Non-invasive fluorescence imaging is a promising new tool with several advantages over traditional radiography and histology; it is fast and allows whole-body imaging without the need of sacrificing the animals. However, the means of transforming the imaging output into descriptive and reliable quantitative data have been limited. The most commonly used output data, fluorescence emission area as an index of tumor burden does not, however, take the fluorescence signal intensity into account. Furthermore, tumor burden is conventionally measured only in histological sections of hind limbs, whereas fluorescence imaging allows whole-body imaging, but the correlation between these two methods has been poorly studied. We have validated a new image analysis method using GFP-MDA-MB-231(SA) breast cancer cells in a mouse model of breast cancer bone metastasis. Five-week-old female athymic nude mice were inoculated intracardially with MDA-MB-231(SA) breast cancer cells transfected with pTurboGFP-N vector (Evrogen JSC, Moscow, Russia). Three study groups were included (n=12/group): 1) Vehicle, 2) Doxorubicin 2.5 mg/kg, 3) Doxorubicin 5 mg/kg (all groups administered i.p. once a week). The tumor burden was assessed at day 14 and at the end of the study by measuring the total area and signal intensity emitted by GFP-MDA-MB-231(SA) cells. Osteolytic lesion area was measured on day 14 and at the end of the study by radiography. At necropsy, all macroscopic signs were recorded and tissue samples were collected for histology. Based on our earlier in vitro and in vivo studies, GFP-MDA-MB-231(SA) cells retained similar tumor growth profile and metastatic characteristics as parental cells. To measure the tumor burden by fluorescent imaging we created a value called tumor burden index which takes into account both the signal area and intensity emitted by the cancer cells transfected with GFP. The development of osteolytic lesions and tumor area was inhibited by doxorubicin at 5mg/kg. This anti-tumor effect of doxorubicin was more prominent when the tumor area was measured using the tumor burden index compared to conventional histological methods. Furthermore, the tumor burden index correlated well with histological analysis of tumor burden at the sites where histological analyses were performed. These results suggest that GFP imaging is a fast and reliable tool that can be used as quantitative method for assessment of whole-body tumor burden in a mouse model of breast cancer bone metastasis. This method negates the need to use laborious and time-consuming histology for assessing tumor burden.

**Osteoblast Differentiation Induced by Shh-expressing Prostate Cancer Cells Is Enhanced by Ascorbic Acid.** M. L. G. Lamm, S. M. Zunic\*. Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

Metastatic prostate carcinoma, the major cause of mortality among men with advanced prostate cancer, occurs predominantly in bone. Identification of signaling factors that mediate prostate cancer cell-bone stroma interactions is vital to our understanding of prostate cancer metastasis in bone. Sonic hedgehog (Shh), a secreted glycoprotein, is expressed in human prostate cancer tissues and several established human prostate cancer cell lines. We have previously reported that human prostate cancer cells, LNCaP, modified to overexpress Shh (LNShh cells) directly activated the hedgehog pathway in mouse pre-osteoblast MC3T3-E1 cells and induced osteoblast differentiation, a requisite process in prostate cancer metastasis in bone. LNShh-mediated initiation of early phase osteoblast differentiation in MC3T3-E1 cells occurred in the absence of exogenous ascorbic acid (AA), a factor that is routinely added to drive osteoblast differentiation in vitro. The purpose of the present study was to determine the role of exogenous AA in osteoblast differentiation induced by LNShh cells. In a novel co-culture system, MC3T3-E1 cells and control LNCaP or LNShh cells were co-cultured as mixed cell populations within the same culture well or chamber in the absence or presence of AA (50 microgram/ml). AA promoted the deposition of collagen, visualized by von Gieson staining, in the extracellular matrix of mixed co-cultures of MC3T3-E1 cells with either control LNCaP or LNShh cells. AA increased alkaline phosphatase activity and gene expression in mixed co-cultures of MC3T3-E1 and control LNCaP cells, and markedly enhanced Shh-stimulated alkaline phosphatase activity and gene expression in co-cultures of MC3T3-E1 and LNShh cells. Surprisingly, AA enhanced the expression of Shh signaling target genes Ptc1 and Gli1 in MC3T3-E1 cells co-cultured with LNShh but not with control LNCaP cells. To determine whether AA exerted a direct effect on the Shh pathway, MC3T3-E1 cells were cultured in the presence of Shh peptide (Shh-N) and/or AA for 24h. Data show that Shh-N, but not AA, increased Gli1 and Ptc1 expression, and there was no significant enhancement of gene levels by AA in Shh-N-treated cells.

Collectively, these data indicate that Shh and AA initiate early phase osteoblast differentiation via independent pathways. However, AA enhances Shh-mediated actions by indirectly activating the hedgehog pathway. Our studies demonstrate that paracrine signaling between prostate cancer cells and osteoblasts via the Shh pathway is sufficient to induce osteoblast differentiation, and this pathway can be modulated by other differentiation factors including ascorbic acid.

**Inhibition of Multiple Myeloma (MM) Growth and Preservation of Bone with Combined Radiotherapy and Anti-angiogenic Agent.** D. Jia<sup>1</sup>, R. Halakatti<sup>\*1</sup>, C. Jackson<sup>\*1</sup>, L. J. Suva<sup>2</sup>, L. Hennings<sup>\*3</sup>, X. Li<sup>4</sup>, S. Yaccoby<sup>4</sup>, P. M. Corry<sup>\*1</sup>, R. J. Griffin<sup>\*1</sup>. <sup>1</sup>Department of Radiation Oncology, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>2</sup>Department of Orthopedics, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>3</sup>Department of Pathology, U Arkansas for Medical Sciences, Little Rock, AR, USA, <sup>4</sup>Myeloma Institute for Research and Therapy, U Arkansas for Medical Sciences, Little Rock, AR, USA.

MM is characterized by its bone marrow preference and bone destruction. Although radiotherapy has been proven effective in cancer control in general, its use in MM treatment is less than routine except in a palliative setting. The efficacy of radiation (Rad) in MM growth control and bone protection was examined in a mouse model, wherein human MM cells expressing luciferase (Luc) were injected into bone grafts pre-implanted s.c. in SCID mice. The mice were divided into 4 groups: control, anginex (Ax), Rad, and Ax+Rad. Ax, a 33 a.a. anti-angiogenic peptide, was given 3 times a wk at 20 mg/kg/day. Rad was applied to the MM-containing bone grafts in 5 Gy fractions, once per wk, 2h after the last dose of Ax for a total 40 Gy over 8 wk. MM growth was estimated by live imaging Luc activity in bone grafts, measuring the dimensions of the grafts, and quantitating human lambda light chain in serum. Bone grafts were analyzed by histology for cellular and vascular features following radiography and microCT analyses for BMD and architecture. A 114-fold increase in Luc activity over baseline was seen in control mice by wk 8, whereas in mice receiving Ax+Rad Luc activity was reduced to 50% of the baseline. Ax or Rad alone had minimal effects. Luc activity correlated with serum MM marker as well as MM outgrowth from the bone grafts as reflected by graft volume. To evaluate MM relapse following these modalities, tumor growth was monitored for an additional 4 wk after the treatments ended. Graft volume doubled to 3652 mm<sup>3</sup> in the controls over this post-therapy period, reached 2273 mm<sup>3</sup> and 775 mm<sup>3</sup> in Ax- and Rad-treated mice, respectively, but remained small in Ax+Rad group (207 mm<sup>3</sup>). Consequently, bone grafts in the controls were mostly replaced by MM cells, and Ax or Rad alone did not prevent graft destruction. By contrast, vBMD as well as cortical and trabecular structure were preserved in grafts treated with Ax+Rad. Histological analysis showed that the number of MM loci, new blood vessels and bone resorbing osteoclasts were lower, while the number of cuboidal osteoblasts were higher in bone grafts receiving Ax+Rad, as compared with that in the other three groups ( $p < 0.05$ ). Our results demonstrate that radiotherapy, when primed by drugs such as anti-angiogenic agents, can significantly control MM growth and prevent skeletal destruction in this model, thus may have potential in MM focal lesion control.

**Role of Annexin II and Annexin II Receptor in Homing Multiple Myeloma Cells in the Bone Marrow.** D. Del Prete<sup>\*1</sup>, G. Lu<sup>1</sup>, F. Esteve<sup>\*1</sup>, Y. Shiozawa<sup>\*2</sup>, R. S. Taichman<sup>2</sup>, G. D. Roodman<sup>3</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>School of Dentistry, University of Michigan, Ann Arbor, MI, USA, <sup>3</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Annexin II (AXII) is a multi-functional protein expressed on the surface of rejuvenating cells like fibroblasts, endothelial and epithelial cells, and involved in cell proliferation, adhesion and migration. AXII is expressed by osteoblasts (OBs) and stromal cells in the bone marrow and has been shown to play a critical role in the initial adhesion of hematopoietic stem cells (HSCs) to the marrow niche (Blood 2007; 110:82-90). AXII<sup>-/-</sup> mice have fewer HSCs and the adhesion of HSCs to OBs derived from these mice is significantly impaired compared with OBs from wild-type animals. Because myeloma (MM) cells home to the marrow in an analogous fashion to HSC, and AXII mRNA is present in MM cells, we assessed the role of AXII and its receptor (AXIIR) in MM cell interaction with the marrow microenvironment, since the homing of MM cells to the bone marrow is critical for their survival and proliferation. We previously identified an AXIIR on human stromal cells. KM101 human stromal cells and MM.1S myeloma cells as well as primary human stromal and myeloma cells were tested. RT-PCR and Western blot analysis showed that AXII and AXIIR were expressed by all the cell types tested. However, the expression levels of AXII and AXIIR differed between stromal and myeloma cells. Stromal cells expressed high levels of AXII compared with MM cells, and MM cells expressed more AXIIR than stromal cells. Further, cocultures of MM.1S cells with KM101 cells increase AXIIR expression by MM.1S cells. To further characterize the role of AXII in the interaction of MM.1S cells with stromal cells adhesion assays were performed using an AXII-blocking peptide. Adhesion of MM.1S cells to KM101 cells was dose-dependently inhibited by the AXII peptide. These results suggest a potential critical role for AXII and AXIIR in localizing MM cells to the bone marrow.

**Increased Signaling Through p62 in the Multiple Myeloma Microenvironment Increases Myeloma (MM) Cell Growth and Osteoclast (OCL) Formation.** Y. Hiruma, N. Kurihara, G. D. Roodman. Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA.

The bone microenvironment plays a critical role in promoting both tumor growth and bone destruction in MM. Marrow stromal cells produce factors, which stimulate both the growth of MM cells and bone destruction and are key regulators of these processes. Marrow stromal cells produce these factors in increased amounts when they bind MM cells through adhesive interactions mediated via VCAM-1 on stromal cells and  $\beta_1$  integrins on MM cells. We examined the role of sequestosome-1 (p62), a recently described member of the NF- $\kappa$ B signaling pathway, in MM, since p62 sits at the crossroads of multiple signaling pathways potentially involved in both osteoclastogenesis and MM cell growth. Our hypothesis is that inhibiting p62 signaling will block the production of cytokines in the MM-bone microenvironment in response to the increased levels of TNF- $\alpha$  present in the MM microenvironment, decrease VCAM-1 expression on stromal cells, and markedly diminish osteolytic bone destruction and MM growth. Therefore, we isolated primary marrow stromal cells from MM patients and normals and measured p62 and PKC activation in MM marrow. PKC specifically interacts with p62 to increase its downstream signaling. Levels of phospho-PKC and VCAM-1 were significantly elevated in MM patients. We then blocked p62 activity in human stromal cells. p62 siRNA (40 nM) was transduced into normal and MM human stromal cells and p62 expression was decreased by at least 70% in these stromal cells. Stromal cells treated with p62siRNA or control siRNA were cultured with or without MM.1S cells for 3 days in separate experiments. The levels of VCAM-1 in p62siRNA transduced stromal cells were significantly lower than in control siRNA and untreated stromal cells. In addition, IL-6 production was increased when MM.1S myeloma cells were co-cultured with control siRNA treated stromal cells but not with p62siRNA treated stromal cells. Further, stromal cells lacking p62 minimally supported the growth of MM cells compared to control siRNA p62 containing stromal cells. Stromal cells lacking p62 also produced much lower levels of RANKL, and OCL formation was markedly decreased when these cells rather than control stromal cells were cocultured with normal OCL precursors. Studies of the mechanisms responsible for decreased IL-6 and RANKL production and VCAM-1 expression on MM stromal cells lacking p62 showed they resulted from decreased NF- $\kappa$ B and p38MAPK signaling. These results show that signaling through p62 plays an important role in MM cell growth and OCL formation induced by cytokines that are upregulated in the MM microenvironment.

**Fracture Risk in Patients with Different Types of Cancer.** P. Vestergaard<sup>1</sup>, L. Rejnmark<sup>2</sup>, L. Mosekilde<sup>2</sup>. <sup>1</sup>The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark, <sup>2</sup>Department of Endocrinology and Metabolism C, Aarhus Amtssygehus, Aarhus, Denmark.

**Background:** Few studies on the risk of fractures in patients with cancer exist, and little is known on the mechanisms of fractures in patients with cancer. We studied the risk of fracture in patients with various types of cancer.

**Subjects and methods:** Case control study. There were 124,655 fracture cases and 373,962 age and gender matched controls.

**Results:** An increased risk of fractures, primarily within the first year after diagnosis was seen in patients with primary bone cancer (OR=3.51, 95% CI: 1.54-8.01), multiple myeloma (OR=5.21, 95% CI: 2.96-9.19), metastases to the bone (OR=5.28, 95% CI: 3.58-7.79), metastases to other organs than bone (OR=1.85, 95% CI: 1.50-2.29), lung cancer (OR=1.90, 95% CI: 1.51-2.38), and cancer of the liver, gall bladder and pancreas (2.14, 95% CI: 1.39-3.31). For patients with prostate cancer an increase in the risk of fractures was seen with time. Other cancer types were not associated with an increased risk of fractures.

**Conclusions:** A high risk group regarding fractures includes cancers primarily affecting the bone (primary bone cancer, multiple myeloma, metastases to the bone, metastases to other organs than bone, lung cancer, and cancer of the liver, gall bladder and pancreas, and prostate cancer). The main increase in risk of fractures in this group was seen within the first year following diagnosis. A low risk group for fractures included all other cancer types (e.g. cancer of the breast, colon, skin etc). This may have implication for which patients should be selected for prevention against fractures.

**Influence of Imatinib on Bone Remodeling in Juvenile Mice.** J. Boehme<sup>\*1</sup>, M. Suttorp<sup>\*1</sup>, R. Fischer<sup>\*2</sup>, M. Bornhäuser<sup>\*3</sup>, J. A. Gasser<sup>\*4</sup>. <sup>1</sup>Department of Pediatrics, Division of Pediatric Hematology and Oncology, University Hospital Carl Gustav Carus, Dresden, Germany, <sup>2</sup>Institute of Pathology, University Hospital Carl Gustav Carus, Dresden, Germany, <sup>3</sup>Department of Internal Medicine I, University Hospital Carl Gustav Carus, Dresden, Germany, <sup>4</sup>Musculoskeletal Research, Novartis Institutes for BioMedical Research, Basel, Switzerland.

Imatinib (IM) is an effective treatment for chronic myeloid leukemia (CML) which inhibits the receptor tyrosine kinase BCR-ABL and other kinases like c-Kit, PDGF-R and c-FMS. The balance between bone resorption and bone formation under IM may be changed. We investigated the influence of IM on bone remodeling in growing mice.

**Methods:** At the age of 4 weeks, C3H mice were exposed to IM in drinking water for 10 weeks at doses of 80mg/kg/day (A), 110mg/kg/day (B), and 150mg/kg/day (C), resulting in serum levels of 60-674 ng/ml, 36-242 ng/ml and 51-534 ng/ml, respectively. Tibiae were analysed by pQCT, microCT and femora by histomorphometry. The plasma concentration of IM, osteocalcin, and the activity of the tartrate resistant acid phosphatase (TRAP5b) was determined.

**Results:** IM was tolerated well at all doses. At 5, but not 10 weeks, IM significantly and dose-dependently reduced the number of osteoclasts and resorption lacunae in femora of male animals from 23/field (controls) to 15 and 10, respectively. Effects were less pronounced in female mice.

Trabecular BMD was significantly increased in male mice by 8.5% and 9.9%, respectively, in groups B and C, and 5.2% in females (group C). Cortical thickness was increased in males by 6.1% and 11.2%, respectively, in group B and C and 7.5% in females (group C). Cancellous bone as assessed by microCT in males exhibited a significant increase in trabecular bone volume (BV/TV) of 19.7% and 13.2%, respectively, in groups B and C. In females a 10.6% increase was seen in group C. A significant increase in trabecular number (9.2% and 14.4%, respectively, in group B and C) in males and in females (12.8% in group C) was observed. As a result, trabecular connectivity improved significantly by 63% and 64%, respectively, in group B and C in males and by 22% and 38%, respectively, in group B and C in females. Bone biomarkers indicated a significant reduction of TRAP5b activity in groups B and C (both 5.1U/l) compared to controls (7.3U/l) and group A (6.5U/l) while osteocalcin levels remained unchanged.

**Conclusion:** In growing mice, IM reduced osteoclast number and resorption lacunae in long bones but not vertebrae. IM had a mild antiresorptive effect in cancellous bone (trabecular number), increased cortical thickness by inhibiting the expansion of the marrow cavity, and reduced TRAP5b activity. The effect was more pronounced in male mice and at younger age.

**TGF-beta Suppresses Adipocytic Differentiation and Enhances Accumulation of Stromal Cells in Myeloma Bone Lesions.** K. Takeuchi<sup>\*1</sup>, M. Abe<sup>1</sup>, M. Hiasa<sup>\*2</sup>, O. Tanaka<sup>\*1</sup>, S. Nakamura<sup>\*1</sup>, H. Miki<sup>\*1</sup>, K. Kagawa<sup>\*1</sup>, K. Yata<sup>\*1</sup>, T. Hashimoto<sup>\*1</sup>, S. Ozaki<sup>\*1</sup>, S. Kido<sup>1</sup>, T. Matsumoto<sup>1</sup>. <sup>1</sup>Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Health Biosciences, Tokushima, Japan, <sup>2</sup>Department of Orthodontics and Dentofacial Orthopedics, University of Tokushima Graduate School of Health Biosciences, Tokushima, Japan.

Multiple myeloma (MM) preferentially arises in the elderly, and develops devastating bone destruction. Although the bone marrow becomes fatty with normal aging, adipose tissue decreases and stromal cells increase in MM bone lesions. We have demonstrated that TGF-beta acts on stromal cells to inhibit their terminal differentiation into osteoblasts (OBs). TGF-beta is abundantly released and activated by enhanced bone resorption in MM bone lesions. Therefore, mesenchymal stem cell (MSC) differentiation into adipocytes may be suppressed and into stromal cells may be skewed, causing accumulation of stromal cells by enhanced TGF-beta actions in MM bone lesions. The present study was undertaken to clarify the role of bone-derived TGF-beta in MSC differentiation into adipocytes in MM. When C3H10T1/2 mesenchymal and ST2 stromal cells were cultured in an osteogenic medium with BMP-2, a considerable number of adipocytes appeared along with OBs. Addition of TGF-beta almost completely inhibited the adipocytic differentiation, without affecting Runx2 expression. TGF-beta also suppressed adipocytic differentiation of C3H10T1/2 cells facilitated by a PPARgamma ligand, ciglitazone. To simulate MM bone lesions, we co-cultured rabbit bone marrow cells with MM cells on dentine slices placed on membrane filters, and examined ciglitazone-stimulated adipocytic differentiation of C3H10T1/2 cells cultured in the lower chambers. Adipocytic differentiation by ciglitazone was potentially suppressed by TGF-beta, while blockade of TGF-beta actions by a type I receptor kinase inhibitor, SB431542, resumed adipocytic differentiation. In co-cultures without dentine slices, C3H10T1/2 cells differentiated into adipocytes. These results demonstrate that TGF-beta inhibits MSC differentiation into adipocytes while inhibiting terminal OB differentiation to create a stromal cell-rich microenvironment, and suggest that TGF-beta elaborated by enhanced bone resorption in MM bone lesions enhances accumulation of stromal cells to create "MM niche" suitable for MM expansion.

**A New Automated Multiplex Assay for Simultaneous Measurements of 4 Serum Biochemical Markers of Bone Metabolism in Osteoporosis.** A. Claudon<sup>\*1</sup>, P. Vergnaud<sup>\*1</sup>, C. Valverde<sup>\*1</sup>, A. Mayr<sup>\*2</sup>, U. Klause<sup>\*2</sup>, P. Garnero<sup>3</sup>. <sup>1</sup>Synarc, Biochemical Markers, Lyon, France, <sup>2</sup>Roche Diagnostics, Penzberg, Germany, <sup>3</sup>Synarc, Biochemical Markers / INSERM Research Unit 664, Lyon, France.

The serum biochemical markers C-terminal crosslinked telopeptides of type I collagen (CTX) for bone resorption, N-terminal propeptide of type I collagen (PINP) and osteocalcin (OC) for bone formation and intact PTH are commonly used in epidemiological and clinical trials in osteoporosis. Each of these markers is currently measured individually by manual or automated assays requiring a significant sample volume. A fully automated protein-array based assay was developed recently for the simultaneous measurement of these 4 markers in only 20 microliters of serum. The aim of this study was to evaluate the technical and clinical performances of this novel multiplex assay in osteoporosis.

Serum CTX, PINP, OC and PTH were measured by the multiplex (Immunological Multi Parameter Chip Technology, IMPACT, Roche Diagnostics) and the corresponding single automated reference assays (Elecys, Roche) in 157 healthy premenopausal women, 74 healthy men and 56 postmenopausal osteoporotic women before and 6 months after treatment with oral ibandronate (150 mg/month).

Intra and inter assay variation of the multiplex assay was low and similar to single measurements (<10% for all markers). The lower limit of quantification (LLOQ) -which is the minimal concentration of endogenous marker that can be accurately and precisely determined- was lower for all 4 markers with the multiplex than with single assays, especially for CTX (0.023 vs 0.087 ng/ml). In premenopausal women, postmenopausal women with osteoporosis and healthy men, values determined by the multiplex technology highly correlated (r from 0.93 to 0.97, p<0.0001) with the corresponding single assays and absolute levels were comparable. After 6 months of treatment of osteoporotic women with monthly oral ibandronate, CTX, PINP and OC declined by a median of 48%, 63% and 52% (p<0.0001), decreases which were of similar magnitude as those observed with the corresponding single assays. Because of the improved sensitivity of the multiplex assay, CTX levels could be accurately and precisely determined in all samples after 6 months of ibandronate (all values above the LLOQ), whereas 28% of values were below the quantification limit of the single assay.

In conclusion, this novel fully automated protein-array assay allows the precise and sensitive measurements of serum CTX, PINP, OC and intact PTH simultaneously in a low serum volume. This assay should be useful for the investigation of bone metabolism in large clinical studies particularly when sample volume is limited.

**Disclosures:** P. Garnero, None.

**Association of Urinary  $\gamma$ -Glutamyltransferase (GGT) and Serum FGF-23 with Prevalent Fracture: Hiroshima Cohort Study.** S. Fujiwara<sup>1</sup>, N. Masunari<sup>\*1</sup>, I. Takahashi<sup>\*1</sup>, W. Ohishi<sup>\*1</sup>, K. Ikeda<sup>2</sup>. <sup>1</sup>Clinical Studies, Radiation Effects Research Foundation, Hiroshima, Japan, <sup>2</sup>Department of Bone and Joint Disease, National Center for Geriatrics and Gerontology, Hiroshima, Japan.

We have reported that the urinary excretion of  $\gamma$ -glutamyltransferase (GGT), a recently identified bone-resorbing factor (JBC 2004, Endocrinology 2007), and the serum concentration of fibroblast growth factor (FGF)-23, an osteocyte-specific product, are associated with BMD (ASBMR 2007). The objective of the present study was to determine if urinary GGT and serum FGF-23 are associated with prevalent bone fracture in a population-based cohort. The study population consisted of 2,037 subjects (1,314 women and 723 men) aged 59 to 107 years old (average 73), followed up by biennial health examinations. A total of 252 subjects had spine fracture diagnosed by X-ray examination, and 125 had self-reported non-spine fracture. Serum FGF-23 was measured by ELISA. GGT level in the urine was determined by an autoanalyzer and corrected for creatinine concentration. BMD was measured in the spine and the hip by dual X-ray absorptiometry (QDR-4500, Hologic). Written informed consent was obtained from all participants. Multiple logistic regression was used for analysis.

Urinary GGT was significantly associated with prevalent spine fracture; when quartered (Q1-4), subjects with urinary GGT in the highest quartile (Q4) had a relative risk (RR) for spine fracture of 1.57 (95% confidence interval [CI], 1.05-2.34, p=0.03), after adjusting for age, sex and femoral neck BMD, compared with the Q2 reference group. Subjects with serum FGF-23 in the lowest quartile had RR for non-spine fracture of 1.96 (95% CI, 1.12-3.42, p=0.02). No relationship was found between GGT and non-spine fracture or between FGF-23 and spine fracture, after adjusting for age, sex and femoral neck BMD. Thus, urinary GGT and serum FGF-23 are potential markers for prediction of fracture independently of BMD.

**Comparison of the TRACP 5b Specificity of Two Commercial TRACP 5b Assays.** H. Ylipahkala<sup>1</sup>, K. M. Fagerlund<sup>2</sup>, A. J. Jankila<sup>3</sup>, J. M. Halleen<sup>4</sup>. <sup>1</sup>SBA Sciences Ltd, Oulu, Finland, <sup>2</sup>Anatomy, Institute of Biomedicine, University of Turku, Turku, Finland, <sup>3</sup>Medicine, Veterans Affairs Medical Center, Louisville, KY, USA, <sup>4</sup>Pharmatest Services Ltd, Turku, Finland.

Two forms of tartrate-resistant acid phosphatase (TRACP) circulate in human blood, TRACP 5a derived from macrophages and TRACP 5b derived from osteoclasts. Enzymatically active TRACP molecules constitute only 10% of circulating TRACP, while the remaining 90% circulates as fragments. We have studied the TRACP 5b specificity of commercially available BoneTRAP (IDS, Boldon, UK) and MetraTRAP5b (Quidel, San Diego, USA) assays and their clinical performance for monitoring alendronate treatment. BoneTRAP assay includes a monoclonal antibody O1A that binds both TRACP 5a and 5b, but not TRACP fragments. Bound TRACP activity is measured using pNPP as substrate at a TRACP 5b-selective pH 6.1. MetraTRAP5b assay includes two monoclonal antibodies, Trk49 that removes TRACP fragments and Trk62 that is stated to have high specificity for TRACP 5b. Bound TRACP activity is measured using CNPP as substrate at pH 6.4. Human serum TRACP 5a and 5b were separated by cation exchange chromatography and used to study TRACP 5b-specificity of the two assays. Both assays determined equal amounts of TRACP 5b activity, and the cross-reactivity to TRACP 5a was equal for both assays. When the substrate solutions were changed between the two assays, both assays still determined the same equal amounts of TRACP 5b activity as with their original substrates. Both assays determined approximately 5-fold less TRACP 5a activity with CNPP than with pNPP, indicating that CNPP is a more specific substrate for TRACP 5b. With pNPP as substrate, the antibody Trk62 bound TRACP 5a and 5b almost equally, indicating a very high cross-reactivity for TRACP 5a. The performance of the MetraTRAP5b assay is therefore mainly achieved by use of the more specific substrate CNPP, which partly compensates for the high cross-reactivity of the antibody Trk62 to TRACP 5a. We examined the clinical performance of both kits using a panel of serum samples from 137 postmenopausal women taking part in a placebo-controlled intervention trial, in which subjects received 5 mg alendronate per day. Alendronate treatment reduced TRACP 5b values by 53% when measured with the MetraTRAP5b assay, and by 42% when measured with the BoneTRAP assay. However, due to higher variability of the MetraTRAP5b assay, both assays showed similar sensitivity (80.0% vs 81.4%), signal-to-noise ratio (3.19 vs 3.14) and area under ROC curve (0.93 for both). We conclude that the BoneTRAP and MetraTRAP5b assays have equal specificity for TRACP 5b and interference by TRACP 5a, and equal clinical performance for monitoring alendronate treatment.

**PINP, a New Available Rat Bone Formation Marker. Usefulness in Osteopenia Studies Due to Androgen Lack and Ibandronate Treatment.** M. Montero<sup>\*1</sup>, I. Quiroga<sup>\*2</sup>, M. Rubert<sup>\*1</sup>, M. Diaz-Curiel<sup>3</sup>, F. Bausa<sup>\*4</sup>, C. De la Piedra<sup>1</sup>. <sup>1</sup>Biochemistry, Osteoarticular Pathology Laboratory, Fundacion Jimenez Diaz, Madrid, Spain, <sup>2</sup>Endocrinology, Hospital Puerta de Hierro, Madrid, Spain, <sup>3</sup>Internal Medicine, Fundacion Jimenez Diaz, Madrid, Spain, <sup>4</sup>Pharma Research Penzberg, Roche Diagnostics GmbH, Penzberg, Germany.

Ninety six Wistar rats, 9 months old, were sham operated (SHAM) or orchidectomized (OQX): untreated or treated with ibandronate (IBN) and were distributed into two studies, prevention (P) or treatment (T). P study: immediately after surgery animals were submitted to 4 groups which were administered subcutaneously for 20 weeks with either placebo (SHAM; n=12) and OQX (n=12) or with two regimens of IBN (Roche Diagnostics GmbH, Germany): 1 microg/Kg/day (OQX+IBN; n=12) or 28 microg/kg/28 days (OQX+mIBN). T study: all animals were left untreated for 6 months after surgery and subsequently submitted to 4 groups treated in a similar way than in P study: (SHAM2; n=12), (OQX2; n=12), (OQX2+IBN; n=12) and (OQX2+mIBN; n=12). After sacrifice, bone mineral density (BMD) was determined in the whole left femur by DEXA. Serum aminoterminal propeptide of collagen I (PINP, rat specific ELISA, IDS), and tartrate-resistant acid phosphatase, 5b isoenzyme (5b-TRAP ELISA, IDS) were measured. Five and 11 months after orchidectomy, OQX rats showed a decrease in PINP; 5 months after surgery OQX rats presented an increase in TRAP, that reverted 6 months later. Femoral BMD was decreased in OQX rats with respect to their SHAM groups. Both, daily or monthly treatment with IBN in P or T-studies, decreased TRAP and PINP indicating a general decrease in bone remodelling. Femoral BMD was "maintained like" or "recovered until" SHAM levels (P or T study respectively) in OQX groups treated with daily or monthly IBN. The above results suggest that PINP, a new available bone formation marker for rat experimental designs, is useful in studies about osteopenia due to androgen lack and remodelling effects of IBN treatment.

**Dickkopf-1 Predicts the Gain of Bone Mineral Density in Osteoporotic Women on Bisphosphonates.** T. Kocjan<sup>\*1</sup>, G. Hawa<sup>\*2</sup>, B. Lindner<sup>\*2</sup>, S. Maitzen<sup>\*2</sup>, J. Prezelj<sup>\*1</sup>, Z. Trošt<sup>\*3</sup>, J. Marc<sup>\*3</sup>, S. Mencej<sup>\*3</sup>. <sup>1</sup>Department of Endocrinology and Metabolic Diseases, Medical Centre Ljubljana, Ljubljana, Slovenia, <sup>2</sup>Research & Development, BIOMEDICA, Vienna, Austria, <sup>3</sup>Department of Clinical Biochemistry, Faculty of Pharmacy, Ljubljana, Slovenia.

Serum Dickkopf-1 protein (Dkk-1) is a potent inhibitor of bone formation. The aim of our study was to seek for correlation of serum Dkk-1 levels with change in bone mineral density (BMD) over a 1-year period in an osteoporotic female population treated with bisphosphonates.

51 postmenopausal women with newly diagnosed osteoporosis, who had been treated with weekly risedronate or monthly ibandronate plus calcium and vitamin D<sub>3</sub> supplements for 1 year were enrolled. The study was approved by the national medical ethics committee, and written informed consent was obtained from all participants.

Blood samples for determination of Dkk-1 and C-terminal cross linking telopeptide of type I collagen (CTX) were collected at the time of the diagnosis with first BMD measurement and after 3 months. Dkk-1 serum levels were determined by a newly developed ELISA-test. The relevance of circadian change in Dkk-1 serum levels was evaluated and found to be non significant. BMD measurement was then repeated after 1 year of treatment.

A significant negative correlation of serum Dkk-1 levels after 3 month was found with increase in spine and femoral neck BMD after 1 year of treatment.

This suggests that a single determination of serum Dkk-1 level after 3 months might be useful as an early predictor of long-term BMD gain determined by DXA after 1 year of osteoporosis treatment with bisphosphonates. Furthermore, high levels of serum Dkk-1 may identify postmenopausal women with osteoporosis who are not good candidates for bisphosphonate and might benefit more from anabolic treatment.

**Development of a Bone Specific Alkaline Phosphatase Assay on the IDS Automated Analyser 3X3™.** N. Baeyens<sup>\*</sup>, A. K. Barnes<sup>\*</sup>, G. Pirens<sup>\*</sup>, G. Sarlet<sup>\*</sup>, M. Bougoussa<sup>\*</sup>, J. V. Leblond<sup>\*</sup>, M. L. Garrity<sup>\*</sup>. Immunodiagnostic Systems (IDS) Ltd, Bolton, United Kingdom.

Circulating levels of Bone Alkaline Phosphatase (BAP) are believed to reflect the metabolic status of osteoblasts which are involved in the formation of bone. Measurement of BAP has been shown to be useful in evaluating patients with Paget's disease, osteomalacia, primary hyperparathyroidism, renal osteodystrophy, osteoporosis and metastases to bone.

BAP can be currently measured by the IDS OSTASE® ELISA. The present work was conducted to transfer the manual assay onto the IDS Automated Analyser 3X3™. Multiple types of detection are embedded on this analyser, including spectrophotometric and chemiluminescent and will allow a rapid and robust transfer from a manual assay to a fully automated version, without any major modification in reagent formulation or loss of sensitivity. The proposed product will be a colorimetric assay using magnetic particles as the solid phase.

The assay uses the spectrophotometer present on board the analyser, reading the assay at 405 nm wavelength according to a kinetic method measurement. This kinetic value is directly proportional to the BAP activity. The protocol used in the analyser is directly derived from the IDS OSTASE® BAP kit and has been adapted to the analyser, with regard to the machine constraints (e.g. volume sample, time incubation, and washing process). In summary, 75 µl of sample are incubated for 15 min in the presence of antibody linked to biotin, magnetic particles coated to streptavidin are added and incubated for a further 15 min. The BAP/Antibody-biotin complex binds to the magnetic particles. These magnetic particles are captured with magnets and washed by the washing buffer used in the analyser. After that, the magnetic particles containing BAP fixed by antibody are incubated in the presence of pNPP and the absorbance is measured during a short time (300 sec) to obtain the kinetic constant in milli optical density / min at 405 nm.

The Bone specific Alkaline Phosphatase assay on the IDS Automated Analyser 3X3™ shows a measuring range of 2.5 µg/L to 120 µg/L with a analytical sensitivity ≤ 1µg/L, a functional sensitivity close to 2.5 µg/L and a inter-assay imprecision ≤ 7%. The assay demonstrates good correlation with IDS OSTASE® ELISA (from where the reagents are derived) with Analyser = 0.88 x ELISA + 0.25 µg/L with r = 0.91 (n=46).

These results indicate that the automated BAP assay can provide a sensitive and precise immunoassay with a good correlation with the IDS OSTASE® BAP ELISA kit.\*Ostase® is a registered trademark of Hybritech Incorporated, a subsidiary of Beckman Coulter Inc.

**Development of a New N-Mid® Osteocalcin Immunoassay on the IDS Automated Analyser 3X3™.** M. Bougoussa\*, A. K. Barnes\*, G. Pirens\*, G. Sarlet\*, N. Baeyens\*, C. Hagelstein\*, M. L. Garrity\*. Immunodiagnostic Systems (IDS) Ltd, Bolton, United Kingdom.

Osteocalcin or bone Gla protein is a small 49aa protein that is rich in glutamic acid (GLA) and is a vitamin K-dependent protein that has been estimated to represent up to 20% of all non-collagenous protein in bone. A proportion of newly synthesized osteocalcin is released into the circulation, where it can be measured by immunoassay. Assays for osteocalcin are not standardised, and different antibodies clearly recognize different fragments. Antibodies that recognise both the intact and the large N-terminal mid-molecule fragment appear to provide the best clinical information.

The IDS Automated Analyser 3X3™ N-Mid® osteocalcin assay is an adaptation of the IDS Nordic ELISA assay. This assay uses two monoclonal antibodies. The biotinylated antibody is directed against residues 21-29. The second antibody recognizes residues 10-16 and is coupled to an acridinium derivative. After an incubation of 50 µl of sample with the biotinylated and second antibody, 20 µl of streptavidin magnetic particles are added to the mixture. After a second incubation, followed by a washing step, triggers are added and the measured luminescence is directly proportional to the N-Mid® osteocalcin concentration present in the sample.

A first result is available after 45min. The analytical range of the assay is 2 to 120 ng/ml. The performance was established using the CLSI protocol. The analytical sensitivity is ≤0.5 ng/ml and the functional sensitivity is < 3ng/ml. The intra-assay and inter-assay precision are respectively < 6.5 % and <11 %. The osteocalcin recovery and linearity averages 106% and 102% respectively, expressed as Observed/Expected ratios. A correlation study was performed using 72 plasma and serum samples. The assay demonstrates good correlation with the IDS Nordic ELISA kit (R=0.97) and yields the following regression equation: IDS Automated Analyser 3X3™ = 0.92 x ELISA -2.73ng/ml.

The results indicate that the IDS Automated Analyser 3X3™ N-Mid® osteocalcin assay provides a sensitive, specific and reproducible assay with good correlation with the IDS Nordic ELISA kit.

**Use of Conductivity for the Correction of Urinary N-telopeptide.** S. R. Johnson, S. Carlisle\*, A. Krishnankutty\*, K. Higgs\*, K. Zak\*. R&D, SPD, Bedford, United Kingdom.

Urinary N-telopeptide (uNTx) measurements provide valuable clinical information on bone resorption and there are several assays available that can accurately measure uNTx. Measurements are normally corrected by dividing by the urine creatinine concentration to remove the influence of varying urine concentration. However, creatinine is an imperfect molecule for concentration correction because it is known to be affected by a number of variables such as muscularity, age and diet. Urine conductivity has previously been found suitable for normalising other urinary analyte concentrations, such as thromboxane B2, therefore its ability to correct uNTx measurements was examined. In particular, the influence of dietary sodium was studied as sodium ions are a major contributor of total urine conductivity.

An automated method for measurement of conductivity was developed, comprising of a biodot pump dispenser and X/Y/Z robotic arm with auto-sampler, in conjunction with a flow-through micro-conductivity cell and reader, which allowed high through put of samples. A model was built equating conductivity to creatinine using measurements from every single void of urine throughout a 24h period from 40 volunteers. This model was then applied to a study where volunteer's dietary sodium was controlled. Thirty volunteers were recruited and each spent 2 days at normal, low and high dietary sodium intake, during which they provided urine samples. Creatinine, conductivity and uNTx were measured on these samples to examine the robustness of the model.

The mean dietary sodium intake during low, normal and high sodium diets was 1.98, 3.24 and 14.89g for all volunteers. When conductivity measurements, converted using the non-linear model, were used to correct uNTx, mean concentrations for the low, normal and high dietary sodium intake were 29.27, 30.14 and 28.06 nM BCE/mM creatinine equivalent. Therefore conductivity was able to correct urine concentration under varying levels of sodium intake.

This analysis demonstrates that conductivity may be a viable alternative to creatinine for correction of uNTx. Conductivity measurements have the added benefit of being cheap, quick to perform and have low analytical variability.

**Usefulness of Alveolar Bone Density Measurement in Risk Assessment for Bisphosphonate-related Osteonecrosis of the Jaw (BRONJ).** Y. Takaishi<sup>1</sup>, A. Kamada<sup>2</sup>, T. Ikeo<sup>3</sup>, M. Nakajima<sup>4</sup>, T. Miki<sup>5</sup>, T. Fujita<sup>6</sup>. <sup>1</sup>Takaishi Dental Clinic, Himeji, Japan, <sup>2</sup>Biochemistry, Osaka Dental University, Osaka, Japan, <sup>3</sup>Osaka Dental University, Osaka, Japan, <sup>4</sup>Oral and Maxillofacial Surgery, Osaka Dental University, Osaka, Japan, <sup>5</sup>Geriatric Medicine, Osaka City University, Osaka, Japan, <sup>6</sup>Internal Medicine, Katsuragi Hospital, Osaka, Japan.

Bisphosphonate-associated osteonecrosis of the jaw (BRONJ) is becoming a serious concern in dental and medical fields. Although risk factors such as intravenous long term use of potent bisphosphonates, dental surgical procedure including dental extraction and poor oral hygiene and infection have been pointed out, it is imperative to find a reliable test method predicting the occurrence of BRONJ. Around the lesions of BRONJ, increase of alveolar bone density is frequently noted. By using dental radiography with aluminum step wedge pasted to the film to standardize X-ray exposure, density of the alveolar bone was measured at several locations around the right mandibular premolar, placing the X-ray tube parallel to the film.

By using a software (Bone Right, Dentalgraphic•Com company, Himeji), data and histogram of the alveolar bone mineral density (al - BMD) were recorded on the screen of a lap - top computer in a few minutes. This method may also be applied similarly from a panorama film covering the whole series of the teeth in an individual. The radio-opaque BRONJ lesion is surrounded by relatively radiolucent area containing bacterial flora and inflammatory granulation tissue, presenting as chronic suppurative osteomyelitis. The bone mineral density around the osteonecrosis lesions including BRONJ showed an extremely high mineral density, 168±30 (SD) in 8 measurements in 4 cases of jaw osteonecrosis including 1 case following radiation treatment. Significantly higher than the values in 24 measurement in 6 case corresponding regions without BRONJ, 130±27, (P=0.0028). In one subject in whom two extractions were simultaneously carried out, BRONJ occurred only at the location with extremely high alveolar bone density, and not on other site of dental extraction with normal bone density. Alveolar BMD measurement thus appears to predict the occurrence of BRONJ to be useful for detecting subjects at systemic or local risk for occurrence of BRONJ, in addition to low serum CTX suggested as a systemic risk factor for BRONJ.

**Consistency in Measurement Assessments in Different Models of Norland DXA Scanners.** T. V. Sanchez<sup>1</sup>, D. K. Buckingham<sup>2</sup>, D. R. Purvis<sup>2</sup>, C. A. Dudzek<sup>2</sup>. <sup>1</sup>Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA, <sup>2</sup>Research and Development, Norland--a CooperSurgical Company, Fort Atkinson, WI, USA.

The consistency in the measurements made by different models of equipment is an issue in the densitometry community. To examine consistency in how Norland densitometers evaluate bone mineral density, bone mineral content and bone area we have examine scanner measurements done between 1988 and 2008 in processing measurements done on one of two AP Spine phantoms.

As part of the normal production process, at final testing Norland scanners carry out nine scans on one of two AP Spine Phantoms using standard AP Spine scan settings for the model and software being used. To examine consistency in measurements we randomly selected records from twenty-five different scanners of each model produced between January of 1988 and March of 2008. Models represented in this collection included the Norland XR-26, Eclipse, XR-36, Excell, XR-46, XR-600 and XR-800 systems. Each scanner used software current to its production date. The resulting average and standard deviation were compared for each model.

Results (%True) of Measurements on the Primary AP Spine Phantom by Different Scanner Systems Between 1988 and 2008.

	BMD	BMC	Area
XR-26	100.15±0.54	99.89±0.53	99.72±0.35
Eclipse	99.71±0.71	99.49±0.73	99.80±0.44
XR-36	99.95±0.49	99.66±0.54	99.69±0.29
Excell	100.63±0.44	101.22±0.52	100.59±0.38
XR-46	100.50±0.78	100.33±1.01	99.96±0.53
XR-600	100.12±0.24	100.68±0.41	100.56±0.34
XR-800	100.17±0.42	100.33±0.60	100.16±0.43

The results show a consistency in measured bone mineral density, bone mineral content and bone area in the various scanners. The results also demonstrate how the use of the same phantom over time can be employed to demonstrate that equipment is performing consistently over changes in hardware or software.

**The Effect of Vertebral Marrow Fat Content on the Diagnosis of Osteoporosis.** G. M. Blake<sup>1</sup>, J. F. Griffith<sup>2</sup>, D. K. W. Yeung<sup>2</sup>, P. C. Leung<sup>2</sup>, I. Fogelman<sup>1</sup>. <sup>1</sup>King's College London School of Medicine, London, United Kingdom, <sup>2</sup>Prince of Wales Hospital, Chinese University of Hong Kong, Shatin, Hong Kong.

Quantitative examination of iliac crest bone biopsies shows that as subjects become older bone and functional marrow are replaced by adipose tissue. Studies of vertebral marrow fat using nuclear magnetic resonance spectroscopy (MRS) show a highly significant relationship between spine T-score and marrow fat content. These findings suggest that the ability of dual energy x-ray absorptiometry (DXA) scans to identify patients at high risk of fracture is partly explained by the negative effect of increasing marrow fat on bone mineral density (BMD). However, care is necessary in interpreting the relationship between spine T-score and vertebral marrow fat because of a selection effect in which subjects with higher marrow fat are more likely to be found to have osteoporosis. We studied groups of elderly Hong Kong Chinese women (N = 103, mean age 73 y; range 67-84 y) and men (N = 82, mean age 73 y; range 67-101 y) who had spine DXA scans and MRS measurements of L3 marrow fat. The effect of varying marrow fat on BMD was modelled using vertebral body thicknesses measured in 50 men and women. Spine T-scores in each individual were adjusted for the measured marrow fat. Subjects were sorted into their WHO categories based on corrected T-scores, and the relationship between marrow fat and T-score status evaluated using regression analysis and analysis of variance. The average change in marrow fat per T-score unit was used to infer the proportion of the spine BMD fracture discrimination explained by marrow composition. The mean (SD) of the L1-L4 vertebral body thickness was 30.2 (2.1) mm for the Hong Kong women and 33.4 (2.5) mm for the men. When the marrow fat content measured by MRS changed from 0 to 100% the BMD change was estimated to be 0.14 g/cm<sup>3</sup> (1.3 T-score units) in women and 0.16 g/cm<sup>3</sup> (1.3 T-score units) in men. Adjustment of spine BMD for marrow fat reduced the significance of the correlation between marrow fat and T-score in both men and women compared with uncorrected data. However, there was still a trend for marrow fat to increase with decreasing T-score with a slope of  $-1.2 \pm 0.7\%$  per T-score unit ( $p = 0.078$ ) for women and  $-1.4 \pm 0.6\%$  per T-score unit ( $p = 0.023$ ) for men. When the effect of marrow composition on fracture discrimination was evaluated the results showed that 2% of the ability of spine DXA measurements to discriminate fracture risk is explained by the higher vertebral marrow fat content found in osteoporotic subjects. In conclusion, after adjustment for the selection effect patients with osteoporosis were still found to have higher vertebral marrow fat content. However, marrow composition made a negligible contribution to fracture discrimination.

**Correlations between Panoramic Radiomorphometric Indices and Bone Mineral Density in Postmenopausal Women.** A. F. Leite<sup>1</sup>, P. T. S. Figueiredo<sup>2</sup>, C. M. Guia<sup>3</sup>, A. P. Paula<sup>4</sup>, N. S. Melo<sup>5</sup>. <sup>1</sup>Oral Radiology, Department of Dentistry, College of Health Sciences, University of Brasília, Brasília, Brazil, <sup>2</sup>Oral Radiology, Department of Dentistry, College of Health Sciences, University of Brasília, Brasília, Brazil, <sup>3</sup>College of Health Sciences, University of Brasília, Brasília, Brazil, <sup>4</sup>Rheumatology Division, College of Health Sciences, University of Brasília, Brasília, Brazil, <sup>5</sup>Department of Dentistry, College of Health Sciences, University of Brasília, Brasília, Brazil.

The aims of this study were to correlate seven panoramic radiomorphometric indices with the BMDs of L1-L4, femoral neck and total hip, and to evaluate the accuracy of these indices in predicting densitometric diagnoses of osteoporosis, and T-Scores  $\leq -2.0$ . Three hundred and fifty one healthy postmenopausal women aged over 45 years were selected. All performed dual X-ray absorptiometries (QDR 1000, Hologic, USA) and panoramic radiographs (Rotograph Plus; Villa Medical System, Italy). Mandibular cortical indices, simple visual estimations of cortical widths, mental and antegonial indices, antegonial widths, and gonial and antegonial angles were measured. A stepwise forward logistic regression adjusted for age was performed. Significant associations were demonstrated between qualitative indices, cortical measurements and BMDs at the three bone sites ( $p < 0.001$ ). In women with severely eroded mandibular cortices, classified as C3 by the mandibular cortical index, the odds ratio (OR) was 4.82 for having osteoporosis at one of measured sites, and 10.87 for a T-Score  $\leq -2.0$ . In women with very thin mandibular cortices, determined by simple visual estimation of cortical width, the ORs were 8.02 and 5.46 for osteoporosis and T-Score  $\leq -2.0$ , respectively. In conclusion, certain qualitative indices, simpler and easier to be applied, may be considered more accurate panoramic measurements in predicting osteoporosis and T-Score  $\leq -2.0$ .

**6819 Analysis on Measurement of Bone Mineral Density of Phalanges by Radiographic Absorptiometry in Beijing.** J. Wang<sup>1</sup>, Z. Liu<sup>2</sup>, Z. Zhang<sup>1</sup>, P. Zhong<sup>1</sup>, Q. Wang<sup>1</sup>, X. Bi<sup>3</sup>, L. Al-Dayeh<sup>3</sup>. <sup>1</sup>Aviation Industry Center Hospital, Beijing, China, <sup>2</sup>China Osteoporosis Foundation, Beijing, China, <sup>3</sup>CompuMed, Inc., Los Angeles, CA, USA.

Osteoporosis is a very common disease in aging people in China. According to China's 2000 national census, approximately 100 million of its citizens suffer from various stages of osteoporosis. Although the T-Score based WHO criteria for osteoporosis diagnosis were derived from Bone Mineral Density (BMD) measurement of Caucasian women, they are still the mostly referenced standards in practice in China. It is very important to establish Chinese diagnostic standards for osteoporosis prevention and diagnosing. Objective: To measure phalangeal BMD of normal population in Beijing area using Radiographic Absorptiometry(RA); to establish Chinese normal reference database for RA technique and to compare BMD measurement results by RA with that of forearm by SPA. Methods: A study group consisted of 6819 healthy participants aged between 10 to 90 years old (with male 3376, female 3443) was investigated. Middle phalangeal BMD of each participant's index, middle and ring fingers in the non-dominant hand were measured using RA technique (OsteoGram2000 CompuMed, Inc, U.S.A.). The measured results were calculated and grouped according to an age interval of every 10 years. Results: The bone status of each participant was evaluated by two commonly used standards in China; which are the WHO and OCCGS. According to the WHO standard 21% of the females and 4% of the males among the investigated people had osteoporosis status. With the OCCGS standard 33% of the females and 10% of the males had osteoporosis status. Conclusion 1. A normal reference database for phalangeal BMD by RA technique has been established in China for the first time. 2. The OCCGS standard with a cutting point at  $-2.0SD$  might be more appropriate than that of the WHO standard of T-score  $= -2.5$  for Chinese population in osteoporosis disease screening and evaluation when BMD test was performed using RA. 3. The BMD results measured by RA technique are highly correlated to that of forearm by SPA in China.

**Feasibility and Reproducibility of in-vivo Assessment of Trabecular Bone Architecture using MicroMRI-based Method at Multiple Study Centers.** N. B. Watts<sup>1</sup>, S. L. Greenspan<sup>2</sup>, R. Jackson<sup>3</sup>, M. Maricic<sup>4</sup>, W. Liu<sup>5</sup>, B. Kuzmak<sup>6</sup>, A. Grauer<sup>6</sup>, K. Driver<sup>7</sup>, T. Dufresne<sup>7</sup>, P. Chmielewski<sup>7</sup>, B. R. Gombert<sup>8</sup>, P. Seaman<sup>8</sup>, B. Borah<sup>7</sup>. <sup>1</sup>University of Cincinnati, Cincinnati, OH, USA, <sup>2</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>Ohio State University, Columbus, OH, USA, <sup>4</sup>Catalina Pointe Clinical Research, Tucson, AZ, USA, <sup>5</sup>UMDNJ, Newark, NJ, USA, <sup>6</sup>P & G Pharmaceuticals, Mason, OH, USA, <sup>7</sup>P&G Pharmaceuticals, Mason, OH, USA, <sup>8</sup>MicroMRI Inc., Philadelphia, PA, USA.

In-vivo imaging methods such as microMRI and peripheral quantitative CT (pQCT) allows evaluation of architectural changes in common peripheral skeletal sites that commonly fracture. The microMRI method for bone architecture measurement has been validated in a research setting. Prior to use in a longitudinal clinical study, the feasibility of the method needed further evaluation under realistic multicenter study conditions. We assessed the repeatability and reproducibility of architectural indices of the distal radius of the same 6 premenopausal females (age 29 - 42 years) at 5 study centers using a custom-made wrist coil on 1.5 Tesla GE MRI scanners. At each study center, each subject had 2 scans/day on 2 consecutive days performed by the same operator. At 1 center, 2 additional scans were obtained for each subject by a different operator. Data from 1 center was also analyzed by 2 analysts. All scans were completed within about 2 months. Bone volume fraction (BV/TV) and topological parameters (eg, surface to curve ratio and erosion index) were analyzed by MicroMRI Inc. using proprietary software. Additional conventional parameters of trabecular architecture were generated from the raw data using software package developed by Scanco Medical, Inc., available on microCT scanners. The reproducibility was assessed by root mean square coefficient of variations (RMS-CVs) and intraclass correlation coefficients (ICCs) of each of the parameters. Based on the within-site, motion-corrected, slice-matched data, the RMS-CVs for BV/TV and topological parameters ranged from 2.7 - 5.1% and 6.6 - 11.8%, respectively, and are comparable to historical data. The ICCs ( $\leq 0.75$ ) found in this study were lower than historical data ( $>0.80$ ) and may be due to small variance in structural parameters observed in the homogeneous female subjects in this study. BV/TV generated by microMRI and Scanco microCT methods compared favorably with minor differences in RMS-CV and ICC. The operator-to-operator and analyst-to-analyst variability was negligible. In conclusion, results of this study showed that the microMRI method was reproducible and repeatable at multiple study sites with multiple operators and has potential to be used in longitudinal clinical studies to assess treatment-modified changes in bone architecture.

**Usefulness of SpinalMouse as a Screening Tool for the Presence of Vertebral Wedge Deformity.** K. Mikawa, Y. Abe, K. Aoyagi. Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

The purpose of this study was to evaluate the ability of a novel clinical tool, SpinalMouse®, to identify women with vertebral wedge deformities. Subjects comprised 102 women with a mean ( $\pm$ standard deviation) age of  $77.5 \pm 6.7$  years (range, 62-97 years) who visited an orthopedic outpatient clinic due to lower back pain. We measured curvature of the thoracic and lumbar spine using SpinalMouse®, and thoracic kyphotic angle and lumbar lordotic angle were calculated. Lateral spine radiography was performed and radiographic vertebral wedge deformities were assessed by quantitative morphometry. Vertebral anterior and posterior heights were measured and anterior/posterior (AP) ratio was calculated. Vertebral wedge deformity was considered present for AP ratio  $<0.8$ . Other types of vertebral deformity (i.e., central deformity and crush deformity) were not included in this study. Of the 102 subjects, 48 showed  $\geq 1$  thoracic vertebral wedge deformity and 39 had  $\geq 1$  lumbar vertebral wedge deformities. Women with thoracic vertebral wedge deformities displayed a significantly greater thoracic kyphotic angle than women without any thoracic vertebral wedge deformity. Similarly, women with lumbar vertebral wedge deformities showed significantly smaller lumbar lordotic angle than women without any lumbar vertebral wedge deformity. Receiver operating characteristic analysis showed that both thoracic kyphotic angle and lumbar lordotic angle were useful in discriminating women with wedge deformities in respective lesions. Area under the curve was 0.95 for thoracic kyphotic angle in discriminating women with thoracic vertebral wedge deformities and 0.85 for lumbar lordotic angle in discriminating women with lumbar vertebral wedge deformities. When a thoracic kyphotic angle of  $47^\circ$  was used as a cutoff, specificity and sensitivity for identifying individuals with thoracic vertebral wedge deformities were 92% and 91%, respectively. As for lumbar spine, when a lumbar lordotic angle of  $3^\circ$  was used as a cutoff, specificity and sensitivity for identifying individuals with lumbar vertebral wedge deformities were 87% and 75%, respectively. These results suggest that increased thoracic kyphosis and decreased lumbar lordosis as assessed by SpinalMouse® are significantly associated with existing vertebral wedge deformities in the respective lesions. SpinalMouse® could be useful as a screening tool to identify individuals requiring radiographic assessment for vertebral wedge deformities.

**Collecting Bone out of the Medial Condyle of Tibia - A New Method.** S. Jirsakova\*, V. Vyskocil<sup>2</sup>, A. Nemeckova\*, R. Pikner\*, J. Michalek\*. <sup>1</sup>Department of Bone disease, Charles University Hospital, Plzen, Czech Republic, <sup>2</sup>Metabolic Bone Disease Center, Charles University Hospital, Plzen, Czech Republic, <sup>3</sup>Department of Histology and Embryology, Charles University, Plzen, Czech Republic, <sup>4</sup>Metabolic Bone Disease Center, Charles University Hospital, Plzen, Czech Republic, <sup>5</sup>Academy of Sciences of The Czech Republic, Prague, Czech Republic.

The aim of our study was to design and develop a new osseous tissue specimen collecting method that would show advantages in comparison with methods already used. We evaluated microcracks, dynamic parameters and histomorphometry on bone biopsies from medial condyle of tibia in 35 postmenopausal women (age 60-80 yr) who had received bisphosphonate therapy for at least 9 years. We compared results with bone biopsies obtained from 10 cadavers (age 65-78 yr). Bone biopsies from medial condyle of the tibia were obtained after tetracycline double-labeling. The biopsies were taken with a mechanical bone trephine. Bone samples were bulk stained with green calcein as second fluorochrome. The microcracks and dynamic parameters were evaluated with the help of a laser confocal scanning microscope. The histomorphometry analysis of the bone samples was evaluated from semi-thick sections under light microscope. In all alendronate-treated patients the newly formed bone retains its lamellar structure, erosion cavities are shallow, osteoclasts only have few nuclei and there was no evidence of marrow fibrosis or cellular toxicity. Six women treated long-term-wise with alendronate have no visible microfractures. Among treated women, cancellous bone microcrack frequency of bone tissue was with the median crack density 0.130 microcracks/mm<sup>2</sup>, which did differ significantly from that observed in untreated group (0.085 microcracks/mm<sup>2</sup>). The mean cancellous bone microcrack length was 160  $\mu$ m among treated women and did differ significantly from that observed in untreated group (80  $\mu$ m). The mean MAR was normal in treated patients;  $0.71 \pm 0.16 \mu$ m/d. Bone remodeling was suppressed in the treated group, with the mean Ac.f. =  $0.08 \pm 0.07$  /year, MS/BS =  $0.625 \pm 0.713\%$ , BFR/BS =  $0.005 \pm 0.004 \mu$ m<sup>3</sup>/mm<sup>2</sup>/day. The authors developed and described a method for collecting and evaluating bone specimens of osseous tissue from the median condyle of the tibia. Bone specimens collected by the recommended method met the parameters required for qualitative,

quantitative histomorphometrics analysis and microfracture analysis. This method shows advantages in clinical practice in comparison with methods already used.

**Morphometric Determinants of Three Dimensional Femoral Neck Structure and Strength in Older Postmenopausal Women.** R. L. Prince<sup>1</sup>, K. Zhu<sup>2</sup>, M. Pollock\*, V. H. S. Low\*. <sup>1</sup>School of Medicine and Pharmacology, University of Western Australia, Perth, Australia, <sup>2</sup>Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia, <sup>3</sup>Department of Radiology, Sir Charles Gairdner Hospital, Perth, Australia.

Both height and weight are determinants of areal BMD. However the relative importance of body mass and stature to true three dimensional bone structure and strength remains uncertain. This study examines the relationship between body mass and size to femoral neck structure measured using quantitative computed tomography (QCT) and the bone strength calculated from engineering principles.

The study subjects were 186 women aged  $73.6 \pm 8.2$  years enrolled for a dietary intervention study. Potential physical determinants were height, weight and calf girth. Bone structure was measured by QCT (Phillips Brilliance CT) with patients lying on top of the QCT Pro™ calibration phantom and analysed with Mindways QCT Pro software. Linear regression analysis of the determinants of femoral neck structure and strength variables was undertaken using the independent variables age, height, weight and calf girth.

Both height and weight accounted for some of the variance of areal femoral neck (FN) BMD ( $R^2$  Height 5.8%, Weight 5.8%,  $P < 0.01$ ) but not true volumetric FN BMD although there were strong independent correlations of height and weight with FN mass ( $R^2$  Height 15.1%, Weight 8.9%,  $P < 0.01$ ) and volume ( $R^2$  Height 13.4%, Weight 6.7%,  $P < 0.01$ ).

In multiple regression the only significant predictor of total and trabecular FN cross-sectional bone area, related to bone strength in compression, was height accounting for 16% and 7.4% of variation respectively. Regarding femoral neck section modulus, a measure of femoral neck strength in bending, both in plane and out of plane measures were related to height at 19.7% and 16.3% of variation respectively.

These results show that in elderly postmenopausal women true three dimensional volumetric FN BMD is not related to body size. This is because although both FN mass and volume are body size dependent this dependency is proportional and cancels out in the calculation of true BMD. However FN bone strength in compression and bending is related to stature presumably because of the bone size dependency of these measurements. Thus although the relationship between body size and areal FN BMD is an aberration of the method the fact that size is a predictor of strength may account for the clinical predicative value of areal bone density combining as it does both bone size and bone mass into one value.

**Validation of a 2D/3D Generic Mathematical Relationship Between TBS as Assessed by DXA, and BV/TV and TbTh as Assessed by Micro Computed Tomography: An Experimental Study Based on Human Cadaver Vertebrae.** L. Pothuau<sup>1</sup>, N. Barthe<sup>\*2</sup>, M. Isidore<sup>\*3</sup>, P. Carceller<sup>\*1</sup>, D. Hans<sup>4</sup>.  
<sup>1</sup>PTIB - University Hospital of Bordeaux, Med-Imaps, Pessac Cedex, France, <sup>2</sup>University Hospital of Bordeaux, Biophysics Laboratory, Bordeaux, France, <sup>3</sup>University Hospital of Bordeaux, Department of Nuclear Medicine, Bordeaux, France, <sup>4</sup>Center of Bone Disease, Department of Bone and Joint Disease, Lausanne University Hospital, Switzerland.

In a previous study [1], we have established a significant mathematical relationship between Trabecular Bone Score (TBS) as evaluated on 2D simulated projection image and 3D characteristics of bone microarchitecture: bone volume fraction (BV/TV) and trabecular thickness (TbTh). The aim of this study was to independently evaluate the accuracy of this mathematical relationship based on DXA examination of human cadaver vertebrae. 20 dried human cadaver vertebrae were measured on an iDXA densitometer (GE-Lunar) with a specific positioning system miming standard antero-posterior acquisition and immersed in 17 cm of water. A region of interest (ROI) was defined on DXA scan. The DXA image was then exported on a specific workstation for TBS calculation. 3D reconstructions of the vertebrae were obtained by  $\mu$ CT (eXplore Locus, GE). The calibrated 3D grey-level images were analyzed using MicroView-GE software with specific add-on. Auto-threshold was applied and 3D-ROI was defined enclosing complete bone microarchitecture. Standard basic parameters, BV/TV and TbTh, were evaluated in this 3D-ROI. The fit-coefficients  $\{a_{00}, a_{01}, a_{10}, a_{11}\}$  of the generic mathematical relationship  $TBS = [a_{00} + a_{01} * \ln(TbTh)] + [a_{10} + a_{11} * \ln(TbTh)] * BV/TV$  were determined following non-linear regression analysis. The accuracy of the 2D/3D mathematical relationship was evaluated by correlation coefficient and root mean square error between estimated (indirectly from  $\mu$ CT) and experimentally (from DXA image based on in house algorithm [1]) measured values of TBS. The fit-coefficients were:  $a_{00} = -0.717$ ,  $a_{01} = -0.510$  ( $p = 0.0043$ ),  $a_{10} = 0$  (not considered coefficient), and  $a_{11} = -2.028$  ( $p < 0.0001$ ). TBS value estimation was expressed as  $TBS = -0.717 - 0.510 * \ln(TbTh) - 2.028 * \ln(TbTh) * BV/TV$ , and led to a relative accuracy characterized by  $r = 0.93$  and  $RMS-SD = 0.0487$ .

In our study we have confirmed the accuracy of a generic mathematical 2D/3D relationship from DXA examination of human cadaver vertebrae. TBS as evaluated from DXA image directly represents a score of two 3D characteristics of bone microarchitecture BV/TV and TbTh.

**To Avoid Underdiagnosis of Vertebral Fracture, Recognition of True Fracture Line Including Multiple Schmorl's Node Is Necessary.** S. Okamoto<sup>1</sup>, H. Noguchi<sup>\*2</sup>, A. Itabashi<sup>3</sup>, H. Suzuki<sup>\*4</sup>, S. Okamoto<sup>5</sup>. <sup>1</sup>SORF Okamoto Clinic, Oita, Japan, <sup>2</sup>Noguchi Thyroid Clinic and Hospital Foundation, Beppu, Japan, <sup>3</sup>Saitama Center of Bone Research, Saitama, Japan, <sup>4</sup>Suzuki Orthodontic office, Nagasaki, Japan, <sup>5</sup>KS Okamoto Clinic, Shimabara, Japan.

Comparative studies between TV-X ray fluoroscopy with the 3-dimensional CT are performed. The 3-D models showed the vertebral fracture lines are rarely smooth but consist of a mixture of perforated indentations or Schmorl's nodes. To avoid underdiagnosis of vertebral fracture, recognition of true fracture line is definitely necessary. TV-X ray fluoroscopy was performed in 136 normal volunteers and 2,740 female osteoporosis patients. Also we created computerized 3-D renderings of 1280 cases. To make the X-ray pass through straight on the vertebral bodies, we asked the patients in an upright position to move their positions so that the distal and proximal edges of each vertebra would coincide. In 37 young female volunteers, the mean C/P ratios coincide with reported autopsy data of young females who died in their 20s or 30s. The mean is about 15% lower than that of reported conventional X-ray data. The widely used SQE standard stands on the image that a C/P ratio of a mild deformity, 80-75%. In fact, normal vertebrae have -15 to -20% concavity. That is, the vertebral terminal plates are not flat. For example, mean C/P ratio of L2 vertebra is 83% by the analysis of autopsy, CT or TV fluoroscopy, while that of plain X-ray assessment is 98%. That is, conventional X-ray analysis by mid-point digitization made as much as 15% error in measurement. The rim lines of vertebra almost always have remained intact and straight. These lines are readily seen on the plain X-ray. This "flat terminal plate" misconception leads to the serious misdiagnosis of vertebral fractures. The VFA method sometimes uses the rim line to measure and at other times the fractures line, caused by the vagueness of the image. As few osteoporotic fractures are symmetric, blindly taken radiographs or VFA can not avoid obliquely tilted or horizontally rotated vertebral figure. Even though the patient is going to lie down straight, vertebral bodies are tilted. Without positional adjustment, fracture lines are often mistaken for vertebral rim lines in the assessment. For osteoporotic fracture detection, only C/P ratio measurement is enough by our method. Our practical C/P standard ratios (YAM mean  $\pm$  2.5 S.D.) apparent for fractured vertebra were lower than 0.67 at T4 to T7 level, 0.69 at T8 to

T11, 0.71 at T12 to L3 or 0.74 at L4 level. 3D CT also can detect osteoporotic vertebral fractures which are often overlooked behind spinal OA. These finding suggests that vertebral fractures are included in the group of "disk herniation" into the weakened vertebral body through the perforated endplates.

**Effect of Parity on Bone Mineral Density in Premenopausal Women: JPOS Cohort Study.** J. Tamaki<sup>1</sup>, M. Iki<sup>1</sup>, A. Morita<sup>\*2</sup>, Y. Sato<sup>\*3</sup>, E. Kajita<sup>\*4</sup>, S. Kagamimori<sup>\*5</sup>, Y. Kagawa<sup>\*6</sup>, H. Yoneshima<sup>\*7</sup>. <sup>1</sup>Public Health, Kinki Univ. School of Med., Osaka-Sayama, Japan, <sup>2</sup>Nutritional Education Program, National Institute of Health and Nutrition, Tokyo, Japan, <sup>3</sup>Domestic Sciences, Jin-ai Women's College, Fukui, Japan, <sup>4</sup>Public Health & Home Nursing, Nagoya Univ. School of Health Sciences, Nagoya, Japan, <sup>5</sup>Welfare Promotion & Epidemiology, Univ. of Toyama, Toyama, Japan, <sup>6</sup>Kagawa Nutrition Univ., Tokyo, Japan, <sup>7</sup>Shuuwa General Hospital, Kasukabe, Japan.

Only cross-sectional observational or case-control studies have been available which evaluate the effect of parity on BMD. More than 15% of Japanese women between the ages of 20 and 40 are categorized in leanness, and the proportion of young women with less than standard BMI ( $22 \text{ kg/m}^2$ ) would be relatively large across Asia. Therefore, to clarify the effect between parity and body weight on BMD in women at peak bone mass, we analyzed a representative sample of Japanese women with the Japanese Population-based Osteoporosis (JPOS) Cohort Study.

We conducted a baseline survey in 1996 and follow-up surveys in 1999 and 2002. We analyzed 654 premenopausal women aged 20-44 years in 1996 cross-sectionally, and 253 women younger than 45 in 2002 longitudinally. BMD at the lumbar spine (LS), total hip (TH), and the distal 1/3 radius (DR) was examined. For sub-analyses, subjects with BMI less than  $24.2 \text{ kg/m}^2$  were analyzed cross-sectionally and longitudinally.

To clarify the effect of parity after complete recovery from delivery on BMD, multiple liner regression analysis of BMD in 1999 among 224 subjects aged less than 45 years with BMI  $< 24.2$  without delivery between baseline and 3 year follow-up was conducted, which revealed one parity was significantly associated with increased BMD at LS or DR after adjusting for age, weight, height, calcium intake, smoking habit, and exercise habit.

As results of multiple liner regression analysis predicting for change of BMD between baseline and 6 year follow-up among 160 subjects aged less than 45 years with BMI  $< 24.2$ , delivery between the first 3 years was significantly associated with increased BMD at LS, one parity at baseline was significantly associated with increased BMD at TH or DR, and delivery between the first 3 years was significantly and negatively associated with BMD at DR, in each model including age, weight, height, BMD in 1996, change of body weight in 6 years, parity in 1996, delivery during the first 3 years, and delivery during the last 3 years as dependent variables. The analysis among total 654 subjects revealed no significant effect of parity.

Our findings would suggest a positive relationship between parity and bone density at lumbar spine among premenopausal women with standard BMI or less.

**Reimbursement for Bone Mineral Density Testing Among U.S. Medicare Beneficiaries.** J. R. Curtis<sup>1</sup>, A. Laster<sup>\*2</sup>, D. J. Becker<sup>\*3</sup>, L. Carbone<sup>4</sup>, M. Kilgore<sup>\*3</sup>, R. Matthews<sup>\*5</sup>, M. A. Morrissey<sup>\*3</sup>, K. G. Saag<sup>1</sup>, S. B. Tanner<sup>6</sup>, E. Delzell<sup>\*5</sup>. <sup>1</sup>Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, USA, <sup>3</sup>Department of Health Care Organization and Policy, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Veterans Administration Medical Center, University of Tennessee, Memphis, TN, USA, <sup>5</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>6</sup>Department of Medicine, Vanderbilt University, Nashville, TN, USA.

**Introduction:** Although the Bone Mass Measurement Act outlines the indications for central dual energy x-ray absorptiometry (DXA) testing for U.S. Medicare beneficiaries, the practical considerations regarding reimbursement are sometimes ambiguous. We evaluated the impact of gender, ICD-9 code submitted, time since previous DXA, and local Medicare carrier on whether or not the claim was reimbursed.

**Methods:** Using Medicare data from 1999-2005, we studied beneficiaries age  $\geq 65$  with part A+B, not HMO enrollees and in the 5% sample. We identified central DXA claims and evaluated the relationship between reimbursement for DXA and gender, ICD-9 code submitted for reimbursement of central DXA (CPT code 76075), interval of time since a preceding DXA, and Medicare carrier. Multivariable logistic regression was used to evaluate the independent relationship between carrier and reimbursement for DXA.

**Results:** For persons that had no DXA in 1999 or 2000 and who had one in 2001 or 2002, the percentage of DXAs claims denied was 5.3% for women and 9.1% for men. Rates of denial for repeat DXAs performed within 23 months was approximately 19% and did not differ by gender. There was substantial variability in reimbursement by ICD-9 diagnosis code submitted and varied by more than 6-fold. For DXAs repeated at  $< 23$  months, the proportion of claims denied ranged from 2% to 43%, depending on the Medicare carrier.

**Conclusion:** Reimbursement for DXA varies significantly by gender, time since previous

## ASBMR 30th Annual Meeting

DXA, ICD-9 diagnosis code submitted and local Medicare carrier. Greater guidance and transparency in coding policies is needed to improve access to DXA as a covered service for persons with Medicare.

Number of DXAs Performed and Proportion Not Paid, by Gender and Testing Interval

	Women		Men		P value*
	Number Performed	Proportion Not Paid (%)	Number Performed	Proportion Not Paid (%)

**Poor Peripheral Nerve Function Is Related to Lower BMD: The Osteoporotic Fractures in Men Study.** E. S. Strotmeyer<sup>1</sup>, K. A. Faulkner<sup>1</sup>, A. D. Juliano<sup>1</sup>, J. M. Zmuda<sup>1</sup>, A. V. Schwartz<sup>2</sup>, M. Petit<sup>3</sup>, E. Orwoll<sup>4</sup>, J. A. Cauley<sup>1</sup>. <sup>1</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University California, San Francisco, San Francisco, CA, USA, <sup>3</sup>University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Oregon Health & Science University, Portland, OR, USA.

Bone tissue is innervated and neurotransmitters directly affect bone remodeling. Poor motor peripheral nerve (PN) conduction was related to lower hip bone mineral density (BMD) in older adults in a dose-response manner, likely through higher bone area (Strotmeyer et al JBMR 2006). This relationship was not previously examined for sensory PN conduction. PN conduction at the sural sensory nerve (SNAP=amplitude in uV) and peroneal motor nerve (CMAP=amplitude in mV; FWL=mean F-wave latency in ms) were measured with a neurodiagnostic instrument (NC-stat®, NeuroMetrix, Inc.) in 572 community-dwelling men in the Osteoporotic Fractures in Men (MrOS) Study in Pittsburgh, PA. BMD at the total hip and femoral neck (FN), total lean mass (LM) and total fat mass (FM) were measured by DXA (QDR 4500W, Hologic Inc). Participants missing BMD, PN function or diabetes status (DM: self-report, hypoglycemic meds or fasting glucose ≥126 mg/dl) were excluded. In ANCOVA analyses with outcomes of BMD, BMC and area, PN conduction was analyzed as tertiles. Of participants (age 77.5±5.2 years; 99% white), 22% had DM. FN BMD was 4% lower in men with the worst sensory PN conduction compared to the best tertile after adjustment for age, race, diabetes, LM and FM (Table). FN area remained 1% and 3% higher with the worst motor and sensory PN conduction, respectively. Further adjustment for current smoking, drinking frequency, physical activity, calcium or vitamin D supplementation and medication use (corticosteroid, statin, thiazide, thiazolidinedione in DM, and osteoporosis medication) did not change associations. No significant differences were found for PN conduction with FN BMC or for FWL with any bone measure. Our results suggest that the lower BMD in worse sensory PN conduction may be due to an equivalent BMC in a larger hip bone area. Whether differences with worse sensory and motor PN function impact osteoporosis or fracture risk should be investigated in future studies.

FN BMD, BMC and area means by sensory and motor PN function tertile adjusted for age, race, DM, LM,

Motor PN function	Worst tertile CMAP (≤1.49 mV)	Middle tertile CMAP (1.50-3.06 mV)	Best tertile CMAP (≥3.07 mV)
FN BMD, g/cm <sup>2</sup>	0.783	0.797	0.799
FN BMC, g	4.52	4.55	4.56
FN area, cm <sup>2</sup>	5.78 <sup>†</sup>	5.71	5.72
Sensory PN function	Worst tertile SNAP (≤2.55 uV)	Middle tertile SNAP (2.56-4.99 uV)	Best tertile SNAP (≥5.0 uV)
FN BMD, g/cm <sup>2</sup>	0.769* <sup>†</sup>	0.797	0.802
FN BMC, g	4.86	4.57	4.53
FN area, cm <sup>2</sup>	5.83* <sup>†</sup>	5.74	5.66

\*p<0.05 for worst tertile vs. best tertile; <sup>†</sup>p<0.05 for worst tertile vs. best tertile at total hip, adjusted for age, race, DM, LM, and FM

**Osteoporosis in Men: Still Under-Screened and Under-Treated.** C. Anastasopoulou, S. Chandrasekaran\*, M. David\*, A. Chernoff\*. Endocrinology, Albert Einstein Medical Center, Philadelphia, PA, USA.

According to the latest National Osteoporosis Foundation recommendations men with hip fractures and all men age 70 and over should be screened for osteoporosis even in the absence of other risk factors. We conducted a retrospective chart review of men who had sustained hip fractures or were over 70. These were patients who were admitted to an urban

tertiary care medical center or were followed in the outpatient geriatric and general medicine clinics. The purpose of this study was to determine rates of screening for osteoporosis in men and to assess the impact of known risk factors for osteoporosis in this population. Data collection included demographic information (age, race, height, weight), biochemical values (calcium, creatinine, vitamin D levels) and medical information (results of DEXA bone scan, history of fractures, history of other illnesses including diabetes, thyroid and parathyroid problems, collagen diseases, seizure disorder, COPD, transplant history and the use of specific medications, including steroids, thyroid hormone, statins and antiseizure drugs).

A total of 349 charts were reviewed. There were 178 men with fracture; of these, only 1 had DEXA testing performed (0.6%). Among the men over 70, 6 had had a DEXA Scan (3.5%). Table 1 summarizes data by race.

	White	Black	Hispanic	Asian	Unknown	Total
Patient Number	175	147	12	8	7	349
Total Fracture	103	63	8	4	0	178
Weight recorded	31	30	5	2	0	68
Height recorded	25	34	4	1	0	64
Presence of Diabetes	33	36	2	0	0	71
Mean Age (SD)	74(16)	74(11)	67(20)	60(22)	78(5)	
Mean kg Weight(SD)	80(24)	82(19)	79(22)	59(8)		
Mean cm Height(SD)	157(50)	144(50)	142(55)	185		

Most of the parameters under consideration were under-recorded whether for special bloods tests like vitamin D, testosterone or intact PTH levels, or the simplest measurements such as weight, height or mobility status. Among patients that suffered bone fractures only 11 (6%) were prescribed calcium and vitamin D supplements, while none were prescribed bisphosphonates. Of the different risk factors for osteoporosis, race (p value 0.024), diabetes (p value 0.046), History of seizure disorder (p value 0.027) and the use of diuretic (p value 0.003) and antiseizure drugs (p value 0.003) were found to be statistically significant on causing bone fractures.

These observations clearly point to a lack of awareness among physicians of the guidelines for osteoporosis screening and treatment in men. More efforts will be needed to increase doctors' awareness of osteoporosis and its treatment in men so that men will be screened for osteoporosis when they have sustained a fracture, if they are over 70 years of age, or younger in the presence of risk factors.

## SA330

**Ten-year Change in Bone Mineral Density in a Representative Sample of Japanese Women - JPOS Cohort Study.** M. Iki<sup>1</sup>, J. Tamaki<sup>1</sup>, E. Kadowaki<sup>1</sup>, K. Kouda<sup>1</sup>, A. Yura<sup>1</sup>, Y. Ikeda<sup>2</sup>, Y. Sato<sup>3</sup>, A. Morita<sup>4</sup>, S. Kagamimori<sup>5</sup>, Y. Kagawa<sup>6</sup>, H. Yoneshima<sup>7</sup>. <sup>1</sup>Public Health, Kinki University School of Medicine, Osaka-Sayama, Japan, <sup>2</sup>University Hospital Center for Health and Safety, Kinki University School of Medicine, Osaka-Sayama, Japan, <sup>3</sup>Domestic Sciences, Jinai Women's College, Fukui, Japan, <sup>4</sup>Nutritional Education Program, National Institute of Health and Nutrition, Tokyo, Japan, <sup>5</sup>Welfare Promotion and Epidemiology, University of Toyama, Toyama, Japan, <sup>6</sup>Kagawa Nutrition University, Tokyo, Japan, <sup>7</sup>Shuuwa General Hospital, Kasukabe, Japan.

To describe the change in bone mineral density (BMD) in various ages of a representative sample of Japanese women and to examine whether a cohort effect (difference in BMD of subjects with the same age between surveys conducted in different time) exists in this population.

For 1,651 women aged 15 to 79 years at baseline selected randomly from 3 municipalities in Japan, we measured bone mineral density by DXA at the spine (LS), total hip (TH) and distal 1/3 site of the radius (DR), and body size, and obtained lifestyle factors from in-person interviews. Changes in BMD and other variables were determined 3, 6 and 10 years after the baseline.

Among the cohort from which 133 women dropped out during the 10-year follow-up because of deaths and move of residence, 1040 completed the study. 33% of the subjects were still pre-menopausal at follow-up, 42% were already post-menopausal at baseline, and 18% had entered menopause during the follow-up.

The changes in BMD varied according to ages of subjects. BMD did not show any significant change until 45 years at every skeletal site. After that, an abrupt increase in bone loss occurred at each site. Bone loss at LS decreased with increasing age, that at TH was the greatest in the group aged 75 and older, and that at DR showed a constant rate across different ages. These patterns of bone loss were similarly observed during the first 3 years of follow-up and during the last 4 years.

BMD of a particular age group at 10 years after the baseline was compared with BMD of the same age group at baseline. BMD at follow-up was significantly higher than BMD at baseline in several middle-aged and elderly groups, while no significant difference in BMD was observed in young adults. Height and weight did not differ between the subjects who completed the 10-year follow-up and those who did not. Calcium intake of the former subjects was greater than that of the latter in some age-groups. The observed cohort effect in BMD may have been biased by a healthy people effect. If this bias existed, bone health of young adults may have got worse in these 10 years.

Bone health in Japanese middle-aged and elderly women may have improved in the last decade but that in young adults may not.

**Osteoporosis and the Acid-ash Hypothesis: Evidence Based on Bradford Hill's Criteria for Causality.** T. R. Fenton\*, A. W. Lyon\*, D. A. Hanley, S. C. Tough\*, S. Ross\*, M. Eliazziw\*. University of Calgary, Calgary, AB, Canada.

Scientists from several countries claim that the foods that make up the modern diet cause osteoporosis, due to net acid excretion under the acid-ash hypothesis. The purpose of this study was to critically evaluate the evidence in the literature regarding the acid-ash hypothesis as a potential cause of osteoporosis. A systematic review was undertaken based on Hill's criteria of causation: Temporality, Strength, Biological Gradient, Experiment, Consistency, and Biologically Plausibility. Only studies with temporal sequence were included in this review. Although the quantity of calcium excretion in response to acid loads is sufficient that over a lifetime the loss of calcium could explain the development of osteoporosis (Strength & Biological Gradient), the outcome of urinary calcium may be confounded by changes in absorption. Most studies of the hypothesis have used urinary calcium as the outcome, and Experiments of the hypothesis have failed to include the direct measures of osteoporosis. Prospective observational studies of the association between diet acid loads and changes in bone mineral density have had inconsistent results. Internal Consistency for the hypothesis is weak since there is evidence contrary to the hypothesis regarding the purported roles for phosphate (detrimental) and sodium (protective) in terms of calcium excretion, and no clear evidence for the hypothesis purported deleterious effects of grains and organic acid containing fruits on bone health. Biological Plausibility of the acid-ash hypothesis is weak based on the in-vitro studies that indicated increased bone demineralization occurs at low pHs since these studies were conducted at pHs below the physiological range. The use of Hill's criteria to evaluate the relationship between the acid-ash hypothesis and osteoporosis indicates that the evidence to support this hypothesis is weak.

**Glomerular Filtration Rate and Physical Function in Community-Dwelling Japanese Frail Elderlies.** J. Okuno\*, S. Tomura\*, H. Yanagi\*, N. Yabushita\*, T. Okura\*, K. Tanaka\*. Graduate school of Comprehensive Human Sciences, University of Tsukuba, Tsukuba city, Japan.

Chronic kidney disease (CKD) is becoming increasingly recognized as an important comorbid condition in elderly individuals. The risk of falling increases with aging. Falls are associated with deterioration of quality life. Vitamin D deficiency associated with falls and decreased balance. Impaired renal function with aging is detrimental for the conversion of calcidiol to calcitriol (D-hormone) and D-hormone analogue have been shown to decrease the risk of falls. The aim of this study was to assess whether estimated glomerular filtration rate (eGFR, ml/min/1.73m<sup>2</sup>) is associated with physical function in 51 community-dwelling frail elderly enrolled a three-month exercise program for nursing care prevention (76.9±5.9 yr). A longitudinal study conducted in a town near Tsukuba city (latitude 36° north) from June to September in 2006 and 2007 and November to February in 2006. The Ethics Committee of University of Tsukuba approved the study. An interview was conducted based on a questionnaire including experiences of fall or stumbling during the past one year. The serum levels of 25(OH)D, intact parathyroid hormone (iPTH) 1,25-dihydroxyvitamin D (1,25(OH)<sub>2</sub>D), calcium, and creatinine were measured. The following physical tests were measured: timed up and go (TUG), a 5-meter walk, functional reach (FR), one-legged stance with open eyes, tandem stance, tandem walk, hand grip strength, and alternate step-test. Estimated GFR was calculated using the Modification of Diet in Renal Disease (MDRD) formula (<60 versus ≥60 ml/min/1.73m<sup>2</sup>). The rate of participants with GFR<60 was 23.5%. At baseline, age, iPTH, 25(OH)D, and 1,25(OH)<sub>2</sub>D were not different between those with GFR<60 and those with GFR≥60. All physical functions were not different between two groups at baseline and at three months later. Physical functions except FR and hand grip strength improved significantly in those with GFR≥60. On the hand, many of physical functions did not improved in those with GFR<60. GFR were associated with iPTH (P<0.1), iPTH significantly correlated with 25(OH)D (P<0.05), and 25(OH)D significantly correlated with 1,25(OH)<sub>2</sub>D. Although the rate of 25(OH)D<50 nmol/L was not different between two groups, the rate of 1,25(OH)<sub>2</sub>D<42 pg/ml (lowest quartile) in the subjects with GFR<60 was higher than those with GFR≥60, but, not significant (50.0% vs 19.5%). Tandem stance, 5 chair sit to stand, and alternate step-test were significantly affected by GFR by multiple liner regression analysis (β:0.30, -0.32, -0.30, respectively). Our data suggest that eGFR is highly associated with walking ability and balance.

**Seasonal Genetic Influence on Serum 25-hydroxyvitamin D Levels.** G. Snellman\*, H. Melhus<sup>2</sup>, R. Gedeberg<sup>3</sup>, S. Olofsson\*, A. Wolk\*, N. Pedersen\*, K. Michaëlsson<sup>1</sup>. <sup>1</sup>Department of Surgical Sciences Section of Orthopedics, Uppsala, Sweden, <sup>2</sup>Department of Medical Sciences Section of Clinical Pharmacology, Uppsala, Sweden, <sup>3</sup>Department of Surgical Sciences Section of Anaesthesiology and Intensive Care, Uppsala, Sweden, <sup>4</sup>Clinical Research Center, Uppsala, Sweden, <sup>5</sup>Division of Nutritional Epidemiology, Institute of Environmental Medicine, Stockholm, Sweden, <sup>6</sup>Department of Epidemiology and Biostatistics, Stockholm, Sweden.

Environmental factors, mainly nutrition and UV-B radiation, have been considered major determinants of vitamin D status. Nevertheless, they have only explained a modest proportion of the variation in serum 25-OH vitamin D. We aim to present the seasonal genetic impact on serum 25-OH vitamin D levels, an issue not previously resolved, and to illustrate the variability and reliability between three different 25-OH vitamin D assays.

204 same-sex twins were recruited from The Swedish Twin Registry. Serum 25-OH vitamin D was analyzed in three different laboratories, using three different techniques: high performance liquid chromatography and mass spectrometry (HPLC-MS), a radioimmunoassay (RIA), and a chemiluminescent immunoassay (CLIA). The heritability was calculated using genetic modelling techniques to estimate the relative contributions of genetic, shared and non-shared environmental factors to the variation in serum vitamin D.

Our results show high variability in 25-OH vitamin D assay results between the methods. There is a 24.9 nmol/l difference in mean 25-OH vitamin D level between the highest (HPLC-MS) and the lowest (CLIA) values. With a 50 nmol/L cut-off, only 8% of our twins are classified as vitamin D deficient with the HPLC method, 22% with the RIA method but 43% with the CLIA method. Lowest coefficient of variation was observed for the HPLC-MS method. The seasonal variation in heritability of vitamin D status is substantial. When using the HPLC-MS assay results, as much as 76% (95% CI 37-87%) of the variability in 25-OH vitamin D during the warm season (May through October) is explained by genetic factors. On the contrary, the seasonal variation in serum 25-hydroxyvitamin D is largely attributable to shared environmental influences, i.e. solar altitude. Individual environmental influences are found to only explain approximately one fourth of the variation in serum 25-OH vitamin D independent of season.

Our results indicate a strong genetic impact on serum vitamin D status during the warm season. The most likely main contributor to this genetic influence is the skin synthesis of vitamin D. Further studies are warranted to identify genes controlling vitamin D status. The high variability in results between the different serum 25-OH vitamin D assays may lead to substantial misclassification of vitamin D status.

**Soy-based Formula Promotes Bone Growth in Neonatal Piglets by Inducing Osteo-progenitors to Differentiate into Osteoblasts via Enhanced BMP2 Signaling.** J. R. Chen\*, O. P. Lazarenko\*, M. L. Blackburn\*, T. M. Badger\*, M. J. Ronis\*. <sup>1</sup>Pharmacology & Toxicology, University of Arkansas for Medical Sciences / Arkansas Children's Nutrition Center, Little Rock, AR, USA, <sup>2</sup>Physiology, University of Arkansas for Medical Sciences / Arkansas Children's Nutrition Center, Little Rock, AR, USA.

Despite consumption of soy infant formula by 20% of infants in the United States and of soy products by children in most Asian countries, the majority of studies of soy effects on bone in both human and experimental animal models have focused on adults, particularly postmenopausal females. There have been no studies conducted on soy effects on immediate postnatal bone growth and maintenance. Moreover, the molecular mechanisms underlying soy effects have not been well elucidated. In the current study we used neonatal piglets as a model of human infants. Both male and female piglets were breast-fed (BF) or fed dairy-based formula (MF) or soy-based formula (SF) (n = 6/group) from birth until postnatal day 35. After sacrifice, blood, bone, bone marrow and other target tissues were collected for analysis. Bone quality and growth rate were assessed by peripheral quantitative computerized tomography and dynamic histomorphometry of the left tibia. Results showed that bone mineral density, content, and cortical thickness were all greater (P<0.05) in the SF group compared to the BF group. The MF group had minor effects compared to BF. Osteoblast numbers and bone formation rate were increased (P<0.05) in the SF group when compared to BF group; whereas, osteoclast numbers were decreased. Osteoblastogenesis was increased (P<0.05) in the SF group in *ex vivo* bone marrow cell cultures. Alkaline phosphatase and osteocalcin, bone formation markers in serum, were increased (P<0.05); whereas, the bone resorption marker CrossLaps was decreased in the SF group compared to BF group. Real-Time PCR results demonstrated that BMP2 was up-regulated, but RANKL was down-regulated in the SF group compared to BF group (P<0.05). Western Blots showed up-regulation of ERK, p38, Smad1/5/8 and RUNX2 from bone samples in both SF and MF groups compared to BF group (P<0.05). Treatment of C2C12 and ST2 cells with 2.5% serum from SF piglets showed increased (P<0.05) osteoblast differentiation compared to serum from BF piglets. These data indicate that SF has significant effects on promotion of bone growth, and these effects are mediated through enhancing of BMP2 signaling leading to increased osteoblast differentiation. Supported in part by USDA ARS 6251-51000-005-02S-2.

**Weight Reduction Is Not Deleterious for Bone Mass or Strength in Obese Women.** K. Uusi-Rasi, H. Sievänen, P. Kannus\*, M. Pasanen\*, K. Kukkonen-Harjula\*, M. Fogelholm\*. UKK Institute for Health promotion Research, Tampere, Finland.

Obesity is associated with greater bone mass. Therefore, one deleterious consequence of weight loss might be bone loss and increased bone fragility. This was a prospective 12-mo study with 3-mo weight loss following a 9-mo weight maintenance period. All 55 participants were premenopausal women with the mean age (SD) of 40 (5) years and BMI of 33.6 (4.7). All were encouraged to use VLED-products (Cambridge Diet) in reducing body mass. In addition, use of vegetables and energy-free drinks were recommended. The mean daily use of products was 2.8 (0.7) bags providing 41 (10) g of protein and 862 (216) mg of calcium per day from the products.

Body composition and bone mineral mass and strength of the right proximal femur and lumbar spine were assessed by DXA. Cortical (shaft CoD) and trabecular bone density (distal TrD) of the radius and tibia were measured with pQCT. All assessments were done at baseline and 3 and 12 months afterwards. The participants were divided into 5 equal groups (n=11; Q1-Q5) by the absolute loss of body mass during the 3-mo dieting period (Table). Analysis of variance (ANOVA) was used to find between-group difference and linearity in changes of bone characteristics during the 12-mo period.

Absolute changes in bone values were tiny and mostly not associated with weight loss (Table). The between-group differences in changes were statistically significant in CoD of the radial shaft only (p=0.020), and borderline difference was found in femoral neck BMD (p=0.063) and BMC (p=0.088). Only the mean changes in BMD of the femoral neck and trochanter showed a statistically significant linearity between weight loss groups (p=0.035 and 0.036, respectively). At the tibia or spine, there were no significant changes in bone traits in any groups. Even the greatest weight loss (group Q5) did not seem to be harmful for bone mass during a 12-mo time period. Although the Q5 showed a decline in femoral neck BMC, the change was insignificant. Simultaneously total body BMC and radial shaft CoD increased in this group.

The greater weight reduction did not seem to result in greater bone loss compared with minor weight reduction. Sufficient intake of calcium and protein were ensured during dieting, which may partly explain good maintenance of bone mass.

Weight loss groups, mean decline (kg)	Total body BMC	Lumbar spine BMC	Femoral neck BMC	Radial shaft CoD
Q1=4.1 (2.7)	-0.7 (2.9)	0.4 (3.1)	1.2 (3.0)	-0.1 (0.7)
Q2=7.3 (0.4)	-0.6 (4.0)	1.2 (3.7)	1.9 (3.3)	0.4 (0.8)
Q3=9.9 (1.0)	-1.4 (4.3)	-0.4 (3.4)	-0.4 (3.4)	-0.4 (0.7)
Q4=12.9 (0.9)	-0.9 (3.9)	-0.8 (5.9)	1.3 (2.7)	-0.03 (0.7)
Q5=16.3 (1.8)	1.1 (6.0)	-0.4 (3.7)	-1.0 (2.4)	0.8 (1.1)

**Bone Density (BMD), Fracture and Survival in Women in Nursing/Residential Care.** M. N. Dugard\*, T. J. Jones\*, M. W. J. Davie. Charles Salt Research Centre, Robert Jones & Agnes Hunt Orthopaedic Hospital NHS Trust, Oswestry, United Kingdom.

Fractures, a common event in nursing homes (NH/RH) are often associated with low BMD. Because fractures may occur early after entry and drug treatment may take up to 18 month for effect, different strategies for fracture prevention may be required according to survival. To investigate BMD fractures and survival we restudied 156 women in NH/RH aged 56.4-98.8yr screened for fracture risk 3-8yr previously. A questionnaire was completed on all women at the first visit and distal forearm BMD (DTX 100) measured in 137. BMD was expressed as g/cm<sup>2</sup> or as a z score. Women were traced through health records, fracture details being obtained from the each woman's doctor. There were 7 <69yr, 26 70-79yr and 104 women aged >80yr at first interview.

BMD measured 1.3yr (range 0.05-9.3yr) after entry into NH/RH was low (0.317±0.084g/cm<sup>2</sup>, p<0.001). Osteoporosis (BMD<0.34 g/cm<sup>2</sup>) existed in 72.1% of women aged >80yr, compared with 33.4% less than 80yr (p<0.001). Body weight was lower in those >80yr compared with younger women (56.1±12.5 vs 62.3±16.7kg, p<0.05). Cross sectional analysis showed that BMD or body weight <6 months after entering a NH/RH (BMD 0.335±0.085g/cm<sup>2</sup>, weight 57.5±13.4kg) was similar to those >1yr after entry (BMD 0.317±0.082, 58.4±15.1kg). At follow-up 83.9% had died, 14.3% >69yr, 73.1% 70-79yr and 93.1% >80yr. Median survival time after entering a NH/RH was 4.6yr (range 0.4-15.3yr) in all subjects and 4.2yr (0.4-15.3yr) in the >80yr age group. In a Cox proportional hazards model, shortened survival in a NH/RH was associated with lower BMD z score (HR 1.42; 95% CI 1.04-1.93) in women >80yr scanned within 1yr of entry but not by age

at entry or weight. Few fractures occurred in women <70yr. Fracture analysis has been performed on 56 women >80yr (268.2 person yr). There were 22 fractures in 17 women in 4.12yr (Median: range 0.9-15.3yr), the first being 2.5yr (0.1-6.7yr) post entry. Seven women sustained fracture within 1yr of entry. Previous fracture was not a risk factor for future fracture. Post entry fracture rate was 8.2/100 person yr (1.5/100 for hip fracture). BMD was low in 3/4 women sustaining hip fracture (z score -0.474±1.089) and 9/13 women with non-hip fracture (-0.364±0.909) that occurred after entry. Most women in NH/RH have osteoporosis. In those over 80yr low BMD is associated with shorter survival. Fractures are associated with low BMD and may occur soon after entry. BMD measurement should form part of the initial entry assessment. Median survival times indicate that most women will survive long enough to benefit from bisphosphonate therapy.

**Effects of Obesity on Cortical Bone.** S. Ionova\*, S. H. Do\*, H. D. Barth\*, J. W. Ager\*, A. Porter\*, C. Vaisse\*, T. Alliston\*, R. O. Ritchie\*. <sup>1</sup>Material Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA, USA, <sup>2</sup>University of California San Francisco, San Francisco, CA, USA, <sup>3</sup>Imperial College London, London, United Kingdom.

Obesity is associated with a host of biological and physiological changes, among which is a reduced risk of bone fracture in adults. While some studies have found obesity is associated with increased bone size and mass measures, it is still unclear whether the reduced risk stems from a change in bone quantity alone, or whether bone quality is affected as well. The objective of this study is to evaluate the changes in mechanical properties of cortical bone in response to diet-induced obesity in mice. 4 week old C57BL/6 male mice were fed a high fat diet (HFD) (N=15) or standard laboratory chow (N=15) for 16 weeks. All protocols were approved by the Institutional Animal Care and Use Committee and done according to federal guidelines for the care and use of animals in research. Blood was isolated immediately following sacrifice to evaluate serum leptin levels. Bone mass and body composition were evaluated with DEXA. The left femurs were tested in three-point bending to measure strength and bending stiffness. Right femurs were tested in notched three-point bending to measure fracture toughness (loading rate of 0.001mm/s). Bone geometry was evaluated in tomography at the Advanced Light Source and in an environmental scanning electron microscope. As expected, in the high-fat diet fed mice, body weight, fat mass, and leptin levels were significantly increased. In HFD mice, endostial and periosteal diameters, as well as cortical wall thickness increased (all p<0.015), while BMD was unchanged (p=.937). Strength, bending stiffness, and fracture toughness all were reduced in HFD (p<0.007, p=.010, p=.013, respectively). Transmission electron microscope studies point to a qualitative reduction in collagenous organization in HFD versus control group. In summary, diet-induced obesity results in increased bone size (quantity), while reducing bone strength, bending stiffness, and fracture toughness as well as other indicators of bone quality. This study indicates that bone quantity and bone quality play important, albeit counteracting, roles in determining fracture risk.

**Patients with Fragility Fracture Assessed by BMD, Bone DESTINY and Osteoporosis Canada Guidelines.** M. Larche\*, K. Beattie\*, J. D. Adachi, A. Papaioannou, W. Wong Pack\*, W. G. Bensen\*. Dept. of Medicine, McMaster University, Hamilton, ON, Canada.

**Purpose:** Fracture risk and treatment recommendations were compared in female patients with a previous fragility fracture using bone mineral density (BMD), Bone DESTINY and Osteoporosis Canada (OC) guidelines.

**Methods:** All female patients >60 years of age with a previous fragility fracture who underwent a DEXA scan between June and November 2007 were included in the analyses. Fracture risk and treatment recommendations were made based on BMD alone, Bone DESTINY and Osteoporosis Canada (OC) guidelines and results were compared. DESTINY fracture risk was an integration of BMD, age, steroid use, propensity to fall, history of falls and BMI<20 kg/m<sup>2</sup> while OC guidelines included BMD, age and steroid use. The prevalence of women in the high fracture risk group was compared between these three methods.

**Results:** 840 female patients with a previous fragility fracture were included in the analyses. BMD values resulted in treatment recommendations for 39% of patients with a T-score <-2.4 and 61% of patients at a T-score of -2 as shown in Figure 1. Bone DESTINY suggested treatment in 82% of patients with an additional 13% of patients in the moderate risk zone also seen in Figure 1. According to the OC guidelines, 85% of patients were in the high-risk zone with all patients being in the moderate and high risk zones.

**Figure 1.** Recommendations for treatment according to BMD, Bone DESTINY and OC guidelines.

**Conclusions:** Bone DESTINY suggests treatment in a much higher number of fragility fracture patients than BMD alone (82% versus 39% at -2.5), a value which is similar to OC guidelines. Based on the agreement in results between DESTINY and OC guidelines, the simplicity and ease of interpretation make DESTINY an attractive option for reporting fracture risk.

**Long Term Safety of Oral Risedronate Treatment in Men with Osteoporosis as Assessed by Histomorphometry.** R. Recker<sup>1</sup>, R. Eusebio<sup>2</sup>, R. Phipps<sup>2</sup>, S. Xu<sup>2</sup>, D. Vanderschueren<sup>3</sup>, S. Boonen<sup>3</sup>. <sup>1</sup>Osteoporosis Research Center, Creighton University, Omaha, NE, USA, <sup>2</sup>Procter & Gamble, Mason, OH, USA, <sup>3</sup>University Hospital Leuven, Leuven, Belgium.

The effects of 2-4 years of 35 mg once-a-week risedronate treatment on bone quality and bone remodeling were assessed in a 2-year double-blind, placebo-controlled study in men with osteoporosis, followed by a 2-year open-label extension in a subset of subjects who all received risedronate. In the double-blind study, transiliac bone biopsies were obtained after 2-years treatment with placebo (N=7), and risedronate (N=15). During the open label study, 4 of the 7 placebo patients had a second biopsy taken after 2 years of risedronate treatment (total=19), and 9 of the 15 risedronate patients had a second biopsy taken after 4 years of risedronate treatment. There were no significant differences among groups in demographics or in any baseline characteristics including bone mineral density and bone turnover markers. Biopsies were examined for qualitative histological and quantitative histomorphometric differences. All biopsies had lamellar bone structure with no signs of osteomalacia, woven bone or bone marrow fibrosis. Tetracycline label was observed in all samples. Bone remodeling rate as expressed as mineralizing surface/bone surface was significantly lower after 2 and 4 years treatment with risedronate compared to 2 years placebo. Median eroded surface/bone surface (bone resorption parameter) was 2.8% in placebo and 1.7% after 2 years risedronate treatment (p=0.027). Median mineralizing surface/bone surface (bone formation parameter) was 3.6% after 2 years placebo, 1.2% after 2 years risedronate (p=0.0207), and 1.1% after 4 years risedronate treatment. These results indicate continued bone formation and no excessive inhibition of bone turnover with 2 and 4 years treatment with risedronate. There were no significant

differences in structural parameters with treatment. These results are concordant with previous histological studies with risedronate in postmenopausal women with osteoporosis showing that risedronate preserves normal bone structure, quality, and remodeling. This favorable long-term bone safety profile is consistent with that demonstrated in clinical trials in women with postmenopausal osteoporosis.

**Serum Vitamin D Levels Do Not Modify the Response to an Exercise Program Following Hip Fracture: Data from the Baltimore Hip Studies.**

M. C. Hochberg<sup>1</sup>, E. Streeten<sup>1</sup>, J. Yu-Yahiro<sup>2</sup>, W. Hawkes<sup>3</sup>, R. Hebel<sup>3</sup>, R. Miller<sup>3</sup>, D. Orwig<sup>3</sup>, J. Magaziner<sup>3</sup>. <sup>1</sup>Medicine, University of Maryland, Baltimore, MD, USA, <sup>2</sup>Orthopaedic Surgery, Union Memorial Hospital, Baltimore, MD, USA, <sup>3</sup>Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD, USA.

**Background:** While older women with hip fracture often have low serum 25-hydroxyvitamin D (25[OH]D) levels, it is unknown whether recovery after hip fracture is associated with serum 25(OH)D levels.

**Objective:** To assess whether changes in BMD, muscle strength and lower extremity performance (LEGS Score) that occur in the year following hip fracture in response to a home exercise program were modified by baseline serum 25(OH)D levels.

**Methods:** We performed a post-hoc analysis of data from BHS-4, a randomized controlled trial of a home exercise program in 180 community-dwelling older women (mean [SD] age 82.3 [7.0] years) who had been hospitalized for surgical treatment of a hip fracture. Hospitalized women were recruited and baseline data were acquired within 15 days of fracture. BMD at the contralateral hip and grip strength were measured, LEGS Score was assessed and serum was collected at baseline, 2, 6 and 12 months post fracture. Serum samples stored at -70°C were analyzed for 25(OH)D levels in duplicate using DiaSorin RIA. Women were divided into two strata based on serum 25(OH)D levels either below 20 ng/ml or 20 ng/ml or above. Generalized estimating equations, with time and intervention as fixed effects, were used to examine whether 25(OH)D levels modified the effect of exercise on the outcomes.

**Results:** Baseline serum samples from 96 women were assayed for 25(OH)D levels. The mean (SD) 25(OH)D level was 22.8 (13.7) ng/ml and the median was 21.6 ng/ml with an interquartile range of 12.6 to 30.4 ng/ml; 45 (47%) women had a 25(OH)D level below 20 ng/ml. There was no evidence of seasonal variation in baseline 25(OH)D levels. There was no evidence of a significant effect of the home exercise intervention on any of the outcomes in women with 25(OH)D levels either above or below 20 ng/ml; results in Table. **Conclusion:** These data fail to demonstrate that serum 25(OH)D levels modify the effect of a home exercise program on changes in BMD, grip strength and lower extremity performance in the year following hip fracture. Results are limited by small numbers and the lack of ability to examine the potential efficacy of supplementation with vitamin D3 during the year following the fracture.

BMD, Grip Strength and LEGS Score at 2, 6 and 12 Months after Hip Fracture by Serum 25(OH)D Levels				
Outcome	Group	2 Months		12 Months

**Excess of Post-fracture Mortality Among Men and Women: A Relative Survival Analysis.** S. A. Frost\*, N. D. Nguyen, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Group, Garvan Institute of Medical Research, Sydney, Australia.

Although it is now well-established that individuals with fracture are at substantial increased risk of mortality, it is not clear how many deaths can be attributed to fracture. It can however be hypothesized that the excess deaths related to osteoporotic fracture are due to two "causes": one due to fracture and the other due to non-fracture. Therefore, if the expected background mortality rate reflects the effect of "other causes" then it is possible to estimate the excess of mortality due to osteoporotic fracture. The aims of this study were therefore (a) to estimate the "relative survival" among men and women following an osteoporotic fracture, and (b) to estimate the excess of mortality associated with specific fracture site.

The Dubbo Osteoporosis Epidemiological Study was designed as a prospective epidemiologic investigation in which men and women aged 60+ as of 1989 had been followed for 19 years. During this period incidence of atraumatic fractures ascertained by X-ray reports, and mortality was ascertained by personal report and confirmed by the New South Wales Birth, Death and Marriage Registry.

Relative survival can be illustrated by the following comparison: a 60 year-old individual died after a fracture in 2006 is considered to incur a greater loss of life than an individual with the same age died after a fracture in 1980, because the population life expectancy in 2006 is greater than that in 1980. Therefore, relative survival analysis allows a better estimate of the true effect of fracture on mortality. In this study relative survival ratio (RSR) was estimated by taking into account the age-and-sex specific expected survival in the general Australian population.

During the follow-up 585 women and 230 men sustained an incident low-trauma fracture. Death occurred in 138 (24%) women and 108 (47%) men. In men, the RSR of post-fracture mortality at 1, 5 and 10-year was 0.93 (95% CI 0.88 - 0.98), 0.83 (95% CI 0.71 - 0.96), and 0.80 (95% CI 0.56 - 1.05), respectively; in women, the corresponding estimates were: 0.99 (95% CI 0.97 - 1.01), 0.98 (95% CI 0.94 - 1.04), and 0.93 (95% CI 0.81 - 1.04). In both men and women, hip and vertebral fractures were associated with lower RSR. In comparison to forearm fracture, men and women with hip fracture had an 86% and 81%, respectively, increase in relative excess mortality. Men and women with vertebral fractures had a 23% and 96%, respectively, increase in relative excess mortality compared to forearm fractures.

In summary, relative survival analysis indicated that men had a worse outcome than women because the post-fracture risk of death in men was greater in men than in women. In both sexes the excess of mortality associated with osteoporotic fractures was mainly due hip and vertebral fractures.

**Performance Characteristics of a Workflow Tool for the Assessment of Vertebral Shape.** T. Ozanian\*, T. Lacey\*, G. Zubko\*, A. Brett\*, P. Steiger. Optasia Medical, Inc., Burlington, MA, USA.

The purpose of this study is to assess the performance of a new workflow tool based on statistical shape modelling for the characterization of vertebral shape.

We previously described a novel method for the computer-assisted determination of vertebral shape using 95 points representing the circumferential vertebral borders on lateral spine x-rays<sup>1</sup>. We implemented this method in a computer program that allowed an operator to annotate vertebral shapes on lateral radiographs from T4 to L4 as follows: (1) Choose image, (2) place a single point at the approximate centre of each vertebra to be analyzed, (3) using an atlas, label anatomy being analyzed and initialize automated search of vertebral contours, (4) review and correct contours. We assessed effort by measuring the time elapsed for steps 1-4. Four non-expert operators performed the analysis twice on 10 subjects after having been trained on 5 different training subjects. We then compared the results of each operator with those of a reference mark-up by measuring the average distance of all placed points (95 per vertebra, 13 vertebra per subject, 10 subjects = 12,350 points) to the curves defined by reference points. We also measured the ability to repeatedly produce accurate results (precision) by the different operators (inter-operator precision) and by the same operators (intra-operator precision).

All values mean (SD)	Effort [mins] per patient	Results	
		Accuracy [mm] per vertebra	Intra-Operator Precision [mm] per vertebra
Operator 1	8.9 (1.9)	0.92 (0.43)	0.97 (1.25)
Operator 2	7.4 (1.6)	0.85 (0.33)	0.63 (0.71)
Operator 3	6.2 (1.3)	0.85 (0.31)	0.63 (0.93)
Operator 4	6.9 (2.8)	0.91 (0.38)	0.61 (0.86)
Overall	7.4 (1.9)	0.88 (0.36)	0.71 (0.94)

Inter-operator precision was 0.91 (0.92) mm.

These results indicate that the accurate and reproducible computer assisted annotation of vertebral body shape can be accomplished within time constraints that are feasible in a point-of-care setting. The operator error was around 1 mm, which corresponds to about 3% of a vertebral height and compares favourably to the current guidelines for clinical trials,

which specify that changes of 3-4mm or 15-20% constitute vertebral fractures. Prevalent vertebral fractures are important predictors of future osteoporotic fractures in the spine and hip. This method may prove useful as a workflow tool to aid the physician to quantify vertebral shape. Further work is needed to explore how it may assist physicians in the assessment and classification of vertebral fractures. If successful, this tool could help standardize vertebral fracture assessment and make accurate quantitative assessment of vertebral shape feasible in a point-of-care setting.

**Risks and Outcomes for Hip Fractures in a Predominantly African-American Male Veteran Population.** R. U. Hashmi\*<sup>1</sup>, A. Rahman\*<sup>2</sup>, F. P. Perez\*<sup>3</sup>, S. C. Kukreja\*<sup>1</sup>, E. I. Barengolts\*<sup>3</sup>. <sup>1</sup>Medicine, University of Illinois at Chicago, Chicago, IL, USA, <sup>2</sup>Medicine, Weiss Memorial Hospital, Chicago, IL, USA, <sup>3</sup>Medicine, Jesse Brown VA Medical Center, Chicago, IL, USA.

The risks and outcomes associated with hip fractures are not well characterized in male veteran population. In this study we reviewed charts of patients admitted to VA Chicago hospital for hip fracture and for hip replacement surgery from January 2000 to December 2002. This preliminary report includes analysis of 33 age-matched subjects from each group (Table). There was no difference in smoking and alcohol abuse between the groups. DXA was done in 4 (12%) and bisphosphonates were used in 2 (6%) patients with fractures.

Table. Characteristics of cases (hip fracture) and controls (hip replacement).

Variable	Cases	Controls	P Value
Number of Subjects	33	33	x
African Americans, %	62	58	0.7
Age, years $\pm$ SD	69.8 $\pm$ 7.7	69.2 $\pm$ 6.0	0.7
<b>Outcomes</b>	<b>Cases</b>	<b>Controls</b>	<b>P Value</b>
Outcome <sup>1</sup>	1.6 $\pm$ 0.6	1.2 $\pm$ 0.4	<0.0004
Mortality in hospital, %	6.2	2.0	0.5
Mortality 1 year, %	28.1	6.5	0.02
Morbidity in hospital <sup>2</sup> , %	30.3	9.1	0.03
Co-morbid conditions, N $\pm$ SD	6.2 $\pm$ 3.2	4.2 $\pm$ 2.4	0.004
Concomitant medication, N $\pm$ SD	8.0 $\pm$ 3.7	4.3 $\pm$ 2.8	<0.0001
Hospitalization, days $\pm$ SD	7.4 $\pm$ 13.4	2.3 $\pm$ 8.6	0.07
<b>Risk Factors</b>	<b>Cases</b>	<b>Controls</b>	<b>P Value</b>
Seizure disorder, %	15.2	0.0	0.02
Stroke, %	21.2	9.1	0.17
Depression, %	21.2	9.1	0.17
COPD, %	15.2	3.0	0.08
Anti-seizure medication, %	18.2	0.0	0.01
Anti-depressants, %	33.3	9.1	0.02
Calcium supplements, %	36.4	6.1	0.003

<sup>1</sup> Outcome: 1=discharge home, 2=discharge to nursing home, 3=death

<sup>2</sup> Morbidity in the hospital included pneumonia, stroke and falls

<sup>3</sup> Hospitalization during 1 year prior to fracture

There was a high prevalence of seizure disorder, stroke and depression and in-hospital and 1 year mortality was 3-4 fold higher in patients with hip fractures than those with hip replacement. Our data suggest that patients with hip fractures have high prevalence of co-morbid, particularly neurological conditions and poor outcomes. If these data are confirmed, interventions to prevent hip fractures in high risk population with neurological disorders may be warranted.

## SA353

**Impact of an Educational Intervention on Knowledge about Osteoporosis Following a Fragility Fracture.** L. Bessette<sup>1</sup>, S. K. Davison<sup>1</sup>, L. Ste-Marie<sup>2</sup>, S. Jean<sup>3</sup>, M. Beaulieu<sup>4</sup>, M. Baranci<sup>5</sup>, J. P. Brown<sup>1</sup>. <sup>1</sup>CHUL Research Centre, Quebec, QC, Canada, <sup>2</sup>Medicine, University of Montreal, Montreal, QC, Canada, <sup>3</sup>Institut National de Santé Publique du Québec, Quebec, QC, Canada, <sup>4</sup>Merck Frosst, Kirkland, QC, Canada, <sup>5</sup>sanofi-aventis, Laval, QC, Canada.

The objective of this analysis was to evaluate the impact of an educational intervention on general osteoporosis (OP) knowledge in women  $\geq 50$  years who recently suffered a fragility fracture.

Three educational tools were developed: a 15-minute video, written material on OP targeted to participants, and written documentation on OP targeted to physicians. Information was based on the 2002 Clinical Practice Guidelines for the Diagnosis and Management of Osteoporosis in Canada. Six to eight months after the fracture event, women with a fragility fracture were contacted by phone and offered to be randomized to one of three groups: A) the control group (no intervention); B) the documentation group (written documents for the participants and the physician); or C) the video group (a video and the written documentation for both the participants and the physician). All participants completed a phone questionnaire on OP, which included a component on OP knowledge, before the intervention. Twelve months after the intervention participants were re-contacted and the same questionnaire was administered. The current analysis was completed only for participants who were undiagnosed and untreated for OP at randomisation.

Of the 894 women with a fragility fracture, 850 (95%) accepted randomization. Of these, 546 (64%; mean age: 61.7 years) were without OP diagnosis and treatment. Ninety-six percent of these 546 women were contacted and completed the phone questionnaire 12 months after the randomization. The mean knowledge score improved significantly from baseline in both groups B and C (81.6 to 85.5% and, 79.7 to 84.4%, respectively) compared to group A for whom there was little average change (79.9% to 81.9%). As showed in the table, groups B and C improved their knowledge between baseline and 12 month follow-up more so than the group A.

A simple intervention targeting the patient increased general knowledge about OP and its consequences.

% strongly agree or agree with the statement	Groupe A Baseline/12 mo	Group B Baseline/12 mo	Group C Baseline/12 mo
I understand the possible consequences of the fracture on my health well	84.2/85.6%	83.1/92.5%	83.9/91.6%
I know OP and its consequences well	50.0/58.1%	51.1/74.1%	51.6/77.0%
I understand the relationship between OP and my fracture well	61.8/66.8%	66.6/71.9%	57.5/71.0%
I know the treatments for OP well	19.5/24.8%	19.8/38.7%	21.9/45.1%

**Gender Specific Effects of TRPV4 on Osteoblast-Osteoclast Coupling and Risk of Osteoporotic Fractures.** B. C. J. van der Eerden<sup>\*1</sup>, M. Koedam<sup>\*1</sup>, F. Rivadeneira<sup>1</sup>, J. B. J. van Meurs<sup>1</sup>, J. G. J. Hoenderop<sup>\*2</sup>, H. Weinans<sup>\*3</sup>, M. Suzuki<sup>\*4</sup>, R. J. M. Bindels<sup>\*2</sup>, A. G. Uitterlinden<sup>1</sup>, J. P. T. M. van Leeuwen<sup>1</sup>.

<sup>1</sup>Internal Medicine, Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Cell Physiology, Nijmegen Centre for Molecular Life Sciences, Nijmegen, Netherlands, <sup>3</sup>Orthopedics, Erasmus MC, Rotterdam, Netherlands, <sup>4</sup>Molecular Pharmacology, Jichi Medical School, Tochigi, Japan.

TRPV4 is a member of the transient receptor potential (TRP) superfamily and responds to an array of stimuli, including osmolarity, heat, pH, temperature and pressure. Recent findings showing that TRPV4 deficiency leads to reduced sensing of mechanical stimuli led us to explore the role of TRPV4 in bone.

Using real-time PCR, TRPV4 mRNA was abundantly expressed in both osteoblasts and osteoclasts. Femoral cortical and trabecular bone mass (thickness and volume) as assessed by microcomputed tomography was higher in male but not female TRPV4 knockout mice compared to wild type mice.

Next, osteoclast and osteoblast differentiation and function was studied by bone marrow cultures from wildtype and TRPV4 knockout mice. Osteoclast numbers (TRAP staining) as well as the formation of resorption pits (coomassie brilliant blue staining) were significantly reduced in cultures of TRPV4 knockout mice compared to wildtype littermates. In contrast, osteoblast differentiation at day 9 of culture (alkaline phosphatase activity) and matrix mineralization at day 21 (alizarin red) was significantly increased in TRPV4 knockout bone marrow cultures. These data implicate osteoblast-osteoclast uncoupling and support the observed increase in bone mass in male TRPV4 deficient mice. To assess the possible impact of TRPV4 function on osteoporotic outcome in humans, we extracted data from a recently performed genome-wide association study (Illumina 550K SNP array) within the Rotterdam Study ( $\pm 7,500$  individuals, 55 years and older). Two

single nucleotide polymorphisms (SNPs) in the TRPV4 gene showed strong associations with osteoporotic fracture risk (Hazard Ratio 1.79; Confidence Intervals 1.19-2.69), fragility fracture risk (HR 2.58; CI 1.36-4.87) and hip fracture risk (HR 2.75; CI 1.31-5.75) in men, but not in women. This was not affected after adjusting for height, weight, age and bone mineral density (BMD). No associations were found for femoral neck or lumbar spine BMD in either sex.

In conclusion, TRPV4 plays an important role in male but not female bone biology. TRPV4 deficiency results in a male-specific increase in bone mass implicating a negative role for TRPV4 in male bone metabolism. In line with this male specificity, variations in the TRPV4 gene are predicting fracture risk in men but not in women.

**Disability in Patients with Osteoporotic Pertrocantheric Hip Fracture: A Prospective Study.** E. Casado, M. Larrosa\*, C. Galisteo\*, A. Gómez, P. Lisbona\*, E. Graell\*, N. Navarro\*, M. Moreno\*, J. Gratacós\*. Rheumatology, Hospital Sabadell, Sabadell, Spain.

**Background:** Hip fracture in elderly is an important health problem, but the short-medium term disability associated, is not commonly assessed.

**Purpose:** To study the short-medium term (6 months) disability associated to the stable osteoporotic pertrocantheric hip fracture.

**Methods:** Prospective study, with inclusion, during a two-year period (March 2002 - December 2003), of all patients older than 65 years with stable osteoporotic pertrocantheric hip fracture (Kyle I-III) who were attended in a 400-bed hospital in Spain. Patients with a moderate-severe disability (impossible to walk by themselves or Barthel <60) prior to hip fracture were excluded. Functional status was evaluated at inclusion (retrospective measurement of disability prior to fracture), and during follow-up (1,3 and 6 months) using: Barthel Index (0-100), the Activities of Daily Living index (ADL, 0-6), and the evaluation of the Walking Ability (WA) by a validated method that gather the need for walking aids.

**Results:** 82 patients (90% women) with a mean age of  $83 \pm 7$  years were included. The functional status at inclusion was: Barthel index  $61 \pm 22.6$ ; and 44% and 68% of the patients were independent according to ADL and WA scales respectively (table 1). Disability clearly improved during the follow up, but still remained very important after 6 months (table 1). At six months 37 patients (45%) were lost.

**Table:**

	Baseline	1 month	3 months	6 months
Barthel Index	88,3 $\pm$ 10,8	61 $\pm$ 22,6 75	75,9 $\pm$ 22,4	85,4 $\pm$ 15,7
ADL scale*	44%	3,5%	18%	26,5%
WA scale**	68%	0%	9%	21%

\*Independent patients for the 6 basic ADL. \*\*Independent patients for walk

**Conclusion:** Hip fracture, even the most stable type, produces an important disability at medium term that is not always taken into account in these patients.

**Disclosures:** E. Casado, None.

**Family Physician Characteristics that Predict Appropriate X-ray Ordering: Canadian Quality Circle (CQC) National Project.** A. Papaioannou<sup>1</sup>, G. Ioannidis<sup>1</sup>, B. Kvern<sup>\*2</sup>, A. Hodsman<sup>3</sup>, L. Thabane<sup>\*1</sup>, A. Gafni<sup>\*1</sup>, A. Walsh<sup>\*4</sup>, F. Jiwa<sup>5</sup>, J. D. Adachi<sup>1</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada, <sup>2</sup>University of Manitoba, Winnipeg, MB, Canada, <sup>3</sup>University of Western Ontario, London, ON, Canada, <sup>4</sup>Procter and Gamble Pharmaceuticals, Toronto, ON, Canada, <sup>5</sup>Osteoporosis Canada, Toronto, ON, Canada.

The project is an integrated disease management study designed to improve family physicians' (FPs) adherence with the Osteoporosis Canada 2002 guidelines. This analysis examined the association between appropriate x-ray ordering and FPs characteristics. The guidelines recommend that x-rays should be ordered in all patients with kyphosis or height loss. A total of 225 FPs from across Canada completed the physician characteristics questionnaire, which captured 13 physician characteristics including sex; year of graduation from medical school; country of medical school; does the physician have a full or part-time practice, has hospital privileges, provide house calls, or has after hours call coverage for a defined group of patients; does the physician work in a solo or group practice, work in a teaching practice, is involved with an interdisciplinary team on site, uses electronic health records, or mainly uses fee-for-service billings; and is the physician a current member of the college of family physicians of Canada. During the course of the study, FPs examined a total of 13970 patients who were randomly selected from their practices. The generalized estimating equations (GEE) technique was used to examine the

association between appropriate x-ray ordering and physician characteristics. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. Results indicated that 52% (117/225) of FPs were women, 61% (132/216) provided house calls, 71.5% (156/218) provided after hour call coverage, 30% (67/223) worked in a teaching practice, 32% (73/223) worked within an interdisciplinary team, and 85% (192/225) used fee-for-service billings. Patients were younger in practices of women FPs (56.6% versus 66.4% of patients over the age of 65 years) as compared with men FPs. The likelihood of appropriate x-ray ordering was lower if the physician was a woman (OR: 0.76; 95% CI: 0.63, 0.92), provide house calls (OR: 0.71; 95% CI: 0.59, 0.85), worked within an interdisciplinary team (OR: 0.70; 95% CI: 0.56, 0.88), or used fee-for-service billings (OR: 0.66; 95% CI: 0.51, 0.85). The likelihood of appropriate x-ray ordering was higher if the physician provided after hour call coverage (OR: 1.87; 95% CI: 1.46, 2.38) or worked in a teaching practice (OR: 1.29; 95% CI: 1.06, 1.58). In conclusion, physician characteristics may influence x-ray ordering and that appropriate x-ray ordering may result in a greater number of vertebral fractures detected.

**Failure to Perceive Increased Risk of Fracture in Women  $\geq 55$  Years. The Global Longitudinal Registry of Osteoporosis in Women.** E. S. Siris<sup>1</sup>, A. Diez-Perez<sup>2</sup>, S. Boonen<sup>\*3</sup>, C. Cooper<sup>4</sup>, A. LaCroix<sup>5</sup>, N. B. Watts<sup>6</sup>, K. G. Saag<sup>7</sup>, S. Silverman<sup>8</sup>, R. Dedrick<sup>\*9</sup>, S. L. Greenspan<sup>\*10</sup>. <sup>1</sup>Department of Medicine, Columbia University College of Physicians and Surgeons, New York, NY, USA, <sup>2</sup>Hospital del Mar, Barcelona, Spain, <sup>3</sup>Leuven University Center for Metabolic Bone Diseases, Leuven, Belgium, <sup>4</sup>Southampton General Hospital, Southampton, United Kingdom, <sup>5</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, USA, <sup>6</sup>University of Cincinnati, Cincinnati, OH, USA, <sup>7</sup>University of Alabama-Birmingham, Birmingham, AL, USA, <sup>8</sup>David Geffen School of Medicine, Los Angeles, CA, USA, <sup>9</sup>UMASS Medical School, Worcester, MA, USA, <sup>10</sup>University of Pittsburgh, Pittsburgh, PA, USA.

The purpose of the study was to compare self-perceived risk of osteoporotic fracture among women  $\geq 55$  years of age with reported risk factors.

The Global Longitudinal registry of Osteoporosis in Women is an observational follow-up study of women  $\geq 55$  years of age recruited by 540 primary physician practices (17 sites, 10 countries). Practices typical of each region were identified by primary care networks organized for administrative, research or educational purposes. All non-institutionalized patients visiting the practice within the prior 2 years were eligible. Self-administered questionnaires were mailed, with 2:1 over-sampling of women  $\geq 65$  years of age. Data collected included information on demographics; medical history; risk factors for osteoporosis-related fracture; fracture occurrence; and self-report of prevention, diagnosis and treatment of osteoporosis. Respondents rated their perceived risk of fracture vs women of the same age using a 5-point scale from "much lower" to "much higher."

Of the women with no risk factors, 90% believed their risk was the same as or lower than that of women of the same age, whereas the majority of women with risk factors failed to appreciate their increased risk of fracture (Table). Among women diagnosed with osteoporosis, 56% believed they were not at increased risk. One quarter of the 15,163 women with a FRACTURE Index  $\geq 5$  perceived themselves at higher risk.

**Table.** Perceived Risk of Fracture Compared with Women of Same Age

Risk factor	N	Perceived risk of fracture	
		Lower	Higher
No risk factor	20,943	41%	10%
History of fracture	11,544	21%	35%
Maternal hip fracture	5972	28%	26%
Parental hip fracture	7397	28%	25%
Weight <125 lb (57 kg)	7705	32%	26%
Smoker	4391	31%	19%
Alcohol >14 units/week	1604	38%	15%
Current steroid use	1484	22%	39%
Rheumatoid arthritis	5196	25%	28%
FRACTURE Index $\geq 5$	15,163	31%	25%
<b>Diagnosis</b>			
Osteoporosis	9353	18%	44%
Osteopenia	8195	27%	25%
Normal	30,166	42%	8%

Most women at elevated likelihood of osteoporotic fracture do not perceive themselves to be at increased risk.

**Disclosures:** E.S. Siris, Lilly, Merck, Procter & Gamble, sanofi-aventis, Novartis 1.

This study received funding from: The Alliance for Better Bone Health (Procter & Gamble Pharmaceuticals and sanofi-aventis).

**Risk Factors for Fragility Fracture in a Multiracial Cohort of US Women.**

**The Global Longitudinal Registry of Osteoporosis in Women.** S. Silverman<sup>1</sup>, J. Adachi<sup>2</sup>, S. Gehlbach<sup>\*3</sup>, S. L. Greenspan<sup>\*4</sup>, F. Hooven<sup>\*3</sup>, A. LaCroix<sup>5</sup>, R. Lindsay<sup>\*6</sup>, K. G. Saag<sup>\*7</sup>, E. S. Siris<sup>8</sup>, A. Wyman<sup>\*3</sup>, N. B. Watts<sup>9</sup>.

<sup>1</sup>David Geffen School of Medicine, Los Angeles, CA, USA, <sup>2</sup>St. Joseph's Hospital, Hamilton, ON, Canada, <sup>3</sup>UMASS Medical School, Worcester, MA, USA, <sup>4</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>5</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, USA, <sup>6</sup>Helen Hayes Hospital, New York, NY, USA, <sup>7</sup>University of Alabama-Birmingham, Birmingham, AL, USA, <sup>8</sup>Columbia University Medical Center, New York, NY, USA, <sup>9</sup>University of Cincinnati, Cincinnati, OH, USA.

The purpose of the study was to identify risk factors for fragility fracture in a multiracial cohort of women from the USA.

GLOW is a prospective, multinational, observational study. Seventeen sites in 10 countries in North America, Australia and Europe are participating. Practices typical of each region were identified through primary care networks. The present report is limited to data collected from US White, Black and Asian women. All non-institutionalized women  $\geq 55$  years of age who visited the practices within the previous 2 years were eligible. Self-administered questionnaires were mailed (2:1 over-sampling of women aged  $\geq 65$  years).

In a population of 20,888 women from 6 physician practices, 18,613 were White, 1932 were Black and 343 were Asian. Risk factors for fracture (established from studies of primarily White populations) varied among the 3 groups (Table). White women had the highest prevalence of personal history of fracture, parental fracture, alcohol and steroid use. Black women reported higher rates of smoking, use of arms in rising, rheumatoid arthritis and secondary osteoporosis. Asians had the highest prevalence of weight <125 lb. White women reported higher rates of prior fracture than Black women, which varied from 4.8 times higher for rib to 1.1 times higher for ankle fractures. Both Black and Asian women had hip fracture rates similar to those for White women.

**Table.** Age-standardized patient risk factors for fracture, by race

Risk factor (%)	White (n=18,613)	Black (n=1932)	Asian (n=343)
Arms used to assist from sitting	35.7	55.3	24.3
Steroid use	34.9	23.5	19.9
Personal history of fracture	24.2	14.4	18.4
Parental fracture	17.5	7.0	11.3
Secondary osteoporosis	16.0	25.3	17.1
Weight <125 lb (57 kg)	15.6	4.7	47.6
Rheumatoid arthritis	8.0	21.4	11.8
Current smoker	7.3	11.5	2.4
Alcoholic drinks (>14 per week)	2.6	0.3	0.3

Racial differences for prevalent fractures and clinical risk factors for fragility fracture were observed in this US cohort. The prevalence of prior fractures among both Black and Asian women, although less than that of White women, is substantial, and places them at risk for future fracture.

**Association Between BMD Change, Use of Antiresorptive Agents and Fragility Fracture in Women and Men.** C. Berger<sup>\*1</sup>, L. Langsetmo<sup>\*1</sup>, L. Joseph<sup>\*1</sup>, D. A. Hanley<sup>2</sup>, K. S. Davison<sup>3</sup>, R. Josse<sup>4</sup>, N. Kreiger<sup>\*4</sup>, A. Tenenhouse<sup>\*1</sup>, D. Goltzman<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada, <sup>2</sup>University of Calgary, Calgary, AB, Canada, <sup>3</sup>Laval University, Quebec city, QC, Canada, <sup>4</sup>University of Toronto, Toronto, ON, Canada.

Our objective was to determine the relationship between baseline BMD, longitudinal change in BMD, and fragility fractures in men and women, taking or not taking antiresorptive agents (bisphosphonates, estrogen). We studied 3635 women and 1417 men aged 50 to 85 years old from the CaMos cohort with at least two BMD measurements in the first five years, with fracture information in the first seven years, and without long-term glucocorticoid use. Multiple logistic regression models were used to assess the relationship between baseline BMD (lumbar spine, femoral neck, total hip and trochanter), BMD change and fragility fractures (any, main, forearm/wrist, ribs and hip) in users and non-users of antiresorptive agents. All models are adjusted for age, height, BMI, previous fracture, diabetes, osteoarthritis and rheumatoid arthritis. Among antiresorptive non-users, a higher rate of total hip BMD loss is associated with a greater risk of fragility fracture with an odds ratio (OR) of 1.19 (95% CI: 0.94; 1.51) for each 0.01g/cm<sup>2</sup> per year in women, and an OR of 1.60 (95% CI: 1.20; 2.14) for each 0.01g/cm<sup>2</sup> per year in men. Furthermore, the association was even stronger for women with the lowest baseline BMD (first tertile) with an OR of 1.62 (95% CI: 1.12; 2.34) and with the highest loss of BMD with an OR of 1.93 (95% CI: 1.28; 2.90). In men, the association was stronger in those with the lowest baseline BMD with an OR of 1.85 (95% CI: 1.17; 2.93) and in osteopenic men with an OR of 1.73 (95% CI: 1.20; 2.49). In women, the risk of forearm/wrist fragility fracture for a decrease of 0.01g/cm<sup>2</sup> in baseline total hip is 1.04 (95% CI: 1.00; 1.07) in non-users and 1.06 (95% CI: 1.03; 1.08) in users. The risk of forearm/wrist fragility fracture for a decrease of 0.01g/cm<sup>2</sup> per year at the total hip is 1.50 (95% CI: 1.07; 2.11) in non-users compared to 1.03 (95% CI: 0.78; 1.35) in users. The results show that there is an association between the rapidity of bone loss and fragility fractures in non-users, although stronger in non-user men, suggesting that rate of change is an independent risk factor from baseline BMD. Rapid bone loss is an important risk factor for fragility fractures in subgroups of the population such as those who lose bone faster or those with osteopenia. The inconclusive results between rate of BMD loss and risk of fractures in antiresorptive users support the position that prevention of BMD loss is not the only mechanism for fracture protection with antiresorptives.

**Positive Celiac Disease Serology and Bone Mineral Density in Adult Women.** W. D. Leslie, D. Duerksen<sup>\*</sup>. Department of Medicine, University of Manitoba, Winnipeg, MB, Canada.

Celiac disease (CD) is associated with decreased BMD. Seropositivity with tissue transglutaminase antibody (TTG) and/or endomysial antibody (EMA) is highly specific for CD, while antigliadin antibody (AGA) has lower specificity. We investigated the relationship between BMD and CD serology in a clinical cohort of adult women to determine the role of seropositivity as a risk factor for decreased BMD. The Manitoba BMD Database (1990-2007) was linked to a provincial database of CD serology (1996-2007) to identify all women in Manitoba over age 20 with BMD results preceding CD serology by 6 m or less (mean interval 3 m). In women with multiple CD serologies only the first was used. CD seropositivity was defined from high specificity assays (CD-HS: TTG or EMA) or low specificity assays (CD-LS: AGA). ANCOVA models (age, height, weight-adjusted) were used to assess the effect of CD seropositivity on BMD at multiple measurement sites (total hip, lumbar spine L1-4, trochanter and femoral neck). There were 377 matches between the 2 databases (31 CD-HS seropositive, 71 CD-LS seropositive, 296 CD seronegative for both). Mean age was 62 (SD 13) y, and mean Z-scores ranged from -0.30 (SD 1.07) at the femoral neck to -0.86 (SD 1.57) at L1-4. HS-CD seropositivity was associated with lower BMD at all sites, and LS-CD seropositivity was associated with lower BMD at 3 sites (see Table). When HS-CD and LS-CD serology were discordant there was a significant effect of HS-CD seropositivity on BMD ( $P < .05$  for lower BMD at the total hip, trochanter, L1-4) whereas in those with LS-CD seropositivity (with HS-CD negative) BMD was no different from CD seronegative women.

Table: Least-squares mean T-scores ( $\pm$ SE) from ANCOVA models (age, height, weight-adjusted).

	CD-HS Seronegative	CD-HS Seropositive	CD-LS Seronegative	CD-LS Seropositive
Total hip	-1.34 $\pm$ 0.06 *	-1.92 $\pm$ 0.20	-1.30 $\pm$ 0.06 *	-1.65 $\pm$ 0.13
L1-4	-1.96 $\pm$ 0.07 *	-2.59 $\pm$ 0.24	-1.93 $\pm$ 0.09	-2.25 $\pm$ 0.17
Femoral neck	-1.66 $\pm$ 0.05 *	-2.03 $\pm$ 0.16	-1.63 $\pm$ 0.05 *	-1.88 $\pm$ 0.10
Trochanter	-1.62 $\pm$ 0.06 *	-2.29 $\pm$ 0.19	-1.59 $\pm$ 0.06 *	-1.97 $\pm$ 0.13

\*  $P < .05$ , Seronegative vs Seropositive

In conclusion, we found a significantly lower BMD in CD seropositive women compared with seronegative women. This effect was only seen with high specificity CD antibodies (TTG or EMA), and not with low specificity CD antibodies (AGA).

**Predictors of Osteoporosis Management Among Residents Living in Long-Term Care.** L. M. Giangregorio<sup>1</sup>, A. Papaioannou<sup>2</sup>, J. Hirides<sup>\*3</sup>, C. J. Maxwell<sup>\*4</sup>, M. Jantzi<sup>\*3</sup>, J. W. Poss<sup>\*3</sup>. <sup>1</sup>Kinesiology, University of Waterloo, Waterloo, ON, Canada, <sup>2</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>3</sup>Health Studies and Gerontology, University of Waterloo, Waterloo, ON, Canada, <sup>4</sup>Community Health Sciences & Medicine, University of Calgary, Calgary, AB, Canada.

The present study describes the extent to which individuals living in long-term care (LTC) with a recent fracture or diagnosed osteoporosis are receiving osteoporosis management, and identifies factors associated with management.

The sample included 1910 LTC residents living in Ontario and Manitoba, Canada. Data were obtained using the Resident Assessment Instrument Minimum Data Set 2.0. Osteoporosis management was assessed among residents with a diagnosis of osteoporosis or recent fracture. Sociodemographic, clinical and functional characteristics were assessed as correlates of pharmacological osteoporosis management in multivariable logistic regression analyses.

Individuals who had sustained a recent fracture or who had a history of hip fracture or documented osteoporosis represented 27.5% (n = 525) of the sample; use of any osteoporosis medication was reported in 40% of these individuals (from here called the osteoporosis group). Twenty-seven percent (n=140) of residents in the osteoporosis group were documented to be taking both calcium and vitamin D supplementation, 6.5% (n=34) were documented to be taking calcium supplements only, 3.6% (n=19) were taking vitamin D only, and multivitamin use was reported in 19% (n=100) of residents. 54 (10.3%) of residents in the osteoporosis group were taking a bisphosphonate and were not taking vitamin D or a multivitamin. The odds of individuals in the osteoporosis group receiving pharmacological therapy were lower if they had six or more co-morbid conditions, if they used a wheelchair as their primary mode of mobility, if they had depression (DRS 3+), if they had health instability, or if they resided in a facility in Manitoba. Female sex and prescription of ten or more medications were variables positively associated with current use of osteoporosis therapy.

The current study reveals that osteoporosis management is not optimal among individuals at risk of fracture living in LTC facilities, and identifies predictors of osteoporosis management. It may be necessary to incorporate an initiative for health care providers, facility staff, residents and their families to educate them about the importance of fracture prevention strategies in LTC.

**The Relationship Between Focal Erosions and Generalized Osteoporosis in Postmenopausal Women with Rheumatoid Arthritis: The Osteoporosis in Rheumatoid Arthritis (OPiRA) Cohort Study.** D. H. Solomon<sup>1</sup>, J. S. Finkelstein<sup>2</sup>, N. Shadick<sup>\*1</sup>, M. S. LeBoff<sup>3</sup>, C. Winalski<sup>\*4</sup>, M. Stedman<sup>\*5</sup>, R. Glass<sup>\*1</sup>, M. A. Brookhart<sup>\*5</sup>, M. E. Weinblatt<sup>\*1</sup>, E. M. Gravallese<sup>\*6</sup>.

<sup>1</sup>Rheumatology, Brigham and Women's Hospital, Boston, MA, USA,

<sup>2</sup>Endocrinology, Massachusetts General Hospital, Boston, MA, USA,

<sup>3</sup>Endocrinology, Brigham and Women's Hospital, Boston, MA, USA,

<sup>4</sup>Radiology, Cleveland Clinic Foundation, Cleveland, OH, USA,

<sup>5</sup>Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA,

<sup>6</sup>Rheumatology, University of Massachusetts Medical Center, Worcester, MA, USA.

After 10 years of rheumatoid arthritis (RA), half of all patients have focal erosions and the risk of fracture is doubled. However, little information exists about the relationship between focal erosions and bone mineral density (BMD). We enrolled postmenopausal women with RA who were not current users (but could be past users) of any osteoporosis medications. Participants underwent DXA testing at the hip and spine. A single radiologist blinded to the DXA results and other data read all the hand films and scored them using the Sharp method. We examined the relationship between BMD and erosions using correlation coefficients and adjusted linear regression models.

Sharp scores and DXA results (hip or spine) were examined for 163 women, mean age was 62.4 years ( $\pm$  9) with an average duration of RA of 13.7 years. Almost all patients were currently using a disease modifying antirheumatic drug. 63% were rheumatoid factor (RF) positive, the median Health Assessment Questionnaire score was 0.7, and the average DAS-28 was 3.8 ( $\pm$  1.6). The erosion score was significantly correlated with the total hip BMD (Spearman R = -0.33,  $p < 0.0001$ ) but not with the lumbar spine BMD (Spearman R = -0.09,  $p = 0.27$ ). Hip BMD was significantly lower in RF positive women (0.83 g/cm<sup>2</sup>) versus RF negative (0.89 g/cm<sup>2</sup>,  $p = 0.02$ ). In multivariable models that included age, BMI, and cumulative oral glucocorticoid dosage, neither total hip nor spine BMD were

significantly associated with focal erosions. The relationship between total hip BMD and erosions appears different in patients with: fewer years of disease ( $<5$  versus  $\geq 5$  years), higher BMI ( $< 28$  versus  $\geq 28$  kg/m<sup>2</sup>), less cumulative oral steroid use ( $< 960$  versus  $\geq 960$ mg), and lower 25-OH vitamin D levels ( $< 20$  versus  $\geq 20$  ng/dl). These results suggest that total hip BMD, but not lumbar spine BMD, is associated with focal erosions among postmenopausal women with RA, but this association disappeared after adjustment. Positive RF is associated with a reduced BMD. This study is limited by the fact that most patients had long-standing well-controlled RA. While BMD and erosions may be correlated bone manifestations of RA, their relationship is influenced by other disease-related factors and anatomic sites.

**Homocysteine Levels in Relation to Physical Performance.** N. M. Van Schoor<sup>\*1</sup>, S. M. F. Pluijm<sup>\*2</sup>, M. Visser<sup>\*1</sup>, S. Simsek<sup>\*3</sup>, Y. Smulders<sup>\*3</sup>, P. Lips<sup>3</sup>.  
<sup>1</sup>EMGO Institute, VU University Medical Center, Amsterdam, Netherlands, <sup>2</sup>Public Health, Erasmus MC, Rotterdam, Netherlands, <sup>3</sup>Internal Medicine, VU University Medical Center, Amsterdam, Netherlands.

Elevated homocysteine concentrations are associated with osteoporotic fractures, but the pathophysiologic pathway is not clear. Elevated homocysteine levels might lead to osteoporosis and/or increased fall risk. There is some evidence that elevated homocysteine levels may lead to decreased physical performance. In this study, the relationship between homocysteine levels and physical performance will be examined.

The study was performed using data of the Longitudinal Aging Study Amsterdam, an ongoing multidisciplinary cohort study that started in 1992/93. The current study was performed in persons who participated in the medical interview in 1995/96, and were born in or before 1930 (aged 65 years and older as of January 1, 1996) (n=1509). Data on homocysteine, physical performance and potential confounders were available for 1212 persons. EDTA plasma samples were obtained in the morning, after subjects had eaten a light breakfast. Total homocysteine levels were measured with the use of a fluorescence polarization immunoassay on an IMx analyzer (Abbott Laboratories). Physical performance was assessed in 1995/96 using three tests: the chair stand, the walking test and the tandem stand (total score 0-12). The data were analyzed with homocysteine levels in quartiles (with the lowest quartile as the reference group) using multiple regression analyses.

In total, 589 men and 623 women were included with a mean age of 75.4 years (standard deviation=6.5). No interaction with age was found. The interaction with sex was significant (p=0.076 for the fourth quartile). Therefore, further analyses were stratified on sex. Both in men and women, physical performance decreased with increasing quartiles of total homocysteine in the univariate analyses. After adjustment for age, years of education, region, body mass index, alcohol use, smoking, cognition, heart disease, peripheral arterial disease, stroke, serum 25-hydroxyvitamin D and creatinine, homocysteine was no longer significantly associated with physical performance in men. In women, the second quartile (beta= -0.512, p=0.076) and third quartile (beta= -0.450, p=0.151) were no longer statistically significant. However, the fourth quartile remained significantly associated with decreased physical performance as compared to the lowest quartile (beta= -0.898, p=0.013).

In conclusion, elevated homocysteine levels were associated with decreased physical performance in elderly women.

**Risk Factors for Bone Loss in the Hip in 70-Year-Old Women: A Nine-Year Follow-up.** G. Sigurdsson<sup>1</sup>, S. L. Gudmundsdottir<sup>\*1</sup>, D. Oskarsdottir<sup>\*2</sup>, O. S. Indridason<sup>\*1</sup>, L. Franzson<sup>\*3</sup>. <sup>1</sup>Department of Medicine, Landspítali - University Hospital, Reykjavik, Iceland, <sup>2</sup>University of Iceland, Reykjavik, Iceland, <sup>3</sup>Genetic and Molecular Medicine, Landspítali - University Hospital, Reykjavik, Iceland.

The purpose of this study was to examine risk factors for longitudinal bone loss in the hip of 70-year-old women.

Bone mineral density (BMD, g/cm<sup>3</sup>) was measured in the femoral neck, trochanter and total hip using dual X-ray absorptiometry (DXA) at five year intervals, in 1997-1998, 2003-2004 and 2007. At each visit, the women also underwent extensive blood test and answered lifestyle questionnaire. Changes in BMD from baseline and its relationship with baseline BMD, weight, lean and fat mass, markers of bone remodeling, hormones, vitamins and lifestyle according to questionnaire as well as weight changes during follow-

up were examined. The relationship between 2003-2004 measurements and subsequent bone loss was also studied.

Of 308 women initially studied, 162 returned for the final visit. Mean follow-up time was 9.12 years. Mean 9-year bone loss was -0.83%/year in the femoral neck, -0.47%/year in the trochanter (p<0.01 compared to femoral neck), and -0.53%/year in the total hip (p<0.01/0.05 compared to femoral neck/trochanter). Lower baseline (1997) S-25(OH)D correlated with increased bone loss in the femoral neck (r=0.21, p<0.01) and baseline trochanter BMD correlated inversely with trochanter BMD loss (r=-0.41, p<0.01). We found no significant relationship between other baseline measurements and hip BMD change. Based on 2003-2004 measurements, significant risk factors for subsequent bone loss were high serum calcium and low number of leisure walks per week for the femoral neck, lower anabolic index (AI= osteocalcin/crosslaps) and lower estradiol for the trochanter and lower AI for total hip. Bone loss in the femoral neck, trochanter and hip was -9.8%, -7.5% and -8.7% in women experiencing weight loss >5% during follow-up but in women who had stable or increased weight the bone loss was -6.4%, -2.6% and -2.9% respectively (p<0.01 for all sites). Weight loss in the first part of follow-up was not related to bone loss in the latter part of follow up.

This study suggest that high 25(OH)D may reduce longitudinal cortical bone loss. Also, it lends further support to the role of physical activity and weight maintenance as important preventive factors for bone loss in the elderly. Moreover, it shows that the anabolic index, which theoretically gives a ratio of bone formation to bone resorption may predict bone loss and this needs to be studied in more detail.

**Teriparatide Improves Trabecular Architecture as Measured by  $\mu$ CT at Simulated *in vivo* Resolution in the Femoral Neck of Ovariectomized Monkeys.** P. Chen<sup>\*1</sup>, B. Gomberg<sup>\*2</sup>, M. S. Westmore<sup>\*1</sup>, K. Krohn<sup>1</sup>, M. Sato<sup>\*1</sup>.  
<sup>1</sup>Eli Lilly, Indianapolis, IN, USA, <sup>2</sup>MicroMRI Inc, Philadelphia, PA, USA.

Teriparatide (TPTD) has been shown to improve bone mass, spatial architecture and bone strength in ovariectomized monkeys. Recently, techniques were developed to further characterize architectural features of trabecular bone at *in vivo* resolution beyond bone volume fraction and conventional histomorphometry. Digital topological analyses (DTA) were developed initially for high-resolution MRI, it is not clear whether it can also be applied to high-resolution images obtained with  $\mu$ CT. We tested the hypothesis that TPTD can improve trabecular bone micro-architecture in the primate femoral neck (FN), as quantified by DTA at simulated *in vivo* resolution. Ovariectomized monkeys were administered 0 (OVX vehicle, n=20), 1.0 (TPTD1, n=19) or 5.0  $\mu$ g/kg/day (TPTD5, n=20) TPTD for 18 months. At necropsy, L4-6 and proximal femora were excised and adjacent or contralateral bones were processed for histomorphometry and biomechanical analyses for each monkey.  $\mu$ CT images of the FN were acquired *ex vivo* at 15  $\mu$ m isotropic voxel size. Conventional histomorphometry analyses were published previously (Sato et al. 2004). Images were resampled to 75  $\mu$ m isotropic to simulate *in vivo* resolution, and then analyzed by DTA, which comprises thresholding, thinning, and topological classification. The analysis identifies surfaces, profiles, curves, and their mutual junctions representing trabecular variations of plates, rods, and their junctions after thinning, and the DTA parameters reflect the micro-architectural integrity of the trabecular network. TPTD significantly improved trabecular architecture measured at *in vivo* resolution by both histomorphometric and DTA endpoints relative to OVX. Additionally, *in vivo* resolution DTA endpoints correlated significantly with bone strength in both lumbar vertebra and FN. These results show that TPTD improves the trabecular architecture in the FN of primates using DTA analysis at *in vivo* data resolution. The data also demonstrate that DTA parameters correlate well with measures of trabecular bone strength at the vertebra and FN. Further clinical studies are needed to confirm the simulated results shown here.

**Dietary Strontium (Sr) in a Model of Established Osteopenic Rats Reduce the Levels of 25hydroxyvitamin D.** M. M. S. Gonzales Chaves<sup>\*1</sup>, C. Marotte<sup>\*1</sup>, G. G. Pellegrini<sup>\*2</sup>, S. M. Friedman<sup>\*3</sup>, A. Pighin<sup>\*4</sup>, M. C. de Landeta<sup>\*5</sup>, S. N. Zeni<sup>1</sup>. <sup>1</sup>Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, <sup>2</sup>Bioquímica General y Bucal, Facultad de Odontología, UBA, Buenos Aires, Argentina, <sup>3</sup>Bioquímica General y Bucal., Facultad de Odontología, UBA, Buenos Aires, Argentina, <sup>4</sup>Cs.Básicas. Analítica, Universidad Nacional de Luján, Buenos Aires, Argentina, <sup>5</sup>Cs.Básicas.Analítica, Universidad Nacional de Luján, Buenos Aires, Argentina.

Previously we found that vitamin D (vitD) status (i.e.normal or insufficient) interferes with bone mass recovery from bisphosphonate therapy in a model of OVX rats with established osteopenia (Bone 39: 837,2006). Using this model we investigated bone recovery from SrRanelate (SrRa) therapy. After 15 days post surgery and during 45 days, 20 OVX rats fed a diet containing 200IU% D (+D) and 20 a diet lacking vitD (-D) to obtain osteopenic/vitD depleted or depleted groups. Thereafter, 10 -D and 10 +D OVX rats were treated with vehicle (-RaSr) or RaSr (900mg/kg/d) (+RaSr) for 45 days to obtain 4 subgroups (table). A SHAM group was run as control. At 0, 60 and 105 days total skeleton BMD and BMC(teBMC) were assessed by DXA, 25OHD by RIA (Diasorin) and serum Ca and phosphorus (P) by atomic absorption spectrophotometry (AAS) and colorimetric methods, respectively. At day 105, rats were sacrificed and tibia total bone volume (BV/TV) and Sr in bone were determined by histology and AAS, respectively. Results (mean±SE)

Different letter indicates a p<0.05. There were no differences in teBMC, bony Sr and BV/TV between +SrRa treated -D or +D groups. BV/BT in +RaSr was 50% higher than in -SrRa groups but only represented a 10% of SHAM level. The 25OHD levels were significantly lower in +D+RaSr than in +D-RaSr rats. Conclusions: under our experimental conditions Sr may be incorporated into the formed bone independently of vitamin D status. We surprisingly found a diminution in serum 25OHD in +D+SrRa treated rats compared to +D-RaSr groups suggesting, as previously found in chicks (this effect on rats was not previously reported), an inhibition of vitD metabolism to its functional metabolite of nutritional status, 25OHD. (J Biol Chem 247: 5520, 1972).

