are associated with BMD in postmenopausal women, SU418

High impact exercise may have a protective effect on BMD but moderate impact exercise may have negative effect in young women with anorexia nervosa, M324

HSA and physical activity in boys and girls during puberty, SA538

Impact of physical inactivity (10 days bed rest) on markers of bone turnover in young men with low and normal birth weight, SA456

Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184

Increasing the number of steps taken per day leads to a greater weight loss and more favorable body composition in overweight postmenopausal women, SU311

Influence of muscle size and strength on changes in bone mass and size during growth and in response to exercise, SA537

Inhibition of bone biomechanical response to physical activity and loading in mice lacking periostin, 1143

Model of high body mass: BMD, bone markers and adipocytokine levels in high level male rugby players, SA167

Non-steroidal anti-inflammatory use and the response of bone to exercise, M472

Physical activity, BMD and fragility fracture, M325

Positive influence of physical activity on BMD measurements and hip geometry parameters in young adults, M477

Prevention of the metabolic syndrome together with osteoporosis in young men, SU314

Previous sport activity during childhood and adolescence is associated with bone geometry in young adult men, SA541

Relationship between physical fitness and bone and physical activity and Ca retention in adolescent girls, SA553

Serum Vitamin D levels do not modify the response to an exercise program following hip fracture, SA346

Strength training prevents bone loss at the spine in older breast cancer survivors, SA271

Targeted exercise against hip fragility, SA533

Three year school-curriculum-based exercise program in prepubertal children increases bone mineral accrual and bone size but do not influence femoral neck structure, 1107

Treadmill exercise provides only short-term protection against cancellous bone loss with reduced dietary energy intake: endocrine mechanisms, SA449

**Exon 3**

Mutational analysis of  $\beta$ -catenin Exon 3 in benign and malignant parathyroid tumors, M436

**Expansile skeletal hyperphosphatasia (ESH).**

See *Hyperphosphatasia*

**Ext1<sup>+/-</sup>**

Over-expression of CNP enhances the formation of long bone exostoses in Ext1<sup>+/-</sup> mice, SU130

**Extracellular-regulated protein kinase (ERK)**

AG490, a Jak2 specific inhibitor, induces osteoclast survival by activating Akt and ERK signaling pathway, SU108

Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050

Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

Induction of CTGF by TGF $\beta$ 1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066

Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380

Vinculin is involved in hypertrophic differentiation through Raf/MEK/ERK pathway in chondrocytic ATDC5 cells, SA119

**Extracellular-regulated protein kinase 1/2 (ERK1/2)**

- Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185
- Breast cancer derived factors synergize with TGF $\beta$  to induce phosphorylation of ERK1/2 and to stimulate osteoclastogenesis, SU115
- Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177

**Extracellular-regulated protein kinase 5 (ERK5)**

- MEK5/ERK5 signal regulates RANKL-induced osteoclastogenesis, SU103

**F****F2**

- Geometric property QTLs in HcB/8 x HcB/23 F2 cross, F260

**F344**

- Characterization and genetic mapping of bone size phenotypes in GK and F344 rats using a new 3D CT method, M463

**FA1**

- Dlk1/FA1 is a novel factor enhancing osteoclastogenesis and inhibiting bone formation in vitro and in vivo, 1007

**Familial hypocalciuric hypercalcemia (FHH).**

See *Hypercalcemia*

**Familial humeroradioulnar synostosis.** See *Synostosis***Farnesoid X receptor (FXR)**

- Deletion of FXR leads to an osteopenic phenotype in mice, F439

**Farnesyl pyrophosphate synthase**

- Role of active site Thr201 in the inhibition of farnesyl pyrophosphate synthase by NBPs, F407

**Fatty acids**

- Essential fatty acid and fish intake is associated with higher BMD in elderly women and men, F341
- Modulation of osteoclastogenesis by fatty acids, SU071

**Femoral neck structure**

- Contribution of local buckling to femoral neck failure in stance and fall mode simulations: an advanced FEA analysis of elderly cadaver femur data, M489
- Discordance in femoral neck bone density in subjects with OA, M453
- Morphometric determinants of 3D femoral neck structure and strength in older postmenopausal women, SA320
- Regional differences in femoral neck cortical thickness determine hip fragility, M315
- Regional thinning of the femoral neck cortex with advancing age predisposes to hip fracture, SU275
- Three year school-curriculum-based exercise program in prepubertal children increases bone mineral accrual and bone size but do not influence femoral neck structure, 1107

**Femur**

- BMP-3-null aged mice display increased trabecular bone volume and reduced cross sectional area at the mid-femoral diaphysis, SU143
- Differences in BMC at the lumbar spine and proximal femur in South American children of different ethnic groups, SU490
- Femoral strength, bone density, and aging in women and men, 1165
- Generating 3D finite element models of a human proximal femur from 2D DXA data, M467
- Imaging the spatial distribution of proximal femoral response to one year of TPTD therapy, M349
- New link between trabecular properties and T-score at the human femur, SU281

- Optimization of failure load estimation using radiographs of human cadaveric femur, M457
- Protocol for pediatric proximal femur DXA analysis, M506
- Reduction of BMD in the patients with RA is more remarkable at proximal femur than at lumbar spine, SU451
- Tracking of femur length during intrauterine growth, M497
- Vitamin K treatment for one year does not alter femur geometry in postmenopausal women, SA443

**Femur Strength Index**

- Correlation between DXA Femur Strength Index and QUS Heel Stiffness Index in Chinese women, M464

**FHL2**

- FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

**Fibroblast activation protein (FAP)**

- Role of FAP and DPP4 in myeloma bone disease and tumor growth, F288

**Fibroblast growth factor (FGF)**

- Activation of FGF receptors is a novel mechanism by which extracellular Ca stimulates the proliferation of osteoblasts, M088

**Fibroblast growth factor agonist (F2A)**

- Skeletal effects of a F2A in OVX rats, SA388

**Fibroblast growth factor receptor (FGFR)**

- FGFR signaling in the pathogenesis of osteosarcoma, 1233

**Fibroblast growth factor receptor 2 (FGFR2)**

- Dynamic morphological changes in the skulls of mice mimicking human Apert Syndrome resulting from gain-of-function mutation of FGFR2 (P253R), SA248

- Permanent FGFR2 activation promotes osteoblast differentiation in MSCs through activation of PKC signaling, M093

**Fibroblast growth factor, basic (bFGF)**

- bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043
- Improvement of alveolar bone quality by local bFGF injection—histological and cellular biological analysis in a rabbit model, SA162
- NARS induced by bFGF regulates the proliferation and survival of osteoblasts, SA164

**Fibroblast growth factor-1 (FGF-1)**

- FGF-1 inhibits adipogenic differentiation and transdifferentiation of human MSCs, M075

**Fibroblast growth factor-2 (FGF-2)**

- FGF-2 signaling in osteoblasts: Cx43 is a docking platform for PKC $\delta$ , F026
- FGF-2 stimulates RANKL expression in PDB, F480
- FGF-23 and FGF-2 share a common but also have distinct signaling pathways for negative regulation of bone nodule mineralization in cultured osteoblasts, SA206
- Regulation of the BMP-2 distant osteoblast enhancer by FGF-2, SU150
- Targeted overexpression of the nuclear FGF-2 isoforms in osteoblasts induces hypophosphatemia via modulation of FGF-23 and Klotho in mice, 1084

**Fibroblast growth factor-23 (FGF-23)**

- 7B2 protein mediated inhibition of DMP1 cleavage in osteoblasts enhances FGF-23 production in *Hyp*-mice, 1053
- Ablation of the Galnt3 gene in mice leads to low circulating FGF-23 concentrations and hyperphosphatemia despite increased FGF-23 gene expression, 1018
- Altered regulation and expression of FGF-23 in the adenine-induced uremic rat model, SU178
- Association of urinary GGT and serum FGF-23 with prevalent fracture, SA296
- c-Fos is associated with renal FGF-23-mediated signaling, SU173

- Clinical usefulness of measurement of FGF-23 in hypophosphatemic patients, SA470
- Does dietary P influence FGF-23 concentrations in FD patients?, M426
- Effect of treating Vitamin D deficiency on FGF-23 levels in humans, SA209
- Effects of hPTH(1-34) infusion on circulating serum phosphate, 1,25(OH) $_2$ D and FGF-23 levels in healthy men, SU169
- Evaluation of clinical utility of venous sampling for FGF-23 in identifying and confirming responsible tumors for TIO, F163
- Evidence supporting the necessity of GalNac-T3 in the processing of FGF-23 in humans, SA200
- FGF-23 and FGF-2 share a common but also have distinct signaling pathways for negative regulation of bone nodule mineralization in cultured osteoblasts, SA206
- FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177
- FGF-23 and post-transplant hypophosphatemia: evidence for a causative link, SU168
- FGF-23 in Vitamin D deficient older persons, SA203
- Homozygous threonine to methionine substitution in FGF-23 gene is associated with tumoral calcinosis in a 12 year-old girl, SU171
- Local osteocyte defect in *Dmp1* null mice causes overproduction of FGF-23, 1225
- Potential role of FGF-23 in CKD-MBD, WG30
- Rapid detection of intact FGF-23 in tumor tissue from patients with OOM, SA204
- Role of FGF-23 in the early response to the PTH analogue: TPTD, SU174
- Serum FGF-23 level in term infants, SA165
- Signaling of extracellular inorganic phosphate mediated via Na-phosphate co-transporters influences FGF-23 signaling in renal tubular cells, SU172
- Significance of O-linked glycosylation of FGF-23 protein, SA208
- Targeted overexpression of the nuclear FGF-2 isoforms in osteoblasts induces hypophosphatemia via modulation of FGF-23 and Klotho in mice, 1084

**Fibroblasts**

- LMP-1, positive regulator in osteolineage differentiation of human PDL fibroblasts, M051

**Fibroblasts, synovial**

- OAH19, an ethanol extract from combined two herbs, inhibits IL-1 $\alpha$ -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148

**Fibrodysplasia ossificans progressiva (FOP)**

- ACVR1 knock-in mouse model for FOP, 1203

**Fibronectin**

- Circulating fibronectin affects bone matrix, SA151
- Conditional deletion of fibronectin results in a scoliosis-like phenotype, 1046
- Extracellular matrix protein fibronectin positively regulates the osteoclast function, SU069
- Mechanical perturbation of integrin  $\alpha$ 5 with or without association with fibronectin opens Cx43-hemichannels in osteocytes, SA060

**Fibrous dysplasia.** See *Dysplasia***Finite element analysis (FEA)**

- Comparison of voxel-based and smooth FEA to predict damage accumulation in vertebral bodies, SU474
- Contribution of local buckling to femoral neck failure in stance and fall mode simulations: an advanced FEA analysis of elderly cadaver femur data, M489
- Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505
- Estimation of relative stiffness contributions of cortical and trabecular compartments by MRI-based FEA, SU481

## Key Word Index

## ASBMR 30th Annual Meeting

FEA of proximal femur QCT scans for the assessment of hip fracture risk in older men, F321

FEA performed on radius and tibia HR-pQCT images provides new insights for fracture status assessment, 1067

Generating 3D finite element models of a human proximal femur from 2D DXA data, M467

Grayscale MRI based finite element mechanical modeling of trabecular bone at in vivo resolution, SU277

Hip strength estimates by FEA and fracture prediction in women and men, 1167

Microfinite element modeling reveals that transient deficits in cortical bone may underlie the adolescent peak in forearm fractures, 1179

QCT and FEA assessment of proximal femur bone quality and strength in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA509

Unsymmetrical beam theory and finite element method: analysis of murine cortical bone based on  $\mu$ CT imaging, M454

**FIP200**

Role of FIP200 in osteoblast differentiation, M091

**FIT Long-term Extension (FLEX)**

Sites of femoral fractures in the Fracture Intervention Trial (FIT) of ALN and its Long-term Extension (FLEX), SU389

**FK506**

Changes of bone metabolism in immunosuppressant, FK506 treated rats, SU383

**Flavonoids**

IC162, a new flavonoid, preserves bone mass and microarchitecture without affecting uterine weight in OVX rats, SA386

**Flaxseed oil**

Combination of flaxseed and estrogen benefits bone health in the OVX rat model of postmenopausal osteoporosis, SU381

Effect of resveratrol and flax oil on MC3T3-L1 pre-adipocyte and ST2 BMSC proliferation and differentiation, SU059

**FLEX.** See *FIT Long-term Extension*

**Fluid flow**

Adenylyl cyclase 6 mediates primary cilia-regulated decreases in cAMP in bone cells exposed to dynamic fluid flow, 1040

Direct correlation of osteocyte deformation with Ca influx in response to fluid flow shear stress, SA057

Effect of MKP-1 deletion on the fluid shear stress induction of COX-2 expression in osteoblasts, SA529

Primary bone cells of pregnant mice exposed to oscillatory fluid flow, M015

Response of matrix synthesizing MLO-A5 cells to fluid shear, SA067

Role of cell surface ATP synthase in fluid shear stress induced ATP release in osteoblasts, SU039

Strain-induced fluid flow in a 3D porous matrix promotes osteoblastic calcification in vitro, SA525

Tracking adipose differentiation in vitro with aP2-GFP reporters and flow cytometry: lipid staining and macrophage mimicry, SU057

**Fluorescence imaging**

Quantitative image analysis method for measuring whole-body tumor burden in a mouse model of breast cancer bone metastasis, SA282

**Fluoride**

Fluoride effects on bone formation, mineralization and mechanical properties are influenced by genetics, SU465

Stress fracture and vertebral osteosclerosis related to fluorosis induced by excessive gingival topical fluoride application, M444

**Fluoride, serum ionic (SIF)**

Elevated SIF levels in post-menopausal women is due to the enhanced release of fluoride from bone, SA490

SIF levels among hemodialysis patients are positively associated with levels of serum phosphate and intact PTH, SU440

**Fluorosis**

Stress fracture and vertebral osteosclerosis related to fluorosis induced by excessive gingival topical fluoride application, M444

**Focal adhesion kinase (FAK)**

Investigations into the role of FAK in bone marrow-derived osteoclasts, SU111

**Folate**

Lrp6 loss of function impacts bone homeostasis and responds to folate supplementation, F253

**Fourier transfer infrared (FTIR) imaging**

Characterization of the osteotomy callus using FTIR imaging in a rabbit ulnar model, M471

**FoxO**

$\beta$ -catenin protects osteoblasts from oxidative stress by co-activating the expression of pro-survival, but not pro-apoptotic, target genes of the FoxO transcription factors, M010

Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, 1247

**FOXO**

Induction of oxidative stress and diversion of  $\beta$ -catenin from TCF- to FOXO-mediated transcription by GCs or TNF $\alpha$  in osteoblastic cells, SA185

**FOXO1**

FOXO1 signaling in the control of bone mass, 1112

**Foxo3**

Wnt/ $\beta$ -catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243

**FoxOs**

Akt regulates skeletal development through GSK3, mTOR, and FoxOs, 1151

**Fra1**

Progressive lipodystrophy in the osteosclerotic mice over-expressing Fra1, 1149

**Fracture healing**

ALF ameliorates bone dynamics in senescence-accelerated SAMP6 mice and in fracture repair rat model, SU394

Bi-allelic loss of *Nf1* in osteoblasts delays bone fracture healing, SU218

BMP-7 is not required for fracture healing, SU148

Cannabinoid receptor ligands rescue bone loss and stimulate fracture healing, SU375

Changes of biochemical resorption markers during fracture healing in osteoporosis, M290

Chondrocyte differentiation is differentially affected by COX-2 and 5-LO during fracture healing, SU123

Circulating BMP-1 isoforms: novel diagnostic and therapeutic challenges for bone fracture repair, SU142

Comparison of cPTH(1-31) to PTH(1-34) in the enhancement of experimental fracture healing, M161

Development of pharmacological HIF activators for fracture healing, SU052

Effects of PTH on fracture repair in GC treated mice, 1062

Evaluation of circulating osteoprogenitor cells during fracture healing using parabiotic mice, 1260

Evaluation of two novel bone growth factors to enhance fracture healing, SU012

Expression of BMP antagonists during fracture healing, SA160

Impaired fracture healing in the absence of the Vitamin D-24-hydroxylase, Cyp24a1, M222

Induction of ESC-related pluripotency genes in post natal stem cells during fracture healing, F038

LV best enhances fracture repair when administered one week post-fracture, 1300

MSC enhance fracture healing: essential role for cytokines in homing and anti-inflammatory response, SA169

Normal intramembranous fracture healing in mice with transgenic osteoblast-targeted disruption of GC signaling, SA234

OPG serum levels in shaft fractures healing and non-union, M013

Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, 1137

**Fracture Intervention Trial (FIT)**

Sites of femoral fractures in the Fracture Intervention Trial (FIT) of ALN and its Long-term Extension (FLEX), SU389

**Fracture prevention**

8-year fracture and mortality outcomes of the fracture liaison service that provides systematic assessment for prevention of secondary fractures to all patients age 50+ with new low-trauma fractures, SU324

Attitudes to fracture prevention in long-term care facilities, M379

Predictors of patient perceived need for oral bisphosphonates to prevent fracture: the role of the MD-patient relationship, F416

Prevention of non-vertebral fractures with oral Vitamin D is dose dependent, 1242

Strategies for hip fracture prevention in long-term care facilities: a survey of Canadian geriatricians and family physicians, M380

**Fracture risk**

10-year probability of recurrent osteoporotic fractures after a primary wrist fracture in postmenopausal women enrolled in the CaMos cohort, F358

Absolute risk for subsequent fractures fluctuates over time, 1060

Age is the key to assessing fracture risk: FRAX, F306

Areal BMD by DXA may predict similar risk of fracture in elderly women and men due to offsetting effects of bone size and true volumetric BMD, SU267

Assessment of absolute fracture risk and osteoporosis in Chinese, F312

Assessment of fracture risk and treatment of osteoporosis in postmenopausal women: bone density vs. Bone DESTINY, SU251

Assessment of the 10-year risk of fracture in Italian postmenopausal women using BMD and clinical risk factors, SU348

Association between femoral neck BMD and the factor-of-risk for hip fracture derived from direct measurements of strength in human cadaveric femora, 1070

Association of CTR gene polymorphisms with BMD and fracture risk in postmenopausal Koreans, M256

Association of *HSD11B1* polymorphisms with vertebral fracture risk and BMD in postmenopausal Korean population, M260

Bone DESTINY—a one step fracture risk predictor for clinicians, SU504

Bone turnover and incident hip fracture risk, M285

C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292

Comparative antifracture efficacy of N-containing bisphosphonates, SU397

Comparison between logistic regression and artificial neural networks for vertebral fracture risk assessment, SU345

Cortical cross sectional area in young adult men is inversely related to risk of hip fracture in their older relatives, 1281

Development a nomogram for individualizing the absolute risk and time to recurrent fracture, F349

Distribution of risk factors for fracture in women with and without a fracture history, SU342

Do different densitometers, or use of T-score vs. Z-score, affect fracture risk estimation?, SU258

Does dietary protein reduce hip fracture risk in elderly men and women?, SU319

Effect of 10-year fracture risk tool results on likelihood of bisphosphonate prescribing, SU402

Effect of aquatic exercise and education on improving indices of fall risk in older adults with hip OA, M441

Effect of tamoxifen and aromatase inhibitors on the risk of fractures in women with breast cancer, SU227

Effective progressive resistive exercise program from prone position for paravertebral muscles to reduce risk of vertebral fractures, M473

Efficacy of BZA in reducing the incidence of nonvertebral fractures in postmenopausal osteoporotic women at higher fracture risk, M390

Failure to perceive increased risk of fracture in women 55 years, SA360

FEA of proximal femur QCT scans for the assessment of hip fracture risk in older men, F321

Fracture risk and incidence of falls in younger postmenopausal women, 1236

Fracture risk in patients with different types of cancer, SA290

Fracture risk in primary biliary cirrhosis: role of osteopenia and severity of cholestasis, M442

Fracture risk in women aged 65 years or older with once-monthly oral IBN compared with weekly bisphosphonates, M367

Fracture risk in young patients with chronic diseases, SU371

Fracture risk with once-monthly oral IBN compared with weekly bisphosphonates, SU408

FRAX™ and the assessment of ten-year fracture probability in Hong Kong Southern Chinese according to age and BMD femoral neck T-scores, SU264

Geometric evidence of a modeling defect in type 2 diabetic women enrolled in the WHI as a potential explanation for increased fracture risk, 1068

Hip fracture patients at high risk of second hip fracture, 1163

Hip strength estimates by FEA and fracture prediction in women and men, 1167

Inflammatory markers and the risk of hip fracture, F333

Loop diuretic use and rates of hip bone loss, and risk of falls and fractures in older women, F371

Low calcaneal BMD estimated by a peripheral DXA heel scanner is associated with a high risk to have had a distal radius fracture, SU262

Low density lipoprotein-cholesterol levels affect vertebral fracture risk in female patients with PHPT, SA484

No fracture is a poor predictor of fracture risk, SU356

Older men with low serum estradiol and high serum SHBG have an increased risk of fractures, 1279

Once-a-month RIS 150 mg reduced vertebral fracture risk at one year in a historical control analysis, SU403

Osteoporosis diagnosis and incident fracture as a function of prior fractures site in a large clinical cohort, 1235

Overweight children are more at risk to sustain a forearm fracture due to poor bone strength relative to body weight, M458

Percentage body fat and risk of prospective hip fracture in older men and women, F363

Polymorphisms of the ALOX12 gene are associated with increased risk of osteoporotic fracture, SU220

Poor peripheral sensorimotor nerve function is associated with high fall risk, SU323

Possible increased risk of fracture among South Florida White Hispanic women, M402

Post-fracture mortality in men: contributions of sex hormones and BMD as risk factors, 1280

Prediction of fracture risk by LRP5 gene haplotype, SU222

Prediction of osteoporotic fracture risk by 25(OH)D3-1 $\alpha$ -hydroxylase (CYP27B1) gene, M263

Relationship of bone turnover marker (PINP) and changes in femoral neck BMD to fracture risk in women with postmenopausal osteoporosis treated with once-yearly ZOL 5 mg, 1027

Risk factors for bone fracture, elevated by 90-days of bed rest, are reduced by daily exposure to LMMS, M342

Risk factors for fragility fracture in a multiracial cohort of US women, SA362

Risk factors for subsequent fractures within the next year in patients presenting with a clinical fracture, 1237

Risk of hip fracture after bisphosphonate discontinuation, F409

Risks and outcomes for hip fractures in a predominantly African-American male veteran population, SA352

RsaI polymorphism in ESR2 is associated with postmenopausal fracture risk, SU221

Serum estradiol and fracture reduction during treatment with hormone therapy, F383

Simply ask them about their balance—fracture prediction in a nationwide cohort study in twins, 1095

SSRI use and risk of fracture in older women, F351

Subclinical thyroid disease predicts risk of hip fracture, 1208

Ten-year fracture risk assessment in Norland-based equipment in a Chinese population, SU253

Thoracic kyphosis index as a risk factor for incident vertebral fractures and alteration of quality of life in postmenopausal women with osteoporosis, 1130

Three methods of lumbar spine DXA analysis as a means to predict male fracture, 1131

Timed Up and Go test and BMD as predictors of fracture, F373

Trabecular risk of fracture, caused by disuse, is strongly influenced by baseline morphology, 1293

Weight and BMI predict BMD and fractures in women 40 to 59 years, SA438

#### Fractures

“Pathologic” fractures: to include or exclude?, SU321

Accelerated fracture callus remodeling and membranous bone healing in STAT1 deficient mice, SA022

Ambiguity about osteoporosis and osteoporosis care exists despite a screening program to educate fracture patients, M383

Analysis of long bone fracture nonunion by an expression profile of the MMPs and ADAMTS enzyme families, M235

Association of stiffness index and cross-linked NTx with any clinical fractures differs with age and gender, SU350

Association of urinary GGT and serum FGF-23 with prevalent fracture, SA296

Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261

Back pain is reduced in postmenopausal women with severe osteoporosis treated with rPHT(1-34) regardless of incident fractures, SU413

Bisphosphonates and osteoporotic fractures in highly compliant/persistent postmenopausal women, 1025

BMD, fracture and survival in women in nursing/residential care, SA340

Comparison of prediction models for hip, osteoporotic, and any clinical fracture in older women: is more better?, 1057

Concentration of IGF-I in human cortex bone is highly correlated with fracture toughness of the bone, 1069

Cost-effectiveness of IBN therapy for women with postmenopausal osteoporosis with respect to nonvertebral fracture efficacy, SA429

Deformity of the distal radius fractures resulting from falls in Japanese women over 50 years of age is closely associated with BMD of the lumbar spine, SU286

Direct medical costs associated with the treatment of NHNV, hip, and vertebral fractures in a managed care setting, F356

Distribution and rate of clinical fractures in older men without osteoporosis, 1282

Effect of once-yearly ZOL 5 mg infusion on fracture incidence in postmenopausal osteoporosis, 1028

Effects of LASO on fractures and breast cancer, 1288

Excess of post-fracture mortality among men and women, SA348

FEA performed on radius and tibia HR-pQCT images provides new insights for fracture status assessment, 1067

Femoral neck and trochanteric fractures and Vitamin D, SU353

Fracture reduction during two years of treatment with RIS or ALN, SA404

Gender specific effects of TRPV4 on osteoblast-osteoclast coupling and risk of osteoporotic fractures, SA355

Gondanotropins, bone loss and fracture in men, 1278

GWAS reveals genetic variants associated with BMD, osteoporosis and osteoporotic fractures, SA263

Increase in risk of atypical subtrochanteric fractures with ZOL?, F411

Incremental costs associated with selected skeletal fractures, 1024

Influence of bone osteoporotic fractures in the past on the persistence of pharmacological treatment in osteoporosis, M382

Is the association between hypertension and bone osteoporotic fracture expressing a real interdependence?, SU346

Microfinite element modeling reveals that transient deficits in cortical bone may underlie the adolescent peak in forearm fractures, 1179

No fracture is a poor predictor of fracture risk, SU356

Novel hypothesis explains the syndrome of chronic musculoskeletal pain and comorbid painful healed fracture sites in Vitamin D deficiency, SA474

Opioid-induced osteoporosis: delayed bone healing and compression fractures in a man with chronic narcotic use, WG32

Osteoporosis diagnosis and incident fracture as a function of prior fractures site in a large clinical cohort, 1235

In osteoporotic other than in healthy bone, thoracolumbar fractures spare the adjacent discs, SU415

Performance of QUS in comparison to DXA for prediction of prospective fractures among older men and women, 1240

Population burden of first and repeat low-trauma fractures, 1056

Post-fracture initiative in a rural Ontario community hospital, M369

Prediction of incidental low trauma limb fractures in older men and women with QCT variables of bone and muscles in mid-thigh, F369

Prediction of trabecular level microdamage and bone fracture through local strain, SU467

Predictors of poor outcomes following osteoporotic fractures in elderly women and men, 1210

Prevalence of subtrochanteric fractures in patients older than 50 years presenting with a clinical vertebral or non-vertebral fracture, SU390

Proinflammatory marker values at baseline and after a fracture are distinctly different comparing a mouse model of OI with normal controls, M234

## Key Word Index

## ASBMR 30th Annual Meeting

- Significant association between polymorphisms of CYP19A1, fracture incidence and BMD in post-menopausal women, M262
- Single nucleotide polymorphisms in the P2X7 receptor gene are associated with increased postmenopausal bone loss and fracture incidence, SU223
- Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349
- Use of genetic markers in prediction of fractures, 1094
- Variation in the osteocalcin gene: association study of BMD, fracture and changes in body fat mass in elderly women, SU225
- Volumetric bone parameters in relation to fracture history in healthy men at the age of PBM, SU302
- WHO absolute fracture models in older women: how does prediction vary for incident hip and non-spine fractures across T-scores?, 1055
- Women with severe osteoporosis treated with rhPTH(1-34) improve quality of life regardless of incident fractures, SU412
- Fractures, femoral**
- Bisphosphonate-associated femoral fracture: implications for management, WG26
- Clinical outcome in elderly with proximal femur or humerus fractures in an orthogeriatric rehabilitation unit, SU329
- Sites of femoral fractures in the Fracture Intervention Trial (FIT) of ALN and its Long-term Extension (FLEX), SU389
- Subtrochanteric and diaphyseal femur fractures in patients treated with ALN, 1026
- Fractures, fragility**
- Association between BMD change, use of antiresorptive agents and fragility fracture in women and men, SA364
- BMD measurement by DXA after a fragility fracture increases the likelihood of subsequent osteoporosis treatment, SU296
- Correlation of hip geometry and bone density with fragility fracture in Japanese postmenopausal women, SU466
- Evaluation of BMD following an education intervention on osteoporosis offered to women after a fragility fracture, SU330
- Excess medical cost after a fragility fracture during 3-year follow-up, SA422
- Fragility fractures and health status in a multinational cohort, SU340
- Impact of an educational intervention on knowledge about osteoporosis following a fragility fracture, SA353
- Patients with fragility fracture assessed by BMD, Bone DESTINY and osteoporosis Canada guidelines, SA343
- Physical activity, BMD and fragility fracture, M325
- Prevalence of osteoporosis and osteopenia in men and women according to the fragility fracture type, SU294
- Risk factors for fragility fracture in a multiracial cohort of US women, SA362
- Substantial adverse outcomes follow NHNV fragility fractures, 1059
- Targeted exercise against hip fragility, SA533
- Fractures, hip**
- Active shape modeling as a predictor of hip fracture, M317
- Association between femoral neck BMD and the factor-of-risk for hip fracture derived from direct measurements of strength in human cadaveric femora, 1070
- Bone turnover and incident hip fracture risk, M285
- Comparison of prediction models for hip, osteoporotic, and any clinical fracture in older women: is more better?, 1057
- CVD as forecasters of hip fracture: a nationwide cohort study in twins, 1205
- Direct medical costs associated with the treatment of NHNV, hip, and vertebral fractures in a managed care setting, F356
- Disability in patients with osteoporotic pertrochanteric hip fracture, SA357
- Does dietary protein reduce hip fracture risk in elderly men and women?, SU319
- Effect of a one year exercise program on markers of bone metabolism after hip fracture, SA432
- Elevated production of IL-1 $\beta$  and TNF $\alpha$  by PBMC is associated with increased hip fracture risk in elders, 1283
- Ergocalciferol is not bioequivalent to cholecalciferol in Vitamin D insufficient hip fracture cases, 1289
- FEA of proximal femur QCT scans for the assessment of hip fracture risk in older men, F321
- Fractures of the spine and hip increase the risk of death in Canadians, SU351
- High mortality in male nursing home residents with hip fracture, SU326
- Hip fracture patients at high risk of second hip fracture, 1163
- Hip fracture patients with vertebral fractures have more severe osteoporosis and are candidates for more active treatment including PTH, SU274
- Immunohistochemical localisation of SCT in human trabecular bone from fragility hip fracture patients, SA148
- Impact of varying BMD resources on prediction of hip fracture using FRAX™, SU257
- Independent contribution of hip geometry to incident fracture prediction in a large clinical cohort, 1238
- Inflammatory markers and the risk of hip fracture, F333
- Mechanical unloading of the sheep calcaneus: a model for hip fracture, M478
- Osteoporosis in the aging males after hip fracture, SU436
- Pattern of death after hip fracture among institutionalized older people, 1164
- Phase III study of the effects of DMAB on vertebral, nonvertebral, and hip fracture in women with osteoporosis, 1286
- Potential mediators of the reduction in mortality with ZOL after hip fracture, 1030
- Prevalence of vertebral fractures in aging women suffering from hip fracture, SU322
- Protective effect of total and supplemental Vitamin C intake on the risk of hip fracture, 1168
- Quality of life in Mexican hip fractures patients using EUROQOL (EQ-5) after discharge from hip fracture and 6 months of followup, SU419
- RANKL/OPG in primary cultures of osteoblasts from patients with osteoporotic hip fractures, SU009
- Red flags are missed in the prevention of hip fractures, SU432
- Regional thinning of the femoral neck cortex with advancing age predisposes to hip fracture, SU275
- Relationship between serum levels of inflammatory cytokines and bone turnover markers in the year following hip fracture, SU073
- Risk of hip fracture after bisphosphonate discontinuation, F409
- Risks and outcomes for hip fractures in a predominantly African-American male veteran population, SA352
- Role of the lean muscle and fat mass in hip fractures production, SU263
- Secular trends in Swedish hip fracture incidence 1987-2002, 1166
- Serum 25(OH)D and the risk of hip and non-spine fractures in older men, 1277
- Serum Vitamin D levels do not modify the response to an exercise program following hip fracture, SA346
- SHBG levels in older patients with acute hip fracture are correlated with worse function and increased bone resorption, SU363
- Socioeconomic status, BMD testing and hip fracture rates in a universal health-care system, SU293
- Vitamin D deficiency is highly prevalent in Irish hip fracture patients, M294
- WHO absolute fracture models in older women: how does prediction vary for incident hip and non-spine fractures across T-scores?, 1055
- Women who fractured their hips experience greater loss of geometric strength in the contralateral hip during the year following fracture compared to age-matched controls, F345
- Fractures, non-hip non-vertebral (NHNV)**
- Costs associated with NHNV fractures in a managed care setting, SU320
- Efficacy of BZA in reducing the incidence of nonvertebral fractures in postmenopausal osteoporotic women at higher fracture risk, M390
- Trauma type of NHNV fractures in postmenopausal women being treated for osteoporosis in Europe, SU325
- Fractures, proximal humerus**
- Incidence and costs of proximal humerus and wrist fractures in women in France, SU327
- Proximal humerus fractures in men: epidemiology and costs, SU328
- Fractures, rib**
- Epidemiology of rib fractures in older men, F354
- Fractures, spinal**
- Fractures of the spine and hip increase the risk of death in Canadians, SU351
- Fractures, stress**
- Stress fracture and vertebral osteosclerosis related to fluorosis induced by excessive gingival topical fluoride application, M444
- Fractures, tibial**
- Diffuse osteopenia after tibia fracture: benefits of early mobilization and weight bearing, F461
- Use of GFP reporters to assess cell lineage in a murine model of tibial fracture repair, M077
- Fractures, vertebral**
- Active controlled, non-inferiority study to compare the effect of ZT-031 with ALN on the incidence of new vertebral fractures, M347
- To avoid underdiagnosis of vertebral fracture, recognition of true fracture line including multiple Schmorl's Node is necessary, SA324
- BMD and vertebral fracture in women with breast cancer and antiaromatase therapy, SA400
- Bony symptoms and vertebral fractures in GD1: data from the 105 patients of the French Observatoire on Gaucher Disease, SA466
- Calcitonin intramuscular administration for treating acute pain of osteoporotic vertebral compression fractures, SA196
- Comparison between logistic regression and artificial neural networks for vertebral fracture risk assessment, SU345
- Cortical porosity is increased in male osteoporosis with vertebral fracture, 1132
- Densitometric vertebral fracture assessment in postmenopausal women, SU254
- Effective progressive resistive exercise program from prone position for paravertebral muscles to reduce risk of vertebral fractures, M473
- Height loss, vertebral fractures and misclassification of osteoporosis, SU259
- Hip fracture patients with vertebral fractures have more severe osteoporosis and are candidates for more active treatment including PTH, SU274
- Incident vertebral fracture is predicted by prevalent vertebral fracture as identified by the algorithm-based qualitative method, but not by non-osteoporotic short vertebral height, 1128
- Increased risk of morphometric vertebral fracture in postmenopausal women with PHPT, M438
- Lumbar spine TBS complements BMD in the discrimination between vertebral fractured and non-fractured subject, M308

Medication prescription and adherence after hospitalization for osteoporotic vertebral fracture, M381

Once-a-month RIS 150 mg reduced vertebral fracture risk at one year in a historical control analysis, SU403

pQCT predicts vertebral fractures in osteoporotic postmenopausal women, SU472

Predictive validity of the WHO FRAX model, BMD and prevalent vertebral fracture for incident radiographic vertebral fractures, 1127

Prevalence and factors associated to the presence of vertebral fractures in patients with type 2 diabetes mellitus, M447

Prevalence of subtrochanteric fractures in patients older than 50 years presenting with a clinical vertebral or non-vertebral fracture, SU390

Prevalence of vertebral compression fracture deformity by x-ray absorptiometry in patients selected according to simple clinical tests, SU261

Prevalence of vertebral fractures in aging women suffering from hip fracture, SU322

Randomized trial of balloon kyphoplasty and nonsurgical care for acute vertebral fracture, 1243

Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349

Spine shape predicts vertebral fractures in postmenopausal women, 1129

Vertebral fracture in men: level of trauma, BMD and lean body mass, SU360

ZOL treatment of osteoporosis: effects in men, SU398

**Fractures, wrist**

10-year probability of recurrent osteoporotic fractures after a primary wrist fracture in postmenopausal women enrolled in the CaMos cohort, F358

Incidence and costs of proximal humerus and wrist fractures in women in France, SU327

**Framingham Osteoporosis Study**

Bivariate whole genome linkage analysis of femoral bone geometric traits and leg lean mass, M249

Does dietary protein reduce hip fracture risk in elderly men and women?, SU319

Elevated production of IL-1 $\beta$  and TNF $\alpha$  by PBMC is associated with increased hip fracture risk in elders, 1283

Essential fatty acid and fish intake is associated with higher BMD in elderly women and men, F341

GWAS of BMD and hip geometry indices, 1092

Protective effect of total and supplemental Vitamin C intake on the risk of hip fracture, 1168

**Framingham QCT Study**

Ca intake is not associated with increased coronary artery calcification, 1207

**Framingham SHARe Project**

GWAS pleiotropic associations of bone phenotypes, SA251

**FRAX**

Age is the key to assessing fracture risk: FRAX, F306

Case finding for the management of osteoporosis with FRAX—assessment and intervention thresholds for the UK, 1290

FRAX<sup>TM</sup> and the assessment of ten-year fracture probability in Hong Kong Southern Chinese according to age and BMD femoral neck T-scores, SU264

Impact of varying BMD resources on prediction of hip fracture using FRAX<sup>TM</sup>, SU257

Incorporating FRAX<sup>TM</sup> algorithms in models of cost-effectiveness, 1023

Predictive validity of the WHO FRAX model, BMD and prevalent vertebral fracture for incident radiographic vertebral fractures, 1127

Treatment threshold in men on androgen deprivation therapy: T-score vs. FRAX, F308

**FREEDOM Trial**

Phase III study of the effects of DMAB on vertebral, nonvertebral, and hip fracture in women with osteoporosis, 1286

**Frizzled homolog 1 (FZD1)**

Characterization of a promoter polymorphism in FZD1: allele-specific regulation by Egr-1 in osteoblast-like cells, M267

**Frizzled-9**

Mice lacking the Wnt receptor Frizzled-9 display osteopenia caused by decreased bone formation, 1006

**Fructus ligustri lucidi**

Effects of different extracts of *Fructus ligustri lucidi* on Ca balance in normal female rats, M336

**Frzb/sFRP3**

Transcriptional silencing of Frzb/sFRP3 by promoter methylation in osteogenic sarcoma, SU231

**FSH**

Transgenic expression of human FSH in female mice has an anabolic effect on bone, 1224

**FZD1**

Haplotype specific promoter activity of the human *FZD1* gene, M269

**G**

**G protein**

Deletion of the G protein subunit G $\alpha$  in early osteoblasts leads to accelerated osteoblast maturation and formation of woven bone with abnormal osteocytes, resulting in severe osteoporosis, 1254

PTHr1 stimulates bone formation through a distinct  $\beta$ -arrestin dependent pathway independent of G protein activation, 1226

Small G protein Rap1 promotes osteoblast differentiation, M080

XXLs acts as a novel heterotrimeric G protein subunit with an ability to transduce receptor activation into intracellular signaling, F226

**G protein-coupled receptor (GPR30)**

Role of GPR30 in effects of estrogen in OVX mice, SU179

**Ga11**

Effects of Ga11 overexpression on osteoblast signaling and function in transgenic mice, M067

**Ga12**

Stable expression of constitutively active Ga12 in osteoblastic cells promotes matrix protein expression and ALP activity, M068

**Gaq**

Inhibitory role of Gaq/PKC $\delta$  signal in the bone anabolic action of PTH, 1228

**G171V**

G171V and A214V Lrp5 knock-in mice have increased bone mass and strength, and can help precisely define the in vivo functions of Lrp5 during bone growth and homeostasis, 1002

LRP5 G171V mutation and tobacco smoke related bone fragility, M323

**G610C**

Age-associated changes in the material properties of the G610C (Amish) OI mouse model, SA252

**Gab2**

Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119

**Galectin-3 (gal-3)**

Role of gal-3 in OA, M162

**GalNac-T3**

Evidence supporting the necessity of GalNac-T3 in the processing of FGF-23 in humans, SA200

**Galnt3**

Ablation of the Galnt3 gene in mice leads to low circulating FGF-23 concentrations and hyperphosphatemia despite increased FGF-23 gene expression, 1018

**Gamma-glutamyl peptides**

Activation of the CaSR by beta-aspartyl and gamma-glutamyl peptides, M202

**Gammopathy**

Blocking TGF $\beta$  signaling reduces gammopathy and improves bone volume and strength in vivo, F293

**Gastric acidification**

Rachitic defects in tcirg1-dependent osteopetrosis are caused by impaired gastric acidification, 1201

**Gastric bypass surgery**

PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180

**Gastroesophageal reflux disease (GERD)**

Postmenopausal women with GERD and long term treatment with bisphosphonates IV, M361

**Gastrointestinal events**

Treatment discontinuation due to gastrointestinal adverse events and decreased BMD in patients switched from branded ALN to generic ALN, SA414

**Gaucher disease type 1 (GD1)**

Bony symptoms and vertebral fractures in GD1: data from the 105 patients of the French Observatoire on Gaucher Disease, SA466

**GC-1**

TR $\beta$ -specific agonist GC-1 increases bone quality of adult female mice, M228

**GCMB**

Dominant-negative GCMB mutants causing autosomal-dominant HPT—protein expression and cellular localization, SA225

**GDF-8**

Myostatin (GDF-8) regulates the secretion of growth factors localized to the muscle-bone interface, SU153

**Gdf5**

Identification of a transcription factor p63 for transactivation of Wnt9a and Gdf5 causing joint cartilage formation, F116

**GEFOS Consortium**

Large-scale meta-analysis of genome-wide association scans for osteoporosis traits, 1091

**GEM OS2**

Percutaneous injection of GEM OS2 increases vertebral BMD in geriatric female baboons, F376

Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, 1137

**Genome analysis**

Bivariate whole genome linkage analysis of femoral bone geometric traits and leg lean mass, M249

**Genome-wide association study (GWAS)**

GWAS and subsequent replication studies identified ADAMTS18 and TGFBR3 as novel osteoporosis risk genes, 1093

GWAS identified novel susceptibility loci for osteoporosis, SA267

GWAS identified RTP3 as a novel gene for bone strength, SU331

GWAS of BMD and hip geometry indices, 1092

GWAS pleiotropic associations of bone phenotypes, SA251

GWAS reveals genetic variants associated with BMD, osteoporosis and osteoporotic fractures, SA263

Phased GWAS identifies probable new gene affecting BMD, M245

**GERD. See Gastroesophageal reflux disease**

**GFP**

Tracking adipose differentiation in vitro with ap2-GFP reporters and flow cytometry: lipid staining and macrophage mimicry, SU057

Use of GFP reporter mice for assessing osteoprogenitor cell activity in a critical size calvarial defect, SA007

## Key Word Index

## ASBMR 30th Annual Meeting

- Use of GFP reporters to assess cell lineage in a murine model of tibial fracture repair, M077
- Use of GFP reporters to map the progression of multipotential progenitor cells into the osteoblast lineage, SU053
- Ghrelin**
- Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086
- Increased caloric intake in energy deficient exercising with functional hypothalamic amenorrhea women is associated with decreased ghrelin and increased bone formation, SU184
- G $_i$**
- Endogenous G $_i$  signaling in osteoblasts negatively regulates cortical bone formation, 1255
- GISMO Lombardia Database**
- Comparison between logistic regression and artificial neural networks for vertebral fracture risk assessment, SU345
- Is the association between hypertension and bone osteoporotic fracture expressing a real interdependence?, SU346
- Gja1**
- Altered long bone structure in recessive null and dominant negative Cx43 (*Gja1*) mouse mutants, 1110
- GK**
- Characterization and genetic mapping of bone size phenotypes in GK and F344 rats using a new 3D CT method, M463
- Gli2**
- Marked induction of endochondral bone formation by overexpression of a constitutively active Gli2 in MSCs isolated from the healing site, SA049
- Wnt signaling regulates Gli2 and PTHrP expression in human breast cancer cells that cause osteolysis, M278
- Glial cells missing-2 (GCM2)**
- GCM2, the regulator of parathyroid cell fate, transactivates the CaSR gene, M187
- Global Longitudinal Registry of Osteoporosis in Women (GLOW)**
- Distribution of risk factors for fracture in women with and without a fracture history, SU342
- Failure to perceive increased risk of fracture in women 55 years, SA360

- GIP inhibits glucose-induced apoptosis of bone cells, M011
- Protein hydrolyzate directly modulates the expression of GIP by osteoprogenitor cells, SU010
- $\gamma$ -glutamyltransferase (GGT)**
- Association of urinary GGT and serum FGF-23 with prevalent fracture, SA296
- $\gamma$ -glutamyltransferase, serum level of (sGGT)**
- sGGT is one of the factors that determines the response to ALN treatment in osteoporotic women, M421
- Glutathione reductase (GSR)**
- Overexpression of GSR in osteoblasts decreases bone formation and partially prevents OVX-induced bone loss, F024
- Glycation**
- Non-enzymatic glycation increases bone fragility through altered microdamage formation and propagation, F103
- Glycation, non-enzymatic (NEG)**
- NEG alters collagen fibrillar structure and energy dissipation characteristics, SU478
- Glycogen synthase kinase-3 $\beta$  (GSK3 $\beta$ )**
- Osteoblasts apoptosis is mediated through GSK3 $\beta$ , M005
- GNAS**
- Deletion of the *GNAS* antisense transcript results in parent-of-origin specific *GNAS* imprinting defects and phenotypes including PTH-resistance, 1052
- Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259
- Gondanotropins**
- Gondanotropins, bone loss and fracture in men, 1278
- Gothenburg Osteoporosis and Obesity Determinants (GOOD) Study**
- Cortical cross sectional area in young adult men is inversely related to risk of hip fracture in their older relatives, 1281
- gp38**
- Early osteocyte marker, E11/gp38 is highly elevated in new bone formed in response to distraction as compared to existing bone, SA136
- Gpr30**
- Non-genomic estrogen receptor Gpr30 is a Runx2 responsive gene that is required for osteoblast proliferation, F572
- GPR55**
- Cannabinoid receptor GPR55 affects osteoclast function in vitro and bone mass in vivo, 1221
- GPRC6A**
- GPRC6A null mice exhibit osteopenia and feminization, F004
- Granulin/epithelin precursor (GEP)**
- In vivo knockdown of GEP, a novel growth factor in cartilage, led to defects in cartilage and OA, 1048
- Grape seed extract**
- Grape seed extract suppresses IL-23/Th17 inflammatory pathways and bone destruction in CIA, SU093
- Gremlin**
- Nov induces gremlin expression by post transcriptional mechanisms, F141
- Growth factor, vascular endothelial (VEGF)**
- Dwarfism and osteopenia in mice with inactivated HRE in the VEGF gene promoter, 1152
- Human osteoblasts synthesize VEGF in response to ACTH, SA236
- VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029
- VEGF induction provides evidence for different signaling pathway activation by large and small osteoclasts, SU106

**Growth factors**

- Ablation of IGF-I signaling in osteoprogenitors decreases bone formation and blunts the skeletal response to PTH, 1193
- Adipocyte-secreted protein URB is a potent stimulator of bone formation, F006
- Age-related changes in BMD, cross-sectional area and the strength of rat femur; an involvement of suppression of GH-IGF-1 signaling, SA467
- Alterations in bone structure and growth in dwarf rats with a depressed GH/IGF-I axis, SA178
- Anabolic PTH treatment mobilizes BMSC and osteoprogenitors towards bone surfaces, SA229
- bFGF induces the expression of a subset of Bcl-2 family genes to inhibit the apoptosis of ATDC5 chondroprogenitor cells, SU043
- BMP-2 inactivates TAK1-ATF2 signaling pathway in chondrocytes, F186
- BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/Akt regulates NFATc1 expression and its nuclear translocation, 1081
- BMP-3-null aged mice display increased trabecular bone volume and reduced cross sectional area at the mid-femoral diaphysis, SU143
- BMP-6 from bone regulates serum glucose via IGF-1 released from pancreas, SU141
- BMP-7 is not required for fracture healing, SU148
- BMPR2 is dispensable for formation of the limb skeleton, SU145
- Canonical Wnt signaling suppresses BMP-4 accumulation from C3H10T1/2 cells transfected with BMP-4 expression vector, SA156
- Catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation, SU137
- CCR2 receptor signaling is involved in bone mass regulation and mediates the response to anabolic but not catabolic regimens of PTH(1-34), SU158
- CD47 (IAP) is an important modulator of osteoclast and osteoblast differentiation in vitro and in vivo, F093
- Central and peripheral leptin treatment produce similar increase in cortical and trabecular bone mass in ob/ob mice, SU164
- Characterization of Jab1-interacting motif in LMP-1, SA023
- Chemerin and CMKLR1 expression and function in human bone marrow MSC adipogenesis, SU165
- Circulating BMP-1 isoforms: novel diagnostic and therapeutic challenges for bone fracture repair, SU142
- Circulating OPG and its ligand in post operative biliary atresia: relationship with metabolic bone disease, M406
- CPTH; prediction of novel functions, structural features and potential receptor, SU072
- Craniofacial bone defect in Nell-1 mutant mice associated with dysregulated Runx2 and Osx expression, F174
- Critical role of TGF $\beta$  signaling pathways in skeletal development, 1079
- Decreased bone formation, increased bone resorption, and osteopenia in mice lacking SP, SU160
- Dependence of post natal osteogenic differentiation on BMP-2, SA001
- Distinct biological activity of IL-8 isoforms, SU162
- Effects of beta-D-glucopyranoside from *Phellodendron Amurense* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117
- Effects of IL-27 on regulation of osteoclastogenesis by way of T cells, SU081
- Endocrine IGF-I maintains linear growth in the total absence of tissue IGF-1, SA184
- Endorphins regulate bone material properties by actions through dynorphin, 1195
- Ephrin B1 reverse signaling regulates bone formation via influencing osteoblast activity in mice, 1194
- FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177
- Gene transcripts related to T-cell activation, proliferation, and cytokine signaling show significant effects on BMD variation in baboons, M241
- Grape seed extract suppresses IL-23/Th17 inflammatory pathways and bone destruction in CIA, SU093
- H4R is expressed by both OA and RA human tissues, SU159
- Hedgehog signaling regulates growth plate chondrocyte proliferation and growth factor expression, SU161
- High bone turnover in mice lacking the growth factor Mdk, 1198
- Identification and analysis of human LMP gene promoter region, M034
- IFN- $\gamma$  inhibits TNF $\alpha$ -induced osteoclastogenesis in vitro and in vivo, SU152
- IGF-I secreted from osteoblasts as a major chemotactic factor for osteoblasts, SA179
- IL-1 $\beta$ -induced hepcidin expression in synovial membranes of patients with OA is associated with TNF $\alpha$  repression, SU157
- IL-12 induces apoptosis in TNF $\alpha$ -mediated osteoclastogenesis in vivo, SA166
- IL-12 stimulates the OIP-1 gene expression in CD4<sup>+</sup> T-cells, SA173