**Aging Dependent and Independent Effects of b2 Adrenergic Receptor Signaling on Bone Formation Induced by Intermittent PTH Treatment in Female Mice.** R. Hanyu<sup>1</sup>, Y. Saita<sup>\*1</sup>, J. Nagata<sup>1</sup>, Y. Izu<sup>1</sup>, H. Hemmi<sup>1</sup>, S. Takade<sup>2</sup>, Y. Ezura<sup>1</sup>, H. Kurosawa<sup>\*3</sup>, M. Noda<sup>1</sup>. <sup>1</sup>Dept Molecular Pharmacology Medical Research Institute Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>Department of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan, <sup>3</sup>Department of Orthopedics, Juntendo University school of Medicine, Tokyo, Japan.

Intermittent administration of PTH enhances bone mass levels in postmenopausal osteoporosis patients. This enhancement by PTH on bone mass is modulated by the sympathetic tone through its action on b2 adrenergic receptor. However, whether aging could affect such action of PTH in the presence or absence of sympathetic tone has not been known. We therefore examined the effects of the presence and absence of b2 adrenergic receptor on the anabolic action of intermittent PTH treatment in young adult mice(9w) and compared the results to those in aged adult mice(54w). Cancellous bone mass was enhanced by the treatment with PTH in aged mice, however there was only a trend for the increase in young adult mice. Base line levels of such fraction of bone mass in cancellous bone were about 15% in young while they were about 5% for the aged animal. Interestingly, the enhancement of PTH was approximately 80% in aged mice, but such modulation was only about 30% in young adult mice. In the absence of b2 adrenergic receptor the basal levels of fraction of bone volume were higher than wild type, and in contrast to wild type, PTH no longer enhanced the bone mass levels in both young and aged adult mice. Analysis of the axial bone (vertebrae) also revealed similar trend. However, in this case young adult wild type animals responded to PTH (p< 0.05). Such trend was observed but not statistically significant in aged adult mice. In the absence of b2 adrenergic receptor base line levels were higher than wild type aged mice but such difference was less in young adult mice. Intermittent PTH treatment in the absence of b2 adrenergic receptor was no longer observed in both young and aged adult mice. In contrast to the cancellous bone, cortical bone volume as well as the bone mineral density, which mostly represent the cortical compartment, were similar regardless of the age on the treatment with PTH in the absence or presence of b2 adrenergic receptor. Mean cortical bone thickness was similar. However in terms of cortical bone volume, aged KO mice tended to exhibit higher bone mass levels compared to the young adult KO or WT mice. In conclusion, our data indicated that there were the age dependent and independent effects of the presence or absence of b2 adrenergic receptor signaling on intermittent PTH treatment for its anabolic action.

**Prior Treatment with Vitamin K<sub>2</sub> Significantly Improves the Efficacy of Risedronate.** Y. Mikuni-Takagaki<sup>1</sup>, Y. Matsumoto<sup>\*2</sup>, Y. Kozai<sup>\*2</sup>, K. Miyagawa<sup>\*1</sup>, K. Naruse<sup>\*3</sup>, H. Wakao<sup>\*2</sup>, R. Kawamata<sup>\*2</sup>, I. Kashima<sup>\*2</sup>, T. Sakurai<sup>\*1</sup>. <sup>1</sup>Functional Biology, Kanagawa Dental College, Yokosuka, Japan, <sup>2</sup>Maxillofacial Diagnostic Science, Kanagawa Dental College, Yokosuka, Japan, <sup>3</sup>Orthopedic Surgery, Kitasato University School of Medicine, Sagami-hara, Japan.

The objective of this study was to determine the best combinatory administration method of bisphosphonate (risedronate) with vitamin K<sub>2</sub> (MK-4) to improve the strength of osteoporotic bone.

Female 9-week ICR mice were given ovariectomy or sham operation. Thirty days later, they were divided into treatment groups (n=8), based on the 16-week daily administration of risedronate (R) and/or MK-4 (K). Ovariectomized (OVX) and sham operated (sham) mice groups and the groups of ovariectomized mice given the treatments were: daily concomitant administration of R and K throughout (2RK), alternate-day administration throughout (R→K), 8 weeks of R followed by 8 weeks of K (R→K), K followed by R (K→R), or given R and then withdrawn (R→w/dr), K and then withdrawn (K→w/dr), concomitant administration and then withdrawn (RK→w/dr). Mice were terminated after 8- or 16-week treatment. Femurs were subjected to analyses of bone mineral density (BMD) and structure by peripheral quantitative computed tomography (pQCT) and micro focus X-ray tube computed tomography (μCT). Quality of bone was also examined by confocal laser Raman spectroscopic measurements. The serum levels of metabolic markers were measured at 0 (before the treatments), 8, 12, and 16 weeks. Three point bending and compression tests were carried out to assess the mechanical properties of femoral diaphyses and distal metaphyses.

At the 8th week mid point, the trend of improved bone strength was suggested in groups treated with risedronate or MK-4 alone. Quality of bone, judged from the increased matrix-to-mineral ratio and posttranslational processing of collagenous protein, was significantly improved by treating mice with MK-4 alone. Concomitant administration, RK, did not provide equivalent parameters. At the 16th week, cortical BMD in K→R and R→w/dr group femoral diaphyses showed significantly higher values than in the control OVX group. Trabecular structure of K→R and K→w/dr femurs was significantly improved in comparison to the OVX controls. Mechanical tests showed significant improvement of femur strength only in K→R in both diaphyses and metaphyses. Risedronate treatment after MK-4 (K→R) seems to have prevented the CTx rise, which was observed after the withdrawal of MK-4 in K→w/dr.

In conclusion, sequential administration (K→R) was superior to other combinations in treating osteoporotic model mice. Prior treatment with vitamin K<sub>2</sub> significantly improved the efficacy of risedronate by improving the quality of bone matrix.

**Toremifene Inhibits Osteoclast Activity in vitro and Prevents Orchiectomy-induced Bone Resorption in Male Rats.** S. Raghoebari<sup>1</sup>, J. T. Dalton<sup>\*1</sup>, N. Doyle<sup>2</sup>, J. Jolette<sup>2</sup>, S. Y. Smith<sup>2</sup>, K. A. Veverka<sup>1</sup>, R. Narayanan<sup>\*1</sup>. <sup>1</sup>Preclinical Research, GTx, Inc, Memphis, TN, USA, <sup>2</sup>Preclinical Research, CRL, Montreal, QC, Canada.

Recent clinical trials in men undergoing androgen deprivation therapy (ADT) for prostate cancer indicated that toremifene (TOR), a SERM, elicited anti-osteoporotic effects. However, the mechanism for this bone protective effect of TOR in males undergoing ADT is not clear. Using orchiectomy-induced bone resorption in adult male rats and rat bone marrow cell culture in the presence of M-CSF and RANKL, we evaluated the mechanism of TOR action in bone. Estradiol was used in vitro for comparison. For the in vivo study, ~9 mo old male rats were randomly assigned to each of five groups containing 10 animals each: baseline, Sham, ORX control and ORX groups treated with TOR at 10 or 30 mg/kg/day. TOR was administered once daily by gavage for 12 months starting one day post-ORX. Biochemical markers of bone resorption (urinary DPD and serum CTx) were evaluated. Cortical (tibia diaphysis) and cancellous (L2 and tibia metaphysis) bone regions were analyzed by histomorphometry. In vitro, TOR at 10<sup>-6</sup> to 10<sup>-8</sup> M significantly inhibited osteoclastogenesis (p<0.05 vs. vehicle control) as evidenced by lower number of TRAP-positive multinucleated osteoclasts in bone marrow cultures. In rats, ORX-induced bone turnover as evidenced by increases in CTx and decreases in DPD was suppressed by treatment with TOR at 10 and 30 mg/kg/day. Histomorphometric evaluations of cancellous bone in Sham animals revealed decreases in fractional bone volume (BV/TV) relative to baseline, with further decreases in ORX rats, primarily due to decreases in trabecular number (Tr.N) and separation (Tr.S). These structural changes were associated with marked increases in bone formation rates (BFR) and mineralizing surfaces (MS/BS) consistent with accelerated bone turnover. TOR at 10 and 30 mg/kg consistently reduced Oc.S/BS at both tested sites, demonstrating its bone antiresorptive effects. At the tibia diaphysis, ORX animals showed decreased cortical bone area (Ct.Ar) and width (Ct.Wi) compared to aged Sham males principally due to an increased medullary cavity area (Me.Ar). ORX increased endocortical labeled surface (Ec.L.Pm/Ec.Pm) and BFR but reduced the periosteal labeled surface (Ps.L.Pm/Ps.Pm) significantly (p<0.05). TOR treatment canceled the ORX-induced effects on the periosteal and endocortical surfaces, consistent with reduced bone turnover. In summary, toremifene inhibited

osteoclastogenesis in vitro and showed antiresorptive activity in the bones of orchidectomized male rats, providing a mechanistic basis for its bone sparing effects in men on ADT.

**Raloxifene Ameliorates Detrimental Collagen Cross-link Formation in Bone from an Ovariectomized Rabbits With or Without Hyperhomocysteinemia.** M. Saito, K. Marumo\*, Y. Kida\*, C. Ushiku\*, S. Soshi\*, A. Shinohara\*. Orthopaedic Surgery, Jikei University School of Medicine, Tokyo, Japan.

Collagen cross-links are a determinant of bone quality. Cross-links involve two different types; enzymatic divalent immature and trivalent mature cross-links and glycation induced crosslinking (AGEs; pentosidine). We first reported in a human study that hyperhomocysteinemia (HHCY) in patients with an osteoporotic fracture might lead to detrimental crosslinking in bone. Interestingly, homocysteine interferes with normal collagen cross-link formation. Raloxifene (RLX) is thought to ameliorate poor bone quality in osteoporosis. However, there is presently no evidence to demonstrate whether RLX alters the collagen cross-link formation in estrogen-deficiency either with or without HHCY. In order to clarify this issue, we established a rabbit model in which collagen abnormalities were induced by an ovariectomy (OVX) with or without a HHCY and investigated the effects of RLX on collagen cross-link formation in the bone. We divided mature New Zealand white rabbits into the following 6 groups (n=6-9 per group): 1) sham operation, 2) sham+ 1% methionine (Met) diet, 3) OVX only, 4) OVX+ RLX (10mg/kg/day) treated group, 5) OVX+ 1% Met diet, 6) OVX+1% Met diet +RLX. RLX or vehicle was administered by oral gavage for 16 weeks after an initial 16 weeks of OVX or OVX+ 1% Met diet. The femur, vertebra, urine, and blood were collected. We measured cross-link contents in bone by our established HPLC method. Homocysteine levels in the Met diet groups were significantly higher (p<0.001) than the normal diet groups. Met diet without OVX resulted in a significant reduction in enzymatic cross-link content (79-85%, p<0.01) and a marked increase in the pentosidine content (120-179%, p<0.05). The OVX group without the Met diet showed a significant reduction in enzymatic cross-links to the same extent as the Met diet group, whereas the increase in pentosidine was weaker than Met diet group. The OVX+Met diet group showed the most severe detrimental cross-link patterns in the bone. Enzymatic cross-link formation in the OVX +RLX group and the OVX+Met diet +RLX group was restored to the same level as that of the sham group. Pentosidine content in the bone from the RLX treated groups with OVX showed no significant difference in comparison to the sham group. These findings suggest that 1) not only OVX, but also HHCY induced collagen cross-link abnormalities as well as human osteoporosis, as reported previously, and 2) RLX may increase enzymatic cross-links, while reducing either the glycation or oxidation induced pentosidine in both OVX and HHCY in the OVX rabbit model. In conclusion, RLX may improve bone quality via the alteration of enzymatic and glycation induced cross-links of collagen.

**Effect of Raloxifene and Alfacalcidol on Bone and Joint Pain Assessed by Fall of Skin Impedance (Electroalgometry).** T. Fujita<sup>1</sup>, M. Ohue<sup>2</sup>, Y. Fujii<sup>3</sup>, Y. Takagi<sup>3</sup>. <sup>1</sup>Medicine, Calcium Research Institute, Kishiwada, Japan, <sup>2</sup>Orthopedic Surgery, Katsuragi Hospital, Kishiwada, Japan, <sup>3</sup>Medicine, National Hospital System Hyogo Chuo Hospital, Sanda, Japan.

By measuring fall of skin impedance in response to exercise loading using an electroalga - meter (EAM), attempts were made to assess the effect of raloxifene and alfacalcidol on back or knee pain in postmenopausal patients with osteoporosis and/or osteoarthritis against alfacalcidol alone. Subjective pain was simultaneously recorded on a visual rating scale (VRS) dividing the distance between severe and unbearable pain at 100 and no pain at 0. Patients consulting Osteoporosis and Osteoarthritis Clinic of Katsuragi Hospital giving consent to the study after a full explanation on the purpose, method and possible risk of the study were asked to join Group EA to be given 60mg raloxifene and 1µg alfacalcidol or Group A to be given only 1µg alfacalcidol daily in chronological sequence. Exercise loading consisted of standing from a sitting position on a chair and knee bending mainly for knee loading (ST), walking about 30 steps on a flat corridor, climbing up about 10 stairs and down about 10 stairs for combined knee and spine loading (WK), and lying flat on an examining table and standing up again mainly for spine loading (LY). On average of all exercise loading, EAM showed significantly superior analgesic effect in EA than A (p=0.0239), but subjective assessment by VRS failed to do so (p=0.0739). On standing up, EA significantly more efficiently decreased pain (p=0.0017) than A according to VRS, but less clear difference was noted by EAM (p=0.0531). On WK, on the contrary, significant improvement in EA than A was noted by EAM (p=0.110), but only a tendency of improvement was noted on VRS. On climbing up stairs, only EAM revealed a significant improvement in Group EA, but not in A. On LY, only EAM detected significantly better analgesic effect of EA over A (p=0.048). Instead of the complete dependence of pain evaluation on subjective judgement, additional assessment by using an objective and quantitative electroalgometry apparently made it possible to analyze the mechanism of

pain sensation and action of analgesic agents in more detail. Electroalgometry appearing to be especially sensitive to measure pain on walking confirmed the analgesic effect of raloxifene with alfacalcidol on pain associated with osteoporosis and osteoarthritis.

## SA385

**Bazedoxifene (BZA) in Combination with Conjugated Estrogens (CE) Improves Bone Mass and Strength in the Ovariectomized (OVX) Rat.** E. Viassero<sup>1</sup>, S. Y. Smith<sup>1</sup>, L. Chouinard<sup>1</sup>, R. Samadfam<sup>1</sup>, C. H. Turner<sup>2</sup>, D. Minck<sup>3</sup>, B. Komm<sup>3</sup>. <sup>1</sup>Charles River Laboratories, Montreal, QC, Canada, <sup>2</sup>Indiana University, Indianapolis, IN, USA, <sup>3</sup>Wyeth Research, Collegeville, PA, USA.

Estrogen replacement therapy reduces accelerated bone remodelling, prevents bone loss and increases bone mass (particularly at cancellous bone sites), but is also associated with limiting uterotrophic effects. SERM's bind to estrogen receptors and are intended to prevent OVX-induced bone loss with a favourable influence on lipid profile and an absence of uterotrophic effects. In this study, the combined effects of co-administration of the SERM BZA with CE were evaluated. BZA/CE was administered by oral gavage to OVX Sprague-Dawley rats (24/group) once daily for 52 weeks. BZA was dosed at 0.1, 0.3, or 1.0 mg/kg/day and 2.5 mg/kg/day CE. Additional groups received BZA (0.3 mg/kg/day) or CE alone. OVX and Sham control groups received vehicle. Clinical serum chemistries were measured and bone turnover was monitored using biochemical markers and dynamic histomorphometry (animals were injected with two fluorochrome labels prior to bone harvesting). Bone densitometry (DXA and pQCT) was measured at the lumbar spine, femur and tibia. Histomorphometry was performed on the tibial diaphysis, L1 and L2 vertebra. Destructive testing was performed by 3-point bending of the femur diaphysis, shearing of the femur neck, and compression of lumbar vertebral specimens. Microscopic evaluations were performed on reproductive tissues. BZA/CE prevented OVX-induced increases in serum cholesterol and at 0.3/2.5 and 1.0/2.5 mg/kg/day partially inhibited the uterotrophic effect observed with CE alone. At all dose levels BZA/CE decreased bone turnover, completely prevented bone loss due to OVX and preserved bone mass and strength to at least Sham control levels. The high dose combination was associated with increases in biochemical markers of bone formation consistent with preservation of bone mass and slight increases in trabecular bone mass compared to Shams, suggesting this combination may have a superior effect on bone. There were trends that biomechanical competency was also improved at the lumbar spine and femur diaphysis. Overall, protective effects on bone were observed at both appendicular (tibia, femur) and axial (lumbar spine) sites in cancellous and cortical bone. No deleterious microscopic effects (bone quality and/or mineralization) were noted after daily treatment at doses up to BZA/CE 1.0/2.5 mg/kg/day. Combination treatment with BZA and CE may be an effective clinical treatment to prevent the effects of estrogen depletion and maintain bone mass and strength, while reducing serum lipid levels and the uterotrophic effects associated with estrogen treatment alone.

**IC162, a New Flavonoid, Preserves Bone Mass and Microarchitecture without Affecting Uterine Weight in Ovariectomized (OVX) Rats.** H. Xie\*, E. Liao\*. Institute of Endocrinology & Metabolism, The Second Xiangya Hospital of Central South University, Changsha, China.

Flavonoids including genistein have structural similarity to estrogen and have been reported to prevent bone loss caused by estrogen deficiency. IC162 is a new flavonoid compound isolated from vegetable sources. The present study was undertaken to investigate the effects of IC162 on bone and uterus under conditions of estrogen deficiency caused by ovariectomy (OVX). Female Sprague-Dawley rats were randomly divided into six groups: (I) sham operation + vehicle treatment (sham, n = 8); (II) OVX + vehicle treatment (V, n = 9); (III) OVX + 10 µg/kg/d 17β-estradiol treatment (E<sub>2</sub>, n = 8); (IV) OVX + 50mg/kg/d genistein treatment (Gen, n = 7); (V) OVX + 33 µg/kg/d IC162 treatment (TL, n = 10); (VI) OVX + 330 µg/kg/d IC162 treatment (TH, n = 8). At 8 months of age, the rats were either sham-operated or OVX, and then treated daily by intraperitoneal injection of vehicle, E<sub>2</sub>, genistein, or IC162. After 8 weeks of treatment, bone mineral density (BMD) and bone mineral content (BMC) of the vertebrae and femur were determined by Dual-energy X-ray absorptiometry (DEXA) and microcomputed tomography (µCT), and uterine weight was measured. Vehicle-treated OVX rats showed significant decreases in BMD, BMC, trabecular bone volume (Tb.BVf), trabecular thickness (Tb.Th) and cortical thickness (Cr.Th), and a significant increase in trabecular separation (Tb.Sp) compared to sham controls. These alterations were prevented by treatment of OVX rats with IC162 or E<sub>2</sub>. Genistein treatment had the weakest effect on improving these parameters. In addition, treatment with E<sub>2</sub> increased uterine weight to the value of sham controls in OVX rats. Treatment with genistein partially restored uterine weight in OVX rats. However, IC162 had no effect on uterine weight. We conclude that IC162 is efficacious for the preservation of bone mass but does not adversely affect uterine. Hence, our data strongly suggest that IC162 merits investigation as a potential therapeutic alternative to hormone replacement for osteoporosis.

**A Juvenile Murine Model of Ovariectomy-induced Trabecular and Cortical Osteoporosis.** L. Oste<sup>\*1</sup>, P. L. Salmon<sup>2</sup>, G. Kerckhofs<sup>\*3</sup>, L. Van Rompaey<sup>\*1</sup>, G. Dixon<sup>1</sup>. <sup>1</sup>Galapagos plc, Mechelen, Belgium, <sup>2</sup>SkyScan N.V., Kontich, Belgium, <sup>3</sup>Department of Metallurgy and Materials Engineering, Catholic University of Leuven, Leuven, Belgium.

**Introduction.** The ovariectomised mouse is routinely used as a model of osteoporosis, and commonly a mature adult age such as 4 months at surgery is used. Here we validate a murine ovariectomy model in young (6 week) growing mice in three strains, evaluating trabecular and cortical osteopenia by micro-computed tomography (micro-CT) bone morphometry.

**Materials and Methods.** Mice from the BALBc, C3H and C57BL/6 strains were either ovariectomised or sham operated at 6 weeks age, and femurs and tibias were harvested from them five weeks later. Micro-CT morphometric analysis of these bones was carried out on the distal femur and proximal tibia.

**Results.** All three strains showed substantial trabecular bone loss due to ovariectomy, slightly less in BALBc than in the C3H or C57BL/6 strains. Architectural parameters such as Trabecular pattern factor and fractal dimension showed profound structural change in the C3H and C57BL/6 strains but less change in BALBc. All three strains showed significant cortical osteopenia in the ovariectomised groups but with a different pattern between strains: while the cortex expanded in BALBc and C3H mice both periosteally and endosteally, in the C57BL/6 mice the periosteum contracted slightly. Cortical porosity showed a large ovariectomy-related increase in the BALBc and C3H strains but less change in C57BL/6.

**Conclusions.** Comparing the results to published data for the more mature mouse OVX model, OVX-related osteopenia in both trabecular and cortical bone is much more pronounced and significant in the younger mice. Older mouse bone morphometry is compromised by sparse trabecular bone. The growing mouse OVX model is justified by evidence that the changes seen are directly linked to withdrawal of estrogen, not an epiphenomenon of growth, and that, architecturally, these changes are generally similar in young and old age. Specific cortical OVX-related changes namely thinning, periosteal and endosteal expansion, endocortical trabecularisation and increased porosity, all associated with human perimenopausal femoral osteoporosis, were all seen in this growing mouse OVX model. Thus a growing mouse OVX model may be useful in studying effects of estrogen on bone throughout female adulthood.

**Skeletal Effects of a Fibroblast Growth Factor Agonist (F2A) in Ovariectomized Rats.** S. E. Franz<sup>\*1</sup>, M. K. Altman<sup>\*1</sup>, J. N. Stabley<sup>\*2</sup>, J. I. Aguirre<sup>1</sup>, M. E. Leal<sup>1</sup>, X. Lin<sup>\*3</sup>, P. O. Zamora<sup>\*3</sup>, T. J. Wronski<sup>1</sup>. <sup>1</sup>Physiological Sciences, University of Florida, Gainesville, FL, USA, <sup>2</sup>Applied Physiology and Kinesiology, University of Florida, Gainesville, FL, USA, <sup>3</sup>BioSurface Engineering Technologies, Inc, Rockville, MD, USA.

F2A is a synthetic peptide designed as an agonist for FGF2. It binds with high affinity to FGF receptor 1. A previous study showed that F2A, when applied locally, accelerated bone repair in a rabbit experimental model of tibial fractures. The purpose of the current study was to determine if systemically-administered F2A had skeletal effects in ovariectomized (OVX) rats and adverse side effects in non-skeletal tissues. Groups of sham-operated and OVX rats were maintained untreated for six weeks postovariectomy to allow for cancellous bone loss to occur in the latter animals. These groups (N=6) were then treated IP with vehicle or varying doses of F2A (0.3, 1.0, or 3.0 mg/kg) for 14 consecutive days. All rats were injected SC with declomycin and calcein 10 and 3 days prior to necropsy, respectively, in order to measure surface-referent, bone formation rate. At necropsy, hematocrit was found to be normal in all F2A-treated OVX rats. Histological samples of the liver, kidney, lung, and heart showed no significant abnormalities in these animals. The proximal tibial metaphyses of vehicle-treated OVX rats were characterized by cancellous osteopenia and increased bone turnover compared with vehicle-treated control rats. F2A did not increase tibial cancellous bone or osteoid volume at any dose tested, but OVX rats treated with 1 mg/kg did exhibit a significant 25% increase in osteoclast surface, an index for bone resorption. Normal fluorochrome labeling of bone occurred, which indicates that mineralization of osteoid was not impaired by F2A, as was previously observed in FGF2-treated OVX rats. Furthermore, all 3 doses of F2A induced a modest increase in cancellous bone formation rate. In contrast, periosteal bone formation in the tibial diaphysis was unaffected by F2A treatment. Based on our past studies with systemically-administered FGF2, the skeletal effects of F2A are more subtle than those of FGF2. F2A appears to induce a modest increase in both bone resorption and formation, but these skeletal processes are in balance so that cancellous bone mass is not increased in F2A-treated OVX rats. However, F2A did not induce the anemia and impaired bone mineralization seen with FGF2. The increase in cancellous bone formation and the lack of side effects is supportive of F2A for local bone fracture applications. Therefore, locally-delivered F2A appears to have a favorable pharmacokinetic profile, and yet has minimal side effects even if the peptide circulates systemically.

**The Use of Alternative Medicine for Treating Osteoporosis in Korea.** S. Han<sup>\*</sup>, J. Park<sup>\*</sup>, Y. Park<sup>\*</sup>, E. Bae<sup>\*</sup>, Y. Kim<sup>\*</sup>. Department of Family Medicine, Dong-A University Hospital, Pusan, Republic of Korea.

As life expectancy increases, the interest in osteoporosis is now an international trend. People in Korea are becoming more and more interested in osteoporosis, but many patients still prefer alternative medicines such as health foods than going to the hospital. The authors of this study aimed at surveying what the Korean patients select as a treatment for osteoporosis and wanted to offer the information to doctors.

The study took place in 3 cities of Korea from June, 2007 to December, 2007. The objectives were 1,524 randomly selected postmenopause women between the age of 50 and 70, and a questionnaire was performed.

74% of the objectives had bone mineral densitometry(BMD) tests. 36% of them were diagnosed with osteoporosis, and 64% had been diagnosed with osteopenia.

Among them, 83% had experienced one or more alternative medicine such as health foods. Safflower seed(64%), glucosamine(43%), calcium complex food(41%), chlorella(29%), vitamin D enriched food(25%), herb medicine(21%), ginseng steamed red(19%), plant estrogen(18%), soybean protein food(15%), acupuncture(6%), physical therapy such as cupping(5%) were included in the descending order.

The mean term they took the medications was 7.5 months.

The satisfaction on the alternative medicines was the highest in safflower seed (53%), and calcium complex food(42%), ginseng steamed red(41%), plant estrogen(35%), herb medicine(28%) followed. The satisfaction on alternative medicine itself (42%) was slightly higher than treatment from doctors(38%).

Many patients use alternative medicine for the treatment of osteoporosis, and they are highly satisfied with it. It would be very helpful if the doctors take interest in alternative medicine in treating osteoporosis and provide the patients with accurate information.

**Strontium Ranelate and Teriparatid (PTH 1-34) Enhance Fracture Healing in Osteoporotic Sprague Dawley - Rats.** B. Habermann<sup>\*1</sup>, G. Olender<sup>\*2</sup>, C. Eberhardt<sup>\*1</sup>, P. Augat<sup>\*2</sup>, A. A. Kurth<sup>\*1</sup>. <sup>1</sup>Orthopedic Hospital Frankfurt, Frankfurt, Germany, <sup>2</sup>Biomechanical Research Laboratory Murnau, Murnau, Germany.

Strontium ranelate and PTH 1-34 both result in an increased formation of bone when given to patients with osteoporosis. The purpose of the study was to elaborate if strontium ranelate and PTH 1-34 affect fracture healing when given the first time after an osteoporotic fracture and if they show any benefit in stability of the callus.

45 Sprague Dawley rats were ovariectomized at the age of 12 weeks. After 12 weeks, an osteopenia was diagnosed using Dual x-ray energy (DXA). Then, a standardized closed mid-diaphyseal fracture of the femur stabilized by a K-wire was produced. Afterwards, the animals were randomly put into three groups. The first group was substituted with 0.9% NaCl s.c., the second received 20 µg PTH 1-34 3x/week s.c. and the last group was treated with 600 mg strontium ranelate per kg body weight orally. After 28 days the bones were excised. The samples were subsequently scanned using MicroCT and, afterwards, torsion testing on the bones was done.

Strontium ranelate and PTH 1-34 both showed a significant increase in bone volume of the callus. (strontium ranelate +46.4%, p<0.05; PTH 1-34 +31.9%, p<0.05) though difference among them was not significant. This was also expressed in callus tissue volume (strontium ranelate +32.4%, p<0.05, PTH 1-34 +6%, p>0.05) while the increase under substitution with strontium was significantly higher (+ 24.8%, p<0.05). Torsion to bone fracture was significant higher under substitution with strontium ranelate while substitution with PTH 1-34 showed no difference.

Strontium ranelate and PTH 1-34 are both considered to be anabolic when given to patients with osteoporosis. Intermittent substitution of PTH 1-34 causes an increase in bone mineral density by an enhancement of osteoblast proliferation. Strontium ranelate does not only increase collagen synthesis and enhance the activity of osteoblasts by activating the calcium sensing receptor but also causes a downregulation of osteoclast activity by reducing preosteoclast differentiation. There is evidence that it also modifies the OPG/RANK(L) system.

Our results support that both strontium ranelate and PTH 1-34 may enhance fracture healing with an increase in callus tissue and bone volume. Callus in strontium substituted animals seems to be more resistant to torsion in comparison to sham-treated animals or animals being treated with PTH 1-34. Strontium had significant better results in torsion testing to the fracture point. This may be an effect from a higher callus volume and callus bone volume / tissue volume.

The animal experiments were approved by the Regierungspräsidium Darmstadt, Germany (F-119/04). This study was supported by the Elsbeth Bonhoff Stiftung.

**QUS, BMD and QCT in Women with Established Osteoporosis Treated with Teriparatide.** C. Cepollaro<sup>1</sup>, R. Monaco<sup>\*1</sup>, F. Cioppi<sup>\*1</sup>, L. Masi<sup>1</sup>, A. Falchetti<sup>1</sup>, G. Marcucci<sup>\*1</sup>, G. Caracchini<sup>\*2</sup>, G. D'Elia<sup>\*2</sup>, A. Tanini<sup>\*1</sup>, M. Brandi<sup>1</sup>.

<sup>1</sup>Department of Internal Medicine, University of Florence, Florence, Italy, <sup>2</sup>SOD Radiodiagnostica 1 CTO, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy.

This study was aimed to evaluate the effect of a 18-month teriparatide treatment on bone mineral density (BMD), quantitative ultrasound (QUS) and quantitative computed tomography (QCT) in women with established osteoporosis. We studied 31 women with established osteoporosis previously treated with antiresorptive drugs. They were given teriparatide (Forsteo, Eli Lilly) by subcutaneous injection, at the dose of 20 µg once daily, plus calcium and Vitamin D. In all subjects BMD at lumbar spine (BMD-LS), femoral neck (BMD-FN) and total femur BMD (BMD-T) was assessed at baseline, and every 6 months for 18 months. At the same time we also performed QUS at phalanges, by Bone Profiler-IGEA (amplitude dependent speed of sound: AD-SoS, ultrasound bone profile index: UBPI, bone transmission time: BTT). At baseline and after 18 months vertebral QCT scans of the first, second and third lumbar vertebrae were obtained using a specific software (OSTEO) to quantify the volumetric mineral density (vBMD) of somatic trabecular bone.

Teriparatide significantly ( $p<0.001$ ) increased BMD-LS; no significant variation in femoral subregions was found during the study period even though BMD-T tended to increase with the duration of PTH treatment and BMD-FN showed a reduction at month 6 with a progressively return to basal values. No significant changes were observed also for UBPI and AD-SoS, even if the last decreased at month 6 and thereafter it tended to increase. BTT significantly decreased at all time points ( $p<0.05$ ). Teriparatide induced an important and significant ( $p<0.001$ ) increase in vBMD at lumbar spine, as assessed by QCT. Our study shows that in women with established osteoporosis teriparatide determined the expected increase in BMD and vBMD at lumbar spine, with a less strong or negative effect at skeletal sites mainly composed by cortical bone. Further studies in larger population would be necessary to define the clinical role of QUS parameters in patients treated with teriparatide.

**Teriparatide Therapy in a Community Setting: Persistence and Use of Other Osteoporosis Medications in DANCE.** K. Taylor<sup>1</sup>, D. T. Gold<sup>2</sup>, P. Miller<sup>3</sup>, P. Chen<sup>\*1</sup>, M. Wong<sup>1</sup>, K. Krohn<sup>1</sup>. <sup>1</sup>Eli Lilly, Indianapolis, IN, USA, <sup>2</sup>Duke University, Durham, NC, USA, <sup>3</sup>Colorado Center for Bone Research, Lakewood, CO, USA.

The Direct Assessment of Non-vertebral Fracture in Community Experience (DANCE) observational study completed enrollment of 4106 patients on Dec 3 2007. Study investigators prescribe TPTD 20 µg/d for up to 24 months to patients, and follow them for another 24 months. As this cohort matures, more robust "real world" observations may be derived from patients' experience with teriparatide (TPTD) in a community setting. Poor persistence to osteoporosis therapy can reduce therapeutic benefit, despite the fracture risk reductions shown in clinical trials [Mayo Clin Proc 2006;81:1013-22]. Overall 1-yr persistence with osteoporosis therapies was found to be between 25-45% [Maturitas 2004;48:271-87, Arch Int Med 2005;165:2414-9]. This updated analysis from DANCE shows the persistency to therapy in 1637 patients with data on their first and last dose of TPTD (Figure). The percentage of patients remaining at 6, 12, 18, and 24 months was 69%, 55%, 45%, and 23%, respectively.

Of the 256 patients (16%) who reported concomitant use of  $\geq 1$  other bone-active agent during the TPTD treatment phase, 214 (84%) had initiated these other agents prior to starting TPTD. Estrogen was most often used ( $n=111$ ), followed by alendronate ( $n=57$ ), raloxifene ( $n=45$ ), risendronate ( $n=32$ ), and calcitonin ( $n=25$ ). After cessation of TPTD therapy, 747 patients (45.6%) reported using  $\geq 1$  other bone-active agent in the follow-up phase, and of these patients, 220 reported having used  $\geq 1$  other bone-active agent concomitantly during the TPTD treatment phase. Bisphosphonates, such as alendronate ( $n=244$ ), ibandronate ( $n=226$ ), risendronate ( $n=152$ ), and zoledronic acid ( $n=23$ ), were most commonly used in the follow-up phase. Estrogen ( $n=104$ ) and raloxifene ( $n=76$ ) were also used. In summary, the present analysis shows that 1) about half of patients who started TPTD persist with therapy at 1 year; 2) patients who took other bone-active agents concomitantly with TPTD had initiated use of these agents prior to starting TPTD; and 3) about half of patients take other bone-active agents after stopping TPTD therapy. Continued analysis of the DANCE cohort may provide insight on factors affecting persistence to TPTD therapy, on how TPTD is used among a spectrum of osteoporosis medications, and offer new approaches to optimize TPTD use in the community.

**Repetitive Rapid Delivery of Pharmacologically-Active hPTH 1-34 Across Human Skin Without Injection.** S. Ish Shalom<sup>1</sup>, Y. Kenan<sup>\*2</sup>, T. Matsumoto<sup>\*3</sup>, R. Neer<sup>4</sup>. <sup>1</sup>Metabolic Bone Diseases Unit, Rambam Medical Center, Haifa, Israel, <sup>2</sup>TransPharma Medical Ltd, Lod, Israel, <sup>3</sup>Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medical Sciences, Tokushima, Japan, <sup>4</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

TransPharma has developed a system for transdermal delivery of hPTH 1-34 (TD) to alleviate the discomfort of injections (SC) and improve patient acceptance of and compliance with hPTH 1-34 therapy. The system utilizes RF ablation to create MicroChannels in the upper skin, allowing rapid diffusion of peptide from a subsequently-applied drug patch into the inner skin and systemic circulation. We compared the safety, tolerability, pharmacokinetics (PK), and type I procollagen N-terminal propeptide (PINP) based pharmacodynamic (PD) profile of TD vs. SC hPTH 1-34 administered once-daily for 7 days. 48 healthy post-menopausal women, age  $65 \pm 4$  years, were randomly allocated in 3 blocks of 16 to a daily TD dose of 50, 70, or 90 µg or a daily SC dose of 20 µg (FORTEO®). On days 1 and 7 we measured fasting serum PINP 1 hour before dosing (after which participants ate breakfast), and measured serum hPTH 1-34 15 minutes before and 0.25, 0.5, 1, 1.5, 2, 2.5, 3, 4, 6, 8, 10, 14 and 24 hours after TD or SC administration of the peptide. To minimize assay-related bias, all sera for a woman were measured in the same hPTH 1-34 or PINP assay. In each treatment group the mean PK profile on day 7 (presented in the Table below) did not differ significantly from that on day 1, indicating reproducible peptide delivery and no peptide accumulation.

Treatment	Cmax (pg/ml) mean $\pm$ SD	Tmax (h) mean $\pm$ SD (range)	AUC <sub>0-1</sub> (hr*pg/ml) mean $\pm$ SD	PINP absolute change from baseline (µg/L) (% Change) mean $\pm$ SD
TD 50 µg (n = 12)	53 $\pm$ 16	2.0 $\pm$ 0.5 (1.5-2.5)	135 $\pm$ 48	13 $\pm$ 7 (28 $\pm$ 15)
TD 70 µg (n = 12)	68 $\pm$ 28	2.3 $\pm$ 0.3 (1.5-2.5)	162 $\pm$ 73	13 $\pm$ 9 (26 $\pm$ 15)
TD 90 µg (n = 12)	90 $\pm$ 37	2.5 $\pm$ 0.6 (1.5-4.0)	250 $\pm$ 116	12 $\pm$ 9 (22 $\pm$ 15)
SC 20 µg (n = 10-12)	72 $\pm$ 21	0.6 $\pm$ 0.4 (0.25-1.0)	117 $\pm$ 45	8 $\pm$ 17 (20 $\pm$ 29)

Cmax occurred approximately 2 hours after TD application and 0.6 h after SC injection. Serum hPTH 1-34 was quantifiable 1.5-3.5 hours longer after TD dosing than after 20µg SC dosing. The bioavailability of TD hPTH 1-34, calculated from the area under the time-concentration curves, was ~40% of SC injection. Following 6 days of hPTH 1-34 treatment, serum PINP increased significantly in each treatment group by paired t-test ( $p^* < 0.0001 - 0.05$ ). Transdermal therapy was well-tolerated; application sites showed only very minor and transient erythema and edema, and no infections. These safety, tolerability, PK and early PD data demonstrate that TD hPTH 1-34 is a promising alternative to the currently-marketed injections.

\* P values are based on percent changes

**A Phase 1, Randomized, Double-Blind, Placebo Controlled Trial of the PK/PD Effect and Safety of ZT-031, a hPTH Analog, in Healthy Elderly Women.** C. L. Barclay\*, R. Anderson\*, D. Krause, B. MacDonald. Zelos Therapeutics, Inc, West Conshohocken, PA, USA.

Parathyroid hormone (PTH) mediates its anabolic effect on bone via transient stimulation of PTH receptors (PTHr) on osteoblasts, leading to adenyl cyclase (AC) activation, cyclic AMP production and increased bone formation. AC activation in renal tubular cells results in renal Ca retention and increased PO<sub>4</sub> excretion. ZT-031 is a novel, 31 a cyclic analog of human PTH, currently in late clinical development for the treatment of post-menopausal osteoporosis.

The purpose of this study was to evaluate the safety, PK, and PD effect of ZT-031 in healthy elderly women.

20 healthy adult women  $\geq 65$  years of age (mean 69 y) were randomized to 7 days of treatment with 20, 30, or 40  $\mu$ g of ZT-031 or placebo, given by daily SC injection. PD markers included urine cAMP on Days (D) 1 and 7 pre- and 2h post-dose. PK parameters were evaluated using a validated ELISA. Safety parameters included adverse events (AEs), EKGs and serum Ca as well as urinary Ca and PO<sub>4</sub>.

Urine cAMP increased in dose-proportional fashion 2h after dosing on D1 and 7; increases are shown in the Table.

Dose	20 $\mu$ g n=7	30 $\mu$ g n=4	40 $\mu$ g n=6	Placebo n=3
Day 1 Urine cAMP <sup>1,2</sup>	542.7	728.4	1941.3	-15.2
Day 7 Urine cAMP <sup>1,2</sup>	394.3	1026.0	1375.8	28.7

<sup>1</sup>  $\mu$ mol/mmol Cr<sup>2</sup>p < 0.01

By 8 h post-dose, mean urine cAMP returned to baseline (BL) for all groups. Subsequent to the increase in urine cAMP a sequence of reduced urinary Ca and increased urinary PO<sub>4</sub> excretion followed by the converse changes in serum were observed. All changes in Ca and PO<sub>4</sub> profile returned to BL by 8-12 h post dose. PK parameters were similar on Days 1 and 7. C<sub>max</sub> and AUC(0-4h) were approximately dose proportional whereas T<sub>1/2</sub> (average 1.12h for all time points/doses), clearance and volume of distribution were dose-independent. A total of 72 AEs was reported by 17 subjects reported; none was severe or serious. The frequency of AEs did not vary by dose. Headache was the most common AE. Three Ca values > ULN (2.55 mmol/L) were observed, 1 in a 30  $\mu$ g subject and 2 in 40  $\mu$ g group. None was symptomatic, persistent or exceeded 2.61 mmol/L. No subject withdrew due to a treatment-emergent AE. A dose-dependent effect on resting heart rate was observed.

ZT-031 was well tolerated and exhibited dose proportional PD and PK responses in healthy elderly women. The effect on serum and urinary Ca/PO<sub>4</sub> profiles indicated that cAMP generation was secondary to activation of PTHr. The observed PK/PD profiles are appropriate for the intermittent stimulation of PTHr required for the anabolic effects of a PTH analog.

**Bone Mineral Density and Vertebral Fracture in Women with Breast Cancer and Antiaromatase Therapy.** E. Hoppe\*, B. Bouvard\*, C. Lassalle\*, R. Levasseur\*, M. Audran\*, D. Chappard\*, E. Legrand\*.

<sup>1</sup>Rheumatology and Inserm U 922, Centre Hospitalier Universitaire, Angers, France, <sup>2</sup>Inserm U 922, Centre Hospitalier Universitaire, Angers, France.

**Background:** Recovery from breast cancer in women has been achieved using chemotherapy, radiotherapy that can affect bone tissue. Furthermore, aromatase inhibitors therapy can accelerate bone loss and increase the fracture risk.

**Objectives:** Prospective and longitudinal study to evaluate bone mineral density and fractures in 515 women with treated breast cancer, before and after one year of aromatase inhibitors therapy.

**Methods:** Medical history, clinical risk factors for osteoporosis, non spine fractures, hip and spine Bone Mineral Density (BMD) were checked at baseline and after one year of antiaromatase therapy. Bone remodelling was evaluated by serum levels of C-telopeptide (CTX), osteocalcin and bone specific alkaline phosphatase (BSAP). Spinal X-ray films were analyzed independently by two trained investigators who were unaware of the patient status. Vertebral fracture was defined as a reduction of at least 20 percent in the anterior, middle or posterior vertebral height

**Results:** At baseline, 44.2% of women had a BMD T-score <-1 (on spine or hip) and 21.6% had a T-score <-2. Spinal radiographs revealed that 21.7% women had at least one vertebral fracture and 13 (6.8%) had 2 or more vertebral fracture. 13.7% of women reported non spine fractures. Logistic regression analysis showed that age (+5 years : OR=1.46, CI 95% 1.15-1.85), weight (-1 kg : OR =1.14, CI 95% 1.08-1.19), self-reported non spine fracture (OR = 4.17, CI 95% 1.80-9.63) and radiographic vertebral fractures (OR = 6.12, CI 95% 2.42-15.71) were associated with the presence of low BMD (T-score <-2 on spine or hip). Women with osteoporosis (25% of the initial cohort) received risendronate (35 mg weekly) and were investigated after one year of antiaromatase therapy : the mean BMD was increased by 1.77% on spine and by 0.78% on hip. We observed that 5.4% of these women have a new fracture but only 3.6% had a new vertebral fracture.

Women with normal BMD or osteopenia (75% of the initial cohort) didn't received any anti osteoporotic therapy and were investigated after one year: the mean BMD was reduced by

1.25% on spine and by 1.75% on hip. We observed that 5.8% of these women have a new fracture but only 1.5% had a new vertebral fracture.

**Conclusion:** These results strongly suggest that (1) 20 to 25% of women with treated breast cancer have low BMD or osteoporotic fractures before starting antiaromatase therapy (2) these women should benefit from clinical evaluation, BMD measurement and specific bone therapy, (3) in women with normal BMD or osteopenia, the rate of bone loss and the incidence of fractures (after one year) is quite similar that expected for postmenopausal women.

**Renal Safety Across a Wide Range of Dosing Regimens of Risedronate.** P. Miller<sup>1</sup>, R. Miday\*, A. Klemes\*, D. Ramsey\*. <sup>1</sup>Colorado Center for Bone Research, Lakewood, CO, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The incidence of both osteoporosis and renal insufficiency increases with age; thus, the effect of osteoporosis treatments on renal function is a clinical concern. This retrospective analysis was conducted to study the influence of multiple dosing regimens of risedronate on the renal function of postmenopausal women with osteoporosis or osteoarthritis.

Combined data from over 14,000 patients in the Risedronate phase III clinical trials of post-menopausal osteoporosis (PMO) and osteoarthritis were analyzed across multiple dose regimens; 5 and 15 mg daily, 35 and 50 mg weekly, 75 mg on 2 consecutive days monthly or 150 mg monthly, or placebo. Median treatment duration was 2 years. Subgroups with baseline renal function impairment or renal risk factors were also examined. Serum creatinine (SCr), estimated serum creatinine clearance (CrCl - Cockcroft-Gault) and renal function related adverse events (AEs) were analyzed.

94% of subjects were female, with a mean age of 70 years. The frequency distributions of changes in CrCl from baseline to endpoint value were not different between placebo and risedronate groups or between different dose/regimen groups, for each of the populations examined. Also, there was a similar frequency of patients who developed abnormal SCr or who developed SCr increases > 0.5 mg/ml from baseline, within each of the active treatment group and placebo comparisons (Table 1). Patients with baseline renal impairment (CrCl  $\leq$  50 ml/min) or baseline renal risk factors (diabetes mellitus, hypertension, ACE inhibitor or NSAID treatment) also did not show treatment group differences. Renal function-related adverse events were not different across groups, all  $\leq$  2%. While risedronate serum C<sub>max</sub> levels for 75 mg and 150 mg are approximately 11 and 29-fold greater than for 5 mg, there is no indication of adverse renal effects from these higher doses.

Risedronate demonstrates a favorable renal safety profile across a wide range of doses, regimens and patient populations with no evidence of effect on renal function parameters.

Table 1 Renal Safety Endpoints in Risedronate Post-Menopausal Osteoporosis Studies						
Parameter	5 mg Daily		75 mg Two Consecutive Days (Monthly)		150 mg Once a Month	
	Placebo %	5 mg Daily %	5 mg Daily %	75 mg/2cd %	5 mg Daily %	150 mg Monthly %
Serum Cr - Treatment Emergent Abnormal <sup>1</sup>	8.0	8.4	1.7	1.4	1.7	0.8
Serum Cr - 7 from Baseline > 0.5 mg/dL at Endpoint	0.7	0.7	0.3	0.2	0.0	0.3
Renal Function Adverse Events	1.9	1.5	1.1	0.6	0.5	0.5
	Mean(SD)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)	Mean (SD)
CrCl - 7 from Baseline to Endpoint	-0.62 (10.14)	-0.42 (9.56)	-3.62 (11.13)	-4.12 (10.94)	-1.14 (7.59)	-1.45 (8.06)
CrCl - 7 from Baseline to Endpoint (Baseline CRCL $\geq$ 50)	0.95 (6.36)	0.85 (6.40)	0.97 (8.51)	-0.26 (5.44)	-0.35 (4.79)	0.73 (5.96)

<sup>1</sup>Treatment emergent abnormal serum creatinine are patients with a normal baseline creatinine and 1 or more abnormal values after dosing. Number of patients varies depending on analysis but numbers of patients treated are the following: 5 mg Daily Studies (4878 placebo and 4846 5 mg daily), Two Consecutive Days (613 5 mg daily and 616 75 mg/2CD), and Once a Month (642 5 mg daily and 650 150 mg monthly).

## SA404

**Fracture Reduction During Two Years of Treatment with Risedronate or Alendronate, a Retrospective Cohort Study.** P. Delmas<sup>1</sup>, J. Lange<sup>2</sup>, S. Silverman<sup>3</sup>, N. Watts<sup>4</sup>, R. Lindsay<sup>5</sup>. <sup>1</sup>INSERM Research Unit 831, Lyon, France, <sup>2</sup>P&G Pharmaceuticals, Mason, OH, USA, <sup>3</sup>Cedars Sinai Medical Center, Los Angeles, CA, USA, <sup>4</sup>Bone Health and Osteoporosis Center, Cincinnati, OH, USA, <sup>5</sup>Helen Hayes Hospital, West Haverstraw, NY, USA.

In the published REAL cohort study,<sup>1</sup> we observed in the first year of treatment that patients using risedronate had a lower incidence of hip and nonvertebral fractures than patients using alendronate. We now have additional data that extends these observations into a second year of therapy. For the current analysis, we used patients with a single bisphosphonate prescription as a referent cohort.

The original study population of women over age 65 included new users of once-a-week dosing of risedronate (n = 12,215) or alendronate (n = 21,615) who initiated treatment between July 2002 and June 2004 within records of health services utilization. This population is followed through June 2006 or until no longer therapy adherent. As a referent cohort, we selected patients who filled only a single prescription of alendronate or risedronate during the observation period (n = 5,390). Proportional hazard modeling was used to compare the incidence of hip and nonvertebral fractures between cohorts, adjusting for potential differences in baseline fracture risk.

Based on history of clinical fractures and age upon study entry, the cohort at highest baseline fracture risk was the referent cohort, followed by the risedronate cohort, then the alendronate cohort. At the end of two years of observation for the referent cohort, the cumulative incidence of hip fractures was 1.9% and of nonvertebral fractures was 6.3%. Compared to the referent cohort, patients on risedronate had an approximately 40% lower incidence of hip fractures at 6, 12, 18, and 24 months of therapy. For patients on alendronate, a similar lower incidence of hip fractures was observed at 18 and 24 months of therapy but not at 6 or 12 months. Results for the hip and nonvertebral fracture outcomes were similar.

In summary, the results of this observational study indicate 1) the real-world effectiveness of risedronate and alendronate through two years of treatment are consistent with results of randomized controlled trials; 2) the reduction of hip and nonvertebral fractures, relative to the referent cohort, occurs earlier after initiation of therapy with risedronate than with alendronate. Given the low adherence to therapy for chronic medications, the consequence of our observation may impact the cost/effectiveness perspective of each bisphosphonate.<sup>1</sup> Silverman et al. Osteoporosis Int. 18:25-34 (2007)

**Homocystinuria Associated Bone Disease: Effect of Long Term Bisphosphonate Treatment.** M. D'Amours<sup>\*</sup>, A. Răkel<sup>\*</sup>, L. G. Ste-Marie. Endocrinology, Hôpital Saint-Luc, CHUM, University of Montreal, Montreal, QC, Canada.

Homocystinuria is an autosomal recessive disease classically associated with dislocation of the eye lens, mental retardation, hyperhomocysteinemia and skeleton abnormalities such as deformities, vertebral fractures and osteoporosis. The mainstream of treatment consists of dietary amino acids and vitamin supplementation. There is little data in the literature about the effects of bone active agents such as bisphosphonates in this population. Here we report the cases of 2 brothers diagnosed with homocystinuria in childhood (one at age 5 years and the other at 4 months) who were addressed initially for decreased bone density. They were treated with betain, folic acid, vitamin B12 and calcium. Both had a normal development and growth without fractures or deformities except for a moderate scoliosis in the eldest. The biochemical work-up did not show any abnormality of the phosphocalcic metabolism including PTH and 25(OH)vitaminD. Both presented a slightly elevated level of urinary hydroxyproline suggesting increased bone resorption. Their initial bone mineral density (BMD) showed osteopenia affecting lumbar spine (L2-L4: 0.850 and 0.931 g/cm<sup>2</sup> respectively) and femoral neck (0.965 and 1.055g/cm<sup>2</sup> respectively). Alendronate (ALN) was introduced in 1996 in both patients (then aged 23 and 18 year old). Treatment was continued for the next 10 years without any incident fracture. Sequential lumbar spine BMD was unreliable in the eldest because of progressive scoliosis whereas it increased by 18% in the youngest (1.128 g/cm<sup>2</sup> in 2007). Femoral neck BMD remained stable (2007 values: 0.961 g/cm<sup>2</sup> and 1.047 g/cm<sup>2</sup>, respectively). Bone turnover markers, serum osteocalcin (14 and 12ng/ml respectively) and serum C-telopeptide (0.122 and 0.086 ng/ml respectively) were suppressed in these young men. Long term bisphosphonate treatment was associated with the prevention of bone loss and osteoporotic fractures in two patients with homocystinuria. The addition of bisphosphonates to the therapeutic armamentarium for homocystinuria should be considered for fracture prevention.

**Patients Desire of Administration Form and Dose Interval in Bisphosphonate Therapy of Osteoporosis.** C. Günther, A. Kapner<sup>\*</sup>, C. Spanier<sup>\*</sup>, L. Erich<sup>\*</sup>, V. Schäfer<sup>\*</sup>. Fachklinik Johannesbad, Bad Füssing, Germany.

**Introduction:** A drug can only work, if you take it in. This platitude is worth on oral bisphosphonate too and the compliance is according to Hadji@al (ECCEO 2005) in daily taken alendronate 27.8% and in weekly taken alendronate 46.5% after 1 year. This cannot satisfy. Before the back ground of a futural available yearly zoledronate intravenous infusion (meanwhile registered as "Aclasta") we were therefore interested which administration form patients would prefer.

**Material and methods:** From 19.10.2005 to 05.07.2007 we asked 100 patients with osteoporosis (t-score < -2.5), 91 women (Ø 70,7 years old) and 9 men (Ø 69,5 years old), if they would prefer a daily, a weekly or monthly oral bisphosphonate. After this we began the treatment with the wished oral bisphosphonate under basic therapy with calcium and vitamin D. In addition to the first question we asked the patients if they would prefer a yearly intravenous bisphosphonate infusion if it would be available.

**Results:** From the 100 patients nobody wanted a daily oral bisphosphonate, 11 patients wanted a weekly drug and 89 patients a monthly. According to the additional question 57 % of the patients would prefer a yearly intravenous zoledronate infusion in comparison to the 43% which would prefer an oral administration.

**Discussion:** The results show that the majority of patients (89%) prefer the monthly intake of an oral bisphosphonate and only 11% a weekly administration.

If the complete package "Actonel plus Calcium D" - meanwhile available in Germany - can change this relation will be investigated in the next weeks.

Theoretically in the patients who would prefer the yearly zoledronate infusion (57%) could be reached a compliance of 100 % in comparison to the 43% of patients with wished oral administration.

If the "infusion patients" - after registration of "Aclasta" in Germany - switched to infusion indeed will be presented later.

But both application forms - oral and intravenous - will be only effective if a sufficient substitution with vitamin D and calcium is guaranteed. Therefore "Actonel plus Calcium D" in Germany is a good innovation to improve the compliance of patients with osteoporosis.

**Does Alendronate Use Prevent Kyphosis Progression in Older Women?** D. M. Kado<sup>1</sup>, M. H. Huang<sup>\*2</sup>, E. Barrett-Connor<sup>3</sup>, K. Ensrud<sup>4</sup>, A. La Croix<sup>\*5</sup>, S. R. Cummings<sup>6</sup>. <sup>1</sup>Orthopaedic Surgery, University of California, Los Angeles, Los Angeles, CA, USA, <sup>2</sup>University of California, Los Angeles, Los Angeles, CA, USA, <sup>3</sup>University of California, San Diego, La Jolla, CA, USA, <sup>4</sup>University of Minnesota, Minneapolis, MN, USA, <sup>5</sup>University of Washington, Seattle, WA, USA, <sup>6</sup>California Pacific Medical Center, San Francisco, CA, USA.

Hyperkyphosis, or increased thoracic curvature, is commonly observed in older persons. While it is well established that alendronate use decreases the incidence of vertebral fractures and prevents height loss, it is not known whether alendronate use reduces progression of kyphosis. Given that many older women are concerned about the cosmetic deformity known commonly as the dowager's hump, it is of interest to know whether alendronate actually helps mitigate the progression of age-related kyphosis, especially since a substantial number of the most severely affected women have no evidence of underlying vertebral fractures. Therefore, we compared the effects of alendronate to placebo on the progression of kyphosis in 6,459 women aged 55-81 with low bone mass (femoral neck T-score < 0.68 g/cm<sup>2</sup>) using data from the Fracture Intervention Trial (FIT), a randomized blinded trial of alendronate. The kyphosis angle was measured using the Debrunner kyphometer at baseline and closeout in 98% of the participants after an average of 4.2 years.

There were no significant baseline differences between the alendronate and placebo groups in terms of demographic, physical measures, health status, bone mineral density, prevalent vertebral fractures, or kyphosis angle. The mean kyphosis angle was 47.6 degrees (SD = 11.9) and the mean change was an increase of 3.9 (SD = 9.3). For women who did not have baseline vertebral fracture, the average change of kyphosis was 3.9 degrees for both treatment and placebo groups (mean difference = -0.20 degrees, 95% CI: -0.69 - 0.28; p = 0.42). For women who had a baseline vertebral fracture, average changes of kyphosis for the treatment and placebo groups were 4.1 and 4.3 degrees, respectively (mean difference = -0.54, 95% CI: -1.36 - 0.28; p = 0.20). Our data do not demonstrate that kyphosis progression is slowed by alendronate treatment; however, 5% of the participants had changes in kyphosis of greater magnitude (>20 degrees) than would be expected over 4 years, given data from prospective cohort studies. As suggested by findings from prior observational studies, these results support the theory that age-related kyphosis is not primarily caused by underlying spinal osteoporosis, and that its progression may mainly be due to other factors besides vertebral fractures and low bone density.

**Bisphosphonate-associated Osteonecrosis of the Jaw cases in South Korea.** Y. Chung<sup>1</sup>, Y. Kwon<sup>2</sup>, J. Lee<sup>3</sup>, D. Kim<sup>4</sup>, S. Lee<sup>5</sup>, B. Lee<sup>6</sup>. <sup>1</sup>Endocrinology and Metabolism, Ajou University Hospital, Suwon, Republic of Korea, <sup>2</sup>Oral and Maxillofacial Surgery, Kyung Hee University Hospital, Seoul, Republic of Korea, <sup>3</sup>Dentistry, Ajou University Hospital, Suwon, Republic of Korea, <sup>4</sup>Nuclear Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea, <sup>5</sup>Biochemistry and Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>6</sup>Obstetrics and Gynecology, Inha University Hospital, Incheon, Republic of Korea.

**Introduction:** Bisphosphonate-associated osteonecrosis of the jaw (ONJ) is a rare but serious side effect of bisphosphonate therapy. Case reports of ONJ had been reported in many Western countries but relatively few from Asian countries. Recently, we had experienced five cases of ONJ in South Korea. Three of them were related with osteoporosis and two of them were associated with malignancy.

**Case 1:** A 74-year-old woman had been treated with weekly oral alendronate for osteoporosis for 5 years. ONJ of the left mandible precipitated by teeth (1<sup>st</sup> and 2<sup>nd</sup> molars) extraction. The patient had multiple systemic risk factors including old age and diabetes mellitus.

**Case 2:** A 72-year-old woman had been treated with weekly oral alendronate for osteoporosis for 3 years. ONJ of the right mandible and left maxilla area precipitated by teeth extraction. The patient had multiple systemic risk factors including old age, diabetes mellitus, rheumatoid arthritis, and glucocorticoid therapy.

**Case 3:** A 76-year-old woman had been treated with oral alendronate for osteoporosis for 7 years. ONJ of the right mandible precipitated by teeth (canine and premolar) extraction. The patient had multiple systemic risk factors including old age and diabetes mellitus.

**Case 4:** A 56-year-old man who had been diagnosed as Waldenström's macroglobulinemia has been treated with chemotherapeutic agents. Concomitantly, 45mg of pamidronate was injected monthly for 2 years. There was pain and pus drainage in left mandible 1<sup>st</sup> molar tooth area after spontaneous foliation. The patient had multiple systemic risk factors including chemotherapy and glucocorticoid for malignancy.

**Case 5:** A 50-year-old man had been diagnosed as multiple myeloma (non-secretory type). He has been treated with chemotherapeutic agents. Concomitantly, 45mg of pamidronate was injected monthly for 3 years. There was pain and pus drainage in right mandible 1<sup>st</sup> molar tooth area after extraction. The patient had multiple systemic risk factors including chemotherapy and glucocorticoid for malignancy.

**Conclusion:** Bisphosphonate-associated ONJ both in osteoporosis and malignancy might be an emerging issue in Asian countries as well as Western countries.

**SA414**

**Treatment Discontinuation Due to Gastrointestinal Adverse Events and Decreased Bone Mineral Density in Patients Switched from Branded Alendronate to Generic Alendronate.** D. Grima<sup>1</sup>, G. Ioannidis<sup>2</sup>, A. Papaioannou<sup>3</sup>, J. D. Adachi<sup>3</sup>. <sup>1</sup>Center for Osteoporosis and Arthritis Research and Education, Oakville, ON, Canada, <sup>2</sup>McMaster University, Hamilton, ON, Canada, <sup>3</sup>Medicine, St. Joseph's Healthcare - McMaster University, Hamilton, ON, Canada.

**Introduction:** Generic alendronate was introduced in Canada in July 2005 and within 2 months the conversion from brand to generic alendronate was almost complete. The generic has a different dissolution profile compared to brand alendronate which may impact gastrointestinal (GI) adverse events (AE).

**Methods:** A chart review study was conducted of postmenopausal women 50 years of age and older who were on brand alendronate prior to July 2005 from a single clinic that specialized in treating patients with osteoporosis. Data collected included GI AEs, bone mineral density (BMD), osteoporosis therapies used, discontinuation, reason for discontinuation and concomitant use of NSAIDs, PPIs and H2 blockers.

**Results:** A total of 199 women were identified as starting alendronate prior to the introduction of generic alendronate in July 2005 and having visits after this date. Of these 18 switched therapy before July 2005. Of the remaining 181, 53 patients (29%) discontinued alendronate after July 2005, due to GI AEs (27/181) and declining BMD (26/181).

**Discussion:** Generic alendronate may not be as well tolerated as brand alendronate and should not be considered equivalent in all individuals. This may have implications for treatment adherence and effectiveness, as well as the preferential reimbursement of generic alendronate.

**1-Year Analysis of Adherence with Bisphosphonate Treatments in Osteoporotic Patients: Monthly versus Weekly Formulation.** C. Roux<sup>\*1</sup>, E. Côté<sup>2</sup>, F. Mercier<sup>\*3</sup>, A. F. Gaudin<sup>2</sup>. <sup>1</sup>Department of Rheumatology, Paris Descartes University, Paris, France, <sup>2</sup>Economic & Health Outcomes, GlaxoSmithKline France, Marly le Roi, France, <sup>3</sup>StatProcess, Port-Mort, France.

**Purpose:** To assess medication adherence encompassing both compliance and persistence among women newly receiving monthly ibandronate or weekly bisphosphonates (BPs) in general practice.

**Method:** Patient data were retrospectively analysed from a computerized database representative of the French GPs prescriptions (1.6 million patients cover). Eligible women were all patients aged at least 45 years with first prescription of BPs (12 months of prior wash-out) from ibandronate availability in France to the end of the follow-up (Jan.2007-Jan.2008). Two cohorts were formed consisting of patients treated with monthly ibandronate and weekly BPs. Compliance was assessed by medication possession ratio (MPR) calculated by dividing the duration of all filled prescriptions by the follow-up period. Persistence was measured by the time to discontinuation therapy (permissible gap in refills were 45 days for monthly and 30 days for weekly regimen due to a two-week difference in dosing window). Treatment survival analyses were completed in both cohorts and analysed by log-rank test. A backward procedure was used to adjust for confounders.

**Results:** A total of 2,990 women were prescribed for the first time a bisphosphonate treatment: 1,001 received monthly ibandronate and 1,989 received weekly BPs. On average, women were significantly younger in the first cohort than in the second one (68.8 SD:10.3 and 70.4 SD:10.3 years old respectively; p<.001). The mean MPR was higher with monthly than with weekly dosing (84.5% vs 79.5%; p<.001). Kaplan-Meier curves showed that the proportion of women still persistent at 1-year with monthly ibandronate was 17 percentage points higher than those persisting on weekly BPs (47.5% vs 30.5%; p<.0001). This difference was also significant using similar permissible gaps in both cohorts (p<.0001). After adjustment for age, history of fracture, co-treatments, comorbidities and DXA scan, monthly users were 37% (hazard ratio = 0.630 SD:0.0613; P<.0001) less likely to discontinue therapy vs weekly users

**Conclusion:** These results demonstrate that monthly ibandronate improved adherence (i.e.

compliance and persistence) of osteoporotic patients compared with weekly bisphosphonates.

**Development, Reliability, and Validity of a New Preference Satisfaction Questionnaire (PSQ).** D. T. Gold, R. Horne<sup>\*</sup>, C. Hill<sup>\*</sup>, J. Borenstein<sup>\*</sup>, S. Varon<sup>\*</sup>, D. Macarios<sup>\*</sup>. Amgen Inc., Thousand Oaks, CA, USA.

We developed a questionnaire that assesses preference, satisfaction, and bother with a weekly pill versus a 6-monthly, subcutaneous injection for the treatment of postmenopausal osteoporosis.

Thirty-four questions were developed based on literature review and expert input. For nine items, subjects choose one of: the pill, the injection, or neither, with respect to preference, satisfaction, and bother. For 20 items, subjects specify the degree of bother or satisfaction on a 5 point Likert scale for treatment separately (no comparison between treatments). For the remaining five items, subjects select the degree of agreement/disagreement (5 point Likert) with one treatment being favorable over the other on various domains. Two separate, in-depth group interviews were conducted with subjects to evaluate item comprehension, questionnaire length, and identify additional constructs. The PSQ was revised after the first group interviews. Women currently taking or who had previously taken ( $\leq 3$  years) weekly bisphosphonate therapy for osteoporosis were eligible for interviews. Reliability and validity were assessed in a separate study, by incorporating the PSQ into a phase 3 randomized clinical study comparing 60 mg denosumab every 6 month

injection and 70 mg alendronate weekly pill.

Twenty-four subjects participated in initial cognitive interviews. Participants understood the PSQ and did not feel the questions were confusing or contained irrelevant information. 1100 subjects completed the PSQ as part of the clinical study. The construct validity of the PSQ items was investigated through inter-item correlations and correlations between the PSQ items and the EQ-5D. Inter-item correlations supported convergent validity and were for preference items (range 0.62 to 0.97), pill satisfaction items (range 0.23 to 0.90), and injection satisfaction items (range 0.13 to 0.91). Correlations with the EQ-5D were low (range 0.00 to 0.09) supporting divergent validity. The proportion of correlations achieving coefficients of 0.40 or greater among items within the same domain (150/178, 84.3%) is larger than the proportion of coefficients 0.40 or greater among items across domains (122/383, 31.9%), supporting both convergent and divergent validity. Items were retained based on strong inter-item correlations, strong factor loading, and feedback from cognitive interviews. At the scale level, the Cronbach's alpha reliability values for satisfaction, pill-bother and injection-bother were 0.90, 0.85, and 0.62, respectively. The PSQ was refined and formatted appropriately based on the cognitive interview. Results from a large phase 3 trial show good reliability and validity of the preliminary PSQ.

## SA418

**Patient Persistence with Weekly Bisphosphonates for Two Years after Initiation of Therapy: A Retrospective Cohort Study.** D. Gold<sup>1</sup>, N. Borisov<sup>2</sup>, R. Sheer<sup>2</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Therapy persistence is important for a patient to maximize efficacy benefit of medications. The study objective was to assess patient persistence with bisphosphonates during two years of therapy using two integrated administrative medical claims databases (Ingenix Lab/Rx<sup>TM</sup> and Medstat MarketScan<sup>®</sup>).

The study included women 50+ years with a new prescription fill for weekly bisphosphonate (risedronate 35mg or alendronate 35/70 mg) between January 1, 2003 and June 30, 2005. To qualify for the study, patients were required to be continuously enrolled for 6 months prior to and 24 months following the index date (the first script date). The 6-month history was used as a wash-out period and to assess baseline clinical characteristics. During follow-up patient's adherence was defined as a medical possession ratio (MPR) of at least 70%. Proportion of patients with MPR  $\geq$  70% was assessed at 6, 12, 18, and 24 months of therapy. Patients with MPR < 70%, were examined further to assess proportion of patients who reinitiated and remained on the therapy for at least 6 months at any time during follow up. Sensitivity analysis was conducted using different levels of MPR.

We identified 134,032 women with a new prescription for bisphosphonate therapy; mean age was 65 years (SD = 11). Just over half (51%) were persistent with therapy at 12 months, and 41% were still persistent at 24 months after initiation of therapy (Figure 1). Overall, 59% (79,630) of women had MPR < 70% during the follow-up, however, 20% (15,632) of them were persistent with therapy for at least another 6 months, and 8% (6,483) for at least 1 year at some point during follow up. The study demonstrated a decline in patient persistence to approximately 40% over 24 months of bisphosphonate therapy. Although about 60% of women were not persistent with therapy during the follow up, 20% (12% overall) reinitiated and stayed on therapy for at least 6 months. Thus, studies that include efficacy inputs (e.g., cost-effectiveness) should not ignore this cohort of re-starters that attains efficacy for at least another 6 months.

**Hip Structure Analysis for Raloxifene Treatment in Japanese Women with Osteoporosis.** J. Takada<sup>1</sup>, T. J. Beck<sup>2</sup>, T. Miki<sup>3</sup>, Y. Imanishi<sup>4</sup>, K. Nakatsuka<sup>5</sup>, H. Wada<sup>6</sup>, H. Naka<sup>3</sup>, K. Iba<sup>1</sup>, T. Yoshizaki<sup>7</sup>, T. Yamashita<sup>\*1</sup>. <sup>1</sup>Orthopedic Surgery, Sapporo Medical University, Sapporo, Japan, <sup>2</sup>Radiology, The Johns Hopkins University, Baltimore, MD, USA, <sup>3</sup>Geriatrics, Osaka City University, Osaka, Japan, <sup>4</sup>Metabolism, Endocrinology, and Molecular Medicine, Osaka City University, Osaka, Japan, <sup>5</sup>Inoue Hospital, Suita, Japan, <sup>6</sup>Wada Obstetrics and Gynecology Clinic, Asahikawa, Japan, <sup>7</sup>Kitago Orthopedic Clinic, Sapporo, Japan.

Hip Structure Analysis (HSA) was used to measure proximal femur geometry using conventional DXA scans. This study is the first analysis of HSA data in Japanese osteoporotic women treated with raloxifene (60 mg).

198 Japanese osteoporotic women aged between 47 and 83 years of age were treated with raloxifene for at least 6 months. DXA scans were acquired at baseline and every 6-12 months of follow-up. Geometry and BMD were measured at the narrowest point of the neck (NN), intertrochanteric region (IT), and proximal shaft (PS). Measurements included BMD, cortical thickness, cross-sectional area (CSA), section modulus, and buckling ratio. Section modulus is calculated cross-sectional moment of inertia divided by the maximum distance from the bone edge to the centroid ( $d_{max}$ ), and represents the index of bending and torsional strength. Buckling ratio is an index of cortical stability under compressive loads, and calculated as the ratio of  $d_{max}$  to the estimated mean cortical thickness.

The percent changes of BMD between baseline and year 1 at NN, IT, and PS regions were 0.47 %, 2.73 %, and 1.77 %, respectively. Section moduli were 2.53 %, 4.62 %, and 2.56 %, respectively. Buckling ratios were 0.47 %, -2.36 %, and -1.26 %, respectively. Section modulus has a positive relationship with BMD ( $r = 0.535 - 0.794$ ,  $p < 0.001$ ), cortical thickness ( $r = 0.561 - 0.785$ ,  $p < 0.001$ ), and CSA ( $r = 0.797 - 0.879$ ,  $p < 0.001$ ), but a negative relationship with buckling ratio ( $r = -0.361 - -0.648$ ,  $p < 0.001$ ) at three measured regions.

In conclusion, raloxifene treatment in Japanese women with osteoporosis increased BMD and improved structure strength in the femur.

**Arzoxifene in Postmenopausal Women with Normal or Low Bone Mass.** M. Bolognese<sup>1</sup>, J. Krege<sup>2</sup>, W. H. Utian<sup>\*3</sup>, R. Feldman<sup>4</sup>, S. Brody<sup>5</sup>, J. Alam<sup>\*2</sup>, D. L. Meats<sup>\*2</sup>, M. Lakshmanan<sup>2</sup>, L. Plouffe<sup>\*2</sup>, M. Omizo<sup>6</sup>. <sup>1</sup>Bethesda Health Research Center, Bethesda, MD, USA, <sup>2</sup>Lilly Research Laboratories, Indianapolis, IN, USA, <sup>3</sup>North American Menopause Society, Mayfield, OH, USA, <sup>4</sup>Miami Research Associates, Miami, FL, USA, <sup>5</sup>Illinois Bone and Joint Institute, Morton Grove, IL, USA, <sup>6</sup>Oregon Osteoporosis Center, Portland, OR, USA.

Arzoxifene is a benzothiophene estrogen agonist/antagonist that is more potent and bioavailable than raloxifene (Palkowitz et al. 1997). The study was a 24-month, Phase 3, double-blind, multicenter trial of postmenopausal women with femoral neck or lumbar spine bone mineral density (BMD) T-score between -2.5 and 0 randomized to arzoxifene 20 mg/day (N=172) or to placebo (N=159). Elemental calcium 500 mg/day was provided. Primary endpoints were lumbar spine and total hip BMD change and endometrial safety. At baseline, subjects were well matched (Caucasian 83%, mean age 55 years, mean body mass index 28 kg/m<sup>2</sup>, mean lumbar spine BMD 0.95 g/cm<sup>2</sup>, total hip BMD 0.89 g/cm<sup>2</sup>, median CTX 0.58 ng/L, and median PINP 52 mcg/L). At 6 months and at subsequent assessments, BMD increases at all skeletal sites were significant ( $p < 0.05$ ) in the arzoxifene vs placebo group. At 24 months, BMD increases in the arzoxifene vs placebo group were lumbar spine 3.2%, total hip 2.3%, femoral neck 2.1%, and trochanter 3.0% ( $p < 0.001$  for all comparisons). In the arzoxifene vs placebo group, Lumbar spine BMD (2.9%,  $p < 0.001$ ) and total hip BMD (2.2%,  $p < 0.001$ ) increased from baseline to last-observation-carried-forward endpoint. No significant subgroup treatment effect at any skeletal site was observed (years postmenopausal [ $\geq 2$  and  $< 5$  vs  $\geq 5$  years], age [ $< 55$  vs  $\geq 55$  years], and ethnicity [Caucasian vs non-Caucasian]; all  $p > 0.1$ ). At 3 months and at subsequent assessments, CTX and PINP displayed a significant decrease in the arzoxifene vs placebo group ( $p < 0.001$ ), and at 24 months, CTX was decreased by 30% ( $p < 0.001$ ) and PINP was decreased by 31% ( $p < 0.001$ ) in the arzoxifene vs placebo group. There were no significant between-group differences in the incidence of endometrial hyperplasia or cancer as assessed by serial endometrial biopsy (placebo 2, arzoxifene 0) or in endometrial thickness assessed by transvaginal ultrasound. Adverse event monitoring showed no significant increase in adverse events in the arzoxifene group except for the MedDRA term "vulvovaginal mycotic infection" (placebo 0%, arzoxifene 4%,  $p = 0.02$ ). New or worsening hot flashes were not significantly different between the groups (placebo 11%, arzoxifene 12%,  $p = 0.87$ ). There were no deaths or venous thromboembolic events. In postmenopausal women with normal to low bone mass, arzoxifene 20 mg/day demonstrated significant skeletal efficacy and was well tolerated.

**Disclosures:** M. Bolognese, Eli Lilly and Company 1.

## SA422

### Excess Medical Cost after a Fragility Fracture during 3-year Follow-up: Medicare Perspective. D. Brixner<sup>\*1</sup>, N. Borisov<sup>\*2</sup>, C. Purple<sup>2</sup>. <sup>1</sup>University of Utah, Utah, UT, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The medical costs of a fragility fracture are high in the year following the fracture (Ohsfeldt, 2006). This study estimated long-term fracture-related excess medical cost incurred during 3 years following fragility fracture compared to the cost incurred before the fracture.

Using medical claims database (Medstat MarketScan<sup>®</sup>), we conducted a retrospective cohort study among women 65+ years with a new Medicare claim for a closed non-traumatic fracture (index) at any of 7 anatomical sites: hip, leg, humerus, clavicle, pelvis, wrist, or spine between July 1, 2000 and June 30, 2005. Women with a claim for malignant neoplasm, radiation oncology or chemotherapy were excluded. The cohort was followed in 6-month increments over 3-year follow up period. To estimate fracture excess cost each post-fracture time increment was compared to the 6-month before the fracture. The excess cost was examined by place of service, fracture site, and subsequent fractures and reported in 2007 US dollars.

Out of 1,665,837 eligible women 65+ in the database during the study period, we identified 31,758 (3%) women with a Medicare claim for the specified fragility fractures. The total fracture excess medical cost was \$15,522 per patient during 3-year follow-up. Most (76%) of the excess cost was incurred during the first 6 months after the fracture (Figure 1) with costs in inpatient hospital and long term care contributing 55% and 28%, respectively. The excess prescription cost (\$590/patient) contributed 4% to the total excess cost. Nonvertebral fractures accounted for 85% of all fractures (vertebral and nonvertebral) and for 87% (\$13,469/patient) of the total excess cost. Wrist, hip, humerus, and clavicle fractures incurred excess medical costs continuously over each 6 month period of the follow-up; whereas leg, spine and pelvic fractures did not have excess costs beyond 24 months. About 14% (4,419) of women experienced a subsequent fracture during the follow-up with a total \$28,021 in excess medical cost per patient during the entire 3-year period after the index fracture.

Although most of the excess medical cost attributable to fragility fractures occurred in the first 6 months, the cost did not return to the baseline over the 3-year follow-up. This demonstrates the long-term nature of the fragility fracture costs.

Figure 1. Fracture-related excess medical cost

### Cost-Effectiveness of Risedronate vs. Generic Alendronate: 1-year Analysis among Women 50-64 Years Old. D. Grima<sup>\*1</sup>, N. Borisov<sup>2</sup>. <sup>1</sup>Cornerstone Research Group Inc, Burlington, ON, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Generic alendronate to treat osteoporosis was introduced to the US market in February, 2008, at price discounts of 10% to 44% of branded alendronate. A lower price of generic may introduce some savings to a managed care (MC) budget, however, to measure the true cost, therapy's copayments, rebate discounts, and efficacy should be considered. We used a model of postmenopausal osteoporosis to compare the budget impact of risedronate to generic alendronate at a range of generic wholesale acquisition cost (WAC).

The analysis included women 50-64 years, with T-scores <-2.5, under a 1-year time horizon from MC perspective. Fracture rates and costs were derived from US sources. Vertebral and nonvertebral risk reductions were 59% and 47%, respectively, for alendronate and 65% and 74%, respectively, for risedronate. The budget impact analysis included (1) Net Drug Cost (NDC), WAC adjusted for copayment and rebate discount, and, (2) Fracture-related Cost. The discounts on both products were varied independently from 0% to 90%. Annual WAC (before adjustment) and copayment were \$1,001.39 and \$390 for risedronate and \$947.50 and \$130 for branded alendronate, respectively.

The results found risedronate's NDC below generic's NDC at every level of WAC discount due to a higher annual copayment. The difference in copayment and fracture efficacy, resulted in price equivalence of risedronate with no discount to generic alendronate at 30% discount (Figure 1). The efficacy advantage of risedronate translated into cost savings or cost-effectiveness in a wide number of rebate discount scenarios (Figure 2)

. Given current generic alendronate price discount (10%, 19%, 44% of the branded WAC by Watson, Barr, and Teva, respectively), risedronate is more effective and cost-saving without any discounts compared to the Watson and Barr generics and more effective and cost-effective compared to the Teva generic. In case of generics reducing their prices further (up to 61% of branded WAC), risedronate would remain cost-effective at 15% rebate.

Disclosures: D. Grima, P&G 5.

## SA424

### Cost-Effectiveness of Risedronate versus Ibandronate at One Year: The Case of the United Kingdom. D. Farquhar<sup>\*</sup>, M. Pasquale<sup>\*</sup>. Procter & Gamble, Mason, OH, USA.

**Background/Objectives:** A recent observational cohort study directly comparing risedronate to ibandronate showed that women initiating treatment with risedronate had a lower incidence of hip fractures than women initiating treatment with ibandronate (Ringe, 2008). The incidence of hip fracture during the first year of therapy was 0.37% for risedronate and 0.81% for ibandronate (adjusted relative risk for risedronate vs. ibandronate: 0.51 (95% CI 0.30 - 0.87)). Despite limitations in interpretation of observational cohort studies due to the non-randomized nature of the study design, the objective of this analysis was to determine the cost-effectiveness of risedronate compared to ibandronate using these effectiveness data for the case of patients with confirmed osteoporosis in the United Kingdom (UK).

**Methods:** A validated Markov model of osteoporosis (Tosteson, 2001) was used to estimate the impact of therapy on hip fractures and costs. The model simulated a cohort of 1,000 women aged 65+, with BMD ≤ -2.5 and a previous fracture, treated with once-a-week dosing of risedronate or ibandronate over one year. UK data included annual drug cost (risedronate £264.60/year; ibandronate £257.40/year) and one-year fracture costs.

**Results:** In a cohort of 1,000 women treated with risedronate versus ibandronate, the model predicted 11 fewer fractures and a cost savings in total medical costs (drug plus fracture treatment) of £148,160. Risedronate dominates ibandronate in cost-effectiveness. Cost savings by age are specified in Table 1.

Extrapolating this result to the population of women aged 65+ in the UK initiating osteoporosis therapy suggests that risedronate would prevent an additional 1,340 hip fractures in the first 12 months of therapy and a cost savings of over £18 million, compared to ibandronate.

Table 1. Total Medical Cost Savings with Risedronate vs. Ibandronate (Cohort of 1,000)

Age Group	Number of Hip Fractures	Difference in Hip Fractures	Total Medical Cost (Drug + Fracture Treatment)	Cost Savings with Risedronate vs. Ibandronate
65-74	Ris: 4.47 Iban: 7.21	2.74	Ris: £177,848 Iban: 205,569	£27,721
75-84	Ris: 7.27 Iban: 11.73	4.46	Ris: £150,759 Iban: £218,551	£52,647
85+	Ris: 6.44 Iban: 10.39	3.95	Ris: £150,759 Iban: £218,551	£67,792
Total	Ris: 18.18 Iban: 29.33	11.15	Ris: £513,461 Iban: £661,621	£148,160

Disclosures: D. Farquhar, P&G 2.

## SA425

### Cost-Effectiveness of Risedronate versus Ibandronate at One Year: The Case of Germany. J. Brecht<sup>\*1</sup>, M. Pasquale<sup>2</sup>, W. Moehrke<sup>3</sup>, H. Kruse<sup>\*4</sup>. <sup>1</sup>InForMed – Outcomes Research and Health Economics, Ingolstadt, Germany, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA, <sup>3</sup>Procter & Gamble Pharmaceuticals, Schwalbach, Germany, <sup>4</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

**Background/Objectives:** Recently an observational cohort study directly comparing risedronate to ibandronate showed that women initiating treatment with risedronate had a lower incidence of hip fractures than women initiating treatment with ibandronate (Ringe, 2008). The incidence of hip fracture during the first year of therapy was 0.37% for risedronate and 0.81% for ibandronate. Statistically, relative to ibandronate patients, the adjusted relative rate of hip fracture for risedronate patients was 0.51 (95% CI 0.30 - 0.87). The objective of this analysis was to determine the cost-effectiveness of risedronate compared to ibandronate using these effectiveness data for the case of osteoporotic women in Germany.

**Methods:** A validated Markov model of osteoporosis (Tosteson, 2001) was used to estimate the impact of therapy on hip fractures and costs. The model simulated a cohort of 1,000 women aged 65+, with BMD $\leq$ -2.5 and a previous fracture, treated with once-a-week dosing of risedronate or ibandronate over one year. German data included annual drug cost (risedronate €468.32/year; ibandronate €571.20/year) and one-year hip fracture costs €23,895 (Brecht, 2003).

**Results:** In a cohort of 1,000 women aged 65+ treated with risedronate versus ibandronate, the model predicted 6 fewer hip fractures and a cost savings in total medical costs (drug plus fracture treatment) of €282,520, for patients treated with risedronate versus ibandronate (Table 1). Risedronate dominates ibandronate in cost-effectiveness. Extrapolating this result to the population of women aged 65+ in Germany initiating bisphosphonate therapy suggests that risedronate would prevent an additional 1,899 hip fractures in the first 12 months of therapy at a cost savings of over €89 million, compared to ibandronate.

**Conclusions:** Based on "real world" observational data, this analysis of post-menopausal women in Germany aged 65+ suggests risedronate provides more fractures averted at a lower total medical cost, resulting in substantial cost savings compared to treatment with ibandronate.

Table 1. Fracture and Medical Cost Savings with Risedronate vs. Ibandronate (Cohort of 1,000)

Age Group	Fractures Averted with Risedronate vs. Ibandronate	Total Medical Cost (Drug + Fracture Treatment Cost)	Cost Savings with Risedronate vs. Ibandronate
65-69	3	Ris. €593,247Iban. €774,583	€181,336
70-74	4	Ris. €628,297Iban. €831,512	€203,215
75-79	9	Ris. €808,609Iban. €1,123,067	€314,215
80+	10	Ris. €842,505Iban. €1,179,303	€336,798

**Modeled Cost-Effectiveness of Risedronate versus Ibandronate: The Case of Italy.** S. Maggi<sup>\*1</sup>, M. Pasquale<sup>2</sup>, O. Bouin<sup>\*3</sup>. <sup>1</sup>CNR Aging Branch, University of Padua, Padua, Italy, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA, <sup>3</sup>sanofi-aventis, Paris, France.

**OBJECTIVE:** Recently an observational cohort study directly comparing risedronate to ibandronate showed that women initiating treatment with risedronate had a lower incidence of hip fractures than women initiating treatment with ibandronate (Ringe, 2008). The incidence of hip fracture during the first year of therapy was 0.37% for risedronate and 0.81% for ibandronate (adjusted relative risk 0.51, CI: 0.30-0.87). The objective of this analysis was to determine the cost-effectiveness of risedronate compared to ibandronate using these effectiveness data for the case of patients with confirmed osteoporosis in Italy.

**MATERIAL AND METHODS:** A validated Markov model of osteoporosis (Tosteson, 2001) was used to estimate the impact of therapy on hip fractures and costs from the Italian National Health System (NHS) perspective. The analysis included 75 year-old women treated with risedronate or ibandronate for 1 year. The model further simulated downstream costs for an additional 5 years. Country-specific data included general population hip fracture incidence rates and mortality, hip fracture costs (€11,571 in the first year, and €1,320 in subsequent years per fracture, Piscitelli, 2006), and annual drug costs (risedronate €36.34 per box and ibandronate €43.7 per box). Costs and outcomes were discounted at 3%. A differential relative risk reduction of 49% was applied to risedronate vs. ibandronate (Ringe, 2008).

**RESULTS:** In a cohort of 1,000 post-menopausal osteoporotic women with 1 year of treatment the model predicted 8 fewer hip fractures, 7 more QALYs, and a cost savings of €187,407 for risedronate compared to ibandronate. If extrapolated to a population of Italian osteoporotic women aged 70-79, this analysis suggests that 648 additional hip fractures can be avoided and over €14.6 million saved by treating patients with risedronate rather than ibandronate. Sensitivity analysis on the cost of hip fracture confirmed dominance of risedronate versus ibandronate in this patient population.

**CONCLUSIONS:** Based on Italian epidemiological data and "real world" observational effectiveness data, this analysis of post-menopausal women in Italy suggests risedronate provides more fractures averted at a lower total medical cost, resulting in substantial cost savings compared to treatment with ibandronate.

## SA428

**Physician Practices in Bone Density Testing among Medicare Patients.** J. M. Neuner<sup>1</sup>, X. Zhang<sup>\*2</sup>, R. Sparapani<sup>\*2</sup>, P. W. Laud<sup>\*1</sup>, A. B. Nattinger<sup>\*1</sup>.

<sup>1</sup>Medicine, Medical College of Wisconsin, Milwaukee, WI, USA,

<sup>2</sup>Biostatistics, Medical College of Wisconsin, Milwaukee, WI, USA.

**Purpose** Medicare has recently added bone density testing of women 65 and older to its pay-for-performance program, but little is known about current testing. We sought to determine the rate of testing among physician practice panels and the contribution of both

physician and physicians' practice variables to BMD testing.

**Methods:** Women aged  $\geq$  65 enrolled in Medicare between 1999-2003 in CA, FL, IL, or NY were identified using Medicare administrative data. Physicians from these states were identified as "plurality of care" physicians if they saw subjects at least twice over a two-year period, and more than any other general internal medicine, obstetrician/gynecologist (GYN), family medicine, or general practice physician. Logistic regression models of factors associated with subject receipt of  $\geq$ 1 bone density test (ultrasound, central or peripheral DXA) in 2002-2003 was developed with the physician and his/her patient panel as the units of analysis.

**Results:** The 27,882 physicians (51% internal medicine, 32% family medicine, 10% GYN, 6% general practice) were plurality of care physicians for a median of 52 subjects. The median proportion of subjects in a physician panel with bone density tests in 2002-2003 was 27% (interquartile range 16-45%). In a regression model including only physician factors and state (table), the strongest individual predictor of bone density testing was GYN specialty. When patient panel variables were added to the model, specialty effects were reduced for gynecologists (OR 2.59 95% CI 2.53, 2.64) but increased for other specialties. The effects of other physician characteristics on testing were all slightly reduced in the larger model. Higher patient panel age, income, visit number, and percentage of black or Hispanic patients, and lower percentage of Medicaid recipients were all associated with more testing.

**Conclusions** Physician characteristics are strongly associated with bone density testing, but these associations are somewhat attenuated by physician's patient panel characteristics. Given previously described age and racial/ethnic testing disparities and limited data regarding patient preferences, pay-for-performance initiatives may need to emphasize improvements in addition to performance thresholds.

Association of Physician Characteristics with Bone Density Testing			
Physician Characteristics		Odds Ratio	95% CI
Specialty	GYN	3.38	{3.31, 3.44}
	Internal Med	1.49	{1.47, 1.52}
	Family Med	1.23	{1.21, 1.25}
	General Practice	reference	
Female Sex		1.28	{1.27, 1.29}
Panel size >median		1.30	{1.29, 1.31}
Years in Practice>median		0.84	{0.83, 0.84}

## SA429

**Cost-Effectiveness of Ibandronate Therapy for Women with Postmenopausal Osteoporosis with Respect to Nonvertebral Fracture Efficacy.** J. A. Sunycz<sup>\*1</sup>, C. Silberman<sup>2</sup>, S. Poston<sup>\*3</sup>, S. Earnshaw<sup>\*4</sup>. <sup>1</sup>Laurel Highlands Ob/Gyn, Hopwood, PA, USA, <sup>2</sup>Roche, Nutley, NJ, USA, <sup>3</sup>GlaxoSmithKline, Research Triangle Park, NC, USA, <sup>4</sup>RTI, Research Triangle Park, NC, USA.

Bisphosphonate trials in osteoporosis are typically powered to examine change in bone mineral density and/or vertebral fracture incidence. Efficacy against nonvertebral fractures, which are less frequent, is more difficult to demonstrate. A pooled analysis of ibandronate clinical trials has been performed in which the impact of ibandronate therapy on nonvertebral fractures was estimated. In this analysis, we developed a Markov model to examine cost-effectiveness of ibandronate in postmenopausal women with established osteoporosis (vertebral fracture and bone mineral density T-score  $\leq$ -2.5; mean age 78 years) while considering nonvertebral fracture efficacy. The model, based on 5 years of therapy and a lifetime time horizon, compared cost-effectiveness of ibandronate and other bisphosphonates versus no bisphosphonate therapy. Bisphosphonate efficacy was obtained from published meta-analyses. Fracture risks, mortality, resource use, costs, and utilities were obtained from the literature. Persistence rates at 3, 6, 9, and 12 months for patients on monthly bisphosphonate therapy were derived retrospectively from managed care claims. For modeling purposes, other bisphosphonate regimens were assumed to have similar persistence rates to monthly ibandronate. Persistence was extrapolated to a maximum of 5 years. Following discontinuation, treatment benefit declined linearly and proportionally to the duration of active treatment. Yearly drug cost was referenced to wholesale acquisition cost and assumed to be the same for all bisphosphonates. Costs and outcomes were discounted 3% annually. All costs were reported in 2007 US\$. Bisphosphonate therapy conferred improvements in quality-adjusted life years (QALYs) versus no bisphosphonate therapy; ibandronate patients had greater QALY increases than patients on other bisphosphonates (0.0233 vs 0.0197). Fracture care costs were less per patient with ibandronate (\$7,652 vs. \$8,308) or other bisphosphonates (\$7,816 vs. \$8,308) than without any bisphosphonate therapy. Drug costs per patient were similar between ibandronate and other bisphosphonates--\$855 per year. Incremental cost/QALY gained (vs. no therapy) was lower with ibandronate (\$8,512) than with other bisphosphonate therapy (\$18,431). Ibandronate treatment thus resulted in cost-savings compared with other bisphosphonates. Our Markov model predicts that reduced incidence of key nonvertebral fractures with ibandronate may reduce fracture care costs for improved cost-effectiveness in comparison to other bisphosphonates.

## SA430

**Falls Predict Higher Medical Costs among Osteoporosis Patients in Community Setting.** A. I. Wertheimer<sup>\*1</sup>, T. Fan<sup>\*2</sup>, S. S. Sen<sup>\*2</sup>, S. Rajagopalan<sup>\*3</sup>. <sup>1</sup>School of Pharmacy, Temple University, Philadelphia, PA, USA, <sup>2</sup>Global Outcomes Research, Merck & Co., Inc, Whitehouse Station, NJ, USA, <sup>3</sup>Med Data Analytics, Inc., New York, NY, USA.

**OBJECTIVE:** To estimate the direct medical costs of falls in a population of community-dwelling patients with osteoporosis.

**METHODS:** Data from a sample of 462 community-dwelling patients with self-reported diagnosis of osteoporosis from the 2004 Medical Expenditure Panel Survey were included to estimate their fall-associated medical expenses. The results were projected to the entire population of civilian, non-institutionalized elderly in the United States.

**RESULTS:** In 2004, among patients with osteoporosis, 13.6% of the non-institutionalized elderly osteoporotic patients in the United States reported medical conditions related to falls. The estimated total direct medical cost of these conditions was \$1.00 billion - 1.43 billion in 2004 dollars. The mean cost per person who had fallen was \$2,974 in 2004 dollars. Inpatient hospitalizations accounted for 45.6% of total costs, followed by office-based medical visits and home health care, each accounting for about 10% of total direct medical costs, and hospital outpatient visits for 7.6%. About 48.1% of fall-related costs were reimbursed by Medicare. In general linear regression models, a history of fall was a significant predictor of medical expenditures for osteoporosis patients, after adjusting for age, gender, race, education level and geographic region ( $t=-3.13$ ,  $P=0.0019$ ).

**CONCLUSION:** Fall-related medical conditions affect a substantial number of community-dwelling patients with osteoporosis and result in an enormous economic burden in the United States. Actual burden of falls may be significantly higher when nonmedical and indirect costs were included. The results of this study highlighted the importance of research about strategies to prevent falls among patients with osteoporosis.

**Effects of Acanthopanax Senticosus Extract on Bone Metabolism In Korean Postmenopausal Women.** H. Chung<sup>1</sup>, E. Kim<sup>2</sup>, S. Yoon<sup>\*3</sup>, I. Jeong<sup>\*1</sup>, K. Ahn<sup>\*1</sup>, M. Kwon<sup>\*1</sup>, S. Chon<sup>\*1</sup>, S. Oh<sup>\*1</sup>, J. Woo<sup>\*1</sup>, S. Kim<sup>\*1</sup>, J. Kim<sup>\*1</sup>, Y. Kim<sup>\*1</sup>. <sup>1</sup>Medicine, Kyung Hee University, Seoul, Republic of Korea, <sup>2</sup>Medicine, Fatima Hospital, Daegu, Republic of Korea, <sup>3</sup>Food and Nutrition, Yonsei University, Seoul, Republic of Korea.

Acanthopanax senticosus is a traditional herbal medicine for reducing inflammation, enhancing liver function and musculoskeletal system. In preliminary study, Acanthopanax senticosus extract has shown increased osteoblastic cell proliferation, differentiation and bone nodule formation. The purpose of this study was to determine the safety and effect of Acanthopanax senticosus extract as an alternative medicine on bone metabolism in Korean postmenopausal women. The subjects were 81 healthy female with postmenopausal osteopenia and osteoporosis. The subjects were randomly assigned into treatment and control group. Treatment group received Acanthopanax senticosus extract (3g/d) and all subjects were received calcium and vitamin D for 6 months. DXA of spine and hip were obtained at baseline and at 6 months. Level of serum C-telopeptide and osteocalcin were also measured as bone markers. Safety was assessed by recording of all adverse events and regular monitoring of blood biochemical tests. In the treatment group, bone mineral density did not increased at spine and femur compared with the control group. At 6 months, however, levels of serum osteocalcin significantly increased in the treatment group. There are no significant differences of adverse events and biochemical blood tests between the groups. This study suggest that Acanthopanax senticosus extract is safe as an alternative herbal medicine and may have a role in bone metabolism. However, further study for longer period to see BMD changes should be performed.

## SA432

**The Effect of a One Year Exercise Program on Markers of Bone Metabolism after Hip Fracture.** J. Yu-Yahiro<sup>1</sup>, E. Streeten<sup>2</sup>, M. Hochberg<sup>2</sup>, D. Orwig<sup>\*2</sup>, J. Magaziner<sup>2</sup>. <sup>1</sup>Department of Orthopaedics, Union Memorial Hospital, Baltimore, MD, USA, <sup>2</sup>Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD, USA.

A study has been conducted to evaluate the impact of home-based exercise over one year in minimizing losses in bone and muscle. This project compared markers of bone metabolism in hip fracture patients randomized exercise or usual care.

Community dwelling women, with fresh femur fractures were randomized to exercise and usual care groups (N=75 each). Exercisers began the intervention at the end of the usual post-acute physical therapy (mean 72 ± 4.5 days). Exercise was five, 45 minute sessions per week, 3 aerobic and 2 strength training, including a maximum of 56 trainer-supervised sessions decreasing in frequency from the beginning to the end of program.

Serum was collected at baseline (within 15 days of fracture), and 60, 180, and 360 days post fracture. Samples were processed and stored at -70C and analyzed for bone specific alkaline phosphatase (BAP) by immunoradiometric assay, and C-terminal propeptide of type 1 collagen (CICP) and carboxyterminal cross-linked telopeptide of type 1 collagen (CTX) by ELISA. The intention-to-treat principle was followed and generalized estimating equations were used to perform repeated measures analyses with time and intervention as fixed effects.

Of exercisers, 81% were actively followed by a trainer and 18% refused participation after being enrollment. Participants received an average of 44 (78%) of the prescribed visits by the exercise trainer.

Although markers of osteoblastic activity, BAP and CICP appeared to decline over time in both exercisers and controls, there were no significant differences in levels of either marker over time (Table 1). Likewise, there were no differences between the two groups at 2, 6, or 12 months. CTx levels were similar in controls and exercisers at all points with no differences found overtime in either group.

In conclusion, compared to a group receiving usual care post fracture, participation in a year long program of exercise after hip fracture did not cause changes in osteoblastic or osteoclastic activity as evidenced by measurement of three markers of bone metabolism.

Table 1: Serum Markers of Bone Metabolism and Exercise Intervention

Group	2 months mean (SE) n	6 months mean (SE) n	12 months mean (SE) n	Between Group Differences
Control	18.42 (1.65) 56	14.65 (1.42) 57	11.93 (1.03) 53	
BAP				
Exercise	17.84 (2.11) 51	13.35 (0.93) 60	10.97 (0.87) 55	p=0.91
Control	108.9 (8.3) 56	98.1 (6.8) 57	77.5 (5.7) 53	
CICP				
Exercise	116.9 (11.9) 51	89.9 (5.8) 60	81.6 (5.4) 55	p=0.16
Control	0.74 (0.05) 56	0.64 (0.05) 57	0.52 (0.04) 53	
CTX				
Exercise	0.74 (0.05) 51	0.55 (0.03) 60	0.54 (0.04) 55	p=0.103

All time specific differences n.s. at the .05 level.

Note: all post-randomization values (2 months to 12 months) were adjusted for baseline (pre-randomization) values.

**Male Perspectives on Osteoporosis Suggest that Continuous Followup and Tailored Groups for Patient Education Are Important Issues - Focus Group Interviews.** D. S. Nielsen<sup>1</sup>, K. Brixen<sup>2</sup>, L. Huniche<sup>\*3</sup>. <sup>1</sup>Endocrinology, Odense University Hospital, Odense, Denmark, <sup>2</sup>Institute of Clinical Research, University of Southern Denmark, Odense, Denmark, <sup>3</sup>Health, Man & Society, Institute of Public Health, University of Southern Denmark, Odense, Denmark.

Several studies have confirmed that osteoporotic fractures in men are an increasing public health problem. Male osteoporosis, however, is underdiagnosed and undertreated. The purpose of this study was to gain insight into how men experience being diagnosed with osteoporosis and how they handle osteoporosis in their everyday lives. In particular focus was directed on information, patient education, and patients' acceptance of treatment.

**Methods:** Data were collected from 4 focus groups with a total of 16 men aged 52-82 years diagnosed with osteoporosis. Data analysis aimed to elicit knowledge derived from the men's everyday lives and experiences. A thematic analysis approach was used. The analysis was discussed with other researchers, in order to develop analytical categories and interpretations.

**Results:** The interviews illustrated that information, patient education, and acceptance of treatment are of varying importance and utilised in different ways in the everyday lives of men with osteoporosis.

Problem	Impact on everyday life
Difficult to tell friends, family and colleagues about having osteoporosis - osteoporosis is considered a female's disease	Barrier to implement lifestyle changes and abstain from heavy lifting and strenuous jobs - It is important for most men to appear as strong and masculine.
In health promotion campaigns are often used.	Professionals should have a concerned and empathetic approach to patients - Important to patient's motivation, and to how patients handle osteoporosis in the every day life.
The health care system is offering mainly individual consultations.	Most of the men suggested group-based patient education programs. Some preferred being together with women due to women's way of being open about feelings. Others preferred men-only groups to enhance the sharing of experiences.
At times, participants felt it difficult to take the medication.	Motivation fades out with time. A continuous follow up (e.g. once a year) at the doctor or osteoporosis specialist nurse was considered as very important.

**Conclusion:** The study underscores the importance of working with the everyday context and perspective of the patient in the health care system. A better understanding of how osteoporosis affects men may help to develop specific preventive strategies as well as enhancing patients' acceptance of treatment.

**Exploring the Effect of Food Intake On Bone Resorption for Optimal Drug Delivery and Efficacy in Osteoporosis with Oral Calcitonin.** M. A. Karsdal, I. Byrjalsen, B. J. Riis\*, C. Christiansen. Nordic Bioscience, Herlev, Denmark.

Bone resorption displays marked diurnal variation. Completely reversible inhibition of bone resorption may result in best possible efficacy when bone resorption peaks, i.e. during the night. The aim of the study was to assess the pharmacokinetic (PK) and pharmacodynamic (PD) profiles of 0.8 mg of oral salmon calcitonin (sCT) and the effect of timing of drug intake in healthy postmenopausal women.

The study was a randomized, double-blind, double-dummy, placebo-controlled, crossover phase I study to assess the pharmacokinetic (PK) and pharmacodynamic (PD) profiles of 0.8 mg of oral sCT in healthy postmenopausal women. 81 subjects were included. Morning dose was given at 8:00 ( $n=42$ ), a pre-dinner dose given at 17:00 ( $n=20$ ) and evening dose given at 22:00 ( $n=19$ ). Blood sampling occurred before drug intake, and at 5, 10, 15, 30, 45 minutes, 1, 1½, 2, 2½, 3 hours, and every hour until 24 hours after dosing. The absorption of calcitonin was assessed by measurement of plasma sCT concentrations, and bone resorption by the biochemical marker serum CTX-1.

Morning and pre-dinner dosing led to comparable concentrations of sCT (45 pg/ml), whereas there was a tendency towards lower  $C_{max}$  for the evening dosing having a mean of 24 pg/ml. Overall, dosing with oral sCT resulted in significant suppression of serum CTX irrespective of dosing time, although with different pharmacodynamic parameters (Figure 1). The morning dose of oral sCT resulted in a placebo-corrected  $AUC_{0-24hrs}$  of serum CTX of -232 (% x hrs) corresponding to a permanent overall suppression of bone resorption by 10%. The pre-dinner dose was twice as effective in suppression of serum CTX giving a mean  $AUC_{0-24hrs}$  of -603 (% x hours) equal to an overall suppression of 25%. The  $AUC_{0-24hrs}$  of the evening dose was at the same level of magnitude at -538 (% x hrs) although there seemed to be a higher inter-individual variation in the response associated with this dosing time.

**Conclusion:** The study suggests that orally administered 0.8 mg of salmon calcitonin was effective in suppression of serum CTX over 24h irrespective of time of dosing. The pre-dinner dosing at 17:00 resulted in optimum efficacy response corresponding to an overall suppression of bone resorption by 25%. In the optimization of efficacy of completely reversible anti-resorptive drugs, the physiological timing of drug dosage is important to optimise drug efficacy.

**Disclosures:** M.A. Karsdal, None.

## SA437

**Osteoporosis in the Old Old: Review of the Evidence.** C. A. Inderjeeth, A. Foo\*, M. Lai\*. Rehabilitation and Aged Care, Sir Charles Gairdner Hospital, Nedlands, Australia.

Women  $\geq 80$  years of age comprise approximately 8% of the post-menopausal population but contribute  $> 30\%$  of all fragility fractures and 60% of hip fractures because of the high prevalence of osteoporosis and high incidence of falls in this age group. However there is limited data in this age group for treatment.

**Objectives of this review:** To review the published literature on the clinical efficacy and safety of specific anti osteoporosis treatments in the reduction in fracture risk in females in the old old (greater than 80 years of age). The following major endpoints were used in this review:

1. Vertebral fracture reduction at 1 year and 3 years
2. Non-vertebral fracture reduction at 1 year and 3 years
3. Hip fracture reduction at 1 year and 3 years.
4. Safety data with these agents in the old old.

Studies had to be randomised placebo or active comparator control trials of at least 1-year duration including post-menopausal females. Pooled analysis and published sub-group analysis, specifying the sub-group 80 years or older were also included.

**Results:** The only publications that specifically reported data in patients from 80 - 100 years old were pooled analysis of the SOTI and the TROPOS study by Seeman et al and the pooled analysis of VERT MN, VERT NA and HIP study by Boonen *et al*. These results are summarised in table 1.

**Table 1. Fracture Efficacy In Randomised Patients 80-100 Years**

Fracture Risk	STRONTIUM RANELATE STUDIES				RISERDRONATE 5mg STUDIES			
	Placebo	Strontium Ranelate	Relative Risk Reduction (p value)	ARR NNT	Placebo	Risedronate	Relative Risk Reduction (P Value)	ARR NNT
Vertebral Fracture 1 Year	8.3%	3.5%	59% (p=0.002)	4.8% 21	10.9%	2.5%	81% (p < 0.001)	8.4% 12
-3 Years	26.5%	19.1%	32% (p=0.013)	7.4% 14	24.6%	18.2%	44% (p= 0.003)	6.4% 16
Non Vertebral Fracture 1 Year	6.8%	4.0%	41% (p=0.027)	2.8% 36	NA	NA	NA (p=0.66)	NA (NS)
3 Years	19.7%	14.2%	31% (p=0.011)	5.5% 18	16.2%	14.0%	NS 2.2% (NS)	- (NS)
Hip Fracture 3 Years	7.4%	5.2%	41% (NS) (p=0.112)	2.2% (NS)	5.1%	4.2%	NS* (p=0.35)	0.9% (NS)

\* Includes Hip study patients only - selected on the basis of non-skeletal risk factors for hip fractures rather than established osteoporosis.

**Conclusion:** This literature review reinforces the irony that we have the least evidence for fragility fracture reduction in the group at greatest risk who are likely to sustain the greatest potential harm with the greatest risk of disability and mortality and at potentially the greatest cost to society. This calls for better randomised controlled trials to provide better evidence for treatment of this patient group who are likely to place increasing demands on limited per-capita health care resources in future decades.

## SA438

**Weight and Body Mass Index Predict Bone Mineral Density and Fractures in Women 40 to 59 years.** S. N. Morin<sup>1</sup>, J. F. Tsang<sup>\*2</sup>, W. D. Leslie<sup>2</sup>.<sup>1</sup>Medicine, McGill University, Montreal, QC, Canada, <sup>2</sup>Medicine, University of Manitoba, Winnipeg, MB, Canada.

Risk factors for the prediction of osteoporosis and fractures have not been extensively characterized in younger women. We evaluated the associations between weight, body mass index (BMI), Osteoporosis Self-Assessment Tool (OST), bone mineral density (BMD) and fracture risk in women aged 40 to 59 years.

Using administrative databases, we conducted a retrospective cohort study in 8,254 women age 40-59 years who had baseline BMD testing. Cox proportional hazards models were created to examine the associations with weight, BMI, OST, BMD and subsequent non-traumatic fractures during 3.3 years of follow up.

Body weight, BMI and OST had similar overall performance in their ability to classify women with femoral neck T-score  $\leq -2.5$  (area under the ROC curve 0.76; 95% CI: 0.73-0.78, 0.72; 95% CI: 0.70-0.75, 0.77; 95% CI: 0.75-0.79, respectively). During 27,256 person-years of observation, 225 women (2.7 %) experienced one or more incident fractures. After adjustment for age, prevalent fractures and use of systemic corticosteroids, each standard deviation decrease in weight was associated with a 19% increase in the risk of incident fracture (95% CI: 1.01-1.35). Femoral neck BMD and the presence of prevalent fractures were also positively associated with the risk of incident fractures.

Low weight and BMI predict osteoporosis and are associated with an increase in the risk of fractures in younger women. The negative impact of low body weight on bone health should be more widely recognized.

Table Risk of Incident Fractures

	Univariate HR (95% CI)	Multivariate HR (95% CI) without BMD	Multivariate HR (95% CI) with BMD
<b>Model 1</b>			
Weight per SD decrease	1.17 (1.01-1.35)	1.19 (1.03-1.37)	0.97 (0.84-1.14)
Age per decade increase	--	1.07 (0.94-1.22)	0.98 (0.85-1.12)
Prevalent osteoporotic fracture	--	3.28 (2.36-4.57)	2.68 (1.91-3.76)
Systemic corticosteroid use	--	1.24 (0.75-2.04)	0.97 (0.59-1.61)
Femoral neck BMD per SD decrease	--	--	1.61 (1.37-1.89)
<b>Model 2</b>			
BMI per SD decrease	1.17 (1.01-1.35)	1.18 (1.02-1.37)	1.00 (0.86-1.17)
Age per decade increase	--	1.07 (0.94-1.22)	0.98 (0.86-1.12)
Prevalent osteoporotic fracture	--	3.26 (2.35-4.54)	2.70 (1.93-3.78)

**Obesity and Bone Architecture in Men - Can We Apportion the Metabolic and the Mechanical Effect?** P. Szulc, S. Boutroy<sup>\*</sup>, P. D. Delmas. INSERM 831, Hopital E. Herriot, Lyon, France.

Obesity is associated with higher areal bone mineral density (aBMD), but architectural basis and pathophysiological mechanisms underlying this association at the weight-bearing and the non-weight-bearing sites are not fully understood. High resolution peripheral quantitative computed tomography was carried out in 1128 men aged 20 to 88 years at the distal radius and distal tibia by using the XtremeCT device (Scanco Medical AG). Architectural parameters were compared in three groups of men according to their body mass index (BMI): normal weight ( $\leq 25$  kg/m<sup>2</sup>, n=349, mean age - 56 years), overweight ( $25 < \text{BMI} \leq 30$  kg/m<sup>2</sup>, n=555, mean age - 65 years) and obesity ( $> 30$  kg/m<sup>2</sup>, n=224, mean age - 68 years). For the comparisons between the skeletal sites, all the investigated variables were transformed into Z-score using the parameters of the normal weight men as the reference group. At the radius and tibia, total cross-sectional area did not differed across the groups. After adjustment for age, overweight and obese men had significantly higher cortical area and thickness, higher total and trabecular (but not cortical) volumetric BMD (vBMD), higher trabecular number (but not the estimated trabecular thickness) and more homogeneously distributed trabeculae (lower variability of the trabecular separation in an individual). In the overweight and obese men, total, trabecular and outer (subendocortical) trabecular vBMD were similarly increased at the radius (0.25 to 0.39 SD,  $p < 0.005$ -0.0001) and at the tibia (0.31 to 0.45 SD,  $p < 0.001$ -0.0001) compared with the

normal men. In the overweight and obese men, trabecular separation and its variability were similarly reduced at the radius (0.27 to 0.50 SD,  $p < 0.005$ -0.0001) and the tibia (0.23 to 0.58 SD,  $p < 0.01$ -0.0001). By contrast, in comparison with the normal weight men, some parameters were more increased in the obese men at the tibia than at the radius: cortical area (0.61 vs 0.39 SD,  $p < 0.02$ ), trabecular number (0.84 vs 0.62 SD,  $p < 0.03$ ) and the central (inner) trabecular vBMD (0.42 vs 0.26 SD,  $p < 0.03$ ).

Thus, in these predominantly trabecular skeletal sites, obesity was associated with a similar increase in certain parameters at the weight-bearing distal tibia and at the non-weight-bearing distal radius suggesting that they may depend mainly on the metabolic changes related to the obesity e.g., higher peripheral estrogen synthesis. By contrast, in the obese men, the cortical area, the trabecular number and the inner trabecular vBMD were more increased at the weight-bearing distal tibia compared with the non-weight-bearing distal radius suggesting that, in men, the mechanical load may be a significant determinant of these architectural parameters.

Hamrick<sup>7</sup>, C. Isaacs<sup>4</sup>, Q. Mi<sup>6</sup>. <sup>1</sup>Center for Biotechnology and Genomic Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Dept. of Medicine, The Medical School Hospital of Qingdao University, Qingdao, China, <sup>3</sup>Dept. of Medicine, Shangdong University Medical School, Jinan, China, <sup>4</sup>Dept. of Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>5</sup>Dept. of Physiology, Medical College of Georgia, Augusta, GA, USA, <sup>6</sup>Dept. of Pathology, Medical College of Georgia, Augusta, GA, USA, <sup>7</sup>Dept. of Cellular Biology, Medical College of Georgia, Augusta, GA, USA.

High fat diet (HFD) results in obesity, which is well known to affect both bone density and quality in adults. However, it is unclear how HFD affects the bone development during childhood. The purpose of this study was to determine the effect of HFD on bone structure and mechanics in young adult mice. Female CD1 mice were fed with either HFD or normal fat diet (NFD) starting at 4-weeks of age for 10 weeks. The HFD contained 36% fat (15.2% saturated, 20.8% unsaturated) and NFD 4.4% fat (2.5% saturated, 1.9% unsaturated). The bone mineral content (BMC), bone mineral density (BMD), fat and lean mass were examined in 14-week old mice using dual-energy X-ray absorptiometry, and bone biomechanical properties were also evaluated using three-point bending test. The body weight and fat mass in HFD-treated mice increased almost 2-5 fold compared to that in NFD-treated mice, respectively. The whole body BMD, BMC, bone area and lean mass in HFD-treated mice were slightly higher than that in NFD mice ( $P > 0.05$ ). However, the spine BMC and bone area in HFD mice were significantly lower than that in NFD mice ( $P < 0.01$ ), while femoral BMD ( $P < 0.01$ ), BMC ( $P < 0.01$ ) and bone area ( $P < 0.05$ ) in HFD mice were significantly greater than that in NFD mice. But, there was no statistically different in bone biomechanical values between the two groups. When these results were adjusted based on body weight or fat mass, the body BMD, BMC, bone area, and femur BMD and BMC tended to be lower in HFD-treated mice in comparison to NFD mice although the difference was not statistically significant. Our preliminary data suggest that the vertebral bone is more sensitive to HFD-induced bone loss compared to the long bones in young, growing animals. Considering that childhood and adolescence are crucial periods to acquire nearly half of the peak bone mass, high-fat diet in young adult might be one reason for the increasing prevalence of osteoporosis during adult and aging.

**Effects of Diacylglycerol Oil on Body Composition, Bone Mineral Density and Bone Strength in Mice.** H. Choi<sup>\*1</sup>, W. Jung<sup>\*2</sup>, Y. Rhee<sup>1</sup>, S. Kim<sup>\*3</sup>, J. Y. Jeon<sup>\*4</sup>, I. Paik<sup>\*2</sup>, E. Lee<sup>\*1</sup>, S. Lim<sup>1</sup>.

<sup>1</sup>Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Department of Physical Education, Yonsei University, Seoul, Republic of Korea, <sup>3</sup>Department of Internal Medicine, Kwandong University College of Medicine, Goyang, Republic of Korea, <sup>4</sup>Department of Sports and Leisure Studies, Yonsei University, Seoul, Republic of Korea.

Background: A high fat diet (HFD) is known to promote obesity and insulin resistance, causing metabolically deleterious effects on the body. Total fat intake, especially saturated fat intake, has been reported to be associated with a higher risk of osteoporotic fractures. Meanwhile, consuming a diet rich in diacylglycerol (DAG) oil instead of triacylglycerol (TAG) has been reported to have metabolically beneficial effects such as reduction in body weight and abdominal fat and improvement in lipid profile. However, there has been no study investigating the effects of DAG on bone mineral density (BMD) and strength in mice.

Methods: Four-week-old male 38 C57BL/6J mice were divided into 4 groups: the chow diet group (n=10), HFD group (n=9), HFD with high DAG group (n=10), and HFD with exercise group (n=9). After 17 weeks of treatment, body composition and BMD were measured using DXA, and bone strength of the femur was measured by a 3-point bending test.

Results: Body weight was significantly lower in the HFD with high DAG ( $38.3 \pm 2.0$  g) and HFD with exercise ( $36.2 \pm 2.8$  g) groups than the HFD group ( $46.2 \pm 2.3$  g). Percent fat mass was significantly lower in the HFD with exercise group ( $32.7 \pm 5.6\%$ ) than the HFD

group ( $42.7 \pm 3.3\%$ ). The HFD with high DAG ( $0.0668 \pm 0.0041 \text{ g/cm}^2$ ) and HFD with exercise ( $0.0684 \pm 0.0053 \text{ g/cm}^2$ ) groups had significantly higher femur BMD than the HFD group ( $0.0611 \pm 0.0032 \text{ g/cm}^2$ ), although such differences were not found in the 3-point bending test.

Conclusions: DAG may have beneficial effects on BMD. Further studies are needed to elucidate the effects of DAG on the skeleton.

**Vitamin K Treatment for One Year Does Not Alter Femur Geometry in Postmenopausal Women.** N. Vallarta-Ast<sup>1</sup>, D. Krueger<sup>1</sup>, J. W. Suttie<sup>2</sup>, N. Binkley<sup>1</sup>. <sup>1</sup>Osteoporosis Clinical Research Program, University of Wisconsin, Madison, WI, USA, <sup>2</sup>University of Wisconsin, Madison, WI, USA.

A potential role of vitamin K in reducing osteoporotic fracture risk remains controversial. Recently, it has been reported that vitamin K supplementation favorably alters femur geometric parameters. Such effects could lead to a reduction in fracture risk but not be appreciated by bone mineral density as measured by dual energy x-ray absorptiometry (DXA). To investigate this possibility, we re-analyzed femur DXA scans from a prospective randomized clinical study of healthy postmenopausal women without osteoporosis. Briefly, in this study, 381 postmenopausal women were randomly assigned to receive phylloquinone (K1) 1,000 mcg daily, menatetrenone (MK4) 45 mg daily, or placebo for one year. Subjects were [mean ( $\pm$  SE)]  $62.3 (\pm 0.4)$  years and had a mean BMI of  $28.5 (\pm 0.3) \text{ kg/m}^2$ . All participants received daily calcium with vitamin D. DXA scans were performed using a GE Lunar DPX-IQ at baseline and after 6 and 12 months. For this report, the baseline and 12 month femur scans were re-analyzed with software version 4.7. Hip geometric parameters were obtained using the software auto-analysis feature and include femur neck and total femur area, femur neck width, hip axis length (HAL), femur neck cross-sectional area (CSA), femur neck cross-sectional moment of inertia (CSMI) and the GE proprietary femur strength index (FSI).

No change in any of the measured femur geometric parameters was observed in the placebo group and no differences in any parameter were observed with either K1 or MK4 treatment compared with placebo (Table).

Table: Selected femur DXA parameters

Group	N	FN BMC (g)		FN Width (mm)		CSA (mm <sup>2</sup> )		FSI	
		Base	12m	Base	12m	Base	12m	Base	12m
Placebo	124	4.342 (.059)	4.343 (.060)	31.28 (.24)	31.39 (.23)	154.2 (2.2)	153.7 (2.2)	1.29 (.03)	1.31 (.03)
K1	115	4.464 (.062)	4.445 (.062)	31.57 (.21)	31.51 (.21)	159.6 (2.3)	159.4 (2.2)	1.43 (.04)	1.45 (.04)
MK4	119	4.432 (.063)	4.407 (.062)	31.72 (.22)	31.72 (.22)	157.8 (2.3)	157.3 (2.3)	1.40 (.03)	1.39 (.03)

Data presented as mean  $\pm$  SE.

In conclusion, no effect of one-year treatment with vitamins K1 or MK4 on DXA-measured parameters of femur geometry was observed. It remains possible that longer duration studies could identify vitamin K-related changes.

**Goettingen Minipigs - A Model for Ca/Vit D-Deficiency Osteomalacia and Steroid-induced Osteoporosis.** K. E. Scholz-Ahrens<sup>1</sup>, C. C. Glüer<sup>2</sup>, W. Timm<sup>3</sup>, Y. Açı<sup>1</sup>, W. Yan-Clasen<sup>1</sup>, J. Schrezenmeier<sup>1</sup>. <sup>1</sup>Physiologie und Biochemie, Max-Rubner-Institut, Kiel und Karlsruhe, Germany, <sup>2</sup>Medizinische Physik, Klinik für Diagnostische Radiologie, Universitätsklinikum Schleswig-Holstein - Campus Kiel, Kiel, Germany, <sup>3</sup>Klinik für Mund-, Kiefer- und Gesichtschirurgie, Universitätsklinikum Schleswig-Holstein - Campus Kiel, Kiel, Germany.

Ca and Vit D intake of the elderly in Western societies is often inadequate and their Vit D synthesis and renal Ca reabsorption tend to be diminished. To study this condition, we developed a minipig model for osteomalacia by evaluating the effect of Vit D and Ca deficiency in comparison with a model for osteoporosis induced by glucocorticoids. Three diet groups, each made up of ten 30 month-old minipigs, were studied: 1) 0.6% Ca, 6500 IU Vit D/kg diet (control group), 2) 0.2% Ca, no Vit D (osteomalacia); 3) 0.6% Ca, 6500 IU Vit D/kg diet and a daily dose of 1mg/kg BW prednisolone for 8 wks, thereafter 0.5mg/kg BW (osteoporosis). After 15 months, the Ca balance (mg/7d) had decreased in both experimental groups, by 6175 mg ( $\pm$ 2355) in the osteomalacia group ( $p < 0.05$ ), and by 3411 ( $\pm$ 2023) mg in the osteoporosis group ( $p > 0.05$ ), while there was only a small decrease of 388 ( $\pm$ 1146) mg in the control group. The decrease in bone mineral density (BMD, mg/cm<sup>3</sup>) in vivo was similar in both experimental groups ( $51.2 \pm 14.7$  and  $56.7 \pm 8.3$ , respectively), and significantly different from the marginal decline in the control group ( $2.3 \pm 11.8$ ). In the osteomalacia group, plasma concentrations of 25(OH)-Vit D were lower ( $p < 0.05$ ) and of 1,25(OH)<sub>2</sub>-Vit D higher ( $p < 0.05$ ) than in the osteoporosis and control group. Bone alkaline phosphatase levels tended to be higher in the osteomalacia group, compared to the control, and were significantly higher most of the time than in the

osteoporosis group. Bone resorption, evaluated by deoxypyridinoline-crosslinks, was unchanged and not different between groups. Because bone density loss was similar in both conditions, but differed with regard to osteoblast activity and Vit D metabolism, the minipig seems to be a valid model to study Ca/Vit D-deficiency osteomalacia and steroid-induced osteoporosis.

**Effects of Potassium Bicarbonate on Calcium- and Bone Metabolism during High Salt Intake.** P. Frings-Meuthen<sup>\*</sup>, J. Buehlmeier<sup>\*</sup>, N. Baecker<sup>\*</sup>, M. Heer. Institute of Aerospace Medicine, German Aerospace Center, Cologne, Germany.

We have recently shown that high salt intake led to decreases in blood pH and bicarbonate concentration accompanied by increases in bone resorption markers (Frings-Meuthen et al. J Bone Miner Res 2008; 23:517-524). Since pH decrease is a mandatory condition to activate osteoclasts, we hypothesize that the increased bone resorption is initiated by a low-grade metabolic acidosis. Administration of an alkali salt may counteract the acidosis and thereby decrease the bone resorption induced by a high salt intake. In a metabolic ward study with 8 healthy male test subjects (mean age:  $25.8 \pm 3.9$  years; body weight (BW)  $75.4 \pm 3.6$  kg) we examined the ability of KHCO<sub>3</sub> to prevent salt-induced bone loss. 4 days of adaptation with a normal salt intake (2.8 mmol/kgBW/d) were followed by 10 days of high salt intake (7.7 mmol/kgBW/d) combined in one trial with a supplementation of  $3 \times 30$  mmol KHCO<sub>3</sub> per day in a cross-over design. Urinary calcium (UCA) excretion and bone resorption markers (C- and N-terminal telopeptide of type I collagen (CTX, NTX)) were analyzed in all 24-hour urine collections. Fasting morning blood was analyzed for the bone formation markers, bone specific alkaline phosphatase (bAP), and N-terminal of propeptide of type I procollagen (PINP). Postprandial parathyroid hormone (ppPTH) measurements were used to provide an insight into the involvement of PTH in salt-induced bone loss. KHCO<sub>3</sub> supplementation was able to reduce salt-induced calciuria by only 12 % ( $p = 0.04$ ) and NTX excretion by only 8 % ( $p = 0.04$ ); no significant decrease was observed in the bone resorption marker CTX ( $p = 0.18$ ). Bone formation marker PINP ( $p = 0.92$ ) and bAP ( $p = 0.95$ ) remained unchanged. However, ppPTH levels were twofold higher 25 minutes after KHCO<sub>3</sub> supplementation ( $p < 0.001$ ). High salt intake itself did not affect ppPTH. The KHCO<sub>3</sub>-induced PTH increase might play an important role in the attenuated effectiveness of potassium bicarbonate to reduce salt-induced bone loss.

## SA447

**Ovariectomy-Induced Hyperphagia Does Not Modulate Bone Mineral or Bone Strength in Female Sprague-Dawley Rats.** J. M. Y. Jiang<sup>\*</sup>, S. M. Sacco<sup>\*</sup>, W. E. Ward. Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

Osteoporosis is a skeletal disorder characterized by compromised bone strength, leading to an increased susceptibility to fragility fractures. The adult ovariectomized (OVX) rat is the FDA-recommended model for postmenopausal osteoporosis and plays a crucial role in the development of prevention and treatment strategies. While ovariectomy closely mimics the postmenopausal skeleton, it also induces secondary effects of hyperphagia, increased weight gain, and adiposity. Increased body weight is associated with protective effects on bone, and thus may be a confounder in preclinical studies investigating the effects of interventions on bone health. For this reason, pair-feeding is commonly used to control food intake and prevent hyperphagia-associated weight gain. However, the effects of hyperphagia on bone and the importance of pair-feeding have not been elucidated. The objective of this study was to determine whether the type of feeding, pair versus *ad libitum*, modulates bone mineral and bone strength using the OVX rat model of postmenopausal osteoporosis. Three-month old female Sprague-Dawley rats ( $n=14$ /group) were randomized to 1) sham-operated control (SHAM); 2) ovariectomized pair-fed (OVX-PF); or 3) ovariectomized *ad libitum* (OVX-AL). All rats were fed a standard pelleted diet (AIN93M). Pair-feeding involved matching the food intake of OVX-PF rats to the average amount of food eaten by the SHAM group the day before. At the end of 14 weeks, lean mass and fat mass were measured by dual energy x-ray absorptiometry (DEXA). Bone mineral density (BMD) and biomechanical bone strength were assessed at the femur and the lumbar vertebrae (LV). OVX-AL rats consumed more food ( $P < 0.05$ ) than both the SHAM and OVX-PF during the first 5 weeks of study, but hyperphagia disappeared by 7 weeks. Final body weight ( $P < 0.01$ ), weight gain ( $P < 0.01$ ), and fat mass ( $P < 0.05$ ) were higher among OVX-AL rats than both SHAM and OVX-PF rats, while no differences were observed between the SHAM and OVX-PF groups. SHAM rats had higher femur ( $P < 0.001$ ) and LV1-3 BMD ( $P < 0.001$ ) than both the ovariectomized groups. The peak load of LV4 was also significantly higher ( $P < 0.01$ ) among the SHAM rats compared to the ovariectomized groups. No differences in bone outcomes were observed between OVX-PF and OVX-AL groups. In summary, ovariectomy-induced hyperphagia and weight gain do not modulate BMD or biomechanical bone strength at 14 weeks post-ovariectomy. Pair-feeding is not necessary to prevent excess weight gain and adiposity from confounding bone outcomes in this model.

**High-fat Diet Facilitated Decreases in BMD of Ovariectomized Mice and Suppressed the Anabolic Effects of PTH on Bone.** S. Tanaka<sup>1</sup>, A. Sakai<sup>1</sup>, T. Tanigawa<sup>2</sup>, H. Hirasawa<sup>1</sup>, Y. Katae<sup>1</sup>, K. Tanaka<sup>1</sup>, T. Nakamura<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>2</sup>1st medicine, University of Occupational and Environmental Health, Kitakyushu, Japan.

The post-menopausal osteoporosis is caused by decreases in estrogen activity and sequential increases in bone turnover. High-fat diets also decreased bone volume, what we clearly demonstrated in our recent study using mouse given high-fat diet due to increases in bone resorption and decrease in bone formation. We hypothesized that decreases in BMD of estrogen deficient women is facilitated by high-fat diet.

We tested the effects of high-fat diet to the ovariectomized (OVX) mice on bone metabolism and of intermittent administration of PTH on recovery from decreased bone. Seven weeks old, female, C57BL/6J mice were purchased and subjected to 6 groups, sham operated mice given standard chow, OVX mice given standard chow, sham given high-fat diet, OVX given high-fat (OH), sham given high-fat diet and intermittent PTH injection, and OVX given high-fat and PTH, after 1 week acclimatization and operated. Feeding started from 8 weeks age and 3 times per one week PTH injection were performed from 14-week (6 weeks after operation) until the end of the experiment.

Decreases in BMD were observed in the lumbar spine of OVX mice and what was more apparent in OVX mice given high-fat diet, while the lumbar BMD did not decreased in sham operated mice given high-fat diet. The PTH injection partially recovered lumbar BMD up to the OVX mice given standard chow level. In femur, although BMD in OVX mice given standard chow or sham operated mice given high-fat diet did not decrease, BMD in OVX mice given high-fat diet decreased apparently. PTH injection recovered the femoral BMD in OVX mice given high-fat diet to the levels of sham operated or OVX mice given standard chow.

High-fat diet facilitated decreases in BMD of OVX mice and suppressed the anabolic effects of PTH on bone especially in non-weighted site.

## SA449

**Treadmill Exercise Provides Only Short-Term Protection Against Cancellous Bone Loss with Reduced Dietary Energy Intake: Endocrine Mechanisms.** S. N. Swift<sup>1</sup>, K. Baek<sup>1</sup>, M. J. De Souza<sup>2</sup>, S. A. Bloomfield<sup>1</sup>. <sup>1</sup>Intercollegiate Faculty of Nutrition, Health & Kinesiology, Texas A&M University, College Station, TX, USA, <sup>2</sup>Kinesiology, Pennsylvania State University, University Park, PA, USA.

Dietary energy deficits leading to weight loss can induce loss of cancellous bone. We sought to elucidate whether endurance exercise maintains cancellous bone mass in female rats subjected to a 40% energy deficit. Forty Sprague-Dawley virgin female rats 5-mo-old were acclimated to AIN-93M purified diet for 8 wks. For the next 12 wks, the control groups (ADLIB-EX & ADLIB-SED) were fed AIN-93M *ad lib*. Energy restriction with exercise group (ER-EX) and sedentary energy-restriction (ER-SED) groups were fed modified AIN93M diet with 30% and 40% less energy, respectively, with 100% of all other nutrients provided. Exercising rats performed treadmill running 4 d/wk, 90-100 min/d (~60% V<sub>O2</sub> max) to increase weekly energy expenditure by 10%. At day 0, wk 4, and wk 12, urine & serum were collected for ELISA assays on IGF-1, estrogen glucuronide (E1G), leptin, C-terminal telopeptides of type I collagen (CTX) and N-terminal propeptides of type I collagen (PINP). At the same time points, peripheral quantitative tomography (pQCT) scans were performed at the proximal tibia metaphysis (PTM) for cancellous volumetric bone mineral density (vBMD). Body weights for all *ad lib* fed animals increased by 12 wk (+9%) while all ER rats lost weight (-16%), with no effect of exercise in either energy status group. ER decreased cancellous vBMD (-17%) by 12 wk in sedentary animals. Exercise increased cancellous vBMD by 4 wk regardless of energy status (+12%), but did not protect against losses by 12 wk in ER-EX (-9%). Bone turnover appears to be suppressed in both ER groups, with decreases in PINP (-43%) and CTX (-4%) by 12 wk, but not in ADLIB-EX. Serum leptin declines significantly in EX-ER by 4 wk (-75%) and in SED-ER at 12 wk (-96%). Trends were observed for suppression of serum IGF-1 in both ER groups that were significant in ER-EX (-33%) by 12 wk. Uterine weight was significantly lower in ER-EX at 12 wks (-48% vs. ADLIB-EX). In summary, endurance training in energy-replete rats increased cancellous vBMD and protected against bone loss in rats experiencing energy deficits at 4 wk, but not when restriction was maintained for 12 wk. Estrogen status (estimated by uterine weight) and endocrine markers of energy status were maintained in ADLIB-EX rats, but declined over time in all energy-restricted rats (SED and EX). Energy deficit-induced changes in estrogen status, leptin and IGF-1 may contribute to this loss of cancellous bone.

**Prevention of Glucocorticoid-induced Osteoporosis with Alendronate or Alfacalcidol in Patients with Ophthalmologic Diseases.** T. Ikeda<sup>1</sup>, C. Hamanishi<sup>1</sup>, S. Souen<sup>2</sup>. <sup>1</sup>Orthopaedic Surgery, Kinki Univ. School of Medicine, Osaka, Japan, <sup>2</sup>Orthopaedic Surgery and Rheumatology, Kinki Univ. Nara Hospital, Nara, Japan.

Glucocorticoid (GC)-induced osteoporosis is a major public health problem for patients taking GC therapy. To clarify the drug therapy strategy for the increased risk fracture, we studied the changes in bone mineral density (BMD) by dual energy X-ray absorptiometry after initiating high dose GC treatment over 12 months in patients with ophthalmologic diseases. Alendronate or alfacalcidol treatment was started concurrently with GC treatment. We studied 36 Japanese patients (12 male and 24 female) suffering from ophthalmologic diseases who required long-term (>3 months) treatment with oral GC at an average daily dose of at least 10 mg prednisolone.

The mean BMD in alfacalcidol group were continuously lower than it's baseline during 12 months treatment. The lowest mean changes of BMD were observed at 9 months in both alendronate group (-1.14%) and for alfacalcidol group (-5.01%).

In male subjects, the mean changes of BMD for alendronate group were greater than for alfacalcidol group at 3 months and 6 months after treatment. In female alfacalcidol group, significant BMD reductions from baseline were observed in comparison to female alendronate group at both 3 and 6 months. In addition, we checked urinary excretion of type I collagen cross-linked N-telopeptides corrected for creatinine (NTx/Cr) data as a marker for bone turnover. For alendronate group, the mean percentage changes from baseline were -41.7% and -42.3% at 3 and 6 months after treatment, respectively. For alfacalcidol group, the mean percentage changes from baseline were 11.3% and -4.4% at 3 and 6 months after treatment, respectively. In alendronate group, the mean decrements of NTx/Cr were statistically greater in comparison to alfacalcidol group.

In conclusion, we have investigated the preventive effect of alendronate or alfacalcidol for GC-induced osteoporosis in patients with ophthalmologic field diseases. Alendronate is efficacious in preventing bone mass at the lumbar spine in above populations. In addition, alfacalcidol might be efficacious in the restricted population such as male subjects as a second-line anti-osteoporotic agents.

In this study, the enrolled population includes relative young female population and also includes male patients, and the comparison between postmenopausal patients and premenopausal patients might be important, therefore, we should design further studies to solve these points.

**Effects of Intermediate Doses of Glucocorticoids on Bone Turnover and Circulating Dkk-1, MIF, sRANKL and OPG in Patients with Interstitial Lung Disease. A Three-Month Longitudinal Study.** A. Dovio<sup>\*</sup>, E. Palmas<sup>\*</sup>, L. Saba<sup>\*</sup>, A. Termine<sup>\*</sup>, E. Bianco<sup>\*</sup>, L. Mercante<sup>\*</sup>, C. Albero<sup>\*</sup>, A. Angeli. Dept. of Clinical and Biological Sciences, University of Turin, Orbassano - Torino, Italy.

High-dose glucocorticoid (GC) administration causes early and transient increase of bone resorption. Whether such an increase occurs also for intermediate and low doses is unknown. Dynamics over time of this effect, relationships to routes of administration and schedules of tapering down doses, and underlying mechanisms are unclear. We have performed a longitudinal study lasting a 3-month span in patients diagnosed as having interstitial lung disease responsive to GCs and starting treatment with intermediate doses. Fourteen patients (M/F 8/6; age 54, 34-77 yr (median, range)) suffering from sarcoidosis (n=10), nonspecific interstitial pneumonia (n=2), usual interstitial pneumonia (n=1), desquamate interstitial pneumonia (n=1) were included. All patients did not take drugs affecting bone, including GCs, in the previous 6 months. Serum osteocalcin (OC), C-telopeptide of type I collagen (CTX), Dickkopf-1 (Dkk-1), osteoprotegerin (OPG), total soluble RANKL (sRANKL), and macrophage migration inhibitory factor (MIF) were measured by commercially available ELISAs at baseline, after 3 days and after 1, 2, 4, 8, 12 weeks of treatment. The starting dose was 25 (n=3) - 50 mg (n=11) of prednisone; the dose at week 12 was 12.5 (5-25) mg; cumulative dose and average daily dose were 1925 (1225-2975) mg and 23 (15-35) mg, respectively. With this regimen, GCs caused a rapid decrease of serum OC (P<0.001 by multiple measures ANOVA - at day 3 median -34%, P<0.001 vs baseline by Dunnett's test), persistent up to week 2, with a subsequent progressive raise until week 12; levels comparable to baseline, however, were not attained. CTX showed a marginally significant trend to an early increase (P=0.10 by ANOVA), peaking at day 7 (median +28%, P=0.02 vs baseline by Dunnett's test) and declining thereafter. Consistently, OC/CTX ratio showed a rapid, marked and sustained decrease (P<0.001). Serum OPG showed an early and persistent decrease (P<0.01 by ANOVA - at day 7 median -19%, P=0.03 vs baseline by Dunnett's test). No significant effect of GC therapy was noticed on serum sRANKL, MIF and Dkk-1. Our data indicate that also a regimen of intermediate doses of GCs with rapid tapering down is able to alter in a few days the balance between bone resorption and formation. They lend support to the preventive use of antiresorptive drugs in patients starting such regimens. Less availability of OPG in the bone microenvironment deserves attention among mechanisms accounting for the early increase of bone resorption.

**Impaired Angiogenesis and Compromised Fluid Volume Accompanies Increased Osteoblast and Osteocyte Apoptosis with Glucocorticoid Excess: Interconnected Pathogenetic Changes Responsible for the Loss of Bone Strength.** Q. Liu<sup>\*1</sup>, C. Wan<sup>1</sup>, Y. Wang<sup>1</sup>, E. A. Hogan<sup>\*2</sup>, S. B. Berryhill<sup>\*2</sup>, S. C. Manolagas<sup>2</sup>, T. L. Clemens<sup>1</sup>, R. S. Weinstein<sup>2</sup>. <sup>1</sup>Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Glucocorticoid (GC) excess causes a decline in bone strength that is greater than the loss of bone mass, but the mechanisms behind these phenomena remain unknown. Based on evidence that glucocorticoids may affect blood flow as well as the vasculature itself, we have undertaken in vivo and in vitro studies to elucidate the effects of GCs on bone fluid and vasculature in the mouse and the cellular and molecular mechanism responsible for such effects. After 28 days of administration of prednisolone to 8-month-old C57Bl/6 mice, vertebral and femoral BMD decreased by 4.5-6.6% ( $p < 0.003$ ), osteoblast and osteocyte apoptosis increased by 160-250% ( $p < 0.01$ ), while vertebral compression strength and femoral 3-point bending decreased by 25% ( $p < 0.04$ ). These changes were associated with a striking decrease in interstitial fluid, as determined by 2-dimensional fluorescent imaging of the osteocyte-lacunar-canalicular system using Procion Red-a metabolically inert tracer. Further, prednisolone decreased vertebral vessel volume and surface area by 79-74% ( $p < 0.05$ ), as determined by 3-dimensional microCT imaging following lead chromate perfusion. The changes in fluid and vasculature volume were associated with diminished immunostaining for the endothelial markers CD34 and von Willebrand factor-factor VIII complex in cancellous bone sections. In agreement with the in vivo data, dexamethasone (DEX) (1, 10, 100 nM) impaired endothelial sprouting as assessed by CD31 immunostaining in fetal metatarsals from both wild type mice and mice overexpressing VEGF. Likewise, DEX dose dependently (1 nM-1  $\mu$ M) impaired tube-like structure formation of cultured human umbilical vein endothelial cells (HUVECs). At higher doses (1  $\mu$ M), DEX induced HUVEC apoptosis as determined by increased caspase 3/7 activity ( $p < 0.05$ ). At 10 and 100 nM, DEX decreased BrdU positive cell numbers, while at a low dose (1 nM), modestly increased BrdU positive cell numbers. Collectively, these results strongly suggest that decreased osteocyte-lacunar-canalicular fluid volume, diminished bone vasculature, increased osteoblast and osteocyte apoptosis, and impaired angiogenesis represent interconnected pathogenetic changes that are responsible for the disproportional loss of bone strength over bone mass with glucocorticoid excess.

**Development of Empirical Model Using <sup>41</sup>Ca for the Study of Bone Remodeling in Human.** M. Sharma<sup>\*</sup>, S. K. Hui. Department. of Therapeutic Radiology, University of Minnesota, Minneapolis, MN, USA.

Osteoporotic fractures are a significant public health problem, resulting in substantial morbidity and mortality. Initial studies show that the <sup>41</sup>Ca assay may become useful diagnostic tool for monitoring metabolic bone disease and its treatment management (1, 2). There is lack of empirical model to study the effect of bone loss and antiresorptive therapy on <sup>41</sup>Ca based bone turnover assay. The purpose of this study is to (a) develop a general empirical model that can describe <sup>41</sup>Ca tracer kinetics in human; (b) study its feasibility to monitor metabolic bone disease and (c) monitor response to preventive drugs. A mathematical model has been developed using the Berkeley software to study calcium kinetics and investigate bone turnover. Difference in the contributions of oral and intravenous drug is also taken into account. The rate of bone loss has been parameterized to detect percent change in bone turnover with the severity of disease. The change in <sup>41</sup>Ca/Ca from steady state during metabolic bone disease causing bone loss is calculated over time. Bone dynamics after bisphosphonate drug intervention is simulated and verified. Our model based on four compartments fits well with the available experimental data (1,2). Figure 1 and its inset reflects the bone loss due to severity of disease by urine calcium ratio increase over time compared to the steady state. The relative effect of bisphosphonate intervention at 15% bone loss is shown in Figure 2. Early intervention (day 750) with drug shows early recovery of bone remodeling compared to late intervention (day 880).

The present <sup>41</sup>Ca tracer kinetics model will be a useful tool to understand how <sup>41</sup>Ca assay monitor bone remodeling is affected by disease progression and drug intervention. This may allow better treatment management to prevent bone fracture and will be a useful guide in the use of <sup>41</sup>Ca assay for clinical scenarios.

**Impact of Physical Inactivity (10 Days Bed Rest) on Markers of Bone Turnover in Young Men with Low and Normal Birth Weight.** K. Karnik<sup>1</sup>, D. Talbot<sup>\*1</sup>, J. Dick<sup>\*1</sup>, M. Sonne<sup>\*2</sup>, L. Højbjerg<sup>\*2</sup>, A. Alibegovic<sup>\*3</sup>, B. Stallknecht<sup>\*2</sup>, F. Dela<sup>\*2</sup>, A. Vaag<sup>\*3</sup>. <sup>1</sup>Corporate Research, Unilever plc, Bedfordshire, United Kingdom, <sup>2</sup>University of Copenhagen, Copenhagen, Denmark, <sup>3</sup>Steno Diabetes Centre, Copenhagen, Denmark.

Physical activity plays an important role in maintaining skeletal integrity throughout life. Reduced skeletal loading, as often seen in the elderly as a result of long term bed rest and reduced mobility, has been shown to result in bone loss. It has been proposed that low birth weight is associated with changes in adult body composition including low bone mineral content. In this study, we compare the effect of bed rest for 10 days on the bone turnover markers in young men with low and normal birth weight.

40 healthy men aged 21-28 yrs were recruited in the study, 20 of which were low birth weight (LBW) individuals born at term and 20 were normal birth weight (NBW) individuals born at term. Participants were confined to a hospital bed for 10 days and consumed a standardised diet. At the end of the intervention period, all the participants underwent 4-weeks of rehabilitation training programme under supervision.

At the end of the intervention, serum carboxy-terminal collagen crosslink (CTX) increased by 31.6% in the entire group, which was statistically significant ( $p < 0.0001$ ). The mean percent increase from baseline for serum CTX for the LBW group was 37% and for NBW group was 28%. Although, the differences between LBW and NBW groups for percent change in CTX did not reach the level of statistical significance, there was a trend for higher bone resorption as a result of bed rest in the LBW group. At the end of bed rest period, serum parathyroid hormone decreased significantly ( $p < 0.001$ ) in the entire group. The mean percent decrease was 24% in the LBW group and 23% in NBW group. The difference between the groups was not statistically significant. There was no difference in the levels of serum osteocalcin as a result of bed rest.

These results confirm the detrimental effect of bed rest on the skeletal health as evident by the increase in serum CTX. Our findings also suggest a trend for greater loss of skeleton in the LBW group as a result of bed rest. This particular finding needs to be investigated further with larger number of participants.

**Influence of Markers of Bone Turnover on Calcaneal Quantitative Ultrasound: Results from the European Male Ageing Study (EMAS).** S. R. Pye<sup>\*1</sup>, T. W. O'Neill<sup>1</sup>, H. Borghs<sup>\*2</sup>, D. Vanderschueren<sup>2</sup>, J. E. Adams<sup>3</sup>, K. A. Ward<sup>3</sup>, G. Bartfai<sup>\*4</sup>, F. Casanueva<sup>\*5</sup>, J. D. Finn<sup>\*6</sup>, G. Forti<sup>\*7</sup>, A. Giwercman<sup>\*8</sup>, I. T. Huhtaniemi<sup>\*9</sup>, K. Kula<sup>\*10</sup>, M. Punab<sup>\*11</sup>, A. J. Silman<sup>\*1</sup>, F. C. Wu<sup>\*6</sup>, S. Boonen<sup>2</sup>. <sup>1</sup>ARC Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, <sup>2</sup>Katholieke Universiteit Leuven, Leuven, Belgium, <sup>3</sup>Department of Imaging Science and Biomedical Engineering, The University of Manchester, Manchester, United Kingdom, <sup>4</sup>University of Szeged, Szeged, Hungary, <sup>5</sup>University of Santiago de Compostela, Santiago de Compostela, Spain, <sup>6</sup>Department of Endocrinology, The University of Manchester, Manchester, United Kingdom, <sup>7</sup>University of Florence, Florence, Italy, <sup>8</sup>Lund University, Malmö, Sweden, <sup>9</sup>Imperial College, London, United Kingdom, <sup>10</sup>University of Lodz, Lodz, Poland, <sup>11</sup>University of Tartu, Tartu, Estonia.

The majority of studies on biochemical measurements of bone turnover have focused on women with fewer data in middle aged and elderly men. The aim of this analysis was to characterize the influence of bone markers on calcaneal ultrasound measurements in middle aged and elderly European men. Men aged between 40 & 79 years were recruited from population registers in 8 European centres. Subjects were invited to attend for quantitative ultrasound (QUS) of the calcaneus (Hologic - SAHARA) and a fasting blood sample from which the bone markers serum N-terminal propeptide of type I procollagen (PINP) and crosslinks (-Ctx) were measured. In three of the recruitment centres, osteocalcin (OC) and serum C-terminal telopeptide of type I collagen (ICTP) were also measured. Height and weight were assessed in all subjects. The relationships between QUS parameters (broadband ultrasound attenuation [BUA] and speed of sound [SOS]) and bone markers were assessed using linear regression with adjustments made for age, height, weight and centre. 3136 men, mean age 60.0 years (standard deviation [SD]=11.0) were included in the analysis. Mean BUA was 80.1 dB/MHz (SD=19.0) and SOS 1550.6 m/s (SD=34.1). Mean PINP was 41.6 ng/ml (SD=17.6), OC 22.1 ng/ml (SD=7.1), -Ctx 353.6 pg/ml (SD=181.8) and ICTP 3.2 ng/ml (SD=0.9). There was a significant decrease in OC levels with age ( $\beta = -0.066$ ;  $p < 0.01$ ) and an increase in ICTP ( $\beta = 0.024$ ;  $p < 0.001$ ). PINP and -Ctx were unrelated to age. Higher -Ctx levels were associated with lower BUA ( $\beta = -0.006$ ; 95% CI -0.010, -0.003) and SOS ( $\beta = -0.016$ ; 95% CI -0.022, -0.009). Higher OC levels were associated with lower BUA ( $\beta = -0.159$ ; 95% CI -0.304, -0.014) while higher PINP levels were associated with lower SOS ( $\beta = -0.114$ ; 95% CI -0.180, -0.048). ICTP levels were not associated with either QUS parameter. In this population survey of middle aged and elderly European men, higher levels of bone turnover markers were associated with lower QUS parameters.

**Bone Loss With Smoke Exposure and Lrp5 Expression.** G. K. Alvarez, B. T. Hackfort<sup>\*</sup>, M. P. Akhter, J. A. Yee, D. M. Cullen. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Smoking is a risk for osteoporosis associated with low bone mass and poor fracture healing, but the mechanism for these effects is unknown. This study examined the interaction of Lrp5 receptor (low density lipoprotein like receptor protein) and smoke exposure on bone. Lrp5 is a Wnt co-receptor and the G171V mutation in LRP5 (HBM) is a gain of function mutation with greater WNT/ $\beta$  catenin signaling that results in high bone mass.

We examined bones after 12 wks of smoke exposure in WT (C57Bl6), Lrp5<sup>+/-</sup>, and HBM female (5.3  $\pm$  0.5mo) and male mice. Mice were randomly assigned to control or smoke exposure (3 hrs/d 5 d/wk at 129 $\pm$ 38 mg/mm<sup>3</sup>TSP). Female femora (15/grp) were processed for cortical and cancellous histomorphometry. Measurements included area (total, marrow, bone volume -BV/TV), mineralizing surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS). Male tibiae (8/grp) were cleaned, frozen at -80C, mRNA extracted, and mRNA quantified relative to control (ABI 7500, control GAPDH). Differences due to smoke and genotypes were analyzed by GLM. There were no differences in initial body weight (25  $\pm$  3 g), but controls gained more weight than treated mice by 12 wks. In cortical bone there was no difference due smoke exposure in total area, but marrow area was greater in Wt and HBM mice than control mice (table). Exposure to smoke increased periosteal BFR in the Lrp5<sup>+/-</sup> mice, but not in WT and HBM mice. There were no effects on endocortical BFR. Cancellous BV/TV was significantly lower in HBM mice after smoke exposure, but not in WT or Lrp5<sup>+/-</sup> mice where initial BV/TV was <3%. MS/BS was depressed in WT mice and tended downward in the other genotypes. Osteoclast surface was lower in the HBM animals than the other genotypes, but there was no smoking effect. Analysis of WNT responsive genes showed that Cyclin D1, associated with cell proliferation, was suppressed with smoke exposure in Wt (0.6  $\pm$  0.1) and Lrp5<sup>+/-</sup> (0.7 $\pm$ 0.1) mice, but not HBM mice (1.0  $\pm$  0.1). PTGS2 was elevated in response to smoke exposure in HBM (3.2  $\pm$  1.2), but not in Lrp5<sup>+/-</sup> (1.8  $\pm$  0.8) or WT (0.5  $\pm$  0.1) mice.

Smoke exposure resulted in cortical and cancellous bone loss especially in HBM mice, but HBM cancellous BV/TV remained 10 fold greater than in WT and Lrp5<sup>+/-</sup> bone. Bone turnover reached a steady state after 12 wks of treatment. While the HBM gain of function mutation maintained or increased gene expression for the WNT responsive genes tested, this did not prevent bone loss. \

**Profile Analysis of Rodent Metaphyseal Trabecular Bone Reveals a Biphasic Dose-Dependent Response To Administered Bone Active Agents.** A. Pitsillides<sup>1</sup>, P. L. Salmon<sup>2</sup>, A. Tivesten<sup>3</sup>, S. Moverare-Skrtic<sup>3</sup>, C. Ohlsson<sup>3</sup>, L. Oste<sup>4</sup>, G. Dixon<sup>4</sup>, A. Idris<sup>5</sup>, R. Van T'Hof<sup>6</sup>. <sup>1</sup>Royal Veterinary College, London, United Kingdom, <sup>2</sup>SkyScan, Kontich, Belgium, <sup>3</sup>Sahlgrenska Institute, Goteborg, Sweden, <sup>4</sup>Galapagos plc, Mechelen, Belgium, <sup>5</sup>Molecular Medicine Centre, Edinburgh University, Edinburgh, United Kingdom.

The rodent bones in the vicinity of the knee - the proximal tibia and distal femur - are standard sites for bone morphometric analysis for disease models such as ovariectomy-induced osteoporosis. There are two ways in which the amount of metaphyseal trabecular bone can change: either by a change to the balance of formation and resorption at the surface of the trabecular bone throughout the metaphysis, or, in young rodents, by a change to the rate of output of secondary trabecular bone from the growth plate and primary spongiosa.

Here we review three rodent OVX studies involving ovariectomy and drug treatment of (initially) 2-3 month old rodents, all employing micro-CT imaging. The 3D images of the whole metaphyses are reanalysed to assess the profile of trabecular percent crosssectional area (BA/TA) with increasing distance from the growth plate - the "metaphyseal profile" - in order to elucidate the relative roles of these two above mechanisms in bringing about change in metaphyseal trabecular volume. These studies include treatment with the sex steroids estrogen and testosterone, the bisphosphonate alendronate, PTH and the novel antiresorptive ABD365.

The results suggest a biphasic dose-dependent effect of treatment. Where trabecular volume in OVX rodents is restored by administered treatment to levels similar to or just above sham control levels, the first mechanism is predominant, the alteration of remodeling balance throughout the metaphysis, causing uniform elevation of the metaphyseal profile but no change to its slope. However where a treatment causes trabecular volume to be elevated to a level substantially above sham control levels, an upturn in the metaphyseal profile occurs in the metaphyseal region closest to the growth plate, implicating the additional effect of a second mechanism, that of an increased rate of new trabecular bone output at the growth plate.

Sex steroids and alendronate are both demonstrated to elevate trabecular volume to well above the sham level in a manner involving this latter mechanism. This indicates that even generally anti-resorptive compounds such as the bisphosphonate alendronate, at high enough dose levels, can stimulate increased growth plate formation of trabecular bone.

**Trabecular Bone Loss in Response to Transient Muscle Paralysis Is Not Gender Dependent.** T. S. Gross, S. Srinivasan, B. J. Ausk\*, S. L. Poliachik\*, S. D. Bain. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Whether gender provides systemic influences that significantly impact disuse induced bone loss remains controversial. In general, however, the female skeleton is thought to be more sensitive than the male skeleton to bone loss observed in models such as hindlimb suspension. In this study, we sought to clarify this relation in an in vivo model in which focal osteoclastogenesis is induced by transient muscle paralysis. High resolution (11 micron) microCT images of the proximal tibia metaphysis and lower resolution images of the entire lower limb (21 micron) were obtained for 7 female and 7 male C57B6 mice (16 wk) immediately prior to injection of Botox into the calf muscle group (2U/100 g, d 0). In vivo scans of all mice were also obtained by d 7 and d 15 post post induction of muscle paralysis. Standard image analysis procedures were used to determine trabecular bone parameters within the proximal tibia, while the lower resolution imaging was used to assess soft tissue volume changes. All data were assessed by comparison with time zero data. Lower limb soft tissue volume was significantly decreased by 7 d (F:  $-11.8 \pm 3.5\%$ , M:  $-11.5 \pm 1.9\%$ ) and further decreased by 15 d (F:  $-24.2 \pm 7.3\%$ , M:  $-21.8 \pm 3.5\%$ ; all  $p < 0.01$ ), with no gender based differences. Within 7 d, proximal tibia BV/TV was significantly diminished in both female ( $-61.7 \pm 10.2\%$ ,  $p=0.02$ ) and male mice ( $-44.4 \pm 6.4\%$ ,  $p=0.02$ ). The loss of BV/TV in female mice was significantly greater than that of male mice ( $p=0.03$ ). Further BV/TV degradation was observed by 15 d but the magnitude of bone loss was equal across gender (F:  $-70.2 \pm 9.3\%$ ; M:  $-70.6 \pm 6.9\%$ , both  $p<0.01$ ). At both time points, degraded BV/TV was associated with a significant erosion of trabecular thickness, decreased trabecular number, and increased trabecular spacing. No gender based statistical differences were identified for any of these morphological parameters. In summary, we found that female mice demonstrated a more rapid loss of BV/TV within the first 7 d than male mice, but the extent of bone trabecular degradation was equivalent across gender by 15 d. Whether this transient difference arose due to gender associated levels of basal bone turnover will require further clarification. In our view, the equivalent degradation of muscle volume across gender and equivalent deterioration of trabecular architecture within 15 d suggests that the signaling pathway responsible for rapidly initiating osteoclastogenesis following transient muscle paralysis is the same in females and males. These results also suggest that gender based differences previously observed in other disuse models may be associated with acute osteoblastic responses identified in those models.

**Brain-derived Serotonin Positively Regulates Bone Mass Accrual.** V. K. Yadav\*, F. Oury\*, J. Ryu\*, N. Suda\*, P. Ducy\*, G. Karsenty. Genetics and Development, Columbia University, New York, NY, USA.

Serotonin (5-hydroxytryptamine) is a biogenic amine that functions both as a neurotransmitter in mammalian central nervous system and as a hormone in the periphery where most of (~95%) it is produced. Remarkably serotonin does not cross the blood-brain barrier thus it has potentially two different functions depending on its site of synthesis. Serotonin synthesis is initiated following tryptophan hydroxylation by an enzyme called tryptophan hydroxylase (Tph). Brain-derived serotonin synthesis is initiated by Tph2 and peripheral-derived serotonin is initiated by Tph1. To analyse the spatio-temporal pattern of serotonin expression and the function of brain-derived serotonin on bone mass, we introduced a LacZ allele in the mouse *Tph2* locus by homologous recombination in embryonic stem cells. LacZ staining during embryonic development and postnatally delineated serotonergic neurons in the mouse brain and showed that in the adult, Tph2 neurons are clustered in to six groups in the brain stem, those neuronal groups are known as dorsal, ventral and caudal raphe nuclei. Furthermore, histological analysis of the vertebrae and long bones revealed that *Tph2*-deficient mouse develop a severe low bone mass phenotype early during adult life thus identifying serotonin as the first bona fide neuropeptide regulating bone mass. Histomorphometric analysis revealed that this is due to a decrease in bone formation and an increase in bone resorption. We have also identified through genetic means one of the 14 serotonin receptor that is responsible for the regulation of bone mass. We will present at the meeting the signaling pathway in which brain-derived serotonin acts.

**Kenney-Caffey Syndrome in a Caucasian Man.** P. Tondapu\*, C. V. Odvina<sup>2</sup>. <sup>1</sup>Mineral Metabolism, UT Southwestern Medical Center, Dallas, TX, USA, <sup>2</sup>Charles and Jane Pak Center for Mineral Metabolism, UT Southwestern Medical Center, Dallas, TX, USA.

29 year old white man presented to our Mineral Metabolism Clinic with history of hypocalcemia, hypomagnesemia, short stature and hypoparathyroidism. He was born full term by spontaneous vaginal delivery, weighing 6 lb 11oz. There is no family history of consanguinity. He developed generalized tonic clonic seizures about 1 week after birth and was found to have hypocalcemia. Initial diagnosis was pseudohypoparathyroidism and he was managed with calcium supplements. Subsequent evaluation revealed papilledema. Cranial sutures fused at age 4. At age 12 years and 10 months, he had a bone age of a 14 year old and at age 13 1/2 years; he was -3.14 SD (29kg) for weight and -3.22 SD (134 cm)

for height. Additional work up showed low calcium, magnesium and PTH but normal somatomedin C and IGFBP 3 which ruled out growth hormone deficiency. He has poor vision all his life and is legally blind without glasses but has no hearing problem. When he was seen at our clinic, it was noticed that he has short stature (135 cm), brachydactyly and facial dysmorphism with microcephaly, micrognathia, deep set eyes, hypotelorism, beaked nose and poor dentition with malformed tooth. He has had multiple fractures related to trauma and poor union in one of them. He has not been taking calcium regularly and has had multiple admissions for hypocalcemia. Work up showed normal serum magnesium, low calcium and PTH. Fractional excretion of magnesium was 2.7%, which ruled out renal magnesium wasting as the cause of hypomagnesemia. DEXA scan showed high Z score (+3.2) at the spine and slightly low Z scores at the hip(-0.5) and distal 1/3 of the radius (-1.7). Karyotype is normal male (46XY). Because of the clinical findings, we suspected Kenney-Caffey syndrome and DNA was sent for genetic testing to confirm the diagnosis. Kenney-Caffey syndrome is an extremely rare hereditary skeletal disorder characterized by osteosclerotic bone dysplasia with associated hypocalcemia, dental caries and ocular abnormalities. Kenney-Caffey and related disorder HRD map to 1q42-q43 and are due to mutations in the tubulin specific chaperone E (TBCE) gene, a protein involved in tubulin folding. Most of the cases that had been described in the literature were of Arab decent. To the best of our knowledge, there is only one reported case of this syndrome in a Caucasian patient.

**Bony Symptoms and Vertebral Fractures in Gaucher Disease Type 1. Data from the 105 Patients of the French Observatoire on Gaucher Disease.** R. Javier\*, R. Jaussaud\*, C. Rose\*, P. Chérin\*, E. Noël\*, C. de Roux Serratrice\*, D. Dobbelaere\*, A. Hartmann\*, E. Hachulla\*, B. Grosbois\*, C. Roux\*. <sup>1</sup>Rheumatology, University Hospital, Strasbourg, France, <sup>2</sup>Internal Medicine, Hôpital Robert Debré, Reims, France, <sup>3</sup>Haematology, Hôpital St Vincent de Paul, Lille, France, <sup>4</sup>Internal Medicine, Pitié-Salpêtrière, Paris, France, <sup>5</sup>Internal Medicine, University Hospital, Strasbourg, France, <sup>6</sup>Internal Medicine, Hôpital St Joseph, Marseille, France, <sup>7</sup>Paediatrics, University Hospital, Lille, France, <sup>8</sup>Neurology, Hôpital Pitié-Salpêtrière, Paris, France, <sup>9</sup>Internal Medicine, Hôpital Claude Huriez, Lille, France, <sup>10</sup>Internal Medicine, Hôpital Sud, Rennes, France, <sup>11</sup>Rheumatology, Hôpital Cochin, Paris, France.

**Background/objectives:** Gaucher disease type1 (GD1) is a rare disease with a heterogeneous clinical presentation. A French national prospective registry was implemented to describe the clinical features of adult GD1 patients with focus on bone symptoms and their impact on patients' quality of life.

**Methods:** Clinical data were collected during a routine visit. No additional tests were performed. A specific case report form was designed to guide the physicians.

**Results:** From March 2005 to September 2006, 105 patients were included and represent about one third of the French GD1 population. Mean age (SD) was 45 (14) years (54% female). Early diagnosis (< 1 year after the first signs) was less frequent when first signs are skeletal manifestations (25% vs 47%). 85% of patients had a history of bony symptoms including osteonecrosis in 30 % and 17% of patients had undergone joint replacement at a mean age (SD) of 40 (10) years. Other manifestations are bone infarction 28 %, bone crisis 21 %, peripheral fracture 18 % and vertebral fractures (VF) 15% (to be compared to 9-11% in the literature). Almost all vertebrae can be involved, from T3 to L5, and many patients have 2 to 4 concomitant VF. Most of these VF, even those of grade 3 according to Genant classification, occurred spontaneously or for minimal trauma at a mean age of 43 years (min-max: 29-61). Chronic back pain remained in half of these patients. Of the 64 patients with bone mineral density data available, 44% had osteopenia and 18% had osteoporosis. **Conclusion:** These results illustrate the high frequency of bone fragility in GD1 patients and the frequency of VF. Bone disease remains a major issue in GD1 patients and a multidisciplinary team approach including bone evaluation and specific bone fragility treatment seems essential for optimizing patients' care.

**Age-Related Changes in Bone Mineral Density, Cross-Sectional Area and the Strength of Rat Femur; an Involvement of Suppression of Growth Hormone-IGF-1 Signaling.** M. Tomita<sup>1</sup>, S. Motokawa<sup>\*2</sup>, H. Shindo<sup>\*1</sup>, K. Kumagai<sup>\*1</sup>, I. Shimokawa<sup>\*3</sup>. <sup>1</sup>Orthopedic Surgery, Nagasaki University Graduate School of Medicine, Nagasaki, Japan, <sup>2</sup>Orthopedic Surgery, National Nagasaki Medical Center, Ohmura, Japan, <sup>3</sup>Investigative Pathology, Nagasaki University Graduate School of Medicine, Nagasaki, Japan.

In order to investigate aging-related changes in the bone structure and strength and an involvement of the growth hormone (GH)-insulin-like growth factor (IGF)-1 axis, we examined bone mineral density (BMD), cross-sectional area (Area), and bone strength strain index (SSI) of rat femoral bone by peripheral quantitative computed tomography (pQCT).

**Materials and Methods:** We used wild type (WT) male Wistar rats and the transgenic rat strain (mini), in which GH secretion was suppressed by overexpression of anti-sense GH gene. F1 hybrid rats (F1), which showed intermediate phenotypes in the GH-IGF-1 level and body weight between WT and mini rats, were also used. Rats were sacrificed at 6, 15, and 24 months of age (mo). The cancellous bone parameters of BMD, Area, and SSI were measured at 12mm proximal side from growth plate of distal femur by pQCT.

**Results:** 1) WT showed the highest BMD of total, subcortical bone, and cancellous bone at 6, 15, and 24 mo. F1 showed the intermediate values of BMD between WT and mini rats at 6, 15, and 24 mo. Cancellous bone showed the most apparent age-dependent decrease in all groups.

2) Areas of total, subcortical bone, and cancellous bone at 6, 15, and 24 mo were highest in WT. And F1 showed the intermediate value of those three groups at 6, 15, 24 mo. Area continued to increase between 6 and 24 mo in WT, but in F1 and mini Area it increased from between 6 and 15 mo, but not thereafter.

3) All SSI's (X-, Y-, and polar-) showed almost same age-dependent change as was in Area. WT showed the highest values of SSI in 6, 15, and 24 mo. In WT, SSI continued to increase between 6 and 24 mo, but in F1 and mini, SSI increased between 6 and 15 mo, but decreased thereafter.

**Discussion:** Age-dependent changes were the most obvious in cancellous bone BMD in all groups. Area and SSI showed almost same age dependent-changes but those were different from those of BMD. These data suggested that bone strength correlated not only to BMD, but also Area. Senile bone frailty might cause the changes of bone morphology. Suppression of GH secretion decreased all of BMD, Area, and SSI. GH secretion level plays a role in maintenance of the bone quality during the aging.

**Adult Hypophosphatasia Treatment with Teriparatide.** P. M. Camacho<sup>1</sup>, A. M. Mazhari<sup>\*1</sup>, R. Kadanoff<sup>\*2</sup>. <sup>1</sup>Endocrinology, Loyola University Medical Center, Maywood, IL, USA, <sup>2</sup>Rheumatology, Loyola University Medical Center, Maywood, IL, USA.

Hypophosphatasia is a rare inherited metabolic bone disorder that is characterized by defective bone mineralization due to a deficiency of tissue-nonspecific alkaline phosphatase (TNSALP), which results from a deactivating gene mutation. Inorganic phosphate accumulates extracellularly impairing bone mineralization.

A 68-year-old African-American female was evaluated at the Loyola University Osteoporosis and Metabolic Bone Disease Center in April 2006 for low bone mass and low serum total alkaline phosphatase (AP). She reported a femur fracture at age 27 after a fall and a metatarsal fracture in her 50's. She was treated with prednisone since 2002 (ranging from 10-60 mg/day) for her dermatomyositis. She had a maternal history of fractures. Other medical illnesses included hypertension, Reynaud's, reflux disease and pulmonary fibrosis. The patient was on esomeprazole, ranitidine, methotrexate, tacrolimus (for dermatomyositis), furosemide and calcium carbonate. She had been on ergocalciferol 50,000 international units/wk and oral ibandronate 150 mg for 6 months prior to her initial visit.

The diagnosis of hypophosphatasia was based on the following biochemical findings and clinical history: persistently low AP ranging from 11-20 U/L (30-110 U/L), low bone specific alkaline phosphatase (BSAP) ranging from 2.9-3.4 ug/L (7-22 ug/L), high pyridoxal 5'-phosphate (PLP) 95 ng/mL (5-30 ng/mL) and history of low-trauma fractures. Her baseline urinary N-telopeptide on ibandronate was 32 nm BCE/mm creat (26 - 124). She had a normal serum creatinine, ionized calcium, phosphorus, intact PTH and 25 OH-Vitamin D and 24-urine calcium. Mutation analysis for TNSALP gene is pending.

Her DXA scan in 2005 showed lumbar spine bone mineral density (BMD) of 1.006 gm/cm<sup>2</sup>, T-score -1.6, Z-score -1.4; mean femoral neck BMD of 0.693 gm/cm<sup>2</sup>, T-score -2.9 and Z-score -2.8. There was a significant decline of 14% in the hip and 13% in the spine and compared to the 2003 DXA.

In May 2006, ibandronate was discontinued and four months later, BSAP remained low at 2.9 ug/L. Teriparatide 20 ug subcutaneously was given. BSAP subsequently increased to 5 U/L at 7 months. After 13 months of teriparatide therapy, BSAP increased to 7 U/L, AP increased from 14 to 26 IU/L and PLP decreased from 95 to 78 ng/mL.

Her follow up DXA in October of 2007 (spine BMD 1.012 gm/cm<sup>2</sup>, T-score -1.6 and mean femoral neck BMD 0.714 gm/cm<sup>2</sup>, T-score -2.3) showed stable BMD of the lumbar and femoral neck regions. She did not report any fractures during the treatment period.

Our results showed beneficial effects of teriparatide on adult hypophosphatasia which is similar to two previously reported cases. Teriparatide is a promising agent for this metabolic bone disease.

**Clinical Usefulness of Measurement of Fibroblast Growth Factor 23 (FGF23) in Hypophosphatemic Patients-Proposal of Diagnostic Criteria using FGF23 Measurement.** I. Endo<sup>1</sup>, S. Fukumoto<sup>2</sup>, K. Ozono<sup>3</sup>, N. Namba<sup>3</sup>, H. Tanaka<sup>4</sup>, D. Inoue<sup>5</sup>, M. Minagawa<sup>6</sup>, T. Sugimoto<sup>7</sup>, M. Yamauchi<sup>7</sup>, T. Michigami<sup>8</sup>, T. Matsumoto<sup>1</sup>. <sup>1</sup>Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medical Sciences, Tokushima, Japan, <sup>2</sup>Division of Nephrology & Endocrinology, Medicine, University of Tokyo Hospital, Tokyo, Japan, <sup>3</sup>Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan, <sup>4</sup>Pediatrics, Okayama Saiseikai-Sogo Hospital, Okayama, Japan, <sup>5</sup>Third department of Medicine, Teikyo University School of Medicine, Chiba, Japan, <sup>6</sup>Pediatrics, Chiba University Graduate School of Medicine, Chiba, Japan, <sup>7</sup>Endocrinology/Metabolism and Hematology/Oncology, Shimane University School of Medicine, Shimane, Japan, <sup>8</sup>Bone and Mineral Research, Osaka Medical Center for Maternal and Child Health, Osaka, Japan.

Fibroblast growth factor 23 (FGF23) plays central roles in the development of hypophosphatemic diseases such as tumor-induced osteomalacia (TIO) and X-linked hypophosphatemic rickets/osteomalacia (XLH). However, clinical usefulness of FGF23 measurement has not been established. The objective of this study is to validate FGF23 measurement and establish diagnostic criteria for these diseases. In this cross-sectional study, we examined serum intact-FGF23 concentrations by two-site IRMA (Kainos, Japan) and other biochemical parameters of phosphate metabolism in 32 patients with TIO, 28 patients with XLH and 16 hypophosphatemic patients with other causes including vitamin D deficiency, Fanconi's syndrome and Cushing's syndrome. These patients were recruited by questionnaires to members supported by grants from Research on Measures for Intractable Diseases by Japanese Ministry of Health, Labor and Welfare. In patients with TIO, serum phosphate was 1.67 +/- 0.08 mg/dl with severely suppressed TmP/GFR (1.24 +/- 0.08) and high FGF23 (1149 +/- 541 pg/ml). In patients with XLH, basically the same findings were observed with serum FGF23 being 155 +/- 30 pg/ml. FGF23 was above the upper limit of the reference range in most patients even under medical treatment with active vitamin D3 and/or phosphate. The lowest FGF23 in these patients was 38.0 pg/ml. In contrast, FGF23 in hypophosphatemic patients with other causes was undetectable in 12 out of 16 patients and the highest FGF23 in this group was 23.9 pg/ml. These results clearly indicate that FGF23 measurement is useful for the differential diagnosis of hypophosphatemic diseases caused by excess FGF23 actions and other etiologies. We propose that the intact FGF23 of more than 30 pg/ml in hypophosphatemic patients indicates the presence of diseases caused by FGF23.

**Vitamin D Deficiency in Inner City Infants: Impact of DBP Genotype.** T. O. Carpenter<sup>1</sup>, J. H. Zhang<sup>\*2</sup>, F. Herreros<sup>\*1</sup>, E. Torrealba-Fox<sup>\*1</sup>, C. Simpson<sup>\*3</sup>, M. Savoye<sup>\*1</sup>, N. Held<sup>\*1</sup>, B. Ellis<sup>\*1</sup>, D. E. C. Cole<sup>4</sup>. <sup>1</sup>Pediatrics (Endocrinology), Yale University School of Medicine, New Haven, CT, USA, <sup>2</sup>The Cooperative Studies Program Coordinating Center, VA Connecticut Healthcare System, West Haven, CT, USA, <sup>3</sup>Internal Medicine, Yale University School of Medicine, New Haven, CT, USA, <sup>4</sup>Laboratory Medicine and Pathobiology, Medicine, and Genetics, University of Toronto, Toronto, ON, Canada.

The prevalence of nutritional rickets is not known but is thought to occur more frequently in northern latitudes and in urban settings. Biochemical abnormalities are detectable before overt skeletal disease is seen. To ascertain risk for development of nutritional rickets in a northern latitude urban environment, we sampled over 500 healthy infants (6 mos - 3 yrs old) during well-child visits to neighborhood clinics in our area. Demographics and detailed diet histories (3 separate 24-hr recall interviews) were obtained. Serum Ca (10.1 ± 0.5 mg/dl), P (5.4 ± 1.7 mg/dl), alkaline phosphatase (AP, 322 ± 453 IU/L), PTH 22 ± 19 nEq/ml, 25-OHD (25D, 27 ± 6 ng/ml), and 1,25(OH)2D (1,25D, 66 ± 24 pg/ml) were measured and genotypes for VDR, TRPV6, and DBP were analyzed. Average daily intakes of calcium (745 ± 299 mg), phosphate (772 ± 280 mg), and protein (39 ± 15 g) were calculated (NDS, U. Minn.).

Prevalences of hypovitaminosis D (25D < 20 ng/ml), hyperparathyroidism, and elevated AP were 12.9%, 24.4%, and 12.6 % respectively. 3.5% of subjects had elevations in both PTH and AP. 25D correlated negatively with PTH (R = -0.098, P = 0.02), but not significantly with AP. In patients with normal PTH, 25D was 27 ± 6 ng/ml. In a preliminary genetic analysis, DBP D432E genotype correlated closely with both 25D (levels lowest in DD genotype, which was less than DE, which was less than EE, P = 0.003) and 1,25D (highest in DD, which was greater than DE and EE, P = 0.02). T436K also correlated with 25D (levels in TT greater than TK and KK, P = 0.018) and 1,25D (TT greater than TK,

which was greater than KK,  $P = 0.037$ ). Multivariate regression adjusting for age and season indicates that both DBP loci are significant ( $P < 0.002$ ) predictors of 1,25D, while D432E is the stronger predictor ( $P = 0.02$ ) of 25D. Analysis of VDR and TRPV6 genotypes were unrevealing.

This study suggests a lower than expected "risk" for rickets based on the limited number of combined biochemical abnormalities observed. These data provide useful population reference data for 25-OHD levels in the pediatric population where vitamin D deficiency is often suspected, and for which age-specific normative data is rarely provided for interpretation. Finally there is a significant dependence of both 25D and 1,25D levels on DBP genotype. DBP genotype may impact the interpretation of 25D level as an index of total body vitamin D stores in this population.

**A Novel Hypothesis Explains the Syndrome of Chronic Musculoskeletal Pain and Comorbid Painful Healed Fracture Sites in Vitamin D Deficiency.** T. R. Roesel. Deployment Health Clinical Center, Walter Reed Army Medical Center, Washington, DC, USA.

Vitamin D deficiency was found in 93% of 150 patients from the general population with chronic musculoskeletal pain (Plotnikoff, Mayo Clin Proc. 2003; 78:1463). A retrospective chart review revealed vitamin D deficiency in nearly half (49%) of 61 service members with chronic pain who returned from Iraq and Afghanistan (Roesel, J Occ Environ Med. 2008, in press). Service members were referred over an 18 month period from March 2005 until September 2006 to a program for graded exercise and cognitive behavior therapy, and were screened for vitamin D deficiency. Referral was for treatment of post traumatic stress disorder or multiple unexplained physical symptoms. Vitamin D deficiency was defined as  $<20$  ng/ml. Five of these veterans with chronic musculoskeletal pain and vitamin D deficiency had healed, but still painful, deployment-related fracture sites. Holick (Mayo Clin Proc. 2003 Dec; 78(12):1457) has proposed that vitamin D deficiency associated bone and muscle pain is generated by inadequate mineralization of the endosteal and periosteal bone matrix leading to matrix swelling that stimulates periosteal nerve pain fibers. Since service members also revealed concomitant chronic widespread musculoskeletal pain beyond the localized bone injury, a new alternative and augmentative hypothesis is hereby proposed to explain the phenomenon of chronic pain in the presence of vitamin D deficiency. Recent identification of vitamin D receptors in the hypothalamus and amygdala by Eyles et al. (J Chem Neuroanat. 2005; 29:21), suggests that vitamin D deficiency may impair known descending pain inhibitory pathways that regulate the peri-aqueductal grey matter, which in turn controls ascending pain signals travelling through the spinothalamic tract. Thus, the localized chronic bone pain at the fracture site, as well as the co-morbid chronic musculoskeletal pain beyond the fracture site, can be explained through vitamin D deficiency through these two mechanisms, one at the healed fracture site, and the other within the central nervous system. Anecdotal improvement in generalized and local pain seen with supplementation suggests that further studies are needed to determine to what extent vitamin D supplementation prevents or ameliorates chronic generalized musculoskeletal pain and localized pain at healed fracture sites in this newly defined syndrome.

**Large Collaborative Study on Geographic Variation of SQSTM1 Mutations in Paget's Disease of Bone in Italy.** L. Gennari<sup>1</sup>, F. Gianfrancesco<sup>\*2</sup>, M. Di Stefano<sup>\*3</sup>, D. Rendina<sup>\*4</sup>, D. Merlotti<sup>1</sup>, T. Esposito<sup>\*2</sup>, V. De Paola<sup>1</sup>, A. Aloia<sup>\*2</sup>, G. Martini<sup>1</sup>, M. Mazzetti<sup>\*3</sup>, S. Gallone<sup>\*5</sup>, I. Rainero<sup>\*5</sup>, L. Pinessi<sup>\*5</sup>, G. Isaia<sup>3</sup>, P. Strazzullo<sup>\*4</sup>, R. Nuti<sup>1</sup>, G. Mossetti<sup>\*4</sup>. <sup>1</sup>Internal Medicine, Endocrine-Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy, <sup>2</sup>Institute of Genetics and Biophysics, CNR, Naples, Italy, <sup>3</sup>Internal Medicine, University of Turin, Turin, Italy, <sup>4</sup>Clinical and Experimental Medicine, Federico II University of Naples, Naples, Italy, <sup>5</sup>Neuroscience, University of Turin, Turin, Italy.

Paget disease of bone (PDB) is a chronic disease of the skeleton with a consistent genetic component. The geographic distribution of PDB is not uniform, with a higher prevalence of the disease in populations of British descent. Moreover increased prevalence areas have been described in different Countries. We recently characterized an area of increased prevalence of PDB in the region of Campania, in Southern Italy. Patients from this region also showed increased severity of disease with peculiar phenotypic characteristics and an increased number of familial cases. In this study we examined the clinical characteristics, and the prevalence and type of SQSTM1 mutations in a large sample of 542 unrelated PDB subjects from several regions including 164 patients from Campania. Nine different mutations in SQSTM1 gene were observed in 35.2% and 11.3% of familial and sporadic PDB cases, respectively (equivalent to 15.6% of the overall cohort). Five of these mutations, M401V, A427D, G425E, Y383X and 1224-1226 insT leading to E396X were novel and have not been previously described. The other mutations, P387L, P392L, M404V and G425R have been previously described. An higher prevalence

of SQSTM1 mutations was observed in polyostotic than monostotic cases (7% vs 22%;  $p < 0.005$ ). The distribution of mutations in this sample was more heterogeneous than in other countries, with a significantly increased prevalence of the M404V. In keeping with previous studies, the P392L was however the most common observed mutation in both sporadic and familial cases. Genotype-phenotype analysis confirmed an increased severity of disease and an earlier age of onset in mutations that insert a stop codon. Interestingly, in PDB subjects from Campania a different distribution and a significantly reduced prevalence of mutations was observed with respect to the other regions, despite an increase in disease severity and the higher prevalence of familial cases. In particular, in this region less than 20% of familial PDB had SQSTM1 mutation, as compared to 36-50% in the other regions. This might imply the presence of mutations in different genes as well an increased persistence of a possible environmental trigger, or both these conditions.

**Archaeological Skeletons Support a North-West European Origin for Paget's Disease of Bone.** S. Mays. English Heritage, Portsmouth, United Kingdom.

Although the aetiology of Paget's disease of bone (PDB) remains incompletely understood, it seems clear that there is a strong genetic predisposition. This, coupled with the marked geographic variation in prevalence of PDB, with high prevalences in populations of British origin, has led to the suggestion that the disease originated in Britain and was spread around the world by migration and admixture of British populations(1). The aim of the current work is to investigate this suggestion using the geographical distribution of PDB cases in skeletons excavated from archaeological sites.

The methodology for the study is meta-analysis of the world literature on PDB in archaeological skeletons published from 1889 to the present. Re-evaluation of published work indicates that many dubious archaeological cases of PDB have entered the literature, and have been treated in previous reviews as though they were good data. For diagnosis of PDB in archaeological cases to be reliable it needs to be based on currently acceptable radiographic and/or histological criteria. Published examples, and unpublished cases known to the author, that met these criteria were included in the current study.

Using these criteria, 109 archaeological cases of PDB were identified (table 1). The sex ratio was 2.4: 1 in favour of males. The earliest known cases date from the time of the Roman Empire (1<sup>st</sup>-4<sup>th</sup> cent. AD). No cases were identified outside western Europe. Ninety-four percent of cases came from England. The British cases show no particular geographical distribution; the largest numbers of cases come from London but this simply reflects the large number of archaeological skeletons excavated there.

Country	Males	Archaeological cases of PDB		TOTAL
		Females	Unstated sex	
France	1	1	0	2
Germany	0	0	3	3
Portugal	1	0	0	1
England	49	20	34	103
TOTAL	51	21	37	109

The results indicate that PDB has existed in western Europe for at least 2000 years. The concentration of archaeological cases of PDB in western Europe, and in Britain in particular, supports the hypothesis that PDB originated in that geographical area.

**Efficacy and Safety of Intravenous Zoledronic Acid in the Treatment of Patients with Resistant Paget's Disease of Bone.** J. R. Tucci, Medicine, Roger Williams Medical Center, Providence, RI, USA.

Though responses have been seen in many of our patients with Paget's disease (PD) treated with several potent bisphosphonates, not infrequently, remissions and especially sustained remissions have not been induced. Two recent reports have described greater efficacy and more sustained remissions following zoledronic acid (ZA) as compared with risedronate. Objectives of this study were to determine 1) the efficacy of ZA in patients with PD who had not had a remission or had had a relapse within a year of therapy with other bisphosphonates, 2) the duration of remissions, and 3) the safety of ZA. Inclusion criteria include serum alkaline phosphatase (AP) at least 50% greater than the upper limit of normal and creatinine clearance of  $\geq 35$  ml/min. Six females and 6 males, mean age 78 years, were studied. At baseline, blood chemistry profile, serum 25-OHD, and urine NTx/creatinine (NTx) were obtained. Patients were supplemented with up to 1.5 g of Ca and at least 600 units of vitamin D daily. Patients received an infusion of 5 mg of ZA. 9 to 11 days later, serum Ca levels were measured. AP and NTx were measured at 1, 3, 6, 9, and 12 months and subsequently at 4 monthly intervals. Results: At baseline, serum Ca, phosphate, and 25-OHD levels were within normal limits. Mean creatinine clearance was  $64 \pm 3$  ml/min. Following therapy, 3 patients had mild flu-like symptoms. Nine to 11 days after therapy, mean serum Ca fell from  $9.5 \pm 1.1$  to  $8.9 \pm 1.2$  mg/dl. Two patients developed asymptomatic hypocalcemia with serum Ca of 8 mg/dl and 8.3 mg/dl. Excess AP levels fell by 72-100% in the 12 patients. AP normalization occurred in 11 patients and in all but one patient within 1 to 6 months. Normalization of NTx was evident in these 11 patients and in 10 within 1 month. The following data in 11 patients in remission (mean  $\pm$  SE):

	preRx	1 mo	3 mos	6 mos	9 mos	12 mos	16 mos	Normal Range
AP	321 $\pm$ 65	166 $\pm$ 21	92 $\pm$ 7	80 $\pm$ 7	77 $\pm$ 7	81 $\pm$ 6	84 $\pm$ 8	25-100
NTx	247 $\pm$ 47	32 $\pm$ 8	37 $\pm$ 10	32 $\pm$ 7	37 $\pm$ 9	33 $\pm$ 5	46 $\pm$ 12	19-66

At 16 months, AP and NTx remain normal in 9 patients. At baseline and 6 months, serum 25-OHD levels were  $34 \pm 0.9$  ng/ml and  $33 \pm 1.5$  ng/ml, respectively, and at baseline and 12 months, creatinine clearances were  $64 \pm 3.4$  ml/min and  $68 \pm 5.5$  ml/min, respectively. In summary, in 12 patients with suboptimal responses to previous bisphosphonate therapy, ZA induced a response in all 12 patients with remissions in 11 patients that are continuing at 16 months in 9 patients. Adverse effects were flu-like symptoms in 3 patients and asymptomatic hypocalcemia in 2 patients. These observations in a selected group of patients with resistant PD treated with ZA demonstrate early suppression of pagetic activity, a continuing remission at 16 months in 9 of 12 responders, good tolerability and renal safety.

**Comparison of Intravenous and Intramuscular Neridronate Regimens for the Treatment of Paget's Disease of Bone.** D. Merlotti<sup>1</sup>, D. Rendina<sup>\*2</sup>, G. Mossetti<sup>\*2</sup>, L. Gennari<sup>1</sup>, V. De Paola<sup>1</sup>, G. De Filippo<sup>\*2</sup>, G. Martini<sup>1</sup>, A. Avanzati<sup>\*1</sup>, P. Strazzullo<sup>\*2</sup>, R. Nuti<sup>1</sup>. Internal Medicine, Endocrine-Metabolic Clinics and Biochemistry, University of Siena, Siena, Italy, <sup>2</sup>Department of Clinical and Experimental Medicine, Federico II University of Naples, Naples, Italy.

Aminobisphosphonates represent the most common treatment for Paget's disease of bone (PDB), with the potential for sustained remission. Intravenous regimens with different compounds demonstrated improved efficacy and compliance with respect to oral regimens. In a recent study we demonstrated that either zoledronate (4 mg) and neridronate (200 mg) given as a single intravenous infusion showed a similar efficacy in achieving biochemical remission at 6 and 12 months in up to 90% of patients non-responders to pamidronate. In this study we compared the effects of a same neridronate dose (200 mg) given as intravenous (i.v.) (100 mg infusion over a 2-hours period for 2 consecutive days) or intramuscular (i.m.) (25 mg once a week for 1 month) regimen in 56 patients with active PDB. Randomization was stratified according to baseline total alkaline phosphatase (ALP) levels and previous bisphosphonate treatment. All patients were advised to receive calcium plus vitamin D supplementation throughout the study period (1 g of calcium and 800 UI colecalciferol per day). Blood samples were collected at baseline and after 3, 6, and 12 months. The primary efficacy end-point was the rate of therapeutic response at 6 months, defined as normalization of ALP levels or a reduction of at least 75% in total ALP excess. Serum levels of bone ALP, C-terminal telopeptides of Type I collagen, and 25-hydroxyvitamin D (25 OH-D) were also measured. A significant 40-50% decrease in ALP levels was observed with both regimens after 3 months. At 6 months, 92% and 96% of patients receiving i.v. and i.m. neridronate, respectively had a therapeutic response. Normalization of ALP levels at 6 months was achieved in 89% of patients in i.v. group and in 93% of patients in i.m. group. Interestingly, the response to treatment was significantly correlated with baseline ALP and 25 OH-D levels at 6 months. The decrease in ALP levels was highest in patients with higher baseline total or bone specific ALP levels and with higher 25 OH-D levels at 6 months. Normalization in ALP levels was maintained at 12

months in 22/27 (81.5%) and 24/29 (83%) of patients, in i.v. and i.m. neridronate groups, respectively. Both regimens were well tolerated. The only side effect was an acute phase response, occurring in 11-13% of the patients. In conclusion, both i.m. and i.v. neridronate regimens (at a cumulative dosage of 200 mg in 12 months) showed a similar efficacy in achieving biochemical remission in up to 90% of patients with active PDB.

**Usefulness of *HRPT2* Gene and Parafibromin Studies in Two Patients with Primary Hyperparathyroidism and Uncertain Pathological Assessment.** C. Marcocci<sup>1</sup>, E. Pardi<sup>\*1</sup>, E. Ambrogini<sup>\*1</sup>, C. Banti<sup>\*1</sup>, S. Borsari<sup>\*1</sup>, P. Viacava<sup>\*2</sup>, A. Pinchera<sup>\*1</sup>, F. Cetani<sup>\*1</sup>. <sup>1</sup>Endocrinology, University of Pisa, Pisa, Italy, <sup>2</sup>Oncology, University of Pisa, Pisa, Italy.

*HRPT2* and parafibromin studies improved the diagnostic accuracy in two patients with primary hyperparathyroidism (PHPT) referred to us after parathyroidectomy, in whom the clinical data were at variance with the pathological diagnosis of adenoma and carcinoma, respectively. Patient #1 had had a 1.5-cm tumor easily removed with a histological diagnosis of parathyroid carcinoma and normocalcemia for 2 years. Re-examination of the histology showed no cardinal signs of parathyroid cancer. Patient #2, with severe PHPT, had had the removal of a 3.5-cm tumor described histologically as adenoma. Ten years later PHPT recurred and persisted despite removal of two parathyroid glands that were normal by routine histological examination. Re-review of the initial histology showed a trabecular pattern, fibrous bands, and atypical mitoses, suggesting an atypical adenoma. Because of the suspicion that case #1 could be an atypical adenoma and case #2 a carcinoma further molecular studies were performed. No *HRPT2* and parafibromin abnormalities were identified in patient #1, strongly indicating a benign lesion. In patient #2, an *HRPT2* germline mutation was found (E115X in exon 4) and associated with no parafibromin staining. These data, together with the clinical features, supported the suspicion of a parathyroid carcinoma that was confirmed by histological examination of further slides of the tumor, showing capsular and vascular invasion. A lung 1.5-cm nodule detected by CT was excised. Histology showed a metastasis of parathyroid carcinoma. *HRPT2* gene studies may be of clinical utility in the management of patients with parathyroid tumors of uncertain pathology.

**Low Density Lipoprotein-Cholesterol Levels Affect Vertebral Fracture Risk in Female Patients with Primary Hyperparathyroidism (pHPT).** H. Kaji<sup>1</sup>, I. Hisa<sup>\*1</sup>, Y. Inoue<sup>\*1</sup>, T. Sugimoto<sup>2</sup>. <sup>1</sup>Kobe University Graduate School of Medicine, Kobe, Japan, <sup>2</sup>Shimane University Faculty of Medicine, Izumo, Japan.

Patients with pHPT have reduced bone mineral density (BMD) with enhanced bone turnover. The risk of vertebral and forearm fractures are increased in pHPT patients. Although several reports indicated that increased arterial stiffness and dyslipidemia were observed in pHPT patients, it still remains unclear about the relationships between lipid and bone metabolism in pHPT patients, especially about fracture risk. The present study was performed to examine the relationship between lipid metabolism parameters including body composition and bone metabolism in 116 female patients with pHPT and 116 age-matched control subjects. BMD and body composition were measured by dual-energy x-ray absorptiometry. Serum levels of total cholesterol (T-Chol) and high density lipoprotein-cholesterol (HDL-Chol) as well as albumin (Alb) were significantly lower in pHPT group, compared with those of control group. Fat mass (FM) and lean body mass (LBM) as well as % fat were similar in both groups. Serum levels of all parameters (T-Chol, LDL-Chol, TG and HDL-Chol) were not significantly related to serum levels of calcium and PTH as well as bone metabolic indices. As for BMD parameters, only serum LDL-Chol levels were significantly and negatively related to z-score of BMD at femoral neck, but not those of BMD at lumbar spine and radius. FM was positively related to Z-score of BMD at lumbar spine and femoral neck. On the other hand, LBM was negatively related to serum levels of PTH and bone resorption indices and positively to Z-scores of BMD at all. Serum levels of T-Chol and LDL-Chol were significantly lower in the group with vertebral fractures, compared with the group without vertebral fractures, in only pHPT patients. Serum levels of HDL-Chol, TG and Alb as well as body composition parameters were not significantly different between the groups with and without vertebral fractures in both control and pHPT groups. In a univariate logistic regression analysis, age, height, BMD at lumbar spine and radius, serum levels of creatinine, T-Chol and LDL-Chol were selected for the predictors of vertebral fracture risk. Multiple logistic regression analyses suggest that the relationship between LDL-Chol and vertebral fractures was independent of these parameters. In conclusion, the present study demonstrated that lower serum LDL-Chol levels were related to vertebral fracture risk independently of renal function, age, body size index, BMD, bone turnover and serum levels of Ca, PTH, Alb in pHPT women. Increased LBM seemed to be protective for osteopenia induced by pHPT.

**Normocalcemic Primary Hyperparathyroidism: Update on a New Clinical Phenotype.** H. Lowe\*, D. J. McMahon, M. D. Walker, M. Rubin, J. P. Bilezikian, S. J. Silverberg. College of Physicians & Surgeons, Columbia University, New York, NY, USA.

Patients with elevated parathyroid hormone (PTH) and consistently normal serum calcium levels in whom secondary causes of high PTH have been excluded may represent the earliest presentation of primary hyperparathyroidism (PHPT). We update data on 37 patients (mean age 59 yrs, range 32-78; 95% female) with normal corrected serum calcium ( $9.6 \pm 0.1$  mg/dl; nl: 8.6-10.4) and elevated PTH ( $93 \pm 5$  pg/ml; nl: 10-65) levels. All patients had 25(OH)vitamin D levels  $>20$  ng/dl, 24 hr urinary calcium (Uca)  $<350$  mg/d, normal renal, hepatic, and thyroid function, and no malabsorption. Classical features of PHPT included a history of kidney stones in 5 (14%), and fragility fractures in 4 (11%). In 11 subjects (30%), 1,25(OH)<sub>2</sub>D levels were elevated, while 7 (18%) had high Uca. BMD did not show evidence of preferential bone loss at the more cortical distal 1/3 radius (LS T-Score:  $-2.03 \pm 0.25$ ; FN T:  $-1.84 \pm 0.18$ ; RAD T:  $-1.74 \pm 0.22$ ). Osteoporosis (OP; found in 59%, n=22 patients) was more common at the LS (38%) and FN (41%) than at the RAD (22%).

Patients were followed for  $4 \pm 0.3$  yrs (1-9 yrs), during which 8 subjects (22%) became frankly hypercalcemic. Those who developed hypercalcemia were older ( $64 \pm 2$  vs.  $57 \pm 2$ ,  $P=0.02$ ) and had higher baseline serum calcium levels ( $9.9 \pm 0.2$  mg/dl vs.  $9.5 \pm 0.1$ ,  $P<0.001$ ). Seven patients (5 normocalcemic) developed NIH surgical criteria for hypercalcemic PHPT: marked hypercalciuria in 3; recurrent kidney stone in 1; traumatic fracture in 1; new OP in 4. Repeat BMD testing (n=33) demonstrated that 51% lost  $\geq 5\%$  and 33% lost  $\geq 10\%$  BMD at  $\geq 1$  skeletal sites, with similar declines seen at all sites. Osteoporosis at baseline did not predict who would lose  $\geq 10\%$  BMD (with OP: 7/22, 32%; no OP: 4/15, 27%). Significant bone loss, new OP or new kidney stone developed in 15/37 (40%).

Sestamibi scans were positive in 13/21 cases. Ten patients had successful PTX: 5 hypercalcemic and 5 normocalcemic patients with NIH surgical criteria: kidney stones (n=1), OP (n=4). Pathology in normocalcemic patients showed adenoma (n=2) and hyperplasia (n=3), while hypercalcemic patients had single adenoma (n=3), double adenoma (n=1) or hyperplasia (n=1). One yr post-PTX BMD rose 5% at LS, but was unchanged at FN and RAD.

In summary, these patients with normocalcemic PHPT do not have the typical profile of hypercalcemic PHPT. They present with more signs and symptoms, and develop more complications over time. Despite this,  $>75\%$  of patients remain normocalcemic. There are no predictors of the timing or onset of hypercalcemia. We conclude that these patients do not represent emerging asymptomatic PHPT. Instead they may be an early presentation of a more symptomatic variant of PHPT, some of whom may never become hypercalcemic.

**Antioxydants (Phytoestrogens and Quercetin) Are Potentials Agents Against Rheumatoid Arthritis.** I. Henry-Desailly\*<sup>1</sup>, E. Flipo\*<sup>2</sup>, P. Lefauveau\*<sup>1</sup>, D. Ursu\*<sup>1</sup>, C. Benneteau-Pelissero\*<sup>3</sup>, S. Kamel\*<sup>4</sup>, M. Brazier\*<sup>4</sup>, P. Fardellone\*<sup>2</sup>. <sup>1</sup>Rheumatology, University Hospital, Amiens, France, <sup>2</sup>Rheumatology - Inserm Eri12, University Hospital, Amiens, France, <sup>3</sup>ENITA, Bordeaux, France, <sup>4</sup>Inserm eri12, Faculty of Pharmacy, Amiens, France.

**Objective:** To estimate the influence of alimentary phytoestrogens and quercetin alimentary intake on rheumatoid arthritis (RA).

**Methods:** We performed a case control study comparing 30 women having Rheumatoid Arthritis with 30 controls women matched on BMI and age, (between 45 to 65). The flavonoids exposure was assessed by biological dosages in plasma (pl) and urines (u) by an ELISA immuno-assay (genistein, daidzein, equol) and by liquid chromatography-mass spectrometry (quercetin).

Some patients were excluded if under medical condition (like pregnancy or hormonal dependent cancers,) or treatments (oral contraceptive, hormonal replacement for menopause) which could influence their hormonal status.

We compared the means of phytoestrogens concentration in plasma and urines of the two groups, using matched controls "t" test after log-transformation.

**Results:** Phytoestrogens and quercetin concentrations according to the two groups are shown in the table.

Phytoestrogens and Quercetine (ng/ml)	RA Mean (SD)	Controls Mean (SD)	P
Genistein (u)	225.0 (582.0)	178 (501,4)	0.135
Genistein (pl)	20.9 (83.8)	70,3 (262,3)	0.778
Daidzein (u)	677.7 (1619.7)	359 (786,6)	0.144
Daidzein (pl)	16,4 (57.6)	31.5 (112,2)	0.752
Equol cor (u)	10.7 (33.8)	48,2 (108,4)	<b>0.029</b>
Equol cor (pl)	0.83 (3.7)	0.87 (3,4)	0.991
Quercetine (u)	19,02 (2,05)	18,2 (2,9)	0.530
Quercetine (p)	7,2 (3,2)	10,8 (4,2)	<b>0.038</b>

Equol in urines and quercetin in plasma are the only flavonoids for which we observed a significant difference between the two groups Equol u ( $p=0.029$ ) and Quercetin pl ( $p=0.038$ ).

Equol is chemically unique among the isoflavone, it is the major metabolite of the phytoestrogen daidzein. This phytoestrogen has one of the strongest estrogen activity and could interact with the immunologic system.

Quercetin, flavonol widely distributed in plants has antioxidant properties with antiproliferative, anti-inflammatory and immunosuppressive activities.

**Conclusion:** Our results suggest that equol and quercetin have a protective effect toward the onset of Rheumatoid Arthritis, thanks to their antioxidants and anti-inflammatory properties.

**The Association Between Several Factors Affecting Aortic Calcification and Bone Mineral Density In Postmenopausal Women.** W. H. Choi, H. Han\*, S. M. Hong\*, Y. H. Ahn\*. Endocrinology, Hanyang University, Seoul, Republic of Korea.

**Background:** Aortic calcification increases with age and several epidemiologic studies shows that it is linked to cardiovascular mortality such as myocardial infarction and stroke. Elderly person whose degree of aortic calcification increases greater tends to lose more bone than those whose gain for aortic calcification is minimal. Osteoclastic potential is greater in preosteoclasts from bone marrow in hyperlipidemic compared with normal mice. Therefore we are to evaluate the factors that contributes to vascular calcium accumulation and the association between Lipid profile and bone mineral density(BMD)

**Methods:** Postmenopausal women who visited the health promotion center at Hanyang Univ. hospital from Jan 2003 to Sep 2007 have taken baseline checkup including history taking, physical examination, and blood sampling. Lumbar spinal and femoral BMD was measured by dual energy X-ray absorptiometry(DXA). The presence of aortic calcification was identified by Abdominal CT. According to the extent of sum of aortic calcification observed in all cross sectional area, all patients were divided to 3 groups: None(No calcification), Mild to moderate( $0-180^\circ$ ), Severe( $180-360^\circ$ )

**Results:** Patients with aortic calcification had significantly lower BMD than those without aortic calcification. High triglyceride and low HDL cholesterol was significantly associated with aortic calcification. Diabetic patients had a higher incidence of aortic calcification than non-diabetic patients(83% vs 49%;  $P$  value $<0.01$ ), and they had significantly higher triglyceride and lower HDL cholesterol levels than non-diabetic patients. As the degree of aortic calcification increases, BMD especially femoral BMD tends to decreases. However, none of the lipid profiles was significantly correlated with BMD.

**Conclusion:** There is a reciprocal relationship between degree of aortic calcification and bone mineral density. Among other cardiovascular risk factors, DM is a potent risk factor for aortic calcification. In addition to metabolic stress induced by hyperglycemia, Dyslipidemia may contribute to vascular calcium accumulation. Although dyslipidemia including high TG and low HDL is significantly associated with aortic calcification, there is no meaningful correlation between serum lipid level and BMD.

### Elevated Serum Ionic Fluoride Levels in Post-menopausal Women is Due to the Enhanced Release of Fluoride from Bone. K. Itai<sup>\*1</sup>, M. Ohsawa<sup>\*1</sup>, K. Tanno<sup>1</sup>, T. Onoda<sup>\*1</sup>, T. Sato<sup>\*1</sup>, T. Kuribayashi<sup>\*1</sup>, K. Sakata<sup>\*1</sup>, A. Okayama<sup>\*2</sup>.

<sup>1</sup>Hygiene and Preventive Medicine, Iwate Medical University, Morioka, Japan, <sup>2</sup>The First Institute of Health Service, Anti-Tuberculosis Association, Tokyo, Japan.

Serum ionic fluoride (SIF) levels may reflect changes in bone metabolism along with osteoporosis, especially in the middle-aged and elderly post-menopausal women. However, useful references of age-specific SIF levels and the confounding factors significantly associated with SIF levels have not been fully elucidated in a general population. The purpose of this study is to determine sex- and age-specific mean levels of SIF and to estimate confounding factors associated with SIF levels. A total of 332 participants (167 men and 165 women) were enrolled. Fasting blood samples were collected from all participants. SIF levels were measured by the flow injection method with an ion selective electrode as a detector. A multiple regression analysis was performed to determine confounding factors associated with SIF levels. Participants were divided into sex- and age-specific groups and multivariate-adjusted SIF levels were compared between the groups using ANCOVA after adjustment for the associated factors separately by sex. The crude means of SIF levels ( $\mu\text{mol/l}$ ) were 0.495 in men and 0.457 in women, respectively. Crude SIF levels were positively associated with age in both sexes (see table). Estimated glomerular filtration rate (eGFR) and plasma glucose (FPG) levels were independently associated with SIF levels in both sexes. Menopause status was independently associated with SIF levels in women. Crude and adjusted SIF levels in post-menopausal women were significantly higher than those in pre-menopausal women. Decreased glomerular filtration rate was the most powerful factor that increases SIF levels in men. Elevated SIF levels in post-menopausal women indicate that the enhanced fluoride release from bone exists accompanied with the accelerated bone resorption after menopause.

Crude and adjusted serum ionic fluoride levels stratified by sex and age classes				
Age classes (years)	40-49	50-59	60-69	trend P
Male subjects (n)	55	53	59	-
Crude, $\mu\text{mol/l}$	$0.454 \pm 0.158$	$0.509 \pm 0.159$	$0.519 \pm 0.185$	0.045
Adjusted (95% CI), $\mu\text{mol/l}$	0.463 (0.463-0.506)	0.513 (0.420-0.557)	0.508 (0.469-0.550)	0.143
Female subjects (n)	53	57	55	-
Crude, $\mu\text{mol/l}$	$0.383 \pm 0.135$	$0.470 \pm 0.166$	$0.516 \pm 0.151$	<0.001
Adjusted (95% CI), $\mu\text{mol/l}$	0.439 (0.439-0.489)	0.461 (0.388-0.500)	0.471 (0.423-0.514)	0.418

### Improved Forearm Bone Mineral Density after Treatment with Vitamin D<sub>3</sub> in a Patient 30 Years after Bariatric Surgery. S. E. Williams<sup>1</sup>, A. A. Licata<sup>2</sup>.

<sup>1</sup>Center for Nutrition and Metabolic Medicine, Greene Memorial Hospital, GMH Health Center, Xenia, OH, USA, <sup>2</sup>Metabolic Bone Center, Cleveland Clinic Foundation, Cleveland, OH, USA.

Our purpose is to report a case of severe secondary metabolic bone disease in which a statistically significant increase in forearm bone mineral density occurred as a result of vitamin D<sub>3</sub> supplementation.

A 76-year-old nonambulatory woman who underwent jejunum-ileal bypass (JIB) bariatric surgery in 1974 presented to our metabolic bone center with hypocalcemia, hypovitaminosis D, hyperparathyroidism, proximal weakness, and debilitating bone pain. The DXA T-scores for total hip and forearm were -5.0 and -6.5 standard deviations, respectively. Oral cholecalciferol and calcium were prescribed, and dose adjustments were made in an effort to promote adequate absorption in response to periodic laboratory tests. Our patient required 100,000 IU cholecalciferol and 1800 mg calcium citrate on a daily basis due to iatrogenic malabsorption.

The 25-hydroxyvitamin D level, undetectable at first presentation, returned to normal limits during an 8-month period of aggressive oral supplementation. Lab data are noted in Table 1. During this period the distal forearm bone mineral density increased by 17.9%; there was no significant change in the left total hip.

**Table 1**  
**Data Before and After Supplementation with Cholecalciferol<sup>1</sup>**

Serum Factor	Ref Range	Baseline	After
Albumin (g/dL)	3.4 - 4.7	2.8	3.8
Creatinine (mg/dL)	0.7 - 1.4	1.2	1.4
Total Calcium (mg/dL)	8.5 - 10.5	7.4	8.7
Alkaline Phosphatase (U/L)	40 - 150	456	333
Parathyroid Hormone (pg/mL)	10 - 60	488	190
25-hydroxyvitamin D (ng/mL)	31 - 80	< 7.0	37

<sup>1</sup> First three months: 50,000 IU cholecalciferol twice weekly, patient stopped calcium supplement due to dyspepsia; 4<sup>th</sup> month: 600 mg calcium carbonate tid with meals plus 50,000 IU cholecalciferol daily; 5<sup>th</sup> month: increased cholecalciferol to 100,000 IU daily, and changed to calcium citrate.

We conclude that supplementation with vitamin D<sub>3</sub> and calcium alone can improve forearm bone density in certain skeletal problems and that clinicians must carefully interpret abnormal DXA data, since it may not always reflect primary osteoporosis.

**Disclosures:** S.E. Williams, None.

### (22-52) Adrenomedullin Prevents Systemic Bone Loss Related to Inflammation in Mice. C. Asensio<sup>\*1</sup>, M. Ah-Kioon<sup>\*1</sup>, H. Ea<sup>\*1</sup>, B. Uzan<sup>\*1</sup>, A. Kadri<sup>\*1</sup>, C. Bazille<sup>\*1</sup>, C. Marty<sup>\*1</sup>, C. Collet<sup>\*1</sup>, J. Launay<sup>\*2</sup>, F. Liote<sup>\*1</sup>, M. E. Cohen-Solal<sup>1</sup>. <sup>1</sup>Hôpital Lariboisière, INSERM U606, Paris, France, <sup>2</sup>Hôpital Lariboisière, Laboratoire de Biochimie, Paris, France.

Rheumatoid arthritis is associated with focal and systemic bone loss involving many inflammatory factors. Among them, adrenomedullin (ADM) reduces inflammation in collagen-induced arthritis (CIA) mice model. Moreover, ADM exerts *in vivo* anabolic effects on bone along with *in vitro* anti-apoptotic effects on osteoblast cells. (22-52)ADM, a fragment peptide which binds to ADM receptor, might act as an antagonist of ADM *in vitro* but its *in vivo* effects are unknown. We evaluated the action of ADM and (22-52)ADM, on systemic bone loss in a CIA mice model. DBA/1 mice were immunized with bovine type II collagen and treated with ADM or (22-52)ADM (1.2  $\mu\text{g/g}$  for both) or saline. Total body and vertebral bone mineral densities (BMD) were measured at baseline and at sacrifice (D45), and expressed as Delta BMD. Arthritic scores were evaluated in a blinded manner and histological studies of joints and bone were performed at sacrifice. Histomorphometric parameters were evaluated at the lumbar vertebrae. Bone resorption was quantified using the urinary deoxypyridinoline assay. At 45 days after disease onset, ADM and (22-52)ADM decreased arthritic score compared to saline ( $6.8 \pm 1.6$  and  $5.8 \pm 2$  vs  $11 \pm 3$ , respectively). Moreover, total histological score (inflammation, pannus and cartilage) was decreased with ADM compared to controls ( $1.30 \pm 0.07$  vs  $3.78 \pm 0.26$ ) and further decreased with (22-52)ADM ( $0.56 \pm 0.04$  vs  $3.78 \pm 0.26$ ,  $p < 0.05$ ). Furthermore, CIA induced systemic bone loss, as evidenced by Delta BMD, compared to the naive group (total body (TB):  $17.9 \pm 2.7\%$  vs  $25.5 \pm 0.2\%$ ; vertebrae (V):  $16.8 \pm 2.8\%$  vs  $29.4 \pm 7.7\%$ ). Compared to CIA mice treated with saline, ADM partly prevented CIA-induced bone loss ( $23.6 \pm 2.3\%$  vs  $17.9 \pm 2.7\%$  at TB and  $20.0 \pm 2.8\%$  vs  $16.8 \pm 2.8\%$  at V,  $p = \text{NS}$ ). Moreover, (22-52)ADM also increased BMD ( $25.7 \pm 2.6\%$  vs  $17.9 \pm 2.7\%$  at TB and  $33.2 \pm 3.6\%$  vs  $16.8 \pm 2.8\%$  at V,  $p < 0.05$ ). Indeed, (22-52)ADM increased trabecular bone volume ( $12 \pm 0.6$  vs  $10 \pm 0.5\%$ ,  $p < 0.05$ ) as well as trabecular thickness ( $28.3 \pm 0.8$  vs  $25.2 \pm 0.8 \mu\text{m}$ ,  $p < 0.05$ ) suggesting an effect on bone formation. Urinary deoxypyridinoline levels were increased in CIA compared to naives ( $14.09 \pm 0.92$  vs  $8.22 \pm 0.47$ ,  $p < 0.05$ ) but were unchanged with ADM and (22-52)ADM. In conclusion, both ADM and (22-52)ADM prevented bone loss in CIA mice. (22-52)ADM could prevent bone loss by maintaining osteoblast activity. Although the mechanism of action of each peptide remains to be determined, these molecules might represent a potential interest for the prevention of inflammatory-related bone loss.

### Vitamin D Status and Bone Remodeling Marker CTx-I in Patients with Early Rheumatoid Arthritis (RA): Association with Disease Activity and Joint Damage. M. L. Gonzalez-Casaús<sup>\*1</sup>, P. Aguado<sup>\*2</sup>, M. C. Ordoñez<sup>\*2</sup>, A. Cabezon<sup>\*3</sup>, D. Pascual-Salcedo<sup>\*3</sup>, A. Balsa<sup>\*2</sup>, E. Martín-Mola<sup>\*2</sup>.

<sup>1</sup>Biochemistry, Hospital Central de la Defensa, Madrid, Spain, <sup>2</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain, <sup>3</sup>Immunology, Hospital Universitario La Paz, Madrid, Spain.

**Background:** Vitamin D (VD) is a potent regulator of calcium homeostasis and musculoskeletal function and may also have immunomodulatory effects. The influence of VD on RA is not well defined. The type I collagen C-telopeptide bone breakdown product (CTX-I) has been related with joint damage in chronic persistent arthritis

**Objectives:** To study the association of baseline 25 (OH) D3 serum level with disease activity and with functional scores in patients with early RA, and to investigate the relationship between baseline CTX-I and radiographic joint damage

**Methods:** Patients attending an early arthritis clinic and showing signs of probable RA were studied. Disease activity was recorded at initial evaluation and every 6 months thereafter, taking into account pain, patient and physician assessment, articular indices, acute phase reactants and functional capacity (HAQ). In addition, rheumatoid factor (RF) and cyclic citrullinated peptide antibody levels (anti-CCP) were determined. X-Rays of hands and feet were taken at initial evaluation and every 12 months. Basal levels of serum

calcidiol (SC) and CTX-I were determined by electrochemiluminescence (ECLIA) using an Elecsys analyser (Roche). X-Rays were evaluated by the Sharp-van der Heijde method, following a chronological order and by pairs. Patients were treated according to physician's criteria and biological agents were not used. Results were compared by t test, ANOVA (Scheffe), and correlation studies (Pearson and Spearman), as required

**Results:** 165 patients with RA were studied; 75.8% were female, mean age was  $53 \pm 17$  years and disease duration,  $16 \pm 10$  weeks. 161 (97%) patients fulfilled ACR criteria for RA during follow-up. At baseline, mean SC was  $25.6 \pm 10.7$ . SC levels were not related to RF or anti-CCP antibodies. Eighty-two percent of patients had a vitamin D insufficiency ( $<30$  ng/ml). Basal SC was inversely correlated with patient global disease assessment ( $r = -0.4$ ,  $p=0.05$ ), and with the number of painful joints, both at entry and during the first 2 years ( $r = -0.23$ ,  $p=0.04$ ). Basal CTX-I levels were correlated with radiological damage at all time points; at entry ( $r=0.46$ ;  $p=0.006$ ), at one year ( $r=0.41$ ;  $p=0.03$ ) and at 2 years ( $r=0.38$ ,  $p=0.05$ )

**Disclosures:** M.L. Gonzalez-Casaús, None.

### Application of a Treatment Algorithm to Avoid BMD Loss and Limit Bisphosphonate Use after Kidney and Kidney Pancreas Transplantation.

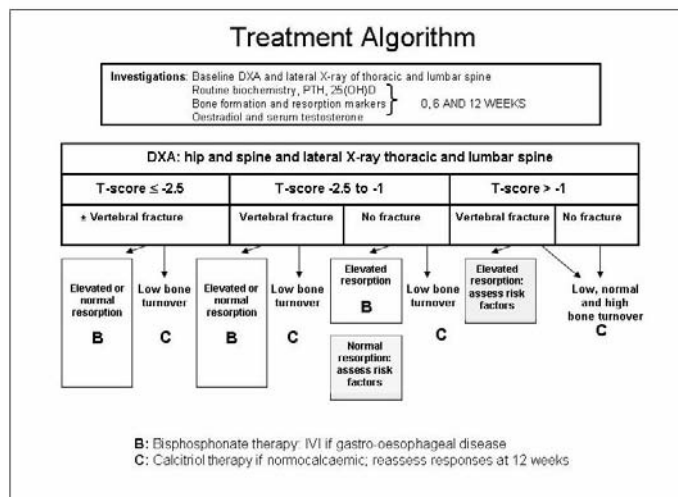

R. Mainra<sup>\*1</sup>, G. J. Elder<sup>2</sup>. <sup>1</sup>Division of Nephrology, St. Paul's Hospital, Saskatoon, SK, Canada, <sup>2</sup>Centre for Transplant and Renal Research, Westmead Millenium Institute, Sydney, Australia.

Despite reduction of glucocorticoid exposure in current immunosuppressive regimens, BMD levels often fall after kidney (K) and kidney pancreas (KP) transplantation and the incidence of post-transplant fractures is high. In meta-analysis, bisphosphonates and vitamin D reduce loss of BMD at the spine and hip but both have potential adverse effects. We studied the consequences of allocating patients to bisphosphonate and calcitriol therapy using a treatment algorithm.

In this prospective study, 155 transplant recipients (K: 92 and KP: 63) were followed for 12 months. Kidney recipients differed from KP recipients by age ( $48 \pm 12$  vs.  $38 \pm 7$  years,  $p<0.0001$ ), dialysis vintage ( $37 \pm 5$  vs.  $17 \pm 2$  months;  $p<0.01$ ) and haemo. vs. peritoneal dialysis (65% vs. 44%,  $p<0.01$ ). Transplant recipients were assessed with bone turnover markers (serum osteocalcin and urinary deoxypyridinoline/creatinine), levels of iPTH, vitamin D and sex hormones 4-6 weeks after transplant. BMD by DXA and lateral spine X-ray were performed. Patients were allocated to bisphosphonate or calcitriol according to an algorithm based on these results and assessment of standard risk factors. Patients with 25OHD levels  $<60$  nmol/L received cholecalciferol.

Using the algorithm, 56% of patients received bisphosphonates. Age was similar between treatment groups as was gender and transplant type. More patients allocated to bisphosphonates were on haemodialysis pre-transplant (66% vs. 43%;  $p=0.02$ ) and were of longer dialysis vintage ( $32 \pm 4$  vs.  $22 \pm 6$  months;  $p=0.006$ ). Patients receiving bisphosphonates had lower baseline BMD at the lumbar spine and femoral neck ( $p<0.0001$  for each). At 12 months, BMD increased in bisphosphonate treated patients at the lumbar spine and femoral neck ( $p=0.0012$  and  $p=0.002$  respectively). BMD in non-bisphosphonate treated patients did not change significantly at any site.

When patients with chronic kidney disease are transplanted, post-transplant laboratory and BMD data may be difficult to interpret due to pre-existing renal osteodystrophy. Targeting therapy using this algorithm resulted in reduced bisphosphonate exposure and potential drug-related risks, while maintaining or improving BMD at all sites.

### Change of Pathological Bone Lesion in Recipients with Renal Osteopathy after Renal Transplantation.

T. Tokumoto<sup>\*1</sup>, T. Nozaki<sup>\*1</sup>, K. Yoshida<sup>\*1</sup>, H. Suzuki<sup>\*1</sup>, T. Akiba<sup>2</sup>, K. Tanabe<sup>\*2</sup>. <sup>1</sup>Kidney Center, Dept. of Urology, Toda Central General Hospital, Saitama, Japan, <sup>2</sup>Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.

**OBJECTIVES:** We expect if chronic renal failure (CRF) is improved after renal transplantation (RTx), dialysis osteopathy is also recover to normal in bone lesion. Nevertheless, it is controversial whether bone lesion is really improved after RTx. In this study, we evaluated whether dialysis osteopathy was pathologically improved after RTx.

**MATERIALS AND METHODS:** Forty-one cases that underwent living related RTx at Toda central general hospital from January, 2004 were enrolled in this 28 males and 13 females. The periods of hemodialysis (HD) were an average of 40.2 months. The immunosuppression was basically triple drug therapy such as FK, MMF and Steroid. The parameter of Ca, P, whole PTH (w-PTH) and metabolic bone marker and bone density (DXA) were examined with relation to dialysis osteopathy in before RTx, and 1 year after RTx. In addition, bone biopsy was performed after having made osteal labeling twice in principle before bone biopsy.

**RESULTS:** All cases are survival and the renal grafts are functioning well in all cases. The mean level of Ca and P before RTx were 9.4mg/dl and 5.5mg/dl, respectively. The mean level of w-PTH was 73.4 pg/ml before RTx. The mean level of ALP was 262.1 U/l before RTx. The mean level of BAP was 29.6 U/l before RTx. The mean of bone volume (BV/TV) before RTx was 18.0%. The mean of osteoid volume (OV/TV) before RTx was 3.6%. The mean of fibrosis volume (Fb.V/TV) before RTx was 0%. The mean of bone formation rate (BFR/BV) before RTx was 25.5 %/year. Both of BV/TV and BFR/BV after RTx were increased pathologically. On the other hand, Fb.V/TV and OV/TV were also remarkably increased. Out of 41 cases, 30 cases (73.2%) were pathologically diagnosed as renal osteodystrophy, 7 cases (17.1%) were aplastic osteopathy, 2 cases (4.9%) were renal osteodystrophy or aplastic osteopathy, one case (2.4%) was osteitis fibrosa and one case (2.4%) was osteomalacia by bone biopsy at RTx. Six cases were already underwent the bone biopsy at 1 year after RTx. Out of these cases, 3 cases were renal osteodystrophy, 2 cases were aplastic osteopathy, and one case was renal osteodystrophy or aplastic osteopathy at RTx. Of 6 cases, 2 cases were pathologically diagnosed as renal osteodystrophy, 2 cases were mixed type, and 2 cases were osteomalacia at 1 year after RTx.

**CONCLUSIONS:** The bone metabolism was greatly improved at one year after RTx, but bone lesion in recipients with renal osteopathy did not seem to be recover pathologically. In particular, the tendency strongly resisted in case of aplastic osteopathy. The further examination by metabolic bone marker and bone biopsy will be needed in future.

## SA499

### Bone Metabolism in Long-term Kidney Transplantation Recipients.

A. Suzuki<sup>1</sup>, H. Sasaki<sup>\*2</sup>, S. Yamamoto<sup>\*1</sup>, S. Sekiguchi<sup>1</sup>, M. Shibata<sup>1</sup>, S. Asano<sup>1</sup>, K. Hoshinaga<sup>\*2</sup>, M. Itoh<sup>\*1</sup>. <sup>1</sup>Division of Endocrinology, Department of Internal Medicine, Fujita Health University, Aichi, Japan, <sup>2</sup>Department of Urology, Fujita Health University, Aichi, Japan.

Recent pharmacological advances in immunosuppressive therapy and transplant techniques have been improving long-term survival of graft recipients. Post-transplantation bone diseases negatively affect quality of life of solid organ recipients, because osteoporosis is prevalent in more than half of them. Bone loss during the first year after transplantation is most pronounced, but bone density development in long-term transplant recipients is still controversial. In the present study, we conducted cross-sectional study for bone metabolism in long-term survivors after kidney transplantation. Subjects were post-renal transplantation recipients ( $n=31$ , M/F=15/16, age  $54.8 \pm 8.9$ ). Mean duration of hemodialysis was  $116 \pm 83.7$  months. Mean duration after renal transplantation was  $14 \pm 3$  years (9-20 years). All the patients were prescribed methylprednisolone ( $4.07 \pm 0.84$  mg/day) with various immunosuppressive agents (cyclosporin, 28/31; mizoribine, 13/31; tacrolimus hydrate, 3/31; mycophenolate mofetil, 5/31). Mean concentrations of serum corrected calcium, phosphate and creatinine were  $9.8 \pm 0.6$  mg/dl,  $2.9 \pm 0.4$  mg/dl and  $1.19 \pm 0.46$  mg/dl, respectively. Mean serum 25-hydroxyvitamin D level was  $20.3 \pm 4.3$  ng/ml, while serum 1,25-dihydroxyvitamin D3 was  $48.5 \pm 15.7$  pg/ml. Mean concentration of intact parathyroid hormone (iPTH) ( $142.8 \pm 74.3$  pg/ml) was about three times higher than that of whole parathyroid hormone (wPTH) ( $54.3 \pm 34.3$  pg/ml). Serum iPTH and wPTH levels were negatively associated with the duration after kidney transplantation, but not with the duration for hemodialysis. In summary, these findings suggest us that long-term survivors after kidney transplantation have less persistent hyperparathyroidism, and that there is huge difference between serum iPTH and wPTH concentrations in post-kidney transplantation recipients.

## SA501

**Marked Vitamin D Deficiency in Recent Heart and Liver Transplant Recipients.** E. M. Stein<sup>1</sup>, A. Cohen<sup>2</sup>, M. Freeby<sup>\*2</sup>, S. Kokolus<sup>\*2</sup>, D. Mancini<sup>\*2</sup>, S. Restaino<sup>\*2</sup>, R. Brown<sup>\*2</sup>, D. J. McMahon<sup>2</sup>, E. Shane<sup>2</sup>. <sup>1</sup>Columbia University, New York, NY, USA, <sup>2</sup>Medicine, Columbia University College of Physicians and Surgeons, New York, NY, USA.

Vitamin D deficiency is an increasingly recognized condition with many serious sequelae. Several factors place patients with end-stage organ failure at particular risk for vitamin D deficiency, including limited sunlight exposure and hepatic dysfunction, resulting from intrinsic liver disease or in heart failure patients, hepatic congestion. Subjects were recruited as part of a randomized trial comparing two bisphosphonates for prevention of bone loss after transplantation. Serum 25-hydroxy vitamin D (25OHD: DiaSorin Chemiluminescent assay) was measured immediately after heart or liver transplantation, and before bisphosphonate therapy. Of 65 subjects studied (mean age: 53 ± 11 years), 44 (68%) received heart and 21 (32%) received liver transplants. Subjects were ethnically diverse, 57% Caucasian, 14% African American, 20% Hispanic, 2% Asian and 8% of other ethnicity. Vitamin D levels did not differ by ethnicity. The distribution of serum 25OHD is shown in the table:

Serum 25OHD (ng/ml)	Study Population (n=65)	Heart Transplant (n=44)	Liver Transplant (n=21)
Mean ± SD	17.1 ± 9.3	19.2 ± 9.4	12.7 ± 7.2
<10	12 (18%)	4 (9%)	8 (38%)
10-20	36 (55%)	26 (59%)	10 (48%)
20-30	12 (18%)	10 (23%)	2 (10%)
≥30	5 (8%)	4 (9%)	1 (5%)

Low 25OHD levels were nearly ubiquitous; 92% had levels below 30 ng/ml, the threshold commonly used to denote sufficiency. Six had levels below 7 ng/ml, the lower limit of detection of the 25OHD assay. The distribution of vitamin D levels was significantly lower among liver than heart transplant recipients ( $p=0.01$ ). Severe vitamin D deficiency was particularly widespread in liver transplant recipients; 8 (38%) had levels <10 ng/ml and of these, 5 (24%) had undetectable levels.

Severe vitamin D deficiency is extremely prevalent among heart and liver transplant recipients. Patients with end-stage liver disease are at exceptionally high risk, likely because of disease related factors such as malabsorption, and impaired hepatic 25-hydroxylation of vitamin D. Patients with severe vitamin D deficiency are at risk for hypocalcemia and tetany after treatment with intravenous bisphosphonates. It is imperative to assess vitamin D status and correct vitamin D deficiency in all patients presenting for transplantation, particularly if intravenous bisphosphonates are prescribed to prevent transplant-related bone loss.

**A Retrospective Study Evaluating the Relationship of Vitamin D 25 OH and Free Testosterone Levels with Changes in Hip Bone Density after Liver Transplantation.** R. K. Bhattacharya<sup>1</sup>, M. Hagan<sup>\*1</sup>, R. Krebill<sup>\*2</sup>, B. Lukert<sup>1</sup>, L. Graves<sup>1</sup>. <sup>1</sup>Endocrinology, University of Kansas, Kansas City, KS, USA, <sup>2</sup>Biostatistics, University of Kansas, Kansas City, KS, USA.

Osteoporosis and increased fracture risk are common complications following orthotopic liver transplantation (OLT). Pre-transplant markers have not been clearly identified to predict post-transplant changes in bone density.

**Aims of this study:** 1. To evaluate changes in BMD post transplantation and to correlate these changes with baseline Vitamin D 25 OH and free testosterone (in males) levels; 2. To explore the relationship between BMD changes and free testosterone levels pre and post transplantation. **Methods:** This retrospective study evaluated the baseline characteristics of 32 individuals (17 men, 15 women) prior to liver transplantation. The individuals were followed for an average of 425 days post-transplantation and the BMD of the spine and hip, free testosterone (men only) and Vitamin D 25 OH were measured. A paired t-test was used to contrast pre-post changes in BMDs after liver transplantation. Spearman's correlation was used to determine the correlations between several parameters.

**Results:** There was a significant decrease in hip BMD after transplantation (4.29%,  $p<.001$ ). Pre-transplant free testosterone positively correlated with percent change in hip BMD in males ( $r = .5827$ ,  $p=.028$ ). Despite having only 12 males with testosterone measurements done post-transplantation, there was a positive correlation with hip BMD ( $r = .77273$ ,  $p=.0053$ ). Pre-transplant free testosterone also correlated positively with post-transplant free testosterone ( $r = .7135$ ,  $p=.0092$ ).

In the entire population the study found no significant change in spine BMD after transplantation. The pre-transplant and post-transplant levels of Vitamin D 25 OH had a significant correlation on the percent change of spine BMD after transplantation (pre-transplant levels:  $r = .5495$ ,  $p=.003$ , post-transplant levels:  $r = .559$ ,  $p=.0104$ ).

**Conclusion:** This study is consistent with other studies demonstrating bone loss following organ transplantation in the first year. Our findings revealed a correlation between 25-OH D and changes in bone density following liver transplantation. In men, free testosterone also correlated with the change in bone density of the hip after transplantation. This study is limited by the small patient numbers. Further studies are needed to confirm these results and to evaluate a true cause and effect. Future studies should be undertaken to evaluate the potential effect of correcting vitamin D and testosterone deficiency to affect BMD changes.

## SA503

**Effect of Risedronate in Liver Transplantation Patients with Low Bone Mass.** S. Guadaluix<sup>\*</sup>, G. Martinez<sup>\*</sup>, B. Cobaleda<sup>\*</sup>, C. Vargas<sup>\*</sup>, D. Lora<sup>\*</sup>, E. Jódar<sup>\*</sup>, J. Meneu<sup>\*</sup>, E. Moreno<sup>\*</sup>, F. Hawkins. University Hospital 12 de Octubre, Madrid, Spain.

Osteoporosis is found in up to 50% of transplant recipients, but the most appropriate preventive measures are not clearly established. The purpose of this study is to analyze the preventive effect of oral risedronate on bone loss in patients with low bone mass detected after liver transplantation (LTx).

**Patients and Methods:** This is a randomized open-label single center prospective study. Eighty-three LTx patients (64 males, 19 females; age  $54.8 \pm 10.6$  years) with lumbar and/or femoral T-score <-1 have been included. After transplantation (mean time  $34 \pm 21$  days) patients were randomly assigned to one of two treatment arms: Group 1 (n=41) received oral risedronate (35 mg once weekly) plus calcium (1000 mg/day) and vitamin D (800 IU); Group 2 (n=42) received calcium and vitamin D at same doses. Primary endpoint was bone mineral density (BMD) change at lumbar spine (L1-L4) and femoral regions (measured at baseline, 6 and 12 months after LTx with an Hologic QDR 4500w densitometer); secondary endpoints include changes in serum  $\beta$ -CTX and PINP. **Results:** No differences were found in baseline characteristics between groups. Forty-three patients (21/22) have completed 12 months of treatment so far. No significant changes in BMD were observed in any group, neither at spine or hip. In Group 1, serum  $\beta$ -CTX decreased after 3 months ( $p=0.008$ ), 6 months ( $p<0.05$ ) and 12 months ( $p=0.008$ ). In Group 2, a significant decrease in  $\beta$ -CTX was also observed. Serum PINP increased in Group 2 after 3, 6 and 12 months of treatment ( $p<0.05$ ). At baseline, 90% of patients had 25-OH vitamin D<sub>3</sub> below 30 ng/ml. In both groups 25-OH vitamin D<sub>3</sub> levels increased at three months ( $p<0.001$ ), maintaining this level throughout the study. Treatment was well tolerated in both groups. **Conclusions:** Preliminary data of our study suggest: 1) risedronate effectively decreases bone resorption after LTx, and 2) LTx patients have low baseline vitamin D levels.

**12 Months of Teriparatide Therapy Increases Ultradistal Radius Bone Strength in Severely Osteoporotic Postmenopausal Women.** H. M. Macdonald<sup>1</sup>, D. A. Hanley<sup>\*2</sup>, S. K. Boyd<sup>1</sup>. <sup>1</sup>Mechanical & Manufacturing Engineering, University of Calgary, Calgary, AB, Canada, <sup>2</sup>Medicine, University of Calgary, Calgary, AB, Canada.

Teriparatide, the amino terminal fragment of parathyroid hormone [PTH (1-34), Forteo<sup>TM</sup>], is an established anabolic therapy for osteoporosis treatment. To date, one study has used non-invasive high-resolution pQCT (HR-pQCT) to quantify changes in bone microarchitecture following PTH administration (JBMR 2007 22:S24). However, PTH-mediated changes in estimated bone strength have not been investigated using novel, subject-specific finite element (FE) analysis with HR-pQCT scans. Thus, we aimed to determine the effects of PTH-therapy on estimated bone strength (ultimate failure load) at the ultradistal (UD) radius in severely osteoporotic postmenopausal women. We used HR-pQCT (Scanco Medical, Switzerland) and FE analysis (Bone 2007 41:129-37) to evaluate changes in estimated UD radius bone strength in 16 women (mean age  $66 \pm 14$  yrs) diagnosed as severely osteoporotic (BMD T-score < -3.5 SD). All women had received bisphosphonate therapy prior to starting on PTH (1-34). We acquired HR-pQCT scans at baseline and 6- and 12-months after initiation of 20 ug/day of PTH (1-34). We analyzed 6-month data for all subjects and 12-month data for 7 of 16 subjects (remaining scans to be analyzed by August 2008). In addition to FE analysis we performed a standard microarchitectural morphological analysis. We used the Wilcoxon Signed Ranks test to compare outcomes before and after treatment. None of the women sustained a fracture during the study. After 6 months, we observed a decrease in bone strength (-5.9%, Table) despite a small increase in trabecular bone volume/total volume (BV/TV). Six months of PTH therapy was also associated with a decrease in cortical density (Dcort) and thickness (C.Th). In contrast, after 12 months we observed a trend for a small increase (+4.3%) in bone strength together with trends for increases in BV/TV, trabecular number (TbN) and thickness (Tb.Th) and continued decreases in Dcort and C.Th. These preliminary data suggest that 12 months of teriparatide therapy may increase UD radius bone strength in severely osteoporotic women, primarily through positive effects on cancellous bone morphology. Further study is needed to determine the influence of the apparent treatment-related increase in cortical porosity (evidenced by the decrease in Dcort) on radius bone strength.

## ASBMR 30th Annual Meeting

**Effect of Risedronate on Bone Strength and Work to Failure Determined by Finite Element Analysis and Simulation of Clinically-Measured Bone Loss and Mineralization Changes.** H. Hong\*, G. J. Gross\*, T. E. Dufresne\*, P. A. Chmielewski\*, R. J. Phipps, B. Borah. Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The reduction in relative fracture risk by risedronate is largely due to the reduction of bone remodeling resulting in the prevention of bone loss, preservation of architecture and increase in mineralization. These factors contribute to the relative difference in bone strength in patients with and without treatment. We performed bone loss simulations and FEA on iliac biopsies to assess bone strength in patients treated with risedronate or placebo. Changes in bone volume and mineralization were simulated to match 3 year results as measured originally by 3D micro-CT (Bone, 2004, 34:736-46; Bone, 2005, 37:1-9). We used 12 baseline biopsy images (4 placebo; 8 risedronate) with varying trabecular bone volumes (11-29%). A uniform volume (3.5 mm<sup>3</sup>, 34 microns resolution) was used to normalize for structural variability in the biopsies. A custom program simulated bone loss through random surface erosion of bone using a 3D Euclidian distance map. The 3D images before and after simulation were directly converted into finite element models for analysis of mechanical properties by compression loading using a non-linear ABAQUS analysis. Simulation of a 26% bone volume loss to match the 3 year placebo-treated group produced deterioration of trabecular architecture that closely matched clinical results. It resulted in ~65% reduction in the apparent properties (stiffness, strength and work to failure) compared to baseline. Reducing bone volume by 26% also reduces mineral density by 26%. Reducing density alone by 26% by simulating loss of tissue mineralization (at constant bone volume) reduced strength by only ~25%, suggesting that bone architecture is a more important determinant of bone strength. To simulate the effect of risedronate treatment, mineralization levels were increased 5% to match the change observed in clinical samples. This resulted in increases in stiffness and strength of 3-4%, and no significant change in work to failure. Thus, simulation of the risedronate and placebo treatment effects on trabecular bone resulted in bone strength ~70% higher for risedronate compared to placebo. In conclusion, the preservation of bone architecture is significantly more important than the increase in mineralization for preserving bone strength with risedronate treatment.

Parameter	% Change vs baseline after 26% reduction in volume Mean (SD)	% Change vs baseline after 26% reduction in density Mean (SD)	% Change vs baseline after 5% increase in density Mean (SD)
Stiffness	-64.9 (8.2)	-25.8 (5.8)	3.8 (1.6)
Strength	-66.5 (6.7)	-25.4 (0.3)	3.5 (0.3)
Work to Failure	-65.2 (2.3)	-26.4 (0.9)	1.7 (1.6)

**Oral Strontium Ranelate Treatment Markedly Improves Implant Osseointegration.** L. Maimoun\*, R. Rizzoli\*, P. Ammann\*. Department of Rehabilitation and Geriatrics, University Hospital, Geneva, Switzerland.

The employment of metallic implantation into bone is frequently used in orthopaedics and dentistry all the more with the aging population. The process of implant osseointegration begins with a phase of bone resorption around the implant, with bleeding and inflammation, and is followed by a phase of bone formation. However, the incidence of implant failure is high due to alteration of bone turnover and tissue quality. Strontium ranelate (SR), efficacious in the treatment of osteoporosis, was shown to inhibit bone resorption, to increase bone formation and to improve bone material quality. Whether SR treatment improves implant osseointegration is not known. We measured the resistance to pull-out of 1 mm diameter titanium rods implanted into the proximal tibia of 6 month-old female rats. The implants, sandblasted and acid-etched along the surface of non threaded part, were inserted into both tibias and the rats received SR (625 mg/kg, 5/7 days, n=15), alendronate (ALN) (18 microg/kg/d, 2/7 days, n=15, positive control) or vehicles (n=15) for 8 weeks. The tibias were then removed for microtomographic histomorphometry and resistance to pull-out was tested by recording the maximal force necessary to completely loosen the implant. Nanoindentation (intrinsic bone tissue quality in the vicinity of the implant) and histomorphometry were performed (in a subgroup of n=7). Results are expressed as means±SEM. Significance of differences were evaluated by analysis of variance (\* p<0.05 vs control).

	Control	Strontium ranelate	Alendronate
Pull out Force (N)	32.52±3.79	43.54±3.03*	48.40±3.05*
Hardness (mPa) trabecular bone	624.8±21.6	721.7±27.6*	654.8±23.3
Hardness (mPa) cortical bone	837.3±24.5	918.5±30.54*	822.8±25.6

Both SR and ALN improved pull-out force compared to the controls, i.e. implant osseointegration. Whereas both treatments positively influenced microarchitecture, one of the determinants of pull-out force, intrinsic bone tissue quality was improved in rats treated with SR but not in rats treated with ALN. Furthermore, dynamic histomorphometry demonstrated tetracycline labelling along the implant in rats treated with SR, but not in rats treated with ALN, compatible with the hypothesis that SR may induce bony ingrowths into the surfaces of the implants. The dose of SR of 625 mg/kg correlates to human therapeutic exposure. In conclusion, whilst both treatments induce a similar pull-out force, only strontium ranelate improves implant osseointegration by positively altering formation of bone and the intrinsic bone material quality in the vicinity of the implant.

**Hip Structural Analysis Based on DXA Data in Women with Postmenopausal Osteoporosis Receiving Once-Monthly Oral Ibandronate for 12 Months.** E. M. Lewiecki<sup>\*1</sup>, H. K. Genant<sup>\*2</sup>, K. Engelke<sup>\*3</sup>, T. Fuerst<sup>\*4</sup>, M. Fries<sup>\*5</sup>, M. Enslin<sup>\*5</sup>, L. A. Fitzpatrick<sup>\*5</sup>, A. Kivitz<sup>\*6</sup>. <sup>1</sup>New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, <sup>2</sup>University of California, San Francisco, and Synarc, Inc, San Francisco, CA, USA, <sup>3</sup>Synarc, Inc, Hamburg, Germany, <sup>4</sup>Synarc, Inc., San Francisco, CA, USA, <sup>5</sup>GlaxoSmithKline, King of Prussia, PA, USA, <sup>6</sup>Altoona Arthritis & Osteoporosis Center, Duncansville, PA, USA.

Bone quality, strength, and geometry contribute to fracture resistance. This 12-month randomized, double-blind, parallel-group, multicenter study determined effects of once-monthly oral ibandronate or placebo on bone quality and strength measured by volumetric quantitative computed tomography (QCT), finite element analysis, and dual-energy x-ray absorptiometry (DXA) in 93 postmenopausal women with BMD T-scores of ≤-2.0 to ≥-5.0. The primary endpoint was total hip volumetric BMD assessed by QCT. Hip structural analysis (HSA) parameters were a secondary endpoint. Femoral DXA was performed at baseline and Month 12. HSA assessed cross-sectional geometry of the intertrochanter region, narrow neck, and femoral shaft. All analyses were exploratory. HSA changes from baseline were evaluable in 42 of 47 ibandronate patients and 37 of 46 placebo patients. Ibandronate induced greater mean percentage increases than placebo in total hip BMD by DXA (1.7% ± 2.8% vs -0.6% ± 2.5%; treatment difference 2.0% [95% CI 0.7% to 3.3%]). Cross sectional moments of inertia improved with ibandronate versus placebo at the shaft (1.9% ± 5.1% vs -0.6% ± 4.5%; treatment difference 2.0% [95% CI -0.2% to 4.2%]) and narrow neck (4.1% ± 9.4% vs -0.7% ± 7.3%; treatment difference 4.0% [95% CI -0.04% to 8.1%]) denoting increased resistance to bending and torsional loading; corresponding intertrochanter data were 4.1% ± 7.5% vs 1.2% ± 8.9%, treatment difference 2.4% (95% CI -1.4% to 6.2%). Average cortical thickness of the narrow neck, a parameter associated with hip fracture resistance, decreased with placebo (-2.1% ± 5.4%) but was maintained with ibandronate (0.3% ± 6.2%); treatment difference 2.2% (95% CI -0.6% to 5.0%). In other regions, average cortical thickness increased with ibandronate and was maintained with placebo (shaft: 2.0% ± 5.2% vs 0.2% ± 5.1%, treatment difference 0.7% [95% CI -1.6% to 3.0%]; intertrochanter: 3.3% ± 6.0% vs 1.4% ± 5.8%, treatment difference 1.3 [95% CI, -1.4% to 4.0%]). Ibandronate treatment for 12 months was associated with trends toward improvement in hip geometry relative to placebo as measured by HSA.

**QCT and FEA Assessment of Proximal Femur Bone Quality and Strength in Women with Postmenopausal Osteoporosis Receiving Once-Monthly Oral Ibandronate for 12 Months.** A. Kivitz<sup>\*1</sup>, T. M. Keaveny<sup>\*2</sup>, H. K. Genant<sup>\*3</sup>, K. Engelke<sup>\*4</sup>, T. Fuerst<sup>\*5</sup>, D. Kopperdahl<sup>\*6</sup>, M. Fries<sup>\*7</sup>, G. Dasic<sup>\*7</sup>, L. A. Fitzpatrick<sup>\*7</sup>, E. M. Lewiecki<sup>\*8</sup>. <sup>1</sup>Altoona Arthritis & Osteoporosis Center, Duncansville, PA, USA, <sup>2</sup>University of California, Berkeley, and O.N. Diagnostics, Berkeley, CA, USA, <sup>3</sup>University of California, San Francisco, and Synarc, Inc, San Francisco, CA, USA, <sup>4</sup>Synarc, Inc., Hamburg, Germany, <sup>5</sup>Synarc, Inc., San Francisco, CA, USA, <sup>6</sup>O.N. Diagnostics, LLC., Berkeley, CA, USA, <sup>7</sup>GlaxoSmithKline, King of Prussia, PA, USA, <sup>8</sup>New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

Decreased femoral bone mineral density (BMD) and cortical thinning are associated with osteoporotic hip fracture risk. We examined effects of once-monthly oral ibandronate on measures of bone strength and quality in a 12-month randomized, double-blind, placebo-controlled study. Postmenopausal women (N=97) aged 55-80 years with BMD T-scores  $\leq -2.0$  and  $\geq -5.0$  received oral ibandronate (150 mg/mo) or placebo. The primary endpoint was assessment of integral (cortical plus trabecular compartments) total hip volumetric BMD by quantitative computed tomography (QCT) after 12 months' ibandronate or placebo treatment in the intent-to-treat population (n=93); secondary analyses included other proximal femur sites and finite element analysis (FEA). All analyses were exploratory. *P*-values were generated post-hoc for descriptive purposes only and were not corrected for multiple comparisons. Integral and trabecular volumetric BMD increased more over 12 months' treatment with ibandronate than placebo in the total hip (integral,  $1.5\% \pm 3.4\%$  vs  $-1.0\% \pm 2.5\%$ ; trabecular,  $2.6\% \pm 8.0\%$  vs  $-2.9\% \pm 5.1\%$ ), trochanter (integral,  $2.5\% \pm 4.2\%$  vs  $-1.0\% \pm 3.4\%$ ), and femoral neck (integral,  $0.8\% \pm 3.2\%$  vs  $-1.4\% \pm 2.5\%$ ). Cortical volumetric BMD changes from baseline in these regions were similar between the groups. The treatment difference in the primary endpoint, integral BMD of the total hip (least-squares means and 95% confidence intervals (CI), ibandronate minus placebo,  $2.2\%$  [0.7%-3.7%],  $P = 0.005$ ) showed a clinically meaningful ibandronate effect. FEA modeling of femoral strength under falling load showed that ibandronate improved strength of the whole proximal femur (treatment difference,  $5.9\%$ ; 95% CI,  $2.7\%$ - $9.0\%$ ,  $P = 0.0004$ ) and the pericortical (treatment difference,  $2.5\%$ ; 95% CI,  $0.6\%$ - $4.5\%$ ,  $P = 0.0113$ ) and trabecular (treatment difference,  $3.5\%$ ; 95% CI,  $1.3\%$ - $5.7\%$ ,  $P = 0.0025$ ) compartments. Once-monthly oral ibandronate for 12 months resulted in integral and trabecular volumetric BMD gains in the proximal femur. FEA modeling demonstrated that ibandronate also improved femoral strength with an increase in pericortical as well as trabecular compartment strength.

**Bone Tissue Quality Is Differently Altered by PTH, Bisphosphonates and SERMs.** T. C. Brennan<sup>\*</sup>, R. Rizzoli, P. Ammann. Faculty of Medicine, Division of Bone Diseases, Geneva University Hospital, Genève, Switzerland.

Bone strength, a determinant of resistance to fracture, depends on bone mineral density, bone geometry, microarchitecture, bone turnover rate and intrinsic bone tissue quality. Despite comparable antifracture efficacy, bone resorption inhibitors and bone anabolic agents are likely to modify the various determinants of bone strength in different ways. To address this hypothesis, we treated 8-month old osteoporotic ovariectomized (OVX) rats with pamidronate (APD, 0.6mg/kg 5 days/month s.c.), PTH(1-34) (10 ug/day, s.c.), raloxifene (3 mg/kg 5/7 days) or vehicle for 16 weeks, and measured maximal load and other biomechanical properties with an axial compression test, areal BMD, microarchitecture by microCT, and intrinsic bone quality by nanoindentation. Markers of bone turnover, deoxypyridinoline (Dpd) and osteocalcin, were also determined. Results are Means  $\pm$  SEM, with significances tested by ANOVA.

Vertebral body	Sham	OVX	APD/OVX	PTH (1-34)/OVX	Raloxifene /OVX
Maximal Load (N)	303.5 $\pm$ 27.3**	215.8 $\pm$ 11.3	321.1 $\pm$ 18.1***	404.9 $\pm$ 25.0***	261.9 $\pm$ 21.7
BV/TV (%)	28.4 $\pm$ 1.25***	18.3 $\pm$ 0.87	23.3 $\pm$ 1.13**	36.4 $\pm$ 1.77***	22.1 $\pm$ 1.06
Total Energy (mN*mm)	4265.2 $\pm$ 84.8*	3891.7 $\pm$ 68.4	4160.6 $\pm$ 136.0	3578.4 $\pm$ 49.0***	4283.2 $\pm$ 62.9*
Osteocalcin (ng/ml)	11.1 $\pm$ 0.68	14.9 $\pm$ 1.30	8.23 $\pm$ 0.05***	23.4 $\pm$ 1.21***	12.3 $\pm$ 1.71

(\*\*\* $p < 0.001$ , \*\* $p < 0.01$  and \* $p < 0.05$  compared to OVX vehicle or \*\*\* $p < 0.001$  compared to Sham) All treatments improved maximal load compared to OVX animals, although the difference was not significant in raloxifene-treated rats. The PTH-induced increase in maximal load was associated with improved microarchitecture, including marked increases in trabecular bone volume and connectivity, leading to values higher than in sham. APD corrected the effects of OVX on trabecular bone volume. Raloxifene had no effect. All treatments increased areal BMD, with potency: PTH>APD>raloxifene. PTH was ineffective in correcting the steep decreases in tissue hardness and working energy caused by OVX. In contrast, APD normalized bone strength, together with a reduced bone turnover and increased hardness. Raloxifene also improved hardness, elastic modulus and markedly enhanced working energy, with low levels of bone turnover markers.

These results demonstrate that inhibitors of bone resorption and stimulators of bone formation reduce fracture risk through different mechanisms. PTH markedly improved bone mass and microarchitecture yet lead to poor trabecular bone quality and increased bone turnover. APD and raloxifene improved bone mass and positively influenced intrinsic bone tissue quality. Through a reduced bone turnover these agents prevented further degradation of mechanical properties.

## SA511

**Development of An Animal Model of Bisphosphonate-Induced Severe Suppression of Bone Turnover.** J. E. Zerwekh<sup>1</sup>, W. Geng<sup>\*1</sup>, C. T. Skurla<sup>\*2</sup>, C. V. Odvina<sup>1</sup>. <sup>1</sup>Center for Mineral Metabolism and Clinical Research, University of Texas Southwestern Medical Center at Dallas, Dallas, TX, USA, <sup>2</sup>Department of Mechanical Engineering, Baylor University, Waco, TX, USA.

There is a growing body of clinical evidence supporting the development of bisphosphonate-induced severe suppression of bone turnover (SSBT) in some patients taking bisphosphonates singly or in combination with other antiresorptive agents. We undertook the development of an animal model of SSBT that recapitulated the histological, biochemical, and biomechanical findings in humans. Twelve ovariectomized adult female Sprague-Dawley rats were allowed to acclimatize to their housing. After 2 weeks, rats were placed in individual metabolic cages and urine collected for 3 subsequent days. Under anesthesia, BMD was assessed by Hologic DEXA, and a blood sample obtained. One-half of the rats then received weekly i.p. injections of alendronate at a dose of 35ug/kg for four months, a dosing regimen calculated to expose the skeleton to the same amount of alendronate obtained from weekly 70 mg oral dosing for a total of 10 years. Control rats received saline. At the end of 4 months, all baseline procedures were repeated. Two animals in the control group died following baseline examination. At sacrifice, one femur was obtained for dynamic histomorphometry and determination of osteocyte density. The contralateral femur was procured for biomechanical testing. Compared to control rats, alendronate-treated rats demonstrated a greater increase in spine BMD ( $30.3 \pm 5.2$  SEM vs  $12.7 \pm 3.6\%$ ,  $p=0.028$ ) and significant reductions in bone turnover as determined from histomorphometry. The most striking finding was the total lack of any identifiable tetracycline double label in cancellous bone compared to controls ( $4.5 \pm 2.1\%$ ). In addition, alendronate-treated rats had significantly lower viable osteocyte number and an increased number of empty lacunae compared to controls ( $238 \pm 29$  vs  $85 \pm 16/\text{mm}^2$ ,  $p=0.004$ ). Biomechanical testing of femurs demonstrated no significant differences between groups for stiffness or maximum flexural strength. However, alendronate-treated rats demonstrated a significant decline in yield strength of the femur compared to controls ( $69 \pm 9$  vs  $53 \pm 11$  MPa,  $p=0.040$ ). Taken together, these findings are consistent with an alendronate-induced suppression of bone turnover characterized by a lack of bone formation, an increase in the number of empty cortical and cancellous osteocytic lacunae, and reduced biomechanical competence as shown by a significant reduction in the yield point. This animal model of bisphosphonate-induced SSBT will be useful to begin to unravel the complex effects of long-term bisphosphonate use on bone cells and biomechanical integrity.

## SA512

**Effects of Resorption Cavities on Strength of Trabecular Bone.** S. K. Easley<sup>\*1</sup>, D. Shindich<sup>\*1</sup>, C. J. Hernandez<sup>2</sup>, T. M. Keaveny<sup>1</sup>. <sup>1</sup>Mechanical Engineering, University of California, Berkeley, Berkeley, CA, USA, <sup>2</sup>Mechanical and Aerospace Engineering, Case Western Reserve University, Cleveland, OH, USA.

Understanding the relation between bone strength and presence of microcavities should provide insight into how osteoporosis and treatments might alter bone quality. While it has been shown that simulated suppression of microcavities in low-density vertebral bone can in theory improve bone quality, commensurate improvements in bone quality have not been observed due to antiresorptive therapy when applied to high-density canine bone. To understand this discrepancy, we sought to quantify the effect of adding cavities to both low-density and high-density bone on strength after accounting for differences in bone volume fraction (BV/TV). Trabecular bone from the human femoral neck (n=14, age:  $70.4 \pm 10.1$ , BV/TV:  $22.5 \pm 5.9\%$ ) and the vertebral body (n=16, age:  $72.9 \pm 11.7$ , BV/TV:  $11.2 \pm 3.7\%$ ) were scanned with micro-CT at 22-micron voxel size. Each image was converted into three finite element (FE) models, using the original image of bone or using images in which cavities (44 microns deep) were digitally added to the bone surface either at random (non-targeted) or in regions of greatest maximum principal strain (targeted). FE analysis was used to compute the compressive strength of each specimen, in its intact and altered states. Results indicated that the presence of cavities deleteriously altered the strength-density relationship as compared to models without cavities ( $p < .001$ ). Strength change per unit percent change in BV/TV due to the addition of non-targeted cavities ( $1.87 \pm 0.23$  MPa/%BV/TV) was two times larger than expected from changes in BV/TV alone ( $0.91$  MPa/%BV/TV). The dependency of percent reduction in strength associated with introducing non-targeted cavities ( $17.1 \pm 2.25$ ) on BV/TV was negligible for the pooled data, while strength reduction associated with targeted cavities was negatively correlated with BV/TV ( $p=.0012$ ), such that at high densities, there was a smaller difference between non-targeted and targeted models. This study indicates that remodeling cavities can have a disproportionate biomechanical effect in high-density bone as well as low-density bone. However, our prior work on high-dose risedronate treatment of dogs (Eswaran, JBMR 2006) revealed no change in the strength-BV/TV relation compared to untreated controls, using the same type of FE analysis techniques as used here on the unmodified micro-CT scans. We conclude that further research is required to determine the conditions (cavity size, drug treatment, skeletal region), if any, under which alteration of the remodeling space might alter bone strength.

## SA513

**Alteration of Trabecular Bone Architecture Following Sciatic Denervation and Subsequent Reinnervation in Rat Proximal Tibiae.** H. Tamaki<sup>1</sup>, K. Yotani<sup>1</sup>, A. Yuki<sup>1</sup>, I. Sakashita<sup>1</sup>, K. Kitada<sup>2</sup>, H. Kirimoto<sup>3</sup>, F. Ogita<sup>1</sup>, H. Takekura<sup>1</sup>. <sup>1</sup>Department of Physiological Sciences, National Institute of Fitness and Sports, Kanoya, Japan, <sup>2</sup>Ishikawa National College of Technology, Kanazawa, Japan, <sup>3</sup>Niigata University of Health and Welfare, Niigata, Japan.

Disused rat hindlimb caused by sciatic denervation is characterized by osteopenia accompanying alterations in trabecular bone architecture. We studied the effects of short-term denervation followed by reinnervation on the 2-dimensional architecture of trabecular bone using a unilateral sciatic nerve freezing model rat of temporary disuse. Male Fischer-344 rats aged 11-weeks underwent unilateral hind-limb denervation by either sciatic neurectomy (SN) or nerve freezing (NF) by contact with a stainless steel rod cooled in liquid nitrogen, while control rats were sham-operated. Right and left tibiae of denervated and control rats were obtained at 0, 1, 2, 3, 4 and 5 weeks after surgery. After fixation with a mixture of 1% glutaraldehyde, 1% formaldehyde and 0.05%  $\text{CaCl}_2$  in 0.1M sodium cacodylate buffer (pH. 7.3), the tibiae were demineralized in 0.1M disodium ethylenediaminetetraacetic acid (pH 7.3) for 6 weeks at 4°C, dehydrated through a graded ethanol series, and then embedded in paraffin. Histomorphometric analyses were performed on longitudinal sections of proximal tibial metaphyseal secondary spongiosa. Sciatic denervation by SN or NF resulted in a marked loss of trabecular bone, mostly within first 2 weeks after denervation. Trabecular bone area decreased and gradually recovered with the breaking point at 3 weeks, returning to approximately 55% of basal-control levels (at 0 weeks) by 5 weeks after NF. Both the thickness and length of trabecular bone were significantly decreased after denervation. Trabecular thickness at 5 weeks after NF was significantly greater compared to that at 3 weeks after NF and at 5 weeks after SN, while decreased trabecular length after NF did not during the experimental period. These findings suggest that 1) sciatic nerve freezing results in marked loss of trabecular bone, mostly within the first 2 weeks after surgery; 2) temporary denervation and subsequent reinnervation reversibly affects trabecular bone architecture, particularly trabecular thickness.

## SA514

**Beta-Adrenergic Receptor Agonist Administration During Hindlimb Unloading Effectively Mitigates Reductions in Cancellous Bone Formation.** J. M. Swift<sup>1</sup>, S. N. Swift<sup>2</sup>, S. A. Bloomfield<sup>2</sup>. <sup>1</sup>Health and Kinesiology, Texas A&M University, College Station, TX, USA, <sup>2</sup>Health and Kinesiology, Intercollegiate Faculty of Nutrition, Texas A&M University, College Station, TX, USA.

Significant losses in bone mass during extended duration spaceflight pose a major challenge to manned exploration. One ground-based technique for effectively modeling cardiovascular and skeletal effects of spaceflight is rodent hindlimb unloading (HU). HU significantly decreases bone formation rate (BFR/BS) at the proximal tibia metaphysis (PTM) and blood flow to long bone metaphyses. In addition, our lab has demonstrated that dobutamine (DOB), a beta-adrenergic receptor agonist (ADRB), prevents significant declines in PTM total volumetric bone mineral density (vBMD) during HU. The purpose of this study was to assess the effectiveness of DOB in attenuating HU-associated decrements in static and dynamic histomorphometric properties at the PTM. Six-month-old male Sprague-Dawley rats were randomly assigned to cage control (CC) or HU groups (n=24/group). Half of each group was given one daily injection (4 mg/kg BW/d) of DOB (n=12) or an equal volume of saline (VEH; n=12). Two and nine days prior to sacrifice, animals were given subcutaneous doses of calcein (25 mg/kg). After 28 days of HU, undemineralized proximal tibiae were processed for histomorphometric analyses. The 4µm sections (Von Kossa and tetrachrome counter-stained) were analyzed for metaphyseal bone volume (BV/TV), osteoblast surface (Ob.S/BS), osteoclast surface (Oc.S/BS), and trabecular thickness, number and separation (Tb.Th, Tb.N, Tb.S). Unstained 8µm sections quantified mineralizing surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS). At the PTM, HU resulted in no significant changes in BV/TV, Ob.S/BS, Oc.S/BS, Tb.Th, Tb.N, and Tb.Sp. HU did result in significant reductions of MS/BS (-46%), MAR (-25%), and BFR/BS (-58%; p<0.01). However, HU animals treated with DOB had significantly higher MS/BS (105%), MAR (35%), and BFR (168%) than their VEH-treated counterparts (p<0.01). No significant differences were detected for these values in the CC rats given DOB vs. CC-VEH (p>0.05). These results, in combination with previous *in vivo* peripheral quantitative computed tomography data, suggest that DOB administration during HU prevents significant declines in total vBMD at PTM by mitigating associated decrements in BFR/BS. Future work will determine if these positive effects of ADRB administration are due to enhanced blood flow to the unweighted limbs.

## SA515

**Significant Trabecular Bone Degradation Occurs within Five Days of Muscle Paralysis.** S. L. Poliachik\*, S. D. Bain, S. Srinivasan, B. J. Ausk\*, D. Threer\*, P. Huber\*, T. S. Gross. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Previously, we have shown that transient muscle paralysis induced by Botox leads to significant bone loss within 3 wk. Furthermore, we have shown that electrical stimulation of the paralyzed muscle fails to prevent this bone loss. The inability of electrical stimulation to prevent this bone loss led us to hypothesize that muscle paralysis leads to an irreversible activation of osteoclastogenesis that cannot be overcome by electrical stimulation intervention. To investigate this hypothesis, we utilized high-resolution microCT to assess the longitudinal changes in trabecular bone of the proximal tibia following transient calf paralysis.

Experimentally, high-resolution microCT images spanning a 2 mm section of the proximal tibia metaphysis were obtained for 28 female C57BL/6 mice (16 wk) immediately prior to injection of Botox into the calf muscle group (2U/100g, d 0). During the course of the study, groups of mice (n = 4) were scanned every other day, beginning d 3 after Botox injection, and ending on d 17 (maximum of 3 live scans per mouse, interim scans separated by 8 d; each total scan time lasting less than 35 min). All mice were sacrificed and a final scan was performed on d 21. Standard image analysis procedures were used to determine trabecular bone parameters for each scan, while ANOVA with multiple comparisons was used to define temporal differences across groups.

Profound degradation of BV/TV was evident within 5 d (-58.1%, p<0.001) after calf paralysis and a maximum loss of BV/TV was observed at d 11 (-75.3%, p<0.001). While the greatest trabecular bone loss occurred in the proximal tibia metaphysis by d 11, some recovery of BV/TV was evident by d 21 (+23.8% vs. d 11; -51.5% vs. d 0). Maximal decrease in trabecular thickness (-20.03%, p=0.018) was observed at d 11 and trabecular number (-22.4%, p=0.007) at d 15, with upturn evident by d 21 (+13.1% vs. d 11; +12.7% vs. d 15, respectively).

The magnitude and rapidity of trabecular bone loss observed in this study was surprising, and is similar in magnitude and time course to pathological bone resorption that is induced by pharmacological doses of Vitamin D or PTH. The rapid nature of the skeleton's response to muscle paralysis may also explain, at least in part, the relative ineffectiveness of external muscle stimulation in the treatment of spinal cord injury patients. Further investigations in this model will provide a critical context from which to explore activating mechanisms of osteoclastogenesis, and the apparent role of normal muscle function as an active mediator of skeletal homeostasis.

**Musculoskeletal Disuse Worsens the Acute Detrimental Effects of Heavy Particle Radiation on Osteoblastogenesis.** K. Yumoto\*, R. Mojarrab\*, J. Arakaki\*, A. Wang\*, D. Hilton\*, E. A. C. Almeida\*, C. Limoli\*, N. D. Searby\*, R. K. Globus<sup>1</sup>. <sup>1</sup>NASA Ames Research Center, Moffett Field, CA, USA, <sup>2</sup>Radiation Oncology, University of California Irvine, Irvine, CA, USA.

Space presents many challenges to human health, including radiation exposure and musculoskeletal disuse. Astronauts lose bone in long duration missions and recovery after return to earth occurs slowly. Although the detrimental effects of disuse on bone are clear, we do not know how the cells needed for skeletal recovery from spaceflight are affected by space-relevant radiation either alone or in combination with musculoskeletal disuse. To test this, 16 week old, male C57BL/6 mice were either continuously hind limb unloaded (HU) or normally loaded (NL), then irradiated (IR) four days later with Fe-56 (1GeV at 0, 0.1, 0.5 or 2.0 Gy) at the NASA Space Radiation Laboratory (Brookhaven National Laboratory). Tissues were harvested after three more days (total time of HU was 7 days). Bone marrow cells (BMCs) were flushed from femora, counted, plated at constant density, and grown *ex vivo* with osteogenic or osteoclastogenic additives. Cultures were analyzed for osteoblastogenesis (alkaline phosphatase, ALP- positive colonies and enzymatic activity, DNA content as surrogate for cell number) or for osteoclastogenesis (count of multinucleated TRAP-positive cells). Proximal tibiae were analyzed by microcomputed tomography to assess cancellous structure. IR dose-dependently reduced the numbers of marrow cells freshly harvested from bone but HU had no effect. All the groups demonstrated comparable osteoclastogenesis. IR of NL mice had no effect on growth of osteogenic cells *ex vivo* but did inhibit osteoblastogenesis (74, 80 and 53% relative to controls with 0.1, 0.5 and 2 Gy, respectively). HU alone also inhibited osteoblastogenesis (75% of controls). Together, IR and HU had a greater effect than either treatment alone; HU plus 0.5 Gy IR showed the lowest ALP activity (41% of controls). Despite the short duration of this study, IR with only 0.1 Gy caused a 16% reduction in cancellous bone volume fraction and 21% decrease in connectivity compared to control. HU did not have an additional effect on the acute bone loss caused by IR. In sum, low doses of heavy particle radiation caused a rapid decline in cancellous bone volume fraction and inhibited osteoblastogenesis while musculoskeletal disuse worsened the inhibitory effects of radiation on osteoblastogenesis. We hypothesize musculoskeletal disuse sensitizes bone marrow osteoprogenitors to radiation and speculate that radiation exposure in microgravity can impair skeletal recovery from disuse.

**Effects of Running Exercise on Bone Quality After Immobilization.** Z. Peng<sup>1</sup>, H. K. Väänänen<sup>2</sup>. <sup>1</sup>Pharmatest Services Ltd, Turku, Finland, <sup>2</sup>Department of Anatomy, Institute of Biomedicine, University of Turku, Turku, Finland.

Previous studies have shown that exercise improves mechanical properties of bone in growing rats. The aim of the present study was to investigate whether running exercise can improve bone quality after immobilization. Sixty-seven 10-week-old Sprague-Dawley male rats were used in this experiment. The right hind legs of 59 animals were immobilized with plaster cast in plantar flexion for 3 weeks. After removing the casts, the animals were divided into free activity and treadmill running groups (10 m/min for 30 min/day, 5 days/week). Tetracycline and calcein were injected 6 and 2 days before sacrifice, respectively. Bone samples were collected from the immobilized legs and the non-immobilized control legs of each animal, and analyzed at 0, 3, 5, 7 and 11 weeks with peripheral quantitative computed tomography (pQCT), histomorphometry and mechanical testing. Immobilization inhibited longitudinal growth of the femur and decreased cortical bone mineral density (BMD), trabecular bone volume (TBV) and tibia ash weight. Running exercise helped to restore the cortical BMD and TBV of the immobilized leg to the level of the non-immobilized control leg. Exercise also increased the growth rate of the immobilized leg and the length of its femur. Three weeks immobilization decreased cantilever bending strength of the femoral neck (FN), but not the three point bending strength of the tibial diaphysis (TD). However, after removing the casts, the strength of the TD was significantly lower in the immobilized leg compared with the control leg. The running exercise was not able to improve the strengths of the FN and TD. Alterations of the cross sectional moment of inertia resulted in different bending strengths of TD between the two legs, and suggested that the alteration of the bone structural properties were related to the pressure of muscles on the bone tissues. Although running exercise significantly increased bone formation rate in the immobilized legs compared with the control legs at the end of the experiment, changes in stress-strain of the tibia revealed that immobilization decreased plastic properties of the bone material. These results demonstrate that running exercise can accelerate the restoration of bone after immobilization, and that a longer than 3-week immobilization may induce irreversible functional decreases in bone quality.

**Bilateral Bone Density Loss after Unilateral Disuse in the Forearm.** J. A. Spadaro, W. H. Short\*, P. R. Shee\*, R. M. Hickman\*. Orthopedic Surgery, Upstate Medical University, Syracuse, NY, USA.

An opportunity arose to determine if changes occurred in the contralateral forearm of subjects with BMD losses due to injury-initiated disuse in one forearm in data from the e-Bone study. We, like many others, assumed that the "normal" forearm would either remain unchanged or perhaps experience a slight BMD increase due to some increased use. The e-Bone study was a randomized, double blind, sham controlled trial approved by the IRBPHS at SUNY Upstate Medical University (ASBMR 2007 T430). Entry (baseline) was 6-8 weeks after a distal radius fracture or carpal surgery and 99 subjects were randomized to wear a distal forearm PEMF transducer or sham device, 1-4 hours per day for 8 weeks on their involved forearm. Bone mineral density (BMD) and geometry at several sites in both forearms were measured by DXA and peripheral CT at baseline, 8, 16, and 24 weeks. Complete data was available in 82 subjects. Bone formation marker (BSAP) was unchanged on average at 8 weeks vs. baseline, while the resorption marker (CTX) was decreased. In the immobilized forearm, BMD losses by DXA were 5-7 % in the ultra-distal region and 3-4% in the midshaft (p<0.005). Since no detectable changes were observed with PEMF, we analyzed the entire group of subjects for changes in the contralateral forearm.

Results showed a statistically significant and substantial BMD loss in the contralateral forearm on average, despite inter-subject variability. The loss tended to increase over the observation period to 24 weeks after baseline, as has been typically observed for an injured extremity (Fig. 1). The magnitude of loss was about half of that in the injured side at the ultra-distal site (2-4%), but similar to the injured side at the radial shaft site (2-4%).

We hypothesize that this contralateral loss is due to either: (a) systemic hyper-resorptive effects from the injury and/or 'disuse' of the injured side, or (b) may be related to a generalized lower activity level after a forearm injury. This phenomenon needs further exploration and suggests caution in using the uninjured limb as control when studying unilateral BMD changes. (Supported by NIH, NIAMS.)

**Immediate Abnormalities at the Chondro-Osseous Junction due to Severe Spinal Cord Injury in Growing Rats.** L. R. Morse\*, B. Solomon\*, P. Stashenko\*, R. A. Battaglin\*. <sup>1</sup>Physical Medicine and Rehabilitation, Harvard Medical School, Boston, MA, USA, <sup>2</sup>Cytokine Biology, Forsyth Institute, Boston, MA, USA.

Spinal cord injury is associated with rapid bone loss and arrested long bone growth by a mechanism that is poorly understood. In this study we sought to determine the effects of severe T10 contusion spinal cord injury (SCI) on the chondro-osseous junction in adolescent rats. A severe lower thoracic (vertebral T10) spinal cord injury was generated by weight drop contusion (10g x 50mm). Severely injured and body weight-matched naïve (no surgery, n=4) male Sprague-Dawley (SD) rats were studied. At 2 days post-injury, hindlimb functional deficits, bone mineral density assessment by PIXImus scan, histological analysis of the distal femoral metaphysis, and immunohistochemical staining for Substance P were performed. At 2 days post-injury, we observed severe hindlimb functional deficits typical of this model. We detected an increase in trabecular osteoclast activation, a decrease in hypertrophic chondrocytes per column of growth plate, a reduction in growth plate width, and an increase in bone levels of Substance P in the injured animals. We demonstrated a rapid activation of trabecular osteoclasts and growth plate arrest due to loss of hypertrophic chondrocytes following contusion spinal cord injury in rodents. These changes are associated with increased substance P expression suggesting that this neurotransmitter may be involved in the mechanism of bone loss and long bone growth arrest following spinal cord injury. If confirmed, Substance P is a potential therapeutic target to alleviate the bony sequelae of spinal cord injury in humans.

**Effects of Simulated Resistive Exercise on Cortical Bone in the Tibia Mid-Diaphysis of Hindlimb Unloaded Rats.** H. A. Hogan<sup>1</sup>, J. M. Swift<sup>2</sup>, M. I. Nilsson\*, S. A. Bloomfield<sup>2</sup>. <sup>1</sup>Mechanical Engineering, Texas A&M University, College Station, TX, USA, <sup>2</sup>Health and Kinesiology, Texas A&M University, College Station, TX, USA.

The objective of this study was to characterize the effects of controlled electrical muscle stimulation on cortical bone in the tibia mid-diaphysis of hindlimb unloaded (HU) adult male rats. This same general muscle stimulation procedure has been used successfully previously as a countermeasure, but the focus has been on cancellous bone in the proximal tibia metaphysis (PTM). Previous studies showed dramatic anabolic effects in the PTM using eccentric muscle contractions of either 500ms or 1000ms duration. In order to more closely simulate actual resistive exercise in the current study, the protocol used a combination of 1000ms of isometric contraction followed by 1000ms of eccentric contraction. Six-mo. male Sprague-Dawley rats were randomly assigned to cage control (CC; n=12), hindlimb unloading plus muscle stimulation (HU+STIM; n=10), or HU plus anesthesia as another control (HU+AN; n=6) groups. The HU+STIM animals were anesthetized and subjected to muscle stimulation every other day (4 sets of 5 reps) for the 28 days of HU, while HU+AN animals were anesthetized without stimulation following the same schedule. In vivo peripheral quantitative computed tomography (pQCT) scans were taken at the tibial mid-diaphysis on anesthetized animals on days 0 and 28 to assess bone properties. Simulated exercise had a beneficial effect on both BMC and vBMD. The pre-to-post change for HU+STIM animals was +9% for BMC and +5% for vBMD, which are similar to results from the 500ms and 1000ms protocols in previous studies. There was no change for HU+AN, and an 8% increase for CC animals. In addition, tibiae were excised post-sacrifice for determination of mechanical properties at the mid-diaphysis using 3-point bending. Surprisingly, simulated exercise had little effect on mechanical properties. Comparing endpoint values (28d) between HU+STIM and HU+AN, the ultimate load was essentially the same, and there was a trend (non-significant) toward lower stiffness, elastic modulus, and yield stress (~5%). The only dramatic difference was for the total energy absorbed, or work-to-fracture, which was 34% higher for HU+STIM. We speculate that the lack of a beneficial effect on most mechanical properties may be due to differences in the organic matrix, perhaps less mature due to cross-sectional remodeling. Another possible reason may be the relatively low number of animals for biomechanics.

**Mechanical Strain Prevents Adipogenesis in Mesenchymal Stem Cells By Stimulating a Durable  $\beta$ -Catenin Signal.** B. Sen\*, Z. Xie\*, N. Case<sup>1</sup>, M. Ma\*, C. Rubin<sup>2</sup>, J. Rubin<sup>1</sup>. <sup>1</sup>Medicine, UNC-CH, Chapel Hill, NC, USA, <sup>2</sup>Biomedical Engineering, SUNY, Stony Brook, NY, USA.

The ability of exercise to decrease fat mass and increase bone mass may arise through mechanical biasing of mesenchymal stem cell (MSC) commitment towards osteoblastogenesis and away from adipogenesis. To study the effect of mechanical strain on lineage selection we ascertained that C3H10T1/2 MSC cultured in a highly adipogenic "A" medium contained lipid at 3 days, and nearly all cells stained for oil-red-O after 5 days. PPAR $\gamma$  and adiponectin mRNA (RT-PCR) and protein (Western) was present at 3d and continued to rise at 5d. Active and total  $\beta$ -catenin levels fell sharply over the 5 d of adipogenesis. Application of strain daily (3600 cycles, 2%) inhibited adipocyte differentiation as measured by decreased cellular lipid droplets at 3 and 5d. Strain as well inhibited expression of PPAR $\gamma$  mRNA by nearly 50%, and

adiponectin by 75%, changes were confirmed by Western. The decrease in  $\beta$ -catenin seen during adipogenesis was entirely prevented by daily application of strain. Cyclin D1 expression reflected the change in  $\beta$ -catenin: cyclin D1 mRNA fell to  $51 \pm 5\%$  after 5 d in A medium compared to cells in growth medium. Mechanical challenge increased cyclin D1 mRNA to  $195 \pm 23\%$  at 3d, and nearly 3-fold at 5d ( $p < 0.01$ ) compared to unstrained cells in A medium. Expression of second  $\beta$ -catenin response gene, WISP1, paralleled that of cyclin D1: WISP1 dropped to  $21 \pm 1\%$  by 5d in A medium ( $p < 0.05$ ), and increased with mechanical strain to  $245 \pm 46\%$  and  $611 \pm 116\%$  after 3d and 5d respectively ( $p < 0.05$  for both). LiCl similarly prevented adipogenesis, implicating  $\beta$ -catenin in strain's ability to inhibit adipogenesis. Mechanical strain activated AKT followed by inactivation of GSK3 $\beta$ , demonstrated by increase in phospho-forms of both kinases after strain, suggesting a possible pathway for mechanical control of  $\beta$ -catenin activity. Finally, in cultures subjected to mechanical strain, there was enhanced potential for entry into the osteoblast lineage: cells were cultured in A medium  $\pm$  strain for 3 d, followed by 2 d of BMP2 treatment to induce osteoblast differentiation. In unstrained cultures, Runx2 and osterix did not rise in response to BMP2, but in cultures subjected to mechanical strain, BMP2 increased expression of Runx2 by 40% and osterix by 68%. These results indicate that MSC commitment to adipogenic lineage can be suppressed by mechanical signals even during highly adipogenic conditions, and implicate  $\beta$ -catenin activation as a mechanism. Further, by preserving  $\beta$ -catenin levels, mechanical strain allows MSC to be more responsive to osteogenic factors. Our work suggests that exercise should have positive effects for both osteoporosis and obesity by affecting MSC lineage allocation.

**The Effects of Electrical Stimulation on Nitric Oxide Expression and Osteocyte Viability in Ovariectomized Rats.** A. P. R. Lirani-Galvao<sup>\*1</sup>, P. Chavassieux<sup>2</sup>, N. Portero-Muzy<sup>\*2</sup>, O. L. Silva<sup>\*3</sup>, C. Bergamaschi<sup>\*1</sup>, M. Lazaretti-Castro<sup>1</sup>, P. D. Delmas<sup>2</sup>. <sup>1</sup>Departamento de Medicina, Universidade Federal de Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>INSERM Unit 831, Université de Lyon, Lyon, France, <sup>3</sup>Bioengenharia, Universidade de Sao Paulo, Sao Paulo, Brazil.

We have previously shown in rats that electrical stimulation (ES) may prevent the increased bone turnover, microarchitecture deterioration and bone loss induced by ovariectomy (OVX) (J. Bone Miner. Res. 22 Suppl1:S447, 2007). Osteocytes have been hypothesized to mediate this effect by releasing biochemical signals such as nitric oxide (NO). The aim of the present study was to investigate the potential role of NO in the response to ES on the osteocyte viability in OVX rats. Sixty rats (200-220g) were divided into 6 groups: SHAM; SHAM treated with 6mg/d of L-NAME, an inhibitor of NO synthase (SHAM-L); ovariectomized (OVX); OVX treated with L-NAME (OVX-L) or subjected to an electrical stimulation (OVX-ES) or both (OVX-L-ES) for 12 weeks.

The expressions of endothelial NO synthase (eNOS) and inducible NOS (iNOS) and osteocyte apoptosis (caspase-3 and TUNEL) were assessed by immunostaining. eNOS and iNOS were similarly expressed in subperiosteal regions of the cortices of metaphysis and diaphysis of tibiae in SHAM group, but they were not detected in OVX and L-NAME treated groups. In OVX-ES group, similar expressions of eNOS and iNOS were detected in cortical bone of tibial diaphysis as in SHAM. When compared to SHAM, OVX significantly increased the percentage of apoptotic cells and empty lacunae ( $p < 0.05$ ) but this effect was prevented by ES. SHAM-L and OVX-L showed a diminished percentage of apoptotic osteocytes when compared to SHAM and OVX, respectively. Interestingly, this difference was not observed between OVX-L-ES and OVX-ES.

In conclusion, ES may counteract the effects of OVX on bone tissue in rats through the activation of iNOS and eNOS, preserving the osteocyte viability and secondary acting on bone remodelling to maintain the bone structure and architecture. It was not possible, however, to identify if L-NAME blocks the effects of ES on osteocytes, since their effects on these cells are similar. Regarding osteocyte viability it seems that the effects of ES and L-NAME are similar. We hypothesized that the decreased percentage of apoptotic osteocytes in groups under L-NAME may be due to bone mechanical stimulation caused by high blood pressure levels induced by NO blockage (Turner et al., Bone 1997, 21:487-90). However, the other results cited above suggest that NO may mediate the effects of ES on bone tissue.

**Strain-Induced Fluid Flow in a Three-Dimensional Porous Matrix Promotes Osteoblastic Calcification *in vitro*.** S. M. Tanaka<sup>1</sup>, M. Kakio<sup>\*2</sup>, K. Yamakoshi<sup>\*2</sup>. <sup>1</sup>Institute of Nature and Environmental Technology, Kanazawa University, Kanazawa, Ishikawa, Japan, <sup>2</sup>Graduate School of Natural and Science Technology, Kanazawa University, Kanazawa, Ishikawa, Japan.

Bone strain generated by external loading force induces fluid flow in bone matrix, which creates fluid shear stress on bone cells. Strain-induced fluid flow is known to play a dominant role in the regulation of stress-sensitive genes in osteoblasts *in vitro*, compared to substrate strain alone [1]. The purpose of this study is to investigate the capability of strain-induced fluid flow to promote osteoblastic calcification *in vitro*. Osteoblasts differentiated

from mesenchymal stem cells in rat bone marrow were seeded into a porous scaffold made of type I collagen (16 mm in length x 20 mm in width x 2 mm in thickness, pore size: about 100  $\mu$ m) at a cell number of  $0.7 \times 10^6$  with an osteogenic medium containing 50  $\mu$ g/ml L-ascorbic acid, 10 mM  $\beta$ -glycerolphosphate, and  $10^{-8}$ M dexamethasone. A sinusoidal mechanical load with a magnitude of 2000  $\mu$ strain was applied to the scaffold at 0.8 Hz for 3 minutes per day for 35 days using a piezoelectric mechanical stimulator to give cyclic strain-induced fluid flow to the cells in the porous scaffold [1]. The degree of osteoblastic calcification in a scaffold was monitored non-destructively once a day using an optical sensing unit composed of four light emitting diodes (LED) and a photodiode (PD) placed under a culture chamber. The LEDs irradiate a scaffold with near-infrared light at 850 nm increasing its intensity ( $I_0$ ) and the intensity of diffuse reflectance light ( $I$ ) from the scaffold is measured by the PD. Using the slope of  $I_0$ - $I$  curve, the degree of calcification is evaluated as bulk density ( $\text{mg}/\text{cm}^3$ ). In the scaffolds stimulated by strain-induced fluid flow, bulk density started to increase after day 10 and reached finally to about  $30 \text{ mg}/\text{cm}^3$ . On the other hand, the controls without the stimulation did not represent a remarkable increase in bulk density. The results indicated that strain-induced fluid flow could be a potent enhancer for osteogenesis *in vitro*.

**Mechanical Loading Upregulates Expression of the Transcription Factor EGR2/Krox-20 by a COX2-mediated Mechanism.** G. Zaman<sup>\*</sup>, L. K. Saxon, B. Javaheri<sup>\*</sup>, A. Sunters<sup>\*</sup>, J. S. Price, L. E. Lanyon. Basic Sciences, The Royal Veterinary College, London, United Kingdom.

Microarray analysis of mRNA extracted from the tibiae of 8 female C57BL/6 mice showed differential regulation of 621 genes between bones that had been subjected *in vivo* to a single period of dynamic axial loading (2 Hz for 30 seconds) capable of stimulating osteogenesis, compared with unloaded contra-lateral bones. At 3 hours after loading one of the genes showing substantial (1.9 fold) differential up-regulation was EGR2/Krox-20. Expression levels were restored to those in controls by 8 hours after loading. These results were confirmed by quantitative real-time PCR (qRT-PCR).

*In vitro*, monolayer cultures of primary osteoblast-like cells prepared from C57BL/6 mouse long bones and UMR106 cells, when subjected to a single period of mechanical strain (peak strain 3400 microstrain, 1 Hz, 600 cycles), showed a maximal 2 and 3 fold increase respectively in EGR2 mRNA levels (by qRT-PCR) 1 hour after exposure to strain. This strain-related increase in EGR2 mRNA levels was abolished by the COX2 inhibitor NS398 (1  $\mu$ M) and imitated (2.6 fold increase) by exogenous prostaglandin (PG) E2 (5  $\mu$ M). The PGE2-induced increase in EGR2 expression was abolished by blocking the EP1 & EP2 PG receptors (30  $\mu$ M AH6809), whereas inhibiting the EP4 receptor inhibitor (30  $\mu$ M AH23848) only partially lowered expression (by 29%). The PKC agonist PMA (500 nM) caused a significant increase in EGR2 mRNA expression whereas exogenous dibutyryl-cyclic AMP (100  $\mu$ M), which activates PKA signaling, caused a significant decrease. Consistent with this finding, pretreatment with the PKA antagonist H89 (1  $\mu$ M) significantly increased PGE2-induced EGR2 expression.

That bone cells respond to mechanical strain by COX2 mediated release of prostanoids has been recognized for some time. The immediate downstream consequences of this PG release have been unclear. The data reported here suggest that one of these downstream targets is EP receptor-mediated increase in the expression of EGR2, a zinc finger transcription factor belonging to the Early Growth Response (EGR) family. EGR2 has previously been reported to be involved in osteoblast differentiation and to act as a pro-survival factor. Suppression of EGR2 expression has been implicated in glucocorticoid-induced osteoporosis and EGR2 mutant mice have defective bone formation. To our knowledge EGR2 has never before been implicated in bone cells' responses to mechanical loading.

**Integrin Mediated Mechanical Forces Stimulate Differentiation of Mesenchymal Stem Cells.** P. Müller\*, A. Kasten\*, C. Bergemann\*, J. Rychly. Laboratory for Cell Biology, University of Rostock, Rostock, Germany.

Mesenchymal stem cells are multipotent and differentiate into different phenotypes including osteoblasts in dependence on the environment. Mechanical forces play a significant physiological role in the control of cells. Although evidence exists that mechanical forces are a significant factor to drive mesenchymal stem cells towards the osteogenic differentiation, little is known how physical forces contribute to the decision for a defined differentiation pathway. Concerning the mechanisms, how cells sense mechanical forces, adhesion receptors like integrins function as mechanotransducers and mediate applied forces from the extracellular matrix to the cytoskeleton in the cell interior. Therefore we applied a technique to mechanically stress integrin receptors on the apical surface of adherent cells, using antibody coating magnetic beads.  $\beta 1$ -integrin receptors of human bone marrow derived mesenchymal stem cells were mechanically stressed for 15 min with 1 Hz. Scanning electron microscopy revealed that stressing the receptors induced a slight distortion of the cell surface in the vicinity of a bead but had no effect on the global cell shape. Mechanical stress to the integrin receptor induced a signal transduction which was detected by activation of the MAP-kinases ERK 1/2 and the signaling protein Akt. To test the effect of mechanical integrin stress on the differentiation of mesenchymal stem cells, we analysed the expression of characteristic marker proteins for osteogenic and adipogenic differentiation using real-time PCR and Western blot. Mechanical stress induced an increased expression of the transcription factor Runx2 as well as VEGF, collagen I and ALP on the mRNA level within 1 hour after the applied stress. This indicated that integrin mediated mechanical forces induced the osteogenic differentiation of mesenchymal stem cells. Analyses of the expression of PPAR $\gamma$ , a marker for the adipogenic differentiation pathway, revealed a pronounced increase of the mRNA due to mechanical stress after 24 h. Together, the results demonstrated that mechanical integrin stress drives mesenchymal stem cells both to the osteoblastic and adipogenic differentiation. It appeared that expression of osteogenic markers occurred faster, whereas proteins related to the adipogenic pathway are stimulated later by mechanical forces. We conclude that mechanical forces mediated by integrin receptors are able to stimulate the differentiation of mesenchymal stem cells into different directions and the final cellular phenotype will be determined in the context with different other environmental factors.

**Effect of MKP-1 Deletion on the Fluid Shear Stress Induction of COX-2 Expression in Osteoblasts.** L. Ma<sup>\*1</sup>, M. Mehrotra<sup>\*2</sup>, S. Choudhary<sup>1</sup>, L. Raisz<sup>1</sup>, C. Pilbeam<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Department of Pathology and Laboratory Medicine, Medical University of South Carolina, Charleston, SC, USA.

Mitogen activated protein (MAP) kinase phosphatase-1 (MKP-1) can dephosphorylate and inactivate MAP kinases, including extracellular signal-regulated kinase (ERK). ERK activation has been shown to be important for the fluid shear stress (FSS) induction of cyclooxygenase-2 (COX-2), the major enzyme regulating prostaglandin production, in osteoblasts. The goal of this study was to evaluate the role of MKP-1 in the FSS regulation of COX-2. We applied 30 min of FSS (pulsatile, 10 dynes/cm<sup>2</sup>) to MC3T3-E1 cells or calvarial osteoblasts, followed by static culture for up to 4 h. Calvarial osteoblasts were sequentially digested from neonatal calvariae of MKP-1 wild type (WT) and knockout (KO) mice, and populations 2-5 were pooled, grown to confluence and replated for experiments. mRNA and protein expression was measured by real-time PCR and Western blot, respectively. In MC3T3-E1 cells, FSS stimulated a 6-fold induction of MKP-1 mRNA and an 8-fold induction of COX-2 mRNA. The induction of both MKP-1 and COX-2 peaked 30 min after cells were returned to static culture (post-FSS). The FSS induction of ERK phosphorylation in MC3T3-E1 cells was biphasic, peaking at 30 min of FSS and decreasing at 30 min to 1 h in post-FSS culture before increasing again at 2-4 h. Treatment with a specific ERK inhibitor PD98059 (50  $\mu$ M) significantly decreased COX-2 induction. In calvarial osteoblasts from MKP-1 WT and KO mice, the temporal patterns of FSS-stimulated ERK phosphorylation and COX-2 mRNA expression were similar to those seen in MC3T3-E1 cells. However, the FSS-stimulated phosphorylation of ERK was increased in MKP-1 KO osteoblasts at all time points compared to WT osteoblasts. FSS-stimulated COX-2 mRNA expression was also increased in MKP-1 KO osteoblasts compared to WT osteoblasts. These data suggest that FSS-stimulated MKP-1 expression limits the FSS stimulation of both ERK phosphorylation and COX-2 expression. We conclude that FSS-stimulated MKP-1 expression may be important for regulating responses to mechanical loading of bone.

**Interfacial Tissue Response is Influenced by Local Strain Created During Implant Micromotion.** R. M. Wazen<sup>\*1</sup>, J. B. Brunski<sup>\*2</sup>, J. A. Currey<sup>\*2</sup>, J. A. Helms<sup>\*3</sup>, P. Leucht<sup>\*3</sup>, A. Nanci<sup>\*1</sup>. <sup>1</sup>Faculty of Dentistry, Université de Montréal, Montréal, QC, Canada, <sup>2</sup>Rensselaer Polytechnic Institute, Troy, NY, USA, <sup>3</sup>Stanford University, Stanford, CA, USA.

During healing of an implant in bone, loading can create implant micromotion at the bone-implant interface. Mechanical conditions and interfacial strain associated with implant micromotion also contribute to the regulation of cell and tissue healing response. Excessive implant micromotion can lead to fibrous encapsulation and implant loosening. The objective of this study was to characterize the influence of interfacial strain in the environment of an implant on bone healing in a mouse. The micromotion system consisted of a miniature device in which pin or screw-shaped implants were installed through a hole drilled in one cortex of the tibia. These implants were placed in holes of different sizes to produce interfaces with (1) no initial contact between implant and bone, and (2) a direct bone-implant contact. Implants were subjected to a displacement of 150  $\mu$ m at ~1 cycle/sec for 60 cycles/day for a 7 day period. Control implants in both types of interfaces were stabilized throughout the 7-day healing period. Undecalcified tissue sections of control and strained interfaces at 7 days were prepared and stained with Goldner to evaluate tissue reaction in relation to higher strain regions present at the ridges and base of the pin implants, and lower strain regions on the smooth sides of the pins. Experimental strain analyses and finite element simulations were used to characterize interfacial strain fields. In stable implants, normal bone formation occurs consistently around the implants. In implants subjected to micromotion, bone regeneration was disrupted in areas of high strain concentrations (e.g., greater than 30%), whereas lower strain values contributed to bone formation. These results suggest that in the early healing period, high principal tensile and/or compressive strains interfered with normal bone regeneration. It is concluded that implant micromotion as well as interfacial strain field contribute to regulating the interfacial mechanobiology at healing bone-implant interfaces.

**Bone Resorption and Articular Cartilage Degenerative Changes Following Performance of High Repetition High Force Tasks Are Attenuated by Secondary Ibuprofen Treatment.** M. F. Barbe<sup>1</sup>, M. Amin<sup>\*2</sup>, M. Harris<sup>\*2</sup>, J. B. Driban<sup>\*3</sup>, F. F. Safadi<sup>4</sup>, A. E. Barr<sup>\*5</sup>. <sup>1</sup>Physical Therapy; Anat & Cell Biology, Temple University, Philadelphia, PA, USA, <sup>2</sup>Physical Therapy, Temple University, Philadelphia, PA, USA, <sup>3</sup>Kinesiology, Temple University, Philadelphia, PA, USA, <sup>4</sup>Anat & Cell Biology, Temple Medical School, Philadelphia, PA, USA, <sup>5</sup>Physical Therapy, Thomas Jefferson University, Philadelphia, PA, USA.

Using our rat model of voluntary repetitive and forceful reaching, we have shown that high repetition low force tasks result in increased osteoclasts and macrophages in forelimb musculoskeletal tissues. Here, our purpose was to determine if high demand repetitive tasks lead to bone resorption, cartilage damage and increased serum biomarkers of bone and cartilage turnover, and if the mechanism has an inflammatory component. 54 young adult, female Sprague-Dawley rats were trained to perform an upper extremity high force lever pulling task (60% max. force) at high reach rates (12 reaches/min) (HRHF) for 12 weeks; 21 were treated with ibuprofen (oral; 45 mg/kg body weight/day) from the end of wk 4 to wk 12 while continuing to perform the task. Results were compared to 12 normal and 9 ibuprofen treated age- and weight-matched controls. After perfusion fixation, micro-CT analysis was used to examine distal forelimb bones from 3 rats/gp. We observed decreased trabecular number and increased trabecular separation in 12 wk HRHF rats (Tb N/mm: 1.75  $\pm$  0.19 and Tb Sp (um): 0.36  $\pm$  0.03) compared to controls (Tb N/mm: 2.33  $\pm$  0.21 and Tb Sp): 0.26  $\pm$  0.006), changes ameliorated by ibuprofen (Tb N/mm: 2.22  $\pm$  0.39 and Tb Sp: 0.32  $\pm$  0.06) ( $p < 0.01$ ). Forelimb bones ( $n = 6$ /gp) were embedded, sectioned, stained immunostained and osteoclasts counted. Osteoclasts increased in distal radius and ulna at the periosteal-bone interface and trabecular surfaces in 12 wk HRHF rats ( $p < 0.001$ ). Bones were also stained with Safranin O to examine wrist joint surfaces for cartilage changes. Safranin O losses were observed in the articular cartilages of 12 wk HRHF rats only. Serum from all rats was assessed using ELISA for bone turnover markers ( $n = 6$ -9/gp). Serum C12C, CTX1 and TRAP5b were significantly increased in the 12 wk HRHF rats (1.5 fold, 1.79 fold and 1.28 fold increases, respectively). Ibuprofen treatment did not ameliorate TRAP5b increases, but reduced C12C, CTX 1 and the ratio of CTX/TRAP5b levels back to control levels ( $p = 0.04$ ,  $p < 0.001$ ,  $p < 0.01$ , respectively). Thus, performance of the HRHF task for 12 weeks resulted in increased osteoclast numbers and activity, and bone resorption in forelimb bones. These changes were attenuated by secondary intervention with ibuprofen, thus suggesting that these changes are at least partially induced by inflammatory processes.

**Targeted Exercise against Hip Fragility.** R. Nikander<sup>1</sup>, P. Kannus<sup>\*1</sup>, P. Dastidar<sup>\*2</sup>, M. Hannula<sup>\*3</sup>, L. Harrison<sup>\*2</sup>, T. Cervinka<sup>\*3</sup>, N. G. Narra<sup>\*3</sup>, R. Aktour<sup>\*3</sup>, T. Arola<sup>\*3</sup>, H. Eskola<sup>\*3</sup>, S. Soimakallio<sup>\*4</sup>, A. Heinonen<sup>5</sup>, J. Hyttinen<sup>\*3</sup>, H. Sievänen<sup>1</sup>. <sup>1</sup>UKK Institute, Tampere, Finland, <sup>2</sup>Radiology, Regional Medical Imaging Center, Tampere University Hospital, Tampere, Finland, <sup>3</sup>Biomedical Engineering, Tampere University of Technology, Tampere, Finland, <sup>4</sup>Radiology, Regional Imaging Center, Tampere University Hospital, Tampere, Finland, <sup>5</sup>Health Sciences, University of Jyväskylä, Jyväskylä, Finland.

**Objectives** To investigate whether sports involving either high-magnitude vertical impacts (triplejumping and high-jumping), moderate-magnitude impacts from rapidly varying and odd directions (soccer and squash-playing), high-magnitude muscle forces (power-lifting), low-magnitude impacts at high repetition rate (endurance running), or non-weight bearing muscle activity at high repetition rates (swimming) would strengthen the cortical bone at the proximal femur, and if so, to what extent and at which anatomic regions of the femoral neck.

**Design** Cross-sectional study

**Setting** The UKK Institute for Health Promotion Research and Tampere University Hospital, Finland in 2007-2008

**Participants** 91 adult female athletes, with ~10 years of intense sport-specific training on average and competing actively at the national or international level, and 20 non-athletic female referents

**Main outcome measures** Segmental cortical thickness at the femoral neck and trochanteric region of the proximal femur as assessed by three-dimensional magnetic resonance imaging of the whole proximal femur.

**Results** At the inferior segment, only the high-impact group differed significantly (~55%,  $p=0.012$ ) from the reference group, while at anterior segment, the cortical thickness in both the high-impact and odd-impact group differed from the reference group (~20%,  $p=0.042$  and  $p=0.044$ , respectively). Similarly, the posterior cortical wall was ~20% thicker ( $p=0.014$  and  $p=0.006$ , respectively) in these two groups. At the superior segment, the cortical thicknesses did not significantly differ between the groups.

**Conclusion** Long-term high-impact and odd-impact exercise-loading has similar ability to strengthen the femoral neck cortical bone - not only at the primary weight-bearing inferior segment but also at the lateral segments of the femoral neck, considered critical in terms of hip fragility. Since odd-impact exercises are mechanically less demanding to joints, muscles, and bones than vertical high-impact exercises, this type of training, comprising moderate-magnitude impacts from odd directions, is recommended as a feasible basis for devising targeted exercises against hip fragility.

**Bone Density Comparisons in Young Male Rock Climbers, Weight Lifters and Sedentary Controls.** V. D. Sherk, M. G. Bembem\*, D. A. Bembem. Health and Exercise Science, University of Oklahoma, Norman, OK, USA.

Technical free rock climbing is a physically demanding activity that has gained popularity in recent years, but it is unclear how climbing affects bone health. The combination of impact loading received on the body when taking a lead or bouldering fall and the dynamic movements required for climbing often mimic calisthenic, resistance training or plyometric exercises, therefore, this recreational activity may have bone loading effects. The purpose of this study was to compare bone density of the total body, AP lumbar spine, dual proximal femur and forearm in advanced rock climbers (RC), resistance trained men (RT), and untrained controls (CTR), ages 18-35 years. Fifteen advanced rock climbers, 16 resistance-trained men, and 16 untrained men volunteers were recruited for the study. Areal bone mineral density (aBMD) and bone mineral content (BMC) were assessed using DXA (GE Lunar Prodigy, enCORE 2006 version 10.50.086). Body composition variables (% body fat, fat mass, bone free lean body mass) were obtained from the total body scan analysis. Subjects also completed questionnaires to assess physical activity (Baecke) and daily calcium intake. No significant ( $p > 0.05$ ) group differences in calcium intake, body weight, or bone free lean body mass were observed. RT ( $22.3 \pm 0.5$  yrs) was significantly ( $p < 0.05$ ) younger than other two groups (RC  $25.9 \pm 1.4$  years; CTR  $26.7 \pm 1.3$  years). RC reported being more physically active than RT and CTR, and they had a significantly ( $p < 0.05$ ) lower % body fat ( $14.5 \pm 4.8\%$ ) and fat mass ( $10.9 \pm 1.2$  kg) than RT ( $19.4 \pm 2.2\%$  and  $10.9 \pm 1.2$  kg) and CTR ( $27.3 \pm 2.3\%$  and  $23.2 \pm 2.6$  kg). One-way ANOVA showed that RT had significantly ( $p < 0.05$ ) greater aBMD at the L1-L4 spine and femoral neck than RC and CTR, and RC had significantly lower aBMD at the 33% radius than CTR. After adjusting for fat mass, RT also had significantly ( $p < 0.05$ ) total body BMD than CTR. In conclusion, rock climbers exhibited similar BMD values as controls for the spine and hip sites, however, their mean forearm BMD was approximately 10% lower than controls.

Table 1. Areal Bone Mineral Density Values for Rock Climber (RC), Resistance Trained (RT), and Control (CTR) Subjects. (Means  $\pm$  SE)

aBMD site (g/cm <sup>3</sup> )	RC (n=15)	RT (n=16)	CTR (n=16)
Total Body	1.246 $\pm$ 0.024	1.319 $\pm$ 0.020	1.268 $\pm$ 0.019
L1-L4 AP Spine	1.203 $\pm$ 0.031	1.341 $\pm$ 0.031 <sup>a</sup>	1.217 $\pm$ 0.020
Total Hip	1.111 $\pm$ 0.033	1.215 $\pm$ 0.027	1.142 $\pm$ 0.032
Femoral Neck	1.092 $\pm$ 0.032	1.267 $\pm$ 0.034 <sup>a</sup>	1.129 $\pm$ 0.035
Trochanter	0.907 $\pm$ 0.026	0.966 $\pm$ 0.023	0.920 $\pm$ 0.035
33% Radius	0.882 $\pm$ 0.030 <sup>b</sup>	0.954 $\pm$ 0.023	0.979 $\pm$ 0.018

<sup>a</sup> Significantly greater than RC and CTR,  $p < 0.05$ ; <sup>b</sup> Significantly lower than CTR,  $p < 0.05$ .

**Jumping Mechanography Safely Evaluates Muscle Performance in Older Adults.** B. Buehring, S. Valentine\*, A. Woods\*, M. Checovich, D. Krueger, N. Binkley. Osteoporosis Clinical Research Program, University of Wisconsin, Madison, WI, USA.

Neuromuscular function declines with advancing age and is strongly associated with increased risk for falls, hip fractures and decreased quality of life. A variety of tests, e.g., chair-rise or timed-up-and-go, assess muscle function. However, a need exists for more sensitive tools to evaluate interventions designed to enhance neuromuscular performance. Jumping mechanography quantitatively measures an individual's ability to generate power and correlates with the methods noted above. However, only limited data evaluating the safety of older adults performing maximal countermovement jumps (CJ) on a force platform exists. As such, this study investigated safety and utility of jumping mechanography in 40 (20 men/20 women), community-dwelling adults over age 60. At baseline, jumping mechanography of two-leg CJ was performed on a force platform (Leonardo, Novotec, Pforzheim, Germany). All participants completed three maximal CJ; maximal jump height [cm] and specific power [W/kg] were calculated. Main outcomes were worsening pain and new vertebral fracture. Pain was assessed using a visual analog pain scale before and immediately after jumping and 7 days later. Bone mineral density (BMD) and vertebral fracture assessment (VFA) were performed using a Lunar iDXA densitometer (GE Healthcare, Madison, WI) prior to CJ and VFA was repeated in 7 days. Stadiometer measured height was obtained at baseline and day 7. Data were analyzed using linear regression and t-test. Age [mean ( $\pm$  SD, range)] and BMI were  $77 (\pm 9, 63-91)$  years and  $25.5 (\pm 3.6, 19.4-34.1)$  kg/m<sup>2</sup> respectively. Mean lowest T-score of the L1-4 spine, total femur or femur neck was  $-1.43 (\pm 1.1; \text{range } 2.4 \text{ to } -3.1)$ . At baseline, 6 participants had prevalent fractures; 4 had multiple fractures. Power and jump height were lower in older volunteers and did not differ by gender. Mean jump height in women was  $14.4 \text{ cm} \pm 5.8$  and  $16.4 \text{ cm} \pm 6.8$  in men. Mean power in women was  $19.2 \text{ W/kg} \pm 5.6$  and  $21.1 \text{ W/kg} \pm 6.3$  in men. Pain was low at baseline and follow-ups, ranging from 0 to 5. Pain was reported by 8 individuals before jumping; after jumping, 4 reported a pain change of 1, two noted new pain, one worsened and one improved. A week later, compared to baseline, 6 reported worsening pain and 6 improved. No height or vertebral fracture status change was observed after jumping. In summary, jumping mechanography demonstrates lower jump height and generated power with advancing age. Additionally, it is safe with no substantial increase in pain or worsening of vertebral fracture status in older adults, including those with low BMD and prevalent vertebral fracture. Further evaluation of this methodology as a tool to evaluate change in neuromuscular performance of older adults is indicated.

**The Influence of Muscle Size and Strength on Changes in Bone Mass and Size During Growth and in Response to Exercise: A Longitudinal Study.** G. Ducher<sup>1</sup>, R. Daly<sup>2</sup>, J. Black<sup>\*3</sup>, C. Turner<sup>\*4</sup>, S. Bass<sup>1</sup>. <sup>1</sup>Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia, <sup>2</sup>Department of Medicine, Western Hospital, The University of Melbourne, Melbourne, Australia, <sup>3</sup>Musculoskeletal Research Centre, La Trobe University, Heidelberg, Australia, <sup>4</sup>Biomedical Engineering, Indiana University-Purdue University, Indianapolis, IN, USA.

The objective of the study was to investigate the influence of growth and exercise-related changes in muscle size and strength on the changes in bone mass and geometry. Fifty-two competitive tennis players (26 boys), mean age 13.7 yrs (range 6.7-16.5 yrs), had their dominant and non-dominant humeri scanned by MRI at baseline and 12 months. Total bone and muscle cross-sectional areas (BCSA and MCSA) were determined from the mid (40-50%) and distal humerus (60-70%). Humeral bone mass (BMC) was derived from the whole body DXA scan and grip strength was assessed using a dynamometer. Annual changes ( $\Delta$ ) were calculated for height and all the aforementioned parameters. Pubertal status was self-assessed using Tanner stages.