- Importance of melastatin-like transient receptor potential 7 and Mg in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor, M008
- Improvement of alveolar bone quality by local bFGF injection—histological and cellular biological analysis in a rabbit model, SA162
- Increased circulating DKK1 in acute coronary syndrome—association with platelet release and endothelial inflammatory response, SU167
- Increased expression of OPN in PBMC is associated with alteration in the fractions of lymphocytes in hindlimb-unloaded mice, M175
- Induction of CTGF by TGF $\beta$ 1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066
- Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374
- Intermittent injection of recombinant osteocalcin improves glucose tolerance and insulin sensitivity, F168
- Interplay between BMP and TGF $\beta$  signaling in osteoblast differentiation, SA031
- Is GH/IGF-I mediated mechanism involved in regulating gender differences in bone size?, SA180
- JNK activation is involved in TNF $\alpha$ -stimulated Smurf1 expression, SA016
- Low serum IGF-I alters the cortical bone response to estrogen deficiency, SU190
- LPA enhances the viability of rat growth plate chondrocytes through the inhibition apoptosis and the promotion of cellular maturation, SU156
- Mechanism of action of lactoferrin's bone anabolic activity, SA175
- Mice lacking the GH receptor in liver have normal skeletal growth and bone volume despite virtual absence of circulating IGF-1, F181
- MKP-1 is an endogenous negative regulator of pro-inflammatory cytokines in BMSC, SU013
- Model of high body mass: BMD, bone markers and adipocytokine levels in high level male rugby players, SA167
- MSC enhance fracture healing: essential role for cytokines in homing and anti-inflammatory response, SA169
- Myostatin (GDF-8) regulates the secretion of growth factors localized to the muscle-bone interface, SU153
- NADPH oxidase/Nox signaling stimulates myofibroblast Mx2 transcription via H<sub>2</sub>O<sub>2</sub>, 1083
- Negative regulation of Tcf/Lef-dependent transcription by the BMP/Smad4 signaling axis, SU144
- OPG production by breast cancer cells is modulated by steroid hormones and confers resistance against TRAIL-induced apoptosis, M271
- Osteocalcin is a stress hormone: interaction with the sympathetic nervous system, M059
- Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135
- Osteotropic peptides: anabolic and osteogenic effects, M045
- Permanent FGFR2 activation promotes osteoblast differentiation in MSCs through activation of PKC signaling, M093
- PGE2 as a potential mediator of PTH-dependent regulation of HSCs, F171
- Physiological concentrations of inhibin A are anabolic, affecting both trabecular and cortical bone in normal intact mice, M177
- PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027
- PLC $\gamma$ 2 as a promising therapeutic target in RA, F176
- Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, 1082
- Protein sulfation is required to prevent chondrocytes autophagy and growth factor signaling during endochondral ossification, SU119
- PTHrP is processed by skin keratinocytes and has immunomodulation properties, SA216
- Real time oscillations in TNF-induced gene expression MAPK phosphorylation and promoter binding, SU087
- Recombinant congenic strain (B.H-6) establishes that trabecular bone mass and bone marrow adiposity are distinct and heritable phenotypes, F265
- Recovery of bone architecture after RANKL administration in rats is characterized by increased bone mass on existing trabeculae assessed by in vivo  $\mu$ CT, SU076
- Relationship between serum levels of inflammatory cytokines and bone turnover markers in the year following hip fracture, SU073
- Rheumatoid synoviocytes are stimulated with IL-23 to enhance osteoclastogenesis through upregulation of RANKL expression, SU084
- Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043
- Safety and efficacy of BMP-7 putty in a rabbit model of posterolateral vertebral lumbar fusion, SU149
- Serum IGF-1 is a developmental determinant of bone size, SA183
- Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177
- Sympathetic tone mediates leptin's inhibition of insulin secretion by modulating osteocalcin bioactivity, F034

## Key Word Index

## ASBMR 30th Annual Meeting

Synergistic activation of osteogenesis in MLPC by oxysterols, SU038

T cells amplify the anabolic action of PTH through Wnt10b signaling, 1197

Targeted overexpression of the nuclear FGF-2 isoforms in osteoblasts induces hypophosphatemia via modulation of FGF-23 and Klotho in mice, 1084

Tcf is required for Wnt11 mediated osteoblast differentiation, M058

TGF $\beta$  inhibits BMP signaling and osteogenesis through the TGF $\beta$  and BMP R-Smad direct interaction, 1080

TGF $\beta$  receptor I kinase inhibitor increases bone mass in normal mice, SA172

TGF $\beta$ 1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

Tissue-engineering and co-culture system based disc regeneration MSC's role, SA189

Transcription factor NFATp regulates BMP-induced chondrocyte differentiation in a tissue-specific manner, SU020

Transient expression of CXCR2 in human MSC stimulates chemotaxis toward CXCR2 ligand 8 and increased mineralization in the presence of osteogenic medium, SA170

In vivo knockdown of GEP, a novel growth factor in cartilage, led to defects in cartilage and OA, 1048

Wnt pathway regulation by demineralized bone requires TGF $\beta$ /BMP signaling, SU138

Wnt7a and Wnt7b evoke overlapping yet distinct transcriptional responses during the osteogenic programming of mesenchymal progenitors by Msx2, 1196

**Growth hormone (GH)**

Alterations in bone structure and growth in dwarf rats with a depressed GH/IGF-I axis, SA178

Anabolic skeletal effects of a GH-derived peptide (AOD9604) in the OVX rat model of osteoporosis, SU373

Differential effects of GH and 1  $\alpha$  calcidol on cancellous and cortical bone in hypophysectomized rats, SU501

Effects of GH on bone micro-architecture by in vivo  $\mu$ CT, SA547

Effects of long-term administration of high-dose GH on body composition and bone mineralization, SA571

FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177

Interaction of combined intervention of PTH and GH on trabecular and cortical bone formation and resorption in the hypophysectomized rats, SU502

Is GH/IGF-I mediated mechanism involved in regulating gender differences in bone size?, SA180

Mice lacking the GH receptor in liver have normal skeletal growth and bone volume despite virtual absence of circulating IGF-1, F181

Relationship between adipokines and biochemical bone markers in osteoporotic women before and after GH supplementation, M289

Relationship between biochemical bone markers in osteoporotic women before and after 6 months treatment with either GH, Sr ranelate or GH plus Sr, M291

**Growth hormone, human (hGH)**

Sca-1<sup>+</sup> HSC-based hGH gene therapy enhanced endosteal bone resorption in mice, M233

Study of hGH and IGF-1 receptors in the human fetal femoral growth plate, SU128

**Growth plates**

Bone tether formation in femoral and basicranial growth plates have similar responses to growth disruptions due to nuclear VDR genotype and mineral homeostasis, M164

Chondrocyte-derived Ihh is required for osteoblast differentiation despite reconstitution of a normal growth plate, 1154

Gene expression profiling within murine growth plates using DNA microarrays, M156

Hedgehog signaling regulates growth plate chondrocyte proliferation and growth factor expression, SU161

Mechanisms of endplate failure in the human vertebral body, M413

Postnatal deletion of PTH/PTHrP receptor in growth plate chondrocytes leads to growth plate fusion, F114

Quantification of non-mineralized tissue via  $\mu$ CT as a readout for GC effects on rat growth plate, M136

Regulation of autophagy in the epiphyseal growth plate by AMPK and mTOR requires HIF-1, SU134

Specific inactivation of AF-1 in ER $\alpha$  results in growth plate closure while total inactivation of ER $\alpha$  results in increased growth plate width in elderly female mice, 1181

Study of hGH and IGF-1 receptors in the human fetal femoral growth plate, SU128

Thyroid hormone activates Wnt signaling pathways in rat growth plate chondrocytes, M157

Tissue-specific KO of the CaSR in chondrocytes inhibits IGF-1 signaling and delays differentiation in the growth plate, 1261

**Grx5**

Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009

**G $\alpha$**

Expression of an engineered G $\alpha$ -coupled receptor in osteoblasts affects intramembranous and endochondral bone formation during bone repair, F127

Expression of an engineered G $\alpha$ -coupled receptor, Rs1, in mature osteoblasts is sufficient to drive a dramatic anabolic skeletal response, 1077

Ligand activation of the engineered G $\alpha$ -coupled receptor Rs1 in osteoblasts promotes trabecular bone formation, 1076

**Gsa**

Deletion of the G protein subunit Gsa in early osteoblasts leads to accelerated osteoblast maturation and formation of woven bone with abnormal osteocytes, resulting in severe osteoporosis, 1254

**GSK3**

Akt regulates skeletal development through GSK3, mTOR, and FoxOs, 1151

Transcriptional regulation of Cx43 by  $\beta$ -catenin, a pathway activated by PGE $_2$ -PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

**GSK3-beta**

SOST blocks GSK3-beta inhibitor-induced ALP activity, SU036

**GTPase**

Proteomic identification and characterization of the small GTPase Rab18 in human osteoclasts, SU109

**GWAS**. See *Genome-wide association study*

**H**

**H3**

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**H4**

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**Halofuginone (Hfg)**

Hfg inhibits melanoma bone metastases and TGF $\beta$  signaling, F190

**Hardness**

Long-term treatment with oral bisphosphonates in postmenopausal women: effects on the degree of mineralization and microhardness of bone, 1029

**HcB/8**

Geometric property QTLs in HcB/8 x HcB/23 F2 cross, F260

Strong and extensive epistatic interactions affect bone traits in a mouse reciprocal intercross of HcB/8 and HcB/23, SA125

**HcB/23**

Geometric property QTLs in HcB/8 x HcB/23 F2 cross, F260

Strong and extensive epistatic interactions affect bone traits in a mouse reciprocal intercross of HcB/8 and HcB/23, SA125

**Health care**. See also *Alternative medicine; Medicare*

Costs associated with NHNV fractures in a managed care setting, SU320

Designing a Latino osteoporosis awareness campaign, SU312

Do physicians who practice together provide similar osteoporosis care?, SU401

Falls predict higher medical costs among osteoporosis patients in community setting, SA430

Incorporating FRAX<sup>TM</sup> algorithms in models of cost-effectiveness, 1023

Incremental costs associated with selected skeletal fractures, 1024

Osteoporosis: evaluation of screening patterns primary care group practice, SU272

Predictors of osteoporosis management among residents living in long-term care, SA368

Quarterly intravenous IBN acid in the community setting in England, SU409

Questionnaire-based osteoporosis risk assessment in a rural area primary care setting, SU354

Relative contributions of nonvertebral efficacy, vertebral efficacy, and persistence in determining cost-effectiveness: the case of osteoporosis and implications for payers, M371

Socioeconomic status, BMD testing and hip fracture rates in a universal health-care system, SU293

Treating osteoporosis in the elderly: an environmental scan of nursing home prescribing in Ontario, Canada, SU404

**Heart transplant**

Marked Vitamin D deficiency in recent heart and liver transplant recipients, SA501

**Hedgehog proteins**

Hedgehog pathway is activated in osteosarcoma and cyclopamine prevents osteosarcoma growth by cell cycle regulation, SU241

Hedgehog signaling regulates growth plate chondrocyte proliferation and growth factor expression, SU161

**Heel Stiffness Index**

Correlation between DXA Femur Strength Index and QUS Heel Stiffness Index in Chinese women, M464

**Height loss**

Height loss, vertebral fractures and misclassification of osteoporosis, SU259

**Helsinki Study of Very Low Birth Weight**

Preterm birth and BMD in young adulthood, 1103

**Hematopoiesis**

Impact of PTH on cells of the hematopoietic lineage, 1159

PTH stimulates hematopoiesis and increases survival in irradiated mice, 1015

Role of Ostm1 in bone, hematopoiesis and neuronal development, 1271

**Hematopoietic cells**

Drugs which inhibit osteoclast function suppress tumor growth and alter hematopoietic cell populations in bone, F270

Hematopoietic cells in the bone marrow augment anabolic actions of PTH, M181

**Hematopoietic stem cells (HSC).** See *Stem cells*  
**Hemodialysis**

- Acute change in iCa directly affects bone formation independent of PTH action during hemodialysis, SU437
- Association of the marker of ABD with malnutrition-inflammation complex in hemodialysis patients, SU446
- Biomechanical impact of chronic hemodialysis on bones and muscles, SU269
- Hemodialysis patients rapidly lose their bone minerals after 60 years of age, SU438
- Parathyroidectomy improves quality of life in hemodialysis patients with HPT2, SA212
- Serum intact PTH of 100 to 150 pg/ml is associated with greatest survival in maintenance hemodialysis patients, SU445
- SIF levels among hemodialysis patients are positively associated with levels of serum phosphate and intact PTH, SU440

**Hemophilia A**

- Osteoporosis in a murine model of hemophilia A, M480

**Heparan sulfate proteoglycans (HSPG)**

- HSPG modulate osteogenic differentiation through heparan sulfate chains, M094

**Hepatic osteodystrophy.** See *Osteodystrophy***Hepatitis C-associated osteosclerosis (HCAO)**

- Recovery from HCAO following anti-viral treatment, F488

**Hepcidin**

- IL-1 $\beta$ -induced hepcidin expression in synovial membranes of patients with OA is associated with TNF $\alpha$  repression, SU157

***Herba epimedii***

- Bone anabolic effects of icariin and total flavonoid fraction of *Herba epimedii* in OVX mice, M337

**Heterochromatin**

- TZD modify nuclear heterochromatin architecture, SU056

**Heterogeneous nuclear ribonucleoproteins (hnRNP).** See *Ribonucleoproteins***Heterozygosity**

- Morquio Syndrome variant: two siblings with atypical phenotype and novel compound heterozygosity, M240

**hFVIII**

- Differences in femoral bone structure between juvenile non-transgenic and transgenic rabbits with the WAP-hFVIII gene construct, SA132

**High g environments**

- Effects of a high g environment on BMD in UK fast-jet trainee pilots, SU473
- Increased osteoclast differentiation and bone resorption during spaceflight, SU094

**High mobility group AT-hook 2 (HMGA2)**

- Common single nucleotide polymorphism in the HMGA2 gene is associated with bone mass in men, SA268

**High mobility group box protein (HMGB)**

- TSH inhibits the expression of HMGB, a regulator of TNF $\alpha$  transcription, in osteoclastogenesis, 1117

**HIP**

- Gender-specific changes in bone microstructure of mice lacking ribosomal protein L29/HIP, SA133

**Hip replacement**

- Low systemic BMD increases implant migration in cementless hip replacement, F458

**Hip structure analysis (HSA)**

- HSA and physical activity in boys and girls during puberty, SA538
- HSA based on DXA data in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA507
- HSA for RLX treatment in Japanese women with osteoporosis, SA419
- HSA in women, SU270

**Hiroshima Cohort Study**

- Association of urinary GGT and serum FGF-23 with prevalent fracture, SA296

**Histamine H4 receptor (H4R)**

- H4R is expressed by both OA and RA human tissues, SU159

**Histomorphometry**

- Bone histomorphometry in patients with Crohn's Disease, SU462
- Bone turnover evaluated by a combined Ca balance and <sup>45</sup>Ca kinetic study, and dynamic histomorphometry, M137
- Dynamic histomorphometry of mineralized tissue using cryosections of murine bone and teeth, M138
- Histomorphometric evaluation in an experimental model of hepatic osteodystrophy, M480
- Long term safety of oral RIS treatment in men with osteoporosis as assessed by histomorphometry, SA344

**Histone deacetylase (HDAC)**

- HDAC inhibitors suppress IL-1 $\beta$ -induced NO and PGE<sub>2</sub> production in human chondrocytes, SU116
- NFATc1 mediates HDAC-dependent transcriptional repression of osteocalcin expression during osteoblast differentiation, 1145

**Histone deacetylase 1 (HDAC1)**

- Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**Histone deacetylase 2 (HDAC2)**

- Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**Histone deacetylase 7 (HDAC7)**

- PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027

**Histone deacetylase inhibitors (HDI)**

- HDI, Vorinostat, blocks growth and associated osteolysis of cancer cells within bone, but reduces bone volume in non-tumor bearing bones in mice, M279

**Homocysteine**

- Homocysteine accumulates in bone tissue by collagen binding and adversely affects bone, M417
- Homocysteine levels in relation to physical performance, SA372

**Homocystinuria**

- Homocystinuria associated bone disease: effect of long term bisphosphonate treatment, SA406

**Horizon Pivotal Fracture Trial**

- Effect of once-yearly ZOL 5 mg infusion on fracture incidence in postmenopausal osteoporosis, 1028
- Effect of once-yearly ZOL on integral BMD of the spine, SU405
- Increase in risk of atypical subtrochanteric fractures with ZOL?, F411

**Hormone deficiency**

- Mechanical loading prevents bone loss due to hormone-deficiency in female mice, M474

**Hormone therapy**

- Impact of adjuvant hormonal therapy on bone loss depending on initial adjuvant chemotherapy and menstrual status, M415
- Influence of long-term hormone replacement therapy on tibia bone mineral mass and mass distribution in postmenopausal women, F420
- Serum estradiol and fracture reduction during treatment with hormone therapy, F383
- Treatment threshold in men on androgen deprivation therapy: T-score vs. FRAX, F308

**Hormones**

- Hormonal influences on volumetric bone density and geometric properties in obesity, SU367

**Hormones, calcitropic and phosphotropic**

- Ablation of the Galnt3 gene in mice leads to low circulating FGF-23 concentrations and hyperphosphatemia despite increased FGF-23 gene expression, 1018

- Activation of the CaSR by beta-aspartyl and gamma-glutamyl peptides, M202
- Altered regulation and expression of FGF-23 in the adenine-induced uremic rat model, SU178
- Analysis of chromosome breaks in osteoblasts and non-osteoblastic cells treated with intermittent PTH, M191
- Analytical validation of LIA and ELEC methods for the determination of osteocalcin, SA191
- Angiotensin II type 2 receptor blockade increases bone mass, SU007
- Association between Cx43 and  $\beta$ -arrestin is required for cAMP-dependent osteoblast survival induced by PTH, 1227
- Association of the marker of ABD with malnutrition-inflammation complex in hemodialysis patients, SU446
- Behavior of circulating rat(s) PTH molecular forms in HPT2 related to Vitamin D deficiency and renal failure, M194
- Bone turnover evaluated by a combined Ca balance and <sup>45</sup>Ca kinetic study, and dynamic histomorphometry, M137
- c-Fos is associated with renal FGF-23-mediated signaling, SU173
- C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223
- Calciphylaxis in a patient with HPT and normal kidney function, WG33
- Calcitonin attenuates the anabolic effect of PTH in vivo and rapidly upregulates SCT expression, F195
- Calcitonin receptor on osteoclasts plays a physiological role to protect against HCa in mice, SA197
- CaSR mediated signaling in human vascular smooth muscle cells, M200
- $\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, 1013
- Circulating concentrations of 25(OH)D after a single oral dose of 100,000 IU of Vitamin D2 or Vitamin D3, M212
- Clinical implications of commercial biotin-based detection systems in PTH assays, M435
- Cloning and functional analysis of human Nurrl (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161
- Continuous rat parathyroid cell line expressing PTH, M184
- Deletion of CYP27B1 reverts the premature aging phenotype of the Klotho-null mice, F069
- Development of nephrotic in transgenic rats over expressing Type III Na-dependent phosphate transporter, SU170
- Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199
- Dimerization and trafficking of the CaSR to the plasma membrane, M205
- Dominant tissue accumulation of MIBI in parathyroid glands in uremic rats, SA222
- Dominant-negative GCMB mutants causing autosomal-dominant HPT—protein expression and cellular localization, SA225
- Effect of treating Vitamin D deficiency on FGF-23 levels in humans, SA209
- Effects of hPTH(1-34) infusion on circulating serum phosphate, 1,25(OH)<sub>2</sub>D and FGF-23 levels in healthy men, SU169
- Effects of intermittent human PTH administration on bone union with hydroxyapatite blocks at the site of cancellous bone osteotomy in OVX rats, SA214
- Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

## Key Word Index

## ASBMR 30th Annual Meeting

Efficient expression of the full-length CaSR in insect cells, M198

Evidence for a role of prolactin in Ca homeostasis: regulation of intestinal TRPV6 and intestinal Ca absorption by prolactin, 1223

Extended lactation is associated with failure to restore BMD 6 months after resumption of menstrual cycle, M305

FGF-23 and FGF-2 share a common but also have distinct signaling pathways for negative regulation of bone nodule mineralization in cultured osteoblasts, SA206

FGF-23 and post-transplant hypophosphatemia: evidence for a causative link, SU168

FGF-23 in Vitamin D deficient older persons, SA203

Functional induction of target genes in parathyroid cell by direct injection technique, M185

Hematopoietic cells in the bone marrow augment anabolic actions of PTH, M181

High bone mass due to increased bone formation in mice lacking the CTR, SA192

High expression of the Ca/phosphate-regulating hormone STC2 is associated with renal calcification in the Klotho mutant mice, SA201

HPT and renal insufficiency, WG29

Identification and optimization of residues in PTH and PTHrP that determine altered modes of binding to the PTH/PTHrP receptor, F224

Impact of PTH on cells of the hematopoietic lineage, 1159

Increased bone volume and correction of HYP mouse hypophosphatemia in the Klotho/HYP Mouse, 1017

Influence of PHP on BMD and vertebral morphometry, M190

Inhibitory role of Gαq/PKCδ signal in the bone anabolic action of PTH, 1228

Interaction of combined intervention of PTH and GH on trabecular and cortical bone formation and resorption in the hypophysectomized rats, SU502

Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380

Intestinal-specific VDR null mice maintain normal calcemia but display severe bone loss, F238

KO of the PTHrP gene in breast cancer cells inhibits tumor progression and metastatic spread in vivo, 1016

Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194

Local osteocyte defect in *Dmp1* null mice causes overproduction of FGF-23, 1225

Long-acting PTH ligand that binds to a distinct PTH receptor conformation (R0) can stimulate increases in markers of both bone resorption and bone formation in mice, F221

Low density lipoprotein-cholesterol levels affect vertebral fracture risk in female patients with pHPT, SA484

Low serum osteocalcin predicts carotid plaques and indicators of the metabolic syndrome, SA198

Marrow ablation induces periosteal bone formation and potentiates the effect of PTH on endosteal bone formation in rat femurs, M208

Mechanical unloading partially rescues hypophosphatemic rickets in *Dmp1*-null mice, 1162

Mechanism of enhanced 19-nor-2a-(3-hydroxypropyl)-1a,25-(OH)<sub>2</sub>D<sub>3</sub> anti-cancer activity in prostate cancer cells, M216

MEPE C-terminal ASARM-peptide, promotes hypophosphatemia, bone defects and increases adiposity, F207

MEPE regulates bone remodelling independent of serum phosphate and alters renal vascularization, F205

Metabolic alkalosis transition in renal proximal tubule cells facilitates an increase in CYP27B1, while blunting responsiveness to PTH, M196

Molecular basis of PHPT: adenomatous parathyroid cells are resistant to L-amino acids, M203

Molecular mechanisms involved in PTH-induced apoptosis in Caco-2 intestinal cells, M189

N-terminal fragment of PTHrP promotes the GC-related deficiency of bone regeneration after bone marrow ablation in mice, M195

Negative relationship between PTH and Vitamin D: is there an age and a gender effect?, M179

New intact PTH assay on the IDS Automated Analyser 3x3™, M209

New long-acting PTH/PTHrP hybrid analog that binds to a distinct PTHR conformation has superior efficacy in a rat model of HPT, F483

Nmp4-KO mice exhibit a complex phenotype, M193

Normocalcemic PHPT: update on a new clinical phenotype, SA486

Novel and sensitive immunoassay for PTHrP, M182

Osteogenic action of Ex-4 in normal and insulin-resistant state, M424

Osteopenia in CKD: effects of phosphate overload, SU447

Parathyroidectomy improves quality of life in hemodialysis patients with HPT2, SA212

Phex binds to SNARE-associated protein snapin and co-localizes in vesicle-enriched, extracellular matrix micro-environment mediating mineral crystal nucleation, F066

Phosphatonins and liver resection-related hypophosphatemia, SU176

Positive effect of GLP-1 upon bone formation and resistance in insulin-resistant rats, M425

Possible pathogenic role of aberrant Klotho expression in PHPT and HPT2, SA227

Post-mitotic preosteoblasts are the targets of the anabolic actions of intermittent PTH on periosteal bone, 1157

Potential role of FGF-23 in CKD-MBD, WG30

PTH and not Vitamin D predicts age-related bone loss in the elderly, M178

PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180

PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calceineurin pathways, SA033

PTH signaling through LRP5/6 in osteoblasts, 1014

PTH stimulates hematopoiesis and increases survival in irradiated mice, 1015

PTH-gene family in the cartilaginous fish, *Callorhynchus milii*, M183

PTHrP1 mutations associated with Ollier Disease result in receptor loss of function, SA258

PTHrP1 stimulates bone formation through a distinct β-arrestin dependent pathway independent of G protein activation, 1226

PTHrP blockade inhibits tumor progression in a model of human breast cancer, F213

PTHrP regulates mammary gland ductal elongation during puberty, F228

PTHrP-induced Wnt signaling specifies the mammary mesenchyme, F219

Rapid detection of intact FGF-23 in tumor tissue from patients with OOM, SA204

Regulation of nuclear import of the PTHR, M210

Regulation of renal Klotho: the importance of ERα, SA211

Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211

Requirement of the bone for Vitamin D for 1,25(OH)<sub>2</sub>D<sub>3</sub> synthesis and bone mineralization, M224

Role of FGF-23 in the early response to the PTH analogue: TPTD, SU174

Role of OPG/RANKL system for bone loss in PHPT, M192

Role of the transcription factor SOX4 in the skeletal response to intermittent PTH, SA220

Selective removal of PLC signaling in novel PTH(1-28) analogs abolishes regulation of NaPi-IIc but not NaPi-IIa, M186

Serum intact PTH of 100 to 150 pg/ml is associated with greatest survival in maintenance hemodialysis patients, SU445

Serum PTH response to oral Ca load in Asian adolescents, M188

Signaling of extracellular inorganic phosphate mediated via Na-phosphate co-transporters influences FGF-23 signaling in renal tubular cells, SU172

Significance of O-linked glycosylation of FGF-23 protein, SA208

At similar plasma 25(OH)D levels, fat mass influence PTH levels in the state of Vitamin D insufficiency, SA218

Skeletal dysmorphology of mice lacking the mid-region, nuclear localization sequence and C-terminus of PTHrP, 1160

Subcutaneous administration of salmon calcitonin: bone protective effect in adjuvant arthritis prevention model in rats, SA193

Synergistic role of Npt2a and Npt2c in inorganic phosphate metabolism of mice, F473

Target ablation of PPR in osteocytes induces hypocalcemia and impairs bone structure, 1158

Transgenic ASARM-peptide overexpression with reduced serum phosphate and 1,25(OH)<sub>2</sub>D<sub>3</sub> leads to decreased BMD and obesity, F210

Transgenic expression of human FSH in female mice has an anabolic effect on bone, 1224

Vitamin D deficiency in inner city infants: impact of DBP genotype, SA472

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

In vivo longitudinal QCT analysis PTH efficacy in a rat cortical defect model, M207

What is your patient's Vitamin D status? Clinical consideration of variability in a 25(OH)D measurement, SU427

Wintertime Vitamin D supplementation inhibits seasonal variation of calcitropic hormones and maintains bone turnover in healthy men, SU433

XXLαs acts as a novel heterotrimeric G protein subunit with an ability to transduce receptor activation into intracellular signaling, F226

**Hormones, endogenous**

Predictive capacity of biochemical markers of bone turnover and endogenous hormones for osteoporosis in men, SU334

**Hormones, sex**

Influence of sex hormones on BMD in middle aged and elderly men, SU335

Post-fracture mortality in men: contributions of sex hormones and BMD as risk factors, 1280

Reduced serum osteocalcin and sex hormone binding globulin in men with type II diabetes, SU461

Relationship of QUS at phalanges with hand and axial BMD, sex hormones and bone turnover markers in elderly women, M320

**Hormones, stress**

Osteocalcin is a stress hormone: interaction with the sympathetic nervous system, M059

**Hox**

Essential Hox gene function in limb skeletal and synovial joint formation, M151

**HOXA10**  
PBX1 interaction with HOXA10 regulates timing and expression of phenotypic bone genes during osteoblastogenesis, SU019

**HRPT2**  
Usefulness of *HRPT2* gene and parafibromin studies in two patients with PHPT and uncertain pathological assessment, SA482

**HSD11B1**  
Association of *HSD11B1* polymorphisms with vertebral fracture risk and BMD in postmenopausal Korean population, M260

**HSP27**  
Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185

**Human immunodeficiency virus (HIV)**  
Cortical and trabecular microarchitecture in HIV-infected postmenopausal women, SU458  
Determinants of low BMD in HIV infected postmenopausal women, SU455  
Efficient and stable gene expression into human osteoclasts using an HIV-1 based lentiviral vector, SU113  
Vitamin D insufficiency is common in racially diverse postmenopausal women with HIV, M448

**Hydrogels**  
Nanogel cross-linking hydrogel as a drug delivery system for TNF $\alpha$  antagonist, M121  
Sequestration, proliferation and differentiation of osteoblasts in hydrogels for tissue engineering applications, SA143

**Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)**  
NADPH oxidase/Nox signaling stimulates myofibroblast Msx2 transcription via H<sub>2</sub>O<sub>2</sub>, 1083

**Hydroxyapatite (HA)**  
DMP1 fragments interact differently with HA: insights into mechanism of action, SA140  
Effects of intermittent human PTH administration on bone union with hydroxyapatite blocks at the site of cancellous bone osteotomy in OVX rats, SA214  
Local administration with PTX-loaded HA-alginate beads for metastatic spine cancer in rats, M274  
Resorption mechanism of HA and  $\beta$ TCP coating layer, SA100

**Hydroxychloroquine**  
Nonsteroid responsive HCa associated with sarcoidosis—a rapid response to hydroxychloroquine, WG28

**1 $\alpha$ -hydroxylase**  
Expression of 1 $\alpha$ -hydroxylase (CYP27B1) in BMSC, SA237

**25-hydroxylase**  
CYP27A1 mutations at Phe147 confer 25-hydroxylase activity towards a Vitamin D<sub>2</sub>-type sidechain, M231

**11 $\beta$ -hydroxysteroid dehydrogenase**  
Expression of 11 $\beta$ -hydroxysteroid dehydrogenase during murine osteoclast formation, SA235

**5-hydroxytryptamine**. See *Serotonin*

**Hydroxytyrosol**  
High concentrations of hydroxytyrosol and quercetin antioxidants enhance adipogenesis and inhibit osteoblastogenesis in MSCs, SA037

**25-hydroxyvitamin D (25(OH)D)**  
25(OH)D acts on Ca and skeletal homeostasis independent of 1,25(OH)<sub>2</sub>D in vivo, M214  
25(OH)D levels in children with CKD as measured by tandem mass spectrometry, SU485  
Albuminuria, 25(OH)D, 1,25(OH)<sub>2</sub>D, and intact PTH in older adults, SU442  
Circulating concentrations of 25(OH)D after a single oral dose of 100,000 IU of Vitamin D2 or Vitamin D3, M212

Clinically useful paradigm for interpretation of serum 25(OH)D levels with simultaneously measured PTH levels, M437

Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

Dietary Sr in a model of established osteopenic rats reduce the levels of 25(OH)D, SA377

Effect of skin color and oral Vitamin D supplementation on serum 25(OH)D in adolescent girls, SU395

Effect of Vitamin D2 or Vitamin D3 supplementation on serum 25(OH)D, SU425

Effects of 50,000 IU of Vitamin D<sub>2</sub> twice per month on circulating 25(OH)D and Ca levels, SU426

Efficacy and safety of short term treatment with different doses of cholecalciferol on 25(OH)D levels in postmenopausal females with osteoporosis, SU434

Evaluation of automated methods for quantifying serum 25(OH)D, SU206

Low plasma 25(OH)D and VDR polymorphisms are associated with increased breast cancer risk, SU202

Low serum 25(OH)D is associated with higher rates of hip bone loss in older men, F367

New 25(OH)D assay on the IDS Automated Analyser 3x3™, SU200

New data on the impact of renal function on the relationship between 25(OH)D and PTH, 1031

Polymorphisms in *CYP24A1*, the gene encoding 25(OH)D-24-hydroxylase, are associated with BMD, SA266

Seasonal genetic influence on serum 25(OH)D levels, SA334

Serum 25(OH)D and the risk of hip and non-spine fractures in older men, 1277

Serum 25(OH)D measurement and histomorphometric analysis of iliac crest biopsies from 1180 patients reveals a high prevalence of Vitamin D-dependent osteomalacia, 1134

At similar plasma 25(OH)D levels, fat mass influence PTH levels in the state of Vitamin D insufficiency, SA218

Single dose of 100,000 IU D3 appears to be insufficient to achieve desirable levels of 25(OH)D in patients with hypovitaminosis D, SU430

Vitamin D supplementation intake among osteoporosis patients aged 50 years and older at various 25(OH)D levels in the US, M400

What is your patient's Vitamin D status? Clinical consideration of variability in a 25(OH)D measurement, SU427

**25-hydroxyvitamin D<sub>3</sub> (25(OH)D<sub>3</sub>)**  
25(OH)D<sub>3</sub>-24-hydroxylase (CYP24A1): mutagenesis and activity studies reveal important residues involved in regioselectivity and substrate access, SU199

Decreasing calcidiol (25OHD<sub>3</sub>) in serum is related to impaired function and increased mortality in the elderly, SU204

Effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> and 25(OH)D<sub>3</sub> on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207

Prediction of osteoporotic fracture risk by 25(OH)D<sub>3</sub>-1 $\alpha$ -hydroxylase (CYP27B1) gene, M263

**Hyp**  
7B2 protein mediated inhibition of DMP1 cleavage in osteoblasts enhances FGF-23 production in *Hyp*-mice, 1053

**HYP**  
Increased bone volume and correction of HYP mouse hypophosphatemia in the *Klotho*/HYP Mouse, 1017

**Hypercalcemia (HCa)**  
Calcitonin receptor on osteoclasts plays a physiological role to protect against HCa in mice, SA197

Documented response to cinacalcet in two cases of acquired hypocalciuric HCa, M197

Establishment of a murine model of HCa by overexpression of sRANKL using an adenovirus vector, SU082

Infantile HCa: relationship of dietary intake of Ca and Vitamin D to serum and urine levels, SU491

Nonsteroid responsive HCa associated with sarcoidosis—a rapid response to hydroxychloroquine, WG28

**Hypercalcemia, familial hypocalciuric (FHH)**  
Association of FHH and mandible lesions in two kindreds, M427  
Functional characterization of unreported CaSR in four Italian kindreds with FHH, M204  
Skeletal consequences of FHH and PHPT, M206

**Hypercalciuria**  
Bisphosphonates in children with hypercalciuria and reduced BMD, M429  
Effect of hypercalciuria and diet on bone in genetic hypercalciuric stone-forming rats, SU213  
Renal leak hypercalciuria: a potential cause of tertiary hyperparathyroidism, M430

**Hypercalciuria, idiopathic (IHC)**  
ALN and indapamid alone or in combination in the management of IHC associated with osteoporosis, 1245

**Hyperhomocysteinemia**  
RLX ameliorates detrimental collagen cross-link formation in bone from an OVX rabbits with or without hyperhomocysteinemia, SA382

**Hyperparathyroidism**  
Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

**Hyperparathyroidism, normocalcemic primary (NPHPT)**  
Prevalence and demographics of asymptomatic NPHPT in the United States, M431

**Hyperparathyroidism, primary (PHPT)**  
Cardiovascular manifestations of mild PHPT, 1034  
Changes in cardiovascular function after parathyroidectomy in mild PHPT, M434  
Increased risk of morphometric vertebral fracture in postmenopausal women with PHPT, M438  
Low density lipoprotein-cholesterol levels affect vertebral fracture risk in female patients with PHPT, SA484  
Molecular basis of PHPT: adenomatous parathyroid cells are resistant to L-amino acids, M203  
Normocalcemic PHPT: update on a new clinical phenotype, SA486  
Possible pathogenic role of aberrant *Klotho* expression in PHPT and HPT2, SA227  
Role of OPG/RANKL system for bone loss in PHPT, M192  
Skeletal consequences of FHH and PHPT, M206  
Usefulness of *HRPT2* gene and parafibromin studies in two patients with PHPT and uncertain pathological assessment, SA482

**Hyperparathyroidism, secondary (HPT2)**  
Behavior of circulating rat(s) PTH molecular forms in HPT2 related to Vitamin D deficiency and renal failure, M194  
Efficacy of the Vitamin D supplementation in patients with hypovitaminosis D and HPT2, SU431  
Parathyroidectomy improves quality of life in hemodialysis patients with HPT2, SA212  
Possible pathogenic role of aberrant *Klotho* expression in PHPT and HPT2, SA227  
Suppression of canonical wnt signaling by *Dkk1* attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215

**Hyperparathyroidism, tertiary**

## Key Word Index

## ASBMR 30th Annual Meeting

Renal leak hypercalciuria: a potential cause of tertiary hyperparathyroidism, M430

**Hyperphagia**

OVX-induced hyperphagia does not modulate bone mineral or bone strength in female Sprague-Dawley rats, SA447

**Hyperphosphatasia**

Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SQSTM1* (sequestosome 1), SU210

**Hyperphosphatasia, expansile skeletal (ESH)**

OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563

**Hyperphosphatemia**

Ablation of the Galnt3 gene in mice leads to low circulating FGF-23 concentrations and hyperphosphatemia despite increased FGF-23 gene expression, 1018

Postprandial hyperphosphatemia is a novel risk factor for CVD by involving endothelial dysfunction, SU443

**Hyperphosphatemia, transient (TH)**

Prevalence of TH among healthy infants and toddlers, SA564

**Hyperpolarization-activated cyclic nucleotide (HCN)**

Pacemaker channel, HCN, controls functions of osteoclasts, SU100

**Hypertension.** See also *Blood pressure*

Is the association between hypertension and bone osteoporotic fracture expressing a real interdependence?, SU346

**Hyperthyroidism**

Body composition changes after radioiodine treatment of hyperthyroidism, M433

**Hypocalcemia**

Target ablation of PPR in osteocytes induces hypocalcemia and impairs bone structure, 1158

**Hypogonadism**

DHT administration is effective for the prevention of hypogonadal bone loss, SU193

Effects of aromatase inhibitor therapy on BMD in hypogonadal elderly men, 1135

Toward a physiologically-based definition of hypogonadism in men: dose-response relationship between testosterone and bone resorption, 1102

**Hypoparathyroidism (HPT)**

Calciophylaxis in a patient with HPT and normal kidney function, WG33

Circulating osteoblast lineage cells increase with PTH treatment of HPT, 1146

Dominant-negative GCMB mutants causing autosomal-dominant HPT—protein expression and cellular localization, SA225

HPT and renal insufficiency, WG29

New long-acting PTH/PTHrP hybrid analog that binds to a distinct PTHR conformation has superior efficacy in a rat model of HPT, F483

PTH increases bone turnover in HPT, F485

PTH reverses abnormal bone remodeling and structure in HPT, 1036

Safety and efficacy of long-term PTH replacement in a pediatric patient with inherited HPT, F217

**Hypoparathyroidism, primary (PHP)**

Influence of PHP on BMD and vertebral morphometry, M190

**Hypophosphatasia (HPP)**

Adult HPP treatment with TPTD, SA468

Autosomal recessive HPP manifesting in utero with long bone deformity but showing spontaneous postnatal improvement, SA562

c.1250A>G, p.N417S is a common American

Enzyme replacement therapy prevents dental defects in the *Akp2*<sup>-/-</sup> mouse model of infantile HPP, F107

Relative efficacy of “treating” versus “preventing” infantile HPP in *Akp2*<sup>-/-</sup> mice by enzyme replacement therapy, 1054

**Hypophosphatasia, pseudo**

c.1250A>G, p.N417S is a common American TNSALP mutation involved in all clinical forms of HPP, including pseudo-HPP, SA566

**Hypophosphatemia**

Clinical usefulness of measurement of FGF-23 in hypophosphatemic patients, SA470

FGF-23 and post-transplant hypophosphatemia: evidence for a causative link, SU168

Increased bone volume and correction of HYP mouse hypophosphatemia in the *Klotho*/HYP Mouse, 1017

MEPE C-terminal ASARM-peptide, promotes hypophosphatemia, bone defects and increases adiposity, F207

Phosphatonins and liver resection-related hypophosphatemia, SU176

Targeted overexpression of the nuclear FGF-2 isoforms in osteoblasts induces hypophosphatemia via modulation of FGF-23 and *Klotho* in mice, 1084

**Hypophosphatemia, X-linked (XLH)**

Aberrant *PheX* function in osteocytes has limited effects on bone mineralization in XLH, 1051

Characterization of the enthesopathy of XLH in the Hyp mouse, SA254

PHEX cleavage of SIBLING-ASARM peptides as a mechanism underlying osteomalacia in XLH, 1199

Rare cases of XLH rickets/osteomalacia mimicking ARHR/osteomalacia, F469

**Hypothalamic amenorrhea.** See *Amenorrhea***Hypothyroidism**

Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259

Hypothyroidism is not deleterious to the skeleton during early fetal development, SA123

**Hypovitaminosis D**

Air pollution might be a neglected risk-factor of hypovitaminosis D, SU306

Efficacy of the Vitamin D supplementation in patients with hypovitaminosis D and HPT2, SU431

Single dose of 100,000 IU D3 appears to be insufficient to achieve desirable levels of 25(OH)D in patients with hypovitaminosis D, SU430

Which is the best oral high-dose Vitamin D<sub>3</sub> regimen for postmenopausal women with hypovitaminosis D?, SU429

**Hypoxia**

Hypoxia promotes ligand-independent activation of the ACVR1 (R206H) mutant receptor in C2C12 cells, M243

**Hypoxia inducible factor (HIF)**

Development of pharmacological HIF activators for fracture healing, SU052

**Hypoxia inducible factor-1 (HIF-1)**

Regulation of autophagy in the epiphyseal growth plate by AMPK and mTOR requires HIF-1, SU134

**Hypoxia inducible factor-1 $\alpha$  (HIF-1 $\alpha$ )**

Evidence that differentiated bone cells display an autophagic response regulated by HIF-1 $\alpha$ , F058

Inhibition of HIF-1 $\alpha$  alone or combined with TGF $\beta$  blockade prevents breast cancer bone metastases, 1085

**Hypoxia-inducible factor-2 $\alpha$  (HIF-2 $\alpha$ )**

CXCL12 expression is regulated by HIF-2 $\alpha$  in MM plasma cells, SU080

**Hypoxia-responsive element (HRE)**

Dwarfism and osteopenia in mice with inactivated HRE in the VEGF gene promoter, 1152

**1 $\alpha$ -hydroxylase**

Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

Prediction of osteoporotic fracture risk by 25(OH)D3-1 $\alpha$ -hydroxylase (CYP27B1) gene, M263

**I****I $\kappa$ B kinase  $\beta$  (IKK $\beta$ )**

Ubiquitin-like domain of IKK $\beta$  is critical for osteoclastogenesis, SU112

**I $\kappa$ B- $\alpha$** 

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

**Ibandronate (IBN)**

Comparison of the effects of IBN alone with IBN in combination with SNAC on bone density and bone strength in OVX rats, SU391

Cost-effectiveness of IBN therapy for women with postmenopausal osteoporosis with respect to nonvertebral fracture efficacy, SA429

Cost-effectiveness of RIS versus IBN at one year: the case of the United Kingdom, SA424

Cost-effectiveness of RIS versus IBN at one year: the case of Germany, SA425

Efficacy and safety of monthly oral IBN in postmenopausal women with low bone density, SU384

Fracture risk in women aged 65 years or older with once-monthly oral IBN compared with weekly bisphosphonates, M367

Fracture risk with once-monthly oral IBN compared with weekly bisphosphonates, SU408

HSA based on DXA data in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA507

Intravenous IBN for prevention of early bone loss after kidney transplantation, F413

Modeled cost-effectiveness of RIS versus IBN: the case of Italy, SA427

PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299

QCT and FEA assessment of proximal femur bone quality and strength in women with postmenopausal osteoporosis receiving once-monthly oral IBN for 12 months, SA509

Quarterly intravenous IBN acid in the community setting in England, SU409

Regional differences of femoral BMD changes after one year once-monthly IBN as measured by 3D QCT, SU260

**Ibuprofen**

Bone resorption and articular cartilage degenerative changes following performance of high repetition high force tasks are attenuated by secondary ibuprofen treatment, SA532

**IC162**

IC162, a new flavonoid, preserves bone mass and microarchitecture without affecting uterine weight in OVX rats, SA386

**Icariin**

Bone anabolic effects of icariin and total flavonoid fraction of *Herba epimedii* in OVX mice, M337

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

**ICTP**

Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287

**Idiopathic juvenile osteoporosis (IJO).** See*Osteoporosis***Idiopathic multicentric osteolysis with****nephropathy (IMON).** See *Osteolysis***IDS Automated Analyser 3x3™**

Development of a bone specific ALP assay on the IDS Automated Analyser 3x3™, SA302

Development of a new N-Mid® osteocalcin immunoassay on the IDS Automated Analyser 3x3™, SA303

New 25(OH)D assay on the IDS Automated Analyser 3x3™, SU200

New intact PTH assay on the IDS Automated Analyser 3x3™, M209

**IFN-β**IFN-β is a key molecule in inhibition of human osteoclast differentiation by 1α,25-dihydroxyvitamin D<sub>3</sub>, SU090**IFN-γ**

IFN-γ inhibits TNFα-induced osteoclastogenesis in vitro and in vivo, SU152

**Ihh**

Chondrocyte-derived Ihh is required for osteoblast differentiation despite reconstitution of a normal growth plate, 1154

**IL6**Genetic variation in *IL6* and *LRP5* is associated with osteoporosis in the Marshfield Clinic Personalized Medicine Project, SU365**Iliac crest**

Serum 25(OH)D measurement and histomorphometric analysis of iliac crest biopsies from 1180 patients reveals a high prevalence of Vitamin D-dependent osteomalacia, 1134

**Imatinib (IM)**

Influence of IM on bone remodeling in juvenile mice, SA292

**Immune system**

Important contribution of the immune system in regulating the tumor/bone vicious cycle independent from osteoclasts, 1086

Key mechanism underlying the immunosuppressive effects of Vitamin D: 1,25(OH)<sub>2</sub>D<sub>3</sub> is a transcriptional modulator of IL-17, F246

PTHrP is processed by skin keratinocytes and has immunomodulation properties, SA216

**Indapamid**

ALN and indapamid alone or in combination in the management of IHC associated with osteoporosis, 1245

**Indolent systemic mastocytosis (ISM).** See*Mastocytosis***Infantile osteopetrosis (IO).** See *Osteopetrosis***Infections, bacterial**

Novel modification of bone grafts inhibits bacterial colonization, M169

**Infections, viral**

Cortical and trabecular microarchitecture in HIV-infected postmenopausal women, SU458

Determinants of low BMD in HIV infected postmenopausal women, SU455

Prevalence and incidence of viral infections among musculoskeletal tissue donors and first-time blood donors, SA549

Randomized controlled trial of Vitamin D3 supplementation for the prevention of viral upper respiratory tract infections, M217

Vitamin D insufficiency is common in racially diverse postmenopausal women with HIV, M448

**Inhibin**

Inhibin directly targets suppression of isolated human osteoclast precursor development and activity, SA086

Physiological concentrations of inhibin A are anabolic, affecting both trabecular and cortical bone in normal intact mice, M177

**Inpp4b**

Inpp4b as a regulator of bone mass, F089

**Insulin**

Intermittent injection of recombinant osteocalcin improves glucose tolerance and insulin sensitivity, F168

Sympathetic tone mediates leptin's inhibition of insulin secretion by modulating osteocalcin bioactivity, F034

**Insulin-like growth factor binding protein 2 (IGFBP2)**

IGFBP2 and bone loss in aging women and men, 1284

**Insulin-like growth factor binding protein 3 (IGFBP3)**

Association study of the TF and IGFBP3 gene polymorphisms with an osteonecrosis of femoral head in Korean population, SU226

**Insulin-like growth factor binding protein 5 (IGFBP5)**

NFI transcription factors regulate IGFBP5 gene transcription in human osteoblasts, SU015

**Insulin-like growth factor binding protein 6 (IGFBP6)**

IGFBP6 Is a negative regulator of osteoblast differentiation and bone formation, SA182

**Insulin-like growth factor-1 (IGF-1)**

Age-related changes in BMD, cross-sectional area and the strength of rat femur; an involvement of suppression of GH-IGF-1 signaling, SA467

Alterations in bone structure and growth in dwarf rats with a depressed GH/IGF-I axis, SA178

BMP-6 from bone regulates serum glucose via IGF-1 released from pancreas, SU141

Endocrine IGF-1 maintains linear growth in the total absence of tissue IGF-1, SA184

IGF-1 secreted from osteoblasts as a major chemotactic factor for osteoblasts, SA179

Mice lacking the GH receptor in liver have normal skeletal growth and bone volume despite virtual absence of circulating IGF-1, F181

Overcoming the zone of chondrocyte death associated with osteochondral harvest by sequential treatment with collagenase and IGF-1, SU129

Serum IGF-1 is a developmental determinant of bone size, SA183

Study of hGH and IGF-1 receptors in the human fetal femoral growth plate, SU128

Tissue-specific KO of the CaSR in chondrocytes inhibits IGF-1 signaling and delays differentiation in the growth plate, 1261

Twist1 haploinsufficiency is associated with reduced IGF-1 levels and an osteoporotic phenotype, SU029

**Insulin-like growth factor-2 (IGF-2)**

Bone length was differentially promoted in the left/right hindlimbs with knee loading and administration of IGF-2, M476

**Insulin-like growth factor-I (IGF-I)**

Ablation of IGF-I signaling in osteoprogenitors decreases bone formation and blunts the skeletal response to PTH, 1193

Age-related impairment of IGF-I receptor activation is associated with changes in integrin and SHP-2 expression, M096

Concentration of IGF-I in human cortex bone is highly correlated with fracture toughness of the bone, 1069