Growth effect (nondominant humerus):  $\Delta$ BMC,  $\Delta$ BCSA,  $\Delta$ MCSA and  $\Delta$  grip strength were closely related to the increase in height ( $r=0.35-0.71$ ,  $p<0.05-0.0001$ ). Baseline pubertal status was a significant predictor of  $\Delta$ BMC and  $\Delta$ BCSA only after adjustment for  $\Delta$  height ( $r=0.26-0.40$ ,  $p<0.01-0.07$ ). Although  $\Delta$ BMC and  $\Delta$ BCSA correlated with  $\Delta$ MCSA ( $r=0.30-0.55$ ,  $p<0.005$ ) and  $\Delta$  grip strength ( $r=0.33-0.40$ ,  $p<0.05$ ), hierarchical regression showed that  $\Delta$  height and baseline pubertal status explained 36-55% of the variance for the  $\Delta$ BMC and  $\Delta$ BCSA ( $p<0.05$ ) and neither  $\Delta$ MCSA nor  $\Delta$  grip strength contributed to the model. Exercise effect: The dominant humerus, which was submitted to repetitive loading through tennis playing, showed 44-66% greater  $\Delta$ BMC and  $\Delta$ BCSA than the nondominant humerus ( $p<0.0001$ ). The difference in  $\Delta$ BMC between both humeri remained significant after adjustment for  $\Delta$ MCSA or  $\Delta$  grip strength ( $p<0.01$ ). This suggests that non-muscular factors contributed to the exercise-induced increase in bone mass and bone size. The average training volume throughout the year (hours/wk) was a significant predictor of  $\Delta$ BMC and  $\Delta$ BCSA ( $r=0.28-0.41$ ,  $p<0.05$ ), even after adjustment for  $\Delta$ MCSA. The largest proportion of the variance in  $\Delta$ BMC was explained by  $\Delta$  height and baseline pubertal status (33%,  $p<0.0001$ ) with an extra 9% explained by the average training volume ( $p=0.009$ ).

Changes in body size affect both muscle and bone tissues, largely explaining the strong associations between changes in bone mass or size and muscle size. Additional loading (tennis playing) stimulates bone accrual independently of changes in muscle size or muscle strength, possibly through repetitive impacts.

**HSA and Physical Activity in Boys and Girls During Puberty.** G. Y. Rochefort<sup>\*1</sup>, R. El Hage<sup>\*2</sup>, D. Courteix<sup>\*1</sup>, E. Lespessailles<sup>1</sup>, C. L. Benhamou<sup>1</sup>, C. Jacob<sup>\*2</sup>, C. Jaffre<sup>\*1</sup>. <sup>1</sup>Rheumatology, INSERM U658, IPROS, CHR Orleans, Orleans, France, <sup>2</sup>Faculty of Arts and Sound Sciences, Physical Education Division, Tripoli, Libyan Arab Jamahiriya.

**Introduction:** Physical loading increases bone mass, bone mineral density and bone strength during puberty. During adolescence, sexual dimorphism in bone, lean and fat mass increases, giving rise to greater size and strength of the male skeleton. However, little is known about the gender differences in femoral neck geometry in adolescent athletes.

**Methods:** 12 adolescent boys and 8 adolescent girls participated in this study (mean age 15.25 +/- 1.07 years). They were all athletes practicing impact sports (mean 8h/week). Body composition, total body, lumbar spine and femoral neck bone mineral content (BMC) and bone mineral density (BMD) were measured by dual-energy X-ray absorptiometry (DXA). Hip Structure Analysis (HSA) software was used to analyze bone densitometry scans. HSA was derived from images acquired from bone mineral scanners at femoral necks. The main structural parameters derived by HSA are the bone cross-sectional area (CSA), the section modulus (Z) and the cross-sectional moment of inertia (CSMI). A bone Strength Index (SI = Z/height) and two related bone strength (RBS\_lean and RBS\_weight) were calculated to express bone morphology based on known relationships. Physical activity and daily calcium intake were calculated using questionnaires.

**Results:** Results are presented in table below. Height, weight, lean mass and calcium intake were significantly greater in boys compared to girls. BMC measurements were also greater in boys than in girls. After adjustment by anthropometric parameters all differences disappeared. Cross-sectional area (CSA), section modulus (Z) the cross-sectional moment of inertia (CSMI) and the SI were greater in boys compared to girls. In contrast, SI normalized to lean mass or weight (RBS\_lean and RBS\_weight) did not differ between the two groups.

**Conclusion:** These data suggest that the differences between girls and boys at this age seem only bound to anthropometric differences and that the physical activity does not seem to have a sex-specific action on the bone parameters analyzed in this study.

(Mean +/- SD)	Boys (n=12)	Girls (n=8)
BMC (g)	2.57 +/- 0.42	2.02 +/- 0.23
BMD (g/cm <sup>2</sup> )	1.20 +/- 0.13	1.11 +/- 0.06
CSA (cm <sup>2</sup> )	4.27 +/- 0.64	3.37 +/- 0.30
CSMI	4.23 +/- 0.76	2.63 +/- 0.41
Z (cm <sup>3</sup> )	2.34 +/- 0.37	1.66 +/- 0.18
SI (Z/height)	7.39 +/- 2.05	7.05 +/- 0.92
RBS_lean	0.025 +/- 0.003	0.026 +/- 0.002
RBS_weight	0.021 +/- 0.002	0.020 +/- 0.002

## SA539

**Bone Volumetric Density, Geometry and Strength in Male and Female Collegiate Runners.** A. J. Thieschafer<sup>\*1</sup>, J. M. Hughes<sup>\*1</sup>, K. L. Popp<sup>\*1</sup>, B. Kaufman<sup>\*1</sup>, R. J. Wetzsteon<sup>2</sup>, S. D. Stovitz<sup>\*3</sup>, M. A. Petit<sup>1</sup>. <sup>1</sup>School of Kinesiology Laboratory of Musculoskeletal Health, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Children's Hospital of Philadelphia, Philadelphia, PA, USA, <sup>3</sup>Department of Medicine, University of Minnesota, Minneapolis, MN, USA.

Given the characteristics of the mechanical loads on bone during running, this activity should theoretically have a positive effect on bone strength. However several studies suggest runners have low or normal areal bone mineral density (aBMD, g/cm<sup>2</sup>) compared to non-running controls. Bone geometry can adapt in ways that improve bone strength with no change in bone density or mass. The purpose of this study was to explore differences in tibial bone geometry, volumetric density (vBMD, mg/mm<sup>3</sup>), and estimates of bone strength in runners and healthy, inactive controls. We used peripheral quantitative computed tomography (pQCT, Orthometrix XCT 3000) to assess tibial bone properties in male (n = 21) and female (n = 38) runners and inactive age-matched healthy controls (n = 17 males, 32 females) aged 18-35 (mean 22.6±3.3yrs). We measured vBMD, bone area (ToA, mm<sup>2</sup>) and an index of compressive bone strength (bone strength index; BSI, mg<sup>2</sup>/mm<sup>4</sup>= ToA \* ToD<sup>2</sup>) at the distal (4%) tibia. At the midshaft sites (50 and 66% tibia) ToA and cortical (CoA, mm<sup>2</sup>) bone area, cortical density (CoD, mg/cm<sup>3</sup>), cortical thickness (CoTh, mm), estimated bending strength (strength strain index; SSIp, mm<sup>3</sup>) and muscle cross-sectional area (MCSA) were assessed. We used analysis of covariance (ANCOVA) adjusting bone outcomes for age, tibia length and body weight. At the distal (4%) tibia, female runners had significantly greater BSI (+19%, p < 0.05) due to a larger ToA (+11%, p < 0.05), but no difference in vBMD compared to controls. At the proximal sites, female runners also had significantly greater bone strength (SSIp +17-19%, p < 0.001) due to a greater ToA (+14%), CoA (+15%), and CTh (+8-9%) but no difference in vBMD compared to female controls. Male runners, compared to controls had significantly greater CTh (+8-14%, p < 0.05) at both proximal sites as well as a greater CoA (+11%, p < 0.009) at the 66% site, but no differences in bone strength or vBMD. Greater bone strength in female runners was attributable to greater bone area rather than density. In contrast, there was no difference in bone strength between male groups; however male runners had favorable bone geometric properties. These data suggest that running may optimize bone geometry resulting in increased bone strength in females.

**Bone Geometry, Strength, and Muscle Mass in Female Distance Runners with a History of Stress Fracture.** K. L. Popp<sup>\*1</sup>, J. M. Hughes<sup>\*1</sup>, A. J. Thieschafer<sup>\*1</sup>, S. A. Novotny<sup>\*1</sup>, S. D. Stovitz<sup>\*2</sup>, S. Koehler<sup>\*3</sup>, M. A. Petit<sup>1</sup>. <sup>1</sup>Kinesiology, University of Minnesota, Minneapolis, MN, USA, <sup>2</sup>Medicine, University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>Allina Clinics, Northfield, MN, USA.

Stress fractures are common among distance runners. While stress fractures are associated with low areal bone mineral density, little is known about the correlation of lower extremity stress fractures with both bone structure and muscle mass. The purpose of this study was to determine differences in bone geometry, estimates of bone strength, and muscle size in female runners with and without a history of stress fractures. A total of 39 competitive female distance runners aged 18-35, with (SFX, n = 19) or without (NSFX, n = 20) a history of lower limb stress fracture were recruited for this cross-sectional study. Peripheral Quantitative Computed Tomography (pQCT, Orthometrix XCT 3000) was used to assess volumetric bone mineral density (vBMD, mm<sup>3</sup>), bone area (ToA, mm<sup>2</sup>), and estimated compressive bone strength (bone strength index; BSI= ToA \* ToD<sup>2</sup> (bone density)) at the distal tibia (4%). Total (ToA, mm<sup>2</sup>) and cortical (CoA, mm<sup>2</sup>= ToA \* ToD<sup>2</sup>) bone area, cortical density, and estimated bone bending strength (stress strain index; SSIp, mm<sup>3</sup>) were measured at the 15%, 25%, 33%, 45%, 50% and 66% sites. Muscle cross sectional area (MCSA) was measured at the 50% and 66% sites. Questionnaires were used to assess health and training history. There were no significant differences in age, BMI, years of training, miles run per week, or age of menarche between groups. Women with a history of SFX had significantly smaller (7 - 8%) CoA at the 45%, 50%, and 66% sites in both the right and left legs (p < 0.05 for all). SSIp was significantly lower (9 - 10%) at the 50% and 66% sites. Runners with a history of stress fracture also had smaller MCSA (7 - 8%) at the 66% site in both the legs. The remaining bone parameters, including vBMD were not significantly different between groups. After adjusting for MCSA there were no differences between groups for any measured bone outcomes. These findings suggest that bone CoA, strength and MCSA are all lower in runners with a history of stress fracture. However, the lower bone CoA and strength were adapted to the lower muscle size, suggesting interventions to reduce stress fracture risk might be aimed at improving muscle size and strength.

**Previous Sport Activity During Childhood and Adolescence Is Associated with Bone Geometry in Young Adult Men.** M. Nilsson<sup>\*</sup>, C. Ohlsson<sup>\*</sup>, D. Mellström<sup>\*</sup>, M. Lorentzon<sup>\*</sup>. Center for Bone Research at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Physical activity (PA) during growth has been associated with altered cortical bone geometry, but it remains uncertain if the PA induced increments in cortical bone size remain when the level of PA is diminished or ceased. The aim of this study was to investigate if PA during growth is associated with areal bone mineral density (aBMD) and cortical bone geometry parameters in currently inactive men at the age of peak bone mass (PBM).

In this population-based study, 367 currently physically inactive men, 19.0 ± 0.6 (mean±SD) years old, were included. DXA was used to assess aBMD at several bone sites, whereas cortical bone geometry and trabecular vBMD at the tibia and radius were measured using pQCT. A standardized questionnaire was used to collect information about previous sport activity (SA).

Regression analysis (including covariates age, height, weight, calcium intake, smoking, and duration of inactivity) revealed that previous SA was independently associated with aBMD, at weight-bearing sites, and with cortical bone size of the tibia (cross sectional area (CSA), periosteal circumference (PC)). Previous SA explained 7.9% of the total variation in cortical CSA. Subjects, who ceased their sport activity for up to 6.5 years previously, still had greater cortical PC and CSA of the tibia, at the age of PBM, than ever inactive subjects.

In conclusion we demonstrate that SA during childhood and adolescence is associated with aBMD and bone geometry in currently physically inactive Swedish men at the age of PBM, suggesting that SA during growth confers positive effects on bone geometry even though SA is ceased.

**Path Analysis (Structural Equation Modeling) and Covariation of Bone Traits following Delayed Puberty.** V. R. Yingling. Kinesiology and Anatomy and Cell Biology, Temple University, Philadelphia, PA, USA.

Functional interactions among morphological and tissue-quality bone traits are hypothesized to be part of a biological paradigm that results in multiple paths to achieve organ-level functionality. This focus on relationships between bone traits and not individual bone trait differences may elucidate new mechanisms of bone adaptation.

Therefore, the purpose was to illustrate that functional relationships between bone traits and body weight were altered by a delay in puberty using path analysis. Twenty-three day old female rats were randomly assigned into a control group and experimental groups that received injections of Gonadotropin releasing hormone antagonists. Femora were embedded for histomorphometric analyses. A path model was constructed to test the hypothesis that variability in bone size (T.Ar/Length) and body size (Body Weight) is related to variability in relative cortical area (Ct.Ar/T.Ar) and % ash content. The model for the control groups (Figure 1) had excellent "goodness of fit" indicators. The chi-square was non significant ( $p = 0.493$ ). The CFI (Comparative Fit Index) was 1.0; greater than 0.9 indicates a good fit. The RMSEA (Root Mean Square Error of Approximation) was 0.00; less than 0.05 indicates a good model fit. The model indicates that 56% of the variation of Ct.Ar/T.Ar is explained by Body Weight and bone size. Similar results were found in mice. Percent ash content was not affected by body weight or (Ct.Ar/T.Ar). In summary, control animals alter their relative cortical area by a direct relationship with body weight. A negative relationship was found between bone size (T.Ar/Length) and relative cortical area. Comparing these results to the model for the delayed puberty group (Figure 2) indicates that these relationships are no longer valid. Following a delay in pubertal timing only 9% of the variation in Ct.Ar/T.Ar was explained by body weight and bone size. To sum up, the path analysis suggests that (for these data sets) there is an effect of delayed puberty on the relationship between body weight, bone size and relative cortical area.

**Figure 1:**  
 $\text{Ct.Ar/T.Ar} = 0.52\text{BodyWeight} - 0.76\text{T.Ar/Length}$ ,  $R^2=0.56$   
 Chi-square = 0.471, df=1, p-value=0.493  
 CFI=1.0, RMSEA=0.00

**Figure 2:**  
 $\text{Ct.Ar/T.Ar} = 0.18\text{BodyWeight} - 0.30\text{T.Ar/Length}$ ,  $R^2=0.09$   
 Chi-square = 3.430, df=1, p-value=0.064  
 CFI=0.46, RMSEA=0.289

**Effect of Particle Size of Calcium Carbonate Supplement on Calcium Retention in Adolescent Girls.** A. E. Elble<sup>\*1</sup>, K. M. Hill<sup>2</sup>, C. Y. Park<sup>\*2</sup>, B. R. Martin<sup>2</sup>, C. M. Weaver<sup>2</sup>. <sup>1</sup>Foods & Nutrition and Public Health, Purdue University, West Lafayette, IN, USA, <sup>2</sup>Foods & Nutrition, Purdue University, West Lafayette, IN, USA.

Previously we reported that substituting small for large (commercial standard) particle sized calcium (Ca) carbonate in diets of growing female rats resulted in higher calcium absorption and retention (JBMR 21: S184, Abst SA 368, 2006). Here we assessed the effect of large versus small calcium carbonate particle size and small particle Ca carbonate versus placebo on Ca retention in adolescent girls. Twenty-eight adolescent girls ( $13.1 \pm 1.7$ y) participated in two 3-wk controlled feeding trials separated by a 1-wk washout period. During both sessions, the subjects consumed a diet identical in nutrient profile tailored to their individual energy needs containing 650 mg Ca/d. Using a cross-over design, one group (n=18) received an additional 650mg/d Ca via supplementation delivered twice a day in a 325mg Ca dose as either an average of 18 micron sized Ca carbonate (large) or 13 micron sized Ca carbonate (small). A second group (n=10) received the small particle sized Ca carbonate or placebo. All 24-h urine and feces were collected throughout the study and analyzed for calcium content by Inductively Coupled Plasma Spectrophotometry (ICP). The overall balance results (Balance = Ca intake - urine Ca -

fecal Ca) indicated that the small particle size supplement resulted in greater calcium retention compared to placebo ( $p<0.05$ ). However, there was no significant difference ( $p = 0.39$ ) in Ca retention due to particle size of the supplement. Thus, the rat model did not predict the effect of particle size on Ca retention in humans. Unlike the rat study which started the treatment diet during weanling and continued throughout adolescence, the human subjects received the treatment during peak skeletal acquisition. Perhaps the overwhelming effects of growth during puberty overpowered the more subtle effect of Ca particle size treatment.

**The Effects of Growth Hormone on Bone Micro-Architecture by In Vivo Micro-CT.** E. Kristensen<sup>\*1</sup>, B. Hallgrímsson<sup>2</sup>, D. W. Morck<sup>\*3</sup>, S. K. Boyd<sup>1</sup>.

<sup>1</sup>Mechanical and Manufacturing Engineering, University of Calgary, Calgary, AB, Canada, <sup>2</sup>Cell Biology and Anatomy, University of Calgary, Calgary, AB, Canada, <sup>3</sup>Faculty of Veterinary Medicine, Faculty of Science, University of Calgary, Calgary, AB, Canada.

Children deficient in growth hormone (GH) are typically treated with injections of GH to attain normal body size. Dosage, duration of treatment, and age of onset of treatment all contribute to body shape and size. Untreated GH deficiency during puberty leads to low lumbar spine bone mineral density (BMD) when compared to age-matched healthy controls. Also, increasing the duration and decreasing the age of onset of treatment contribute to improved BMD [1]. BMD is the current gold-standard parameter to assess efficacy of GH treatment on bone. Presently, the effect of GH treatment on bone micro-architecture has not been investigated, as micro-architecture cannot be derived from BMD measurements.

The study's purpose was to perform a longitudinal assessment of the onset of GH treatment on bone micro-architecture using micro-computed tomography (micro-CT). Ghrhr homozygous 'little' mice have reduced GH synthesis and release, although injection of exogenous GH can stimulate growth. Heterozygous mice have normal GH synthesis and release. A total of six experimental groups were studied. Two groups of homozygous mice received daily injections of GH starting at 21 days of age (early treatment group; ETG), or at 35 days of age (late treatment group; LTG). Two additional homozygous groups included vehicle controls (daily saline injections) and untreated controls. All injections ended at age 60 days. Two heterozygous groups were examined: a group receiving no treatment and a radiation control group. Micro-CT scans of the fourth lumbar vertebra were obtained for all groups (except radiation control) at age 21, 27, 35, 45, and 60 days (vivaCT 40, Scanco Medical AG). The radiation control group was scanned at days 21 and 60 only. Bone architectural parameters were calculated (IPL v. 4.29d, Scanco) and statistical tests determined treatment effects ( $p<0.05$ ).

Relative to heterozygotes, there is a significant reduction in trabecular bone thickness in the untreated 'little' mice. There is no change in micro-architecture in the ETG as compared to the untreated homozygous mice. In the LTG relative to the untreated GH deficient mice, there is a trend towards increased bone quality, however these results are non-significant, likely due to small sample sizes (n=4 to n=8) at the current stage of study. Additional animals are being added to each group to increase statistical power. The data suggests support for the hypothesis that there is a benefit to late treatment, but no gains in bone quality when GH treatment is administered early.

**Prevalence and Incidence of Viral Infections among Musculoskeletal Tissue Donors and First-Time Blood Donors.** F. Yao\*, M. Zheng, D. Wood\*. Centre for Orthopaedic Research, University of Western Australia, Nedlands WA, Australia.

Musculoskeletal tissue is second only to blood as the most frequently transplanted human tissue, and there continues to be an enormous demand for these allografts throughout the world. Little information is known about the risks associated with musculoskeletal tissue donation.

Our objective was to define the prevalence and incidence of viral markers of human immunodeficiency virus (HIV), hepatitis B virus (HBV), hepatitis C virus (HCV), and human T-cell lymphotropic virus (HTLV) in musculoskeletal tissue donors in Australia, and to compare the results with recently published data on rates of viral infection among tissue donors from Canada, Scotland, and the United States.

We studied blood serum samples from 12,415 consecutive musculoskeletal tissue donors from 3 large musculoskeletal tissue banks in Australia from 1993 through 2004. We defined prevalence as the number of donors with confirmed positive test results divided by the total number of donors tested. We estimated the incidence of new infections among donors by using a method similar to that of Zou and colleagues (1). We then compared the serologic data with those of first-time blood donors obtained during the same period.

The prevalence of viral markers in Australian musculoskeletal tissue donors was much higher than in Australian first time blood donors, by factors of about 10 for HIV, 3 for HBV, 2.5 for HCV, and 35 for HTLV ( $P < 0.05$ ). The prevalence of viral markers was greater in tissue donors than blood donors in all countries, except for anti-HIV antibody in Scottish tissue donors (Table 1). The prevalence of viral markers was higher in tissue donors in Australia than in Canada and Scotland. Estimated incidence rates of viral infections were also higher among tissue donors than first-time blood donors in Australia, Canada, and the United States.

We believe these findings have important implications. Monitoring viral prevalence and incidence among tissue donations is a vital tool for evaluating the safety of the tissue supply and provides important information with which to implement appropriate public health measures and policies.

**Born Small Is Not Bad for Bone.** Q. Wang<sup>1</sup>, A. Iyytikainen<sup>2</sup>, M. Alen<sup>3</sup>, E. Tylavsky<sup>4</sup>, E. Seeman<sup>1</sup>, S. Cheng<sup>2</sup>. <sup>1</sup>ECE, Repatriation Hospital/Austin Health, The University of Melbourne, Heidelberg West, VIC 3081, Australia, <sup>2</sup>Health Sciences, The University of Jyväskylä, Jyväskylä, Finland, <sup>3</sup>The University of Oulu, Oulu, Finland, <sup>4</sup>Department of Preventive Medicine, The University of Tennessee Health Science Center, Knoxville, TN, USA.

Intrauterine growth is believed to be important in development of peak bone mass (PBM). We tested the hypothesis that born small adversely affects bone mineral content (BMC) at maturity. Crown-heel length (CHL) at birth and 1 year were documented from growth charts while BMC and areal bone mineral density (aBMD) of total body and sub-regions were assessed by dual-energy X-ray absorptiometry (GE Lunar) at 18.3 ± 1.0 yrs in 150 Finnish girls. Gestational age at birth ranged from 33 to 43 weeks (40 ± 1.5 weeks). Contrary to our hypothesis, BMC or aBMD of any site at 18 yrs was not predicted by CHL or birth weight (all NS). Growth rate in the first year of life did not track; 23% of girls increased their trait percentile and 23% decreased their trait percentile by > 1 quartile of their CHL despite no difference in their gestational age at birth (39.4 ± 1.2 vs. 40.4 ± 1.1 weeks,  $p = 0.084$ ). Girls with catch-up growth were shorter at birth than those with slowdown grow (48.6 ± 1.0 vs. 50.9 ± 1.2,  $p < 0.01$ ), but longer (77.1 ± 1.7 vs. 73.4 ± 1.4 cm) at 1yr and taller at 18 yrs (168.1 ± 4.5 vs. 163.7 ± 4.4,  $p < 0.01$ ). Although being born smaller, BMC of total body and sub-regions at 18 yrs of age was 12.4% to 17.4% more in girls with catch-up growth than those with slowdown growth ( $p < 0.01$ ). This difference in BMC at 18 yrs between the two groups was independent of CHL and weight at birth, but not independent of CHL and weight at 1yr or 18 yrs. Being born small is not a risk factor of suboptimal PBM, perhaps due to programming that facilitates expression of the phenotype during the first year of life.

**Relationship between Physical Fitness and Bone and Physical Activity and Calcium Retention in Adolescent Girls.** K. M. Hill, A. E. Elble\*, C. Y. Park\*, B. R. Martin, S. L. Mobley\*, C. M. Weaver. Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

Adolescence is a crucial period for bone growth as half of the adult skeletal mass is accrued during this time. Physical activity has been associated with beneficial effects on bone mass in adolescents. However, the influence of physical activity on calcium (Ca) retention in adolescents is unknown. The purpose of this study was to determine the relationships between physical fitness scores and bone parameters and between Ca retention and physical activity (PA). Secondary data analysis from a 6-wk Ca metabolic balance study in adolescent girls ( $n = 48$ ; ages 11-14 y) was performed. As a part of the metabolic study, subjects consumed a controlled diet and 24-hour urine and feces were collected. Ca retention was determined by dietary Ca intake minus urinary and fecal Ca. PA was assessed over four days during each 3-wk session by hip-worn omnidirectional accelerometers. Physical fitness was assessed by three fitness tests: push-ups, sit-ups, and sit-and-reach. Dual-energy x-ray absorptiometry (DXA), peripheral quantitative computed tomography (pQCT), and ultrasound (QUS) were used to determine bone parameters. Body composition was determined by DXA. Relationships among variables were analyzed by Pearson correlations; Paired t-tests were used to assess the influence of PA on Ca retention. Push-up fitness scores were positively associated with several bone parameters including radius total BMD and cortical BMD ( $r = 0.37, 0.36$ , respectively,  $p < 0.01$ ) from pQCT and heel BMD ( $r = 0.34, p < 0.05$ ) from QUS. Push-up fitness scores were also associated with percent fat mass ( $r = -.37, p = 0.01$ ) and percent lean mass ( $r = 0.38, p = 0.01$ ). PA assessed by accelerometry was not significantly related to Ca retention. PA may influence Ca retention if a broad range of PA were studied in contrast to our summer camp setting. Push-up fitness scores may best reflect habitual PA that influences bone mass at the forearm in adolescent girls.

**The Effect of 12 Months Gymnastics Participation on Bone Mass Accrual in 4 to 7 Year Olds.** M. C. Erlandson\*, A. D. G. Baxter-Jones. College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

Studies of postpubertal gymnasts have constantly shown them to have greater bone mineral content (BMC) than age and maturity matched controls. However, it is unknown if this increased mineralization is the result of training or due to a genetic predisposition. The aim of this study was to assess the effect of 12 months gymnastics participation on BMC accrual in young prepubertal children. Gymnasts and controls were measured at baseline and after 12 months. Age, height, weight and dual-energy X-ray absorptiometry (DXA) of the whole body (WB), total hip (TH) and lumbar spine (LS) BMC were measured annually. Data were analyzed using analysis of variance (ANOVA) and covariance (ANCOVA; covariates, age, initial bone values, and changes in height and weight). Data are presented as mean ± SD. Three groups were identified: Gymnasts (Gym,  $n=54$ , age=5.6 ± 1.1), Gymnast who left the sport (Nongym,  $n=31$ , age=6.2 ± 1.2) and controls (Cont,  $n=75$ , age=5.9 ± 1.1). At study entry no significant differences ( $p > 0.05$ ) were found between the groups for age, height, weight or any BMC measures. At 12 months the mean adjusted BMC values for Gym, Nongym and Cont were 774.1 ± 8.7, 791.3 ± 9.9, 765.5 ± 7.2 g for WB, 9.5 ± 0.3, 9.7 ± 0.3, 9.2 ± 0.2 g for TH and 17.6 ± 0.2, 17.6 ± 0.3, 17.1 ± 0.2 g for LS (means adjusted for age, baseline BMC, change ht, change wt). No group differences were found at any site ( $p > 0.05$ ). The results from this study indicate that the effects of gymnastics training consistently reported in postpubertal adolescent samples were not present in this cohort at this young age, either a study entry or after 12 months of participation. To answer the question as to whether positive changes in bone mass accrual observed in adolescent gymnasts are due to prolonged training this cohort requires further follow-up measures spanning the pubertal period.

**Valproate: A Model for Adverse Psychoactive Drug Effects on Bone Mineral Density.** B. L. Gracious<sup>1</sup>, D. Heyer<sup>\*2</sup>, M. Parkhurst<sup>\*3</sup>, S. Messing<sup>\*4</sup>, J. Puzas<sup>5</sup>. <sup>1</sup>Psychiatry and Pediatrics, University of Rochester Medical Center, Rochester, NY, USA, <sup>2</sup>Neurology, University of Rochester Medical Center, Rochester, NY, USA, <sup>3</sup>Psychiatry, University of Rochester Medical Center, Rochester, NY, USA, <sup>4</sup>Biostatistics, University of Rochester Medical Center, Rochester, NY, USA, <sup>5</sup>Orthopedics, University of Rochester Medical Center, Rochester, NY, USA.

**Purpose:** To implement controlled translational experiments at cellular and human levels using valproic acid (VPA) as a model drug that may adversely affect BMD.

**Aim I:** Determine alkaline phosphatase (AP), Type I collagen, and osteocalcin production in osteoblasts exposed to VPA; **Aim II:** Compare BMD, bone biomarkers, and cortisol as potential mediators in teen girls with bipolar disorder treated with VPA.

**Methods:** AIM I: Primary rat osteoblasts (PROs) were exposed to control vs. VPA media, at human sub-, supra-, and therapeutic concentrations in culture. Protein was extracted across time points up to 18 days. Total protein and AP were measured via photospectroscopy, staining, and ELISA to examine changes in expression across time and conditions. AIM II: A cross-sectional matched study of teen girls taking VPA for Bipolar I disorder compared BMD via DXA and bone biomarkers with girls with BP I disorder not taking VPA and healthy controls.

**Results:** There is a differential effect of VPA on osteoblast AP production related to time and dose, with high therapeutic doses initially stimulating but then suppressing AP production. Interim analysis of DXA and biomarkers in bipolar teen girls exposed to VPA versus controls does not yet show separation between groups, however, salivary cortisol and BSAP trended higher in the VPA group.

**Conclusions:** VPA directly affects primary rat osteoblasts, altering alkaline phosphatase production, which at higher therapeutic doses may result clinically in decreased bone formation. VPA-induced elevations of cortisol in humans may also play a role in adverse effects on BMD. There are likely multiple mechanisms by which VPA affects bone mineral metabolism. Clinical implications include that VPA dose and serum level necessary to treat patients may largely determine effect on BMD. Effects may also be different between cancellous and trabecular bone at different serum levels. Further basic and clinical prospective study of bone formation and resorption in response to VPA levels and sustained release dosing versus immediate release dosing is warranted.

**Disclosures:** B.L. Gracious, None.

**BMD Changes Over Time Associated with Illness and Recovery in Young Women with Anorexia Nervosa.** E. J. Waugh<sup>1</sup>, B. Woodside<sup>\*2</sup>, P. Cote<sup>\*3</sup>, D. E. Beaton<sup>\*4</sup>, G. A. Hawker<sup>1</sup>. <sup>1</sup>Osteoporosis, Women's College Hospital, Toronto, ON, Canada, <sup>2</sup>Psychiatry, University Health Network, Toronto, ON, Canada, <sup>3</sup>Rehabilitation Solutions, University Health Network, Toronto, ON, Canada, <sup>4</sup>Mobility Program, St. Michael's Hospital, Toronto, ON, Canada.

We examined the effect of duration of illness and recovery of anorexia nervosa (AN) on BMD in a retrospective cohort study of patients aged 17-40 yrs who had received inpatient treatment for AN over a 12-yr time period. A detailed illness history was obtained by a Life History Calendar semi-structured interview. BMD at the lumbar spine L1-L4 (LSP), femoral neck (FN) and total body (TB) was measured by DXA. Low BMD was defined as a Z-score value  $\leq -1.5$  at one more sites.

We recruited 190 participants from two centers. At interview, mean age was  $27.2 \pm 5.6$  yrs and mean BMI was  $19.4 \pm 3.4$  ( $11.1 - 35.5$ )  $\text{kg/m}^2$ . Age at AN onset was  $18.2 \pm 4.2$  ( $10-32$ ) yrs, duration of illness was  $5.9 \pm 4.6$  ( $1 - 25$ ) yrs and lowest lifetime BMI was  $13.9 \pm 2.3$  ( $7.2 - 18.0$ )  $\text{kg/m}^2$ . Eighty-three participants were recovered (achieved a BMI  $\geq 18.5$   $\text{kg/m}^2$  and resumed menstruation); duration of recovery was  $4.8 \pm 3.9$  ( $0.8 - 26$ ) yrs. Linear regression was used to estimate the rate of change in BMD Z-score values per year of illness and recovery, adjusted for weight.

Figure 1 shows the relationships between durations of illness and recovery and LSP z-scores. Similar relationships were observed at the FN and TB (data not shown). A gradual and linear loss of BMD was associated with duration of illness ( $\beta = -0.05/\text{yr}$ , 95% CI -0.09, -0.009). The decline in LSP z-scores commenced immediately after onset of AN: 26.7% of participants ill for 1 yr had low BMD. In contrast, a rapid increase in BMD was associated with the first 3 yrs of recovery ( $\beta = 0.59/\text{yr}$ , 95% CI 0.23, 0.95) followed by stabilization of BMD after 3 yrs ( $\beta = 0.02/\text{yr}$ , 95% CI -0.7, 0.12). Low BMD was observed in 67% of those recovered for  $< 1$  yr but only persisted in 25% of those recovered for 1 yr and 10% of those recovered for  $\geq 2$  yrs.

**Disclosures:** E.J. Waugh, None.

## SA559

**The Effect of Bed Rest on Bone Turnover in Adolescents Hospitalized for Anorexia Nervosa.** A. D. DiVasta<sup>\*1</sup>, H. A. Feldman<sup>\*2</sup>, A. Quach<sup>\*1</sup>, C. M. Gordon<sup>1</sup>. <sup>1</sup>Adolescent Medicine, Children's Hospital Boston, Boston, MA, USA, <sup>2</sup>Clinical Research Program, Children's Hospital Boston, Boston, MA, USA.

Bone loss is a well-established medical complication of anorexia nervosa (AN). At highest risk for skeletal insults may be those adolescents who become so malnourished that they require medical hospitalization to manage their illness and low weight. Current clinical standards often require bed rest for the duration of hospital stay. However, studies of healthy adults demonstrate that even short-term immobilization leads to disruptions in normal patterns of bone turnover. Our study aimed to determine the effect of short-term bed rest and relative immobilization on bone turnover in adolescents hospitalized for AN. In this observational study, 28 female adolescents (mean age=16.7 ± 2.3 y) were prospectively enrolled upon hospitalization. Eligible patients met DSM-IV diagnostic criteria for AN, and had no other co-morbid conditions or medication use known to affect bone health. As per standard care, all patients were placed on bed rest and graded nutritional therapy. Weight was measured daily, in a standard fashion. Markers of bone formation [bone-specific alkaline phosphatase (BSAP) and osteocalcin (OC)] and bone resorption [urinary N-telopeptides (NTx)] were measured in a fasting state at baseline and days 1, 2, 3, and 5 of hospitalization. Results are presented as adjusted trend estimates from repeated-measures regression analysis. During the 5 days of hospitalization, mean weight increased by 0.33 kg/day (p<0.001). BSAP declined by 0.18 ± 0.07 ng/mL/day (p=0.01). Serum OC, interestingly, increased by 0.24 ± 0.1 ng/mL/day (p=0.02). Urine NTx reached a nadir on day 3, declining -7.0 ± 2.7 nM BCE/mM Cr (p=0.01), but then returned to baseline levels by day 5 (p>0.05; Figure 1). After controlling for weight gain, as well as age, baseline percentage of ideal weight, duration of amenorrhea, hours of weekly exercise, and family history of osteoporosis, the effect of time on BSAP was no longer significant (p=0.24).

Limitation of physical activity during hospitalization for patients with AN leads to a suppression of both bone formation and resorption, and a potential imbalance of bone turnover. Future interventional studies involving mechanical stimulation and/or weight-bearing activity are needed to determine whether medical protocols prescribing strict bed rest are appropriate.

**The Effect of Vitamin D<sub>2</sub> and Vitamin D<sub>3</sub> on Intestinal Calcium Absorption in Nigerian Children with Rickets.** T. D. Thacher<sup>1</sup>, M. O. Obadofin<sup>\*2</sup>, K. O'Brien<sup>3</sup>, S. A. Abrams<sup>\*4</sup>. <sup>1</sup>Family Medicine, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Family Medicine, Jos University Teaching Hospital, Jos, Nigeria, <sup>3</sup>Division of Nutritional Sciences, Cornell University, Ithaca, NY, USA, <sup>4</sup>USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, USA.

Children with nutritional rickets due to calcium deficiency have high serum 1,25(OH)<sub>2</sub>D values. We examined if additional vitamin D increased calcium absorption. We randomly assigned 17 Nigerian children with rickets, ages 2-10 years, to either vitamin D<sub>3</sub> (cholecalciferol; n=8) or vitamin D<sub>2</sub> (ergocalciferol; n=9) 1.25 mg given orally. Using stable isotope methods, fractional calcium absorption was determined at baseline and 3 days after vitamin D administration. Mean daily dietary calcium intakes were 182±73 mg, and mean baseline 25(OH)D concentrations were 20 ng/mL (range 5-31 ng/mL). Three days after oral vitamin D, the increase in serum vitamin D<sub>3</sub> (52±22 ng/mL) in the cholecalciferol group and vitamin D<sub>2</sub> (48±18 ng/mL) in the ergocalciferol group demonstrated equivalent drug absorption. The increase in 25(OH)D was equivalent with cholecalciferol (29±10 ng/mL) and ergocalciferol (29±17 ng/mL). Mean 1,25(OH)<sub>2</sub>D values increased from 143±76 pg/mL to 243±102 pg/mL (P=0.001), and the increase in 1,25(OH)<sub>2</sub>D did not differ between ergocalciferol and cholecalciferol (107±110 and 91±102 ng/mL, respectively). The rise in 1,25(OH)<sub>2</sub>D was explained almost entirely by the baseline 25(OH)D concentration (r<sup>2</sup>=0.72; P<0.001). The increase in serum calcium was similar with cholecalciferol (0.29±0.34 mg/dL) and ergocalciferol (0.41±0.51 mg/dL; P=0.57) and significantly greater than baseline values (P=0.004). 24-hour urinary calcium excretion did not differ before

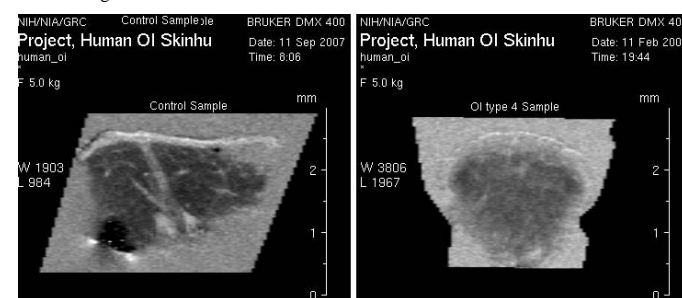

(1.4±1.9 mg) or after (1.4±1.7 mg) vitamin D administration. Mean fractional calcium absorption did not differ before (52.6±21.4%) or after (53.2±23.5%) vitamin D administration, and there was no significant difference between the effect of ergocalciferol and cholecalciferol on calcium absorption. Fractional absorption of calcium was not closely related to concentrations of 25(OH)D (r=0.01, P=0.93) or 1,25(OH)<sub>2</sub>D (r=0.21, P=0.24). The effect of vitamin D on calcium absorption did not vary with baseline 25(OH)D values or with the absolute increase in 25(OH)D or 1,25(OH)<sub>2</sub>D values. Despite the marked rise in 1,25(OH)<sub>2</sub>D in response to oral vitamin D, consistent with vitamin D inadequacy, no augmentation of fractional absorption of calcium absorption occurred. Ergocalciferol and cholecalciferol appear to be bioequivalent.

**Identification of Skin Abnormalities in Osteogenesis Imperfecta Patients by Magnetic Resonance Imaging-A Pilot Study.** C. L. Raggio<sup>\*1</sup>, K. W. Fishbein<sup>\*2</sup>, E. M. Carter<sup>\*3</sup>, M. Kim<sup>\*4</sup>, N. Pleshko<sup>5</sup>, R. G. Spencer<sup>\*6</sup>. <sup>1</sup>Orthopaedic Surgery, Hospital for Special Surgery, New York, NY, USA, <sup>2</sup>National Institutes on Aging, National Institutes of Health, Baltimore, MD, USA, <sup>3</sup>Kathryn O. and Alan C. Greenberg Center for Skeletal Dysplasias, Hospital for Special Surgery, New York, NY, USA, <sup>4</sup>Mineralized Tissue Laboratory, Hospital for Special Surgery, New York, NY, USA, <sup>5</sup>Biomechanics, Exponent, Philadelphia, PA, USA, <sup>6</sup>Nuclear Magnetic Resonance Unit, National Institute on Aging, National Institutes of Health, Baltimore, MD, USA.

Osteogenesis imperfecta (OI) is a genetic disorder characterized by bone fragility and frequent fractures. Diagnosis is based on clinical and radiological criteria, which can be nonspecific in mild-to-moderate cases, and increasingly by genetic testing, which is time-consuming. We tested the hypothesis that magnetic resonance imaging (MRI) can detect skin abnormalities that correlate with OI genotype and phenotype. Our primary research objectives were to determine: 1. whether MRI can differentiate between skin from OI and control subjects; 2. whether nondestructive MRI analysis is supported by invasive but highly specific Fourier transform infrared spectroscopic imaging (FT-IRIS); and 3. whether there is a relationship between type I collagen genotype, skeletal phenotype, and skin phenotype across patients of all ages. MRI analysis of 3-mm full-thickness forearm skin biopsies from OI (n=6) and non-OI control (n=2) subjects was performed, followed by FT-IRIS. MRI parameters, including T1, T2, and magnetization transfer (MT), were compared to FT-IRIS parameters characterizing dermal collagen. Initial findings showed clear differences in both MRI and FT-IRIS parameters between patients with OI and controls. Findings within the OI group correlated with the severity of clinical phenotype; epidermal and dermal layers were thinner in OI patients compared to controls (See attached T2 image) with the degree of thinning correlating with the severity of OI phenotype. MRI revealed fat deposits within the dermis of OI skin only. FT-IRIS revealed differences in collagen orientation in the dermis of OI skin compared to controls. We conclude that MRI is sensitive to presence and severity of OI in human skin, as confirmed by FT-IRIS analysis. This supports the potential for developing an MRI approach for rapid non-invasive diagnosis of children with OI.

**Autosomal Recessive Hypophosphatasia Manifesting in Utero with Long Bone Deformity but Showing Spontaneous Postnatal Improvement.** D. A. Stevenson<sup>\*1</sup>, J. C. Carey<sup>\*1</sup>, S. P. Coburn<sup>\*2</sup>, K. L. Ericson<sup>\*2</sup>, J. L. B. Byrne<sup>\*3</sup>, S. Mumm<sup>4</sup>, M. P. Whyte<sup>4</sup>. <sup>1</sup>Division of Medical Genetics, Dept Pediatr, Univ Utah; Shriners Hospt Children, Salt Lake City, UT, USA, <sup>2</sup>Dept Chemistry, Indiana Univ-Purdue Univ, Fort Wayne, IN, USA, <sup>3</sup>Div Maternal-Fetal Medicine, Dept ObGyn, Univ Utah, Salt Lake City, UT, USA, <sup>4</sup>Washington Univ Schl Med; Shriners Hospt Children, St. Louis, MO, USA.

Hypophosphatasia (HPP) is the heritable metabolic disorder of the skeleton and dentition featuring highly variable expressivity conditioned primarily by gene dosage effect and the variety of loss-of-function mutations in the tissue nonspecific alkaline phosphatase gene (*TNSALP*). Extracellular accumulation of the *TNSALP* substrate inorganic pyrophosphate, an inhibitor of skeletal mineralization, accounts for the accompanying rickets or osteomalacia. Four principal forms have been characterized based on age at diagnosis of underlying skeletal disease: perinatal, infantile, childhood, and adult

HPP. Patient age when skeletal problems first manifest generally predicts the clinical course, with autosomal recessive perinatal HPP causing bone disease *in utero* that is obvious at birth and typically lethal soon after. Milder forms may be due to autosomal dominant or autosomal recessive inheritance.

We describe a boy with HPP detected prenatally by sonography showing long bone deformity (Figure) which spontaneously improved *in utero* and after birth. His older brother has the childhood form of HPP without clinical findings until after infancy. Both boys are compound heterozygotes for the same *TNSALP* missense mutations (c.526G>A, p.Ala176Thr in exon 6, and c.814C>T, p.Arg272Cys in exon 8), documenting autosomal recessive inheritance for their HPP. The parents are carriers for HPP, but are clinically unaffected (Table).

Our findings show that prenatal detection of HPP by sonography because of bowing of long bones caused by autosomal recessive inheritance does not necessarily predict lethality, but can represent variable expressivity or the effects of modifiers on the *TNSALP* defects.

FIGURE. The patient had sharp, mid-diaphyseal angulation (arrow) of his right humerus at 20 weeks gestation.

TABLE Biochemical Studies Indicating Hypophosphatasia

Test	Patient (Sib #1)	Father	Mother	Sister (Sib #2)	Brother (Sib #3)	Normal Range*	
Age (years)**	3	29	28	4	2.5	6	Pediatric Adult
Serum ALP (IU/L)	47	55	32	308	36	63	133-347 30-114

**Prevalence of Transient Hyperphosphatasemia among Healthy Infants and Toddlers.** S. Y. Huh\*, H. A. Feldman\*, C. M. Gordon. Children's Hospital, Boston, MA, USA.

Transient hyperphosphatasemia (TH) is a condition characterized by a temporary elevation of serum alkaline phosphatase in the absence of bone or liver disease. The epidemiology and etiology of TH are not well-understood. Our study goal was to describe the prevalence and clinical characteristics of TH in a cohort of healthy infants and toddlers. We performed a secondary data analysis of 364 children, aged 8 to 24 months, enrolled in a study examining the epidemiology of vitamin D deficiency. After obtaining parental consent, children were enrolled at well-child visits conducted from October 2005 to June 2007 in an urban primary care pediatric clinic. Children with a chronic disease or using medications known to affect bone metabolism were excluded. At enrollment, we collected data regarding child age, gender, height, and weight; maternal race/ethnicity; and season (fall/winter, October to March, or spring/summer, April to September). We measured serum levels of alkaline phosphatase (AP), 25-hydroxyvitamin D [25(OH)D], parathyroid hormone, calcium, and magnesium. We defined TH as an AP > 1000 U/L at enrollment. We examined simple associations and used multiple logistic regression to evaluate the association between clinical characteristics and TH.

Nine of 364 children (2.5%) had an AP > 1000 U/L (mean 2165 U/L, range 1006 to 4293 U/L). Twenty-four children had a high AP that did not meet the definition for TH (mean 546 U/L, range 423 to 835 U/L). Three hundred thirty-two children had a normal AP (mean 261 U/L, range 100 to 400 U/L). Among the 9 children with TH, mean age was 11.8 months (range 9.0 to 19.0 months) and 5 children (56%) had mothers of black race. Fifty-six percent of children with TH were enrolled during the winter, compared with 50% of children with a normal AP. Compared to the 332 children with a normal AP, children with TH had similar mean serum levels of 25(OH)D (32.3 vs. 34.9 ng/mL), PTH (30.0 vs. 27.6 pg/mL), calcium (10.6 vs. 10.4 mg/dL), and magnesium (2.3 vs. 2.3 mg/dL); mean weight-for-length Z-score (0.23 vs. 0.31 SD) and length-for-age Z-score (-0.09 vs -0.06 SD) were also similar. Child age, gender, weight-for-length Z-score, length-for-age Z-score, and serum 25(OH)D levels were not associated with TH in a multivariable model. In conclusion, the 2.5% prevalence found within this study suggests that TH is not a rare condition among healthy infants and toddlers. In this small sample, TH was not associated with anthropometric measures, vitamin D deficiency, or biomarkers of bone turnover. Recognition of this benign condition is important to avoid unnecessary investigations.

**Pediatric Crohn Disease Is Associated with Negative Calcium Balance and Increased Renal Losses of Calcium.** F. A. Sylvester<sup>1</sup>, M. Lincoln<sup>\*1</sup>, L. T. Fourman<sup>\*2</sup>, K. O. O'Brien<sup>\*2</sup>. <sup>1</sup>Pediatric Gastroenterology, Connecticut Children's Medical Center, Hartford, CT, USA, <sup>2</sup>Division of Nutr Sciences, Cornell University, Ithaca, NY, USA.

Pediatric Crohn disease (CD) is associated with significant deficits in bone mass, but the responsible mechanisms are not clear. The purpose of this study was to examine calcium balance in children with CD in remission using stable isotopes of calcium. We excluded subjects exposed to glucocorticoids in the previous 3 months. We enrolled 9 subjects (mean  $12.9 \pm 2.6$  [9.1-15.4] y, 7 M). We measured BMD by DXA (GE Lunar Prodigy Advanced). Subjects received  $972 \pm 47$   $\mu$ g/kg  $^{45}$ Ca IV over 5 min and  $3777 \pm 117$   $\mu$ g/kg  $^{44}$ Ca in milk as part of a meal. We recorded their food intake for subsequent dietary analysis. During a 1-day inpatient stay, we collected timed samples of blood, a 24-h urine collection, and all stools. As outpatients, subjects collected 3 spot urine samples/day and all stools for 5 days. Calcium was extracted from each sample for analysis by mass spectrometry (Thermoquest Triton TI Magnetic Sector Thermal Ionization Mass Spectrometer) and atomic absorption spectrometry. We determined fractional absorption of calcium and endogenous fecal losses. In addition, we performed sum-of-exponential and multi-compartmental modeling of the time-dependent disappearance of intravenous tracer from plasma with the Simulation, Analysis, and Modeling computer program. Data were compared to published normative age- and sex-matched data. We used two-tailed paired t-tests to determine significance between CD and healthy subjects, and two-tailed unpaired t-tests when data was not available to match each subject to an appropriate healthy counterpart. We compared the two groups in terms of Ca intake, intestinal absorption, bone deposition, bone resorption, urinary calcium excretion, endogenous fecal excretion, and calcium balance. Mean BMI Z-score was  $-0.61 \pm 0.79$  kg/m<sup>2</sup>. Lumbar spine BMD Z-score was <-1 in 4/9 subjects with CD (mean  $-0.70 \pm 1$ ). Average calcium intake was  $1257 \pm 446$  mg/d. Mean bone Ca deposition was lower than expected in relation to normative data in healthy children ( $1.98 \pm 0.34$  g/day;  $p = 0.013$ ), whereas fractional absorption of calcium was normal. Calcium balance was significantly lower in combined Tanner stages 3 and 4 subjects with CD ( $37 \pm 25$  mg/day;  $p = 0.029$ ). Urinary calcium excretion exceeded values in healthy counterparts by  $104 \pm 127$  mg/day ( $p = 0.040$ ). Fecal excretion was not significantly different than in controls. In summary, children with CD in remission are in a state of negative calcium balance, especially in late puberty, characterized by excessive urinary losses of calcium. Based on these data, we predict an annual loss of 1.6% of skeletal calcium, which may affect the achievement of peak bone mass.

**c.1250A>G, p.N417S is a Common American *TNSALP* Mutation Involved in all Clinical Forms of Hypophosphatasia (HPP), Including Pseudo-HPP.**

D. Wenkert<sup>1</sup>, W. H. McAlister<sup>2</sup>, S. Mumm<sup>2</sup>, M. P. Whyte<sup>2</sup>. <sup>1</sup>Shriners Hospt for Children, St. Louis, MO, USA, <sup>2</sup>Washington Univ Schl of Medicine, St. Louis, MO, USA.

Hypophosphatasia (HPP) is an inborn error of metabolism caused by loss-of-function mutation(s) in the gene encoding the tissue nonspecific isoenzyme of alkaline phosphatase (*TNSALP*). HPP is highly variable in severity, ranging from tooth manifestations only, to death in utero from profound skeletal hypomineralization. The 7 clinical forms are perinatal, infantile (lethal in 50% of patients), childhood (rickets, +/- short stature, and delayed fracture healing), adult (fractures from osteomalacia), odonto-HPP (early loss of 1° dentition), "benign prenatal" (in utero bowing with improvement ex utero), and pseudo-HPP (infantile HPP phenotype, but normal serum alkaline phosphatase (ALP) activity in clinical laboratories).

We describe 19 individuals with a p.N417S mutation near the active site of *TNSALP*. Of the ~170 patients with HPP followed at our research center, 12 carried this c.1250A>G mutation (representing 7 families) and were studied with fasting serum, 24 hour urine collections, and radiologic studies. Serum and DNA were obtained from 7 additional unrelated patients. None was receiving multivitamins. All manifested *TNSALP* substrate accumulation. The average pyridoxal 5'-phosphate (PLP) and inorganic pyrophosphate (PPi) accumulation in compound heterozygotes was 3x greater than that in individuals with a single *TNSALP* c.1250A>G allele.

5 patients with c.1250A>G were compound heterozygotes, and presented with benign prenatal, infantile, childhood, and pseudo-HPP. Perinatal HPP in a compound heterozygote has been previously reported for the c.1250A>G *TNSALP* mutation. The 14 individuals who carry c.1250A>G as a single mutation of *TNSALP* represented carriers (6), odonto (4), mild childhood (1), adult (2), and benign prenatal (1). Thus, the c.1250A>G is a common, "mild," *TNSALP* mutation that may be susceptible to other genetic or environmental factors, and occurs in all forms of HPP, including pseudo-HPP.

**Dysosteosclerosis in a 2-Year-Old Girl: Investigation of a Rare, Sclerosing Bone Disorder.**

D. Wenkert<sup>1</sup>, W. H. McAlister<sup>2</sup>, S. Mumm<sup>2</sup>, M. P. Whyte<sup>1</sup>. <sup>1</sup>Shriners Hospt Children, St. Louis, MO, USA, <sup>2</sup>Wash U Sch Med, St. Louis, MO, USA.

Dysosteosclerosis (OMIM # 224300) is an extremely rare, sclerosing bone disorder. Pts typically acquire short stature, optic atrophy, and blindness. Some develop cranial nerve palsies, developmental or dental problems, and frequent fractures. Bone histology suggests disrupted osteoclast function.

We investigated a 23 mo girl of Turkish descent whose episodic joint pain prompted a skeletal survey at age 7 mos. She was the 3<sup>rd</sup> child of unrelated parents in their 30's, and was 6-lb, 19", and 38-wks gestation at birth. At age 5 mo, CT for rapidly increasing head size showed prominent ventricles, sulci, and subarachnoid spaces. Tooth eruption and development were normal. She had recurrent ENT and skin infections. Between our evaluations at ages 11 and 23 mos, weight was ~30%, but length fell to -2.4 SD, and head circumference was +4 SD with frontal bossing, flattened nasal bridge, low-set ears, white sclera, 9 normal teeth, genu valgum, and normal joints.

Family history was negative for bone disease. Her mother, 5'1", had cholesteatomas with residual deafness. Her father was healthy. Their radiographs were unremarkable.

Pt x-rays showed progressive metaphyseal widening and sclerosis of all long bones, medial clavicular expansion, orbital and facial sclerosis, basilar thickening, "bone-in-bone" in the pelvis, 10 rib and one femur fracture, flattened and beaked vertebrae in keeping with dysosteosclerosis (Fig). With generous dietary calcium, she had slight hypercalcemia, intermittent hypercalciuria, and normal serum PTH and phosphorus. Alkaline phosphatase and osteocalcin seemed low. Heavy metal screening was negative. The significant elevations in serum LDH or the brain isoform of creatine kinase, seen in osteopetrosis (OPT), were absent. Hemogram suggested no bone marrow suppression. Commercial mutation analysis of the chloride channel 7 (*CLCN7*), T-cell immune regulator 1 (*TCIRG1*), and OPT-associated transmembrane protein 1 (*OSTM1*) genes revealed a heterozygous transition in *CLCN7* (T181M) thought not to be pathogenic because this amino acid is not conserved across species, and occurred in her father. We showed no defects in the RANK (exon 1) or OPG genes, but an unreported heterozygous change in *TNFSF11* (RANKL, c.107C>G, p.P36R).

Our patient's findings suggest that dysosteosclerosis is a form of OPT, but without the serologic hallmarks or mutations in established OPT genes.

**First Clinical Application of Electric Stimulation on Human Distracted Bone.**

Y. Nabil<sup>\*1</sup>, H. Selim<sup>\*2</sup>, O. Hegge<sup>\*3</sup>, M. D'Angelo<sup>4</sup>, A. A. Selim<sup>\*5</sup>. <sup>1</sup>Dental Surgery Department, Military Hospital, Cairo, Egypt, <sup>2</sup>Maxillary Oral Surgery, Ain Shams University Dental School, Cairo, Egypt, <sup>3</sup>Rehabilitation and Rheumatology Department, Ain Shams University School of Medicine, Cairo, Egypt, <sup>4</sup>Anatomy and Cell Biology, Philadelphia College of Osteopathic Medicine, Philadelphia, PA, USA, <sup>5</sup>College of Science, Biomedical research group, KFUPM, Dhahran, Saudi Arabia.

Skeletal tissue is subjected to several biological and physiological forces that modulate its regenerative responses. Management of skeletal deformities in the maxillofacial region has presented a challenge to clinicians. Successful animal model applications of distraction osteogenesis (DO), also refer to as osteodistraction, in the maxillofacial complex has been extensively reported. DO is a surgical technique that uses the body's own repairing mechanisms as allies for optimal tissue reconstruction and this method has joined the conventional techniques for comprehensive treatment of patients with skeletal insufficiencies. Distraction osteogenesis is known to produce mechanical strains that are transformed by bone cells into electrical signals. In accordance with that, several animal studies suggested that the application of electric current may stimulate bone cells to form new bone. In this study, we report the first clinical application of electric stimulation on human distracted bone. Six adult patients underwent segment transfer distraction osteogenesis of mandibular defects combined with the application of direct electric current. We hypothesized that osteodistraction accompanied with electrical stimulation, will make higher speed feasible without compromising bone quality. Direct current of 10  $\mu$ A was started at 7 days postoperatively and continued throughout activation and consolidation periods with a rate of distraction at 2mm per day. The distracted and control non-distracted sides were compared during latency, activation and consolidation periods at 1, 3, 6 and 12 month post operatively. Clinical examination, ultrasonography, digital plain radiographs, bone densitometry and computed tomography demonstrated marked increase in bone density of the distracted bone during the distraction process, at the end of consolidation period and surprisingly the distracted bone demonstrated higher densities compared to control. In conclusion, electric stimulation was an effective method to enhance bone formation in mandibular osteodistraction cases. These data suggests that electric stimulation during osteodistraction may be a good modality to shorten the time needed for distraction osteogenesis and to insure high bone quality during distraction process.

**Alfacalcidol Prevents Aromatase Inhibitor (Letrozole) Induced Bone Mineral Loss in Young Growing Female Rats.** M. H. Idris\*, X. Q. Liu, J. K. Yeh. Metabolism Lab., Winthrop Univeristy Hospital, Mineola, NY, USA.

Long-term aromatase inhibitors use causes bone loss and increase fracture risk secondary to induced estrogen deficiency. We postulated that alfacalcidol (vitamin D3 analog) could prevent the letrozole induced bone mineral loss. Fifty intact 1 month old female rats were randomly divided into five groups with 10 rat each; basal group (B) was sacrificed at start of the experiment; age matched control group (C); letrozole group (L) oral administration of 2 mg/kg per day; alfacalcidol group (A): oral administration of 0.1 ug/kg per day; group L+A: letrozole 2 mg/kg + Alfacalcidol 0.1 ug/kg per day for a period of 8 weeks. When animal sacrificed, serum estrone (E1), estradiol (E2), testosterone (T), LH, FSH, IGF-1 were measured and femoral bone mineral density were scanned by DEXA. Data was analyzed by One-Way ANOVA with group comparison. Eight weeks administration of Letrozole resulted in a significant increase in body weight, tibial and femoral bone length and a significant decrease in the ovary+utrus horn weight as compared to the non-treated groups with or without alfacalcidol. Letrozole administration increased serum T, LH, FSH, IGF-1 and suppressed E1 and E2 significantly. None of those parameters were affected by Alfacalcidol treatment. The result of DEXA shows that Letrozole increased femoral bone area ( $1.8 \pm 0.09 \text{ cm}^2$  vs C;  $1.64 \pm 0.07 \text{ cm}^2$  (mean  $\pm$  S.D.),  $P < 0.05$ ) without a significant effect on the bone mineral content ( $0.39 \pm 0.02 \text{ g}$  vs C;  $0.38 \pm 0.02 \text{ g}$ ). Therefore, the BMD ( $217.8 \pm 4.4 \text{ mg/cm}^2$ ) was significantly lower than that of the control group ( $229.8 \pm 4.9 \text{ mg/cm}^2$ ,  $P < 0.05$ ). Alfacalcidol increased the bone area ( $1.78 \pm 0.07 \text{ cm}^2$ ,  $P < 0.05$ ), bone mineral content ( $0.44 \pm 0.03 \text{ g}$ ,  $P < 0.05$ ) and BMD ( $249.8 \pm 5.9 \text{ mg/cm}^2$ ,  $P < 0.05$ ) as compared to the C group. L+A combine intervention resulted in a significant increase in the bone area ( $1.91 \pm 0.09 \text{ cm}^2$ ,  $P < 0.05$  vs C, L and A groups), bone mineral content ( $0.46 \pm 0.03 \text{ g}$ ,  $P < 0.05$  vs C and L groups) and BMD ( $236.8 \pm 8.0 \text{ mg/cm}^2$ ,  $P < 0.05$  vs C and L groups). This study demonstrates that Letrozole treatment to the young growing female rats enhances body weight and bone elongation due to elevation of both T and IGF-1 with the suppression of E1 and E2. However, the bone density decreased significantly. We believe that Letrozole induced reduction in BMD was secondary to increase bone volume without corresponding increase in mineral deposition. Increased mineral deposition to the growing bone by Alfacalcidol demonstrates that it has therapeutical value in preventing Letrozole induced bone osteopenia.

**The Effects of Long-term Administration of High-dose Growth Hormone on Body Composition and Bone Mineralization.** L. K. Branski\*<sup>1</sup>, D. N. Herndon\*<sup>2</sup>, G. Kulp\*<sup>2</sup>, M. G. Jeschke\*<sup>2</sup>, W. B. Norbury\*<sup>2</sup>, K. E. Naylor\*<sup>3</sup>, R. Eastell\*<sup>3</sup>, G. L. Klein\*<sup>4</sup>. <sup>1</sup>Surgery, Shriners Burns Hospital and University of Texas Medical Branch, Galveston, TX, USA, <sup>2</sup>Surgery, University of Texas Medical Branch and Shriners Burns Hospital, Galveston, TX, USA, <sup>3</sup>Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, <sup>4</sup>Pediatrics, University of Texas Medical Branch and Shriners Burns Hospital, Galveston, TX, USA.

Recovery from massive burn injury is marked by persisting catabolism for up to one year. Treatment with recombinant human growth hormone (rhGH) is reported safe and effective in promoting an anabolic response following burn. The aim of this study was to assess the effects of long-term (one year) treatment with high doses of rhGH on body composition and bone metabolism. 161 pediatric patients with burns >40% total body surface area were studied from 2000-2006. They were prospectively randomized to receive either placebo (control group, n=93) rhGH at a daily dose of 0.1 mg/kg (0.1 group, n=46), or 0.2 mg/kg (0.2 group, n=22) for one year after discharge. Patients were followed from discharge at 6,9,12, and 24 mo post-burn (intent to treat study design). Weight, lean body mass (LBM), total body bone mineral content (BMC) and % total body fat (FAT) were measured at each time point. IGF-1, IGFBP3, PTH, osteocalcin, and serum total calcium were also measured at admission. Urinary NTx was measured at 12 mo. Statistical analysis was performed using Tukey's t-test or repeated measures ANOVA followed by Bonferroni's t-test. In each case %change of each parameter from discharge was compared vs controls. Significance was accepted at  $p < 0.05$ . LBM increased at 9,12, and 24 mo in the 0.1 group ( $p < 0.04$ ) and in the 0.2 group beginning at 6 mo ( $p < 0.02$ ). FAT decrease was seen in the 0.1 group (6,9,12,24 mo,  $p < 0.03$ ) and in the 0.2 group ( $p < 0.04$ ). IGF-1 levels were elevated in both treatment groups compared to control ( $p < 0.05$ ). BMC fell in the 0.2 group at 9 and 12 mo ( $p < 0.02$ ) with elevated osteocalcin ( $p < 0.002$ ) and decreased PTH ( $p < 0.01$ ) at 9 and 12 mo postburn. Urine N-Tx trended toward increase at 12 mo ( $p = 0.06$ ). We conclude that high dose rhGH increases LBM in burned children but with an accompanying decrease in total body BMC and increased bone resorption in the 0.2 mg/kg/d dose at 12 mo post-burn. Data are insufficient at present to determine whether BMC recovers at 24 mo but if as in the GH-associated bone resorption of GH-deficient children at 12 mo it takes another year of administration to show an increase in BMC, cost vs benefit of treatment must be determined to see if any additional therapy is worthwhile.

**Continuous Local Infusion of Alendronate Prevents Osteopenia of the Lengthened Segment During Distraction Osteogenesis.** A. Abbaspour\*<sup>1</sup>, T. Baghdadi\*<sup>1</sup>, R. Espandar\*<sup>1</sup>, S. Saberi\*<sup>1</sup>, P. Heidari\*<sup>1</sup>, S. Takata\*<sup>2</sup>, N. Yasui\*<sup>2</sup>. <sup>1</sup>Orthopedics, Tehran University/ medical science, Tehran, Iran, Islamic Republic of, <sup>2</sup>Orthopedics, Health Bioscience, Tokushima, Japan.

Distraction osteogenesis is a well-established method for bone lengthening with widespread clinical application. However to achieve extensive bone regeneration, the external fixator must be applied for a long period, which may result stress-shielding osteopenia. In this study we performed the ability of continuous local injection of alendronate to the lengthened segment of distraction osteogenesis for prevention of osteopenia.

Seventy-two male rabbits had subperiosteal osteotomy of the left tibia and an external fixator was applied anteromedially. There was a lag phase for one week, a distraction phase for two weeks, and a consolidation phase for five weeks. At the beginning of consolidation phase, alendronate was injected continuously at a rate of  $7.14 \mu\text{g/kg/day}$  into the lengthened segment through a needle and catheter connected to a subcutaneously implanted osmotic pump. Control group received purified buffer solution (PBS-) using the same osmotic pump. The bone formation of lengthening segment evaluated through radiograph measurement, weekly. The bone mineral content (BMC) and bone mineral density (BMD) of lengthened segment, surrounding segment of operated and contra-lateral tibiae measured by DXA weekly. Rabbits were sacrificed at 4, 6, and 8 weeks after operation for examination by pQCT and three-point bend test.

Radiographic evaluation indicated osteopenia significantly prevented in alendronate treated group compared with the PBS- treated group. The BMC of the lengthened segment was 7 times higher in alendronate treated group at 8 weeks ( $P < 0.0001$ ). The mean areal BMD ( $\text{g/cm}^2$ ) at 8 weeks in the lengthened 83% ( $p < 0.0001$ ), in the proximal to the lengthened segment 37% ( $p < 0.001$ ), and the distal to the lengthened segment 43% ( $p < 0.001$ ) were higher in alendronate treated group. The mean volumetric density (BMD) in the lengthened segment at 4 weeks 12% ( $p = 0.35$ ), 6 weeks 89% ( $p < 0.003$ ), and 8 weeks 94% ( $p < 0.001$ ) higher in alendronate treated group. In the proximal and the distal to the lengthened segment at 6 and 8 weeks were significantly higher in alendronate treated group ( $p < 0.001$ ). Three-point bending test demonstrated that alendronate treated bone at 6 and 8 weeks were significantly stronger than PBS- treated group.

This study has demonstrated that continuous local injection of alendronate into the lengthened segment can prevent osteopenia during distraction osteogenesis.

**Dried Plum Polyphenols Increase Insulin-like Growth Factor I (IGF-I) Production in Osteoblast-like Cells.** S. Hooshmand\*, S. C. Chai\*, B. H. Arjmandi\*. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

Osteoblast-like cells (MC3T3-E1) secrete several growth regulating factors include insulin like growth factor I (IGF-I), transforming growth factor beta (TGF- $\beta$ ) and IGF-II in descending order of abundance. It has been shown that these growth factors produced by MC3T3-E1 have autocrine actions on these cells. Amarnani et al. showed that exogenous addition of IGF-I and IGF-II stimulates MC3T3-E1 cell proliferation; however, TGF- $\beta$  inhibited osteoblast proliferation. IGF-I not only causes osteoblast proliferation but also enhances bone

matrix proteins synthesis in these cells. Our earlier clinical study showed that consumption of dried plum increase IGF-I level in serum of osteopenic postmenopausal women. To investigate the mechanism of action of this observation, we treated MC3T3-E1 cells with 0, 10, 100 and 1000  $\mu\text{g/ml}$  dried plum extract for 3, 6, 9, 12 and 15 days. Media were collected every three day to measure alkaline phosphatase (ALP) activity and IGF-I. At the end of 15 day period, RNA was extracted to further measure the mRNA expressions of ALP and collagen. Dried plum extract was able to increase IGF-I significantly in dose of 1000  $\mu\text{g/ml}$  in days of 12 and 15 compare to control group. ALP increased numerically in dose of 1000  $\mu\text{g/ml}$  in day 15. However, this increase in ALP was not significant. Changes in mRNA levels of ALP and collagen will be reported at the time of poster presentation. The findings of this study suggest that polyphenols in dried plum play important role in bone formation.

**Inhibition of Major Bone Catabolic Mediators in Human Subchondral Bone Osteoblasts upon EphB4 Receptor Activation by Ephrin-B2 Ligand: A New Specific Target against Subchondral Bone Resorption in Osteoarthritis.** S. Kwan Tat<sup>\*1</sup>, J. Pelletier<sup>\*1</sup>, N. Amiable<sup>\*1</sup>, C. Boileau<sup>\*1</sup>, N. Duval<sup>\*2</sup>, J. Martel-Pelletier<sup>\*1</sup>. <sup>1</sup>Osteoarthritis Research Unit, University of Montreal Hospital Centre, Notre-Dame Hospital, Montreal, QC, Canada, <sup>2</sup>Centre de Convalescence Pavillon des Charmilles, Montreal, QC, Canada.

Abnormal subchondral bone (SB) metabolism is involved during osteoarthritis (OA). Recently, ephrin-B2 and its specific receptor EphB4 were suggested to be involved in bone homeostasis. We previously reported that human OA SB osteoblasts could be discriminated into two subpopulations: L-OA osteoblasts, which have pro-bone resorption properties, and H-OA osteoblasts, which have pro-formation properties. We investigated, in human OA SB, the importance of the ephrin system during OA. Gene expression was determined using real-time PCR and the intracellular signaling factors determined by specific ELISA. EphB4 expression was significantly elevated in L-OA osteoblasts compared to normal ( $p < 0.002$ ) and H-OA ( $p < 0.0007$ ), whereas there was no difference when normal was compared to H-OA. In L-OA osteoblasts  $PGE_2$  and IL-17 significantly increased the EphB4 level ( $p < 0.04$ ), whereas IL-1 $\beta$ , TNF- $\alpha$ , and IL-6 had no effect. Ephrin-B2 activation of the EphB4 receptor significantly inhibited IL-1 $\beta$ , IL-6, MMP-1, MMP-13, MMP-9 and RANKL levels, whereas MMP-2 and OPG were unaffected. Interestingly, and well in line with the previous data, factors that activated or upregulated EphB4 including ephrin-B2,  $PGE_2$  and IL-17 markedly inhibited bone resorption. Activation of EphB4 resulted in a significant reduction in PI3K/Akt phosphorylation. Data revealed, for the first time, that activation of the EphB4 receptor on L-OA osteoblasts may trigger a switch towards reduced bone resorption, suggesting that ephrin-B2 could act as a specific therapeutic approach to reduce remodeling activity in the human SB osteoblasts.

**Overexpression of the Transcriptional Cofactor Lbh Impairs Angiogenesis and Endochondral Bone Formation During Fetal Bone Development in Chickens.** K. L. Conen<sup>1</sup>, S. Nishimori<sup>\*1</sup>, S. Provot<sup>\*2</sup>, H. M. Kronenberg<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, <sup>2</sup>Department of Anatomy, University of California, San Francisco, CA, USA.

Limb-bud and heart (Lbh) is thought to act as a transcriptional coactivator and is highly conserved among species. We previously showed that Lbh is expressed in proliferative chondrocytes, hypertrophic chondrocytes and the primary spongiosa (PS) of growth plates in mice and chicken. However, its role in endochondral bone formation is still uncharacterized. We hypothesized that Lbh might regulate chondrocyte maturation and PS-formation. To test this hypothesis, we used the avian Replication-Competent ASLV long terminal repeat with Splice acceptor (RCAS) retroviral vector strategy that increases Lbh expression in the developing chicken limb by forced expression of retroviral-encoded Lbh. We found that Lbh overexpression results in mildly shortened skeletal elements with a shortened zone of mineralization in Alcian Blue and Alizarin Red skeletal preparations. Examination of the growth plates between E10 and E11.5, when hypertrophic chondrocytes and the bone collar are seen normally, revealed a delay in vascular invasion and bone collar formation, resulting in a delayed appearance of endochondral ossification centers (OC). TRAP staining of trabecular and cortical bone showed fewer TRAP positive cells in the Lbh-overexpressing bones, demonstrating a delay in cartilage resorption. We also found a reduction in CD31 positive cells within the nascent OC of Lbh-overexpressing wings. Moreover, there was reduced apoptosis and a delay in DNA synthesis within the nascent OC. In situ hybridization analysis showed that the expression of osteopontin mRNA, a typical indication of terminal hypertrophic differentiation in chick fetal growth plates, was markedly decreased, despite relative preservation of the expression of type X collagen mRNA in the adjacent region. Finally, we found a dramatic suppression of Runx2 and VEGF mRNAs in chondrocytes and osteoblasts in Lbh overexpressing bones. These results were confirmed by quantitative RT-PCR analysis using cDNA from both infected and uninfected wings. Taken together, these results suggest that Lbh, normally expressed both in chicken chondrocytes and osteoblasts, may negatively regulate vascular invasion and formation of the early OC. Our data also suggest that Lbh regulates this process at least in part by interfering with VEGF and/or Runx2 expression.

**Selective Retention of Bone Marrow Cells in Repair of Canine Femoral Defect with Polycaprolactone-tricalcium Phosphate Scaffolds.** K. Kumagai<sup>\*1</sup>, J. Otonichar<sup>\*1</sup>, J. Wright<sup>\*2</sup>, L. Griffith<sup>\*2</sup>, C. Boehm<sup>\*1</sup>, R. Rozic<sup>\*1</sup>, K. Powell<sup>\*1</sup>, A. Vasanji<sup>\*1</sup>, T. Saito<sup>\*3</sup>, G. F. Muschler<sup>1</sup>. <sup>1</sup>Orthopaedic Research Center, The Cleveland Clinic Foundation, Cleveland, OH, USA, <sup>2</sup>Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA, USA, <sup>3</sup>Department of Orthopaedic Surgery, Yokohama City University, Yokohama, Japan.

**Introduction:** Bone marrow-derived connective tissue progenitors (CTPs) can be rapidly concentrated into the osteoconductive scaffold when passed through a porous matrix. This clinically useful method called selective cell retention (SCR) technique delivers more progenitor cells and fewer competing cells into a graft site. This study was designed to test the hypothesis that the 3D-structured osteoconductive scaffold matrix in combination with osteogenic cells enhances bone formation in an in vivo bone grafting model.

**Methods:** Four identical 1.0 cm diameter and 1.0cm deep unicortical cylindrical defects were created in the lateral femur of eight dogs. Bone marrow was harvested by aspiration and was heparinized. Non-heparinized bone marrow cells were separately harvested. Three dimensional scaffolds composed of polycaprolactone and tricalcium phosphate were used as the graft matrices after loading of bone marrow cells using SCR system. Four defects were treated with implantation of: 1) scaffold alone, 2) scaffold loaded with 4x volume of bone marrow (4x), 3) scaffold with 1x volume of bone marrow clot (Clot) and 4) scaffold loaded with 4x volume of bone marrow and 1x volume of bone marrow clot (4x+Clot). Bone formation was assessed by quantitative micro CT analysis four weeks after implantation.

**Results:** New bone formation tended to begin at the outer surface contacting the marrow space and to migrate into the scaffold matrix. The better bone formation could be seen in the outer region compared to the center region. The 4x loading graft indicated that the bone ingrowth front migrated to the middle region whereas the bone formation in the scaffold alone grafting stopped at the outer-third region. Although the difference in the mean values of %BV was not significant among the different levels of the grafts, 4x grafting showed greater bone formation compared to the scaffold alone grafting. Then the effect of grafts on the bone formation was evaluated with the radially located regions. An all pairwise multiple comparison test indicated the significant bone formation in the outer region.

**Conclusion:** The bone migration to the inside matrix was moderate in the scaffold alone grafting because of limited delivery of osteogenic CTPs. When the CTPs were retained in the graft matrix, bone ingrowth front moved toward the center region. The SCR system for CTP concentration in 3-D scaffold matrix appears to be effective in bone grafting.

**Disclosures:** K. Kumagai, None.

**Regulation of Dickkopf-1 and Dickkopf-2 is Needed for Osteoblast Terminal Differentiation on Microstructured Titanium Surfaces.** R. Olivares-Navarrete<sup>\*1</sup>, S. Hyzy<sup>\*1</sup>, M. Wieland<sup>\*2</sup>, B. D. Boyan<sup>1</sup>, Z. Schwartz<sup>1</sup>. <sup>1</sup>Georgia Institute of Technology, Atlanta, GA, USA, <sup>2</sup>Institut Straumann, Basel, Switzerland.

Wnt/beta-catenin-signaling plays an important role in wound healing, osteoblast differentiation and bone formation, suggesting that enhanced peri-implant osteogenesis associated with microstructured hydrophilic titanium surfaces in vivo involves specific modulation of this pathway. Expression of Dkk proteins upstream of Wnt-signaling has been shown to inhibit osteogenesis, but Dkk expression after Wnt-signaling induces a terminal osteoblast phenotype. In this study we hypothesized that the microtopography and hydrophilicity of the substrate affect Dkk1 and Dkk2 expression and signaling in osteoblasts and downregulation of Wnt-beta-catenin signaling is necessary for surface-dependent osteoblast differentiation. MG63 cells were grown for 6 days on tissue culture polystyrene (TCPS) and microstructured titanium substrates (PT [Ra<0.2 $\mu$ m], SLA [Ra=4 $\mu$ m], modSLA [hydrophilic-SLA]). Changes in mRNA levels were measured by an RNA-microarray and confirmed by real time PCR. Surface effects on Dkk1 and Dkk2 protein were measured by ELISA. MG63 cells were transduced with lentivirus particles containing the Dkk2-siRNA template and selected with puromycin. MG63 and Dkk2-silenced cells were cultured on the test surfaces +/- exogenous Dkk1 and Dkk2 protein. Alkaline phosphatase specific activity (ALP), OCN, OPG, TGF- $\beta$ 1, VEGF and Dkk2 protein levels were analyzed. Dkk1 and Dkk2 expression and protein content based on RNA-microarray, real time PCR, and direct measurement of Dkk1 and Dkk2 protein were increased on SLA and modSLA. Dkk2 was reduced in siRNA-Dkk2 cells by more than 70%. These cells had significantly lower levels of ALP, OCN, OPG, VEGF and TGF- $\beta$ 1 than MG63 cells on each test surface. Effects of Dkk2 knock-down were comparable on SLA and modSLA. Dkk2 but not Dkk1 protein treatment partially rescued the osteoblast differentiation phenotype in Dkk2-silenced cells, and this effect was dose-dependent. These results indicate a major role for Dkk2 in late-stage osteoblastic differentiation on microstructured and hydrophilic surfaces, and suggest the importance of Wnt/beta-catenin-signaling and Dkk2 during implant osteointegration in vivo.

Renin angiotensin system (RAS) regulates circulating blood volume and blood pressure systemically while RAS also plays a role in local milieu. Previous *in vitro* studies suggested that RAS may be involved in the regulation of bone cells. However, it was not known whether molecules involved in RAS are present in bone *in vivo*. In this paper, we examined the presence of RAS components in adult bone and the effects of angiotensin II type 2 (AT2) receptor blocker on bone mass. Immunohistochemistry revealed that AT2 receptor protein was expressed in both osteoblasts and osteoclasts. In addition, renin and angiotensin II converting enzyme (ACE) were expressed in bone microenvironment. Treatment with AT2 receptor blocker significantly enhanced the levels of bone mass and this effect was based on the enhancement of osteoblastic activity as well as the suppression of osteoclastic activity *in vivo*. These results indicate that RAS components are present in adult bone and that blockade of AT2 receptor results in alteration in bone mass.

**RANKL/OPG in Primary Cultures of Osteoblasts from Patients with Osteoporotic Hip Fractures.** M. J. Montoya<sup>\*1</sup>, M. Giner<sup>\*2</sup>, M. J. Ríos<sup>\*1</sup>, M. A. Vazquez<sup>\*1</sup>, L. Naji<sup>\*1</sup>, R. Pérez-Cano<sup>\*3</sup>. <sup>1</sup>University of Seville, Seville, Spain, <sup>2</sup>University Hospital " Virgen Macarena", Seville, Spain, <sup>3</sup>University of Seville and University Hospital, Seville, Spain.

The OPG/RANKL/RANK system is very important in the balance between bone formation and resorption. There are very few papers that evaluate the OPG/RANKL system in osteoporotic patients and they use cell pools as an experimental model and not isolated OBs, without conclusive results.

M&M: Primary hOB cells were isolated from bone fragments of patients subjected to hip arthrodesis, 21 hOB cultures from osteoporotic (OP) patients and 18 osteoarthritis (OA), (63-92 years). We quantified OPG and RANKL protein levels (ELISA) and the mRNA of OPG, RANKL by semi-quantitative RT-PCR in basal conditions and after adding 17- $\beta$ -estradiol (E2) 10-7M; 1,25(OH)<sub>2</sub>vitaminD (1,25D) 10-8M and E2+1,25D (10-7M and 10-8M).

Results: The hOB cultures from OP patients grow more slowly, during the 1st stage, than OA (31 $\pm$ 2 and 20.4 $\pm$ 1 days respectively, p<0.05). The OP group, secret OPG protein levels significantly higher to OA (7.7 $\pm$ 1 and 4.1 $\pm$ 0.7 pmol/L respectively, p<0.05). The OPG and RANKL mRNA expression is comparable between both groups in basal conditions and after adding E2. The 1,25D and 1,25D+E2 induce an increase in RANKL and RANKL/OPG mRNA expression in OP patients above 200% (p<0.05). None of these increases were significant in cultures from OA patients.

Conclusions: The hOB proceeding from hip OP, initially grow more slowly, but after reaching the first cellular confluence, the growth time is equal to that of OB proceeding from patients with OA. Moreover, the hOB from the OP group present a higher protein secretion of OPG and a higher RANKL gene expression and RANKL/OPG ratio in response to stimuli that increase bone resorption, so making these patients more inclined to a greater bone loss.

**Protein Hydrolyzate Directly Modulates the Expression of Glucose-dependent Insulinotropic Peptide by Osteoprogenitor Cells.** Q. Zhong<sup>\*1</sup>, S. Sridhar<sup>\*1</sup>, K. Ding<sup>\*1</sup>, X. Shi<sup>2</sup>, M. Hamrick<sup>3</sup>, B. Kang<sup>\*4</sup>, W. B. Bollag<sup>\*1</sup>, N. Chutkan<sup>\*4</sup>, K. Insogna<sup>5</sup>, C. M. Isles<sup>4</sup>. <sup>1</sup>Medicine, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Pathology, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Cellular Biology, Medical College of Georgia, Augusta, GA, USA, <sup>4</sup>Orthopaedic Surgery, Medical College of Georgia, Augusta, GA, USA, <sup>5</sup>Medicine, Yale University School of Medicine, New Haven, CT, USA.

Glucose-dependent insulinotropic peptide (GIP) is an incretin hormone released from intestinal endocrine cells in response to nutrient (carbohydrates and fat) ingestion. We have previously shown both *in vitro* and *in vivo* that GIP promotes bone formation both by inhibiting osteoclasts and stimulating the differentiation of bone marrow stromal cells (BMSCs) into mature osteoblasts. We sought to further define the cellular basis for this latter observation. Since GIP has not only been reported to act as a hormone but also as an autocrine/paracrine factor, we examined osteoprogenitor BMSCs for GIP expression. Bone marrow was harvested from C57BL6 mice and enriched for BMSCs using negative and positive selection. BMSCs were analyzed for GIP mRNA expression using real time RT-PCR. Changes in GIP mRNA expression in direct response to nutrient addition to the culture

medium was also examined. BMSCs were grown to 80% confluence and placed in Krebs-Ringer bicarbonate buffer with FBS (0.5%) for 3 hours. The appropriate agonists were then added for 6 hours and mRNA extracted. Protein (in the form of 0.3-2% meat hydrolyzate) significantly and dose-dependently stimulated GIP expression by greater than 20-fold. In contrast, glucose, fat, methylpyruvate and glyceraldehyde (metabolites that bypass glycolysis) had not effect on GIP expression. GIP protein expression, as assessed by immunocytochemistry, was significantly increased only by addition of amino-acids (1.6x vs. control). Notably, as the BMSCs differentiated to osteoblasts GIP expression was lost. Several signaling pathways were evaluated as mediators of protein-stimulated GIP expression. We found that amino acids (but not carbohydrates or fat) stimulated GIP expression through the MAPK pathway, increasing ERK phosphorylation within 1 minute of stimulation, with peak phosphorylation at 10 minutes. Consistent with this finding, the MAPK inhibitor PD98059 (1  $\mu$ M) completely inhibited amino-acid stimulated GIP expression.

In conclusion we have demonstrated the existence of a potential autocrine/paracrine pathway in BMSCs where nutrients (amino-acids) activate the MAPK pathway, increasing GIP expression and ultimately inducing osteoblastogenesis. These data suggest a dual pathway where specific nutrients (carbohydrates and fat) are primarily antiresorptive while other nutrients (protein) are primarily anabolic.

**Neuropeptide Y Effect on Osteoblast Cells.** L. Teixeira<sup>\*1</sup>, A. Nunes<sup>\*2</sup>, M. Sousa<sup>\*2</sup>, M. Lamghari<sup>1</sup>. <sup>1</sup>Laboratório de Biomateriais, INEB - Instituto de Engenharia Biomédica, Porto, Portugal, <sup>2</sup>Molecular Neurobiology, IBMC - Instituto de Biologia Molecular e Celular, Porto, Portugal.

NPY neuronal pathway has been correlated to several physiological processes. Its involvement in bone physiology is currently the focus of much recent area of research.

Recent studies suggested that Neuropeptide Y (NPY) may be involved in the regulation of bone homeostasis and that osteoblasts are under NPY neuronal control. In fact, it has been demonstrated that mice lacking NPY-Y1 and Y2 receptor genes show an increased bone mass. However, the mechanisms behind the biological functions involving NPY receptors are not yet understood. Hence, we investigated, *in vitro*, the expression of Y1 and Y2 receptors, in the osteoblastic lineage and analyzed the osteoblasts response to NPY. We were able to detect Y2 receptor gene expression by osteoblasts only upon continuous stimulation by NPY or Y2 receptor agonist (PYY2-36). We also show that Y1 receptor mRNA expression was down regulated when cells were exposed to NPY or Y2 receptor agonist.

Functional analysis showed that NPY stimulated osteoblast proliferation. However, this effect was not mediated by the Y2 receptor. NPY appeared to promote osteoprogenitor cell differentiation to osteoblasts. The pharmacological stimulation/blockade of Y2 receptor revealed its involvement in this process. In contrast, NPY inhibited calcium deposition in osteoblast extracellular matrix. This effect was not mediated by the Y2 receptor. Lastly, NPY acted on osteoblasts also by modulating RANKL promoter responsiveness.

**Evaluation of Two Novel Bone Growth Factors to Enhance Fracture Healing.** I. Arango-Hisijara<sup>1</sup>, K. Buck<sup>\*1</sup>, F. Del Carpio-Cano<sup>\*1</sup>, S. Rehman<sup>\*2</sup>, W. G. DeLong<sup>\*2</sup>, S. N. Popoff<sup>1</sup>, F. F. Safadi<sup>1</sup>. <sup>1</sup>Department of Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, <sup>2</sup>Department of Orthopaedic Surgery and Sports Medicine, Temple University Hospital, Philadelphia, PA, USA.

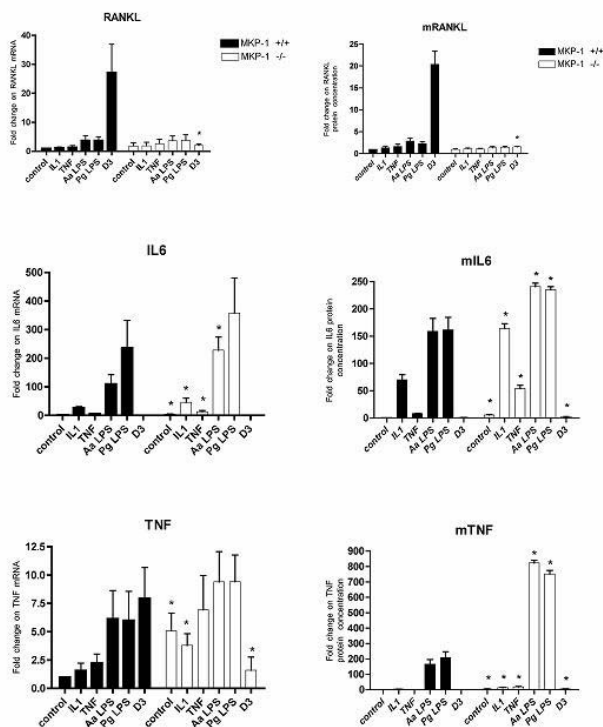

Osteoactivin (OA) and connective tissue growth factor (CTGF) are two novel proteins that have been shown to be anabolic agents in bone. *In vitro* and *in vivo* studies have shown that both CTGF and OA play an important role in osteoblast differentiation and bone formation. In previous studies, we have shown that recombinant CTGF has an osteoinductive effect when injected into the distal femoral marrow cavity of rats, and a peptide derived from the C-terminal domain of OA (OA-P) has osteogenic effects that are similar to the full-length OA protein. In this study, we evaluated the role of CTGF and the OA-peptide using a rat model of femoral fracture. A standard closed femoral fracture was performed on ten week old male Sprague-Dawley rats and the rats were separated into three groups: 1) PBS (negative control); 2) OA-P; 3) adenovirus-CTGF (AV-CTGF). Rats were injected with either PBS, OA-P (100 $\mu$ g) or AV-CTGF at 1, 7 and 14 days post-surgery and followed for 7, 14 or 21 days post-fracture. Radiographs were taken on a weekly basis. Rats were injected with calcein at 7 and 2 days prior to being euthanized at each time point; skeletal tissues were collected and processed for analysis. Radiographic examination of the fracture callus demonstrated greater bony consolidation in the OA-P or AV-CTGF groups compared to control group. Histological analysis of the fracture callus demonstrated greater amounts of periosteal (intramembranous) and endochondral bone formation occurring in the OA-P or AV-CTGF compared to control rats. Calcein labeling demonstrated a significant increase in bone formation rates in the OA-P or AV-CTGF injected rats, providing direct evidence that OA-P or AV-CTGF can increase bone formation at the fracture site. Micro-CT analysis showed a dramatic increase in bone volume in OA-P and AV-CTGF injected rats compared to control group. Overall, animals treated with OA-P or AV-CTGF demonstrated an increase in periosteal and endochondral bone formation at the fracture site, demonstrating OA and CTGF function as anabolic agents to enhance fracture healing. Future studies are underway to examine differential gene expression of the effect of OA-P and AV-CTGF on fracture healing.

## SU013

**MKP-1 Is an Endogenous Negative Regulator of Pro-Inflammatory Cytokines in Bone Marrow Stromal Cells.** C. Rossa<sup>\*1</sup>, M. Liu<sup>\*2</sup>, K. L. Kirkwood<sup>1</sup>. <sup>1</sup>Stomatology, Medical University of South Carolina, Charleston, SC, USA, <sup>2</sup>Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA.

Activation of p38 MAPK by stress, inflammatory and infectious stimuli plays a fundamental role for the expression of cytokines that affect bone turnover, such as IL-6, TNF- $\alpha$  and RANKL. Dual-specificity MAP kinase phosphatase-1 (MKP-1) is an inducible, endogenous negative regulator MAP kinase activation that is localized in the cell nucleus and targets preferentially p38 MAPK. The aim of this study was to determine the role of MKP-1 on the expression of IL-6, TNF- $\alpha$  and RANKL induced by different stimuli in bone marrow stromal cells. Bone marrow stromal cells were collected from MKP-1 knockout C57/Bl6 mice by flushing the marrow cavities of the femur and tibia with cell culture medium. Cells harvested from marrow cavities of wild-type C57/Bl6 mice were used as controls. These cells were stimulated in culture by IL-1 $\beta$ , TNF- $\alpha$ , LPS from *A. actinomycetemcomitans*, LPS from *P. gingivalis* and 1,25 di(OH)vitamin D<sub>3</sub> for 18 hours. The role of MKP-1 was assessed by comparing the levels of cytokine expression by BMSC from knockout and wild-type animals using RT-qPCR and ELISA assays. Cell culture supernatants were used for determination of cytokines by ELISA (n=5). Total RNA was harvested by guanidine isothiocyanate method, reverse transcribed into cDNA and used to assess mRNA level of the cytokines by qPCR (n=5). The results indicated that MKP-1 has an important role on both cytokine- and LPS-induced expression of IL-6 and TNF- $\alpha$ , but not RANKL. Interestingly, MKP-1 is required for the induction of RANKL expression by 1,25 di(OH)vitamin D<sub>3</sub> in BMSC (see figure, \*p<0.05 by unpaired t-test in comparison to the same treatment in WT BMSCs). In conclusion, these results show that MKP-1 plays an important role as an endogenous negative regulatory mechanism for IL-6 and TNF- $\alpha$  expression after inflammatory and infectious stimuli.

**Modulation of Skeletal Modeling by Silica-Based Nanoparticles.** G. R. Beck<sup>1</sup>, S. Ha<sup>\*2</sup>, C. E. Camalier<sup>\*1</sup>, B. Hood<sup>\*3</sup>, T. P. Conrads<sup>\*3</sup>, J. Lee<sup>\*2</sup>, M. N. Weitzmann<sup>1</sup>. <sup>1</sup>Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA, <sup>2</sup>School of Chemistry, Seoul National University, Seoul, Republic of Korea, <sup>3</sup>Clinical Pharmacology, University of Pittsburgh, Pittsburgh, PA, USA.

Nanotechnology is a multidisciplinary field involving the development of engineered "devices", including particles, at the nanometer size (typically 1-100 nm). Recent advances in nanotechnology have raised exciting possibilities for use of nanoparticles as therapeutic interventions and disease imaging. Silica based nanoparticles appear to have good biocompatibility as they are generally thought to be non-toxic in vivo, and consequently are good candidates for use in biomedical applications. We have recently developed a novel 50 nm silica-based fluorescent nanoparticle (designated herein as NP1) for purposes of targeted drug delivery to bone cells. While evaluating the biochemical properties of NP1 relating to toxicity, cell growth and differentiation on a number of different cell types, we were intrigued to discover that NP1 is endowed with potent stimulatory activity on the differentiation and mineralization of osteoblasts in vitro, while concomitantly inhibiting in vitro differentiation of osteoclasts. Preliminary studies in vivo suggest that NP1 is indeed capable of increasing bone mineral density, as assessed by DEXA and  $\mu$ CT.

In order to assess the likely safety profile of these nanoparticles in vivo and to understand potential toxic or non-specific side-effects on skeletal and non-skeletal cells we have begun to define the molecular mechanisms by which they regulate cellular processes. Our studies suggest that one mechanism by which NP1 achieves its stimulatory effects on osteoblasts, and inhibitory effects on osteoclasts, is by suppressing activation of the Nuclear Factor Kappa B (NF- $\kappa$ B), a transcription factor known to repress osteoblast commitment and differentiation, and to be critical for osteoclast differentiation.

The idea that certain nanoparticles themselves might possess intrinsic cell regulatory functions that may be exploitable as pharmaceutical agents is a novel concept and a shift from current attempts to use nanoparticles simply as drug delivery vehicles. In summary, these engineered nanoparticles represent a potentially powerful dual anticatabolic and proanabolic agent for the treatment of numerous skeletal diseases related to bone remodeling without the need for additional drug delivery.

**Nuclear Factor I Transcription Factors Regulate IGF Binding Protein 5 Gene Transcription In Human Osteoblasts.** L. A. Pérez, X. Wang<sup>\*</sup>, K. Howard<sup>\*</sup>, D. Strong, T. Linkhart. Musculoskeletal Disease Center, Loma Linda VA Medical Center, Loma Linda, CA, USA.

Insulin-like growth factor binding protein 5 (IGFBP5) is expressed in many cell types including osteoblasts and modulates IGF activities. IGFBP5 may affect osteoblasts and bone formation, in part by mechanisms independent of binding IGFs. The highly conserved IGFBP5 proximal promoter contains functional cis regulatory elements for C/EBP, Myb and AP-2. We report evidence for a functional Nuclear Factor I (NFI) cis element that mediates activation or repression of IGFBP5 transcription by members of the NFI gene family. All four NFI genes were expressed in human osteoblast cultures and osteosarcoma cell lines. Co-transfection with human IGFBP5 promoter luciferase reporter and murine Nfi expression vectors showed that Nfib was the most active in stimulating transcription. Nfix was less active and Nfia and Nfic were inhibitory. Co-transfection of human NFIB3 (lacking transactivation domain) with Nfib2 isoform dose dependently increased IGFBP5 transcription. Knockdown of NFIB and NFIC expression using siRNA decreased and increased IGFBP5 expression, respectively. Effects of NFIB knockdown on IGFBP5 promoter activity were reversed by overexpressing mouse Nfib. Analysis of IGFBP5 promoter deletion and mutation reporter constructs identified a functional NFI cis element overlapping the AP2 binding site. All four NFI proteins bound the NFI site in electrophoretic mobility shift experiments and NFI-B bound in Chromatin Immunoprecipitation assays. Results suggest that NFI proteins are important regulators of IGFBP5 expression in human osteoblasts and thus in modulating IGFBP5 functions in bone.

## SU016

**Effect of Strontium on PTHrP, OPG and RANKL mRNA Expression in Osteoblastic Like Cells UMR 106.1.** N. Nijs-Dewolf<sup>\*1</sup>, R. Karmali<sup>\*2</sup>, L. Beyer<sup>\*3</sup>, P. J. M. Bergmann<sup>4</sup>. <sup>1</sup>Laboratory of Experimental Medicine, CHU Brugmann (ULB), Brussels, Belgium, <sup>2</sup>Internal Medicine, CHU Brugmann (ULB), Brussels, Belgium, <sup>3</sup>Geriatrics, CHU Brugmann (ULB), Brussels, Belgium, <sup>4</sup>Nuclear Medicine, CHU Brugmann (ULB), Brussels, Belgium.

**AIM:** Sr<sup>2+</sup> increases bone mass by increasing formation and decreasing resorption (Bone 2007;40S1:S5). PTHrP production by osteoblastic cells could regulate bone formation (J Clin Invest 2005;115:2402). Sr<sup>2+</sup> could decrease resorption by regulating the OPG/RANK-L balance (Calcif Tissue Int 2006;78 S1:129). Here we investigated the effect of Sr<sup>2+</sup> on PTHrP, OPG and RANKL expression in osteoblast like cells.

**METHOD:** UMR 106.1 cells were cultivated in EMEM medium with 1 % FCS and 50 ng/mL ascorbic acid. At confluence the cells were placed for 24h in a medium without Ca. SrCl<sub>2</sub> was then added (0.5 - 2 mM) during 1 - 6 hours. Sr<sup>2+</sup> effect was also investigated with 1.25 mM Ca<sup>2+</sup>. Total RNA was reverse transcribed and analyzed by real-time PCR. Hprt1 and ubiquitin C were used as housekeeping genes. Cells incubated without Sr<sup>2+</sup> were used as reference. A gravid uterus and UMR 106.1 cells cultivated in  $\alpha$  MEM -10%FCS were used as positive controls for PTHrP mRNA and for OPG and RANKL mRNA respectively. Water and samples without RT were used as negative controls. The results were expressed as 2 <sup>$\Delta\Delta C_t$</sup>  between cells incubated with and without Sr<sup>2+</sup> in the same incubation.

**RESULTS:** In the absence of Ca<sup>2+</sup>, the expression of PTHrP was significantly increased by Sr<sup>2+</sup> (2 <sup>$\Delta\Delta C_t$</sup> =1.22 (1.07-1.37), p<0.01, n=72). The increase was significant at 1 h., with a maximum for a [Sr<sup>2+</sup>] between 1 and 1.5mM (2 <sup>$\Delta\Delta C_t$</sup> =1.47 (1.09-1.86), p=0.025 at 1mM; 1.37 (1.01-1.74), p=0.047 at 1.5mM, n=6). The expression of OPG mRNA was significantly increased by Sr<sup>2+</sup> (2 <sup>$\Delta\Delta C_t$</sup> =1.18 (1.06-1.31), p<0.01, n=72). The increase was significant after an incubation of 6h, and maximal for a [Sr<sup>2+</sup>] of 2mM (2 <sup>$\Delta\Delta C_t$</sup> =1.66 (1.28-2.05), p<0.01, n=6). In the presence of Ca<sup>2+</sup> 1.25mM, the expression of PTHrP was significantly increased only at 6h (2 <sup>$\Delta\Delta C_t$</sup> =1.29 (1.11-1.45), p<0.001, n=24), with a maximum for [Sr<sup>2+</sup>] 0.5mM, and a decreasing dose-action curve at higher concentrations. Above 1.5mM, there was no significant effect. The expression of OPG was significantly decreased after 3h incubation with Sr<sup>2+</sup> in the presence of Ca<sup>2+</sup>. There was no significant effect of Sr<sup>2+</sup> on the RANKL expression.

**CONCLUSION:** Incubation of OB like cells with Sr<sup>2+</sup> increases PTHrP mRNA expression independently of the presence of calcium in the incubation medium. An increased local production of PTHrP could contribute to increase formation in patients treated with Sr<sup>2+</sup>. OPG expression is only increased by Sr<sup>2+</sup> when cells are incubated without Ca<sup>2+</sup>. There is no effect of Sr<sup>2+</sup> on RANKL in this culture system.

**Disclosures:** N. Nijs-Dewolf, None.

## SU017

**Global Transcriptome Analysis in Mouse Osteoblasts Identifies a Mechanosensing Osteoblast Gene Signature.** A. Rufo<sup>\*</sup>, M. Capulli<sup>\*</sup>, A. Teti, N. Rucci. Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

Mechanical unloading is detrimental for the skeleton, but the underlying molecular mechanisms are not at all elucidated. Global transcriptome analysis of mouse calvarial osteoblasts grown for 5 days at unit gravity (1xg) or under modeled microgravity (0.008xg) in the NASA-developed Rotating Wall Vessel (RWV) bioreactor revealed 45 genes up-regulated and 88 down-regulated in modeled microgravity, with a cut-off >2 and <0.5 respectively and a p value <0.05. We validated a subset of genes by real time RT-PCR and/or protein analysis, thus confirming reliability of microarray data. Degree of modulation of these genes correlated with intensity of gravitational force. Among the regulated genes some were involved in osteoblast differentiation and function, such as Runx2, Sfrp2, osteomodulin, osteoglycin, fibronectin 1 and Ctgf. Interestingly, our results also showed the regulation of some genes whose involvement in bone homeostasis had not yet been recognized, such as the most up-regulated gene, Lcn2 (Lipocalin 2), and the most down-regulated gene, Penk1 (preproenkephalin 1). We also examined potential regulation of genes involved in osteoblast-osteoclast cross-talk, such as RankL and Opg, which were increased and reduced at 0.008xg respectively, leading to a significant increase of the RankL/Opg ratio, confirmed both at mRNA and protein level. This result is consistent with the observation that conditioned media from osteoblasts grown in microgravity stimulated osteoclast formation in mouse bone marrow cell cultures. Another interesting gene up-regulated was IL-6, which has a dual role in bone tissue, as it stimulates osteoclastogenesis and impairs osteoblast differentiation. Transcriptional and protein up-regulation of IL-6 was confirmed, along with its ability to reduce osteoblast proliferation, differentiation and matrix mineralization. Clustering the significantly modulated genes by the GOTM (gene ontology tree machine) software showed up-regulation of genes involved in apoptosis, in the response to stress and in the activity of selected growth factors. Other molecular functions, such as extracellular matrix components, glycosaminoglycan/heparin binding activity and other growth factor activity, were consistently down-regulated. We finally matched our results with other public global gene profiles obtained in loading and unloading conditions and identified a more selected cluster of commonly regulated genes, which could represent a "mechanosensing osteoblast gene signature". We believe that our transcriptome analysis could contribute to recognize novel mechanisms affecting bone mass in unloading conditions and identify new targetable molecules to prevent and/or cure bone pathologies.

## SU018

**T-box 3 Negatively Regulates Osteoblast Differentiation by Inhibiting Expression of Osterix and Runx2.** K. E. Govoni, G. Linares, S. Chen<sup>\*</sup>, S. Pourteymoor<sup>\*</sup>, S. Mohan. JLP VAMC and Loma Linda Univ, Loma Linda, CA, USA.

T-box (Tbx)3, a known transcriptional repressor, is a member of a family of transcription factors which contain a highly homologous DNA binding domain known as the Tbx domain. Mutation of Tbx3 gene results in limb malformation. We recently reported that Tbx3 is required for osteoblast (Ob) proliferation and that growth hormone, an important regulator of skeletal growth, stimulates Tbx3 expression in vitro and in vivo. Based on these findings and that Tbx3 expression increases during Ob differentiation, we predicted that Tbx3 is an important regulator of Ob cell functions. To determine the role of Tbx3 in Obs, we evaluated the consequence of transgenic overexpression of Tbx3, using a retroviral vector, on Ob differentiation. Retroviral overexpression increased Tbx3 expression > 100-fold compared with control (P < 0.01) as determined by real-time RT-PCR. In addition, a significant increase in Tbx3 protein was observed by western immunoblot. To determine the role of Tbx3 in Ob differentiation, MC3T3-E1 cells were plated in media to induce differentiation and mineralized nodule formation. Alizarin Red staining of cells 24 days after addition of differentiation media demonstrated little to no mineralization of Tbx3 overexpressing cells (28  $\pm$  8 vs. 7  $\pm$  1 %). In support of these data, alkaline phosphatase (ALP) activity was reduced 33 to 70% (P < 0.05) in both MC3T3-E1 cells and primary calvaria Obs overexpressing Tbx3. Furthermore, Tbx3 effect on ALP activity was dose dependent. Consistent with reduced differentiation, the increased expression of key Ob marker genes ALP, bone sialoprotein (BSP), and osteocalcin (Oc) within 6 days after addition of differentiation media in control cells (59, 35, and 3-fold; P  $\leq$  0.01, respectively), was not observed in cells overexpressing Tbx3 (ALP 3-fold increase, P < 0.01; BSP 4-fold decrease, P < 0.01; and no change in Oc, P = 0.83). Based on our findings that osterix and runx2 contain Tbx binding site in the regulatory region, we considered the possibility that the negative effect of Tbx3 on Ob differentiation could be mediated via its effects on expression of transcription factors that are critical for Ob differentiation. Accordingly, we found Tbx3 overexpression abolished increased osterix and runx2 expression (12- and 3-fold increase, respectively in controls) observed during normal Ob differentiation. However, expression of Msx2, a transcription factor that does not contain the Tbx binding site, did not differ in expression between control and Tbx3 overexpressing cells over time. Based on these data and our previous findings, we conclude that Tbx3 promotes proliferation and suppresses differentiation of Obs by binding to Tbx binding sites in the regulatory regions of osterix and runx2 to suppress their expression.

## SU019

**PBX1 Interaction with HOXA10 Regulates Timing and Expression of Phenotypic Bone Genes During Osteoblastogenesis.** J. A. R. Gordon, M. Q. Hassan, S. Saini<sup>\*</sup>, A. J. van Wijnen, J. L. Stein, G. S. Stein, J. B. Lian. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

We have recently demonstrated a novel role for the *Abdominal B* class homeobox protein HOXA10 in regulating phenotypic bone genes (Hassan et al. *Mol Cell Biol* 27:3337 2007). HOX factors frequently form multimeric complexes combining with distinct three amino acid loop extension (TALE) class homeodomain proteins to regulate specific transcriptional functions. Here we establish a role for the TALE class protein PBX1 in regulating HOXA10 activity and contributing to the timed expression of bone related genes during osteoblastic differentiation. Exogenous expression of PBX1 in mesenchymal progenitor cells represses the BMP2-induced expression of osteoblast-related genes including RUNX2, osteocalcin and bone sialoprotein. Conversely, disruption of normal PBX1 function by expression of targeted shRNA or alteration of PBX1-DNA binding consensus sequence resulted in increased osteoblast-related gene expression and promoter activity. This regulatory role of PBX1 is further demonstrated by chromatin immunoprecipitation and co-immunoprecipitation experiments showing that HOXA10 and PBX1 interact on osteoblast-related promoters while cells committed to the osteoblast lineage are actively proliferating. This repression complex is also associated with negative modulators of chromatin remodeling, including several histone deacetylases. At the onset of osteocalcin and bone sialoprotein gene expression, the association of HOXA10 and PBX1 is functionally replaced with an activation complex containing HOXA10 and RUNX2. The dissociation of PBX1 from osteoblast-related promoters is coincident with increased histone acetylation and methylation at lysine residues frequently associated with gene activation including H3K4 and H3K36. These HOXA10 co-regulatory protein interactions are consistent with repression and activation of osteoblastic genes during differentiation and identifies a mechanism for the severe skeletal abnormalities observed in PBX-null mice (Selleri et al *Development* 128:3543, 2001). Given our findings we propose that PBX1 plays a central role in the attenuation of HOXA10 as a transcriptional activator of osteoblast-related genes, establishing proper timing of gene expression during osteogenesis.

**Transcription Factor NFATp Regulates BMP-Induced Chondrocyte Differentiation in a Tissue-Specific Manner.** J. G. Yost\*, Q. Lu\*, B. M. Gardner\*, M. Rodova\*, J. Wang. Orthopedic Surgery, University of Kansas Medical Center, Kansas City, KS, USA.

Bone morphogenetic protein (BMP) plays an important role in skeletal development and postnatal bone repair. NFATp (NFAT1/NFATc2) is a member of the NFAT (nuclear factor of activated T cells) family of transcription factors originally identified to be critical in regulating gene transcription in immune response. Previous studies suggested that NFATp also acted as a repressor of chondrogenesis in adult mice. This study was designed to determine if NFATp affects chondrocyte differentiation during BMP-induced endochondral ossification. Recombinant human BMP-7 (rhBMP-7) with type-I collagen as a carrier was implanted into 5-mm cranial bone defects and thoracic subcutaneous pouches created in NFATp<sup>-/-</sup> or wild type (WT) mice. Cellular responses to the implanted material were evaluated by histochemical and immunohistochemical analyses. The expression levels of chondrocyte or osteoblast marker genes were detected by quantitative real-time PCR (qPCR) at days 2, 5, 8, 12, and 21. The results showed that implantation of rhBMP-7 into cranial defects induced bone formation primarily via an intramembranous pathway in the areas close to the dura accompanied by chondrocyte differentiation and endochondral ossification near the skin flap in both NFATp<sup>-/-</sup> and WT mice. Type-X collagen expression peaked at day 8 in both NFATp<sup>-/-</sup> and WT groups, although it remained relatively higher in WT mice at day 12. In contrast, implantation of rhBMP-7 into thoracic subcutaneous tissues first induced differentiation of local mesenchymal stem cells into chondrocytes at day 5, both in WT and NFATp<sup>-/-</sup> mice. However, newly formed chondrocytes differentiated into type-X collagen-expressing hypertrophic chondrocytes with mineralization of cartilage matrix at day 8 in NFATp<sup>-/-</sup> mice, while this process was not evident until days 11-12 in WT mice. BMP-induced cartilage eventually underwent endochondral bone formation in both NFATp<sup>-/-</sup> and WT mice. Further analysis revealed that the expression levels of several proposed positive regulators of chondrocyte terminal differentiation such as Runx2 and Indian hedgehog were significantly higher in cranial bone and surrounding tissues than in subcutaneous tissues. Taken together, our results suggest that the absence of NFATp facilitates terminal differentiation of chondrocytes in a tissue-specific manner during BMP-induced endochondral ossification. This is due, at least in part, to a higher expression of positive regulators of chondrocyte terminal differentiation in the cranial bone environment, resulting in specific patterns of chondrocyte differentiation in the cranial and subcutaneous implants.

## SU021

**Post-translational Regulation of Mx2 Protein.** W. Yoon\*, Y. Cho<sup>1</sup>, J. Cho\*, J. Baek\*, K. Woo\*, H. Ryoo\*. <sup>1</sup>Department of Cell and Developmental Biology, School of Dentistry and DRI, Seoul National University, Korea, Seoul, Republic of Korea, <sup>2</sup>Department of Biochemistry, School of Dentistry, Kyungpook National University, Korea, Daegu, Republic of Korea.

Mx2 is not only essential for epithelial organogenesis or bone formation in early embryonic development of vertebrates, but also a target gene of bone-related cytokines, such as BMP2 and bFGF. Post-translational regulation of protein is fundamental processes in biological control system and little is known about post-translational modifications of Mx2 protein. Here, we investigated the importance of FGF2-induced post-translation processing of Mx2 protein, which is regulated through protein-protein interaction. We identified that Mx2 protein is stabilized in the presence of FGF2. Immunoblot assay of transiently transfected Mx2 in C2C12 cell-line showed that the FGF2 treatment significantly increases the level of Mx2 protein. Blocking JNK activity dramatically decreases the level of Mx2 protein increased by FGF2, while other kinases had no effect on Mx2 level. These results implicate JNK-mediated phosphorylation driven by FGF signal upregulates the stability of Mx2 protein. We also identified that the stability of Mx2 protein requires acetyltransferase activity of p300. Transient cotransfection of Mx2 with p300 showed increased level of Mx2 as well as acetylation of Mx2 protein through Mx2-p300 interaction by immunoprecipitation and immunoblot assays. Increased protein level of Mx2 by p300 reduced ubiquitylation of Mx2 protein, implicating that acetyltransferase activity of p300 prevents Mx2 from ubiquitin-dependent degradation. Additionally, FGF2 treatment strongly increased Mx2-p300 interaction as well as Mx2 protein level. These indicate that FGF2 signal stimulates Mx2 stability via protein acetylation and the same lysine residue(s) of Mx2 can be substrate(s) for both acetylation and ubiquitylation. Finally, we challenged proteomic approach to identify Mx2-binding proteins by using a LC-MS/MS and identified Dlxin-1 among numerous candidates, which is known as a stimulator of Dlx5 transcription activity as well as a target molecule of Prra1, E3 ligase. Co-transfection of Mx2 with Dlxin-1 showed that Dlxin-1 is essential for the Mx2 degradation through the enhancement of binding between Mx2-Prra1, thereby it increases ubiquitylation of Mx2 protein. In summary, we found that intracellular Mx2 protein level is controlled by a balance between ubiquitylation (degradation) and acetylation (stabilization), and FGF2-induced JNK activation makes the balance to the protein acetylation that consequently stabilizes Mx2 protein.

**Mab21 Suppresses the Osteogenic Markers by Recruiting Sin3A and Stimulates Osteoclast by Up-regulation of IL-6 and LIF.** S. Heo\*, E. Cho\*, Y. Jang\*, K. Seul\*, H. Ryoo<sup>2</sup>, J. Kim<sup>1</sup>, J. Cho\*. <sup>1</sup>Biochemistry, Kyungpook National University, Daegu, Republic of Korea, <sup>2</sup>Cell and Developmental Biology, Seoul National University, Seoul, Republic of Korea.

In a previous study, we have shown that the expression of Myeloid Elf-1 like factor (MEF), also known as ELF4, suppresses the osteogenic differentiation by suppressing Runx2 transcriptional activity through directly interacting with it. Also, we found that MEF stimulates the transcription of Mab21L1. To understand the inhibitory mechanism of MEF in osteoblast differentiation, we investigated the role of Mab21 on the osteogenic markers. Mab21L1 suppressed not only the transcriptional activity of IL-6 and osteopontin (OP) but also, of 83bp region of osteocalcin (OC) promoter. The transcriptional repressive activity of Mab21 on those promoters was maintained when the C-terminal of Mab21 is deleted up to N-terminal 114 aa remained. In addition, we found that Mab21 physically interacts with Sin3A, a co-repressor, and the binding was also remained for the N-terminal 114aa of Mab21. Our data suggest that the suppressive effect of MEF might be, in part, accomplished by activating a transcriptional repressor Mab21. Also, the 114aa N-terminus of Mab21 suppresses the OP and OC osteogenic markers by recruiting Sin3A. In addition, our data showed that MEF-transduced osteoblast cells up-regulate the expression of IL-6 and LIF, pro-resorptive and calciotropic factors to osteoclast.

## SU023

**PPARγ2-mediated Proteolytic Degradation of b-catenin Determines an Anti-osteoblastic Effect of Anti-diabetic TZDs.** S. Rahman\*, P. Czernik\*, B. Lecka-Czernik. Department of Orthopaedic Surgery, Center for Diabetes and Endocrine Disease, University of Toledo Medical Center, Toledo, OH, USA.

The transcription factor PPARγ2 is a key regulator of marrow mesenchymal stem cells (MSCs) differentiation. It positively regulates adipocyte and suppresses osteoblast differentiation. Anti-diabetic drugs thiazolidinediones (TZDs), which specifically activate PPARγ protein, upregulate fat production in the bone marrow and cause bone loss in animals and humans. In order to understand the mechanisms of TZD-induced bone loss, we performed microarray analysis of gene expression changes in a cellular model of PPARγ2-controlled MSC differentiation, U-337/2 cells. Cells were treated with a TZD rosiglitazone (R) for 2, 24, and 72h and gene expression was analyzed using Affymetrix platform representing 45,000 gene transcripts. Among the early responders to R were the proteins involved in Wnt signaling pathway, which is essential for MSC differentiation towards osteoblast and bone formation. The expression of two members of Wnt pathway, WISP-1 and Tle3, was significantly altered within 2h post treatment followed by the suppressive effect on the expression of multiple members of this pathway including Fzd receptors, Dkk1, Sfrp1, and Wif1 modulators, and Tcf3 and Tcf4 transcriptional effectors. Cellular silencing of WISP-1 and Tle3 using siRNA suggested that they are not the major mediators of R-induced suppression of osteoblast phenotype. Therefore, we tested whether R affects activity of b-catenin, a key mediator of Wnt signaling activity. We found that R-activated PPARγ2 induced proteolytic degradation of more than 90% of cytoplasmic (active) form of b-catenin as early as within 1 hr post treatment, not affecting a pool of protein bound (inactive) b-catenin. Consistent with this finding, R suppressed transcriptional activity of b-catenin, measured by the activity of TOP-FLASH construct in a luciferase gene reporter assay. Moreover, R suppressed alkaline phosphatase activity even in the presence of LiCl, which stabilizes an active form of b-catenin. To test whether b-catenin degradation is responsible for R anti-osteoblastic effects we modified PPARγ2 protein domains responsible for b-catenin degradation. Using transfected marrow MSC with mutated PPARγ2 constructs, we are currently testing the hypothesis that a lack of PPARγ2 proteolytic activity for b-catenin protects Wnt pathway gene expression and osteoblast phenotype against the negative effects of anti-diabetic TZDs.

**Identification of IRX3 a Novel Transcription Factor During BMP2 Mediated Osteoblast Differentiation.** Y. Bae\*, B. C. Dawson\*, T. Bertin\*, E. Munivez\*, B. Lee. Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

Mesenchymal stem cells have a potential to differentiate to various cell types including osteoblasts, chondrocytes, adipocytes, myoblasts and fibroblasts, depending on the signaling pathway activated during the initial phase of differentiation. These signaling cascades are likely to regulate specific set of early response genes that would govern the final fate of the differentiation process. Osteoblast differentiation can be induced by various stimuli and the most potent inducer are bone morphogenetic proteins (BMPs). Upon the BMP2 treatment, murine premyoblast cell line C2C12 can differentiate into osteoblasts. This *in vitro* biological model allows identifying novel potential regulators involved in osteoblast differentiation. Here, we have examined genes expression during early phase of osteoblast differentiation from C2C12 by 8 hours BMP2 treatment. Gene expression was analyzed by using Mouse Genome 430 2.0 Affymetrix microarray. Real-time quantitative RT-PCR analysis was performed to validate BMP2 mediated osteoblast marker expression from C2C12 cells. A total of 226 genes were differentially regulated after BMP2 treatment. The immediate BMP2 target genes, *Id5*, were highly up-regulated after BMP2 treatment. *Sp7 (Osterix)*, key regulator of osteoblast differentiation, and early

response genes such as *Prrx2*, *Klf10*, *Snai1*, and *Tcf7* were up-regulated upon BMP2 treatment. Interestingly, we have identified a novel transcription factor, Iroquois Homeobox 3 (IRX3), according to its induction upon BMP2 treatment. The expression of *Irx3* was further validated by quantitative RT-PCR along with other early response genes. Consistent with previous report, *in situ* hybridization analysis showed *Irx3* expression at the proximal region of the limb buds of E 11.5 embryo. *Iroquois* homeobox genes are found in all multicellular organisms, and have essential roles in governing various developmental patterning.

In our study, IRX3 protein was identified as a novel transcription factor during early-phase of BMP2 mediated osteoblast differentiation. IRX3 may play a role in the limb development as suggested by its expression pattern. However, the underlying molecular mechanism of IRX3 remains to be elucidated to understand its function during limb development.

**Functional Association of MAP Kinase and Runx2 on Osteoblast Chromatin.** Y. Li\*, Q. Yang\*, C. Ge\*, R. T. Franceschi. Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA.

As previously shown by this laboratory, integrin-mediated osteoblast-ECM interactions are critical for osteoblast differentiation. This response is explained by activation of the Erk-MAP kinase pathway that phosphorylates Runx2 on specific serine residues in the C-terminal proline/serine/threonine-rich domain. In this study, we explore interactions between Runx2 and phospho-Erk on osteoblast chromatin using ChIP analysis. MC3T3-E1 clone 4 cells were cultivated in growth medium (GM = MEM alpha/10% FBS) or differentiation medium (DM = GM+50 ug/mL ascorbate) and chromatin was isolated for ChIP analysis using Runx2 and P-Erk specific antibodies and PCR primers to specific regions of *Ocn*. Runx2 was associated with 2 previously defined *Ocn* promoter binding sites, OSE2a and OSE2b, and this association was not affected by growth in GM or DM. Interestingly, P-Erk was also associated with OSE2a and OSE2b-containing chromatin regions and this interaction was stimulated by DM, a condition known to increase Erk phosphorylation and *Ocn* transcription. This interaction was specific in that it required intact Runx2 binding sites and was blocked by the specific MAPK inhibitor, U0126. Furthermore, neither Runx2 nor P-Erk was detected in association with a distal transcribed region of *Ocn* approx. 500 bp downstream from OSE2a. Taken together, this work shows that Runx2 and P-Erk are physically associated with a bone-related gene in chromatin where they can directly regulate osteoblast-specific transcription.

**Cloning and Functional Expression of the Full Length Mouse GIP Receptor and the Regulation of its Expression in Osteoblasts by the Sp1 Transcription Factor.** B. Kang<sup>1</sup>, J. Xu<sup>\*2</sup>, R. J. Bollag<sup>\*2</sup>, W. B. Bollag<sup>\*3</sup>, N. Chutkan<sup>\*1</sup>, C. M. Isales<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Medical College of Georgia, Augusta, GA, USA, <sup>2</sup>Pathology, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Medicine, Medical College of Georgia, Augusta, GA, USA.

Glucose-dependent insulintropic peptide (GIP) is an incretin hormone secreted from the endocrine cells in the intestine in response to meals. The GIP receptor (GIPR) belongs to the Gprotein-coupled seven transmembrane domain family of receptors that also includes such bone-active hormones as calcitonin and PTH/PTHrP. The GIPR is widely distributed in the body including in the pancreatic islets, brain, intestine and vasculature. Our group was the first to report GIPR expression in osteoblasts and osteoclasts as well as the fact that GIP stimulates bone formation and inhibits bone breakdown. The expression, regulation and signaling characteristics of pancreatic islet GIPR has been reported and splicing variants of the receptor are known to exist but little characterization of the GIPR present in bone cells has been performed previously.

We cloned the mouse GIP receptor (GIPR) complete cDNA by RT-PCR in combination with 5' and 3' RACE using mouse gut total RNA as template. The primers were based on NCBI sequence XM\_884678.2. First, we used primers to clone the coding sequence, and then used 5' RACE to determine the transcription start site; finally 3' RACE was used to decide where transcription ended. We found that our cloned GIPR was 14 bp longer in the 5' end and 121 bp shorter in the 3' end in comparison with the predicted sequence. To characterize the cloned mouse GIPR, we isolated GIPR-expressing stable cell lines after transfecting CHO cells with a plasmid in which the cloned GIPR was inserted into pcDNA3.1 under the control of the CMV promoter. We tested its functionality using [<sup>125</sup>I]-GIP for binding studies and measuring known GIP signaling pathways: intracellular calcium, cAMP and ERK phosphorylation after GIP stimulation. Signaling characteristics of the mouse GIPR were similar to those previously reported for rat and human GIPR, with significant stimulation of all three signaling pathways. To determine how GIPR transcription is regulated in MC3T3 cells (a mouse osteoblastic cell line), we generated a series of GIPR promoter-luciferase reporter constructs. Our data demonstrate that SP1 is a powerful positive regulator while a series of repressive elements are located more upstream. Our data would suggest that osteoblastic GIPR is regulated in a similar fashion to the GIPR present in other tissues in the body.

## SU027

**Protein Kinase D Regulates Histone Deacetylase 7 Localization and Interaction with Runx2 During Bone Morphogenic Protein 2-Stimulated Osteogenesis.** E. D. Jensen<sup>\*1</sup>, R. Gopalakrishnan<sup>1</sup>, J. J. Westendorf<sup>2</sup>. <sup>1</sup>Oral and Maxillofacial Pathology, University of Minnesota School of Dentistry, Minneapolis, MN, USA, <sup>2</sup>Department of Orthopedics, The Mayo Clinic, Rochester, MN, USA.

The transcriptional activity of Runx2 in osteoblasts is determined by associations with co-repressors including histone deacetylase 7 (HDAC7). We previously found that HDAC7 suppression increases the expression of osteoblast maturation genes in bone morphogenic protein 2 (BMP2) stimulated cells. We also found that BMP2 induces export of HDAC7 from the nucleus of osteoblasts and osteoblast progenitors. In this study we demonstrate that BMP2 specifically stimulates redistribution of HDAC7 but not HDAC 4, 5 or 6. We found that HDAC7 subcellular redistribution requires Crm-1 mediated nuclear export, is associated with increased HDAC7 serine phosphorylation, and requires conserved serines in the HDAC7 amino-terminus. To understand the molecular mechanisms of BMP2-induced export of HDAC7, we tested a variety of kinase inhibitors. Only two inhibitors had measurable effects. A CaMK inhibitor (KN93) enhanced basal localization of HDAC7 to the nucleus but did not inhibit export of HDAC7 from the nucleus. In contrast, the PKD inhibitor Gö6976 blocked both basal and BMP2-directed HDAC7 nuclear export. In accord, a constitutively active form of PKD1 stimulated nuclear export of wildtype HDAC7, but not of a mutant HDAC7 protein lacking four serines within consensus PKD phosphorylation sites. Protein Kinase D1 (PKD1) associated with HDAC7 in a BMP2-enhanced manner. Further, constitutively active PKD1 inhibited repression of Runx2-mediated transcription by HDAC7. Inhibition of PKD by Gö6976 severely impaired BMP2 induced osteoblast gene expression. Suppression of HDAC7 did not rescue BMP2 induction of osteoblast marker genes in Gö6976-treated cells, suggesting that PKD-dependent factors beyond attenuation of HDAC7 repressive activity are required for osteoblast differentiation. These results establish a novel pathway by which BMP2 signaling regulates Runx2 activity and gene expression in osseous cells via PKD-dependent inhibition of HDAC7 transcriptional repression.

**Engineering Mice with Multiple BAC Fluorescent Protein Reporter Gene Elements.** P. Maye, M. L. Stover\*, Y. Liu\*, D. Rowe, A. Lichtler. Reconstructive Sciences, UCONN Health Center, Farmington, CT, USA.

Reporter gene mice are valuable animal models for biological research providing a gene expression readout that can contribute to cellular identity within the context of a developmental process. With the advancement of bacterial recombination techniques to engineer reporter gene constructs from BAC genomic clones and the generation of optically distinguishable fluorescent protein reporter genes, there is an unprecedented capability to engineer more informative transgenic reporter mouse models relative to what has been traditionally carried out. We present here the development of a three stage bacterial recombination strategy to physically link multiple genes together with their respective fluorescent protein (FP) reporters in one DNA fragment for the generation of animal models with two to three reporter gene readouts. To test this concept, we have linked two genomic fragments together, one of which contains the TRAP gene and the other DNA fragment contains the genes DMP1 and IBSP. TRAP, DMP1, and IBSP drive the expression of ECFP, mCherry, and Topaz fluorescent protein reporter genes, respectively. We have successfully generated transgenic reporter mice that retain two to three gene readouts. While we continue to characterize these transgenic lines, our analysis suggests that in most mouse lines fluorescent protein reporters from the DMP1-IBSP genomic fragment are strongly expressed in a predictable fashion, while expression of TRAP-ECFP can be more difficult to detect being expressed at lower levels and is best visualized in younger animals. However, the accuracy of TRAP-ECFP expression shows excellent correspondence with histological staining for endogenous TRAP activity. Calvaria and stromal cell cultures derived from these transgenic mouse lines allow easy detection of IBSP and DMP1 expression thereby allowing the visualization and study of osteoblasts and osteocytes *in vitro*. Moreover, these animal models have proven to be an excellent tool for assessing the osteogenic potential of progenitor cells in transplantation studies. Details of the methodology and characterization of different transgenic lines will be presented.

## SU029

**Twist1 Haploinsufficiency Is Associated with Reduced IGF1 Levels and an Osteoporotic Phenotype.** J. Connerney<sup>\*1</sup>, V. Andreeva<sup>\*1</sup>, K. Dowell<sup>\*1</sup>, W. G. Beamer<sup>2</sup>, C. J. Rosen<sup>1</sup>, D. B. Spicer<sup>1</sup>. <sup>1</sup>Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, ME, USA, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME, USA.

Haploinsufficiency of the basic-Helix-Loop-Helix (bHLH) transcription factor Twist1 is associated with Saethre-Chotzen syndrome, which is characterized by premature fusion of the calvaria sutures, termed craniosynostosis. Craniosynostosis occurs around birth, and hence the vast majority of studies have focused on the role of Twist1 during embryonic development and infancy, with very few studies being done in the adult in either mice or humans. Here we have investigated whether *Twist1* haploinsufficiency affects the phenotype of the bones in adult mice. Femurs of wild type and Twist1<sup>+/−</sup> mice were analyzed at 5, 8, and 16 weeks old. At all time points the Twist1<sup>+/−</sup> mice had less body weight than wild type mice, and this was most significant at 16 weeks (p value=.0003). MicroCT analysis of femurs at 5 weeks indicated that Twist1<sup>+/−</sup> mice had significantly less total trabecular volume (p value=.048), trabecular number (p value=.043), mid-shaft cross-sectional area (p value=.025), mid-shaft cortical area (p value=.041), and mid-shaft marrow area (p value=.05) than wild type mice. Bone mineral density (BMD) and percent marrow fat were determined in 8 week and 16 week old mice using a DEXA scan (PIXIMUS). Bones were also analyzed by magnetic resonance imaging (MRI) with transversal measurements of cortical bone and percent marrow fat. Twist1<sup>+/−</sup> mice had lower BMD than wild type mice at 8 weeks, although it was not quite significant, and by 16 weeks it was significantly lower (p value=.0047). The percent marrow fat was not different from wild type mice at 8 weeks, however there was a significant decrease in the Twist1<sup>+/−</sup> mice at 16 weeks (p value=.0017). The decrease in marrow fat was also observed by MRI. Twist1 has been implicated in regulating TNF $\alpha$  expression, however levels of TNF $\alpha$  were similar in Twist1<sup>+/−</sup> and wild type mice. In contrast, serum IGF1 levels were significantly lower in the Twist1<sup>+/−</sup> mice (p value=.0049), which may at least partially account for the bone phenotype in these mice. The effect on both BMD and marrow fat suggests that Twist1 function is required for correct specification and/or differentiation of the bone marrow mesenchymal stem cells.

## SU030

**The Atypical Antipsychotic Clozapine Reduces Rat Osteoblast Proliferation and Osteoclastogenesis at Therapeutic Levels.** J. L. Costa<sup>1</sup>, G. Smith<sup>\*2</sup>, K. Callon<sup>\*1</sup>, J. M. Lin<sup>\*1</sup>, M. Watson<sup>\*1</sup>, P. Shepherd<sup>\*2</sup>, J. Cornish<sup>1</sup>. <sup>1</sup>Medicine, University of Auckland, Auckland, New Zealand, <sup>2</sup>Molecular Medicine and Pathology, University of Auckland, Auckland, New Zealand.

Atypical antipsychotic drugs (AADs) such as clozapine are now widely used in the treatment of schizophrenia, which affects >1% of the world population and has been associated with an increased risk of fracture. Serotonergic signalling has been implicated in regulation of bone mass, so AADs, which are anti-serotonergic, may adversely affect bone mass. In this study, we assessed the skeletal effects of clozapine *in vivo* and *in vitro*, and the effects of haloperidol and quetiapine *in vivo*. Adolescent rats received daily subcutaneous injections of clozapine (10mg/kg), haloperidol (0.25mg/kg), quetiapine (10mg/kg) or vehicle for 28 days, yielding circulating levels similar to therapeutic levels found in human serum. Only haloperidol and clozapine treatment reduced body weight; neither haloperidol nor quetiapine treatment affected bone mass. Compared to vehicle treated controls, however, clozapine significantly reduced bone mineral content (2.03 g  $\pm$  0.06 vs 2.19  $\pm$  0.004, p<0.05) and whole body bone density (0.13 g/cm<sup>2</sup>  $\pm$  0.001 vs 0.14 g/cm<sup>2</sup>  $\pm$  0.002, p<0.01) as measured by DXA. The skeletal effects of clozapine may be in part mediated by indirect endocrine mechanisms, as serum corticosterone levels were higher (371 ng/ml  $\pm$  48 vs 224 ng/ml  $\pm$  18, p<0.001) and testosterone levels were lower (192 pg/ml  $\pm$  50 vs 630  $\pm$  136, p<0.01) after 7 daily injections with clozapine, compared to control animals. However, clozapine may also act directly on bone. We found that clozapine (0.1 $\mu$ M- 10 $\mu$ M) dose-dependently reduced proliferation of primary rat osteoblasts (ROb), by up to 88%. In preliminary experiments, these doses of clozapine also increased apoptosis of ROB, and reduced osteoclastogenesis in murine bone marrow cultures. Taken together, these data suggest that clozapine exerts adverse skeletal effects by both indirect and direct mechanisms in rodents, the latter potentially by its anti-serotonergic actions. Long-term clozapine treatment for schizophrenia in humans may therefore have detrimental effects on bone health.

**Prostaglandins Enhance Extracellular Matrix Mineralization Through the Enhancement of Both Na-dependent Phosphate Transport Activity and ALP Activity in Osteoblast-like Cells.** S. Asano, S. Sekiguchi, M. Shibata, A. Yokoyama\*, K. Inagaki\*, H. Kakizawa\*, N. Hayakawa\*, N. Oda\*, A. Suzuki, M. Itoh\*. Department of Internal Medicine, Fujita Health University, Aichi, Japan.

Prostaglandins (PGs) are important regulators of bone formation and resorption. Among them, PGD<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  have been reported to be released from osteoblastic cells, and to stimulate the proliferation of these cells. Inorganic phosphate (Pi) transport probably represents an important function of bone forming cells in relation to extracellular matrix mineralization. We have previously reported that both PGD<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  stimulate Na-

dependent Pi transport in MC3T3-E1 osteoblast-like cells. In the present study, we additionally investigated the effect of these PGs on Pi transport in osteoblast-like MC3T3-E1 cells and their effects on their extracellular mineralization. Both PGD<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  stimulated Na-dependent Pi transport dose-dependently in the range between 10<sup>-10</sup> M and 10<sup>-6</sup> M in MC3T3-E1 cells. The effect of PGF<sub>2 $\alpha$</sub>  was time-dependent up to 24 h, but the effect of PGD<sub>2</sub> showed its peak at 6 h, and then decreased to base line at additional 24 h. The long-term treatment with PGF<sub>2 $\alpha$</sub>  and PGD<sub>2</sub> stimulated the calcification of MC3T3-E1 cells in the range between 10<sup>-10</sup> M and 10<sup>-6</sup> M. Phosphonoformic acid, an inhibitor for Pit-1, attenuated the mineralization by PGs. These PGs stimulated proliferation and suppressed alkaline phosphatase (ALP) activity during proliferative phase, but enhanced ALP activity in the phase of differentiation.

In summary, these results suggest that PGD<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  stimulate the proliferation of osteoblast-like cells, and enhance the extracellular matrix mineralization through the enhancement of both Na-dependent phosphate transport activity and ALP activity.

## SU032

**Substance P Stimulates Bone Marrow Stromal Cell Osteogenic Activity and Osteoclast Differentiation and Function *in vitro*.** L. Wang, R. Zhao, X. Shi\*, W. S. Kingery. PM&R Service (117), VAPAHCS, Palo Alto, CA, USA.

Substance P (SP) is a neuropeptide richly distributed in the sensory nerve fibers innervating the medullar tissues of bone as well as the periosteum. It has been proposed that this sensory neuron-osseal network is involved in modulating bone remodeling. Our previous studies demonstrated that inhibition of neuropeptide signaling after capsaicin treatment or chronic administration of a SP receptor antagonist resulted in a loss of bone mass and a reduction in bone strength in mature rat limbs. We therefore hypothesized that SP plays an important role in maintaining bone integrity through regulating osteogenesis and osteoclastogenesis. To test this hypothesis, primary bone marrow stromal cells (BMSC) and macrophages (BMM) were cultured from the long bones of the 6 week-old C57BL/6 mice. Immunocytochemical staining and RT-PCR demonstrated that NK1, a SP preferred receptor, localized on the plasma membrane and in the cytoplasm of primary mouse osteoblasts and osteoclasts. SP treatment stimulated BMSC proliferation on BrdU incorporation in a dose-dependent manner. The osteogenic effects of continuous exposure to SP (10<sup>-8</sup>-10<sup>-12</sup>M) were examined after 7, 14, and 21 days of BMSC culture. The 10<sup>-12</sup>M concentration of SP had the greatest stimulatory effect on BMSC differentiation by significantly increasing alkaline phosphatase (ALP) activity and stimulating ALP and osteocalcin gene expression after 14 and 21 days. The effect of SP on osteoclast differentiation and function was also studied. SP dose-dependently increased tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells and increased total pit erosion area on dentine discs in the BMM culture in the presence of M-CSF and RANKL. Furthermore, SP stimulated protein production of RANKL in the BMM culture in a dose dependent manner. In conclusion, NK1 receptors are expressed by primary osteoblasts and osteoclast precursors. SP stimulated osteoblast and osteoclast differentiation and function *in vitro*. SP neurotransmitter release from sensory neurons could potentially regulate local bone turnover *in vivo*.

**Calcitonin-Gen Related Peptide (CGRP) Stimulates Osteogenesis and Inhibits Osteoclastogenesis *in vitro*.** L. Wang, X. Shi\*, R. Zhao, W. S. Kingery. PM&R Service (117), VAPAHCS, Palo Alto, CA, USA.

CGRP is a neuropeptide richly distributed in sensory nerve fibers innervating the medullar tissues of bone as well as the periosteum. It has been proposed that this sensory neuron-osseal network is involved in modulating bone remodeling. Previously we observed that inhibition of neuropeptide signaling after capsaicin treatment or sciatic nerve section resulted in a reduction of trabecular bone mass and hypothesized that CGRP plays an important role in maintaining bone integrity. To better understand the effects of CGRP signaling at the cellular level we examined the effects of CGRP on osteogenesis and osteoclastogenesis *in vitro*. Bone marrow stromal cells (BMSC) and macrophages (BMM) were cultured from mouse long bones. Immunocytochemical staining and real time PCR demonstrated expression of the CGRP receptor calcitonin receptor-like receptor (CRLR) and its chaperone receptor activity modifying protein (RAMP1), co-localized on the plasma membrane and in the cytoplasm of primary osteoblasts and osteoclasts. CGRP treatment stimulated BMSC proliferation on the BrdU assay and increased alkaline phosphatase (ALP) activity, at day 14 to day 21 of cell culture, in a dose-dependent manner. CGRP treatment also upregulated the expression of ALP, osteocalcin, collagen type I, and RUNX2 mRNA in the BMSC at day 7 and 14. Furthermore, CGRP treatment dose-dependently inhibited the generation of functional osteoclasts from BMM cultures. CGRP significantly decreased tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells and decreased bone resorption activity. In addition, levels of osteoclastic genes like TRAP and Cathepsin K mRNA were significantly down-regulated by CGRP. Collectively, these data confirm that CGRP has the potential to maintain a positive bone mass by directly stimulating BMSC proliferation and osteoprogenitor cell differentiation and inhibiting osteoclastogenesis by decreasing osteoclast number and resorption activity.

**Menaquinone-4 Derived from Phylloquinone Regulates Osteoblast Function.** K. Nakagawa\*, N. Sawada\*, Y. Suhara\*, T. Okano. Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

Vitamin K serves as a coenzyme for vitamin K-dependent carboxylase (gamma-glutamyl carboxylase : GGCX). GGCX converts glutamate residues into gamma-carboxyglutamate (Gla) residues in vitamin K-dependent proteins, such as blood coagulation factors (prothrombin, factors IX and X) and bone formation factors (osteocalcin and matrix Gla protein). Thus, vitamin K may exert beneficial effects on bone formation and remodeling. There are two forms of naturally occurring vitamin K, phylloquinone (PK) and menaquinones (MK-n). Moreover, menadiolone or vitamin K3 (K3) is a synthetic compound lacking a side chain. Clinically, MK-4 the most common form of vitamin K, has been shown to prevent bone fractures. This osteoprotective effect is more pronounced in MK-4 than in PK, and hence MK-4 has been used to treat osteoporotic patients in Japan. MK-4 has been shown to act as a ligand for the steroid and xenobiotic receptor (SXR) in human osteoblastic cells. It transcriptionally regulates gene expression and represents a new pathway of vitamin K action. Recently, we demonstrated that deuterium labeled-PK (PK-d7) and deuterium labeled-K3 (K3-d8) administration resulted in the accumulation of MK-4-d7 in tissues [J.Biol.Chem. 283, 11270-11279, (2008)], particularly in liver, brain and bone. Moreover, K3-d8 was converted into MK-4-d7 in human osteoblast-like MG-63 cells. This is the first direct evidence using deuterium labeled compounds and LC-APCI-MS/MS analysis demonstrating that PK and K3 are converted into MK-4 in bone, especially by osteoblasts. To clarify the role of MK-4 biosynthesis in osteoblasts, we examined the biological activity of MK-4 and other vitamin K derivatives in MG-63 cells. We constructed SXR-GAL4 expression vectors containing full-length human SXR and GAL4 DNA-binding site using hybrid luciferase assay system. As a result, MK-4 was shown to be most active in terms of SXR-mediated transcriptional activity. GGCX activity and calcification-inducing activity in MG-63 cells. In LC-APCI-MS/MS analysis, K3 was converted into MK-4 in a dose-dependent fashion in MG-63 cells. The cells treated with K3-d8 significantly increased transcriptional activity in SXR-GAL4 hybrid luciferase assay. These results suggest that MK-4 derived from K3, functions as a ligand of SXR and as a cofactor of GGCX for bone formation by osteoblasts. Our results indicate that MK-4 is a true physiologically active form of vitamin K for bone formation and originated from dietary vitamin K.

**Angiopietin-1 Enhanced Bone Morphogenetic Protein-2 Induced Osteoblast Differentiation.** I. Bae\*, B. Jeong\*, Y. Kim\*, R. T. Franceschi<sup>2</sup>, G. Koh\*, J. Koh<sup>1</sup>. <sup>1</sup>Pharmacology and Dental Therapeutics, Dental Science Research Institution and Brain Korea 21 Project, Chonnam National University Dental School, Gwangju, Republic of Korea, <sup>2</sup>Periodontics and Oral Medicine, University of Michigan Dental School, Ann Arbor, MI, USA, <sup>3</sup>Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea.

In process of bone development and fracture healing, vascular formation (angiogenesis) preceded bone formation. However, roles of angiogenic factors in bone formation are not fully determined. This study was designed to examine whether angiopietin-1 (Ang-1), an important modulator of vascular homeostasis and angiogenesis, is involved in bone morphogenetic protein (BMP)-2 induced osteoblast differentiation using a soluble, stable, and potent Ang-1 variant, replacing the N-terminal portion of Ang-1 with short coiled-coil domain of cartilage oligomeric matrix protein (COMP). In osteoblast-like cell lines and primary calvarial cells, expression of Ang-1 and its Tie-2 receptor mRNA was screened by RT-PCR analysis, and was also monitored during osteoblast differentiation induced by BMP-2 and/or ascorbic acid (AA) and  $\beta$ -glycerolphosphate (GP). C3H10T1/2 and C2C12 cells showed strong expression of Tie-2 mRNA. Under the presence of BMP-2 and/or AA and b-GP, expression of Ang-1 and Tie-2 mRNA increased with induction of alkaline phosphatase (ALP) and osteocalcin (OC) mRNA in C3H10T1/2 and primary mouse calvarial cells. Overexpression of Comp-Ang-1 using adenoviral vectors significantly enhanced BMP2-induced ALP activity and OC production, as well as formation of mineralized nodules. Promoter study also revealed that Comp-Ang-1 stimulated the BMP-2 transactivation of OG2 and 6xOSE promoter genes. In Western blot analysis, Comp-Ang-1 enhanced BMP-2 induction of p38 MAPK and Akt phosphorylation in C3H10T1/2 cells. These results suggest that Ang-1 can enhance BMP-2 induced osteoblast differentiation through MAPK and Akt pathways. The study was supported by BK21 project for school of dentistry funded by the Korea government.

## SU036

**SOST Blocks GSK3-beta Inhibitor-Induced Alkaline Phosphatase Activity.** T. Grabenstaetter\*, Y. Sakane\*, C. Jacobi\*, C. Lu\*, A. Bauer\*, C. Fernandez\*, P. Ramage\*, L. Hartmann\*, O. Leupin<sup>1</sup>, M. Kneissel<sup>1</sup>, C. Halleux<sup>1</sup>. <sup>1</sup>Novartis Institutes for BioMedical Research, Basel, Switzerland, <sup>2</sup>Novartis Institutes for BioMedical Research, Sanghai, China, <sup>3</sup>Cellzome AG, Heidelberg, Germany.

SOST is a selective, potent osteocyte secreted negative regulator of bone formation. It was initially thought to act in adult bone as a BMP antagonist. Subsequently, SOST was found to bind to LRP5/6 *in vitro* and to antagonize canonical Wnt signaling downstream of BMP signaling. The rationale that SOST might impact adult bone formation by inhibition of canonical Wnt signaling is supported by the phenotypic overlap in human bone overgrowth disorders related to loss-of-function mutations in *SOST* and gain-of-function mutations in *LRP5*. In the present study, we examined how SOST exerts its inhibitory effect on alkaline phosphatase (ALP) and mineralization in UMR106 and MC3T3-E1-1b osteoblastic cell lines. We found that SOST potently inhibited Wnt1-induced Supertopflash reporter activity in UMR106 cells. It inhibited mineralization in this cell line in absence of exogenous BMP or Wnt. Likewise, SOST inhibited BMP2-induced mineralization in MC3T3 cells. Furthermore, SOST inhibited BMP2- and Wnt3a-induced ALP activity. The BMP antagonist noggin blocked BMP-2-induced but not Wnt3a-induced ALP activity. SOST decreased Wnt3a-induced ALP activity in the presence of noggin confirming its action downstream of BMP receptors. LRP5/6 antagonist Dkk1 and SOST additively decreased BMP2- and Wnt3a-induced ALP activity. An LRP5/6 antibody partially decreased Wnt3a-induced ALP, confirming that LRP5/6 are, at least partially, implicated in Wnt3a-induced ALP activation. However, we found that SOST is still fully inhibitory when ALP activity was induced downstream of LRP5/6 by blocking GSK3-beta with lithium chloride or GSK3-inhibitor IX. Interestingly, we found ALP to be a putative interaction partner for SOST in addition to LRP5/6 in a proteomic approach consisting of the purification of expressed TAP tagged SOST in UMR106 cells. In line with this notion, we observed in a biochemical ALP assay, that SOST weakly inhibited ALP activity. In conclusion, we corroborate that SOST can inhibit Wnt signaling induction of ALP downstream of BMP signaling. However, we also find that SOST is able to inhibit ALP activity downstream or independently of GSK3-beta. Our data raise the possibility that SOST may bind ligands beyond LRP5/6 to exert its action in bone. Such a hypothesis is supported by our observation that SOST, aside from a disulphide-linked core, is largely unstructured according to NMR based studies, a characteristic that is frequently observed in proteins involved in protein-protein interactions and would therefore suggest SOST binding to one or more different proteins.

**Neuroendocrine Activation of AMP-activated Protein Kinase (AMPK) in Osteoblasts.** M. Shah\*, B. Kola\*, A. Suters\*, M. Korbonits\*, C. C. Chen<sup>1</sup>. <sup>1</sup>VBS, Royal Veterinary College, London, United Kingdom, <sup>2</sup>Department of Endocrinology, Queen Mary's School of Medicine and Dentistry, London, United Kingdom.

Adenosine 5'-monophosphate-activated protein kinase (AMPK), a regulator of energy homeostasis, has a central role in mediating the appetite-modulating and metabolic effects of many hormones and neuromodulators, including leptin, ghrelin, and noradrenalin, as well as the antidiabetic drugs metformin and glitazones. Since all these compounds also regulate bone mass, we tested whether AMPK is activated in osteoblasts in response to these hormones and antidiabetic drugs and whether stimulation of AMPK activity in osteoblasts plays a role their function. Two osteoblastic cell lines UMR106 and ROS 17/2.8 rat osteosarcoma cell lines, as well as osteoblasts isolated from new-born rat calvaria, were cultured in the presence of various hormones and neuromodulators. AMPK activity in cell lysates was measured by a functional kinase assay using SAMS, a synthetic peptide substrate of AMPK, as well as by western blotting using an antibody recognizing AMPK $\alpha$  phosphorylated at Thr-172. Osteoblast cell proliferation was determined by cell counting using the "In Cyto" system, while osteoblast differentiation was evaluated by alkaline phosphatase activity. We first showed that treatment of osteoblastic cell lines for 1 hour with AICAR, a cell-permeable analogue of natural activator AMP, stimulates Thr-172 phosphorylation of AMPK and dose-dependently increases its activity. Both propranolol (a non-specific beta-adrenergic antagonist) and ghrelin (a growth hormone secretagogue and orexigenic hormone) dose-dependently stimulated AMPK activity in osteoblastic cells. In contrast, we did not show any effect of estrogens or dexamethasone on AMPK activity in osteoblasts. Stimulation of AMPK activity in osteoblasts was associated with decreased proliferation but increased differentiation. The antidiabetic drug metformin also dose-dependently stimulated AMPK activity and osteoblast differentiation. Interestingly, AMPK phosphorylation and activity were upregulated in osteoblasts when subjected to mechanical loading *in vitro*. Our preliminary results in primary osteoblasts derived from rat calvaria suggest that the effects of propranolol and ghrelin effects on AMPK activation may be dependent on the state of osteoblast differentiation. Our results confirm the existence of a hormonal link between bone mass and energy metabolism and are consistent with AMPK playing a role in osteoblast function. Further studies will determine the role of AMPK in skeletal physiology.

### Synergistic Activation of Osteogenesis in Multi-Lineage Progenitor Cells by Oxysterols. W. Huang, R. Jarrahy\*, G. H. Rudkin\*, D. T. Yamaguchi, T. A. Miller\*. VA Greater LA Healthcare Systems, Los Angeles, CA, USA.

Oxysterols are naturally occurring cholesterol oxidation products capable of inducing osteogenic differentiation. The purpose of this study is to examine the effect of oxysterols on osteogenic differentiation of Multi-lineage Progenitor cells (MLPC), a cell line that is isolated from post-partum human umbilical cord blood and capable of differentiating into various tissue types. We also compared the effect of oxysterols on MLPCs cultured on two- and three-dimensional systems.

MLPCs (BioE, Inc) were cultured in alpha-MEM medium containing 20% FBS. One day after cells were seeded onto PLGA films or scaffolds, osteogenic differentiation medium was added to induce differentiation. Cells were pulse-treated with 10  $\mu$ m of various oxysterols or their equal ratio mixture for a period of 3 days. Cells were then harvested at day 1, 3, 7, 10, and 14 for total RNA preparation. Real-time RT-PCR assay was performed to examine expression of osteogenic marker genes. At day 14, some cultures were histologically processed and stained with Alizarin Red for Mineralization.

When MLPCs grown on PLGA films were treated with individual isomers of oxysterols (20S, 22S, and 22R), there were modest increases (2-4-fold) in expression of osteoblastic marker genes, including Cbfa-1, alkaline phosphatase (ALP), bone sialoprotein (BSP) and osteocalcin (OCN). The increases were 2-3 fold greater when cells were grown in 3-D PLGA scaffolds. Strikingly, when both 2-D and 3-D cultured cells were treated with an equal ratio mixture of three oxysterol isomers, there was an additional 10-20-fold increase on top of the increase induced by individual isomers. In addition, the oxysterol mixture induced robust mineralization of MLPC cells grown both on 2-D and 3-D cultures in comparison to modest mineralization caused by individual isomers. The synergistic effect of the oxysterol mixture is partially mediated by ERK MAP kinase.

Collectively, our data indicate that oxysterols, especially their equal-ratio mixtures, have a great potential to healing bony defect. The potent osteo-inductive activity of oxysterols on 3-D cultured MLPC makes them ideal candidates for creating a clinically useful bone graft substitute.

### The Role of Cell Surface ATP Synthase in Fluid Shear Stress Induced ATP Release in Osteoblasts. S. Majumdar, K. Czymbek\*, M. Malik\*, R. L. Duncan. Biological sciences, University of Delaware, Newark, DE, USA.

Bone formation is tightly controlled by the mechanical environment of the skeleton and is mediated through activation of osteoblasts. One of its initial osteoblastic responses to fluid shear stress (FSS) is the vesicular release of ATP from the cell and data from our lab, as well as numerous others, indicate that binding of this nucleotide to purinergic receptors is essential for mechanotransduction in bone. While these data highlight the importance of ATP signaling in the mechanosensitivity of bone, the mechanism of ATP release remains elusive. Caveolin 1 is a membrane protein present in lipid rafts and intracellular vesicles that has been implicated in several signaling functions in osteoblasts. The recent discovery of ATP synthase on the cell surface of many cell types has led us to postulate that ATP synthase on the membrane of osteoblasts is scaffolded by caveolin 1 and is critical for vesicular ATP release into the extracellular milieu as well as in the formation of ATP filled vesicles in preparation for release. Using both immunofluorescence and western analyses, we found ATP synthase to be present on the cell membrane of MC3T3-E1 osteoblasts. Co-immunoprecipitation and imaging studies demonstrated that ATP synthase and caveolin 1 co-immunoprecipitate and that ATP synthase appears to be closely associated with lipid rafts on the cell surface. Transmission electron microscopy demonstrated that caveolin 1 was on both the surface and cytoplasmic vesicles in static cells and that subjecting MC3T3-E1 cells to 12 dynes/cm<sup>2</sup> FSS increased the number of vesicles in the cell, suggesting that FSS may increase recycling of caveolin 1 scaffolds. Quinacrine staining of acidic vesicles, denoting the presence of ATP loaded vesicles indicated that FSS rapidly depletes these vesicles in osteoblasts, but addition of methyl  $\beta$ -cyclodextrin, a cholesterol chelating agent which disrupts lipid rafts, greatly enhanced the number and the size of these ATP filled vesicles. These data suggest that dissociating ATP synthase from lipid rafts on the membrane causes more caveolin 1-ATP synthase (CAS) vesicles to accumulate in the cytoplasm and increase the amount of ATP loaded into each individual vesicle. This mechanism may be central to ATP packaging into CAS vesicles for shear challenge and subsequent activation of purinergic signaling to elicit an anabolic response of the bone as a result

### P2X<sub>7</sub> Receptor Activation Mediates PKC $\alpha$ Translocation in Osteoblasts Through Alteration in Actin Cytoskeletal Organization. V. P. Fomin, P. Timothee\*, K. Czymbek\*, R. L. Duncan. Biological Sciences, University of Delaware, Newark, DE, USA.

Osteoblasts respond to mechanical load with a rapid increase in intracellular calcium concentration ([Ca<sup>2+</sup>]<sub>i</sub>) that is essential for load-induced bone formation. This increase in Ca<sup>2+</sup><sub>i</sub> induces vesicular release of ATP that, in turn, stimulates bone cells in an autocrine/paracrine manner through activation of purinergic receptors, P2X or P2Y. P2X receptors

are ligand-gated channels while P2Y receptors are G-protein coupled receptors. While we have shown that the P2X<sub>7</sub> receptors are essential for the response of the skeleton to mechanical loads, activation of second messenger systems, such as protein kinases A and C (PKA and PKC), are also necessary for the complete response of osteoblasts to load. Since activation of PKC and PKA is dependent on activation of G-protein coupled receptors, we predicted that P2Y receptors would be responsible for the mechanically-induced activation of PKC in osteoblasts. To test whether stimulation of purinergic receptors causes activation and translocation of PKC, primarily PKC $\alpha$ , in osteoblasts we infected MC3T3-E1 preosteoblastic cells with an adenoviral cDNA construct for PKC $\alpha$ -GFP to monitor the kinase in live osteoblasts. The PKC $\alpha$ -GFP infected osteoblasts were also loaded with Ca<sup>2+</sup> fluorescent indicator, Fura Red, to allow simultaneous imaging of PKC $\alpha$  translocation and [Ca<sup>2+</sup>]<sub>i</sub>. When 0.5mM ATP was added to infected MC3T3-E1 osteoblasts, a rapid increase in [Ca<sup>2+</sup>]<sub>i</sub> was observed with no change in PKC $\alpha$  distribution within the cell. However, addition of 0.5mM BzATP, a specific agonist for P2X<sub>7</sub> receptors, produced rapid increase in [Ca<sup>2+</sup>]<sub>i</sub> followed by translocation of PKC $\alpha$  to the cell periphery. This effect of BzATP on PKC $\alpha$  translocation was abrogated by addition of the Rho kinase (ROCK) inhibitor, Y27632, suggesting an involvement of the actin cytoskeleton in the regulation of PKC $\alpha$  translocation. While these findings are contradictory to our hypothesis that a G-protein coupled purinergic receptor must be involved in PKC activation in the osteoblast, these data are supportive of the role of P2X<sub>7</sub> in the regulation of the cellular response to mechanical loading. However, the translocation of PKC $\alpha$  may be an indirect response of changes in the actin cytoskeleton, possibly through activation of myosin light chain kinase, to increase the cellular tension.

### Characterization of Osteoblastic Properties of 7F2 and UMR-106 Cultures after Acclimation to Reduced Levels of Fetal Bovine Serum. S. Ganguly\*, L. A. Ashley\*, G. C. Howard\*, R. D. Grey\*, C. M. Pendleton\*, L. D. Castle\*, M. E. Fultz\*, D. K. Peyton\*, D. L. DeMoss. Biological Sciences, Morehead State University, Morehead, KY, USA.

Estrogen plays an important role in skeletal physiology by maintaining a remodeling balance between the activity of osteoblasts and osteoclasts. In an attempt to decipher the mechanism through which estrogen elicits its action on osteoblasts, experimentation necessitated the development of a culturing environment reduced in estrogenic compounds. The selected media (OPTI-MEM) is enriched to sustain cultures under reduced fetal bovine serum (FBS) conditions and is devoid of the pH indicator phenol red, a suspected estrogenic agent. This protocol reduced the concentration of FBS supplementation to 0% through successive, 24-hour incubations with diminishing amounts of total FBS (1%, 0.1%, and 0%) and incorporated the use of charcoal filtered FBS for comparative purposes. The protocol does not appear to alter the viability, cell morphology or osteoblast-like phenotype of 7F2 and UMR-106 cell lines when compared to control cells grown in various concentrations of FBS. Although the rate of mitotic divisions declined, the 7F2 and UMR-106 cultures continued to express osteoblast specific markers and exhibited estrogen responsiveness. Osteoblasts should express characteristic phenotypic markers. Utilizing a variety of techniques, 7F2 and UMR-106 cultures exposed to media devoid of FBS maintained the ability to express the following markers: alkaline phosphatase, osteopontin, receptor activator of nuclear factor (NF)- $\kappa$ B ligand, parathyroid hormone receptor 1, procollagen type I  $\alpha$ 1, runt-related transcription factor 2 and osteocalcin. Cells cultured using this protocol retained the ability to express the specific osteoblastic markers examined and some markers exhibited  $\beta$  estradiol responsiveness. Hence, the cell culture protocol developed allowed cultures to proliferate while maintaining their osteoblastic phenotype and provides an alternative avenue to study the anti-resorptive role of estrogen on skeletal turnover.

### Reciprocal Relation Between MR Measures of Marrow Adiposity and Cortical Bone in the Appendicular Skeleton of Healthy Adults. P. P. Campbell\*, D. Lee, S. Bluml\*, T. Wren, V. Gilsanz. Radiology, Childrens Hospital Los Angeles, Los Angeles, CA, USA.

Considerable data indicate that mesenchymal stem cells (MSC) in the bone marrow differentiate into osteoblasts or adipocytes through alternative activation of mutually exclusive transcriptional programs.

Using the three-point Dixon (3PD) magnetic resonance (MR) technique, which provides measures of fat content in any tissue, we examined the relations between marrow adiposity and bone accumulation in the appendicular skeleton. MR measures of percent marrow fat (MF) and cortical bone area (CBA) at the mid-third of the femurs were obtained in 20 healthy white adults (10 females and 10 males), 18-68 years of age.

There were strong negative correlations between values for MF and CBA throughout the MR images at the mid-third of the femurs. This was true for each femur in all subjects;  $r$ 's ranged from -0.6 to -0.9; all  $p$ 's  $\leq$  0.01. When subjects were grouped by gender, the means for the associations between MF and CBA were strongly negative ( $r$  = -0.80 and -0.75 for females and males, respectively; both  $p$ 's  $\leq$  0.001) (see table below). Similar findings were observed when the means for the associations of all males and females were combined, and when the right and left femurs were analyzed independently.

We conclude that the amount of cortical bone in the appendicular skeleton is inversely related to marrow adiposity. These results provide support for the growing body of

evidence indicating an inversely coupled relationship between osteogenesis and adipogenesis in the skeleton.

	Correlations Between MF and CBA		
	Females (n = 10)	Males (n = 10)	Combined (n = 20)
Mean $\pm$ SD	-0.80 $\pm$ 0.12	-0.75 $\pm$ 0.14	-0.76 $\pm$ 0.13
(range)	(-0.55 - -0.97)	(-0.48 - -0.95)	(-0.48 - -0.97)

**bFGF Induces the Expression of a Subset of Bcl-2 Family Genes to Inhibit the Apoptosis of ATDC5 Chondroprogenitor Cells.** J. Choi<sup>\*1</sup>, H. Kim<sup>\*1</sup>, Y. Kim<sup>\*2</sup>. <sup>1</sup>Biochemistry, Chungbuk National University, Cheong-Ju, Republic of Korea, <sup>2</sup>Orthopaedic, Chungbuk National University, Cheong-Ju, Republic of Korea.

In response to proper extracellular stimuli, chondroprogenitor cell lines such as ATDC5 can be induced either for chondrogenic differentiation or for cellular proliferation. Although Fibroblast Growth factors (FGFs) including basic Fibroblast Growth factor (bFGF) have been known for their pleiotropic effect on the cell survival and apoptosis, the underlying mechanism during this process remains poorly characterized. Through this study using Ribonuclease Protection Assay, Real-Time PCR, FACS and other molecular biology techniques, we attempted to investigate molecular mechanism by which bFGF influenced on a cell physiology of ATDC5 chondroprogenitor cells and induced differential gene expression. A subset of Bcl-2 family genes was found to be up-regulated at the transcription level by bFGF in a NFkB dependent manner. Treatment of siRNAs against these genes attenuates the bFGF mediated protection of ATDC5 cells from apoptosis as assessed by FACS analysis of PI or Annexin-V stained cells. These data suggest a protective role of bFGF in the ATDC5 cell survival through induction of prosurvival Bcl2 family genes. Our findings may provide a therapeutic basis for bFGF in promoting chondrogenic cell survival in inflammatory disease including osteoarthritis.

**TNF-alpha and IL-1beta Stimulate ALP Activity and Mineralization but Decreases RUNX2 Expression and Osteocalcin Secretion in Human Mesenchymal Stem Cells.** D. Jian<sup>\*1</sup>, O. Broux<sup>\*2</sup>, P. Lencel<sup>\*2</sup>, O. Ghali<sup>\*2</sup>, C. Chauveau<sup>\*2</sup>, J. Devedjian<sup>\*2</sup>, P. Hardouin<sup>2</sup>, D. Magne<sup>\*2</sup>. <sup>1</sup>Orthopaedic Surgery, Shanghai Jiaotong University Sixth People Hospital, Shanghai, China, <sup>2</sup>Cellular and Molecular Biology EA2603, ULCO/Lille University, Boulogne/Mer, France.

Effects of inflammation on osteoblast differentiation appear contradictory. Indeed, joint inflammation leads to bone erosions in rheumatoid arthritis whereas it induces syndesmophytes and new bone formation in ankylosing spondylitis. Aims of the present study were to clarify the effects of TNF-alpha and IL-1beta on osteoblast differentiation and calcification in human mesenchymal stem cells (MSCs) and bone marrow stromal cells (BMSCs), and to determine whether these cytokines are redundant or not. Cell differentiation was assessed by quantitative PCR, ELISA, measure of alkaline phosphatase (ALP) activity by the method of Lowry and mineralization by Alizarin red staining. Results indicated that in both cultures TNF-alpha (from 0.1 to 10 ng/ml) and IL-1beta (from 0.1 to 1 ng/ml) stimulated calcification, which was not due to cell death but was linked to a stimulation of ALP expression and activity. Addition of 50 ng/ml IL-1 receptor antagonist in TNF-alpha-treated cultures revealed that whereas IL-1 was responsible for TNF-alpha-stimulated RANKL secretion, it was unnecessary for TNF-alpha-increased ALP activity. In addition, both TNF-alpha and IL-1beta decreased RUNX2 expression and osteocalcin secretion suggesting that RUNX2 is not involved in calcification. To check this hypothesis, dominant negative RUNX2 was overexpressed in osteosarcoma SaOS-2 cells. In transfected cells, ALP expression and activity were not reduced in absence of functional RUNX2, suggesting that RUNX2 plays no role in ALP activity and mineralization in differentiated osteoblasts. Finally, the finding that TNF-alpha and IL-1beta decrease expression of alpha1(I) collagen in MSCs and BMSCs might explain why inflammation decreases bone formation whereas it induces syndesmophyte formation in collagen-rich entheses.

**Regulation of Osteogenesis by Wnt Signaling in Rat Mesenchymal and Human Adipose-Derived Stem Cells.** A. Regmi<sup>\*</sup>, X. Yang<sup>\*</sup>, R. J. Galvin, A. G. Geiser. Musculoskeletal Research, Eli Lilly and Company, Indianapolis, IN, USA.

Stimulation of new bone formation is a goal for treating conditions such as osteoporosis where decreased bone formation or the balance between formation and resorption leads to weakened bones and the risk of fractures. Bone formation may be stimulated by favoring the differentiation of progenitor cells towards the osteoblast lineage. This study evaluated the relative role of wnt in sensitizing either rat marrow mesenchyme (RMM) or human adipose derived stem cells (ASC) to osteogenic signals. ASC cells were cultured in WNT3A-conditioned media (WNT3A) for 1-7 days and osteogenic genes (i.e., alkaline phosphatase (ALPL), osteomodulin (OMD), plasminogen activator inhibitor 2 (SERPINB2)) or wnt-pathway regulated genes (Dickkopf 2 (DKK2) and AXIN2) were measured by real-time PCR. These genes were robustly regulated by WNT3A within 1-day. Osteogenesis was confirmed in both cell types by accumulation of calcified mineral matrix detected by labeling with calcein or alizarin red. Pretreatment of both cell types by WNT3A for 24-hrs followed by removal of WNT3A and subsequent induction of mineralization by osteogenic cocktail (10 mM b-glycerolphosphate, 1 mM ascorbate and 100 nM corticosteroid) showed significant increases in fluorescent calcein by 4 days (ASC) or 7 days (RMM). When both cell types were co-incubated for 14-days in the presence of both mineralizing cocktail and WNT3A, the ASC but not the RMM showed significant increases in the mineral matrix. These data suggest that both cell types have the capacity to respond to WNT3A stimulation. However, lack of increased mineralization with continuous WNT-signaling in the rat cell population indicates that the marrow derived cells are different in response compared to ASCs. This difference could be due to heterogeneity of the marrow cell population. These findings indicate that both populations of progenitor cells are driven to osteogenic differentiation by wnt signaling, but they differ in response to wnt signaling when other osteogenic stimuli are present.

**Blockade of Ephrin/EphB4 Signaling within the Osteoblast Lineage Reduces Osteoblast Differentiation and Mineralization.** E. H. Allan<sup>\*1</sup>, S. Pompolo<sup>\*1</sup>, J. H. Gooi<sup>\*1</sup>, M. T. Gillespie<sup>1</sup>, N. A. Sims<sup>1</sup>, V. Krasnopetrov<sup>\*2</sup>, T. J. Martin<sup>1</sup>. <sup>1</sup>St Vincent's Institute, Melbourne, Australia, <sup>2</sup>Vasgene Therapeutics, Inc, Los Angeles, CA, USA.

Members of the ephrin and Eph family are local mediators of cell function acting largely through contact-dependent processes in physiological development and maturity. Osteoclast-derived ephrinB2 has been shown previously to act upon the receptor tyrosine kinase, EphB4 in osteoblasts through a contact-dependent mechanism to favour bone formation. The aim of the present study was to investigate the consequences of interaction of the ligand, ephrinB2, produced by osteoblasts, with its receptor, EphB4, within the same cell lineage. PTH and PTHrP enhanced ephrinB2 mRNA and protein levels up to 6-fold in murine osteoblastic cell lines, primary murine calvarial osteoblasts and UMR106 rat osteogenic sarcoma cells, but did not affect the levels of EphB4 or any of several other ephrin and Eph products in these cells. In order to block ephrinB2/EphB4 interaction within the osteoblast population, we used either a synthetic peptide antagonist of ephrinB2/EphB4 receptor interaction (Koople *et al.*, 2005 J Biol Chem 280:17301), or recombinant soluble extracellular domain of EphB4 (sEphB4), an antagonist of both forward and reverse EphB4 signaling (Kertesz *et al.*, 2006 Blood 107:2330). In murine mesenchymal cells (Kusa 4b10) grown under osteoblast differentiating conditions, the effect of both agents on osteoblast gene expression (real time RT-PCR) and on mineralization (Alizarin staining) were measured when cultures were differentiated in the presence of ascorbate and beta glycerolphosphate (for mineralization). Osteoblast genes expressed late in differentiation, DMP-1, and interferon induced transmembrane protein 5 (Ifitm5) were significantly down-regulated (2 fold in both cases) by both agents and mineralization was significantly inhibited in a dose-dependent manner by the peptide receptor antagonist and sEphB4. Immunohistochemistry of sections of paraffin-embedded 3 week old male rat femur revealed differential ephrinB2 expression, with groups of osteoblasts on mature trabecular bone positive for ephrinB2, while immature (woven) bone osteoblasts were negative suggesting the action may be most relevant in mature bone. Osteoclasts also stained positively for ephrinB2, as previously reported.

Thus the functional consequence of blocking ephrinB2/EphB4 signaling in osteoblasts in this study was to inhibit mineralization and the expression of several osteoblast genes involved late in osteoblast differentiation. This is consistent with ephrinB2/EphB4 signaling within the osteoblast lineage having a paracrine role in osteoblast differentiation, in addition to the proposed role of osteoclast-derived ephrinB2.

**Hormonal Control of RANKL Expression Is Independent of Runx Family Proteins: Evidence That Commitment to the Osteoblast Lineage Is Not a Requirement for the Stromal Cells That Support Osteoclast Differentiation.** C. Galli<sup>1</sup>, Q. Fu<sup>\*1</sup>, W. Wang<sup>\*2</sup>, B. R. Olsen<sup>\*2</sup>, R. L. Jilka<sup>1</sup>, S. C. Manolagas<sup>1</sup>, C. A. O'Brien<sup>1</sup>. <sup>1</sup>Endo/Metab, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas for Med. Sciences, Little Rock, AR, USA, <sup>2</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, USA.

Differentiation of bone resorbing osteoclasts from hematopoietic precursors depends upon expression of RANKL by stromal cells, which some evidence suggests are precursors of osteoblasts. It has been shown previously that hormonal-responsiveness of the murine RANKL gene is mediated in part by a distal enhancer, designated the Distal Control Region (DCR). In addition, the DCR binds Runx2, a transcription factor required for commitment to the osteoblast lineage, supporting the idea that osteoclast-supporting stromal cells may be osteoblast progenitors. However, dibutyl-*l*-cAMP is able to stimulate RANKL mRNA expression to the same extent in mouse embryonic fibroblasts (MEFs) from both wild-type and Runx2-deficient mice. MEFs express significant levels of Runx1 and Runx3, which can bind to the same DNA sequence as Runx2, raising the possibility that these other members of the Runx family may compensate for the lack of Runx2. Consistent with this possibility, we found that Runx1 was able to bind to the Runx2 binding sequence in the DCR in electrophoretic mobility shift assays. To determine whether any member of the Runx family is required for the expression of RANKL, we silenced CBF $\beta$ , an essential cofactor required for the transcriptional activity of all Runx proteins, in a stromal/osteoblastic cell line using short hairpin RNAs introduced via lentiviral transduction. Basal and PTH-stimulated RANKL mRNA levels were not altered by the suppression of CBF $\beta$ , while mRNAs for known Runx2 target genes, such as osteocalcin, bone sialoprotein, and osterix were dramatically reduced. Similar results were obtained when CBF $\beta$  was silenced in MEFs or primary osteoblastic cells obtained from mouse calvaria. Lastly, we investigated whether Runx proteins were required for the transcriptional activity of the DCR. Silencing of CBF $\beta$  in stromal/osteoblastic cells stably transfected with a chimeric reporter construct, consisting of the DCR inserted upstream from a minimal RANKL promoter, did not block the ability of PTH or dibutyl-*l*-cAMP to stimulate the reporter construct. These results demonstrate that Runx family proteins are not required for RANKL expression or DCR activity in stromal/osteoblastic cells or primary fibroblasts. Moreover, they suggest that commitment to the osteoblast lineage is not a requirement for stromal cells that support osteoclast differentiation.

**BMP-6 Stimulated Osteogenesis of HOB Cultures Is Associated with Suppression of PYK2.** L. Buckbinder<sup>1</sup>, W. Grasser<sup>\*2</sup>, P. Bonnette<sup>\*1</sup>, A. Baumann<sup>\*2</sup>, K. Riccardi<sup>\*2</sup>, B. Robinson<sup>\*2</sup>, V. Paralkar<sup>2</sup>. <sup>1</sup>CVMED Exploratory Biology, Pfizer Inc., Groton, CT, USA, <sup>2</sup>Healthy Ageing Translational Pharmacology, Pfizer Inc., Groton, CT, USA.

We recently identified the PYK2 tyrosine kinase as a negative regulator of bone formation *in vivo* and during the osteogenic differentiation of hMSC cultures (PNAS 2007, **104**, 10619-24). In this report we characterize the expression of PYK2 during osteogenesis of human osteoblast cultures (HOBs). As we observed in hMSC cultures, adenovirus mediated down regulation of PYK2 with shRNA yielded enhanced osteogenesis. In time course experiments, we find that PYK2 protein levels increase during the differentiation of HOBs, with a peak that coincides at the time of high alkaline phosphatase activity. PYK2 levels then decrease as the cells progress to mineralization. We find that BMP6, which stimulates osteogenesis in HOB cultures (Int. Ortho. 2007, **31**, 759-765), leads to both a reduction of active PYK2, as well as total PYK2 protein levels across all time points. Quantitative PCR analysis demonstrates that PYK2 is regulated at the RNA level throughout differentiation in response to BMP6 treatment. In addition, we find that the phosphorylation state of a PYK2 substrate, paxillin pY31, mirrors the levels of active PYK2, and is reduced in response to BMP6 treatment. Furthermore, active forms of FAK and Src, proteins often associated with PYK2 signaling pathways, were found to undergo only relatively minor changes during differentiation or in response to BMP6 treatment. Thus we find: 1) that PYK2, a negative regulator of osteogenesis, is itself regulated at the RNA level during osteogenic differentiation of HOBs, and 2) that pro-osteogenic BMP-6 treatment down-modulates the expression of PYK2. These data suggest that PYK2 induction serves in a feed back loop to limit osteogenesis and that BMP6 acts on this inhibitor by repressing its expression at the RNA level.

**Isolation and Characterization of Osteoblasts from Alveolar Bones of Aged Donors.** M. Aino<sup>\*1</sup>, M. Saito<sup>\*2</sup>, A. Umezawa<sup>\*3</sup>, T. Noguti<sup>\*1</sup>, T. Yoneda<sup>2</sup>. <sup>1</sup>Dept Periodont, Aichi-gakuin Univ, Nagoya,Aichi, Japan, <sup>2</sup>Dept Mol Cell Biochem, Osaka Univ Grad Sch Dent, Suita,Osaka, Japan, <sup>3</sup>Dept Reprod Biol Pathol, Natl Res Inst Child Hlth Develop, Tokyo, Japan.

Establishment of human osteoblasts that retain bone-forming capacity is one of the prerequisites for successful bone regeneration therapy. Since the demand for bone

regeneration considerably increases in elderly, use of osteoblasts derived from these aged individuals should significantly facilitate bone regeneration therapy. However, isolation of osteoblasts from elderly is difficult mainly due to a limited proliferative capacity of these osteoblasts with conventional culture techniques. Here we show a novel culture technique of human osteoblasts isolated from jaw/alveolar bones of elderly donor. We also characterized the phenotype of these osteoblasts *in vitro* and *in vivo*. We attempted to isolate osteoblasts using alveolar bones of 27-, 52-, 53- and 66-year-old donors. Those bones, which were readily obtainable during the course of tooth extraction, were sequentially digested by collagenase and primary human alveolar bone osteoblasts (HAOBs) were isolated. HAOBs from all of the individuals were successfully expanded and continually grow more than 60 population doublings (PDs) in a defined medium. HAOBs exhibited high alkaline phosphatase activity and mineralized nodule formation and expressed osteoblast marker genes such as *runx2*, *osterix*, *osteocalcin* and *bone sialoprotein* upon treatment with rhBMP-2. These characteristics of HAOBs remained unchanged until 16 PDs but were significantly lost after 29 PDs. Affimetrix HG-U133 Gene Chip analysis using HAOBs at 6 PDs and 35 PDs showed that osteocalcin mRNA expression was down-regulated in HAOBs at 35 PDs compared with 6PDs, suggesting that osteogenic phenotype was decreased with increasing cell divisions. To examine bone forming capacity of HAOBs *in vivo*, HAOBs at 6 PDs were subcutaneously transplanted into the dorsal skin in severe combined immunodeficiency (SCID) mice. Histological examination revealed that the transplanted HAOBs formed bone tissues with human vimentin expression 4 weeks after the transplantation, showing that these bones were formed by HAOBs. RT-PCR analysis also showed that these bones expressed human bone sialoprotein and osteocalcin mRNA. In conclusion, our results show that the culture technique used here allows us to successfully grow human osteoblasts of aged donors. They also suggest that HAOBs are a useful cell source for future application to cell based bone regeneration therapy for local bone diseases such as periodontal diseases.

**Adipose Tissue Derived Mesenchymal Stem Cells: Differentiation into Osteoblastic Phenotype and Interaction with Nanostructured Titanium Alloys.** S. Sorace<sup>\*1</sup>, I. Tognarini<sup>\*1</sup>, R. Zonefrati<sup>\*1</sup>, G. Galli<sup>\*1</sup>, G. D. Zappoli Thyron<sup>\*1</sup>, A. M. Carossino<sup>\*1</sup>, F. Marini<sup>\*1</sup>, S. Ciuffi<sup>\*1</sup>, A. Facchini<sup>\*2</sup>, E. Sbaiz<sup>\*2</sup>, A. Tanini<sup>1</sup>, M. L. Brandi<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, University of Florence, Florence, Italy, <sup>2</sup>Lima-Lto spa Medical System, Villanova di San Daniele Del Friuli, Udine, Italy.

The purpose of the present work is to examine the effect of different nanostructured Titanium alloys on osteogenic differentiation of adipose tissue mesenchymal stem cells (AMSCs). Previous work in this laboratory has demonstrated that AMSCs have the same ability to produce bone matrix as bone marrow derived stem cells (BMMSCs) and that Ti6Al4V surfaces exhibit an osteoinductive action on AMSCs, promoting their differentiation into functional osteoblasts and increasing bone formation. In this study *in vitro* tests were used to assay the ability of nanostructured Ti6Al4V and Ti13Nb13Zr to promote and to maintain the osteogenic differentiation on three primary cultures of AMSCs, using polystyrene (PS) and normal human osteoblast cells (NHost) for comparison.

AMSCs were seeded onto Titanium alloys or PS and cultured for up to 40 days. Cell morphology, adhesion, proliferation and differentiation were evaluated by Laser Scanning Confocal Microscopy analysis, cell counting and alkaline phosphatase (ALP) activity evaluation.

Significant differences were observed in term of cell morphology and adhesion when cells were seeded on the three substrates. Morphological analysis revealed that after 4 days of culture both Nhost and AMSCs on nanostructured alloys were less spread, but formed a higher number of focal contacts than on PS. Moreover AMSCs on Ti6Al4V and Ti13Nb13Zr, when compared to cells cultured on PS, displayed a lower proliferation and a greater level of differentiation towards an osteoblastic phenotype, as demonstrated by an increased ALP activity and a higher expression of osteopontin, osteocalcin and collagen type I.

In conclusion our preliminary results confirm that the nanonization of the Titanium alloys promotes cellular adhesion and suggest that the nanostructured surfaces may have an osteoinductive action on AMSCs, leading to interesting alternatives in the design of efficient prostheses.

**Osteoformin Increases the Levels of Intracellular Calcium of Human Preosteoblast Cells in Culture.** L. X. Bi<sup>1</sup>, E. G. Mainous<sup>1</sup>, Y. Zeng<sup>\*2</sup>, Z. Gugala<sup>\*2</sup>, W. J. Buford<sup>\*2</sup>. <sup>1</sup>Dept. of Surgery, University of Texas Medical Branch, Galveston, TX, USA, <sup>2</sup>Dept. of Orthopaedics & Rehabilitation, University of Texas Medical Branch, Galveston, TX, USA.

Our previous studies have shown that Osteoformin (negatively charged polypeptide) increases activity of alkaline phosphatase, expression of type-I collagen and BMP-7 and bone mineralization (Bi LX et al, JBMR 18: S212 Suppl. 2, 2003), and activities of intercellular gap junctional communication of human preosteoblast cells in culture (Bi LX et al, JBMR 22: S142-143, Suppl. 1, 2007). To investigate an early response of preosteoblast cells to osteoformin, we examined the levels of intracellular calcium concentration using Laser scanning confocal microscope. Human preosteoblast cells were cultured in a-minimum essential medium [a-MEM] and 10% fetal bovine serum with or without osteoformin (5ug/ml) for 3 and 5 days. The cells were loaded with 5  $\mu$ M fluo-4

AM (Molecular Probes, USA). After 30 min of dye loading at 37°C in the dark, the coverslips were placed in a stainless steel chamber (Attofluor, 2 ml volume, Molecular probes) that was mounted on a thermostatically controlled stage (37°C) of an inverted confocal laser scanning microscope (AXIOVERT, LSM PASCAL, Zeiss, Germany). The cells were washed with DPBS free Calcium at pH 7.4 and observed using a Zeiss 40× water lens. For imaging of the Ca2+-sensitive fluo-4 fluorescence, excitation wavelength of 488 nm was provided by an argon laser. Fluorescence signals were filtered at 505 nm long-pass and recorded using a photomultiplier of the LSM Pascal. Osteoformin enhanced levels of intercellular calcium concentration by 41% and 22% (P<0.01), respectively, compared to that of the control group. We conclude that osteoformin significantly enhances intracellular calcium concentration which is associated with gene expression and osteoblast differentiation in vitro. It might be an important regulator of bone formation by accelerating fracture and bone defect healing, and controlling bone diseases.

**Development of Pharmacological HIF Activators for Fracture Healing.** S. R. Gilbert<sup>\*1</sup>, X. Shen<sup>\*1</sup>, C. Wan<sup>\*2</sup>, M. Sweetwyne<sup>\*3</sup>, J. E. Murphy-Ullrich<sup>\*2</sup>, T. Clemens<sup>2</sup>. <sup>1</sup>Surgery, U. Alabama Birmingham, Birmingham, AL, USA, <sup>2</sup>Pathology, U. Alabama Birmingham, Birmingham, AL, USA, <sup>3</sup>Cell Biology, U. Alabama Birmingham, Birmingham, AL, USA.

Delayed or failed bone healing is a significant clinical problem resulting in a high burden of disease to individuals and society. Current biologic approaches to aid healing predominantly involve growth factors which can be prohibitively expensive. We have recently identified the hypoxia inducible factor (HIF) pathway as a key transcriptional activator of angiogenesis which is required for skeletal repair. In this study, we investigated the utility of prolyl hydroxylase inhibitors, which elevate HIFs as a means to activate angiogenesis in a mouse model of long bone fracture. Several small molecules including desferrioxamine (DFO), L-mimosine (L-mim) and dimethyloxallyl glycine (DMOG) robustly activated a HIF-responsive reporter gene, and increased HIF-1 $\alpha$  and VEGF expression in mesenchymal stromal cells in vitro. We next tested these agents in a functional angiogenesis assay. Capillary sprouting from explanted mouse embryo metatarsals was evaluated by CD31 staining after exposure to DFO and DMOG, and was found to be robust. These agents only slightly inhibited collagen processing as assessed by Western blotting for both secreted and intracellular collagen I. We then evaluated DFO application after midshaft femur fracture stabilized by intramedullary fixation. DFO or saline was directly injected at the fracture site every other day for five doses. At two weeks post-fracture, mice were sacrificed and perfused with a silicone lead contrast agent for angiography. DFO treatment dramatically increased vascularity as assessed by microCT angiography. Vessel volume/tissue volume and vessel number in the region of interest surrounding the fracture site were elevated 4 fold. The enhanced vascularity was associated with complete radiographic union by 4 weeks. We conclude that HIF activation using a small molecule prolyl hydroxylase inhibitor increases angiogenesis in the setting of healing long bone fractures. The agent tested in this study is relatively inexpensive and has been in clinical use for some time as an iron chelator. This finding may have implications for the treatment of clinical non-unions which are frequently associated with hypovascularity.

**Use of GFP Reporters to Map the Progression of Multipotential Progenitor Cells into the Osteoblast Lineage.** Y. H. Wang, X. Jiang<sup>\*</sup>, L. Wang<sup>\*</sup>, I. Kalajzic, D. W. Rowe. Univ Connecticut Health Center, Farmington, CT, USA.

Mapping lineage progression, especially a lineage branch point, is a major challenge to our understanding of the molecular events that determine lineage specification. The pericyte is emerging as the cell within a wide variety of adult tissues with potential for differentiation into numerous elements of the musculoskeletal system. We have shown that the smooth muscle alpha actin promoter reporter (SMAA-GFP) identifies a heterogeneous population of cells, some of which appear to be progenitor cells for bone, fat and vascular smooth muscle by in vitro differentiation and in vivo transplantation. The present study was designed to develop evidence for the direct transition of this cell type into an osteoblast. Mice double transgenic for SMAA-GFP (green) and Col3.6-CFP (blue) were bred and subjected to a tibial fracture protocol. In this model, weak blue preosteoblasts have developed by day 4 on the periosteal surface distal to the fracture site. These cells progressed toward the fracture site and by day 7 they became strong blue and began to deposit a woven mineralized bone matrix. Activation of SMAA (green) was observed by day 2-3 at the leading edge of the blue preosteoblasts. At the junction of the two colors, double positive cells were visible. While the source of these cells was still conjecture, SMAA green cells were abundant around small blood vessel whose walls have a ragged appearance. To determine if this green to blue cell progression can be observed in primary osteogenic cultures, calvarial cultures from the double transgenic mice were examined for GFP expression during the initial expansion phase of the culture. By day 3, numerous green cells and occasional blue or blue/green were present in the sparsely populated culture. However by day 6, the culture was highly confluent with a preponderance of blue/green and blue cells. The visual progression was confirmed by fluorescent activated cell sorting (FACS) analysis in which a large population of GFP-negative cells at day 3 have progressed to blue/green or green cells by day 6. However, when calvarial cultures derived from SMAA-GFP(green)/Col2.3-CFP(blue) double transgenic were examined, green cells were the predominant cell at day 7 while the proportion of blue only cells have increased by day 14. FACS analysis demonstrated two distinct populations of green or blue cells that

developed at the expense of the other with very few double positive cells. Thus the visual reporters suggest a progression of SMAA(-) => SMAA(+) => SMAA(+)/Col3.6(+) => Col3.6(+)/Col2.3(+). This strategy should be useful in defining a lineage branch point when applied to reporters for the osteogenic and adipogenic lineages.

**Osteogenic Potential of Periodontal Ligament Cells in vivo.** T. Hiraga<sup>1</sup>, T. Ninomiya<sup>\*2</sup>, A. Hosoya<sup>\*1</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Histology and Cell Biology, Matsumoto Dental University, Nagano, Japan, <sup>2</sup>Institute for Oral Science, Matsumoto Dental University, Nagano, Japan.

Periodontal disease characterized by destruction of periodontal tissues is a major cause of tooth loss in adults and represents a substantial public health burden. However, predictable regeneration is not always achieved by the currently-available techniques. Periodontal ligament (PDL) is a unique connective tissue that not only connects cementum and alveolar bone to support teeth but also plays an important role in reconstructing periodontal tissues. Several lines of evidence suggest that PDL cells have osteoblast-like properties; however, their bone-forming activity has not been extensively studied yet. Thus, in the present study, we examined osteogenic potential of PDL cells in vivo. PDL cells were isolated from rat molars by enzymatic digestion. The PDL cells exhibited substantial alkaline phosphatase activity and induced mineralization at levels equivalent to primary calvarial osteoblastic cells in vitro. RT-PCR analyses showed that the PDL cells expressed the osteoblast markers, Runx2, osterix, and osteocalcin. These results suggest that PDL cells share similar phenotypes with osteoblasts. In support of the notion that PDL cells contain multipotent mesenchymal cells, a small population of the PDL cells showed the differentiation to oil red O-positive adipocytic cells. To examine the osteogenic activity of PDL cells in vivo, PDL cells isolated from green fluorescent protein (GFP)-transgenic rats were implanted with hydroxyapatite (HA) disks into wild-type rats. Five weeks after the implantation, the pores in HA disks were occupied by GFP-positive cells. Mineralized matrix formation was also found on the surface of HA pores. At 12 weeks, some of the pores were filled with bone-like mineralized matrices (BLMM). Immunohistochemical studies showed that the BLMM were positive for the bone matrix proteins, osteopontin, bone sialoprotein, and osteocalcin. Of note, they also revealed that most of osteoblast-like and osteocyte-like cells on and in the BLMM were GFP-positive, suggesting that the BLMM were directly formed by the inoculated PDL cells. The existence of cement lines and multinucleated TRAP-positive osteoclasts indicates that the BLMM experienced remodeling. On the pore surfaces, we found that Sharpey's fiber-like structures were embedded in cementum-like mineralized layers. Thus, it is likely that the PDL cells also have a potency to differentiate to other periodontal cells, including cementoblasts. In conclusion, these results suggest that PDL cells possess the osteogenic potential in vivo. PDL cells could be a useful source for regenerative therapies of periodontal diseases.

**Different Osteogenic Properties of Human Bone Marrow Stromal Cells from Different Skeletal Site Origin.** H. Park<sup>\*</sup>, J. Lee<sup>\*</sup>, D. Kwon<sup>\*</sup>, J. Kim<sup>\*</sup>, J. Cho. Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea.

There are reports regarding skeletal site-related differences, such as the affects on anatomic skeletal site-specific differences in autologous graft and skeletal site-related phenotypic and functional properties. Also, in recent proteomic analysis (our unpublished observation) some chondrogenic factors were up-regulated in the long bone origin hBMSCs (by the 3 day-treatment of BMP2) implicating their different bone formation process compared to that of flat bones. These evidences suggest that there are differences in bone metabolism dependent on their skeletal sites. In this study, we investigated skeletal site-related differences in human bone metabolism in multipotent mandible (orofacial) - and iliac crest (axial) - derived human bone marrow stromal cells (hBMSCs). First, we established hBMSCs selecting by single colonies among adherent cells exhibiting a typical fibroblast-like morphology. Isolated putative hBMSCs were shown individual colony-forming ability and mesenchymal lineage differentiation potential. Second, we investigated the gene expression pattern of osteogenic and chondrogenic-related representative transcription factors and marker genes along osteogenic differentiation of both human mandible- and iliac crest- derived BMSCs by means of Real-Time PCR analysis based on their different developmental bone formation process. In an osteogenic medium, the mRNA expression pattern of osteogenic- and chondrogenic-related genes revealed overall higher mRNA levels in mandible-derived hBMSCs (MandBMSCs) compared to those of iliac crest-derived hBMSCs (IliacBMSCs). Interestingly, the maximum of expression of runx2, osteonectin, osteopontin in IliacBMSCs were shown retarded pattern, three- or four-day intervals, compared to those in MandBMSCs. Type 11 collagen was maximally expressed on day 7 of differentiation in both MandBMSCs and IliacBMSCs with similar pattern. Aggrecan was expressed higher in MandBMSCs than in IliacBMSCs at the beginning of osteogenic differentiation, and was dramatically decreased on day 7. In IliacBMSCs, however, although expression level was low, it peaked twice in its expression; day 2 and day 7. These results indicate that MandBMSCs differentiate into osteoblast earlier than IliacBMSCs by expressing osteogenic markers earlier and probably not inducing the chondrogenic markers significantly in osteogenic stimulation.

**Thiazolidinediones Modify Nuclear Heterochromatin Architecture.** M. Moreau<sup>\*1</sup>, H. Libouban<sup>\*1</sup>, M. J. Y. Audran<sup>2</sup>, D. Chappard<sup>1</sup>. <sup>1</sup>Faculty of Medicine, INSERM U922, Angers, France, <sup>2</sup>Rheumatology, University Hospital, Angers, France.

Thiazolidinediones (TZDs) are an adjunctive therapy for diabetes mellitus. TZDs act by binding to PPAR $\gamma$  (peroxisome proliferator-activated receptors- $\gamma$ ). PPAR $\gamma$  is a key element for the differentiation of Mesenchymal stem cells (MSCs) into adipocytes when osterix and runx2 differentiate into osteoblasts. In vitro TZDs induce storage of cytoplasmic droplets lipids, but nuclear chromatin has been not very studied in this process. The murine Pluripotent Mesenchymal Cell line C3H10T1/2 was cultured in DMEM medium in presence of Pioglitazone (PGZ) [5 $\mu$ M] or rosiglitazone (RGZ) [0.5 $\mu$ M] during 5-6-7-8 days. Cells were fixed with 10% formaldehyde and stained with Oil red O. Nuclei were stained with Harris Hematoxyline. Cells cultured without TZDs (fig.A) and adipocytes with perceptible lipids droplets (fig.B), were photographed at x1000 magnification and pictures were standardized and analysed with the MAZDA texture analysis logiciel (Institute of Electronics, Lodz, Poland). The Nucleus area and Run length parameters have been calculated. N-area decrease suddenly at J5 for RGZ and J6 for PGZ. SRE-short run emphasis, expected to be large for fine texture, decrease. LRE-long run emphasis, expected to be large for coarse structure texture, increase at J7 for PGZ and RGZ with apparition of large dark run with compact texture. GLN-gray level nonuniformity measures the similarity of gray level values throughout the image, decrease with the decrease of clear run of euchromatin. RLN-run length nonuniformity measures the similarity of the length of the runs throughout the image, decrease with the decrease of clear run euchromatin and the increase of dark run heterochromatin (but less than the clear runs). RP-run percentage measures the homogeneity and the distribution of runs of an image in a specific direction, decrease.

Conclusion: TZDs modify the cellular metabolism when the C3H10T1/2 cells differentiate into adipocyte and probably induce inactivation of some genes who induce decrease of nucleus size and increase of chromatin condensation.

**Tracking Adipose Differentiation in Vitro with aP2-GFP Reporters and Flow Cytometry: Lipid Staining and Macrophage Mimicry.** J. R. Harrison<sup>1</sup>, M. S. Kronenberg<sup>\*2</sup>, D. W. Rowe<sup>2</sup>. <sup>1</sup>Craniofacial Sciences, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Reconstructive Sciences, University of Connecticut Health Center, Farmington, CT, USA.

Cell culture of whole bone marrow leads to the appearance of bone marrow stromal cells (BMSC), which can be induced to differentiate into osteoblasts, adipocytes, chondrocytes and myoblasts. In studies designed to simultaneously track osteoblast and adipose differentiation, we have used transgenic mice that express GFP under the control of the FABP4 (aP2) promoter. Cells of the adipose lineage selectively express this marker in vivo and in vitro. However, aP2 is also expressed in macrophages, leading us to more closely examine the identity of the presumptive adipocytes in BMSC cultures. Bone marrow was flushed from femurs and tibiae of mice carrying either aP2/GFP(topaz) or aP2/GFP(cyan) transgenes to establish BMSC cultures. After 10-11 days, cultures were

either left untreated or given an adipogenic treatment (ADP; 0.5  $\mu$ M rosiglitazone, 1  $\mu$ M insulin). Cultures were stained with LipidTOX, a fluorescent dye that selectively binds neutral lipids, scanned by fluorescence microscopy, and harvested for analysis on an LSRII flow cytometer after staining with fluorochrome-conjugated antibodies against the macrophage cell surface markers CD11b and F4/80.

Surprisingly, flow cytometry indicated that 50% or more of the cells in BMSC cultures were derived from the myeloid lineage, staining positive for CD11b and F4/80. Microscopy and flow cytometry both revealed expression of the GFP transgene within 48 h of ADP. Typically, 7-8% of the total cells were positive for GFP at 48 h, decreasing slightly to around 5% by day 7. Flow cytometry revealed that approximately half of all GFP-positive cells in BMSC cultures were positive for CD11b and F4/80, identifying them as macrophages. LipidTOX fluorescence, which lagged slightly behind transgene expression, was also equally distributed between macrophage and non-macrophage (adipocyte) compartments, and was closely associated with transgene expression. Thus, it was not possible to distinguish these cell types based on their ability to take up and store fat. Staining of terminal cultures with Oil Red O showed parallel results with the vital LipidTOX dye. A similar macrophage profile has been observed in cultures derived from the adipose stromal-vascular compartment.

These results indicate that macrophages are a significant component of BMSC cultures that persist, differentiate and accumulate fat following ADP treatment. Therefore, studies on adipogenesis in BMSC cultures using conventional fat staining techniques may be confounded by the presence of lipid-containing macrophages.

**SATB2 Overexpression Promotes Osteoblast Differentiation and Enhances Regeneration of Bone Defects.** E. Brewer<sup>\*</sup>, J. Zhang<sup>\*</sup>, Q. Tu, J. Tang<sup>\*</sup>, J. Chen. General Dentistry, Tufts University School of Dental Medicine, Boston, MA, USA.

SATB2, a gene expressed in branchial arches and in cells of osteoblast lineage, is identified as responsible for preventing craniofacial abnormalities and defects in osteoblast differentiation and function. In knockout experiments, mice lacking SATB2 were found to exhibit craniofacial abnormalities and defects in osteoblast differentiation and function. These knockout embryos displayed delayed bone formation and defects in extracellular matrix deposition, causing craniofacial abnormalities such as cleft palate. To investigate the role of SATB2 overexpression in enhancing bone regeneration, we transduced murine bone marrow stromal cells (BMSCs) isolated from 6-week-old BSP9.0Luc/ACTB-EGFP mice to achieve SATB2 overexpression in these cells. These mice were generated by cross-breeding a male ACTB-EGFP mouse with a homozygote mBSP9.0Luc female mouse. Luciferase expression is driven by BSP promoter, while GFP expression is driven by beta-actin promoter and cytomegalovirus enhancer. GFP staining was used to track the fate and migration of BMSCs, whereas luciferase staining served as a marker for osteogenic differentiation of the transplanted BMSCs. Cells transduced with empty vector served as controls. Real-time RT-PCR was performed to determine the expression levels of BSP, Osx, and Runx2. In addition, cell migration assays were performed to investigate the role of SATB2 in promoting engraftment of adult stem cells during wound regeneration. The SATB2 overexpressing BMSCs were implanted into the mandibular and femoral bone defects of 10-week-old B6D2F1 mice, a species from which mBSP9.0Luc mice are derived. In addition to histomorphometric analysis, the expressions of luciferase, GFP and BSP were determined using immunohistochemical staining, and real-time RT-PCR. SATB2 overexpression in BMSCs induced increased expression of bone matrix proteins and osteogenic transcription factors such as BSP, Osx, and Runx2 in these cells. Migration rate was also increased in SATB2 overexpressing BMSCs. These results are significant because cellular migration is a central process in development as well as tissue regeneration. Immunohistochemical staining and real-time RT-PCR analysis demonstrated that luciferase expression, which indicated transplanted BMSCs undergoing osteogenic differentiation, was higher in SATB2 overexpressing group compared to the control group. As a result, transplantation of SATB2 overexpressing BMSCs promotes bone tissue regeneration. These findings suggest that SATB2 may play an important role in the regeneration of tissues to a normal, pre-disease state.

**The Effect of Resveratrol and Flax Oil on MC3T3-L1 Pre-Adipocyte and ST2 Bone Marrow Stromal Stem Cell Proliferation and Differentiation.** O. J. Kelly, Y. Kim<sup>\*</sup>, P. Liu, H. Shin, C. C. Douglas<sup>\*</sup>, J. Ilich. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

Osteoporosis and obesity may be linked as both are caused by an imbalance in bone marrow stem cell metabolism. Resveratrol, a phytoestrogen found in grape skin, used primarily in cancer research for its anti-proliferative and anti-inflammatory properties may have applications in osteoporosis and obesity by regulating differentiation of stem cells into osteoblast or adipocyte lineage. Flax oil, a source of the essential n-3 fatty acid, alpha-linolenic acid, and lignans, also is employed in cancer research. The aim of this study is to investigate if resveratrol and/or flax oil have dual functions (anti-adipogenic and pro-osteoblastogenic) in the bone microenvironment. Experiments were carried out in standard tissue culture conditions (96 well plates) for a duration of 6 days; 48 hours after seeding, cells were dosed with resveratrol and/or flax oil and the media was changed every two days. ST2 cells were allowed to differentiate into osteoblasts using ascorbic acid and glycerophosphate. Cell numbers (proliferation) were assessed using the cell counting kit (Dojindo, Japan). Resveratrol treatment (96 hours) significantly (P<0.001) inhibited

MC3T3-L1 proliferation at 12.5, 25 and 50 microM, however, there was no significant difference between the concentrations tested. Flax seed oil at 10, 20, 40 and 80 microL/mL did not have any significant effect on the proliferation of MC3T3-L1 cells compared to control; however there was a tendency for high lignan flax oil to reduce proliferation. In ST2 cells, resveratrol (96 hours) at 25, 50 and 100 microM significantly ( $P<0.001$ ) inhibited cell proliferation with the higher doses having the greater effects. Flax oil, dissolved in ethanol (1microL/mL) as a vehicle, significantly increased ST2 cell proliferation at 5 ( $P<0.001$ ) and 10 microL/mL ( $P<0.05$ ) however ethanol alone, also increased proliferation of ST2 cells ( $P<0.001$ ). Neither resveratrol nor flax oil (including high lignan) had a significant effect on differentiating ST2 cells however, there was a propensity for resveratrol and flax seed oil combined to increase cell proliferation in differentiating ST2 cells. Results from this preliminary research suggest that resveratrol at low doses (12.5 microM) inhibits pre-adipocyte proliferation as well as the ST2 proliferation at higher concentrations ( $>25$  microM). Flax oil did not affect pre-adipocytes, but increased proliferation of ST2 cells; however the ethanol (flax vehicle) may be the driving force for this outcome. The effects of resveratrol and flax oil need to be examined in more detail to derive some practical applications.

**Distinct Modes of Osteoblastic Differentiation from Bone Marrow Stromal and Vascular Smooth Muscle Cells: Induction by BMP-2 and PKA and Suppression by Vitamin D Derivatives.** D. Inoue, R. Okazaki. Third Department of Internal Medicine, Teikyo University School of Medicine, Ichihara-shi, Chiba, Japan.

Epidemiological evidence has suggested a link between vascular calcification and osteopenia. Although vascular smooth muscle cells (VSMCs) have been shown to express osteoblastic phenotype under certain conditions, regulatory mechanisms of VSMC differentiation into osteoblast-like cells are not completely understood. In the present study, we attempted to establish an in vitro model of BMP-2 induced osteoblastic differentiation from VSMCs using a mouse VSMC cell line, p53LMAC01 (MACO), and to compare its mode of differentiation with that of a mouse bone marrow stromal cell line, ST-2. Treatment with BMP-2 induced ALP activity and mRNA expression within 3 days in MACO, although to a weaker extent than ST-2. Only 1hr treatment with BMP-2 was sufficient to induce ALP after 3 days in ST-2, while 24hr treatment was necessary for MACO to differentiate. In ST-2, Runx2, Msx2 and Osterix were constitutively expressed, and the expression was slightly up-regulated by BMP-2 after 24 hrs and maintained thereafter. In MACO, only Runx2 was induced by BMP-2 within 24 hrs, and Msx2 and Osterix was unchanged. As previously reported, forskolin slightly enhanced BMP-2 induced ALP in ST-2, and both basal and induced ALP activities were strongly suppressed by a PKA inhibitor, H89. In MACO, effect of H89 on the basal ALP activity was marginal, but forskolin induced ALP to a much larger extent, which was completely blocked by H89. These results indicate a critical role of PKA in osteoblastic differentiation and a lower basal activity of PKA in MACO compared to ST-2. We also found that calcitriol inhibited BMP-2-induced ALP in a dose-dependent manner with a significant effect from 0.3 nM in ST-2 but that this effect was a hundred times weaker in MACO even though VDR mRNA was expressed at a comparable level. 22-oxacalcitriol (OCT), a non-calcemic analogue of vitamin D, was 10 times more potent than calcitriol. The inhibitory effect vitamin D could not be explained by alterations in the expression level of Runx2, Msx2 or osterix. Interestingly, inhibitory effect of calcitriol on ALP induction required 24hr pretreatment before exposure to BMP-2, suggesting that transcriptional induction of an unknown factor is necessary. In summary, we have established an in vitro culture system of early osteoblastic differentiation of VSMCs and demonstrated a distinct mode of regulation from marrow stromal cells. Our results suggest that escape from the inhibitory effect of vitamin D contributes to pathological vascular calcification and further implicate a requirement of PKA-stimulating factors in addition to BMP-2.

**Osteogenic Cell Lineages Show Differential Responsiveness to Angiogenic Signals.** J. L. Fitch<sup>1</sup>, D. N. Kotton<sup>\*2</sup>, L. C. Gerstenfeld<sup>1</sup>, T. A. Einhorn<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Boston University School of Medicine, Boston, MA, USA, <sup>2</sup>Pulmonary Center, Boston University School of Medicine, Boston, MA, USA.

Both osteogenesis and angiogenesis are essential for skeletal development and bone repair. Previous studies have suggested that osteogenic cells express and respond to angiogenic signals, including VEGF. The expression of VEGF ligands and receptors, and cellular responses to VEGF(s) was assessed during osteogenic differentiation of primary murine marrow stromal cultures (MSC). Fluorescence-activated cell sorting (FACS) analysis of the cells present in control cultures at day 6 indicates that while there are hematopoietic (CD45+, CD31-) and mesenchymal (CD45-, CD31+) populations present in these cultures, there was an almost complete absence of cells of the endothelial (CD45-, CD31+) lineage. During osteogenic differentiation of MSCs, increased expression of the genes encoding VEGFs A and C was observed but expression of the genes encoding their receptors VEGFR1 (flt1), 2 (flt1) and 3 (flt4) decreased. Enhancement of osteogenic differentiation via addition of exogenous rhBMP2 or 7 did not result in significant increases in expression of either VEGF ligands or receptors. Addition of exogenous rhVEGFA-162, which is recognized by both VEGFRs 1 and 2 did not cause observable changes in expression of genes encoding matrix factors produced by differentiated osteogenic cells (bone sialoprotein (bsp) and osteocalcin (oc)). VEGFA-162 did, however, result in increased expression of factors indicative of angiogenic progression, including VEGFRs 2 and 3. Therefore, rhVEGFd, which is specific for VEGFR3 was

exogenously added to our MSC cultures. Treatment with VEGFd resulted in down-regulation of matrix factors osteopontin (opn) and bsp early in the time course of differentiation. At 21 days, however, the expression of opn, bsp and oc returned to levels observed in control (no treatment) cultures. These results suggest that osteogenic cells selectively respond to VEGFd through the VEGFR3. They also suggest that VEGFa has very little direct autocrine activity within osteogenic cells; rather, they are responsive to secondary paracrine signaling mediated by feedback from vascular or lymphatic endothelial cells which produce VEGFd. These data further suggest that the promotion of osteogenic differentiation *in vivo* occurs as a result of interactions with angiogenic cells through paracrine effects or as a consequence of increased oxygenation or nutrition resulting from angiogenesis.

**Induction of Runx2 and Osterix by Bisphosphonate Promote Osteogenic Differentiation.** N. Saoji<sup>\*1</sup>, S. Sittitavornwong<sup>\*1</sup>, N. Said-Al-Naiet<sup>\*1</sup>, H. Chen<sup>1</sup>, H. F. Thomas<sup>\*1</sup>, S. E. Gutierrez<sup>\*2</sup>, A. Javed<sup>1</sup>. <sup>1</sup>Oral & Maxillofacial Surgery, University of Alabama, School of Dentistry, Birmingham, AL, USA, <sup>2</sup>Biología Molecular, Universidad de Concepción, Concepción, Chile.

Bisphosphonate is widely used as an effective treatment to prevent bone loss associated with osteoporosis and bone metastasis. Bisphosphonate treatment however is linked with osteonecrosis of the jaws but its effects on the mesenchymal cells of the jaw and teeth remains unknown. To test this, we isolated Pulp and PDL tissue from non-infected, impacted third molars of healthy individuals. Primary mesenchymal cells from pulp and PDL were cultured in various concentrations of bisphosphonate to evaluate their viability, growth, and differentiation properties. Pulp cells exhibited a 10-fold increased sensitivity to oral forms of bisphosphonate and an early susceptibility to the IV form of bisphosphonate when compared to PDL cells. Proliferation of both PDL and pulp cells was inhibited by bisphosphonate. When cultured in osteogenic media, PDL and pulp cells differentiated to osteoblast with a progressive increase in ALP activity, matrix synthesis and mineral deposition. Surprisingly, bisphosphonate treatment resulted in enhanced osteoblast differentiation of PDL and pulp cells. For a molecular understanding of how bisphosphonate stimulated osteoblast differentiation, we analyzed profile of gene expression. At earlier time points, expression of Runx2 and Osterix, the two essential regulators of osteoblast differentiation was increased two fold. This coincided with an increased expression of ALP, osteopontin, and osteocalcin. Immunofluorescence studies demonstrated that bisphosphonate treatment enhances nuclear accumulation of Runx2 but did not alter its association with splicing factor SC35. These results provide evidence that in tooth derived mesenchymal cells, bisphosphonate target Runx2 to activate program of osteoblast differentiation.

**R-spondin 2 Is a Novel Osteogenic Factor Required for Wnt11 Mediated Osteoblast Differentiation.** M. S. Friedman<sup>\*1</sup>, S. M. Owersman<sup>\*1</sup>, W. Luo<sup>\*2</sup>, K. D. Hankenson<sup>3</sup>. <sup>1</sup>Thermogenesis Corporation, Rancho Cordova, CA, USA, <sup>2</sup>University of Michigan, Ann Arbor, MI, USA, <sup>3</sup>Animal Biology, University of Pennsylvania, Philadelphia, PA, USA.

The four members of the R-spondin family share structural features including two conserved cysteine rich domains and a thrombospondin type I repeat. R-spondins interact with Frizzled and LRP family members and enhance Wnt signaling. We previously reported that Wnt11 increases osteoblast differentiation and activates Rspo2 expression in MC3T3 E1.14 pre-osteoblasts. We hypothesized that Rspo2 may be involved in Wnt11-induced osteoblast differentiation. Rspo2 was retrovirally overexpressed in MC3T3 E1.14 pre-osteoblasts. We observed that Rspo2 potentially synergized BMP-induced alkaline phosphatase expression and matrix mineralization (Alizarin red S). We examined osteoblast-specific gene expression in Rspo2 overexpressing cells relative to Wnt11 overexpressing and GFP control cells, with and without BMP treatment. BMP-treated Rspo2 cells show statistically significant higher levels of osterix, Bsp, Dmp1, and Phex expression relative to BMP treated Wnt11 and GFP control cells. To evaluate if Rspo2-mediated gene expression was dependent on Tcf/beta-catenin signaling, we retrovirally overexpressed dominant/negative Tcf4 in Rspo2 overexpressing cells. dnTcf4 expression in Rspo2 cells significantly decreases osterix expression to levels comparable to GFP control cells. Phex expression is also decreased in Rspo2-dnTcf4 cells relative to Rspo2 cells, but remains higher than Wnt11 overexpressing cells. To determine if Rspo2 expression was necessary for Wnt11-enhanced osteoblast differentiation, we used retroviral-based micro RNAi to knock-down expression of Rspo2. GFP cells were infected with a control LacZ miRNAi retrovirus, while Wnt11 cells were infected with either a LacZ control miRNAi retrovirus or the Rspo2 miRNAi retrovirus. Knock-down of Rspo2 expression in Wnt11 cells decreases Wnt11-enhanced alkaline phosphatase induction to near control levels. Importantly, knock-down of Rspo2 expression resulted in a nearly complete blockade of mineralization. We also evaluated levels of osteoblast associated gene expression in Wnt11 expressing/Rspo2 knockdown cells. By quantitative PCR, Rspo2 expression in knock-down cells was reduced by 99% relative to the Wnt11-LacZ miRNA control cells. Knockdown of Rspo2 in untreated Wnt11 cells significantly decreased expression of Otoraplin/Cdrap, Bsp, and Phex. BMP treated Wnt11-Rspo2 knockdown cells also demonstrate significantly reduced expression of BSP and Phex. We conclude that Rspo2 expression is both necessary and sufficient to mediate the effects of Wnt11-enhanced osteoblast differentiation.

**Dock5 an Essential Rac Exchange Factor in Osteoclasts that Controls Adhesion Structure Organization and Bone Resorbing Activity.** A. Blangy<sup>1</sup>, H. Brazier<sup>\*1</sup>, V. Vives<sup>\*1</sup>, J. Toubol<sup>\*1</sup>, G. Pawlak<sup>\*2</sup>, M. Laurin<sup>\*3</sup>, J. F. Cote<sup>\*3</sup>.

<sup>1</sup>RhoGTPases in osteoclast biology, CNRS UMR5237, Montpellier, France, <sup>2</sup>CRI U823/UJF, Grenoble, France, <sup>3</sup>Clinical Research Institute of Montreal, Montréal, QC, Canada.

RhoGTPase signaling pathways have essential functions in osteoclast biology. Dock5 belongs to the Dock/CZH family of exchange factors, a group of proteins that activate RhoGTPases. It is the closest homolog to Dock180. We reported previously that the expression of Dock5 increased during RANKL-induced osteoclast differentiation and that its suppression was not compatible with cell survival during osteoclastogenesis (Brazier et al, JBMR, 2006, 21(9), 1387). We further studied Dock5 to identify its functions in osteoclasts.

We showed by quantitative reverse PCR that Dock5 mRNA was predominantly expressed in osteoclasts and to a lesser extent in placenta. Its level of expression was very low in all other mouse tissues tested including mammary gland and total bone marrow. By GTP-trapping assays, we also showed that Dock5 was an activator of Rac. As its closest homolog Dock180, Dock5 guanine nucleotide exchange activity was inhibited by its amino-terminal SH3 domain and could be activated through its binding to the adaptor protein Elmo.

In osteoclasts, we found that endogenous and overexpressed Dock5 localized to adhesion structures: the podosome belt and the sealing zone. Using small interfering RNAs, we performed a partial silencing of Dock5, reducing the protein levels by 70%. This was compatible with osteoclast survival and differentiation and it did not affect the fusion index. Interestingly, Dock5 deficient osteoclasts presented very few podosomes and they were unable to assemble a podosome belt. When plated on mineralized substrates, the osteoclasts failed to contract and to organize a sealing zone. Consequently, reduction of Dock5 expression in osteoclasts impaired mineralized matrix resorption. Lower Dock5 expression also resulted in strong reduction of the level of active Rac in osteoclasts. The influence of Dock5 on mouse bone density in vivo is under investigation. Dock5 expression was deleted and micro-computed tomography analyses of the mice will be discussed.

These observations suggest that Dock5 is a major activator of Rac in osteoclasts and that the exchange factor plays an essential role for adhesion structure organization and then mineralized matrix resorption. As a Rac activator predominantly expressed in osteoclasts, Dock5 represents an interesting new candidate for antiresorptive therapy.

**Identification of the Regulatory Mechanism(s) of Protein Tyrosine Phosphatase (PTP-PEST) Associating with the Sealing Ring Formation and Bone Resorption in Osteoclasts.** M. A. Chellaiiah<sup>1</sup>, M. D. Schaller<sup>\*2</sup>.

<sup>1</sup>Department of Biomedical Sciences, Dental School, University of Maryland, Baltimore, MD, USA, <sup>2</sup>Department of Cell & Developmental Biology, University of North Carolina, North Carolina, NC, USA.

Sealing ring formation is a prerequisite for efficient bone resorption by osteoclasts. Although the role of WASP, Src, and the phosphatase PTP-PEST in actin-rich sealing ring formation has been identified, the potential regulatory mechanism(s) mediated by PTP-PEST is poorly understood. In order to determine the role of PTP-PEST in sealing ring formation, osteoclasts (OCs) were transfected with PTP-PEST, constitutively active-Src (CA-Src mutated at Y527F), and dominant negative-Src (DN-Src mutated at K297R and Y527F) constructs by adenoviral delivery. Some cultures transfected as above were either treated with a phosphatase inhibitor, phenyl arsine oxide (PAO) or bisphosphonates (BPs; alendronate or pamidronate). Untreated but transfected as well as untransfected OCs were used as controls. We observed an increase in the phosphorylation of cortactin at Y421, WASP at Y294 (Y294, corresponding to Y291 in human) and Src at Y418 in OCs transfected with PTP-PEST and CA-Src as compared with control untransfected and DN-Src transfected OCs. Additionally, a decrease in the phosphorylation of Src at Y527 was observed in OCs expressing PTP-PEST. Colocalization of c-Src/WASP, c-Src/cortactin, WASP/cortactin, c-Src/PTP-PEST, and WASP/PTP-PEST was observed in the sealing ring of OCs expressing CA-Src and PTP-PEST constructs. However, these cells failed to display colocalization of cortactin/PTP-PEST in the sealing ring. An increase in the number of OCs displaying sealing ring was observed. This corresponded well with the increase in bone resorption activity of these OCs. OCs treated with BPs and PAO inhibited the processes listed above, although at various levels, in OCs expressing PTP-PEST construct. BPs have been shown to inhibit phosphatases that modulate dephosphorylation of Src at Y527. Inhibition of PTP-PEST activity by BPs reduces the dephosphorylation state of c-Src at Y527 and activity of c-Src as well. Consequently, this may have caused a decrease in the phosphorylation state of cortactin and WASP, formation of ternary complex (WASP•cortactin•Arp2/3 complex), sealing ring formation, and bone resorption. We suggest that BPs affect the function of OCs via inhibiting downstream signaling pathways mediated by PTP-PEST and c-Src. PAO and BPs did not reduce the above-mentioned processes in OCs expressing CA-Src construct because of the mutation at Y527F. Taken together, our observations indeed have demonstrated that PTP-PEST has a regulatory role in the dephosphorylation of c-Src at Y527 and activates it.

## SU066

**TRIP6 Regulates Osteoclast Formation, Adhesion, and Resorptive Capacity.** B. K. McMichael, B. S. Lee. Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA.

Members of the LIM domain-containing zyxin family of proteins shuttle between the nucleus, where they are involved in transcriptional regulation, and the cytoplasm, where they localize to focal adhesions. TRIP6 (Thyroid Hormone Receptor-interacting Protein 6), like other members of the zyxin family, contains transcriptional transactivation domains and LIM domains. In the nucleus of non-bone cells, TRIP6 has been shown to activate AP1 sites, coactivate transcription with v-Rel, and be involved in activation of NFκB and ERK pathways. In fibroblasts, it was shown that Src phosphorylation of TRIP6 in the cytoplasm enhances migration. Because NFκB and Src signaling pathways play vital roles in osteoclast formation and function, we have begun to examine how TRIP6 activity may affect osteoclast motility and resorptive capacity.

A role for TRIP6 in osteoclast function was first indicated by its direct binding to tropomyosin-4, an actin-binding protein that we previously showed to play a role in regulating osteoclast adhesion complexes (i.e. podosomes and the sealing zone). Immunocytochemistry of osteoclasts on glass and bone demonstrated TRIP6 to reside primarily in the nuclei, but with some presence in podosomes and the sealing zone. Suppression of TRIP6 by RNA interference resulted in increased cell fusion of both RAW264.7 and marrow-derived precursors. When plated on glass, TRIP6-suppressed cells also demonstrated increased spreading and enhanced podosome numbers at the cell periphery. On bone, these cells exhibited increased spreading, and altered sealing zone dimensions, pit formation, and overall resorptive capacity.

Stable overexpression of wild-type TRIP6 in cells on bone led to altered sealing zone dimensions while causing a dramatic increase in total resorption. To define the role of Src-mediated phosphorylation of TRIP6 in osteoclasts, either wild-type TRIP6 or TRIP6 mutated at Tyr-55 were transiently expressed in mature osteoclasts. Inhibition of Src-mediated TRIP6 phosphorylation by a Tyr-Phe substitution in cells on bone enhanced nuclear localization of TRIP6, and suppressed sealing zone formation and resorptive capacity. In contrast, the phosphomimetic Tyr-Glu substitution resulted in increased formation of sealing zones and actin patches, and enhanced resorption. These data suggest TRIP6 regulates osteoclast fusion and function in part through a Src-dependent pathway to regulate sealing zone formation, and thus resorption.

## SU067

**The Role of Alpha Gene Tropomyosins in Osteoclast Function.** P. Kotadiya<sup>\*</sup>, B. S. Lee. Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA.

Tropomyosins (Tms) are actin-binding proteins that stabilize microfilaments and inhibit or recruit binding of other actin-associated proteins. In nonmuscle cells, over twenty alternately spliced isoforms are expressed from four distinct genes, namely the alpha, beta, gamma, and delta genes. Recent studies have indicated that individual Tm isoforms are distributed to different intracellular locations where they regulate specific actin pools. The goal of this work is to determine the roles of alpha gene tropomyosin isoforms in mature osteoclast activity.

Four alpha gene, non-muscle Tms are expressed in osteoclasts, namely Tm-2, -3, -5a, and -5b. Tm-2 and -3 are closely related high molecular weight tropomyosins that differ from the low molecular weight Tm-5a and -5b only by alternately spliced exons that encode the amino termini. However, this difference of 80 amino acid residues mediates markedly different patterns of expression, subcellular distribution, and function for these Tms. The high molecular weight Tm-2/3 are not expressed in the monocytic lineage precursors of osteoclasts, but are strongly upregulated late in osteoclastogenesis. In contrast, low molecular weight Tms are present in monocytic precursors and are modestly upregulated early during osteoclast formation. Further, Tm-5a/b are strongly enriched in adhesion complexes of osteoclasts, while Tm-2/3 are distributed internally throughout the cells, and are not strongly associated with these actin-rich adhesion structures. RNAi-mediated suppression of Tm-2/3 causes increased spreading and flattening of the cells, while overexpression causes decreased spreading and induction of actin patches or stress-fiber like actin filaments. These results demonstrate that Tm-2/3 are expressed in fusing osteoclasts to regulate the cytoskeletal scaffolding of these large multinucleated cells. In contrast, suppression of Tm-5a/b causes clustering and thickening of adhesion complexes when cells are plated on glass, and a thinning of the complexes when cells are plated on bone, demonstrating the role of these Tms in regulation of cell adhesion. Therefore, the alternately spliced exons that form the N-termini and upstream sequences in the alpha gene mediate differential patterns of expression, subcellular location, and function in osteoclasts.

**Formation of Podosome Belts by Osteoclasts on Plastic Correlates with Resorptive Activity.** J. L. Ross\*, K. Fuller, T. J. Chambers. Department of Histopathology, St George's Hospital Medical School, London, United Kingdom.

Resorption of bone by osteoclasts is accompanied by the formation of characteristic actin rings in the bone-apposed pole of the cell. It is considered that these actin rings reflect the formation of peripheral sealing zones of close adhesion to the bone surface, within the confines of which the cell secretes protons and hydrolytic enzymes. It seems likely that in vivo, osteoclasts undertake resorptive activity (secretion of protons and hydrolytic enzymes) only on bone surfaces. The characteristics of the bone surface that induce resorptive activity in osteoclasts are unknown.

When osteoclasts are incubated on plastic or glass substrates they can form belts of podosomes that resemble the actin rings formed by osteoclasts during bone resorption. However, the relationship between podosome belts and actin rings is controversial. We therefore decided to analyse this relationship by comparing makers of resorptive behaviour in osteoclasts expressing actin rings and podosome belts.

We have previously found that secretion of tartrate-resistant acid phosphatase (TRAP) by osteoclasts on bone correlates with bone resorption. Therefore, we tested the correlation between podosome belts, actin rings and TRAP release by osteoclasts on plastic and bone. To do this, osteoclasts were generated in vitro from non-adherent murine bone marrow cells by incubation in RANKL and M-CSF for 5 days. The osteoclasts were then lifted into suspension and sedimented onto slices of devitalized bovine bone, or onto plastic coverslips previously coated with vitronectin, collagen or fibronectin.

Both vitronectin and collagen stimulated TRAP release from osteoclasts on plastic. TRAP release was up to ten times greater on vitronectin-coated than uncoated plastic, and was over three times greater than on bone. TRAP release on collagen was biphasic, rising to twice the level induced by bone before falling at higher collagen densities. The proportion of osteoclasts exhibiting podosome belts on plastic correlated with TRAP release for both vitronectin- and collagen-coated plastic. In contrast, osteoclasts on coverslips coated with fibronectin neither released TRAP nor formed podosome belts.

These results suggest that vitronectin- and collagen-coating of plastic induces resorptive behavior in osteoclasts, and that, despite the difference in appearance, podosome belts, like actin rings, signify actively resorbing cells.

**The Extracellular Matrix Protein Fibronectin Positively Regulates the Osteoclast Function.** A. Gramoun\*, D. P. Trebec<sup>2</sup>, N. Azizi\*, J. Sodek\*, M. F. Manolson<sup>1</sup>. <sup>1</sup>Dentistry, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Department of Biochemistry, University of Toronto, Toronto, ON, Canada.

The extracellular matrix (ECM) proteins and their fragments play critical and controversial roles in connective tissue homeostasis. Osteoclasts (OCs), the bone resorbing multinucleated cells, are formed by fusion of mononuclear precursors. The ECM proteins, vitronectin (VN), fibronectin (FN) and osteopontin (OPN), all implicated in arthritis, interact with OCs through the surface receptors known as integrins. To determine the effects of VN, FN and OPN on OC formation and resorptive activity RAW 264.7 cells were plated and differentiated (using 100 ng/ml RANKL) on dishes or Osteologic™ slides precoated with 0.01-20 µg/ml FN, VN, and OPN; concentrations shown not to affect cell proliferation. After 96 hours of differentiation, dose response experiments showed that OC number on VN and FN remained significantly lower than those on OPN and the uncoated controls. Furthermore, the number of mononuclear TRAP+ cells (preOCs) at 48 hours and large OCs (> 10 nuclei) at 96 hours showed that while FN did not affect preOC number, it significantly decreased OC multinucleation compared to the uncoated control. OPN conversely had the opposite effect. When 20 µg/ml of FN was added to cultures plated on OPN on day 0 or on day 2 of differentiation, OC number was reduced by 40% indicating that FN was able to inhibit OPN's stimulatory effect on OC formation by preventing preOC fusion. Resorption studies revealed that both FN and OPN increased the total area of resorption and resorptive activity/OC by 40% compared to VN and the uncoated control groups. Further, FN increased the released TRAP5b/OC in cultures. Sealing zone formation (assessed by counting the number of actin rings) was 70% higher on FN than on any of the other experimental groups. Nitric oxide (NO) levels (as measured by Griess reagent) were significantly elevated by FN but not in any of the other groups. This increase in NO levels was associated with an increase in interleukin 1β (IL1β). IL1β levels were reduced in the presence of the NO-synthase inhibitor L-N<sup>G</sup>-monomethyl Arginine in a dose dependant manner. Functionally blocking the OC attachment formed on FN using anti-αvβ3 antibody did not interfere with their attachment. While the anti-α5β1 antibody significantly inhibited OC adhesion to FN. In conclusion, despite its inhibitory effect on preOC fusion and OC formation, FN significantly enhanced resorption/OC and due to an increase of the activity of the formed OCs. FN's induction of NO and IL1β, could both explain the increased OC activity. This study has identified a new role for FN as a key player in the regulation of bone metabolism and a positive modulator of OC activity.

**1,25-dihydroxyvitamin D<sub>3</sub> Can Directly Induce Osteoclast Formation in Osteoclast Precursors in the Absence of RANKL.** N. Kurihara<sup>1</sup>, Y. Hiruma<sup>1</sup>, J. A. Lorenzo<sup>2</sup>, G. D. Roodman<sup>3</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Medicine/Endocrinology, University of Connecticut, Farmington, CT, USA, <sup>3</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

1,25-(OH)<sub>2</sub>D<sub>3</sub> can induce osteoclast (OCL) formation indirectly by increasing the expression of RANKL and decreasing the expression of osteoprotegerin (OPG) in marrow stromal cells and osteoblasts. Consistent with this observation, RANKL or RANK receptor knockout mice are profoundly osteopetrotic. This result could reflect that 1,25-(OH)<sub>2</sub>D<sub>3</sub> exclusively induces OCL formation via RANKL or that normal OCL precursors, which express VDR, can only directly form OCL in response to supra-physiologic levels of 1,25-(OH)<sub>2</sub>D<sub>3</sub> (10<sup>-9</sup> to 10<sup>-8</sup>M), which are used in vitro but are not produced in vivo. To test this hypothesis, normal human marrow cultures were treated with 10<sup>-11</sup> to 10<sup>-7</sup>M 1,25-(OH)<sub>2</sub>D<sub>3</sub> or 50 ng/ml RANKL and with or without 50 ng/ml OPG. OPG completely inhibited OCL formation induced by RANKL. OPG also inhibited OCL formation induced by (10<sup>-8</sup>M) 1,25-(OH)<sub>2</sub>D<sub>3</sub> by approximately 40% in normal marrow cultures. Normal marrow cultures only formed OCL in the presence of high levels (10<sup>-9</sup> to 10<sup>-8</sup>M) of 1,25-(OH)<sub>2</sub>D<sub>3</sub>. The OCL that formed with 1,25-(OH)<sub>2</sub>D<sub>3</sub> in the absence of RANKL, resorbed dentine. RANKL levels were 177±5 pg/ml in normal marrow cultures treated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> (10<sup>-8</sup>M). In contrast, OPG did not inhibit OCL formation in cultures of highly purified early human OCL precursors (CFU-GM) treated with 10<sup>-11</sup> to 10<sup>-7</sup>M 1,25-(OH)<sub>2</sub>D<sub>3</sub>, but totally blocked the effects of RANKL on these cells. RANKL was undetectable in cultures of highly purified human OCL precursors treated with 10<sup>-8</sup>M 1,25-(OH)<sub>2</sub>D<sub>3</sub>, consistent with the absence of stromal cells in these cultures. Importantly, CFU-GM derived from RANK<sup>-/-</sup> or wild type (WT) mouse spleen cells formed OCL when treated with 10<sup>-8</sup>M 1,25-(OH)<sub>2</sub>D<sub>3</sub>, but only WT CFU-GM formed OCL in the presence of 50 ng/ml RANKL plus 30 ng/ml M-CSF. OCL formation by RANK<sup>-/-</sup> cells was significantly decreased compared to WT cells, but the OCL that formed resorbed dentine. These results demonstrate that supra-physiologic concentrations of 1,25-(OH)<sub>2</sub>D<sub>3</sub> stimulate OCL formation by both direct (RANKL-independent) and indirect (RANKL-dependent) mechanisms.

**Modulation of Osteoclastogenesis by Fatty Acids.** G. A. Williams\*, J. Lin\*, A. McGibbon\*, M. Watson\*, K. E. Callon\*, J. E. Dunford\*, A. B. Grey\*, D. Naoi\*, J. Cornish\*, I. R. Reid<sup>1</sup>. <sup>1</sup>Medicine, University of Auckland, Auckland, New Zealand, <sup>2</sup>Fonterra Research Centre, Palmerston North, New Zealand, <sup>3</sup>Botnar Research Centre, University of Oxford, Oxford, United Kingdom.

Clinical studies have shown that total body fat mass is related to both bone density and fracture risk, and that fat ingestion reduces bone turnover. These effects are at least partially mediated by endocrine mechanisms, but it is also possible that lipids might act directly on bone. Because milk is a rich source of lipids in mammals, we initially assessed the effects of broad fractions of milk lipids in primary cultures of osteoblasts, bone marrow and neonatal mouse calvariae. Inhibition of osteoclastogenesis in murine bone marrow cultures was apparent with several milk fractions and their hydrolysates, so we proceeded to assess the effects of free fatty acids in this model. Saturated fatty acids (0.1-10 µg/mL) inhibited osteoclastogenesis in bone marrow cultures. This effect was maximal for C14:0 (28% inhibition, p<0.01), C16:0 (50% inhibition, p<0.05) and C18:0 (29% inhibition, p<0.01) at 10µg/mL. Similar effects were observed in RAW 264 cells, suggesting that the fatty acids act directly on osteoclast precursors to inhibit differentiation. The introduction of >1 double bond abrogated this effect, and even led to its reversal. ω3 and ω6 fatty acids had comparable low activity. Osteoblast proliferation was modestly increased (29% and 24% for C16:0 and C18:0 respectively, at 1µg/ml (P<0.01), ruling out a non-specific toxic effect. Fatty acids that inhibited osteoclastogenesis did not change expression of RANKL or osteoprotegerin in osteoblastic cells nor did they affect the activity of key enzymes in the mevalonate pathway. However, members of a family of G protein coupled receptors known to bind medium and long-chain fatty acids were found to be expressed in osteoblastic (GPR120) and osteoclastic (GPR40, 41, 43, 120) cells. These findings suggest a novel link between lipid and bone metabolism which might contribute to the positive relationship between adiposity and bone density, as well as providing novel targets for pharmaceutical and nutraceutical development.

**Carboxyl-terminal Parathyroid Hormone (CPTH); Prediction of Novel Functions, Structural Features and Potential Receptor.** A. A. Selim<sup>\*1</sup>, R. Bringhurst<sup>2</sup>. <sup>1</sup>Biomedical Technology Research Group, KFUPM, Dhahran, Saudi Arabia, <sup>2</sup>Harvard Medical School, Endocrine Unit, MGH, Boston, MA, USA.

**Background:** Parathyroid hormone (PTH) is the major physiological regulator of blood calcium and phosphate, and it exerts potent effects upon cells in bone, cartilage, and kidney. The PTH1 receptor (PTH1R) recognizes the highly conserved amino (NH2)-terminal domain of PTH (and the homologous NH2 terminus of PTHrP) and thus is fully activated by both PTH-(1-34) and the intact hormone, PTH-(1-84). Carboxyl (C) fragments of intact PTH-(1-84), such as PTH-(39-84) or PTH-(53-84), do not bind or activate the PTH1R. A possible physiological role for this region of the hormone is suggested by observations that the amino acid sequence of the COOH-terminal domain is highly homologous across species. Furthermore, direct physical evidence of a putative receptor, i.e., a carboxyl-terminal PTH receptor (CPTHR) with binding specificity for COOH-terminal PTH sequences, was obtained by cross-linking of 125I-[Tyr34]-hPTH-(19-84) (which does not bind to the PTH1R) to 40-kDa and 90-kDa proteins in the ROS 17/2.8 rat osteosarcoma cell line.

**Objectives:**

To characterize CPTH functional and structural features using bioinformatic analytical tools. The premise is that such characterization would allow for future experimental examinations on the pathophysiology of diseases involving significant changes in CPTH expression levels or mode of function.

**Methods:** Several bioinformatic tools were utilized including Pfam, ELM, ProFun, PFP, Consensus Secondary Structure Prediction server and I-TASSER.

**Results:**

1- ELM predicted N-Arg dibasic convertase cleavage site at position 40-42, Casien Kinase II (CK2) phosphorylation site (71-74), Protein kinase C phosphorylation site (53-55).

2- Function prediction analysis suggested that CPTH may play a role in the following biological processes; cell proliferation (growth factor), cAMP metabolism, cell-cell signaling, calcium ion homeostasis, GTPase activity and GTP binding.

3-Secondary and Tertiary structure predictions suggested that CPTH has two helical domains on its termini at positions (23-35) and (74-83) as well as coils and sheets regions in the middle (36-73).

**Conclusions:** CPTH bioinformatic analysis data provide useful resources for researchers to understand and manipulate CPTH functions and to predict potential CPTH receptor(s).

## SU073

**Relationship between Serum Levels of Inflammatory Cytokines and Bone Turnover Markers in the Year Following Hip Fracture.** J. A. Chan<sup>\*1</sup>, R. R. Miller<sup>\*1</sup>, J. A. Yu-Yahiro<sup>2</sup>, W. G. Hawkes<sup>\*1</sup>, J. R. Hebel<sup>\*1</sup>, M. D. Shardell<sup>\*1</sup>, G. E. Hicks<sup>\*1</sup>, M. C. Hochberg<sup>1</sup>, E. A. Streeten<sup>1</sup>, J. Magaziner<sup>1</sup>, D. Orwig<sup>1</sup>. <sup>1</sup>Epidemiology and Preventive Medicine, University of Maryland Baltimore, Baltimore, MD, USA, <sup>2</sup>Department of Orthopaedics, Union Memorial Hospital, Baltimore, MD, USA.

The purpose of this study was to examine the relationship between serum levels of inflammatory cytokines and markers of bone turnover in the year following hip fracture. Women who sustain a hip fracture have increased rates of bone loss (decline in BMD) as well as continually elevated serum levels of inflammatory cytokines up to one year post-fracture. Several proinflammatory cytokines have been associated with bone remodeling; however with inconsistent results. Furthermore, little is known about a potential relationship after hip fracture.

The Baltimore Hip Studies (BHS4) cohort was a randomized clinical trial in which participants were assigned to either a home-based exercise program or standard of care group. Women age 65 years and older (mean 82 years  $\pm$  6.8) were enrolled within 15 days after fracture (n=180).

Serum samples were analyzed for sTNF- $\alpha$ R1, IL-6, bone alkaline phosphatase (BAP), C-terminal telopeptide of type I collagen (CTX), and C-terminal propeptides of type I procollagen (CICP) at baseline and 2-, 6-, and 12-months after fracture. Generalized estimating equations were used to model the association of sTNF- $\alpha$ R1 and IL-6 levels with markers of bone turnover over time adjusting for age, BMI, type of fracture and intervention group.

The analysis included 88, 95, 107, and 91 participants at baseline, 2-, 6-, and 12-months after fracture respectively. Higher levels of sTNF- $\alpha$ R1 were associated with higher levels of CTX during the year after fracture (p<0.0001). For each ng/ml increase in sTNF- $\alpha$ R1, CTX was 0.16 (95% CI: 0.10, 0.22), 0.14 (95% CI: 0.05, 0.22), 0.12 (95% CI: 0.04, 0.20), and 0.09 (95% CI: 0.02, 0.16) ng/ml higher at baseline, 2-, 6-, and 12-months. Serum IL-6 levels were also positively associated with CTX levels during the year post-fracture (p<0.0001). There was no evidence of association between sTNF- $\alpha$ R1 and IL-6 with either BAP or CICP (p>0.10).

These data demonstrate that serum levels of sTNF- $\alpha$ R1 and IL-6 are positively associated with increased bone turnover. The results suggest that inflammation leads to increased bone resorption, contributing to the excess decline in bone mineral density in the year following hip fracture.

Mean difference in CTX (ng/ml) per ng/ml of sTNF- $\alpha$ R1 and per 10 pg/ml of IL-6 (higher vs lower)

	sTNF- $\alpha$ R1 (ng/ml) CTX ng/ml (95% CI)	P-value	IL-6 (10 pg/ml) CTX ng/ml (95% CI)	P-value
<b>Baseline</b>	0.16 (0.10, 0.22)	<.0001	0.03 (0.005, 0.06)	0.0222
<b>2 month</b>	0.14 (0.05, 0.22)	0.0028	0.03 (-0.02, 0.07)	0.19
<b>6 month</b>	0.12 (0.04, 0.20)	0.0043	0.01 (-0.04, 0.07)	0.66
<b>12 month</b>	0.09 (0.02, 0.16)	0.0073	0.07 (0.05, 0.09)	<.0001

**The Tyrosine Kinase Inhibitor Dasatinib Decreases Osteoclast Formation and Activity *in vitro*.** K. Vandyke<sup>\*</sup>, A. L. Dewar<sup>\*</sup>, A. N. Davis<sup>\*</sup>, S. Fitter<sup>\*</sup>, T. P. Hughes<sup>\*</sup>, L. B. To<sup>\*</sup>, A. C. W. Zannettino<sup>\*</sup>. Division of Haematology, The Hanson Institute, The Institute of Medical and Veterinary Science, Adelaide, Australia.

We have previously shown that the tyrosine kinase inhibitor imatinib mesylate potently inhibits osteoclast formation and activity due, in part, to its specificity for the macrophage colony stimulating factor (M-CSF) receptor, c-fms. We have also shown that imatinib therapy is associated with altered bone remodelling and an increase in trabecular bone volume in chronic myeloid leukaemia patients. In the present study, we examined whether a second-generation tyrosine kinase inhibitor, dasatinib, could similarly inhibit c-fms activation and osteoclastogenesis. Initially, we assessed whether dasatinib could affect c-fms phosphorylation in human peripheral blood CD14<sup>+</sup> mononuclear cells (PBMNC) and mouse bone marrow monocytes (mBM) using Western blotting. We next examined the effects of dasatinib treatment on cell proliferation/survival in M-CSF-dependent (FDC-fms and mBM) and -independent (RAW-264.7) cells. Additionally, we investigated if dasatinib affected osteoclast formation and activity in PBMNC, mBM and RAW-264.7 cells.

Our studies show that dasatinib inhibits the activation of c-fms by M-CSF at pharmacologically-relevant concentrations (5 nM) in PBMNC and mBM. Furthermore, dasatinib treatment dose-dependently decreased cell numbers in FDC-fms (IC<sub>50</sub> = 57.8 nM) and mBM (IC<sub>50</sub> = 5.0 nM) cultured with M-CSF. In contrast, cell numbers were not significantly altered by dasatinib-treatment in M-CSF-independent RAW-264.7 cells (p = 0.4894) or in FDC-fms cells cultured in IL-3 (p = 0.2008). In PBMNC and mBM cultures stimulated with RANKL and M-CSF, the number of TRAP-positive, multinucleated osteoclasts was significantly reduced in the presence of 20 nM dasatinib in PBMNC (p < 0.001; IC<sub>50</sub> = 10.5) and 10 nM dasatinib in mBM (p < 0.01; IC<sub>50</sub> = 8.0 nM), relative to vehicle controls. In addition, there was a dose-dependent decrease in bone resorption by osteoclasts at 2.5 nM dasatinib and higher (p < 0.05; IC<sub>50</sub> = 2.4 nM [PBMNC] and 3.5 nM [mBM]). In RAW-264.7 cells cultured with RANKL alone, osteoclast numbers were significantly decreased at 20 nM dasatinib and higher (p < 0.05) relative to vehicle.

These studies show for the first time that dasatinib treatment is associated with a decrease

in osteoclast formation and activity in both human and murine systems *in vitro*. This decrease can partly be attributed to an inhibition of signal transduction through c-fms. These data suggest that decreased bone resorption may be a potential side-effect of dasatinib therapy and these *in vitro* findings warrant further investigation *in vivo*.

## SU075

**Angiogenic Potential of Osteoclasts.** F. C. Cackowski<sup>\*1</sup>, R. J. Choksi<sup>\*1</sup>, J. J. Windle<sup>\*2</sup>, D. Roodman<sup>3</sup>. <sup>1</sup>Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, <sup>3</sup>Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

It is our hypothesis that in diseases associated with increased osteoclast (OCL) activity, OCL secrete, or release from matrix, factors that stimulate angiogenesis either directly or by induction of angiogenic factor secretion by other cell types. Further, agents such as bisphosphonates may in part suppress angiogenesis through their effects on osteoclast activity. In support of this hypothesis, we demonstrated that human OCL secrete numerous pro-angiogenic factors including angiopoietin-1, angiopoietin-4, IL-8, osteopontin, and MCP-1, and that conditioned media (CM) from cultures of highly purified human OCL formed *in vitro* from normal bone marrow stimulated angiogenesis in co-cultures of fibroblasts and endothelial cells. OCL CM induced angiogenesis to a greater extent than CM from macrophages on a per cell basis. To determine if OCL stimulated angiogenesis in a bone microenvironment, we used the fetal mouse metatarsal angiogenesis assay to determine if the OCLs present in these bones contribute to their angiogenic potential. This assay employs bone explants from fetal mice, which contain OCLs, osteoblasts, fibroblasts and endothelial cells, to permit testing modulators of OCL activity for their effects on angiogenesis in a bone microenvironment. The OCL inhibitor osteoprotegerin (OPG) reproducibly inhibited basal angiogenesis in this assay even though metatarsals treated with OPG remained responsive to VEGF. Thus, OPG did not directly suppress the angiogenic capacity of endothelial cells. Further, activity of tartrate resistant alkaline phosphatase, a measure of OCL activity, was significantly reduced in the metatarsals at concentrations of OPG that inhibited angiogenesis. These data support the hypothesis that suppression of OCL activity can decrease angiogenesis in the bone microenvironment and that increased OCL activity in conditions such as inflammatory arthritis and bone metastasis may contribute to the increased angiogenesis found in these conditions.

**Recovery of Bone Architecture after RANKL Administration in Rats Is Characterized by Increased Bone Mass on Existing Trabeculae Assessed by *in vivo* Micro-CT.** G. M. Campbell<sup>1</sup>, M. S. Ominsky<sup>\*2</sup>, S. K. Boyd<sup>1</sup>. <sup>1</sup>University of Calgary, Calgary, AB, Canada, <sup>2</sup>Amgen Inc, Thousand Oaks, CA, USA.

Receptor activator of nuclear factor NF- $\kappa$ B ligand (RANKL) is required for osteoclast production and survival. Excess RANKL expression has been linked to post-menopausal bone loss. We have employed a model that introduces an excess-RANKL state in order to mimic osteoporotic bone loss and potential recovery. The purpose of this study was to determine (1) if changes in the trabecular architecture of rats injected with soluble RANKL follow the same patterns as the ovariectomized (OVX) rat and (2) the architectural patterns during recovery following withdrawal of RANKL injections.

Female retired breeder Wistar rats aged 7-9 months were assigned to one of four groups: high-dose RANKL (0.25mg/kg s.c. 5dy/wk), low-dose RANKL (0.05mg/kg s.c. 5dy/wk), vehicle or OVX (N = 8/gp). RANKL injections began at the time of surgery, and were stopped at wk 6. The right proximal tibial metaphysis was micro-CT scanned *in vivo* (vivaCT 40, Scanco Medical, Switzerland) at a voxel size of 12.5  $\mu$ m every two weeks from wk 0 to wk 12 and every four weeks from wk 12 to wk 20 (9 scans/rat). Bone volume ratio (BV/TV), trabecular thickness (Tb.Th), separation (Tb.Sp), number (Tb.N), connectivity density (Conn.D), structure model index (SMI) and cortical thickness (Ct.Th) were determined. Paired t-tests were used to detect changes from week to week and from baseline values.

The patterns of bone loss during the injection period were similar in the OVX and RANKL groups; however the rate and magnitude differed. At wk 2, the mean BV/TV in the high group was significantly reduced to 52% of the baseline value and was further reduced to 39% at wk 4. Significant changes in BV/TV of the low group were first observed at wk 6 (94% of baseline). BV/TV in the OVX group was reduced to 90% of baseline at wk 2, and 77% at wk 6. Throughout the injection period, significant changes were observed in the high RANKL and OVX group for all parameters, and in the low RANKL group for all parameters except Tb.N. After stopping injections, full recovery of Tb.Th and Ct.Th and partial recovery of BV/TV (55% of baseline) and SMI (1.34 to 0.89 above baseline) occurred in the high dose group. In the low dose group, BV/TV, SMI and Tb.Th recovered fully. Conn.D and Tb.N showed no improvement after withdrawal of RANKL in either group. RANKL treatment had a dose-dependent effect on the tibia of the rat and appeared to affect the architecture in a similar manner to OVX. Changes to BV/TV, Tb.Th, SMI and Ct.Th due to RANKL injection appear to be reversible, while changes to Conn.D and Tb.N do not. Direct observation by registration of the micro-CT data showed thin trabeculae that became thicker following RANKL withdrawal.

**Comparison of Direct Osteoclastogenic Potential on Osteoclast Precursor Cells Among Proinflammatory Cytokines.** S. Park<sup>\*</sup>, J. Ju<sup>\*</sup>, J. Park<sup>\*</sup>, H. Oh<sup>\*</sup>, H. Kim<sup>\*</sup>. Internal Medicine, Division of Rheumatology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Various cytokines play an important role in the pathogenesis of autoimmune disease such as rheumatoid arthritis. Bone destruction which comes from cytokine-associated inflammation finally results in joint dysfunction. This study was performed to examine the direct influences of these cytokines on osteoclast precursor cells during the osteoclastogenesis and to compare the osteoclastogenic potentials among TNF $\alpha$ , IL-1, IL-6, IL-17, and IL-23. Monocytes which were derived from mice bone marrow were prepared for progenitor cells of osteoclasts. Precursor cells were incubated in the presence of M-CSF (30 ng/ml) for the first 2 days and then IL-1 (0.1 ng/ml~10 ng/ml), IL-6 (0.1 ng/ml~10 ng/ml), IL-17 (0.1 ng/ml~10 ng/ml), IL-23 (0.1 ng/ml~10 ng/ml), and TNF (0.1 ng/ml~10 ng/ml) in the presence of M-CSF for a further 7 days. Every culture condition was treated with various concentration of RANKL (1, 5, 10, 50, and 100 ng/ml). Permissive level of RANKL was essential for osteoclastogenesis in every condition. IL-1 and TNF $\alpha$  enhanced osteoclastogenesis, but IL-6 inhibited osteoclastogenesis on the contrary. IL-1 showed most powerful potential for osteoclastogenesis in dose dependent manner. Interestingly, during the later time of osteoclastogenesis, TNF $\alpha$  enhanced osteoclastogenesis in the moderate dose of RANKL 50ng/ml, but dose-dependently inhibited osteoclastogenesis in concentration of 100ng/ml RANKL. IL-1 was universally pro-osteoclastogenic, and IL-6 was universally anti-osteoclastogenic. TNF $\alpha$  had the various effects on osteoclast precursor according to treatment time and RANKL concentration. It was interesting to compare osteoclastogenic potential of various proinflammatory cytokines in the same condition and would be more interesting to elucidate the difference of intracellular signaling in the cytokine-associated osteoclastogenesis.

**TGF- $\beta$ 1 Induces Human Osteoclast Apoptosis.** N. Houde<sup>\*</sup>, E. Chamoux, M. Bisson<sup>\*</sup>, S. Roux. Rheumatology, Faculty of Medicine, University of Sherbrooke, Sherbrooke, QC, Canada.

Transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) is the most abundant TGF- $\beta$  isoform detected in bone. TGF- $\beta$ 1 is stored in the bone matrix and may be released and activated during osteoclastic bone resorption. The effects of TGF- $\beta$ 1 on bone cells are complex and may depend on cell differentiation stage, TGF- $\beta$ 1 concentration and *in vitro* culture conditions. We previously showed that TGF- $\beta$ 1 induces apoptosis in human osteoclasts, however the mechanisms involved in these cells are not known, and the aim of the present study was to evaluate the apoptotic intracellular pathways activated by TGF- $\beta$ 1 in human osteoclasts. We used cord blood monocytes as osteoclast precursors. In long term cultures in the presence of MCSF and RANKL, multinucleated cells (MNCs) that express osteoclast markers form and are able to resorb bone. By immunocytochemistry we showed that these MNCs express both type I and II TGF- $\beta$ 1 receptors. Apoptosis was evaluated using a TUNEL-derived method, and in the presence of 1 ng/ml of TGF- $\beta$ 1, apoptosis was significantly increased to 48.8 $\pm$ 3% of the MNCs compared to 33.6 $\pm$ 3% in control cultures (p<0.01). In these cultures, the rate of TGF- $\beta$ 1-induced apoptosis significantly decreased in the presence of a caspase 9 inhibitor (36.6 $\pm$ 4% vs 44.3 $\pm$ 2.3% in control cultures, p<0.05) but not with an inhibitor of caspase 8. In addition, the expression of activated caspase-9 evaluated by immunocytochemistry was significantly increased (52 $\pm$ 1.8% vs 39.5 $\pm$ 2.6%, p<0.05). In various cells, TGF- $\beta$ 1 signaling involves primarily Smad proteins, but also interferes with intracellular modulators of apoptosis such as JNK, p38, Akt, NF- $\kappa$ B and Bcl2 family members. Using Western blot analysis to evaluate the expression of phosphorylated (activated) MAPKs and Smad2, we showed that upon TGF- $\beta$ 1 stimulation, activation of p38 occurred after 15 min (1.86 fold higher at 15 min vs non-treated cells, p<0.01), followed by a slight activation of JNK between 15 and 30 min. Moreover, the main activation was observed for Smad2 with a high level of phosphorylation after 60 min (up to 7 fold increase compared to non-treated cells). In contrast, the phosphorylation of ERK1/2 was not increased upon TGF- $\beta$ 1 stimulation. Our results suggest that TGF- $\beta$ 1 induces human osteoclast apoptosis, a process involving Smad signaling as well as Stress-Activated Protein Kinase (p38, JNK) activation. These signaling cascades may modulate the intrinsic pathway of apoptosis in osteoclasts, reflected by caspase 9 activation. This may represent a regulatory mechanism involved in the inhibition of osteoclast activity by TGF- $\beta$ 1 during bone resorption.

**Elevated Serum Levels of CXCL12 Is Associated with Increased Osteoclast Activity and Osteolytic Bone Disease in Multiple Myeloma Patients.** P. Diamond<sup>\*1</sup>, A. Labrinidis<sup>\*1</sup>, S. K. Martin<sup>\*1</sup>, S. Gronthos<sup>1</sup>, L. To<sup>\*1</sup>, N. Fujii<sup>\*2</sup>, P. O'Loughlin<sup>\*1</sup>, A. Evdokiou<sup>\*1</sup>, A. C. W. Zannettino<sup>\*1</sup>. <sup>1</sup>Department of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, <sup>2</sup>Department of Bioorganic Medicinal Chemistry, Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan.

Multiple myeloma (MM) is an incurable plasma cell (PC) malignancy able to mediate massive destruction of the axial and craniofacial skeleton. The aim of this study was to investigate the role of the potent chemokine, CXCL12 (also termed stromal derived factor 1, SDF-1) in the recruitment of OC precursors to the bone marrow (BM). Our studies show that MM PC produce significant levels of CXCL12 protein and exhibit elevated plasma levels of CXCL12 when compared with normal, age-matched subjects. The level of CXCL12 positively correlated with the presence of multiple radiological bone lesions in individuals with MM, suggesting a potential role for CXCL12 in OC precursor recruitment and activation. To examine these findings further, PB-derived CD14<sup>+</sup> OC precursors were cultured in an *in vitro* OC-potentiating culture system in the presence of recombinant human CXCL12. Whilst failing to stimulate an increase in TRAP<sup>+</sup>, multinucleated OC formation, CXCL12 mediated a dramatic increase in both the number and the size of the resorption lacunae formed. The increased OC motility and activation in response to CXCL12 was associated with an increase in the expression of a number of bone resorption-related genes including, RANKL, TRAP, matrix metalloproteinase-9 (MMP-9), Carbonic Anhydrase II (CA-II), and Cathepsin K. These findings are further supported by our recent *in vivo* studies where the human MM PC line, RPMI-8226, or genetically modified RPMI-8226 over-expressing CXCL12, were directly injected into the intra-tibial space of athymic nude mice, mimicking MM PC infiltration. The osteoclast activating potential of MM PC-derived CXCL12 was assessed by micro-CT, histological analyses and serum markers of bone loss. While implantation of RPMI-8226 into the tibiae resulted in a 5% decrease in bone volume (BV; compared with vehicle control), RPMI-8226 over-expressing CXCL12 mediated a 13% decrease in BV and a concomitant increase in osteolytic lesions and serum collagen I breakdown products. Furthermore, MM PC mediated osteolysis was significantly inhibited in animals receiving the CXCL12/CXCR4 antagonist, T140. These studies show that synthesis of high levels of CXCL12 by MM PC may contribute to the development of osteolytic lesions seen in patients with MM, by recruiting OC precursors to local sites within the BM and enhancing their motility and bone resorbing activity. Therefore, inhibition of CXCL12-CXCR4 may be an effective modality to inhibit osteolysis in MM patients.

**CXCL12 Expression Is Regulated by HIF-2 $\alpha$  in Multiple Myeloma Plasma Cells.** S. K. Martin<sup>\*1</sup>, P. Diamond<sup>\*1</sup>, L. B. To<sup>\*1</sup>, D. Peet<sup>\*2</sup>, S. Gronthos<sup>1</sup>, A. C. W. Zannettino<sup>\*1</sup>. <sup>1</sup>Department of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, <sup>2</sup>School of Molecular and Biomedical Science, University of Adelaide, Adelaide, Australia.

Multiple myeloma (MM) is an incurable haematological malignancy characterised by increased bone marrow (BM) angiogenesis and extensive lytic bone disease. Previous studies from our laboratory show that MM plasma cells represent an abundant source of the chemokine CXCL12, which serves to recruit both osteoclastic and vascular endothelial cells proximal to the MM plasma cells, thereby facilitating disease progression (Zannettino *et al.* 2005, Martin *et al.* 2006). Given the role of hypoxia-inducible factor-1 (HIF-1 $\alpha$ ) in inducing CXCL12 expression in other systems (Ceradini *et al.* 2004), we examined whether hypoxia could stimulate MM PC expression of CXCL12. Using the MM PC line, LP-1, our studies show that exposure to hypoxia induces a time dependent expression of CXCL12 mRNA and protein. By examining the hypoxia-induced expression profiles of CXCL12, HIF-1 $\alpha$  and HIF-2 $\alpha$  in the MM PC line LP-1, our results suggest that HIF-2 $\alpha$  is the primary regulator of CXCL12 expression under hypoxia. To examine this further, we engineered MM cells to express constitutive, high levels of HIF-1 $\alpha$  or HIF-2 $\alpha$ . Over-expression studies in MM cells show that HIF-1 $\alpha$  had little effect on CXCL12 expression, while HIF-2 $\alpha$  over-expression resulted in a 7.6 fold increase of CXCL12 mRNA and a 1.6 fold increase of CXCL12 protein. HIF-2 $\alpha$  regulation of CXCL12 was further examined using lentiviral expression constructs expressing shRNA for HIF-2 $\alpha$ . HIF-2 $\alpha$  knockdown in LP-1 cells resulted in a significant (p=0.01) decrease in CXCL12 expression. Finally, binding of HIF-2 $\alpha$  to the CXCL12 promoter was confirmed using CXCL12 promoter luciferase assay reporter gene studies, electrophoretic mobility shift and chromatin immunoprecipitation assays. These studies demonstrate, for the first time, that hypoxia regulates CXCL12 expression in MM PCs and occurs predominantly via activation of HIF-2 $\alpha$ .

**The Effects of IL-27 on Regulation of Osteoclastogenesis by Way of T Cells.** S. Kamiya<sup>\*1</sup>, T. Fukawa<sup>\*1</sup>, C. Nakamura<sup>\*2</sup>, T. Yoshimoto<sup>\*3</sup>, S. Wada<sup>1</sup>. <sup>1</sup>Clinical Sciences, Josai International University, Chiba, Japan, <sup>2</sup>Bio-analytical Chemistry, Josai International University, Chiba, Japan, <sup>3</sup>Intractable Immune System Disease Research Center, Tokyo Medical University, Tokyo, Japan.

A number of evidence has shown that bone remodeling process was affected by host immune reactions. Above all, cytokines that could modulate T cell functions were much focused in this area. Interleukin (IL) -27, a member of the IL-6/IL-12 family, has been shown to initiate type 1 helper T (Th1) cell responses and, however, to suppress excessive immune responses. Here, we examined the effects of this cytokine on osteoclast (OC) formation induced by M-CSF/RANKL in the presence of T cells.

Mouse bone marrow macrophage like cells (BMMs) were prepared from bone marrow cells with M-CSF, and were cocultured with activated T cells which were partially purified from isolated splenocytes by adhesion properties and were stimulated by anti-CD3 antibody.

When T cells were activated by 0.2  $\mu$ g/ml anti-CD3 antibody and cocultured with BMMs in the presence of M-CSF/sRANKL, the number of OC was reduced compared with that of co-cultures with innate T cells. The addition of IL-27 in this culture much strongly and significantly inhibited OC formation. To understand this phenomenon more precisely, we explored possible factors which could be produced by the activated T cells and modulate OC formation. Although the production of TNF $\alpha$ , IL-4, and IFN $\gamma$ , detected by ELISA, was not changed in T cells treated with IL-27, the production of IL-10 was increased by ~200% in T cells treated with IL-27. In this process, we found that treatment with IL-27 also significantly reduced sRANKL production in activated T cells. This effect of IL-27 on sRANKL production was observed in Th1 and Th2 cell subsets. Furthermore, FACS analysis revealed that treatment with IL-27 suppressed the expression of membrane-bound RANKL on the Th1 and Th2 cells, but not on osteoblasts stimulated by IL-6. The effects of IL-27 on RANKL expression of Th17 cells are under investigation.

In this study, we found that IL-27 inhibited OC formation when cocultured with activated T cells. The effects of IL-27 would be associated with modified cytokine-expression profile of the T cells. The findings observed in this study would suggest that IL-27 may play crucial roles for OC formation in autoimmune-related skeletal diseases.

**Establishment of a Murine Model of Hypercalcemia by Overexpression of sRANKL Using an Adenovirus Vector.** H. Yasuda<sup>1</sup>, Y. Furuya<sup>\*1</sup>, Y. Tomimori<sup>\*1</sup>, K. Mori<sup>\*1</sup>, J. Miyazaki<sup>\*2</sup>, T. Enomoto<sup>\*1</sup>. <sup>1</sup>Nagahama Institute for Biochemical Science, Oriental Yeast Co., Ltd., Shiga, Japan, <sup>2</sup>Graduated School of Medicine, Osaka University, Osaka, Japan.

Hypercalcemia is a significant complication of certain human malignancies, and is primarily caused by release of calcium from bone due to marked bone resorption by osteoclast activation. Animal models with hypercalcemia are useful tools for drug development and basic researches. In this study, we tried to generate a murine model overexpressing soluble receptor activator of NF-kappa B ligand (sRANKL) using an adenoviral vector. Adenoviral vector encoding sRANKL gene was injected i.p. to male C57BL/6 mice. As a negative control, adenoviral vector encoding LacZ gene was injected. Sera were collected at days 0, 7, and 14 for measurements of biochemical markers of bone turnover and sRANKL. Food and water intakes and body weights were measured every 3 or 4 days. All the mice were sacrificed 2 weeks after injection and their femurs were collected for measurements of bone mineral density (BMD). Serum sRANKL levels dramatically increased on day 7. Serum calcium levels increased peaking on day 7 and eventually returned to baseline levels on day 14. Food intakes and body weights significantly declined on day 7. These results indicated that the mice exhibited hypophagia that was one of symptoms of hypercalcemia. Increases in bone resorption and formation markers with a decrease in BMD were observed on day 14. The results reflect an acceleration of bone formation following activation of osteoclasts, namely coupling. In conclusion, we established a hypercalcemia model by overexpression of sRANKL. This model would be useful for researches of hypercalcemia and coupling between bone resorption and bone formation.

**Lipopolysaccharide Suppresses RANK Gene Through the Down-Regulation of PU.1 and MITF.** R. Kitazawa<sup>1</sup>, J. Ishii<sup>\*1</sup>, T. Kondo<sup>1</sup>, K. Mori<sup>1</sup>, K. P. McHugh<sup>2</sup>, S. Kitazawa<sup>1</sup>. <sup>1</sup>Department of Pathology, Kobe University, Graduate School of Medicine, Kobe, Japan, <sup>2</sup>Orthopaedic Research, Beth Israel Deaconess Medical Center, Boston, MA, USA.

Receptor Activator of NF-kB (RANK) expressed on osteoclasts and their precursors is a receptor for RANKL, and signals transduced by RANK-RANKL interaction are prerequisite for the differentiation and activation of osteoclasts. We cloned and characterized a 6-kb fragment containing the 5'-flanking region of the mouse RANK gene. A fragment of 1-kb from the transcription start sites containing four Sp-1 sites and putative binding sites for MITF, CRE/AP-1 and PU.1 was ligated to the pGL3-basic vector, as pGL3-WT, and the promoter activity was confirmed by transfection studies using RAW

264.7 cells. By EMSA, the oligonucleotide spanning the PU.1 (-497/-463) showed a specific DNA protein binding that was washed out with excess amounts of the cold competitor containing the consensus PU.1 binding sequence. Moreover, the oligonucleotide spanning the proximal MTF binding site (-114/-93) showed a specific DNA protein binding that was block-shifted with an anti-MTF antibody. Co-transfection studies with MTF- and PU.1- expression vectors revealed that MTF and PU.1 increased RANK promoter activity 3- and 2-fold, respectively, and 6-fold synergistically. Mutagenesis of the PU.1 site, generated as pGL3-PU.1m, diminished the inducible effect of the PU.1-expression vector on the promoter activity; mutagenesis of the MTF site, generated as pGL3-MTFm, nullified the effect of the MTF-expression vector. Taken together, these results show that RANK transcription is positively regulated by both PU.1 and MTF. The effect of lipopolysaccharide (LPS) on RANK gene expression, analyzed by in situ hybridization using mouse bone tissue, showed that intra-peritoneal injection of LPS remarkably decreased RANK transcripts of both precursor and mature osteoclasts. Furthermore, assessed by quantitative real-time PCR, LPS treatment of RAW.264.7 cells decreased their RANK mRNA expression by 70%, mirroring the decrease of PU.1 and MTF mRNA. Transfection studies using the pGL3-RANK constructs revealed that short-term treatment of LPS decreased the promoter activity of pGL3-WT by 70%, but not that of pGL3-PU.1m or pGL3-MTFm. Although LPS has been reported to promote osteoclastogenesis in chronic and local pyogenic inflammation such as periodontitis by the indirect actions of other cytokines including the up-regulation of RANKL in odontoblast or osteoblastic cells, we speculate that LPS per se may directly suppress RANK expression on the osteoclast cell lineage, at least in part, by down-regulating the expression of PU.1 and MTF genes in acute and systemic severe endotoxemia, such as in septic shock.

**Rheumatoid Synoviocytes Are Stimulated with IL-23 to Enhance Osteoclastogenesis Through Upregulation of RANKL Expression.** J. Min\*. Rheumatism Research Center, Catholic University of Korea, Seoul, Republic of Korea.

Purpose of this study is to delineate the osteoclastogenic effect of IL-23 via the fibroblast like synoviocyte (FLS). FLSs were separated from synovia of patients with rheumatoid arthritis (RA) and osteoarthritis (OA), and they were stimulated with IL-23. Receptor activator of nuclear factor kappa B ligand (RANKL) expression was measured by real time PCR and immunostaining. Osteoclast precursor cells were cocultured with IL-23-stimulated RA and OA FLS, respectively, and subsequently stained with mature osteoclast markers. In this study, we found that IL-23 upregulates RANKL expression on FLS and thus contributes to osteoclastogenesis. This indirect pathway is NF- $\kappa$ B and STAT3-mediated. We also discovered that RA FLS was more responsive to IL-23 in RANKL expression than OA FLS or normal FLS. We propose that IL-23-enhanced osteoclastogenesis of RA is mediated not only by IL-23-induced RANKL expression but also by the higher responsiveness of RA FLS to IL-23. Based on the results of this study, IL-23 might be a promising therapeutic target for the treatment of RA-associated bone destruction.

**Mechanism of BMP-2 Enhancement of PGE<sub>2</sub> Stimulated Osteoclastogenesis.** K. A. Blackwell<sup>1</sup>, P. Hortschansky<sup>2</sup>, S. Sanovic<sup>1</sup>, C. Alander<sup>1</sup>, L. Raisz<sup>1</sup>, C. Pilbeam<sup>1</sup>. <sup>1</sup>New England Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Leibniz Institute for Natural Product Research and Infection Biology, Hans-Knöll-Institute (HKI), Jena, Germany.

Bone morphogenetic protein-2 (BMP-2) at high doses can enhance bone repair in animals. Combination therapy with other osteoinductive agents may be a strategy to decrease the dose of BMP-2 required and increase cost effectiveness. Preclinical models have suggested that prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) or prostaglandin receptor agonists may increase the anabolic effects of BMP-2. However, PGE<sub>2</sub> is also a potent stimulator of osteoclastogenesis and the effect of the combination of BMP-2 and PGE<sub>2</sub> on osteoclast formation, which may oppose the anabolic response, has not been explored. To study osteoclastogenesis in the presence of osteoblastic cells, we cultured whole bone marrow from femora and tibiae of CD1 mice. Cells were plated at 1 $\times$ 10<sup>6</sup> cells/cm<sup>2</sup> and treated with BMP-2 (100 ng/ml), PGE<sub>2</sub> (1  $\mu$ M), or the combination for up to 8 days. Cultures were stained for tartrate-resistant acid phosphatase (TRAP) activity and osteoclasts were defined as TRAP positive multinucleated cells (MNCs) with 3 or more nuclei. mRNA levels of receptor activator of NF- $\kappa$ B ligand (RANKL) and osteoprotegerin (OPG) were measured by quantitative RT-PCR. To study the direct effects on osteoclast precursors, we cultured spleen cells with macrophage colony stimulating factor (30 ng/ml) and RANKL (30 ng/ml) for 7 to 8 days and measured TRAP+ MNCs.

In marrow cultures, BMP-2 treatment alone did not increase osteoclast number compared with control at any time point. PGE<sub>2</sub> increased osteoclast numbers on days 5-7 of culture. BMP-2 + PGE<sub>2</sub> increased osteoclast number 2-3-fold compared with PGE<sub>2</sub> alone. In spleen cultures, BMP-2 and PGE<sub>2</sub> treatment did not increase osteoclast formation compared with control. In marrow cultures, PGE<sub>2</sub> increased RANKL mRNA levels 6- to 13-fold. BMP-2 alone, or in the presence of PGE<sub>2</sub>, had no effect on RANKL mRNA expression. Either BMP-2 or PGE<sub>2</sub> alone decreased OPG mRNA levels by 34-40%. BMP-2 + PGE<sub>2</sub> further suppressed OPG compared with PGE<sub>2</sub> or BMP-2 alone to 43-54%. PGE<sub>2</sub> increased the RANKL:OPG ratio, which was further increased in the presence of BMP-2. Our results

suggest that BMP-2 enhances PGE<sub>2</sub> stimulated osteoclast formation by increasing the RANKL:OPG ratio, primarily by decreasing OPG.

**Roles of Cxcl2 in Osteoclast Precursor Cells.** J. Ha\*, H. Kim. Cell and Developmental Biology, Dental Research, Seoul, Republic of Korea.

Recently, some chemokines were shown to be expressed in bone cells and regulate the activity of osteoblasts and osteoclasts. But many chemokines remain to be elucidated for their role in bone microenvironment. We have shown that osteoclast precursors, bone marrow macrophages (BMMs), have CXCR2 chemokine receptor. BMMs highly expressed CXCR2 and decreased during osteoclastogenesis. The ligand of CXCR2, CXCL2, is known to be induced by endotoxin in macrophages. But we first found that osteoclastogenic cytokines (M-CSF and RANKL) can induce CXCL2 expression. CXCL2 was up-regulated in osteoclastic culture condition as determined by RT-PCR, Westernblot, and ELISA analysis. RANKL could induce CXCL2 expression and M-CSF addition elicited synergy in the RANKL induced CXCL2 expression. Up-regulation of CXCL2 by RANKL was through JNK and p38 dependent pathway. To specifically assess the role of CXCL2 in BMMs, we studied the effect of recombinant CXCL2 on BMMs. CXCL2 potently increased osteoclastogenesis dose dependent manner. TRAP positive multinucleated cells significantly increased with treatment of recombinant cxcl2 at BMM and pOC stage of differentiation. CXCL2 secreted by RANKL could stimulate the adhesion and migration of BMMs. Neutralization of CXCL2 with CXCL2 specific antibody at pOC stage potently inhibited osteoclastogenesis. However, in the presence of CXCL2 specific antibody, BMMs could not survive. Therefore, we checked the effect of CXCL2 on proliferation of BMMs. CXCL2 alone could not induce proliferation of BMMs but CXCL2 enhanced proliferation of BMMs in a dose dependent manner with low dose of M-CSF. Using siRNA system, BMMs treated with CXCL2 siRNA cultured with M-CSF and RANKL could not proliferate comparing with scrambled siRNA-treated cells. In summary, CXCL2 induced by RANKL can increase the adhesion, migration, and proliferation of osteoclast precursors and ultimately enhance osteoclastogenesis. These events may contribute to the recruitment of osteoclast precursors to bone lesion and inflammatory regions in vivo under pathological conditions.

**Real Time Oscillations in TNF-induced Gene Expression MAP Kinase Phosphorylation and Promoter Binding.** J. Iqbal\*, L. Sun, L. Zhu\*, G. Yang\*, M. Zaidi. Medicine, Mount Sinai School of Medicine, New York, NY, USA.

With only few exceptions that include Hes-1 p53, and I $\kappa$ B, the expression of genes has never been shown to be oscillatory. Here, we show that TNF triggers oscillations in >5000 genes. Microarrays performed at 30-minute intervals revealed that 15% of genes in the murine genome underwent a >3-fold increase in expression, with 89% oscillating at frequencies as low as every 50 minutes. Analysis of two sub-clusters by qPCR revealed continuous oscillations. Such oscillations, but with unique induction profiles, were also triggered by the related cytokines RANK-L. Further analysis showed that multiple signaling components downstream of the TNF receptor, such as TRAF-1, also underwent oscillations. TNF likewise triggered oscillations in the phosphorylation of three MAP kinases, as well as p65. An NF- $\kappa$ B super-repressor altered oscillation amplitude and frequency, attesting to a role for NF- $\kappa$ B as a modulator of such cyclical activation. Finally, we studied how these oscillations can combine in a ligand-specific manner at the level of the promoter to initiate gene transcription. For this, we utilized the late onset gene CD38, since TNF, but not the related cytokine RANK-L, induces its expression. Quantitative ChIP analysis revealed that TNF induced oscillations in p65 and p50 recruitment to the CD38 promoter, which correlated with MAP kinase-induced AP-1 recruitment. Through re-ChIP analysis, we determined the formation of a unique transcriptional complex on the promoter at 3 hours post-TNF addition, which corresponded to the onset of CD38 transcription. RANK-L, in contrast, was unable to combinatorially recruit AP-1 and NF- $\kappa$ B transcription factors to the CD38 promoter, despite inducing the activation of both signaling pathways. These results constitute a new paradigm through which cells dynamically coordinate time-resolved gene transcription by the formation of novel time-specific transcriptional complexes. Considering this dynamism, timed analyses of gene transcription, MAP kinase phosphorylation and promoter binding should become the experimental norm.

**Differential Contribution of Osteoclast- and Osteoblast-Lineage Cells to Lipopolysaccharide Modulation of Osteoclastogenesis.** V. Alshits\*, Z. Bar-Shavit. Experimental Medicine and Cancer Research, Hebrew University, Jerusalem, Israel.

Bacterial infections cause pathological bone loss by accelerating differentiation and activation of the osteoclast. A variety of bacteria-derived molecules have been shown to enhance osteoclast differentiation via activation of Toll-like receptors (TLRs). Lipopolysaccharide (LPS), activating TLR4, is the most studied bacterial-derived molecule in this regard. The interactions of LPS with TLR4 in both osteoclast- and osteoblast-lineage cells contribute to its osteoclastogenic effect. Here we examine the relative contribution of each of the lineages to LPS osteoclastogenic effect. To answer this question we chose to employ the co-culture system. To this end we used C3H/HeN (wt) and C3H/HeJ (mut) mice expressing a functional and a non-functional mutant TLR4, respectively. We performed our analyses in mixed co-cultures of osteoclast precursors (OCPs) and osteoblasts (OBs) containing all 4 possible combinations (OCPs.wt/OBs.wt, OCPs.mut/OBs.mut, OCPs.wt/OBs.mut and OCPs.mut/OBs.wt). This approach enables us to examine LPS modulation of one lineage (wt-derived) in the presence of the other (mut-derived). We first confirmed that both osteoclast- and osteoblast-lineage cells derived from C3H/HeJ do not respond to LPS. We found that LPS increased osteoclastogenesis in OCPs.wt/OBs.wt and did not affect osteoclastogenesis in OCPs.mut/OBs.mut. In the 2 mixed co-cultures there was a reduction in the LPS ability to affect osteoclast differentiation. The LPS osteoclastogenic activities in OCPs.wt/OBs.mut and in OCPs.mut/OBs.wt were 57% and 22% of the activity in OCPs.wt/OBs.wt, respectively. LPS induced TNF-alpha expression in OCPs.wt/OBs.wt, but not in OCPs.mut/OBs.mut. This activity was impaired in the mixed co-cultures; the inhibition was more prominent in OCPs.mut/OBs.wt. Our data are consistent with the dependence of LPS-induced osteoclastogenesis on TLR4 on both, OCPs and OBs and show that the activation of TLR4 in OCPs is more crucial to induction of osteoclastogenesis than activation of the osteoblastic TLR4. Our data also indicate that OCPs-derived TNF-alpha modulates the activity of the OBs and OBs-derived TNF-alpha modulates the activity of the OCPs.

**The Matrix PRoline/arginine-rich End Leucine-rich Repeat Protein (PRELP) Interferes with the NF-kappaB Pathway and Impairs Osteoclast Formation and Activity.** N. Rucci<sup>1</sup>, A. Rufo<sup>\*1</sup>, M. Alamanou<sup>\*1</sup>, M. Capulli<sup>\*1</sup>, A. Del Fattore<sup>\*1</sup>, D. Heinegard<sup>\*2</sup>, A. Teti<sup>1</sup>. <sup>1</sup>Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy, <sup>2</sup>Department of Experimental Medical Science, University of Lund, Lund, Sweden.

PRELP is a heparin binding anchor protein, highly expressed in cartilage and developing bone. We found that a peptide corresponding to its heparin-binding domain (hbdPRELP) irreversibly impaired osteoclastogenesis of non-fractionated mouse bone marrow cultures or purified bone marrow macrophages, and inhibited bone resorption and mature osteoclast adhesion. hbdPRELP specifically affected late pre-fusion osteoclasts with a mechanism dependent on chondroitin sulfate cell surface proteoglycans, while not on heparan sulfate. Tagged hbdPRELP co-localized with cell surface chondroitin sulfate, was internalized in endosomes and transferred to the nucleus with a mechanism dependent on cell activity and abolished by chondroitinase treatment of cells. Internalization also required annexin II, which co-localized with cell surface chondroitin sulfate and tagged hbdPRELP, with which it formed a complex, revealed by immunoprecipitation. hbdPRELP translocated to the nucleus, bound p65 NF-kappaB subunit and inhibited its DNA binding by 50%, leading to a significant reduction of the downstream osteoclast-specific genes cathepsin K, calcitonin receptor, metalloproteinase 9, RANK, TRAcP, DC-STAMP and CD44. Consistently, in hbdPRELP-treated pre-fusion osteoclasts no nuclear localization was found for the transcriptional factor NFATc1. hbdPRELP did not prevent RANKL-induced MAPK phosphorylation, nor did it trigger apoptosis, as showed by normal nuclear morphology and lack of modulation of caspase 3 and Bax/Bcl-2 protein expression. Finally, effects of hbdPRELP appeared osteoclast-specific, as the peptide failed to affect mouse calvarial osteoblast differentiation, function, gene expression and transcription of osteoclastogenic cytokines. In conclusion, the heparin binding domain of PRELP is a novel direct negative regulator of osteoclast formation blocking NF-kappaB signaling in late pre-fusion osteoclast precursors with no effect on osteoblasts. We believe that these data could allow a deeper understanding of osteoclast biology as well as the direct involvement of matrix molecules in bone remodeling.

**IFN-beta Is a Key Molecule in Inhibition of Human Osteoclast Differentiation by 1alpha, 25-dihydroxyvitamin D<sub>3</sub>.** S. Sakai<sup>\*1</sup>, H. Takaishi<sup>2</sup>, K. Matsuzaki<sup>\*2</sup>, H. Kaneko<sup>\*2</sup>, M. Furukawa<sup>2</sup>, A. Shiraishi<sup>\*1</sup>, T. Suda<sup>\*3</sup>, T. Miyamoto<sup>4</sup>, Y. Toyama<sup>\*2</sup>. <sup>1</sup>Product Research Department, Chugai Pharmaceutical CO., LTD, Gotemba, Japan, <sup>2</sup>Department of Orthopedic Surgery, Keio University, Tokyo, Japan, <sup>3</sup>Department of Cell Differentiation, Keio University, Tokyo, Japan, <sup>4</sup>Department of Orthopedic Surgery, Department of Musculoskeletal Reconstruction and Regeneration, Department of Cell Differentiation, Keio University, Tokyo, Japan.

Vitamin D plays a critical role in calcium and bone metabolism. In cocultures of the bone marrow and osteoblastic cells, 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub>, an active form of vitamin D<sub>3</sub>, induces the expression of RANKL in osteoblastic cells and thereby stimulating osteoclastogenesis. This fact leads to the widespread belief that active vitamin D<sub>3</sub> is a bone-resorbing hormone. On the other hand, active vitamin D<sub>3</sub> treatment reduces bone resorption and bone fracture risks in osteoporotic patients, however, the molecular mechanisms how active vitamin D<sub>3</sub> inhibits bone resorption are largely unknown. In this study, we revealed that 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> directly inhibits human osteoclastogenesis through IFN- $\beta$  and NFATc1 axis. CFU-GM cells generated from human bone marrow cells were used for this study as osteoclast progenitor cells. CFU-GM cells were stimulated with 30 ng/mL M-CSF and 30 ng/mL RANKL for 6 days to generate multinucleated (n>3) osteoclasts (OCLs). 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> significantly inhibited OCLs formation in a dose-dependent manner. Vitamin D receptor (VDR) was detected in CFU-GM cells indicating that 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> may inhibit osteoclastogenesis directly through VDR. The expression of IFN- $\beta$ , a strong inhibitor of osteoclastogenesis, was significantly upregulated by 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> treatment. To elucidate the role for IFN- $\beta$  in the inhibitory effect of 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> on osteoclastogenesis, we added the neutralizing antibody against IFN- $\beta$  into the culture medium. The expression of NFATc1, a downstream molecule of RANKL-RANK signaling, and osteoclast differentiation were significantly restored by treatment with anti IFN- $\beta$  antibody. Taken together, our data suggest a novel mechanism that 1 $\alpha$ ,25(OH)<sub>2</sub>D<sub>3</sub> inhibits osteoclastogenesis through the upregulation of IFN- $\beta$ , which downregulates NFATc1 expression in osteoclast progenitor cells in an autocrine/paracrine manner.

**In vitro Aging of Young Bone Enhances Osteoclastogenesis.** D. J. Leeming, I. Byrjalsen, K. Henriksen, M. G. Sørensen, P. Qvist, C. Christiansen\*, M. A. Karsdal. Nordic Bioscience, Herlev, Denmark.

**Purpose:** Bone remodeling is essential for maintaining the quality of bone. Preliminary data have suggested that osteoclasts prefer to resorb aged bone compared to that of young bone by in vitro culturing of human osteoclasts. To further elucidate this mechanism we biochemically increased the age of young bones, by in-vitro incubation, and investigated the effect of bone age on the differentiation and activity of osteoclast precursors cultured on bone slices.

**Methods:** Cortical bone slices from a 9-month-old calf and an 8-year-old cow were incubated for 0, ½, 1, 2½, or 7 months at 37°C in 70% EtOH. The bone slices from each incubation step were stored at -80°C until use. The age of the bone slices were measured as the ratio between newly synthesized non-isomerized ( $\alpha$ CTX) and isomerized ( $\beta$ CTX) C-telopeptide of type I collagen, a ratio that reflects the age of collagen type I. CD14 positive monocytes were isolated from human peripheral blood, seeded on bone slices, and cultured in 1% serum for 30 days in the presence of 25ng/ml of M-CSF and RANKL to follow osteoclastogenesis. Osteoclastic resorption was assayed using the resorption markers  $\alpha$ CTX and  $\beta$ CTX, as well as hydroxyproline, in the conditioned medium collected during culture. Osteoclast number was investigated by measurement of TRAcP activity in conditioned medium. Total cell viability was assessed by the metabolic dye Alamar Blue.

**Results:** The  $\alpha/\beta$  CTX ratio measured in bone slices revealed that young bone was aged by incubation at 37° C. The  $\alpha/\beta$  CTX ratio in young bone decreased with increased time of incubation reaching the lowest level after 2½ month of incubation. In contrast the ratio in aged bone remained virtually unchanged during the in-vitro incubation.

Osteoclasts cultured on the in-vitro aged young bone slices released higher amounts of  $\alpha$ CTX,  $\beta$ CTX and hydroxyproline in an age-dependent manner (2-fold and 700-fold increased at 7 months, p<0.001). On the eight-year-old bone there was minute change in the release of resorption markers with increased in-vitro age. Total cell viability was higher on bone slices from the in-vitro aged young bone (p<0.001) as compared with the initial young bone. On the aged bone, the cell viability was relatively constant with increasing in-vitro age.

**Conclusions:** These data indicate that the osteoclastogenesis, number and activity of osteoclasts precursors are enhanced on aged bone compared to young bone. We speculate that that a biochemical change of the bone matrix accumulates during aging, which promote osteoclastogenesis and thereby results in increased numbers of mature resorbing osteoclasts on old bone.

## SU092

**Transactivation of RANKL by C/EBP $\beta$  and C/EBP $\delta$  in Adipocyte Lineage Cells.** S. Takeshita, T. Fumoto\*, K. Ikeda. Bone and Joint Disease, National Center for Geriatrics and Gerontology, Obu, Japan.

Although RANKL expression has been studied in osteoblastic/stromal cells, the cell types in the bone microenvironment which actually express RANKL *in vivo* remain unknown. We reported that adipogenic cultures of mouse whole bone marrow cells induced robust formation of extremely long-lived osteoclasts in the absence of any exogenous osteotropic hormones or RANKL, and that the expression of RANKL was induced in such cultures (ASBMR 2007). Further, when the bone marrow stromal cell lines ST2 and MC3T3-G2/PA6 were stimulated to adipogenic differentiation, RANKL was transiently induced with concomitant down-regulation of OPG, suggesting that pre-adipocytes express RANKL and support osteoclastogenesis. In the present study, we examined the molecular mechanism by which RANKL gene expression is induced during adipocytic differentiation. When an NIH3T3 fibroblastic cell line was transduced with retroviral vectors encoding adipogenic transcription factors, C/EBP $\beta$  and C/EBP $\delta$  induced RANKL expression, while PPAR $\gamma$  did not. In transient transfection into NIH3T3 cells and luciferase reporter assays, C/EBP $\beta$  stimulated RANKL promoter activity, while mutations in the binding sites of C/EBP $\beta$  abrogated the Luc activity. Chromatin immunoprecipitation assays revealed that C/EBP $\beta$  and C/EBP $\delta$  bind to RANKL promoter *in vivo*, suggesting that RANKL is a direct target of these adipogenic transcription factors. The pre-adipocyte capacity to express RANKL and support osteoclastogenesis may contribute to the accelerated osteoclastogenesis which develops with aging under the influence of the adipose tissue-rich microenvironment in bone marrow.

**Grape Seed Extract (GSE) Suppresses IL-23/Th17 Inflammatory Pathways and Bone Destruction in Collagen Induced Arthritis.** J. Min\*. Rheumatism Research Center, Catholic University of Korea, Seoul, Republic of Korea.

**Objective :** Rheumatoid arthritis (RA) is a chronic inflammatory disease that a hallmark is a persistent inflammation of the synovium of the joints, leading to destruction of the surrounding bone and cartilage and ultimately joint deformities. we have investigated therapeutic effect of GSE, antioxidant compounds containing Procyanidins from Vitis vinifera seeds, on Type II collagen-induced arthritis (CIA) in mice

**Methods :** After GSE or saline administration, animals were monitored for 10 weeks. The progression of CIA (incidence, severity) was evaluated by arthritis scoring of paws. Histopathologic changes (cartilage destruction and pannus formation) and expression of inflammatory cytokines (IL-1b, TNF $\alpha$ , IL-17) within the knee joints were evaluated by immunohistochemistry. CII-specific IgG1 and IgG2a levels in serum and IL-23, IL-17, TNF- $\alpha$  and IL-4 concentrations in cultured supernatants were measured by ELISA and FACS. Osteoclasts were measured by tartrate-resistant acid phosphatase (TRAP) staining assay on RANKL and M-CSF induced osteoclast formation system. The number of TRAP positive multinucleated cells in cultures was counted.

**Results :** GSE treated arthritis mice suppressed bone erosion and destruction with an decrease in TRAP-positive osteoclasts. Treatment with GSE significantly reduced bone erosion and destruction with an decrease in TRAP-positive osteoclasts and the severity of osteolysis in CIA mice. In vitro examinations using bone marrow cultures containing M-CSF plus RANKL indicated that the osteoclast development was suppressed by GSE treatment. Histological analysis shows that cell infiltration and cartilage destruction was dramatically reduced and expression of IL-1b, TNF $\alpha$ , IL-23, IL-17 in the arthritic joint after treatment with GSE. Treatment of mice with GSE also decreased the amounts of CII-specific IgG2a and led to significant reduction of IL-17 and TNF- $\alpha$  production in cultured supernatant compared to saline-treated mice.

**Conclusion :** This study revealed GSE may be new effective agents for attenuating the joint destruction in RA.

**Increased Osteoclast Differentiation and Bone Resorption During Spaceflight.** A. Di Benedetto\*, C. Camerino\*, R. Tamma\*, G. Colaianni\*, G. Greco\*, M. Strippoli\*, R. Vergari\*, A. Grano\*, L. Mancini\*, A. Zallone. Human Anatomy and Histology, University of Bari, Bari, Italy.

Serious effects on human health are experienced after long duration space missions. Prolonged exposure to microgravity seems to affect several physiological systems. Bone loss is considerable, with losses of 1-2% of bone mass per month in flight, occurring predominantly in the load bearing regions of the legs and lumbar spine. Microgravity induces an uncoupling of bone remodeling between bone formation and resorption that could lead to bone loss. Both processes are probably involved, but their relative importance and how they are orchestrated remain unclear. In order to fully understand the mechanisms underlying this bone loss we participated to the FOTON M3 mission launched on September 2007 that carried three experiments OSTEO, OCLAST and PITS developed by our team. We studied for the first time the *in vitro* effect of microgravity on osteoclasts (OCs) and our preliminary results indicate that OCs are directly affected. The OSTEO experiment was performed within a perfusion system of bioreactors, where the differentiation of precursors cells in mature OCs was tested on a synthetic 3D bone-like biomaterial, *skelite*, that partially reproduces the chemical composition and physical structure of natural bone. The aim was to analyze the gene expression pattern of osteoclasts differentiation in microgravity, compared with ground controls. RNA extracted from the cells was examined by RT-PCR. The preliminary results indicate that genes involved in osteoclast final maturation and activity, as integrin beta3, cathepsin K, MMP9 are upregulated in microgravity compared to ground control, while other genes were substantially at the same level. In OCLAST and PITS experiments, bone resorption by mature OCs was studied and the cells were cultured on bovine bone slices. The experiments, started in orbit, lasted 4 days. After landing the amount of collagen telopeptides, as index of bone resorption, was measured in OCLAST samples, while, for a genetic screening RNA was obtained from PITS samples. We found an increase in bone resorption after 4 days of space flight, indicated by higher telopeptide concentration and upregulation of genes related to osteoclast activity. These results are consistent with an increased osteoclastogenesis observed by our group in simulated microgravity conditions, and indicate osteoclasts precursors as direct target of microgravity.

## SU095

**Implication of Prostaglandin D<sub>2</sub> in the Birth and Death of Human Osteoclasts.** M. A. Gallant\*, M. Durand\*, A. J. de Brum-Fernandes. Division of Rheumatology, Université de Sherbrooke, Sherbrooke, QC, Canada.

Bone resorption depends on osteoclastogenesis, individual osteoclast activity and on osteoclast apoptosis. The lifespan of osteoclasts is tightly regulated by many growth factors and survival signals. We recently demonstrated that human osteoclasts produce prostaglandins in resting conditions (Hackett et al, J of Rheum July 2006), and that prostaglandin D<sub>2</sub> (PGD<sub>2</sub>) can decrease osteoclasts differentiation and bone resorption (Durand et al, JBMR July 2008).

The objectives of the present study were to determine the effects of PGD<sub>2</sub> on osteoclastogenesis and on osteoclast apoptosis. CD14+ cells were purified from human peripheral blood and cultured for 7, 14 and 21 days in presence of RANKL and M-CSF to induce osteoclast differentiation. PGD<sub>2</sub> or specific PGD<sub>2</sub> receptors agonists were added to study the effects of DP and CRTH2 receptor activation. The expression of NFAT-C1 and PU.1, two transcription factors implicated in osteoclast differentiation, and of TRAP5b and Cathepsin K, mature osteoclasts markers, was determined using real-time quantitative PCR. Osteoclasts apoptosis was quantified using the TACS Blue kit from R&D Systems. Results show that NFATC-1 gene expression is decreased by half, while PU.1 gene expression was brought down to 75% upon PGD<sub>2</sub> stimulation. The use of specific agonists indicated that both PGD<sub>2</sub> receptors were implicated in this effect. The Cathepsin K gene was also downregulated by 75% by PGD<sub>2</sub> during the differentiation course, while TRAP gene expression was transiently decreased by 50% during the 14 first days of differentiation by PGD<sub>2</sub> receptor CRTH2 only. To study the role of PGD<sub>2</sub> in osteoclasts apoptosis, mature differentiated osteoclasts were stimulated with PGD<sub>2</sub> and apoptosis was evaluated. Results demonstrate that PGD<sub>2</sub> doubles human osteoclasts apoptosis compared to the basal apoptosis in the control conditions.

In conclusion, this study indicates that PGD<sub>2</sub> is controlling human osteoclasts differentiation at the molecular level, by decreasing the expression of essential transcription factors, what is corroborated by a decrease in the expression of mature osteoclast markers. PGD<sub>2</sub> also increases osteoclasts apoptosis. These results indicate that activation of PGD<sub>2</sub> receptors could inhibit bone resorption.

**Simvastatin Induces Wnt Signaling and Reduces CSF-1 Secretion and RANKL/OPG Ratio to Block Osteoclast Differentiation.** C. C. Mandal<sup>1</sup>, N. Ghosh-Choudhury<sup>2</sup>. <sup>1</sup>Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, <sup>2</sup>Pathology, University of Texas Health Science Center at San Antonio and South Texas Veterans Health Care System, San Antonio, TX, USA.

An improper balance in bone remodeling, caused by increased osteoclast (OC) function, leads to debilitating diseases like osteoporosis and multiple myeloma. OC activities critically depend on osteoblast (OB)-derived factors. Colony stimulating factor-1 (CSF-1) and receptor activator of NFκB ligand (RANKL) are positive regulators of OC formation while osteoprotegerin (OPG), a soluble decoy for RANKL, balances the activity of RANKL during OC differentiation. We have shown recently that statins stimulate OB differentiation. Since statins suppress bone resorption we evaluated the clinical potential of simvastatin (Sim) in treating diseases originating from increased OC activity. We determined the effect of simvastatin on OC formation in a coculture assay using 2T3 osteoblasts and mouse spleen derived OC precursor cells. 5 μM Sim completely blocked OPG-induced formation of TRAP positive multinucleated (MNC) osteoclasts with significant reduction in TRAP enzyme activity. To elucidate the mechanism, we examined the effect of Sim on osteoclastogenic CSF-1 expression. Sim dose-dependently inhibited CSF-1 mRNA expression as determined by Northern blotting and real time qRT-PCR, resulting from reduced transcriptional activity of CSF-1 promoter. This translated into significant reduction in CSF-1 protein secretion as judged by ELISA. Real time qRT-PCR and transcriptional assays showed significant attenuation of osteoclastogenic RANKL expression upon Sim treatment. At the same time, Sim increased OPG expression resulting in reduction of RANKL/OPG ratio. Activation of Wnt signaling is reported to inhibit OC differentiation. To understand the signaling mechanism underlying statin-induced inhibition in expression of OB-derived OC differentiation factors, we tested the involvement of Wnt signaling pathway. Activation of Wnt signal transduction stimulates β-catenin translocation to the nucleus. We found that Sim induced translocation of β-catenin into the nucleus as determined by the immunoblotting of the nuclear fractions from 2T3 osteoblasts. Nuclear β-catenin increases transcription of Wnt-responsive genes. We used the reporter construct TOP-flash, which contains the Wnt-sensitive TCF/Lef1-responsive DNA element. Sim dose-dependently increased the TCF/Lef1 responsive reporter activity. Together these data for the first time show reduction of CSF-1 secretion and RANKL/OPG ratio in osteoblasts treated with Sim together with activation of Wnt signaling. Thus we provide a novel mechanism for reduced OC differentiation in response to Sim.

**Vimentin Binds c-Fms in an M-CSF Dependent Manner and Regulates Osteoclast Differentiation.** Y. Ito, H. Zhao, J. Chappel, S. L. Teitelbaum, F. P. Ross. Department of Pathology and Immunology, Washington University, St. Louis, MO, USA.

M-CSF is central to the differentiation, proliferation and survival of osteoclasts and their precursors. We previously reported that M-CSF regulates osteoclast differentiation and macrophage proliferation via the phosphoinositide 3-kinase (PI3K)/Akt pathway. Specific signals downstream of Akt that regulate the cytoskeleton remain incompletely defined. To identify novel Akt targets we treated BMMs with M-CSF and blotted lysates with a rabbit monoclonal antibody (PAS) that recognizes peptides or proteins containing R-X-R-X-X-phospho-(Ser/Thr). We found that many proteins are phosphorylated in response to M-CSF in a time-dependent manner. To investigate the Akt substrates which interact with c-Fms, the M-CSF receptor, total cell lysates of M-CSF-treated cells were immunoprecipitated with anti-c-Fms Ab and then immuno-blotted with anti-PAS. We found a single 57kDa-protein which we subjected to mass spectrometry and identified the molecule as vimentin, an intermediate filament protein. Using reciprocal immuno-precipitation/ western blot analysis we confirmed the M-CSF dependent interaction between c-Fms and vimentin. In addition, pre-treatment of BMMs with Ly294002, a PI3K inhibitor blocks binding of the receptor and intermediate filament protein. We next examined whether Akt can phosphorylate vimentin directly by *in vitro* kinase assay. Recombinant vimentin and Akt or p70S6 kinase (S6K), a Ser/Thr kinase which acts downstream of PI3K and the target of rapamycin (mTOR), were incubated in the presence or absence of ATP. Samples were immuno-blotted with anti-PAS Ab. S6K, but not Akt, phosphorylates vimentin ATP-dependently. Consistent with this observation, rapamycin, an inhibitor of mTOR, blocks the interaction between c-Fms and vimentin in response to M-CSF. To address the role of vimentin in osteoclast biology, we depleted vimentin by transducing BMMs with vimentin-specific shRNA lentiviral vector. Vimentin depletion suppresses but does not eliminate osteoclast differentiation. Brd U incorporation into M-CSF treated vimentin knockdown BMMs is significantly decreased. The levels of phospho-JNK, ERK and Akt are all decreased significantly in vimentin knockdown BMMs in response to M-CSF, as compared control cells. Therefore, we have identified vimentin is a novel M-CSF/c-Fms downstream signaling molecule regulating macrophage proliferation and osteoclast differentiation.

**Cell Cycle-Arrested Quiescent Osteoclast Precursors (QOP) Are Cells Committed to the Osteoclast Lineage.** A. Arai<sup>1</sup>, T. Mizoguchi<sup>1</sup>, A. Muto<sup>1</sup>, Y. Kobayashi<sup>1</sup>, I. Kawahara<sup>1</sup>, K. Yamada<sup>2</sup>, N. Udagawa<sup>3</sup>, N. Takahashi<sup>1</sup>.

<sup>1</sup>Institute for Oral Science, Matsumoto Dental University, Shiojiri, Nagano, Japan, <sup>2</sup>Department of Orthodontics, Matsumoto Dental University, Shiojiri, Nagano, Japan, <sup>3</sup>Department of Biochemistry, Matsumoto Dental University, Shiojiri, Nagano, Japan.

We have identified QOP as the direct precursors of osteoclasts (JBMR 22 Suppl 1: S082, 2007). *In vivo* studies have shown that osteoblasts prepare the osteoclast niche, in which QOP are maintained for a long period under the undifferentiated state. QOP in the osteoclast niche expressed both RANK and c-Fms (RANK<sup>+</sup>/c-Fms<sup>+</sup>) and differentiated into osteoclasts without cell proliferation. Here, we examined functional properties of QOP in comparison with those of bone marrow-derived macrophages (BMMφ), osteoclast progenitor cells. (1) Flow cytometric analysis showed that 0.2% of mononuclear cells in the total mouse bone marrow cells expressed both RANK and c-Fms. RANK<sup>+</sup>/c-Fms<sup>+</sup> cells isolated by magnetic cell sorting differentiated into osteoclasts even in the presence of hydroxyurea, an inhibitor of DNA synthesis, in the presence of RANKL and M-CSF. BMMφ were obtained by culturing mouse bone marrow cells with M-CSF. BMMφ failed to differentiate into osteoclasts in the presence of hydroxyurea. (2) F4/80 is a marker of mature macrophages. Immunocytochemical studies showed that BMMφ strongly expressed F4/80, but most of RANK<sup>+</sup>/c-Fms<sup>+</sup> cells failed to express F4/80. Double staining of tibial sections with anti-F4/80 and -RANK antibodies showed that RANK-positive cells failed to express F4/80. (3) In phagocytosis experiments using latex beads, BMMφ showed potent phagocytic activity. In contrast, most of RANK<sup>+</sup>/c-Fms<sup>+</sup> cells failed to incorporate latex beads. (4) Dendritic cells and osteoclasts are differentiated from the common precursors. BMMφ and RANK<sup>+</sup>/c-Fms<sup>+</sup> cells were cultured with GM-CSF, followed by LPS, to induce dendritic cell differentiation. BMMφ could differentiate into CD11c and CD86 double-positive dendritic cells under the culture condition, but RANK<sup>+</sup>/c-Fms<sup>+</sup> cells could not. These results suggest (1) that QOP are non-proliferating cells committed to the osteoclast lineage, and (2) that these characteristics of QOP make it possible for QOP to promptly differentiate into osteoclasts in response to bone-resorbing stimuli in the osteoclast niche.

**Identification, Characterization and Isolation of Peripheral Osteoclast Progenitors.** C. Jacome-Galarza<sup>1</sup>, K. Lamothe<sup>1</sup>, J. Lorenzo<sup>2</sup>, H. L. Aguila<sup>1</sup>.

<sup>1</sup>Immunology, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Osteoclasts are cells of hematopoietic origin derived from monocyte progenitors that develop in the bone marrow. Using flow cytometry, we have characterized the phenotype of bone marrow progenitors and isolated cells with clonal ability to generate osteoclasts in *in vitro* readout assays. These cells have the phenotype B220<sup>+</sup> CD3<sup>+</sup> CD11b<sup>lo</sup> CD115<sup>+</sup> CD117<sup>+</sup>, and also generate macrophages and dendritic cells when cultured in media containing differential cytokines. Cells with osteoclastogenic potential are also found in periphery and it has been proposed that they can contribute to pathologies associated to bone destruction in inflammatory processes. To test if the fate of these cells is regulated by microenvironmental influences we need to have strict ways to identify them. Using similar approaches to the ones used to study bone marrow precursors we have dissected cell populations from blood and spleen. We have found that the phenotype of peripheral osteoclast progenitors is different to the ones in bone marrow. They are negative for lymphoid markers (CD3 and B220), and the majority is positive for the myeloid marker CD11b. Further dissection of these populations, using anti CD115/c-fms antibodies, showed that positive and negative fractions can generate osteoclasts. The negative fraction seems to contain a population of progenitors that develop rapidly into osteoclasts at a low frequency, while the CD115 positive population develops osteoclasts at high frequency. Lineage relationships between these populations and further dissection using Gr-1, F4.80 and CD11c markers are being considered. CD117 is poorly expressed in osteoclastogenic precursors in the periphery.

In these studies we isolate progenitors from mice expressing GFP under the control of the col3.6 promoter. We reported that this promoter is active in hematopoietic cells, preferentially in the osteoclast lineage. Even when an explanation for this apparently anomalous behavior is not known, we have taken advantage of the system to visualize osteoclastogenesis in real time. This allows us to compare the kinetics of osteoclast formation between different putative progenitors, including fusion between different populations. Also it allows us to track the fate of progenitors *in vivo* after adoptive transfer. We have detected GFP/TRAP positive cells associated to endosteal areas shortly after transplanting hematopoietic stem cells from these mice into lethally irradiated recipients. Our findings will be important to identify equivalent populations in human peripheral blood to study their correlation with pathologies associated to bone resorption.

**The Pacemaker Channel, HCN, Controls Functions of Osteoclasts.** T. Notomi<sup>\*1</sup>, M. Kuno<sup>1</sup>, H. Amano<sup>2</sup>, T. M. Skerry<sup>3</sup>. <sup>1</sup>Molecular and Cellular Physiology, Graduate School of Medicine, Osaka City University, Osaka, Japan, <sup>2</sup>Department of Pharmacology, School of Dentistry, Showa University, Tokyo, Japan, <sup>3</sup>Academic Unit of Bone Biology, School of Medicine & Biomedical Sciences, University of Sheffield, Sheffield, United Kingdom.

Hyperpolarization-activated cyclic nucleotide (HCN) modulated channels plays fundamental roles as the pacemaker in excitable cells including those in the central nervous system and heart. Previously we reported that an HCN subtypes (HCN2) influences bone mass and strength. Since the role of other HCN subtypes in bone remains unknown, we investigated their functions.

The mRNA and protein for all four HCN subtypes, HCN1-4, were identified in mouse bone (C57/BL6, 4wk-old) by RT-PCR and immunoblotting. Localization of HCNs revealed site specific expression of different subtypes. HCN1 and HCN4 were both expressed in bone resorbing osteoclasts. HCN1 immunoreactivity was abundant in the sealing zone and ruffled border that is responsible for acid secretion. HCN2 and HCN3 were expressed in bone marrow cells and osteoblasts respectively. Patch clamp recordings from RAW cell showed the characteristic inward currents (I<sub>h</sub>) generated by HCN, and further that acidic condition accelerated the activation of I<sub>h</sub>. Following acute acidosis of osteoclasts loaded with a pH sensitive-dye, we showed that proton extrusion was inhibited by HCN antagonist (ZD7288) with a similar potency to the proton pump blocker (Bafilomycin). The differentiation of osteoclast from bone marrow cells was also inhibited by ZD7288.

Our findings suggested that HCNs have the key roles in the skeleton and particularly that HCN1 is important in osteoclast function. The regulation of HCN function by pH at sealing zone and ruffled border sites suggests that the role of the channels involves local proton homeostasis in the resorption lacuna.

**Endocytotic Processes Underlying Calcium-induced Inhibition of Plasma Membrane Vacuolar-type H<sup>+</sup>-ATPase in Murine Osteoclasts.** H. Sakai, T. Notomi<sup>\*</sup>, Y. Moriura<sup>\*</sup>, J. Kawawaki<sup>\*</sup>, M. Kuno. Osaka City Univ. Grad. Sch. Med., Osaka, Japan.

Vacuolar-type H<sup>+</sup>-ATPases (V-ATPases) are widely distributed from yeast to mammals and could transport H<sup>+</sup> across membranes against negative pH gradients. They acidify intracellular vesicles and generate proton-motive force. In osteoclasts, V-ATPases are rich at the ruffled membrane facing to the bone surface and plays an important role in acid secretion into the resorption pit. Acids demineralize bone tissue and Ca<sup>2+</sup> is accumulated in the closed extracellular compartment. The elevated Ca<sup>2+</sup> in turn inhibits osteoclast functions, thus serving as a negative feedback signal for bone resorption. As the V-ATPase is an electrogenic H<sup>+</sup> pump, electrophysiological recordings provide a most direct and quantitative method to evaluate the activity of functional V-ATPases. We recently succeeded to record proton currents of the plasma membrane V-ATPase in RAW264-derived osteoclast-like cells using the conventional whole-cell clamp technique, and revealed that the pump activity was inhibited by increased extracellular Ca<sup>2+</sup> (Sakai et al., 2006). V-ATPases are recruited to the plasma membrane by exocytotic fusion of lysosomal membranes. In this study, we investigated whether endocytotic/exocytotic processes were involved in the Ca<sup>2+</sup>-induced inhibition of the V-ATPase monitoring the cell capacitance (C<sub>m</sub>), a parameter parallel to surface area. The C<sub>m</sub> was calculated from capacitive currents evoked by depolarization pulses. Extracellular Ca<sup>2+</sup> (5-40 mM) decreased the H<sup>+</sup> current and the C<sub>m</sub> with similar time courses. Ca<sup>2+</sup>-induced inhibition was dose-dependent and was mimicked by Mg<sup>2+</sup>. The decrease in the C<sub>m</sub> by 40 mM Ca<sup>2+</sup> was ~15 pF, corresponding to ~10% of the control C<sub>m</sub> (~150 pF). An endocytotic inhibitor, bafilomycin A<sub>1</sub>, inhibited the Ca<sup>2+</sup>-induced decrease in the C<sub>m</sub>. Bafilomycin A<sub>1</sub>, however, did not decrease the C<sub>m</sub> further when the C<sub>m</sub> had been diminished already by high Ca<sup>2+</sup>. Thus Ca<sup>2+</sup> and bafilomycin may share the same mechanism in the inhibition. These data suggest that extracellular Ca<sup>2+</sup> triggers internalization of the V-ATPase through endocytosis, which may decrease the pump activity.