Dried plum polyphenols increase IGF-I production in osteoblast-like cells, SU002

Is GH/IGF-I mediated mechanism involved in regulating gender differences in bone size?, SA180

Low serum IGF-I alters the cortical bone response to estrogen deficiency, SU190

**Integrin**

Age-related impairment of IGF-I receptor activation is associated with changes in integrin and SHP-2 expression, M096

Disruption of the syndecan-1/integrin axis is a novel target for myeloma therapy, 1229

Integrin mediated mechanical forces stimulate differentiation of MSCs, SA528

Integrin-associated protein upregulates osteogenesis-related transcription factors via TGFβ and BMP pathways, SA028

Mechanical perturbation of integrin α5 with or without association with fibronectin opens Cx43-hemichannels in osteocytes, SA060

**Integrin associated protein (IAP)**

CD47 (IAP) is an important modulator of osteoclast and osteoblast differentiation in vitro and in vivo, F093

**Integrin-linked kinase (ILK)**

Inactivation of the ILK in osteoblasts increases mineralization, M061

**Interferon γ (INFγ)**

INFγ attenuates BMP-2 signaling via Stat-1 binding of Smad4 in the cytoplasm, SU139

Low dose administration of INFγ stimulates osteoblastogenesis and prevents ovariectomy-induced osteoporosis in C57BL/6 mice, M334

**Interleukin-1 (IL-1)**Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNFα/IL-1-mediated osteoclastogenesis, 1118**Interleukin-1α (IL-1α)**

Betulin down regulates IL-1α-stimulated aggrecanases and MMP gene expression in human chondrocytes, M147

OAH19, an ethanol extract from combined two herbs, inhibits IL-1α-induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148

**Interleukin-1β (IL-1β)**

Elevated production of IL-1β and TNFα by PBMC is associated with increased hip fracture risk in elders, 1283

HDAC inhibitors suppress IL-1β-induced NO and PGE<sub>2</sub> production in human chondrocytes, SU116

IL-1β-induced hepcidin expression in synovial membranes of patients with OA is associated with TNFα repression, SU157

TNFα and IL-1β stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

**Interleukin-6 (IL-6)**High levels of IL-6 and hyper-responsivity to 1,25(OH)<sub>2</sub>D<sub>3</sub> are both required for development of Pagetic osteoclasts, F478

Increased proinflammatory cytokines TNF-α and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022

Rapid-nontranscriptional action of 1,25(OH)<sub>2</sub>D<sub>3</sub> induces IL-6 production in osteoclast precursors expressing MVNP, 1186**Interleukin-8 (IL-8)**

Distinct biological activity of IL-8 isoforms, SU162

Systemic IL-8 increases bone resorption in vivo, 1234

**Interleukin-12 (IL-12)**

IL-12 induces apoptosis in TNFα-mediated osteoclastogenesis in vivo, SA166

IL-12 stimulates the OIP-1 gene expression in CD4<sup>+</sup> T-cells, SA173**Interleukin-17 (IL-17)**Key mechanism underlying the immunosuppressive effects of Vitamin D: 1,25(OH)<sub>2</sub>D<sub>3</sub> is a transcriptional modulator of IL-17, F246**Interleukin-23 (IL-23)**

Grape seed extract suppresses IL-23/Th17 inflammatory pathways and bone destruction in CIA, SU093

Rheumatoid synoviocytes are stimulated with IL-23 to enhance osteoclastogenesis through upregulation of RANKL expression, SU084

**Interleukin-27 (IL-27)**

Effects of IL-27 on regulation of osteoclastogenesis by way of T cells, SU081

## Key Word Index

## ASBMR 30th Annual Meeting

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

**Inulin, agave**

Effects of agave inulin on Ca metabolism in Japanese young adults, M332

**Iron (Fe)**

PGC-1 $\beta$  and iron uptake in the mitochondrial activation of osteoclasts, L222

**IRX3**

Identification of IRX3 a novel transcription factor during BMP-2 mediated osteoblast differentiation, SU024

**Isoflavones**

Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503  
Evaluating the effect of soy and isoflavones on BMD in older women, M353  
Neonatal exposure to soy isoflavones attenuates deterioration of bone tissue in female but not male mice after cessation of sex steroid production, SU476

**Isotropy, resolution**

Implications of resolution isotropy on apparent topology of trabecular bone architecture in MRI, SU280

**IVVY**

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQG<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, L118

**J****Jagged1**

Jagged1 stimulation by PTH(1-34) in mature osteoblasts is not required for HSC expansion, L078

**Jak2**

AG490, a Jak2 specific inhibitor, induces osteoclast survival by activating Akt and ERK signaling pathway, SU108

**Japanese Population-based Osteoporosis (JPOS) Cohort Study**

Effect of parity on BMD in premenopausal women, SA325  
Ten-year change in BMD in a representative sample of Japanese women, SA330

**JDM. See Dermatomyositis****JNK. See c-Jun N-terminal kinase****Jumonji**

Regulation of the osteoblast-specific transcription factor Osx by NO66, a Jumonji family histone demethylase, F017

**Jun activation-domain binding protein (Jab1)**

Characterization of Jab1-interacting motif in LMP-1, SA023

**JunB**

Age-related bone loss in mice associated with ubiquitin ligase Smurf1 degradation of JunB protein and reduced osteoblast proliferation, L113

**JunD**

Coactivator MBF1 binds to JunD and protects its transcriptional activity against oxidative stress to prevent age-related suppression of osteoblast differentiation, L248

**K****K/BxN**

Deficiency of the nucleocytoplasmic shuttling protein CIZ suppresses K/BxN serum-induced model of RA, M446

**Kallikrein-4 (KLK-4)**

Identification of DPP-I as a potential activator of KLK-4, SA155

**Kenney-Caffey syndrome**

Kenney-Caffey syndrome in a Caucasian man, SA464

**Keratinocytes**

1,25(OH)<sub>2</sub>D<sub>3</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in regulating cellular proliferation in cultured normal human keratinocytes and transformed prostate cells, M215

PTHrP is processed by skin keratinocytes and has immunomodulation properties, SA216

**Kidney disease, chronic (CKD)**

25(OH)D levels in children with CKD as measured by tandem mass spectrometry, SU485

Comparison of 1,25(OH)<sub>2</sub>D<sub>3</sub> and calcitriol effects in an adenine-induced model of CKD reveals differential control over serum Ca and phosphate, SU448

Glomerular filtration rate and physical function in community-dwelling Japanese frail elderly, SA332

Interactions between obesity, CVD and bone formation, M451

Kidney disease is associated with abnormal cortical geometry independent of age and gender, SU441

Osteopenia in CKD: effects of Ca overload, SU449

Osteopenia in CKD: effects of phosphate overload, SU447

Patients with CKD and low 1/3 radius and femoral neck BMD have markedly abnormal cortical and trabecular microstructure by HR-pQCT, L033

Potential role of FGF-23 in CKD-MBD, WG30

Protective actions of Vitamin D analogs in the vascular calcification of CKD, SU450

Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211

**Kidney dysfunction**

Kidney dysfunction disturbs collagen maturation in ABD as assessed by confocal laser Raman spectroscopy, SU439

**Kidney transplantation**

Application of a treatment algorithm to avoid BMD loss and limit bisphosphonate use after kidney and kidney/pancreas transplantation, SA497

Bone metabolism in long-term kidney transplantation recipients, SA499

Change of pathological bone lesion in recipients with renal osteopathy after renal transplantation, SA498

Intravenous IBN for prevention of early bone loss after kidney transplantation, F413

Pretransplant parathyroid function predicts laboratory and BMD changes after kidney and kidney/pancreas transplantation, L032

**KIMS Survey**

FGF-23 and parameters of Ca and bone metabolism are positively influenced by GH replacement in adult GH deficiency patients from the KIMS survey, SU177

**Kremen-1 (Krm-1)**

Deletion of the Dkk-1 Krm-1 and Krm-2 in mice leads to increased bone formation and bone mass, L004

**Kremen-2 (Krm-2)**

Deletion of the Dkk-1 Krm-1 and Krm-2 in mice leads to increased bone formation and bone mass, L004

Transgenic overexpression of the Wnt antagonist Krm-2 in osteoblasts leads to severe impairment of bone formation and increased bone resorption, L003

**Krox-20**

Mechanical loading upregulates expression of the transcription factor EGR2/Krox-20 by a COX-2-mediated mechanism, SA526

**Kyphoplasty, balloon**

Randomized trial of balloon kyphoplasty and nonsurgical care for acute vertebral fracture, L243

**Kyphosis**

Does ALN use prevent kyphosis progression in older women?, SA410

Factors associated with kyphosis progression in older age, F365

**Kyphosis, thoracic**

Sr ranelate prevents the progression of thoracic kyphosis in postmenopausal women with osteoporosis, L241

Thoracic kyphosis index as a risk factor for incident vertebral fractures and alteration of quality of life in postmenopausal women with osteoporosis, L130

**L****L-amino acids**

Molecular basis of PHPT: adenomatous parathyroid cells are resistant to L-amino acids, M203

**L-serine (L-Ser)**

Novel role of L-Ser for the activation of RANKL-RANK signaling machinery in osteoclastogenesis in vitro, SA082

**L29**

Gender-specific changes in bone microstructure of mice lacking ribosomal protein L29/HIP, SA133

**L527del**

Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471

**Lactation**

Extended lactation is associated with failure to restore BMD 6 months after resumption of menstrual cycle, M305

Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194

Osteocytic perilacunar remodeling as a significant source of Ca during lactation, M110

**Lactoferrin**

Mechanism of action of lactoferrin's bone anabolic activity, SA175

**Lactose intolerance**

Lactose intolerance does not have effect on bone status in adolescence, SU285

**Lamellar bone**

Changes in chemical, mechanical, and structural properties of lamellar bone during young adulthood, SU475

**Lamin A/C**

Impaired bone formation in mice lacking lamin A/C activation leads to severe osteopenia, F131

Inhibition of lamin A/C attenuates osteoblast differentiation and stimulates osteoclastogenesis through enhanced RANKL signaling, M070

**Lasofloxifene (LASO)**

Effects of LASO on bone turnover markers, L287

Effects of LASO on fractures and breast cancer, L288

Randomized double blinded controlled trial of individual response in biochemical markers of bone turnover to LASO therapy, M507

**Latexin (Lxn)**

Lxn is a novel effector of BMP-2 signaling in modulation of chondrocyte differentiation, SU117

**LCT**

13910C>T LCT promoter polymorphism in the Spanish population, M265

**LDLR-/-**

OPN deficiency reduces aortic calcification and oxidative stress in diabetic LDLR-/- mice, F109

**Lead (Pb)**

Effect of Pb on bone mineral properties from female adult C57/BL6 mice, M146

**Lef**

Negative regulation of Tcf/Lef-dependent transcription by the BMP/Smad4 signaling axis, SU144

**Leg lean mass**

Bivariate whole genome linkage analysis of femoral bone geometric traits and leg lean mass, M249

**LEPREI**

Hotspot splicing mutation in *LEPRE1* affects P3H1 and causes recessive OI, SU215

**Leptin**  
Central and peripheral leptin treatment produce similar increase in cortical and trabecular bone mass in ob/ob mice, SU164  
Sympathetic tone mediates leptin's inhibition of insulin secretion by modulating osteocalcin bioactivity, F034

**Letrozole**  
ALF prevents aromatase inhibitor (letrozole)-induced bone mineral loss in young growing female rats, SA570

**Leukemia, acute lymphoblastic (ALL)**  
Advanced vertebral compression at diagnosis among children with ALL, SU483

**LIA.** See *Diasorin Liaison*

**LIF**  
Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022

**Ligament, anterior cruciate (ACL)**  
Bone geometry and bone strength are compromised in patients with ACL reconstruction, M487

**Ligamentum flavum**  
Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135

**Light scattering**  
Non-invasive detection of bone microdamage by light scattering, M462

**LIM kinase 1 (LIMK1)**  
Role of LIMK1 in osteoclast cytoskeletal remodeling and bone resorption, 1116

**LIM mineralization protein (LMP)**  
Identification and analysis of human LMP gene promoter region, M034

**LIM mineralization protein-1 (LMP-1)**  
Characterization of Jab1-interacting motif in LMP-1, SA023  
LMP-1, positive regulator in osteolineage differentiation of human PDL fibroblasts, M051

**Limb-bud and heart (Lbh)**  
Overexpression of the transcriptional cofactor Lbh impairs angiogenesis and endochondral bone formation during fetal bone development in chickens, SU004

**Lipodystrophy**  
Progressive lipodystrophy in the osteosclerotic mice over-expressing Fra1, 1149

**Lipopolysaccharide (LPS)**  
Differential contribution of osteoclast- and osteoblast-lineage cells to LPS modulation of osteoclastogenesis, SU088  
LPS suppresses RANK gene through the down-regulation of PU.1 and MITF, SU083  
LPS-induced inhibition of osteogenesis is TNF $\alpha$  dependent, M019  
RANKL-mediated osteoclast lineage commitment dictates the role of LPS in osteoclast differentiation, SA088

**Lipoproteins**  
Low density lipoprotein-cholesterol levels affect vertebral fracture risk in female patients with PHPT, SA484

**5-lipoxygenase (5-LO)**  
Chondrocyte differentiation is differentially affected by COX-2 and 5-LO during fracture healing, SU123

**Lithium (Li)**  
Li affects matrix mineralization by decreasing tissue non-specific ALP levels in osteoblasts, SA071

**Lithocholic acid**  
Lithocholic acid downregulates the effects of Vitamin D<sub>3</sub> on primary human osteoblasts, SA030

**Liver transplantation**  
Effect of RIS in liver transplantation patients with low bone mass, SA503  
Marked Vitamin D deficiency in recent heart and liver transplant recipients, SA501

Retrospective study evaluating the relationship of Vitamin D 25 OH and free testosterone levels with changes in hip bone density after liver transplantation, SA502

**Liver X receptors**  
Cholesterol sensing receptors, Liver X receptor  $\alpha$  and  $\beta$ , have novel and distinct roles in osteoclast differentiation and activation in bone, F085

**Liver-enriched inhibitory protein (LIP)**  
Cooperativity between VDR and LIP in the regulation of TRPV6 identifies a novel function for LIP as a transcriptional activator, SU198

**LMMS.** See *Low magnitude mechanical stimulations*

**LNcaP**  
Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNcaP human prostate cancer cells, 1089

**Long bones**  
Altered long bone structure in recessive null and dominant negative Cx43 (*Gjal*) mouse mutants, 1110  
Autosomal recessive HPP manifesting in utero with long bone deformity but showing spontaneous postnatal improvement, SA562  
DHCR24 gene is mandatory for the proper growth of long bone, SU118  
Distinctive anabolic roles of 1,25(OH)<sub>2</sub>D<sub>3</sub> in teeth and mandible versus long bones, M213  
Enhanced osteogenic potential of alveolar vs. long bone derived BMSC, M095  
Over-expression of CNP enhances the formation of long bone exostoses in Ext1<sup>+/+</sup> mice, SU130  
Quantitation of bone marrow fat in long bones of mice using MRI or  $\mu$ CT, M145

**Losartan®**  
Losartan® (Cozaar) increases appendicular bone formation by inhibiting osteoclastogenesis, M126

**Lovastatin (LV)**  
LV best enhances fracture repair when administered one week post-fracture, 1300

**Low intensity pulsed ultrasound (LIPUS).** See *Ultrasound*

**Low magnitude mechanical stimulations (LMMS)**  
"Vibes" Trial: LMMS to improve BMD, M397

**Low-density lipoprotein receptor related protein 5 (LRP5)**  
BMD-associated SNP lies in a Runx2 binding site of the LRP5 promoter, M264  
Bone formation in mice with variations in Lrp5 expression, F550  
Bone loss with smoke exposure and Lrp5 expression, SA459  
Bone response to mechanical loads and Lrp5 genotype, M020  
G171V and A214V Lrp5 knock-in mice have increased bone mass and strength, and can help precisely define the in vivo functions of Lrp5 during bone growth and homeostasis, 1002  
Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108  
LRP5 G171V mutation and tobacco smoke related bone fragility, M323  
Prediction of fracture risk by LRP5 gene haplotype, SU222  
PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038  
PTH signaling through LRP5/6 in osteoblasts, 1014  
In vivo load activated propagation of  $\beta$ -catenin signaling in osteocytes through coordinated downregulation of inhibitors of Lrp, 1041

Wnt/LRP5-independent inhibition of osteoblastic cell differentiation by SCT, 1256

**Low-density lipoprotein receptor related protein 6 (LRP6)**  
Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108  
Lrp6 loss of function impacts bone homeostasis and responds to folate supplementation, F253  
PTH signaling through LRP5/6 in osteoblasts, 1014

**LRP5**  
Genetic variation in *IL6* and *LRP5* is associated with osteoporosis in the Marshfield Clinic Personalized Medicine Project, SU365  
Genetic variation in *LRP5* associates with metabolic characteristics in healthy prepubertal children, 1176

**Lrp5**  
Osteoblast-specific deletion of *Lrp6* reveals distinct roles for *Lrp5* and *Lrp6* in bone development, 1001

**Lrp6**  
Osteoblast-specific deletion of *Lrp6* reveals distinct roles for *Lrp5* and *Lrp6* in bone development, 1001

**Lung disease**  
Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

**Lupus**  
Are there any ethnic differences in BMD in a lupus cohort?, SU358

**Luteolin**  
Effect of luteolin on bone loss, microarchitecture and bone resorption in OVX mice, M128

**Lymphocytes**  
Increased expression of OPN in PBMC is associated with alteration in the fractions of lymphocytes in hindlimb-unloaded mice, M175

**Lymphoid enhancer binding factor-1 $\delta$ N (Lef-1 $\delta$ N)**  
Overexpression of Lef-1 $\delta$ N increases bone mass in mice, 1258

**Lyn**  
Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119

**Lysophosphatidic acid (LPA)**  
LPA enhances the viability of rat growth plate chondrocytes through the inhibition apoptosis and the promotion of cellular maturation, SU156  
LPA regulates osteoclast survival and retraction, SU105

**Lysosomal proteins**  
Identification of osteoclast lysosomal proteins by mass spectrometry, SA077

## M

**M-CSF**  
BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242  
Recombinant mouse M-CSF receptor C-fms inhibits TNF $\alpha$ -induced osteoclastogenesis, M112  
Vimentin binds c-Fms in an M-CSF dependent manner and regulates osteoclast differentiation, SU097

**Mab21**  
Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022

**MafB**

## Key Word Index

## ASBMR 30th Annual Meeting

All-*trans*-retinoic acid (Vitamin A) increases expression of MafB and inhibits osteoclast formation by interfering with differentiation of osteoclast progenitor cells, M117

**Magnesium (Mg)**  
Importance of melastatin-like transient receptor potential 7 and Mg in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor, M008  
Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211

**Magnetic resonance imaging (MRI)**  
Estimation of relative stiffness contributions of cortical and trabecular compartments by MRI-based FEA, SU481  
Grayscale MRI based finite element mechanical modeling of trabecular bone at in vivo resolution, SU277  
Identification of skin abnormalities in OI patients by MRI, SA561  
Implications of resolution isotropy on apparent topology of trabecular bone architecture in MRI, SU280  
Proximal femoral fragility and age-related white matter lesions by brain MRI in elderly subjects, 1096  
Quantitation of bone marrow fat in long bones of mice using MRI or  $\mu$ CT, M145  
Reciprocal relation between MR measures of marrow adiposity and cortical bone in the appendicular skeleton of healthy adults, SU042  
Reduction of MRI processing time for assessment of trabecular bone microarchitecture, SU282  
Solid-state  $^{31}\text{P}$  MRI quantifies mineralization changes in OVX rat bone, M422  
In vivo bone matrix density measurements by water and fat suppressed projection MRI (WASPI), SA102

**Magnetic resonance imaging, micro ( $\mu$ MRI)**  
Evaluation of the detection sensitivity of simulated trabecular bone loss in  $\mu$ MRI at in vivo resolution, M312  
Feasibility and reproducibility of in-vivo assessment of trabecular bone architecture using  $\mu$ MRI-based method at multiple study centers, SA314  
Twelve month changes in trabecular microarchitecture assessed by  $\mu$ MRI in postmenopausal women on antiresorptive versus anabolic therapy, 1020

**Malnutrition**  
Association of the marker of ABD with malnutrition-inflammation complex in hemodialysis patients, SU446

**Mammary glands.** See also *Cancer, breast*  
Bzb, a proteasome inhibitor, prevents metastatic breast cancer osteolysis and reduces mammary fat pad tumor growth in mice, F277  
Ectopic Runx2 expression disrupts normal acini structure in mammary epithelial cells, F279  
PTHrP regulates mammary gland ductal elongation during puberty, F228  
PTHrP-induced Wnt signaling specifies the mammary mesenchyme, F219

**Mandible**  
Distinctive anabolic roles of  $1,25(\text{OH})_2\text{D}_3$  in teeth and mandible versus long bones, M213

**MAP kinase**  
Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050

**MAP kinase phosphatase-1 (MKP-1)**  
Effect of MKP-1 deletion on the fluid shear stress induction of COX-2 expression in osteoblasts, SA529  
MKP-1 is an endogenous negative regulator of pro-inflammatory cytokines in BMSC, SU013

MKP-1 protects bone mass via negative regulation of osteoclast differentiation and activation, 1219

**MAPK.** See *Mitogen-activated protein kinase*

**Marrow.** See *Bone marrow*

**Marshfield Clinic Personalized Medicine Project**  
Genetic variation in *IL6* and *LRP5* is associated with osteoporosis in the Marshfield Clinic Personalized Medicine Project, SU365

**MASTER**  
Continued evidence for safety and efficacy of RIS in men with osteoporosis, M360

**Mastocytosis, indolent systemic (ISM)**  
Prevalence of osteoporosis in ISM, SU268

**Matrix extracellular phosphoglycoprotein (MEPE)**  
MEPE C-terminal ASARM-peptide, promotes hypophosphatemia, bone defects and increases adiposity, F207  
MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, *Dlx3*, *Dlx5* and *Runx2*, SA064  
MEPE regulates bone remodelling independent of serum phosphate and alters renal vascularization, F205

**Matrix metalloproteinase (MMP)**  
Analysis of long bone fracture nonunion by an expression profile of the MMPs and ADAMTS enzyme families, M235  
Betulin down regulates *IL-1 $\alpha$* -stimulated aggrecanases and MMP gene expression in human chondrocytes, M147  
Effects of beta-D-glucopyranoside from *Phellodendron Amurense* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117  
Inhibition of MMP activity delays bone repair whereas inhibition of osteoclast function and formation does not, SA075

**Matrix metalloproteinase-1 (MMP-1)**  
OAH19, an ethanol extract from combined two herbs, inhibits *IL-1 $\alpha$* -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148  
PGD2 downregulates MMP-1 and MMP-13 expression in human OA chondrocytes, SA152

**Matrix metalloproteinase-2 (MMP-2)**  
Regulation of parameters of bone quality by MMP-2 and MMP-9, 1144

**Matrix metalloproteinase-9 (MMP-9)**  
Regulation of parameters of bone quality by MMP-2 and MMP-9, 1144

**Matrix metalloproteinase-13 (MMP-13)**  
Novel MMP-13-derived peptides demonstrate non-covalent interaction of MMP-13 with the TGF $\beta$  large latent complex, 1189  
OAH19, an ethanol extract from combined two herbs, inhibits *IL-1 $\alpha$* -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148  
PGD2 downregulates MMP-1 and MMP-13 expression in human OA chondrocytes, SA152

**MBF1**  
Coactivator MBF1 binds to JunD and protects its transcriptional activity against oxidative stress to prevent age-related suppression of osteoblast differentiation, 1248

**MC3T3-E1**  
Chemical composition and nanoscale structure of RIS-treated mineralizing MC3T3-E1 cells, M023  
PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calcineurin pathways, SA033  
Regulation of intracellular signaling of MC3T3-E1 osteoblasts by the extracellular matrix, SA139  
Silencing of PDIA3 (ERp60) reduces the rapid membrane response to  $1,25(\text{OH})_2\text{D}_3$  in MC3T3-E1 osteoblast-like cells, M227

**MC3T3-L1**

Effect of resveratrol and flax oil on MC3T3-L1 pre-adipocyte and ST2 BMSC proliferation and differentiation, SU059

**MCSA.** See *Muscle cross-sectional area*

**Measles virus nucleocapsid protein (MVNP)**  
Co-expression of p62<sup>392L</sup> and MVNP in osteoclast precursors increases the formation of osteoclasts that express a pagetic phenotype, F476  
Rapid-nontranscriptional action of  $1,25(\text{OH})_2\text{D}_3$  induces *IL-6* production in osteoclast precursors expressing MVNP, 1186

**Mechanical loading**  
Anabolic response to skeletal loading in mice with targeted disruption of PTN gene, 1142  
Androgen receptor disruption increases the osteogenic response to mechanical loading in male mice, 1140  
Bone cell response to neurotransmitters and mechanical loading, SA009  
Bone strength in overweight children is adapted to mechanical loads from walking, but is low for higher loading activities, M482  
Cost-effective rack and pinion system for torsion testing of rodent bones, M465  
Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244  
Inhibition of bone biomechanical response to physical activity and loading in mice lacking periostin, 1143  
Intermittent, short duration cyclic loading attenuates disuse osteoporosis without affecting resorption, M483  
Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108  
Load induced changes in trabecular and cortical bone are dose dependent in both C57BL/6 and C3H/HeJ mice, F527  
Loading duration influences the degree of inhibition of bone loss using dynamic muscle stimulation in a disuse rat model, 1297  
Mechanical loading prevents bone loss due to hormone-deficiency in female mice, M474  
Mechanical loading upregulates expression of the transcription factor *EGR2/Krox-20* by a COX-2-mediated mechanism, SA526  
Mechanical unloading partially rescues hypophosphatemic rickets in *Dmp1*-null mice, 1162  
Microdamage repair and remodeling requires mechanical loading, 1299  
Osteogenic potential of bone marrow, compromised by disuse, is normalized by brief exposure to a low-level mechanical signal, M486  
SDF-1 is expressed in osteocytes and periosteal cells in response to mechanical loading, M105  
Transcriptional regulation of *Cx43* by  $\beta$ -catenin, a pathway activated by PGE $_2$ -PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

**Mechanical stimuli, low magnitude (LMMS)**  
Risk factors for bone fracture, elevated by 90-days of bed rest, are reduced by daily exposure to LMMS, M342

**Mechanography**  
Jumping mechanography safely evaluates muscle performance in older adults, SA535

**Mecp2**  
Mecp2 null mice display multiple skeletal abnormalities, M242

**Medical records, electronic**  
Electronic medical record based "ALERT System" improved diagnosis and treatment of osteoporosis in orthopaedic out-patient clinic, SU416

**Medicare**  
Excess medical cost after a fragility fracture during 3-year follow-up, SA422

Physician practices in bone density testing among Medicare patients, SA428  
 Reimbursement for BMD testing among US Medicare beneficiaries, SA326

**Medications**  
 Comparative gastrointestinal safety of weekly oral bisphosphonates, M358  
 Differences in safety and efficacy of generic and original branded once weekly bisphosphonates, M359  
 Exploring the effect of food intake on bone resorption for optimal drug delivery and efficacy in osteoporosis with oral calcitonin, SA436  
 Influence of bone osteoporotic fractures in the past on the persistence of pharmacological treatment in osteoporosis, M382  
 Interventions to improve adherence and persistence with osteoporosis medications: a systematic literature review, M370  
 Medication prescription and adherence after hospitalization for osteoporotic vertebral fracture, M381  
 Medication switching in postmenopausal women on osteoporosis, M376  
 Optimizing bioavailability of oral administration of small peptides through pharmacokinetic and pharmacodynamic parameters, M398  
 Osteoporosis therapy following bone densitometry—patient expectations as determinants of drug initiation and persistence, M377  
 Patient refill behavior among select daily, weekly, monthly, and annual dosing regimens, M373  
 Patients desire of administration form and dose interval in bisphosphonate therapy of osteoporosis, SA408  
 Predictors of self-reported non-persistence with oral bisphosphonates due to perceived side effects or other reasons, M378  
 Preference and satisfaction with a 6-monthly subcutaneous injection versus a weekly tablet for treatment of low bone mass, M372  
 Prospective observational study of osteoporosis medication use in postmenopausal women in the European Union, SU347  
 Psychotropic drugs have contrasting skeletal effects that are independent of their negative effects on activity levels, M423  
 Vitamin D<sub>3</sub> treatment of elderly people—twice a day or every four months? A comparative study of efficacy and safety of two oral dosages with same annual dose of 292,000 units, SU422

**Mef2c**  
 Deletion of *Mef2c* in osteocytes decreases *Sost* expression and increases bone mass, F054

**MEK**  
 Vinculin is involved in hypertrophic differentiation through Raf/MEK/ERK pathway in chondrocytic ATDC5 cells, SA119

**MEK5**  
 MEK5/ERK5 signal regulates RANKL-induced osteoclastogenesis, SU103

**Melanoma**  
 Hfg inhibits melanoma bone metastases and TGF $\beta$  signaling, F190  
 Melanoma-induced bone loss is mediated by the rapid recruitment of osteoclasts, SU233

**Melastatin**  
 Importance of melastatin-like transient receptor potential 7 and Mg in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor, M008

**Menaquinone-4 (MK-4)**  
 Conversion of Vitamin K analogues to MK-4 in osteoblastic cells, M064  
 Effect of low dose Vitamin K2 (MK-4) supplementation on bio-indices in postmenopausal Japanese women, SU307  
 Menaquinone-4 derived from phyloquinone regulates osteoblast function, SU034

**Menarche.** See also *Menstruation*

Age at menarche associated with bone strength in girls, SU493  
 Contribution of birth status, age at menarche and lifestyle factors to skeletal formation in junior and senior high school students, M492  
 Deleterious effect of late menarcheal age on bone microstructure in both distal radius and tibia, 1239  
 Influence of pubertal timing on bone trait acquisition: predetermined trajectory detectable five years before menarche, 1106

**Menin**  
 Possible physiological function of menin protein as transcriptional factor that modulates miRNA expression during osteogenesis, M036

**Menstruation.** See also *Menarche*  
 Bone mass recovers in young women with anorexia nervosa who are both weight and menstrual recovered, F339  
 Effects of diet and menstrual cyclicity on bone mass accumulation in pubertal monkeys, M499  
 Elevated androgens are associated with increased bone formation in premenopausal exercising oligomenorrheic women, SU191  
 Extended lactation is associated with failure to restore BMD 6 months after resumption of menstrual cycle, M305  
 Impact of adjuvant hormonal therapy on bone loss depending on initial adjuvant chemotherapy and menstrual status, M415

**Mesenchymal stem cells (MSC).** See *Stem cells*

**Metabolic acid**  
 Activation of P2X7 nucleotide receptors increases metabolic acid production by osteoblastic cells, M065

**Metabolic acidosis**  
 Effect of metabolic acidosis on BMD and bone microarchitecture in normal and OVX rats, M409

**Metabolic syndrome**  
 Low serum osteocalcin predicts carotid plaques and indicators of the metabolic syndrome, SA198  
 Negative association between the metabolic syndrome and BMD in Korean adults, SU304  
 Prevention of the metabolic syndrome together with osteoporosis in young men, SU314  
 Relationship between the metabolic syndrome and BMD in Korean middle-aged women, SU291

**Metastasis-associated protein 1 (Mta1)**  
 Premature aging-like phenotypes in Mta1 null mice, F494

**Methionine**  
 Homozygous threonine to methionine substitution in FGF-23 gene is associated with tumoral calcinosis in a 12 year-old girl, SU171

**2-methoxyestradiol (2ME2)**  
 2ME2 alters eIF4E activity and causes protein synthesis inhibition in osteosarcoma cells, SU240  
 2ME2 blocks prostate cancer bone metastases, F272

**Mevalonate**  
 Inhibition of the mevalonate pathway rescues the DEX-induced suppression of the mineralization of osteoblastic cells, SA230

**MIA3**  
 MIA3, a novel secreted factor, regulates chondrogenic differentiation in the developing mouse embryo, 1043

**MIBI**  
 Dominant tissue accumulation of MIBI in parathyroid glands in uremic rats, SA222

**Microgravity**  
 Combined effects of irradiation and unloading on murine bone, 1295  
 Deciphering the cellular defects of osteoblasts in microgravity, SA013

Modeled microgravity sensitizes osteoclast precursors to RANKL mediated osteoclastogenesis by increasing DAP12, M114  
 Silencing of RhoGTPases counteract microgravity-induced effects on osteoblasts, SA011

**Microporosity.** See *Porosity*

**Midkine (Mdk)**  
 High bone turnover in mice lacking the growth factor Mdk, 1198

**MIF**  
 Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

**Mineral bone disorder (MBD)**  
 Potential role of FGF-23 in CKD-MBD, WG30

**mir-206**  
 Noncanonical Wnt signaling is involved mir-206 expression in osteoblastic differentiation, SA021

**miRNA.** See *Ribonucleic acid*

**Mitf**  
 AP-1 and Mitf interact with NFATc1 to stimulate Cat K promoter activity in osteoclast precursors, SA076

**MITF**  
 LPS suppresses RANK gene through the down-regulation of PU.1 and MITF, SU083

**Mitochondria**  
 Enhanced mitochondrial biogenesis contributes to Wnt induced osteogenic differentiation of C3H10T1/2 cells, SA043  
 PGC-1 $\beta$  and iron uptake in the mitochondrial activation of osteoclasts, 1222

**Mitogen-activated protein kinase (MAPK)**  
 Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185  
 BMP-2 induces *Osx* expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020  
 Functional association of MAPK and Runx2 on osteoblast chromatin, SU025  
 Involvement of caveolae in 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>-dependent activation of MAPKs in skeletal muscle cells, SA243  
 MAPK-dependent inhibition of osteocalcin gene expression by TGF $\beta$ , M033  
 Proinflammatory cytokine TWEAK induces SCT expression in human immature osteoblasts in a MAPK dependent fashion, M046  
 Real time oscillations in TNF-induced gene expression MAPK phosphorylation and promoter binding, SU087

**MIV-701**  
 Cat K inhibitor, MIV-701, suppresses bone resorption markers in healthy postmenopausal women, F433

**MK-822**  
 Randomized, double-blind, placebo-controlled study of ODN (MK-822) in the treatment of postmenopausal women with low BMD, 1291

**MLO-A5**  
 Response of matrix synthesizing MLO-A5 cells to fluid shear, SA067

**MLO-Y4**  
 LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

**MMP-9**  
 Loss of *MMP-9* results in improved healing, and remodeling of adhesions in a murine model of flexor tendon repair, F153

**Monoclonal gammopathy of undetermined significance (MGUS)**  
 Microstructural changes at the ultradistal radius in MGUS, SU238

**Monocyte chemoattractant protein-1 (MCP-1)**  
 Study about the association of circulating MCP-1 levels with lumbar BMD in Korean women, M407

**Monocytes**

## Key Word Index

## ASBMR 30th Annual Meeting

BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242

In vivo differential expression profiling study on human circulating monocytes suggested a novel CRAT and CPT2 network underlying smoking and BMD, SU155

**Monosodium urate monohydrate crystals (MSUM)**

Normal human osteoblasts internalize MSUM by phagocytosis and autophagy, M057

**Morphological atherosclerosis calcification distribution (MACD)**

MACD index is a strong predictor of cardiovascular death and include the predictive power of BMD, SU463

**Morquio Syndrome**

Morquio Syndrome variant: two siblings with atypical phenotype and novel compound heterozygosity, M240

**Mortality**

Pattern of death after hip fracture among institutionalized older people, 1164

**mRNA.** See *Ribonucleic acid*

Effect of  $\text{Sr}^{2+}$  on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

**MrOS Study.** See *Osteoporotic Fractures in Men Study*

**Msx1**

Msx1 homeogene specific and non-redundant function in oral bones, M016

**Msx2**

NADPH oxidase/Nox signaling stimulates myofibroblast Msx2 transcription via  $\text{H}_2\text{O}_2$ , 1083

Post-translational regulation of Msx2 protein, SU021

Proteins involved in mineralization expressions perturbations in bones and teeth of Msx2 mutant mouse mandibles, SA150

Wnt7a and Wnt7b evoke overlapping yet distinct transcriptional responses during the osteogenic programming of mesenchymal progenitors by Msx2, 1196

**mTOR**

Akt regulates skeletal development through GSK3, mTOR, and FoxOs, 1151

Regulation of autophagy in the epiphyseal growth plate by AMPK and mTOR requires HIF-1, SU134

**Multilineage progenitor cells (MLPC).** See *Progenitor cells*

**Multiple myeloma (MM).** See *Myeloma*

**Muscle atrophy**

Inhibition of bone loss and muscle atrophy by DHT in a mouse hindlimb disuse model, SU377

**Muscle cells**

Antiapoptotic action of  $17\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185

CaSR mediated signaling in human vascular smooth muscle cells, M200

Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060

Human skeletal muscle cells undergo matrix mineralization in an osteogenic pellet culture assay, M135

Involvement of caveolae in  $1\alpha,25(\text{OH})_2\text{D}_3$ -dependent activation of MAPKs in skeletal muscle cells, SA243

**Muscle cross-sectional area (MCSA)**

Validating pQCT MCSA measurement, SU278

**Muscle function**

Effect of three different doses of Vitamin D<sub>3</sub> (ergocalciferol) on muscle function and strength in women > 65 years, M405

Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244

Gene expression in blast-injured muscle: insights into the mechanism of heterotopic ossification, SU163

Influence of hip flexor or knee extensor muscle strength on spinal sagittal alignment or falls, SU454

Muscle power and tibial bone strength in older women, SU362

Musculoskeletal disuse worsens the acute detrimental effects of heavy particle radiation on osteoblastogenesis, SA517

Randomised controlled trial of the effects of Vitamin D supplementation upon muscle function in adolescent girls, SU428

Therapy with ALF leads to a significant increase in muscle power and balance, SU444

Vitamin D and physical performance in African American women, M218

**Muscle loss**

Low magnitude vibration can inhibit muscle loss and increase mineralizing bone surfaces in aging mice, M173

**Muscle mass**

Bone geometry, strength, and muscle mass in female distance runners with a history of stress fracture, SA540

**Muscle paralysis**

Significant trabecular bone degradation occurs within five days of muscle paralysis, SA515

Trabecular bone loss in response to transient muscle paralysis is not gender dependent, SA462

**Muscle size**

Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244

Influence of muscle size and strength on changes in bone mass and size during growth and in response to exercise, SA537

**Muscular dystrophy, Duchenne (DMD)**

Effect of non-ambulation on bone strength in boys with DMD, WG1

Forearm pQCT measurements in males with DMD, SU492

**Mustn1**

In vivo downregulation of *Mustn1* mRNA leads to musculoskeletal defects, 1192

**MVNP.** See *Measles virus nucleocapsid protein*

**Myoblasts**

Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135

**MyD88**

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

**Myeloma**

Anti-myeloma effects of osteoblasts is mediated through production of SLRPs, M001

BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242

Disruption of the syndecan-1/integrin axis is a novel target for myeloma therapy, 1229

EphB4 expression in osteoblasts is regulated by myeloma cells and the Wnt signaling pathway, SU232

Host bone marrow-derived stromal cells promote myeloma initiation and development of osteolysis, 1088

Role of FAP and DPP4 in myeloma bone disease and tumor growth, F288

TGF $\beta$  suppresses adipocytic differentiation and enhances accumulation of stromal cells in myeloma bone lesions, SA294

ZOL inhibits the capacity of myeloid-immune suppressor cells in myeloma to form osteoclasts, SU230

**Myeloma, multiple (MM)**

Activin A mediates MM bone disease which is reversed by RAP-011, a soluble activin receptor, 1231

Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287

CXCL12 expression is regulated by HIF-2 $\alpha$  in MM plasma cells, SU080

Elevated serum levels of CXCL12 is associated with increased osteoclast activity and osteolytic bone disease in MM patients, SU079

Increased signaling through p62 in the MM microenvironment increases myeloma cell growth and osteoclast formation, SA289

Inhibition of MM growth and preservation of bone with combined radiotherapy and anti-angiogenic agent, SA285

Platelets contribute to circulating levels of Dkk-1: clinical implications in MM, SU228

Preclinical validation of a novel Dkk1 neutralizing antibody for the treatment of MM related bone disease, SU239

Role of AXII and AXIIR in homing MM cells in the bone marrow, SA287

**Myoblasts**

Dual roles of Smad proteins in the conversion from myoblasts to osteoblastic cells by BMPs, SA161

**Myostatin**

Myostatin (GDF-8) regulates the secretion of growth factors localized to the muscle-bone interface, SU153

## N

## N-Mid®

Development of a new N-Mid® osteocalcin immunoassay on the IDS Automated Analyser 3x3™, SA303

## N-telopeptides of type I collagen (NTx)

Association of stiffness index and cross-linked NTx with any clinical fractures differs with age and gender, SU350

## N-terminally extended XLas (XXLas)

XXLas acts as a novel heterotrimeric G protein subunit with an ability to transduce receptor activation into intracellular signaling, F226

## NADPH

NADPH oxidase/Nox signaling stimulates myofibroblast Msx2 transcription via  $\text{H}_2\text{O}_2$ , 1083

## Nanotechnology

Adipose tissue derived MSCs: differentiation into osteoblastic phenotype and interaction with nanostructured Ti alloys, SU050

Chemical composition and nanoscale structure of RIS-treated mineralizing MC3T3-E1 cells, M023

Modulation of skeletal modeling by silica-based nanoparticles, SU014

Multi-walled carbon nanotubes inhibit osteoclast differentiation by inhibiting nuclear translocation of NFATc1, M113

Nanogel cross-linking hydrogel as a drug delivery system for TNF $\alpha$  antagonist, M121

Nanotechnological scaffold with combination of PGE<sub>2</sub> receptor EP4 agonist and rhBMP2, enhances bone repair in the defect of mouse calvarium bone, SA105

## NaPi-IIa

Selective removal of PLC signaling in novel PTH(1-28) analogs abolishes regulation of NaPi-IIc but not NaPi-IIa, M186

## NaPi-IIc

Selective removal of PLC signaling in novel PTH(1-28) analogs abolishes regulation of NaPi-IIc but not NaPi-IIa, M186

## Narcotics

Opioid-induced osteoporosis: delayed bone healing and compression fractures in a man with chronic narcotic use, WG32

## NARS

NARS induced by bFGF regulates the proliferation and survival of osteoblasts, SA164

## National Osteoporosis Foundation (NOF)

What proportion of older women would receive drug treatment under the new NOF guidelines?, 1022

**National Osteoporosis Risk Assessment (NORA) Survey**  
Fracture risk and incidence of falls in younger postmenopausal women, 1236

**NCK1**  
Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026

**Nell-1**  
Craniofacial bone defect in Nell-1 mutant mice associated with dysregulated Runx2 and Osx expression, F174

**Neogenin**  
Regulation of chondrogenesis and bone development by neogenin via BMP pathway, SU127

**Nephroblastoma overexpressed (Nov)**  
Nov induces gremlin expression by post transcriptional mechanisms, F141

**Nephrotic syndrome**  
Development of nephrotic in transgenic rats over expressing Type III Na-dependent phosphate transporter, SU170

**Neridronate**  
Comparison of intravenous and intramuscular neridronate regimens for the treatment of PDB, SA481  
Polyostotic form of FD in a 13 year old Colombian girl exhibiting clinical and biochemical response to neridronate intravenous therapy, SU211

**Nervous system, sympathetic**  
Osteocalcin is a stress hormone: interaction with the sympathetic nervous system, M059

**Neural networks, artificial**  
Comparison between logistic regression and artificial neural networks for vertebral fracture risk assessment, SU345

**Neurofibromatosis 1 (NF-1)**  
Vitamin D deficiency, osteomalacia and high bone turnover in patients with NF-1, F465

**Neuronal development**  
Role of Ostm1 in bone, hematopoiesis and neuronal development, 1271

**Neuropeptide Y (NPY)**  
NPY effect on osteoblast cells, SU011  
Osteocytes can modulate osteoblastic activity via NPY signaling, SA056

**Neurotransmitters**  
Bone cell response to neurotransmitters and mechanical loading, SA009

**Neutrophil**  
Neutrophil-like PLB-985 cells induce differentiation of human blood monocytic precursors into functional osteoclasts via a RANKL-dependent mechanism, SA092

**NF- $\kappa$ B**  
Expression of NF- $\kappa$ B ligand and regulation of osteoclastogenesis by bone marrow adipocytes, SA078

**NfI**  
Bi-allelic loss of *NfI* in osteoblasts delays bone fracture healing, SU218

**NFAT**  
Nicotine induces chondrogenesis via calcineurin/NFAT, SU133

**NFATc1**  
AP-1 and Mitf interact with NFATc1 to stimulate Cat K promoter activity in osteoclast precursors, SA076  
BMP-2 stimulates a feedback activation loop for expression of NFATc1 in osteoblasts, F002  
BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/Akt regulates NFATc1 expression and its nuclear translocation, 1081  
Multi-walled carbon nanotubes inhibit osteoclast differentiation by inhibiting nuclear translocation of NFATc1, M113

NFATc1 mediates HDAC-dependent transcriptional repression of osteocalcin expression during osteoblast differentiation, 1145

**NFATp**  
Transcription factor NFATp regulates BMP-induced chondrocyte differentiation in a tissue-specific manner, SU020

**NHNV fractures. See Fractures**

**Nicotine**  
Nicotine induces chondrogenesis via calcineurin/NFAT, SU133

**Nitric oxide (NO)**  
Effects of electrical stimulation on NO expression and osteocyte viability in OVX rats, SA524  
HDAC inhibitors suppress IL-1 $\beta$ -induced NO and PGE<sub>2</sub> production in human chondrocytes, SU116  
NO has a powerful effect of osteoclast cells, M131  
Phosphate induced apoptosis in growth plate chondrocytes via a NO and JNK-dependent pat, SA113

**Nitric oxide synthase, endothelial (eNOS)**  
Effects of statins on eNOS and BMP-2 in osteoblasts, SU378

**Nitrogen**  
Impact of dietary protein on Ca homeostasis and nitrogen excretion in the presence and absence of KHCO<sub>3</sub>, SU305

**Nitroglycerin**  
Prevention of postmenopausal osteoporosis using nitroglycerin, M354

**Nitroglycerin as an Option: Value in Early Bone Loss (NOVEL) Study**  
Prevention of postmenopausal osteoporosis using nitroglycerin, M354

**Nkx3.2**  
Nkx3.2 is an important mediator of hypoxia-induced chondrocytic differentiation, F112

**NMDA**  
Mice lacking NMDA receptor expression in osteoblasts have pronounced vertebral bone abnormalities, F012

**Nmp4**  
Nmp4-KO mice exhibit a complex phenotype, M193

**NO66**  
Regulation of the osteoblast-specific transcription factor Osx by NO66, a Jumonji family histone demethylase, F017

**Non-steroidal anti-inflammatory drugs (NSAIDs)**  
Non-steroidal anti-inflammatory use and the response of bone to exercise, M472

**NORA Survey. See National Osteoporosis Risk Assessment Survey**

**Notch**  
Notch inhibits NFAT transactivation in osteoblast cultures, 1111  
Notch pathway is activated in osteosarcoma and inhibitors of  $\gamma$ -secretase inhibit osteosarcoma growth by cell cycle regulation, SU229  
Notch signaling inhibits chondrogenesis and subsequently promotes chondrocyte maturation, 1268  
Notch signaling regulates osteoblast maturation transition to mineralization phase, SA068

**NOVEL Study. See Nitroglycerin as an Option: Value in Early Bone Loss Study**

**Nox**  
NADPH oxidase/Nox signaling stimulates myofibroblast *Msx2* transcription via H<sub>2</sub>O<sub>2</sub>, 1083

**Npt2a**  
Synergistic role of Npt2a and Npt2c in inorganic phosphate metabolism of mice, F473

**Npt2c**  
Synergistic role of Npt2a and Npt2c in inorganic phosphate metabolism of mice, F473

**NR4A2**

Cloning and functional analysis of human Nurr1 (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161

**NTX**  
Bone degradation marker CTX shows unique properties in disease monitoring compared to NTX, ICTP and bALP in MM, M287

**Nuclear factor  $\kappa$ B (NF- $\kappa$ B)**  
Bridging vascular calcification and osteoporosis: the function of receptor activator of nuclear factor  $\kappa$ B, M419  
Matrix PRELP interferes with the NF- $\kappa$ B pathway and impairs osteoclast formation and activity, SU089

**Nuclear factor  $\kappa$ B2 (NF- $\kappa$ B2)**  
In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, 1009

**Nuclear factor I (NFI)**  
NFI transcription factors regulate IGFBP5 gene transcription in human osteoblasts, SU015

**Nuclear factor of activated T-cells (NFAT)**  
Notch inhibits NFAT transactivation in osteoblast cultures, 1111

**Nuclear factor-E2 related factor-1 (Nrf1)**  
Targeted disruption of Nrf1 in osteoblasts leads to reduced bone size and dramatic alterations in trabecular bone microstructure in mice, 1190

**Nuclear magnetic resonance (NMR)**  
Proton NMR study of transverse relaxation in rabbit and rat cortical bone, M470

**Nuclear receptor interacting protein 1 (NRIP1)**  
*NRIP1*, a novel osteoporosis candidate gene identified by expression and association analyses, M254

**Nucleotide pyrophosphatase/phosphodiesterase-1 (NPP1)**  
Proteoliposomes carrying ALP and NPP1 as matrix vesicle mimetics, SA061

**Nurr1**  
Cloning and functional analysis of human Nurr1 (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161

**NuSAP**  
Reduced cell proliferation and chondrodysplasia in mice lacking the mitotic protein NuSAP, SU120

## O

**OAH19**  
OAH19, an ethanol extract from combined two herbs, inhibits IL-1 $\alpha$ -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148

**ob/ob**  
Central and peripheral leptin treatment produce similar increase in cortical and trabecular bone mass in ob/ob mice, SU164

**Obesity. See also Body composition; Weight**  
Diet induced obesity compromises the osteogenic potential of the bone marrow, F047  
Effects of obesity on cortical bone, SA342  
Hormonal influences on volumetric bone density and geometric properties in obesity, SU367  
Interactions between obesity, CVD and bone formation, M451  
Obesity and bone architecture in men—can we apportion the metabolic and the mechanical effect?, SA440  
Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238  
Obesity is associated with higher BMD, lower bone resorption and slower hip bone loss: are these associations mediated by adipokines?, SU369  
Overweight children are more at risk to sustain a forearm fracture due to poor bone strength relative to body weight, M458

## Key Word Index

## ASBMR 30th Annual Meeting

PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180

Transgenic ASARM-peptide overexpression with reduced serum phosphate and 1.25(OH)2D3 leads to decreased BMD and obesity, F210

Vitamin D insufficiency in obesity, SA239

Vitamin D status in severely obese individuals can be predicted by demographic and lifestyle factors, SU201