## SU102

**IL-27/WSX-1 Signaling Inhibits RANKL-induced Osteoclastogenesis through STAT1 Activation: A Possible Involvement in TLR4/MyD88-mediated Inflammatory Arthritis.** M. Furukawa, H. Takaishi, M. Yoda<sup>\*</sup>, T. Tohmonda<sup>\*</sup>, J. Takito<sup>\*</sup>, S. Sakai, M. Matsumoto<sup>\*</sup>, Y. Toyama<sup>\*</sup>. Orthopaedic, Keio university, Tokyo, Japan.

IL-27, a novel IL-12 family member of cytokines, has a role in limiting the intensity and duration of adaptive immune responses in controlling the early Th1 initiation and IFN- $\gamma$  production in naive CD4<sup>+</sup> T cells. Even though osteoclastogenic helper T cell subset links T cell activation and bone destruction, further clarification of the paradigms of early Th1 commitment step would provide approaches to therapeutic intervention. To elucidate a role of IL-27 in the regulation of inflammatory bone destruction, we examined a direct effect of IL-27 on human and mouse osteoclast precursors and analyzed the downstream signaling pathways of IL-27. 1) Mononuclear cells were isolated from bone marrow obtained through prosthetic joint replacement surgery by light density separation using MethoCult culture system. Recombinant IL-27 strongly inhibited RANKL-induced osteoclastogenesis from human colony-forming units granulocyte-macrophage (CFU-GM) cells. 2) IL-27 induced the phosphorylation of STAT1 and STAT3. IL-27 increased STAT1 mRNA by 20-fold in human CFU-GM cells. 3) IL-27-induced suppression of osteoclastogenesis was rescued by Fludarabine, STAT1 inhibitor. 4) IL-27 downregulated c-Fos protein and its transcriptional target NFATc1 mRNA in human CFU-GM cells. Confocal microscopy detected little nuclear NFATc1 in the multinucleated and mononucleated cells treated with IL-27. 5) IL-27 did not change the level of IFN- $\gamma$  and IL-10, anti-osteoclastogenic cytokine, in human CFU-GM cells. 6) Expression of p28 and EBI3 was increased by LPS stimulation. WSX-1-Fc chimera partially rescued the inhibition of osteoclastogenesis induced by LPS. 7) IL-27 weakly inhibited RANKL and M-CSF induced osteoclastogenesis from mouse bone marrow macrophages (BMM $\Phi$ ) through STAT1 activation. IL-27 induced IL-12 receptor mRNA expression in BMM $\Phi$ . 8) Escherichia coli-primed WSX-1 (a component of IL-27 receptor) KO mice after intraarticular challenge with LPS were more susceptible to reactive arthritis due to increased proinflammatory cytokine production. Taken together, IL-27/WSX-1 signaling inhibits RANKL-induced osteoclastogenesis through STAT1 activation. Recent study showed that IL-27 negatively regulates the development of Th17 during chronic inflammation, and neutralization of the p28 subunit exerts an anti-inflammatory effect. Therefore, IL-27/WSX-1 signal is a therapeutic target for suppressing inflammatory bone destruction in TLR4/MyD88-mediated arthritis.

**MEK5/ERK5 Signal Regulates RANKL-induced Osteoclastogenesis.** S. Uchikawa<sup>1</sup>, H. Takaishi<sup>1</sup>, T. Hikata<sup>1</sup>, A. Hakozaiki<sup>1</sup>, M. Furukawa<sup>1</sup>, S. Tomita<sup>\*1</sup>, T. Tohmonda<sup>\*1</sup>, M. Yoda<sup>\*1</sup>, J. Takito<sup>1</sup>, M. Matsumoto<sup>\*2</sup>, Y. Toyama<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Keio University, Tokyo, Japan, <sup>2</sup>Spine and Spinal Cord Disease, Keio University, Tokyo, Japan.

ERK5 belongs to an evolutionally conserved subfamily of mitogen-activated protein kinases (MAPKs) including extracellular-regulated protein kinase 1 and 2 (ERK1/2), c-Jun NH2-terminal protein kinases (JNKs), and p38 MAPKs. ERK5 activity is activated by growth factors, oxidative stress and serum stimulation via its TEY motif by MEK5. At present, details of the regulatory mechanism and a physiological function of the MEK5/ERK5 signaling in bone metabolism are unexplored. We aimed to clarify the role of the signaling in osteoclast differentiation. Western blots and RT-PCR revealed the expression of endogenous MEK5 and ERK5 in the bone marrow macrophages derived from ddY mouse and RAW264.7 cells. The activity of MEK5 and ERK5 was examined by measuring the luciferase reporter activity using pAP-1 luc and c-fos promoter luc in Cos7 cells. Cotransfection of a constitutive-active form of MEK5 with ERK5 increased the AP-1 luc activity by 200-fold and raised the c-fos promoter activity by 20-fold. But cotransfection of wild type or inactive form of MEK5 with ERK5 into Cos7 cells had no effects on the reporter activities. We used siRNA technology to examine the role of MEK5 in osteoclastogenesis. RAW264.7 cells were seeded at 5 x 10<sup>3</sup> cells/48-well. Next day, 30  $\mu$ M MEK5 siRNA or control siRNA was added to the medium. Osteoclast differentiation was induced by 50 ng/ml RANKL and the number of TRAP positive multinuclear cells was counted. MEK5 siRNA decreased the endogenous MEK5 mRNA to 10 % and attenuated the formation of TRAP positive multinuclear cells to 30% of control. From these results, we concluded that MEK5/ERK5 pathway probably regulated the transcriptional activity of c-fos and that the MEK5/ERK5 signaling acted as a positive regulator in RANKL-mediated osteoclastogenesis. We are currently exploring the upstream and downstream molecules of the MEK5/ERK5 signaling in osteoclastogenesis. Moreover, the analysis of physiological role of MEK5 *in vivo* is under investigation in our laboratory.

### A Novel Role for Thrombopoietin in Regulating Osteoclast Development.

A. F. Taylor<sup>\*1</sup>, C. L. T. Barnes<sup>\*2</sup>, M. C. Horowitz<sup>3</sup>, M. A. Kacena<sup>1</sup>.  
<sup>1</sup>Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Mallinckrodt Institute of Radiology, Barnes-Jewish Hospital, Washington University School of Medicine, St. Louis, MO, USA, <sup>3</sup>Orthopaedics and Rehabilitation, Yale University School of Medicine, New Haven, CT, USA.

Recent studies suggest that megakaryocytes (MKs) may play a significant role in skeletal homeostasis, as evident by the fact that multiple MK related diseases result in osteoclastogenesis. We have previously demonstrated that MKs have a pleiotropic effect on osteoblasts (OBs) and osteoclasts (OCs). Briefly, culturing OBs in contact with MKs increases OB proliferation, while co-culturing OC precursors with MKs or MK conditioned media results in an inhibition of OC formation. As OCs and MKs are derived from the same hematopoietic precursor, in these studies we sought to examine the potential role of the major MK growth factor, thrombopoietin (TPO), on osteoclastogenesis.

Using real-time PCR, Western blotting and immunocytochemistry we have identified c-mpl, the TPO receptor, in both primary (bone marrow macrophages from C57BL/6 mice (BMMs)) and clonal OC progenitors. Moreover, we also detected in these cells Ink, an important protein regulator of TPO induced intracellular signaling. Western blotting demonstrates that treating BMMs with 100 ng/ml of TPO activates a variety of intracellular signaling mechanisms, including phosphorylating members of the MAPK, and STAT signaling pathways. Western blotting also illustrated that AKT is not phosphorylated in BMMs treated with TPO.

To study the role of TPO in osteoclastogenesis, BMMs ( $1 \times 10^5$  cells/ml), were cultured with M-CSF (30 ng/ml) and RANKL (50 ng/ml) to induce OC formation. TPO (0.1-1000 ng/ml) was titrated into these cultures and OCs were identified as tartrate resistant acid phosphatase positive (TRAP<sup>+</sup>) giant cells with >3 nuclei. TPO treatment significantly enhanced OC formation up to six-fold ( $p < 0.01$ ). Interestingly, these data are dramatically different from the ten-fold decrease ( $p < 0.001$ ) we previously observed when we co-cultured BMMs with MKs.

These data also illustrate dramatic differences between the direct and indirect effect of TPO on osteoclastogenesis. Indirectly, TPO inhibits OC formation through the stimulation of MKs, while direct TPO application enhances osteoclastogenesis. Given that TPO is secreted by bone marrow stromal cells, and thus could act directly on OC precursors in vivo, these data highlight a novel and potentially therapeutic role for TPO in regulating osteoclastogenesis.

### Lysophosphatidic Acid Regulates Osteoclast Survival and Retraction.

D. M. Lapierre<sup>\*</sup>, M. M. Leblanc<sup>\*</sup>, A. Pereverzev<sup>\*</sup>, S. J. Dixon, S. M. Sims<sup>\*</sup>.  
 Physiology and Pharmacology, The University of Western Ontario, London, ON, Canada.

Lysophosphatidic acid (LPA) is a bioactive phospholipid consisting of a phosphoglycerol backbone with one fatty acyl chain. The functions of LPA are mediated primarily through five receptors (LPA1-5), which couple to multiple G proteins. In several cell types, LPA induces diverse responses, including differentiation, chemotaxis, migration, survival. LPA is released by activated platelets and is thought to play roles in wound healing and tumor progression. We have recently shown that osteoblasts also produce LPA, raising the possibility that LPA may mediate local signaling in bone between osteoblasts and osteoclasts. However, nothing is known about possible actions of LPA on osteoclasts. The aim of this study was to investigate the responses of osteoclasts to LPA. Osteoclasts were isolated from the long bones of neonatal rats and cytosolic free calcium concentration was measured using the calcium-sensitive dye fura-2. Focal application of LPA (5  $\mu$ M) elicited acute, transient increases in cytosolic calcium to peak amplitude of  $207 \pm 35$  nM above basal levels (mean  $\pm$  SEM). This response was concentration-dependent, with half maximal effects observed at 3  $\mu$ M LPA, and was blocked by the LPA1/3 receptor antagonist VPC-32183. In contrast to the effect of LPA, the inactive control compound oleoyl glycerol (3  $\mu$ M) did not evoke a rise of cytosolic calcium. Predominant expression of LPA1 (Edg2) was revealed by real-time RT-PCR analysis of purified osteoclasts generated in cultures of murine bone marrow cells. Digital time-lapse microscopy revealed that LPA (5  $\mu$ M) induced acute retraction of osteoclasts (planar area of osteoclasts was reduced to  $52 \pm 3\%$  of initial area). Cell counting and assessment of nuclear morphology were used to quantify osteoclast survival and apoptosis. LPA (5  $\mu$ M) enhanced survival of rat osteoclasts over a period of 18 hours from  $18 \pm 5\%$  to  $35 \pm 7\%$  ( $P < 0.001$ ). This effect was blocked by VPC-32183. At 6 hours, LPA (5  $\mu$ M) reduced the percentage of osteoclasts undergoing apoptosis from  $55 \pm 2\%$  to  $38 \pm 2\%$  ( $P < 0.001$ ), consistent with the effects of LPA on survival. This effect was also blocked by VPC-32183. This study reveals that osteoclasts express LPA1 and respond directly to LPA with elevation of cytosolic calcium and cellular retraction. Moreover, LPA reduces osteoclast apoptosis, enhancing survival. Thus, LPA may mediate intercellular signaling between osteoblasts and osteoclasts, a novel signaling axis in bone.

### VEGF Induction Provides Evidence for Different Signaling Pathway Activation by Large and Small Osteoclasts.

D. P. Trebec<sup>1</sup>, J. N. M. Heersche<sup>\*2</sup>, M. F. Manolson<sup>2</sup>. <sup>1</sup>Dept. of Biochemistry, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Increased bone resorption in several bone diseases (e.g. rheumatoid arthritis) is associated with increased osteoclast (OC) size in the affected areas, suggesting this increase in OC size is related to pathological resorptive activity. We have previously shown that large OCs ( $\geq 10$  nuclei) were more active and resorbed more bone and more frequently than smaller OCs (2-5 nuclei) (Lees et al, 2001). In addition, we found that large OCs express higher levels of activating receptors than small OCs (Trebec et al, 2007). We hypothesized that large and small OCs activate different signaling pathways in response to activating factors such as IL-1 $\beta$  and RANKL. Consequently, we performed a signaling pathway microarray using RNA isolated from large and small OCs differentiated from RAW 264.7-cells in the presence of RANKL to identify any differences in common signaling pathways. RNA was also isolated from large and small OCs exposed to IL-1 $\beta$  for 3 hours and compared to unstimulated OCs to identify early pathway activation events. Arrays demonstrated that overall a greater number of pathway target genes were activated in large OCs than in small OCs and at higher levels. There was also differential activation of vascular endothelial growth factors (VEGF). Small OCs expressed VEGF-C while large OCs expressed little VEGF-C resulting in 2.5-fold higher expression in small OCs compared to large. In response to IL-1 $\beta$  the difference between large and small OCs increased to 10-fold. In contrast, VEGF-A was expressed by large OCs but little induction was seen in small OCs resulting in 11-fold higher expression in large OCs compared to small OCs. However, VEGF-A expression in large OCs decreased in response to IL-1 $\beta$  and only a 4.5-fold difference in expression was seen in large OCs compared to small OCs treated with IL-1 $\beta$ . Furthermore, inhibitor studies suggested that the induction of VEGF-C and VEGF-A are mediated by different pathways and not solely through NF- $\kappa$ B signaling. In summary, these results suggest that large and small OCs use different signaling pathways. We currently hypothesize that the VEGFs in large and small OCs are induced by pathways other than the NF- $\kappa$ B pathway. This could provide information regarding their differential activation in response to activating factors under pathological conditions. The variations in VEGF expression could, in turn, result in different downstream activities of these OCs. Establishing mechanistic differences between large and small OCs could be exploited to stop pathological bone loss, or could be used as a marker for pathological bone loss in diseased versus normal tissue.

### RANKL Induces Calcium Channel Activation in Human Osteoclasts.

E. Chamoux<sup>1</sup>, M. Bisson<sup>\*2</sup>, M. Payet<sup>\*3</sup>, S. Roux<sup>2</sup>. <sup>1</sup>Rheumatology, Faculty of Medicine, University of Sherbrooke & Bishop's University, Sherbrooke, QC, Canada, <sup>2</sup>Rheumatology, Faculty of Medicine, University of Sherbrooke, Sherbrooke, QC, Canada, <sup>3</sup>Physiology - Biophysics, Faculty of Medicine, University of Sherbrooke, Sherbrooke, QC, Canada.

Most of the signaling effectors downstream RANK activation are calcium sensitive. However, early signaling events after RANKL binding remain scarcely understood, particularly for intracellular calcium mobilization in human osteoclasts. Using a model of primary human osteoclasts, our aim was to determine the characteristics of calcium response after RANKL binding. Cord blood monocytes were incubated for 18 days in presence of RANKL and M-CSF, thus leading to fully matured osteoclasts. Prior to experimentation, osteoclasts were loaded with Fura2-AM for 30 min, washed and up to 30 cells were selected for computation. Cells were sequentially excited with 340 and 380nm rays and optical densities of Fura2-emitted 510 nm rays were recorded. A ratio of calcium-bound (excited at 340 nm) to calcium-free (excited at 340 nm) Fura-2 light emission was thus generated. As Fura-2 is only found intracellularly, an increased ratio corresponds to an elevation of calcium ions in the cytosol. After a short equilibration period (stabilized ratio), cells were stimulated with various doses of RANKL. All doses varying from 10 to 200ng/ml of RANKL induced a rapid and significant increase in intracellular calcium. In order to better characterize the origin of this calcium spark, EGTA was added to the medium and lead to an almost complete reversal. Similarly, no calcium spark was observed when stimulations were conducted in calcium-free medium. We then depleted intracellular calcium stores by incubating cells overnight with Thapsigargin before RANKL stimulations. This did not affect the intracellular calcium increase, suggesting that the ion is brought from the extracellular medium. To further confirm these results, which differ from what has been described in rodent osteoclasts, we pre-incubated cells with a phospholipase C inhibitor (U73122) for 10 min before stimulation, in order to prevent intracellular store mobilization from inositol phosphate release. This condition again did not affect the RANKL-induced calcium spark. In contrast, the depolarization of membranes with KCl (200mM) induced an intracellular calcium increase similar to the one observed with RANKL, suggesting that a voltage-dependant calcium channel is present on human osteoclasts. Overall, our results showed that RANKL induces a strong elevation of intracellular calcium. Our experiments also strongly suggest an extracellular origin for this RANKL-induced calcium increase, likely due to the opening of calcium channels, which we have not identified yet, at the surface of human osteoclasts.

**AG490, A Jak2 Specific Inhibitor, Induces Osteoclast Survival by Activating Akt and ERK Signaling Pathway.** H. Kwak\*<sup>1</sup>, H. Sun\*<sup>2</sup>, H. Kim\*<sup>2</sup>, J. Lee\*<sup>2</sup>, H. Ha\*<sup>2</sup>, Z. Lee\*<sup>2</sup>. <sup>1</sup>Anatomy, School of Medicine, Wonkwang University, Iksan, Republic of Korea, <sup>2</sup>Cell & Developmental Biology, College of Dentistry, Seoul National University, Seoul, Republic of Korea.

Osteoclasts are multinucleated cells with the unique ability to resorb bone. Elevated activity of these cells under pathological conditions leads to the progression of bone erosion, such as osteoporosis, periodontal disease, and rheumatoid arthritis. Thus, the regulation of osteoclast apoptosis is important for bone homeostasis. In this study, we examined the effects of the Janus tyrosine kinases (JAK) 2 specific inhibitor AG490 on osteoclast apoptosis. We showed that AG490 greatly inhibited osteoclast apoptosis under conditions of survival factors deprivation and that suppressed the cleavage of pro-caspase-9 and -3 to its active forms. AG490 stimulated the phosphorylation of Akt and ERK. Adenovirus-mediated expression of dominant negative (DN)-Akt and DN-Ras in osteoclasts inhibited the survival of osteoclast despite the presence of AG490. Cytochrome c release during osteoclast apoptosis was inhibited by AG490 treatment, which was inhibited in the presence of LY294002 or U0126. AG490 suppressed pro-apoptotic proteins Bad and Bim, which was inhibited in osteoclasts infected with DN-Akt and DN-Ras adenovirus. In addition, constitutive active (CA)-MEK and (myristoylate) Myr-Akt adenovirus suppressed the cleavage of pro-caspase-9 and -3 and inhibited osteoclast apoptosis induced by etoposide. Taken together, our results suggest that AG490 inhibited cytochrome c release into cytosol at least partly by inhibiting pro-apoptotic proteins Bad and Bim and in turn suppressed caspase-9 and -3 activation, thereby inhibiting osteoclast apoptosis.

**Proteomic Identification and Characterization of the Small GTPase Rab18 in Human Osteoclasts.** A. Taylor\*, M. Rogers, F. Coxon\*. University of Aberdeen, Aberdeen, United Kingdom.

Rabs are a large family (>70 members) of small GTPases that play a crucial role in the regulation of intracellular vesicular trafficking. The correct subcellular localisation, and therefore function, of these proteins is dependent on prenylation, which involves the attachment of isoprenoid groups to C-terminal cysteine residues. We have found that anti-resorptive phosphonocarbonylate drugs specifically inhibit Rab prenylation, highlighting the critical role of these GTPases for osteoclast function. However, the expression profile and role of specific Rab GTPases in osteoclasts remains poorly understood. We have therefore employed a proteomic approach to identify the Rab GTPases that are highly expressed in osteoclasts. PBMCs were isolated from whole blood of healthy volunteers and osteoclasts generated by culturing with M-CSF and RANKL. These mature osteoclasts were then lysed in buffer containing triton X114, which enabled enrichment of the Rab GTPases following fractionation into aqueous and detergent-rich phases, since the prenylated Rab proteins partition into the latter. Enriched proteins were then separated by 2D SDS-PAGE and prenylated Rabs identified by overlaying with an identical gel from lysates of cells in which prenylated Rabs had been metabolically labelled using [<sup>14</sup>C]mevalonate. Selected spots were trypsin-digested and proteins identified by peptide analysis using MALDI-ToF. An alternative approach was also used, in which proteins enriched as above were separated by 1D SDS-PAGE, then spots corresponding to the molecular weight of Rabs (21-28kDa) were picked for analysis by LC-MS/MS. Using these two approaches we have identified 19 Rabs in human osteoclasts (all 19 by LC-MS/MS, but only 8 using MALDI-TOF), as well as Rap1, a prenylated GTPase that we previously showed to be highly expressed in osteoclasts. The Rabs identified include several that have been previously described in osteoclasts, including Rab7, Rab3D, Rab6 and Rab11 but also several that have not previously been described in osteoclasts. These include Rab18, for which there is no known role in any cell type, although it has been shown to localise to lipid droplets in several cell types. Using western blotting and immunostaining, we have confirmed that Rab18 is expressed in vesicular structures in osteoclasts, although its abundance is unaltered during RANKL-induced osteoclast differentiation. Moreover, EGFP-Rab18 clearly localised to the surface of lipid containing vesicles (particularly when formation of these vesicles was stimulated by incubation of the osteoclasts with oleic acid), but did not localise to endosomal vesicles. We are now analysing the function of Rab18 in osteoclasts using adenoviral delivery of a dominant-negative form and knockdown of expression using siRNA.

**Adiponectin Inhibits Osteoclast Formation via AKT Signaling Pathway.** Q. Tu, J. Zhang\*, B. Xu\*, E. Brewer\*, J. Chen. Department of General Dentistry, Tufts University School of Dental Medicine, Boston, MA, USA.

Adiponectin is an adipose tissue-derived hormone that has important functions in the regulation of lipid and glucose metabolism, immunity, cancer and bone formation. A link between adiponectin and bone homeostasis has been documented. A recent study revealed that adiponectin is able to inhibit RANKL-induced osteoclast differentiation. However, the signaling mechanisms responsible for the action of adiponectin remain largely unknown. The current study aimed to determine the signaling pathways in adiponectin-mediated inhibitory effects in osteoclast differentiation. We characterized molecules of the RANKL-stimulated NFATc1 signaling using RAW264.7 cells stably transfected with a luciferase reporter driven by an osteoclast specific cathepsin K (CtSK) promoter. We also determined the transduction pathway of kinase AKT in regulating apoptosis of osteoclasts and NFATc1 level in nuclei by

fluorescence peptide substrate-based assay, homogeneous caspase assays (Promega) and gene expression quantification. The results showed that recombinant globular adiponectin strongly inhibited CtSK promoter activity in a dose- and time-dependent manner in RAW264.7 cells cultured in the presence of RANKL, which was consistent with our observation that the expressions of RANKL-induced NFATc1 and other osteoclastic differentiation markers such as cathepsin K or TRACP were reduced significantly. MTT survival assay demonstrated that adiponectin decreased RAW264.7 cell proliferation during RANKL-mediated differentiation. Caspase activity assays also showed that the activity levels of apoptosis executioner caspases-3 and initiator caspases-8 and -9 were much higher in RAW264.7 cells treated with adiponectin and RANKL than in those treated with RANKL alone for 3 days. Moreover, RAW264.7 cells treated with adiponectin exhibited decreased activation of AKT signaling, an anti-cell apoptosis and pro-NFATc1 activation pathway signaled by RANKL. Furthermore, overexpression of APPL1, a key adaptor protein mediating adiponectin signaling and coordinating different pathways, reduced AKT-mediated downstream events. Taken together, our findings for the first time indicate that adiponectin negatively regulate RANKL-mediated osteoclast formation by decreasing osteoclastogenesis and osteoclast survival, and increasing osteoclast apoptosis via suppressing AKT pathway. APPL1 may act as a critical regulator of the crosstalk between adiponectin signaling and RANKL signaling pathways.

**Investigations into the Role of Focal Adhesion Kinase (FAK) in Bone Marrow-Derived Osteoclasts.** B. J. Ray\*, A. H. Bouton\*. Microbiology, University of Virginia, Charlottesville, VA, USA.

The focal adhesion kinase (FAK) family of protein tyrosine kinases contains two members, FAK and proline-rich tyrosine kinase 2 (Pyk2), which are both expressed in osteoclasts. Pyk2<sup>-/-</sup> mice are mildly osteopetrotic and display defects in sealing zone formation and bone resorption. FAK is also thought to be involved in bone resorption; however a global FAK knockout is embryonic lethal in mice, making it difficult to evaluate the role of FAK in bone and other tissues. Our lab has developed a mouse model in which FAK is conditionally deleted in cells of the myeloid lineage, which includes osteoclasts. Five-week old mice with this conditional knockout contained equivalent numbers of osteoclast progenitor cells in bone marrow compared to control mice. Differentiation of bone marrow cells into preosteoclasts and multinucleated osteoclasts does not appear to be impaired in FAK<sup>-/-</sup> cells compared to their wildtype counterparts. However, FAK<sup>-/-</sup> osteoclasts display defects in bone resorption marked by a decrease in the area of degradation pits that form on bone discs. This coincides with potential abnormalities in podosome and sealing zone structure. Preliminary data using total internal reflection fluorescence (TIRF) microscopy indicate that cortactin, which is a major plaque protein that is present in these structures, may be mislocalized in FAK<sup>-/-</sup> osteoclasts. These data show for the first time that, in addition to Pyk2, FAK also plays a critical role in osteoclast function. Future studies will focus on identifying common and unique functions of FAK and Pyk2 within this cell population and on determining whether FAK expression in osteoclasts impacts bone density.

**The Ubiquitin-Like Domain of IKK $\beta$  Is Critical for Osteoclastogenesis.** J. Otero\*<sup>1</sup>, Y. Zhang\*<sup>2</sup>, M. Kuziez\*<sup>2</sup>, S. Dai\*<sup>2</sup>, Y. Abu-Amer\*<sup>2</sup>. <sup>1</sup>Orthopedic Surgery and DBBS, Washington University School of Medicine, Saint Louis, MO, USA, <sup>2</sup>Orthopedic Surgery and Cell Biology & Physiology, Washington University School of Medicine, Saint Louis, MO, USA.

Nuclear Factor kappa B (NF- $\kappa$ B) is a family of transcription factors with conserved structural and functional characteristics that regulates various cellular and pathological processes such as immune system development, cell survival, and inflammatory signaling. NF- $\kappa$ B is considered an immune-modulator of rheumatoid arthritis and inflammatory osteolysis. NF- $\kappa$ B is also essential for osteoclast development and survival, evidenced by the osteopetrotic phenotype displayed by mice doubly deficient in subunits NF- $\kappa$ B1 and NF- $\kappa$ B2. Under normal and naïve conditions, NF- $\kappa$ B proteins are bound to inhibitory proteins and reside inactive in the cytoplasm. A wide range of cellular stimuli prompt activation of NF- $\kappa$ B. This activation is controlled by the upstream I $\kappa$ B kinase (IKK) complex which contains, among other proteins, IKK $\alpha$ , IKK $\beta$ , and IKK $\gamma$ . The role of IKK $\alpha$  and IKK $\beta$  in the skeletal development and inflammatory osteolysis has been described. However, the precise molecular mechanisms underlying IKK regulation of osteoclasts remains enigmatic. Since mice lacking IKK $\beta$  in osteoclast precursors suffer from osteopetrosis due to a defect in osteoclastogenesis, it is critical to functionally identify the domains of IKK $\beta$  which are required for its function in the setting of osteoclast differentiation. Prior studies have shown that the NEMO-binding domain of IKK $\beta$  regulates osteoclastogenesis and inflammatory osteolysis. Another candidate domain which has been shown to be absolutely required for IKK $\beta$  function is the Ubiquitin-Like Domain (ULD). Using retroviral delivery system compatible with osteoclast precursors, we demonstrate that IKK $\beta$  which lacks the ULD (IKK $\beta$  dULD) fails to rescue osteoclastogenesis in osteoclast precursors deficient in endogenous IKK $\beta$  compared with successful rescue using the wild type IKK $\beta$  form. Furthermore, IKK $\beta$  lacking the ULD domain (dULD) inhibits osteoclastogenesis in wild-type osteoclast precursors, and this inhibition correlates with a defect in p65 nuclear translocation and NF- $\kappa$ B DNA binding activity in response to RANKL. IKK $\beta$  dULD is also capable of inhibiting NF- $\kappa$ B activity in response to overexpression of wild-type IKK $\beta$  in IKK $\beta$ -deficient mouse embryonic fibroblasts, indicating that it possesses dominant negative activity. Our studies suggest that the ubiquitin-like domain of IKK $\beta$  may be a useful target for the treatment of osteoclast mediated diseases.

### Efficient and Stable Gene Expression into Human Osteoclasts Using an HIV-1 Based Lentiviral Vector. K. Chu<sup>1</sup>, K. G. Cornetta<sup>\*2</sup>, M. J. Econs<sup>1</sup>.

<sup>1</sup>Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA.

**Introduction:** Since osteoclasts are terminally differentiated cells without proliferating activity, efficient and stable gene expression into these cells remains a difficulty. In the current study, we investigate gene transduction into human pre-osteoclasts by a replication defective lentivirus-based vector containing a modified HIV-1 genome.

**Methods:** Human pre-osteoclasts (differentiating osteoclasts) were transduced with lentiviruses bearing an enhanced green fluorescence protein reporter gene. Transduction efficiencies were measured by flow cytometry for EGFP protein expression. Sorted human transduced pre-osteoclasts were re-plated and differentiated under hM-CSF and hRANKL. Mature osteoclasts were then analyzed by the cell viability assay, TRACP assay, and pit formation assay.

**Results:** Efficient gene transduction was obtained at multiplicity of infection of 10 and gene expression lasted for over 4 weeks using our protocol. Lentiviral transduction did not affect osteoclast survival, formation, or function.

**Conclusions:** These results establish an efficient method for gene transduction into human pre-osteoclasts using a lentiviral vector. Importantly, these transduced pre-osteoclasts could differentiate into mature osteoclasts without a negative impact from the lentiviruses. This protocol provides a new tool for studies of osteoclast biology. Further work in this area may open new avenues for the study of osteoclast gene signaling and gene therapy of disorders of osteoclast function.

### Suppression of TREM-2 Expression and TREM-2-mediated Costimulation of RANK Signaling by Cytokines that Inhibit Human Osteoclast Differentiation. K. Park-Min<sup>\*1</sup>, M. Humphrey<sup>\*2</sup>, M. Nakamura<sup>\*3</sup>, L. B. Ivashkiv<sup>\*1</sup>.

<sup>1</sup>Hospital for Special Surgery, New York, NY, USA, <sup>2</sup>Department of Medicine and Microbiology and Immunology, VA Medical Center and University of Oklahoma Health Science Center, Oklahoma City, OK, USA, <sup>3</sup>Department of Medicine, VA Medical Center, University of California, San Francisco, CA, USA.

TREM-2 (triggering receptor expressed on myeloid cells 2) is an ITAM-associated immunoreceptor that plays an important role in bone resorption and osteoclastogenesis in humans by providing costimulation for signaling by RANK (Receptor Activator of Nuclear Factor  $\kappa$  B), a key receptor required for osteoclast differentiation. We found that TREM-2 expression is induced in parallel with RANK expression during generation of human osteoclast precursors and in synovial macrophages in rheumatoid arthritis. In contrast to RANK, TREM-2 expression was not dependent on M-CSF and was inhibited by interferons (IFNs) and interleukin-10 (IL-10), potent inhibitors of human osteoclastogenesis. IL-10 inhibited TREM-2 expression by a transcriptional mechanism and suppressed costimulation of RANK signaling, leading to the attenuation of calcium oscillations, NFATc1 expression, and inhibition of a newly described CaMKII-MEK-ERK calcium-dependent signaling pathway downstream of RANK. These findings provide a new mechanism of inhibition of human osteoclast differentiation and implicate regulation of TREM-2 expression as an important component of human osteoclast differentiation that can be effectively targeted for inhibition.

### Breast Cancer Derived Factors Synergize with TGF $\beta$ to Induce Phosphorylation of ERK1/2 and to Stimulate Osteoclastogenesis. K. Tiedemann<sup>\*1</sup>, O. Hussein<sup>\*1</sup>, E. Gusev<sup>\*1</sup>, P. M. Siegel<sup>\*2</sup>, S. V. Komarova<sup>1</sup>.

<sup>1</sup>Faculty of Dentistry, McGill University, Montreal, QC, Canada, <sup>2</sup>Departments of Biochemistry and Medicine, McGill University, Montreal, QC, Canada.

**Background:** Breast cancer metastasizes to bone, giving rise to osteolytic lesions. Tumor cells cannot resorb bone but act by stimulating osteoblasts to produce osteoclastogenic cytokine RANKL, which subsequently stimulates osteoclast formation. We have recently found that soluble factors secreted from human breast carcinoma cells (MDA-MB-231), also can directly stimulate osteoclast formation from RANKL-primed precursors. The objective of this study was to examine signaling events induced in osteoclast precursors by breast cancer-derived factors.

**Method:** Osteoclast precursors, RAW 264.7 murine monocytic cells were primed with RANKL for 2 days, after which the cells were either cultured without addition, or were treated with RANKL or conditioned medium (CM) from MDA-MB-231 cells. Protein was extracted from parallel samples after 15 min - 2 h of treatment. To study calcium dynamics, osteoclast precursors were loaded with calcium sensitive dye fura-2 and examined using microspectrofluorimetry.

**Results:** MDA-MB-231 CM strongly induced sustained phosphorylation of ERK1/2, which was evident for at least 1 h after initiation of the treatment. In contrast, no significant

ERK1/2 phosphorylation was observed in RANKL-treated or untreated osteoclast precursors. Treatment of MDA-MB-231 CM with a neutralizing antibody for TGF $\beta$  did not affect ERK1/2 phosphorylation at early time points (30 min), but inhibited it at later times (1 h). Similar to the effects of anti-TGF $\beta$ , inhibition of MEK1/2 with PD98059 prevented ERK1/2 phosphorylation at 1 h. Since it was recently shown that PKC $\alpha$  may directly phosphorylate ERK1/2, we assessed its role using PKC inhibitor Go6976. Inhibition of PKC prevented ERK1/2 phosphorylation at all times. Since PKC $\alpha$  is a calcium-dependent isoform, we assessed if MDA-MB-231 CM affects calcium levels in osteoclast precursors. We have found that both in untreated RAW 264.7 cells and in osteoclast precursors primed with RANKL for 2 days, MDA-MB-231 CM (but not control media conditioned by normal breast cells MCF10A) induced elevation in cytosolic free calcium, resulting in calcium oscillations in some cells.

**Conclusion:** We have found that calcium/PKC pathway synergizes with TGF $\beta$ /MAPK pathway at the level of ERK1/2 phosphorylation, likely contributing to RANKL-primed osteoclast precursors' ability to respond to breast cancer-derived factors. Supported by CIHR, CRC and NSERC

### Histone Deacetylase Inhibitors Suppress Interleukin-1 $\beta$ -induced Nitric Oxide and Prostaglandin E<sub>2</sub> Production In Human Chondrocytes. N. Chabane<sup>\*</sup>, N. Zayed<sup>\*</sup>, H. Afif<sup>\*</sup>, J. Martel-Pelletier<sup>\*</sup>, J. P. Pelletier<sup>\*</sup>, H. Fahmi<sup>\*</sup>.

CHUM, Université de Montréal, Montreal, QC, Canada.

**Objective:** Overproduction of nitric oxide (NO) and prostaglandin (PG) E<sub>2</sub> plays an important role in the pathogenesis of osteoarthritis (OA). In the present study, we determined the effect of trichostatin A (TSA) and butyric acid (BA), two histone deacetylase (HDAC) inhibitors, on NO and PGE<sub>2</sub> synthesis, inducible NO synthase (iNOS) and cyclooxygenase (COX)-2 expression, and NF- $\kappa$ B DNA-binding activity, in interleukin-1 $\beta$  (IL-1)-stimulated human OA chondrocytes, and on IL-1-induced proteoglycan degradation in cartilage explants.

**Methods:** Chondrocytes were stimulated with IL-1 in the absence or presence of increasing concentrations of TSA or BA. The production of NO and PGE<sub>2</sub> was evaluated using Griess reagent and an enzyme immunoassay, respectively. The expression of iNOS and COX-2 proteins and mRNAs were evaluated using Western blotting and real-time reverse transcriptase-polymerase chain reaction (RT-PCR), respectively. Proteoglycan degradation was measured with dimethylmethylene blue assay. Electrophoretic mobility shift assay (EMSA) was utilized to analyze the DNA binding activity of NF- $\kappa$ B.

**Results:** HDAC inhibition with TSA or BA resulted in a dose-dependent inhibition of IL-1-induced NO and PGE<sub>2</sub> production. IL-17- and tumor necrosis factor- $\alpha$  (F- $\alpha$ )-induced NO and PGE<sub>2</sub> production was also inhibited by TSA and BA. This inhibition correlated with the suppression of iNOS and COX-2 protein and mRNA expression. TSA and BA also prevented IL-1-induced proteoglycan release from cartilage explants. Finally, we demonstrate that the DNA-binding activity of NF- $\kappa$ B, was induced by IL-1, but was not affected by treatment with HDAC inhibitors.

**Conclusions:** These data indicate that HDAC inhibitors suppressed IL-1-induced NO and PGE<sub>2</sub> synthesis, iNOS and COX-2 expression, as well as proteoglycan degradation. The suppressive effect of HDAC inhibitors is not due to impaired DNA-binding activity of NF- $\kappa$ B. These findings also suggest that HDAC inhibitors may be of potential therapeutic value in the treatment of OA.

### Latexin Is a Novel Effector Of BMP-2 Signaling in Modulation of Chondrocyte Differentiation. I. Kadouchi<sup>\*1</sup>, K. Sakamoto<sup>\*2</sup>, T. Murakami<sup>\*3</sup>,

E. Kobayashi<sup>\*3</sup>, Y. Hoshino<sup>\*1</sup>, A. Yamaguchi<sup>2</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Jichi Medical University, Tochigi, Japan, <sup>2</sup>Section of Oral Pathology, Tokyo Medical and Dental University, Tokyo, Japan, <sup>3</sup>Division of Organ Replacement Research, Center of Molecular Medicine, Jichi Medical University, Tochigi, Japan.

We identified latexin (Lxn), a unique inhibitor of endogenous carboxypeptidase A, as a downstream target of BMP-2 signaling in mesenchymal cell lines by microarray analysis using Runx2-deficient cells with or without BMP-2 treatment. Lxn expression was also significantly upregulated in MC3T3-E1 and C2C12 cells with BMP-2 treatment. In situ hybridization and immunohistochemical staining revealed that Lxn was expressed in chondrocytes and perichondrium in day 13.5 embryo, and in the mesenchymal cells and chondrocytes at the site of bone regeneration in adult mice. Lxn expression was increased in parallel with the chondrogenic differentiation of C3H10T1/2 cells cultured under a high-density micromass condition with BMP-2 treatment. We generated C3H10T1/2 cells that stably overexpressed Lxn using a retroviral vector. In the Lxn-overexpressing C3H10T1/2 cells, chondrogenic potential was significantly increased compared with the original C3H10T1/2 cells, as demonstrated by the alcian blue staining and the expression of *type II collagen*, *type X collagen* and *aggrecan*. Our data indicates that Lxn is a downstream factor of BMP-2 signaling and may play an important role in modulating the chondrogenic differentiation.

**DHCR24 Gene Is Mandatory for the Proper Growth of Long Bone.** R. Mirza<sup>\*1</sup>, T. Miyamoto<sup>2</sup>, T. Kaji<sup>\*3</sup>, Y. Murata<sup>\*4</sup>, H. Seo<sup>\*1</sup>. <sup>1</sup>Biomedical Science, College of Life and Health Sciences, Chubu University, Kasugai, Japan, <sup>2</sup>Department of Orthopedic Surgery, Keio University School of Medicine, Tokyo, Japan, <sup>3</sup>Pharmaceutical Research Unit, Research and Development division, Mitsubishi Pharma Corporation, Yokohama, Japan, <sup>4</sup>Department of Genetics, Research Institute of Environmental Medicine, Nagoya University, Nagoya, Japan.

DHCR24 gene encodes an enzyme catalyzing conversion of desmosterol to cholesterol. Desmosterolosis is an autosomal recessive disease due to mutations in DHCR24 gene, with severe developmental abnormalities including limb anomalies and short stature. To find out the mechanisms involved in these abnormalities, we utilized DHCR24 knockout mice in our study. It is known that DHCR24 can protect cells from oxidative stress in some cell lines, but its function on bone growth has not been studied yet. As the DHCR24<sup>-/-</sup>(KO) mice die soon after birth, we investigated the growth of metatarsal bone in culture obtained from newborn KO mice. The longitudinal growth of bone was retarded and the rate of bone growth started to decrease significantly after one week of culture. The metatarsal bone of one week culture showed less proliferating chondrocytes in the growth plate. At the same time, abnormal hypertrophy of the chondrocytes in the prehypertrophic zone was observed in the bone from KO mice. It is recently reported that oxidative stress could induce chondrocyte hypertrophy. We demonstrated that DHCR24 acts as potent ROS scavenger. These observations led us to treat the bone from KO mice with an antioxidant, NAC (N-acetyl L cysteine). The treatment could recover the hypertrophy of chondrocyte and could restore the proliferating zone after one week of culture. Since hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) treatment for 48 hrs has been shown to induce the genes for the chondrocyte hypertrophy such as mmp13, collagen type X and Runx2 in the ATDC5 cells. We infected the ATDC5 cells with adenovirus expressing DHCR24. As expected, the expression of the above mentioned genes was significantly decreased in the adenovirus infected cells after H<sub>2</sub>O<sub>2</sub> treatment. Thus DHCR24 gene can protect chondrocytes from H<sub>2</sub>O<sub>2</sub> induced hypertrophy. This is the first demonstration that expression of DHCR24 gene is mandatory for proper bone growth.

**Protein Sulfation Is Required to Prevent Chondrocytes Autophagy and Growth Factor Signaling During Endochondral Ossification.** C. Settembre<sup>\*1</sup>, E. Artega<sup>\*1</sup>, M. D. McKee<sup>\*2</sup>, A. Ballabio<sup>\*3</sup>, G. Karsenty<sup>\*1</sup>. <sup>1</sup>Columbia University, NY, NY, USA, <sup>2</sup>McGill University, Montreal, QC, Canada, <sup>3</sup>Tigem, Napoli, Italy.

Growth plate extracellular matrix is mainly composed of collagen fiber and proteoglycans. Proteoglycans consists of a core protein decorated by highly sulfated sugar chains, known as glycosaminoglycans (GAGs). Although the extent of proteoglycan sulfation regulates many developmental processes its role during endochondral ossification has not been systematically analyzed. The extent of sulfation of the GAGs moiety of proteoglycans is regulated by a group of enzymes called sulfatases whose activity is regulated by Sulfatase Modifying Factor 1 (Sumf1). Sumf1 is highly expressed in proliferating chondrocytes and osteoblasts and its inactivation in humans results in severe and complex skeletal abnormalities. Thus to address the importance of protein sulfation during endochondral ossification we generated and analyzed Sumf1<sup>-/-</sup> mice. This analysis showed that the extent of protein sulfation affects profoundly chondrocytes survival. Indeed, in absence of Sumf1 proliferating chondrocytes die through autophagy and produce less extracellular matrix. Remarkably none of these cellular abnormalities are observed in osteoblasts. Additionally proteoglycan sulfation regulates chondrocytes maturation. Preliminary results suggest that this latter function of Sumf1 relates to the importance of proteoglycan sulfation in transducing appropriately FGF signaling in the growth plate. Together these results establish that extracellular matrix through the extent of GAG sulfation affects endochondral ossification by acting on chondrocytes in several ways: it prevents chondrocytes autophagy, promotes ECM production and favours growth factor signaling.

**Reduced Cell Proliferation and Chondrodysplasia in Mice Lacking the Mitotic Protein NuSAP.** A. Vanden Bosch<sup>\*1</sup>, S. Torrekens<sup>\*1</sup>, M. Van Camp<sup>\*1</sup>, R. Bouillon<sup>1</sup>, P. Carmeliet<sup>\*2</sup>, G. Carmeliet<sup>1</sup>. <sup>1</sup>Experimental Medicine, KULeuven, Leuven, Belgium, <sup>2</sup>VIB Vesalius Research Center, KULeuven, Leuven, Belgium.

During endochondral ossification, chondrocyte proliferation and differentiation within the cartilage growth plate are the driving forces behind longitudinal bone growth. Proliferation is strictly controlled by several cell cycle checkpoints including the spindle checkpoint, however, their role in bone development is largely unknown. NuSAP is a spindle-associated protein, expressed in proliferating cells and essential for normal mitosis of cultured cells and developing mouse embryos. To investigate whether triggering mitotic defects would activate cell cycle control mechanisms during bone development, we generated chondrocyte-specific NuSAP null mice by crossing *Nusap*<sup>fl/fl</sup> mice with mice expressing the Cre recombinase driven by the collagen 2 promoter (*Nusap*<sup>chm/-</sup>). *Nusap*<sup>chm/-</sup> mice were born at a normal frequency and were comparable in size and weight to control (*Nusap*<sup>chm+/+</sup>) mice. However, mutant mice died at birth, due to asphyxia, for their ribs were splayed and their sternum was shorter, resulting in a narrow, bell-shaped thoracic cage.

The long bones of *Nusap*<sup>chm/-</sup> pups at embryonic day 18.5 (E18.5) were shorter than those of control littermates (tibias: 3.5 mm compared to 4.1 mm for controls; p=0.003). Furthermore, H&E staining revealed that NuSAP inactivation lead to a chondrodysplasia characterized by smaller growth plates, disturbed columnar organization of the flat chondrocytes and a manifest disorganization of the hypertrophic zone. The number of hypertrophic chondrocytes was decreased, their size was highly variable and empty lacunae were present between cells. As expected, proliferation, assessed by BrdU incorporation, was significantly decreased, and almost absent in the region of the flat chondrocytes of *Nusap*<sup>chm/-</sup> growth plates. Apoptosis on the other hand, was increased and present at abnormal sites, as shown by TUNEL labeling. The mechanism responsible for induction of apoptosis was investigated. In primary chondrocyte cultures derived from E18.5 *Nusap*<sup>chm/-</sup> embryos, p53 levels were three-fold increased compared to controls. Concomitantly, the expression of the cell cycle inhibitor p21 and of the pro-apoptotic protein Bax was markedly increased.

In summary, our results demonstrate that mitotic defects in chondrocytes, induced by NuSAP deficiency, lead to p53-dependent apoptosis. NuSAP is thus essential for chondrocyte proliferation and for maintaining normal growth plate architecture and function.

**Role of Wdr5 in Endochondral Bone Formation During Chicken Limb Development.** S. Zhu<sup>1</sup>, E. Zhu<sup>\*1</sup>, S. Provot<sup>2</sup>, F. Gori<sup>1</sup>. <sup>1</sup>Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA, <sup>2</sup>Department of Anatomy, UCSF, San Francisco, CA, USA.

Wdr5 is expressed in chondrocytes and osteoblasts in vitro and in vivo. While in vitro stable expression of Wdr5 dramatically accelerates osteoblast differentiation, silencing of Wdr5 markedly inhibits osteoblast differentiation. Targeted expression of Wdr5 to osteoblasts, using the 2.3-kb fragment of the mouse  $\alpha(1)$  I collagen promoter results in accelerated osteoblast differentiation during mouse embryonic development. To address whether Wdr5 is required for endochondral bone formation in vivo, a Replication Competent Avian No Splicer (RCAN) system delivering Wdr5 short hairpin RNA (shRNA) was utilized to silence Wdr5 expression throughout the developing chicken limb. High-titer RCAN-shWdr5 and RCAN-scrambled retroviral inoculates were injected into the right limb bud of chick embryos at Hamburger&Hamilton (HH) stage 18-20 (E3-3.5), when mesenchyme condensation begins. Embryos were harvested at HH stage 35 (E8.5), 36 (E10.5) and 38 (E12.5) to evaluate chondrocyte and osteoblast differentiation. The uninfected left wings served as controls. Alcian Blue and Alizarin Red staining of whole mount skeletons showed that RCAN-shWdr5 infected wings were shorter and displayed reduced mineralized bone compared to uninfected left wings at all time points. Histological analyses showed that RCAN-shWdr5 infected wings displayed a smaller hypertrophic chondrocyte layer and a delay in vascular invasion compared to uninfected left wings. Histological analyses were confirmed by in situ hybridization. While, the uninfected left wings displayed a normal pattern of chondrocyte and osteoblast maturation, RCAN-shWdr5 infected wings displayed higher expression of Sox9 and reduced type X collagen, and osteopontin expression compared to uninfected left wings, suggesting that silencing of Wdr5 resulted in delay of chondrocyte differentiation. RCAN-shWdr5 infected wings displayed also reduced type I collagen expression and mineral deposition as shown by Von Kossa staining, suggesting that silencing of Wdr5 also resulted in impaired osteoblast differentiation. Some of RCAN-shWdr5 infected wings exhibited a more severe phenotype. These wings displayed considerably shorter and thicker skeletal elements of the zeugopod and stylopod and absence of mineralized bone relative to the uninfected left wings. Proximal elements of the autopod, such as the carpo-metacarpus, were significantly shorter and phalanges 3 and 4 were missing, suggesting that Wdr5 is required for proper limb patterning and outgrowth. Taken together, these findings demonstrate that Wdr5 is required for proper endochondral bone formation and suggest that Wdr5 may play a role in limb patterning and outgrowth.

**TGF $\beta$  and Smad3-dependent Repression of Runx2 Function in ATDC5 Chondrocytes.** E. N. Chin\*, T. Alliston. Orthopaedic Surgery, University of California, San Francisco, San Francisco, CA, USA.

Transforming growth factor- $\beta$  (TGF $\beta$ ) is an essential anabolic cytokine for articular chondrocytes. TGF $\beta$  induces the expression of extracellular matrix proteins such as aggrecan and collagen II, and inhibits resting articular chondrocytes from undergoing hypertrophic differentiation. The mechanisms by which TGF $\beta$  inhibits terminal chondrocyte differentiation remain unclear. Previously, we demonstrated that TGF $\beta$  inhibits terminal osteoblast differentiation by repressing the expression and function of Runx2. Specifically, TGF $\beta$  inhibits Runx2 function through Smad3-mediated recruitment of class II histone deacetylases to Runx2-binding promoter elements. In chondrocytes, Runx2 drives terminal differentiation, hypertrophy, and the expression of hypertrophy of late-stage differentiation markers, including collagen X and matrix metalloproteinase-13 (MMP-13). TGF $\beta$  can inhibit the expression of both collagen X and MMP-13. Thus, we seek to determine if TGF $\beta$  represses Runx2 function in chondrocytes to inhibit the expression of late-stage differentiation markers and the progression of hypertrophic chondrocyte differentiation. Here we test the hypothesis that TGF $\beta$  represses Runx2 through a Smad3-dependent mechanism.

Murine ATDC5 chondroprogenitor cells were transiently transfected with a synthetic Runx2-responsive promoter reporter construct, pOSE2-Luciferase. Reporter activity was normalized to  $\beta$ -galactosidase expression from a cotransfected control plasmid. Consistent with previous reports, overexpression of Runx2 increased relative luciferase activity. However, treatment with TGF $\beta$ 1 repressed the activity of this Runx2 reporter plasmid in a dose dependent manner. Cotransfection of a constitutively active TGF $\beta$  type I receptor construct also repressed pOSE2-Luc reporter activity. To determine if TGF $\beta$  repression of pOSE2-Luc reporter activity was Smad3-dependent, ATDC5 cells were cotransfected with a Smad3 expression construct. Overexpression of Smad3 conferred even greater TGF $\beta$ -dependent repression of pOSE2-Luc activity. TGF $\beta$ /Smad3 dependent repression of pOSE2-Luc activity in chondrocytes was comparable to that observed in osteoblasts and mesenchymal cells. Using a combination of quantitative reverse-transcription PCR and additional promoter-reporter constructs, we are currently investigating the extent to which TGF $\beta$  and Smad3 repress Runx2 function to regulate the transcription of chondrocyte genes. In conclusion, TGF $\beta$  and Smad3 repress the transcriptional activity of Runx2 in chondrocytes and may play a role in the regulation of endogenous chondrocyte gene expression and chondrocyte differentiation.

**Chondrocyte Differentiation Is Differentially Affected by Cyclooxygenase-2 and 5-Lipoxygenase during Fracture Healing.** J. A. Cottrell\*, J. P. O'Connor. Biochemistry & Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

Bone regeneration following a fracture is critically regulated by arachidonic acid (ArA) metabolism. Following release from membrane stores, ArA is converted into prostaglandins or leukotrienes via cyclooxygenase-2 (COX-2) or 5-lipoxygenase (5-LO) activity. Using radiographic, histomorphometric, and mechanical testing analyses, we have demonstrated that COX-2 and 5-LO have diametric effects on bone regeneration. Whereas fracture healing is impaired in COX-2 knockout mice, fracture healing is dramatically accelerated and enhanced in 5-LO knockout mice. Similarly, fracture healing is impaired in rats treated with a COX-2 inhibitor (celecoxib) but is accelerated in rats treated with a 5-LO inhibitor (AA-861). To elucidate the mechanism by which COX-2 and 5-LO regulates fracture healing, cell proliferation and gene expression were analyzed during femur fracture healing in female Sprague-Dawley rats treated with oral doses of celecoxib, AA-861, or vehicle (1% methylcellulose). Following fracture, cell proliferation analysis showed that callus cell proliferation peaked at day 2 after fracture in rats treated with AA-861 as compared to day 4 in vehicle-treated rats. Celecoxib treatment significantly reduced callus cell proliferation even though the 4-day calluses from the celecoxib-treated rats had the highest number of cells. RT-qPCR analysis of chondrocyte differentiation markers revealed that Type II collagen expression was significantly elevated in celecoxib and AA-861 treated rat fracture calluses. However, only AA-861 treatment significantly increased Type X collagen expression. These data indicate that COX-2 and 5-LO regulate chondrocyte differentiation during fracture healing endochondral ossification. COX-2 appears to be necessary for the progressive differentiation of chondrocytes whereas 5-LO activity appears to normally limit this progression. By altering chondrocyte differentiation during fracture healing, loss or inhibition of COX-2 delays healing while loss or inhibition of 5-LO accelerates healing.

**Phosphate Regulates Chondrocyte Differentiation, Proliferation and Apoptosis in a Model of Embryonic Endochondral Bone Formation.** A. A. Zalutskaya, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Phosphate is required for terminal differentiation of hypertrophic chondrocytes during postnatal growth plate maturation. To investigate whether extracellular phosphate plays a role during embryonic endochondral bone formation, we performed investigations in the mouse metatarsal culture model. This model recapitulates *in vivo* bone development in culture and circumvents the homeostatic changes that occur in the intact animal. Metatarsals were isolated from day 15.5 C57BL/6J embryos and cultured in phosphate-free high glucose DMEM (1% Pen/Strep, 0.05mg/ml ascorbic acid and 0.25% heat-inactivated FBS) for 4, 8 and 12 days (37°C, 5% CO<sub>2</sub>) with 1.25 mM (control) and 7 mM phosphate (high). The length of each metatarsal was measured at the time of isolation, as well as at the end of the 12 day culture period. Frozen sections were obtained to permit histology, immunohistochemistry, TUNEL and *in situ* hybridization analyses with digoxigenin-UTP labeled probes. Metatarsals cultured with 7 mM phosphate showed a decrease in growth and proliferation compared to 1.25 mM phosphate. Histologic analysis and *in situ* hybridization with Collagen II, Collagen X and Osteopontin revealed an early enhancement of hypertrophic chondrocyte differentiation in metatarsals cultured with 7 mM phosphate (4 days), followed by a decrease in osteopontin expression (8 and 12 days), compared to 1.25 mM phosphate. In contrast to the control, Von Kossa staining showed no mineralization in metatarsals cultured with 7 mM phosphate. TUNEL assays revealed a dramatic increase in apoptosis of hypertrophic chondrocytes in metatarsals cultured with high phosphate. Immunohistochemistry with anti-cleaved caspase-9 antibody showed an increase in activated caspase-9 in hypertrophic chondrocytes of metatarsals cultured with 7 mM phosphate compared to 1.25 mM. Treatment of metatarsals with 20  $\mu$ M Z-LEHD-FMK caspase-9 inhibitor inhibited apoptosis and partially reversed the growth inhibition observed with 7 mM phosphate. Thus, our studies demonstrate that embryonic hypertrophic chondrocytes are susceptible to phosphate mediated apoptosis by activation of the caspase-9-mediated mitochondrial pathway in the metatarsal culture system.

## SU125

**A Novel Model System for Drug Discovery in Osteoarthritis: Monitoring Whole Tissue Turnover in Murine Femur Heads.** K. Henriksen, S. H. Madsen\*, N. Schultz\*, G. Thomsen\*, A. V. Neutzsky-Wulff, M. A. Karsdal. Pharmacology, Nordic Bioscience A/S, Herlev, Denmark.

Osteoarthritis (OA) is a complicated disease of the whole joint. The pathology is a characterized by chondrocyte hypertrophy and cartilage degradation, but also subchondral changes in osteoclastic bone resorption and osteoblastic bone formation. No *ex vivo* models allowing investigation of turnover in the whole joint exist. We developed a femur head model, and characterized the response to both catabolic and anabolic stimulation with respect to changes in whole tissue turnover, monitored using a panel of biochemical markers of bone and cartilage turnover.

Femur heads from three week old mice were isolated and cultured for 10 days in DMEM containing either IL-1 $\alpha$  [10 ng/ml], PTH [100ng/mL], or the general MMP inhibitor GM6001 [10  $\mu$ M]. The conditioned medium was kept for analysis of biochemical markers of bone and cartilage turnover, including CTX-I (bone resorption), ALP activity (Bone formation), CTX-II (cartilage degradation), PIINP (cartilage formation), TRACP (osteoclast number), aggrecanase activity (Bachem substrate cleavage and 374ARGS-fragment release), MMP activity (Bachem substrate cleavage and 342FFGV-fragment release), and GAG release (cartilage turnover). Overall cell numbers were monitored using the dye Alamar Blue. Passive release from metabolically inactive femur heads was measured as background.

Stimulation of the femur heads with IL-1 $\alpha$  led to a two-fold increase in CTX-I release, which was abrogated by addition of GM6001. IL-1 $\alpha$  induced a three-fold increase in sGAG release, which was unaffected by GM6001. CTX-II release was abrogated by IL-1 $\alpha$ , as well as GM6001. The osteoclast marker TRACP increased by 50%. PIINP release was reduced by 50% in the presence of IL-1 $\alpha$ , whereas GM6001 did not affect it. PTH on the other hand augmented cartilage formation measured by PIINP, but did not affect sGAG release.

We have developed a whole tissue model to monitor both cartilage and bone in one single system, which is highly responsive to both catabolic and anabolic stimulation. This is useful to investigate the interaction between cartilage and bone cell types. This model may be more representative for screening and testing potential novel treatments for OA, than traditional single cell culture systems.

**Trps1 Represses Runx2 During Endochondral Bone Formation.** D. Napierala<sup>1</sup>, K. Choudhry<sup>\*1</sup>, E. Munivez<sup>\*1</sup>, T. Bertin<sup>\*1</sup>, B. Lee<sup>2</sup>. <sup>1</sup>Baylor College of Medicine, Houston, TX, USA, <sup>2</sup>Baylor College of Medicine, Howard Hughes Medical Institute, Houston, TX, USA.

Runx2 is a transcription factor that specifies osteoblast cell fate commitment and chondrocyte maturation. Runx2 is also expressed early in mesenchymal condensations. However, in mesenchyme destined for chondrogenic lineages Runx2 is down-regulated. Also later, during endochondral ossification Runx2 is attenuated in prehypertrophic

chondrocytes where the balance of cellular proliferation versus terminal hypertrophy is maintained. Here we present evidence that the Trps1 transcriptional repressor physically interacts with Runx2 and inhibits Runx2-mediated trans-activation. Interestingly, during skeletal development, Trps1 is highly expressed in chondrogenic mesenchyme and prehypertrophic chondrocytes, where Runx2 is attenuated. Moreover, Trps1 mutant mice demonstrate increased Runx2 expression in growth plate chondrocytes and perichondrial cells, accompanied by elevated expression of Runx2 target genes: Ihh and collagen type X, and advanced mineralization of perichondrium. These molecular in vitro studies and analyses of growth plate abnormalities in Trps1 mutant mice demonstrate that Trps1 is a novel Runx2 repressor in developing endochondral bones.

**The Regulation of Chondrogenesis and Bone Development by Neogenin via BMP Pathway.** Z. Zhou, D. Lee\*, J. Xie\*, L. Zhou\*, Y. Liu\*, L. Mei\*, W. Xiong. Medical College of Georgia, Augusta, GA, USA.

Neogenin, an immunoglobulin family transmembrane receptor, is implicated in axon guidance, neuronal differentiation, morphogenesis, and apoptosis. It is widely expressed in different tissues, including bones. However, the role of neogenin in bone development is unknown. We here characterized the skeletal phenotypes of mice lacking neogenin. Neogenin mutant mice showed defect in limb development at embryonic stage, and reduced endochondral ossification and angiogenesis at the early postnatal stage. Bone size and bone volumes were decreased in p30 neogenin mutant mice. Cultured osteoblast from neogenin mutant mice exhibited defective osteoblast differentiation and bone formation, in vitro. The epiphyseal cartilage and cultured osteoblasts from neogenin mutant mice also showed impaired BMPs signaling. Together, we speculated that neogenin appears to be involved in the regulation of chondrogenesis and bone development through BMP signaling pathways. The underlying molecular mechanism is under further characterizing.

**Study of Growth Hormone (hGH) and Insulin-like Growth Factor (IGF) Type 1 Receptors in the Human Fetal Femoral Growth Plate.** M. Edwards<sup>1</sup>, C. G. Goodyer<sup>2</sup>. <sup>1</sup>Experimental Medicine, McGill University, Montreal, QC, Canada, <sup>2</sup>Pediatrics, Experimental Medicine, McGill University, Montreal, QC, Canada.

**Introduction:** hGH plays an essential role in human postnatal growth. The long bones of the skeletal system are major targets for hGH, where it is thought to affect final adult height by promoting chondrocyte proliferation and differentiation within the growth plate and bone mineral density by regulating osteoblast activities. The effectiveness of hGH depends on the availability of its receptor (hGHR) on target cells. GHR expression has been demonstrated in long bone chondrocytes and osteoblasts of the bovine, mouse and rat; however, comparable studies in the human have not been reported and there is a general lack of information concerning hGH effects on human long bone development in the fetus. Dysfunctional bone development can underlie abnormal growth patterns, osteoporosis and bone cancers. Approximately 50% of pediatric endocrine clinic patients have abnormal growth patterns for which there is no known medical explanation. In adults, especially women and the elderly, osteoporosis is an even greater problem, affecting more than 75 million people in North America, Europe and Japan alone. Osteosarcomas, the most common type of malignant pediatric bone cancers in North America, have one of the highest mortality rates of pediatric cancers. We have, therefore, begun a systematic analysis of the hGH/hGHR/IGF axis in human fetal long bones. Here we report immunohistochemical data on hGHR and IGF-1R expression in human (n=3, 14-16 week fetal age) femur growth plates.

**Results:** The femurs were fixed in 4% paraformaldehyde, decalcified, paraffin embedded and sectioned at 5µm. Sections underwent a citrate-buffer antigen retrieval step followed by incubation with either a mouse anti-hGHR monoclonal primary antibody (mAb263)/goat anti-mouse IgG Alexa Fluor 488 conjugated secondary antibody or rabbit anti-IGF-1R polyclonal primary antibody/goat anti-rabbit IgG Alexa Fluor 594 conjugated secondary antibody. The growth plate distribution of hGHR- and IGF-1R-expressing chondrocytes in the resting, proliferating and hypertrophic zones was compared with markers for specific chondrocyte subpopulations (parathyroid hormone receptor 1 [proliferating], collagen X [hypertrophic]). Both hGHR and IGF-1R were expressed in all chondrocytes of the femoral growth plate at this stage in fetal long bone development, demonstrating punctate as well as general cytoplasmic staining, with variable intensities in cells of the different zones.

**Conclusion:** These findings demonstrate expression of hGHR and IGF-1R in human fetal long bone chondrocytes prior to midgestation and suggest a role for hGH and IGF function in early stages of normal human bone development.

## SU129

**Overcoming the Zone of Chondrocyte Death Associated with Osteochondral Harvest by Sequential Treatment with Collagenase and IGF-1.** A. J. McGregor<sup>\*1</sup>, B. A. Amsden<sup>\*1</sup>, S. D. Waldman<sup>\*2</sup>. <sup>1</sup>Chemical Engineering, Queen's University, Kingston, ON, Canada, <sup>2</sup>Mechanical Engineering, Chemical Engineering, Queen's University, Kingston, ON, Canada.

Osteochondral harvesting has been shown to induce a zone of chondrocyte death (ZCD) which has been implicated in the poor cartilaginous integration of the graft with the surrounding host tissue after implantation. This zone originates from the cut surface and can extend up to 400 µm into the tissue, limiting the ability of chondrocytes to migrate through the dense extracellular matrix (ECM) to the wound edge. The aim of the current study is to determine if the ZCD can be reduced by disrupting the ECM using collagenase and treating the tissue with IGF-1 as a means of inducing a chemotactic and/or proliferation response on the chondrocytes. Bovine articular cartilage explants were harvested and a ZCD was induced using the OATS osteochondral harvesting tool. Explants were either treated for 10 minutes with 0.15% collagenase or left untreated. After enzymatic disruption of the ECM, samples were cultured in serum-free media supplemented with or without IGF-1 (25 ng/mL). Cultures were harvested weekly (at 7, 15, 21 days) and stained with calcein AM and ethidium homodimer to assess cell viability. The ZCD was measured using confocal microscopy and statistically compared amongst the different treatment groups. Results indicated that there was a significant effect of the various culture conditions on the ZCD ( $p < 0.001$ ). Collagenase treatment reduced the ZCD by approximately 40% compared to control (control:  $140 \pm 17 \mu\text{m}$ ; collagenase:  $241 \pm 21 \mu\text{m}$ ). Although IGF-1 supplementation alone had no discernable effect on the ZCD, IGF-1 supplementation after pre-treatment with collagenase significantly reduced the ZCD by 80% compared to control (IGF-1:  $255 \pm 13 \mu\text{m}$ ; collagenase + IGF-1:  $48 \pm 13 \mu\text{m}$ ). In addition, there appeared to be a linear trend in the collagenase + IGF group whereby the ZCD decreased over time (Day 7:  $65 \pm 18 \mu\text{m}$ ; Day 21:  $34 \pm 9 \mu\text{m}$ ). Thus, treating osteochondral grafts with collagenase and IGF-1 induces chondrocyte repopulation of the ZCD generated by osteochondral graft harvesting. This effect should allow for an increased number of chondrocytes near the graft edge to promote cartilaginous integration with surrounding native cartilage after implantation.

**Over-expression of CNP Enhances the Formation of Long Bone Exostoses in Ext1<sup>+/+</sup> Mice.** H. Bukulmez<sup>\*1</sup>, F. Khan<sup>\*1</sup>, C. Fernando<sup>\*2</sup>, J. S. Grewal<sup>\*1</sup>, A. Bilgin<sup>\*1</sup>, J. D. Esko<sup>\*3</sup>, M. L. Warman<sup>4</sup>. <sup>1</sup>Genetics/Pediatrics, CWRU/NEOUCOM, Cleveland/Akron, OH, USA, <sup>2</sup>Otolaryngology, CWRU, Cleveland, OH, USA, <sup>3</sup>Cellular and Molecular Medicine, UCSD, La Jolla, CA, USA, <sup>4</sup>Orthopaedics and Genetics, Children's Hospital Boston, Harvard Medical School, Boston, MA, USA.

Multiple hereditary exostoses (MHE) is an autosomal dominant skeletal disorder caused by heterozygous loss-of-function mutations in either EXT1 or EXT2, which encode enzymes involved in heparan sulfate biosynthesis. Although exostoses in patients with EXT mutations can occur at diverse skeletal sites and can undergo malignant degeneration, the exostoses in Ext1 heterozygous (Ext1<sup>+/+</sup>) mice predominantly affect the ribs and do not become malignant.

In this study we bred Ext1<sup>+/+</sup> mice to transgenic mice that over-express C-type natriuretic peptide under the control of the type II collagen promoter/enhancer (CNP<sup>col2aITG</sup>). The purpose of this study was to determine whether CNP over expression would enhance the Ext1<sup>+/+</sup> phenotype. By itself, CNP over-expression causes skeletal overgrowth, but does not produce exostoses. Ext1<sup>+/+</sup> and CNP<sup>col2aITG</sup> mice were mated and 27 offspring were followed for up to 8 months. Non-rib exostoses were detected clinically and/or radiographically, and they were examined histologically following sacrifice.

Eight of the 27 offspring developed non-rib exostoses (2 vertebral, 2 femoral head, 1 distal femur, 1 proximal tibia, 1 distal radius, and 1 ischial bone) and these 8 offspring were both Ext1<sup>+/+</sup> and CNP<sup>col2aITG</sup>. Of the remaining 19 mice in which we did not observe long bone or vertebral exostoses, 9 were Ext1<sup>+/+</sup> and CNP<sup>col2aITG</sup>, 4 were Ext1<sup>+/+</sup> and non-transgenic for CNP, and 6 were entirely wild-type. The histologic appearance of each exostosis was similar to that of human exostotic lesions.

We find that CNP over-expression can enhance the exostoses phenotype in Ext1<sup>+/+</sup> mice. At present, we do not know whether CNP enhances the phenotype indirectly by increasing chondrocyte proliferation or directly by activating a signaling pathway that depends upon Ext1.

**Continuous Culture of Tissue Engineered Cartilage.** A. A. Khan<sup>\*1</sup>, J. M. Suits<sup>\*1</sup>, R. A. Kandel<sup>\*2</sup>, S. D. Waldman<sup>\*3</sup>. <sup>1</sup>Chemical Engineering, Human Mobility Research Centre, Kingston General Hospital, Queen's University, Kingston, ON, Canada, <sup>2</sup>Department of Pathology and Laboratory Medicine, Mount Sinai Hospital, Toronto, ON, Canada, <sup>3</sup>Chemical Engineering, Mechanical and Materials Engineering, Human Mobility Research Centre, Kingston General Hospital, Queen's University, Kingston, ON, Canada.

The use of bioreactors for cartilage tissue engineering has become increasingly important as traditional batch-fed culture is not optimal for tissue growth *in vitro*. Most tissue engineering bioreactors rely on convection as the primary means to provide mass transfer; however, convective transport of nutrients can also impart potentially unwanted or uncontrollable mechanical stimuli to the cells resident in the construct. The reliance on diffusive transport may not necessarily be ineffectual as previous studies have observed improved tissue growth when the constructs were cultured in elevated volumes of media. In this study, to approximate an infinite reservoir of media, we investigated the effect of continuous culture on cartilaginous tissue growth *in vitro*. Isolated bovine articular chondrocytes were seeded on Millicell™ filters and after two weeks of pre-culture, the constructs were cultivated under continuous media flow (5 to 10 µL/min) for a period of one week. Tissue engineered cartilage constructs cultivated in the continuous flow bioreactor significantly accumulated more collagen and proteoglycans (between 50-70%). These changes were similar in magnitude to the reported effect of through-thickness perfusion without the need for large volumetric flow rates. In addition, tissues cultivated in the reactor appeared to adopt an appearance closer to the characteristic structure of native articular cartilage. Tissues grown in the reactor displayed some evidence of the stratified morphology of native cartilage as well as containing stores of intracellular glycogen. Future studies will investigate the effect of long-term culture in the reactor in terms of ECM accumulation and subsequent changes in mechanical function.

**Disclosures:** A.A. Khan, None.

## SU132

**Identification And Characterization of 3.6 Col I Positive Cells from Mouse Temporomandibular Joint.** J. Chen<sup>\*1</sup>, Y. Bi<sup>\*2</sup>, M. F. Young<sup>2</sup>, S. Wadhwa<sup>\*1</sup>. <sup>1</sup>Craniofacial sciences, University of Connecticut Health Center, Farmington, CT, USA, <sup>2</sup>Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research, US National Institutes of Health, Bethesda, MD, USA.

The mandibular condylar cartilage (MCC) is unique from other articular cartilages in that it is derived from periosteum and composed of fibrocartilage. Little is known about the exact stages of MCC cell differentiation. Due to its periosteal origin, we hypothesized that the early osteoblast differentiation marker (3.6 kb fragment of the rat collagen type I promoter (3.6 Col I)) would be an early marker for MCC cell differentiation. To test the hypothesis, transgenic mice containing the 3.6 Col I fused to a Topaz-fluorescent protein (3.6 Col I-GFP), the 3.6 Col I fused to CRE recombinase (3.6 Col I-CRE), the collagen type II promoter fused to a Cyan-fluorescent protein (Col II-GFP), and Rosa26-LacZ mice (containing floxed beta-galactosidase gene) were used in this study. In addition, primary cells obtained from digesting MCC from 3.6 Col I-GFP mice were cultured for colony-forming units (CFUs).

The mandibular condylar cartilage is organized into 4 zones -1. articular zone, 2. polymorphic zone (contains the precursor cells), 3. flattened zone (Col II expression), and 4. hypertrophic zone (Col X expression). Using histology, we found that the 3.6 Col I-GFP expression is localized in the polymorphic zone and distinct from Col II-GFP expression, which is localized in the flattened zone of the MCC. Cell fate mapping experiments, by the breeding of 3.6 Col I-CRE mice with the Rosa26-LacZ, revealed that beta-galactosidase expression was not only in the polymorphic, but also in the flattened and hypertrophic zones of the MCC. In vitro studies further showed that the CFUs from the MCC were not 3.6 Col I positive but were able to differentiate to fat (oil red staining), bone (alizarin red staining) and cartilage (alcian blue staining).

Our results indicate that 3.6 Col I expression is an early marker of MCC cell maturation. In our current working model we believe that MCC differentiation proceeds by the initial formation of precursor/progenitor cells that are negative for 3.6 Col I expression. Later stages progress to be 3.6 Col I positive, followed by Col II and then to Col X expression. This is the first report showing the expression of 3.6 Col I promoter and the identification of mesenchymal precursors in the mouse MCC. These data provide an important foundation for future work further defining regenerative therapies of the TMJ.

**Nicotine Induces Chondrogenesis via Calcineurin/NFAT.** H. Ho<sup>\*</sup>, X. Lu<sup>\*</sup>, D. Hoak<sup>\*</sup>, J. E. Puzas, R. J. O'Keefe, M. J. Zuscik. Orthopaedics, University of Rochester, Rochester, NY, USA.

Cigarette smoking is documented to have deleterious effects on skeletal healing based on human data and animal studies. While numerous compounds present in smoke likely contribute to its influence on healing, little is known about the key effectors or their underlying mechanisms of action. One important bioactive molecule in smoke is nicotine,

which can impact effects on cells that express nicotinic acetylcholine receptors (nAChRs). In previous work studying the influence of nicotine on skeletal repair, we found that i) mesenchymal stem cells (MSCs) express the nAChR, ii) activation of the receptor leads to initiation of its calcium channel function, and iii) cartilage deposition *in vitro* and *in vivo* is enhanced following exposure to nicotine. To study the signaling mechanisms that are activated and their contribution to nicotine's chondrogenic effect, we have examined the activation of calcineurin and subsequent nuclear translocation of NFATc1. We have also assessed the role of this pathway in nicotine's phenotypic effects. C3H10T1/2 cells were plated in monolayer and NFAT signaling was assessed using a luciferase-based reporter (NFAT-luc), western blotting, and NFATc1 cell localization studies. Then, pharmacologic blockade of calcineurin was employed to evaluate the dependence of nicotine on this pathway to enhance chondrogenesis in limb bud MSCs. Regarding signaling, nicotine evoked a dose-dependent activation of NFAT-luc that was 5-fold at the 5 microM dose. Western blotting corroborated this finding by revealing a 10-fold increase in nuclear NFATc1 that was coupled with a 60% reduction of its cytoplasmic pool following a 6 hr treatment with 5 microM nicotine. Fluorescence studies also demonstrated strong localization of eGFP-NFATc1 in the nucleus of cells following 120 min treatment with 10 microM nicotine. These results implicate the calcineurin/NFAT pathway in nicotine's effects on MSCs. To confirm this, limb bud MSCs were cultured in micromass and the ability of nicotine to accelerate chondrogenesis was examined in the presence and absence of cyclosporine A (CSA), an inhibitor of calcineurin. Similar to positive control treatment with BMP-2, nicotine enhanced cartilage nodule formation by 7 days relative to untreated cultures. This positive effect of nicotine was lost in cells treated with 0.2 microg/ml CSA during the 7 day culture period. Overall, nicotine was not only found to induce NFAT signaling in MSCs, but activation of this pathway was found to be required for the positive effect of nicotine on chondrogenesis. This is consistent with the known function of NFAT as an inducer of chondrogenesis and identifies a potential mechanism underlying the influence of cigarette smoke/nicotine on repair processes that rely on an endochondral phase of healing.

**Regulation of Autophagy in the Epiphyseal Growth Plate by AMPK and mTOR Requires HIF-1.** J. Bohensky<sup>\*</sup>, I. M. Srinivas, V. Srinivas<sup>\*</sup>. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

During maturation chondrocytes experience ER stress and increase their intracellular calcium levels. It has been proposed that this sensitizes the cells to apoptogens. Increased calcium levels also activate the energy sensor, AMPK. We have previously shown that another energy sensor, HIF-1 induced autophagy as an intermediate step in the maturation of the chondrocyte, allowing the chondrocyte to reach the terminally differentiated state in its stressful microenvironment. The goal of the study is to examine the role of sensor molecules, mTOR and AMPK in regulating chondrocyte survival and autophagy in the growth plate in relationship to HIF-1. We showed that chondrocytes expressed the energy sensor AMPK $\alpha$ 1 and that activation of this protein is dependent on HIF-1. Furthermore its activation by thapsigargin, an ER stressor is also dependent on HIF-1. This activation was shown to promote autophagy and correlates with determinants of chondrocyte energy metabolism. Using serum-starved AMPK silenced cells, we show that AMPK is required for the induction of the autophagic response. We also note that there is a change in chondrocyte sensitivity to apoptogens, due to alterations in levels of bound Bcl-2, activation of caspase-8 and cleavage of BID. To test the hypothesis that AMPK signaling directly promotes autophagy we inhibited AMPK activity in mTOR silenced cells and showed that while mTOR suppression induced autophagy, AMPK inhibition did not block this activity. Based on this finding, it is concluded that activation of autophagy is due to AMPK's regulatory effects on mTOR and regulated by HIF-1.

In conclusion it is suggested that the maturation-dependent decrease in the chondrocyte energy status activates AMPK. As this protein promotes autophagy, the post-mitotic chondrocytes remain viable and can complete their life cycle. Once terminally differentiated, these late autophagic cells are sensitized to local apoptogens. Activation of apoptosis serves to delete hypertrophic chondrocytes from the plate thereby permitting osteoblast invasion and metaphyseal bone formation.

**Osteogenesis Effect of Human Ligamentum Flavum, Myoblast, Osteoblast and Mesenchymal Stem Cell by DBM and BMP-2.** J. Lee<sup>\*1</sup>, H. Kim<sup>\*1</sup>, U. Kwon<sup>\*1</sup>, C. Lee<sup>\*1</sup>, M. Nan<sup>\*1</sup>, K. Lee<sup>\*1</sup>, H. Kim<sup>\*1</sup>, I. Kwon<sup>\*2</sup>, H. Chun<sup>\*3</sup>, E. Moon<sup>\*1</sup>, H. Lee<sup>\*1</sup>, S. Moon<sup>\*1</sup>. <sup>1</sup>Orthopaedic surgery, Yon-sei University, Seoul, Republic of Korea, <sup>2</sup>Kyung Hee University, Seoul, Republic of Korea, <sup>3</sup>Mechanical Engineering, Yon-sei University, Seoul, Republic of Korea.

Demineralized bone matrix (DBM) derived from human tissues and Bone morphogenetic protein-2(BMP-2) induces bone formation and spinal fusion. Ligamentum flavum (LF) and mesenchymal stem cell (MSC) was reported to have osteogenic potential with stimulation of BMP-2. It can be hypothesized that LF, MSC, Osteoblast and Myoblast treated with BMP-2, DBM and mixture of BMP-2 and DBM can be a substitute for autogenous bone graft in spinal fusion. Therefore, we cultured all cells with BMP-2, DBM and mixture of BMP-2 and DBM. They were analyzed osteogenic differentiation. LF from stenotic lumbar spine, Osteoblast, Myoblast and MSC were harvested and cultured. Then all cells were treated with BMP-2, DBM and mixture of BMP-2 and DBM for 0 and 7day. Cellular proliferation was assessed by alamarblue assay. Reverse transcription-polymerase chain reaction (RT-PCR) for osteocalcin and collagen type I was performed. Alkaline phosphatase activity and Von-kossa staining was done. All cells showed increased

proliferation rate without cytotoxicity compared to control group. Human LF cells with DBM, BMP-2, mixture of BMP-2 and DBM demonstrated two times more upregulation of Collagen type I compared to control group in RT-PCR. Also MSC and Osteoblast cells with BMP-2 group demonstrated upregulation of Osteocalcin in RT-PCR. Furthermore all cells cultured with DBM, BMP-2, mixture of BMP-2 and DBM showed positive alkaline phosphatase activity and Von-kossa staining. In conclusion, All groups of all cells showed increase in proliferation rate and upregulation of osteogenic phenotypes. Furthermore all cells showed positive ALP activity and Von-kossa staining. Given osteogenic potential of human LF, MSC and Osteoblast with all tissues with DBM and/or BMP-2 can be used for bone graft substitute in spinal surgery.

**Biological Activation of Biomaterials by Recombinant Adeno-Associated Virus Vector.** H. Ito<sup>1</sup>, T. Nasu<sup>\*1</sup>, R. Tsutsumi<sup>\*1</sup>, T. Kitaori<sup>\*1</sup>, E. M. Schwarz<sup>2</sup>, T. Nakamura<sup>\*1</sup>. <sup>1</sup>Orthopaedic Surgery, Kyoto University Graduate School, Kyoto, Japan, <sup>2</sup>The Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

**Introduction:** Recently many kinds of biomaterials have been used in reconstructive surgery. The common problem of all biomaterials is that they are less capable of activating recipient tissues biologically. In order to add the property of biological activity to biomaterials, administration of growth factors or mesenchymal stem cells is also considered but has not been established. We examined if rAAV vectors on biomaterials could effectively induce gene transduction.

**Material & methods:** On hydroxyapatite,  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) and titanium alloy plates, rAAV vectors were immobilized by lyophilization. The activities of  $\beta$ -galactosidase ( $\beta$ -gal) were assayed with the Luminescent  $\beta$ -gal assay kit. The lyophilized hydroxyapatite disc with rAAV-LacZ or -BMP-2 was inserted into the dorsal muscle of adult Wistar rat operatively under sterile condition. The extraction of the materials was performed 2, 4, and 8 weeks after operation. The frozen sections were stained with  $\beta$ -gal and nuclear fast red. Fixed discs with rAAV-BMP were treated into paraffin sections and stained with hematoxylin and eosin.

**Results:** *Lyophilized rAAV on biomaterials:* The respective  $\beta$ -gal activity of rAAV-treated fibroblasts on each material was significantly higher than that of control.

*In vivo transduction:* At 4 weeks, almost all pores of implants in each group were filled with fibrous tissues, but the AAV-treated sample showed a remarkable staining of the cells compared with control. At 8 weeks, the pores were almost completely filled with fibrous tissues. The evaluation of  $\beta$ -gal activity demonstrated that the activity in rAAV group was higher than those in control group at each time point, and the statistical significances were detected at 4 and 8 weeks.

*Hydroxyapatite with lyophilized rAAV-BMP:* At 4 and 8 weeks, mature bone formation started to be seen only on BMP-treated hydroxyapatite blocks, but only immature bone was observed on control.

**Discussion:** In recent reports of rAAV as a gene transducer, vectors were injected locally or systemically. In this experiment rAAV vectors were lyophilized on biomaterials without injection. The present result shows that the major bone-related materials can be used combined with rAAV, and that rAAV-BMP can, indeed, induce de novo bone formation in rat back muscles. Not only hydroxyapatite with rAAV-BMP but another biomaterial or rAAV with another gene may be epochal material in clinical occasions in the future.

**Catecholamines Accelerate BMP-induced Osteoblastic Differentiation and Bone Formation.** T. Uemura<sup>\*</sup>, Y. Ohta<sup>\*</sup>, Y. Nakao<sup>\*</sup>, Y. Hashimoto<sup>\*</sup>, K. Takaoka. Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

It has recently been reported that the sympathetic nervous system is involved in regulation of osteoblastic function mainly through  $\beta$ -type adrenergic receptors on the cell surface. The stimulatory effects of the sympathetic nervous system are mediated by catecholamines, such as adrenaline, noradrenaline and dopamine, which elevate the intracellular cyclic adenosine 3', 5'-monophosphate (cAMP) level through the Gs-coupled receptors. In a previous study, we showed that intracellular cAMP accumulation consistently enhanced bone morphogenetic protein (BMP)-induced osteoblastic differentiation, predominantly via the protein kinase A (PKA) signaling pathway. This study was designed to substantiate the potential of these catecholamines to enhance BMP-induced bone formation.

To confirm the action of the catecholamines in elevating the intracellular cAMP level in osteoblastic cell lines, changes of cAMP levels in these cells after addition of catecholamines (adrenaline, noradrenaline and dopamine) were assayed in time sequence. Intracellular cAMP levels increased significantly within 15 minutes by addition of the respective catecholamine. Changes of alkaline phosphates (ALP) levels in osteoblastic cell lines by BMP with or without catecholamine treatment were assayed after 3 days incubation. The ALP levels were consistently elevated by rhBMP-2(100 ng/ml) and the elevation of ALP levels were further enhanced by treatment with each catecholamine (adrenaline;  $10^{-7}$ ,  $10^{-8}$ M, noradrenaline;  $10^{-8}$ M, and dopamine;  $10^{-8}$ M).

To investigate the ability of these catecholamines to augment the bone-inducing action of BMP under *in vivo* condition, 30 mg of polymer discs (poly-D, L-lactic acid-p-dioxanone-polyethylene glycol block copolymer; PLA-DX-PEG) containing rhBMP-2(5  $\mu$ g) with or

without catecholamines (10, 20, 40  $\mu$ g) were implanted into the dorsal muscle pouch of mice. All ossicles induced by BMP were harvested 3 weeks later and examined by radiological and histological analyses. On soft X-ray radiogram, all of the ossicles revealed a trabecular network encased within a shell-shaped bone and the ossicles induced by rhBMP-2 when used in conjunction with each catecholamine (adrenaline; 10, 20, 40  $\mu$ g, noradrenaline; 40  $\mu$ g, and dopamine; 10, 20, 40  $\mu$ g) were significantly larger in size and higher in bone mineral content (BMC) on dual-energy X-ray absorptiometry (DXA) compared with those induced by rhBMP-2 alone.

In this study, we showed that catecholamines accelerate BMP-induced osteoblastic differentiation and bone formation probably by increasing cAMP via the PKA signaling pathway.

## SU138

**Wnt Pathway Regulation by Demineralized Bone Requires TGFbeta/BMP Signaling.** S. Zhou, J. Glowacki. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Allogeneic demineralized bone is used extensively as a clinical material because it has osteoinductive and osteoconductive properties. Demineralized bone powder (DBP) induces chondrogenic differentiation of human dermal fibroblasts (hDFs), but the initiating mechanisms have not been characterized. BMPs have been isolated from DBP, but it is not known whether BMPs recapitulate all the events induced by DBP in target cells. We had previously reported that DBP and BMP-2 regulate common and distinct pathways, and, further, that DBP stimulates the two distinct Smad pathways responsive to either TGF/activin or BMP. In this study, we tested the hypothesis that DBP, BMP-2, and TGF- $\beta$ 1 would similarly affect expression of Wnt signaling genes. A three-dimensional collagen scaffold was used in which hDFs were cultured with and without 3 mg DBP in a 3-D porous collagen sponge or with 10 ng/ml TGF- $\beta$ 1 or 100 ng/ml rhBMP-2. Total RNA was isolated after 3 days of culture, a time that precedes differentiation. Effects of DBP, BMP-2, and TGF- $\beta$ 1 on Wnts in hDFs were compared by microarray, RT-PCR, and Western blot analysis. Of the canonical Wnts, Wnts 2 and 10b were upregulated by all three agents; only DBP and TGF- $\beta$ 1 stimulated Wnt 7b and 16b and downregulated Wnt 2b; only DBP stimulated Wnt 3a; only BMP-2 induced Wnt 1. Of non-canonical Wnt/Ca<sup>2+</sup> members, Wnt 4, 5a, and 11 were upregulated by only DBP and TGF- $\beta$ 1. DBP and TGF- $\beta$ 1 stimulated  $\beta$ -catenin, but BMP-2 did so only weakly and inconsistently. LiCl and Wnt-agonist SB216763 mimicked DBP stimulation of Runx2 and SOX9. Stimulation of  $\beta$ -catenin and Wnts by DBP was attenuated by SB413542, an inhibitor of TGF- $\beta$ 1 activin receptor-like kinases. Thus, DBP's stimulation of Wnt genes and of  $\beta$ -catenin partially requires TGF- $\beta$ /activin signaling. In sum, BMP-2 does not, but TGF- $\beta$  does recapitulate many of DBP's effects on Wnt pathways in human target cells. DBP stimulation of  $\beta$ -catenin and Wnts involves TGF- $\beta$ 1 activin receptor-like kinases.

Thus, there are many effects of DBP that are not shared with BMP-2, which is the putative active component of DBP. DBP contains substantial amounts of TGF- $\beta$  and other factors that can contribute to DBP's effects *in vivo*.

**Interferon- $\gamma$  Attenuates BMP-2 Signaling Via Stat-1 Binding Of Smad4 In The Cytoplasm.** F. A. Sylvester<sup>1</sup>, N. Wyzga<sup>\*2</sup>. <sup>1</sup>Pediatric Gastroenterology, Connecticut Children's Medical Center, Hartford, CT, USA, <sup>2</sup>Research, Saint Francis Hospital & Medical Center, Hartford, CT, USA.

Activated T lymphocytes can affect osteoblast formation. We have previously shown that interferon- $\gamma$  (INF- $\gamma$ ), the prototypical Th1 cytokine, inhibits osteoblast development *in vitro*. We hypothesized that this effect is due to the blockade of BMP-2 signaling, a key osteogenic factor. To test this hypothesis, we treated ST-2 cells, a mouse clonal stromal cell line, with BMP-2  $\pm$  INF- $\gamma$  under osteogenic conditions at different time points. We found that treatment with INF- $\gamma$  significantly decreased the transactivation of the reporter construct 12X-SBE-Luc, under the control of a minimal osteocalcin promoter, suggesting that INF- $\gamma$  blocks the Smad-dependent BMP-2 pathway. We then investigated if the concentration of each of the different molecules involved in the canonical BMP-2 pathway was affected by treatment with INF- $\gamma$ . In ST-2 cells treated with BMP-2  $\pm$  INF- $\gamma$ , we did not detect differences in Western blot band density of the following factors: inactive or phosphorylated R-Smads 1, 5, 8; Smad 4, or the inhibitory Smad 6 or Smad 7. We also did not see differences in the concentration of the E-ubiquitin ligases Smurfs 1 and 2. Blockade of the proteasome with several inhibitors did not rescue the effect of INF- $\gamma$ . We repeated these experiments in the pre-osteoblastic cell line MC3T3 cells with identical results. These data suggested that treatment of stromal cells or pre-osteoblasts with INF- $\gamma$  did not alter the concentration of the components of the BMP-2 pathway, and that these factors are not degraded by ubiquitination. We then explored the possibility that the complex formed by Smad4 and R-Smads 1,5,8 was sequestered in the cytoplasm under the influence of INF- $\gamma$ . Using confocal microscopy, we observed that Smad4 accumulated in the cytoplasm of ST-2 cells treated with BMP-2 + INF- $\gamma$ . Co-immunoprecipitation experiments revealed that Smad4 bound to Stat-1 in cells treated with INF- $\gamma$ . Phosphorylated (activated) Stat-1 did not immunoprecipitate with Smad4. ST-2 cells treated with BMP-2 upregulated the expression of Stat-1, which was further increased by adding INF- $\gamma$ . In summary, INF- $\gamma$  blocks BMP-2 signaling by binding of Stat1 to Smad4 in the cytoplasm of osteogenic cells, preventing its nuclear localization. This provides a novel mechanism by which an inflammatory cytokine may affect bone formation.

**Bone Morphogenetic Protein-6 (BMP-6) from Bone Regulates Serum Glucose via IGF-1 Released from Pancreas.** P. Simic<sup>\*1</sup>, L. Grgurevic<sup>\*1</sup>, I. Orlic<sup>\*1</sup>, M. Zuvic<sup>\*2</sup>, S. Vukicevic<sup>1</sup>. <sup>1</sup>Laboratory for Mineralized Tissues, Zagreb Medical School, Zagreb, Croatia, <sup>2</sup>Department of Oncology and Nuclear Medicine, Clinical Hospital Centre Zagreb, Zagreb, Croatia.

Systemic administration of BMP-6 restores the bone volume (BV) in osteoporotic rats (Simic et al, J Biol Chem, 2006) and lowers the blood glucose in *Bmp-6*<sup>-/-</sup> and non obese diabetic mice (Orlic et al, Calc Tiss Int, 2007). We hypothesized that BMP-6 released from the bone might mediate the endocrine function of the pancreas. We therefore revisited the phenotype of the *Bmp-6*<sup>-/-</sup> mouse and found that the loss of *Bmp-6* function exerts both an abnormal bone development and the reduced pancreatic function. Although long bones of the wild type (WT) and *Bmp-6*<sup>-/-</sup> littermates are of a similar size and shape, BV is reduced up to 120% and 80% at embryonic day 15 and 17, respectively. Apart from the abnormal bone development, *Bmp-6*<sup>-/-</sup> born mice have a reduced number of Langerhans islands with a lower serum insulin and a subsequent increase of the serum glucose levels. Exogenously injected BMP-6 (60 µg/kg/3xweek) reduced the blood glucose in 2h and at 3 weeks of therapy increased the BV of *Bmp-6*<sup>-/-</sup> mice to normal. To test whether the endogenous BMP-6 deposited in the bone matrix could be released into the circulation and affect the serum glucose level we treated *Bmp-6*<sup>-/-</sup> and WT mice with 3 injections of phosphate (0.6 mg/kg i.v.) to stimulate the bone resorption. This resulted in the identification of BMP-6 in plasma of WT mice by liquid chromatography - tandem mass spectrometry and immuno blot analysis. WT mice exposed to the glucose tolerance test at days 3, 5 and 7 following the phosphate overload resulted in a reduction of glycemia in animals with measurable bone serum level of BMP-6 as compared to control WT mice (P<0.01). Molecular analyses of tissue samples revealed that BMP-6 released from bone inhibited the hepatic glucose production and increased the expression of IGF-1 in the pancreas, and elevated the serum concentration of IGF-1. In addition, co-administration of an IGF-1 neutralizing antibody to these mice reduced the BMP-6 glucose lowering effect. These results suggest that BMP-6 has a unique developmental role both in the bone and pancreas, while in the post natal life BMP-6 released from the bone regulates the glucose homeostasis via releasing IGF-1 from the pancreas.

**Circulating BMP-1 Isoforms: Novel Diagnostic and Therapeutic Challenges for Bone Fracture Repair.** L. Grgurevic<sup>\*1</sup>, B. Macek<sup>\*2</sup>, M. Mann<sup>\*2</sup>, S. Vukicevic<sup>1</sup>. <sup>1</sup>Laboratory for Mineralized Tissues, Zagreb Medical School, Zagreb, Croatia, <sup>2</sup>Department of Proteomics and Signal Transduction, Max-Planck-Institute for Biochemistry, Martinsried, Germany.

We hypothesized that bone, kidney and liver injury results in the release of different endogenous bone morphogenetic proteins (BMPs) into circulation reflecting the success of regeneration. Plasma (50 ml) from normal individuals (16) and from patients with a long bone fracture (6), chronic renal failure (8) and liver cirrhosis (7) were collected, purified by heparin beads and all protein bands from SDS gel electrophoresis have been analyzed by liquid chromatography - tandem mass spectrometry (LC-MS) and immuno blots. While only mature BMP-6 was detected in plasma of healthy individuals, surprisingly BMP1-3 isoform of the BMP-1 gene, a procollagen C-protease, was found in serum of healthy individuals and in patients with CRF. BMP-1-3 has not been previously detected at the protein level, while BMP-1-1, originally isolated with other BMPs from the bone matrix, did not circulate. As there was no information available on the function of BMP-1-3 isoform we cloned, expressed and purified the protein and raised specific polyclonal neutralizing antibodies for in vitro and in vivo experiments. BMP-1-3 isolated from the plasma of normal individuals lacked the prodomain and was active in processing procollagen I in vitro. As BMP1-3 was not found in the plasma of patients with a single fracture we administered intravenously I<sup>125</sup> labeled BMP-1-3 to rats with a fractured femur and found by microradiography that it accumulated in the bone callus. Moreover, when rats with a fracture were injected intravenously (iv) with recombinant human BMP-1-3 (25 g/kg 5 x weekly for two weeks) the femurs healed significantly faster than in control animals. To check whether the amount of BMP-1-3 in the serum was physiologically relevant the BMP-1-3 circulating in the plasma was neutralized with an iv injected BMP-1-3 neutralizing antibody (12 g/kg 2x weekly for two weeks). Subsequently, the femurs were fractured in the same rats and it was found that the bone healing was significantly delayed suggesting that the presence of BMP-1-3 in blood was important for bone regeneration. Next, we tested the potential mechanism of action of BMP1-3 in the rat calvariae assay and found that BMP-1-3 added to the culture medium supported the release of BMP-6 and -7, which then stimulated the synthesis of extracellular matrix, in particular procollagen I and III. In conclusion, we discovered for the first time that BMP1-3 isoform, and not BMPs, circulates in the human and rat serum, significantly enhancing bone regeneration, providing thus a diagnostic and therapeutic challenge.

**Bmp3-Null Aged Mice Display Increased Trabecular Bone Volume and Reduced Cross Sectional Area at the Mid-Femoral Diaphysis.** R. Raz<sup>1</sup>, L. Huang<sup>1</sup>, D. A. Panus<sup>\*2</sup>, Y. Xue<sup>\*1</sup>, D. M. Valenzuela<sup>\*1</sup>, G. D. Yancopoulos<sup>\*1</sup>, A. Murphy<sup>\*1</sup>, M. Bouxsein<sup>\*2</sup>, V. Rosen<sup>3</sup>, A. N. Economides<sup>1</sup>. <sup>1</sup>Regeneron Pharmaceuticals, Tarrytown, NY, USA, <sup>2</sup>Beth Israel Deaconess Medical Center, Boston, MA, USA, <sup>3</sup>Harvard School of Dental Medicine, Boston, MA, USA.

BMP3 was originally purified from bovine bone matrix as osteogenin, an activity with osteogenic function. However, it has later been identified as an inhibitor of osteogenic BMPs and a negative regulator of bone density in mice. Using VelociGene® technology, we have generated *Bmp3* homozygous-null (KO) mice where the first exon (encoding the N-terminal part of the precursor region) was replaced in frame with the LacZ reporter. We used micro-computed tomography to evaluate trabecular bone microarchitecture in the distal femur and the vertebral body, as well as cortical bone morphology in the mid-femoral diaphysis. We found that in aged animals (36 to 44 wks), trabecular bone volume in the distal femur and vertebral body was significantly higher in KO compared to wild type littermate controls (30% to 70%) primarily due to increased trabecular number. At the mid-femoral diaphysis, the relative cortical bone area fraction and cortical thickness was unchanged, but the total cross-sectional area, bone area and medullary area were smaller in KO than in controls, correlating with a reduction in body weight. The results of this study confirm that BMP3 is a negative modulator of bone density *in vivo* and uncover a role for BMP3 in the regulation of body mass.

**Negative Regulation of Tcf/Lef-dependent Transcription by the BMP/Smad4 Signaling Axis.** V. S. Salazar, G. Mbalaviele, R. Civitelli. Internal Medicine, Washington University Medical School, Saint Louis, MO, USA.

β-catenin and BMP signaling are critical regulators of osteogenesis. To understand how these pathways interact during osteoblastogenesis, and to determine the biologic importance of such interactions, we used the mouse embryonic fibroblasts (C3H10T1/2) to characterize how BMP signals affect canonical β-catenin/Tcf/Lef activity. We previously reported that phosphorylation of β-catenin at S33/S37/T41 dramatically decreases after 5 min of BMP-2 exposure, coinciding with β-catenin/Smad4 co-immunoprecipitation. Immunoblot of fractionated cell proteins or expression of chimeric EGFP-β-catenin protein indicates that BMP-2 promotes nuclear accumulation of β-catenin. Intriguingly however, a Tcf/Lef-dependent luciferase reporter is not stimulated by 24hr of BMP-2. EMSA on nuclear fractions from BMP-2 treated cells reveals that BMP-2 causes β-catenin and Smad4 to assemble a nucleoprotein complex at consensus Smad4-binding DNA sequences. We concordantly find that expression of a transcriptionally-defective β-catenin mutant blocks BMP-2 stimulation of a Smad-dependent luciferase reporter. The collective data lead us to hypothesize that BMP signals can act through Smad4 to regulate β-catenin activity thus antagonizing Tcf/Lef-dependent transcription. To test this hypothesis, we manipulated Smad4 expression levels using either Smad4 siRNA or a Smad4 expression plasmid. As expected, activation of a Smad-dependent luciferase reporter is dose-dependently decreased by Smad4 knockdown and enhanced by Smad4 overexpression. Conversely, Tcf/Lef reporter activity is dose-dependently decreased by Smad4 overexpression and is enhanced by silencing of Smad4. We also find that Smad4 abundance is inversely proportional to Tcf/Lef activity at the human *Cyclin-D1* promoter, as well as to endogenous gene expression of murine *Cyclin-D1*, a canonical Wnt gene target. And in fact, knockdown of Smad4 synergistically enhances the ability of Wnt3a or activated β-catenin to induce *Cyclin-D1* transcription (>6 and >17-fold, respectively). Our results provide evidence that BMP signals can act through Smad4 to interact with β-catenin in a manner that antagonizes canonical Wnt activity at the level of Tcf/Lef-dependent transcription. This novel signaling mechanism may impact osteoblast cell number or cell fate.

## SU145

**BMPR2 Is Dispensable for Formation of the Limb Skeleton.** L. Gamer<sup>\*1</sup>, K. Tsuji<sup>\*1</sup>, K. Cox<sup>\*1</sup>, E. Gagarin<sup>\*1</sup>, H. Beppu<sup>\*2</sup>, V. Rosen<sup>1</sup>. <sup>1</sup>Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, <sup>2</sup>Cardiovascular Research Center, Massachusetts General Hospital, Boston, MA, USA.

In vivo studies examining the role of BMPs in skeletal development have established a requirement for BMP signaling during endochondral ossification and identified specific functions for individual type I BMP receptors. Initiation of BMP signaling is dependent on activation of the type I BMP receptor by the constitutively active type II BMP receptor after ligand binding occurs. In this study, we focus on the regulatory role of the type II BMP receptor in endochondral ossification. Of the 3 type II BMP receptors identified, ActRIIA and ActRIIB are multifunctional, serving as type II receptors for BMPs and also for activin-like ligands while BMPRII (BMPRII) only functions as a BMP receptor. Based on the specificity of BMPRII and the fact that loss of either ActRIIA or ActRIIB is not associated with deficits in limb development, we hypothesized that BMPRII is essential for BMP signaling during embryonic skeletal development. Using a conditional deletion

approach, we removed BMPR2 from early limb mesoderm prior the onset of skeletogenesis by crossing Bmpr2 floxed mice with mice carrying the Prx1cre transgene and analyzed Bmpr2Prx1cre mice at E16, P0, and weeks 1-6 after birth. At each of these times, mice lacking limb expression of BMPR2 appeared to have normal skeletons and could not be distinguished from control littermates. No anomalies in limb skeletal patterning or joint morphogenesis were observed in the absence of BMPR2. Detailed analysis of limb skeletons from newborn Bmpr2Prx1cre mice showed no changes in the expression of markers for chondrogenesis (Col2, Col10, Ihh) or osteogenesis (Runx2, OPN, OCN) and X-rays taken of Bmpr2Prx1cre limbs weekly for the first 6 weeks after birth showed no spontaneous fractures or appearance of osteopenia conditions that are associated with reduced BMP signaling. From these data we conclude that BMPR2 is not required for endochondral ossification in the limb and that loss of BMPR2 is compensated for through the use of ActRIIA and/or ActRIIB as type II BMP receptors.

## SU146

**Efficacy of Single-Level Instrumented Posterolateral (Intertransverse) Lumbar Spinal Fusion (PLF) in Baboons with BMP-7 Putty.** A. Pierce<sup>1</sup>, M. Goad<sup>1</sup>, M. H. Alaoui-Ishmaili<sup>2</sup>, D. Schrier<sup>1</sup>. <sup>1</sup>Preclinical Development, Stryker Biotech, Hopkinton, MA, USA, <sup>2</sup>Biology, Stryker Biotech, Hopkinton, MA, USA.

BMP-7 putty is indicated for use as an alternative to autograft in revision PLF. BMP-7 putty consist of 3.5 mg bone morphogenetic protein-7 (BMP-7) with 1 g type I collagen particles and 200 mg carboxymethylcellulose (CMC) as a handling excipient. This baboon study assessed safety and efficacy of BMP-7 putty in an instrumented model of PLF. Twenty-four adult male baboons (26 ± 4.7kg) were used in this IACUC-approved study. Surgery consisted of single level lumbar vertebral (L4-L5) fusion with pedicle screw and rod fixation along with the BMP-7 putty (n=20) or iliac crest autograft (n=4). BMP-7 putty treated animals had 0.5 mL of putty implanted subcutaneously as a distant site control. Fusion was assessed by radiograph and biomechanical testing. BMP-7 groups were 0 (collagen and CMC, only), 0.33, 1, 2, and 4 mg of BMP-7/mL putty. Total volume of BMP-7 putty was 12 mL per level. Safety assessment included clinical observations, clinical pathology (hematology, serum chemistry), body weights, organ weights, necropsy, and histology of selected tissues. Serum BMP-7 concentrations and anti-BMP-7 antibodies were analyzed.

None of the animals had any evidence of altered clinical or necropsy parameters: clinical pathology, organ weights, body weights, macroscopic, or microscopic findings in tissues other than the vertebral fusion site, were within the range of normal. A separate subcutaneous implant site had no evidence of the BMP-7 putty grossly or microscopically (i.e. no bone or inflammation) by 16 weeks. The new bone formed had normal cortical and cancellous bone with central bone marrow. Anti-BMP-7 antibodies were measured in the serum of half the autograft and 0 mg/mL BMP-7 putty animals. Three of four animals treated with 0.33 mg/mL BMP-7 putty and all animals treated with 1, 2, or 4 mg/mL BMP-7 putty exhibited antibodies against BMP-7. However, robust fusion was noted in all BMP-7 treated animals except one animal in the 0.33 mg/mL BMP-7 putty group. No animals in the 0 mg/mL putty group fused and all autograft animals fused.

The results of this study provide evidence of a BMP-7 dose-response in instrumented PLF in a non-human primate with radiographical and biomechanical parameters similar to or better than autograft. No adverse or abnormal findings were seen associated with BMP-7 putty implantation in a baboon model of instrumented PLF.

## SU147

**Congenic Mouse Models Provide Novel Evidence of Caveolae-1 alpha Domain Regulation of Osteoblast Differentiation.** B. Bragdon<sup>1</sup>, J. Bonor<sup>1</sup>, A. St. Jeanos<sup>1</sup>, K. L. Shultz<sup>2</sup>, W. G. Beamer<sup>2</sup>, A. Nohe<sup>1</sup>. <sup>1</sup>Dept. of Chem. and Bio. Engineering, University of Maine, Orono, ME, USA, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME, USA.

Osteoblasts and osteoclasts must communicate and differentiate correctly for proper bone development and maintenance. With the use of congenic mouse models, C57BL/6J (B6) and B6.C3H-1-12 (1-12), to define mechanisms for altered bone mineral density (BMD), it reasons the communication and signaling is altered as well. An early initiating signal to differentiate into osteoblasts is bone morphogenetic proteins (BMPs). Involved with the onset of BMP signal are plasma membrane domains resembling flask-shaped invaginations called caveolae. There are two isoforms of caveolae-1 (Cav-1), alpha and beta, currently evidence is absent on the role of Cav-1 isoforms possess on osteoblast differentiation; although there is evidence that support caveolae are involved with osteoblast differentiation. Our current model of BMP-2 signaling links BMP receptor (BMPR) dynamics to those of Cav-1 alpha and beta. The interaction of Cav-1 beta to that of the constitutively active BMPR complex silences its signal. Upon activation, this receptor redistributes to Cav-1 alpha beta or alpha alone where it is no longer silenced, however evidence for this is lacking.

We advanced this model of receptor dynamics with control mice, B6, and a Chromosome 1 congenic mouse strain, 1-12, with an increased peak BMD. To determine the signaling differences due to altered caveolae domains, we did an assessment of B6 and 1-12 bone marrow stromal cells by confocal microscopy with state of the art family image correlation spectroscopy (FICS), novel approaches with atomic force microscopy (AFM), and gene activation with reporter gene assays. The results illustrated that 1-12 cells exhibited a repressed BMP-2 signal compared to that of B6 cells. By AFM and FICS measurements the membrane of 1-12 cells showed a reduced recruitment of Cav-1 beta into Cav-1 alpha and the rearrangement

of BMPR Ia to Cav-1 alpha was not observed. Due to the lack of membrane domain rearrangements, enhanced signaling of BMP-2 did not occur. Although 1-12 does have the increase peak BMD, we hypothesize these cells are further along development and therefore additional BMP-2 activation for early differentiation is not required. The signaling differences between the congenic mouse models have furthered the signaling model. This provides new evidence to support that Cav-1 alpha are located independent of Cav-1 beta. This data supports that the different isoforms have adverse effects on osteoblast differentiation. In addition, further therapies will develop from identifying the mechanisms of early osteoblast differentiation of mice models with a higher peak BMD.

**BMP7 Is not Required for Fracture Healing.** K. Tsuji<sup>1</sup>, D. Graf<sup>2</sup>, K. Cox<sup>3</sup>, A. Economides<sup>3</sup>, V. Rosen<sup>1</sup>. <sup>1</sup>Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, <sup>2</sup>Institute of Immunology, Biomedical Sciences Research Center 'Al. Fleming', Hellas, Greece, <sup>3</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, NY, USA.

Sequential changes in expression of individual BMPs occur during fracture healing in mice. Increased BMP2 levels are observed within the first 24 hours after fracture and this spike in BMP2 expression activates periosteal cells to begin the repair process. In contrast to BMP2 expression, a spike in BMP7 expression is observed between days 14 to 21 post fracture at the time of cartilaginous callus replacement by bone. Based on this expression pattern, we hypothesized that BMP7 regulates osteogenesis during the late stages of fracture healing. To examine this hypothesis, we established mice in which BMP7 is removed from limb mesenchyme prior to the onset of skeletogenesis by crossing mice carrying floxed BMP7 alleles with mice carrying cre recombinase driven by the Prx1 promoter (*Bmp7<sup>flx</sup>;Prx1::cre*). *Bmp7<sup>flx</sup>;Prx1::cre* mice form limb skeletal elements in the absence of BMP7 and no BMP7 is present in extracellular matrix of these limb bones. We monitored *Bmp7<sup>flx</sup>;Prx1::cre* mice through 14 weeks of age by X-ray and found no change in postnatal bone morphology. To determine if BMP7 is required for fracture repair, we made transverse femur fractures in 10 week-old *Bmp7<sup>flx</sup>;Prx1::cre* and control littermates and monitored the fracture healing process by X-ray and histology. As predicted, loss of BMP7 did not affect the activation of periosteal cell proliferation early in fracture repair. We also observed bridging callus formation at day 10 post fracture in the absence of BMP7 and bony union after 20 days in *Bmp7<sup>flx</sup>;Prx1::cre* mice by X-ray. These results show that the spike in BMP7 production in late stages of fracture healing is not required for completion of the repair process and allow us to conclude that BMP7 is not necessary for fracture healing.

## SU149

**Safety and Efficacy of BMP-7 Putty in a Rabbit Model of Posterolateral Vertebral Lumbar Fusion.** M. Goad<sup>1</sup>, A. Pierce<sup>1</sup>, M. H. Alaoui-Ishmaili<sup>2</sup>, D. Schrier<sup>1</sup>. <sup>1</sup>Preclinical Development, Stryker Biotech, Hopkinton, MA, USA, <sup>2</sup>Biology, Stryker Biotech, Hopkinton, MA, USA.

The efficacy, safety and pharmacokinetics of BMP-7 putty (BMP-7 with collagen and carboxymethylcellulose) were evaluated in a surgical model of posterolateral vertebral transverse process fusion (PLF) in male and female New Zealand White (NZW) rabbits. Five treatment groups (3/sex/group) included a sham surgery control, 3 BMP-7 putty groups and a group injected IV with BMP-7 (for PK analysis). During surgery, 1.5mL of the BMP-7 putty was placed on each side of the vertebrae between transverse processes L4 and L5. The IV group was injected with 1mg/kg of 6mg/mL BMP-7 on Day 0. Animals were monitored for clinical observations, body weights, and food consumption. PK serum samples were collected on Day 0, 14, and 35. Serum for anti-BMP-7 antibodies were collected before surgery and on Days 14 and 35. Clinical pathology (hematology, serum chemistry, coagulation, and urinalysis) was assessed pre-dose and before euthanasia. On Day 35, animals were euthanized and selected tissues were evaluated microscopically. BMP-7 putty-treated rabbits had bone formed based on radiographs and macroscopic fusion assessments. BMP-7 putty treated animals had new bone at the site of BMP-7 putty placement; this new cortical and cancellous bone had medullary cavities. Low but persistent BMP-7 serum concentrations were seen in the implanted groups suggesting that it is released slowly from the putty. Anti-BMP-7 antibodies were not detected in the sham control or IV-treated groups; all BMP-7 putty-implanted rabbits had detectable anti-BMP-7 antibodies on Days 14 and 35. No BMP-7 related adverse effects were seen in the putty-treated animals compared with sham controls. Animals in all surgical groups had mild to moderate chronic focal inflammation along the surgical/incision site as expected with a surgical procedure.

In conclusion, BMP-7 was effective and safe in a rabbit model of vertebral transverse process fusion. No evidence of toxicity was seen at any BMP-7 dose. The PK analysis was consistent with slow release of BMP-7 from the implant site. Although anti-BMP-7 antibodies were noted in BMP-7 treated animals 14 days after implant, these antibodies had no apparent effect on efficacy or safety. Moreover, an immune response is expected in animals treated with a xenogeneic protein. The No Observed Adverse Effect Level (NOAEL) for BMP-7 putty (surgically-dosed) and BMP-7 (IV-dosed) in NZW rabbits are greater than 12 mg BMP-7 (in 3mL BMP-7 putty) and 1 mg/kg BMP-7 IV. These results are consistent with clinical data that indicate that BMP-7 putty is safe and effective.

## SU150

**Regulation of the Bmp2 Distant Osteoblast Enhancer by Fibroblast Growth Factor 2.** R. L. Chandler<sup>\*1</sup>, R. L. Ostroff<sup>\*1</sup>, S. Jiang<sup>\*2</sup>, M. B. Rogers<sup>\*2</sup>, D. P. Mortlock<sup>1</sup>. <sup>1</sup>Molecular Physiology & Biophysics, Vanderbilt, Nashville, TN, USA, <sup>2</sup>Biochemistry and Molecular Biology, UMDNJ New Jersey Medical School, Newark, NJ, USA.

Factors that induce Bmp2 expression are of particular interest as they may indicate pathways components controlling bone formation. We have previously identified a distant 3' enhancer for Bmp2, ~156 kilobases downstream of its dual promoters, that controls its expression in pre-osteoblasts. FGF (Fibroblast Growth Factor) signaling is critical for proper development of osteoblasts in intramembranous and long bones, and FGF2 can induce Bmp2 expression in cultured mouse calvaria and MC3T3-E1 cells. We transfected Bmp2-LacZ BAC (Bacterial Artificial Chromosome) constructs into MC3T3-E1 cells to determine their response to FGF2. This revealed that Bmp2 BACs could be induced by FGF2 treatment in culture only when the BAC insert extended into the distant 3' flanking region. We have established transgenic mice carrying an Hsp68LacZ reporter minigene linked to the +156 kilobase enhancer, and this confers *in vivo* expression specific to differentiating osteoblasts. Explanted long bones from fetal transgenic mice were cultured *in vitro* and found to maintain LacZ expression for at least four days. When cultured in presence of ascorbate and beta-glycerophosphate for 7-10 days, osteogenic cells migrated into the dish and produced alizarin-red-staining matrix. The area of new matrix was preceded by a wave front of LacZ-positive cells. Primary cell cultures were also established from transgenic explants. These cultures failed to maintain robust LacZ expression, but LacZ could be strongly re-induced following 24 hours of FGF2 treatment. Finally, we examined effects of FGF2 on the +156 kilobase enhancer in the context of Bmp2 promoter constructs. Bmp2 transcripts initiate at either of two sites (termed distal and proximal promoters) separated by approximately 700 bases. When transfected into MC3T3-E1 cells under unstimulated conditions, the enhancer had little or modest ability (less than 2-fold) to enhance expression of Bmp2 fragments spanning the distal, or both promoters. However, FGF2 treatment resulted in an almost 8-fold enhancer-dependent and dose-dependent induction of the distal promoter fragment. FGF2 had no effect on promoter constructs lacking the enhancer. Surprisingly, FGF2 also had no effect on the enhancer in the context of a fragment spanning both the distal and proximal start sites, suggesting a repressor exists between the promoters. Taken together, these data further indicate that FGF signaling regulates Bmp2 in developing osteoblasts, and that this effect is mediated by interactions between the distant 3' enhancer and sequences near the promoter(s).

**IFN- $\gamma$  Inhibits TNF- $\alpha$ -induced Osteoclastogenesis *in vitro* and *in vivo*.** H. Kohara, H. Kitaura, Y. Fujimura<sup>\*</sup>, M. Yoshimatsu, T. Eguchi<sup>\*</sup>, Y. Morita<sup>\*</sup>, N. Yoshida<sup>\*</sup>. Division of Orthodontics and Dentofacial Orthopedics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

It has been reported that RANKL expressed by osteoblasts is essential for inducing osteoclastic differentiation. Recently, it has been found that osteoclastic differentiation is also induced by the inflammatory cytokine TNF- $\alpha$ . IFN- $\gamma$  has an important role in host defense at inflammatory sites. Many reports show that IFN- $\gamma$  inhibits RANKL-induced osteoclastogenesis. However, there are few reports of the effects of IFN- $\gamma$  on TNF- $\alpha$ -induced osteoclastogenesis. In this study, we investigated the effect of IFN- $\gamma$  to TNF- $\alpha$ -induced osteoclastogenesis *in vitro* and *in vivo*. Bone marrow cells were collected from 5-week-old C57BL/6 mice. Bone marrow cells and macrophages were cultured with M-CSF, TNF- $\alpha$  and various concentrations of IFN- $\gamma$  (0.1~100ng/ml). The cultured cells were then stained with TRAP. We subcutaneously injected TNF- $\alpha$  with or without IFN- $\gamma$  into supra-calvariae of mice for 5 consecutive days. Mice were sacrificed on day 6. Histological sections of calvariae taken from each mouse were stained with TRAP. IFN- $\gamma$  inhibited TNF- $\alpha$ -induced osteoclastogenesis in a dose-dependent manner *in vitro*. IFN- $\gamma$  also blocked the generation of osteoclasts in response to TNF- $\alpha$  *in vivo*. Furthermore, we found that IFN- $\gamma$  inhibited M-CSF-induced cell proliferation in a dose dependent manner. We analyzed the expression of CDK inhibitor p16, which is known to inhibit cell proliferation, by RT-PCR. IFN- $\gamma$  increased the expression of p16. The mechanism of inhibition was postulated as being that p16 was induced by the IFN- $\gamma$  inhibited interaction of CDK and cyclin D, which induced cell proliferation. These results indicated that IFN- $\gamma$  inhibits the effects of the cytokines such as RANKL, TNF- $\alpha$  and M-CSF involved in osteoclastogenesis. IFN- $\gamma$  may control not only the host defense but also osteoclastogenesis at an inflammatory site.

**Myostatin (GDF-8) Regulates the Secretion of Growth Factors Localized to the Muscle-Bone Interface.** S. Patterson<sup>\*</sup>, W. Hill<sup>\*</sup>, P. McNeill<sup>\*</sup>, C. M. Isaacs, M. Hamrick. Medical College of Georgia, Augusta, GA, USA.

A close functional association between muscle and bone is indicated by the coupling of muscle and bone anabolism and catabolism during growth, development and aging. The

traditional explanation for this coupling is that a muscle-bone mechanostat exists in which bone adapts to the strains placed on it by muscles. The cellular and molecular mechanisms that link muscle and bone anabolism are, however, poorly understood. It is known that muscle flaps accelerate fracture healing, suggesting that muscle tissue itself can provide a direct anabolic stimulus to bone by not only providing a vascular supply but also by serving as a local source of growth factors. We sought to test this hypothesis by determining first whether IGF-1 and TGF $\beta$ 1, two factors known to regulate bone formation, were present at the muscle bone interface *in vivo* and second, whether the secretion of these factors from myotubes was altered with myostatin treatment *in vitro*. Immunohistochemistry shows that both IGF-1 and TGF $\beta$ 1 are abundant at the interface between periosteum and muscle along the radius and ulna in the mouse forelimb. Mouse C2C12 myotubes were cultured in differentiating medium and treated with myostatin (0.1-1.0  $\mu$ g/ml), and conditioned medium collected at 4, 8 and 10 days for ELISA assays of secreted IGF-1 and TGF $\beta$ 1. Results show that TGF $\beta$ 1 is significantly (10-fold) more abundant in medium than IGF-1 at 4 days of differentiation, and remains more abundant at 10 days (+50%). Myostatin treatment (1.0  $\mu$ g/ml) significantly (~35%) decreases IGF-1 secretion by 8 days of culture, whereas myostatin (0.1  $\mu$ g/ml) significantly (~15%) increases TGF $\beta$ 1 secretion at 10 days. These findings suggest that muscle itself is a source of secreted growth factors, and that regulation of muscle growth and development by myostatin may in turn influence the local abundance of growth factors available for osteoprogenitor cells in the periosteum.

Funding for this research was provided by the National Institutes of Health (AR049717).

***In vivo* Differential Expression Profiling Study on Human Circulating B Cells Suggested a Novel EGFR and CALM3 Network Underlying Smoking and BMD.** P. Xiao<sup>1</sup>, X. D. Chen<sup>\*1</sup>, Y. Chen<sup>\*1</sup>, F. Pan<sup>\*1</sup>, H. Jiang<sup>\*1</sup>, B. Y. Sha<sup>\*1</sup>, R. R. Recker<sup>1</sup>, H. W. Deng<sup>\*2</sup>. <sup>1</sup>Osteoporosis Research Center, Creighton University Medical Center, Omaha, NE, USA, <sup>2</sup>Departments of Orthopedic Surgery and Basic Medical Sciences, University of Missouri-Kansas City, Kansas City, MO, USA.

B lymphocytes play important roles in bone homeostasis. Studies showed that B cells may participate in osteoclastogenesis via expression of osteoclast-related factors, such as transforming growth factor beta (TGF $\beta$ ) and osteoprotegerin (OPG). Our recent genome-wide expression study on human B cells also suggested a novel ER- $\alpha$  and MAPK3 network for postmenopausal osteoporosis. Smoking is an important risk factor for low BMD and related with the apoptosis of B cells. In this study, we aimed to explore important genes that may underlie the mechanism of smoking-related osteoporosis using functional genomic approach. We recruited 40 unrelated postmenopausal Caucasian women aged 54-60, 20 with high BMD (spine or hip Z-score > 0.84) and 20 with low BMD (spine or hip Z-score < -0.84). Each BMD group consisted of 10 smoking and 10 non-smoking subjects. Total RNA from circulating B cells for each subject was extracted and hybridized to an Affymetrix HG-U133A GeneChip<sup>®</sup> array. Significant genes underlying both smoking and BMD were tested by two-way ANOVA and the raw p values were adjusted with Bonferroni procedure for multiple testing. Seventeen significant genes were identified. In particular, network analysis (www.ingenuity.com) showed an interesting gene network centered by epidermal growth factor receptor (EGFR) and calmodulin 3 (CALM3) genes. EGFR gene is important for both osteoclasts and osteoblasts. CALM3 is a critical regulator of osteoclastic differentiation, function and survival. It was also found that CALM3 regulated intracellular trafficking of EGFR and MAPK signaling pathway. This is the first *in vivo* genome-wide expression study on human B cells for smoking-related osteoporosis. Our results suggested that a novel network including EGFR and CALM3 genes may involve in smoking-related bone metabolism.

## SU158

**CCR2 Receptor Signaling Is Involved in Bone Mass Regulation and Mediates the Response to Anabolic but not Catabolic Regimens of PTH(1-34).** E. A. Smith, N. A. Hanson\*, D. T. Crawford\*, T. A. Brown, L. Buckbinder. Pfizer Global R&D, Groton, CT, USA.

Chemokine signaling through CCR2 and the CCR2-ligand MCP1 have been implicated in both osteoclastogenesis and osteoblast function. This study first aimed to evaluate the role of CCR2-mediated signaling on bone mass using CCR2 knockout mice. It has also recently been demonstrated that MCP-1 is upregulated after intermittent but not continuous treatment with PTH(1-34) (X Li, et al. JBC 282: 33098, 2007). This study also examined the role of CCR2 signaling in the bone response to both intermittent and continuous PTH(1-34). Female CCR2<sup>-/-</sup> mice at 18 weeks have increased aBMD of the lumbar spine measured by pDXA between 12 and 18 weeks of age (+6-10%, p<0.05), yet lumbar vertebral trabecular BV/TV is decreased by 25% (p<0.0001) measured by  $\mu$ CT. This suggests that the increase in aBMD is due to changes in cortical bone. The femoral diaphysis in CCR2<sup>-/-</sup> mice has an increased polar moment of inertia (+24%, p=0.0001) with decreased cortical thickness (-10%, p<0.0001) and increased marrow volume (+23%, p<0.0001), suggesting that the cortical bone phenotype is due to periosteal expansion. Serum CTx (RatLAPS, Nordic Biosciences Diagnostics) was decreased in CCR2<sup>-/-</sup> compared to WT mice at 18 weeks (-39.8%, p<0.001) while serum osteocalcin (RIA, Alpco, Windham, NH) was unchanged. CCR2<sup>-/-</sup> and WT mice were then administered intermittent (40ug/kg/day, SC) PTH(1-34) (iPTH) or continuous (40ug/kg/day, Alzet osmotic pump) PTH(1-34) (cPTH) for 6 weeks beginning at 12 weeks. iPTH increased lumbar trabecular BV/TV by 30% in WT mice (p<0.0001), while BV/TV only increased 15% in CCR2<sup>-/-</sup> mice (p=0.005). Two-way ANOVA revealed a significant interaction of genotype x treatment (p=0.004). iPTH also increased cortical thickness of the femoral mid-diaphysis by 8.8% in WT mice (p=0.001) but by only 3.7% in CCR2<sup>-/-</sup> mice (p=0.037). Again, the interaction of genotype x treatment was significant by two-way ANOVA (p=0.046). In contrast, cPTH did not affect trabecular BV/TV in the lumbar spine or distal femur in WT or CCR2<sup>-/-</sup> mice. CPTH decreased cortical thickness in both WT (-5.6%, p=0.06) and CCR2<sup>-/-</sup> mice (-6%, p=0.002) (genotype x treatment not significant by 2-way ANOVA). In summary, CCR2<sup>-/-</sup> mice have a high bone mass phenotype in the cortical envelope but a low bone mass phenotype in the trabecular compartment. CCR2<sup>-/-</sup> mice exhibited a blunted anabolic response to iPTH but an equivalent catabolic response to cPTH compared to WT mice. Taken together, these data suggest that chemokine signaling through CCR2 regulates trabecular and cortical bone mass and in part mediates the anabolic response to intermittent but not the catabolic response to continuous PTH(1-34).

**Histamine H4 Receptor (H4R) Is Expressed By Both Osteoarthritic (OA) And Rheumatoid Arthritis (RA) Human Tissues.** C. Manacu\*<sup>1</sup>, M. Dion\*<sup>1</sup>, L. H. Attalah\*<sup>1</sup>, R. Renous\*<sup>2</sup>, M. Frohn\*<sup>3</sup>, G. Y. Ng\*<sup>3</sup>, F. Moldovan<sup>2</sup>. <sup>1</sup>Université de Montréal, Montreal, QC, Canada, <sup>2</sup>Centre de Recherche CHU Sainte-Justine, Montreal, QC, Canada, <sup>3</sup>AMGEN inc., Thousand Oaks, CA, USA.

The objective of this study was to determine whether the H4R is pharmacologically expressed in normal, OA and RA human tissues, and the types of cells expressing this receptor. Human synovial tissues from OA and RA patients were investigated using RT-PCR, immunohistochemistry and by competitive radiolabeled antagonist binding assays. To determine the phenotype of the cells expressing H4R, mast cells were revealed using anti-tryptase and c-kit antibodies. Dendritic cells, macrophage and endothelial cells were revealed using S100, CD68 and the Von Willebrand factor respectively. CD4 was used as a marker for mature helper T cells, and CD8 as a marker for mature Cytotoxic T cells. The H4 receptor was detected at RNA and protein levels in both OA and RA synovial tissues, with a significantly greater number of cells staining positive in inflammatory RA tissues. In synovial membranes from patients with RA, H4 receptor was detected in mast and dendritic cells as well as in the macrophage-like type B synoviocytes infiltrating within the vascular wall, in the diffuse cellular infiltrate and in the superficial lining cell layer and in the pannus. When vessels from rheumatoid synovial membranes or OA showed features of vasculitis, a positive signal for H4 receptor was detected within the media and adventitia of the vascular wall but not in the internal tunic endothelial cells (intima, which stains positive for the von Willebrand factor). In contrast, fibroblast-like synovial cells, follicular aggregates and CD8 positive cells were all negative for H4R. In newly dissociated and cultured human OA synoviocytes, specific [3H] radiolabeled antagonist binding was displaced by the selective H4R antagonist JNJ 7777120 and Thioperamide. This study shows the *in situ* localization of H4R in human OA and RA tissues in both infiltrating immune cells and synoviocytes associated with disease pathogenesis. We provide also first pharmacological evidence of H4R expression by radiolabeled binding. Hence, H4R may be an attractive target in the development of new approaches for therapeutic treatment of OA and RA and possibly other diseases where histamine plays a crucial event in mediating leukocyte trafficking and tissue degradation.

**Decreased Bone Formation, Increased Bone Resorption, and Osteopenia in Mice Lacking Substance P.** S. Hou<sup>1</sup>, L. Wang<sup>1</sup>, I. Sabsovich<sup>2</sup>, R. Zhao<sup>2</sup>, T. Wei\*<sup>2</sup>, W. S. Kingery<sup>1</sup>. <sup>1</sup>Physical Medicine and Rehabilitation Service, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA. Department of Orthopedics, Stanford University School of Medicine, Stanford, CA, USA, <sup>2</sup>Physical Medicine and Rehabilitation Service, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA, USA.

Substance P (SP) is a neuropeptide which is extensively distributed in the sensory neurons innervating bone. There is evidence that SP can regulate bone cell function in vitro, but it is unclear whether SP can modulate bone modeling or remodeling in vivo. To answer this question we characterized the bone phenotype of mutant mice with a targeted deletion of the Tac1 gene expressing SP. Immunocytochemical staining and RT-PCR were used to demonstrate the expression of the SP NK1 receptor on MC3T3-E1 osteoblastic cells and Raw 264.7 osteoclastic cells. The phenotype of 2-month-old and 5-month-old Tac1<sup>-/-</sup> mice and their corresponding wild-type controls were characterized using microCT imaging, static and dynamic bone histomorphometry, and by measuring urinary collagen degradation products. No differences were observed between the Tac1<sup>-/-</sup> mice and their wild-type controls in body weight, rotarod testing, femur and tibia bone length, and gastrocnemius and soleus muscle weights. By 5 months of age both the wild-type and Tac1<sup>-/-</sup> mice had developed trabecular osteopenia, but relative to the wild-type mice, SP deficient mice had significantly greater cortical and trabecular bone loss. The 5-month-old Tac1<sup>-/-</sup> mice also exhibited decreased bone formation rates, increased osteoclast number per bone surface, and increased urinary levels of deoxypyridinoline cross-links. In conclusion, these in vivo data suggest that SP signaling does not contribute to bone modeling, but has a positive effect on age-related bone remodeling that may be due to a direct neural-osseal stimulatory effect on osteoblast function.

**Hedgehog Signaling Regulates Growth Plate Chondrocyte Proliferation and Growth Factor Expression.** J. A. Horton\*, B. S. Margulies, M. J. Allen, T. A. Damron. Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY, USA.

Growth plate chondrocyte proliferation and differentiation are governed by a feedback loop involving Indian hedgehog (Ihh) and parathyroid hormone-related peptide (PTHrP). PTHrP is understood to act as a negative regulator of chondrocyte maturation. The precise role of Ihh-signaling in this loop is unclear, though it has been proposed that Ihh may promote chondrocyte proliferation, in part by regulating PTHrP and/or IGF2 expression. Modulation of Smoothened (Smo) activity by the agonist purmorphamine (PUR) or the antagonist cyclopamine (CYC) has been demonstrated to alter hedgehog pathway signal transduction in several cell types. The purpose of this study was to evaluate the response of growth plate chondrocytes to manipulation of the hedgehog signaling pathway using these agents. We hypothesized that cells exposed to PUR would exhibit increased proliferation, Gli-mediated transcription and up-regulated expression of specific factors including PTHrP and IGF2, while treatment with CYC would have the opposite effect. Primary rat costal chondrocytes were exposed 10  $\mu$ M PUR or CYC, and data were normalized to control cells treated with 0.5% DMSO vehicle. Changes in cell viability were determined by MTT assay. Flow cytometry was used to assess agent induced alterations in cell cycle kinetics. Gli-mediated transcription was assessed using a Gli-luciferase reporter plasmid, and sub-cellular localization of Gli2 was observed by immunocytochemistry. Expression of PTHrP, IGF2, and their respective receptors, and key cell cycle regulators were assayed by RT-PCR, immunoblotting and/or immunocytochemistry. Chondrocytes exposed to PUR for 72 hours showed a 26.3% increase in viable cell number, while CYC-treated cells were reduced up to 20.1%. Cell cycle analysis showed that PUR treatment reduced the S-phase fraction and increased the G2/M population phase. CYC treated cells accumulated in S-phase and showed reduced nuclear localization of PCNA and cyclin D1. Gli-luciferase reporter activity was increased 3-fold by PUR exposure, and was accompanied by nuclear translocation of Gli2. Gli2 was largely excluded from the nuclei of CYC treated cells, however reporter activity was not affected by CYC. PUR treated cells showed up-regulation of PTHrP and IGF2 at the protein and mRNA levels, while CYC down-regulated factors. Neither agent affected the expression or localization of the respective transmembrane receptors, PTHR1 and IGF1R, Smo or Ihh. Taken together, our results demonstrate that hedgehog signaling, downstream of Smo, participate in the regulation of growth plate chondrocyte proliferation and cell cycle progression, as well as inducing the expression of several pro-mitotic gene products, including PTHrP and IGF2.

**The Distinct Biological Activity of Interleukin 8 Isoforms.** K. M. Nicks, N. S. Akel\*, D. Gaddy, L. J. Suva. Physiology and Biophysics & Orthopaedic Surgery, UAMS, Little Rock, AR, USA.

Previous studies have shown that the chemokine interleukin 8 (IL-8) is able to directly stimulate human osteoclast formation independent of RANKL expression and that human breast cancer and ovarian cell lines secrete distinct IL-8 isoforms (IL-8 (1-77) and (6-77)).

In this study, the role of the two tumor-secreted IL-8 isoforms was examined *in vitro*. Both isoforms were tested for their ability to bind to the specific IL-8 receptors CXCR1 and CXCR2, to recruit human neutrophils and to promote human osteoclastogenesis. The IL-8 isoforms specifically bound both human CXCR1 and CXCR2. Interestingly, the binding affinity of IL-8 (1-77) to CXCR1 (the primary IL-8 receptor) was significantly greater than IL-8 (6-77) ( $IC_{50}$   $5 \times 10^{-9}$  M vs.  $10^{-6}$  M), whereas there was no difference in affinity for CXCR2. Human neutrophils (expressing CXCR1 and 2) were isolated from peripheral blood and chemotaxis assessed using standard 24-well microchemotaxis chambers covered with polyethylene terephthalate membranes. The lower wells were filled with various concentrations of either IL-8 (1-77), (6-77) or medium without IL-8 peptide. The neutrophils rapidly passed through the membranes toward the wells of the lower chamber containing either IL-8 peptide. No significant differences in chemotaxis were observed with either IL-8 peptide (50% migration at  $5 \times 10^{-8}$  M). In contrast, human osteoclastogenesis was significantly greater when human osteoclast precursors isolated from peripheral blood were stimulated with IL-8 (1-77) than with (6-77). The difference in osteoclastogenic potency was related to the binding affinity of the peptides to CXCR1, the only receptor expressed on osteoclasts and their precursors. In addition, the osteoclastogenic potential of IL-8 was completely inhibited by the CXCR1-specific antagonist (reperitaxin) demonstrating receptor specificity. The activity of RANKL was unaffected by the addition of reperitaxin. To confirm the potency of the IL-8 peptides, purified CD14+ human osteoclast precursors were treated with (1-77) and (6-77). Similar differences in IL-8 peptide potencies were observed, with IL-8 (1-77) inducing significantly more TRAP positive osteoclasts than (6-77), demonstrating a selectivity difference between the response of human neutrophils and osteoclasts to IL-8 isoforms. Collectively, these data demonstrate that tumor-derived IL-8 isoforms have significant distinct effects on osteoclastogenesis that require further investigation.

**Gene Expression in Blast-Injured Muscle: Insights into the Mechanism of Heterotopic Ossification.** A. B. Aragon<sup>\*1</sup>, W. M. Jackson<sup>\*2</sup>, J. Onodera<sup>\*2</sup>, R. S. Tuan<sup>\*2</sup>, L. J. Nesti<sup>1</sup>. <sup>1</sup>Department of Orthopaedics and Rehabilitation, Walter Reed Army Medical Center, Washington, DC, USA, <sup>2</sup>Cartilage Biology and Orthopaedics Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, USA.

Post-traumatic heterotopic ossification (HO) occurs at a high frequency in time-of-war extremity injuries; however the etiology of HO is poorly understood. We have previously identified a population of multipotent mesenchymal progenitor cells (MPCs) within traumatized muscle. Dysregulation of traumatic and wound healing factors could signal these MPCs to become osteoprogenitors and initiate ectopic bone formation. Therefore, the hypothesis of this study was that osteogenic cytokines are up-regulated in traumatically injured muscle tissue. Our specific aims were (1) to identify the cytokines that are up regulated in the injured muscle, (2) to verify the expression of these cytokines in the tissue, and (3) to localize these cytokines within the traumatized muscle relative to the populating cells. Debrided muscle samples were obtained during serial washouts of traumatic extremity wounds, and untraumatized muscle was obtained from elective orthopaedic reconstructions. Cytokine expression was assayed by homogenizing the tissue samples in the TRIzol reagent to extract mRNA and protein. mRNA was analyzed with real-time RT-PCR for cytokines associated with HO (i.e., BMP-4, gremlin, etc) and with a SuperArray RT2Profiler array containing primers for 84 cytokines and cytokine receptors. Cytokine and cellular localization was assayed using immunohistochemistry on tissue samples that were fixed, paraffin embedded and sectioned. We identified a cytokine gene expression profile associated with the traumatized muscle, which included up-regulation of cytokines associated with osteogenic induction (i.e., IL-6, GDF-5, BMP-1). There was no significant up-regulation of the cytokines typically involved in HO formation (i.e., BMP-4, as occurs in the genetic disorder Fibrodysplasia ossificans progressiva). The expression of the up-regulated cytokines in the traumatized muscle tissue was verified by western blotting. In addition, the immunohistochemistry demonstrated that these traumatic cytokines were expressed in a region-specific distribution. This study further characterizes interactions at the cellular and tissue levels that participate in the etiology of HO. Through a greater understanding of how traumatic cytokines are regulated and localized in injured muscle, we hope to better define the key events that contribute to this pathological process and identify novel targets for prophylactic or therapeutic interventions.

**Central and Peripheral Leptin Treatment Produce Similar Increase in Cortical and Trabecular Bone Mass in ob/ob Mice.** S. M. Bartell<sup>\*1</sup>, D. R. Gaddam<sup>\*1</sup>, S. Ambati<sup>\*1</sup>, S. Rayalam<sup>\*1</sup>, D. L. Hartzell<sup>\*1</sup>, M. Hamrick<sup>\*2</sup>, J. She<sup>\*3</sup>, M. A. Della-Fera<sup>\*1</sup>, C. A. Baile<sup>1</sup>. <sup>1</sup>Dept of Animal & Dairy Science, University of Georgia, Athens, GA, USA, <sup>2</sup>Dept of Cellular Biology & Anatomy, Medical College of Georgia, Augusta, GA, USA, <sup>3</sup>Dept of Pathology, Medical College of Georgia, Augusta, GA, USA.

Central or peripheral leptin administration reduces body weight, food intake, & body fat in leptin deficient ob/ob mice. However, opposing reports dominate when assessing the effects of leptin on cortical & trabecular bone mass in rodents. This study's objective was to determine effects of central & peripheral administration of leptin on bone metabolism in cortical & trabecular bone in ob/ob mice (15 wk old, init. BW=61.3g). Leptin was continuously delivered intracerebroventricularly (ICV, 0 or 1.5µg/d) or subcutaneously

(SQ, 0 or 10µg/d) via osmotic pumps for 12 days (n=10). Mice were injected intraperitoneally with calcein, a fluorochrome label, to measure bone formation during the experimental period. There were no significant differences in bone parameters between the modes of leptin administration. Regardless of mode of administration, leptin increased whole body bone mineral density (BMD; 0.0565 vs 0.0542 vs 0.0503g/cm<sup>2</sup>, p=0.0003; mean of ICV vs SQ leptin treatments vs controls), & bone mineral content (BMC; 0.518 vs 0.483 vs 0.397g, p=0.001), lumbar BMD (0.0943 vs 0.0891 vs 0.0723g/cm<sup>2</sup>, p=0.0002) & BMC (0.034 vs 0.031 vs 0.024g, p<0.0001), proximal femoral BMD (0.0995 vs 0.0973 vs 0.0732g/cm<sup>2</sup>, p=0.0002) & BMC (0.051 vs 0.052 vs 0.039g, p=0.0006), distal tibial BMD (0.0856 vs 0.0825 vs 0.0675g/cm<sup>2</sup>, p=0.0009), cortical (4.74 vs 5.29 vs 2.64microns/d, p<0.0001) & trabecular (5.26 vs 6.12 vs 2.65microns/d, p<0.0001) mineral apposition rate, serum osteocalcin (96.408 vs 123.481 vs 35.493ng/mL, p<0.0001), pyridinoline (PYD) (2.577 vs 2.447 vs 0.831nmol/L, p=0.04), & RANK-L (145.51 vs 186.93 vs 111.21pg/mL, p<0.001) concentrations. These observed increases in BMD, BMC, bone formation & bone marker concentrations indicate that both SQ & ICV (1/7th the SQ dose) leptin administration increased cortical & trabecular bone equally in ob/ob mice.

**Chemerin and CMKLR1 Expression and Function in Human Bone Marrow Mesenchymal Stem Cell Adipogenesis.** A. A. Roman<sup>\*</sup>, C. J. Sinal. Pharmacology, Dalhousie University, Halifax, NS, Canada.

Osteoporosis is a progressive skeletal disorder characterized by low bone mass and microarchitectural deterioration of bone tissue that ultimately leads to an increase in bone fragility and susceptibility to fracture. A hallmark characteristic of osteoporotic bone is an increase in fatty marrow that develops as a consequence of an increase in the number of marrow adipocytes. Recent findings demonstrate that this increase in marrow adipocytes is directly related to bone loss, as adipocytes share a common mesenchymal stem cell (MSC) precursor with bone forming osteoblasts. As marrow adipogenesis is attributable to alterations in bone marrow MSC differentiation, and not to adipocyte infiltration from tissues outside the bone, manipulation of the physiological milieu of MSCs to favour osteoblast formation over adipocyte formation may offer a novel target for the treatment of osteoporosis. In the bone marrow, many factors influence the fate of MSCs including secreted signalling molecules, such as cytokines and nutritional factors, such as Vitamin D. Recently, our laboratory identified chemerin as a signaling molecule released from adipocytes that regulates adipogenesis by activation of chemokine like receptor-1(CMKLR1). The purpose of this study was to characterize the expression and function of chemerin and CMKLR1 in the adipogenic differentiation of human bone marrow derived MSCs. Chemerin and CMKLR1 mRNA and protein expression were evaluated using quantitative real time PCR and western blotting, respectively. We have identified that chemerin and CMKLR1 are expressed in human bone marrow derived MSCs and that the expression of chemerin and CMKLR1 are increased during adipogenesis, *in vitro*. We have also demonstrated that treatment of adipocyte precursors with Vitamin D *in vitro* caused a significant induction in chemerin expression, therefore providing support for one mechanism whereby chemerin may be directly regulated to affect bone formation.

**The Effects of Exercise and Estrogen on Osteoprotegerin in Premenopausal Women.** S. L. West<sup>\*1</sup>, J. L. Scheid<sup>\*1</sup>, S. Awidishu<sup>\*1</sup>, M. J. De Souza<sup>2</sup>. <sup>1</sup>University of Toronto, Toronto, ON, Canada, <sup>2</sup>Penn State University, University Park, PA, USA.

The benefits of exercise are widely recognized, however physically active women can develop exercise associated menstrual cycle disturbances such as amenorrhea (i.e., estrogen deficiency) secondary to a chronic energy deficiency. The purpose of this cross-sectional observational study was to assess the effects of exercise status and estrogen deficiency on osteoprotegerin (OPG) and its relationship to bone turnover in premenopausal women. Serum OPG, urinary c-telopeptides (uCTX), urinary estrone 3-glucuronide (E1G), urinary pregnanediol 3-glucuronide (PdG) and bone mineral density (BMD) by DXA were measured repeatedly in 67 women. Volunteers were retrospectively grouped: 1) Sedentary menstruating group (SedMen n=8), 2) Exercising menstruating group (ExMen, n=36), 3) Exercising amenorrheic group (ExAmen, n=23). One-way ANOVAs were performed, and LSD post-hoc tests were performed when differences were detected. Subjects were similar with respect to age (24.2±1.0 yrs), weight (57.8±1.7 kg), height (164.3±1.3 cm), and BMI (21.5±0.6 kg/m<sup>2</sup>) (p>0.05). ExMen and ExAmen groups were more aerobically fit than the SedMen group (p=0.003). E1G mean (p<0.001), E1G AUC (p<0.001), and PdG AUC (p=0.018) were lower in the ExAmen group vs. the SedMen and ExMen groups. uCTX was elevated (p=0.033) in the ExAmen group (281.8±40.3 ug/L/mmCr), compared with the SedMen and ExMen groups (184.5±22.4, 197.2±14.7 ug/L/mmCr, respectively). OPG was concomitantly suppressed (p=0.005) in the ExAmen group (4.6±0.2 pmol/L) vs. ExMen group (5.2±0.2 pmol/L), and OPG was also lower in the SedMen group (4.1±0.3 pmol/L) compared with the ExMen group. Findings were translated to BMD; the ExAmen group had suppressed total body BMD (p=0.014) and L2-L4 BMD (p=0.015) vs. the ExMen group. Our results suggest that OPG responds to the bone loading effect of exercise, and that suppressed OPG may play a role in the etiology of increased bone resorption observed in exercising women with hypothalamic amenorrhea.

### Increased Circulating Dickkopf-1 in Acute Coronary Syndrome - Association with Platelet Release and Endothelial Inflammatory Response.

T. Ueland\*, K. Otterdal\*, T. Lekva\*, W. Sandberg\*, B. Halvorsen\*, J. Bollerslev, E. Oie\*, L. Gullestad\*, P. Aukrust\*. Rikshospitalet-Radiumhospitalet Medical Center, oslo, Norway.

**Purpose:** Increasing evidence indicates a pathological link between atherogenesis and osteoporosis. The Wnt signaling pathway plays an important role in regulating bone remodeling and we sought to investigate the role of Dickkopf (DKK)-1 in atherogenesis and plaque destabilization. **Methods:** We investigated this by different experimental approaches including studies in patients with stable (n = 40) and unstable angina (n = 40) and healthy control subjects (n = 20). **Results:** The following was discovered: 1) patients with stable, and particularly those with unstable, angina had markedly raised serum levels of DKK-1 compared with control subjects. 2) Platelets are a rich source of DKK-1 and release large amounts upon activation. This release was inhibited by preincubation with PGE1, suggesting that DKK-1 is secreted from alpha-granules during activation. 3) DKK-1 protein was detected in atherosclerotic plaques and coronary thrombi. 4) endothelial cells produce DKK-1 upon stimulation with CD40L in vitro. 5) siRNA-mediated knocking down of DKK-1 in endothelial cells decreased the production of IL-8 suggesting that DKK-1 may enhance endothelial inflammatory response. 6) Aspirin reduced the SFLRN-stimulated release of DKK-1 from platelets, and when administered to healthy control subjects for 7 days, it reduced circulating DKK-1. **Conclusion:** The data may suggest a pathogenic role for DKK-1 in atherogenesis involving modulation of platelet-induced inflammatory responses in endothelial cells.

**Disclosures:** T. Ueland, None.

### FGF-23 and Post -Transplant Hypophosphatemia: Evidence for a Causative Link.

A. Trombetti<sup>1</sup>, L. Richert<sup>\*1</sup>, K. Hadaya<sup>\*2</sup>, J. D. Graf<sup>\*3</sup>, P. Y. Martin<sup>\*2</sup>, R. Rizzoli<sup>1</sup>. <sup>1</sup>Department of Rehabilitation and Geriatrics, University Hospital of Geneva, Geneva 14, Switzerland, <sup>2</sup>Nephrology Service, University Hospital of Geneva, Geneva 14, Switzerland, <sup>3</sup>Central Laboratory, University Hospital of Geneva, Geneva 14, Switzerland.

**Objective:** Hypophosphatemia is frequent in the early post-transplant period. Fibroblast growth factor-23 (FGF-23) may be involved in hypophosphatemia pathogenesis. Other factors could modulate serum phosphate level such as increased parathyroid hormone (PTH) level, renal function and dietary phosphorus intake. Therefore, we tested the hypothesis that FGF-23 level is associated with decreased serum phosphate levels and renal phosphate threshold (TmPi/GFR) independently of renal and parathyroid function, and of dietary phosphate intake in renal transplant recipients.

**Methods:** We investigated 48 recipients of kidney transplant. Plasma PTH, calcitriol, FGF-23 (intact FGF-23, Kainos Laboratories, Inc., Tokyo, Japan, and C-terminal FGF-23 fragments, Immotopics, San Clemente CA, USA) were measured 11 days [95% CI, 9.1-15.9] after renal transplantation. Fasting plasma and urinary calcium, phosphate and creatinine were also measured simultaneously and renal tubular reabsorption of phosphate was calculated as well as renal function, using the Cockcroft and Gault formula. Hypophosphatemic and patients with normal phosphate level were compared by a non-parametric test. Correlations between serum phosphate levels, renal phosphate threshold and recorded variables were determined by simple or multiple linear regression analyses.

**Results:** Hypophosphatemia, defined as a serum phosphate level  $\leq 0.8$  mmol/l, was observed in 26 (54%) of the patients in the early post transplant period. Patient with hypophosphatemia had a significantly higher level of both intact and C-terminal FGF23 ( $238 \pm 215$  vs  $99 \pm 125$  ng/l for the intact,  $p < 0.05$ ;  $486 \pm 520$  vs  $275 \pm 460$  U/ml for the C-terminal assay,  $p < 0.01$ ). In univariate analysis, intact FGF-23 was inversely correlated with plasma phosphate ( $r^2 = 0.16$ ,  $p < 0.03$ ) and renal tubular reabsorption of phosphate ( $r^2 = 0.19$ ,  $p < 0.03$ ). The association between C-terminal form and plasma phosphate was of borderline significance ( $r^2 = 0.06$ ,  $p < 0.1$ ), while the inverse association was significant for renal phosphate threshold ( $r^2 = 0.13$ ,  $p < 0.02$ ).

When PTH levels, renal function and dietary phosphate intake were included in a multivariate model, PTH and FGF-23 remained independently associated with renal phosphate threshold. These variables explained 46% of the variance of TmPi/GFR (p value for the model  $< 0.001$ ).

**Conclusion:** Our study strongly suggest that FGF-23 may be a causative factor for the developpement of hypophosphatemia in conjunction with increased levels of PTH in the early post-transplant period.

**Disclosures:** A. Trombetti, None.

## SU169

### Effects of hPTH(1-34) Infusion on Circulating Serum Phosphate, 1,25-dihydroxyvitamin D and FGF-23 Levels in Healthy Men.

S. M. Burnett-Bowie, M. P. Henao\*, M. E. Dere\*, H. Lee\*, B. Z. Leder. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

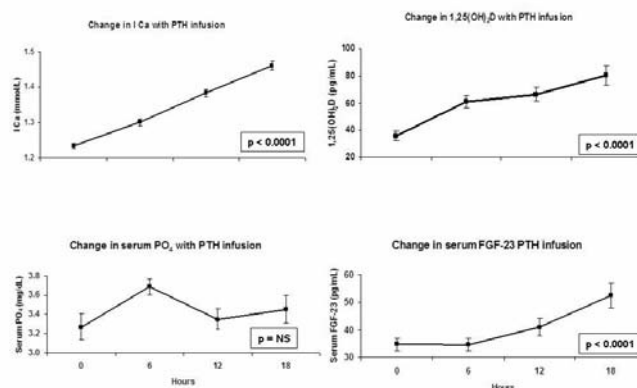

**Introduction:** Fibroblast growth factor 23 (FGF23) is a phosphate ( $PO_4$ )-regulating hormone that promotes renal  $PO_4$  wasting and suppresses 1,25-dihydroxyvitamin D ( $1,25(OH)_2D$ ) production. PTH also promotes renal  $PO_4$  wasting but, in contrast to FGF23, stimulates  $1,25(OH)_2D$  production. While studies suggest that dietary  $PO_4$ , serum  $PO_4$ , and  $1,25(OH)_2D$  stimulate FGF23 secretion, the relationship between FGF23 and PTH is

unclear. Furthermore, the acute effect of a pharmacologic dose of PTH on FGF23 secretion is unknown.