Weight reduction is not deleterious for bone mass or strength in obese women, SA338

**OCT-1547**

Ca signaling is a major target of OCT-1547, a small molecule osteoporosis drug candidate, M339

**Odanacatib (ODN)**

Bone effects of ODN in adult OVX rabbits, SA073

Effects of ODN on bone biomarkers in OVX non-human primates, F297

Effects of ODN on bone mass and turnover in estrogen deficient adult rhesus monkeys, SA072

Effects of the Cat K inhibitor ODN on osteoclast-mediated bone resorption, M127

Efficacy of ODN in the OVX rhesus monkey as measured with pQCT, M343

ODN increases bone strength and maintains bone quality in estrogen deficient adult rhesus monkeys, F508

Randomized, double-blind, placebo-controlled study of ODN (MK-822) in the treatment of postmenopausal women with low BMD, 1291

**Odd-skipped related 1 (Osr1)**

Abnormality of bone formation in transgenic mice expressing Osr1, M144

**Odd-skipped related 2 (Osr2)**

Functional role of Osr2 in preosteoblastic cells, M006

**Odontoblasts**

Dlx5 overexpression stimulates odontoblast differentiation and function, M054

**Oleuropein**

Oleuropein from olive stimulates the differentiation and mineralization of cultured osteoblasts and inhibits the formation of osteoclasts in culture, M081

**Oligomenorrhea**

Elevated androgens are associated with increased bone formation in premenopausal exercising oligomenorrheic women, SU191

**Ollier Disease**

PTHR1 mutations associated with Ollier Disease result in receptor loss of function, SA258

**Oncogenic osteomalacia (OOM). See Osteomalacia**

**Ontario Osteoporosis Strategy for Inpatient Rehabilitation**

Assessment of a provincial strategy for osteoporosis best practices, M401

Post-fracture osteoporosis intervention strategy, M322

**Ophthalmologic diseases**

Prevention of GC-induced osteoporosis with ALN or ALF in patients with ophthalmologic diseases, SA450

**OPTAMISE Study**

Imaging the spatial distribution of proximal femoral response to one year of TPTD therapy, M349

One year of TPTD treatment increases hip strength in subjects with recent history of anti-resorptive treatment, F396

**Oral bones**

Mxs1 homeogene specific and non-redundant function in oral bones, M016

**Osseointegration**

Oral Sr ranelate treatment markedly improves implant osseointegration, SA506

**Ossification, endochondral**

$\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, 1013

Overexpression of CCN2/CTGF in cartilage shows prolonged bone length resulting from stimulation of chondrogenesis, chondrocyte growth, apoptosis, and bone mineralization during endochondral ossification, M153

Protein sulfation is required to prevent chondrocytes autophagy and growth factor signaling during endochondral ossification, SU119

Transcription factor Dmrt2 controls endochondral ossification through regulating type 10 collagen (Col10a1) gene expression, 1045

**Ossification, heterotopic**

Gene expression in blast-injured muscle: insights into the mechanism of heterotopic ossification, SU163

**Ossification, meniscal**

Development of OA and its relationship to meniscal ossification in Dunkin Hartley guinea pigs, M154

**Osteoactivin**

Evaluation of two novel bone growth factors to enhance fracture healing, SU012

**Osteoarthritis (OA)**

Activation of  $\beta$ -catenin signaling in articular chondrocytes leads to OA-like phenotype in adult  $\beta$ -catenin conditional activation mice, 1047

Advanced hip assessment and BMD in Japanese women with OA, M449

BT-201, a butanol extract of *Panax notoginseng* inhibits progression of joint degeneration in a rat model of OA, M152

Comparison of 2D and 3D subchondral bone texture parameters in severe OA knees, M302

Development of OA and its relationship to meniscal ossification in Dunkin Hartley guinea pigs, M154

Discordance in femoral neck bone density in subjects with OA, M453

Effect of aquatic exercise and education on improving indices of fall risk in older adults with hip OA, M441

Effect of bisphosphonate treatment of OA in a guinea pig model, M149

Effects of beta-D-glucopyranoside from *Phellodendron Amurense* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117

H4R is expressed by both OA and RA human tissues, SU159

IL-1 $\beta$ -induced hepcidin expression in synovial membranes of patients with OA is associated with TNF $\alpha$  repression, SU157

Investigation into the impact of OA changes on BMD measurements in patients with high bone mass, SA257

Longitudinal relationships between cartilage and bone turnover in OA, SA129

Novel model system for drug discovery in OA: monitoring whole tissue turnover in murine femur heads, SU125

OAH19, an ethanol extract from combined two herbs, inhibits IL-1 $\alpha$ -induced expression of MMP-1 and MMP-13 in OA human cartilage and synovial fibroblast, M148

PGD2 downregulates MMP-1 and MMP-13 expression in human OA chondrocytes, SA152

Proinflammatory mediators downregulate PPAR $\gamma$ 1 expression and activity in OA synovial fibroblasts, M159

PTH has direct anabolic effects on OA articular cartilage in vitro and in vivo, M155

Relationship between BMD of the lumbar spine and knee OA in South Korean, SU298

Role of gal-3 in OA, M162

Targeted expression of SOX9 in hypertrophic chondrocytes leads to enhanced adipogenic activity and spontaneous OA in transgenic mice, SA115

In vivo knockdown of GEP, a novel growth factor in cartilage, led to defects in cartilage and OA, 1048

**Osteoblastic differentiation**

(Ala-Gly) $_n$  sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167

Adipose tissue derived MSCs: differentiation into osteoblastic phenotype and interaction with nanostructured Ti alloys, SU050

Ang-1 enhanced BMP-2 induced osteoblast differentiation, SU035

Blockade of Ephrin/EphB4 signaling within the osteoblast lineage reduces osteoblast differentiation and mineralization, SU046

Catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation, SU137

CD47 (IAP) is an important modulator of osteoclast and osteoblast differentiation in vitro and in vivo, F093

Chondrocyte-derived Ihh is required for osteoblast differentiation despite reconstitution of a normal growth plate, 1154

Coactivator MBF1 binds to JunD and protects its transcriptional activity against oxidative stress to prevent age-related suppression of osteoblast differentiation, 1248

Congenetic mouse models provide novel evidence of caveolae-1 $\alpha$  domain regulation of osteoblast differentiation, SU147

Coordinate regulation of PTHrP and PTHR1 in the osteoblast differentiation of C2C12 cells promoted by BMP-2, SA157

Deletion of ADAM15 decreases osteoblast differentiation and bone formation in vitro, M073

Depletion of the chromosome remodeling subunit BRM accelerates differentiation of osteoblast precursors, M038

Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060

Effect of a novel splice-site mutation of PHEX gene during osteoblast differentiation, M092

Effects of serum factors during osteoblast differentiation—implication for the pathogenesis of osteoporosis in Crohn's Disease, M450

Enamel matrix derivative (emdogain) enhance osteoblast differentiation on Ti surfaces, M030

Enhanced mitochondrial biogenesis contributes to Wnt induced osteogenic differentiation of C3H10T1/2 cells, SA043

Fat suppresses osteoblast differentiation by soluble factors that induce apoptosis, M003

FGF-1 inhibits adipogenic differentiation and transdifferentiation of human MSCs, M075

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

Identification of IRX3 a novel transcription factor during BMP-2 mediated osteoblast differentiation, SU024

IGFBP6 Is a negative regulator of osteoblast differentiation and bone formation, SA182

Impairment of osteoblast lineage differentiation leads to increased osteoclastogenesis in OI murine, 1202

- Induction of Runx2 and Osx by bisphosphonate promote osteogenic differentiation, SU062
- Inhibition of lamin A/C attenuates osteoblast differentiation and stimulates osteoclastogenesis through enhanced RANKL signaling, M070
- Interplay between BMP and TGF $\beta$  signaling in osteoblast differentiation, SA031
- Mature human adipocytes differentiated from BMSCs, SA042
- Microporosity in b-TCP ceramics may be detrimental to MSC survival and osteoblastic differentiation, SA015
- NFATc1 mediates HDAC-dependent transcriptional repression of osteocalcin expression during osteoblast differentiation, 1145
- Noncanonical Wnt signaling is involved mir-206 expression in osteoblastic differentiation, SA021
- Oleuropein from olive stimulates the differentiation and mineralization of cultured osteoblasts and inhibits the formation of osteoclasts in culture, M081
- Osteoblast differentiation induced by Shh-expressing prostate cancer cells is enhanced by ascorbic acid, SA284
- Osteopenia by high alcohol consumption in the absence of ALDH2 attribute to the disturbance of the differentiation in osteoblasts, M326
- Overexpression of  $\alpha$ -catenin in C3H10T1/2 cells increases osteoblast differentiation, SA046
- Overexpression of androgen receptor in mature osteoblasts and osteocytes inhibits osteoblast differentiation, SU192
- Permanent FGFR2 activation promotes osteoblast differentiation in MSCs through activation of PKC signaling, M093
- PTH/PTHrP mediated stimulation of osteoblast differentiation involves Epac-Rap1 dependent processes, SA025
- Pulse treatment with ZOL causes sustained commitment of bone marrow derived MSC for osteogenic differentiation, M072
- R-spondin 2 is a novel osteogenic factor required for Wnt11 mediated osteoblast differentiation, SU063
- Regulation of Dkk-1 and Dkk-2 is needed for osteoblast terminal differentiation on microstructured Ti surfaces, SU006
- Regulation of osteoblast differentiation by miRNA, M087
- Role of FIP200 in osteoblast differentiation, M091
- Role of pyrophosphate and inorganic phosphate in PKA-mediated osteoblastic differentiation and mineralization of primary murine aortic cells, M143
- Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043
- SATB2 overexpression promotes osteoblast differentiation and enhances regeneration of bone defects, SU058
- Small G protein Rap1 promotes osteoblast differentiation, M080
- T-box 3 negatively regulates osteoblast differentiation by inhibiting expression of Osx and Runx2, SU018
- Tcf is required for Wnt11 mediated osteoblast differentiation, M058
- TGIF regulation of bone mass: impaired osteoblast differentiation, SA018
- TIEG: a key regulator of Runx2 and Osx gene expression and osteoblast differentiation, M052
- WNT-4 acts through the non-canonical pathways to stimulate osteoblast and BMSC differentiation, F050
- Osteoblastogenesis**
- Effect of 1,25(OH) $_2$ D $_3$  and 25(OH)D $_3$  on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207
- Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189
- High concentrations of hydroxytyrosol and quercetin antioxidants enhance adipogenesis and inhibit osteoblastogenesis in MSCs, SA037
- Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374
- Low dose administration of INF $\gamma$  stimulates osteoblastogenesis and prevents ovariectomy-induced osteoporosis in C57BL/6 mice, M334
- Musculoskeletal disuse worsens the acute detrimental effects of heavy particle radiation on osteoblastogenesis, SA517
- PBX1 interaction with HOXA10 regulates timing and expression of phenotypic bone genes during osteoblastogenesis, SU019
- VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029
- Osteoblasts**
- (Ala-Gly) $_n$  sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167
- 1,25(OH) $_2$ D $_3$  regulates collagen maturation in osteoblastic cell culture system, SU208
- 7B2 protein mediated inhibition of DMP1 cleavage in osteoblasts enhances FGF-23 production in *Hyp*-mice, 1053
- Abrogation of Cbl-PI3K interaction in mice results in increased bone volume and osteoblast proliferation, 1150
- Accelerated fracture callus remodeling and membranous bone healing in STAT1 deficient mice, SA022
- Acid-induced stimulation of bone resorption is decreased in OGR1 KO mouse calvariae, M021
- Activation of FGF receptors is a novel mechanism by which extracellular Ca stimulates the proliferation of osteoblasts, M088
- Activation of P2X7 nucleotide receptors increases metabolic acid production by osteoblastic cells, M065
- Age-related bone loss in mice associated with ubiquitin ligase Smurf1 degradation of JunB protein and reduced osteoblast proliferation, 1113
- Aging of human BMSC: role of WNT pathways, SA048
- Ahnak regulates Ca signaling and ATP release in osteoblasts in response to mechanical stimulation, SA027
- ALN affects cross-talk of osteoclasts and osteoblasts in vivo, SU392
- Altered long bone structure in recessive null and dominant negative Cx43 (*Gjal*) mouse mutants, 1110
- Analysis of chromosome breaks in osteoblasts and non-osteoblastic cells treated with intermittent PTH, M191
- Anti-myeloma effects of osteoblasts is mediated through production of SLRPs, M001
- Association between Cx43 and  $\beta$ -arrestin is required for cAMP-dependent osteoblast survival induced by PTH, 1227
- Atypical antipsychotic clozapine reduces rat osteoblast proliferation and osteoclastogenesis at therapeutic levels, SU030
- Availability of cytoplasmic  $\beta$ -catenin impacts mechanical signaling in osteoblasts, 1253
- Bi-allelic loss of *Nf1* in osteoblasts delays bone fracture healing, SU218
- BMP-2 induces Osx expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020
- BMP-2 stimulates a feedback activation loop for expression of NFATc1 in osteoblasts, F002
- BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/Akt regulates NFATc1 expression and its nuclear translocation, 1081
- BMP-6 stimulated osteogenesis of HOB cultures is associated with suppression of PYK2, SU048
- BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098
- Bone cell response to neurotransmitters and mechanical loading, SA009
- Bone response to mechanical loads and Lrp5 genotype, M020
- Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050
- Breast cancer cell conditioned media stimulates osteoblastic cells to attract breast cancer cells, SA276
- Brief pulsing electromagnetic field exposure differentially effects cell cycle in proliferating and confluent osteoblasts, M004
- Bril localization in mouse and rat bones, M025
- Butyrate stimulates mineralized nodule formation and OPG expression by osteoblasts, M012
- c-Src-regulated osteoblast-mimicry in breast cancer bone metastasis: the role of RAMP2 and BSP2, M275
- C/EBP $\beta$  overexpression causes osteopenia, SA005
- $\beta$ -catenin protects osteoblasts from oxidative stress by co-activating the expression of pro-survival, but not pro-apoptotic, target genes of the FoxO transcription factors, M010
- Ccrn4l*, a peripheral clock gene, influences stromal cell allocation, bone mass, and marrow adiposity in mice and humans, 1073
- CFTR regulates osteoblast bone formation independent of chloride conductance, 1274
- CGRP stimulates osteogenesis and inhibits osteoclastogenesis in vitro, SU033
- Characterisation of an antigen found in giant cell tumor and osteosarcoma cells, SU244
- Characterization of a promoter polymorphism in FZD1: allele-specific regulation by Egr-1 in osteoblast-like cells, M267
- Characterization of osteoblastic properties of 7F2 and UMR-106 cultures after acclimation to reduced levels of fetal bovine serum, SU041
- Chemerin and CMKLR1 targeted gene delivery identifies a novel molecular switch in the treatment of osteoporosis, M071
- Chemical composition and nanoscale structure of RIS-treated mineralizing MC3T3-E1 cells, M023
- Circulating osteoblast lineage cells increase with PTH treatment of HPT, 1146
- Cloning and functional expression of the full length mouse GIP receptor and the regulation of its expression in osteoblasts by the Sp1 transcription factor, SU026
- CNBP conditional KO mice show severe osteoporosis-like phenotype, F014
- Comparison of gene expression in osteocytes versus osteoblasts, M056
- Comparison of the effects of zoledronates on the differentiation of human bone marrow and amniotic fluid derived MSCs, SA045
- Concentration of connective tissue progenitors in autologous cancellous bone graft enhances new bone formation in a canine femoral defect model, SA039
- Conditional deletion of BMP-2 gene in early osteoblasts leads to reduction in the total bone marrow MSCs and their capacity to form osteoblast precursors, 1114

## Key Word Index

## ASBMR 30th Annual Meeting

- Conditional disruption of *Pkd1* in osteoblasts results in osteopenia due to direct impairment of osteoblast-mediated bone formation, SA019
- Conditional knockout of the CaSR in osteoblasts alters regulators of Wnt signaling, delays cell differentiation, and promotes apoptosis in bone, 1156
- Continuous local infusion of ALN prevents osteopenia of the lengthened segment during distraction osteogenesis, SU001
- Conversion of Vitamin K analogues to MK-4 in osteoblastic cells, M064
- Critical role of Cx43 in postnatal skeletal growth and bone mass acquisition, 1257
- CT-1 is an osteoclast-derived coupling factor required for normal bone remodeling, M014
- Deciphering the cellular defects of osteoblasts in microgravity, SA013
- Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026
- Deletion of the Dkk-1 Krm-1 and Krm-2 in mice leads to increased bone formation and bone mass, 1004
- Deletion of the G protein subunit G $\alpha$  in early osteoblasts leads to accelerated osteoblast maturation and formation of woven bone with abnormal osteocytes, resulting in severe osteoporosis, 1254
- Deletion of the Wnt signaling antagonist sFRP4 in mice induces opposite bone formation phenotypes in trabecular and cortical bone, 1005
- Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109
- Dermo1 lineage tracing identifies early osteoprogenitor cells in adult murine bone marrow MSC cultures, SA051
- Development of high-throughput screening system for osteogenic drugs using cell-based sensor, M082
- Different osteogenic properties of human BMSC from different skeletal site origin, SU055
- Differential contribution of osteoclast- and osteoblast-lineage cells to LPS modulation of osteoclastogenesis, SU088
- Disuse with a rapid bone loss affects the expression profile of osteoblastic and resorption genes, F516
- Dlx5 overexpression stimulates odontoblast differentiation and function, M054
- DNA methylation analysis of osteogenic gene promoter regions in mouse BMSC, M035
- Dried plum polyphenols increase IGF-I production in osteoblast-like cells, SU002
- Dual roles of Smad proteins in the conversion from myoblasts to osteoblastic cells by BMPs, SA161
- Effect of MKP-1 deletion on the fluid shear stress induction of COX-2 expression in osteoblasts, SA529
- Effect of osteoblast depletion on hematopoietic niches in the bone marrow, F041
- Effect of resveratrol and flax oil on MC3T3-L1 pre-adipocyte and ST2 BMSC proliferation and differentiation, SU059
- Effect of Sr<sup>2+</sup> on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016
- Effects of ALN and RLX on the RANKL/OPG system in primary cultures of human osteoblasts, M101
- Effects of Ga11 overexpression on osteoblast signaling and function in transgenic mice, M067
- Effects of statins on eNOS and BMP-2 in osteoblasts, SU378
- Endogenous G $\beta$  signaling in osteoblasts negatively regulates cortical bone formation, 1255
- Engineering mice with multiple BAC fluorescent protein reporter gene elements, SU028
- Enhanced osteogenic potential of alveolar vs. long bone derived BMSC, M095
- Enrichment of type XI collagen and 6b N-terminal domain at sites of mineral nucleation within osteoblastic cultures, SA070
- EphB4 expression in osteoblasts is regulated by myeloma cells and the Wnt signaling pathway, SU232
- Ephrin B1 reverse signaling regulates bone formation via influencing osteoblast activity in mice, 1194
- Ethanol alters estrogen receptor signaling and activates senescence pathways in osteoblasts while estradiol attenuates ethanol effects, SU182
- Evaluation of circulating osteoprogenitor cells during fracture healing using parabiotic mice, 1260
- Evaluation of two novel bone growth factors to enhance fracture healing, SU012
- Expression of an engineered G $\gamma$ -coupled receptor in osteoblasts affects intramembranous and endochondral bone formation during bone repair, F127
- Expression of an engineered G $\gamma$ -coupled receptor, Rs1, in mature osteoblasts is sufficient to drive a dramatic anabolic skeletal response, 1077
- Expression of bone-related genes by peripheral blood CD34 cells, M083
- Expression profiles of Wnt signaling pathway components in response to cAMP stimulation at different stages of osteoblast maturation, M040
- FGF-2 signaling in osteoblasts: Cx43 is a docking platform for PKC $\delta$ , F026
- FGF-23 and FGF-2 share a common but also have distinct signaling pathways for negative regulation of bone nodule mineralization in cultured osteoblasts, SA206
- FOXO1 signaling in the control of bone mass, 1112
- Functional association of MAPK and Runx2 on osteoblast chromatin, SU025
- Functional role of Osr2 in preosteoblastic cells, M006
- G171V and A214V Lrp5 knock-in mice have increased bone mass and strength, and can help precisely define the in vivo functions of Lrp5 during bone growth and homeostasis, 1002
- GC signaling in osteoblasts maintains normal bone structure in mice, F233
- GC signaling through osteoblasts is essential for cranial skeletal development, 1267
- Gender specific effects of TRPV4 on osteoblast-osteoclast coupling and risk of osteoporotic fractures, SA355
- Gene expression analysis of in vitro-aged and immortalized human MSCs, M047
- GILZ promotes osteoblast development and modulates RANKL/OPG levels, M049
- Global transcriptome analysis in mouse osteoblasts identifies a mechanosensing osteoblast gene signature, SU017
- GPRC6A null mice exhibit osteopenia and feminization, F004
- High bone mass phenotype in the bone specific Dlx3 KO mice, M027
- High concentrations of hydroxytyrosol and quercetin antioxidants enhance adipogenesis and inhibit osteoblastogenesis in MSCs, SA037
- Hormonal control of RANKL expression is independent of Runx family proteins: evidence that commitment to the osteoblast lineage is not a requirement for the stromal cells that support osteoclast differentiation, SU047
- hPTHrP 1-36 stimulates PKA-dependent phosphorylation and nuclear translocation of  $\beta$ -catenin in neonatal mouse calvarial bone cells, F032
- HSPG modulate osteogenic differentiation through heparan sulfate chains, M094
- Human osteoblasts synthesize VEGF in response to ACTH, SA236
- Human osteoprogenitor cell adhesion and spreading on functionalized Ti surfaces followed by QCM and CLSM, SA101
- Imaging of mineralization kinetics suggests that the transition from osteoblast to osteocyte initiates prior to mineral deposition, F062
- Impaired angiogenesis and compromised fluid volume accompanies increased osteoblast and osteocyte apoptosis with GC excess, SA453
- Importance of melastatin-like transient receptor potential 7 and Mg in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor, M008
- Inactivation of Dlx5 gene results in altered osteoblast-osteoclast coupling inducing increased bone resorption and reduced cortical thickness in male mice, F010
- Inactivation of the ILK in osteoblasts increases mineralization, M061
- Increased osteoclasts in Brl mouse model for OI are independent of decreased osteoblast matrix production and RANKL/OPG ratio, but are associated with increased osteoclast precursors in marrow, SU209
- Induction of CTGF by TGF $\beta$ 1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066
- Induction of oxidative stress and diversion of  $\beta$ -catenin from TCF- to FOXO-mediated transcription by GCs or TNF $\alpha$  in osteoblastic cells, SA185
- INF $\gamma$  attenuates BMP-2 signaling via Stat-1 binding of Smad4 in the cytoplasm, SU139
- Inhibition of BMP pathway and osteoclast activity in osteoblastic prostate cancer lesion in bone, F283
- Inhibition of major bone catabolic mediators in human subchondral bone osteoblasts upon EphB4 receptor activation by Ephrin-B2 ligand, SU003
- Inhibition of the mevalonate pathway rescues the DEX-induced suppression of the mineralization of osteoblastic cells, SA230
- Integrin mediated mechanical forces stimulate differentiation of MSCs, SA528
- Integrin-associated protein upregulates osteogenesis-related transcription factors via TGF $\beta$  and BMP pathways, SA028
- Interaction of Ciz, a nucleocytoplasmic shuttling transcription factor with C-propeptides of type I collagen, M044
- Isolation and characterization of osteoblasts from alveolar bones of aged donors, SU049
- Jagged1 stimulation by PTH(1-34) in mature osteoblasts is not required for HSC expansion, 1078
- Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194
- Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009
- Li affects matrix mineralization by decreasing tissue non-specific ALP levels in osteoblasts, SA071
- Ligand activation of the engineered G $\gamma$ -coupled receptor Rs1 in osteoblasts promotes trabecular bone formation, 1076
- Lithocholic acid downregulates the effects of Vitamin D $_3$  on primary human osteoblasts, SA030
- Longevity gene *SIRT-1* independently controls both osteoblast and osteoclast function, 1098
- Loss of classical ERE signaling results in suppression of early commitment of BMSC to osteoblasts, F029
- Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, 1247

- LPS-induced inhibition of osteogenesis is TNF $\alpha$  dependent, M019
- Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022
- MAPK-dependent inhibition of osteocalcin gene expression by TGF $\beta$ , M033
- Mapping the interrelationship of the adipogenic and osteogenic lineage with visual reporters, M097
- Mechanical loading upregulates expression of the transcription factor EGR2/Krox-20 by a COX-2-mediated mechanism, SA526
- Mechanical strain prevents adipogenesis in MSC by stimulating a durable  $\beta$ -catenin signal, SA522
- Menaquinone-4 derived from phyloquinone regulates osteoblast function, SU034
- Mice lacking NMDA receptor expression in osteoblasts have pronounced vertebral bone abnormalities, F012
- Mice lacking the novel transmembrane protein Opt develop catastrophic defects in bone modeling, 1075
- Mice lacking the Wnt receptor Frizzled-9 display osteopenia caused by decreased bone formation, 1006
- Molecular mechanisms underlying matrix vesicle-induced mineralization during bone formation, SA063
- Molecular phenotyping of osteoblastic and osteocytic cell fractions isolated from mouse calvaria, M106
- Msx1 homegene specific and non-redundant function in oral bones, M016
- NARS induced by bFGF regulates the proliferation and survival of osteoblasts, SA164
- Neuroendocrine activation of AMPK in osteoblasts, SU037
- NFI transcription factors regulate IGFBP5 gene transcription in human osteoblasts, SU015
- Non-genomic estrogen receptor Gpr30 is a Runx2 responsive gene that is required for osteoblast proliferation, F572
- Normal human osteoblasts internalize MSUM by phagocytosis and autophagy, M057
- Normal intramembranous fracture healing in mice with transgenic osteoblast-targeted disruption of GC signaling, SA234
- Notch inhibits NFAT transactivation in osteoblast cultures, 1111
- Notch signaling regulates osteoblast maturation transition to mineralization phase, SA068
- Novel modification of bone grafts inhibits bacterial colonization, M169
- NPY effect on osteoblast cells, SU011
- Osteoblast and osteoclast involvement in the pathogenesis of a mouse model for CMD, 1204
- Osteoblast-specific deletion of *Lrp6* reveals distinct roles for *Lrp5* and *Lrp6* in bone development, 1001
- Osteoblast-targeted deletion of the GC receptor has little impact on PBM but attenuates DEX-induced suppression of bone formation, F452
- Osteoblastic androgen receptor regulates cortical BMD, 1122
- Osteoblasts apoptosis is mediated through GSK3 $\beta$ , M005
- Osteoclast precursors play a role in recruiting breast cancer cells and osteoblasts onto the bone in vitro, SA278
- Osteocytes can modulate osteoblastic activity via NPY signaling, SA056
- Osteoformin increases the levels of intracellular Ca of human preosteoblast cells in culture, SU051
- Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135
- Osteogenic cell lineages show differential responsiveness to angiogenic signals, SU061
- Osteogenic potential of human bone marrow and circulating Stro-1<sup>+</sup>/CD45<sup>low</sup> cells, M078
- Osteogenic potential of PDL cells in vivo, SU054
- Osx is required for skeletal growth and bone homeostasis after birth, 1074
- Osx, a positive regulator in adult bone formation, F008
- Overexpression of GSR in osteoblasts decreases bone formation and partially prevents OVX-induced bone loss, F024
- Overexpression of Lef-1 $\delta$ N increases bone mass in mice, 1258
- P2X<sub>7</sub> receptor activation mediates PKC $\alpha$  translocation in osteoblasts through alteration in actin cytoskeletal organization, SU040
- P2Y<sub>2</sub> receptor activation regulates RhoA-mediated stress fiber formation in osteoblasts, SA035
- PAR-2 activation induces bone resorption via RANKL upregulation in human OA subchondral bone osteoblasts, M018
- PBX1 interaction with HOXA10 regulates timing and expression of phenotypic bone genes during osteoblastogenesis, SU019
- PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts, F079
- Possible physiological function of menin protein as transcriptional factor that modulates miRNA expression during osteogenesis, M036
- Post-mitotic preosteoblasts are the targets of the anabolic actions of intermittent PTH on periosteal bone, 1157
- Post-translational regulation of Msx2 protein, SU021
- PPAR $\gamma$ 2-mediated proteolytic degradation of  $\beta$ -catenin determines an anti-osteoblastic effect of anti-diabetic TZDs, SU023
- Primary bone cells of pregnant mice exposed to oscillatory fluid flow, M015
- Program of miRNAs control BMP-2 induced bone phenotype development, M090
- Progressive lipodystrophy in the osteosclerotic mice over-expressing Fra1, 1149
- Proinflammatory cytokine TWEAK induces SCT expression in human immature osteoblasts in a MAPK dependent fashion, M046
- Prostaglandins enhance extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity in osteoblast-like cells, SU031
- Proteasome inhibition counteracts the negative effect of GC treatment on bone metabolism by stimulating osteoblasts and inhibiting osteoclasts in vitro, SA231
- PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calcineurin pathways, SA033
- PTH regulation of Osx transcription in osteoblasts, M042
- PTH signaling through LRP5/6 in osteoblasts, 1014
- RANKL suppression by siRNAs in rat primary osteoblasts, M032
- RANKL/OPG in primary cultures of osteoblasts from patients with osteoporotic hip fractures, SU009
- RBP1 is critical for Runx2 expression, transcriptional activity and nodule formation in osteoblasts, M037
- Regulation of bone formation by osteoclasts involves Wnt/BMP signaling and the chemokine S1P, M017
- Regulation of intracellular signaling of MC3T3-E1 osteoblasts by the extracellular matrix, SA139
- Regulation of osteogenesis by Wnt signaling in rat MSC and human ASC, SU045
- Regulation of RUNX2 at the nuclear lamina, M055
- Regulation of Runx2 function in osteoblasts by sex steroid receptors, M099
- Regulation of the BMP-2 distant osteoblast enhancer by FGF-2, SU150
- Regulation of the osteoblast-specific transcription factor Osx by NO66, a Jumonji family histone demethylase, F017
- Regulatory signaling pathways in BMP mediated osteogenesis of adult human MSC cultures, M060
- Role of ATF4 in osteoblast proliferation and survival, M079
- Role of cell surface ATP synthase in fluid shear stress induced ATP release in osteoblasts, SU039
- Roles of ZOL in bone healing and osteoblast functions, 1064
- Runx2 threshold for the CCD phenotype, M041
- Selective retention of bone marrow cells in repair of canine femoral defect with polycaprolactone-tricalcium phosphate scaffolds, SU005
- Sequestration, proliferation and differentiation of osteoblasts in hydrogels for tissue engineering applications, SA143
- Serine protease inhibitor AEBSF blocks transcription of Phex by osteoblasts, M053
- Silencing of RhoGTPases counteract microgravity-induced effects on osteoblasts, SA011
- SIRT1 is a regulator of MSC lineage allocation, M085
- SOST blocks GSK3-beta inhibitor-induced ALP activity, SU036
- Soy-based formula promotes bone growth in neonatal piglets by inducing osteo-progenitors to differentiate into osteoblasts via enhanced BMP-2 signaling, SA336
- SP stimulates BMSC osteogenic activity and osteoclast differentiation and function in vitro, SU032
- Sr ranelate decreases osteoblast-induced osteoclastogenesis through the involvement of the CaSR, F389
- Sr ranelate protects osteoblasts from apoptosis independently of the CaSR, M007
- Stable expression of constitutively active G $\alpha$ 12 in osteoblastic cells promotes matrix protein expression and ALP activity, M068
- Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036
- Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, 1089
- Strain-induced fluid flow in a 3D porous matrix promotes osteoblastic calcification in vitro, SA525
- Suppression of canonical wnt signaling by Dkk1 attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215
- Targeted disruption of Nrf1 in osteoblasts leads to reduced bone size and dramatic alterations in trabecular bone microstructure in mice, 1190
- Targeted disruption of PPAR $\gamma$  in BMSC reveals its role in aging-induced bone loss, 1148
- Targeted overexpression of the nuclear FGF-2 isoforms in osteoblasts induces hypophosphatemia via modulation of FGF-23 and Klotho in mice, 1084
- Telomerase deficiency leads to decrease bone mass and impaired MSCs functions in telomerase deficient (TERC<sup>-/-</sup>) mice, 1147
- TGF $\beta$  blockade inhibits osteolytic but not osteoblastic prostate cancer metastases, SA274
- TGF $\beta$  signaling in stromal cells facilitates osteoblastic lesions in prostate cancer, 1087
- TNF $\alpha$  and IL-1 $\beta$  stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044
- Towards development of a PSi-based hybrid biomaterial with osteoconductivity and osteoinductivity, M028

## Key Word Index

## ASBMR 30th Annual Meeting

Tracking adipose differentiation in vitro with aP2-GFP reporters and flow cytometry: lipid staining and macrophage mimicry, SU057

Traf2 regulates BMP signaling pathway in osteoblastic cells, M063

Transcriptional activation of osteocalcin by Runx2 during osteoblast development is controlled at the post-translational level, M031

Transgenic mice over-expressing TIEG in osteoblasts display a gender specific bone phenotype, M024

Transgenic overexpression of the Wnt antagonist Krm-2 in osteoblasts leads to severe impairment of bone formation and increased bone resorption, 1003

TRIP-1 is eIF3i: a key regulator of osteoblast activity, 1259

TZD modify nuclear heterochromatin architecture, SU056

Use of  $\alpha$ -SMA-GFP transgene to identify periodontium derived osteoprogenitors, SA040

Use of GFP reporters to assess cell lineage in a murine model of tibial fracture repair, M077

Use of GFP reporters to map the progression of multipotential progenitor cells into the osteoblast lineage, SU053

Various roles of syndecan family in osteoblastic cells, SA147

VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029

Wdr5 is required for chromatin modifications at the Runx2 promoter, M039

Wnt/LRP5-independent inhibition of osteoblastic cell differentiation by SCT, 1256

**Osteocalcin**

Analytical validation of LIA and ELEC methods for the determination of osteocalcin, SA191

Development of a new N-Mid<sup>®</sup> osteocalcin immunoassay on the IDS Automated Analyser 3x3<sup>TM</sup>, SA303

Intermittent injection of recombinant osteocalcin improves glucose tolerance and insulin sensitivity, F168

Low serum osteocalcin predicts carotid plaques and indicators of the metabolic syndrome, SA198

MAPK-dependent inhibition of osteocalcin gene expression by TGF $\beta$ , M033

NFATc1 mediates HDAC-dependent transcriptional repression of osteocalcin expression during osteoblast differentiation, 1145

Osteocalcin is a stress hormone: interaction with the sympathetic nervous system, M059

Plasma osteocalcin is inversely related to fat mass and plasma glucose in elderly Swedish men, SU459

Reduced serum osteocalcin and sex hormone binding globulin in men with type II diabetes, SU461

Sympathetic tone mediates leptin's inhibition of insulin secretion by modulating osteocalcin bioactivity, F034

TNF $\alpha$  and IL-1 $\beta$  stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

Transcriptional activation of osteocalcin by Runx2 during osteoblast development is controlled at the post-translational level, M031

Variation in the osteocalcin gene: association study of BMD, fracture and changes in body fat mass in elderly women, SU225

**Osteocalcin, uncarboxylated (ucOC)**

Clinical significance of ucOC in GIO, M299

Serum ucOC concentration are related to renal function in type 2 diabetes patients, M443

ucOC is an endocrine link between the skeleton and the glucose metabolism, F444

ucOC level in healthy Korean women, M300

**Osteoclast inhibitory peptide-1 (OIP-1)**

IL-12 stimulates the OIP-1 gene expression in CD4<sup>+</sup> T-cells, SA173

**Osteoclastic differentiation**

All-*trans*-retinoic acid (Vitamin A) increases expression of MafB and inhibits osteoclast formation by interfering with differentiation of osteoclast progenitor cells, M117

ANKH mutation causing CMD inhibits osteoclast differentiation, SU214

CD47 (IAP) is an important modulator of osteoclast and osteoblast differentiation in vitro and in vivo, F093

Cholesterol sensing receptors, Liver X receptor  $\alpha$  and  $\beta$ , have novel and distinct roles in osteoclast differentiation and activation in bone, F085

DARC regulates osteoclast differentiation via modulating chemokine effects on migration/fusion of osteoclast precursors, M115

Estrogen suppresses RANKL-induced osteoclastic differentiation of human monocytes via an ER $\alpha$  associated cytoplasmic signaling complex, but ER $\alpha$  is downregulated during osteoclastic differentiation, 1125

Fungal secondary metabolites beauvericin and enniatin inhibit osteoclast differentiation and bone resorption, M130

IFN- $\beta$  is a key molecule in inhibition of human osteoclast differentiation by 1 $\alpha$ ,25-dihydroxyvitamin D<sub>3</sub>, SU090

Increased osteoclast differentiation and bone resorption during spaceflight, SU094

MKP-1 protects bone mass via negative regulation of osteoclast differentiation and activation, 1219

Multi-walled carbon nanotubes inhibit osteoclast differentiation by inhibiting nuclear translocation of NFATc1, M113

Primary human bone marrow adipocytes stimulate osteoclast differentiation, M111

Pyrophosphates stimulates osteoclast differentiation and bone resorption, SA084

RANKL-mediated osteoclast lineage commitment dictates the role of LPS in osteoclast differentiation, SA088

Sim induces Wnt signaling and reduces CSF-1 secretion and RANKL/OPG ratio to block osteoclast differentiation, SU096

SP stimulates BMSC osteogenic activity and osteoclast differentiation and function in vitro, SU032

Suppression of TREM-2 expression and TREM-2-mediated costimulation of RANK signaling by cytokines that inhibit human osteoclast differentiation, SU114

Vimentin binds c-Fms in an M-CSF dependent manner and regulates osteoclast differentiation, SU097

Wnt5a regulates osteoclast differentiation in physiological and pathological conditions, 1012

**Osteoclastogenesis**

Atypical antipsychotic clozapine reduces rat osteoblast proliferation and osteoclastogenesis at therapeutic levels, SU030

BMSC up-regulate M-CSF receptor in monocytes to disrupt dendritic cell differentiation while facilitating osteoclastogenesis in myeloma, SU242

Brain-type creatine kinase is required for RANKL-induced osteoclastogenesis, M116

Breast cancer derived factors synergize with TGF $\beta$  to induce phosphorylation of ERK1/2 and to stimulate osteoclastogenesis, SU115

CGRP stimulates osteogenesis and inhibits osteoclastogenesis in vitro, SU033

Comparison of direct osteoclastogenic potential on osteoclast precursor cells among proinflammatory cytokines, SU077

Dietary normalization of Ca absorption in mice genetically deficient in CaSR and 25(OH)D-1 $\alpha$ -hydroxylase results in non-lethal, severe hyperparathyroidism with reduced osteoclastogenesis, M199

Differential contribution of osteoclast- and osteoblast-lineage cells to LPS modulation of osteoclastogenesis, SU088

DLK1/FA1 is a novel factor enhancing osteoclastogenesis and inhibiting bone formation in vitro and in vivo, 1007

Downregulation of Cx43 expression and osteoclastogenesis by a bioceramic bone graft substitute, M119

Effects of IL-27 on regulation of osteoclastogenesis by way of T cells, SU081

ER $\alpha$  deletion in cells of the monocyte/macrophage lineage increases osteoclastogenesis and abrogates the pro-apoptotic effect of E<sub>2</sub> on osteoclasts, 1097

Expression and function of synoviolin in human osteoclastogenesis, SA080

Expression of NF- $\kappa$ B ligand and regulation of osteoclastogenesis by bone marrow adipocytes, SA078

IFN- $\gamma$  inhibits TNF $\alpha$ -induced osteoclastogenesis in vitro and in vivo, SU152

IL-12 induces apoptosis in TNF $\alpha$ -mediated osteoclastogenesis in vivo, SA166

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

Impairment of osteoblast lineage differentiation leads to increased osteoclastogenesis in OI murine, 1202

Inhibition of lamin A/C attenuates osteoblast differentiation and stimulates osteoclastogenesis through enhanced RANKL signaling, M070

Isoform-specific expression of PPARs and gene regulation during osteoclastogenesis in RAW/C4 cells, M118

Losartan<sup>®</sup> (Cozaar) increases appendicular bone formation by inhibiting osteoclastogenesis, M126

Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119

Mechanism of BMP-2 enhancement of PGE<sub>2</sub> stimulated osteoclastogenesis, SU085

MEK5/ERK5 signal regulates RANKL-induced osteoclastogenesis, SU103

Modeled microgravity sensitizes osteoclast precursors to RANKL mediated osteoclastogenesis by increasing DAP12, M114

Modulation of osteoclastogenesis by fatty acids, SU071

Novel role of L-Ser for the activation of RANKL-RANK signaling machinery in osteoclastogenesis in vitro, SA082

Novel splicing variants of ADAM8 stimulate tumor-induced bone metastasis by increasing invasion and osteoclastogenesis, F286

PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts, F079

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

Recombinant mouse M-CSF receptor C-fms inhibits TNF $\alpha$ -induced osteoclastogenesis, M112

Reduced osteoclastogenesis and RANKL expression in marrow from women taking ALN, SU400

Regulation of bone mass and osteoclastogenesis by the CEACAM1, F091

- Rheumatoid synoviocytes are stimulated with IL-23 to enhance osteoclastogenesis through upregulation of RANKL expression, SU084
- S100 protein directly and indirectly affects RANKL-stimulated osteoclastogenesis, SA090
- Sr ranelate decreases osteoblast-induced osteoclastogenesis through the involvement of the CaSR, F389
- Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEE<sup>559-564</sup> and PVQEQG<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, 1118
- TSH inhibits the expression of HMGB, a regulator of TNF $\alpha$  transcription, in osteoclastogenesis, 1117
- TSP-1 and CD47 regulate osteoclastogenesis but have distinct effects on bone metastasis, 1232
- Ubiquitin-like domain of IKK $\beta$  is critical for osteoclastogenesis, SU112
- VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029
- In vitro aging of young bone enhances osteoclastogenesis, SU091
- Osteoclasts**
- 1,25(OH)<sub>2</sub>D<sub>3</sub> can directly induce osteoclast formation in osteoclast precursors in the absence of RANKL, SU070
- In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, 1009
- Acidosis augments the resorptive capacity of human osteoclasts by increasing lysosomal acidification, M122
- Adiponectin inhibits osteoclast formation via AKT signaling pathway, SU110
- AG490, a Jak2 specific inhibitor, induces osteoclast survival by activating Akt and ERK signaling pathway, SU108
- ALN affects cross-talk of osteoclasts and osteoblasts in vivo, SU392
- Angiogenic potential of osteoclasts, SU075
- AP-1 and Mitf interact with NFATc1 to stimulate Cat K promoter activity in osteoclast precursors, SA076
- Are all anti-resorptive treatments the same? Lessons learned from inhibition of human osteoclastic bone resorption by alternative pathways, M129
- Atypical osteoclast phenotype after long-term ALN therapy for osteoporosis, SU399
- Biochemical characterization of ER $\alpha$  co-regulators in multinucleated mature osteoclasts, 1126
- Bisphosphate protect cartilage by reducing chondrocyte apoptosis and reduce bone loss by suppressing osteoclast in adjuvant arthritis, M428
- Brain-type creatine kinase is required for RANKL-induced osteoclastogenesis, M116
- Breast cancer derived factors synergize with TGF $\beta$  to induce phosphorylation of ERK1/2 and to stimulate osteoclastogenesis, SU115
- Bridging vascular calcification and osteoporosis: the function of receptor activator of nuclear factor  $\kappa$ B, M419
- BSP deficiency impairs osteoclast differentiation and resorption in vitro, SA142
- Calcitonin receptor on osteoclasts plays a physiological role to protect against HCa in mice, SA197
- Cannabinoid receptor GPR55 affects osteoclast function in vitro and bone mass in vivo, 1221
- Cbl-PI3K interaction regulates osteoclast function, differentiation and survival, 1011
- Cell cycle-arrested QOP are cells committed to the osteoclast lineage, SU098
- Chloride channel CIC-7 mediates acidification of the resorption lacuna in osteoclasts, M123
- Class IA PI3Ks are indispensable for osteoclast function by regulating cytoskeletal organization and cell death, 1115
- Co-expression of p62<sup>P392L</sup> and MVNP in osteoclasts precursors increases the formation of osteoclasts that express a pagetic phenotype, F476
- Comparison of direct osteoclastogenic potential on osteoclast precursor cells among proinflammatory cytokines, SU077
- CT-1 is an osteoclast-derived coupling factor required for normal bone remodeling, M014
- DC-STAMP regulates bone metabolism through cell-cell fusion of osteoclasts, F087
- Differential contribution of osteoclast- and osteoblast-lineage cells to LPS modulation of osteoclastogenesis, SU088
- Dkl1/FA1 is a novel factor enhancing osteoclastogenesis and inhibiting bone formation in vitro and in vivo, 1007
- Dock5, an essential Rac exchange factor in osteoclasts that controls adhesion structure organization and bone resorbing activity, SU064
- Downregulation of Cx43 expression and osteoclastogenesis by a bioceramic bone graft substitute, M119
- Drugs which inhibit osteoclast function suppress tumor growth and alter hematopoietic cell populations in bone, F270
- Effect of luteolin on bone loss, microarchitecture and bone resorption in OVX mice, M128
- Effect of MSCs in coculture with osteoclasts: a contact mediated and dose-dependent effect?, SA094
- Effects of exercise intensity on the bone metabolic response to running, M481
- Effects of the Cat K inhibitor ODN on osteoclast-mediated bone resorption, M127
- Efficient and stable gene expression into human osteoclasts using an HIV-1 based lentiviral vector, SU113
- Elevated serum levels of CXCL12 is associated with increased osteoclast activity and osteolytic bone disease in MM patients, SU079
- Endocytotic processes underlying Ca-induced inhibition of plasma membrane V-ATPase in murine osteoclasts, SU101
- Expression and function of synoviolin in human osteoclastogenesis, SA080
- Expression of 11 $\beta$ -hydroxysteroid dehydrogenase during murine osteoclast formation, SA235
- Extracellular matrix protein fibronectin positively regulates the osteoclast function, SU069
- Formation of podosome belts by osteoclasts on plastic correlates with resorptive activity, SU068
- Gastric proton pump inhibitors failed to affect bone resorption and formation, SA095
- Gender specific effects of TRPV4 on osteoblast-osteoclast coupling and risk of osteoporotic fractures, SA355
- High dose of RANKL rescues integrin  $\alpha_v$ <sup>-/-</sup> osteoclast phenotype, F081
- High levels of IL-6 and hyper-responsivity to 1,25(OH)<sub>2</sub>D<sub>3</sub> are both required for development of Pagetic osteoclasts, F478
- Hormonal control of RANKL expression is independent of Runx family proteins: evidence that commitment to the osteoblast lineage is not a requirement for the stromal cells that support osteoclast differentiation, SU047
- Identification of osteoclast lysosomal proteins by mass spectrometry, SA077
- Identification of the regulatory mechanism(s) of PTP-PEST associating with the sealing ring formation and bone resorption in osteoclasts, SU065
- Identification, characterization and isolation of peripheral osteoclast progenitors, SU099
- Implication of PGD<sub>2</sub> in the birth and death of human osteoclasts, SU095
- Important contribution of the immune system in regulating the tumor/bone vicious cycle independent from osteoclasts, 1086
- Inactivation of Dlx5 gene results in altered osteoblast-osteoclast coupling inducing increased bone resorption and reduced cortical thickness in male mice, F010
- Increased osteoclasts in Brl mouse model for OI are independent of decreased osteoblast matrix production and RANKL/OPG ratio, but are associated with increased osteoclast precursors in marrow, SU209
- Increased signaling through p62 in the MM microenvironment increases myeloma cell growth and osteoclast formation, SA289
- Inhibin directly targets suppression of isolated human osteoclast precursor development and activity, SA086
- Inhibition of BMP pathway and osteoclast activity in osteoblastic prostate cancer lesion in bone, F283
- Inhibition of MMP activity delays bone repair whereas inhibition of osteoclast function and formation does not, SA075
- Inpp4b as a regulator of bone mass, F089
- Investigations into the role of FAK in bone marrow-derived osteoclasts, SU111
- Isoform-specific expression of PPARs and gene regulation during osteoclastogenesis in RAW/C4 cells, M118
- Lack of calcitonin accentuates bone loss during lactation by enhanced osteoclast formation and reduced osteoblast formation, SA194
- Large osteoclasts in pediatric OI patients receiving intravenous pamidronate, SU497
- Longevity gene *SIRT-1* independently controls both osteoblast and osteoclast function, 1098
- Losartan<sup>®</sup> (Cozaar) increases appendicular bone formation by inhibiting osteoclastogenesis, M126
- Loss of a single bim allele recovers the defective osteoclast function in bcl-2<sup>-/-</sup> mice but does not restore the anabolic action of PTH, 1217
- Loss or gain of FoxO function in osteoclasts and osteoblasts alters the rate of apoptosis and BMD in mice, 1247
- LPA regulates osteoclast survival and retraction, SU105
- LPS suppresses RANK gene through the down-regulation of PU.1 and MITF, SU083
- Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119
- Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022
- Matrix PRELP interferes with the NF- $\kappa$ B pathway and impairs osteoclast formation and activity, SU089
- Mechanism of BMP-2 enhancement of PGE<sub>2</sub> stimulated osteoclastogenesis, SU085
- MEK5/ERK5 signal regulates RANKL-induced osteoclastogenesis, SU103
- Melanoma-induced bone loss is mediated by the rapid recruitment of osteoclasts, SU233
- Mice deficient in Pyk-2 have impaired OVX-induced bone resorption, F098
- Microarchitecture and tissue age influence in vivo bone resorption, M125
- Modeled microgravity sensitizes osteoclast precursors to RANKL mediated osteoclastogenesis by increasing DAP12, M114
- Modulation of osteoclastogenesis by fatty acids, SU071
- Multinuclear expression of ER $\alpha$  in mature osteoclasts, SU186
- Neutrophil-like PLB-985 cells induce differentiation of human blood monocytic precursors into functional osteoclasts via a RANKL-dependent mechanism, SA092
- NO has a powerful effect of osteoclast cells, M131
- Novel role for TPO in regulating osteoclast development, SU104

## Key Word Index

## ASBMR 30th Annual Meeting

Novel role of L-Ser for the activation of RANKL-RANK signaling machinery in osteoclastogenesis in vitro, SA082

Novel selective P2X<sub>7</sub> receptor antagonist inhibits human osteoclast formation in vitro, M120

Oleuropein from olive stimulates the differentiation and mineralization of cultured osteoblasts and inhibits the formation of osteoclasts in culture, M081

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

Osteoblast and osteoclast involvement in the pathogenesis of a mouse model for CMD, 1204

Osteoclast precursors play a role in recruiting breast cancer cells and osteoblasts onto the bone in vitro, SA278