**Methods:** 20 healthy men, aged 20-45, with normal serum calcium,  $PO_4$  and renal function were treated with human parathyroid hormone (1-34) (hPTH(1-34)) at a dose of 44ng /kg/ hour for 24 hours. Blood ionized calcium levels were monitored regularly and the infusion discontinued if ionized calcium exceeded 1.5 mmol/L. ANOVA was performed to determine if our primary endpoints (serum  $PO_4$  and FGF23) or secondary endpoints ( $1,25(OH)_2D$ , ionized calcium and serum N-telopeptide) changed over time. If such a change were detected, paired t-tests were performed to compare hour 6, 12, or 18 data to baseline.

**Results:** Compared to baseline, serum FGF23,  $1,25(OH)_2D$ , ionized calcium and N-telopeptide increased significantly over the 18-hour hPTH(1-34) infusion ( $p < 0.0001$ ), while serum  $PO_4$  did not change. Specifically, serum FGF23 increased from  $35 \pm 10$  pg/mL at baseline to  $53 \pm 20$  pg/mL at 18 hours ( $p = 0.0002$ );  $1,25(OH)_2D$  increased from  $36 \pm 16$  pg/mL at baseline to  $80 \pm 33$  pg/mL at 18 hours ( $p < 0.0001$ ); ionized calcium increased from  $1.23 \pm 0.03$  mmol/L at baseline to  $1.46 \pm 0.05$  mmol/L at hour 18 ( $p < 0.0001$ ); and serum N-telopeptide increased from  $17 \pm 4$  nM BCE at baseline to  $28 \pm 8$  nM BCE at peak ( $p < 0.0001$ ). Serum  $PO_4$  was  $3.3 \pm 0.6$  mg/dL at baseline, transiently rose to  $3.7 \pm 0.4$  mg/dL at hour 6 ( $p = 0.0016$ ), and then returned to  $3.4 \pm 0.5$  mg/dL at hour 12 ( $p = 0.651$ ).

**Conclusions:** hPTH(1-34) infusion significantly increases endogenous  $1,25(OH)_2D$  and FGF23 levels within 18 hours in healthy men. Additionally, we observed a transient rise in serum  $PO_4$  that is likely due to PTH mediated bone resorption. Prior animal and *in vitro* data suggest that neither PTH nor calcium stimulate FGF23 secretion, but that serum  $PO_4$  and  $1,25(OH)_2D$  do. Our data support the assertion that  $1,25(OH)_2D$  is a potent physiologic stimulator of FGF23 secretion, and that serum  $PO_4$  may be a stimulator of FGF23 secretion.

### Development of Nephrotic In Transgenic Rats Over Expressing TypeIII Na-Dependent Phosphate Transporter.

S. Sekiguchi, S. Asano, M. Shibata, A. Yokoyama\*, K. Inagaki\*, H. Kakizawa\*, N. Hayakawa\*, N. Oda\*, A. Suzuki, M. Itoh\*. Division of Endocrinology, Fujita Health University, Toyoake Aichi, Japan.

Phosphate uptake at the cellular membrane is essential to maintain the cell activity because phosphate has to be supplied for ATP synthesis. On the contrary, accumulating evidence suggests that phosphate overload from the extracellular milieu would be stressful for the cells, resulting in the apoptosis of the cells. We have previously reported that the overexpression of a type III Pi transporter (Pit-1) in rats induces the phosphate-dependent cellular stress, which results in the damage of the filtration at glomerulus without affecting renal function itself. In the present study, we further investigate the effect of over expression of Pit-1 on the kidney in Pit-1 transgenic (Tg) rats, and analyzed the mechanism of the development of nephrotic syndrome.

On day 10 after birth, when its glomerulus achieved development, there was no difference of glomerulus between wild type (WT) and Tg rats under electron microscope (EM). However, glomerulus in Tg rats progressively exhibits diffuse loss of processes of visceral epithelial cells (podocytes) and thickened basement membrane under EM after 8 weeks old. At 8 months old, when Tg rats were going to die because of cachexia, glomerulus in Tg rats had thickened basement membrane, increased mesangial matrix, and were sclerosed and hyalinized. In order to further explore the mechanism of the development of nephrotic syndrome in Pit-1 Tg rats, we next examined the effect of extracellular phosphate on primary cultured podocyte from both WT and Tg rats. A two fold increase of Pi transport activity was recorded in primary cultured podocyte from Tg rats compared with WT littermates. More apoptosis of podocytes by high phosphate in extracellular milieu was found in Tg rats than in WT by TUNEL method.

In conclusion, our findings suggest us that cell stress by extracellular Pi induces apoptosis of podocyte, and continuous stress on podocytes by Pit-1 overexpression at least in part explains the progress of glomerulus damage, which results in the nephrotic syndrome.

**A Homozygous Threonine to Methionine Substitution in FGF23 Gene Is Associated with Tumoral Calcinosis in a 12 Year-old Girl.** N. S. Dunbar<sup>1</sup>, C. Nelson-Williams<sup>2</sup>, R. L. Lifton<sup>2</sup>, T. O. Carpenter<sup>1</sup>. <sup>1</sup>Pediatrics, Yale University, New Haven, CT, USA, <sup>2</sup>Genetics, Yale University, New Haven, CT, USA.

Familial tumoral calcinosis (FTC) is a rare disorder of phosphate metabolism characterized by ectopic calcified masses as well as vascular calcifications. Patients are hyperphosphatemic with elevated or inappropriately normal circulating 1, 25 dihydroxyvitamin D (1,25D). The calcified lesions can cause pain, decreased mobility, loss of function and disfigurement. Inactivating mutations of fibroblast growth factor 23 (FGF23), GalNAc transferase 3 (GALNT3), and Klotho (KL) have been identified in patients with autosomal recessive FTC.

A previously healthy 12 year old Caucasian girl noted tenderness and swelling over the back of her neck. A large, well-defined, multilocal calcific mass was identified sonographically in the posteriolateral aspect of the left neck, extending from the posterior arch of the first cervical vertebra to the thoracic inlet. A chalky, non-purulent slurry periodically drained from the site of an open biopsy. Circulating phosphorus levels ranged from 4.8 to 5.1 mg/dl (high normal to slightly elevated), serum calcium levels ranged from 9.2 to 9.6 mg/dl (normal), and circulating 1,25D was 71 pg/ml (increased). Circulating PTH was normal (20 nleq/ml). The threshold maximum for renal tubular phosphate reabsorption (TMP/GFR) was 5.2 mg/dl. Serum FGF23 using an assay detecting the intact molecule (Kainos, Japan) was 24 pg/ml but no immunoreactive species was detected using an assay directed toward the C-terminus of the molecule (Immutopics). Surgical debulking was performed.

Mutational analysis was performed employing direct sequencing of the FGF23, KLOTHO and GALNT3 genes on DNA derived from peripheral leukocytes. A homozygous G->A transition was identified in the FGF23 gene indicating a T239M substitution in the protein. This missense mutation replaces a noncharged, polar, hydrophilic residue with a non-polar, hydrophobic one, suggesting a potential functional consequence of this mutation. The discordance in results when employing two different assays is not clear at this time, but may represent an effect of the mutation on interaction with antibodies used in FGF23 assays.

**Signaling of Extracellular Inorganic Phosphate Mediated via Sodium-Phosphate Co-transporters Influences FGF23 Signaling in Renal Tubular Cells.** M. Yamazaki<sup>1</sup>, T. Okada<sup>1</sup>, K. Tachikawa<sup>1</sup>, K. Ozono<sup>2</sup>, T. Michigami<sup>1</sup>. <sup>1</sup>Department of Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, <sup>2</sup>Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan.

FGF23 increases renal phosphate excretion by binding FGF receptor and membrane-bound form of klotho. However, the impact of serum levels of inorganic phosphate (Pi) on the effect of FGF23 remains uninvestigated. Thus, we have examined the effects of extracellular Pi on FGF23 signaling utilizing renal tubular cell line HEK293. Real-time PCR for klotho demonstrated its low expression in HEK293 cells. HEK293 cells were capable of responding to treatment with recombinant FGF23[R179Q], a constitutively active form of FGF23, based on the phosphorylation of ERK1/2 and the expression of early growth response-1 (Egr-1), and over-expression of klotho markedly enhanced the response in HEK293 as previously reported. Then, we examined the effects of increased extracellular Pi on phosphorylation of ERK1/2 and expression of Egr-1. Interestingly, treatment with increased Pi (4 mM) resulted in phosphorylation of ERK1/2. The time course of phosphorylation of ERK1/2 induced by increased extracellular Pi was similar to that induced by FGF23[R179Q]. In addition, increased extracellular Pi induced the expression of Egr-1 within 30 min., and simultaneous treatment with increased Pi and FGF23[R179Q] exerted additive effects, suggesting the commonality between FGF23 and extracellular Pi in terms of the downstream signaling networks. Increased extracellular Pi induced the phosphorylation of c-Raf as well, indicating the activation of Raf/MEK/ERK pathway. Since the increase in extracellular Pi failed to induce phosphorylation of FRSS2α (FGF receptor substrate 2α), the cascade upstream of ERK1/2 in Pi-induced signaling is likely to be different from that in FGF23-induced signaling. Treatment with phosphonoformic acid (PFA), an inhibitor of Na<sup>+</sup>/Pi co-transporters, abolished the effects of increased extracellular Pi on phosphorylation of ERK1/2 and induction of Egr-1 expression. Real-time PCR for Na<sup>+</sup>/Pi co-transporters revealed the dominant expression of type III co-transporter PiT-1 and the marginal expression of type IIa and IIc co-transporters in HEK293 cells. The knockdown of PiT-1 utilizing siRNA reduced the Pi-induced phosphorylation of ERK1/2. Over-expression of type IIa co-transporter enhanced the phosphorylation of ERK1/2 and the up-regulation of Egr-1. These results suggest that increased extracellular Pi exerts an influence on FGF23-signaling by the interaction with ERK1/2 pathway, depending on Na<sup>+</sup>/Pi co-transporters.

**c-Fos Is Associated with Renal FGF23-Mediated Signaling: Effect of the Hyp Mutation.** E. Farrow<sup>1</sup>, L. Summers<sup>1</sup>, S. Davis<sup>1</sup>, S. Schiavi<sup>2</sup>, K. White<sup>1</sup>. <sup>1</sup>Medical and Molecular Genetics, Indiana University, Indianapolis, IN, USA, <sup>2</sup>Genzyme Corporation, Framingham, MA, USA.

Fibroblast growth factor-23 (FGF23) is a key regulator of phosphate metabolism, and requires a heteromeric complex of Klotho (KL) and a canonical FGF receptor (FGFR) to initiate MAPK signaling in the kidney. The mRNA levels for the transcription factor, Early growth response gene-1 (EGR1) can be used as an index for FGF23 bioactivity. The Hyp mouse, a model of X-linked hypophosphatemic rickets (XLH), is characterized by hypophosphatemia associated with significantly increased serum FGF23 concentrations, however the relative level of FGF23 activity in the kidney in these animals is unknown. The goals of the present studies were to identify new genes within FGF23-mediated signaling pathways, and to further understand FGF23 activity in the Hyp mouse. FGF23-regulated genes were identified via array technology using kidney RNA isolated from wild type mice injected with 10 µg FGF23 and sacrificed after 1 h. Using qPCR on kidney RNA, c-Fos was found to be elevated by 13-fold compared to control animals (p<0.05). The positive control, EGR1, showed a 70-fold increase (p<0.01) at the same time point. To confirm these results, HEK293 cells stably expressing membrane Klotho (mKL) were treated with 100 pg/mL of FGF23 for 30 and 60 minutes. qPCR analyses showed time dependent increases of 3- and 6-fold for c-Fos mRNA at 30 and 60 minutes when compared to vehicle treated cells. As expected, EGR1 mRNA increased 5- and 15-fold at 30 and 60 minutes, respectively. Hyp mice are known to manifest increased FGF23 levels, similar to most patients with XLH. At six weeks of age, male Hyp mice had over a 12-fold elevation in serum FGF23 concentrations when compared to wild type mice (1275 vs 92 pg/ml; p<0.05). However, in contrast to the substantial increases in c-Fos and EGR1 RNA observed in the FGF23-injected mice, expression of these genes was only 2-fold elevated in Hyp mice kidneys compared to sex- and age-matched wild type littermates (p<0.05). These results suggest that FGF23 signaling may be altered in Hyp mice given their significantly elevated serum FGF23 levels. Consistent with the apparent reduction of FGF23 signaling in Hyp, KL mRNA was reduced by 60% in these mice compared to wild type littermates. In summary, we have identified c-Fos as an FGF23-responsive gene in vivo and in vitro, and have determined that Hyp mice have low, but measurable signaling in the kidney in the face of markedly elevated FGF23 concentrations. Taken together, our results indicate that FGF23 signaling involving c-Fos and EGR1 is down regulated in the Hyp mouse despite elevated serum FGF23 concentrations, and the mechanisms for this reduced activity likely involve suppressed KL mRNA.

**Role of Fibroblast Growth Factor-23 (FGF-23) in the Early Response to the PTH Analogue; Teriparatide.** M. Sridharan<sup>1</sup>, P. Manghat<sup>1</sup>, D. MacDonald<sup>2</sup>, I. Fogelman<sup>2</sup>, A. S. Wierzbicki<sup>3</sup>, W. D. Fraser<sup>3</sup>, G. Hampson<sup>1</sup>. <sup>1</sup>Chemical Pathology, St Thomas Hospital, London, United Kingdom, <sup>2</sup>Nuclear Medicine, Guy's Hospital, London, United Kingdom, <sup>3</sup>Clinical Chemistry, Royal Liverpool University Hospital, London, United Kingdom.

The importance of FGF-23 in phosphate metabolism is well established. FGF-23 is produced by osteoblasts and osteocytes. Recent studies indicate that it may be implicated in bone formation and is regulated by PTH. Intermittent PTH administration has anabolic effects on bone. The aim of our study was therefore to investigate firstly the early effect of intermittent PTH on circulating FGF-23 and secondly the relationship between FGF-23 and bone and mineral metabolism following intermittent PTH.

We studied 26 women aged (mean [SD] :75.8 [5.4] years) treated with the recombinant PTH analogue 1-34 (Teriparatide) for established postmenopausal osteoporosis. We investigated their early response following treatment with Teriparatide for 6-9 months. Bone mineral density (BMD) was measured by DXA at the lumbar spine (LS) and Total Hip (TH) at baseline and at 6-9 months. Biochemical markers of bone turnover; PINP, Bone alkaline phosphatase (BALP), osteocalcin (OC) and urine CTX were measured at baseline, 1-3 months and 6-9 months. Circulating FGF-23 was determined at the same time-points using the Immuntopics C-terminal FGF-23 ELISA. BMD at the LS increased significantly (mean [SEM] 6.6% [0.9]). No significant change was seen at the TH. Significant increases in the bone turnover markers were observed at 1-3 months with further increases at 6-9 months (PINP ug/L baseline 41.8 [5.4], 6-9 months 147.7 [18.6]; BALP ug/L 16.4 [2.1], 27.0 [2.8]; OC ug/L 8.8 [1.4], 13.2 [1.9]; uCTX ug/mmol creatinine 188.0 [27.4], 579.0 [113.1] p<0.05). Serum albumin adjusted calcium (mmol/L) increased significantly from baseline (mean [SD] baseline 2.37 [0.09], 6-9 months 2.46 [0.12] (p<0.05). This was accompanied by a significant reduction in PTH ng/L (baseline 40.4 [4.8], 6-9 months 34.4 [5.1] p<0.01). No significant change in serum phosphate was seen. Baseline FGF-23 ranged from 1 to 847 U/ml. There was a significant correlation between FGF-23 and PTH at baseline (r=0.618, p=0.0048). FGF-23 increased significantly at 6-9 months (median [range] baseline 39 [1-847], 6-9 months 55 [3-1457] p=0.017). Early changes in serum calcium were associated with changes in FGF-23 at 6-9 months (r=0.47, p=0.026). A significant correlation was seen between the changes in FGF-23 and PINP at 6-9 months (r=0.78 and p<0.001). In conclusion, the data suggest that intermittent PTH regulates circulating FGF-23 and this factor may be implicated in bone and mineral metabolism following PTH administration for post-menopausal osteoporosis.

**Phosphatonins and Liver Resection-Related Hypophosphatemia.** O. Nafidi<sup>\*1</sup>, R. W. Lapointe<sup>\*1</sup>, R. Lepage<sup>\*1</sup>, J. H. Brossard<sup>1</sup>, R. Kumar<sup>\*2</sup>, P. D'Amour<sup>1</sup>. <sup>1</sup>CHUM - Hôpital Saint-Luc, Departments of Medicine, Biochemistry and Surgery, Université de Montréal, Montréal, QC, Canada, <sup>2</sup>Departments of Internal Medicine, Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA.

Post-hepatectomy hypophosphatemia (HP) is believed to be the result of metabolic demands by the regenerating liver. However, we and others have reported excessive fractional urinary phosphate excretion ( $F_{\text{e}}\text{PO}_4$ ) early after hepatectomy in possible association with hypocalcemia and increased circulating levels of Intact PTH. In this study we explored the role of three phosphatonins comparatively to PTH in post-hepatectomy HP. Serum phosphate (Pi), ionized calcium ( $\text{Ca}^{2+}$ ),  $\text{HCO}_3^-$ , pH and  $F_{\text{e}}\text{PO}_4$  (24 hour collection) were measured before and serially on postoperative (po) days 1, 2, 3, 5 and 7 in 18 patients undergoing successful liver resection. At identical time-points, we quantified I-PTH and carboxyterminal (C) and intact (I) fibroblast growth factor-23 (FGF-23), FGF-7 and frizzled related-protein-4 (FRP-4). pH decreased to  $7.32 \pm 0.01$  on po day 1 and the acidosis was resolved by po day 2 without respiratory alkalosis.  $\text{Ca}^{2+}$  declined (N:  $1.16-1.29$ ) to  $1.10 \pm 0.01$  mmol/L ( $p < 0.01$ ) while I-PTH (N:  $1.4-6.8$  pmol/L) peaked to  $8.8 \pm 0.9$  ( $p < 0.001$ ). Pi (N:  $0.7-1.3$  mmol/L) fell on the first 2 po days to  $0.66 \pm 0.03$  mmol/L ( $p < 0.001$ ) during which  $F_{\text{e}}\text{PO}_4$  (N: 10-15%) peaked to  $25.1 \pm 2.3\%$  ( $p < 0.05$ ). The I-PTH peak on po day 1 was correlated both with the latter ( $r = 0.65$ ,  $p = 0.006$ ) and with po day 1 serum  $\text{Ca}^{2+}$  ( $r = -0.62$ ,  $p = 0.016$ ). I-FGF-23 dropped to  $7.8 \pm 6.9$  pmol/L on po day 3 ( $p < 0.001$ ) with parallel kinetics to Pi. C-FGF-23 (N < 100 RU/ml) increased to  $70.1 \pm 28.8$  RU/ml in po day 2 (NS). I-FGF-23 and C-FGF-23 were not correlated and both were not associated with  $F_{\text{e}}\text{PO}_4$ . FGF-7 rose continually to  $52.4 \pm 8.9$  pg/ml (NS) on po day 7 while FRP-4 increased slightly to  $104.8 \pm 17.4$  ng/ml on po day 1 (NS). Both FGF-7 and FRP-4 kinetics were not associated with Pi and  $F_{\text{e}}\text{PO}_4$ . HP and hyperphosphaturia were constant postoperative findings after hepatectomy. Decreased po I-FGF-23 may have resulted from a low Pi negative feedback. The I-FGF-23 decline coincided with the peak  $F_{\text{e}}\text{PO}_4$  itself associated with the I-PTH level at the start of the urine collection. FGF-7 and FRP-4 did not play a phosphaturic role after hepatectomy in the group of patients as a whole, but may have in some individuals. More investigations are needed to explore the mechanism of post-hepatectomy HP.

**FGF-23 and Parameters of Calcium and Bone Metabolism Are Positively Influenced by GH Replacement in Adult Growth Hormone Deficiency Patients from the KIMS Survey.** W. J. Fassbender<sup>1</sup>, S. Schmitz<sup>\*1</sup>, P. Kann<sup>2</sup>, U. C. Stumpf<sup>3</sup>. <sup>1</sup>Internal Medicine - Endocrinology, Hospital zum Heiligen Geist, Kempen, Germany, <sup>2</sup>Internal Medicine - Endocrinology, Diabeteology, University Hospital Philipps University Marburg, Marburg, Germany, <sup>3</sup>Traumatology and Handsurgery, University Hospital Heinrich Heine University Duesseldorf, Duesseldorf, Germany.

**Introduction:** Growth hormone deficiency leads to reduction in bone turnover, mainly due to alterations in PTH circadian rhythmicity as well as to a lack of sensitivity of the kidney and bone to the effects of PTH. These mechanisms may be responsible for the reduction in bone turnover and the development of osteoporosis. Patients with GHD show abnormalities of renal phosphate metabolism, which may also contribute to the pathogenesis of bone loss in these patients. GH treatment leads to restoration of renal tubular reabsorption and sensitivity of target organs to PTH and bone turnover and to improvement of BMD under ongoing GH replacement therapy. **Materials and Methods:** The aim of our study was to investigate the role of the phosphatonine FGF-23 in this complex process. We measured the relationship between the parameters of calcium metabolism such as Calcium, Phosphate, Creatinine and PTH and their correlation to the phosphatonine FGF-23 and 25-OH VitaminD levels in GDH patients before, after six and twelve months therapy with growth hormone. **Results:** EDTA-Plasma (due to better stability than serum samples) of 15 patients was investigated. Arithmetic means for intact FGF-23 before therapy were 17.3 pg/ml, after 6 months therapy 15.3 pg/ml and 23 pg/ml at 12 months (all  $p < 0.001$ ). C-terminal FGF-23 initial was 58 U/ml, at 6 months 47 U/ml and at month 12 108.6 U/ml (all  $p < 0.001$ ). Calcium values were 2.38, 2.44 and 2.43 mmol/l. Corresponding phosphate levels were 3.04, 3.39 and 3.08 mg/dl (all  $p < 0.001$ ). As expected, FGF-23 was inversely correlated to serum phosphate.

**Discussion:** The results suggest that GH supplementation in GHD patients leads to normalization of tubular reabsorption of phosphate due to regulation by FGF-23 and reverses the GHD-induced relative phosphate-deficient state. Restoration of physiological regulation of phosphate metabolism emphasizes the beneficial effect of GH supplementation of GHD patients on bone remodeling.

**Altered Regulation and Expression of FGF23 in the Adenine-induced Uremic Rat Model.** D. Cuerrrier<sup>\*</sup>, C. Helvig<sup>\*</sup>, A. Kharebov<sup>\*</sup>, K. Ryder<sup>\*</sup>, J. Kim<sup>\*</sup>, B. Ireland<sup>\*</sup>, M. Petkovich. Cytochroma Inc., Markham, ON, Canada.

FGF23 is a systemic hormone involved in phosphate homeostasis. Circulating FGF23 is produced primarily in bone and is independently regulated by circulating  $1,25-(\text{OH})_2\text{D}_3$  and elevated serum phosphorus levels. In addition, circulating FGF23 can limit intestinal absorption of phosphate by suppressing renal expression of CYP27B1, thereby limiting production of  $1,25-(\text{OH})_2\text{D}_3$  and decreasing renal phosphate reabsorption leading to a decrease in circulating phosphorus levels. Recently, FGF23 was proposed to upregulate renal CYP24 expression which could lead to further decrease  $1,25-(\text{OH})_2\text{D}_3$  levels and intestinal absorption of phosphate. Hyperphosphatemic patients with chronic kidney disease (CKD) show significant elevation of circulating FGF23 levels, exacerbating a deficiency in renal  $1,25-(\text{OH})_2\text{D}_3$  production. In this study, we have examined the profile of FGF23 expression in the adenine-induced uremic rat model. Circulating FGF23 levels was found to be upregulated 50-fold in the plasma of uremic rats relative to normal rats.  $1,25-(\text{OH})_2\text{D}_3$  treatment resulted in an additional 6-fold increase. Interestingly, tissue profiling of FGF23 revealed upregulation of its expression by 50-fold in the kidney of uremic rats relative to normal rats. Moreover, renal FGF23 expression in the adenine model was unaffected by  $1,25-(\text{OH})_2\text{D}_3$  treatment, indicating a different mode of regulation compared to bone FGF23. These results suggest a possible role of FGF23 in a paracrine or autocrine regulation of CYP27B1 and CYP24 in the kidney with relevance to vitamin D deficiency observed in CKD.

**Disclosures:** D. Cuerrrier, None.

**The Role of the G Protein-coupled Receptor GPR30 in Effects of Estrogen in Ovariectomized Mice.** S. H. Windahl<sup>1</sup>, N. Andersson<sup>1</sup>, A. Chagin<sup>\*2</sup>, U. E. Mårtensson<sup>\*3</sup>, H. Carlsten<sup>\*1</sup>, B. Olde<sup>\*3</sup>, L. M. F. Leeb-Lundberg<sup>\*3</sup>, C. Swanson<sup>\*1</sup>, L. Sälvendahl<sup>\*2</sup>, M. K. Lagerquist<sup>1</sup>, C. Ohlsson<sup>1</sup>. <sup>1</sup>Department of Medicine, Center for Bone Research, Sahlgrenska Academy, Gothenburg, Sweden, <sup>2</sup>Department of Woman and Child Health, Pediatric Endocrinology Unit, Karolinska Institute, Stockholm, Sweden, <sup>3</sup>Department of Experimental Medical Science, Unit of Drug Target Discovery, Lund University, Lund, Sweden.

Estrogen exerts a variety of important physiological effects, which have been suggested to be mainly mediated via the two known nuclear estrogen receptors (ERs)  $\alpha$  and  $\beta$ . *In vitro* studies suggest that the G protein-coupled receptor GPR30 is also a functional estrogen receptor. The aim of the present study was to determine the *in vivo* role of GPR30 for several well-known estrogen-regulated parameters.

Three-month-old ovariectomized (ovx) GPR30<sup>-/-</sup> and WT mice were treated with either placebo or different doses of estradiol (0, 30, 70, 160 or 830 ng/mouse/day) (E2). The estrogenic responses on most investigated parameters including increase in bone parameters (total body BMD, trabecular bone mineral density and cortical bone mineral content), increase in uterine weight, thymus atrophy, fat mass reduction and increase in bone marrow cellularity were for all investigated E2 doses similar in WT and GPR30<sup>-/-</sup> mice. However, the inhibitory effect of E2 on longitudinal bone growth, reflected by reduced femur length and distal femur growth plate width, seen in the adult ovx WT mice was not seen in the ovx GPR30<sup>-/-</sup> mice.

These *in vivo* findings demonstrate that GPR30 is required for a normal estrogenic response in the growth plate but not for several other estrogen-regulated parameters.

## SU180

**Cell Type Specific Regulation of Transcription by Estrogen.** S. A. Krum<sup>1</sup>, M. Brown<sup>\*2</sup>. <sup>1</sup>Orthopaedic Surgery, UCLA, Los Angeles, CA, USA, <sup>2</sup>Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA.

Estrogen is an important regulator of female development, and also plays a role in the bone, among other tissues. The effects of estrogen are mediated by two nuclear receptors: estrogen receptor alpha (ER $\alpha$ ) and estrogen receptor beta (ER $\beta$ ). ER $\alpha$  and ER $\beta$  are both expressed in many cell types, but at lower levels than those found in reproductive tissues. The mechanism by which estrogen exerts tissue-specific effects, remains to be explained. We have compared the global gene expression profile of the MCF7 breast cancer cell line with that of the osteoblast-like cell line U2OS-ER $\alpha$  by expression microarrays. We find that fewer than 10% of the estrogen-regulated genes are common to both cell types. We have validated many of these genes in primary calvarial osteoblasts. To dissect the mechanism underlying the cell-type specific estrogen regulation of gene expression in MCF7 and U2OS-ER $\alpha$  cells, we compared the ER $\alpha$  binding sites in the two cell types obtained by performing chromatin immunoprecipitation (ChIP) on genomic tiling arrays (ChIP-on-chip). ER $\alpha$  binding in U2OS-ER $\alpha$  cells best correlates with genes up-regulated in U2OS-ER $\alpha$  cells, and not with down-regulated genes or genes up-regulated in MCF7 cells. Furthermore, we discovered a correlation between the number of ER $\alpha$  binding sites and gene induction. More specifically, ER $\alpha$  is recruited to multiple enhancers near genes that are induced by estrogen. Interestingly, while the forkhead factor FoxA1 plays a critical role in defining the ER $\alpha$  binding sites in MCF7 cells, it is not expressed in U2OS-ER $\alpha$  cells and forkhead motifs are not enriched in the ER $\alpha$  binding sites in these cells. Finally, the ER $\alpha$  binding sites are correlated with cell-type specific epigenetic histone modifications. These results support a model for the cell-type specific action of estrogen being driven primarily through cell-type specific ER $\alpha$  occupancy of epigenetically marked cis-regulatory regions of target genes.

**Altered TNSALP Expression and Phosphate Regulation Contribute to Reduced Mineralization in Mice Lacking Androgen Receptor.** H. Kang<sup>\*</sup>, C. Huang<sup>\*</sup>, K. Huang. Graduate Institute of Clinical Medical Sciences, Chang Gung University, Kaohsiung, Taiwan.

While androgen receptor (AR)-deficient mice developed osteopenia in endochondral bones due to the high bone turnover with increased bone resorption by osteoclasts, little is known about the mechanism of intramembranous bone loss contributed by AR in osteoblasts. Here we discovered a dramatic decrease in the area of calcification, new bone, and the number of osteocytes in calvaria from AR-deficient mice related to a reduction in mineralization caused, in part, by the diminished activity of AR-deficient osteoblasts. Enforced AR expression in differentiated osteoblasts boosts mineralization while knockdown of AR expression prevents androgen-induced mineralization. We identified the tissue-nonspecific alkaline phosphatase (TNSALP) and several members of small integrin binding ligand N-linked glycoprotein (SIBLING) gene family as androgen target genes required for AR-mediated bone formation. We show that inorganic phosphate (Pi) levels and TNSALP activity increased in response to androgen/AR and Pi signals increase the expression and translocation of AR. The ectopic expression of TNSALP or Pi partially rescued the bone loss due to AR deficiency. Thus, androgen/AR signaling plays an essential role in bone formation by coordinating the expression of genes associated with phosphate regulation.

**Ethanol Alters Estrogen Receptor Signaling and Activates Senescence Pathways in Osteoblasts While Estradiol Attenuates Ethanol Effects.** J. R. Chen<sup>\*1</sup>, O. P. Lazarenko<sup>\*2</sup>, R. L. Haley<sup>\*3</sup>, T. M. Badger<sup>\*2</sup>, M. J. Ronis<sup>\*1</sup>. <sup>1</sup>Pharmacology & Toxicology, University of Arkansas for Medical Sciences / Arkansas Children's Nutrition Center, Little Rock, AR, USA, <sup>2</sup>Physiology, University of Arkansas for Medical Sciences / Arkansas Children's Nutrition Center, Little Rock, AR, USA, <sup>3</sup>Physical Medicine and Rehabilitation, University of Arkansas for Medical Sciences / Arkansas Children's Nutrition Center, Little Rock, AR, USA.

Epidemiological and animal studies suggest that chronic alcohol consumption increases the risk of osteoporosis. However, the mechanisms underlying alcohol-induced bone loss are largely unknown. Using bone from chronic ethanol (EtOH) infused cycling female rats and osteoblastic cells *in vitro*, we have been able to determine the direct effects of ethanol (EtOH) and the interaction with estrogen signaling pathways in osteoblasts. We found that EtOH increased (P<0.05) estrogen receptor alpha (ER $\alpha$ ) and beta (ER $\beta$ ) RNA and encoded ER $\alpha$  protein levels in bone *in vivo* and in osteoblasts *in vitro* when analyzed by real-time RT-PCR and Western blotting. Treatment with 17 $\beta$ -estradiol (E2) subcutaneously, *in vivo*, or pre-treatment of osteoblasts with E2, *in vitro*, antagonized all the effects of EtOH on ER expression in bone and osteoblastic cells (P<0.05). ER $\alpha$  agonist propylpyrazoletriol (PPT) and ER $\beta$  agonist diarylpropionitrile (DPN) attenuated (P<0.05) EtOH-induced ER $\alpha$  and ER $\beta$  gene over expression, respectively, indicating non-ER specific actions of EtOH on osteoblasts. In addition E2 attenuated EtOH-induced activation of p53 and p21 in bone tissue *in vivo* and osteoblasts *in vitro*. UMR-106 osteoblastic cells were transiently

transfected with ER $\alpha$ -ECFP for ER $\alpha$  translocation analysis, and transiently transfected with ERE-TK-Luc or p21 promoter pGL2-p21-Luc reporter plasmids with or without co-transfection of ER $\alpha$  for expression analysis using luciferase assays. Similar to estrogen receptor antagonist ICI 182,780, EtOH blocked nuclear translocation of ER $\alpha$ -ECFP in the presence of E2. EtOH down-regulated (P<0.05) the ERE-luc reporter activity, however, E2 blocked this EtOH effect in osteoblasts. On the other hand, EtOH transactivated the luciferase activity of the p21 promoter region independent of additional exogenous ER $\alpha$ . EtOH activated (P<0.05) senescence-associated beta-galactosidase activity in rat stromal osteoblasts, while E2 attenuated this EtOH action. We conclude that inhibitory cross-talk between EtOH and E2 in osteoblasts on ERs, p53/p21 and cell senescence provides a pathophysiologic mechanism underlying bone loss and the protective effects of estrogens in alcohol-exposed females. *Supported in part by R01 AA12928 (M.J.R.).*

**Genetic Variations in Sex Steroid-Related Genes as Predictors of Serum Estrogen Levels in Men.** A. Eriksson<sup>1</sup>, M. Lorentzon<sup>1</sup>, L. Vandenput<sup>1</sup>, E. Labrie<sup>\*2</sup>, M. Lindersson<sup>\*3</sup>, A. Syvänen<sup>\*3</sup>, E. S. Orwoll<sup>4</sup>, S. R. Cummings<sup>5</sup>, J. S. Lee<sup>\*6</sup>, J. M. Zmuda<sup>\*7</sup>, Ö. Ljunggren<sup>\*3</sup>, M. K. Karlsson<sup>\*8</sup>, D. Mellström<sup>1</sup>, C. Ohlsson<sup>1</sup>. <sup>1</sup>Center for Bone Research at the Sahlgrenska Academy, Göteborg University, Göteborg, Sweden, <sup>2</sup>Laboratory of Molecular Endocrinology and Oncology, Laval University Hospital Research Center and Laval University, Québec, QC, Canada, <sup>3</sup>Department of Medical Sciences, Uppsala University, Uppsala, Sweden, <sup>4</sup>Oregon Health and Science University, Portland, OR, USA, <sup>5</sup>CPMC Research Institute, UC San Francisco, San Francisco, CA, USA, <sup>6</sup>Department of Internal Medicine, University of California Davis, Sacramento, CA, USA, <sup>7</sup>Department of Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>8</sup>Department of Clinical Sciences, Lund University, Lund, Sweden.

Epidemiological studies have reported that many conditions including osteoporosis are associated with serum levels of sex steroids. Sex steroid levels are believed to be influenced by genetic factors, but there is no reported genetic variation, which in a reproducible manner predicts estradiol (E2) or testosterone (T) levels in men. The aim of this study was to identify genetic variations in sex steroid-related genes which are associated with serum E2 and/or T in men. Single nucleotide polymorphism (SNP) markers (n= 604) with minor allele frequencies of  $\geq 5\%$  in 50 major sex-steroid related genes were selected from HapMapData Rel 21a/phaseII using a pairwise correlation method ( $r^2 \geq 0.80$ ), including 10 kb upstream and 5 kb downstream of each gene. Genotyping of these markers was performed on the Illumina Bead Station system in the GOOD study (n=1041 men, 18.9 $\pm$ 0.6 yr). Replications of significant associations were performed in the MrOS Sweden study (n=2568 men, 75.5  $\pm$  3.2 yr) and in the MrOS US study (n=1922 men, 73.5  $\pm$  5.8 yr). Serum E2, T and estrone (E1) levels (n=5531) were analyzed using gas chromatography/mass spectrometry (GC-MS). The screening in the GOOD cohort identified the SNP rs2470152 in intron 1 of the CYP19 gene, which codes for aromatase, responsible for the final step of biosynthesis of E2 and E1, to be most significantly associated with E2 levels (p = 2  $\times$  10<sup>-6</sup>). This association was confirmed both in the MrOS Sweden study (p = 9  $\times$  10<sup>-7</sup>) and in the MrOS US study (p = 1  $\times$  10<sup>-4</sup>). When analyzed in all subjects (n=5531) rs2470152 was clearly associated with both E2 (p = 2  $\times$  10<sup>-14</sup>) and E1 (p = 8  $\times$  10<sup>-19</sup>) levels. Subjects with the GG genotype had 8-13 % higher E2 and 10-16 % higher E1 levels, depending on cohort, than subjects with the AA genotype. AG subjects had intermediate levels. In conclusion, the SNP rs2470152 of the CYP19 gene is clearly associated with serum E2 and E1 levels in men. Further studies are needed to determine the impact of this SNP for sex-steroid-related disorders such as osteoporosis, and fractures.

## SUI84

**Increased Caloric Intake in Energy Deficient Exercising with Functional Hypothalamic Amenorrhea Women Is Associated with Decreased Ghrelin and Increased Bone Formation: Preliminary Data from an RCT to Reverse Exercise-Associated Menstrual Disturbances.** J. L. Scheid<sup>\*1</sup>, N. I. Williams<sup>2</sup>, S. L. West<sup>\*1</sup>, S. Awdishu<sup>\*1</sup>, M. J. De Souza<sup>2</sup>. <sup>1</sup>University of Toronto, Toronto, ON, Canada, <sup>2</sup>Penn State University, University Park, PA, USA.

Exercise-associated menstrual disturbances (EAMD), such as amenorrhea, are observed secondary to a chronic energy deficiency and are associated with low bone mass. We report data from an ongoing 12 month randomized controlled trial to determine the effectiveness of increased caloric intake to reverse amenorrhea, and improve bone health. Subjects were categorized by menstrual and ovulatory status into either an ovulatory control (OvCon, n=13), EAMD + calories (EAMD+Cal, n= 5) group, or an EAMD control group (n= 2). Subjects in the EAMD+Cal group were required to increase daily caloric intake (20-30%) above their baseline energy needs. Resting energy expenditure (REE), dietary energy intake, daily energy expenditure, body composition, serum markers of bone formation (PINP) and resorption (sCTX), fasting ghrelin and triiodothyronine (TT3), and daily urinary ovarian steroids (E1G and PdG) were assessed during the study. Statistical analysis includes t-tests to determine baseline differences, repeated measures ANOVA to determine longitudinal differences between baseline and intervention, and correlations to identify significant associations. Presented are preliminary data for 13 OvCon and 5 EAMD+Cal participants who have completed 2 of 12 months of intervention. Groups were similar for age (25.1±1.6 y), weight (58.7±1.9 kg) and history of exercise (605±143 min/week). The EAMD+Cal group experienced a mean increase in body weight of 0.4kg and an increased energy prescription of 536±69 kcal/day above baseline energy status. A significant time x group interaction was observed for change in caloric intake (p=0.020), body fat percentage (p=0.024), and ghrelin (p=0.040). Body fat was increased and ghrelin was decreased over time in the EAMD+Cal compared to the OvCon group. No changes were observed in REE, TT3, PINP, or sCTX. Decreases in ghrelin were associated with a higher caloric prescription ( $r=-0.18$ ,  $p=0.006$ ) and decreases in ghrelin were associated with increased bone formation ( $r=0.956$ ,  $p=0.011$ ) in the EAMD+Cal group. Increased caloric intake and or weight gain was associated with 3/5 and 4/5 subjects resuming menses within 4 and 6 months, respectively. Our preliminary results suggest that increased caloric intake and related weight gain were associated with the resumption of menses in exercising amenorrheic women. Increased caloric intake was associated with reductions in ghrelin, and increased bone formation.

**The Antiapoptotic Action of 17 $\beta$ -Estradiol in Skeletal Muscle Cells Involves ERK 1/2, p38 MAPK, ASK-1 and HSP27.** A. C. Ronda\*, N. Zanetti\*, A. Vasconsuelo\*, L. Milanese\*, A. Russo de Boland\*, R. L. Boland. Dept. Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina.

Estrogens exert antiapoptotic effects in various cell types, e.g. vascular endothelial, smooth muscle and breast cancer cells. We have previously reported that 17 $\beta$ -estradiol inhibits apoptosis through estrogen receptors with non-nuclear localization, e.g. mitochondria and endoplasmic reticulum, in the mouse skeletal muscle C2C12 cell line. The steroid hormone abrogates DNA damage, PARP cleavage and cytochrome c release induced by H<sub>2</sub>O<sub>2</sub> or etoposide. This mechanism involves fast activation of the PI3K/Akt/Bad pathway. It was demonstrated that the estrogen also triggers rapid phosphorylation of ERK 1/2 and p38 MAPK. Using specific inhibitors it was shown that both MAPKs mediate the effects of estradiol on Akt and Bad phosphorylation, cytochrome c and Smac/Diablo release, caspase 3 and PARP cleavage, and morphological changes of the cells. Interestingly, we found that ERK1/2 activated by 17 $\beta$ -estradiol is located mainly in mitochondria. Parallel studies showed that the interaction between proapoptotic kinase ASK-1 with phospho-Akt increases in presence of estrogen. This fact suggests another possible point of negative regulation of the apoptotic cascade by Akt. Furthermore, evidence was obtained that 17 $\beta$ -estradiol at longer exposure times increases the expression of HSP27. Assays under apoptotic conditions linked this chaperone to the protective action of the hormone, specifically regulating caspase-3 activity. Immunocytochemistry and co-immunoprecipitation assays revealed interaction of HSP27 and ER  $\beta$  in mitochondria. Altogether, these data imply that ERK 1/2, p38 MAPK, ASK-1 and HSP27 play a role in the mechanism underlying the antiapoptotic action of 17 $\beta$ -estradiol in skeletal muscle cells.

**Multinuclear Expression of ER $\alpha$  in Mature Osteoclasts.** M. Youn\*, I. Takada\*, S. Kondou\*, Y. Imai, S. Kato. Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan.

Osteoclasts became multinucleate during processes of maturation that are governed by a number of regulators including transcription factors. Although osteoclasts, as multinucleate cells, are unique among bone cells, little is still known about gene regulation network between multiple nuclei in the mature osteoclast. To address this point, we tested if gene expression occurs in a limited number or all of the osteoclastic nuclei. For this

purpose, the expressions of estrogen receptor alpha (ER $\alpha$ ) transcript and protein were measured in mature osteoclasts since we recently provided genetic evidence that the osteoprotective estrogen action was mediated by the osteoclastic ER $\alpha$ . In multinucleated osteoclasts differentiated from RAW264 cells or bone marrow cells by stimulation with receptor activator of nuclear factor-kappaB (RANKL) / Macrophage colony-stimulating factor (M-CSF), levels of ER $\alpha$  mRNA and protein were measured by real-time RT-PCR and immunocytochemistry, respectively. Notably, ER $\alpha$  was expressed in all multiple nuclei in osteoclasts of both origins. Additionally, to understand molecular mechanisms of the osteoprotective estrogen action, the expression levels of some osteoclast-specific genes were examined. When mature osteoclasts were treated with estrogens, the expressions of Cathepsin K (CtsK) and tartrate-resistant acid phosphatase (TRAP) were reduced at both the mRNA and protein levels. However, estrogen treatment did not affect the size of multinucleated osteoclasts or the number of nuclei in a mature osteoclast. These results indicate that in mature osteoclasts, estrogens inhibit the expression of osteoclast-specific genes through ER $\alpha$  present in all of multiple nuclei. Functional competence of the receptor was further confirmed by detection of Ser167-phosphorylated ER $\alpha$  in all nuclei of a single osteoclastic cell, suggesting that ER $\alpha$  protein is functional in mature osteoclasts in similar fashion as in other ER $\alpha$ -expressing cells like female reproductive cells, for example. Thus, these findings suggest that the osteoprotective estrogen action in mature osteoclasts is mediated by ER $\alpha$  in all of the cell multiple nuclei.

**Carborane BE360, One of the Carbon-Containing Polyhedral Boron-Cluster Compounds, Is a New Type of Selective Estrogen Receptor Modulator.** M. Inada<sup>1</sup>, T. Tominari<sup>\*1</sup>, M. Hirata<sup>1</sup>, C. Matsumoto<sup>\*1</sup>, M. Takita<sup>1</sup>, Y. Endo<sup>\*2</sup>, C. Miyaura<sup>1</sup>. <sup>1</sup>Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, <sup>2</sup>Division of Organic and Medicinal Chemistry, Tohoku Pharmaceutical University, Sendai, Japan.

Carboranes (dicarba-closo-dodecaboranes) are a class of carbon-containing polyhedral boron-cluster compounds having exceptional hydrophobicity, interacts hormone receptors in the result of computer docking simulation. We designed carborane compounds with an affinity for estrogen receptor (ER) and synthesized these compounds to search for effective agents to treat osteoporosis. Among several carborane compounds, we noted two compounds, BE120 and BE360. BE120 has a carborane structure with one phenol and is the most potent compound bearing a carborane cage exhibiting a binding affinity for ER. Its binding affinity with ER $\alpha$  is 10-fold greater than that of 17 $\beta$ -estradiol (E2). BE360 has a carborane structure with two phenols, and its ER binding affinities are 1.6-fold to ER $\alpha$  and 0.15-fold to ER $\beta$  compared with E2. To examine the estrogenic activity of these compounds in bone, ovariectomized (OVX) mice were given BE120, BE360 or E2 subcutaneously for 4 weeks using a miniosmotic pump. Reduced uterine weight in OVX mice was completely restored by not only E2 but also BE120. However, 1000-fold higher doses of BE360 did not increase the uterine weight of OVX mice. Histological analysis also showed that BE360 did not exhibit any estrogenic activity in the uterus. In OVX mice, the trabecular bone volume of the femoral distal metaphysis was reduced markedly, when measured by DEXA and histological analysis. Treatment with BE120 at 1-30 ng/head/day markedly prevented bone loss in OVX mice, and its effective doses in bone and uterus were similar to those of E2. BE360 at 1-30  $\mu$ g/head/day dose-dependently restored bone loss in OVX mice to a sham level without estrogenic action in the uterus. Therefore, 1000-fold higher doses of BE360 were needed to prevent bone loss in OVX mice compared with that of E2 and BE120. These results indicate that BE360 binds to ERs and exhibits estrogenic action in bone to prevent bone loss without inducing estrogenic action in the uterus, suggesting its possible application to osteoporosis as a new type of selective estrogen receptor modulator (SERM). To examine the effects of BE360 in androgen deficiency, male mice were sham-operated or orchidectomized (ORX) and a subgroup of ORX mice was treated with BE360. Treatment with BE360 at 1-30  $\mu$ g/head/day prevented bone loss in ORX mice without androgenic action on the sex organs. We currently tested anti-androgenic carboranes in ORX mice to clarify androgenic action in male bone metabolisms, which may be a new candidate of selective androgen receptor modulator (SARM).

**Genetic Variation of the SHBG Gene, SHBG Levels and Bone Parameters.** L. Stolk<sup>\*1</sup>, F. Rivadeneira<sup>1</sup>, J. B. J. van Meurs<sup>1</sup>, P. Arp<sup>\*1</sup>, M. Jhamai<sup>\*1</sup>, M. C. Zillikens<sup>\*1</sup>, A. Hofman<sup>\*2</sup>, F. H. de Jong<sup>\*1</sup>, H. A. P. Pols<sup>\*1</sup>, A. G. Uitterlinden<sup>1</sup>. <sup>1</sup>Internal Medicine, Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Epidemiology, Erasmus MC, Rotterdam, Netherlands.

Sex hormone-binding globulin (SHBG) binds testosterone (T) and estradiol (E2), thereby regulating their access to target tissue. Several studies showed that elderly men and women with high SHBG levels had higher risk for fractures (fx) and lower lumbar spine bone mineral density (LS-BMD) and found SHBG polymorphisms to be associated with SHBG levels in men and women, and hip BMD in men. In elderly men and women of the Rotterdam study we investigated the effect of SHBG levels (determined by direct immunoassays) on both BMD and fx risk, and also studied the association of 24 SNPs in a 154kb region surrounding the SHBG-gene with SHBG levels, estradiol levels and BMD and fx risk. Correlation of SHBG-levels, LS and femoral neck (FN) BMD was calculated using linear regression. The effect of quartiles (Q1 - Q4) of plasma SHBG on fx was

calculated using logistic regression. In 5974 subjects Illumina 550K SNP genotypes were available while 2 additional SNPs were genotyped using Taqman. Association of 24 SNPs (MAF >5%) with plasma SHBG (n=1339 subjects with data (swd)) and E2 levels (n=1133 swd), LS-BMD (n=4757 swd), FN-BMD (n=4758 swd) and vertebral (n=2914 swd) and non-vertebral (n=5596 swd) fx risk were calculated using a X2 test. Associations were significant if  $p < 2.08 \times 10^{-3}$  (Bonferroni corrected). SHBG levels correlated with LS-BMD  $r = -0.25$ ,  $p = 4 \times 10^{-19}$  (0.03 g/cm<sup>2</sup> (0.17SD) difference for Q1 vs. Q4 of SHBG), and with FN-BMD  $r = -0.30$ ,  $p = 7 \times 10^{-29}$  (0.026 g/cm<sup>2</sup> (0.2SD) difference for Q1 vs. Q4 of SHBG) in 1280 subjects. Plasma SHBG levels were 3.5 nmol/L (9%) higher in subjects with vertebral fx (n=795 swd,  $p=0.03$ ), and 5.2 nmol/L (13%) higher in subjects with non vertebral fx (n=1435 swd,  $p=1.4 \times 10^{-6}$ ). 9 out of the 24 SNPs were associated with plasma SHBG levels ( $P < 2.08 \times 10^{-3}$ ) with an allele-dose effect varying between 4.2 (10.5%) and 2.1 (5%) nmol/L per allele. All 9 SNPs are located in or 5' of the SHBG gene, with the two SNPs with the highest effect size within 5 kb in the 5' region. For LS and FN BMD and for fractures none of the SNPs were associated. In this study we confirmed the correlation of plasma SHBG-levels with LS and FN BMD, and with fracture risk. We found 9 SNPs 5' or in the SHBG gene to be associated with plasma SHBG-levels, with 8.4 nmol/L (21%) difference between extreme genotypes. From this and the SHBG levels studies we then expect a 0.008 g/cm<sup>2</sup> difference (0.04 SD) in BMD, while we only had power to detect a 0.085 SD difference. Thus, larger studies are required to confirm a genetic effect while also other loci than SHBG might contribute to explain variance in SHBG levels, and thus with BMD and/or fx risk.

**Estrogens Reverse a Potentiating Effect of the Unliganded Estrogen Receptor on BMP-induced Transcription and Osteoblastogenesis by Promoting ERK-dependent Smad1 Phosphorylation at the Linker Region.** M. Martin-Millan, L. Han, E. Ambrogini, A. Warren\*, M. Almeida, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Estrogens attenuate osteoclastogenesis and osteoblastogenesis, and maintain focal balance between resorption and formation by stimulating osteoclast and attenuating osteoblast apoptosis. But, it is unclear whether some or all of these effects are mediated via *cis* or *trans* interactions of the estrogen receptor (ER $\alpha$  or  $\beta$ ) with DNA or kinase-mediated extranuclear actions of the ERs. Based on evidence that estrogens suppresses BMP-induced osteoblastogenesis, and that Smad1/5/8 phosphorylation at the linker region by kinases such as ERK, JNK, and p38 promotes Smad proteasomal degradation, we have explored the possibility that estrogens inhibit osteoblastogenesis through a kinase-mediated action. We report that inducible expression of the ER $\alpha$  in the human osteoblast-like cell line U2OS, or transfection of C2C12 cells with increasing amounts of plasmids encoding the ER $\alpha$  or the ER $\beta$ , dose-dependently increased BMP-induced transcription, as measured by a Smad6-luciferase reporter construct and promoted the expression of BMP2-induced genes like Mx2, alkaline phosphatase and Smad 6. On the other hand, silencing the ER $\alpha$  by shRNA in C2C12, the pre-osteoblasts 2T3, or primary cultures of murine bone marrow, attenuated the effect of BMP on osteoblastogenesis and BMP-induced transcription, as did ICI182,780 ( $10^{-7}$  M), the ER antagonist that promotes its degradation. ER $\alpha$  was co-immunoprecipitated with Smad1 and Smad4 in all these cell models. Moreover, 17 $\beta$ -estradiol (E<sub>2</sub>) at  $10^{-7}$  M abrogated BMP-2 induced phosphorylation of Smad1/5/8 at the C-terminal region as well as BMP2-induced Smad6 transcription. Furthermore, E<sub>2</sub> as well as FGF, used as a positive control, phosphorylated Smad1 at the linker region, as determined by an antibody specific for phospho-Smad1<sup>MAPK</sup> (p-serine 214), generously provided by Dr. De Robertis (Howard Hughes Medical Institute, Los Angeles, CA). And, the effects of E<sub>2</sub> on BMP-2 induced Smad1/5/8 phosphorylation at the C terminus and Smad6 transcription were completely reversed by the specific MEK antagonist PD98059. Consistent with this, E<sub>2</sub> inhibited BMP-2 induced differentiation in calvaria derived osteoblasts from knock-in mice in which classical ER $\alpha$  signaling through ERE sites has been selectively eliminated while preserving non-classical signaling (ER $\alpha$ <sup>NERKL</sup>). These results provide a molecular mechanism of the suppressive effect of estrogens on osteoblastogenesis and support the notion that this effect is exerted via an extranuclear action of the ER.

**Low Serum IGF-I Alters the Cortical Bone Response to Estrogen Deficiency.** J. C. Fritton\*, K. B. Emerton\*, H. Sun\*, Y. Kawashima\*, A. Sinofsky\*, W. Mejia\*, Y. Wu\*, M. B. Schaffler\*, M. Bouxsein\*, C. J. Rosen\*, S. Yakar\*. <sup>1</sup>Orthopaedics and Endocrine Divisions, Mount Sinai School of Medicine, New York, NY, USA, <sup>2</sup>Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA, <sup>3</sup>Maine Medical Center Research Institute, Scarborough, ME, USA.

Postmenopausal women with low circulating IGF-I levels have accelerated loss of BMD by DEXA. However, the contribution of cortical bone has not been teased out. In animal models, abrupt estrogen loss is associated with aggressive endosteal bone erosion that rapidly leads to degradation of mechanical function because of a high rate of marrow expansion. We hypothesized that the cortical response to ovariectomy-induced bone loss would be altered with low circulating IGF-I. To test our hypothesis we employed 12-week-old, liver IGF-I deficient (LID) mice that were generated previously using the

Cre-loxP system. LID mice exhibit 75% reductions in circulating IGF-I levels and 3-4fold increases in serum GH levels that are maintained 12 weeks after ovariectomy. Both 4 and 8 weeks after ovariectomy dampened resorption was revealed on the endosteal surface in LID versus control mice. Furthermore, maintenance of cortical bone area was found in LID mice (Figure 1, Table 1). We speculate that this altered adaptation represents a lag in osteoclastic response to ovariectomy, possibly due to increased serum GH, which remains elevated in LID female mice even 12 weeks post OVX. Further work is required to determine the mechanisms behind this cortical bone maintenance after abrupt estrogen loss. N.B. The first two authors contributed equally to this study.

**Elevated Androgens Are Associated with Increased Bone Formation in Premenopausal Exercising Oligomenorrheic Women.** S. Awdishu\*, S. L. West\*, J. L. Scheid\*, M. J. De Souza\*. <sup>1</sup>Exercise Science, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Kinesiology, Penn State University, State College, PA, USA.

Androgens have multiple actions on the skeleton, specifically, hyperandrogenism may promote osteoblast function. Oligomenorrhea (i.e., menses occurring at intervals of 36-90 days) in exercising women may be associated with hyperandrogenism. The purpose of this cross-sectional observational study was to evaluate the relationship between androgen status and bone formation in premenopausal exercising women. Serum procollagen type 1 propeptide (PINP), calculated free testosterone (cFreeT), calculated bioavailable testosterone (cbioT), free androgen index (FAI), sex-hormone binding globulin (SHBG), urinary estrone 3-glucuronide (E1G), and urinary pregnanediol 3-glucuronide (PdG) were measured repeatedly in 29 women. Volunteers were retrospectively grouped: 1) Exercising ovulatory group (ExOvul n=20), and 2) Exercising oligomenorrheic group (ExOligo, n=9). Independent t-tests and correlations to detect significant associations were performed. Subjects were similar with respect to age ( $24.0 \pm 1.44$  yrs), weight ( $57.8 \pm 1.3$  kg), height ( $163.5 \pm 1.0$  cm), and BMI ( $21.4 \pm 0.5$  kg/m<sup>2</sup>) ( $p > 0.05$ ). The ExOligo group had suppressed PdG AUC ( $p = 0.003$ ), and similar E1G AUC ( $p > 0.05$ ) to the ExOvul group. cFreeT ( $p = 0.003$ ), cbioT ( $p = 0.003$ ), and FAI ( $p = 0.006$ ) were elevated, while SHBG ( $p = 0.039$ ) was suppressed in the ExOligo group compared to the ExOvul group. Bone formation, as indicated by PINP, was elevated ( $p = 0.011$ ) in the ExOligo group compared with the ExOvul group ( $141.6 \pm 25.1$  and  $78.7 \pm 10.4$  ug/L, respectively). PINP was positively correlated with cFreeT ( $p = 0.031$ ,  $r = 0.451$ ), and with cbioT ( $p = 0.030$ ,  $r = 0.452$ ). The results of this study demonstrate that oligomenorrhea in premenopausal exercising women is associated with hyperandrogenism, and elevated androgen levels may be contributing to the etiology of increased bone formation in these women.

**Overexpression of Androgen Receptor in Mature Osteoblasts and Osteocytes Inhibits Osteoblast Differentiation.** X. Zhang, K. Wiren. VA Medical Center, Oregon Health & Science Univ, Portland, OR, USA.

Mature osteoblasts/osteocytes are important mediators of androgen action in the skeleton. The direct mechanisms by which androgens influence bone cells are not fully understood. In these initial studies, we have focused on AR2.3-transgenic cultures with overexpression in mature osteoblasts/osteocytes. To assess the direct effects of androgen signaling during osteoblast differentiation, we are studying the effects of DHT on cell differentiation in primary calvarial cultures (mOB) derived from AR2.3-transgenic fetal mice. Osteoblast function is assessed by determining cell growth, alkaline phosphatase activity, and mineral deposition. Osteoblastic cells were isolated after collagenase digestion from neonatal calvaria from both wild-type (wt) and AR2.3-transgenic (AR2.3-tg) mice. Beginning at day 7, cultures were switched to differentiation medium containing 50µg/ml ascorbic acid. From day 14 on, 5 mM  $\beta$ -glycerophosphate was added to the differentiation media. The mineralization was assessed by alizarin red assay. AR2.3 stable cells were established by co-transfecting with col2.3AR and pRSVneo plasmid DNA in MC3T3-E1 cells under G418 selection. Changes in gene expression (type I collagen and osteocalcin) were determined with qRT-PCR analysis. We first determined the level of AR abundance in both wt and AR2.3-tg cultures by Western analysis, with polyclonal rabbit AR antibodies (ARN-20). As expected, AR levels increase during differentiation in both cultures. The highest level of AR overexpression noted after day 21 in AR2.3-tg cultures. We then assessed growth characteristics of wt and AR2.3-tg cultures without hormone treatment. Osteoblastic cells from both transgenic and wild-type mice display similar growth kinetics. We also determined mineralization capacity, and observed no significant difference between AR2.3-tg versus wt cultures without hormone addition. To assess the consequences of androgen signaling, cultures were treated continuously with vehicle or  $10^{-8}$ M DHT (a nonaromatizable androgen) in charcoal-stripped serum. We characterized DHT action on osteoblast differentiation by determination of alkaline phosphatase (an osteoblast marker activity) and gene expression. Cultures treated with DHT for 14 days showed significant inhibition in alkaline phosphatase activity, with the most robust inhibition observed in AR2.3-tg cultures. Consistent with these results, analysis of gene expression after DHT treatment in stably transfected MC3T3 cultures employing the same promoter showed significant inhibition of both collagen and osteocalcin gene expression. These results are consistent with a reduction in osteoblast differentiation and may reflect the reduced osteoblast vigor observed in AR2.3-tg mice.

**DHT Administration Is Effective for the Prevention of Hypogonadal Bone Loss.** A. A. Semirale, K. M. Wiren. Behavioral Neuroscience, Oregon Health & Science University, Portland, OR, USA.

Generally characterized as anabolic hormones, androgens have pervasive effects on many tissues including bone. Since low bone density and osteoporosis are often coupled with a hypogonadal state in both men and women, sex steroids are implicated in the maintenance of skeletal health. However, the specific effects of androgens on skeletal homeostasis remain poorly characterized and understudied. To gain better insight into the cell types important for mediating the effects of androgens on bone, we constructed and compared two distinct transgenic lines of mice employing different  $\alpha 1(I)$ -collagen promoter fragments to control skeletally-targeted AR overexpression. The col3.6 AR-transgenic (AR3.6-tg) mice demonstrate AR overexpression throughout the osteoblast lineage including the periosteum, while col2.3 (AR2.3-tg) mice have more restricted overexpression in mature osteoblasts and osteocytes. To assess the effect of the non-aromatizable androgen DHT on bone mineral, we compared a treatment versus prevention experimental paradigm in a rodent model of hypogonadal bone loss. AR-transgenic mice and wild-type B6D2F2 littermates were gonadectomized or sham operated, receiving subcutaneous DHT pellet implants either at the time of surgery or after a two month delay. Following six weeks of DHT administration, bone mineral was assessed by whole body DXA. In the treatment model, after two months in a hypogonadal state, wild type mice of both genders lose significant BMD and BMC. In this setting, six weeks of DHT treatment was effective at partially restoring lost bone mineral. In contrast, while both AR2.3-tg and AR3.6-tg male and female mice similarly lost BMD and BMC, they were resistant to the effects of DHT treatment over the same time frame. In the prevention model, during a high bone turnover state, both male and female wild type mice were protected from bone mineral loss when DHT was present compared to placebo controls. AR3.6-tg and AR2.3-tg male mice were also protected from bone loss following gonadectomy and AR3.6-tg males even gained BMD and BMC with six weeks of DHT administration. In contrast, female AR2.3-tg and AR3.6-tg mice did not benefit and continued to lose bone mineral in the presence of DHT. In summary androgen therapy may be beneficial for the prevention of hypogonadal bone loss, but is less effective at restoring lost bone.

**Is Vitamin D Deficiency More Common in Children with Cerebral Palsy than in Healthy Children?** S. Yigit<sup>1</sup>, B. McKinney<sup>2</sup>, J. Pedersen<sup>\*1</sup>, B. Draheim<sup>\*2</sup>, F. Sylvester<sup>3</sup>. <sup>1</sup>Pediatric Endocrinology, Connecticut Children's Medical Center, Hartford, CT, USA, <sup>2</sup>Special Kids Support Center, Connecticut Children's Medical Center, Hartford, CT, USA, <sup>3</sup>Pediatric Gastroenterology and Nutrition, Connecticut Children's Medical Center, Hartford, CT, USA.

Children with cerebral palsy (CP) may be at higher risk for vitamin D (vit D) deficiency because of limited exposure to unfiltered sunlight, impaired nutrition because of swallowing dysfunction and use of anticonvulsants that increase vit D breakdown. In addition, vit D deficiency is more prevalent in Northern latitudes, even among healthy children. Therefore, we hypothesized that children with CP have a higher prevalence of vit D deficiency than their unaffected siblings. To test this hypothesis, we measured serum 25 (OH) vit D (RIA, Immunodiagnostic Systems Ltd, Fountain Hills, AZ) levels in children with CP and their unaffected, healthy siblings living in the same household. Seasonal differences were examined. Vit D deficiency was defined as serum level  $\leq 15$  ng/ml and vit D insufficiency as serum level  $\leq 20$  ng/mL based on previously published pediatric studies. 31 children with CP and 31 healthy siblings as controls between ages of 6-18 years were enrolled. 12.9 % of children with CP were vit D deficient while 29 % of the siblings were deficient. Vit D insufficiency was found in 29 % of children with CP and 38.7 % of healthy siblings. Only 20 % of the children with CP and 13 % of healthy siblings had 25 (OH) vit D level of more than 30 ng/ml, a level considered as optimal. While the mean 25 (OH) vit D levels were low on both groups, healthy siblings had a significantly lower 25 (OH) vit D levels compared to the children with CP (mean 25 (OH) vit D level for children with CP  $24.5 \pm 12.9$ , healthy siblings  $19.6 \pm 8.4$ ,  $p=0.04$ ). Low vit D levels were more prevalent in healthy siblings during winter season (mean 25 (OH) vit D level for children with CP  $33.2 \pm 16.5$ , healthy siblings  $19.8 \pm 8.8$ ,  $p=0.01$ ). 80 % of the healthy siblings were consuming  $\leq 1$  serving of milk per day. 58.8 % of the children with CP who had sufficient vit D levels were on supplemental tube feedings. Only one CP patient with vit D deficiency was on tube feedings but was on a ketogenic diet. None of the healthy siblings were taking vit D supplements while only 2 children with CP were on multivitamin supplements. Vit D deficiency/ insufficiency appear to be a prevalent public health care problem in both children with CP and healthy children. Although children with CP have higher risk factors, healthy siblings seem to have a higher prevalence of vit D deficiency/ insufficiency. Children with CP who are on tube feedings are less likely to develop vit D deficiency/ insufficiency. Healthy children may need counseling for prevention.

**Vitamin D Toxicity Due to a Commonly Available Remedy From the Dominican Republic.** H. Lowe<sup>\*1</sup>, N. Binkley<sup>2</sup>, W. S. Blaner<sup>\*1</sup>, L. A. Plum<sup>\*2</sup>, J. P. Bilezikian<sup>1</sup>. <sup>1</sup>College of Physicians & Surgeons, Columbia University, New York, NY, USA, <sup>2</sup>University of Wisconsin-Madison, Madison, WI, USA.

Vitamin D toxicity is a known cause of hypercalcemia. We report a series of 8 patients presenting with hypercalcemia and found to be vitamin D toxic due to recently ingesting Soladek<sup>®</sup>, a supplement manufactured in the Dominican Republic and readily available over the counter in New York City (NYC). All patients were ambulatory with normal previous serum calcium levels, despite harboring, in many cases, a disorder that can be associated with hypercalcemia (squamous cell cancer (n=1), lymphoma (n=1), hyperthyroidism (n=2), mycobacterial or pneumocystis infection (n=2)). Cases presented with hypercalcemia (range: 10.8-17.2 mg/dl, nl: 8.4-9.8), suppressed PTH (range: <3 to 11 pg/ml), elevated 25(OH)Vitamin D (25OHD, range: 94-525 ng/ml, nl: 20-57) and in some cases elevated 1,25(OH)<sub>2</sub>Vitamin D (1,25OHD, range: 39 to >200 pg/ml, nl: 15-75) levels. All patients were treated with aggressive hydration, and all but 2 received a bisphosphonate and/or glucocorticoid, with subsequent normalization of serum calcium and a substantial decrease in vitamin D levels over weeks to months. Soladek is commonly used in the Dominican Republic for prevention and treatment of the common cold or any general illness. According to the manufacturer's label, each 5mL vial contains Vitamin D (600,000 IU), Vitamin A (120,000 IU), and Vitamin E (5 mg). Instructions are for biweekly to monthly dosing, or as directed by a physician. We purchased 2 vials of the product from the same lot, at a Dominican market in NYC. Laboratory analysis by HPLC revealed that the vial of supplement (5 mL) contains Vitamin D3 (864,000 IU) and Vitamin A (predominantly retinyl palmitate 123,500 IU). These amounts are, respectively, >400X and 5X the safe daily upper limits of Vitamins D and A as recommended by the Food and Nutrition Board of the Institute of Medicine. The circulating 25OHD was solely due to endogenous conversion of vitamin D because there was no 25OHD in the preparation itself as assayed by reverse phase HPLC. This report calls attention to a preparation readily available in the Dominican Republic (and therefore also in many parts of the United States) that contains toxic amounts of vitamins D and A, and can be associated with hypercalcemia. In most of these patients, there was another potential cause of hypercalcemia in addition to the use of Soladek. Elevated levels of 25OHD, to concentrations that are often associated with hypercalcemia, were most likely due to exogenous intake from the vitamin supplement. Although hypercalcemia due to exogenous use of vitamin D is unusual, it is important to consider it in the differential diagnosis particularly among individuals who have access to Soladek.

**Improved Motor Performance in Vitamin D Deficient Mice with VDRMs.** L. Porras\*, Q. Zeng\*, R. L. Cain\*, K. Stayrook\*, L. Burris\*, M. Carson\*, J. Dodge\*, J. Andrews\*, H. U. Bryant, M. Sato, Y. L. Ma. Eli Lilly and Company, Indianapolis, IN, USA.

Vitamin D receptors are found expressed in the muscle, brain and the spinal cord, the areas involved in the regulation of motor function and behavior. In humans, vitamin D deficiency is often accompanied by muscle pain, weakness and other neuromuscular disorders. In vitamin D receptor knock out mice, neurological and behavioral disorders have been observed; therefore vitamin D receptors are known to play an important role in neuromuscular function. The goals for our study were to examine whether neuromuscular coordination was impaired in mice maintained on a vitamin D deficient diet and how vitamin D receptor ligands would affect motor performance. Female Balb/C mice were maintained on either a vitamin D deficient (D-) or normal diet from the embryo gestation stage, or weanling stage until 6 weeks of age, or older. Serum calcium levels were not significantly altered in mice fed D- from the weanling stage, but were slightly decreased in mice maintained on D- from the embryo gestation stage. Body weight of D- mice tended to be slightly heavier than normal diet fed mice, which was due to increased whole body fat to lean mass ratio, as accessed by quantitative magnetic resonance (Echo systems). Although muscle wet weight and grip strength were not significantly different, inverted screen testing revealed a 20-50% impairment in the mobility of mice fed D- when compared to normal diet fed mice. Non-hypercalcemic doses of 1, 25(OH)<sub>2</sub>D<sub>3</sub> and our orally active, tissue selective, non-secosteroidal, VDRM dose-dependently improved inverted screen performance of D- fed mice. Fiber cross sectional area analyses showed a trend towards bigger gastrocnemius muscles of 1,25(OH)<sub>2</sub>D<sub>3</sub> and VDRM-treated mice. Our data indicate that 1,25(OH)<sub>2</sub>D<sub>3</sub> and VDRMs have positive effects in regulating motor performance in mice maintained on a vitamin D deficient diet.

**Measurements of Vitamin D Do Not Necessarily Reflect What You Give to Your Patients.** E. Cavalier<sup>1</sup>, C. Cormier<sup>2</sup>, J. Souberbielle<sup>3</sup>. <sup>1</sup>Clinical Chemistry, University Hospital of Liege, University of Liege, Liege, Belgium, <sup>2</sup>Rheumatology, University Paris-V, Hôpital Cochin, AP-HP, Paris, France, <sup>3</sup>Clinical Chemistry, University Paris Descartes, Inserm U845, and, Hôpital Necker, Service d'Explorations Fonctionnelles, AP-HP, Paris, France.

A Laboratory error is defined by ISO 22369 Standard as « Any error, from analyses prescription to the final report of the results, bad interpretation of these ones and inappropriate reaction in front of them ». We present here what might thus be considered as a laboratory error in a 25-hydroxyvitamin D (25VTD) determination. Indeed, we report the case of a 60 yo woman diagnosed as having a VTD deficiency (serum 25VTD measured with the automated Roche Elecsys method at 12 ng/mL) who was given a single 60000IU VTD2 dose. Two weeks later, the serum 25VTD measured with the same assay did not change and was still at 11 ng/mL. She was then referred to our unit for extensive laboratory testing. All the tests that we performed 3 month later were normal, including 25VTD (50 ng/mL with the Diasorin RIA). In order to explain the discrepant results between the Roche and Diasorin methods, we studied in 11 healthy subjects (5 men, 6 women aged 21-62) the elevation of 25VTD after a single 60000IU VTD2 dose. Samples were drawn before (D0), 7 (D7) and 28 days (D28) after the supplementation and we used a third method (HPLC), which separates 25VTD2 and 25VTD3, as a reference. At D0, the mean 25VTD concentration±SD of our volunteers was similar with the RIA (29.3±6.8 ng/mL) and the Elecsys (30.2±6.0 ng/mL) but slightly higher (p<0.001) with HPLC (33.1±8.1 ng/mL). Five, 6 and 8 subjects had a 25VTD concentration >30 ng/mL on D0 with RIA, Elecsys, and HPLC respectively. At D7, 25VTD increased only with the RIA and HPLC assays. This increase was due solely to an increase in 25VTD2, as indicated by the HPLC data. All the subjects had a 25VTD concentration >30 ng/mL with the RIA and HPLC assay, whereas this was the case in only two subjects when the Elecsys assay was used. At D28, 25VTD remained >30 ng/mL in all subjects with RIA and HPLC, whereas the level was <30 ng/mL in all subjects with the Elecsys assay. Although skin exposure to UVB produces VTD3 and food sources of VTD contain mainly VTD3, supplementation is often made with VTD2, especially in the USA. As long as VTD2 is available, it is mandatory to measure 25VTD with a method that recognizes both 25VTD2 and 25VTD3. The case briefly described above shows that measuring 25VTD with an assay exclusively specific for 25VTD3, like Roche Elecsys, may underestimate VTD status and thus potentially lead to overtreatment, and to expensive and stressful explorations.

**Cooperativity between VDR and Liver Enriched Inhibitory Protein (LIP) in the Regulation of TRPV6 Identifies a Novel Function for LIP as a Transcriptional Activator.** B. S. Benn<sup>\*1</sup>, M. B. Meyer<sup>\*2</sup>, J. W. Pike<sup>2</sup>, S. Christakos<sup>1</sup>. <sup>1</sup>Biochemistry and Molecular Biology, UMDNJ- New Jersey Medical School, Newark, NJ, USA, <sup>2</sup>Biochemistry, University of Wisconsin, Madison, WI, USA.

1,25-Dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>) is known to increase the rate of calcium entry into the intestinal cell. Recently the apical calcium channel TRPV6, which is co-localized with calbindin and is induced by 1,25(OH)<sub>2</sub>D<sub>3</sub> in intestine, has been identified, suggesting a calcium entry mechanism. Previous studies have shown that vitamin D response elements (VDREs) located at -1.2, -2.1 and -4.3 kb in the human TRPV6 promoter are required for the full transcriptional response to 1,25(OH)<sub>2</sub>D<sub>3</sub> and that the VDREs at -2.1 and -4.3 appear to be most significant for 1,25(OH)<sub>2</sub>D<sub>3</sub> mediated transcriptional activation. C/EBPβ has been shown previously to enhance 1,25(OH)<sub>2</sub>D<sub>3</sub> mediated 24(OH)ase promoter activation. To determine if the C/EBPβ isoforms LIP and LAP are involved in 1,25(OH)<sub>2</sub>D<sub>3</sub> mediated hTRPV6 transcription, Caco-2 cells were transfected with the hTRPV6 promoter (-7000/+160) and increasing concentrations of LIP or LAP in the presence or absence of 10<sup>-8</sup>M 1,25(OH)<sub>2</sub>D<sub>3</sub>. Increasing concentrations of LIP, which has been reported to repress LAP induced transcription, was consistently found to result in a significant potentiation of 1,25(OH)<sub>2</sub>D<sub>3</sub> induced hTRPV6 transcription (2-4 fold; p<0.05 compared to 1,25(OH)<sub>2</sub>D<sub>3</sub> treatment alone; maximal 1,25(OH)<sub>2</sub>D<sub>3</sub> induced transcription in the presence of LIP was 20-25 fold). LIP alone had no effect on hTRPV6 transcription. Increasing concentrations of LAP, C/EBPα or C/EBPδ in the presence or absence of 1,25(OH)<sub>2</sub>D<sub>3</sub> also had no effect on hTRPV6 transcription. In COS-7 cells LIP enhancement of VDR mediated hTRPV6 transcription was not observed, suggesting cell type specificity. LIP enhancement of 1,25(OH)<sub>2</sub>D<sub>3</sub> induced transcription was also observed using a hTRPV6 promoter construct with a mutation in the -2.1 VDRE but with a functional -4.3 VDRE. No effect of LIP was observed using a hTRPV6 promoter construct with the -4.3 and -2.1 VDREs mutated. Caco-2 cells were transfected with an ~200bp construct containing the -4.3 VDRE upstream of the minimal thymidine kinase (tk) promoter. Results of these experiments yielded a similar enhancement with LIP. Further, co-immunoprecipitation experiments indicated that VDR and LIP interact. ChIP/re-ChIP experiments indicated that VDR and LIP can bind simultaneously to the hTRPV6 promoter at the -4.3 VDRE. These findings suggest a novel function for LIP where LIP acts as a transcriptional activator in the 1,25(OH)<sub>2</sub>D<sub>3</sub> mediated regulation of TRPV6.

## SU199

**25-OH-D<sub>3</sub>-24-hydroxylase (CYP24A1): Mutagenesis and Activity Studies Reveal Important Residues Involved in Regioselectivity and Substrate Access.** M. Kaufmann\*, D. E. Prosser\*, B. O'Leary\*, V. Byford\*, G. Jones. Biochemistry, Queen's University, Kingston, ON, Canada.

CYP24A1 catalyzes the multi-step catabolism of 1α,25-(OH)<sub>2</sub>D<sub>3</sub> via alternative C24 or C23 hydroxylation pathways ending in either calcitroic acid or 1α,25-(OH)<sub>2</sub>D<sub>3</sub>-26,23-lactone. We set out to test the relative importance of A326, M416 & M252 in regioselectivity and catalytic efficiency using homology modeling, sequence alignment and mutagenesis of hCYP24A1 at residues of predicted structural & functional importance. Metabolism of 1α,25-(OH)<sub>2</sub>D<sub>3</sub> was studied in transfected V79-4 cells & products were analyzed by HPLC coupled- PDA, <sup>3</sup>H-detection or LC-MS. Previous research revealed that residues 326 in hCYP24A1 (PNAS 104:12673-8) and 416 in rCYP24A1 (Mol Pharmacol 70:120-8) are important determinants of regioselectivity. The substitution A326G in hCYP24A1, which catalyzes mainly C24-hydroxylation, resulted in a shift in preference to C23 hydroxylation, similar to the G326-containing opossum CYP24A1. The mutation T416M, in rCYP24A1, as it is in the human, also increased preference for C23-hydroxylation. In order to study which of these two residues is a more important determinant of regioselectivity in hCYP24A1, we created a A326G/M416T double mutant. The activity of the double mutant was characterized by mainly 1α,25-(OH)<sub>2</sub>D<sub>3</sub>-26,23-lactone production, similar to A326G, without any formation of tetranor-1α,25-(OH)<sub>2</sub>D<sub>3</sub>, which was the major C24-hydroxylation product formed by M416T. This suggested that A326 is a more important determinant of regioselectivity than M416 in hCYP24A1. Studies of M252T revealed a dramatic reduction in activity, and an apparent metabolic block in the C24-hydroxylation pathway. At μM substrate, CYP24A1 is characterized by the production of proximal pathway intermediates whereas nM substrate results in primarily terminal pathway products, tetranor-1α,23-(OH)<sub>2</sub>D<sub>3</sub> and calcitroic acid. At μM substrate, the M252T metabolic profile is dominated by 1α,24,25-(OH)<sub>3</sub>D<sub>3</sub>, with smaller amounts of 1α,23,25-(OH)<sub>3</sub>D<sub>3</sub>, and arrest of the 24-hydroxylation pathway occurring at the level of 24-oxo-1α,23,25-(OH)<sub>3</sub>D<sub>3</sub>. Unlike hCYP24A1, this profile remains unchanged as the substrate is decreased. These data suggest that substrate and initial product access to the active site is impeded by M252T, and that further metabolism towards calcitroic acid is blocked. Highly conserved Met252 is located near the end of the F-helix in a putative substrate access channel and could potentially interact with the substrate A-ring. In summary, we have identified two residues critical to CYP24A1 function, that enhance our knowledge of how 1α,25-(OH)<sub>2</sub>D<sub>3</sub> gains access to and is held within the active site.

**Disclosures:** M. Kaufmann, None.

## SU200

**A New 25-Hydroxy Vitamin D Assay on the IDS Automated Analyser 3x3™.** L. A. Mudford\*, A. A. Tang\*, S. Middlemist\*, C. J. Fox\*, C. M. Roffe\*, M. J. Gardner\*, D. Laurie\*, A. K. Barnes\*, M. L. Garrity\*. Immunodiagnostic Systems (IDS Ltd), Boldon, United Kingdom.

The importance of measuring 25-Hydroxy Vitamin D (25-OH D) to determine a patient's vitamin D status is becoming more widely recognised as part of a panel of tests for a variety of conditions including bone diseases, muscle function, diabetes, immune disorders, heart and circulatory disease, cancer and nervous system disorders. The 25-OH D assay will be part of a comprehensive panel of bone and growth tests on the new IDS Automated Analyser 3X3™. The purpose of this study was to develop and evaluate an assay for the determination of 25-OH D using this new fully automated, random access analyser. This analyser will enable clinical laboratories to determine 25-OH D, PTH, Calcium and Phosphorus from a single specimen tube. The IDS Automated Analyser 3X3™ contains integrated measurement modules for concurrent analysis of different types of diagnostic test, to include immunochemistry, biochemistry and coagulation. The 25-OH D assay uses the immunochemistry module of the IDS Automated Analyser 3X3™ and is performed as a chemiluminescent immunoassay. This utilises an acridinium labelled antibody, which emits light upon treatment with hydrogen peroxide and sodium hydroxide. This light is measured as relative light units (RLU) and quantified by a luminometer. The 25-OH D assay is a competitive immunoassay which comprises of an automated sample pre-treatment step, followed by the addition of a neutralising and displacing solution and the acridinium labelled antibody. After an incubation step magnetic particles labelled with 25-OH D are added to the assay mixture, which compete with the sample 25-OH D for the acridinium labelled antibody. Therefore the signal produced is inversely proportional to the concentration of 25-OH D in the sample. The analytical sensitivity of this assay has been determined as 1.2ng/mL and the functional sensitivity has been determined as less than 3.2ng/mL. The assay range is 0-200ng/mL with patient sample correlation to IDS 25-OH D RIA (n=78) of  $r = 0.93$  with an intercept of -0.66 and slope of 1.11 (linear regression). Linearity performed by diluting a high sample in a low sample gave a mean observed/expected value of 93.0% and recovery performed by spiking 25-OH D into samples gave a mean recovery of 103.6%. This automated 25-OH D assay is co-specific for both 25-OH D<sub>2</sub> and 25-OH D<sub>3</sub>. The assay shows the potential to be an excellent addition to the new bone panel on the IDS Automated Analyser 3X3™ essential for the measurement of a patients vitamin D status, with good correlation and sensitivity that will provide an accurate and rapid measurement of 25-OH D in the clinical laboratory.

## SU201

**Vitamin D Status in Severely Obese Individuals Can Be Predicted By Demographic and Lifestyle Factors.** E. M. Stein<sup>1</sup>, N. Sinha<sup>2</sup>, D. Ortiz<sup>2</sup>, G. Strain<sup>3</sup>, A. Pomp<sup>3</sup>, G. Dakin<sup>3</sup>, D. J. McMahon<sup>1</sup>, R. Bockman<sup>1</sup>, S. J. Silverberg<sup>1</sup>. <sup>1</sup>Medicine/ Endocrinology, Columbia University College of Physicians and Surgeons, New York, NY, USA, <sup>2</sup>Medicine/ Endocrinology, Weill Cornell Medical College, New York, NY, USA, <sup>3</sup>Surgery, Weill Cornell Medical College, New York, NY, USA, <sup>4</sup>Medicine/ Endocrinology, Weill Cornell Medical College and Hospital for Special Surgery, New York, NY, USA.

The factors governing vitamin D insufficiency in severe obesity are not well understood. The purpose of this study was to assess vitamin D status and whether factors important in normal weight populations influence vitamin D levels in severely obese individuals.

56 obese (BMI>35kg/m<sup>2</sup>) men and women (20-64 years) awaiting bariatric surgery were enrolled in this cross-sectional investigation. Study measurements included dietary calcium and vitamin D intake, sun exposure, intact parathyroid hormone (PTH) and 25-hydroxyvitamin D (25OHD).

Serum 25OHD was below 30 ng/ml in 85% of subjects, and was inversely associated with BMI ( $r = -0.36$ ;  $p < 0.01$ ). Seventy-five percent of individuals had secondary hyperparathyroidism (mean PTH  $72 \pm 34$  pg/ml). African American (AA) race was independently associated with 25OHD level ( $r = -0.35$ ;  $p < 0.01$ ), and levels below 20 ng/ml were found in 90% of AA subjects (vs. 51% of non-AA). Sun exposure was directly associated with 25OHD ( $r = 0.33$ ;  $p = 0.02$ ), and 25OHD levels were highest in the summer (summer:  $22.8 \pm 6.5$  ng/ml vs. non-summer:  $16.5 \pm 9.0$  ng/ml;  $p = 0.02$ ). The association between 25OHD and dietary/supplement vitamin D was not significant. In a stepwise regression model, BMI, sun exposure, African American race, and PTH predicted 40% of the variance in 25OHD levels ( $p$ -value  $< 0.0001$  overall model). When PTH was taken out of the model, BMI was the strongest predictor of 25OHD level; each increase in BMI of 1 kg/m<sup>2</sup> was associated with a decrease of 0.5 ng/ml in 25OHD level ( $p < 0.01$ ).

In conclusion, severely obese individuals share many risk factors for vitamin D deficiency with the general population; those who are most overweight, African American, and have limited sunlight exposure are at greatest risk. Although many of these risk factors are not easily modifiable, they can be utilized to identify the patients at greatest risk for vitamin D deficiency, and to foster crucial repletion prior to bariatric surgery.

**Low Plasma 25-Hydroxyvitamin D and Vitamin D Receptor Polymorphisms Are Associated with Increased Breast Cancer Risk.** K. D. Crew<sup>\*1</sup>, M. D. Gammon<sup>\*2</sup>, D. L. Hershman<sup>\*1</sup>, S. Cremers<sup>3</sup>, E. Dworakowski<sup>\*3</sup>, E. Shane<sup>3</sup>, M. Kappil<sup>\*4</sup>, M. Terry<sup>\*5</sup>, A. I. Neugut<sup>\*1</sup>, R. M. Santella<sup>\*4</sup>. <sup>1</sup>Medicine and Epidemiology, Columbia University, New York, NY, USA, <sup>2</sup>Epidemiology, University of North Carolina, Chapel Hill, NC, USA, <sup>3</sup>Medicine, Columbia University, New York, NY, USA, <sup>4</sup>Environmental Health Sciences, Columbia University, New York, NY, USA, <sup>5</sup>Epidemiology, Columbia University, New York, NY, USA.

Vitamin D has been associated with decreased risk of several cancers, including breast cancer. In experimental studies, vitamin D has been shown to inhibit cell proliferation and induce differentiation and apoptosis in normal and malignant breast cells. Using a population-based case-control study on Long Island, NY, we examined associations of breast cancer with plasma 25-hydroxyvitamin D [25-OHD] levels, a measure of body stores of vitamin D, and vitamin D receptor (VDR) polymorphisms (*FokI*, *Apal*, *BsmI*, and *TaqI*). In-person interviews and blood specimens were obtained from 1,026 incident breast cancer cases diagnosed in 1996-1997 and 1,075 population-based controls. Median age was 57.3 years (range 20-95); 93.4% of the study population was white and 67% postmenopausal. Plasma 25-OHD was measured in batched, archived specimens by Diasorin radioimmunoassay. The mean (SD) plasma 25-OHD concentration was 27.1 (13.0) and 29.7 (15.1) ng/ml in the cases and controls, respectively ( $P < 0.0001$ ). Plasma 25-OHD was inversely associated with breast cancer risk in a concentration-dependent fashion. Compared to women with vitamin D deficiency (25-OHD  $< 20$  ng/ml), plasma 25-OHD  $\geq 40$  ng/ml was associated with reduced breast cancer risk (OR = 0.58, 95% CI = 0.38-0.90). A greater protective effect was observed in postmenopausal compared to premenopausal women, and the effect did not vary according to tumor hormone receptor status. Additionally, the presence of at least one variant allele in *TaqI* (*Tt* or *tt*) was associated with a modest decrease in breast cancer risk (OR = 0.83, 95% CI = 0.69-0.99). Among women with vitamin D deficiency, the *FokI* *ff* genotype correlated with reduced risk of breast cancer (OR = 0.49, 95% CI = 0.29-0.81). No significant associations were noted with *Apal* and *BsmI* genotypes and breast cancer risk. In summary, these results add to a growing body of evidence that adequate vitamin D stores may prevent breast cancer development. Whereas circulating 25-OHD levels of  $> 32$  ng/ml are associated with normal mineral metabolism, our data suggest that the optimal level for breast cancer prevention is  $\geq 40$  ng/ml. Well-designed clinical trials are urgently needed to determine whether vitamin D supplementation is effective for breast cancer chemoprevention.

## SU203

**Vitamin D Status in Young Women Is Strongly Negatively Related to Body Weight, Body Mass Index and Body Fat, but Is Not Associated to Bone Mass.** R. Kremer<sup>1</sup>, P. Campbell<sup>\*2</sup>, T. Reinhardt<sup>3</sup>, V. Gilsanz<sup>2</sup>. <sup>1</sup>Medicine, McGill University, Montreal, QC, Canada, <sup>2</sup>Radiology, University of Southern California, Los Angeles, CA, USA, <sup>3</sup>Metabolic Diseases/Immunology, National Animal Disease Center, Ames, IA, USA.

Available data in elderly adults suggest that circulating 25-hydroxyvitamin D (25OHD) concentrations are positively correlated with bone mineral density (BMD) and inversely associated with obesity. To characterize whether these relations are also present at the time of peak bone mass, we examined the associations between serum 25OHD measures using a radioimmunoassay and values for weight (wt) and body mass index (BMI), and bone and fat determinations obtained by dual energy x-ray absorptiometry (DXA) and computed tomography (CT) in 90 white females, ages 16-22 years, who had achieved sexual and skeletal maturity. Significant negative relations were present between serum 25OHD and weight, BMI and all imaging measures of body fat (see Table). Values for PTH were also inversely correlated to 25OHD. In contrast, no relation was observed between circulating 25OHD and CT or DXA measurements in the appendicular or axial skeleton. Similar relations were seen in the 53 (59%) women with vitamin D deficiency/insufficiency ( $\leq 29$  ng/ml), but were not present in the 37 (41%) with  $\geq 30$  ng/ml vitamin D levels. In conclusion, we found strong negative relations between vitamin D values and measures of weight, BMI and body adiposity, but no relation with bone mass in young women.

**Decreasing Calcidiol (25-OHD3) In Serum Is Related to Impaired Function and Increased Mortality in The Elderly.** E. Waern<sup>\*1</sup>, C. Christiansen<sup>2</sup>, E. Haug<sup>\*3</sup>, E. Rothenberg<sup>\*4</sup>, D. Mellström<sup>1</sup>. <sup>1</sup>Centre for Bone Research at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>2</sup>Center for Clinical and Basic Research, Ballerup, Denmark, <sup>3</sup>Hormone Laboratory, Aker University Hospital, Oslo, Norway, <sup>4</sup>Dept of Clinical Nutrition, Sahlgrenska University Hospital, Gothenburg, Sweden.

**Introduction:** The main target organs for vitamin D are the small intestine, the kidneys and the skeleton, tissues related to calcium metabolism. However, recent years investigations have discovered vitamin D receptors in many other tissues and vitamin D deficiency may increase the risk of many common chronic diseases and have effects on function and mortality.

**Population and Method:** A representative sample of 70 years old were invited to participate in a prospective study of ageing. 806 subjects were invited, 619 accepted to participate (317 women, 302 men). 405 participants were re-examined at 76 years of age. In 377 men and women serum levels of calcidiol (25-hydroxyvitamin D) were followed longitudinally.

The study included an interview as well as a thorough medical and laboratory examination. Venous sample were obtained at 7.30-8.00 am after 10 hours fast.

The serum levels were related to several variables known to affect the vitamin-D levels such as dietary intake and out-door activities. The correlation between vitamin D levels and muscle-strength, pulmonary-function, walking, daily intake of vitamin D, number of daily activities and mortality were studied.

**Results:** In the 377 individuals followed longitudinally the mean serum concentrations of 25-OHD3 were 73.7 nmol/L at 70 years of age and 62.9 nmol/L at the age of 76 years, not significantly different from the total group examined at 70

and 76 years of age. A decrease with 12 % in men and 17 % in women.

Men had a slightly, but significantly, higher 25-OHD concentrations than women. Both men and women decreased in weight and height with increasing age but there were no correlation to vitamin D-levels. The daily intake of vitamin D were lower in 76 years of age compared to 70 years of age (5.8 - 4.5 µg) and was below the daily recommended intake in Sweden (10 µg). The daily intake were correlated to the serum concentrations of calcidiol ( $r=0.28$ ,  $p=0.005$ ).

Serum levels of vitamin-D were related to muscle-strength ( $r=0.21$ ,  $p=0.0001$ ), pulmonary-function ( $r=0.15$ ,  $p=0.001$ ), walking ( $r=0.22$ ,  $p=0.0001$ ) and daily activities ( $r=0.21$ ,  $p=0.0001$ ). Low vitamin D levels were related to increased mortality.

**Conclusion:** The serum levels of calcidiol decreases with increasing age and correlates to the daily intake.

Low vitamin-D levels is correlated to impaired muscle-strength and pulmonary function and increased mortality.

**Disclosures:** E. Waern, None.

**Prevalence of Vitamin D Deficiency Among Surgical Orthopedic Patients: A Single Center Analysis.** L. Bogunovic<sup>\*1</sup>, L. Shindle<sup>\*1</sup>, J. Virbalas<sup>\*1</sup>, B. Beamer<sup>\*1</sup>, N. Karkare<sup>\*1</sup>, J. Nguyen<sup>\*2</sup>, J. M. Lane<sup>3</sup>. <sup>1</sup>Metabolic Bone Disease, Hospital for Special Surgery, New York, NY, USA, <sup>2</sup>Research, Hospital for Special Surgery, New York, NY, USA, <sup>3</sup>Metabolic Bone Disease, Orthopedic Trauma, Hospital for Special Surgery, New York, NY, USA.

The purpose of this study was to determine the prevalence of 25-hydroxy vitamin D deficiency ( $\leq 20$  ng/mL) among surgical orthopedic patients at our institution.

Six hundred and nineteen adults, ages 18-98, underwent pre-operative measurement of 25-hydroxy vitamin D (25OHD). Surgical candidates from the following six services were included in the study: Sports Medicine, Arthroplasty, Orthopedic Trauma, Foot and Ankle, Hand, and Metabolic Bone Disease. On the following four services 25OHD was assessed in patients with a specific diagnosis and/or intervention: Sports Medicine (meniscal and anterior cruciate ligament repair), Arthroplasty (total knee and total hip replacement), Hand (colles' fracture), and Metabolic Bone Disease (vertebral compression fracture). In both the Foot and Ankle and the Orthopedic Trauma services, 25OHD status was assessed in all surgical candidates. Patient 25OHD status was categorized as being normal ( $\geq 32$  ng/mL), insufficient (20-32 ng/mL), or deficient ( $\leq 20$  ng/mL). Additional variables included the following: age, sex, race, and body mass index (BMI kg/m<sup>2</sup>).

At our institution, 44% of patients were found to have abnormal levels of 25OHD ( $< 32$  ng/mL). The highest rates of deficiency were seen in the trauma population where the risk of vitamin D deficiency was three times that seen on the other services ( $p<0.05$ ) (fig. 1). Race also appears to be a factor. Average vitamin D in the obese group (BMI  $> 30$ ) was found to be 37.5 ng/mL and 21.8 ng/mL in the black population, a difference which is significant ( $p<0.001$ ). There appears to be a significant difference in the vitamin D levels between the BMI groups ( $p=0.0001$ ). Mean vitamin D level in the obese group (BMI  $> 30$ ) is statistically lower when compared to the two other BMI groups, normal (BMI=18.5-24.9) and overweight (BMI=25-29.9) ( $p<0.001$  and  $p=0.018$  respectively).

The results of this study give an overview of vitamin D status among the surgical orthopedic population at our institution. Given the importance of vitamin D on bone and muscle health, pre-operative assessment of 25OHD status appears to be valuable.

**Evaluation of Automated Methods for Quantifying Serum 25-Hydroxyvitamin D.** H. E. C. Hanwell<sup>\*</sup>, D. Wagner<sup>\*</sup>, R. Vieth. Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

The accepted biomarker of vitamin D nutritional status is serum 25-hydroxyvitamin D [25(OH)D]. However, a clear understanding of vitamin D research is confounded by the variability among assays used for measuring 25(OH)D.

The purpose of this study was to compare two new automated assays with the well-established reference method, the DiaSorin radioimmunoassay (RIA) for serum 25(OH)D quantification.

The 25(OH)D from human sera (n=160) was quantified using the RIA and two automated non-radioactive immunoassays: DiaSorin Liaison Total 25(OH)D and Roche Elecsys 25-OH. Correlation was assessed with the Pearson test and agreement with the Bland-Altman method.

The RIA and Liaison correlated well ( $r = 0.919$ ) with negligible bias (bias  $\pm$  95% limits of agreement =  $-0.72 \pm 16.01$  nmol/L). The Roche correlated similarly with both the RIA and Liaison but with higher bias versus the RIA ( $r = 0.871$ ; bias =  $-2.55 \pm 21.06$  nmol/L) than the Liaison ( $r = 0.861$ ; bias =  $-1.72 \pm 21.34$  nmol/L). Imprecision (CV%) within-run for the RIA, Liaison and Roche was 9.66%, 6.29%, and 4.52%, and between-run was 10.8%, 6.67%, and 9.13%, respectively.

In conclusion, the Liaison Total 25(OH)D demonstrated a stronger correlation and better agreement with the reference method (DiaSorin RIA) than the Roche Elecsys 25-OH for quantification of serum 25(OH)D.

## SU207

**Effect of 1,25-Dihydroxyvitamin D<sub>3</sub> and 25-Hydroxyvitamin D<sub>3</sub> on Osteoblastogenesis and Bone Strength in Vitamin D Sufficient Growing Mice.** L. Rossdeutsch<sup>\*1</sup>, D. C. Huang<sup>1</sup>, X. F. Yang<sup>1</sup>, F. T. Marino<sup>\*2</sup>, J. Barralet<sup>\*2</sup>, R. Kremer<sup>1</sup>. <sup>1</sup>Department of Medicine and Center for Bone and Periodontal Research, McGill University, Montreal, QC, Canada, <sup>2</sup>Faculty of Dentistry, McGill University, Montreal, QC, Canada.

Vitamin D and its active metabolites have been shown to exert a positive effect on bone in human and animal models of osteoporosis. However, the beneficial effect of vitamin D on peak bone mass is controversial. In this study, we analyzed 4-week old vitamin D-replete female FVB mice treated with a continuous infusion of either 1,25(OH)<sub>2</sub>D<sub>3</sub> (12 pM/24h and 24 pM/24h), 25-OHD<sub>3</sub> (2000 pM/24h) or vehicle for eight weeks using Alzet osmotic minipumps. In this model peak bone mass is achieved around twelve weeks. At sacrifice, ex-vivo cultures of bone marrow mesenchymal stem cells (BM-MSC) were prepared and induced to differentiate with an osteogenic medium. BM-MSC obtained from mice treated with 1,25(OH)<sub>2</sub>D<sub>3</sub> demonstrated a significant (2.5 fold) increase of CFU-OB stained with alkaline phosphatase or alizarin red as compared to controls. In contrast, no effect was observed in BM-MSC obtained from mice treated with 25-OHD<sub>3</sub>. In the 1,25(OH)<sub>2</sub>D<sub>3</sub>-treated groups blood calcium levels remained within the normal range in the low dose group but increased in the hypercalcemic range in the high dose group. In 25-OHD<sub>3</sub>-treated animals 25-OHD<sub>3</sub> levels increased by two fold but blood calcium levels did not differ significantly from controls. We next analyzed in detail the skeletal phenotype by mineral bone density (BMD), 3D micro-CT, histomorphometry and three-point bending test. BMD, microarchitectural parameters and mechanical strength remained unchanged in both the low dose 1,25(OH)<sub>2</sub>D<sub>3</sub> and 25-OHD<sub>3</sub>-treated groups as compared to controls. In contrast, BMD and bone strength decreased significantly in the high dose 1,25(OH)<sub>2</sub>D<sub>3</sub>-treated group. Histomorphometric analysis indicated a significant increase in the number of osteoblasts in the 1,25(OH)<sub>2</sub>D<sub>3</sub>-treated groups but not in the 25-OHD<sub>3</sub>-treated group as compared to controls. In summary our data indicate that 1,25(OH)<sub>2</sub>D<sub>3</sub> stimulate osteoblastogenesis and does not affect bone strength at low dose but decreases bone strength at high dose. In contrast 25-OHD<sub>3</sub> has no effect on either osteoblastogenesis or bone strength. Our data do not support a beneficial effect of either 1,25(OH)<sub>2</sub>D<sub>3</sub> or its inactive precursor on peak bone mass in vitamin D-replete female growing mice.

**Disclosures:** L. Rossdeutsch, None.

## SU208

**1,25(OH)<sub>2</sub>D<sub>3</sub> Regulates Collagen Maturation in Osteoblastic Cell Culture System.** H. Nagaoka\*, Y. Mochida, P. Atsawasuwan\*, M. Kaku\*, M. Yamauchi. Dental Research Center, University of North Carolina, Chapel Hill, NC, USA.

The biologically active form of vitamin D<sub>3</sub>, 1,25(OH)<sub>2</sub>D<sub>3</sub> (1,25VD), has a broad range of physiological effects, however, little is known about its effect on collagen quality in bone. The objectives of this study were to investigate the effects of 1,25VD on gene expression of enzymes critical for collagen cross-linking and collagen post-translational modifications using an osteoblastic cell culture system. MC3T3-E1 (MC) cells were cultured and treated with ethanol (E), cholecalciferol (VD) or 1,25VD. The former two served as controls. Total RNA was isolated at four time points (12, 24, 48 and 72 hours), mRNA expression of Cbfa1/Runx2, type I collagen alpha 2 chain (Col1a2), lysyl hydroxylase isoforms (LH1-3), lysyl oxidase isoforms (LOX, LOXL1-4) and GAPDH (internal control) was analyzed by real-time PCR and the relative gene expression was calculated. In another set of experiments, MC cells were cultured under the same condition for 2 weeks, cell/matrix layer was collected, reduced with standardized NaBH<sub>4</sub>, hydrolyzed with 6N HCl and subjected to quantitative amino acid and cross-link analyses. The analyses were performed in triplicate. The results of two control groups (E and VD) were essentially identical to each other for both experiments. Of the mRNA expression examined, LH2 in the 1,25 VD treated group showed a 3.5 fold increase at 12 hr and 5-7 fold increases at 48-72 hr compared to controls. LH1 expression also showed 2-4 fold increases by the treatment at all time points analyzed. LOXL2 expression in the treated group showed a 12 fold increase at 12 hr and a 40 fold increase at 48hr. Other isoforms did not show significant differences. Cbfa1/Runx2 expression was decreased with the 1,25 VD treatment. The biochemical analysis demonstrated that the extent of lysine hydroxylation of collagen was significantly higher (~45%) in the 1,25VD treated group than that of controls. The major collagen cross-links in all groups were dihydroxylysinoxonolucine (DHLNL), hydroxylysinoxonolucine (HLNL) and pyridinoline (Pyr). Of those, DHLNL and Pyr were significantly higher in the 1,25VD treated group (1.85 and 5 folds, respectively) than those of controls while HLNL was comparable to control groups. Hydroxylysine aldehyde, as its reduced form, was detected only in the 1,25 VD treated group. These findings indicate that 1,25VD upregulates the gene expression of specific LH and LOX isoforms in osteoblastic cells resulting in higher levels of lysine hydroxylation, hydroxylysine aldehyde-derived cross-links and a total number of cross-links. Thus, 1,25VD may control the stability and maturation of collagen in bone.

## SU209

**Increased Osteoclasts in Brlt Mouse Model for Osteogenesis Imperfecta Are Independent of Decreased Osteoblast Matrix Production and RANKL/OPG Ratio, but Are Associated with Increased Osteoclast Precursors in Marrow.** P. Collin-Osdoby\*, T. E. Uveges<sup>2</sup>, W. A. Cabral\*, L. Goldberg\*, G. A. Gronowicz\*, P. Osdoby<sup>1</sup>, J. C. Marini<sup>2</sup>. <sup>1</sup>Department of Biology and Division of Bone and Mineral Metabolism, Washington University, St. Louis, MO, USA, <sup>2</sup>Bone & Extracellular Matrix Branch/NICHD/NIH, Bethesda, MD, USA, <sup>3</sup>Department of Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA.

The Brlt mouse, a knock-in model for moderately severe osteogenesis imperfecta, has a glycine substitution (G349C) in half of type I collagen  $\alpha 1(I)$  chains and a 45% reduction in cortical and trabecular bone volume. We examined the cellular contribution to Brlt bone phenotype in 2 and 6 month old mice using static and dynamic histomorphometry, quantitative immunohistochemistry and real-time RT-PCR. Brlt Obs/BS is comparable to wild-type before and after puberty; also, both genotypes have equivalent numbers of CFU, showing that marrow can replenish osteoblasts equally. However, osteoblast matrix production (MAR) decreases to half of wild-type values after puberty, suggesting that production of matrix by individual Brlt osteoblasts declines after puberty. In contrast, Brlt OcS/BS is increased 36-45% at 2 and 6 months compared to wild-type, as are the number of TRAP positive cells, 57% and 47%, respectively. Furthermore, the greater size and staining intensity of TRAP positive cells in Brlt suggests that the activity of individual osteoclasts may be increased. In total RNA from Brlt femora, TRAP expression was almost double WT levels. As a result of this cellular uncoupling, Brlt BFR declines from a normal level at 2 months to half of wild-type at 6 months. The combination of increased osteoclast activity and decreased osteoblast matrix production causes the weak Brlt femoral geometry. Quantitative immunohistochemistry and real time RT-PCR examination of the basis of the Brlt cellular imbalance revealed increased RANK, RANKL and OPG levels in Brlt, although Brlt's RANKL/OPG ratio was comparable to wild-type. Alternatively, the elevation of Brlt RANK transcripts suggests that more osteoclast precursors may be present. Marrow cultured from 2 month old mice in the presence of MCSF and RANKL yielded a 7-fold increase in the number of TRAP positive cells in Brlt vs wild-type mice. Although the genetic cause of classical OI is structurally defective type I collagen in bone matrix, this work shows that cellular asynchrony is a crucial contributor to the tissue-level mechanism of decreased bone volume in Brlt. The elevated osteoclast number and function in Brlt is mediated by non-RANK/RANKL pathway(s) which increase the number of RANK-expressing osteoclast precursors. Defining these pathways may lead to novel therapeutic approaches for OI.

**Hyperphosphatasia: A Unique Type Without Mutations in *TNFRSF11A* (RANK), *TNFRSF11B* (OPG), or *SQSTM1* (Sequestosome 1).** S. Minisola<sup>1</sup>, A. Scillitani<sup>2</sup>, V. Guarnieri<sup>2</sup>, G. Guglielmi<sup>2</sup>, C. Battista<sup>2</sup>, M. L. Mascia<sup>1</sup>, P. Ballanti<sup>1</sup>, E. Romagnoli<sup>1</sup>, X. Zhang<sup>3</sup>, S. Mumm<sup>3</sup>, M. P. Whyte<sup>3</sup>. <sup>1</sup>Univ Rome "Sapienza", Rome, Italy, <sup>2</sup>S. Giovanni Rotondo Hospt, Foggia, Italy, <sup>3</sup>Shriners Hospt for Children and Washington Univ Schl Med, St Louis, MO, USA.

We report a 49-year-old man with a seemingly unique type of hyperphosphatasia. His mother carried a presumptive diagnosis of Paget's disease of bone (PDB). At age 27 years, he developed widespread skeletal pain. Serum total alkaline phosphatase (ALP) activity was elevated almost 10-fold, while liver function testing and principal parameters of calcium homeostasis were normal. There was no mental retardation. Since 1997, several hospitalizations occurred for bone pain unresponsive to non-steroidal anti-inflammatory drugs. Calcitonin for two years transiently relieved his discomfort; bisphosphonates led to brief normalization of serum ALP only after i. v. pamidronate and zoledronate. Sequential Tc-99m methylene diphosphonate bone scans showed progressive involvement, including newly affected bones. Distinctive radiographic features were multiple osteolytic areas of the skull, enlargement of the first and second lumbar vertebrae, selective sclerotic lesions of the long bones together with normal epiphyses, and non-progressive, indistinctly margined, osteolytic lesions (Fig 1). Histopathologic, histomorphometric, and ultrastructural analysis of affected bone revealed some similarities with PDB (increased trabecular remodeling and paramyxovirus-like structures in osteoclast nuclei). However, in contrast to advanced PDB, trabecular bone volume was decreased and trabeculae were disconnected (Fig 2). Moreover, osteoclasts were not "hypernucleated". Mutation analysis of the *TNFRSF11A* (exon 1), *TNFRSF11B*, and *SQSTM1* genes did not reveal a mutation in RANK, OPG, or Sequestosome 1, respectively. Thus, our patient's clinical, radiographic, and histopathological features appear unique. This disorder, perhaps familial and genetically based, should be added to the hyperphosphatasia syndromes.

**A Polyostotic Form of Fibrous Dysplasia in a 13 years Old Colombian Girl Exhibiting Clinical and Biochemical Response to Neridronate Intravenous Therapy.** A. Falchetti, E. Parra Prada\*, L. Masi, S. Ciuffi\*, F. Marini\*, F. Franceschelli\*, D. Strigoli\*, A. Tanini, M. Brandi. Internal Medicine, University of Florence, Florence, Italy.

Fibrous Dysplasia (FD), a rare skeletal disorder due to activating mutations of *GNAS1* gene, is characterized by impaired proliferation of the medullary fibrous tissue, abnormal bone matrix, focal areas of woven bone and osteolytic areas. The clinical consequences are represented by bone deformities and increased skeletal fragility. FD rarely occur as an isolated monostotic or polyostotic form, and more frequently is a component of the McCune-Albright Syndrome (MAS) in which bone deformities are associated to precocious puberty, endocrinopathies and coffee-milk spotty skin. Similarly to the Paget's disease of bone, FD exhibits increase of the bone alkaline phosphatase (BAP) and other bone turnover markers (BTMs). Symptoms consist of bone pain, long or facial bones deformities and pathological fractures. We describe a case of a 13 years old Colombian girl resident in Italy since from 2006. Familial history is negative for bone metabolic disorders. In 2003, due to strong pain of the face, with a tumefaction on the right side, a diagnosis of FD by CT has been made. Moreover, she had coffee-milk spots in the limbs and at gluteus level. Clinical examination evidenced pain at the level of the right humer, ulna, left femur, right tibia and a moderate impaired deambulation. BAP and deoxypyridinoline (DPD), were increased. Biopsy of the affected maxillary bone showed features of a dysplasia. Skeletal scintigraphy evidenced a polyostotic form: skull, left humer distal epiphysis, left ulnar diaphysis, medial arch of the sixth left rib, right femur proximal epiphysis, and right tibia distal diaphysis. Clinical and biochemical assessments were not suggestive for MAS. In order to differentially diagnosed this FD with Paget-like syndromes, mutational analysis of the exon 1 of *TNFRSF11A* gene has been made with a negative result. Currently, mutational analysis of *GNAS1* gene has been performing. On October 2007, we decided to treat this case by intravenous infusion of neridronate, an amino-bisphosphonate (a-BP) already used in children affected by Osteogenesis Imperfecta, 2 mg/kg of body weight every three months. A daily supplementation with calcium carbonate, 1 g/day, and cholecalciferol, 800 UI/day, has been also associated. Since from the third month of therapy, bone pain disappeared, BAP and DPD resulted within the normal ranges and at the control X-rays an improvement of bone mineralization has been observed. Up to date no side effects has been reported. We suggest that neridronate is able to improve both clinical and biochemical features of FD and it could be added to the therapeutical harmamentarium.

**Additional Clinical Features of Idiopathic Multicentric Osteolysis with Nephropathy (OMIM %166300).** D. Wenkert<sup>1</sup>, W. H. McAlister<sup>2</sup>, M. P. Whyte<sup>1</sup>. <sup>1</sup>Shriners Hospt for Children, St. Louis, MO, USA, <sup>2</sup>Washington Univ Schl of Medicine, St. Louis, MO, USA.

Idiopathic multicentric osteolysis with nephropathy (IMON) presents in early childhood with carpal-tarsal destruction followed by nephropathy causing renal failure. The genetic basis is unknown. In 3 sporadic cases, we excluded mutation of the matrix metalloproteinase 2 (MMP2) gene (CORR 462:80, 2007) known to cause nodulosis-arthropathy-osteolysis, Winchester, and Torg syndromes. Here, we report further clinical features shared among these 3 boys, and an additional boy and 3 girls with IMON. Each patient (ages 3 to 21 yrs) had carpal, tarsal, and elbow osteolysis. 5 had knee swelling and contraction, and all but one (age 3 years) had proteinuria (onset 2 months to 12 yrs). Skin: 5 had one or more skin lesions: plantar foot nodules (3), neck "lumps" (2), axillary piloleiomyoma (1), and keloids (1). Temporal Mandibular Joint: 6 pts had small oral apertures (4), and/or retrognathia (5). 1 panorex (age 3 yrs) showed TMJ destruction. Growth varied from 15-90% in height. All patients were slender (~90% ideal body weight (4)), some had poor wt gain (79%-84% IBW (3)). Faces: All had a similar micrognathia, retrognathia, maxillary hypoplasia, prominent eyes (all previously reported) as well as a long narrow nose, flat profile, and remarkably long, dark eyelashes. Headaches were common. Platybasia affected 3 of 4 pts. MRI (1 pt) revealed a Chiari I malformation with obstructive hydrocephalus. 1 pt was hypothyroid. Ophthalmologic: There was delayed visual maturation, retino-choroidal colobomas and corneal opacities (1) and uveitis thought to be due to gold therapy (1), as well as significant visual loss from corneal clouding (1) and strabismus (1). Bone Density: L<sub>1-4</sub> BMD z score (prior to bisphosphonate) seemed bimodal: -1.8 to -2.5 in 3 pts; the other 4 had z-scores of -0.6 to 0.1. TNF inhibitor Rx: ESR was occasionally elevated (20's - 30's). Remarkable symptomatic improvement occurring in 2 pts receiving etanercept waned over 6 months without cessation of osteolysis. The distinct facial appearance of IMON may lead to early recognition and guide clinicians to avoid nephrotoxic agents. The pattern of osteolysis (carpal-tarsal, sucked candy appearance of proximal metacarpals, without widening of metacarpals and metatarsals or interphalangeal arthropathy) is distinct from the MMP-2 associated disorders, but osteoporosis, and skin nodules can not distinguish between the disorders. We suggest that all pts with possible IMO be monitored for proteinuria, signs of Chiari malformation, hypothyroidism, ophthalmologic difficulties, and TMJ disease. These features of IMON may be clues to the pathogenesis and guide candidate gene analysis.

## SU213

**Effect of Hypercalciuria and Diet on Bone in Genetic Hypercalciuric Stone-forming Rats.** M. Grynpas<sup>1</sup>, S. Waldman<sup>\*1</sup>, D. Holmyard<sup>\*1</sup>, D. Bushinsky<sup>2</sup>. <sup>1</sup>Pathology, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Medicine, University of Rochester, Rochester, NY, USA.

Hypercalciuria is the most common metabolic abnormality in patients with Ca containing kidney stones. Patients with hypercalciuria often excrete more Ca than they absorb, indicating a net loss of total body Ca, almost certainly derived from bone. Studies have shown a decrease in bone mineral density (BMD) and an increase in fractures in hypercalciuric stone formers compared to controls. However, in human stone formers it is difficult to determine if the reduction in BMD is due to a primary bone disorder or to any number of dietary factors, such as sodium, Ca and protein, which may be altered in stone formers over their lifetime. To study the independent effects of hypercalciuria on bone, we utilized the genetic hypercalciuric stone-forming (GHS) rats which were established by successively inbreeding the most hypercalciuric progeny of hypercalciuric Sprague-Dawley rats. 46th generation female GHS and control (Ctl) rats were placed in metabolic cages and fed a similar amount of either a low Ca (0.02% Ca, LCD) or a high Ca (1.2% Ca, HCD) diet for 6 weeks, and then their femurs, tibiae, humeri and lumbar spines were studied for BMD, histomorphometry, degree of mineralization and mechanical properties. All comparisons are to Ctl rats, n=8 in each group. Urine Ca was significantly greater in the GHS rats on both diets. GHS fed HCD had reduced cortical (humerus) and trabecular (L1-L5 vertebrae) BMD while GHS rats fed LCD had a reduction in BMD that did not differ from Ctl. Histomorphometric analysis demonstrated that GHS rats fed HCD had a significant decrease in trabecular volume and thickness while LCD led to a ~20 fold increase in both osteoid surface and volume. GHS rats fed HCD had no change in vertebral strength (failure stress), ductility (failure strain), stiffness (modulus) or toughness while in the humerus there was a reduction in ductility and toughness and an increase in modulus indicating that the defect in mechanical properties in GHS rats is mainly manifested in cortical, rather than trabecular bone. GHS rat cortical bone is more mineralized than trabecular bone and LCD led to a decrease in the mineralization profile. Thus the GHS rats, fed an ample Ca diet, have reduced bone mineral density with reduced trabecular volume, mineralized volume and thickness and their bones are more brittle and fracture prone, indicating that hypercalciuric stone-forming rats have an intrinsic bone disorder that is not secondary to diet. It is unclear whether therapy to reduce stone formation in the GHS rats will restore the mechanical properties of their bone.

**ANKH Mutation Causing Craniometaphyseal Dysplasia Inhibits Osteoclast Differentiation.** N. Park\*, Y. Jung\*, H. Kim\*, S. Kim, E. Park, J. Choi\*. Biochemistry & Cell Biology, Skeletal Diseases Genome Research Center, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea.

*ANKH* is responsible gene for craniometaphyseal dysplasia (CMD), a childhood disease characterized by sclerosis of the skull and abnormal modeling of the long bones. The mechanism of skeletal abnormality, however, has not been determined in CMD patients. Previously, *ANKH* was identified as one of upregulated membrane proteins during osteoclastogenesis (Ha BG et al., Proteomics, in press). In this study, we identified and characterized a novel *ANKH* mutation causing CMD with changing amino acids 290-295 of *ANKH* (YGWLTE) into *ANKH* (QG). After cloning of mutant construct (*ANKH290QG*) with full length context, we characterized *ANKH290QG* with respect to the protein localization, and bone cell functions particularly during osteoclastogenesis. In transient transfection assay, *ANKH290QG* mutant protein was localized in membrane as wild type *ANKH*. During osteoclastogenesis, *ANKH290QG* stable cells showed the inhibition of osteoclastogenesis, which was confirmed by TRAP staining and expression of osteoclast markers by RT-PCR. Probenecid, *ANKH* inhibitor, suppressed *RANKL* mediated osteoclast differentiation. Collectively, these results indicate that skeletal abnormality in CMD patients is due in part to the inhibition of osteoclast differentiation by *ANKH* mutation.

## SU215

**A Hotspot Splicing Mutation in *LEPRE1* Affects Prolyl 3-hydroxylation and Causes Recessive Osteogenesis Imperfecta.** A. Willaert<sup>\*1</sup>, S. Symoens<sup>\*1</sup>, F. Malfait<sup>\*1</sup>, K. Gevaert<sup>\*2</sup>, P. Coucke<sup>\*1</sup>, A. De Paepe<sup>\*1</sup>. <sup>1</sup>Department of Medical Genetics, Ghent University, Ghent, Belgium, <sup>2</sup>Department of Medical Protein Research, VIB/Department of Biochemistry, Ghent University, Ghent, Belgium.

Recently, it has been shown that recessive forms of Osteogenesis Imperfecta (OI) can be caused by the absence of 3-hydroxylation of Pro986 in the  $\alpha 1(I)$ -collagen chain, resulting from mutations in prolyl 3-hydroxylase 1 (P3H1) or cartilage-associated protein (CRTAP), which, together with cyclophilin B (CyPB) are constituents of the prolyl 3-hydroxylation complex. We screened *LEPRE1* (encoding P3H1), *CRTAP* and *CyPB* by complete cDNA and/or genomic DNA sequencing in a European/Middle East cohort of lethal/severe OI patients without a type I collagen mutation.

While no mutations were found in *CRTAP* and *CyPB*, novel homozygous and compound heterozygous mutations were identified in *LEPRE1* in 5 patients. Patient 1 is homozygous for a frameshift mutation (c.1365\_1366delAGinsC) in exon 9, resulting in a premature termination codon in the same exon. Patient 2 and 3, which are sibs, are homozygous for a nonsense mutation (c.628C>T) in exon 3. Patient 4 carries a heterozygous nonsense mutation (c.1102C>T) in exon 6. Finally, a recurrent splice site mutation (c.2055+18G>A) was identified in patients 4 and 5, respectively in heterozygous and homozygous state. As expected from the different ethnicity of patients 4 and 5, haplotype analysis suggests that c.2055+18G>A is a hotspot mutation. As confirmed by RT-PCR, the latter mutation converts a suboptimal into an optimal donor splice site in intron 14, resulting in a full switch in donor splice site utilization. Consequently, this mutation results in the absence of the only splice form of P3H1 which contains the endoplasmic reticulum (ER) retention signal KDEL and which is therefore putatively responsible for the prolyl 3-hydroxylation function of P3H1 in the ER. While western blotting of fibroblast protein extracts shows absence of P3H1 protein in patients compared to controls, tandem mass spectrometry and SDS-PAGE analysis indicate respectively a severe reduction of  $\alpha 1(I)$ Pro986 3-hydroxylation and a resulting overmodification of type I (pro)collagen chains in all patients. In conclusion, we identified 4 novel *LEPRE1* mutations in lethal/severe OI patients of European/Middle East descent with one hotspot splice site mutation, specifically affecting the P3H1 splice form responsible for  $\alpha 1(I)$ Pro986 3-hydroxylation. Other splice forms of P3H1 can not rescue this function and could be responsible for the other presumed functions of P3H1, which include a role as growth suppressor and a role as the extracellular matrix proteoglycan, leprecan.

## SU216

**Two Novels SQSTM1 Mutations in American Patients with Paget's disease of Bone.** L. Michou<sup>\*1</sup>, J. Morissette<sup>\*1</sup>, A. Marquis<sup>\*1</sup>, E. R. Brochu<sup>\*1</sup>, J. P. Brown<sup>1</sup>, E. S. Siris<sup>\*2</sup>. <sup>1</sup>CHUL Research Centre, Quebec, QC, Canada, <sup>2</sup>Columbia-Presbyterian Medical Centre, New York, NY, USA.

Since 2002, 14 mutations of SQSTM1 gene have been reported in familial and sporadic patients affected by Paget's disease of bone in different populations.

We performed a systematic screening for SQSTM1 mutations in 52 consecutively evaluated patients with Paget's disease of bone living in the US. Those patients have a typical phenotype of Paget's disease of bone. They live in the New York City area and have a heterogeneous ethnic background. DNA was isolated from whole blood, and sequencing of exon 7 and 8 was performed. Of the 52, two were sisters, but the remainder were unrelated.

Five of the unrelated patients (10%) have SQSTM1 mutations and no mutation was detected in the 2 sisters. Three patients carried a 1215C>T (P392L) mutation, of whom only one had a positive family history. Two patients carried novel SQSTM1 mutations also located in the exon 8 coding for the ubiquitin-binding associated domain. One carried a 1290T>A (L417Q) mutation and the other had a 1209C>T (A390V) mutation. Both patients with novel SQSTM1 mutations have polyostotic Paget's disease with elevated alkaline phosphatase at diagnosis. The patient who carried the A390V mutation had a family history of Paget's disease of bone in the mother and in a sister. The SQSTM1 mutation rate in those unrelated American patients is similar to that reported in European populations.

Our results differ from those of a recently published study on SQSTM1 mutation in patients with Paget's disease of bone from Texas and California where the authors found no SQSTM1 mutation in 73 unrelated patients, whereas eight SQSTM1 mutations were found in the 39 patients with a family history of Paget's disease of bone. Five of them had a P392L mutation; one carried a 1215delC (L394X) mutation, one carried a 1210delT (394X) mutation, and one a P387L mutation. No novel SQSTM1 mutation was reported in this population. We report here preliminary results of a mutation screening in 52 patients with Paget's disease from the US. Five patients carried SQSTM1 mutations. Two novel SQSTM1 mutations were reported; L417Q and A390V, and three patients carried a P392L mutation.

**Disclosures:** L. Michou, Novartis France 3.

## SU217

**Bone Mineral Density in Children and Adolescents with Sickle Cell Disease: A Descriptive Analysis.** L. J. Chambers<sup>\*1</sup>, L. Hillman<sup>2</sup>. <sup>1</sup>Pediatrics, Scott and White Hospital, Temple, TX, USA, <sup>2</sup>Child Health, University of Missouri - Columbia, Columbia, MO, USA.

**Objective:** Stallings has reported low serum 25-hydroxy vitamin D (25-OHD) in children with Sickle Cell Disease (SCD) in Philadelphia. We wished to assess the frequency of low serum 25-OHD in a more southern location and evaluate its' effects on mineral metabolism and bone mineralization.

**Methods:** Fourteen children with SCD were assessed for serum 25-OHD, Ca, PTH, bone alkaline phosphatase (BAP), urine free pyridinoline (PYD) and DXA of whole body, spine and femur.

**Results:** Two clearly vitamin D deficient children were found. A 17-year old male had a 25-OHD of 5 ng/ml and a Ca of 8.9mg/dl however PTH, BAP and PYD were normal. Whole body and femur DXA were within normal range, >2 SD but spine was low, <2 SD. An 11-year old female had a 25-OHD of 11 ng/ml with a Ca of 8.5 mg/dl, PTH of 145 pg/ml and BAP of 150 u/L. However all DXA scans were within normal range. Mean 25-OHD for the entire group was 20±7ng/ml, with 8 of 14 below 20 ng/ml and all but one below 30 ng/ml. These values are below that seen in local Caucasian children (35±13 ng/ml), however African-American controls are needed. Nine of 14 children had at least one low DXA and 3 had two low DXAs, defined as a BMD < 2SD below the mean for age. Four of 14 had low whole body, 6/14 low lumbar and 7/14 low femur. Excluding the above vitamin D deficient child, PTH was appropriate at 31±18 pg/ml. BAP at 94±36u/L and PYD/Cr at 69±92nmol/mmol were also appropriate for growing children. Correlations between vitamin D status and DXA were not seen. Liver function tests were normal and hip x-rays showed infarcts in only one child. DXA did not correlate with hemoglobin.

**Conclusion:** The data supports that, even in Missouri, African-American SCD patients have unacceptably low 25-OHD levels and unacceptably poor bone mineralization. The inability to correlate 25-OHD and DXA probably relates to 25-OHD being a relatively acute measure and DXA being a chronic measure. Oral supplementation with at least 1,000 IU D/d should be given to all SCD patients. Correction of vitamin D deficiency will probably not eliminate low DXA because of the complexity of SCD, however we were not able to identify specific confounding factors related to Sickle Cell Disease.

## SU218

**Bi-allelic Loss of *Nf1* in Osteoblasts Delays Bone Fracture Healing.** W. Wang<sup>\*1</sup>, J. S. Nyman<sup>2</sup>, B. Livesay<sup>\*1</sup>, F. Elefteriou<sup>1</sup>. <sup>1</sup>Vanderbilt Center for Bone Biology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA, <sup>2</sup>Vanderbilt Center for Bone Biology, Department of Orthopaedics, Vanderbilt University Medical Center, Nashville, TN, USA.

The etiopathology of Neurofibromatosis (NF1) bone pseudoarthrosis (PA) is unclear. As a result, this bone fracture healing defect cannot be prevented, and even with modern orthopaedic techniques a complete and durable union is difficult to achieve, leading to lifelong disability and amputation in the most severe cases. The congenital, localized, unilateral and non-systematic nature of the lesion strongly suggests that *Nf1* loss-of-heterozygosity (LOH) is necessary for pseudoarthrosis to occur. However, the cellular complexity of the bone marrow environment coupled with the difficulty of identifying *Nf1* mutations has hampered the characterization of the mechanism(s) whereby NF1 pseudoarthrosis develops. In an effort to address this question, we have generated a mouse model (the *Nf1<sub>ob</sub><sup>-/-</sup>* mice) characterized by bi-allelic *Nf1* deletion specifically in osteoblasts, the bone forming cell, with the hypothesis that *Nf1* LOH in the mesenchymal osteoprogenitor lineage causes the bone quality and healing defects characteristic of NF1 PA. Using this mouse model, we previously found that *Nf1* regulates normal bone remodeling by inhibiting collagen synthesis and mineralization by osteoblasts and the formation of osteoclasts, via a signaling pathway involving Ras, ERK, RSK2 and the transcription factor ATF4. In this study, we used a tibia fracture model to determine whether lack of *Nf1*'s function in osteoblasts causes the NF1 bone healing defects. Our results, based on 3D-microtomography and histomorphometric measurements indicate that the formation of the fracture callus is delayed in *Nf1<sub>ob</sub><sup>-/-</sup>* mice: 21 days post-fracture, the callus of *Nf1<sub>ob</sub><sup>-/-</sup>* mice is bigger and less calcified than the one of WT littermates, still displays cartilaginous remnants, and is also characterized by bone surfaces covered with a thick osteoid surface, which is reminiscent of what is observed in human NF1 PA lesions. *In vitro*, *Nf1<sup>-/-</sup>* osteoblasts are characterized by constitutive Ras and ERK activation, which can be inhibited by the inhibitory effect of lovastatin on Ras prenylation. Based on this proof-of-concept result and previous data, we propose that lovastatin may have multiple beneficial actions on the NF1 skeletal defects: not only may it improve the low bone mineral density of NF1 patients in general, it may also prevent NF1 pseudoarthrosis. The *Nf1<sub>ob</sub><sup>-/-</sup>* mice is a valuable pre-clinical model to test this hypothesis.

## SU219

**The Functional Polymorphism in COL1A2 (Ala459Pro) that is Associated with Intracranial Aneurysms, Shows Heterozygous Disadvantage Concerning Bone Mineral Density and Stroke in Elderly Men - MrOS Sweden.** K. M. Lindahl<sup>\*1</sup>, H. Brändström<sup>\*1</sup>, M. K. Karlsson<sup>\*2</sup>, A. H. Holmberg<sup>\*2</sup>, C. Ohlsson<sup>\*3</sup>, D. Mellström<sup>\*3</sup>, E. Orwoll<sup>\*4</sup>, H. Mallmin<sup>\*5</sup>, A. Kindmark<sup>1</sup>, Ö. Ljunggren<sup>1</sup>. <sup>1</sup>Medical Sciences, Uppsala, Sweden, <sup>2</sup>Clinical Sciences, Malmö, Sweden, <sup>3</sup>Clinical Sciences, Gothenburg, Sweden, <sup>4</sup>Oregon Health and Science University, Portland, OR, USA, <sup>5</sup>Surgical Sciences, Uppsala, Sweden.

Genetics play an important role in the development of osteoporosis and a prime candidate gene is the collagen alpha 2 (I) gene (COL1A2). A coding polymorphism of COL1A2 (Ala459Pro) has previously been associated with intracranial aneurysms. Here the significance of this polymorphism in relation to bone phenotype and incidence of stroke and myocardial infarction (MI) has been studied.

The polymorphic site Ala459Pro (rs42524) was studied by fluorescence polarization detection technique in part of the Swedish MrOs cohort (n=2004). At inclusion bone mineral density (BMD) was measured by Dual energy X-ray Absorptiometry (DXA) and the participants were interviewed using a structured questionnaire concerning previous and current health issues.

A significant association measured by overall *p* was found between the heterozygous genotype and lower BMD at total hip (*p*=0.015) (figure 1), femoral neck (*p*=0.036) and trochanter (*p*=0.010). When comparing both homozygotes to heterozygotes (GG and CC vs. GC) a significant association was established between lower BMD at total hip (2.0%; *p*=0.0098), femoral neck (1.7%; *p*=0.027) and trochanter (2.1%; *p*=0.0096) and heterozygous genotype. This genotype also increased the risk for stroke (OR 1.4; *p*=0.0498). There was a trend for association between heterozygous genotype and decreased BMD of total body (0.7%; *p*=0.089) and increased risk of MI (OR 1.3; *p*=0.065). There was no association between the genotype and BMD of lumbar spine.

This study indicates that the genotype "GC" leads to a heterozygous disadvantage, compared to both the more favorable homozygous variants, affecting BMD and risk of suffering a stroke.

P-value for different genotypes versus bone and vascular phenotype				
Characteristic	GC vs. GG	GC vs. CC	GC vs. GG+CC	Overall p
BMD femoral neck	0.048	0.026	0.027	0.036
BMD total hip	0.019	0.019	0.0098	0.015
BMD trochanter	0.021	0.011	0.0096	0.010
BMD total body	0.089	0.51	0.089	0.23
BMD L1-L4	0.14	0.88	0.16	0.32
Stroke	0.050	0.53	0.0498	0.14
Myocardial Infarction	0.079	0.27	0.065	0.17

## SU220

**Polymorphisms of the ALOX12 Gene Are Associated with Increased Risk of Osteoporotic Fracture.** T. Harsløf<sup>\*</sup>, L. Husted<sup>\*</sup>, M. Carstens<sup>\*</sup>, L. Stenkaer<sup>\*</sup>, B. Langdahl. Department of Endocrinology and Metabolism, Aarhus University Hospital, Aarhus C, Denmark.

Osteoporosis is a common disorder with a multifactorial pathogenesis. Stimulation of the PPAR $\gamma$ -receptor with ligands produced by the ALOX enzymes forces mesenchymal stem cells to develop in the adipocyte direction at the expense of osteoblasts leading to decreased osteoblast number and BMD. Previously, polymorphisms of the ALOX12 gene have been associated with osteoporosis.

The aim of this study was to examine the effect of ALOX12 polymorphisms on BMD and the risk of vertebral fractures. On the basis of patterns of linkage disequilibrium between SNPs throughout the gene we chose 10 polymorphisms for investigation.

The polymorphisms were investigated in a case-control study comprising 462 osteoporotic patients and 336 controls. Polymorphisms were examined using Taqman assays and BMD was examined by DXA.

Rs3840880, rs9897850 and rs1126667 were significantly associated with vertebral fractures in women (*P*<0.05 for all). The increased fracture risk was found in individuals heterozygous for the polymorphisms. The frequencies of heterozygosity were higher in patients with osteoporotic fractures than in normal controls: rs3840880: 53.9 % vs. 42.5 %, *P*=0.014 rs9897850: 54.8 % vs. 42.9 %, *P*=0.011 and rs1126667: 53.5 % vs. 42.5 %, *P*=0.019. Furthermore, lumbar spine (Ls) BMD was significantly lower in individuals heterozygous at these three polymorphic loci and at the rs2292350 locus (*P*<0.05 for all). None of the other polymorphisms were associated with BMD or fracture risk.

The four polymorphisms were in strong linkage disequilibrium (LD) (*D'*=1.0, *r*<sup>2</sup> = 0.47 - 0.98) and rs1126667 was in complete LD with rs1042357. Rs1126667 is situated in exon 6 and causes a change of amino acid 261 from arg to gln whereas rs3840880 and rs9897850 are located in the promoter region and rs2292350 lies in intron 2.

Molecular heterosis is the term for the phenomenon that heterozygosity for a given genotype influences a certain trait, and it has previously been described in a number of human conditions including osteoporosis (PLOD1 and PPAR $\gamma$  genes). In a such case classic haplotype analysis does not make sense since only one allele is considered and both alleles need being taken into account, however, the two most common haplotypes were exactly opposite to each other and we were therefore able to show that individuals possessing one copy of each and, thus being heterozygous at all 4 loci, had an increased risk of fracture compared to those being homozygous at all loci (*P*=0.025).

Based on the observations above we suggest that polymorphisms of the ALOX12 gene are associated with increased risk of osteoporotic fractures and decreased LsBMD through molecular heterosis.

**Disclosures:** T. Harsløf, None.

## SU221

**The RsaI Polymorphism in ESR2 Is Associated with Postmenopausal Fracture Risk.** N. Gonzalez-Bofill<sup>1</sup>, L. Husted<sup>1</sup>, P. Vestergaard<sup>2</sup>, C. Tofteng<sup>\*2</sup>, P. Eiken<sup>\*3</sup>, K. Brixen<sup>4</sup>, B. Langdahl<sup>1</sup>. <sup>1</sup>Endocrinology and Metabolism, Århus Hospital, Århus, Denmark, <sup>2</sup>Endocrinology and Metabolism, Hvidovre Hospital, Copenhagen, Denmark, <sup>3</sup>Endocrinology and Metabolism, Hillerød Hospital, Hillerød, Denmark, <sup>4</sup>Endocrinology and Metabolism, Odense Hospital, Odense, Denmark.

Estrogen participates in the acquisition and maintenance of BMD by binding to its receptors, ER $\alpha$  and ER $\beta$ . Polymorphisms in the genes encoding these receptors, ESR1 and ESR2 have previously been associated with bone health outcomes. We and others have previously found that the AluI polymorphism in the 3'UTR of ESR2 and a haplotype including this polymorphism are associated with fracture risk in elderly populations. In the present study we wanted to investigate the effect of four polymorphisms in ESR2: a polymorphism in intron 2 (rs1256031), a synonymous RsaI polymorphism in exon 5 (rs1256049), a CA-repeat polymorphism (D14S1026) in intron 5 and an AluI polymorphism in the 3'UTR (rs4986938) on BMD and risk of fractures in 1717 perimenopausal women. We also wanted to examine the effect on postmenopausal bone loss and response to HRT. Genotyping for the SNPs was performed by TaqMan assays and the number of CA-repeats was determined by capillary electrophoresis. BMD was measured by DXA.

The four studied polymorphisms were in Hardy-Weinberg equilibrium with the following allele frequencies: rs1256031 A/G 0.52/0.48; RsaI C/T 0.97/0.03; AluI C/T 0.65/0.35. The CA-repeat polymorphism was classified in low-high number of repeats with a cut-point of 21 repeats. The allele frequencies for this polymorphism were L/H 0.23/0.77. The RsaI and the CA-repeat polymorphisms were in linkage disequilibrium, as were the rs1256031 and the AluI polymorphisms, and haplotypes could therefore be estimated.

We found no convincing effect of any of the four polymorphisms or haplotypes on perimenopausal BMD, postmenopausal bone loss or response to HRT. However, we found that in the group of women not treated with HRT, those carrying the T-allele of the RsaI polymorphism or 1 or 2 copies of haplotype RsaI-CA (T-L) had lower fracture incidence ten years after menopause (7.4% vs. 16.9% in non-carriers and 7.4% vs.17.0% in non-carriers, respectively, *p*=0.02).

Conclusion: The RsaI polymorphism in ESR2 and a haplotype containing this polymorphism are associated with risk of fractures, despite not being associated with perimenopausal bone mass, postmenopausal bone loss or response to HRT. None of the other polymorphisms or haplotypes are associated with fracture risk, perimenopausal bone mass, postmenopausal bone loss or response to HRT.

**Disclosures:** N. Gonzalez-Bofill, None.

## SU222

**Prediction of Fracture Risk by LRP5 Gene Haplotype.** B. H. Tran, N. D. Nguyen, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Polymorphisms of the low density lipoprotein receptor related protein 5 (LRP5) gene have been shown to be linked to or associated with bone mineral density (BMD), but their association with fracture risk is not known. The present study sought to assess the association between LRP5 gene polymorphisms and fracture risk in women by using haplotype analysis.

Haplotype tagging single nucleotide polymorphisms (in order rs314776, rs3736228, rs4988320, rs4988321, rs556442, rs587808 and rs660925) of LRP5 gene was determined in a sample of 1286 (821 women) participants from a population-based cohort. Bone mineral density (BMD) was measured at baseline. During the follow-up period of 1989-2006, 125 men and 338 women sustained at least one fracture.

There were no statistically significant association between any single SNP and BMD or fracture risk. The seven SNPs were in tight linkage disequilibrium which were ultimately used to construct a haplotype block. Using bioinformatic tools (haplo.assoc and haplo.ccs program), 7 haplotypes accounted for ~90% of the sample. Further haplotype analysis showed that three haplotypes [CCAGAAGC (3% in the population), CCGGAGA (3%) and TCGGGAG (2%)] were associated with variation in BMD. Furthermore, carriers of haplotype CTGGGGA (6% in the population) had an increased risk of fracture (RR: 1.4, 95% CI: 1.1-3.0), hip fracture (2.2, 1.0-4.9) and wrist fracture (2.4, 1.1-4.9), after adjusting for age and BMD. There was no significant association between any haplotype and BMD or fracture risk in men. The proportion of fracture cases that is attributable to the haplotype was 2.3%.

These results suggest that common genetic variation at the LRP5 gene was modestly associated with fracture risk in women independent of its association with BMD. The present study also suggests that a haplotype-based analysis is more powerful than a SNP-based analysis in the detection of association.

**Single Nucleotide Polymorphisms in the P2X7 Receptor Gene Are Associated with Increased Postmenopausal Bone Loss and Fracture Incidence.** N. R. Jorgensen<sup>1</sup>, L. B. Husted<sup>2</sup>, P. Schwarz<sup>3</sup>, C. L. Tofteng<sup>4</sup>, J. B. Jensen<sup>5</sup>, N. Nissen<sup>6</sup>, P. Eiken<sup>6</sup>, L. Ødum<sup>1</sup>, B. L. Langdahl<sup>2</sup>. <sup>1</sup>Dep. of Clinical Biochemistry, Roskilde University Hospital, Roskilde, Denmark, <sup>2</sup>Dep. of Endocrinology and Metabolism, Aarhus University Hospital, Aarhus, Denmark, <sup>3</sup>Research Center for Ageing and Osteoporosis, Glostrup University Hospital, Glostrup, Denmark, <sup>4</sup>Dep. of Endocrinology, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, <sup>5</sup>Dep. of Endocrinology, Odense University Hospital, Odense, Denmark, <sup>6</sup>Dep. of Endocrinology, Hilleroed Hospital, Hilleroed, Denmark.

The purpose of the study was to examine the association of single nucleotides polymorphisms (SNP) in the purinergic P2X7 receptor to bone mass and vertebral fracture incidence in a cohort of post-menopausal women.

Two thousand and sixteen early postmenopausal women were included in the DOPS study and followed for 10 years. 1093 did not receive any HRT while 135 were treated continuously with HRT. Genotyping was performed on DNA from 1710 participants using TaqMan assays. Genotyping was done for five non-synonymous SNP placed in exons (Gly150Arg, His155Tyr, Arg307Gln, Ala348Thr, and Thr357Ser) and for one placed in an intron-splicing site (151+1: G-T).

The following allele frequencies were found: 151+1:GT (G/T: 0.99/0.01), Gly150Arg (G/A: 0.98/0.02), His155Tyr (C/T: 0.57/0.43), Arg307Gln (G/A: 0.99/0.01), Ala348Thr (G/A: 0.61/0.39), and Thr357Ser (C/G: 0.91/0.09). For all SNP Hardy-Weinberg equilibrium was found. Firstly, association of SNP to bone mineral density (BMD) right after menopause was examined. No association was found for any of the SNP with respect to BMD in hip or at the lumbar spine. Next, the association to BMD five and ten years after menopause was examined as well as rate of bone loss during the first five and ten post-menopausal years. We found a significant association between the Arg307Gln SNP with the highest rate of bone loss in the femoral neck in individuals and the GA genotype at both five and ten years (5/10 years: -2.0/-0.9 % per year) compared to the GG genotype (5/10 years: -1.2/-1.4 % per year) ( $p$ -value=0.009/0.004). The same was found for bone loss in total hip. Next, we examined the association between P2X7 genotype and fracture incidence ten years after menopause. Interestingly, we found a significant association between the Ala348Thr SNP and fracture incidence with the following incidences for individuals carrying the three genotypes: GG: 0.13, GA: 0.10, AA: 0.04 ( $p$ -value=0.035). No significant associations to any of the other SNP could be detected.

In conclusion, SNP in the P2X7 receptor gene are associated with bone loss after menopause as well as susceptibility to vertebral fractures in women. Further studies are needed to consolidate these findings.

**Loss of Function Polymorphisms in The P2X<sub>7</sub> Receptor Gene Are Associated with Accelerated Lumbar Spine Bone Loss in Postmenopausal Women.** A. Gartland<sup>1</sup>, K. K. Skarratt<sup>2</sup>, L. J. Hocking<sup>3</sup>, L. Stokes<sup>2</sup>, R. Clifton-Bligh<sup>2</sup>, C. Parsons<sup>3</sup>, W. D. Fraser<sup>4</sup>, D. M. Reid<sup>3</sup>, J. S. Wiley<sup>2</sup>, J. A. Gallagher<sup>4</sup>. <sup>1</sup>Academic Unit of Bone Biology, The University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>Department of Medicine, University of Sydney at Nepean Hospital, Sydney, Australia, <sup>3</sup>Division of Applied Medicine, University of Aberdeen, Aberdeen, United Kingdom, <sup>4</sup>The University of Liverpool, Liverpool, United Kingdom.

The gene for the P2X<sub>7</sub> receptor (P2RX7) is highly polymorphic with at least six known loss of function (LOF) single nucleotide polymorphisms (SNP) (151+1, c.474G>A, c.946C>A, c.1096C>G, c.1513A>C, and c.1729T>A). Two SNPs have previously been shown to be associated with an increased 10-year fracture risk in elderly postmenopausal Danish women. In addition, we recently reported association of c.946A with low lumbar spine (LS) bone mineral density (BMD), a key determinant of fracture risk, in younger postmenopausal women. The purpose of this study was to determine if other functional P2RX7 SNPs are associated with loss of BMD. We genotyped 508 postmenopausal women from the Aberdeen Prospective Osteoporosis Screening Study (APOSS) for six known functional P2RX7 SNPs. Females were recruited randomly from among the general population in the North East of Scotland from 1990-94 when aged 45-54y. Lumbar spine (LS) BMD was measured at baseline and at 6-7 year follow up when blood samples were collected for DNA extraction. P2RX7 genotyping was performed by homogeneous mass extension. Allelic frequencies for all P2RX7 SNPs were in Hardy-Weinberg equilibrium ( $p$ -values 0.2-1.0). We found association of c.946A with lower LS-BMD at baseline ( $p$ =0.006,  $\beta$ =-0.12) and follow-up ( $p$ =0.004,  $\beta$ =-0.13). Further analysis showed that the rate of loss of LS-BMD in a combined group of subjects who have a single LOF SNP at either 151+1, c.474, c.946, c.1096, and c.1729 ( $n$ =109) was five fold greater than subjects who were wild type at all known LOF positions ( $n$ =77) (rate of loss = 0.0064g/cm<sup>2</sup>/year and 0.0012g/cm<sup>2</sup>/year respectively,  $p$ =0.011, unpaired t-test). The significant difference in rate of LS-BMD loss disappears if subjects with the c.1513C allele are included in the combined group. A possible explanation is that although c.1513A>C SNP results in defective pore formation, the ATP-operated P2X<sub>7</sub> receptor channel remains intact. In contrast, the combined SNPs affect both channel and pore functionality. This analysis suggests that not only is the c.946A LOF SNP associated with low LS-BMD, but that other LOF SNPs, which result in similar pathophysiology of the P2X<sub>7</sub> receptor, are associated with accelerated bone loss at this site. The effect of the LOF SNPs on loss of BMD were not evident at the femoral neck, emphasising a site-specific effect of P2RX7 SNPs on BMD.

**Disclosures:** A. Gartland, None.

## SU225

**Variation in the Osteocalcin Gene: Association Study of BMD, Fracture and Changes in Body Fat Mass in Elderly Women.** F. McGuigan<sup>1</sup>, K. Ivaska<sup>1</sup>, P. Gerdhem<sup>2</sup>, H. Luthman<sup>1</sup>, K. Åkesson<sup>1</sup>. <sup>1</sup>Lund University, Malmö, Sweden, <sup>2</sup>Karolinska Institute, Stockholm, Sweden.

Limited information exists on variation in the Osteocalcin (OC) gene and bone phenotypes in various populations. The aim of this study was to determine the relationship between variation in OC, a marker of bone remodelling, and bone density and fracture in elderly women. In view of recent findings linking OC to energy metabolism, we are also evaluating the relationship with body fat parameters.

The study was performed in the Malmö Osteoporosis Prospective Risk Assessment study (OPRA) cohort, consisting of 1044 elderly women, all 75-yrs old at baseline which has been followed for up to 9 years. With respect to measures of adiposity, bone density and fracture, we analysed genotypes and derived haplotypes of 4 SNPs around the OC locus on chromosome 1, including rs18002487 located in the promoter. Only haplotypes with a >95% probability were used in the analysis.

Four of the 7 haplotypes observed in the population accounted for 85% of the alleles at the OC locus (Hap1 28%; Hap2 21%; Hap4 17%; Hap5 19%).

Individually, SNPs rs1800247 and rs2842880 were associated with percentage body fat ( $p$ =0.045 and 0.009 respectively) which was highest in the variant homozygotes.

Differences in the 5 year percentage change in fat mass were observed for rs1800247 ( $p$ =0.004), rs2842880 ( $p$ =0.012) and rs933489 ( $p$ =0.003). Variant homozygotes of rs1800247 and rs2842880 lost body fat whereas rs933489 variant homozygotes increased in adiposity. Haplotype analyses revealed only Hap1 to be related with body composition (total body fat mass at 5 years,  $p$ =0.028).

Individually, only rs2842880 was associated with BMD (FN,  $p$ =0.026). At baseline, Hap2 was associated with LS ( $p$ =0.03) and TB BMD ( $p$ =0.037). Bone mass increased incrementally with the number of haplotype alleles carried.

At 5 year follow-up Hap1 was associated with LS ( $p$ =0.038) and TB BMD ( $p$ =0.033). BMD decreased as haplotype allele number increased. Hap2 carriers exhibited similar trends at the LS ( $p$ =0.019).

We found no association with fracture sustained during lifetime, however for fractures sustained after the age of 50, Chi2 analysis identified differences associated with carriers of Hap1 ( $p$ =0.042) and Hap2 ( $p$ =0.045). Regression analysis identified Hap1 as a predictor of fracture ( $p$ =0.008) independent of BMD and body composition.

Our findings suggest that variation in the OC gene is linked to BMD and fracture in elderly caucasian women. Furthermore, and interestingly we can not exclude an independent influence on changes in fat mass, not previously recognized.

## SU226

**Association Study of the TF and IGFBP3 Gene Polymorphisms with an Osteonecrosis of Femoral Head in Korean Population.** J. Hong<sup>\*1</sup>, T. Kim<sup>\*1</sup>, E. Park<sup>2</sup>, S. Kim<sup>3</sup>. <sup>1</sup>Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, <sup>2</sup>Department of Pathology and Regenerative Medicine, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, <sup>3</sup>Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea.

Osteonecrosis of the femoral head (ONFH) is devastating disease that frequently leads to the progressive collapse of the femoral head. The pathophysiology of ONFH is not completely elucidated, but it has been suggested that common pathogenesis involves the interruption of blood supply to femoral head. The disruption of the blood supply to the bone often caused hypoxia, which is the first stimulus for angiogenesis. Therefore, we hypothesized that angiogenesis regulated by hypoxia may play an important role in development or progression of osteonecrosis.

Transferrin (TF) and IGF-Binding Proteins 3 (IGFBP3) plays an important role in angiogenesis induced by hypoxia. TF is essential for iron regulation and acts as an angiogenesis factor produced by hypertrophic cartilage during endochondral bone formation. IGFBP3 is the most abundant in the circulation. It increases the bone resorption and reduces bone formation. Also, TF as an IGFBP-3 binding protein could enhance the modulation of cell proliferation and apoptosis. TF specifically might modulate IGFBP-3 activity by binding IGFBP-3.

To examine the associations between the TF/IGFBP3 gene polymorphisms and ONFH in Korean population, we selected several polymorphic sites of TF/IGFBP3 from public databases, and genotyped in 460 ONFH patients and 300 control subjects. We classified the patients according to etiology: alcohol-induced, steroid-induced, and idiopathic ONFH subgroup. Three SNPs (rs1880669, rs2692695 and rs2718806) in TF gene and two SNPs (rs2453839 and rs3110697) in IGFBP3 gene were associated with increased risk of ONFH. The stratified analysis by etiology revealed that two SNPs (rs1880669 and rs2692695) of TF gene and rs2453839 of IGFBP3 were significantly associated with increased risk of ONFH in idiopathic patients ( $P=0.0008$ - $0.0204$ , OR 1.38-2.37 in TF gene,  $P=0.0066$ , 8.67 in IGFBP3 gene). Our results suggest that TF and IGFBP3, hypoxia induced angiogenesis gene, are related to non-traumatic ONFH in Korean population. Defining the genetic susceptible factors for development of ONFH may provide more effective therapeutic implications and early diagnosis for disease.

**Effect of Tamoxifen and Aromatase Inhibitors on the Risk of Fractures in Women with Breast Cancer.** P. Vestergaard<sup>1</sup>, L. Rejnmark<sup>2</sup>, L. Mosekilde<sup>2</sup>.

<sup>1</sup>The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark,

<sup>2</sup>Department of Endocrinology and Metabolism C, Aarhus Amtssygehus, Aarhus, Denmark.

One prior study has pointed at an increased risk of hip fractures in users of tamoxifen among women with breast cancer compared to non-users. We studied the risk of fractures among women who had used tamoxifen or aromatase inhibitors compared to non-users.

**Subjects and methods:** Case control study in women. There were 64,548 fracture cases and 193,641 age and gender matched controls.

**Results:** Use of tamoxifen in general was not associated with any significant change in the risk of any fracture, wrist fractures, and spine fractures. A significantly decreasing relative risk of fractures was seen with increasing dose although the risk never declined statistically significantly below that in non-users. An increased risk of hip fractures was seen, but the increase was limited to patients who had used low average doses (<20 mg of tamoxifen per day) and were prior users (i.e. had not used tamoxifen within the last year). Aromatase inhibitors were associated with a significant increase in overall risk of fractures and in the risk of hip fractures.

**Conclusions:** Tamoxifen does not seem to be bone protective in such a degree that the risk of fractures decreases below that of non-users. Tamoxifen per se does not seem to increase the risk of fractures. Aromatase inhibitors were associated with a significant increase in the risk of fractures. In women at high risk of fractures, supplementary measures i.e. bisphosphonates may be considered.

**Platelets Contribute to Circulating Levels of Dickkopf-1 (Dkk-1): Clinical Implications in Multiple Myeloma.** N. Voorzanger-Rousselot<sup>\*1</sup>, D. Goehrig<sup>\*2</sup>, P. Clézardin<sup>2</sup>, T. Facon<sup>\*3</sup>, P. Garnero<sup>4</sup>. <sup>1</sup>Molecular Markers, Synarc, Lyon, France, <sup>2</sup>INSERM U664, Lyon, France, <sup>3</sup>Services des Maladies du Sang, Hôpital Huriez, CHRU Lille, Lille, France, <sup>4</sup>Molecular Markers, SYNARC and INSERM U664, Lyon, France.