Osteoclast-independent function of Cat K: regulation of TLR-9 signaling in autoimmunity, F074

Over-expression of RAGE prevents OVX-mediated bone loss in CD1 mice, M132

Pacemaker channel, HCN, controls functions of osteoclasts, SU100

PGC-1 $\beta$  and iron uptake in the mitochondrial activation of osteoclasts, 1222

Phthalein monophosphates are specific substrates for TRACP5b, M284

PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts, F079

PKC $\delta$  is important for acidification of the lysosomes and resorption lacuna in osteoclasts, M124

Proteasome inhibition counteracts the negative effect of GC treatment on bone metabolism by stimulating osteoblasts and inhibiting osteoclasts in vitro, SA231

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

Proteomic identification and characterization of the small GTPase Rab18 in human osteoclasts, SU109

R740S, a dominant V-ATPase a3 mutation, causes osteopetrosis in mice, 1218

Rac 1 and 2, in combination, mediate osteoclast function and survival, 1220

RANKL induces Ca channel activation in human osteoclasts, SU107

Rapid-nontranscriptional action of 1,25(OH)<sub>2</sub>D<sub>3</sub> induces IL-6 production in osteoclast precursors expressing MVNP, 1186

Recombinant mouse M-CSF receptor C-fms inhibits TNF $\alpha$ -induced osteoclastogenesis, M112

Reduced osteoclastogenesis and RANKL expression in marrow from women taking ALN, SU400

Regulation of bone mass and osteoclastogenesis by the CEACAM1, F091

Resorption mechanism of HA and  $\beta$ TCP coating layer, SA100

Role of alpha gene tropomyosins in osteoclast function, SU067

Role of LIMK1 in osteoclast cytoskeletal remodeling and bone resorption, 1116

Roles of Cxcl2 in osteoclast precursor cells, SU086

S100 protein directly and indirectly affects RANKL-stimulated osteoclastogenesis, SA090

SLP-76 couples Syk to the osteoclast cytoskeleton in vitro and in vivo, 1010

Syk tyrosine 317 negatively regulates osteoclast function, 1120

Tec kinases, therapeutic targets for bone destructive diseases, F083

TGF $\beta$ 1 induces human osteoclast apoptosis, SU078

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, 1118

Transactivation of RANKL by C/EBP $\beta$  and C/EBP $\delta$  in adipocyte lineage cells, SU092

TRIP-6 regulates osteoclast formation, adhesion, and resorptive capacity, SU066

TSG-6 acts synergistically with OPG to inhibit bone resorption, SA097

TSH inhibits the expression of HMGB, a regulator of TNF $\alpha$  transcription, in osteoclastogenesis, 1117

Twisted gastrulation-deficient mice exhibit osteopenia through enhanced osteoclast function, 1008

Tyrosine kinase inhibitor dasatinib decreases osteoclast formation and activity in vitro, SU074

Ubiquitin-like domain of IKK $\beta$  is critical for osteoclastogenesis, SU112

Ucn strongly suppresses the formation and function of osteoclasts via a novel mechanism, SA096

VEGF induction provides evidence for different signaling pathway activation by large and small osteoclasts, SU106

In vitro aging of young bone enhances osteoclastogenesis, SU091

ZOL inhibits the capacity of myeloid-immune suppressor cells in myeloma to form osteoclasts, SU230

**Osteoconductivity**

Towards development of a PSi-based hybrid biomaterial with osteoconductivity and osteoinductivity, M028

**Osteocytes**

Aberrant *Phex* function in osteocytes has limited effects on bone mineralization in XLH, 1051

Adenylyl cyclase 6 mediates primary cilia-regulated decreases in cAMP in bone cells exposed to dynamic fluid flow, 1040

Analysis of CXCR7-deficient mice reveals CXCR7 expression in osteocytes but no apparent bone phenotype, M104

In bone, RPTP $\mu$  is exclusively expressed in osteocytes and may affect bone mass, SA052

Cis-regulatory motifs and computationally-derived transcriptional networks predict dynamic motions for osteocytes, M103

Comparison of gene expression in osteocytes versus osteoblasts, M056

Deletion of *Mef2c* in osteocytes decreases *Sost* expression and increases bone mass, F054

Direct correlation of osteocyte deformation with Ca influx in response to fluid flow shear stress, SA057

Early osteocyte marker, E11/gp38 is highly elevated in new bone formed in response to distraction as compared to existing bone, SA136

Effect of RIS on osteocyte viability in paired biopsies from early postmenopausal women, M420

Effect of SSBT on osteocyte viability, F405

Effect of the dietary Ca/P ratio on the rate of skeletal accrual in mice, M333

Effects of electrical stimulation on NO expression and osteocyte viability in OVX rats, SA524

Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385

Estrogen deficiency alters the localized material properties of the peri-lacunar bone matrix in old rats, M107

Evidence that differentiated bone cells display an autophagic response regulated by HIF-1 $\alpha$ , F058

Expression of human SCT in heterologous eukaryotic insect and *E. coli* expression systems, SA059

Imaging of mineralization kinetics suggests that the transition from osteoblast to osteocyte initiates prior to mineral deposition, F062

Impaired angiogenesis and compromised fluid volume accompanies increased osteoblast and osteocyte apoptosis with GC excess, SA453

Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108

LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

Local osteocyte defect in *Dmp1* null mice causes overproduction of FGF-23, 1225

Mechanical perturbation of integrin  $\alpha$ 5 with or without association with fibronectin opens Cx43-hemichannels in osteocytes, SA060

MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2, SA064

Molecular phenotyping of osteoblastic and osteocytic cell fractions isolated from mouse calvaria, M106

Notch signaling regulates osteoblast maturation transition to mineralization phase, SA068

Osteocyte-specific ablation of canonical Wnt signaling induces severe osteoporosis, 1037

Osteocytes can modulate osteoblastic activity via NPY signaling, SA056

Osteocytic perilacunar remodeling as a significant source of Ca during lactation, M110

Overexpression of androgen receptor in mature osteoblasts and osteocytes inhibits osteoblast differentiation, SU192

PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038

PTH-induced bone mass gain is blunted but not abolished in *SOST* overexpressing and deficient mice, 1039

SDF-1 is expressed in osteocytes and periosteal cells in response to mechanical loading, M105

Target ablation of PPR in osteocytes induces hypocalcemia and impairs bone structure, 1158

TIEG1 KO mice display defects in the bone matrix immediately surrounding osteocytes, SA065

Transcriptional regulation of Cx43 by  $\beta$ -catenin, a pathway activated by PGE<sub>2</sub>-PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

Validation of an immunoassay for the determination of PINP in rat serum, M296

In vivo load activated propagation of  $\beta$ -catenin signaling in osteocytes through coordinated downregulation of inhibitors of Lrp, 1041

**Osteodistraction**

First clinical application of electric stimulation on human distracted bone, SA568

**Osteodystrophy**

Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259

**Osteodystrophy, hepatic**

Histomorphometric evaluation in an experimental model of hepatic osteodystrophy, M480

**Osteoformin**

Osteoformin increases the levels of intracellular Ca of human preosteoblast cells in culture, SU051

**Osteogenesis**

Androgen receptor disruption increases the osteogenic response to mechanical loading in male mice, 1140

Apc-mediated control of  $\beta$ -catenin is essential for both chondrogenic and osteogenic differentiation of skeletal precursors, SA130

BMP-6 stimulated osteogenesis of HOB cultures is associated with suppression of PYK2, SU048

Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050

C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223

CGRP stimulates osteogenesis and inhibits osteoclastogenesis in vitro, SU033

Continuous local infusion of ALN prevents osteopenia of the lengthened segment during distraction osteogenesis, SU001

Dependence of post natal osteogenic differentiation on BMP-2, SA001

Development of high-throughput screening system for osteogenic drugs using cell-based sensor, M082

Diet induced obesity compromises the osteogenic potential of the bone marrow, F047

Different osteogenic properties of human BMSC from different skeletal site origin, SU055

DNA methylation analysis of osteogenic gene promoter regions in mouse BMSC, M035

Enhanced mitochondrial biogenesis contributes to Wnt induced osteogenic differentiation of C3H10T1/2 cells, SA043

Enhanced osteogenic potential of alveolar vs. long bone derived BMSC, M095

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

HSPG modulate osteogenic differentiation through heparan sulfate chains, M094

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

Identification and characterization of angiogenesis-inducing secretory molecules from osteogenically differentiated MSC, M163

Induction of Runx2 and Osx by bisphosphonate promote osteogenic differentiation, SU062

Integrin-associated protein upregulates osteogenesis-related transcription factors via TGF $\beta$  and BMP pathways, SA028

LPS-induced inhibition of osteogenesis is TNF $\alpha$  dependent, M019

Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022

Mapping the interrelationship of the adipogenic and osteogenic lineage with visual reporters, M097

Mineralization potential and orientational aspects of osteogenic cell cultures by Raman spectroscopy, M084

Osteogenesis effect of human ligamentum flavum, myoblast, osteoblast and MSC by DBM and BMP-2, SU135

Osteogenic action of Ex-4 in normal and insulin-resistant state, M424

Osteogenic potential of bone marrow, compromised by disuse, is normalized by brief exposure to a low-level mechanical signal, M486

Osteogenic potential of human bone marrow and circulating Stro-1<sup>+</sup>/CD45<sup>low</sup> cells, M078

Osteogenic potential of PDL cells in vivo, SU054

Osteotropic peptides: anabolic and osteogenic effects, M045

PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027

Possible physiological function of menin protein as transcriptional factor that modulates miRNA expression during osteogenesis, M036

Pulse treatment with ZOL causes sustained commitment of bone marrow derived MSC for osteogenic differentiation, M072

R-spondin 2 is a novel osteogenic factor required for Wnt11 mediated osteoblast differentiation, SU063

Regulation of osteogenesis by Wnt signaling in rat MSC and human ASC, SU045

Regulatory signaling pathways in BMP mediated osteogenesis of adult human MSC cultures, M060

Short-term deleterious skeletal response to hindlimb suspension involves multifaceted compromises in cells of the osteogenic lineage, F523

SP stimulates BMSC osteogenic activity and osteoclast differentiation and function in vitro, SU032

Synergistic activation of osteogenesis in MLPC by oxysterols, SU038

TGF $\beta$  inhibits BMP signaling and osteogenesis through the TGF $\beta$  and BMP R-Smad direct interaction, 1080

Transient expression of CXC receptor 2 in human MSC stimulates chemotaxis toward CXC ligand 8 and increased mineralization in the presence of osteogenic medium, SA170

Wnt7a and Wnt7b evoke overlapping yet distinct transcriptional responses during the osteogenic programming of mesenchymal progenitors by Msx2, 1196

**Osteogenesis imperfecta (OI)**

Bisphosphonate, pamidronate, suppresses the pro-inflammatory response in a mouse model of OI as well as normal littermates, SU386

Hotspot splicing mutation in *LEPRE1* affects P3H1 and causes recessive OI, SU215

Identification of skin abnormalities in OI patients by MRI, SA561

Impairment of osteoblast lineage differentiation leads to increased osteoclastogenesis in OI murine, 1202

Increased osteoclasts in Brl mouse model for OI are independent of decreased osteoblast matrix production and RANKL/OPG ratio, but are associated with increased osteoclast precursors in marrow, SU209

Large osteoclasts in pediatric OI patients receiving intravenous pamidronate, SU497

Proinflammatory marker values at baseline and after a fracture are distinctly different comparing a mouse model of OI with normal controls, M234

Randomized dose comparison of pamidronate in children with types III and IV OI, SU496

Recurring mutation causing severe/lethal recessive type VIII OI in African-Americans originated in West Africa more than 300 years ago, SA262

Spectrum of OI mutations in Sweden, SA247

In utero stem cell therapy as treatment for classical OI using the knock in murine model BrlIV, F500

**Osteogenesis, distraction (DO)**

Endothelial progenitor cell mobilization during DO in human, SA053

Impaired bone healing in a BMP-2 KO mouse model of DO, SA159

Reconstruction of massive skeletal defects due to osteomyelitis by DO, M160

**Osteogenic sarcoma. See Sarcoma**

**Osteoinductivity**

Towards development of a PSi-based hybrid biomaterial with osteoconductivity and osteoinductivity, M028

**Osteolysis**

Biomechanical and geometrical property changes in rat tibias with tumor-induced osteolysis after anti-resorptive or anti-cancer treatments, SU236

Bzb, a proteasome inhibitor, prevents metastatic breast cancer osteolysis and reduces mammary fat pad tumor growth in mice, F277

Elevated serum levels of CXCL12 is associated with increased osteoclast activity and osteolytic bone disease in MM patients, SU079

HDI, Vorinostat, blocks growth and associated osteolysis of cancer cells within bone, but reduces bone volume in non-tumor bearing bones in mice, M279

Host bone marrow-derived stromal cells promote myeloma initiation and development of osteolysis, 1088

Monoclonal antibody to TGF $\beta$  inhibits tumor burden and osteolysis in a pre-clinical model of bone metastasis, SA187

TGF $\beta$  blockade inhibits osteolytic but not osteoblastic prostate cancer metastases, SA274

Wnt signaling regulates Gli2 and PTHrP expression in human breast cancer cells that cause osteolysis, M278

**Osteolysis, idiopathic multicentric with nephropathy (IMON)**

Additional clinical features of IMON, SU212

**Osteomalacia**

Goettingen minipigs—a model for Ca/Vitamin D-deficiency osteomalacia and steroid-induced osteoporosis, SA445

Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374

PHEX cleavage of SIBLING-ASARM peptides as a mechanism underlying osteomalacia in XLH, 1199

Rare cases of XLH rickets/osteomalacia mimicking ARHR/osteomalacia, F469

Serum 25(OH)D measurement and histomorphometric analysis of iliac crest biopsies from 1180 patients reveals a high prevalence of Vitamin D-dependent osteomalacia, 1134

Vitamin D deficiency, osteomalacia and high bone turnover in patients with NF-1, F465

**Osteomalacia, oncogenic (OOM)**

Rapid detection of intact FGF-23 in tumor tissue from patients with OOM, SA204

**Osteomalacia, tumor-induced (TIO)**

Evaluation of clinical utility of venous sampling for FGF-23 in identifying and confirming responsible tumors for TIO, F163

**Osteomyelitis**

Colistin-impregnated bone cement beads prevent multi-drug resistant *Acinetobacter* osteomyelitis, M236

Reconstruction of massive skeletal defects due to osteomyelitis by DO, M160

**Osteomyelitis, sclerosing**

Diffuse sclerosing osteomyelitis of the mandible, WG25, M452

**Osteonecrosis**

Usefulness of alveolar bone density measurement in risk assessment for BRONJ, SA305

**Osteonecrosis of the jaw (ONJ)**

Application of preventive measures minimizes the occurrence of ONJ in patients with bone loss treated with bisphosphonates, F281

Bisphosphonate-associated ONJ cases in South Korea, SA412

Case presentation: bisphosphonate induced ONJ in Pagetic jaw bone, WG24

ONJ: ZOL 5 mg experience in a variety of osteoporosis indications, 1246

**Osteonectin**

Differential regulation of gene expression by SNPs in the osteonectin/SPARC 3 untranslated region, M270

Regulation of osteonectin/SPARC by miRNA-29, 1155

**Osteopathy, renal**

## Key Word Index

## ASBMR 30th Annual Meeting

- Change of pathological bone lesion in recipients with renal osteopathy after renal transplantation, SA498
- Osteopenia**
- Bisphosphonate-induced osteopetrosis: novel bone modeling defects, metaphyseal osteopenia, and osteosclerosis fractures after drug exposure ceases, F569
- C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223
- C/EBP $\beta$  overexpression causes osteopenia, SA005
- Changes in serum PINP in orchidectomized osteopenic rats treated with PTH and ALN, M295
- Conditional disruption of *Pkd1* in osteoblasts results in osteopenia due to direct impairment of osteoblast-mediated bone formation, SA019
- Continuous local infusion of ALN prevents osteopenia of the lengthened segment during distraction osteogenesis, SU001
- Decreased bone formation, increased bone resorption, and osteopenia in mice lacking SP, SU160
- Defects in MSC self-renewal lead to an osteopenic phenotype in *Bmi-1* null mice, 1050
- Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109
- Dietary Sr in a model of established osteopenic rats reduce the levels of 25(OH)D, SA377
- Diffuse osteopenia after tibia fracture: benefits of early mobilization and weight bearing, F461
- Dwarfism and osteopenia in mice with inactivated HRE in the VEGF gene promoter, 1152
- Effects of estrogen therapy and fluocalcic effervescent on the BMD and bone metabolism of surgical menopause women with osteopenia, M392
- Fracture risk in primary biliary cirrhosis: role of osteopenia and severity of cholestasis, M442
- Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214
- GPRC6A null mice exhibit osteopenia and feminization, F004
- Mediation of bone loss with ultrasound induced dynamic mechanical signals in an OVX rat model of osteopenia, F536
- Mice lacking the Wnt receptor Frizzled-9 display osteopenia caused by decreased bone formation, 1006
- Osteopenia by high alcohol consumption in the absence of ALDH2 attribute to the disturbance of the differentiation in osteoblasts, M326
- Osteopenia in CKD: effects of Ca overload, SU449
- Osteopenia in CKD: effects of phosphate overload, SU447
- PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299
- Prevalence of osteoporosis and osteopenia in men and women according to the fragility fracture type, SU294
- Twisted gastrulation-deficient mice exhibit osteopenia through enhanced osteoclast function, 1008
- Osteopenia, thyrotoxicosis-induced**
- Double deletion of  $\alpha 2a$ - and  $\alpha 2c$ -adrenergic receptors results in a phenotype of high bone mass and in resistance to the thyrotoxicosis-induced osteopenia, F244
- Osteopetrosis**
- R740S, a dominant V-ATPase  $\alpha 3$  mutation, causes osteopetrosis in mice, 1218
- Rachitic defects in *tcirg1*-dependent osteopetrosis are caused by impaired gastric acidification, 1201
- Osteopetrosis, infantile (IO)**
- Effect of bone marrow transplantation in a child with malignant IO, SU498
- Osteopontin (OPN)**
- Changes in bone matrix material properties due to OPN deficiency, F149
- Increased expression of OPN in PBMC is associated with alteration in the fractions of lymphocytes in hindlimb-unloaded mice, M175
- OPN deficiency reduces aortic calcification and oxidative stress in diabetic LDLR $^{-/-}$  mice, F109
- Role of OPN in beta-adrenergic signaling induced bone loss in vivo, M174
- Osteoporosis**
- Bisphosphonate-induced osteopetrosis: novel bone modeling defects, metaphyseal osteopenia, and osteosclerosis fractures after drug exposure ceases, F569
- Bridging vascular calcification and osteoporosis: the function of receptor activator of nuclear factor  $\kappa B$ , M419
- Chemerin and CMKLR1 targeted gene delivery identifies a novel molecular switch in the treatment of osteoporosis, M071
- CNBP conditional KO mice show severe osteoporosis-like phenotype, F014
- Deletion of the G protein subunit G $\alpha$  in early osteoblasts leads to accelerated osteoblast maturation and formation of woven bone with abnormal osteocytes, resulting in severe osteoporosis, 1254
- Do type I collagen homotrimers contribute to osteoporosis by altering bone remodeling?, SA146
- Evidence of increase in vertebral body dimensions in postmenopausal women with osteoporosis, M313
- Formation of new trabeculae in a female patient with osteoporosis treated with TPTD, demonstrated with in-vivo-assessment of 3D bone microarchitecture with HR-pQCT, M352
- Genome-wide CNV study identified a novel susceptibility gene *UGT2B17* for osteoporosis, M404
- GWAS identified novel susceptibility loci for osteoporosis, SA267
- Increased non-enzymatic glycation of cancellous bone due to decrease in remodeling during ALN therapy of osteoporotic women, 1071
- NRIP1*, a novel osteoporosis candidate gene identified by expression and association analyses, M254
- Osteocyte-specific ablation of canonical Wnt signaling induces severe osteoporosis, 1037

Bone fragility beyond BMD: a French prospective experience, SU288

Bone mass recovers in young women with anorexia nervosa who are both weight and menstrual recovered, F339

## Key Word Index

## ASBMR 30th Annual Meeting

- Bone turnover and incident hip fracture risk, M285
- Ca intake and serum bone formation markers are associated with the functional single nucleotide polymorphism in the TNSALP gene, SU308
- Ca intake is not associated with increased coronary artery calcification, 1207
- Carotid plaque causes low spinal BMD in Korean postmenopausal women with diabetes, SU359
- Casual decomposition of risk factors in osteoporosis burden, SU339
- Circulating DKK1 levels are reduced in young subjects with low bone mass, F455
- Common single nucleotide polymorphism in the *HMG2* gene is associated with bone mass in men, SA268
- Comparison between logistic regression and artificial neural networks for vertebral fracture risk assessment, SU345
- Comparison of prediction models for hip, osteoporotic, and any clinical fracture in older women: is more better?, 1057
- Compartment specific genetic analysis of trabecular and cortical volumetric BMD in men, SU284
- Composite bone score with QCT bone measurements and fracture history, SU289
- Comprehensive genetic analysis of bone volume in men, M268
- Correlations between panoramic radiomorphometric indices and BMD in postmenopausal women, SA311
- Cortical bone acquisition in the appendicular skeleton of healthy young females is reciprocally related to marrow adiposity, M074
- Cortical bone mass and structure in older Afro-Caribbean and Caucasian men, SU300
- Cortical cross sectional area in young adult men is inversely related to risk of hip fracture in their older relatives, 1281
- Cost-effectiveness of RIS versus IBN at one year: the case of the United Kingdom, SA424
- Costs associated with NHNV fractures in a managed care setting, SU320
- CVD as forecasters of hip fracture: a nationwide cohort study in twins, 1205
- Deformity of the distal radius fractures resulting from falls in Japanese women over 50 years of age is closely associated with BMD of the lumbar spine, SU286
- Designing a Latino osteoporosis awareness campaign, SU312
- Determinants of trabecular and cortical volumetric BMD differ in men of African ancestry, SU299
- Development a nomogram for individualizing the absolute risk and time to recurrent fracture, F349
- Dietary patterns in Canadian men and women ages 25 and older: relationship to BMI and BMD, SU309
- Differences in fall rates and predictors of falls by sex, 1058
- Disability in patients with osteoporotic peritrochanteric hip fracture, SA357
- Distribution and rate of clinical fractures in older men without osteoporosis, 1282
- Distribution of risk factors for fracture in women with and without a fracture history, SU342
- Does dietary protein reduce hip fracture risk in elderly men and women?, SU319
- Effect of a one year exercise program on markers of bone metabolism after hip fracture, SA432
- Effect of metabolic acidosis on BMD and bone microarchitecture in normal and OVX rats, M409
- Effect of parity on BMD in premenopausal women, SA325
- Effects of exercise and milk intake on bone in adolescents, SU301
- Effects of neurological impairment and functional mobility on BMD following stroke, SU364
- Elevated production of IL-1 $\beta$  and TNF $\alpha$  by PBMC is associated with increased hip fracture risk in elders, 1283
- Epidemiology of rib fractures in older men, F354
- Essential fatty acid and fish intake is associated with higher BMD in elderly women and men, F341
- Evaluation of BMD following an education intervention on osteoporosis offered to women after a fragility fracture, SU330
- Excess medical cost after a fragility fracture during 3-year follow-up, SA422
- Excess of post-fracture mortality among men and women, SA348
- Factors associated with kyphosis progression in older age, F365
- Failure to perceive increased risk of fracture in women 55 years, SA360
- Falls predict higher medical costs among osteoporosis patients in community setting, SA430
- Femoral neck and trochanteric fractures and Vitamin D, SU353
- Femoral strength, bone density, and aging in women and men, 1165
- Fracture risk in young patients with chronic diseases, SU371
- Fractures of the spine and hip increase the risk of death in Canadians, SU351
- Fragility fractures and health status in a multinational cohort, SU340
- Frequent apheresis for platelet and plasma donations constitutes an independent risk factor for decreased BMD, F327
- Genetic locus on chromosome 1q influences bone loss in young Mexican American adults, M250
- Genetic variation in *IL6* and *LRP5* is associated with osteoporosis in the Marshfield Clinic Personalized Medicine Project, SU365
- Genetic variations in sex steroid-related genes as predictors of serum estrogen levels in men, SU183
- Gondanotropins, bone loss and fracture in men, 1278
- GWAS and subsequent replication studies identified ADAMTS18 and TGFBR3 as novel osteoporosis risk genes, 1093
- GWAS identified RTP3 as a novel gene for bone strength, SU331
- GWAS of BMD and hip geometry indices, 1092
- GWAS pleiotropic associations of bone phenotypes, SA251
- GWAS reveals genetic variants associated with BMD, osteoporosis and osteoporotic fractures, SA263
- High impact exercise may have a protective effect on BMD but moderate impact exercise may have negative effect in young women with anorexia nervosa, M324
- High mortality in male nursing home residents with hip fracture, SU326
- Higher BMD is associated with increased odds of carotid atherosclerosis in postmenopausal women not currently using estrogen therapy, 1206
- Higher BMD loss in older men with diabetes, 1209
- Hip fracture patients at high risk of second hip fracture, 1163
- Hip strength estimates by FEA and fracture prediction in women and men, 1167
- Homocysteine levels in relation to physical performance, SA372
- HSA in women, SU270
- IGFBP2 and bone loss in aging women and men, 1284
- Impact of an educational intervention on knowledge about osteoporosis following a fragility fracture, SA353
- Impact of physical inactivity (10 days bed rest) on markers of bone turnover in young men with low and normal birth weight, SA456
- Incidence and costs of proximal humerus and wrist fractures in women in France, SU327
- Inflammatory markers and the risk of hip fracture, F333
- Influence of markers of bone turnover on calcaneal QUS, SA457
- Influence of sex hormones on BMD in middle aged and elderly men, SU335
- Is the association between hypertension and bone osteoporotic fracture expressing a real interdependence?, SU346
- Lack of correlation between glycemic control and BMD in type 2 diabetic women, SU255
- Lack of seasonal variation of bone resorption in elderly women in relation to periodicity of sunlight exposure at a northerly latitude, F337
- Lactose intolerance does not have effect on bone status in adolescence, SU285
- Large scale candidate gene analysis identifies an association between the CDK6 locus and trabecular volumetric BMD at the lumbar spine in older men, M266
- Large-scale meta-analysis of genome-wide association scans for osteoporosis traits, 1091
- Late pregnancy serum Vitamin D and longitudinal bone loss during pregnancy, F544
- Lean body mass is a better predictor of BMD than leg power or grip strength in healthy caucasian adults, SU290
- Linkage and association study of chromosome 1p36 with BMD in southern Chinese, SU295
- Loop diuretic use and rates of hip bone loss, and risk of falls and fractures in older women, F371
- Low calcaneal BMD estimated by a peripheral DXA heel scanner is associated with a high risk to have had a distal radius fracture, SU262
- Low serum 25(OH)D is associated with higher rates of hip bone loss in older men, F367
- Low Vitamin D levels and risk of death in older men, F335
- Mathematical model of remodeling cycles with feedback mechanism for maintaining the balance between bone resorption and formation, WG27
- Menopausal and postmenopausal women have significantly higher bone resorption and oxidative stress parameters than premenopausal women, SU336
- Mouse-to-human strategy to identify bone strength QTL genes, SA120
- Multinational comparison of bone health in women 55 years of age and older, SU344
- Negative association between the metabolic syndrome and BMD in Korean adults, SU304
- Neglected role of intracortical remodeling in age-related bone loss, 1101
- No fracture is a poor predictor of fracture risk, SU356
- Normative Z-scores from the CaMOS youth cohort, SU292
- Obesity and bone architecture in men—can we apportion the metabolic and the mechanical effect?, SA440
- Obesity is associated with higher BMD, lower bone resorption and slower hip bone loss: are these associations mediated by adipokines?, SU369
- Older men with low serum estradiol and high serum SHBG have an increased risk of fractures, 1279
- Opioid-induced osteoporosis: delayed bone healing and compression fractures in a man with chronic narcotic use, WG32
- Osteoporosis in elderly fallers, underdiagnosed and undertreated, SU248
- Osteoporosis in men: still under-screened and under-treated, SA329
- Pattern of death after hip fracture among institutionalized older people, 1164
- Physical activity, BMD and fragility fracture, M325
- Physician practices in bone density testing among Medicare patients, SA428
- Poor peripheral nerve function is related to lower BMD, SA328

Poor peripheral sensorimotor nerve function is associated with high fall risk, SU323

Population burden of first and repeat low-trauma fractures, 1056

Positive Celiac disease serology and BMD in adult women, SA366

Post-fracture initiative in a rural Ontario community hospital, M369

Post-fracture mortality in men: contributions of sex hormones and BMD as risk factors, 1280

Post-fracture osteoporosis intervention strategy, M322

Predictive capacity of biochemical markers of bone turnover and endogenous hormones for osteoporosis in men, SU334

Predictors of osteoporosis management among residents living in long-term care, SA368

Predictors of poor outcomes following osteoporotic fractures in elderly women and men, 1210

Prevalence of osteoporosis and osteopenia in men and women according to the fragility fracture type, SU294

Prevalence of osteoporosis in ISM, SU268

Prevalence of subtrochanteric fractures in patients older than 50 years presenting with a clinical vertebral or non-vertebral fracture, SU390

Prevalence of vertebral fractures in aging women suffering from hip fracture, SU322

Prospective observational study of osteoporosis medication use in postmenopausal women in the European Union, SU347

Protective effect of total and supplemental Vitamin C intake on the risk of hip fracture, 1168

Proximal femoral fragility and age-related white matter lesions by brain MRI in elderly subjects, 1096

Proximal humerus fractures in men: epidemiology and costs, SU328

Questionnaire-based osteoporosis risk assessment in a rural area primary care setting, SU354

Radiation-induced bone loss: description of dose, time course, age, strain and sex variables, SU368

Rate of bone loss is greater in young adult men than women, SU297

Reciprocal relation between MR measures of marrow adiposity and cortical bone in the appendicular skeleton of healthy adults, SU042

Recognition and treatment of male osteoporosis is low, SU332

Reduced renal function is associated with increased rates of bone loss at the hip and spine, SU357

Reduction of BMD in the patients with RA is more remarkable at proximal femur than at lumbar spine, SU451

Regional differences in the management of osteoporosis, SU287

Relationship between BMD of the lumbar spine and knee OA in South Korean, SU298

Relationship between clinical risk factors for osteoporosis and BMD in women aged less than 50 years, SU355

Relationship between focal erosions and generalized osteoporosis in postmenopausal women with RA, SA370

Relationship between the metabolic syndrome and BMD in Korean middle-aged women, SU291

Retrospective study evaluating the relationship of Vitamin D 25 OH and free testosterone levels with changes in hip bone density after liver transplantation, SA502

Risk factors for fragility fracture in a multiracial cohort of US women, SA362

Risk factors for low BMD in healthy men age 50 years or older, SU341

Risks and outcomes for hip fractures in a predominantly African-American male veteran population, SA352

Rosiglitazone-induced change in BMD among African Americans with type 2 diabetes mellitus or impaired glucose tolerance, SU315

Seasonal genetic influence on serum 25(OH)D levels, SA334

Secular trends in Swedish hip fracture incidence 1987-2002, 1166

Self-reported weight at birth predicts measures of femoral size but not volumetric BMD in elderly men, SU338

Serum 25(OH)D and the risk of hip and non-spine fractures in older men, 1277

Serum Vitamin D levels do not modify the response to an exercise program following hip fracture, SA346

Simply ask them about their balance—fracture prediction in a nationwide cohort study in twins, 1095

Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349

Socioeconomic status, BMD testing and hip fracture rates in a universal health-care system, SU293

SSRI use and risk of fracture in older women, F351

Study about the association of circulating MCP-1 levels with lumbar BMD in Korean women, M407

Subclinical thyroid disease predicts risk of hip fracture, 1208

Substantial adverse outcomes follow NHNV fragility fractures, 1059

Temporal trends in vertebral size and shape from medieval to modern-day, M459

Ten-year change in BMD in a representative sample of Japanese women, SA330

Timed Up and Go test and BMD as predictors of fracture, F373

Timing of repeated BMD measurements: development of an absolute risk-based prognostic model, F347

Trauma type of NHNV fractures in postmenopausal women being treated for osteoporosis in Europe, SU325

Type 1 diabetes is associated with lower BMD in premenopausal women but not in middle-aged men, SU456

ucOC level in healthy Korean women, M300

Use of genetic markers in prediction of fractures, 1094

Vertebral fracture in men: level of trauma, BMD and lean body mass, SU360

Very high frequency of poor Vitamin D status in French women with bone fragility, SU352

Vitamin D concentrations of healthy children living in the Calgary health region, SU396

Vitamin D deficiency is highly prevalent in Irish hip fracture patients, M294

Vitamin D insufficiency together with high serum levels of Vitamin A increase the osteoporosis risk in postmenopausal women, M292

Vitamin D supplementation intake among osteoporosis patients aged 50 years and older at various 25(OH)D levels in the US, M400

In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154

In vivo differential expression profiling study on human circulating monocytes suggested a novel CRAT and CPT2 network underlying smoking and BMD, SU155

Volumetric bone parameters in relation to fracture history in healthy men at the age of PBM, SU302

Weight and BMI predict BMD and fractures in women 40 to 59 years, SA438

Weight reduction is not deleterious for bone mass or strength in obese women, SA338

WHO absolute fracture models in older women: how does prediction vary for incident hip and non-spine fractures across T-scores?, 1055

Women who fractured their hips experience greater loss of geometric strength in the contralateral hip during the year following fracture compared to age-matched controls, F345

#### **Osteoporosis, glucocorticoid-induced (GIO)**

BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

Clinical significance of ucOC in GIO, M299

Effect of a single 5-mg infusion of ZOL on bone turnover markers versus oral RIS (5 mg/day) over 1 year in patients with GIO, M362

Effect of a single infusion of ZOL 5 mg versus oral RIS 5 mg on BMD at lumbar spine, hip, femoral neck and trochanter in patients with GIO, F403

TPTD versus ALN for treatment of GIO, 1171

#### **Osteoporosis, idiopathic**

Marked abnormalities in cortical and trabecular microarchitecture and strength in premenopausal women with idiopathic osteoporosis, M310

Opioid-induced osteoporosis: delayed bone healing and compression fractures in a man with chronic narcotic use, WG32

#### **Osteoporosis, pathophysiology**

(22-52) ADM prevents systemic bone loss related to inflammation in mice, SA493

Acute COPD exacerbations are associated with uncoupling of bone resorption from bone formation, M414

Age at menarche associated with bone strength in girls, SU493

Bilateral bone density loss after unilateral disuse in the forearm, SA519

BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

Bone is more susceptible to Vitamin K deficiency than liver, SU316

Bone loss with smoke exposure and Lrp5 expression, SA459

Bone resorption markers in saliva, M288

Central control of bone remodeling: neurohypophysial hormone oxytocin is decreased in severe postmenopausal osteoporosis, M418

Changes in histomorphometric parameters after menopause, SU333

Clinical significance of ucOC in GIO, M299

Deletion of FXR leads to an osteopenic phenotype in mice, F439

Detrimental effects of abdominal irradiation on the skeleton in growing mice, M412

Double deletion of  $\alpha 2a$ - and  $\alpha 2c$ -adrenergic receptors results in a phenotype of high bone mass and in resistance to the thyrotoxicosis-induced osteopenia, F244

Effect of Pb on bone mineral properties from female adult C57/BL6 mice, M146

Effects of diacylglycerol oil on body composition, BMD and bone strength in mice, SA442

Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

Effects of serum factors during osteoblast differentiation—implication for the pathogenesis of osteoporosis in Crohn's Disease, M450

ER $\alpha$  deletion in cells of the monocyte/macrophage lineage increases osteoclastogenesis and abrogates the pro-apoptotic effect of E<sub>2</sub> on osteoclasts, 1097

Expression of NF- $\kappa$ B ligand and regulation of osteoclastogenesis by bone marrow adipocytes, SA078

## Key Word Index

## ASBMR 30th Annual Meeting

GC-induced bone loss in mice is dependent on beta 2-adrenergic signaling, M102  
 Goettingen minipigs—a model for Ca/Vitamin D-deficiency osteomalacia and steroid-induced osteoporosis, SA445  
 High level dietary P and Cd exacerbate OVX-induced bone loss, M301  
 High-fat diet facilitated decreases in BMD of OVX mice and suppressed the anabolic effects of PTH on bone, SA448  
 Homocysteine accumulates in bone tissue by collagen binding and adversely affects bone, M417  
 Impact of adjuvant hormonal therapy on bone loss depending on initial adjuvant chemotherapy and menstrual status, M415  
 Impact of dietary protein on Ca homeostasis and nitrogen excretion in the presence and absence of  $\text{KHCO}_3$ , SU305  
 Impaired angiogenesis and compromised fluid volume accompanies increased osteoblast and osteocyte apoptosis with GC excess, SA453  
 Impaired methylation capacity is associated with low BMD, SU317  
 Longevity gene *SIRT-1* independently controls both osteoblast and osteoclast function, 1098  
 Mechanisms of endplate failure in the human vertebral body, M413  
 Osteoporosis and the acid-ash hypothesis, SA331  
 Overexpression of sFRP1 inhibits bone formation and attenuates PTH bone anabolic effects, 1100  
 OVX-induced hyperphagia does not modulate bone mineral or bone strength in female Sprague-Dawley rats, SA447  
 Oxidative stress stimulates the synthesis of PPAR $\gamma$ 2, and ligand-activated PPAR $\gamma$ 2 sequesters  $\beta$ -catenin leading to suppression of TCF-mediated transcription, 1099  
 Oxytocin directly regulates skeletal homeostasis, SA199  
 Percentage body fat and risk of prospective hip fracture in older men and women, F363  
 Psychotropic drugs have contrasting skeletal effects that are independent of their negative effects on activity levels, M423  
 RLX ameliorates detrimental collagen cross-link formation in bone from an OVX rabbits with or without hyperhomocysteinemia, SA382  
 Role of OPN in beta-adrenergic signaling induced bone loss in vivo, M174  
 SHBG levels in older patients with acute hip fracture are correlated with worse function and increased bone resorption, SU363  
 Toward a physiologically-based definition of hypogonadism in men: dose-response relationship between testosterone and bone resorption, 1102  
 Trabecular bone loss in response to transient muscle paralysis is not gender dependent, SA462  
 Treadmill exercise provides only short-term protection against cancellous bone loss with reduced dietary energy intake: endocrine mechanisms, SA449  
**Osteoporosis, treatment (clinical)**  
 1-year analysis of adherence with bisphosphonate treatments in osteoporotic patients, SA415  
 12 months of TPTD therapy increases ultradistal radius bone strength in severely osteoporotic postmenopausal women, SA504  
 Active controlled, non-inferiority study to compare the effect of ZT-031 with ALN on the incidence of new vertebral fractures, M347  
 Acute phase response and bone metabolism marker after intravenous bisphosphonate in osteoporotic patients with rheumatism, M364  
 Adherence in patients with severe osteoporosis treated with TPTD, M384

ALN and indapamid alone or in combination in the management of IHC associated with osteoporosis, 1245  
 ALN treatment for juvenile osteoporosis, M366  
 Application of preventive measures minimizes the occurrence of ONJ in patients with bone loss treated with bisphosphonates, F281  
 ARZ in postmenopausal women with normal or low bone mass, SA421  
 Assessment of adherence to treatment of osteoporosis with RLX and/or ALF in postmenopausal Japanese women, M387  
 Assessment of serum Ca and bone resorption markers in patients transitioned from ALN to DMAB, M394  
 Attitudes to fracture prevention in long-term care facilities, M379  
 Atypical osteoclast phenotype after long-term ALN therapy for osteoporosis, SU399  
 Back pain is reduced in postmenopausal women with severe osteoporosis treated with rhPTH(1-34) regardless of incident fractures, SU413  
 Bisphosphonate-associated femoral fracture: implications for management, WG26  
 Bisphosphonate-associated ONJ cases in South Korea, SA412  
 Bisphosphonates and osteoporotic fractures in highly compliant/persistent postmenopausal women, 1025  
 BMD and biochemical marker response rates in postmenopausal women after treatment with ZOL, F401  
 BMD response to treatment with rhPTH in patients previously treated with bisphosphonates, M348  
 C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292  
 Calcitonin intramuscular administration for treating acute pain of osteoporotic vertebral compression fractures, SA196  
 Case finding for the management of osteoporosis with FRAX—assessment and intervention thresholds for the UK, 1290  
 Cat K inhibitor, MIV-701, suppresses bone resorption markers in healthy postmenopausal women, F433  
 Comparative antifracture efficacy of N-containing bisphosphonates, SU397  
 Comparative gastrointestinal safety of weekly oral bisphosphonates, M358  
 Continued evidence for safety and efficacy of RIS in men with osteoporosis, M360  
 Correlates of osteoporosis treatment persistence for patients new to therapy and patients with recent switches, M375  
 Cost-effectiveness of IBN therapy for women with postmenopausal osteoporosis with respect to nonvertebral fracture efficacy, SA429  
 Cost-effectiveness of RIS versus IBN at one year: the case of Germany, SA425  
 Cost-effectiveness of RIS vs. generic ALN, SA423  
 Danish patients treated with TPTD, M350  
 Development, reliability, and validity of a new PSQ, SA417  
 Differences in safety and efficacy of generic and original branded once weekly bisphosphonates, M359  
 Do physicians who practice together provide similar osteoporosis care?, SU401  
 Does ALN use prevent kyphosis progression in older women?, SA410  
 Double-blind, placebo-controlled, dose-response study of BZA in Japanese postmenopausal women with osteoporosis, M391  
 Effect of a single 5-mg infusion of ZOL on bone turnover markers versus oral RIS (5 mg/day) over 1 year in patients with GIO, M362  
 Effect of a single infusion of ZOL 5 mg versus oral RIS 5 mg on BMD at lumbar spine, hip, femoral neck and trochanter in patients with GIO, F403

Effect of bodyweight on clinical response to ZT-031: development of a simple, improved dosing regimen for PTH analogs, M346  
 Effect of DMAB vs ALN on bone turnover markers and BMD changes at 12 months based on baseline bone turnover level, 1285  
 Effect of low dose Vitamin K2 (MK-4) supplementation on bio-indices in postmenopausal Japanese women, SU307  
 Effect of once-yearly ZOL 5 mg infusion on fracture incidence in postmenopausal osteoporosis, 1028  
 Effect of once-yearly ZOL on integral BMD of the spine, SU405  
 Effect of RIS in liver transplantation patients with low bone mass, SA503  
 Effect of RIS on bone density in HSC transplant patients, SU407  
 Effect of skin color and oral Vitamin D supplementation on serum 25(OH)D in adolescent girls, SU395  
 Effect of SSBT on osteocyte viability, F405  
 Effect of three different doses of Vitamin D<sub>2</sub> (ergocalciferol) on muscle function and strength in women > 65 years, M405  
 Effect of Vitamin D2 or Vitamin D3 supplementation on serum 25(OH)D, SU425  
 Effect of ZOL (single 5-mg infusion) on lumbar spine BMD versus oral RIS (5 mg/day) over 1 year in subgroups of patients receiving GC therapy, M363  
 Effective progressive resistive exercise program from prone position for paravertebral muscles to reduce risk of vertebral fractures, M473  
 Effectiveness of bisphosphonate therapy in a real-world setting, M356  
 Effects of a targeted bone and muscle loading program on QCT bone geometry and strength, muscle size and function in older men, 1244  
 Effects of *Acanthopanax senticosus* extract on bone metabolism in Korean postmenopausal women, SA431  
 Effects of ARZ on bone turnover and safety in postmenopausal women with low bone mass, M386  
 Effects of DMAB vs ALN on BMD, bone turnover markers, and safety in women previously treated with ALN, M395  
 Effects of estrogen therapy and fluocalcic effervescent on the BMD and bone metabolism of surgical menopause women with osteopenia, M392  
 Effects of LASO on bone turnover markers, 1287  
 Effects of LASO on fractures and breast cancer, 1288  
 Effects of low dose estrogen therapy on the BMD and bone metabolism of menopausal women, M393  
 Efficacy and safety of monthly oral IBN in postmenopausal women with low bone density, SU384  
 Efficacy and safety of short term treatment with different doses of cholecalciferol on 25(OH)D levels in postmenopausal females with osteoporosis, SU434  
 Efficacy of BZA in reducing the incidence of nonvertebral fractures in postmenopausal osteoporotic women at higher fracture risk, M390  
 Efficacy of the Vitamin D supplementation in patients with hypovitaminosis D and HPT2, SU431  
 Efficacy of whole-body vibration in reducing bone loss in postmenopausal women, M396  
 Electronic medical record based "ALERT System" improved diagnosis and treatment of osteoporosis in orthopaedic out-patient clinic, SU416  
 Ergocalciferol is not bioequivalent to cholecalciferol in Vitamin D insufficient hip fracture cases, 1289  
 Evaluating the effect of soy and isoflavones on BMD in older women, M353

- Evaluation of BMD changes in women with severe osteoporosis after TPTD treatment, M355

- TPTD in bisphosphonate-resistant osteoporosis—clinical and  $\mu$ CT data, 1172
- TPTD therapy in a community setting: persistence and use of other osteoporosis medications in DANCE, SA395
- TPTD versus ALN for treatment of GIO, 1171

## Key Word Index

## ASBMR 30th Annual Meeting

- Treating osteoporosis in the elderly: an environmental scan of nursing home prescribing in Ontario, Canada, SU404
- Treatment discontinuation due to gastrointestinal adverse events and decreased BMD in patients switched from branded ALN to generic ALN, SA414
- Treatment with daily subcutaneous PTH (1-84) in women with severe postmenopausal osteoporosis, 1170
- Vitamin D<sub>3</sub> treatment of elderly people—twice a day or every four months? A comparative study of efficacy and safety of two oral dosages with same annual dose of 292,000 units, SU422
- Vitamin K treatment for one year does not alter femur geometry in postmenopausal women, SA443
- Which is the best oral high-dose Vitamin D<sub>3</sub> regimen for postmenopausal women with hypovitaminosis D?, SU429
- Wintertime Vitamin D supplementation inhibits seasonal variation of calcitropic hormones and maintains bone turnover in healthy men, SU433
- Women with severe osteoporosis treated with rhPTH(1-34) improve quality of life regardless of incident fractures, SU412
- ZOL prevents accelerated bone loss after discontinuation of TPTD, M365
- ZOL treatment of osteoporosis: effects in men, SU398
- Osteoporosis, treatment (preclinical)**
- ALF ameliorates bone dynamics in senescence-accelerated SAMP6 mice and in fracture repair rat model, SU394
- Anabolic daily intermittent PTH 1-84 reduces bone blood vascular bed and induces dramatic changes in the bone/vessel spatial relationship, 1061
- Anabolic skeletal effects of a GH-derived peptide (AOD9604) in the OVX rat model of osteoporosis, SU373
- Bone anabolic effects of icariin and total flavonoid fraction of *Herba epimedii* in OVX mice, M337
- Bone effects of ODN in adult OVX rabbits, SA073
- Bone-building effects of the oral CaSR antagonist, ronacaleret, in OVX rats, SU372
- BZA in combination with conjugated estrogens improves bone mass and strength in the OVX rat, SA385
- Ca signaling is a major target of OCT-1547, a small molecule osteoporosis drug candidate, M339
- Cannabinoid receptor ligands rescue bone loss and stimulate fracture healing, SU375
- Carborane BE360, one of the carbon-containing polyhedral boron-cluster compounds, is a new type of selective estrogen receptor modulator., SU187
- Cissus quadrangularis* attenuates OVX induced bone loss in mice, M403
- Combination of flaxseed and estrogen benefits bone health in the OVX rat model of postmenopausal osteoporosis, SU381
- Comparison of the effects of IBN alone with IBN in combination with SNAC on bone density and bone strength in OVX rats, SU391
- Development of an animal model of bisphosphonate-induced severe suppression of bone turnover, SA511
- Dietary Sr in a model of established osteopenic rats reduce the levels of 25(OH)D, SA377
- Diffuse osteopenia after tibia fracture: benefits of early mobilization and weight bearing, F461
- Dried plum alters bone metabolism via a different mechanism than PTH, M341
- Effect of cannabinoid CB1 receptor ligands on body weight and bone mass in mice, M340
- Effects of agave inulin on Ca metabolism in Japanese young adults, M332
- Effects of co-treatment with an Scl-Ab and ALN in OVX rats, 1213
- Effects of different extracts of *Fructus ligustri lucidi* on Ca balance in normal female rats, M336
- Effects of ODN on bone biomarkers in OVX non-human primates, F297
- Effects of ODN on bone mass and turnover in estrogen deficient adult rhesus monkeys, SA072
- Effects of PTH on fracture repair in GC treated mice, 1062
- Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385
- Efficacy of ODN in the OVX rhesus monkey as measured with pQCT, M343
- Fully human anti-DKK1 antibodies increase bone formation and resolve osteopenia in mouse models of estrogen-deficiency induced bone loss, 1214
- Fusion protein of PTH and a collagen binding domain shows superior efficacy and longer duration of action compared to PTH(1-34) as an anabolic bone agent in normal female mice, 1063
- Green tea polyphenols protect bone microarchitecture in female rats with chronic inflammation-induced bone loss, M338
- IC162, a new flavonoid, preserves bone mass and microarchitecture without affecting uterine weight in OVX rats, SA386
- Improved bone mass after co-administration of Sr ranelate and RIS in a rat model of osteoporosis using “in-vivo”  $\mu$ CT, SU393
- Increases in BMD observed with Scl-Ab treatment are reversible, 1211
- Inhibition of bone loss and muscle atrophy by DHT in a mouse hindlimb disuse model, SU377
- Injection of MSCs overexpressing both CXCR4 and RANK-Fc effectively prevented OVX-induced bone loss, F391
- Intermittent, short duration cyclic loading attenuates disuse osteoporosis without affecting resorption, M483
- Juvenile murine model of OVX-induced trabecular and cortical osteoporosis, SA387
- Low dose administration of INF $\gamma$  stimulates osteoblastogenesis and prevents ovariectomy-induced osteoporosis in C57BL/6 mice, M334
- Male and female cynomolgus monkey models of osteoporosis, SU435
- Mechanical loading prevents bone loss due to hormone-deficiency in female mice, M474
- Neonatal exposure to soy isoflavones attenuates deterioration of bone tissue in female but not male mice after cessation of sex steroid production, SU476
- Osteogenic potential of bone marrow, compromised by disuse, is normalized by brief exposure to a low-level mechanical signal, M486
- Percutaneous injection of GEM OS2 increases vertebral BMD in geriatric female baboons, F376
- PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299
- Prior treatment with Vitamin K<sub>2</sub> significantly improves the efficacy of RIS, SA379
- Profile analysis of rodent metaphyseal trabecular bone reveals a biphasic dose-dependent response to administered bone active agents, SA460
- Proteasome inhibition counteracts the negative effect of GC treatment on bone metabolism by stimulating osteoblasts and inhibiting osteoclasts in vitro, SA231
- R-spondin 1 reduces bone loss in human TNF transgenic and OVX mice, 1215
- RIS has a more rapid onset of remodeling suppression than ALN in rabbit vertebral trabecular bone, SU387
- RIS prevents early radiation-induced bone loss at multiple skeletal sites, 1066
- Rodent model to evaluate the effect of dietary protein on intestinal Ca absorption, M330
- Role of active site Thr201 in the inhibition of farnesyl pyrophosphate synthase by NBP, F407
- Roles of ZOL in bone healing and osteoblast functions, 1064
- Sca-1<sup>+</sup> HSC-based hGH gene therapy enhanced endosteal bone resorption in mice, M233
- Scl-Ab increases bone formation and decreases bone resorption in distal tibial metaphyseal trabecular bone in OVX rats, F394
- Secretomic analysis of Ca supplement-mediated bone remodeling, M022
- Selective p38 $\alpha$  inhibitor prevents bone loss induced by estrogen deficiency, M335
- Short-term effect of ZOL on the superficial vascularisation of membranous bone sites, SU382
- Skeletal effects of a F2A in OVX rats, SA388
- Solid-state <sup>31</sup>P MRI quantifies mineralization changes in OVX rat bone, M422
- Soluble activin receptor type IIA fusion protein, ACE-011, increases bone mass by stimulating bone formation and inhibiting bone resorption in cynomolgus monkeys, SU376
- Sr ranelate decreases osteoblast-induced osteoclastogenesis through the involvement of the CaSR, F389
- Studying cellular uptake and distribution of bisphosphonate in vivo using fluorescently-labelled analogues of RIS, 1065
- TOR inhibits osteoclast activity in vitro and prevents orchietomy-induced bone resorption in male rats, SA381
- TPTD improves trabecular architecture as measured by  $\mu$ CT at simulated in vivo resolution in the femoral neck of OVX monkeys, SA375
- Transition from ALN to DMAb resulted in further reductions in local and systemic bone turnover parameters and reduced cortical porosity in OVX cynomolgus monkeys, 1216
- Use of alternative medicine for treating osteoporosis in Korea, SA390
- Osteoporotic Fractures in Men (MrOS) Study**
- Comprehensive genetic analysis of bone volume in men, M268
- Distribution and rate of clinical fractures in older men without osteoporosis, 1282
- Epidemiology of rib fractures in older men, F354
- Functional polymorphism in COL1A2 (Ala459Pro) that is associated with intracranial aneurysms, shows heterozygous disadvantage concerning BMD and stroke in elderly men, SU219
- Gondanotropins, bone loss and fracture in men, 1278
- Higher BMD loss in older men with diabetes, 1209
- Poor peripheral nerve function is related to lower BMD, SA328
- Self-reported weight at birth predicts measures of femoral size but not volumetric BMD in elderly men, SU338
- Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349
- Osteopotential (Opt)**
- Mice lacking the novel transmembrane protein Opt develop catastrophic defects in bone modeling, 1075
- Osteoprogenitor cells**
- Ablation of IGF-I signaling in osteoprogenitors decreases bone formation and blunts the skeletal response to PTH, 1193
- All-trans-retinoic acid (Vitamin A) increases expression of MafB and inhibits osteoclast formation by interfering with differentiation of osteoclast progenitor cells, M117
- Anabolic PTH treatment mobilizes BMSC and osteoprogenitors towards bone surfaces, SA229

Dermo1 lineage tracing identifies early osteoprogenitor cells in adult murine bone marrow MSC cultures, SA051

Evaluation of circulating osteoprogenitor cells during fracture healing using parabiotic mice, 1260

Identification, characterization and isolation of peripheral osteoclast progenitors, SU099

Protein hydrolyzate directly modulates the expression of GIP by osteoprogenitor cells, SU010

Use of  $\alpha$ -SMA-GFP transgene to identify periodontium derived osteoprogenitors, SA040

Use of GFP reporter mice for assessing osteoprogenitor cell activity in a critical size calvarial defect, SA007

In vivo demonstration that PTH acts on early osteoprogenitor cells to enhance bone formation during repair of critical-size calvarial defects, M062

#### Osteoprotegerin (OPG)

Butyrate stimulates mineralized nodule formation and OPG expression by osteoblasts, M012

Circulating OPG and its ligand in post operative biliary atresia: relationship with metabolic bone disease, M406

Effect of  $\text{Sr}^{2+}$  on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

Effects of ALN and RLX on the RANKL/OPG system in primary cultures of human osteoblasts, M101

Effects of exercise and estrogen on OPG in premenopausal women, SU166

Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

GILZ promotes osteoblast development and modulates RANKL/OPG levels, M049

Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SOST* (sequestosome 1), SU210

Increased osteoclasts in Brl mouse model for OI are independent of decreased osteoblast matrix production and RANKL/OPG ratio, but are associated with increased osteoclast precursors in marrow, SU209

LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563

OPG production by breast cancer cells is modulated by steroid hormones and confers resistance against TRAIL-induced apoptosis, M271

OPG serum levels in shaft fractures healing and non-union, M013

RANKL/OPG in primary cultures of osteoblasts from patients with osteoporotic hip fractures, SU009

Role of OPG/RANKL system for bone loss in PHPT, M192

Sim induces Wnt signaling and reduces CSF-1 secretion and RANKL/OPG ratio to block osteoclast differentiation, SU096

TSG-6 acts synergistically with OPG to inhibit bone resorption, SA097

#### Osteosarcoma

2ME2 alters eIF4E activity and causes protein synthesis inhibition in osteosarcoma cells, SU240

Alpha-Ca/CaMKII controls osteosarcoma cell migration, SU234

Characterisation of an antigen found in giant cell tumor and osteosarcoma cells, SU244

FGFR signaling in the pathogenesis of osteosarcoma, 1233

Hedgehog pathway is activated in osteosarcoma and cyclopamine prevents osteosarcoma growth by cell cycle regulation, SU241

Notch pathway is activated in osteosarcoma and inhibitors of  $\gamma$ -secretase inhibit osteosarcoma growth by cell cycle regulation, SU229

#### Osteosclerosis

Bisphosphonate-induced osteopetrosis: novel bone modeling defects, metaphyseal osteopenia, and osteosclerosis fractures after drug exposure ceases, F569

Osteosclerotic prostate cancer metastasis to murine bone: enhanced with increased bone turnover, SA269

Progressive lipodystrophy in the osteosclerotic mice over-expressing Fra1, 1149

Recovery from HCAO following anti-viral treatment, F488

Stress fracture and vertebral osteosclerosis related to fluorosis induced by excessive gingival topical fluoride application, M444

#### Osteotropic peptides. See Peptides

#### Osterix (Osx)

(Ala-Gly)n sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167

BMP-2 induces Osx expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020

BMSC and Osx contributing to osseointegration of dental implants, SA138

Craniofacial bone defect in Nell-1 mutant mice associated with dysregulated Runx2 and Osx expression, F174

Induction of Runx2 and Osx by bisphosphonate promote osteogenic differentiation, SU062

Osx is required for skeletal growth and bone homeostasis after birth, 1074

Osx, a positive regulator in adult bone formation, F008

PTH regulation of Osx transcription in osteoblasts, M042

Regulation of the osteoblast-specific transcription factor Osx by NO66, a Jumonji family histone demethylase, F017

T-box 3 negatively regulates osteoblast differentiation by inhibiting expression of Osx and Runx2, SU018

TIEG: a key regulator of Runx2 and Osx gene expression and osteoblast differentiation, M052

#### Ostm1

Role of Ostm1 in bone, hematopoiesis and neuronal development, 1271

#### Oxysterols

Synergistic activation of osteogenesis in MLPC by oxysterols, SU038

#### Oxytocin

Central control of bone remodeling: neurohypophyseal hormone oxytocin is decreased in severe postmenopausal osteoporosis, M418

Oxytocin directly regulates skeletal homeostasis, SA199

Oxytocin inhibits bone formation through the activation of the sympathetic tone, 1200

## P

#### p.N417S

c.1250A>G, p.N417S is a common American TNSALP mutation involved in all clinical forms of HPP, including pseudo-HPP, SA566

#### P2X<sub>7</sub>

Activation of P2X<sub>7</sub> nucleotide receptors increases metabolic acid production by osteoblastic cells, M065

Loss of function polymorphisms in the P2X<sub>7</sub> receptor gene are associated with accelerated lumbar spine bone loss in postmenopausal women, SU224

Novel selective P2X<sub>7</sub> receptor antagonist inhibits human osteoclast formation in vitro, M120

P2X<sub>7</sub> receptor activation mediates PKC $\alpha$  translocation in osteoblasts through alteration in actin cytoskeletal organization, SU040

Single nucleotide polymorphisms in the P2X<sub>7</sub> receptor gene are associated with increased postmenopausal bone loss and fracture incidence, SU223

#### P2Y<sub>2</sub>

P2Y<sub>2</sub> receptor activation regulates RhoA-mediated stress fiber formation in osteoblasts, SA035

#### p38

Antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185

BMP-2 induces Osx expression through up-regulation of Dlx5 and its phosphorylation by p38 MAPK, F020

Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177

#### p38 $\alpha$

Selective p38 $\alpha$  inhibitor prevents bone loss induced by estrogen deficiency, M335

#### p57<sup>Kip2</sup>

C/EBP $\beta$ /p57<sup>Kip2</sup> signaling maintains transition from proliferation to hypertrophic differentiation of chondrocytes during skeletal growth, 1187

#### p62

Increased signaling through p62 in the MM microenvironment increases myeloma cell growth and osteoclast formation, SA289

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

#### p62<sup>P392L</sup>

Co-expression of p62<sup>P392L</sup> and MVNP in osteoclast precursors increases the formation of osteoclasts that express a pagetic phenotype, F476

#### p63

Identification of a transcription factor p63 for transactivation of Wnt9a and Gdf5 causing joint cartilage formation, F116

#### p66<sup>shc</sup>

Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380

#### P253R

Dynamic morphological changes in the skulls of mice mimicking human Apert Syndrome resulting from gain-of-function mutation of FGFR2 (P253R), SA248

#### Paclitaxel (PTX)

Local administration with PTX-loaded HA-alginate beads for metastatic spine cancer in rats, M274

#### Paget's Disease (PD)

High levels of IL-6 and hyper-responsivity to 1,25(OH)<sub>2</sub>D<sub>3</sub> are both required for development of Pagetic osteoclasts, F478

OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563

#### Paget's Disease of bone (PDB)

Archaeological skeletons support a North-West European origin for PDB, SA477

Case presentation: bisphosphonate induced ONJ in Pagetic jaw bone, WG24

Comparison of intravenous and intramuscular neridronate regimens for the treatment of PDB, SA481

Efficacy and safety of intravenous ZOL in the treatment of patients with resistant PDB, SA479

FGF-2 stimulates RANKL expression in PDB, F480

## Key Word Index

## ASBMR 30th Annual Meeting

Identification of a novel mutation (78dup27) of the *TNFRSF11A* gene in a Chinese family with early onset PDB, M237  
 Large collaborative study on geographic variation of *SQSTM1* mutations in PDB in Italy, SA475  
 PDB: a histologic and histomorphometric analysis of bone biopsies from 754 patients, 1133  
 Two novel *SQSTM1* mutations in American patients with PDB, SU216

**Pain**

Back pain is reduced in postmenopausal women with severe osteoporosis treated with rhPTH(1-34) regardless of incident fractures, SU413  
 Effect of RLX and ALF on bone and joint pain assessed by fall of skin impedance (electroalgotometry), SA384  
 Novel hypothesis explains the syndrome of chronic musculoskeletal pain and comorbid painful healed fracture sites in Vitamin D deficiency, SA474

**Pamidronate**

Bisphosphonate, pamidronate, suppresses the pro-inflammatory response in a mouse model of OI as well as normal littermates, SU386  
 Large osteoclasts in pediatric OI patients receiving intravenous pamidronate, SU497  
 Randomized dose comparison of pamidronate in children with types III and IV OI, SU496

***Panax notoginseng***

BT-201, a butanol extract of *Panax notoginseng* inhibits progression of joint degeneration in a rat model of OA, M152

**Pancreas transplantation**

Application of a treatment algorithm to avoid BMD loss and limit bisphosphonate use after kidney and kidney/pancreas transplantation, SA497  
 Pretransplant parathyroid function predicts laboratory and BMD changes after kidney and kidney/pancreas transplantation, 1032

**Parafibromin**

Usefulness of *HRPT2* gene and parafibromin studies in two patients with PHPT and uncertain pathological assessment, SA482

**Parathyroid**

Continuous rat parathyroid cell line expressing PTH, M184  
 Dominant tissue accumulation of MIB1 in parathyroid glands in uremic rats, SA222  
 Pretransplant parathyroid function predicts laboratory and BMD changes after kidney and kidney/pancreas transplantation, 1032

**Parathyroid cells**

Functional induction of target genes in parathyroid cell by direct injection technique, M185  
 GCM2, the regulator of parathyroid cell fate, transactivates the CaSR gene, M187  
 Molecular basis of PHPT: adenomatous parathyroid cells are resistant to L-amino acids, M203

**Parathyroid hormone (PTH)**

Ablation of IGF-I signaling in osteoprogenitors decreases bone formation and blunts the skeletal response to PTH, 1193  
 Acute change in iCa directly affects bone formation independent of PTH action during hemodialysis, SU437  
 Aging dependent and independent effects of b2 adrenergic receptor signaling on bone formation induced by intermittent PTH treatment in female mice, SA378  
 Albuminuria, 25(OH)D, 1,25(OH)<sub>2</sub>D, and intact PTH in older adults, SU442  
 Anabolic daily intermittent PTH 1-84 reduces bone blood vascular bed and induces dramatic changes in the bone/vessel spatial relationship, 1061  
 Anabolic PTH treatment mobilizes BMSC and osteoprogenitors towards bone surfaces, SA229

Analysis of chromosome breaks in osteoblasts and non-osteoblastic cells treated with intermittent PTH, M191  
 Association between Cx43 and  $\beta$ -arrestin is required for cAMP-dependent osteoblast survival induced by PTH, 1227  
 Behavior of circulating rat(s) PTH molecular forms in HPT2 related to Vitamin D deficiency and renal failure, M194  
 BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098  
 Bone tissue quality is differently altered by PTH, bisphosphonates and SERMs, SA510  
 Calcitonin attenuates the anabolic effect of PTH in vivo and rapidly upregulates SCT expression, F195  
 $\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, 1013  
 CCR2 receptor signaling is involved in bone mass regulation and mediates the response to anabolic but not catabolic regimens of PTH(1-34), SU158  
 Changes in serum PINP in orchidectomized osteopenic rats treated with PTH and ALN, M295  
 Circulating osteoblast lineage cells increase with PTH treatment of HPT, 1146  
 Clinical implications of commercial biotin-based detection systems in PTH assays, M435  
 Clinically useful paradigm for interpretation of serum 25(OH)D levels with simultaneously measured PTH levels, M437  
 Cloning and functional analysis of human Nurr1 (NR4A2) promoter: critical role in the regulation of CYP27B1 by PTH and CREB phosphorylation, 1161  
 Comparison of cPTH(1-31) to PTH(1-34) in the enhancement of experimental fracture healing, M161  
 Continuous rat parathyroid cell line expressing PTH, M184  
 Deletion of the *GNAS* antisense transcript results in parent-of-origin specific *GNAS* imprinting defects and phenotypes including PTH-resistance, 1052  
 Dried plum alters bone metabolism via a different mechanism than PTH, M341  
 Effect of bodyweight on clinical response to ZT-031: development of a simple, improved dosing regimen for PTH analogs, M346  
 Effects of intermittent human PTH administration on bone union with hydroxyapatite blocks at the site of cancellous bone osteotomy in OVX rats, SA214  
 Effects of PTH on fracture repair in GC treated mice, 1062  
 Expansion of mesenchymal progenitors in an in vivo model of constitutive activation of the PTH/PTHrP receptor, 1263  
 Fusion protein of PTH and a collagen binding domain shows superior efficacy and longer duration of action compared to PTH(1-34) as an anabolic bone agent in normal female mice, 1063  
 Hematopoietic cells in the bone marrow augment anabolic actions of PTH, M181  
 High-fat diet facilitated decreases in BMD of OVX mice and suppressed the anabolic effects of PTH on bone, SA448  
 Hip fracture patients with vertebral fractures have more severe osteoporosis and are candidates for more active treatment including PTH, SU274  
 Hip structural analysis and volumetric QCT in postmenopausal women from the PaTH Study: mono- or combination therapy with ALN and PTH, M306  
 Identification and optimization of residues in PTH and PTHrP that determine altered modes of binding to the PTH/PTHrP receptor, F224

Impact of PTH on cells of the hematopoietic lineage, 1159  
 Inhibitory role of *Gaq*/PKC $\delta$  signal in the bone anabolic action of PTH, 1228  
 Interaction of combined intervention of PTH and GH on trabecular and cortical bone formation and resorption in the hypophysectomized rats, SU502  
 Intermittent PTH administration increases bone mass and strength in aged mice by antagonizing oxidative stress-induced osteoblast apoptosis via ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, SU380  
 Jagged1 stimulation by PTH(1-34) in mature osteoblasts is not required for HSC expansion, 1078  
 Long-acting PTH ligand that binds to a distinct PTH receptor conformation (R0) can stimulate increases in markers of both bone resorption and bone formation in mice, F221  
 Loss of a single bim allele recovers the defective osteoclast function in *bcl-2*<sup>-/-</sup> mice but does not restore the anabolic action of PTH, 1217  
 Marrow ablation induces periosteal bone formation and potentiates the effect of PTH on endosteal bone formation in rat femurs, M208  
 Metabolic alkalosis transition in renal proximal tubule cells facilitates an increase in CYP27B1, while blunting responsiveness to PTH, M196  
 Mice deficient in BSP display impaired modeling and remodeling and respond to ovariectomy but not to the cortical anabolic effect of PTH, 1191  
 Molecular mechanisms involved in PTH-induced apoptosis in Caco-2 intestinal cells, M189  
 Negative relationship between PTH and Vitamin D: is there an age and a gender effect?, M179  
 New data on the impact of renal function on the relationship between 25(OH)D and PTH, 1031  
 New intact PTH assay on the IDS Automated Analyser 3x3<sup>TM</sup>, M209  
 New long-acting PTH/PTHrP hybrid analog that binds to a distinct PTHrP conformation has superior efficacy in a rat model of HPT, F483  
 Novel CaSR antagonist leads to dose-dependent transient release of PTH after oral administration to healthy volunteers, 1173  
 OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076  
 Overexpression of sFRP1 inhibits bone formation and attenuates PTH bone anabolic effects, 1100  
 PGE2 as a potential mediator of PTH-dependent regulation of HSCs, F171  
 Post-mitotic preosteoblasts are the targets of the anabolic actions of intermittent PTH on periosteal bone, 1157  
 Postnatal deletion of PTH/PTHrP receptor in growth plate chondrocytes leads to growth plate fusion, F114  
 PTH and not Vitamin D predicts age-related bone loss in the elderly, M178  
 PTH has direct anabolic effects on OA articular cartilage in vitro and in vivo, M155  
 PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180  
 PTH increases bone turnover in HPT, F485  
 PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calceineurin pathways, SA033

PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038

PTH regulation of *Osx* transcription in osteoblasts, M042

PTH reverses abnormal bone remodeling and structure in HPT, 1036

PTH signaling through LRP5/6 in osteoblasts, 1014

PTH stimulates hematopoiesis and increases survival in irradiated mice, 1015

PTH-gene family in the cartilaginous fish, *Callorhynchus milii*, M183

PTH-induced bone mass gain is blunted but not abolished in *SOST* overexpressing and deficient mice, 1039

PTH/PTHrP mediated stimulation of osteoblast differentiation involves Epac-Rap1 dependent processes, SA025

Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211

Role of FGF-23 in the early response to the PTH analogue; TPTD, SU174

Role of the transcription factor SOX4 in the skeletal response to intermittent PTH, SA220

Safety and efficacy of long-term PTH replacement in a pediatric patient with inherited HPT, F217

Selective removal of PLC signaling in novel PTH(1-28) analogs abolishes regulation of NaPi-IIc but not NaPi-IIa, M186

Serum intact PTH of 100 to 150 pg/ml is associated with greatest survival in maintenance hemodialysis patients, SU445

Serum PTH response to oral Ca load in Asian adolescents, M188

SIF levels among hemodialysis patients are positively associated with levels of serum phosphate and intact PTH, SU440

At similar plasma 25(OH)D levels, fat mass influence PTH levels in the state of Vitamin D insufficiency, SA218

Suppression of canonical wnt signaling by Dkk1 attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215

T cells amplify the anabolic action of PTH through Wnt10b signaling, 1197

Treatment with daily subcutaneous TPTD (1-34) compared with daily subcutaneous PTH (1-84) in women with severe postmenopausal osteoporosis, 1170

In vivo demonstration that PTH acts on early osteoprogenitor cells to enhance bone formation during repair of critical-size calvarial defects, M062

In vivo longitudinal QCT analysis PTH efficacy in a rat cortical defect model, M207

**Parathyroid hormone receptor (PTHrP)**

New long-acting PTH/PTHrP hybrid analog that binds to a distinct PTHR conformation has superior efficacy in a rat model of HPT, F483

Regulation of nuclear import of the PTHR, M210

**Parathyroid hormone receptor 1 (PTHr1)**

Coordinate regulation of PTHrP and PTHR1 in the osteoblast differentiation of C2C12 cells promoted by BMP-2, SA157

Intracellular PTHR2 alters cell proliferation and pattern of gene expression while antagonizing PTHR1 signaling in chondrocytic CFK2 cells, SA121

PTHr1 mutations associated with Ollier Disease result in receptor loss of function, SA258

PTHr1 stimulates bone formation through a distinct  $\beta$ -arrestin dependent pathway independent of G protein activation, 1226

**Parathyroid hormone receptor 2 (PTHr2)**

Intracellular PTHR2 alters cell proliferation and pattern of gene expression while antagonizing PTHR1 signaling in chondrocytic CFK2 cells, SA121

**Parathyroid hormone related protein (PTHrP)**

ADAMTS-7, a direct targeting molecule of PTHrP, is a novel potent mediator of chondrogenesis, 1262

C-terminal fragment of PTHrP (107-139), exerts osteogenic features in both regenerating and nonregenerating bone in mice with diabetes-related osteopenia, SA223

$\beta$ -catenin directly binds to a specific intracellular domain of PTH/PTHrP receptor and regulates the signaling in chondrocytes during endochondral ossification, 1013

Coordinate regulation of PTHrP and PTHR1 in the osteoblast differentiation of C2C12 cells promoted by BMP-2, SA157

Effect of  $\text{Sr}^{2+}$  on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

Effects of extracellular matrix properties and elastic modulus on the expression of PTHrP by human breast cancer cells, M280

Expansion of mesenchymal progenitors in an in vivo model of constitutive activation of the PTH/PTHrP receptor, 1263

hPTHrP 1-36 stimulates PKA-dependent phosphorylation and nuclear translocation of  $\beta$ -catenin in neonatal mouse calvarial bone cells, F032

Identification and optimization of residues in PTH and PTHrP that determine altered modes of binding to the PTH/PTHrP receptor, F224

KO of the PTHrP gene in breast cancer cells inhibits tumor progression and metastatic spread in vivo, 1016

N-terminal fragment of PTHrP promotes the GC-related deficiency of bone regeneration after bone marrow ablation in mice, M195

New long-acting PTH/PTHrP hybrid analog that binds to a distinct PTHR conformation has superior efficacy in a rat model of HPT, F483

Novel and sensitive immunoassay for PTHrP, M182

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

Postnatal deletion of PTH/PTHrP receptor in growth plate chondrocytes leads to growth plate fusion, F114

PTH/PTHrP mediated stimulation of osteoblast differentiation involves Epac-Rap1 dependent processes, SA025

PTHrP blockade inhibits tumor progression in a model of human breast cancer, F213

PTHrP is processed by skin keratinocytes and has immunomodulation properties, SA216

PTHrP nuclear localization sequence and C-terminus regulate craniofacial development, 1264

PTHrP prevents chondrocyte premature hypertrophy by inducing cyclin D1-dependent Runx2 and 3 phosphorylation and degradation, 1044

PTHrP regulates mammary gland ductal elongation during puberty, F228

PTHrP-induced Wnt signaling specifies the mammary mesenchyme, F219

Skeletal dysmorphology of mice lacking the mid-region, nuclear localization sequence and C-terminus of PTHrP, 1160

Wnt signaling regulates Gli2 and PTHrP expression in human breast cancer cells that cause osteolysis, M278

**Parathyroid hormone, carboxyl-terminal (CPTH)**

CPTH; prediction of novel functions, structural features and potential receptor, SU072

**Parathyroid hormone, cyclic (cPTH)**

Comparison of cPTH(1-31) to PTH(1-34) in the enhancement of experimental fracture healing, M161

**Parathyroid hormone, human (hPTH)**

Effects of hPTH(1-34) infusion on circulating serum phosphate, 1,25(OH)<sub>2</sub>D and FGF-23 levels in healthy men, SU169

Phase 1, randomized, double-blind, placebo controlled trial of the PK/PD effect and safety of ZT-031, a hPTH analog, in healthy elderly women, SA399

Repetitive rapid delivery of pharmacologically-active hPTH 1-34 across human skin without injection, SA397

Short duration pharmacokinetic profile of ZT-031 (cyclic PTH [1-31]), a novel hPTH analog, M345

**Parathyroid hormone, recombinant human (rhPTH)**

Back pain is reduced in postmenopausal women with severe osteoporosis treated with rhPTH(1-34) regardless of incident fractures, SU413

BMD response to treatment with rhPTH in patients previously treated with bisphosphonates, M348

Women with severe osteoporosis treated with rhPTH(1-34) improve quality of life regardless of incident fractures, SU412

**Parathyroidectomy**

Changes in cardiovascular function after parathyroidectomy in mild PHPT, M434

Parathyroidectomy improves quality of life in hemodialysis patients with HPT2, SA212

**Paravertebral muscles**

Effective progressive resistive exercise program from prone position for paravertebral muscles to reduce risk of vertebral fractures, M473

**Parietal bone**

Histologic and radiographic analysis of osteopromotive property of demineralized allogenic dentin matrix in parietal bone defects in rabbit, M168

Therapeutic effects of one-year ALN treatment in three cases of osteoporosis with parietal thinning, M410

**PaTH Study**

Hip structural analysis and volumetric QCT in postmenopausal women from the PaTH Study: mono- or combination therapy with ALN and PTH, M306

**Pathogenesis**

Effects of serum factors during osteoblast differentiation—implication for the pathogenesis of osteoporosis in Crohn's Disease, M450

**PBMC. See Peripheral blood mononuclear cells**

**PBX1**

PBX1 interaction with HOXA10 regulates timing and expression of phenotypic bone genes during osteoblastogenesis, SU019

**PEARL Trial. See Postmenopausal Evaluation and Risk-reduction with Lasofoxifene Trial**

**Pediatric bone disease. See also Bone acquisition**

25(OH)D levels in children with CKD as measured by tandem mass spectrometry, SU485

Advanced vertebral compression at diagnosis among children with ALL, SU483

Arterial compliance is associated with change in bone strength in children, F552

Background UVB exposure in pregnancy and skeletal development in childhood, 1104

Birth weight predicts bone size, adult weight predicts BMC and BMD in young Gambian adults, M498

BMD in children and adolescents with sickle cell disease, SU217

BMD shows no peak from birth to youth as measured by QCT, F310

Body fatness negatively associated with BMD and hip geometry indices in adolescents, F546

Bone health impairment in children with chronic Ca and Vitamin D deficiency due to nutritional allergies, SU503

Bone status evaluation in pre-pubertal children with CF, SU486

Born small is not bad for bone, SA551

## Key Word Index

## ASBMR 30th Annual Meeting

Changes in volumetric bone density and bone strength at the tibial midshaft in boys and girls 12-17 years of age, SU469

Childhood cortical bone and skeletal age show bivariate genetic linkage to chromosome 2p, 1177

Clinical tool for adjusting BMD Z-scores for body size in growing children, 1105

Comparison of the effect of puberty on hip structure in boys and girls, F554

Contribution of birth status, age at menarche and lifestyle factors to skeletal formation in junior and senior high school students, M492

Differences in BMC at the lumbar spine and proximal femur in South American children of different ethnic groups, SU490

Dysosteosclerosis in a 2-year-old girl: investigation of a rare, sclerosing bone disorder, SA567

Effect of 12 months gymnastics participation on bone mass accrual in 4 to 7 year olds, SA555

Effect of bed rest on bone turnover in adolescents hospitalized for anorexia nervosa, SA559

Effect of bone marrow transplantation in a child with malignant IO, SU498

Effect of non-ambulation on bone strength in boys with DMD, WG1

Effect of particle size of Ca carbonate supplement on Ca retention in adolescent girls, SA545

Effect of Vitamin D<sub>2</sub> and Vitamin D<sub>3</sub> on intestinal Ca absorption in Nigerian children with rickets, SA560

Elevated systolic blood pressure is positively related to bone mass measurements in overweight pre-pubertal and pubertal children, M496

Ethnicity-specific bone changes during adolescent growth: pQCT analysis of the tibia, M502

Evaluating bone microstructure at the distal tibia in children, F315

Genetic variation in *LRP5* associates with metabolic characteristics in healthy prepubertal children, 1176

Heel ultrasound and consolidation of PBM in young women, M504

How does body fat influence bone health in childhood? A Mendelian randomisation approach, 1175

Infantile HCa: relationship of dietary intake of Ca and Vitamin D to serum and urine levels, SU491

Influence of pubertal timing on bone trait acquisition: predetermined trajectory detectable five years before menarche, 1106

Interaction between the skeletal parameter BMD and lifestyle factors in 390 adolescent daughter-mother pairs, F548

Is it time to update normative values for ionized Ca and urine Ca? Creatinine ratios in healthy Canadian infants, SU487

Is Vitamin D deficiency more common in children with cerebral palsy than in healthy children?, SU194

Longitudinal analysis of calcaneal QUS measures during childhood, M321

Maternal nutrient restriction during pregnancy results in significant alterations in fetal skeletal development in the baboon, M494

Microfinite element modeling reveals that transient deficits in cortical bone may underlie the adolescent peak in forearm fractures, 1179

Modeling pathways for bone loss in childhood malignancies, SU237

Newborn infant bone mineralization is affected by their umbilical cord length, SU495

Normal reference values for QUS bone densitometry of the calcaneus in Chinese children and adolescents, SU489

Overweight children are more at risk to sustain a forearm fracture due to poor bone strength relative to body weight, M458

Path analysis (structural equation modeling) and covariation of bone traits following delayed puberty, SA543

Pediatric Crohn's Disease is associated with negative Ca balance and increased renal losses of Ca, SA565

Preterm birth and BMD in young adulthood, 1103

Prevalence of TH among healthy infants and toddlers, SA564

Prevention of nutritional rickets in Nigerian children with dietary Ca supplementation, M491

Protocol for pediatric proximal femur DXA analysis, M506

Randomised controlled trial of the effects of Vitamin D supplementation upon muscle function in adolescent girls, SU428

Relationship between physical fitness and bone and physical activity and Ca retention in adolescent girls, SA553

Relationship of urinary excretion of C-telopeptides to growth in children, F301

Suboptimal Vitamin D status in pregnant adolescents is associated with neonatal Vitamin D insufficiency, F557

Three year school-curriculum-based exercise program in prepubertal children increases bone mineral accrual and bone size but do not influence femoral neck structure, 1107

Tracking of femur length during intrauterine growth, M497

Use of bone biomarkers as an endpoint in a pediatric study of ALN, SU488

Vitamin D dose response study in Canadian infants, 1108

Vitamin D insufficiency: seasonal variation in healthy 6-12 year old African American and Caucasian children, SU482

Vitamin D supplementation in breast fed infants, SU500

Vitamin K intake is positively related to trabecular bone microarchitecture in children, M505

**PEG-PLA**  
Functionalization of a PLGA/PEG-PLA composite electrospon scaffold with rhBMP-2 plasmid DNA for bone regeneration, SA124

**Peptide of type 1 pro-collagen (P1NP)**  
Validation of an immunoassay for the determination of P1NP in rat serum, M296

**Peptides**  
Optimizing bioavailability of oral administration of small peptides through pharmacokinetic and pharmacodynamic parameters, M398

**Peptides, osteotropic**  
Osteotropic peptides: anabolic and osteogenic effects, M045

**Peptones**  
PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180

**Periodontal ligament (PDL)**  
LMP-1, positive regulator in osteolineage differentiation of human PDL fibroblasts, M051  
Osteogenic potential of PDL cells in vivo, SU054

**Periodontium**  
Use of  $\alpha$ -SMA-GFP transgene to identify periodontium derived osteoprogenitors, SA040

**Periosteal bone**  
Post-mitotic preosteoblasts are the targets of the anabolic actions of intermittent PTH on periosteal bone, 1157

**Periosteal cells**  
Extracellular matrix protein periostin regulates periosteal apposition, 1178  
SDF-1 is expressed in osteocytes and periosteal cells in response to mechanical loading, M105

**Periostin**

Extracellular matrix protein periostin regulates periosteal apposition, 1178

Inhibition of bone biomechanical response to physical activity and loading in mice lacking periostin, 1143

**Peripheral blood mononuclear cells (PBMC)**  
Elevated production of IL-1 $\beta$  and TNF $\alpha$  by PBMC is associated with increased hip fracture risk in elders, 1283  
Increased expression of OPN in PBMC is associated with alteration in the fractions of lymphocytes in hindlimb-unloaded mice, M175

**Peroxisome proliferator-activated receptor (PPAR)**  
Isoform-specific expression of PPARs and gene regulation during osteoclastogenesis in RAW/C4 cells, M118

**Peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ )**  
Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

**Peroxisome proliferator-activated receptor gamma-1 (PPAR $\gamma$ 1)**  
Proinflammatory mediators downregulate PPAR $\gamma$ 1 expression and activity in OA synovial fibroblasts, M159

**Peroxisome proliferator-activated receptor gamma-2 (PPAR $\gamma$ 2)**  
Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374  
Oxidative stress stimulates the synthesis of PPAR $\gamma$ 2, and ligand-activated PPAR $\gamma$ 2 sequesters  $\beta$ -catenin leading to suppression of TCF-mediated transcription, 1099  
PPAR $\gamma$ 2-mediated proteolytic degradation of  $\beta$ -catenin determines an anti-osteoblastic effect of anti-diabetic TZDs, SU023  
Targeted disruption of PPAR $\gamma$  in BMSC reveals its role in aging-induced bone loss, 1148

**PGC-1 $\beta$**   
PGC-1 $\beta$  and iron uptake in the mitochondrial activation of osteoclasts, 1222

**Phagocytosis**  
Normal human osteoblasts internalize MSUM by phagocytosis and autophagy, M057

**PHD2**  
Deletion of the oxygen-sensor PHD2 in chondrocytes results in increased cartilage and bone mineralization, 1153

**Phe147**  
CYP27A1 mutations at Phe147 confer 25-hydroxylase activity towards a Vitamin D<sub>2</sub>-type sidechain, M231

**Phellodendron Amurensis**  
Effects of beta-D-glucopyranoside from *Phellodendron Amurensis* on the production of inflammatory cytokines, growth factors, MMP, and on bone markers in human subchondral OA osteoblasts, SA117

**Phex**  
Aberrant *Phex* function in osteocytes has limited effects on bone mineralization in XLH, 1051

**Phex**  
Deprivation of Vitamin A results in a partial rescue of the mineralization defects in *Phex*-deficient Hyp mice, F202  
Effect of a novel splice-site mutation of *PHEX* gene during osteoblast differentiation, M092  
*Phex* binds to SNARE-associated protein snapin and co-localizes in vesicle-enriched, extracellular matrix micro-environment mediating mineral crystal nucleation, F066  
*PHEX* cleavage of SIBLING-ASARM peptides as a mechanism underlying osteomalacia in XLH, 1199

Screening the PHEX gene in a large cohort of hypophosphatemic rickets allowed the description of a missense mutation not responsible for the disease on a highly conserve amino acid residue, M246

Serine protease inhibitor AEBSF blocks transcription of PheX by osteoblasts, M053

**Phosphates**

Altered TNSALP expression and phosphate regulation contribute to reduced mineralization in mice lacking androgen receptor, SU181

Comparison of 1,25(OH)<sub>2</sub>D<sub>2</sub> and calcitriol effects in an adenine-induced model of CKD reveals differential control over serum Ca and phosphate, SU448

Controlled drug release from Ca phosphate-based orthopaedic implants, SU235

High expression of the Ca/phosphate-regulating hormone STC2 is associated with renal calcification in the Klotho mutant mice, SA201

Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471

MEPE regulates bone remodelling independent of serum phosphate and alters renal vascularization, F205

Osteopenia in CKD: effects of phosphate overload, SU447

Phosphate regulates chondrocyte differentiation, proliferation and apoptosis in a model of embryonic endochondral bone formation, SU124

PTH increases after oral peptones administration in obese subjects treated with roux-en-y gastric bypass surgery: role of phosphate on the rapid control of PTH release, M180

SIF levels among hemodialysis patients are positively associated with levels of serum phosphate and intact PTH, SU440

Transgenic ASARM-peptide overexpression with reduced serum phosphate and 1,25(OH)<sub>2</sub>D<sub>3</sub> leads to decreased BMD and obesity, F210

**Phosphates, inorganic**

Role of pyrophosphate and inorganic phosphate in PKA-mediated osteoblastic differentiation and mineralization of primary murine aortic cells, M143

Signaling of extracellular inorganic phosphate mediated via Na-phosphate co-transporters influences FGF-23 signaling in renal tubular cells, SU172

Synergistic role of Npt2a and Npt2c in inorganic phosphate metabolism of mice, F473

**Phosphatidylinositol 3-kinases (PI3K)**

BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/Akt regulates NFATc1 expression and its nuclear translocation, 1081

Class IA PI3Ks are indispensable for osteoclast function by regulating cytoskeletal organization and cell death, 1115

Transcriptional regulation of Cx43 by  $\beta$ -catenin, a pathway activated by PGE<sub>2</sub>-PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

**Phosphatonins**

Phosphatonins and liver resection-related hypophosphatemia, SU176

**Phospholipase C (PLC)**

Selective removal of PLC signaling in novel PTH(1-28) analogs abolishes regulation of NaPi-IIc but not NaPi-IIa, M186

**Phospholipase C gamma 2 (PLC $\gamma$ 2)**

PLC $\gamma$ 2 as a promising therapeutic target in RA, F176

**Phosphorus (P)**

Does dietary P influence FGF-23 concentrations in FD patients?, M426

Effect of the dietary Ca/P ratio on the rate of skeletal accrual in mice, M333

High level dietary P and Cd exacerbate OVX-induced bone loss, M301

Solid-state <sup>31</sup>P MRI quantifies mineralization changes in OVX rat bone, M422

### Phthalein monophosphates

Phthalein monophosphates are specific substrates for TRACP5b, M284

**Phylloquinone**

Menaquinone-4 derived from phylloquinone regulates osteoblast function, SU034

**Phytoestrogens**

Antioxidants (phytoestrogens and quercetin) are potentials agents against RA, SA487

**Pkd1**

Conditional disruption of *Pkd1* in osteoblasts results in osteopenia due to direct impairment of osteoblast-mediated bone formation, SA019

**Plasma clearance**

Skeletal plasma clearance, as measured by quantitative radionuclide studies, is correlated with bone turnover markers at 3 months of TPTD therapy, F398

**Platelets**

Platelet VDR levels are reduced in osteoporotic patients, SA241

Platelets contribute to circulating levels of Dkk-1: clinical implications in MM, SU228

**Platinum (Pt)**

Effects of Pt group metals treatment on the bone of developing chick embryos, M141

**PLB-985**

Neutrophil-like PLB-985 cells induce differentiation of human blood monocytic precursors into functional osteoclasts via a RANKL-dependent mechanism, SA092

**Pleiotrophin (PTN)**

Anabolic response to skeletal loading in mice with targeted disruption of PTN gene, 1142

**PLGA**

Functionalization of a PLGA/PEG-PLA composite electrospun scaffold with rhBMP-2 plasmid DNA for bone regeneration, SA124

**Plums**

Dried plum alters bone metabolism via a different mechanism than PTH, M341

Dried plum polyphenols increase IGF-I production in osteoblast-like cells, SU002

**Pluronic F108**

Thermoreversible Pluronic F108 gel as a universal tissue immobilization material for  $\mu$ CT analyses, SU468

**PMEPA1**

TGF $\beta$  activates prostate cancer bone metastases, pro-osteolytic gene expression and the new TGF $\beta$  signaling regulator PMEPA1, SA273

**Podosome**

Formation of podosome belts by osteoclasts on plastic correlates with resorptive activity, SU068

**Pollution**

Air pollution might be a neglected risk-factor of hypovitaminosis D, SU306

**Polycaprolactone-tricalcium phosphate**

Selective retention of bone marrow cells in repair of canine femoral defect with polycaprolactone-tricalcium phosphate scaffolds, SU005

**Polymers, resorbable**

Clinical application of resorbable polymers in guided bone regeneration, SA003

**Polyomamiddle T antigen (PyMT)**

Vitamin D delays breast cancer progression in the PyVMT transgenic mouse model, 1185

**Polyphenols**

Green tea polyphenols protect bone microarchitecture in female rats with chronic inflammation-induced bone loss, M338

**POMOST Study**

Influence of bone osteoporotic fractures in the past on the persistence of pharmacological treatment in osteoporosis, M382

**POROS Study. See Primary Care Osteoporosis Risk of Fracture Screening Study**

**Porosity**

Cortical porosity is increased in male osteoporosis with vertebral fracture, 1132

Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385

Microporosity in b-TCP ceramics may be detrimental to MSC survival and osteoblastic differentiation, SA015

OPG and bisphosphonates had differential effects on osteoclast numbers, bone marrow fibrosis and cortical porosity in a mouse model of constitutive activation of the PTH/PTHrP receptor, M076

Transition from ALN to DMAb resulted in further reductions in local and systemic bone turnover parameters and reduced cortical porosity in OVX cynomolgus monkeys, 1216

In vivo quantification of intra-cortical porosity in human cortical bone using HR-pQCT in patients with type II diabetes, M309

**POSSIBLE EU®**

Prospective observational study of osteoporosis medication use in postmenopausal women in the European Union, SU347

**POSSIBLE US™**

Correlates of osteoporosis treatment persistence for patients new to therapy and patients with recent switches, M375

Gastrointestinal side effects in postmenopausal U.S. women on osteoporosis therapies, SU417

Medication switching in postmenopausal women on osteoporosis, M376

**Postmenopausal Evaluation and Risk-reduction with Lasofoxifene (PEARL) Trial**

Effects of LASO on bone turnover markers, 1287

**Potassium bicarbonate (KHCO<sub>3</sub>)**

Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

Impact of dietary protein on Ca homeostasis and nitrogen excretion in the presence and absence of KHCO<sub>3</sub>, SU305

**PP1c**

Point mutation of endofin at PP1c-binding domain induces angiogenesis and bone formation in mice by sensitizing BMP signaling, 1082

**Preference satisfaction questionnaire (PSQ)**

Development, reliability, and validity of a new PSQ, SA417

**Pregnancy**

Advancing maternal age is associated with lower peak BMD in the male offspring, M327

Background UVB exposure in pregnancy and skeletal development in childhood, 1104

Late pregnancy serum Vitamin D and longitudinal bone loss during pregnancy, F544

Maternal nutrient restriction during pregnancy results in significant alterations in fetal skeletal development in the baboon, M494

Pregnancy upregulates duodenal Ca-transport genes and normalizes Ca homeostasis in *Vdr* null mice, M230

Suboptimal Vitamin D status in pregnant adolescents is associated with neonatal Vitamin D insufficiency, F557

**Preosteoblast cells**

Osteonin increases the levels of intracellular Ca of human preosteoblast cells in culture, SU051

**Primary Care Osteoporosis Risk of Fracture Screening (POROS) Study**

Baseline characteristics of women taking part in an osteoporosis intervention, SU370

**Procollagen I N-terminal propeptide (PINP)**

Changes in serum PINP in orchidectomized osteopenic rats treated with PTH and ALN, M295

PINP, a new available rat bone formation marker: usefulness in osteopenia studies due to androgen lack and IBN treatment, SA299

## Key Word Index

## ASBMR 30th Annual Meeting

Relationship of bone turnover marker (PINP) and changes in femoral neck BMD to fracture risk in women with postmenopausal osteoporosis treated with once-yearly ZOL 5 mg, 1027  
Serum PINP is a sensitive marker of bone formation in mouse OVX model, M293

**Progenitor cells**

Use of endothelial progenitor cells to promote bone healing, SA104  
Use of GFP reporters to map the progression of multipotential progenitor cells into the osteoblast lineage, SU053

**Progenitor cells, multilineage (MLPC)**

Synergistic activation of osteogenesis in MLPC by oxysterols, SU038

**Progesterone**

Augmentation of PBM occurs in female and male mice without progesterone nuclear receptors, F249

**Progressive diaphyseal dysplasia. See Camurati-Engelmann disease****Prolactin**

Evidence for a role of prolactin in Ca homeostasis: regulation of intestinal TRPV6 and intestinal Ca absorption by prolactin, 1223

**Proline/arginine-rich end leucine-rich repeat protein (PRELP)**

Matrix PRELP interferes with the NF- $\kappa$ B pathway and impairs osteoclast formation and activity, SU089

**Prolyl 3-hydroxylase 1 (P3H1)**

Hotspot splicing mutation in *LEPRE1* affects P3H1 and causes recessive OI, SU215  
P3H1 and CRTAP are mutually stabilizing in the endoplasmic reticulum collagen prolyl 3-hydroxylation complex, 1049

**Prostaglandin**

Prostaglandins enhance extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity in osteoblast-like cells, SU031

**Prostaglandin D<sub>2</sub> (PGD<sub>2</sub>)**

Implication of PGD<sub>2</sub> in the birth and death of human osteoclasts, SU095  
PGD<sub>2</sub> downregulates MMP-1 and MMP-13 expression in human OA chondrocytes, SA152

**Prostaglandin E (PGE)**

PGE receptor EP4 antagonist attenuates growth and metastases of cancer, 1230

**Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>)**

HDAC inhibitors suppress IL-1 $\beta$ -induced NO and PGE<sub>2</sub> production in human chondrocytes, SU116  
Mechanism of BMP-2 enhancement of PGE<sub>2</sub> stimulated osteoclastogenesis, SU085  
Nanotechnological scaffold with combination of PGE<sub>2</sub> receptor EP4 agonist and rhBMP2, enhances bone repair in the defect of mouse calvarium bone, SA105  
PGE<sub>2</sub> as a potential mediator of PTH-dependent regulation of HSCs, F171  
Transcriptional regulation of Cx43 by  $\beta$ -catenin, a pathway activated by PGE<sub>2</sub>-PI3K-GSK3 signaling in mechanically loaded osteocytes, 1042

**Prostate**

1,25(OH)<sub>2</sub>D<sub>3</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in regulating cellular proliferation in cultured normal human keratinocytes and transformed prostate cells, M215

**Prostate cancer. See Cancer****Proteasome**

Bzb, a proteasome inhibitor, prevents metastatic breast cancer osteolysis and reduces mammary fat pad tumor growth in mice, F277

Proteasome inhibition counteracts the negative effect of GC treatment on bone metabolism by stimulating osteoblasts and inhibiting osteoclasts in vitro, SA231

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

**Protein disulfide isomerase A3 (PDIA3)**

Silencing of PDIA3 (ERp60) reduces the rapid membrane response to 1,25(OH)<sub>2</sub>D<sub>3</sub> in MC3T3-E1 osteoblast-like cells, M227

**Protein hydrolyzate**

Protein hydrolyzate directly modulates the expression of GIP by osteoprogenitor cells, SU010

**Protein inhibitor of activated STAT3 (PIAS3)**

PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts, F079

**Protein kinase A (PKA)**

Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060

hPTHrP 1-36 stimulates PKA-dependent phosphorylation and nuclear translocation of  $\beta$ -catenin in neonatal mouse calvarial bone cells, F032

PTH induces COX-2 in MC3T3-E1 osteoblasts via cAMP-PKA and Ca-calcineurin pathways, SA033

Role of pyrophosphate and inorganic phosphate in PKA-mediated osteoblastic differentiation and mineralization of primary murine aortic cells, M143

**Protein kinase C (PKC)**

Inhibitory role of G $\alpha$ /PKC $\delta$  signal in the bone anabolic action of PTH, 1228

Permanent FGFR2 activation promotes osteoblast differentiation in MSCs through activation of PKC signaling, M093

PKC $\delta$  is important for acidification of the lysosomes and resorption lacuna in osteoclasts, M124

**Protein kinase C $\alpha$  (PKC $\alpha$ )**

P2X<sub>7</sub> receptor activation mediates PKC $\alpha$  translocation in osteoblasts through alteration in actin cytoskeletal organization, SU040

**Protein kinase C $\delta$  (PKC $\delta$ )**

FGF-2 signaling in osteoblasts: Cx43 is a docking platform for PKC $\delta$ , F026

**Protein kinase D (PKD)**

PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027

**Protein tyrosine phosphatase (PTP)**

Identification of the regulatory mechanism(s) of PTP-PEST associating with the sealing ring formation and bone resorption in osteoclasts, SU065

**Proteinase-activated receptor-2 (PAR-2)**

PAR-2 activation induces bone resorption via RANKL upregulation in human OA subchondral bone osteoblasts, M018

**Proteoliposomes**

Proteoliposomes carrying ALP and NPP1 as matrix vesicle mimetics, SA061

**Proton pump inhibitors**

Gastric proton pump inhibitors failed to affect bone resorption and formation, SA095

**Pseudohypoparathyroidism (PHP)**

Hypothyroidism and autism combined with PHP in the absence of Albright's hereditary osteodystrophy and *GNAS* imprinting changes, SA259

**Psoriasis**

BMD and body composition in postmenopausal women with psoriasis and psoriatic arthritis, SU337

**Psoriatic arthritis. See Arthritis****PTEN**

VEGF and PTEN regulate bone homeostasis via control of osteoblastogenesis, osteoclastogenesis and adipocyte differentiation, M029

**PTH and Alendronate Comparative Efficacy****(PACE) Study**

Active controlled, non-inferiority study to compare the effect of ZT-031 with ALN on the incidence of new vertebral fractures, M347

**PTH/PTHrP receptor (PPR)**

Target ablation of PPR in osteocytes induces hypocalcemia and impairs bone structure, 1158

**PU.1**

LPS suppresses RANK gene through the down-regulation of PU.1 and MITF, SU083

**Puberty, delayed**

Path analysis (structural equation modeling) and covariation of bone traits following delayed puberty, SA543

**Pulmonary disease, chronic obstructive (COPD)**

Acute COPD exacerbations are associated with uncoupling of bone resorption from bone formation, M414

**PVQEET<sup>559-564</sup>**

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, 1118

**PVQEQQ<sup>604-609</sup>**

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, 1118

**Pyk-2**

Mice deficient in Pyk-2 have impaired OVX-induced bone resorption, F098

**PYK2**

BMP-6 stimulated osteogenesis of HOB cultures is associated with suppression of PYK2, SU048

**Pyrophosphates**

Pyrophosphates stimulates osteoclast differentiation and bone resorption, SA084

Role of pyrophosphate and inorganic phosphate in PKA-mediated osteoblastic differentiation and mineralization of primary murine aortic cells, M143

**Q****Q-GWUS. See Ultrasound****Qualeffo-41**

Vitamin D deficiency is associated with diminished quality of life based on Qualeffo-41 questionnaire analysis, SU424

**Quality of life, health-related**

Association between falls and health-related quality of life, SU420

**Quantitative computed tomography (QCT). See Computed tomography****Quantitative trait loci (QTL)**

Epistasis between QTLs for bone density variation in Copenhagen X Dark Agouti F2 rats, M253

Geometric property QTLs in HcB/8 x HcB/23 F2 cross, F260

Mouse-to-human strategy to identify bone strength QTL genes, SA120

Recalculation of genome scans on a common genetic map enhances our ability to identify common bone density QTL in new and historical data, 1276

**Quantitative ultrasound (QUS). See Ultrasound****Quartz crystal microbalance (QCM)**

Human osteoprogenitor cell adhesion and spreading on functionalized Ti surfaces followed by QCM and CLSM, SA101

**Quercetin**

Antioxidants (phytoestrogens and quercetin) are potential agents against RA, SA487

High concentrations of hydroxytyrosol and quercetin antioxidants enhance adipogenesis and inhibit

osteoblastogenesis in MSCs, SA037

**Quiescent osteoclast precursors (QOP)**

Cell cycle-arrested QOP are cells committed to the osteoclast lineage, SU098

**R****R-Smad**

TGF $\beta$  inhibits BMP signaling and osteogenesis through the TGF $\beta$  and BMP R-Smad direct interaction, 1080

**R-spondin 1**

R-spondin 1 reduces bone loss in human TNF transgenic and OVX mice, 1215

**R-spondin 2**

R-spondin 2 is a novel osteogenic factor required for Wnt11 mediated osteoblast differentiation, SU063

**R0**

Long-acting PTH ligand that binds to a distinct PTH receptor conformation (R0) can stimulate increases in markers of both bone resorption and bone formation in mice, F221

**R206H**

Hypoxia promotes ligand-independent activation of the ACVR1 (R206H) mutant receptor in C2C12 cells, M243

**R740S**

R740S, a dominant V-ATPase  $\alpha 3$  mutation, causes osteopetrosis in mice, 1218

**Rab18**

Proteomic identification and characterization of the small GTPase Rab18 in human osteoclasts, SU109

**Rac**

Dock5, an essential Rac exchange factor in osteoclasts that controls adhesion structure organization and bone resorbing activity, SU064

Rac 1 and 2, in combination, mediate osteoclast function and survival, 1220

**Radiation therapy**

Combined Cs-137 gamma irradiation and hindlimb unloading rapidly decreased cancellous bone volume fraction in the mouse lumbar vertebrae, M469

Combined effects of irradiation and unloading on murine bone, 1295

Degradation of allograft bone quality by gamma irradiation is not explained by altered enzymatic or non-enzymatic cross-links, M460

Detrimental effects of abdominal irradiation on the skeleton in growing mice, M412

Musculoskeletal disuse worsens the acute detrimental effects of heavy particle radiation on osteoblastogenesis, SA517

Radiation-induced bone loss: description of dose, time course, age, strain and sex variables, SU368

RIS prevents early radiation-induced bone loss at multiple skeletal sites, 1066

**Radiation, ultraviolet (UV)**

Vitamin D (cholecalciferol) production does not increase linearly with UV dose, M226

**Radiogrammetry, digital x-ray**

ALN treatment in postmenopausal Romanian women followed by BMD-digital x-ray radiogrammetry, M357

**Radiographic texture analysis (RTA)**

RTA of densitometric calcaneal images differs between subjects with and without GC use, M314

**Radioiodine**

Body composition changes after radioiodine treatment of hyperthyroidism, M433

**Radiomorphometry**

Correlations between panoramic radiomorphometric indices and BMD in postmenopausal women, SA311

**Radiotherapy**

Inhibition of MM growth and preservation of bone with combined radiotherapy and anti-angiogenic agent, SA285

**Radius**

Deleterious effect of late menarcheal age on bone microstructure in both distal radius and tibia, 1239

FEA performed on radius and tibia HR-pQCT images provides new insights for fracture status assessment, 1067

Microstructural changes at the ultradistal radius in MGUS, SU238

**Raf**

Vinculin is involved in hypertrophic differentiation through Raf/MEK/ERK pathway in chondrocytic ATDC5 cells, SA119

**Raloxifene (RLX)**

Assessment of adherence to treatment of osteoporosis with RLX and/or ALF in postmenopausal Japanese women, M387

Effect of RLX and ALF on bone and joint pain assessed by fall of skin impedance (electroalgotometry), SA384

Effect of RLX treatment on BMD might be influenced by UGT1A1\*28 polymorphism, M257

Effects of ALN and RLX on the RANKL/OPG system in primary cultures of human osteoblasts, M101

HSA for RLX treatment in Japanese women with osteoporosis, SA419

RLX ameliorates detrimental collagen cross-link formation in bone from an OVX rabbits with or without

hyperhomocysteinemia, SA382

Safety and effectiveness profile of RLX in long-term prospective observational study, M385

**RAMP2**

c-Src-regulated osteoblast-mimicry in breast cancer bone metastasis: the role of RAMP2 and BSP2, M275

**Rancho Bernardo Study**

Albuminuria, 25(OH)D, 1,25(OH) $_2$ D, and intact PTH in older adults, SU442

Incident vertebral fracture is predicted by prevalent vertebral fracture as identified by the algorithm-based qualitative method, but not by non-osteoporotic short vertebral height, 1128

Lean body mass is a better predictor of BMD than leg power or grip strength in healthy caucasian adults, SU290

**RAP-011**

Activin A mediates MM bone disease which is reversed by RAP-011, a soluble activin receptor, 1231

**Rap1**

PTH/PTHrP mediated stimulation of osteoblast differentiation involves Epac-Rap1 dependent processes, SA025

Small G protein Rap1 promotes osteoblast differentiation, M080

**RAW**

Isoform-specific expression of PPARs and gene regulation during osteoclastogenesis in RAW/C4 cells, M118

**Receptor activator of nuclear factor- $\kappa$ B (RANK)**

In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, 1009

CXCL13 stimulates RANK ligand expression in SCC, SU247

Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SOST* (sequestosome 1), SU210

Injection of MSCs overexpressing both CXCR4 and RANK-Fc effectively prevented OVX-induced bone loss, F391

LPS suppresses RANK gene through the down-regulation of PU.1 and MTF, SU083

Novel role of L-Ser for the activation of RANKL-RANK signaling machinery in osteoclastogenesis in vitro, SA082

OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

Suppression of TREM-2 expression and TREM-2-mediated costimulation of RANK signaling by cytokines that inhibit human osteoclast differentiation, SU114

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, 1118

**Receptor activator of nuclear factor- $\kappa$ B ligand (RANKL)**

1,25(OH) $_2$ D $_3$  can directly induce osteoclast formation in osteoclast precursors in the absence of RANKL, SU070

In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, 1009

Brain-type creatine kinase is required for RANKL-induced osteoclastogenesis, M116

CED: a unique variant featuring a novel, heterozygous, leucine repeat mutation in *TGF $\beta$ 1* together with a novel, homozygous, missense change in *TNFSF11* encoding RANKL, F256

Effect of Sr<sup>2+</sup> on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

Effects of ALN and RLX on the RANKL/OPG system in primary cultures of human osteoblasts, M101

**Receptor activator of nuclear factor- $\kappa$ B ligand, soluble (sRANKL)**

Effects of intermediate doses of GCs on bone turnover and circulating Dkk-1, MIF, sRANKL and OPG in patients with interstitial lung disease, SA451

Establishment of a murine model of HCa by overexpression of sRANKL using an adenovirus vector, SU082

**Receptor activator of nuclear factor- $\kappa$ B ligand (RANKL)**

Estrogen suppresses RANKL-induced osteoclastic differentiation of human monocytes via an ER $\alpha$  associated cytoplasmic signaling complex, but ER $\alpha$  is downregulated during osteoclastic differentiation, 1125

FGF-2 stimulates RANKL expression in PDB, F480

GILZ promotes osteoblast development and modulates RANKL/OPG levels, M049

High dose of RANKL rescues integrin  $\alpha_v$ -osteoclast phenotype, F081

Hormonal control of RANKL expression is independent of Runx family proteins: evidence that commitment to the osteoblast lineage is not a requirement for the stromal cells that support osteoclast differentiation, SU047

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

Increased osteoclasts in Brl mouse model for OI are independent of decreased osteoblast matrix production and RANKL/OPG ratio, but are associated with increased osteoclast precursors in marrow, SU209

Inhibition of lamin A/C attenuates osteoblast differentiation and stimulates osteoclastogenesis through enhanced RANKL signaling, M070

LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

MEK5/ERK5 signal regulates RANKL-induced osteoclastogenesis, SU103

Modeled microgravity sensitizes osteoclast precursors to RANKL mediated osteoclastogenesis by increasing DAP12, M114

Neutrophil-like PLB-985 cells induce differentiation of human blood monocytic precursors into functional osteoclasts via a RANKL-dependent mechanism, SA092

## Key Word Index

## ASBMR 30th Annual Meeting

Novel role of L-Ser for the activation of RANKL-RANK signaling machinery in osteoclastogenesis in vitro, SA082

PAR-2 activation induces bone resorption via RANKL upregulation in human OA subchondral bone osteoblasts, M018

PIAS3 negatively regulated RANKL-mediated osteoclastogenesis directly in osteoclast precursors and indirectly via osteoblasts, F079

RANKL induces Ca channel activation in human osteoclasts, SU107

RANKL suppression by siRNAs in rat primary osteoblasts, M032

RANKL-mediated osteoclast lineage commitment dictates the role of LPS in osteoclast differentiation, SA088

RANKL/OPG in primary cultures of osteoblasts from patients with osteoporotic hip fractures, SU009

Recovery of bone architecture after RANKL administration in rats is characterized by increased bone mass on existing trabeculae assessed by in vivo  $\mu$ CT, SU076

Reduced osteoclastogenesis and RANKL expression in marrow from women taking ALN, SU400

Rheumatoid synoviocytes are stimulated with IL-23 to enhance osteoclastogenesis through upregulation of RANKL expression, SU084

Role of OPG/RANKL system for bone loss in PHPT, M192

S100 protein directly and indirectly affects RANKL-stimulated osteoclastogenesis, SA090

Sim induces Wnt signaling and reduces CSF-1 secretion and RANKL/OPG ratio to block osteoclast differentiation, SU096

Transactivation of RANKL by C/EBP $\beta$  and C/EBP $\delta$  in adipocyte lineage cells, SU092

**Receptor for advanced glycation endproducts (RAGE)**

Over-expression of RAGE prevents OVX-mediated bone loss in CD1 mice, M132

**Receptor transporting protein 3 (RTP3)**

GWAS identified RTP3 as a novel gene for bone strength, SU331

**Receptor-like protein tyrosine phosphatase  $\mu$  (RPTP $\mu$ )**

In bone, RPTP $\mu$  is exclusively expressed in osteocytes and may affect bone mass, SA052

**Recombinant adeno-associated virus (rAAV)**

Biological activation of biomaterials by rAAV vector, SU136

**Recombinant human platelet-derived growth factor BB (rhPDGF-BB)**

Percutaneous injection of GEM OS2 increases vertebral BMD in geriatric female baboons, F376

Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, I137

**Renal function**

Behavior of circulating rat(s) PTH molecular forms in HPT2 related to Vitamin D deficiency and renal failure, M194

c-Fos is associated with renal FGF-23-mediated signaling, SU173

HPT and renal insufficiency, WG29

MEPE regulates bone remodelling independent of serum phosphate and alters renal vascularization, F205

New data on the impact of renal function on the relationship between 25(OH)D and PTH, I031

Pediatric Crohn's Disease is associated with negative Ca balance and increased renal losses of Ca, SA565

Reduced renal function is associated with increased rates of bone loss at the hip and spine, SU357

Regulation of renal Klotho: the importance of ER $\alpha$ , SA211

Renal leak hypercalciuria: a potential cause of tertiary hyperparathyroidism, M430

Renal safety across a wide range of dosing regimens of RIS, SA402

Serum uOC concentration are related to renal function in type 2 diabetes patients, M443

Signaling of extracellular inorganic phosphate mediated via Na-phosphate co-transporters influences FGF-23 signaling in renal tubular cells, SU172

**Resveratrol**

Effect of resveratrol and flax oil on MC3T3-L1 pre-adipocyte and ST2 BMSC proliferation and differentiation, SU059

Mechanism of action of the anti-aging agent resveratrol on bone, I136

**Retinoblastoma binding protein-1 (RBP1)**

RBP1 is critical for Runx2 expression, transcriptional activity and nodule formation in osteoblasts, M037

**Rheumatism**

Acute phase response and bone metabolism marker after intravenous bisphosphonate in osteoporotic patients with rheumatism, M364

**Rheumatoid arthritis (RA). See Arthritis**

**RhoA**

P2Y<sub>2</sub> receptor activation regulates RhoA-mediated stress fiber formation in osteoblasts, SA035

**RhoB**

Identification of RhoB as a key target involved in cell motility and bone metastasis, F291

**RhoGTPases**

Silencing of RhoGTPases counteract microgravity-induced effects on osteoblasts, SA011

**Ribonucleic acid interference (RNAi)**

Allele specific silencing of Collagen 1 Alpha genes in primary human bone cells using RNAi, M232

**Ribonucleic acid, messenger (mRNA)**

DKK1 is regulated by mRNA stability and epigenetic mechanisms in bone metastasis, I090

In vivo downregulation of *Mustn1* mRNA leads to musculoskeletal defects, I192

**Ribonucleic acid, micro (miRNA)**

Possible physiological function of menin protein as transcriptional factor that modulates miRNA expression during osteogenesis, M036

Program of miRNAs control BMP-2 induced bone phenotype development, M090

Regulation of osteoblast differentiation by miRNA, M087

Regulation of osteonectin/SPARC by miRNA-29, I155

**Ribonucleic acid, short hairpin (shRNA)**

Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009

**Ribonucleic acid, small interfering (siRNA)**

RANKL suppression by siRNAs in rat primary osteoblasts, M032

**Ribonucleoproteins, heterogeneous nuclear (hnRNP)**

Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240

**Rickets**

Effect of Vitamin D<sub>2</sub> and Vitamin D<sub>3</sub> on intestinal Ca absorption in Nigerian children with rickets, SA560

Prevention of nutritional rickets in Nigerian children with dietary Ca supplementation, M491

Rare cases of XLH rickets/osteomalacia mimicking ARHR/osteomalacia, F469

**Rickets, autosomal recessive hypophosphatemic (ARHR)**

Late presentation of ADHR, WG31

Rare cases of XLH rickets/osteomalacia mimicking ARHR/osteomalacia, F469

**Rickets, hypophosphatemic**

Mechanical unloading partially rescues hypophosphatemic rickets in *Dmp1*-null mice, I162

Screening the PHEX gene in a large cohort of hypophosphatemic rickets allowed the description of a missense mutation not responsible for the disease on a highly conserve amino acid residue, M246

**Risedronate (RIS)**

Chemical composition and nanoscale structure of RIS-treated mineralizing MC3T3-E1 cells, M023

Continued evidence for safety and efficacy of RIS in men with osteoporosis, M360

Cost-effectiveness of RIS versus IBN at one year: the case of the United Kingdom, SA424

Cost-effectiveness of RIS versus IBN at one year: the case of Germany, SA425

Cost-effectiveness of RIS vs. generic ALN, SA423

Effect of a single 5-mg infusion of ZOL on bone turnover markers versus oral RIS (5 mg/day) over 1 year in patients with GIO, M362

Effect of a single infusion of ZOL 5 mg versus oral RIS 5 mg on BMD at lumbar spine, hip, femoral neck and trochanter in patients with GIO, F403

Effect of RIS in liver transplantation patients with low bone mass, SA503

Effect of RIS on bone density in HSC transplant patients, SU407

Effect of RIS on bone strength and work to failure determined by FEA and simulation of clinically-measured bone loss and mineralization changes, SA505

Effect of RIS on osteocyte viability in paired biopsies from early postmenopausal women, M420

Effect of ZOL (single 5-mg infusion) on lumbar spine BMD versus oral RIS (5 mg/day) over 1 year in subgroups of patients receiving GC therapy, M363

Effects of Vitamin K2 and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385

Fracture reduction during two years of treatment with RIS or ALN, SA404

Improved bone mass after co-administration of Sr ranelate and RIS in a rat model of osteoporosis using "in-vivo"  $\mu$ CT, SU393

Improvement in quality of life among women treated with RIS, SU414

Long term safety of oral RIS treatment in men with osteoporosis as assessed by histomorphometry, SA344

Modeled cost-effectiveness of RIS versus IBN: the case of Italy, SA427

Once-a-month RIS 150 mg reduced vertebral fracture risk at one year in a historical control analysis, SU403

Prior treatment with Vitamin K<sub>2</sub> significantly improves the efficacy of RIS, SA379

Renal safety across a wide range of dosing regimens of RIS, SA402

RIS has a more rapid onset of remodeling suppression than ALN in rabbit vertebral trabecular bone, SU387

RIS prevents early radiation-induced bone loss at multiple skeletal sites, I066

Studying cellular uptake and distribution of bisphosphonate in vivo using fluorescently-labelled analogues of RIS, I065

**RNA. See Ribonucleic acid**

**Roche Elecsys (ELEC)**

Analytical validation of LIA and ELEC methods for the determination of osteocalcin, SA191

**Ronacaleret**

Bone-building effects of the oral CaSR antagonist, ronacaleret, in OVX rats, SU372

Ronacaleret, a novel CaSR antagonist, demonstrates potential as an oral bone-forming therapy in healthy postmenopausal women, I174

**ROS**

Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009

**Rosiglitazone**

Rosiglitazone-induced change in BMD among African Americans with type 2 diabetes mellitus or impaired glucose tolerance, SU315

**Rsl1**

Expression of an engineered G<sub>s</sub>-coupled receptor, Rsl1, in mature osteoblasts is sufficient to drive a dramatic anabolic skeletal response, 1077

Ligand activation of the engineered G<sub>s</sub>-coupled receptor Rsl1 in osteoblasts promotes trabecular bone formation, 1076

**RsaI**

RsaI polymorphism in ESR2 is associated with postmenopausal fracture risk, SU221

**Runx**

Hormonal control of RANKL expression is independent of Runx family proteins: evidence that commitment to the osteoblast lineage is not a requirement for the stromal cells that support osteoclast differentiation, SU047

**Runx2**

BMD-associated SNP lies in a Runx2 binding site of the LRP5 promoter, M264

Craniofacial bone defect in Nell-1 mutant mice associated with dysregulated Runx2 and Osx expression, F174

Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109

Ectopic Runx2 expression disrupts normal acini structure in mammary epithelial cells, F279

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

Functional association of MAPK and Runx2 on osteoblast chromatin, SU025

Ghrelin inhibits early osteogenic differentiation of C3H10T1/2 cells by suppressing Runx2 expression and enhancing PPAR $\gamma$  and C/EBP $\alpha$  expression, M086

Icariin induces osteogenic differentiation in vitro in a BMP- and Runx2- dependent manner and bone regeneration in vivo, M089

Induction of Runx2 and Osx by bisphosphonate promote osteogenic differentiation, SU062

MEPE expression is regulated by BMP-2 signaling through the activation of its downstream transcription factors, Dlx3, Dlx5 and Runx2, SA064

Non-genomic estrogen receptor Gpr30 is a Runx2 responsive gene that is required for osteoblast proliferation, F572

PKD regulates HDAC7 localization and interaction with Runx2 during BMP-2-stimulated osteogenesis, SU027

PTHrP prevents chondrocyte premature hypertrophy by inducing cyclin D1-dependent Runx2 and 3 phosphorylation and degradation, 1044

RBP1 is critical for Runx2 expression, transcriptional activity and nodule formation in osteoblasts, M037

Regulation of RUNX2 at the nuclear lamina, M055

Regulation of Runx2 function in osteoblasts by sex steroid receptors, M099

Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043

Runx2 threshold for the CCD phenotype, M041

T-box 3 negatively regulates osteoblast differentiation by inhibiting expression of Osx and Runx2, SU018

TGF $\beta$  and Smad3-dependent repression of Runx2 function in ATDC5 chondrocytes, SU122

TIEG: a key regulator of Runx2 and Osx gene expression and osteoblast differentiation, M052

TNF $\alpha$  and IL-1 $\beta$  stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

Transcriptional activation of osteocalcin by Runx2 during osteoblast development is controlled at the post-translational level, M031

Trps1 represses Runx2 during endochondral bone formation, SU126

Wdr5 is required for chromatin modifications at the Runx2 promoter, M039

**Runx3**

PTHrP prevents chondrocyte premature hypertrophy by inducing cyclin D1-dependent Runx2 and 3 phosphorylation and degradation, 1044

**S****S100**

S100 protein directly and indirectly affects RANKL-stimulated osteoclastogenesis, SA090

**Saliva**

Bone resorption markers in saliva, M288

**Salt**

Effects of KHCO<sub>3</sub> on Ca and bone metabolism during high salt intake, SA446

**SAMP6**

ALF ameliorates bone dynamics in senescence-accelerated SAMP6 mice and in fracture repair rat model, SU394

**Sarcoidosis**

Nonsteroid responsive HCa associated with sarcoidosis—a rapid response to hydroxychloroquine, WG28

**Sarcoma, osteogenic**

Transcriptional silencing of Frzb/sFRP3 by promoter methylation in osteogenic sarcoma, SU231

**Sarcopenia**

Shared genetics within the musculoskeletal system: a pleiotropic approach to osteoporosis and sarcopenia, WG2

**SATB2**

SATB2 overexpression promotes osteoblast differentiation and enhances regeneration of bone defects, SU058

**Schmorl's Node**

To avoid underdiagnosis of vertebral fracture, recognition of true fracture line including multiple Schmorl's Node is necessary, SA324

**Sciatic denervation**

Alteration of trabecular bone architecture following sciatic denervation and subsequent reinnervation in rat proximal tibiae, SA513

**Scl-Ab. See Anti-sclerostin monoclonal antibody****Sclerosis, aortic valve**

Relationship between low bone mass and aortic valve sclerosis in Korean men and women, SU452

**Sclerostin (SCT)**

30IT/C of SCT modulates BMD by Wnt and estrogen signaling pathways, 1270

Calcitonin attenuates the anabolic effect of PTH in vivo and rapidly upregulates SCT expression, F195

Expression of human SCT in heterologous eukaryotic insect and *E. coli* expression systems, SA059

Immunohistochemical localisation of SCT in human trabecular bone from fragility hip fracture patients, SA148

LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

Proinflammatory cytokine TWEAK induces SCT expression in human immature osteoblasts in a MAPK dependent fashion, M046

Widespread expression of SCT in adult and embryonic cartilage and bone, cells of the developing central nervous system and epithelia of the embryonic kidney and intestine, SA055

Wnt/LRP5-independent inhibition of osteoblastic cell differentiation by SCT, 1256

**Scoliosis**

Conditional deletion of fibronectin results in a scoliosis-like phenotype, 1046

 **$\gamma$ -secretase**

Notch pathway is activated in osteosarcoma and inhibitors of  $\gamma$ -secretase inhibit osteosarcoma growth by cell cycle regulation, SU229

**Secreted frizzled-related protein 1 (sFRP1)**

Overexpression of sFRP1 inhibits bone formation and attenuates PTH bone anabolic effects, 1100

**Secreted frizzled-related protein 4 (sFRP4)**

Deletion of the Wnt signaling antagonist sFRP4 in mice induces opposite bone formation phenotypes in trabecular and cortical bone, 1005

**Sensorimotor nerves**

Poor peripheral sensorimotor nerve function is associated with high fall risk, SU323

**Sequestosome 1**

Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SOSTM1* (sequestosome 1), SU210

**Ser1386Pro**

Mouse with a Ser1386Pro mutation in the C-propeptide domain of *col2a1* provides a model for SEDC, 1269

**SERM**

Bone tissue quality is differently altered by PTH, bisphosphonates and SERMs, SA510

**Serotonin**

Brain-derived serotonin positively regulates bone mass accrual, SA463

Gut-derived serotonin is an inhibitor of bone formation, M069

**Serum ionic fluoride (SIF). See Fluoride****Serum level of  $\gamma$ -glutamyltransferase. See  $\gamma$ -glutamyltransferase****Severe suppression of bone turnover (SSBT).**

See *Bone turnover*

**Sex hormone-binding globulin (SHBG). See Globulin****Sexual dimorphism**

Crosstalk between androgen receptor and Wnt signaling mediates sexual dimorphism during bone mass accrual, 1121

**Sfrp2**

Brachy-syndactyly caused by loss of *Sfrp2* function, F118

**SH2**

Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026

**SH3**

Deficiency of NCK1, an actin cytoskeletal modulator with SH2/SH3 motifs, induces bone loss via suppression of bone formation and induction of biochemical high bone turnover state, M026

**Shh**

Osteoblast differentiation induced by Shh-expressing prostate cancer cells is enhanced by ascorbic acid, SA284

Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, 1089

**SHP-1**

Lyn, opposite to c-Src, negatively regulates osteoclastogenesis in vitro and in vivo via its interaction with SHP-1 and Gab2, 1119

## Key Word Index

## ASBMR 30th Annual Meeting

**SHP-2**

Age-related impairment of IGF-I receptor activation is associated with changes in integrin and SHP-2 expression, M096

**shRNA. See Ribonucleic acid****Sickle cell disease**

BMD in children and adolescents with sickle cell disease, SU217

**Signal transducer and activator of transcription 1 (STAT1)**

Accelerated fracture callus remodeling and membranous bone healing in STAT1 deficient mice, SA022

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

INF $\gamma$  attenuates BMP-2 signaling via Stat-1 binding of Smad4 in the cytoplasm, SU139

**Signal transducer and activator of transcription 3 (STAT3)**

Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, 1089

**Silicon, porous (PSi)**

Towards development of a PSi-based hybrid biomaterial with osteoconductivity and osteoinductivity, M028

**Silk protein**

(Ala-Gly) $_n$  sequences configured silk protein scaffold induces osteoblast differentiation and bone formation via increased Cbfa1 and Osx expression, M167

**Simvastatin (Sim)**

Sim induces Wnt signaling and reduces CSF-1 secretion and RANKL/OPG ratio to block osteoclast differentiation, SU096

**Sin3A**

Mab21 suppresses the osteogenic markers by recruiting Sin3A and stimulates osteoclast by up-regulation of IL-6 and LIF, SU022

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**Single nucleotide polymorphisms (SNP)**

BMD-associated SNP lies in a Runx2 binding site of the LRP5 promoter, M264

Differential regulation of gene expression by SNPs in the osteonectin/SPARC 3 untranslated region, M270

**siRNA. See Ribonucleic acid****SIRT-1**

Longevity gene *SIRT-1* independently controls both osteoblast and osteoclast function, 1098

**Sirtuin 1 (SIRT1)**

Calorie restriction prevents age-related trabecular bone loss via SIRT-1, 1251

SIRT1 is a regulator of MSC lineage allocation, M085

**Skeletal development**

Akt regulates skeletal development through GSK3, mTOR, and FoxOs, 1151

Background UVB exposure in pregnancy and skeletal development in childhood, 1104

Bone microarchitecture is dependent upon collagen  $\alpha 1$ (XI) expression during development, F135

Childhood cortical bone and skeletal age show bivariate genetic linkage to chromosome 2p, 1177

Connective tissue progenitor cell contribution to ectopic skeletogenesis, F044

Contribution of birth status, age at menarche and lifestyle factors to skeletal formation in junior and senior high school students, M492

Critical role of Cx43 in postnatal skeletal growth and bone mass acquisition, 1257

Critical role of TGF $\beta$  signaling pathways in skeletal development, 1079

Defining epistasis in a double congenic mouse: implications for the skeleton, M252

Detrimental effects of abdominal irradiation on the skeleton in growing mice, M412

Effect of the dietary Ca/P ratio on the rate of skeletal accrual in mice, M333

Effects of Pt group metals treatment on the bone of developing chick embryos, M141

Endogenous GC are critical for the development of skeletal fragility with aging in mice, 1250

Essential Hox gene function in limb skeletal and synovial joint formation, M151

GC signaling through osteoblasts is essential for cranial skeletal development, 1267

High-fat diet negatively regulates bone development in growing mice, SA441

Hypothyroidism is not deleterious to the skeleton during early fetal development, SA123

Increased maternal fat intake increases skeletal mass in congenic mice, M495

Maternal nutrient restriction during pregnancy results in significant alterations in fetal skeletal development in the baboon, M494

Mecp2 null mice display multiple skeletal abnormalities, M242

Mice lacking the GH receptor in liver have normal skeletal growth and bone volume despite virtual absence of circulating IGF-1, F181

Modulation of skeletal modeling by silica-based nanoparticles, SU014

Osx is required for skeletal growth and bone homeostasis after birth, 1074

PTHrP nuclear localization sequence and C-terminus regulate craniofacial development, 1264

Skeletal consequences of FHH and PHPT, M206

Skeletal dysmorphology of mice lacking the mid-region, nuclear localization sequence and C-terminus of PTHrP, 1160

ucOC is an endocrine link between the skeleton and the glucose metabolism, F444

In vivo downregulation of *MyoD* mRNA leads to musculoskeletal defects, 1192

**Skin abnormalities**

Identification of skin abnormalities in OI patients by MRI, SA561

**Skin color**

Effect of skin color and oral Vitamin D supplementation on serum 25(OH)D in adolescent girls, SU395

**SLC34A3**

Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471

**SLP-76**

SLP-76 couples Syk to the osteoclast cytoskeleton in vitro and in vivo, 1010

 **$\alpha$ -SMA-GFP**

Use of  $\alpha$ -SMA-GFP transgene to identify periodontium derived osteoprogenitors, SA040

**Smad**

BMP-2-stimulated signaling niche in osteoblasts comprising of Smad and PI3K/ Akt regulates NFATc1 expression and its nuclear translocation, 1081

Both the Smad and ERK MAP kinase pathway play critical roles in BMP-2-induced osteogenic transcription factors expression, M050

Dual roles of Smad proteins in the conversion from myoblasts to osteoblastic cells by BMPs, SA161

Induction of CTGF by TGF $\beta$ 1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066

**Smad1**

Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

**Smad3**

TGF $\beta$  and Smad3-dependent repression of Runx2 function in ATDC5 chondrocytes, SU122

**Smad4**

INF $\gamma$  attenuates BMP-2 signaling via Stat-1 binding of Smad4 in the cytoplasm, SU139

Negative regulation of Tcf/Lef-dependent transcription by the BMP/Smad4 signaling axis, SU144

**Small integrin-binding ligand N-linked****glycoproteins (SIBLING)**

PHEX cleavage of SIBLING-ASARM peptides as a mechanism underlying osteomalacia in XLH, 1199

**Small leucine-rich proteoglycans (SLRP)**

Anti-myeloma effects of osteoblasts is mediated through production of SLRPs, M001

**Smoking**

Bone loss with smoke exposure and Lrp5 expression, SA459

Genetic variation in *IL6* and *LRP5* is associated with osteoporosis in the Marshfield Clinic Personalized Medicine Project, SU365

LRP5 G171V mutation and tobacco smoke related bone fragility, M323

Smoking is an independent predictor of low BMD, prevalent vertebral fractures and incident fractures in elderly men, SU349

In vivo differential expression profiling study on human circulating B cells suggested a novel EGFR and CALM3 network underlying smoking and BMD, SU154

In vivo differential expression profiling study on human circulating monocytes suggested a novel CRAT and CPT2 network underlying smoking and BMD, SU155

**Smurf1**

Age-related bone loss in mice associated with ubiquitin ligase Smurf1 degradation of JunB protein and reduced osteoblast proliferation, 1113

JNK activation is involved in TNF $\alpha$ -stimulated Smurf1 expression, SA016

**Snail**

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

**Snapin**

Phex binds to SNARE-associated protein snapin and co-localizes in vesicle-enriched, extracellular matrix micro-environment mediating mineral crystal nucleation, F066

**SNARE**

Phex binds to SNARE-associated protein snapin and co-localizes in vesicle-enriched, extracellular matrix micro-environment mediating mineral crystal nucleation, F066

**Sodium (Na)**

Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471

Prostaglandins enhance extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity in osteoblast-like cells, SU031

Signaling of extracellular inorganic phosphate mediated via Na-phosphate co-transporters influences FGF-23 signaling in renal tubular cells, SU172

**Sodium N-[8-(2-****hydroxybenzoyl)amino]caprylate (SNAC)**

Comparison of the effects of IBN alone with IBN in combination with SNAC on bone density and bone strength in OVX rats, SU391

**Sost**

Deletion of *Mef2c* in osteocytes decreases *Sost* expression and increases bone mass, F054

**SOST**

PTH-induced bone mass gain is blunted but not abolished in *SOST* overexpressing and deficient mice, 1039

**SOST**

SOST blocks GSK3-beta inhibitor-induced ALP activity, SU036

**Southampton Womens Survey**  
Late pregnancy serum Vitamin D and longitudinal bone loss during pregnancy, F544

**SOX4**  
Role of the transcription factor SOX4 in the skeletal response to intermittent PTH, SA220

**Sox9**  
Targeted expression of SOX9 in hypertrophic chondrocytes leads to enhanced adipogenic activity and spontaneous OA in transgenic mice, SA115  
Transcription factor Znf219 regulates chondrocyte differentiation through forming transcription factory complex with Sox9, 1265  
Wnt target gene Twist1 inhibits Sox9, the master regulator of chondrogenesis, 1266

**Soy**  
Early exposure to soy isoflavones modulates bone mineral, strength and microarchitecture in CD1 mice, M503  
Evaluating the effect of soy and isoflavones on BMD in older women, M353  
Neonatal exposure to soy isoflavones attenuates deterioration of bone tissue in female but not male mice after cessation of sex steroid production, SU476  
Soy-based formula promotes bone growth in neonatal piglets by inducing osteoprogenitors to differentiate into osteoblasts via enhanced BMP-2 signaling, SA336

**Soy Phytoestrogen as Replacement Estrogen (SPARE) Study**  
Possible increased risk of fracture among South Florida White Hispanic women, M402

**Sp1**  
Cloning and functional expression of the full length mouse GIP receptor and the regulation of its expression in osteoblasts by the Sp1 transcription factor, SU026

**SPARC**  
Regulation of osteonectin/SPARC by miRNA-29, 1155

**SPARC 3**  
Differential regulation of gene expression by SNPs in the osteonectin/SPARC 3 untranslated region, M270

**SPARE Study.** See *Soy Phytoestrogen as Replacement Estrogen Study*

**Spectrometry, mass**  
Identification of osteoclast lysosomal proteins by mass spectrometry, SA077

**Spectrometry, tandem mass**  
25(OH)D levels in children with CKD as measured by tandem mass spectrometry, SU485

**Spectroscopy, confocal laser Raman**  
Kidney dysfunction disturbs collagen maturation in ABD as assessed by confocal laser Raman spectroscopy, SU439

**Spectroscopy, Raman**  
Mineralization potential and orientational aspects of osteogenic cell cultures by Raman spectroscopy, M084  
Non-invasive in vivo Raman spectroscopy in mice, SU480

**Sphingosine-1-phosphate (S1P)**  
Regulation of bone formation by osteoclasts involves Wnt/BMP signaling and the chemokine S1P, M017

**Spinal alignment**  
Influence of hip flexor or knee extensor muscle strength on spinal sagittal alignment or falls, SU454

**Spinal cord injury**  
Immediate abnormalities at the chondro-osseous junction due to severe spinal cord injury in growing rats, SA520

**SpinalMouse®**  
Usefulness of SpinalMouse® as a screening tool for the presence of vertebral wedge deformity, SA316

**Spine cancer.** See *Cancer*

**Spine, lumbar**  
Deformity of the distal radius fractures resulting from falls in Japanese women over 50 years of age is closely associated with BMD of the lumbar spine, SU286  
Differences in BMC at the lumbar spine and proximal femur in South American children of different ethnic groups, SU490  
Effect of ZOL (single 5-mg infusion) on lumbar spine BMD versus oral RIS (5 mg/day) over 1 year in subgroups of patients receiving GC therapy, M363  
Efficacy of single-level instrumented posterolateral (intertransverse) lumbar spinal fusion in baboons with BMP-7 putty, SU146  
Large scale candidate gene analysis identifies an association between the CDK6 locus and trabecular volumetric BMD at the lumbar spine in older men, M266  
Loss of function polymorphisms in the P2X<sub>7</sub> receptor gene are associated with accelerated lumbar spine bone loss in postmenopausal women, SU224  
Lumbar spine TBS complements BMD in the discrimination between vertebral fractured and non-fractured subject, M308  
Reduction of BMD in the patients with RA is more remarkable at proximal femur than at lumbar spine, SU451  
Relationship between BMD of the lumbar spine and knee OA in South Korean, SU298  
Safe zone for percutaneous extrapedicular surgical approach to the lumbar spine, M344

**Spondylitis, ankylosing (AS).** See *Ankylosing spondylitis*

**Spondylo-epi-metaphyseal dysplasia.** See *Dysplasia*

**Spondyloepiphyseal dysplasia congenita (SEDC)**  
Mouse with a Ser1386Pro mutation in the C-propeptide domain of *col2a1* provides a model for SEDC, 1269

**SQSTM1**  
Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SQSTM1* (sequestosome 1), SU210  
Large collaborative study on geographic variation of *SQSTM1* mutations in PDB in Italy, SA475

**SQSTM1**  
Two novel SQSTM1 mutations in American patients with PDB, SU216

**Squamous cell carcinoma (SCC).** See *Carcinoma*

**Src**  
Induction of CTGF by TGFβ1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066

## Key Word Index

## ASBMR 30th Annual Meeting

Reconstituting marrow-derived extracellular matrix *ex vivo*: an optimal niche for retaining the properties of human MSCs, M165

Regulation of osteogenesis by Wnt signaling in rat MSC and human ASC, SU045

Regulatory signaling pathways in BMP mediated osteogenesis of adult human MSC cultures, M060

SIRT1 is a regulator of MSC lineage allocation, M085

Telomerase deficiency leads to decrease bone mass and impaired MSCs functions in telomerase deficient (TERC<sup>-/-</sup>) mice, I147

TGFβ1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

Tissue-engineering and co-culture system based disc regeneration MSC's role, SA189

TNFα and IL-1β stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

Transient expression of CXC receptor 2 in human MSC stimulates chemotaxis toward CXC ligand 8 and increased mineralization in the presence of osteogenic medium, SA170

**Steroids**

1,25(OH)<sub>2</sub>D<sub>3</sub> is as effective as 1,25(OH)<sub>2</sub>D<sub>3</sub> in regulating cellular proliferation in cultured normal human keratinocytes and transformed prostate cells, M215

25(OH)D acts on Ca and skeletal homeostasis independent of 1,25(OH)<sub>2</sub>D *in vivo*, M214

25(OH)D<sub>3</sub>-24-hydroxylase (CYP24A1): mutagenesis and activity studies reveal important residues involved in regioselectivity and substrate access, SU199

Altered TNSALP expression and phosphate regulation contribute to reduced mineralization in mice lacking androgen receptor, SU181

Antipapoptotic action of 17β-estradiol in skeletal muscle cells involves ERK 1/2, p38 MAPK, ASK-1 and HSP27, SU185

Augmentation of PBM occurs in female and male mice without progesterone nuclear receptors, F249

Biochemical characterization of ERα co-regulators in multinucleated mature osteoclasts, I126

Cell type specific regulation of transcription by estrogen, SU180

Challenge of continuous exogenous GC administration in mice, M100

Characterization of interactions between the unliganded VDR and effectors of the canonical Wnt signaling pathway, I183

Cholesterol sensing receptors, Liver X receptor α and β, have novel and distinct roles in osteoclast differentiation and activation in bone, F085

Cooperativity between VDR and LIP in the regulation of TRPV6 identifies a novel function for LIP as a transcriptional activator, SU198

Crosstalk between androgen receptor and Wnt signaling mediates sexual dimorphism during bone mass accrual, I121

CYP27A1 mutations at Phe147 confer 25-hydroxylase activity towards a Vitamin D<sub>2</sub>-type sidechain, M231

DHT administration is effective for the prevention of hypogonadal bone loss, SU193

Differential cellular and molecular responses of intestinal epithelium to high Ca diet and 1,25(OH)<sub>2</sub>D<sub>3</sub>, M229

Distinctive anabolic roles of 1,25(OH)<sub>2</sub>D<sub>3</sub> in teeth and mandible versus long bones, M213

DNA demethylation for hormone-induced transcriptional derepression, I182

Effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> and 25(OH)D<sub>3</sub> on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207

Effect of 1α,25-dihydroxy Vitamin D3 on proliferation and differentiation of C2C12 myoblast, SA245

Effect of a dissociating GC receptor modulator on bone cells, SA232

Effects of ALF on bone and skeletal muscle in GC-treated rats, M219

Elevated androgens are associated with increased bone formation in premenopausal exercising oligomenorrheic women, SU191

ERα expression in mesenchymal cells is crucial for the bone protective effects of estrogen, I123

Estrogen suppresses RANKL-induced osteoclastic differentiation of human monocytes via an ERα associated cytoplasmic signaling complex, but ERα is downregulated during osteoclastic differentiation, I125

Estrogens reverse a potentiating effect of the unliganded estrogen receptor on BMP-induced transcription and osteoblastogenesis by promoting ERK-dependent Smad1 phosphorylation at the linker region, SU189

Ethanol alters estrogen receptor signaling and activates senescence pathways in osteoblasts while estradiol attenuates ethanol effects, SU182

Evaluation of automated methods for quantifying serum 25(OH)D, SU206

Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240

Expression of 1α-hydroxylase (CYP27B1) in BMSC, SA237

Expression of 11β-hydroxysteroid dehydrogenase during murine osteoclast formation, SA235

Expression of VDR in the developing zebrafish embryo, M220

GC signaling in osteoblasts maintains normal bone structure in mice, F233

Genetic model to study 1,25(OH)<sub>2</sub>D action in classical and non-classical target tissues, I184

Genetic variation of the SHBG gene, SHBG levels and bone parameters, SU188

Genetic variations in sex steroid-related genes as predictors of serum estrogen levels in men, SU183

Goettingen minipigs—a model for Ca/Vitamin D-deficiency osteomalacia and steroid-induced osteoporosis, SA445

High prevalence of Vitamin D insufficiency in a young adult population, M221

Improved motor performance in Vitamin D deficient mice with VDRMs, SU196

Involvement of caveolae in 1α,25(OH)<sub>2</sub>D<sub>3</sub>-dependent activation of MAPKs in skeletal muscle cells, SA243

Key mechanism underlying the immunosuppressive effects of Vitamin D: 1,25(OH)<sub>2</sub>D<sub>3</sub> is a transcriptional modulator of IL-17, F246

Loss of classical ERE signaling results in suppression of early commitment of BMSC to osteoblasts, F029

Measurements of Vitamin D do not necessarily reflect what you give to your patients, SU197

Multinuclear expression of ERα in mature osteoclasts, SU186

Neonatal exposure to soy isoflavones attenuates deterioration of bone tissue in female but not male mice after cessation of sex steroid production, SU476

New 25(OH)D assay on the IDS Automated Analyser 3x3™, SU200

Normal intramembranous fracture healing in mice with transgenic osteoblast-targeted disruption of GC signaling, SA234

Novel ERα variant signals rapidly from the caveolae of traditional ERα-negative cells, I124

OPG production by breast cancer cells is modulated by steroid hormones and confers resistance against TRAIL-induced apoptosis, M271

Osteoblast-targeted deletion of the GC receptor has little impact on PBM but attenuates DEX-induced suppression of bone formation, F452

Osteoblastic androgen receptor regulates cortical BMD, I122

Overexpression of androgen receptor in mature osteoblasts and osteocytes inhibits osteoblast differentiation, SU192

Platelet VDR levels are reduced in osteoporotic patients, SA241

Pregnancy upregulates duodenal Ca-transport genes and normalizes Ca homeostasis in *Vdr* null mice, M230

Randomized controlled trial of Vitamin D3 supplementation for the prevention of viral upper respiratory tract infections, M217

Rapid-nontranscriptional action of 1,25(OH)<sub>2</sub>D<sub>3</sub> induces IL-6 production in osteoclast precursors expressing MVNP, I186

Reconstruction of massive skeletal defects due to osteomyelitis by DO, M160

Regulation of Runx2 function in osteoblasts by sex steroid receptors, M099

Role of GPR30 in effects of estrogen in OVX mice, SU179

Sex steroids have site specific effects on muscle and bone geometry in young adult males, M416

Silencing of PDIA3 (ERp60) reduces the rapid membrane response to 1,25(OH)<sub>2</sub>D<sub>3</sub> in MC3T3-E1 osteoblast-like cells, M227

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

Specific inactivation of AF-1 in ERα results in growth plate closure while total inactivation of ERα results in increased growth plate width in elderly female mice, I181

Sunscreen use and Vitamin D status, M225

TRβ-specific agonist GC-1 increases bone quality of adult female mice, M228

Vitamin D (cholecalciferol) production does not increase linearly with UV dose, M226

Vitamin D and physical performance in African American women, M218

Vitamin D delays breast cancer progression in the PyVMT transgenic mouse model, I185

Vitamin D insufficiency in obesity, SA239

Vitamin D status, bone mass, and bone metabolism in postmenopausal women and men older than 50 attended in a primary care center of Spain, M223

**Stress, oxidative**

β-catenin protects osteoblasts from oxidative stress by co-activating the expression of pro-survival, but not pro-apoptotic, target genes of the FoxO transcription factors, M010

Menopausal and postmenopausal women have significantly higher bone resorption and oxidative stress parameters than premenopausal women, SU336

Relationship among nutritional status, oxidative stress and bone density in institutionalized elderly, SU310

**Stro-1+**

Osteogenic potential of human bone marrow and circulating Stro-1+/CD45<sup>low</sup> cells, M078

**Stroke**

Effects of neurological impairment and functional mobility on BMD following stroke, SU364

**Stromal cell-derived factor-1 (SDF-1)**

SDF-1 is expressed in osteocytes and periosteal cells in response to mechanical loading, M105

**Stromal cells.** See also *Bone marrow stromal cells*

*Ccrn4l*, a peripheral clock gene, influences stromal cell allocation, bone mass, and marrow adiposity in mice and humans, I073

Hormonal control of RANKL expression is independent of Runx family proteins: evidence that commitment to the osteoblast lineage is not a requirement for the stromal cells that support osteoclast differentiation, SU047

Host bone marrow-derived stromal cells promote myeloma initiation and development of osteolysis, 1088

Suppression of canonical wnt signaling by Dkk1 attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215

TGF $\beta$  signaling in stromal cells facilitates osteoblastic lesions in prostate cancer, 1087

TGF $\beta$  suppresses adipocytic differentiation and enhances accumulation of stromal cells in myeloma bone lesions, SA294

**Strontium (Sr)**

Dietary Sr in a model of established osteopenic rats reduce the levels of 25(OH)D. SA377

Effect of Sr<sup>2+</sup> on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

**Strontium ranelate**

Improved bone mass after co-administration of Sr ranelate and RIS in a rat model of osteoporosis using "in-vivo"  $\mu$ CT, SU393

Oral Sr ranelate treatment markedly improves implant osseointegration, SA506

Relationship between biochemical bone markers in osteoporotic women before and after 6 months treatment with either GH, Sr ranelate or GH plus Sr, M291

Sr ranelate decreases osteoblast-induced osteoclastogenesis through the involvement of the CaSR, F389

Sr ranelate prevents the progression of thoracic kyphosis in postmenopausal women with osteoporosis, 1241

Sr ranelate protects osteoblasts from apoptosis independently of the CaSR, M007

**Subchondral bone**

PAR-2 activation induces bone resorption via RANKL upregulation in human OA subchondral bone osteoblasts, M018

**Substance P (SP)**

Decreased bone formation, increased bone resorption, and osteopenia in mice lacking SP, SU160

SP stimulates BMSC osteogenic activity and osteoclast differentiation and function in vitro, SU032

**Sunlight**

Lack of seasonal variation of bone resorption in elderly women in relation to periodicity of sunlight exposure at a northerly latitude, F337

**Sunscreens**

Sunscreens use and Vitamin D status, M225

**Superoxide dismutase (SOD)**

Lentiviral shRNA mediated inhibition of Grx5 expression induces apoptosis via a mechanism involving increased ROS and cardiolipin oxidation, and reduced SOD activity, M009

**Syk**

SLP-76 couples Syk to the osteoclast cytoskeleton in vitro and in vivo, 1010

Syk tyrosine 317 negatively regulates osteoclast function, 1120

**Syndecan**

Various roles of syndecan family in osteoblastic cells, SA147

**Syndecan-1**

Disruption of the syndecan-1/integrin axis is a novel target for myeloma therapy, 1229

**Syndecan-2 (synd2)**

Wnt/ $\beta$ -catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243

**Synostosis, familial humeroradioulnar**

Familial humeroradioulnar synostosis maps to chromosome 7p15, M251

**Synoviocytes, rheumatoid**

Rheumatoid synoviocytes are stimulated with IL-23 to enhance osteoclastogenesis through upregulation of RANKL expression, SU084

**Synoviolin**

Expression and function of synoviolin in human osteoclastogenesis, SA080

**T****T cells**

Effects of IL-27 on regulation of osteoclastogenesis by way of T cells, SU081

Gene transcripts related to T-cell activation, proliferation, and cytokine signaling show significant effects on BMD variation in baboons, M241

IL-12 stimulates the OIP-1 gene expression in CD4<sup>+</sup> T-cells, SA173

T cells amplify the anabolic action of PTH through Wnt10b signaling, 1197

**T-box 3**

T-box 3 negatively regulates osteoblast differentiation by inhibiting expression of Osx and Runx2, SU018

**T-scores**

Do different densitometers, or use of T-score vs. Z-score, affect fracture risk estimation?, SU258

FRAX<sup>TM</sup> and the assessment of ten-year fracture probability in Hong Kong Southern Chinese according to age and BMD femoral neck T-scores, SU264

WHO absolute fracture models in older women: how does prediction vary for incident hip and non-spine fractures across T-scores?, 1055

**T $\beta$ RI**

T $\beta$ RI inhibitor rescues uncoupled bone remodeling in two different animal disease models, 1273

**T2\***

Measurement of T2\* relaxation time of the trabecular bone network at 7T and 3T compared to topological and structural measurements from HR-pQCT, F317

**T137M**

Human SLC34A3/NaPi-IIc mutations T137M and L527del uncouple Na-phosphate co-transport, F471

**TAK1**

BMP-2 inactivates TAK1-ATF2 signaling pathway in chondrocytes, F186

**Tamoxifen**

Effect of tamoxifen and aromatase inhibitors on the risk of fractures in women with breast cancer, SU227

**Tantalum (Ta)**

Evaluation of tibial bone density surrounding Ta tibial implants in TKA, SU266

**Tartrate-resistant acid phosphatase 5b (TRACP5b)**

Comparison of the TRACP 5b specificity of two commercial TRACP 5b assays, SA298

Phthalein monophosphates are specific substrates for TRACP5b, M284

Stability of TRACP 5b in rat and mouse serum, M286

**TCF**

Induction of oxidative stress and diversion of  $\beta$ -catenin from TCF- to FOXO-mediated transcription by GCs or TNF $\alpha$  in osteoblastic cells, SA185

Kinase activation and osteocyte survival promoted by mechanical stimulation require LRP5/6 signaling and  $\beta$ -catenin accumulation, but not  $\beta$ -catenin/TCF-dependent transcription, M108

Negative regulation of Tcf/Lef-dependent transcription by the BMP/Smad4 signaling axis, SU144

Tcf is required for Wnt11 mediated osteoblast differentiation, M058

Wnt/ $\beta$ -catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243

**tcirg1**

Rachitic defects in tcirg1-dependent osteopetrosis are caused by impaired gastric acidification, 1201

**Tec**

Tec kinases, therapeutic targets for bone destructive diseases, F083

**Teeth**

ALN transiently impairs removal of alveolar bone and healing of the root socket after tooth extraction in rats, 1275

BMSC and Osx contributing to osseointegration of dental implants, SA138

Distinctive anabolic roles of 1,25(OH)<sub>2</sub>D<sub>3</sub> in teeth and mandible versus long bones, M213

Enzyme replacement therapy prevents dental defects in the *Akp2*<sup>-/-</sup> mouse model of infantile HPP, F107

**Telomerase**

Telomerase deficiency leads to decrease bone mass and impaired MSCs functions in telomerase deficient (TERC<sup>-/-</sup>) mice, 1147

**Tendon repair**

Loss of *MMP-9* results in improved healing, and remodeling of adhesions in a murine model of flexor tendon repair, F153

**Tendons**

TIEG1 KO mice display defects in the molecular structure of tendon fibers, M133

**TERC<sup>-/-</sup>**

Telomerase deficiency leads to decrease bone mass and impaired MSCs functions in telomerase deficient (TERC<sup>-/-</sup>) mice, 1147

**Teriparatide (TPTD)**

12 months of TPTD therapy increases ultradistal radius bone strength in severely osteoporotic postmenopausal women, SA504

Adherence in patients with severe osteoporosis treated with TPTD, M384

Adult HPP treatment with TPTD, SA468

Danish patients treated with TPTD, M350

Evaluation of BMD changes in women with severe osteoporosis after TPTD treatment, M355

Formation of new trabeculae in a female patient with osteoporosis treated with TPTD, demonstrated with in-vivo-assessment of 3D bone microarchitecture with HR-pQCT, M352

Histomorphometric and biochemical bone formation responses to first and second cycles of TPTD treatment, 1169

Histomorphometric changes by TPTD in ALN pre-treated women with osteoporosis, 1019

Imaging the spatial distribution of proximal femoral response to one year of TPTD therapy, M349

One year of TPTD treatment increases hip strength in subjects with recent history of anti-resorptive treatment, F396

Previous antiresorptive agents use did not hinder the increase of bone turnover marker in TPTD use, M351

QUS, BMD and QCT in women with established osteoporosis treated with TPTD, SA393

Role of FGF-23 in the early response to the PTH analogue; TPTD, SU174

Skeletal plasma clearance, as measured by quantitative radionuclide studies, is correlated with bone turnover markers at 3 months of TPTD therapy, F398

TPTD improves trabecular architecture as measured by  $\mu$ CT at simulated in vivo resolution in the femoral neck of OVX monkeys, SA375

TPTD in bisphosphonate-resistant osteoporosis—clinical and  $\mu$ CT data, 1172

TPTD therapy in a community setting: persistence and use of other osteoporosis medications in DANCE, SA395

## Key Word Index

## ASBMR 30th Annual Meeting

- TPTD treatment in a young man with IJO diagnosis, SU499
- TPTD versus ALN for treatment of GIO, 1171
- Treatment with daily subcutaneous TPTD (1-34) compared with daily subcutaneous PTH (1-84) in women with severe postmenopausal osteoporosis, 1170
- ZOL prevents accelerated bone loss after discontinuation of TPTD, M365
- Testosterone**
- Replacing testosterone in male cardiac transplant patients exerts multiple benefits on bone mass, libido and sexual activity, M388
- Retrospective study evaluating the relationship of Vitamin D 25 OH and free testosterone levels with changes in hip bone density after liver transplantation, SA502
- Toward a physiologically-based definition of hypogonadism in men: dose-response relationship between testosterone and bone resorption, 1102
- TG interacting factor (TGIF)**
- TGIF regulation of bone mass: impaired osteoblast differentiation, SA018
- TGF $\beta$  inducible early gene (TIEG)**
- TIEG: a key regulator of Runx2 and Osx gene expression and osteoblast differentiation, M052
- Transgenic mice over-expressing TIEG in osteoblasts display a gender specific bone phenotype, M024
- TGF $\beta$  inducible early gene 1 (TIEG1)**
- TIEG1 KO mice display defects in the bone matrix immediately surrounding osteocytes, SA065
- TIEG1 KO mice display defects in the molecular structure of tendon fibers, M133
- TGF $\beta$ I**
- CED: a unique variant featuring a novel, heterozygous, leucine repeat mutation in *TGF $\beta$ I* together with a novel, homozygous, missense change in *TNFSF11* encoding RANKL, F256
- TGFBFR3**
- GWAS and subsequent replication studies identified ADAMTS18 and TGFBFR3 as novel osteoporosis risk genes, 1093
- th3**
- $\mu$ CT abnormalities in the th3 mouse model of thalassemia start at a young age and are associated with decreased bone turnover, SA128
- T<sub>H</sub>17**
- Possible role for the T<sub>H</sub>17 system in a mouse model of AS, SU460
- Th17**
- Grape seed extract suppresses IL-23/Th17 inflammatory pathways and bone destruction in CIA, SU093
- Thalassemia intermedia (TI)**
- $\mu$ CT abnormalities in the th3 mouse model of thalassemia start at a young age and are associated with decreased bone turnover, SA128
- Thiazolidinediones (TZD)**
- PPAR $\gamma$ 2-mediated proteolytic degradation of  $\beta$ -catenin determines an anti-osteoblastic effect of anti-diabetic TZDs, SU023
- TZD modify nuclear heterochromatin architecture, SU056
- Threonine**
- Homozygous threonine to methionine substitution in FGF-23 gene is associated with tumoral calcinosis in a 12 year-old girl, SU171
- Threonine (Thr201)**
- Role of active site Thr201 in the inhibition of farnesyl pyrophosphate synthase by NBPs, F407
- Thrombopoietin (TPO)**
- Novel role for TPO in regulating osteoclast development, SU104
- Thrombospondin-1 (TSP-1)**
- TSP-1 and CD47 regulate osteoclastogenesis but have distinct effects on bone metastasis, 1232
- Thrombospondin-2 (TSP-2)**
- Changes in marrow cell dynamics and bone geometry with aging in TSP-2 null mice, 1249
- Thyroid cancer.** See *Cancer*
- Thyroid disease**
- Subclinical thyroid disease predicts risk of hip fracture, 1208
- Thyroid hormone**
- Thyroid hormone activates Wnt signaling pathways in rat growth plate chondrocytes, M157
- Thyroid hormone  $\beta$  (TR $\beta$ )**
- TR $\beta$ -specific agonist GC-1 increases bone quality of adult female mice, M228
- Thyroid hormone receptor-interacting protein 1 (TRIP-1)**
- TRIP-1 is eIF3i: a key regulator of osteoblast activity, 1259
- Thyroid hormone receptor-interacting protein 6 (TRIP-6)**
- TRIP-6 regulates osteoclast formation, adhesion, and resorptive capacity, SU066
- Thyroid stimulating hormone (TSH)**
- TSH inhibits the expression of HMGB, a regulator of TNF $\alpha$  transcription, in osteoclastogenesis, 1117
- Tibia**
- Aged and young adult BALB/c male mice respond similarly to in vivo tibial compression, M475
- Changes in volumetric bone density and bone strength at the tibial midshaft in boys and girls 12-17 years of age, SU469
- Collecting bone out of the medial condyle of tibia, SA318
- Deleterious effect of late menarcheal age on bone microstructure in both distal radius and tibia, 1239
- Ethnicity-specific bone changes during adolescent growth: pQCT analysis of the tibia, M502
- FEA performed on radius and tibia HR-pQCT images provides new insights for fracture status assessment, 1067
- Flexible tibia model predicts bone strains during walking, M479
- Investigation of the fatigue behaviour of rabbit tibiae: effects of sex and age, SU470
- Timed Up and Go test**
- Timed Up and Go test and BMD as predictors of fracture, F373
- Tissue donors**
- Prevalence and incidence of viral infections among musculoskeletal tissue donors and first-time blood donors, SA549
- Tissue engineering**
- Continuous culture of tissue engineered cartilage, SU131
- Sequestration, proliferation and differentiation of osteoblasts in hydrogels for tissue engineering applications, SA143
- TiO<sub>2</sub>-scaffolds for use in bone tissue engineering, SA137
- Tissue-engineering and co-culture system based disc regeneration MSC's role, SA189
- Tissue-nonspecific alkaline phosphatase (TNSALP).** See *Alkaline phosphatase*
- Tissue-specific alkaline phosphatase.** See *Alkaline phosphatase*
- Titanium (Ti)**
- Adipose tissue derived MSCs: differentiation into osteoblastic phenotype and interaction with nanostructured Ti alloys, SU050
- Enamel matrix derivative (emdogain) enhance osteoblast differentiation on Ti surfaces, M030
- Human osteoprogenitor cell adhesion and spreading on functionalized Ti surfaces followed by QCM and CLSM, SA101
- Regulation of Dkk-1 and Dkk-2 is needed for osteoblast terminal differentiation on microstructured Ti surfaces, SU006
- Titanium oxide (TiO<sub>2</sub>)**
- TiO<sub>2</sub>-scaffolds for use in bone tissue engineering, SA137
- TLR4**
- IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102
- TNF- $\alpha$  related apoptosis inducing ligand (TRAIL)**
- OPG production by breast cancer cells is modulated by steroid hormones and confers resistance against TRAIL-induced apoptosis, M271
- TNF-like weak inducer of apoptosis (TWEAK)**
- Proinflammatory cytokine TWEAK induces SCT expression in human immature osteoblasts in a MAPK dependent fashion, M046
- TNF-stimulated gene-6 (TSG-6)**
- TSG-6 acts synergistically with OPG to inhibit bone resorption, SA097
- TNFRSF11A**
- Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SQSTM1* (sequestosome 1), SU210
- Identification of a novel mutation (78dup27) of the *TNFRSF11A* gene in a Chinese family with early onset PDB, M237
- OPG deficiency mimicked by a novel 15-base pair tandem duplication in *TNFRSF11A* encoding RANK: merging the juvenile PD and ESH phenotypes, F563
- TNFRSF11B**
- Hyperphosphatasia: a unique type without mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SQSTM1* (sequestosome 1), SU210
- TNFSF11**
- CED: a unique variant featuring a novel, heterozygous, leucine repeat mutation in *TGF $\beta$ I* together with a novel, homozygous, missense change in *TNFSF11* encoding RANKL, F256
- Tobacco.** See *Smoking*
- Toll-like receptor-9 (TLR-9)**
- Osteoclast-independent function of Cat K: regulation of TLR-9 signaling in autoimmunity, F074
- Tomography (CT).** See *Computed tomography*
- Toremifene (TOR)**
- C-telopeptide and bone ALP predict morphometric vertebral fracture risk in a pivotal Phase III trial of TOR in men on ADT, 1292
- TOR inhibits osteoclast activity in vitro and prevents orchietomy-induced bone resorption in male rats, SA381
- Total knee arthroplasty (TKA).** See *Arthroplasty*
- Trabecular bone**
- Contributions of trabecular and cortical components to biomechanical properties of human vertebrae, M455
- Deletion of the Wnt signaling antagonist sFRP4 in mice induces opposite bone formation phenotypes in trabecular and cortical bone, 1005
- Dependence of endosseous implant anchorage on mechanostuctural determinants of peri-implant bone trabeculae, 1298
- Do racial differences exist in cortical and trabecular bone?, M468
- Effects of resorption cavities on strength of trabecular bone, SA512
- Estimation of relative stiffness contributions of cortical and trabecular compartments by MRI-based FEA, SU481
- Feasibility and reproducibility of in-vivo assessment of trabecular bone architecture using  $\mu$ MRI-based method at multiple study centers, SA314
- Grayscale MRI based finite element mechanical modeling of trabecular bone at in vivo resolution, SU277
- Immunohistochemical localisation of SCT in human trabecular bone from fragility hip fracture patients, SA148
- Juvenile murine model of OVX-induced trabecular and cortical osteoporosis, SA387

Load induced changes in trabecular and cortical bone are dose dependent in both C57BL/6 and C3H/HeJ mice, F527

Marked abnormalities in cortical and trabecular microarchitecture and strength in premenopausal women with idiopathic osteoporosis, M310

Measurement of T2\* relaxation time of the trabecular bone network at 7T and 3T compared to topological and structural measurements from HR-pQCT, F317

Physiological concentrations of inhibin A are anabolic, affecting both trabecular and cortical bone in normal intact mice, M177

Prediction of trabecular level microdamage and bone fracture through local strain, SU467

Profile analysis of rodent metaphyseal trabecular bone reveals a biphasic dose-dependent response to administered bone active agents, SA460

RIS has a more rapid onset of remodeling suppression than ALN in rabbit vertebral trabecular bone, SU387

Scl-Ab increases bone formation and decreases bone resorption in distal tibial metaphyseal trabecular bone in OVX rats, F394

Significant trabecular bone degradation occurs within five days of muscle paralysis, SA515

Subject-specific mechanical properties of trabecular bone using a low-dose imaging, SU471

Targeted disruption of Nrf1 in osteoblasts leads to reduced bone size and dramatic alterations in trabecular bone microstructure in mice, I190

Transmenopausal changes in the trabecular bone intrinsic properties, SU479

**Trabecular Bone Score (TBS)**

Lumbar spine TBS complements BMD in the discrimination between vertebral fractured and non-fractured subject, M308

**Traf2**

Traf2 regulates BMP signaling pathway in osteoblastic cells, M063

**TRAF6**

Proteasome inhibitors attenuate osteoclastogenesis and bone resorption via the modulation of RANK-mediated TRAF6, p62 and I $\kappa$ B- $\alpha$  signaling cascades, SA099

**Transcriptome analysis**

Global transcriptome analysis in mouse osteoblasts identifies a mechanosensing osteoblast gene signature, SU017

**Transferrin (TF)**

Association study of the TF and IGFBP3 gene polymorphisms with an osteonecrosis of femoral head in Korean population, SU226

**Transforming growth factor  $\beta$  (TGF $\beta$ )**

Blocking TGF $\beta$  signaling reduces gammopathy and improves bone volume and strength in vivo, F293

Breast cancer derived factors synergize with TGF $\beta$  to induce phosphorylation of ERK1/2 and to stimulate osteoclastogenesis, SU115

Combined TGF $\beta$  receptor I kinase inhibitor and bisphosphonates are additive to reduce breast cancer bone metastases, F275

Critical role of TGF $\beta$  signaling pathways in skeletal development, 1079

Hfg inhibits melanoma bone metastases and TGF $\beta$  signaling, F190

Inhibition of HIF-1 $\alpha$  alone or combined with TGF $\beta$  blockade prevents breast cancer bone metastases, I085

Integrin-associated protein upregulates osteogenesis-related transcription factors via TGF $\beta$  and BMP pathways, SA028

Interplay between BMP and TGF $\beta$  signaling in osteoblast differentiation, SA031

MAPK-dependent inhibition of osteocalcin gene expression by TGF $\beta$ , M033

Monoclonal antibody to TGF $\beta$  inhibits tumor burden and osteolysis in a pre-clinical model of bone metastasis, SA187

Novel MMP-13-derived peptides demonstrate non-covalent interaction of MMP-13 with the TGF $\beta$  large latent complex, I189

TGF $\beta$  activates prostate cancer bone metastases, pro-osteolytic gene expression and the new TGF $\beta$  signaling regulator PMEPA1, SA273

TGF $\beta$  and Smad3-dependent repression of Runx2 function in ATDC5 chondrocytes, SU122

TGF $\beta$  blockade inhibits osteolytic but not osteoblastic prostate cancer metastases, SA274

TGF $\beta$  inhibits BMP signaling and osteogenesis through the TGF $\beta$  and BMP R-Smad direct interaction, I080

TGF $\beta$  receptor I kinase inhibitor increases bone mass in normal mice, SA172

TGF $\beta$  signaling in stromal cells facilitates osteoblastic lesions in prostate cancer, I087

TGF $\beta$  suppresses adipocytic differentiation and enhances accumulation of stromal cells in myeloma bone lesions, SA294

TGF $\beta$ - and BMP-signaling pathways have antagonistic effects during chondrogenesis, F158

*Wnt* pathway regulation by demineralized bone requires TGF $\beta$ /BMP signaling, SU138

**Transforming growth factor  $\beta$ 1 (TGF $\beta$ 1)**

Induction of CTGF by TGF $\beta$ 1 in osteoblasts: independent effects of Src and Erk on Smad signaling, M066

TGF $\beta$ 1 induces human osteoclast apoptosis, SU078

TGF $\beta$ 1 induces migration of Sca-1 and CD29-positive MSC in coupling bone resorption and formation, F188

**Transient receptor potential 7**

Importance of melastatin-like transient receptor potential 7 and Mg in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor, M008

**TRAP**

Obesity induced by high dietary fat leads to increased bone resorption marker, TRAP, and decreased bone mass in mice, M238

**$\beta$ -tricalcium phosphate ( $\beta$ TCP)**

Percutaneous injection of GEM OS2 increases vertebral BMD in geriatric female baboons, F376

Resorption mechanism of HA and  $\beta$ TCP coating layer, SA100

Stimulation of fracture healing by rhPDGF-BB combined with  $\beta$ TCP/collagen matrix in a diabetic rat fracture model, I137

**Tricho-dento-osseous syndrome (TDO)**

Molecular consequences of a mutant Dlx3 affecting bone homeostasis in TDO, I272

**Triggering receptor expressed on myeloid cells 2 (TREM-2)**

Suppression of TREM-2 expression and TREM-2-mediated costimulation of RANK signaling by cytokines that inhibit human osteoclast differentiation, SU114

**Tropomyosins**

Role of alpha gene tropomyosins in osteoclast function, SU067

**TRPM8**

Stat3 induces osteoblastic bone metastases through up-regulating the expression of Shh and a Ca channel TRPM8 in the LNCaP human prostate cancer cells, I089

**Trps1**

Trps1 represses Runx2 during endochondral bone formation, SU126

**TRPV4**

Gender specific effects of TRPV4 on osteoblast-osteoclast coupling and risk of osteoporotic fractures, SA355

**TRPV6**

Cooperativity between VDR and LIP in the regulation of TRPV6 identifies a novel function for LIP as a transcriptional activator, SU198

Evidence for a role of prolactin in Ca homeostasis: regulation of intestinal TRPV6 and intestinal Ca absorption by prolactin, I223

**Tumor necrosis factor (TNF)**

In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, I009

R-spondin 1 reduces bone loss in human TNF transgenic and OVX mice, I215

Real time oscillations in TNF-induced gene expression MAPK phosphorylation and promoter binding, SU087

**Tumor necrosis factor  $\alpha$  (TNF $\alpha$ )**

Elevated production of IL-1 $\beta$  and TNF $\alpha$  by PBMC is associated with increased hip fracture risk in elders, I283

IFN- $\gamma$  inhibits TNF $\alpha$ -induced osteoclastogenesis in vitro and in vivo, SU152

IL-1 $\beta$ -induced hepcidin expression in synovial membranes of patients with OA is associated with TNF $\alpha$  repression, SU157

IL-12 induces apoptosis in TNF $\alpha$ -mediated osteoclastogenesis in vivo, SA166

Increased proinflammatory cytokines TNF- $\alpha$  and IL-6 correlate with pathological bone turnover markers in diabetic patients with acute Charcot foot, F491

Induction of oxidative stress and diversion of  $\beta$ -catenin from TCF- to FOXO-mediated transcription by GCs or TNF $\alpha$  in osteoblastic cells, SA185

JNK activation is involved in TNF $\alpha$ -stimulated Smurf1 expression, SA016

LPS-induced inhibition of osteogenesis is TNF $\alpha$  dependent, M019

Nanogel cross-linking hydrogel as a drug delivery system for TNF $\alpha$  antagonist, M121

Recombinant mouse M-CSF receptor C-fms inhibits TNF $\alpha$ -induced osteoclastogenesis, M112

Stimulation of macrophage TNF $\alpha$  production by orthopaedic wear particles requires activation of the ERK 1/2/Egr-1 pathway but is independent of p38 and JNK, SA177

Three RANK cytoplasmic motifs, IVVY<sup>535-538</sup>, PVQEET<sup>559-564</sup> and PVQEQQ<sup>604-609</sup>, play a critical role in TNF $\alpha$ /IL-1-mediated osteoclastogenesis, I118

TNF $\alpha$  and IL-1 $\beta$  stimulate ALP activity and mineralization but decreases RUNX2 expression and osteocalcin secretion in human MSC, SU044

TSH inhibits the expression of HMGB, a regulator of TNF $\alpha$  transcription, in osteoclastogenesis, I117

**Tumor necrosis factor receptor (TNFR)**

Association between polymorphisms in TNFR genes and circulating TNFR levels, and BMD in postmenopausal Korean women, M258

**Tumor necrosis factor Tg (TNF-Tg)**

In the absence of NF- $\kappa$ B2, TNF induces osteoclast formation in vivo independent of RANKL/RANK and more severe arthritis in TNF-Tg mice, I009

**Tumor-induced osteomalacia (TIO). See Osteomalacia**

**Tumors. See also Cancer**

Drugs which inhibit osteoclast function suppress tumor growth and alter hematopoietic cell populations in bone, F270

**Tumors, parathyroid**

Mutational analysis of  $\beta$ -catenin Exon 3 in benign and malignant parathyroid tumors, M436

**Twist1**

Twist1 haploinsufficiency is associated with reduced IGF-1 levels and an osteoporotic phenotype, SU029

Wnt target gene Twist1 inhibits Sox9, the master regulator of chondrogenesis, I266

**Type III Na-dependent phosphate transporter**

## Key Word Index

## ASBMR 30th Annual Meeting

Development of nephrotic in transgenic rats over expressing Type III Na-dependent phosphate transporter, SU170

**Tyrosine**  
Studies on the deposition of ochronotic pigment in AKU reveal tyrosine metabolism in human chondrocytes, M166  
Tyrosine kinase inhibitor dasatinib decreases osteoclast formation and activity in vitro, SU074

**Tyrosine 317**  
Syk tyrosine 317 negatively regulates osteoclast function, 1120

**U**

**UGT1A1\*28**  
Effect of RLX treatment on BMD might be influenced by UGT1A1\*28 polymorphism, M257

**UGT2B17**  
Genome-wide CNV study identified a novel susceptibility gene *UGT2B17* for osteoporosis, M404

**Ultrasound**  
Heel ultrasound and consolidation of PBM in young women, M504  
Mediation of bone loss with ultrasound induced dynamic mechanical signals in an OVX rat model of osteopenia, F536

**Ultrasound, low intensity pulsed (LIPUS)**  
LIPUS synergistically modulates SCT and OPG/RANKL ratio in MLO-Y4 osteocytes in vitro, M109

**Ultrasound, quantitative (QUS)**  
Calcaneal QUS measurement of 2323 healthy adults in southwest China, M318  
Comparison of HR-pQCT to DXA and QUS for the assessment of ex-vivo bone strength, M466  
Correlation between DXA Femur Strength Index and QUS Heel Stiffness Index in Chinese women, M464  
Influence of markers of bone turnover on calcaneal QUS, SA457  
Longitudinal analysis of calcaneal QUS measures during childhood, M321  
Normal reference values for QUS bone densitometry of the calcaneus in Chinese children and adolescents, SU489  
Performance of QUS in comparison to DXA for prediction of prospective fractures among older men and women, 1240  
QUS, BMD and QCT in women with established osteoporosis treated with TPTD, SA393  
Relationship of QUS at phalanxes with hand and axial BMD, sex hormones and bone turnover markers in elderly women, M320

**Ultrasound, quantitative guided-wave (Q-GWUS)**  
Assessment of cortical thickness and BMD in the radius by low-frequency Q-GWUS, M319

**Ultraviolet radiation**  
Background UVB exposure in pregnancy and skeletal development in childhood, 1104

**Umbilical cord**  
Newborn infant bone mineralization is affected by their umbilical cord length, SU495

**UMR 106.1**  
Effect of  $\text{Sr}^{2+}$  on PTHrP, OPG and RANKL mRNA expression in osteoblastic-like cells UMR 106.1, SU016

**UMR-106**  
Characterization of osteoblastic properties of 7F2 and UMR-106 cultures after acclimation to reduced levels of fetal bovine serum, SU041

**Uncarboxylated osteocalcin (unOC).** See *Osteocalcin*

**URB**  
Adipocyte-secreted protein URB is a potent stimulator of bone formation, F006

**Urinary N-telopeptide (uNTx)**

Use of conductivity for the correction of uNTx, SA304

**Urocoitin (Ucn)**  
Ucn strongly suppresses the formation and function of osteoclasts via a novel mechanism, SA096

## V

**Vacuolar-type  $\text{H}^+$ -ATPase (V-ATPase)**  
Endocytotic processes underlying Ca-induced inhibition of plasma membrane V-ATPase in murine osteoclasts, SU101  
R740S, a dominant V-ATPase  $\alpha 3$  mutation, causes osteopetrosis in mice, 1218

**Valine80**  
A allele at Valine80 of the CYP19 gene is a risk factor for aromatase inhibitors associated bone loss, 1021

**Valproate**  
Valproate: a model for adverse psychoactive drug effects on BMD, SA556

**Vascular endothelial growth factor (VEGF).** See *Growth factor*

**Vascular system**  
Anabolic daily intermittent PTH 1-84 reduces bone blood vascular bed and induces dramatic changes in the bone/vessel spatial relationship, 1061

**Vdr**  
Pregnancy upregulates duodenal Ca-transport genes and normalizes Ca homeostasis in *Vdr* null mice, M230

**VDRM**  
Improved motor performance in Vitamin D deficient mice with VDRMs, SU196

**Vertebrae**  
Advanced vertebral compression at diagnosis among children with ALL, SU483  
Assessment of changes in thoracic and lumbar vertebrae in T-type  $\text{Ca}_v3.2$  (a1H) VSCC KO mice, M170  
Comparison of voxel-based and smooth FEA to predict damage accumulation in vertebral bodies, SU474  
Contributions of trabecular and cortical components to biomechanical properties of human vertebrae, M455  
Evaluation of osteoporosis vertebrae fragility by Connecting Path method, M307  
Evidence of increase in vertebral body dimensions in postmenopausal women with osteoporosis, M313  
Influence of PHP on BMD and vertebral morphometry, M190  
Mechanisms of endplate failure in the human vertebral body, M413  
Mice lacking NMDA receptor expression in osteoblasts have pronounced vertebral bone abnormalities, F012  
Performance characteristics of a workflow tool for the assessment of vertebral shape, SA350  
Temporal trends in vertebral size and shape from medieval to modern-day, M459  
In vivo measurements of vertebral body dimensions by 3D-XA and their relation with age, M316

**Vertebral wedge deformities**  
Usefulness of SpinalMouse® as a screening tool for the presence of vertebral wedge deformity, SA316

**Very low birth weight (VLBW).** See *Birth weight*

**VIBE Study.** See *eValuation of IBN Efficacy Database Fracture Study*

**Vibration**  
Randomized, placebo-controlled, double blind study on high frequency, low intensity vibration in bone mass, muscle strength and quality of life in children with motor disabilities, F435

**Vimentin**  
Vimentin binds c-Fms in an M-CSF dependent manner and regulates osteoclast differentiation, SU097

**Vinculin**

Vinculin is involved in hypertrophic differentiation through Raf/MEK/ERK pathway in chondrocytic ATDC5 cells, SA119

**Vitamin A.** See also *All-trans-retinoic acid*  
*All-trans-retinoic acid* (Vitamin A) increases expression of MafB and inhibits osteoclast formation by interfering with differentiation of osteoclast progenitor cells, M117  
Deprivation of Vitamin A results in a partial rescue of the mineralization defects in Phex-deficient Hyp mice, F202  
Vitamin D insufficiency together with high serum levels of Vitamin A increase the osteoporosis risk in postmenopausal women, M292

**Vitamin C**  
Protective effect of total and supplemental Vitamin C intake on the risk of hip fracture, 1168

**Vitamin D.** See also *Cholecalciferol*  
Anti-fall efficacy of oral supplemental Vitamin D and active Vitamin D, SU423  
Distinct modes of osteoblastic differentiation from BMSC and vascular smooth muscle cells: induction by BMP-2 and PKA and suppression by Vitamin D derivatives, SU060  
Effect of 1,25(OH) $_2$ D $_3$  and 25(OH)D $_3$  on osteoblastogenesis and bone strength in Vitamin D sufficient growing mice, SU207  
Effect of skin color and oral Vitamin D supplementation on serum 25(OH)D in adolescent girls, SU395  
Efficacy of the Vitamin D supplementation in patients with hypovitaminosis D and HPT2, SU431  
Evidence of a role for the human Vitamin D response element binding protein, hnRNP C1/C2 in chromatin remodeling and transcript splicing, F240  
Femoral neck and trochanteric fractures and Vitamin D, SU353  
Impaired fracture healing in the absence of the Vitamin D-24-hydroxylase, Cyp24a1, M222  
Infantile HCa: relationship of dietary intake of Ca and Vitamin D to serum and urine levels, SU491  
Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in male mice increases osteoblastogenesis and inhibits bone matrix mineralization leading to osteomalacia, SU374  
Key mechanism underlying the immunosuppressive effects of Vitamin D: 1,25(OH) $_2$ D $_3$  is a transcriptional modulator of IL-17, F246  
Late pregnancy serum Vitamin D and longitudinal bone loss during pregnancy, F544  
Low Vitamin D levels and risk of death in older men, F335  
Measurements of Vitamin D do not necessarily reflect what you give to your patients, SU197  
Negative relationship between PTH and Vitamin D: is there an age and a gender effect?, M179  
Osteoporosis patients behaviours and understanding of the importance of Ca and Vitamin D supplementation, M331  
Prevention of non-vertebral fractures with oral Vitamin D is dose dependent, 1242  
Protective actions of Vitamin D analogs in the vascular calcification of CKD, SU450  
PTH and not Vitamin D predicts age-related bone loss in the elderly, M178  
Randomised controlled trial of the effects of Vitamin D supplementation upon muscle function in adolescent girls, SU428  
Relationship between Vitamin D and PTH: serum Ca and Mg are major determinants of PTH in patients with mild CKD, M211  
Requirement of the bone for Vitamin D for 1,25(OH) $_2$ D $_3$  synthesis and bone mineralization, M224

Retrospective study evaluating the relationship of Vitamin D 25 OH and free testosterone levels with changes in hip bone density after liver transplantation, SA502

Serum 25(OH)D measurement and histomorphometric analysis of iliac crest biopsies from 1180 patients reveals a high prevalence of Vitamin D-dependent osteomalacia, 1134

Serum Vitamin D levels do not modify the response to an exercise program following hip fracture, SA346

Sunscreen use and Vitamin D status, M225

Superiority of ALF over plain Vitamin D in men with osteoporosis, SU421

Suppression of bone resorption markers by Ca and Vitamin D separately and in combination, M329

Very high frequency of poor Vitamin D status in French women with bone fragility, SU352

Vitamin D (cholecalciferol) production does not increase linearly with UV dose, M226

Vitamin D and physical performance in African American women, M218

Vitamin D concentrations of healthy children living in the Calgary health region, SU396

Vitamin D delays breast cancer progression in the PyVMT transgenic mouse model, 1185

Vitamin D dose response study in Canadian infants, 1108

Vitamin D status and bone remodeling marker CTx-I in patients with early RA: association with disease activity and joint damage, SA496

Vitamin D status in severely obese individuals can be predicted by demographic and lifestyle factors, SU201

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

Vitamin D status, bone mass, and bone metabolism in postmenopausal women and men older than 50 attended in a primary care center of Spain, M223

Vitamin D supplementation in breast fed infants, SU500

Vitamin D supplementation intake among osteoporosis patients aged 50 years and older at various 25(OH)D levels in the US, M400

Vitamin D toxicity due to a commonly available remedy from the Dominican Republic, SU195

What is your patient's Vitamin D status? Clinical consideration of variability in a 25(OH)D measurement, SU427

Wintertime Vitamin D supplementation inhibits seasonal variation of calcitropic hormones and maintains bone turnover in healthy men, SU433

#### Vitamin D deficiency

Behavior of circulating rat(s) PTH molecular forms in HPT2 related to Vitamin D deficiency and renal failure, M194

Bone health impairment in children with chronic Ca and Vitamin D deficiency due to nutritional allergies, SU503

Effect of treating Vitamin D deficiency on FGF-23 levels in humans, SA209

Ergocalciferol is not bioequivalent to cholecalciferol in Vitamin D insufficient hip fracture cases, 1289

FGF-23 in Vitamin D deficient older persons, SA203

Goettingen minipigs—a model for Ca/Vitamin D-deficiency osteomalacia and steroid-induced osteoporosis, SA445

High prevalence of Vitamin D insufficiency in a young adult population, M221

Improved motor performance in Vitamin D deficient mice with VDRMs, SU196

Is Vitamin D deficiency more common in children with cerebral palsy than in healthy children?, SU194

Marked Vitamin D deficiency in recent heart and liver transplant recipients, SA501

Novel hypothesis explains the syndrome of chronic musculoskeletal pain and comorbid painful healed fracture sites in Vitamin D deficiency, SA474

Prevalence of Vitamin D deficiency among surgical orthopedic patients, SU205

At similar plasma 25(OH)D levels, fat mass influence PTH levels in the state of Vitamin D insufficiency, SA218

Suboptimal Vitamin D status in pregnant adolescents is associated with neonatal Vitamin D insufficiency, F557

Vitamin D deficiency in inner city infants: impact of DBP genotype, SA472

Vitamin D deficiency is associated with diminished quality of life based on Qaleffo-41 questionnaire analysis, SU424

Vitamin D deficiency is highly prevalent in Irish hip fracture patients, M294

Vitamin D deficiency, osteomalacia and high bone turnover in patients with NF-1, F465

Vitamin D insufficiency in obesity, SA239

Vitamin D insufficiency is common in racially diverse postmenopausal women with HIV, M448

Vitamin D insufficiency together with high serum levels of Vitamin A increase the osteoporosis risk in postmenopausal women, M292

Vitamin D insufficiency: seasonal variation in healthy 6-12 year old African American and Caucasian children, SU482

#### Vitamin D receptor (VDR)

Associations of the VDR and calcitonin receptor genes with bone density, bone turnover markers and fracture incidence with regard to Ca intake level in Slovak postmenopausal women, M261

Bone tether formation in femoral and basicranial growth plates have similar responses to growth disruptions due to nuclear VDR genotype and mineral homeostasis, M164

Characterization of interactions between the unliganded VDR and effectors of the canonical Wnt signaling pathway, 1183

Cooperativity between VDR and LIP in the regulation of TRPV6 identifies a novel function for LIP as a transcriptional activator, SU198

Expression of VDR in the developing zebrafish embryo, M220

Intestinal-specific VDR null mice maintain normal calcemia but display severe bone loss, F238

Low plasma 25(OH)D and VDR polymorphisms are associated with increased breast cancer risk, SU202

Platelet VDR levels are reduced in osteoporotic patients, SA241

Snail downregulates VDR expression by recruiting Sin3A, HDAC1 and HDAC2 to multiple regions of VDR promoter and deacetylating histone H3/H4, F242

#### Vitamin D<sub>2</sub>. See also Ergocalciferol

Circulating concentrations of 25(OH)D after a single oral dose of 100,000 IU of Vitamin D<sub>2</sub> or Vitamin D<sub>3</sub>, M212

CYP27A1 mutations at Phe147 confer 25-hydroxylase activity towards a Vitamin D<sub>2</sub>-type sidechain, M231

Effect of three different doses of Vitamin D<sub>2</sub> (ergocalciferol) on muscle function and strength in women > 65 years, M405

Effect of Vitamin D<sub>2</sub> and Vitamin D<sub>3</sub> on intestinal Ca absorption in Nigerian children with rickets, SA560

Effect of Vitamin D<sub>2</sub> or Vitamin D<sub>3</sub> supplementation on serum 25(OH)D, SU425

Effects of 50,000 IU of Vitamin D<sub>2</sub> twice per month on circulating 25(OH)D and Ca levels, SU426

#### Vitamin D<sub>3</sub>

Circulating concentrations of 25(OH)D after a single oral dose of 100,000 IU of Vitamin D<sub>2</sub> or Vitamin D<sub>3</sub>, M212

Effect of 1 $\alpha$ ,25-dihydroxy Vitamin D<sub>3</sub> on proliferation and differentiation of C2C12 myoblast, SA245

Effect of Vitamin D<sub>2</sub> and Vitamin D<sub>3</sub> on intestinal Ca absorption in Nigerian children with rickets, SA560

Effect of Vitamin D<sub>2</sub> or Vitamin D<sub>3</sub> supplementation on serum 25(OH)D, SU425

Improved forearm BMD after treatment with Vitamin D<sub>3</sub> in a patient 30 years after bariatric surgery, SA492

Lithocholic acid downregulates the effects of Vitamin D<sub>3</sub> on primary human osteoblasts, SA030

Randomized controlled trial of Vitamin D<sub>3</sub> supplementation for the prevention of viral upper respiratory tract infections, M217

Single dose of 100,000 IU D<sub>3</sub> appears to be insufficient to achieve desirable levels of 25(OH)D in patients with hypovitaminosis D, SU430

Vitamin D<sub>3</sub> treatment of elderly people—twice a day or every four months? A comparative study of efficacy and safety of two oral dosages with same annual dose of 292,000 units, SU422

Which is the best oral high-dose Vitamin D<sub>3</sub> regimen for postmenopausal women with hypovitaminosis D?, SU429

#### Vitamin K

Bone is more susceptible to Vitamin K deficiency than liver, SU316

Conversion of Vitamin K analogues to MK-4 in osteoblastic cells, M064

Vitamin K intake is positively related to trabecular bone microarchitecture in children, M505

Vitamin K treatment for one year does not alter femur geometry in postmenopausal women, SA443

#### Vitamin K<sub>2</sub>

Effect of low dose Vitamin K<sub>2</sub> (MK-4) supplementation on bio-indices in postmenopausal Japanese women, SU307

Effects of Vitamin K<sub>2</sub> and RIS on bone formation and resorption, osteocyte lacunar system and porosity in the cortical bone of GC-treated rats, SU385

Prior treatment with Vitamin K<sub>2</sub> significantly improves the efficacy of RIS, SA379

#### Voltage sensitive calcium channels (VSCC). See Calcium channels

#### Vorinostat

HDI, Vorinostat, blocks growth and associated osteolysis of cancer cells within bone, but reduces bone volume in non-tumor bearing bones in mice, M279

## W

#### WAP

Differences in femoral bone structure between juvenile non-transgenic and transgenic rabbits with the WAP-hFVIII gene construct, SA132

#### WASPI. See Magnetic resonance imaging

#### Wdr5

Role of Wdr5 in endochondral bone formation during chicken limb development, SU121

Wdr5 is required for chromatin modifications at the Runx2 promoter, M039

#### Weight. See also Body composition; Obesity

Birth weight predicts bone size, adult weight predicts BMC and BMD in young Gambian adults, M498

Bone mass recovers in young women with anorexia nervosa who are both weight and menstrual recovered, F339

Bone strength in overweight children is adapted to mechanical loads from walking, but is low for higher loading activities, M482

Effect of bodyweight on clinical response to ZT-031: development of a simple, improved dosing regimen for PTH analogs, M346

Effect of cannabinoid CB1 receptor ligands on body weight and bone mass in mice, M340

## Key Word Index

## ASBMR 30th Annual Meeting

Elevated systolic blood pressure is positively related to bone mass measurements in overweight pre-pubertal and pubertal children, M496

Increasing the number of steps taken per day leads to a greater weight loss and more favorable body composition in overweight postmenopausal women, SU311

Influence of body weight on cost-effectiveness of bone densitometry and treatment for osteoporosis among older women and men without prior fracture, F426

Overweight children are more at risk to sustain a forearm fracture due to poor bone strength relative to body weight, M458

Vitamin D status in young women is strongly negatively related to body weight, BMI and body fat, but is not associated to bone mass, SU203

Weight and BMI predict BMD and fractures in women 40 to 59 years, SA438

Weight reduction is not deleterious for bone mass or strength in obese women, SA338

**WHI.** See *Women's Health Initiative*

**Whole-body vibration**

Efficacy of whole-body vibration in reducing bone loss in postmenopausal women, M396

**Wnt**

*Wnt* pathway regulation by demineralized bone requires TGF $\beta$ /BMP signaling, SU138

**Wnt**

30IT/C of SCT modulates BMD by Wnt and estrogen signaling pathways, 1270

Aging of human BMSC: role of WNT pathways, SA048

BMP/Wnt antagonists are upregulated by DEX in osteoblasts and reversed by ALN and PTH: potential therapeutic targets for GIO, M098

Canonical Wnt signaling suppresses BMP-4 accumulation from C3H10T1/2 cells transfected with BMP-4 expression vector, M098

Characterization of interactions between the unliganded VDR and effectors of the canonical Wnt signaling pathway, 1183

Conditional knockout of the CaSR in osteoblasts alters regulators of Wnt signaling, delays cell differentiation, and promotes apoptosis in bone, 1156

Crosstalk between androgen receptor and Wnt signaling mediates sexual dimorphism during bone mass accrual, 1121

Deletion of the Wnt signaling antagonist sFRP4 in mice induces opposite bone formation phenotypes in trabecular and cortical bone, 1005

Enhanced mitochondrial biogenesis contributes to Wnt induced osteogenic differentiation of C3H10T1/2 cells, SA043

EphB4 expression in osteoblasts is regulated by myeloma cells and the Wnt signaling pathway, SU232

Expression profiles of Wnt signaling pathway components in response to cAMP stimulation at different stages of osteoblast maturation, M040

FHL2 mediates DEX-induced MSC osteogenic differentiation by activating Wnt/ $\beta$ -catenin signaling and Runx2 expression, M048

Mice lacking the Wnt receptor Frizzled-9 display osteopenia caused by decreased bone formation, 1006

Multiple WNT signaling antagonists are differentially expressed over time in inflammatory arthritis, WG41

Noncanonical Wnt signaling is involved mir-206 expression in osteoblastic differentiation, SA021

Osteocyte-specific ablation of canonical Wnt signaling induces severe osteoporosis, 1037

PTH receptor signaling in osteocytes increases bone mass and the rate of bone remodeling through Wnt/LRP5-dependent and -independent mechanisms, respectively, 1038

PTHrP-induced Wnt signaling specifies the mammary mesenchyme, F219

Regulation of bone formation by osteoclasts involves Wnt/BMP signaling and the chemokine S1P, M017

Regulation of osteogenesis by Wnt signaling in rat MSC and human ASC, SU045

Runx2 and canonical Wnt signaling cooperatively regulate BMP-induced differentiation pathways of adult dural cells into osteoblasts or chondrocytes, M043

Sim induces Wnt signaling and reduces CSF-1 secretion and RANKL/OPG ratio to block osteoclast differentiation, SU096

Stable isotopic labeling of amino acids in cultured human BMSC: application to BMP-2 induced Wnt/ $\beta$ -catenin signaling, SA036

Suppression of canonical wnt signaling by Dkk1 attenuates PTH-mediated peritrabecular stromal cell response and new bone formation in a model of HPT2, F215

Thyroid hormone activates Wnt signaling pathways in rat growth plate chondrocytes, M157

Transgenic overexpression of the Wnt antagonist Krm-2 in osteoblasts leads to severe impairment of bone formation and increased bone resorption, 1003

Wnt signaling regulates Gli2 and PTHrP expression in human breast cancer cells that cause osteolysis, M278

Wnt target gene Twist1 inhibits Sox9, the master regulator of chondrogenesis, 1266

Wnt/ $\beta$ -catenin/TCF is a constitutive repressor pathway interfering with Foxo3-mediated induction of synd2, a tumor suppressor in osteosarcoma cells, SU243

Wnt/LRP5-independent inhibition of osteoblastic cell differentiation by SCT, 1256

**Wnt inhibitory factor 1 (WIF1)**

Polymorphisms in the WIF1 gene are associated with BMD in elderly Swedish women, SA264

**WNT-4**

WNT-4 acts through the non-canonical pathways to stimulate osteoblast and BMSC differentiation, F050

**Wnt5a**

Wnt5a regulates osteoclast differentiation in physiological and pathological conditions, 1012

**Wnt7a**

Wnt7a and Wnt7b evoke overlapping yet distinct transcriptional responses during the osteogenic programming of mesenchymal progenitors by Msx2, 1196

**Wnt7b**

Wnt7a and Wnt7b evoke overlapping yet distinct transcriptional responses during the osteogenic programming of mesenchymal progenitors by Msx2, 1196

**Wnt9a**

Identification of a transcription factor p63 for transactivation of Wnt9a and Gdf5 causing joint cartilage formation, F116

**Wnt10b**

T cells amplify the anabolic action of PTH through Wnt10b signaling, 1197

**Wnt11**

R-spondin 2 is a novel osteogenic factor required for Wnt11 mediated osteoblast differentiation, SU063

Tcf is required for Wnt11 mediated osteoblast differentiation, M058

**Women's Health Initiative (WHI)**

Bone turnover and incident hip fracture risk, M285

Geometric evidence of a modeling defect in type 2 diabetic women enrolled in the WHI as a potential explanation for increased fracture risk, 1068

Inflammatory markers and the risk of hip fracture, F333

Serum estradiol and fracture reduction during treatment with hormone therapy, F383

**World Health Organization (WHO)**

Predictive validity of the WHO FRAX model, BMD and prevalent vertebral fracture for incident radiographic vertebral fractures, 1127

WHO absolute fracture models in older women: how does prediction vary for incident hip and non-spine fractures across T-scores?, 1055

**WSX-1**

IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation: a possible involvement in TLR4/MyD88-mediated inflammatory arthritis, SU102

**X**

**X-linked hypophosphatemia (XLH).** See *Hypophosphatemia*

**X-ray**

Family physician characteristics that predict appropriate x-ray ordering, SA359

**X-ray absorptiometry (DXA).** See *Absorptiometry*

**X-tremeCT.** See also *Computed tomography*

Evaluating bone microstructure at the distal tibia in children, F315

**Z****Z-scores**

Clinical tool for adjusting BMD Z-scores for body size in growing children, 1105

Do different densitometers, or use of T-score vs. Z-score, affect fracture risk estimation?, SU258

**Zinc-finger protein 521 (Zfp521)**

Deletion of Zfp521, an antagonist to Runx2 and Ebf1 transcriptional activity, leads to osteopenia and a defect in matrix mineralization in mice, 1109

**Znf219**

Transcription factor Znf219 regulates chondrocyte differentiation through forming transcription factory complex with Sox9, 1265

**Zoledronates**

Comparison of the effects of zoledronates on the differentiation of human bone marrow and amniotic fluid derived MSCs, SA045

Zoledronate protects bone but not soft tissue from prostate cancer progression in a nude mouse model, M282

**Zoledronic acid (ZOL)**

BMD and biochemical marker response rates in postmenopausal women after treatment with ZOL, F401

Effect of a single 5-mg infusion of ZOL on bone turnover markers versus oral RIS (5 mg/day) over 1 year in patients with GIO, M362

Effect of a single infusion of ZOL 5 mg versus oral RIS 5 mg on BMD at lumbar spine, hip, femoral neck and trochanter in patients with GIO, F403

Effect of once-yearly ZOL 5 mg infusion on fracture incidence in postmenopausal osteoporosis, 1028

Effect of once-yearly ZOL on integral BMD of the spine, SU405

Effect of ZOL (single 5-mg infusion) on lumbar spine BMD versus oral RIS (5 mg/day) over 1 year in subgroups of patients receiving GC therapy, M363

Efficacy and safety of intravenous ZOL in the treatment of patients with resistant PDB, SA479

Increase in risk of atypical subtrochanteric fractures with ZOL?, F411

Monthly intravenous ZOL suppresses tissue-level remodeling significantly more than daily oral ALN in the mandible and rib of skeletally mature female dogs, SU388

ONJ: ZOL 5 mg experience in a variety of osteoporosis indications, 1246  
Potential mediators of the reduction in mortality with ZOL after hip fracture, 1030  
Pulse treatment with ZOL causes sustained commitment of bone marrow derived MSC for osteogenic differentiation, M072  
Relationship of bone turnover marker (PINP) and changes in femoral neck BMD to fracture risk in women with postmenopausal osteoporosis treated with once-yearly ZOL 5 mg, 1027  
Roles of ZOL in bone healing and osteoblast functions, 1064  
Short-term effect of ZOL on the superficial vascularisation of membranous bone sites, SU382  
ZOL inhibits the capacity of myeloid-immune suppressor cells in myeloma to form osteoclasts, SU230  
ZOL prevents accelerated bone loss after discontinuation of TPTD, M365  
ZOL treatment of osteoporosis: effects in men, SU398

**ZT-031**

Active controlled, non-inferiority study to compare the effect of ZT-031 with ALN on the incidence of new vertebral fractures, M347  
Effect of bodyweight on clinical response to ZT-031: development of a simple, improved dosing regimen for PTH analogs, M346  
Phase 1, randomized, double-blind, placebo controlled trial of the PK/PD effect and safety of ZT-031, a hPTH analog, in healthy elderly women, SA399