The Wnt signaling pathway plays an important role in regulating bone metabolism. Levels of Dickkopf-1 (Dkk-1) -a soluble inhibitor of Wnt- measured in the bone marrow aspirates of patients with multiple myeloma (MM) have shown to be associated with radiological bone lesions. The clinical value of circulating Dkk-1 measurements is currently unclear. The aim of the study was to evaluate circulating levels of Dkk-1 in

patients with MM and investigate whether platelets contribute to its level.

Dkk-1 was measured by ELISA in serum (activation of platelets during the clotting phase) and paired plasma (no platelet activation) samples of 30 patients with MM stage II or III (mean age: 59 years from 44 to 72 years) and 33 healthy age-matched controls. To assess platelet contribution to circulating Dkk-1 levels, platelet-rich plasma was obtained from 5 healthy individuals and platelets were activated with thrombin receptor activator peptide 6 (TRAP-6) (from 0 to 6μM) or native collagen (0 to 10μg/ml). Expression and localization of Dkk-1 by platelets, was analyzed by RT-PCR and immunogold electron microscopy, respectively.

As shown on the table, serum levels of Dkk-1 were significantly higher than in paired plasma samples both in patients with MM and in controls, suggesting a release of Dkk-1 from platelets during the clotting phase. Plasma- but not serum- levels of Dkk-1 were significantly increased (+205 %  $p=0.0002$ ) in patients with MM compared to healthy controls. Both TRAP-6 and collagen induced a dose dependent release of Dkk-1 by platelets. Electron microscopy revealed the presence of Dkk-1 protein within the  $\alpha$ -granules of platelets, although RT-PCR failed to show mRNA expression. This suggests that the origin of platelet Dkk-1 is endocytosis of circulating Dkk-1 rather than endogenous synthesis.

Subjects	Dkk-1 levels (mean $\pm$ SD), ng/ml	
	Serum	Plasma
Multiple Myeloma (n=30)	7.00 $\pm$ 1.49*	4.47 $\pm$ 0.81#
Controls (n=33)	4.13 $\pm$ 2.58**	1.47 $\pm$ 0.18

\* $p<0.05$  \*\* $p<0.001$  vs paired plasma samples

#  $p<0.0001$  vs controls

In conclusion platelets contribute significantly to circulating levels of Dkk-1. Measurement of Dkk-1 in plasma, rather than in serum is recommended to limit the interference of platelet contribution, and improve the sensitivity to detect alterations of the Wnt signaling pathway in multiple myeloma.

## SU229

**Notch Pathway Is Activated In Osteosarcoma and Inhibitors of  $\gamma$ -secretase Inhibit Osteosarcoma Growth By Cell Cycle Regulation.** M. Tanaka<sup>\*</sup>, T. Setoguchi, M. Hirotsu<sup>\*</sup>, H. Sasaki<sup>\*</sup>, S. Komiya. Department of Orthopaedic Surgery, Kagoshima University, Kagoshima City, Japan.

**Purpose:** The Notch signaling pathway functions as an organizer in embryonic development. Recent studies have shown constitutive activation of the Notch pathway in various types of malignancies. However, it remains unclear whether Notch pathway is activated in human osteosarcoma. In an attempt to better understand osteosarcoma pathogenesis, we investigated the expression and activation of Notch proteins in osteosarcoma and examined the effect of  $\gamma$ -secretase inhibitor (GSI) to osteosarcoma growth. GSI are considered pan-Notch inhibitors. And also, we examined the molecular mechanism of osteosarcoma growth inhibition by GSI.

**Materials and Methods:** RT-PCR and immunohistochemistry was performed using human osteosarcoma cell lines and human osteosarcoma samples. Cells were treated with various GSIs to inhibit Notch activation. RBP-jk siRNA was used to confirm the effect of Notch signal inhibition. Nude mice were injected with osteosarcoma cells intradermally. Cell cycle was analyzed by flowcytometry. The expression of the components of cell cycle machinery was analyzed by quantitative RT-PCR and western blot.

**Results:** RT-PCR revealed high levels expression of Notch related genes in all of osteosarcomas cell lines. And also, 7 osteosarcoma human samples also showed high levels expression of Notch related genes. In addition, immunohistochemistry showed high expression of NIC in nucleus of osteosarcoma cell lines and human osteosarcoma samples. And also, expression of Jagged1 and Hes1 was observed in human osteosarcoma samples. These data suggest that notch signaling pathways are activated in osteosarcoma. MTT assay showed that GSI and RBP-jk siRNA suppressed the growth of the osteosarcoma cell lines in vitro. Intraperitoneally GSI administration dramatically inhibited the osteosarcoma xenografts growth in vivo. Kaplan-Meier analysis showed that GSI administration confers statically significant survival benefit. When osteosarcoma cell were cultured without GSI, 39.8 % cells were in G1 phase. On the other hand, when cultured with GSI, 53.3 % cells were in G1 phase. These data suggest that GSI promoted G1 arrest. Real time RT-PCR revealed that GSI suppressed transcription of cyclin D1, D3, cyclin E1, E2, and Skp2. Western blot revealed GSI promoted suppression of cyclin D1, D3, cyclin E1, E2, c-Myc, and Skp2 proteins. On the other hand, P21<sup>cip1</sup> protein was upregulated by GSI treatment. These data suggest that GSI suppressed osteosarcoma growth and promoted G1 arrest by regulation of cell cycle regulators expression.

**Discussion:** These data suggest that inactivation of Notch may be a therapeutic approach for treating patients suffering from osteosarcoma.

**Disclosures:** M. Tanaka, None.

**Zoledronic Acid Inhibits the Capacity of Myeloid-Immune Suppressor Cells in Myeloma to Form Osteoclasts.** J. Zhuang, C. M. Edwards, J. Zhang, S. T. Lwin\*, G. R. Mundy. Vanderbilt Center for Bone Biology, Nashville, TN, USA.

Bisphosphonates accumulate in the bone matrix and cause direct inhibition of osteoclasts (OCs) by their effect on mature multinucleated bone resorbing cells. Powerful nitrogen-containing bisphosphonates such as zoledronic acid are taken up under the ruffled border of multinucleated OCs and inhibit enzymes important in mevalonic acid synthesis, causing loss of osteoclast polarity and apoptosis (Coxon et al. Bone 2005). Little is known of the effects, if any, on osteoclast precursors, which are not polarized or developed ruffled borders. We have found that a subset of primitive hematopoietic precursor cells called myeloid immune suppressor cells (MISCs), which are Gr-1 and CD11b positive, accumulate significantly in bone marrow and spleen during myeloma progression, and promote myeloma growth. We have also found that MISCs in myeloma-bearing mice are osteoclast precursors and have increased capacity to form OCs. We hypothesized that bisphosphonates have inhibitory effects on MISCs, as well as on mature OCs. Results: We used the well-characterized 5TGM1 murine model of myeloma. 5TGM1-GFP tagged myeloma cells were inoculated via tail vein. Zoledronic acid (ZA) 100ug/kg was injected subcutaneously 2/week from time of tumor inoculation (n=8). We found that ZA reduces the proportion of spleen MISCs by 30% as well as OC number in myeloma bearing mice by histology ( $6.13 \pm 2.34$  vs  $0.88 \pm 0.16$ /mm bone surface). MISCs were sorted from these mice by magnetic beads. After 14 day culture with M-CSF (25ng/ml) and RANKL (50ng/ml) in vitro, ZA treatment of mice impairs the capacity of harvested MISCs to form OCs (OC number/x100 field  $42.4 \pm 4.0$  vs  $25.6 \pm 3.5$ ,  $p < 0.01$ ). To identify the potential of MISCs to form dendritic cells (DCs), we cultured MISCs from myeloma-bearing mice with GM-CSF (20ng/ml) for 8 days and determined the CD11c+ cells by flow cytometry. ZA reduced the proportion of CD11c+ (from 60% to 44%), indicating the capacity of MISCs to form DCs is also suppressed. We did not find inhibition of prenylation of small GTPases, namely Rap1A and Rab6 in MISCs from myeloma-bearing mice treated with ZA. This suggests that the effect of ZA on MISCs is not mediated by effects on the mevalonate pathway, and thus may be indirect. We have also found that after co-culture with MISCs for 96h, the inhibition of CD4+ T cell proliferation by tumor MISCs was reversed in the ZA treated group ( $52.9 \pm 12.1\%$  vs  $78.2 \pm 8.7\%$  viable cells compared with control MISCs,  $P < 0.05$ ). Thus we conclude that when myeloma-bearing mice are treated with ZA, MISCs are reduced, and the residual MISCs have reduced capacity to form not only OCs, but also DCs. Our conclusions are that ZA inhibits precursors of OCs, and this effect is likely indirect and independent of effects of ZA on GTPase prenylation in OCs.

**Disclosures:** J. Zhuang, None.

**Transcriptional Silencing of Frzb/sFRP3 by Promoter Methylation in Osteogenic Sarcoma.** T. Tsuchiya\*, K. L. Shogren\*, E. Mahlum\*, A. Maran\*, M. Yaszemski\*, G. Sarkar\*. <sup>1</sup>Orthopedic Department, Yamagata University, Yamagata, Japan, <sup>2</sup>Orthopedic Department, Mayo clinic, Rochester, MN, USA.

Frzb/sFRP3 is an antagonist of the transmembrane frizzled receptor, a component of the Wnt signaling pathway, and has been suggested to be a candidate tumor suppressor in several human malignancies. Frzb/sFRP3 belongs to a family of five genes that includes sFRP1, sFRP2, sFRP4, and sFRP5. These last four genes were reported to be inactivated by promoter hypermethylation in some cancers. Frzb/sFRP3 has also been reported to be inactivated in some cancers, but it is not known whether the inactivation is due to promoter methylation. Consequently, the mechanism underlying inactivation of sFRP3 remains unknown. We previously demonstrated severe suppression of Frzb/sFRP3 mRNA expression in osteogenic sarcoma (OGS). In this report, we have tested the hypothesis that the inactivation of Frzb/sFRP3 mRNA expression was due to promoter methylation. Our investigation shows that demethylation treatment restored the expression of Frzb/sFRP3 mRNA in 4 osteogenic sarcoma cell lines. Bisulfite treated-DNA sequencing confirmed methylation of the Frzb/sFRP3 promoter in all 4 OGS cell lines. In addition, we screened 9 other OGS cell lines, through bisulfite treated DNA sequencing, which showed methylation at some CpG-residues in the Frzb/sFRP3 promoter in 6 of these 9 OGS cell lines. Thus our findings demonstrate that 10 (77%) out of 13 OGS cell lines show at least partial methylation in the Frzb/sFRP3 promoter. This is the first report providing a correlation between inactivation of Frzb/sFRP3 mRNA expression with methylation of the cognate promoter.

**EphB4 Expression in Osteoblasts is Regulated by Myeloma Cells and the Wnt Signaling Pathway.** A. L. Bates\*, S. T. Lwin\*, G. R. Mundy, C. M. Edwards. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Multiple myeloma (MM) is associated with a destructive osteolytic bone disease, characterized by an increase in osteoclastic bone resorption and a reduction in osteoblastic bone formation. The coupling between osteoblasts and osteoclasts during normal bone homeostasis may be due to bidirectional signaling between the ligand ephrinB2 on osteoclasts, and its receptor EphB4 on osteoblasts. Reverse signaling through ephrinB2 inhibits osteoclast activity whereas forward signaling through EphB4 stimulates osteoblast differentiation. Since the normal coupling of bone resorption to formation is dysregulated in MM, we hypothesized this may be mediated by modifications in the EphB4/ephrinB2 receptor/ligand interaction. Our previous studies have suggested that myeloma cells release a soluble factor which mediates a decrease in EphB4 expression by osteoblasts. The aim of the present study was to further study the regulation of EphB4 expression in osteoblasts, focusing on regulation by (i) myeloma cells and (ii) the Wnt signaling pathway. Although conditioned media from 5TGM1 myeloma cells significantly decreased EphB4 expression in osteoblasts, it had no effect on ephrinB2 protein or mRNA expression, suggesting that the effect of myeloma cells is specific for EphB4. 2T3 osteoblasts were cultured for 48h in the presence or absence of 5TGM1 myeloma cells. Following coculture, myeloma cells were separated by differential trypsinization, and a purity of >95% confirmed by flow cytometry. Real-time PCR demonstrated an 85% decrease in EphB4 expression by osteoblasts following direct culture with myeloma cells, as compared with osteoblasts cultured alone. In contrast, no change in expression of alkaline phosphatase, collagen 1 or Runx2 was found by PCR, suggesting that the decrease in EphB4 expression is not related to osteoblast differentiation. MM bone disease is associated with inhibition of Wnt signaling in osteoblasts. Transfection of C2C12 osteoblasts with constitutively active beta-catenin resulted in a significant increase in EphB4 promoter activity, whereas dominant-negative TCF4 significantly reduced EphB4 promoter activity. Treatment of either C2C12 or 2T3 osteoblasts with 20mM LiCl, which acts to inhibit GSK-3beta and increase Wnt signaling, increased both EphB4 promoter expression and EphB4 mRNA expression. This suggests that EphB4 in osteoblasts is a target of beta-catenin. Taken together, our studies suggest that MM cells decrease EphB4 expression by osteoblasts, and implicate the Wnt signaling pathway in the regulation of EphB4. Therefore, down-regulation of EphB4 by MM cells may disrupt the normal coupling of bone formation to resorption and contribute to MM bone disease.

## SU233

**Melanoma-Induced Bone Loss is Mediated by the Rapid Recruitment of Osteoclasts.** J. R. Edwards, L. C. Dumitrescu\*, J. A. Sterling, S. T. Lwin\*, G. R. Mundy. Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA.

Dramatic bone destruction is a common feature of tumor-bone metastasis, resulting in extensive bone loss, chronic pain and often represents the terminal phase of disease. Despite the common consensus that osteoclasts remain the sole bone-resorbing cell of the body, recent studies have suggested that melanoma-associated bone loss is not mediated by osteoclasts (Sanchez-Sweetman *et al*, 1997; Jones *et al*, 2006). Since we have been unable to find convincing evidence that bone osteolysis in any cancer occurs independent of osteoclasts, we studied melanoma-osteoclast interactions using the identical bone metastasis model employed above. *In vivo* bone mass was assessed by uCT and histomorphometry, and direct evidence of osteoclast involvement determined by TRAP and vitronectin receptor (VNR) staining, and by examining urinary markers of resorption. *In vitro* resorption assays and molecular studies were used to identify potential mechanisms of melanoma-osteoclast interactions. C57Bl6 mice inoculated with B16F10 melanoma cells or PBS by intra-cardiac injection were sacrificed at day 18 or 24, upon which the tumor burden was clearly obvious by a blackened marrow cavity. This corresponded with a significant decrease in bone volume in both groups, and interestingly DPD analysis indicated a higher level of resorptive activity at the earlier time point. This corresponded with a greater increase in osteoclast surface/bone surface ratio at day 18 (59%) than that seen at day 24 (28%), compared to control animals. Treatment of normal marrow cells with media conditioned by B16F10 or Mel A melanoma cells showed a significant dose-dependent increase in TRAP+, VNR+ osteoclast formation and correlated with increased resorption on dentine discs. RT-PCR analysis identified expression of the osteolytic factors PTHrP and MIP-1α in both cell lines. These studies demonstrate a clear osteoclast-related bone loss associated with melanoma metastasis and identify factors capable of stimulating osteoclast activity. These findings are consistent with a central role for osteoclasts in the extensive osteolysis observed in melanoma bone metastases.

**Alpha-Calcium/Calmodulin Dependent Kinase II Controls Osteosarcoma Cell Migration.** K. Yuan\*, M. Zayzafoon. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Calcium/Calmodulin dependent kinase II (CaMKII) is a multifunctional serine/threonine kinase that is highly expressed in neuronal cells, but is also expressed in other cells. We have previously shown that alpha-CaMKII controls the growth of osteosarcoma through regulating p21<sup>CIP/KIP</sup> expression. CaMKII has also been implicated in the modulation of cell migration. The purpose of this study was to determine the role of CaMKII in regulation of osteosarcoma cell migration. First immunohistochemistry staining for phosphorylated alpha-CaMKII was performed on osteosarcoma tissue microarray slides. Results of the immunophenotypic evaluation of tissue microarray showed that 65% of patients were positive staining for phosphorylated alpha-CaMKII. We used a lentivirus to deliver designed human alpha-CaMKII-targeted short hairpin RNAs (shRNA) into MG63 human osteosarcoma cell lines and examined shRNA inhibition ability. The gene expression and protein level of alpha-CaMKII decreased 81% in stable alpha-CaMKII shRNA expression cells, when compared to scramble shRNA expression cells. A wound-healing assay revealed that alpha-CaMKII knock-down cells are unable to migrate efficiently into in vitro wound space, the cells moved in original wound space decreased 40% as compared to scramble shRNA expression cells. Results from a transwell migration assay also showed that alpha-CaMKII knock down MG63 cells decreased their migration ability, suppression of the alpha-CaMKII caused a 49% reduction in the number of cells that traversed the membrane versus nonsilencing control. F-Actin staining results showed that the number of both filopodia and lamellipodia formed in alpha-CaMKII knock-down cells was decreased 75% and 79%, respectively, compared to scramble shRNA expression cells, suggesting the low motility ability of alpha-CaMKII knock-down cells. Furthermore, scramble shRNA expression cells have an asymmetrical focal adhesions distribution; comparatively, alpha-CaMKII knock-down cells exhibit more peripherally distributed focal adhesions along the entire basal surface of the cell. These results suggest that alpha-CaMKII controls the migration of osteosarcoma cells by regulating filopodia and lamellipodia formation and is implicated in the modulation of osteosarcoma metastasis.

**Controlled Drug Release from Calcium Phosphate-Based Orthopaedic Implants.** G. Zhu\*, M. Saadia\*, S. J. Lippard\*, L. D. Silverman\*. <sup>1</sup>Chemistry, MIT, Cambridge, MA, USA, <sup>2</sup>Chemistry, Yeshiva University, New York, NY, USA.

A route to making novel controlled-drug release coatings on porous calcium phosphate-based orthopaedic implants was explored by binding lifesaving drugs, including the antibiotic gentamicin (G) and chemotherapeutic agent cisplatin (cis-[Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>], cDDP), to poly-L-glutamic acid (pg) adsorbed on implant surfaces. pg adsorbed onto hydroxyapatite powder (HA) was used to test the concept. G was adsorbed onto the coated powder to make a 0.83% G drug release product (G/pgHA), with controls made by impregnation of non-coated HA at equal drug loading (G/HA). In vitro release rates were measured in PBS buffer (4.0 mg/mL, pH 7.4, 37°C), with sequential removal/replacement of buffer in some experiments. Samples reached equilibrium with buffer in < 1 h, with less G released by G/pgHA (53%) than by G/HA (71%). Fig 1A shows slower drug release for G/pgHA vs. G/HA with sequential buffer replacement.

cDDP was loaded on pgHA and HA controls by overnight mixing and filtration, to make 5.3% and 5.7% cPT products, respectively. Drug release was measured in simulated body fluid (4.5 mg/mL, pH 7.4, room temperature) via centrifugation and AA analyses. Release of cDDP with buffer exchange (Fig 1B) shows slower drug release from cDDP/pgHA vs. cDDP/HA over 6 days.

The drug loading in G/pgHA is sufficient to kill staphylococci in 500 cc of tissue from 1 g of powder. The G/pgHA data represents a series of sequential equilibria, analogous to chromatographic migration that would occur in a large piece of coated porous implant material in vivo. The experiment demonstrates that: (1) G is bound to pgHA in clinically significant quantities, (2) it is released more slowly than the control, and (3) it is completely removed under the sequential sampling conditions, which is important for prevention of breeding antibiotic resistant bacteria. We anticipate that G release will be significantly slower in a larger porous implant sample in the presence of clotted blood in a surgical site in vivo (J Orthopaedic Res (2007) 25:23-9).

The cDDP/pgHA loading is sufficient to kill cancer cells in 3.5 kg of tissue per g cDDP/pgHA. The release rate of cDDP is greatly reduced from pgHA vs. HA. We conclude that

pgHA and acidic polypeptide coated calcium phosphate implants in general represent promising materials for local delivery of a variety of drugs, including gentamicin and cisplatin.

**Biomechanical and Geometrical Property Changes in Rat Tibias with Tumor-Induced Osteolysis after Anti-Resorptive or Anti-Cancer Treatments.** T. Lee<sup>1</sup>, R. C. Soong<sup>2</sup>, Y. H. Chan<sup>3</sup>, S. Das De<sup>4</sup>, J. C. Goh<sup>4</sup>. <sup>1</sup>Division of Bioengineering, National University of Singapore, Singapore, <sup>2</sup>Department of Pathology, National University of Singapore, Singapore, <sup>3</sup>School of Medicine, National University Hospital, Singapore, Singapore, <sup>4</sup>Department of Orthopaedic Surgery, National University Hospital, Singapore, Singapore.

The study investigates the efficacy of anti-cancer (Paclitaxel) and anti-resorptive (Ibandronate) in treating tumor-induced osteolysis by assessing changes in geometrical and mechanical properties of the affected bone. A rat tibia model for tumor-induced osteolysis using W256 malignant breast cancer cells was used. Of the 30 rats implanted with cancer cells, 12 were injected cancer cells only (Canc), 9 received ibandronate (Iban), 9 received paclitaxel (Pac) and 12 underwent a sham operation (Cont). At 10-days intervals up to 30-days, the paired-tibias were assessed by  $\mu$ CT scans to quantify the geometrical parameters. The paired-bones were also assessed by a 3-point bending test using a custom-made jig for their mechanical property.

The total BV was significantly smaller in the tumor-induced compared to the contra-lateral tibia in the Canc group. While the geometric parameters were markedly lower for both Iban and Pac groups, the Iban group seems more successful, with a further 5.5% reduction in total BV difference, in comparison to Pac group. This pattern is repeated in CSA of cortical bones at 25% of the distal femur length.

Higher Tb.Th, Tb.N, BV/TV, and BS/BV of the tumor-implanted femurs were noted in both Iban or Pac groups compared to those in Canc group. With the exception in Tb.N, Iban group was better than Pac group in maintaining the trabecular properties.

The paired-difference in stiffness in the Iban group was lowered to 3.8% at 30-days, whereas the Pac group had a stiffness lowered to 5.7%. The results suggest that both Iban and Pac treatments in tumor osteolysis have the potential to preserve the structural integrity of the affected bones, and improve the mechanical property. While ibandronate results in less reduction imprint the in bone geometry, paclitaxel seems more effective in maintaining its stiffness.

**Modeling Pathways for Bone Loss in Childhood Malignancies: A Prospective Study.** G. El-Hajj Fuleihan<sup>1</sup>, S. Muwakkit<sup>2</sup>, A. Arabi<sup>1</sup>, L. El-Onsi<sup>1</sup>, J. Chaiban<sup>1</sup>, M. Abboud<sup>2</sup>. <sup>1</sup>Calcium Metabolism and Osteoporosis Program, American University of Beirut-Medical Center, Internal Medicine, Beirut, Lebanon, <sup>2</sup>Children Cancer Center, American University of Beirut-Medical Center, Pediatrics, Beirut, Lebanon.

Our group and others have shown that children treated for malignancies have low bone mass due to poor nutrition, direct effects of chemotherapy on bone, as well as effects of chemotherapy and radiation therapy on growth, and gonadal status. We currently report on follow-up of the same cohort investigating predictors of bone mass changes over time. 31 children (N=29 with ALL), mean age 9±2.8 years, 21 still receiving therapy for 80±2.8 weeks, 9 having finished 40±22 weeks prior, and 32 age and gender-matched controls, were followed over 14 months. Age at diagnosis, calcium intake, exercise activity, doses of corticosteroids (CS) and Methotrexate (MTX) received within the follow-up period, and intrathecal MTX-CS therapy were assessed. Blood was obtained for routine chemistries, parathyroid hormone (PTH), 25 hydroxy vitamin D (25-OHD) levels, osteocalcin and crosslaps at baseline and follow-up. Bone mass and body composition were measured at baseline and follow-up. Univariate and multivariate analyses were conducted to evaluate predictors of changes in bone mass. At follow-up, 22/31 remained at Tanner stage 1. Patients had a lower calcium intake, exercise activity, serum calcium, albumin and bone markers levels, and higher PTH levels than controls. They also had higher fat mass and lower bone mass at the spine and hip, and lower increments in bone mass at the total body compared to controls. Predictors of bone mass changes on univariate analyses were: age at diagnosis (R= -0.49 to -0.39, p<0.05), MTX/CS doses (R= -0.54 to -0.37, p<0.05), intrathecal therapy (p<0.03), % changes in lean mass (R=0.38 to 0.54, p<0.04), fat mass and % changes in fat mass (R= -0.46 to -0.41, p<0.02), 25-OHD levels (R=0.38 to 0.41, p<0.04), and PTH levels (R= -0.45 to -0.37, p<0.04). The predictive effect of vitamin D disappeared when adjusting for PTH levels and that of PTH disappeared when adjusting for MTX/CS dose. On multivariate analyses predictors of changes in bone mass, depending on the skeletal site, were: age at diagnosis, fat mass, lean mass, MTX/CS, and intrathecal therapy. Based on our results we propose the following paradigm to outline pathophysiological mechanisms for bone loss in children on therapy for malignancies.

**Microstructural Changes at the Ultradistal Radius in Monoclonal Gammopathy of Undetermined Significance.** N. Charatcharoenwittaya<sup>1</sup>, S. Kumar<sup>2</sup>, S. V. Rajkumar<sup>2</sup>, R. A. Kyle<sup>2</sup>, S. J. Achenbach<sup>3</sup>, M. F. Holets<sup>1</sup>, L. K. McCready<sup>1</sup>, S. Amin<sup>4</sup>, M. T. Drake<sup>1</sup>. <sup>1</sup>Endocrinology, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Hematology/Oncology, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Biostatistics, Mayo Clinic, Rochester, MN, USA, <sup>4</sup>Rheumatology, Mayo Clinic, Rochester, MN, USA.

Recent population-based studies have demonstrated that the risk for fractures is increased in patients with monoclonal gammopathy of undetermined significance (MGUS), a premalignant condition with an approximately one percent annual risk of progression to multiple myeloma. While MGUS has been consistently associated with elevated bone resorption and/or reduced bone formation markers, DXA-based studies evaluating whether areal bone mineral density (aBMD) is reduced in patients with MGUS have yielded conflicting results. Further, although DXA provides quantitative information about bone mass, the microstructural properties of the measured bone which are critical determinants of bone quality and strength, are not measured. To better understand the effect of MGUS on skeletal health, we performed both standard aBMD measurements by DXA, and high resolution 3D-pQCT (XtremeCT, Scanco AG, voxel size ~82 microns) measurements at the ultradistal radius to evaluate bone microstructural parameters, in 25 subjects with MGUS (8 F and 17 M; mean age 71.2 ± 9.5 years). Study subjects were age-, sex-, and BMI-matched (1:2) with control subjects (16 F and 34 M; mean age 71.2 ± 9.8 years) from the local community. Comparison of the MGUS cohort to the control subjects revealed no significant differences in DXA aBMD measurements at the femur, lumbar spine, total spine, forearm, or total body. Trabecular microstructure (bone volume, trabecular number, thickness, or separation) also did not differ in the MGUS compared to control subjects. In contrast, we found that cortical volumetric BMD (vBMD) was significantly decreased (P < 0.02) at the ultradistal radius in subjects with MGUS. Further, endocortical area (P = 0.07) and total bone

area (P = 0.08) demonstrated a trend towards an increase in patients with MGUS, suggesting increased endocortical bone resorption, with perhaps a compensatory increase in periosteal apposition. In summary, these data represent the first assessment of *in vivo* bone microstructure in subjects with MGUS, and demonstrate that (1) the increased incidence of fractures previously found to occur in patients with MGUS may not be reflected in DXA aBMD measurements, which were not different between patients with MGUS and matched controls; and (2) patients with MGUS have reduced cortical vBMD, at least at the distal radius. Further prospective studies are needed to test whether the observed losses of cortical bone predict progression to myeloma.

**Preclinical Validation of a Novel Dkk-1 Neutralizing Antibody for the Treatment of Multiple Myeloma Related Bone Disease.** S. Pozzi<sup>1</sup>, H. Yan<sup>2</sup>, S. Vallet<sup>1</sup>, N. Vaghela<sup>1</sup>, D. Cirstea<sup>3</sup>, L. Santo<sup>3</sup>, S. Mukherjee<sup>2</sup>, T. Hideshima<sup>3</sup>, L. Schirtzinger<sup>4</sup>, S. Kuhstoss<sup>4</sup>, K. C. Anderson<sup>3</sup>, D. Scadden<sup>2</sup>, N. Raju<sup>1</sup>. <sup>1</sup>Massachusetts General Hospital-Dana Farber Cancer Institute-Harvard Medical School, Boston, MA, USA, <sup>2</sup>Massachusetts General Hospital-Harvard Medical School, Boston, MA, USA, <sup>3</sup>Medical Oncology, Dana Farber Cancer Institute-Harvard Medical School, Boston, MA, USA, <sup>4</sup>Eli Lilly and Company, Indianapolis, IN, USA.

Multiple myeloma (MM) is a plasma cell dyscrasia characterized by osteolytic bone lesions in 80% of patients. Bisphosphonates reduce skeletal related events, without impacting bone healing. Increased expression of Dkk1 in a subset of MM patients and its association with lytic bone disease makes it a potential new target for the treatment of myeloma bone disease. Dkk1, an inhibitor of the wingless int (wnt) pathway, is important in osteoblastogenesis. The aim of this study was to test the effect of a Dkk-1 neutralizing chimeric antibody (Mab B3) on osteoblasts (OB), osteoclasts (OC) and MM cells in the context of the bone microenvironment. First, we tested the expression of Dkk1 in plasma and bone marrow of 16 MM patients and 10 MM cell lines. Dkk1 levels were >18 ng/mL in 2 out of 16 patients; levels were comparable in blood and bone marrow plasma. In contrast, very little Dkk1 (2-9 ng/ml) was produced by bone marrow stromal cells (BMSC). One out of 10 MM cell lines (INA-6) expressed low concentrations of Dkk1 in the supernatant. Second, we tested the effect of Mab B3 on MM cell lines, in the presence or absence of BMSC, and on OB and OC from MM patient derived bone marrow. The effects on OC were evaluated by TRAP staining and pit formation. Effects on OB were assayed by alkaline phosphatase staining and alizarin red assays for calcium deposition. Our data demonstrates no direct cytotoxic effects on MM cell lines negative for Dkk1 using Mab B3. Mab B3, however, enhanced OB differentiation and calcium deposition in a dose dependent manner and inhibited OC differentiation and function, as evidenced by a decrease in number of multinucleated TRAP+ cells and a decrease in pit formation. Ongoing studies are addressing the effect of Mab B3 on MM cells in the context of OC and OB. In conclusion our preliminary data suggests that Mab B3 functions as an anabolic agent; a corresponding human monoclonal antibody may be useful for the treatment of MM related bone disease. Future studies will evaluate the effect of Mab B3 in an *in vivo* mouse model of multiple myeloma, alone and in combination with bisphosphonates.

## SU240

**2-Methoxyestradiol Alters eIF4E Activity and Causes Protein Synthesis Inhibition in Osteosarcoma Cells.** K. L. Shogren<sup>1</sup>, E. W. Mahlum<sup>1</sup>, M. J. Yaszemski<sup>1</sup>, A. Maran<sup>1</sup>. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Regulation of protein synthesis plays an important role in the control of malignancy. Majority of the regulation of protein synthesis takes place at the level of translation initiation involving eIF4F protein complex, which consists of three proteins: eIF4E, eIF4A and eIF4B. The eIF4E, which serves as a rate-limiting factor of the eIF4F complex, binds to 7-methyl guanosine triphosphate cap present in most mRNAs, and thereby globally regulates cap-dependent protein synthesis. Previous studies in several systems demonstrate the involvement of eIF4E in malignant transformation and progression.

Osteosarcoma is the most common primary malignant bone tumor that affects children and young adults. Current treatment of osteosarcoma relies on a combination of surgery and chemotherapy. Although this has led to improved survival rate, a definite therapy is yet to be determined in most cases. We have demonstrated that 2-Methoxyestradiol (2-ME), a metabolite of 17beta-estradiol, induces apoptosis and exerts anti-tumor effects in osteosarcoma cells. The molecular mechanism of action of 2-ME on osteosarcoma cells is not well understood, but appears to involve RNA-dependent protein kinase (PKR) signaling.

To further understand the mechanism of 2-ME-induced cell death, we have studied the regulation of translation initiation factor eIF4E in 2-ME-treated osteosarcoma cells by affinity chromatography, co-immunoprecipitation and western blot analysis. Our results show that 2-ME-treatment modulates both eIF4E and eIF4E-binding protein (4EBP1) in MG63 human osteosarcoma cells. 2-ME treatment resulted in a decrease in binding of eIF4E to cap. In addition, analysis of cap-binding complexes showed that 2-ME treatment reduced the association of eIF4E with the eIF4G subunit, and at the same time, its association with eIF4E-BP1 increased. Also, MG63 cells, stably transfected with a cDNA for a "loss of function mutant" RNA-dependent protein kinase (PKR) protein, were resistant to 2-ME-induced regulation of eIF4E. These findings show that 2-ME treatment

results in modifications of the eIF4F complex, which is further supported by the inhibition of protein synthesis in 2-ME-treated cells. Thus, our study suggests that translational regulation plays an important role in 2-ME-mediated control of osteosarcoma cells.

**Hedgehog Pathway Is Activated in Osteosarcoma and Cyclopamine Prevents Osteosarcoma Growth by Cell Cycle Regulation.** M. Hirotsu\*, T. Setoguchi, H. Sasaki\*, S. Komiya\*. Orthopaedic Surgery, Kagoshima University, Kagoshima, Japan.

Hedgehog proteins are essential morphogens and hedgehog signaling pathway plays an important role in embryonic development. Recent studies have shown constitutive activation of hedgehog signaling promote various types of malignancies. However, it remains unclear whether hedgehog pathway is activated in human osteosarcoma. In an attempt to better understand osteosarcoma pathogenesis, we investigated the expression and activation of hedgehog related proteins in osteosarcoma and examined the effect of cyclopamine to osteosarcoma growth. And also, we examined the molecular mechanism of osteosarcoma growth inhibition by cyclopamine. RT-PCR revealed high expression of hedgehog related genes in both osteosarcoma cell lines and human specimens. Immunohistochemistry showed high expression of hedgehog related proteins in both osteosarcoma cell lines and human specimens. Next, we investigated the effects of hedgehog pathway inhibition on osteosarcoma growth. MTT assay showed that cyclopamine and Gli2 siRNA suppressed the growth of the osteosarcoma cell lines in vitro. Cell proliferation assay showed that cyclopamine suppressed the osteosarcoma cell proliferation. Next we performed cell cycle analysis by flow cytometry. As a result, cyclopamine promoted G1 arrest. Next we examined the transcription of the cell cycle related genes which transcription was regulated in cell cycle. Real time RT-PCR and western blot revealed that cyclopamine suppressed transcription of cyclin D1, cyclin E1, Skp2, phosphorlated Rb. And also, P21<sup>cip1</sup> protein was upregulated by cyclopamine treatment. These data suggest that cyclopamine suppressed osteosarcoma growth and promoted G1 arrest by regulation of cell cycle regulators expression. We found that the components of hedgehog pathway were overexpressed in human osteosarcoma. And to explore how hedgehog pathway activation contributes to osteosarcoma growth, we blocked hedgehog pathway. Treatment of osteosarcoma cells with cyclopamine or Gli2 siRNA prevented osteosarcoma growth in vitro. Moreover, flow cytometry for cell cycle analysis showed that cyclopamine promote cell cycle arrest in osteosarcoma in vitro. In addition, we found that expression of cell cycle regulators was regulated by hedgehog signal inhibition with cyclopamine treatment.

These data suggest that inactivation of hedgehog signaling may be a therapeutic approach for the treatment of patients with osteosarcoma.

**Bone Marrow Stromal Cells Up-regulate M-CSF Receptor in Monocytes to Disrupt Dendritic Cell Differentiation While Facilitating Osteoclastogenesis in Myeloma.** M. Abe<sup>1</sup>, M. Hiasa<sup>2</sup>, A. Oda<sup>1</sup>, H. Amou<sup>1</sup>, K. Takeuchi<sup>1</sup>, O. Tanaka<sup>1</sup>, S. Nakamura<sup>1</sup>, H. Miki<sup>1</sup>, K. Kagawa<sup>1</sup>, K. Yata<sup>1</sup>, S. Ozaki<sup>1</sup>, S. Kido<sup>1</sup>, T. Matsumoto<sup>1</sup>. <sup>1</sup>Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan, <sup>2</sup>Department of Orthodontics and Dentofacial Orthopedics, University of Tokushima Graduate School of Medicine, Tokushima, Japan.

Interaction of myeloma (MM) cells with bone marrow stromal cells facilitates osteoclastogenesis and tumor expansion in MM. In contrast to osteoclastogenesis, the number and function of dendritic cells (DCs) are reduced in MM bone lesions, causing immune escape of tumor cells and susceptibility to infection in MM. Because monocytes are a common precursor of both osteoclasts (OCs) and DCs, there is a possibility that monocytic differentiation may be deregulated in MM. In the present study, we therefore explored whether an interaction between MM cells and bone marrow stromal cells plays any role in lineage commitment of monocytic differentiation in MM. Induction of CD1a-positive DCs from monocytes by GM-CSF and IL-4 (25 ng/ml each) was strongly inhibited when co-cultured with human primary bone marrow stromal cells or murine MC3T3-E1 pre-osteoblasts. Interestingly, cell surface M-CSF receptor (M-CSFR) on monocytes was robustly up-regulated when co-cultured with primary stromal cells as well as MC3T3-E1 cells. The up-regulation of M-CSFR in monocytes by stromal cells was further enhanced in the presence of MM cells, while MM cells themselves were without effect. Disruption of M-CSF binding to M-CSFR by a soluble M-CSF-Fc fusion protein abrogated osteoclastogenesis enhanced by co-cultures of U266 cells with rabbit bone cells, and antagonized the suppression of GM-CSF and IL-4-mediated DC differentiation in the presence of stromal cells. These results demonstrate that bone marrow stromal cells are responsible for triggering monocytic differentiation into OC lineage while reciprocally suppressing its DC differentiation in an M-CSF-dependent manner, and that up-regulation of M-CSFR in monocytes by stromal cell-MM interaction at least in part contributes to the M-CSF-mediated up-regulation of OC and down-regulation of DC differentiation. It is suggested that a stromal cell-rich microenvironment created by impaired osteoblast differentiation in "MM niche" plays a critical role in the deregulation of monocytic differentiation to cause bone destruction and immunodeficiency, contributing to the development of the characteristic features of MM.

**Wnt/bCatenin/TCF Is a Constitutive Repressor Pathway Interfering with Foxo3-mediated Induction of Syndecan-2, a Tumor Suppressor in Osteosarcoma Cells.** F. Dieudonné\*, A. Marion\*, E. Haÿ, P. J. Marie, D. Modrowski. Unit 606, INSERM, Paris, France.

Syndecan-2 (synd2) acts as a tumor suppressor in osteosarcoma cells. We previously showed defective synd2 expression and induction in osteosarcoma tissues as compared to normal bone. Our current hypothesis is that this defect contributes to resistance to chemotherapeutic agents. We therefore investigated the mechanisms involved in the control of synd2 expression in basal conditions and after induction by Doxorubicin in human osteosarcoma cells. Using Genomatix software tools we analyzed in silico the 5' region upstream the synd2 gene and identified features for a promoter region and binding sites for members of the TCF/LEF family and forkhead factors. Chromatin immunoprecipitation assays were performed to determine whether these factors bind to these sites. A 3.6 Kb sequence of the 5' region upstream the synd2 gene was cloned in a reporter gene system to perform transactivation assays. Expression of synd2 was also determined by RT-qPCR. Overexpression of TCF4, constitutively active b-catenin or both using transient transfection induced a strong inhibition of basal reporter gene transactivation and of synd2 expression whereas repression of LEF-1 expression by siRNA resulted in increased basal synd2 expression. Treatment with recombinant Wnt3a also reduced synd2 mRNA and this effect was inhibited by DKK1. These results indicate that canonical Wnt signaling is involved in the repression of synd2. In contrast, we found that Doxorubicin increased transactivation of the reporter gene and synd2 expression. The effect of Doxorubicin is in part mediated by Foxo factors. Indeed, Doxorubicin induced the translocation of Foxo3 into the nucleus and siRNA inhibiting Foxo3 expression reduced the inductive effect of Doxorubicin on synd2 expression. Furthermore, overexpression of Foxo3 or a constitutively active form of this factor, Foxo3(A3) resulted in increased synd2 mRNA level. Foxo3 factors are known to compete with TCF/LEF to interact with b-catenin. Western blot analysis showed that Doxorubicin promoted the interaction between b-catenin and Foxo3 in U2OS cells. Additionally, overexpression of TCF4 or active b-catenin or both counteracted the induction of synd2 by Doxorubicin. This suggests that the Wnt pathway actually competes with the induction of synd2 by Doxorubicin. Overall, our data indicate that Wnt/b-catenin/TCF is a constitutive repressor pathway of synd2 expression in osteosarcoma cells. Doxorubicin increases synd2 expression in part through Foxo3 factors that may directly activate transcription and also could act by "hijacking" b-catenin and inhibiting formation of the b-catenin/TCF repressor complexes.

**Characterisation of an Antigen Found in Giant Cell Tumour and Osteosarcoma Cells.** V. J. Green\*, P. W. Wilson\*, A. A. Walsh\*, J. A. Gallagher. Human Anatomy and Cell Biology, University of Liverpool, UK, Liverpool, United Kingdom.

Screening of a panel of monoclonal antibodies has identified a protein abundantly expressed in osteoclasts of giant cell tumour and at lower levels in human osteosarcoma cell lines, SaOS-2, TE-85 and MG63. It has also been seen at low levels in the culture medium from MG63 cells and less frequently in that from TE85 cells, those which represent the earlier stages of differentiation.

Co-localisation studies were performed with confocal microscopy using markers of intracellular organelles including the nucleus, endoplasmic reticulum, endocytic pathway, mitochondria and the golgi apparatus. Live fluorescent imaging was used to monitor the expression of the antigen over a one week period. Purified antibody was directly labelled with Alexa 488 dye, and mixed with the vector Chariot, to facilitate antibody uptake into the cell. MG63 cells were seeded at 30% confluence. Time lapse imaging was performed for the initial three hours to monitor uptake of the antibody, followed up by still image collection at 24 hour intervals for the following 7 days until cells reached confluence.

Immunoprecipitation using Dynal beads was performed and run on 1D gels and stained with Simply Blue Safe Stain, Silver Quest staining and Western blotted using the X cell Surelock mini-cell system.

Co-localisation studies show the antigen co-localises with the Golgi apparatus and not the nucleus, endoplasmic reticulum, endocytic pathway or mitochondria. It appears to remain here through to cell confluence.

Immunoprecipitation reveals a band at 90kDa visible by Western blotting but not by Simply Blue Safe Stain or Silver Quest staining.

It is necessary to eliminate more abundant proteins prior to immunoprecipitation to allow for a scaling up of antigen yield to a level visible with Simply Blue Safe Stain. 2D gel electrophoresis may provide better separation of proteins and clearer isolation of our antigen.

The presence of antigen in the culture medium of MG63 and TE85 cells suggests it may have a role in extracellular signalling.

Screening of an array of cancer tissues including breast, prostate, liver and colo-rectal cancer compared to case matched controls may identify a possible biomarker of disease or disease progression and provide further insights into therapeutic targets useful in the treatment of neoplastic disease.

**BAMBI Gene Is Epigenetically Silenced in a Subset of High-grade Bladder Cancer.** S. Kitazawa, S. Sanda Khin\*, K. Mori, T. Kondo, R. Kitazawa. Department of Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

The BMP and activin membrane-bound inhibitor (BAMBI) is a transmembrane pseudoreceptor, preserved from *Xenopus* to *Homo sapiens*, and antagonizes TGF- $\beta$ /BMP signaling by interacting with TGFRII/BMPRII. In the current study, to evaluate the role of BAMBI in carcinogenesis and cancer progression in human bladder cancer from the viewpoint of both etiological and molecular backgrounds, we first screened the expression pattern of BAMBI protein by immunohistochemistry and the methylation status of the BAMBI gene promoter by the use of clinical specimens, and then the functional aspects of the BAMBI gene by forced-expression and knock-down in cancer cell lines *in vitro*. In the normal or reactive urothelium, BAMBI expression was mostly overlapped with that of BMPRI. A similar colocalization pattern of BAMBI and BMPRI was noted in noninvasive low-grade papillary cancers. In high-grade and invasive cancers, however, two reciprocal immunohistochemical expression patterns were observed: BAMBI-low and BMPRI-high, and BAMBI-high and BMPRI-low, indicating that BAMBI expression is controlled such that it does not interfere cellular demand for TGF- $\beta$ /BMP signaling defined by the level of TGF- $\beta$ /BMP receptors. On the other hand, methylation of one or more genes, especially of sFRP2 and BAMBI, was frequent in high-grade invasive tumors. Moreover, methylation of the BAMBI gene correlated with negative BAMBI expression in primary bladder tumors. Treatment of three bladder cancer cell lines with 5-aza-dC for 7 days restored the expression of BAMBI mRNA in T24 and HTB9. In KU1, where no BAMBI promoter methylation was detected, no significant difference was observed in the expression of the mRNA transcript. Transfection of BAMBI siRNA effectively suppressed BAMBI mRNA expression by at least 60% compared with that of its control, as determined by RT-PCR. Although a slight decrease in the apoptotic count by siRNA transfection was observed in HTB9, BAMBI knockdown did not have much effect on the apoptosis. Cell motility assay, on the other hand, revealed that after 24h treatment with TGF- $\beta$ 1, T24 and HTB9 cells showed a drastic increase in the number of migrated cells which decreased significantly through the forced expression of BAMBI by the transfection of the pEGFP-N3-hBAMBI expression vector in T24 and HTB9. In contrast, TGF- $\beta$ 1 had no effect on the motility of KU1 cells. Since certain subsets of aggressive tumors often promote cell motility, vascular invasion and survival, by inducing epithelial-to-mesenchymal transition by TGF- $\beta$ /BMP in an autocrine and paracrine manner, hypermethylation of the BAMBI gene promoter that leads to BAMBI gene suppression may be one of the indicators of the aggressiveness or the poor prognosis of bladder cancers.

## SU246

**Medullar Carcinoma of the Thyroid and Anomalies of the Calcium Metabolism: Case Report.** C. Poiana\*, M. Carsote\*, C. Chirita\*, D. Hortopan\*, D. Ioachim\*, A. Goldstein\*. <sup>1</sup>Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, <sup>2</sup>Endocrinology, C.I. Parhon Institute of Endocrinology, Bucharest, Romania.

**Introduction.** Medullar carcinoma is a rare form of thyroid cancer, sporadic or hereditary. Most of the cases are aggressive and limited therapeutic options are available once the tumor is spread.

**Aim.** We present a case of sporadic medullar thyroid carcinoma diagnosed almost a decade after a surgical approach of the thyroid. At that moment multiple metastasis were seen together with oncogenic osteomalacia and hypercalcaemia.

**Case Report.** On admission, a 66 years old female patient had progressive neck masses for the last 4 years. The medical history is the following: 11 years ago total thyroidectomy for endemic polinodular goiter was performed. Since the last 4 years she suffered for chronic diarrhea and she was followed up for the progressive enlargement of both thyroid lobes. She refused fine needle aspiration biopsy (FNAB). At this moment, ultrasound showed cervical remnants on the right lobe of 1 by 1 by 2.5 cm and on the left of 3.2 by 3 by 2.6 cm going retrosternal. Also left supraclavicular adenopathy of 4.1 by 3.3 by 4.1cm and left laterocervical adenopathy of 4.5 cm were revealed. The computed tomography showed that the neck mass was spread up to the superior mediastin, and osteolytic lesions were seen on the third dorsal vertebra as well as multiple hepatic metastases. The FNAB suggested medullar carcinoma. The serum parameters showed: hypercalcemia (10.6 mg/dl), normal levels of phosphorus (3.7 mg/dl), normal PTH levels (16 pg/ml) but very low levels of 25-OH vitamin D (11.33 ng/ml). The plasma calcitonin was extremely high (> 2000 ng/ml). The lumbar DXA exam showed low BMD (0.846g/cm<sup>2</sup>), T-Score of -2.9 and Z-Score -1.8. Based on this, medullar carcinoma with multiple metastasis was diagnosed, associated with osteomalacia. The high levels of calcium were suggestive for neoplastic hypercalcemia, marking the terminal disease. The patient suffered 2 months later a fragility fracture on the right arm and she died 10 months later by sepsis due to perineal metastasis.

**Conclusion.** The medullar carcinoma can be a very aggressive form of thyroid cancer that may be associated during the last phase of evolution with endocrine paraneoplastic signs as hypercalcemia, regarded as the most frequent endocrine anomaly on cancer. In this situation, the serum levels of calcium are high even the patient has osteomalacia, possible by tumorigenic cause.

**Disclosures:** C. Poiana, None.

**CXC Chemokine Ligand-13 Stimulates RANK Ligand Expression in Squamous Cell Carcinoma.** S. Yuvaraj<sup>1</sup>, K. Sundaram<sup>1</sup>, W. L. Ries<sup>2</sup>, S. V. Reddy<sup>1</sup>. <sup>1</sup>Charles P. Darby Children's Research Institute, Medical University of South Carolina, Charleston, SC, USA, <sup>2</sup>College of Dental Medicine, Medical University of South Carolina, Charleston, SC, USA.

Head and neck squamous cell carcinoma (SCC) is the most common malignant neoplasm estimated to be more than 40,000 cases per year in the US. These malignant tumors are known to have a potent activity for local bone invasion; however the molecular mechanisms of SCC associated osteolysis is unknown. We showed subcutaneous injection of SCC 14a cells onto the surface of calvaria in NCr-nu/nu athymic mice develop tumors in 4-5 weeks. Histochemical staining demonstrated tumor cell invasion/osteolysis with a significant increase in the numbers of multinucleated TRAP positive osteoclasts at the tumor/bone interface. We identified high levels of chemokine ligand, CXCL13 and RANK ligand (RANKL), a critical osteoclastogenic factor, expression in SCC derived cell lines. Real-time PCR analysis demonstrated that recombinant hCXCL13 treatment (0-25 ng/ml) to SCC 14a cells for 48 hr increases (4-fold) RANKL expression in a dose dependent manner. Interestingly, CXCL13 also induced (2.4-fold) CXCR5 receptor expression in these cells. Western blot analysis further demonstrated that anti-CXCR5 receptor antibody inhibits CXCL13 stimulated RANKL and CXCR5 expression in SCC 14a cells. These results indicate an autocrine regulatory function for CXCL13 in SCC tumor cell invasion/osteolysis. We further examined the molecular mechanism by which CXCL13 regulates RANKL expression. CXCL13 stimulation of SCC14a cells transfected with hRANKL gene promoter-luciferase reporter plasmid demonstrated a significant increase (3.0-fold) in RANKL gene promoter activity. Transcription factors array (super array) screening by real-time PCR identified a 3.2-fold increase in c-Jun mRNA expression in CXCL13 stimulated SCC 14a cells. Also, CXCL13 significantly increased phospho-c-Jun levels in these cells. We further show that JNK (c-Jun N-terminal Kinase) inhibitor suppressed CXCL13 stimulated RANKL expression. These results suggest CXCL13 signaling stimulates RANKL expression and implicates a potential therapeutic target to prevent osteolysis associated with SCC *in vivo*.

**Osteoporosis In Elderly Fallers - Underdiagnosed and Undertreated.** E. Segal\*, N. Mative\*, L. Dvorkin\*, S. Ish-Shalom<sup>1</sup>. <sup>1</sup>Metabolic Bone Diseases Unit, Ramabam Health Care Campus, Haifa, Israel, <sup>2</sup>Department of Gerontology, Western Galilee Hospital, Nahariya, Israel.

Falls are a major risk factor for osteoporotic fractures in the elderly. The use of diagnostic and therapeutic modalities in elderly fallers in Israel has not been assessed.

**Aims:** to assess the use of bone densitometry (DXA) and osteoporosis (OP) treatment in elderly women with propensity to fall; to detect factors interfering with implementation of diagnostic and therapeutic procedures in this population.

**Patients:** 242 community dwelling women, aged 65-91, that were hospitalized in the Western Galilee hospital after a fall.

**Methods:** At hospitalization the patients (pts) were interviewed regarding medical history, previous fractures, nutritional status, DXA and the use of treatment for OP. Three months after hospital discharge a phone interview was performed with all participants. The pts were asked about diagnostic and therapeutic procedures for OP after hospital discharge.

**Results:** 50 pts (20.6%) were diagnosed with OP before hospitalization (group A); 192 pts (79.4%) were not (group B), 164 (85%) of them received a written recommendation to perform DXA examination (group B1); 28 (15%) had not (group B2).

	Group A	Group B	Significance
Age, mean $\pm$ SD	78.4 $\pm$ 8.7	78.4 $\pm$ 9.8	NS
Previous falls	30 (60%)	90 (46.9%)	NS
Previous fractures	11 (22%)	26 (16.5%)	NS
Lack of sun exposure	9 (18%)	41 (21.3%)	NS
Medication Use			
Calcium + D	43 (86%)	57 (14%)	< 0.0001
Alendronate	39 (78%)	0	
Risedronate	4 (8%)	0	

There was no significant difference between the groups in socio-economic and nutritional status, health insurance and use of medications

157 (95) of group B1 pts underwent post hospital discharge phone interview: 46 (24%) performed DXA, 24 (52%) were diagnosed with OP, 6 (13%) with osteopenia.

Of 24 OP pts 14 (58%) were treated with calcium + D before the diagnosis of OP, and all of them after diagnosis. After diagnosis 14 pts (58%) were treated with alendronate, 10 (42%) with risedronate. Of 6 osteopenic pts, 3 (50%) received calcium + D, none was treated for OP although two (30%) had previous OP fractures and according to WHO criteria had severe OP.

Of group B2 one pt (3.5%) performed DXA and was diagnosed with OP; 8 (28.5%) pts received calcium + D. Reasons for not performing DXA: 50 (26%) pts didn't ask, 24 (12.5%) not referred after asking, 28 (14.1%) refused: 13 (6.8%) due to poor health, 13 (6.8%) due to distance, 2 (1%) due to economic problems.

**Conclusion:** In spite of high rate of OP and increased fracture risk, the disease in elderly fallers is underdiagnosed and undertreated. Recommendation in hospital discharge letter may improve the rate of diagnosis and promote treatment initiation.

**Bone Strength Measurement: New Approach.** A. Bazarra-Fernandez\*. ObGyn, Juan Canalejo University Hospital Trust, La Corunna, Spain.

The bone is a physical structure having an irregular shape anisotropy. Precise in vivo measurement of trabecular bone mechanical properties is very important. A method for assessing bone mass and anisotropy is essential at all scales of measurement between the greatest and the smallest scale and over all with trabecular. Compact bone properties constitute another system with microsystems, isotropy and anisotropy and variety of cross-section. The measurement of bone mineral density by dual energy X-ray absorptiometry (DXA) has served as a fit surrogate for the measurement of bone strength. By reason of the two-dimensional nature of DXA, assumptions must be made regarding the tridimensional nature of the bones, dealing with an inference problem from a set of measurements. Therefore, it is tried to regain some information about the third dimension by building a model of the bone, which assumes axial symmetry and asymmetry. By using a model, to be arranged the parameter of this model in such a way that they best fit the data, so it is only gained information about how good the model can explain the data, but it is not gotten any information of how good this model actually is, and maybe there is a much better model. It is very difficult to make good inference of the bone strength. But there are anisotropic problems too, and therefore we will make different inferences. Therefore it is deduced, that this method seems to be very sensitive to error, and it is necessary to know how to deal with these errors, especially with the systematic errors introduced by using a parameterized model.

So, a mathematical, physical and physiological 5-dimensional model must be developed in order to gauge bone properties including geometry (2-dimensional DXA), space, time, motion and stress with a portable-computer-device

**Disclosures:** A. Bazarra-Fernandez, None.

**Quantitative MicroCT Imaging of Adipocyte Volume in Bone Marrow of Mice with High and Low Bone Mass.** D. J. Adams, R. Rydzik\*, V. Diaz-Doran\*, J. Xi\*, C. Ushiku\*. Orthopaedic Surgery, New England Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA.

The relationship between bone density and marrow fat has been of increasing interest due to observations that marrow stromal cells can differentiate either to adipocytes or osteoblasts. Although histology can allow visualization of fat using lipid stains such as oil red O and osmium tetroxide (OsO<sub>4</sub>), adipocytes may be few in number and irregularly distributed, limiting quantitative precision. To remedy this, we have developed a technique for volumetric quantitation of marrow adipocytes in excised whole bones using lipophilic OsO<sub>4</sub> staining and X-ray computed microtomography imaging (μCT). Here, the technique was applied to 10 wk old "high" C3H/HeJ (C3H) and "low" C57Bl/6J (B6) bone density mice to survey marrow fat distribution and potential correlates to site-, strain-, and gender-specific bone mass. Fluorochromes were administered 7 and 2 days prior to sacrifice to confirm site-specific differences in bone formation (C3H > B6). DXA confirmed ~12% higher whole body BMD and fat in C3H vs B6. The femora, tibiae, humeri, L3-4 vertebrae, and sternum were fixed in 10% formalin, with analysis of double labels from contralateral specimens. Morphometry was quantified at 6 μm resolution (Scanco μCT40) prior to decalcifying in 14% EDTA and staining in 2% OsO<sub>4</sub>. Whole bones were imaged again using μCT, providing 3D image arrays of the high contrast spherical adipocytes. Quantitation of fat volume, density, and distribution throughout the marrow was registered to relatively low contrast (decalcified) bone. Complete staining of adipocytes was verified histologically.

Adipocytes were very few in number within the vertebra, humerus, and sternum. In femurs, adipocytes were nearly absent at mid-diaphysis of B6, but well populated in C3H, lining the anterior endocortical border, and 5-fold greater in male vs female. At the distal femur metaphysis, fat volume was similar in C3H vs B6 females, but 8-fold higher in C3H vs B6 males. Metaphyseal fat was similar for C3H male vs female, but 5-fold higher in B6 females vs males. In tibiae, adipocytes spanned the posterior diaphysis and in greater number medially within the proximal metaphysis, where fat volume was 3-fold higher in females vs males and 2-fold higher for C3H vs B6.

C3H maintain higher osteoblast activity and lower apoptosis vs B6, as well as higher mineralization, bone formation rate, and serum IGF-I, but accompanied with relatively lower response to exogenous mechanical stimuli. These genetic differences are often specific to skeletal site and gender. For example, trabecular density at the femur metaphysis is higher in C3H vs B6 for females and equal for males, whereas marrow fat content at the same site follows the opposite relationship.

**Assessment of Fracture Risk and Treatment of Osteoporosis in Postmenopausal Women: Bone Density vs. Bone Destiny.** K. Beattie\*<sup>1</sup>, W. Bensen\*<sup>1</sup>, M. Larche\*<sup>1</sup>, A. Papaioannou<sup>1</sup>, W. Wong Pack\*<sup>1</sup>, J. D. Adachi<sup>2</sup>.

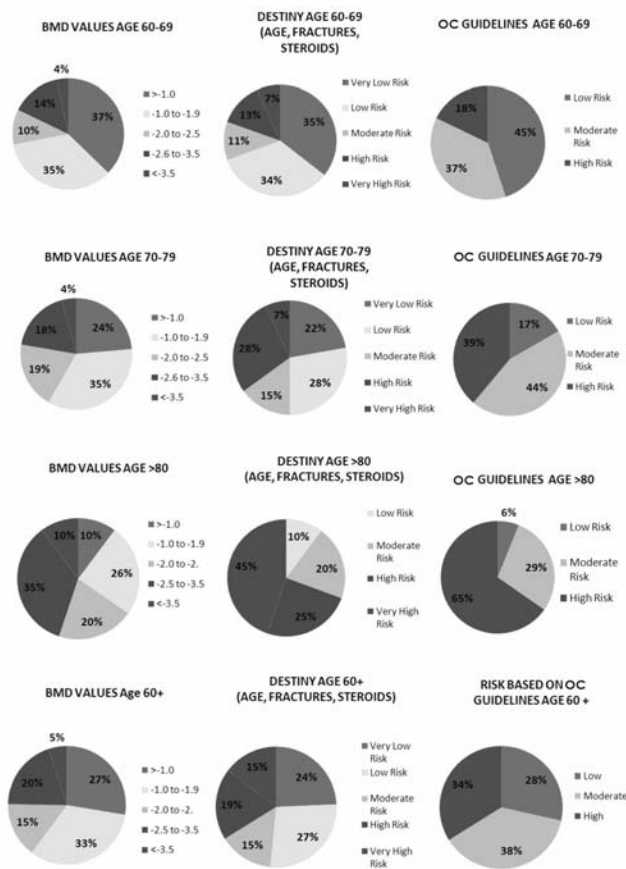

<sup>1</sup>Dept. of Medicine, McMaster University, Hamilton, ON, Canada, <sup>2</sup>Dept. of Medicine, St. Joseph's Healthcare - McMaster University, Hamilton, ON, Canada.

**Purpose:** The objective of this study was to compare the prevalence of high risk fracture patients identified as such by bone mineral density (BMD) alone, by Bone DESTINY and by Osteoporosis Canada (OC) guidelines.

**Methods:** All post-menopausal women > 60 years of age who had undergone their first ever DEXA scan during the period of June to November 2007 were included in the analyses. Based on bone density alone, women were assessed as being at high risk for fracture if they had a bone density in the osteoporotic range (T score < -2.4). These same women were also assessed for fracture risk using Osteoporosis Canada (OC) guidelines and Bone DESTINY, both of which take into account BMD, age, current glucocorticoid use > 3 months and previous fragility fracture. Colour codes were used to identify fracture risk where purple=very high risk, red=high risk, orange=moderate risk, yellow=low and green= very low. The prevalence of women in each of these groups was compared between these three differing criteria. In the BMD and Bone DESTINY data, the high risk and very high risk groups were combined to compare against the OC guideline high risk group.

**Results:** A computer database of all patients who had visited the bone density clinic within the designated time period was searched. Of those searched, 239 were post-menopausal women > 60 years old who visited the clinic for the first time; 118 (49%) were 60-69 years, 72 (30%) were 70-79 years and 49 (21%) were 80 years or older. For each age group, 3 graphs are shown comparing the distribution of females in each fracture risk group according to BMD, Bone DESTINY and OC. BMD alone typically demonstrated the lowest prevalence of women at high risk for fracture compared to DESTINY and OC guidelines which were relatively close. See graphs in Figure 1.

**Figure 1.** Prevalence of fracture risk groups as defined by BMD alone, Bone DESTINY and OC guidelines.

**Conclusions:** These results emphasize the difference between the number of women who are identified as being at high risk for fracture according to BMD alone as compared to Bone DESTINY and OC guidelines. Bone DESTINY results are easily read and interpreted and are consistent with OC guidelines.

**Validation of Bone Mineral Measurements on the New Norland Model XR-600 and XR-800 Using the BMIL QA/QC Phantom.** T. V. Sanchez<sup>1</sup>, G. Ekker<sup>2</sup>, D. K. Buckingham<sup>3</sup>, D. R. Purvis<sup>3</sup>, K. M. Dudzek<sup>3</sup>. <sup>1</sup>Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA, <sup>2</sup>Engineering and Development, Norland--a CooperSurgical Company, Fort Atkinson, WI, USA, <sup>3</sup>Research and Development, Norland--a CooperSurgical Company, Fort Atkinson, WI, USA.

The current study evaluated DXA-based measurements of bone mineral content in the BMIL QA/QC Phantom using the newly released Norland XR-600 and XR-800 scanners. The XR-600 and XR-800 measurements made over the wide range of samples available in the BMIL QA/QC Phantom were compared to measurements seen in the earlier Norland XR-46 scanner.

The commercially available BMIL QA/QC Phantom was evaluated on the three Norland scanners using AP Spine Software at 1.5 x 1.5 mm and scan speeds of 130mm/s (standard) or 65mm/s and both Research and Small Subject Software at 1.0 x 1.0 mm with a scan speed of 15mm/s. The Phantom was scanned 25 times on each setting and operator set regions of interest analyzed bone mineral for the L1, L2, L3 and L4 regions.

When analyzed the studies of L1, L2, L3 and L4 done using AP Spine at 130mm/s on the XR-46 resulted in BMC of 4.557, 15.325, 28.878 and 46.324 g/cm, respectively. Regression analysis between AP Spine mode at 130mm/s on the XR-46 and results on the XR-600 ( $y=1.0223x-0.269$ ;  $r=0.999$ ) and XR-800 ( $y=1.0328x-0.3217$ ;  $r=0.999$ ) indicated strong relationships. Regressions between AP Spine at 65mm/s on the XR-46 and results on the XR-600 ( $y=1.0019x-0.124$ ;  $r=0.999$ ) and XR-800 ( $y=1.0244x-0.0352$ ;  $r=0.999$ ) also indicated strong relationships. Similar finding were seen in regressions between Research Scan Software using the XR-46 and results on the XR-600 ( $y=1.0231x-0.1624$ ;  $r=0.999$ ) and XR-800 ( $y=1.0184x-0.0906$ ;  $r=1.000$ ) and in regression studies when using Small Subject Software on the XR-46 and the XR-600 ( $y=1.0227x-0.1486$ ;  $r=1.000$ ) or XR-800 ( $y=1.0437x-0.3808$ ;  $r=0.999$ ).

Results using the BMIL QA/QC Phantom show that, although fitted with different hardware, the Norland XR-46 and the newer Norland XR-600 and XR-800 systems measure bone mineral content similarly over the wide range found in the phantom. The study also shows the similarity continues using different scanning and analysis softwares. The study also demonstrates the value of the BMIL QA/QC Phantom in evaluating densitometry hardware and software systems.

**Disclosures:** T.V. Sanchez, None.

## SU253

**Ten-Year Fracture Risk Assessment in Norland-based Equipment in a Chinese Population.** J. Wang<sup>1</sup>, Y. Y. Zhen<sup>2</sup>, Y. Liu<sup>3</sup>, W. Y. Shi<sup>4</sup>, T. V. Sanchez<sup>5</sup>. <sup>1</sup>Research and Development, Norland--a CooperSurgical Company, Beijing, China, <sup>2</sup>Surgical Department, Beijing Haidian Hospital, Beijing, China, <sup>3</sup>Peking University Third Hospital, Beijing, China, <sup>4</sup>Research and Development, Beijing Vigor Medical Equipment Company, Beijing, China, <sup>5</sup>Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA.

Until recently the clinical interpretation of an initial DXA-based assessment involved a review of the patient T-score. More recently, however, the literature suggests complementing the T-score based assessment with a Ten-Year Fracture Risk Assessment when reviewing the need for therapy. This study examines the use of the Norland based Femur Neck T-score and a Ten-Year Fracture Risk Assessment in a population of Chinese subjects.

A total of 440 subjects who had gone to Haidian Hospital or Peking University Third Hospital in Beijing for clinical evaluation or for routine "Health Checkup" were evaluated on Norland scanners. All subjects underwent a Hip Scan and an extensive clinical history. The clinical history and the Femur Neck T-score allowed us to carry out a Ten-Year Hip Fracture Risk Assessment using the Chinese Database in the FRAX<sup>TM</sup> WHO Fracture Risk Assessment Tool. These results were then evaluated to estimate the relative impact on clinical assessments made on the basis of a T-score alone, a T-score and Ten-Year Fracture Risk Assessment or a Ten-Year Fracture Risk Assessment alone.

With regards to clinical assessment a T-score value that falls below -2.5 or a Fracture Risk Value greater than 3% would trigger consideration of aggressive therapy. Of the subjects evaluated in this study--352 subjects (80%) would not trigger to aggressive therapy based on result from both the T-score and Fracture Risk Value, 8 subjects (2%) would trigger to aggressive therapy on the T-score but not the Fracture Risk Value, 53 subjects (12%) would trigger aggressive therapy on the Fracture Risk Value but not the T-score and 27 subjects (6%) would trigger to aggressive therapy based on both the T-score and the Fracture Risk Value.

The study has demonstrated an ability to complement the T-score clinical assessment so that an additional twelve percent of subject may be identified for aggressive therapy. The study suggests that the Ten-Year Fracture Risk Assessment was useful to the clinicians trying to determine a clinical course.

## SU254

**Densitometric Vertebral Fracture Assessment in Postmenopausal Women: A Systematic Review.** O. Gajic-Veljanoski<sup>1</sup>, D. A. Butt<sup>2</sup>, D. S. Feig<sup>2</sup>, A. M. Cheung<sup>1</sup>. <sup>1</sup>University Health Network, University of Toronto, Toronto, ON, Canada, <sup>2</sup>University of Toronto, Toronto, ON, Canada.

Vertebral fractures (VFs) are the most common osteoporotic fractures, occurring in 35-50% of women 50 years and older, however, two thirds are asymptomatic. Densitometric Vertebral Fracture Assessment (DXA-VFA) is a new technology for detecting VFs and is a promising clinical alternative to lateral spine radiography because of its low radiation dose, standardized patient positioning, digital single image acquisition and semi-automated analysis.

We performed a systematic review of the literature to examine the diagnostic accuracy of DXA-VFA using lateral spine radiography as the gold standard. We systematically searched Medline, EMBASE and the Cochrane Database of Systematic Reviews (1950-April 2008), and bibliographies, and included original English-language studies assessing the detection of VFs with both DXA-VFA and spine radiography in postmenopausal women. Two reviewers independently assessed studies using validated diagnostic quality criteria. For each study, we analyzed sensitivity and specificity of DXA-VFA for detecting grade I-III VFs (per-subject and per-vertebrae) and calculated likelihood ratios (LRs).

Of 91 identified articles, 11 studies satisfied the eligibility criteria. Eight studies were considered "good" or "fair" quality, with a total study population of 1736 postmenopausal women (mean age > 64 years, body mass index: 25-27 kg/m<sup>2</sup>). The prevalence of VFs was 1.6-11% in low-risk and 14.7-98% in high-risk (osteoporotic) postmenopausal populations. For detecting grade II and III VFs in women without scoliosis, DXA-VFA showed excellent performance with sensitivities 74.4-95% and specificities 93.3-99.5% (positive LRs >13.1 using per-subject analysis). The kappa( $\kappa$ ) agreement between DXA-VFA and gold standard was 0.64-0.97. Only one study reported DXA-VFA sensitivity (50%) and specificity (96.2%) for detecting grade I VFs. Two studies included patients with scoliosis and found moderate performance for detecting any VFs (positive LRs = 4.6-5.5). Inter-observer reliability depended on the method of interpretation of VF severity ( $\kappa=0.51-0.73$  for the semi-quantitative Genant method and 0.60-0.86 for the ABQ, Melton, Eastell, McCloskey methods). The percentage of unreadable vertebrae was substantially higher in DXA scans compared to spine radiographies (5-19.5% vs. 0.5-1.5%).

Our systematic review suggests excellent diagnostic accuracy of DXA-VFA for identifying grade II and III VFs in non-obese postmenopausal women without scoliosis. More research is needed to determine the performance of DXA-VFA for detecting mild VFs in general postmenopausal populations and for detecting any VFs in scoliosis or obese populations.

**Disclosures:** O. Gajic-Veljanoski, None.

## SU255

**Lack of Correlation between Glycemic Control and Bone Mineral Density in Type 2 Diabetic Women.** B. Manwani<sup>\*</sup>, M. S. Leboff, M. Pendergrass<sup>\*</sup>, R. Garg<sup>\*</sup>. Brigham and Women's Hospital, Boston, MA, USA.

Women with type 2 diabetes mellitus (T2DM) have higher bone mineral density (BMD) compared to non-diabetic controls. In spite of that, they have a higher risk of fractures. We hypothesized that poorly controlled T2DM is associated with lower BMD after adjusting for obesity. Medical records of 1397 patients who got a dual-energy x-ray absorptiometry (DXA) scan done in the year 2006 and 2007 at the Brigham and Women's Hospital were studied. After excluding men, patients with type 1 diabetes, coexistent medical conditions like hyperparathyroidism, hyperthyroidism, multiple myeloma, history of organ transplant or chronic steroid use and other disorders affecting bone, 315 women were included in the final analysis. Characteristics of the included women are shown in table 1. On linear regression analysis there was a significant correlation between BMI and BMD parameters. However, there was no correlation between HbA1C and any of the BMD parameters (table 2). Inclusion of BMI into the linear regression model did not make a difference. These results demonstrate no significant effect of glycemic control on BMD in T2DM. However, it confirms that BMI is significantly associated with the BMD at both total hip and spine in patients with T2DM. We speculate that bone structure may be defective in patients with T2DM, thus making them more prone to fractures.

Table 1. Characteristics of patients included in the study.

Age (mean $\pm$ SD) (years)	66.8 $\pm$ 9.8
BMI (kg/sq.m)	32.2 $\pm$ 7.1
HbA1C (%)	7.2 $\pm$ 1.4
Serum Creatinine (mg/dl)	0.96 $\pm$ 0.47
Smokers (n and %)	94 (29.84%)

Table 2. Pearson's correlation between BMD parameters Vs BMI and HbA1C.

	Vs BMI		Vs A1C	
	r	p	r	p
BMD spine	0.361	<0.01	0.103	NS
T score spine	0.375	<0.01	0.040	NS
Z score spine	0.292	<0.01	-0.004	NS
BMD hip	0.459	<0.01	0.067	NS
T score hip	0.454	<0.01	0.015	NS
Z score hip	0.391	<0.01	-0.057	NS

**What Happens to the Availability of DXA if Physicians Stop Performing Them in Their Offices?** J. R. Curtis<sup>1</sup>, A. Laster<sup>\*2</sup>, D. J. Becker<sup>\*3</sup>, L. Carbone<sup>4</sup>, M. Kilgore<sup>\*3</sup>, R. Matthews<sup>\*5</sup>, M. A. Morrissey<sup>\*3</sup>, K. G. Saag<sup>1</sup>, S. B. Tanner<sup>6</sup>, E. Delzell<sup>\*5</sup>. <sup>1</sup>Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, USA, <sup>3</sup>Department of Health Care Organization and Policy, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Veterans Administration Medical Center, University of Tennessee, Memphis, TN, USA, <sup>5</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>6</sup>Department of Medicine, Vanderbilt University, Nashville, TN, USA.

**Introduction:** Reimbursement for central dual-energy x-ray absorptiometry (DXA) performed in non-facility settings (e.g. physician offices) substantially declined for Medicare beneficiaries in 2007 but was stable for DXAs performed in facilities (e.g. hospitals). The effect on the geographic availability of DXA if physicians stopped performing them in non-facility settings because of low reimbursement is unclear.

**Methods:** Using Medicare administrative claims from 1999-2006, we identified DXAs performed in non-facility and facility settings. We evaluated trends in the number of DXA tests performed and the change in the number of non-facility and facility DXA providers for each year. We then used provider zip codes to map the geographic availability of DXAs in 2006 for both types of DXA providers. We then mapped a hypothetical scenario if non-facility DXA providers stopped performing DXAs and only facility DXA providers remained.

**Results:** There were an estimated 2.88 million central DXAs performed in 2006, a 103% increase since 1999. In 2006, 69% of DXAs were performed in non-facility settings, which accounted for 77% of the sites performing DXAs. Over 1999 to 2006, there was an 106% increase in the number of non-facility DXA providers and a 53% increase in the number of facility DXA providers. The location of all DXA providers in 2006 is shown in the Figure, top panel. DXA availability if non-facility DXA providers stopped performing DXAs is shown in the Figure, bottom panel.

**Conclusion:** The majority of DXAs performed in 2006 were performed in non-facility settings (e.g. physician offices). Since 1999, the number of new non-facility providers was more than double the number of new facility providers. Ongoing analyses are evaluating the importance of the current and future geographic availability of DXA on receipt of this service.

**Impact of Varying BMD Resources on Prediction of Hip Fracture using FRAX<sup>TM</sup>.** E. McCloskey, H. Johansson\*, A. Oden\*, J. A. Kanis. WHO Collaborating Centre for Metabolic Bone Diseases, Sheffield, United Kingdom.

In many healthcare systems, including the National Health Service in the UK, widespread use of DXA is not possible and case-finding strategies are promoted. The aim of the present study was to examine the effects of the use of clinical risk factors (CRFs), BMD or the combination using the FRAX<sup>TM</sup> tool for the detection of women at risk of hip fracture.

Data from 10 prospective population based cohorts, in which BMD and CRFs were documented, were used to compute the 10-year probabilities of hip fracture calibrated to the fracture and death hazards of the UK using the FRAX<sup>TM</sup> tool. The base case examined the effects in women at the age of 65 years. Simulation samples of 1000 women were derived with BMD measurements undertaken in none, all or intermediate proportions of the population in order to identify women in whom the probability of hip fracture lay above the 10-year probability of hip fracture at which treatment became cost-effective using data previously published for the UK. For the strategies with limited use of BMD tests, the tests were targeted to those lying nearest the intervention threshold in order to maximise the positive predictive value (PPV) and hence the NNT to prevent 1 hip fracture. When women aged 65 years were assessed with CRFs, increasing the number of BMD tests, from zero up to 100% of women, increased progressively the number of women categorised at high risk and decreased the NNT. The change in NNT was non-linear. NNT was 54 with the use of CRFs alone and fell to 43 when BMD was used in 10-30% of women. When BMD tests were undertaken in all women, the NNT decreased to 33. NNT with the use of BMD alone was 47.

The combined use of BMD and CRFs outperforms the use of BMD or CRFs alone. The input of BMD as part of a FRAX<sup>TM</sup> assessment increases, therefore, the performance characteristics of fracture risk assessment. Whereas the optimal use of the FRAX<sup>TM</sup> tool is with the concurrent use of BMD tests, where resources are limited, the use of BMD tests are optimally targeted to 10-30% of women that lie closest to the intervention threshold.

**Disclosures:** E. McCloskey, None.

## SU258

**Do Different Densitometers, or Use of T-score vs. Z-score, Affect Fracture Risk Estimation?** A. Woods<sup>\*1</sup>, D. Krueger<sup>1</sup>, P. D. Miller<sup>2</sup>, S. Baim<sup>2</sup>, E. M. Lewiecki<sup>3</sup>, N. Binkley<sup>1</sup>. <sup>1</sup>Osteoporosis Clinical Research Program, University of Wisconsin, Madison, WI, USA, <sup>2</sup>Colorado Center for Bone Research, Lakewood, CO, USA, <sup>3</sup>New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

The WHO fracture risk assessment tool (FRAX<sup>TM</sup>) allows input of either the BMD T- or Z-score without regard to the manufacturer of the DXA instrument used. While the White female NHANES database is the international reference standard for femur neck (FN) T-score derivation, manufacturer specific reference databases are used to derive Z-scores and GE Lunar allows for weight adjustment. Whether women receive the same fracture probability result when scanned on different manufacturer's densitometers, and whether use of T- or Z-score alters fracture risk estimation, is not known. This study compared calculated 10-year fracture probability for women imaged on 2 different manufacturer's densitometers and evaluated the impact of T- or Z-score use on fracture risk estimation and subsequent treatment recommendation.

Femur BMD was measured in 60 postmenopausal women; mean (SD) age 62 (9.1) years and weight 142 (29.3) pounds on both Hologic (HOL) Delphi and GE Lunar Prodigy densitometers at 2 centers. Scans were performed in 2003, but analyzed with current software (GE v 11.4, HOL v 12.4), with race entered as White. T- and Z-score agreement was evaluated by linear regression. Age, height, weight, FN or total femur (TF) T-score, Z-score (with and without weight-adjustment for GE) were entered into FRAX<sup>TM</sup> to obtain 10-year fracture probability; no additional clinical risk factors were entered. Treatment was deemed appropriate if the major fracture probability was  $\geq 20\%$  or hip fracture  $\geq 3\%$ .

There is good agreement between HOL and GE for mean FN and TF T- and Z-scores. Additionally, linear regression analysis finds good agreement between HOL and GE,  $r^2$  range 0.69 - 0.95. Similar agreement is present in classifying women as appropriate for therapy regardless of whether GE or HOL T- or Z-score was used ( $p < 0.0001$ ). The same 10 women were identified as appropriate for drug therapy using FN T- and Z-scores; however, one additional woman was identified using the HOL T-score. Eight of these 10 were also identified as appropriate for therapy using the TF scores. However, using GE non-weight-adjusted Z-score 11 and 8 women were identified at the FN and TF respectively.

In conclusion, there is good between-manufacturer agreement in FN and TF T- and Z-scores in white postmenopausal women. As such, the FRAX-calculated 10-year fracture probability and subsequent treatment recommendations are similar whether a woman is imaged on a HOL or GE Lunar densitometer. Whether similar results are obtained in women of different races and in men should be evaluated.

**Disclosures:** A. Woods, None.

## SU259

**Height Loss, Vertebral Fractures and Misclassification of Osteoporosis.** W. Xu<sup>1</sup>, D. L. Medich<sup>1</sup>, G. Enright<sup>1</sup>, M. Ferchak<sup>1</sup>, B. Lane<sup>1</sup>, S. Perera<sup>2</sup>, S. L. Greenspan<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>Department of Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA.

The presence of a vertebral fracture (VF) identifies a patient who has clinical osteoporosis. However, 2/3 to 3/4 of VFs are asymptomatic. Vertebral Fracture Assessment (VFA), a DXA-derived method, assesses VFs. The objectives of this study were 1) to determine the degree of height loss in older men and women that predicts a VF, and 2) to determine if knowledge of VF will alter the classification of osteoporosis based on bone mineral density (BMD) alone. 197 men and women over the age of 65, with no previous history of osteoporosis or use of osteoporosis medications were recruited from the Claude D. Pepper Aging Registry, Benedum Geriatric Center and local advertising. Patients underwent a DXA scan of their spine (including BMD and VFA) and hip, measurement of their height by stadiometer, and a questionnaire regarding young adult peak height. BMD classification for osteoporosis was based on the World Health Organization guidelines of T-score  $\leq -2.5$  SD. The mean age of our population was 75 years old with 45% female. There was a significant association between height loss and one or more VFs (Table;  $p=0.0098$ ), but not between BMD and VFs. 37% of patients with low bone mass (osteopenia, T-score between -2.5 and -1.0 SD) and 43% of patients with normal BMD (T-score  $\geq -1.0$  SD) had one or more VFs. 34% of total participants were osteoporotic, but would have been misclassified by BMD criteria alone. We conclude height loss is an indicator for the presence of VFs. BMD criteria alone may miss older patients who have osteoporosis. VFA and presence of a VF increases the sensitivity of osteoporosis diagnosis in men and women compared to BMD criteria alone.

Table: Height Loss and Risk of Vertebral Fracture

Height Loss (inches)	Odds Ratio	95% Confidence Interval
.5	1.18	1.04-1.34
1.0	1.38	1.09-1.78
1.5	1.63	1.13-2.38
2.0	1.91	1.18-3.18
2.5	2.25	1.23-4.25
3.0	2.65	1.29-5.68

Logistic Regression Model for Risk of 1+ VF Using Height Loss as Predictor

**Regional Differences of Femoral BMD Changes after One Year Once-Monthly Ibandronate as Measured by 3D QCT.** K. Engelke<sup>1</sup>, T. Fuerst<sup>2</sup>, M. Enslin<sup>3</sup>, R. Y. Davis<sup>3</sup>, L. A. Fitzpatrick<sup>3</sup>, D. Ethgen<sup>3</sup>, H. K. Genant<sup>4</sup>. <sup>1</sup>Institute of Medical Physics, University of Erlangen, Erlangen, Germany, <sup>2</sup>Synarc, San Francisco, CA, USA, <sup>3</sup>GlaxoSmithKline, King of Prussia, PA, USA, <sup>4</sup>University of California, San Francisco, CA, USA.

**Objective:** To evaluate local BMD changes in the proximal femur as measured by 3D QCT in postmenopausal osteoporotic women after one year of oral ibandronate.

**Methods:** 93 women (age  $64 \pm 7$ ) were randomized 1:1 to receive oral once-monthly ibandronate ( $n=47$ ; 150 mg) or placebo ( $n=46$ ); all women received calcium 1000 mg/day and vitamin D 400 mg/day. 3D QCT of the proximal femur was performed at baseline and after 12 months. In the 3D QCT analysis (MIAF-Femur) cortical, subcortical and trabecular compartments of the neck, trochanter, intertrochanter and total VOIs were investigated. Extended cortical (trabecular) compartments combined subcortical and cortical (trabecular) VOIs.

Mean percentage change from baseline to month 12 was calculated in placebo and ibandronate groups, with treatment differences and 95% CIs determined by ANOVA adjusting for center and baseline value. Analyses were exploratory; post hoc  $p$  values were generated for descriptive purposes only and were not adjusted for multiple comparisons. **Results:** scans from 39 (32) subjects in the ibandronate (placebo) group were evaluable at both visits. Integral, trabecular, and cortical %BMD treatment differences (95% CI) of the total hip were 2.2% (0.7, 3.7), 4.4% (0.8, 8.0), and 0.5% (-1.2, 2.2), respectively. In contrast to cortical results, the subcortical treatment difference of 3.7% was significant as indicated by a 95% CI that does not include zero (0.96, 6.4). Apart from the femoral neck, 95% CIs of the treatment differences for extended VOIs also indicated significance (see table).

Extended VOI	% BMD changes $\pm$ SD from baseline after 12 month <sup>a</sup>	Placebo Ibandronate	% BMD Treatment Diff (95% CI) <sup>a</sup>	p
Cortical femoral neck	-0.88 (4.13)	0.52 (3.82)	1.14 (-0.50, 2.79)	0.170
Cortical total hip	-0.76 (2.81)	1.24 (3.50)	1.51 (0.02, 3.00)	0.047
Cortical trochanter	-0.64 (3.37)	2.38 (3.93)	2.41 (0.54, 4.28)	0.012
Trabecular femoral neck	-2.38 (3.95)	1.03 (5.58)	2.94 (0.12, 5.77)	0.041
Trabecular total hip	-2.53 (3.84)	2.27 (6.14)	3.98 (1.24, 6.73)	0.005
Trabecular trochanter	-2.81 (4.38)	3.87 (8.79)	5.15 (1.46, 8.85)	0.007

<sup>a</sup>unadjusted means, <sup>a</sup>adjusted for center and baseline value

**Conclusions:** Once-monthly ibandronate increases integral and trabecular BMD of the

proximal femur. This preliminary analysis indicates that BMD changes also occur in the subcortical VOI suggesting that regional differences in the hip may be responsible for increase in bone strength noted on FEA analysis.

## SU261

**Prevalence of Vertebral Compression Fracture Deformity by X-ray Absorptiometry in Patients Selected According to Simple Clinical Tests.** Z. Killinger<sup>\*</sup>, D. Cierny<sup>\*</sup>, L. Baqi<sup>\*</sup>, M. Krizko<sup>\*</sup>, J. Payer<sup>\*</sup>. 5th Department of Internal Medicine, University Hospital In Bratislava, Bratislava, Slovakia.

**Introduction:** Vertebral fracture is a severe complication of osteoporosis because of back pain, impaired quality of life and increased mortality. Despite its common severity and its value to predict further osteoporotic fractures, vertebral fractures are currently underdiagnosed. Performing spine radiographs in all patients screened for osteoporosis may be costly and time consuming. To overcome this issue lateral spine scan could be to obtain using dual energy X-ray absorptiometry (DXA), with a vertebral fracture assessment (VFA). This technique may facilitate detection of vertebral fractures, but in clinical practice is important to select appropriate patients for VFA.

**Aim of the study** was to assess the differences in vertebral fracture prevalence between patients referred for BMD testing according to standard ISCD criteria for bone densitometry (group I - so-called standard group) and a group of patients selected according to simple clinical criteria (group II or so-called high risk group).

**Methods:** Single-energy 20 s morphometry scans were performed using the Hologic Discovery densitometer. Fracture evaluation was performed semiquantitatively using the Genant classification by severity as mild, moderate or severe.

**Characteristic of patients:** We report a study of 277 patients referred for BMD testing. In group I we recruited 147 consecutive postmenopausal women (mean age 75.3 y.) and in group II 130 women (mean age 77.3 y.) selected according to following criteria: height loss of 3 cm or more or thoracic kyphosis or rib-pelvis distance less than 2 fingers or wall-occiput distance greater than 0 cm or weight less than 51kg.

**Results:** Among 147 patients from group I 32% had at least one vertebral fracture, 6% had multiple fractures. 84% of fractures in group I were classified as mild, 10% as moderate and only 6% as severe.

In group II 67% of patients had at least one vertebral fracture, 57% of patients had multiple fractures. 56% of fractures were mild, 30% moderate and 14 % severe.

In both groups together 21,7% of patients with vertebral deformities had osteopenia by WHO criteria and without VFA these high risk patients may not be offered pharmacological therapy.

**Conclusion:** Selection of patients according to described simple clinical parameters seems to be sensitive and it may be reasonable to perform VFA at least in this group of patients. Because of the need for pharmacological intervention in patients with osteopenia and asymptomatic vertebral fractures, we recommend to perform to the scan in patients with selected risk factors.

**Disclosures:** J. Payer, None.

## SU262

**Low Calcaneal Bone Mineral Density Estimated by a Periferal DXA Heel Scanner Is Associated with a High Risk to Have Had a Distal Radius Fracture.** I. Atroshi<sup>1</sup>, F. Ahlander<sup>1</sup>, M. Billsten<sup>1</sup>, D. Mellstrom<sup>2</sup>, C. Ohlsson<sup>2</sup>, O. Ljunggren<sup>3</sup>, H. G. Ahlberg<sup>4</sup>, M. K. Karlsson<sup>4</sup>. <sup>1</sup>Hässelholm Hospital, Department of Orthopaedics, Hässelholm, Sweden, <sup>2</sup>Sahlgrenska University Hospital, Departments of Internal Medicine and Geriatrics, Gothenburg, Sweden, <sup>3</sup>Academic University Hospital, Departments of Medical Science, Uppsala, Sweden, <sup>4</sup>Department of Clinical Science, Malmö University Hospital, Clinical and Molecular Osteoporosis Unit, Malmö, Sweden.

Portable DXA heel scanners have gained interest despite that they are less evaluated than total body scanners. The purpose of this study was to characterize the association between calcaneal BMD and distal forearm fracture risk in elderly women and men. Patients aged 20-80 years with a distal forearm fracture during two consecutive years, were invited to a calcaneal BMD measurement. Of 421 eligible patients, 333 participated; 270 women with a mean age of  $63 \pm 12$  years (mean  $\pm$  SD) and 64 men with a mean age of  $54 \pm 15$  years. A Calscan DXL<sup>®</sup> heel scanner estimated BMD ( $\text{g/cm}^2$ ) and T-scores. 153 women with a mean age of  $58 \pm 13$  years and 305 men with a mean age of  $74 \pm 5$  years, all population based, served as controls. As the controls included women 40-80 years and men 60-80 years, the comparison between fracture cases and controls involved these ages. The prevalence of osteoporosis was determined as well as the ability of calcaneus BMD to discriminate between the distal forearm fracture and the population-based normative cohort by receiver operating characteristic (ROC) analysis. The prevalence of osteoporosis in women aged 40-80 years with a distal forearm fracture was 32% compared with 16% in the controls (age-adjusted prevalence ratio 1.46, 95% CI 1.01-2.11,  $p=0.046$ ). The corresponding proportion in men aged 60-80 years was 44% and 6%, (age-adjusted prevalence ratio 10.5, 5.9-18.7,  $p<0.001$ ). The fracture cohort had lower age-adjusted BMD than the normative cohort, a mean difference in women of  $0.11 \text{ g/cm}^2$  (95% CI 0.10-0.13,  $p<0.001$ ) and in men of  $0.13 \text{ g/cm}^2$  (0.09-0.18,  $p<0.001$ ). One standard deviation (SD) lower BMD was associated with an odds ratio for having a distal forearm fracture of 1.8 (95% CI 1.4-2.3) in women and of 2.3 (1.6-3.3) in men. The area under the curve (AUC) in the ROC analyses was in women 0.63 (95% CI 0.57-0.69,  $p<0.001$ ) and in men 0.77 (95% CI 0.67-0.87,  $p<0.001$ ). The prevalence of osteoporosis is higher in individuals

with a distal forearm fracture than in a normative cohort. Impairment in calcaneal BMD by one SD is associated with an around doubled risk of having had a distal forearm fracture.

**Disclosures:** I. Atroshi, None.

## SU263

**Role of the Lean Muscle and Fat Mass in Hip Fractures Production.** L. del Rio, S. Di Gregorio\*, C. Sole\*, E. Bonel\*, M. Garcia\*, J. Rosales\*. Bone densitometry, CETIR.Centre Medic, Barcelona, Spain.

Low lean mass, has been associated with reduced muscle strength and lower functioning in elders. Also, the fat mass surrounding the proximal femur may help to absorb the energy generated by fall. Both variables can be accurately measured by dual-energy x-ray absorptiometry (DXA) technology.

**Subjects:** 109 female and male patients were divided into two groups, Cases group: 42 hip fracture patients (35 women and 7 men, mean age 63,2 years, mean BMI 78,5) with 29 cervical and 17 trochanter fractures) were selected by a history of low energy hip fracture in the previous six months (mean 3,4  $\pm$ 2,5 month). Control group: 67 patients (54 women and 13 men, mean age 61,9 years, mean BMI 84,1) without hip fracture or history of any condition associated with soft-tissue asymmetry in the lower extremities.

**Method:** Femur and total body DXA scans were performed using a whole body DXA model (GE-Lunar Prodigy) on all patients. BMD (g/cm<sup>2</sup>), BMC (g) and "R" value were evaluated for every femur scan. The "R" value is the ratio between low and high-energy absorptiometry coefficients, has a linear relationship with fat mass and was automatic taken in gluteus and peri-trochanteric area surrounding the hip. In total body scan, fat mass (g), lean mass (g) and bone mass (g), were evaluated from trunk, legs, hips, and whole body.

**Statistics:** Mean and standard deviation of all variables from both groups were compared by T-test, multivariable linear regression model. The results were divided in quartiles and chi-square and odds ratios were obtained from crosstab.

**Results:** Significant differences were found in legs lean mass (p=0,004), total lean mass (p=0,007) and femoral BMD (p<0,0001). Fat mass around the proximal femur did show a protective value against trochanteric hip fractures, especially in patients with a lower bone density in trochanter (p=0,027), but regional fat mass did not have a significant protective effect in femur neck fracture. The odds ratios in the lowest quartile for predicting any hip fracture were: regional fat mass 3,01; legs lean mass 2,65; total femur BMD 2,67; femoral neck BMD 3,46; and trochanter BMD 2,40.

**Conclusion:** A lower proportion of lean mass in legs is related with higher hip fracture risk, even after adjusting for BMD and this may reflect a lower muscle mass probably due to minor physical activity, which in turn leads to a higher risk of fall and subsequent fracture. Also, a lower risk fracture appeared when the proximal femur of the patients were found to be surrounded by larger amount of fat mass, with this having a protective effect against trochanteric hip fractures. In this regards the additional value of body composition capabilities of DXA may enhance the fracture risk calculation in individual patients.

**Disclosures:** L. del Rio, None.

## SU264

**FRAX™ and the Assessment of Ten-Year Fracture Probability in Hong Kong Southern Chinese According to Age and BMD Femoral Neck T-Scores.** S. W. Y. Tsang\*, A. W. C. Kung<sup>1</sup>, J. A. Kanis<sup>2</sup>, H. Johansson<sup>2</sup>, A. Oden<sup>2</sup>. <sup>1</sup>Medicine, The University of Hong Kong, Hong Kong, China, <sup>2</sup>Centre for Metabolic Bone Diseases (WHO Collaborating Centre), University of Sheffield Medical School, Sheffield, United Kingdom.

At present, studies using Asian subjects to estimate the probability of osteoporotic fracture remain sparse. Although the WHO algorithms (FRAX™) risk assessment tool has data for Chinese population, the absolute fracture risk estimated for Chinese living in mainland China may not be applicable to southern Chinese in Hong Kong because of differences in lifestyle habits and subject characteristics. The objective of this study was to estimate the 10-year probability of osteoporotic fracture in Hong Kong southern Chinese according to age and BMD T-score at the femoral neck based on the methodology of FRAX™ risk assessment tool calibrated to the epidemiology of Hong Kong. Fracture data was obtained from the Clinical Data Analysis Reporting System (CDAS) of the Hospital Authority of Hong Kong while population size and death rates were taken from the Hong Kong Government Census and Statistics Department. Fracture probability was calculated using the cut-off values for T-scores derived from the NHANES III data for Caucasian women aged 20-29 years for BMD at the femoral neck.

We found that the 10-year probability of osteoporotic fracture in Hong Kong southern Chinese men and women increased markedly with increasing age and decreasing femoral neck BMD T-score. Furthermore, the results showed that the 10-year absolute fracture risk for Hong Kong southern Chinese was substantially higher than the mainland Chinese and was comparable to Caucasians in other developed countries like USA and UK. Based on this evidence and until we have Hong Kong southern Chinese population-specific information, we recommend the application of the Caucasian risk profile to calculate the absolute fracture risk for Hong Kong southern Chinese subjects.

## SU265

**Bone Mineral Density (BMD) Measurement: an Independent Risk Factor of Breast Cancer Recurrence?** A. Sassi\*, F. Liebens\*, B. Carly\*, S. Rozenberg<sup>1</sup>, M. Tondeur<sup>2</sup>. <sup>1</sup>Department of Obstetrics and Gynaecology, CHU Saint-Pierre, Université Libre de Bruxelles, Brussels, Belgium, <sup>2</sup>Department of Nuclear Medicine, CHU Saint-Pierre, Université Libre de Bruxelles, Brussels, Belgium.

**Background :** Bone mineral density (BMD) may be seen as a marker of lifetime estrogen exposure and high BMD has been associated with an increased breast cancer risk. On the other hand, it is debated whether estrogen induced breast cancer is associated with a favourable prognosis.

**Aim :** We evaluated whether bone mineral density (BMD) measurements are associated with a higher risk of breast cancer recurrence.

**Design :** Retrospective case control matched study.

**Patients & methods:** Review of women diagnosed with breast cancer and followed since 1992. A data bank was constituted of breast cancer patients who had their vertebral or femur BMD measured. Data included prognostic indicators (TNM stage, grading, estrogen and progesterone receptor, HER2/neu, KI67) and osteoporosis risk factors. We included only patients who had their BMD measured at the time of diagnosis. Cases were defined as women with a proven breast cancer recurrence (n=22 mean age  $\pm$  SEM 54.04  $\pm$ 2.9). The controls were chosen out of a series of 254 controls. Each case was matched with two breast cancer patients without recurrence with similar age, prognostic indicators and period of follow-up (n=44, mean age  $\pm$  SEM 53.64  $\pm$ 1.9), while the BMD results and the names of the patients were blinded.

**Statistical analysis :** We calculated the mean BMD between the two controls and tested whether differences between the mean control and the case were not different from zero using paired t-test (p<0.05).

**Results & conclusions:** There were no significant differences in vertebral or femur BMD measurements between cases and controls (respectively mean  $\pm$  SEM : BMDL 1.03  $\pm$  0.02 vs 1.02  $\pm$  0.02; BMD femur 0.893  $\pm$  0.02 vs 0.873  $\pm$  0.02 g/cm<sup>2</sup>).

**Conclusions:** Although this study was only powered to detect a difference of about 7% between pairs, it is unlikely that BMD is an independent risk factor of breast cancer recurrence.

**Disclosures:** S. Rozenberg, None.

This study received funding from: IRIS Foundation.

## SU266

**Evaluation of Tibial Bone Density Surrounding Tantalum Tibial Implants in TKA.** C. Simonelli<sup>1</sup>, T. J. Gioe<sup>2</sup>, S. J. Penny<sup>3</sup>, M. C. Schoeller<sup>1</sup>, A. Harrison<sup>4</sup>. <sup>1</sup>Osteoporosis Services, HealthEast Clinics, Woodbury, MN, USA, <sup>2</sup>Orthopedic Service, Veteran's Administration, Minneapolis, MN, USA, <sup>3</sup>Medical Research, HealthEast, St. Paul, MN, USA, <sup>4</sup>Orthopedics, University of Minnesota, Minneapolis, MN, USA.

Total knee arthroplasty (TKA) with conventional metal-backed tibial implants subjects the tibial metaphysis to stress shielding, with resultant loss of bone density. The biomaterial properties of tantalum closely match that of bone. We hypothesized that tibial bone mineral density (BMD) in patients with porous tantalum (trabecular metal, TM) tibial baseplates would be maintained better than in conventional historic controls, and would more closely parallel tibial BMD in the nonoperative control limb. Forty patients (35 M/ 5 F)  $\leq$  60 years underwent TKA with uncemented TM tibial components (Zimmer NexGen®, Warsaw, IN). All perioperative and postoperative treatments were identical, and patients were allowed immediate weight-bearing. In addition to routine clinical followup with radiographs and validated scoring instruments, patients underwent dual-energy x-ray absorptiometry (DEXA) scans of the bilateral proximal tibiae with designated precision knee software (GE Lunar Prodigy Advance®, v.10.5) preoperatively, and at 2 months, 1 year and 2 years postoperatively. Three selected regions of interest (ROI) (Zone 1=between the pegs; Zone 2= beneath the pegs; Zone 3=directly below entire baseplate) were chosen to evaluate BMD using a standardized protocol. Additional ROI were used to help align the composite template on the non-operated knee. Lumbar spine and hip BMD values were also obtained preoperatively and at two years. Precision analysis revealed precision error  $\leq$  4% for each of the ROI indicating adequate power to detect BMD changes of  $\geq$  8% in an individual patient. BMD was not significantly different between the operative and nonoperative knees in any ROI at any time period. BMD decreased significantly in all ROI in the nonoperative knee at the one-and two-year evaluations (p =.004 to p=.01). Only in Zone 3 (immediately below the baseplate) did the BMD decrease significantly at 2 months (p=.03) and 2 years (p=.05) in the operative knee. This is the first report of BMD measurement surrounding a TM tibial implant utilizing the contralateral non-operative limb as a control. Although BMD decreases immediately below the baseplate at 2 months and 2 years in TM implants, similar changes occur in the nonoperative limb. Trabecular metal implants appear to maintain tibial BMD in a parallel fashion to the nonoperative limb in this population.

**Areal BMD by DXA May Predict Similar Risk of Fracture in Elderly Women and Men due to Offsetting Effects of Bone Size and True Volumetric BMD.** B. Srinivasan<sup>1</sup>, S. Amin<sup>2</sup>, B. L. Riggs<sup>1</sup>, E. J. Atkinson<sup>3</sup>, L. J. McDaniel<sup>4</sup>, L. J. Melton<sup>4</sup>, S. Khosla<sup>1</sup>. <sup>1</sup>Endocrinology, Mayo Clinic, Rochester, MN, USA, <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, MN, USA, <sup>3</sup>Biostatistics, Mayo Clinic, Rochester, MN, USA, <sup>4</sup>Epidemiology, Mayo Clinic, Rochester, MN, USA.

While the current practice in the US is to define osteopenia and osteoporosis in women and men using gender-specific T-scores, the actual areal BMD (aBMD) value by DXA seems to predict equivalent fracture risk in both sexes (Johnell et al., JBM 20:1185, 2005). Since bone size and structure differ considerably between women and men, the reason(s) why absolute aBMD by DXA has equivalent predictive ability for fracture outcomes in both sexes is somewhat unclear. To address this issue, we assessed femur neck (FN) aBMD by DXA and true volumetric BMD (vBMD) and geometry by QCT at the same site in a population-based sample of older (age  $\geq 50$  years) women (n = 157) and men (n = 68). From these subjects, we matched 58 women and 51 men for FN aBMD by DXA.

Table: Data are mean  $\pm$  SEM, p-values are adjusted for age and aBMD

	Older women	Older men	P value
Age, yrs	65.1 $\pm$ 1.3	73.3 $\pm$ 1.4	<0.001
DXA FN areal BMD, gm/cm <sup>2</sup>	0.93 $\pm$ 0.02	0.94 $\pm$ 0.02	--
FN QCT parameters			
Area, cm <sup>2</sup>	6.8 $\pm$ 0.1	9.6 $\pm$ 0.2	<0.001
Total vBMD, mg/cm <sup>3</sup>	331.0 $\pm$ 9.5	286.1 $\pm$ 7.8	<0.001
Cortical vBMD, mg/cm <sup>3</sup>	604.2 $\pm$ 13	587.0 $\pm$ 10	0.470
Trabecular vBMD, mg/cm <sup>3</sup>	202.9 $\pm$ 7.2	176.2 $\pm$ 6.0	<0.001

As shown in the Table, matching for FN aBMD resulted in the men being  $\sim 8$  yrs older than the women. As compared to the women, the men matched for FN aBMD had significantly larger bone area but lower total and trabecular FN vBMD, with similar cortical vBMD. Since both bone size and vBMD contribute to bone strength, and bigger bones have higher aBMD values by DXA due to the intrinsic artifact of this technique, our findings provide a potential explanation for the apparently fortuitous ability of absolute aBMD by DXA to predict equivalent levels of absolute fracture risk (and presumably, bone strength) in women and men: the bone strength gains due to larger bone size in the men matched for aBMD to women are offset by losses in strength due to lower true vBMD values. Additional studies using finite element modeling are needed to further define the relative contributions of bone size and vBMD to bone strength in women vs. men.

## SU268

**Prevalence of Osteoporosis in Indolent Systemic Mastocytosis.** E. van der Veer<sup>1</sup>, W. E. van der Goot<sup>2</sup>, J. G. R. de Monchy<sup>2</sup>, J. C. Kluin-Nelemans<sup>3</sup>, J. J. van Doormaal<sup>2</sup>. <sup>1</sup>Laboratory Medicine, University Medical Center Groningen, Groningen, Netherlands, <sup>2</sup>Allergy, University Medical Center Groningen, Groningen, Netherlands, <sup>3</sup>Hematology, University Medical Center Groningen, Groningen, Netherlands.

**Introduction:** Indolent Systemic Mastocytosis (ISM) is characterized by an accumulation of pathological mast cells in bone marrow. Release of histamine, tryptase, heparin and other mast cells mediators might cause bone destruction.

**Aim:** To establish the prevalence of osteoporosis in ISM-patients, and investigate whether osteoporosis in ISM-patients is accompanied by higher levels of serum tryptase and urinary histamine metabolites.

**Methods:** All patients visiting the multidisciplinary Mastocytosis Outpatient Clinic with ISM according to the WHO criteria (48 men; 66 women) were included. Bone Mineral Density (BMD) of radius, lumbar spine, and femoral neck was measured by Dual-Energy X-ray Absorptiometry. Serum tryptase and urinary methylhistamine (MH) and methylimidazole acetic acid (MIMA) were analyzed. Descriptive statistics were used to define the groups of patients that developed osteoporosis. ROC curves were made to examine the predictive value of tryptase, MH and MIMA for osteoporosis.

**Results:** Analyses were performed on 111 BMD measurements. Three patients were excluded due to lack of adequate BMD data. Osteoporosis (BMD of lumbar spine- or hip-T-score  $\leq -2.5$ SD) was detected in 24% (7/29) and 29% (5/17) of the male patients, younger respectively older than 50 years. If the radius BMD was included this percentage increased to 34% (10/29) for the younger men. For women these percentages were 12% (4/34) and 26% (8/31) respectively, and 12% and 29% if the radius BMD was included. The median ages of the older male and female ISM-group were 57 and 58 years, respectively. Only 2 men and 4 women were  $>65$  years old. Age related prevalence for osteoporosis in the Dutch population (Rotterdam-study) is 0.5% till 5% for men and 3% till 16% for women of the age-groups 55-65 years, respectively. ROC curves of female patients showed a significant test accuracy of MH (AUC=0.718; p=0.002), MIMA (AUC=0.713; p=0.003), and tryptase (AUC=0.646; p=0.049) with a BMD lumbar spine, hip or radius T-score = -2.5 SD as cut-off point. ROC curves of men showed no significance.

**Conclusions:** The prevalence of osteoporosis in ISM-patients under the age of 65 years is high, especially in men  $<50$  years. Elevated levels of MH and MIMA and to a lesser extent tryptase signal this higher risk in women, with a test accuracy of 72%, 71% and 65%, respectively, but not in men. Routine measurement of BMD should be considered in patients with indolent systemic mastocytosis in order to detect and treat osteoporosis.

**Disclosures:** E. van der Veer, None.

## SU269

**Biomechanical Impact of Chronic Haemodialysis (CHD) on Bones and Muscles. A pQCT Study.** S. Feldman\*, I. Grappiolo\*, R. F. Capozza\*, G. Inchauspe\*, B. Radice\*, P. S. Reina\*, S. Castellini\*, G. Nicola\*, F. Acosta\*, J. L. Ferretti, G. R. Cointry\*. CEMFoC, Faculty of Medicine, National University of Rosario, Rosario, Argentina.

This paper aims to describe the impact of CHD on the musculoskeletal system in men and women following biomechanical criteria. Tomographic (pQCT) indicators of bone mass (trabecular and cortical BMC -TbC, CtC-; trabecular vBMD -TbD-; cortical CSA -CtA-), tissue mineralization (cortical vBMD corrected from the partial-volume effect -CtD-), cross-sectional design (endosteal perimeter -EoPm-; cortical thickness -CtTh-; bending and torsion moments of inertia -CSMI's-) and strength (Bone Strength Indices -BSI's-; Stress-Strain Index -SSI-), and of muscle strength (height-adjusted muscle CSA, -mCSA-) were determined in tibial (4, 14, 38, and 66% sites) and radial (4 and 66% sites) scans of 21 men and 14 women aged 15-66 years under CHD. Z-scores of these data were calculated with reference to 260 healthy adults (60 men, 80 pre-MP women, 120 post-MP women) of comparable age. The pQCT data were correlated with serum PTH activity and time on dialysis (TOD).

Both CHD men and women showed significant impairments of TbC and TbD and less intense reductions of CtC, CtA, CtTh, BSI's and SSI. Bone mass loss was generally greater in women than men. EoPm was generally increased. A relatively mild impairment in CSMI's was observed, only significant in women. No changes were induced in CtD. The natural, hyperbolic relationships observed between CSMI's (y) and CtD (x) ("distribution/quality" curves, regarded as descriptive of the functional status of the bone *mechanostat* in the cortices) showed lower ordinates than normal only in the women. The mCSA was generally reduced, especially in the women. Bone mass (but not CSMI's) per unit of mCSA decayed, more severely in the women. The biomechanical changes in bone-muscle interactions were significant only in the tibial, not radial scans. All the described changes correlated significantly with both serum PTH and time on dialysis. The CHD-induced osteopenia was more severe in metaphyseal regions with thin cortices than in diaphyses, and predominantly so in the women. As long as the cortical loss seemed to have resulted predominantly from endosteal resorption, its impact on the CSMI's was relatively mild, and cortical mineralization was rather kept unaltered. The mechanical orientation of bone modeling by bone *mechanostat* as a function of mechanical usage (CSMI/CtD ratio) was affected only in women, reflecting a metabolic (not mechanical) disturbance. Bone loss was associated to PTH activity and TOD in all patients, also suggesting a metabolic disturbance. Predominance of effects in the legs may be associated with stroll-related (i.e. mechanical) problems.

## SU270

**Hip Structure Analysis (HSA) in Women - a Population Based Study.** M. F. Nielsen<sup>1</sup>, J. Ryg<sup>1</sup>, R. Barkmann<sup>2</sup>, C. C. Glüer<sup>2</sup>, K. T. Brixen<sup>1</sup>. <sup>1</sup>Endocrinology, Odense University Hospital, Odense, Denmark, <sup>2</sup>Klinik für Diagnostische Radiologie, Christian-Albrechts-Universität, Kiel, Germany.

Bone mineral density (BMD) is closely related to fracture risk (1), however, several studies have suggested that hip geometry or hip structural analysis (HSA) (2,3) may also predict fracture risk or even improve such prediction. In this study, we aimed at describing age-related changes in HSA in women.

Women aged 20-40 and 55-80 years selected at random from the population listing of Funen County, Denmark, were invited by direct mailing to participate and a total of 453 women were included in the study. Patients with prior bilateral calcaneal fractures, bilateral hip prostheses, cognitive impairment or pregnancy were excluded.

HSA was performed using a Hologic Discovery A densitometer and the recently developed APEX software (version 2.0). Comparisons were performed using T-test.

Results regarding HSA of the narrow neck in pre- and post-menopausal women are shown in table 1. Also, BMD, cross sectional area, cross sectional moment of inertia, width, section modulus correlated directly and significantly (p<0.01) with body weight (controlling for age). In contrast, buckling ratio correlated inversely and significantly (p<0.01) with body weight.

Parameter	Pre-menopausal n = 138	Post-menopausal n = 315	P	Diff. (z-score)
Age	30 [20-40]	59 [55-79]	NA	
BMD (g/cm <sup>3</sup> )	1.04 $\pm$ 0.14	0.88 $\pm$ 0.13	<0.001	-1.14
Cross sectional area (cm)	3.10 $\pm$ 0.47	2.71 $\pm$ 0.40	<0.001	-0.83
Cross sectional moment of inertia (cm <sup>2</sup> ) <sup>2</sup>	2.57 $\pm$ 0.62	2.48 $\pm$ 0.49	NS	-0.15
Width (cm)	3.13 $\pm$ 0.21	3.26 $\pm$ 0.19	<0.001	0.62
Section modulus	1.53 $\pm$ 0.30	1.35 $\pm$ 0.22	<0.001	-0.6
Buckling ratio	8.44 $\pm$ 1.55	11.17 $\pm$ 2.26	<0.001	1.76

We conclude that both BMD, cross sectional area and section modulus are significantly lower in post-menopausal compared with pre-menopausal women while width and buckling ratio of the narrow neck are significantly higher after the menopause.

## SU271

**A Clinical Prediction Rule to Identify Women for Bone Mineral Density Testing at Menopause.** G. A. Hawker, M. Lam\*, P. S. Akhavan\*, E. J. Waugh, S. Jamal, J. Susan, D. A. Sutton\*. Osteoporosis Research Program, Women's College Hospital, Toronto, ON, Canada.

Guidelines to facilitate decision making regarding BMD testing in healthy women around the time of menopause do not currently exist. The objective of this study was to develop a clinical prediction rule for BMD testing in healthy women approaching menopause (aged 40-60 years), suitable for use in primary care. Participants were healthy women aged 40-60 years, referred for a first-ever BMD test at a large urban hospital. Risk factors for low BMD were assessed by a structured self-administered questionnaire. BMD at the lumbar spine, femoral neck and total hip were assessed with DXA. DXA was performed blind to risk assessment. Predictors of low BMD (T-score  $\leq -2.0$  at any site) were determined by multivariate regression. Several algorithms were compared to identify one with the highest sensitivity and acceptable specificity, to discriminate women with/without low BMD. Among 628 participants, 69 (12.6%) had low BMD. The algorithm that recommended testing women who had 1 or more of the following risk factors: weight  $\leq 65$  kg, low trauma fracture after age 40, age at menarche  $> 15$  years, or physical inactivity during adolescence, had a sensitivity of 88.7% and a specificity of 41.3%. Using this algorithm as the decision rule, 38.4% of participants would not have been recommended for testing; among those not recommended, the likelihood of low BMD was 2.9%. A clinical prediction rule to assist in determining the need for initial BMD assessment in healthy perimenopausal women was developed. The rule recommends BMD testing in women who have 1 or more of the following risk factors: weight  $\leq 65$  kg, low trauma fracture after age 40, age at menarche  $> 15$  years, or physical inactivity during adolescence.

## SU272

**Osteoporosis: Evaluation of Screening Patterns Primary Care Group Practice.** K. Cohen\*, D. Maier\*. New West Physicians, Golden, CO, USA.

**Background:** An estimated half of all women over age 50 will have an osteoporosis-related fracture in their lifetime. National osteoporosis clinical guidelines for screening recommend measurement of bone mineral density in average-risk women beginning at age 65. Little data is available regarding compliance with this recommendation.

**Purpose:** To evaluate osteoporosis screening rates in a random sample of women, age 66 or older, in a large multi-site primary care group practice.

**Methods:** The study was conducted in a primary care group practice serving over 180,000 patients in the Denver metropolitan area. Medical records of a random sample of 833 female patients aged 66 years or older were reviewed retrospectively. Patients were seen at one of 13 practice locations, by one of 34 physicians, who practiced either family medicine or internal medicine. Main Outcome Measure: The frequency of osteoporosis screening was calculated. Accepted methods of screening include peripheral bone density measurement by ultrasound or DXA, or central DXA.

**Results:** The physician-specific osteoporosis screening rates varied widely, ranging from 19% to 97%. The practice-specific osteoporosis screening rates ranged from 26% to 91%. Overall, the mean rate of osteoporosis screening among all physicians was 56%.

**Conclusions:** Despite improvements in osteoporosis screening, there continues to be a gap in the quality of care provided compared to national recommended guidelines. Policy changes, performance improvement measures and interventions are needed to improve screening rates in primary care practices.

**Bone Mineral Density Is Associated with Lean Mass and not Fat Mass.** B. H. Arjmandi, S. Hooshmand, R. L. Saadat\*, S. C. Chai\*. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

Obese individuals hold an increased risk of several chronic and degenerative diseases such as cardiovascular disease (CVD). We have shown earlier that body mass index (BMI;  $\text{kg}/\text{m}^2$ ) values can be used as predictor of CVD risk factors. Elsewhere, we reported that a relationship exist between BMI and indices of CVD risk factors including lipid profiles and fasting blood glucose levels in postmenopausal women. To further investigate the relationship between BMI and chronic diseases, we measured C-reactive protein (CRP) level, a marker of inflammation, in 122 osteopenic, otherwise healthy postmenopausal women. These participants were divided into three groups based on their BMI values: 1) normal (18.5-24.9); 2) overweight (25-29.9); and 3) obese ( $\geq 30$ ). BMI was positively correlated with CRP ( $r=0.355$ ;  $P<0.0001$ ) in this population. In addition, overweight and obese individuals had higher serum levels of CRP compared to individuals with normal BMI (Table 1). In contrast to existing relationship between higher BMI and higher incidence of chronic diseases, epidemiological studies have shown that osteoporosis is the only chronic disease that has negative correlation with BMI. To further investigate this relation, we evaluated the correlation between BMI and bone mineral density (BMD) in this osteopenic postmenopausal population.

**Table 1:** Pearson correlation coefficients among BMI values, CRP levels and BMD; and Pearson correlation coefficients among BMD and components of body composition in osteopenic postmenopausal women

	Body Mass Index ( $\text{kg}/\text{m}^2$ )			ANOVA	
	18.5-24.9	25-29.9	$>30$	r	p
C-reactive protein (mg/dL)	1.405 $\pm$ 0.12 <sup>a</sup>	2.286 $\pm$ 0.28 <sup>b</sup>	3.156 $\pm$ 0.42 <sup>b</sup>	0.3547	$<0.0001$
BMD ( $\text{g}/\text{cm}^2$ )	1.077 $\pm$ 0.01	1.087 $\pm$ 0.01	1.119 $\pm$ 0.02	0.222	0.2
	Bone Mineral Density ( $\text{g}/\text{cm}^2$ )			ANOVA	
	18.5-24.9	25-29.9	$>30$	r	p
BMI ( $\text{Kg}/\text{m}^2$ )	18.5-24.9	25-29.9	$>30$	-	0.001
Fat (Kg)	21.367 $\pm$ 0.49	30.993.1 $\pm$ 0.701	42.110 $\pm$ 1.392	-	0.001
Lean (Kg)	35.828 $\pm$ 0.428 <sup>a</sup>	38.315 $\pm$ 0.790 <sup>b</sup>	44.084 $\pm$ 1.155 <sup>c</sup>	0.306	0.0001

Values are means  $\pm$  SEM; N=122

<sup>a,b,c</sup> Values that do not share the same superscript letters are significantly ( $P < 0.05$ ) different from each other

As expected, BMI was positively correlated with BMD (Table 1) which means a negative correlation with osteoporosis; however, when we examined the correlation between BMD and components of body composition including fat mass and lean mass; BMD was highly correlated with lean mass ( $r=0.306$ ;  $P=0.0006$ ) but not with fat mass ( $P=0.94$ ; Table 1). Although these data supports the notion that individuals with higher BMI have lower risk of osteoporosis, break down of body composition clearly demonstrate that the credit for this correlation should be given to lean mass and not fat mass.

**Disclosures:** B.H. Arjmandi, None.

## SU274

**Hip Fracture Patients with Vertebral Fractures Have More Severe Osteoporosis and Are Candidates for more Active Treatment Including PTH.** J. Browne\*, N. Maher\*, M. Healy\*, E. McGovern\*, M. C. Casey\*, J. B. Walsh. Medicine for the Elderly, St James Hospital, Dublin, Ireland.

Patients with hip fracture are at increased risk for further fracture, however prior to having a hip fracture, these patients may demonstrate additional evidence of osteoporosis and be asymptomatic. Vertebral fractures may indicate higher risk of further fracture and should be targeted for optimum fracture prevention.

This was a retrospective review of patients admitted with acute hip fracture who underwent DXA and lateral vertebral assessment (LVA). LVA is performed on all patients that present for DXA in St James Hospital. There was also a retrospective review of bone markers, PTH, vitamin D, and GFR.

Between June 2003 to October 2007, 643 patients were admitted to St James with acute hip fracture. 413 patients subsequently had a DXA scan performed. Of these patients, 9.7% had a previous hip fracture on the opposite side. 34.6% of hip fracture patients had evidence of at least one vertebral fracture, with 22.1% having at least 2 or more vertebral fractures. 55% of vertebral fractures occurred in the thoracic region.

	Differences in patients with only hip fractures and patients with both hip and vertebral fracture	
	Hip and Vertebral Fracture (n=143)	Hip Fracture only (n=270)
Age (yrs)	78.71 (+/- 9.25)	76.87 (+/- 10.56)
Spine BMD ( $\text{g}/\text{cm}^2$ )	0.853 (0.212)	0.929 (+/- 0.215)
Hip BMD ( $\text{g}/\text{cm}^2$ )	0.655 (0.142)	0.739 (+/- 0.165)
CTx (ng/ml)	0.525 (0.067)	0.516 (+/- 0.315)
Osteocalcin (ng/ml)	29.67 (+/- 29.99)	26.03 (+/- 27.1)
PTH (pg/ml)	56.47 (+/- 47.85)	48.59 (+/- 37.81)
Weight (kg)	56.79 (+/- 11.51)	60.97 (+/- 13.56)

In conclusion, over a third of patients with hip fracture have a concurrent vertebral fracture. All patients who have a hip fracture should have their vertebrae assessed. These patients were older and were significantly osteoporotic both in their remaining unfractured hip and vertebrae. PTH level tended to be raised in the vertebral fracture group however there was no difference in bone markers or vitamin D levels. Hip fracture patients who have vertebral fractures appear to be at higher risk of subsequent fracture, highlighting the need for active treatment and should be considered as potential cases for PTH therapy.

**Disclosures:** J. Browne, None.

## SU275

**Breaking an Egg-Shell; Regional Thinning of the Femoral Neck Cortex with Advancing Age Predisposes to Hip Fracture.** K. E. S. Poole<sup>1</sup>, P. M. Mayhew<sup>\*1</sup>, C. M. Rose<sup>\*1</sup>, K. Brown<sup>\*2</sup>, S. K. Kaptoge<sup>\*1</sup>, P. Bearcroft<sup>\*3</sup>, N. Loveridge<sup>\*1</sup>, J. Reeve<sup>1</sup>. <sup>1</sup>Department of Medicine, University of Cambridge, CB2 2QQ, United Kingdom, <sup>2</sup>Mindways Software Inc, Austin, TX, USA, <sup>3</sup>Department of Radiology, University of Cambridge, CB2 2QQ, United Kingdom.

**Purpose:** DXA measurements of the hip are moderately predictive of fracture but 3D measurements have the potential to predict better. This would allow clinicians to target preventive therapies to the majority of current cases who have T-scores > -2.5. In biopsy specimens, ageing was associated with thinning of the supero-posterior (SP) cortex while in intracapsular hip fracture specimens, inferior thinning was also identified. These regions are subjected to a high applied force during sideways falling. The 100 Women Study is a cross-sectional study investigating cortical thickness (C.Th) in life from 20-90 years using multi-slice CT.

**Methods:** 100 healthy women were recruited, stratified by decade from age 20 to 90 (IQR 38-72). Participants consented to an extension of a routine clinical pelvic CT scan (Siemens 64) to include both hips (1mm slice thickness, 0.59 mm voxel size). The starting position for cross sections was a 1mm thick mid-femoral neck slice at an eccentricity (max/min ratio) of 1.4, since this location along the neck axis was highly reproducible and unaffected by age (mean 51% distal, SE 0.016%), being unaffected by age. 5 parallel 1mm slices were evaluated towards the midline. Age effects on regional C.Th were evaluated using linear regression in anatomical quadrants using a fixed threshold of 450mg/cm<sup>3</sup> and Mindways Software (BIT-2). Existing measurements of post-mortem femurs using pQCT and clinical CT were used to validate BIT-2.

**Results:** There was a marked decline in estimated C.Th in the supero-posterior quadrant, from 2.0 mm at age 25 to 0.4mm aged 85 (C.Th =  $2.6 - 0.026 \times \text{Age}$ ,  $r^2 = 0.51$ ,  $p < 0.0001$ ). In contrast, age had no effect on infero-anterior C.Th ( $p = 0.79$ ). Age explained 51%, 31%, and 28% of the variance in SP, SA, and IP C.Th respectively ( $p < 0.0001$ ). Weight had a positive association with IP C.Th ( $p < 0.001$ ) that was age-independent.

**Conclusion:** The thinning of the supero-posterior femoral neck cortex, which can become egg-shell thin by the eighth decade can be estimated in-vivo. Such changes are a cause of the exponentially increased hip fracture susceptibility observed in elderly fallers. Future clinical studies of hip fracture should include measurements of cortical thickness in the proximal femur.

**Disclosures:** K.E.S. Poole, None.

## SU276

**In Vivo Assessment of 3-Dimensional Bone Micro Architecture with HR-pQCT in Patients With and Without Fractures.** H. Radspieler<sup>1</sup>, I. Frieling<sup>2</sup>, M. A. Dambacher<sup>3</sup>, M. Neff<sup>4</sup>. <sup>1</sup>Osteoporosezentrum München, München, Germany, <sup>2</sup>Osteoporosezentrum Hamburg Neuer Wall, Hamburg, Germany, <sup>3</sup>ZORG International, Zollikerberg, Switzerland, <sup>4</sup>Osteoporosezentrum Zürich, Zürich, Switzerland.

Measurement of areal bone mineral density (BMD/DXA) with derived T-scores may not be sufficient to evaluate the individual fracture risk. HR-pQCT reveals volumetric cortical and trabecular bone density and structural parameters as BV/TV, trabecular thickness and separation and cortical thickness.

We examined more than 200 women in the centres of osteoporosis in Hamburg and Munich with normal (T-Score > -1SD), osteopenic (-2.5 SD > T-score < -1.0 SD) or osteoporotic (T-score < -2.5 SD) BMD measured with DXA. In all patients volumetric BMD and trabecular architecture of the radius and tibia were measured by HR-pQCT (XtremeCT<sup>®</sup>, SCANCO Medical AG).

Women with and without fractures showed no significant differences in height and weight but in age (68 vs. 63 y). The median T-scores from DXA measurements in women with and without fractures showed no significant differences (lumbar spine: -2.2 and -2.1, total hip: -2.2 and -2.2, neck: -2.0 and -1.8, respectively).

However, selective and region specific trabecular densities as well as structure parameters measured by HRpQCT differed significantly in osteopenic and osteoporotic women with and without fractures. The mean total density was lower in women with fracture than in women without fractures (D100, 247 vs. 291 mg/ml,  $p < 0.001$ ), as well as the mean trabecular density (Dtrab, 94 vs. 123 mg/ml,  $p < 0.001$ ) and the mean inner trabecular density (Dinn, 49 vs. 75 mg/ml,  $p < 0.001$ ). Furthermore structure parameters in patients with fractures showed significantly increased trabecular separation (TbSp, 678 vs. 548  $\mu\text{m}$ ,  $p < 0.001$ ) and significantly decreased trabecular number (TbN, 1.3 vs. 1.6/mm,  $p < 0.001$ ) as well as BV/TV (7.8 vs. 10.3%,  $p < 0.001$ ) and significantly decreased cortical thickness (CtTh, 623 vs. 735  $\mu\text{m}$ ,  $p < 0.05$ ) with visible inhomogeneity of trabecular structure.

In conclusion, high-resolution peripheral computed tomography might help to predict fracture risk in osteopenic and osteoporotic patients. Especially in patients with osteopenia (according WHO-definition), the T-score seems to underestimate the fracture risk.

**Grayscale MR Image Based Finite Element Mechanical Modeling of Trabecular Bone at In Vivo Resolution.** J. F. Magland<sup>\*1</sup>, C. S. Rajapakse<sup>\*1</sup>, M. J. Wald<sup>\*1</sup>, B. Vasilic<sup>\*1</sup>, X. E. Guo<sup>\*2</sup>, X. H. Zhang<sup>\*2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>Radiology, University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Biomedical Engineering, Columbia University, New York City, NY, USA.

In addition to bone volume fraction (BV/TV), trabecular network architecture is known to significantly impact overall bone strength. Advances in imaging technology now allow images to be acquired at isotropic resolution. The purpose of this work was to explore the association of finite-element (FE)-derived compressive modulus with parameters of scale and topology. MRI of 30 distal tibia specimens from 15 donors (ages 55-85 years) were obtained with a 3D spin-echo sequence after marrow substitution with gadolinium-doped water at 1.5T field strength (128 slices at 160x160x160  $\mu\text{m}^3$ ). The data was subjected to virtual bone biopsy (VBB) processing for structural and mechanical analysis. The entire trabecular bone region was manually selected (excluding the cortex) involving the center 64 slices. FE simulations were performed on the basis of inverted grayscale bone volume fraction maps, with intensities representing fractional voxel occupancy by bone. Each voxel with greater than 20% bone volume was modeled as a single hexahedral element assuming a Young's modulus (YM) of 13 GPa and Poisson's ratio of 0.3 for pure bone. Each element's YM was chosen proportional to BV/TV. Compression in the longitudinal direction was simulated with a piecewise tri-linear equilibrium displacement function using custom-designed software, resulting in solving a sparse system of 3N linear equations in 3N variables (N = number of vertices of elements in the structure, ~2 million on average). These were solved using a preconditioned conjugate gradient algorithm programmed in C++ and run on a Linux workstation with dual quad core Xeon CPUs (3.16 GHz) and 28 GB RAM. For efficiency, four simulations ran simultaneously on separate CPUs of the same machine. Finally, the intrinsic modulus of each structure was obtained by computing surface forces from the displacement function. Each FE simulation completed in around 1 hour. Fig. 1 shows BV/TV and strain maps and association between compressive modulus and structural parameters. Of note is the significant independent contribution of the topological surface-to-curve (S/C) ratio to overall mechanical behavior showing BV/TV and S/C to explain over 90% of the variation in the elastic modulus.

**Fig. 1:** Top left: TB/TV, top right: corresponding strain maps; bottom left: Elastic modulus (MPa) versus BV/TV; bottom right: FE-computed versus predicted modulus using 2-parameter model.

## SU278

**Validating pQCT Muscle Cross-Sectional Area Measurement.** S. Kontulainen<sup>1</sup>, A. Lorbergs<sup>\*1</sup>, J. Johnston<sup>\*2</sup>. <sup>1</sup>University of Saskatchewan, Saskatoon, SK, Canada, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada.

Measurement of muscle cross-sectional area (MCSA) by peripheral QCT (pQCT) is valuable when assessing musculoskeletal adaptation to exercise, inactivity, growth or aging in healthy and clinical populations. There are several acquisition and analysis options available for MCSA but little is known about the validity of these protocols. Our aim was to compare an authenticated MCSA measure (gained using a custom-made, scans-specific (SSp) analysis protocol employing manual correction) with XCT-derived MSCA measures obtained using the recommended manufacturer protocol and modified protocols with and without selected muscle filters.

Twelve healthy volunteers (mean age 28 yrs) participated in the study. Non-dominant leg was scanned at 66% of the distance from the medial malleolus to the medial condyle of the tibia with pQCT (Stratec XCT2000). Images were obtained with recommended muscle scanning (voxel=0.8 mm, scan speed=20 mm/s) and enhanced resolution (0.4 mm and 20 mm/s) protocols. The SSp analysis protocol defined individual thresholds for fat/muscle and muscle/bone boundaries using a custom-written algorithm (Matlab 2007a). SSp MCSA was determined using commercial software (Analyze 6.0). Enhancement of the fat/muscle boundary was accomplished using an edge retaining smoothing filter (ITK Binary Min/Max Curvature Flow Filter). SSp MSCA was obtained using a region growing segmentation technique with scan-specific threshold values, followed by manual correction using a stylus and interactive touch-screen tablet (Cintiq 21UX) to ensure smooth and consistent anatomical representations. XCT6.0 software measures of MSCA were obtained using manufacturer's recommended and modified (using thresholds from SSp analysis) protocols with and without XCT muscle filters (CO1, CO2, CO4). Differences between XCT-derived MCSA values were compared to the SSp MCSA using GLM repeated measures adjusted for multiple comparisons (SPSS15.0). SSp MSCA and XCT-derived MCSA values (mean) and comparisons to the SSp (mean, % diff.) are shown in Table 1.

When using XCT2000 for MCSA analysis filtering the image was required for accurate representation of MCSA with both 0.8mm and 0.4 resolutions. These results are limited for XCT2000, used protocols and healthy young individuals. Similar comparisons are warranted for forearm muscle measurements and other populations.

## SU279

**Precision of pQCT Measurements of Bone and Muscle Area in the Forearm and Lower Limb.** A. Lorbergs<sup>\*1</sup>, S. Jackowski<sup>\*1</sup>, C. Bennett<sup>\*1</sup>, J. Johnston<sup>\*2</sup>, S. Kontulainen<sup>1</sup>. <sup>1</sup>University of Saskatchewan, Saskatoon, SK, Canada, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada.

Precise measures of bone and muscle cross-sectional areas (BCSA and MCSA) are essential in longitudinal studies assessing musculoskeletal changes. Thus, our primary objective was to assess precision of both BCSA and MCSA at forearm and lower leg with two scanning resolutions. Our secondary aim was to investigate whether precision is related to the number of scans recently trained operators have performed.

Healthy adult volunteers (28 women and 10 men, mean age 28.3 yrs, range 18-77 yrs) participated in the study. Two measurements (one day apart) of the non-dominant leg (66% of the distance from the medial malleolus to the medial condyle of the tibia) and forearm (65% of the length from the proximal head the distal margin of the styloid process of the radius) were scanned using pQCT (Stratec XCT2000). Three trained students performed

the scanning.

Recommended muscle scanning (voxel size=0.8 mm, scan speed=20 mm/s) and enhanced resolution (voxel=0.4mm) protocols were used for data acquisition. BCSA (of radius and ulna; tibia and fibula) and MCSA (forearm; lower leg) were analyzed with XCT6.0 software using contour mode 1 with a thresholds of 40 mm/cm<sup>3</sup> to separate fat from muscle and a threshold of 280 mg/cm<sup>3</sup> to separate muscle from bone. Muscle filter CO2 was used at both measured sites. Precision (CV%) was assessed for each operator and mean CVrms (%) was calculated for the each outcome according to Gluer et al (Osteoporosis Int 1995). Spearman rank correlation was used to assess relationship between order of scan and operator's precision (SPSS16.0).

In the forearm, precision of radius and ulna BCSA was 3.7 and 9.2% and precision of MCSA was 1.7% and 1.8%, when measured with the recommended and enhanced resolutions, respectively. In the lower leg, precision of tibia and fibula BCSA was 5.1 and 8.7%, and precision of MCSA was 2.9 and 3.7% with the lower and higher resolutions, respectively. Number of performed scans was only related to the BCSA precision at the forearm when measured with 0.4mm voxels size ( $r = -0.37$ ,  $p=0.02$ ).

Lower resolution seemed to provide more precise MCSA and BCSA measures. Repeatability of BCSA may be enhanced if bones were analyzed separately with another protocol. Additional scans are required to assess the number of practice scans needed to optimize precision when graduate students are trained for the pQCT measurements.

**Implications of Resolution Isotropy on Apparent Topology of Trabecular Bone Architecture in MR Images.** M. J. Wald<sup>\*1</sup>, J. F. Magland<sup>\*1</sup>, C. S. Rajapakse<sup>\*1</sup>, X. H. Zhang<sup>\*2</sup>, E. Guo<sup>2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>Department of Radiology, University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Department of Biomedical Engineering, Columbia University, New York, NY, USA.

Digital topological parameters related to the plate-strut architecture of trabecular bone (TB) derived from in vivo MR images have been shown to be sensitive to disease progression and treatment effects. Signal-to-noise limitations in micro-magnetic resonance imaging (μMRI) usually call for reduced resolution along the loading direction which can potentially compromise the sensitivity of topological parameters to microstructural changes since transversely oriented trabeculae and perforations of plate-like elements may not be detectable. Here we explore the effect of anisotropic voxel size on the digital topological parameters, in particular plates (surfaces) and rods (curves). Fifteen sets of demineralized tibia specimens (from right and left legs) were immersed in water doped with 1 mM gadolinium-DTPA and 10% formalin resulting in a medium closely matching the MRI properties of fatty marrow. The specimens were imaged using a two-channel phased-array ankle coil on a 1.5T Siemens Sonata system. A 3D fast large angle spin echo (FLASE) pulse sequence was used to acquire a 80x50x20 mm<sup>3</sup> volume at an isotropic voxel size of 160μm<sup>3</sup>. Each TB region was manually masked to remove the cortex and any trapped air inclusions. Each dataset was down-sampled along the longitudinal direction to produce datasets with 160x160x480 μm<sup>3</sup> effective resolution. These data were intensity normalized, bone volume fraction (BVf) mapped, skeletonized, and processed using digital topological analysis. The topological parameters were compared at the two resolutions. An average increase in apparent surface density of 7% was observed while the average curve density was reduced by 37% commensurate with a loss of transversely oriented trabeculae (rods). The increase in apparent surface voxels and decrease in curve voxels resulted in an increase in surface-to-curve ratio by 70% and a decrease in erosion index by 30%. The TB cores in Figures 1 b) and c) illustrate preservation of plate-like topology and rod-like trabeculae are either unresolved or become more plate-like at a reduced slice resolution. In conclusion, isotropic resolution is preferred for 3D structural analysis of TB using μMRI in order to detect changes (for example, due to osteoporosis) in rod-like trabeculae.

Figure 1. a) Mean change and standard deviation (%) of topological parameters derived from 30 specimen images due to lowering longitudinal resolution from 160 to 480μm; b, c) virtual cores at 160 and 480 μm longitudinal resolution. Plate perforations visible in b) are not seen in c).

## SU281

**New Link Between Trabecular Properties and T-score at the Human Femur.** M. Ascenzi<sup>1</sup>, N. Hetzer<sup>\*1</sup>, A. Mac<sup>\*1</sup>, A. Lomovtsev<sup>\*1</sup>, R. Rude<sup>2</sup>, A. Nattiv<sup>\*1</sup>, A. Favia<sup>\*3</sup>. <sup>1</sup>Orthopaedic Surgery, UCLA, Los Angeles, CA, USA, <sup>2</sup>Department of Medicine, University of Southern California and Orthopaedic Hospital, Los Angeles, CA, USA, <sup>3</sup>Department of Human Anatomy, University of Bari, Bari, Italy.

The cancellous microstructure in the human femur was investigated to identify parameters relevant to assessment of fracture risk. Preliminary data on independence of trabecular thickness from trabecular density by site prompted the study. The femora of twelve postmenopausal Caucasian female donors, aged 52 to 70, free from metabolic pathologies and medical therapies that can affect the bone tissue, except for postmenopausal osteoporosis, provided the material. A novel analysis of (1) trabeculae by morphometry and (2) bone mineral density (BMD) by dual energy x-ray absorptiometry (DXA), was conducted regionally. First, each proximal femur was DXA-scanned and classified by age and T-score. Second, the distal femur was scanned at the lateral, medial and central regions. Each femur was then sectioned longitudinally to expose the trabeculae, which were labeled manually and measured automatically. The mean trabecular thickness and trabecular density were calculated on a sub-division of the conventional DXA template, consistent with the trabecular patterns that span the proximal femur, and at the medial, central and lateral regions of the distal femur. At each age, the two parameters were found to vary independently from each other and dependently on both region and T-score ( $p < 0.01$  at proximal and  $p < 0.03$  at distal). A pattern of variability emerged in terms of age. Further, the two trabecular parameters allowed computation of lower bound (black in Figure that shows two regions as examples - BMD in  $\text{g/cm}^2$ ) and upper bound (white) for DXA's BMD (grey) for normal T-score (triangle) and below normal T-score (square) by age. Trabeculae at the more mechanically-stimulated sites are here conjectured to degrade more slowly with age under normal conditions, while degradation would accelerate degradation at such sites of the below normal T-score group, consistently with increased fracture risk. Application in clinical imaging technology of the newly proposed femoral template that identifies regions of relatively homogeneous microstructure, is hypothesized to provide information on the trabecular changes due to aging with presence or absence of osteoporosis. Such information offers the prospect of improved assessment of fracture risk.

**Reduction of Magnetic Resonance Image Processing Time for Assessment of Trabecular Bone Microarchitecture.** J. J. Smith, J. T. Kirby<sup>\*</sup>, M. M. Morrissey<sup>\*</sup>, J. T. Edger<sup>\*</sup>, C. M. Modlesky. Health Nutrition and Exercise Sciences, University of Delaware, Newcastle, DE, USA.

High resolution magnetic resonance imaging (MRI) can be used to assess trabecular bone microarchitecture in vivo. Because image processing can be labor intensive, identifying strategies that limit processing time is desirable. The purpose of this study was

to determine if processing a fewer number of magnetic resonance images yields acceptable estimates of trabecular bone microarchitecture in the distal femur of children. Twenty-six high-resolution axial magnetic resonance images were collected from the distal femur of 27 children (6 to 12 y) using a GE 1.5 T MRI (3D fast gradient echo sequence, reconstructed spatial resolution =  $175 \times 175 \times 700 \mu\text{m}^3$ ). The 20 most central images were analyzed for measures of trabecular bone microarchitecture [i.e., apparent trabecular bone volume to total volume (appBV/TV), trabecular number (appTb.N), trabecular thickness (appTb.Th) and trabecular spacing (appTb.Sp)] in the lateral aspect of the distal femur using a program created with Interactive Data Language (Research Systems, Inc). The average values for appBV/TV, appTb.N, appTb.Th and appTb.Sp for the entire set of images (20IM) were compared against values taken from a single image located at the middle of the image set (1IM), average values from 5 images (5IM; every fourth image), and average values from 10 images (10IM; every other image). Paired t-tests and linear regression analysis were used to assess the agreement between trabecular bone microarchitecture measures from 20IM and the other approaches in which fewer images were processed. The 10IM approach provided the best estimates of trabecular bone microarchitecture from 20IM, with no group differences ( $p > 0.05$ ) and a high proportion of the variance explained in appBV/TV ( $r^2 = 0.973$ ) appTb.N ( $r^2 = 0.97$ ), appTb.Th ( $r^2 = 0.98$ ) or appTb.Sp ( $r^2 = 0.97$ ). The 5IM approach also provided good estimates of trabecular bone microarchitecture from 20IM with no group differences ( $p > 0.05$ ) and a high degree of explained variance in appBV/TV ( $r^2 = 0.95$ ), appTb.N ( $r^2 = 0.96$ ), appTb.Th ( $r^2 = 0.95$ ) and appTb.Sp ( $r^2 = 0.96$ ). The 1IM approach provided the worst estimates of trabecular bone microarchitecture. Although there were no group differences ( $p > 0.05$ ), 1IM explained substantially less variance in BV/TV ( $r^2 = 0.740$ ), appTb.N ( $r^2 = 0.725$ ), appTb.Th ( $r^2 = 0.79$ ) and appTb.Sp ( $r^2 = 0.71$ ) from 20IM than the other approaches. The findings suggest that analyzing as few as one fourth of the magnetic resonance images collected can yield accurate estimates of trabecular bone microarchitecture from the entire image set while substantially reducing processing time.

**The Association of Urine Measures of Diet-derived Acid Excretion with Bone Loss and Fractures: The CaMos Study.** T. R. Fenton<sup>\*</sup>, D. A. Hanley, M. Eliasziw<sup>\*</sup>, S. C. Tough<sup>\*</sup>, S. Ross<sup>\*</sup>, A. W. Lyon<sup>\*</sup>. University of Calgary, Calgary, AB, Canada.

The modern diet has been purported to induce osteoporosis due to diet acid-ash, net acid excretion, altered acid-base balance which has been assumed to cause bone demineralization.

The purpose of this study was to examine the associations between urine measures of dietary acid load (pH, sodium, potassium, calcium, magnesium, phosphate, chloride, and sulfate, measured, and organic acids, calculated, in fasting morning urine samples ( $n = 795$ ) with the bone outcomes: changes in bone mineral density (BMD) (femoral neck, lumbar spine, and total hip) and fractures.

Fasting urine samples and DEXA BMD were measured at baseline and at 5-years among the Canadian Multicentre Osteoporosis Study A prospective population-based cohort study. Analyses were undertaken (multiple linear regression for changes in BMD, and logistic regression for the incidence of fractures), controlling for potential confounders eg: age, gender, family history of osteoporosis, physical activity, smoking, calcium intake, vitamin D status, hormonal status, medications, renal function, urine creatinine, change of body mass index.

There was no association between urine pH and either the change of BMD over 5-years or the incidence of fractures over 7 years. Among 11 measured associations between urine measures of dietary acid load and BMD at different sites and fragility fractures, only low urine potassium was associated with increased BMD in the lumbar spine over 5-years, percent explained variance = 4%. Urine potassium was not associated with change at the other bone sites. The finding of only one weak association between urine potassium and the change of spine BMD provided little support for the acid-ash hypothesis. It is unknown if this limited evidence was due to the absence of an association or the limitation of fasting urine samples to be assessed for diet acid load.

**Compartment Specific Genetic Analysis of Trabecular and Cortical Volumetric BMD in Men.** L. Yerges<sup>1</sup>, J. Cauley<sup>1</sup>, S. Moffett<sup>1</sup>, C. Nestlerode<sup>\*1</sup>, K. Ensrud<sup>2</sup>, C. Kammerer<sup>\*1</sup>, L. Marshall<sup>\*3</sup>, A. Hoffman<sup>\*4</sup>, T. Lang<sup>\*5</sup>, R. Ferrell<sup>\*1</sup>, E. Orwoll<sup>3</sup>, J. Zmuda<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of Minnesota, Minneapolis, MN, USA, <sup>3</sup>Oregon Health & Science University, Portland, OR, USA, <sup>4</sup>Stanford University, Palo Alto, CA, USA, <sup>5</sup>University of California, San Francisco, CA, USA.

Quantitative computed tomography (QCT) provides a 3-dimensional measure of volumetric bone mineral density (vBMD) that can resolve both trabecular and cortical bone. Little is known about the genetic determinants of compartment specific vBMD in humans.

To investigate the genetic determinants of cortical (cBMD) and trabecular vBMD (tBMD) at the femoral neck, we systematically screened candidate genes for bone metabolism in 882 Caucasian men aged  $\geq 65$  in the Osteoporotic Fractures in Men Study (MrOS). Tag SNPs from Phase I of the HapMap project, potentially functional SNPs that were either non-synonymous coding SNPs, predicted to alter transcription factor binding or within an

exon splice enhancer site were genotyped.

4108 SNPs in 371 genes were genotyped using the Illumina GoldenGate assay, met quality control criteria, and were analyzed for their association with vBMD. Analyses assumed a recessive and additive model of inheritance and adjusted for participant age and clinic. Principal components eigenanalysis was used to account for population substructure.

10 SNPs across 9 genes were associated with cBMD and 7 SNPs across 7 genes were associated with tBMD at  $p < 0.001$ . None of the SNPs associated with one bone compartment were associated with the other bone compartment at  $p < 0.001$ . For example, the most promising SNP for cBMD was an intronic SNP located in ENPP1, a gene involved in regulating bone mineralization. Specifically, a 4.8% lower cBMD was observed in those with the less common genotype compared to those with the common genotype ( $p = 0.0001$ ). However, no association with trabecular vBMD was observed ( $+0.7$ ,  $p = 0.71$ ). This SNP is associated with cBMD at the femoral shaft, but not with tBMD at the spine. Furthermore, two other SNPs in ENPP1 were associated with cortical vBMD at a less stringent significance level ( $p < 0.01$ ), but neither of these were associated with trabecular vBMD at the femoral neck. Although these findings are preliminary, these data suggest that there may be some genetic factors regulating vBMD that are compartment specific and that QCT may be a useful tool for dissecting the complex genetic architecture of the "BMD phenotype".

### Lactose Intolerance Does Not Have Effect on Bone Status in Adolescence.

S. Yamamoto<sup>1</sup>, T. Yamaura<sup>\*1</sup>, M. Kodama<sup>\*1</sup>, K. Nawata<sup>1</sup>, H. Ishida<sup>1</sup>, K. Uenishi<sup>1</sup>, M. Konishi<sup>\*2</sup>, Q. Zhou<sup>\*2</sup>. <sup>1</sup>Kagawa Nutrition University, Saitama, Japan, <sup>2</sup>GE Healthcare, Madison, WI, USA.

Adequate calcium ingestion during adolescence is necessary for developing peak bone mass and preventing osteoporosis in the future. However, a decline of lactase activity at about the beginning of Japanese adolescence and increase in associated symptoms of lactose intolerance may lead to avoidance of milk consumption. Our study aimed to examine the effect of self-diagnosed lactose intolerance on milk and calcium intake, as well as on bone status in Japanese late adolescence. A total of 2132 subjects (1369 boys and 763 girls) aged 17 or 18 years were divided into 5 groups (0, ~100, ~200, ~400 and 400~ ml/day) according to milk consumption level. All subjects completed questionnaires about milk intake, milk tolerance, and food frequency. Bone status was measured using a calcaneus quantitative ultrasound device (GE Healthcare Lunar, Achilles Insight<sup>TM</sup>). Stiffness Index (SI) was the primary result variable. Milk consumption was positively related to calcium intake in both boys ( $r = 0.656$ ,  $p < 0.001$ ) and girls ( $r = 0.531$ ,  $p < 0.001$ ). Results showed that higher milk intake was associated with higher SI, even after adjusted for exercise level. Lactose Intolerant subjects (306 boys (22.4 %) and 119 girls (15.6 %)) had lower milk and Ca intakes than tolerant subjects. However, there was no significant difference in SI between two groups in both sexes. These results imply that there may be some adaptive mechanism protecting bone in subjects with lower calcium intake level due to low milk consumption among lactose intolerant subjects.

## SU286

### Deformity of the Distal Radius Fractures Resulting From Falls in Japanese Women Over 50 Years of Age Is Closely Associated with Bone Mineral Density of the Lumbar Spine.

A. Sakai<sup>1</sup>, T. Oshige<sup>\*1</sup>, Y. Zenke<sup>\*2</sup>, M. Suzuki<sup>\*1</sup>, Y. Yamanaka<sup>\*1</sup>, T. Nakamura<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>2</sup>Department of Orthopaedic Surgery, Kagawa Rosai Hospital, Marugame, Japan.

**Purpose:** To clarify whether the degree of radiographic pre-treatment distal radius deformity resulting from falls is associated with the degree of bone mineral density (BMD) of the lumbar spine in Japanese women over 50 years of age.

**Methods:** The subjects were 125 consecutive Japanese female patients aged over 50 years with Colles' type (type A and C of AO classification) dorsally angulated distal radius fractures caused by falls. Fractures due to high-energy injuries such as traffic accidents were excluded. The degree of radius deformity was assessed on antero-posterior and lateral radiographs by measuring ulnar variance, radial inclination, and dorsal angulation at initial examination before manual repositioning of the fractured bone. BMD of the lumbar spine was measured by dual energy X-ray absorptiometry.

**Results:** There were significant differences in the respective values of ulnar variance, radial inclination, and dorsal angulation between patients with BMD values less than 70% of the mean value of young adults and those with BMD values of 70% and over. Radius deformity was significantly greater for all three parameters in the former group relative to the latter. The respective values of increased ulnar variance, decreased radial inclination, and increased dorsal angulation significantly correlated with lower BMD. Stepwise regression analysis of data of all subjects revealed that ulnar variance was significantly associated with dorsal angulation, BMD, and radial inclination. The addition of body height, body weight, body mass index, and urinary type I collagen cross-linked N-telopeptides to the regression analysis of data of a subset of patients confirmed that ulnar variance was significantly associated with BMD.

**Conclusions:** There is a significant association between BMD of the lumbar spine and radiographic radius deformity seen in low-energy distal radius fractures resulting from falls in Japanese women over 50 years of age.

### Regional Differences in the Management of Osteoporosis. The Global Longitudinal Registry of Osteoporosis In Women.

R. Lindsay<sup>\*1</sup>, P. Delmas<sup>2</sup>, S. Boonen<sup>\*3</sup>, A. Diez-Perez<sup>4</sup>, R. Dedrick<sup>\*5</sup>, K. G. Saag<sup>\*6</sup>, <sup>1</sup>Helen Hayes Hospital, New York, NY, USA, <sup>2</sup>Hôpital Edouard Herriot, Lyon, France, <sup>3</sup>Leuven University Center for Metabolic Bone Diseases, Leuven, Belgium, <sup>4</sup>Hospital del Mar, Barcelona, Spain, <sup>5</sup>UMASS Medical School, Worcester, MA, USA, <sup>6</sup>University of Alabama-Birmingham, Birmingham, AL, USA.

The purpose of the study is to compare use of diagnostic technology and osteoporosis medication in women  $\geq 55$  years of age in four geographic regions.

The Global Longitudinal registry of Osteoporosis in Women (GLOW) is an observational follow-up study of women  $\geq 55$  years recruited by 540 primary physician practices (17 sites, 10 countries). Practices typical of each region were identified by primary care networks. All non-institutionalized patients visiting the practice within the prior 2 years were eligible. Self-administered questionnaires were mailed, with a 2:1 over-sampling of women aged  $\geq 65$  years. Data collected included information on demographics; medical history; risk factors for osteoporosis-related fracture; fracture occurrence; self-report of diagnosis including bone mineral density testing and treatment with a bone medication (risedronate, etidronate, alendronate, ibandronate, pamidronate, zoledronate, raloxifene, teriparatide, tibolone, calcitonin, strontium ranelate).

Overall, 67% of the 50,226 women in the population reported having had a bone density test; frequency of testing ranged from 51% (Europe) to 85% (Canada). Reported current use of bone medications averaged 27% (range 20% in Europe to 34% in USA). Current use increased with age, and increased with clinical risk: 36% of women with FRACTURE Index<sup>®</sup> scores  $\geq 5$  (indicating a 5-year risk of non-vertebral fracture of 26%) reported taking bone-related medication. Frequencies ranged from 28% in Europe to 43% in Australia. When use was assessed by self-reported diagnosis of osteoporosis or osteopenia, frequency was 68% and 44%, respectively, with 8.7% of women without either diagnosis reporting current use.

**Table.** Bone-density testing and bone medication by region.

	Bone-density test (%)				Bone medication (%)			
	Australia	Canada	Europe	USA	Australia	Canada	Europe	USA
All women	74	85	51	78	28	31	20	34
Age >65 years	78	85	51	79	34	36	22	39
Age >75 years	74	80	44	74	42	41	24	42
Increased risk of fracture								
-Fracture history	85	87	60	80	49	46	33	47
-FRACTURE Index $\geq 5$	77	82	51	75	43	42	28	42
Self-reported diagnosis								
-Normal	63	77	37	66	11	8.9	6.7	11
-Osteoporosis	92	96	82	92	70	70	58	77
-Osteopenia	95	98	84	96	38	46	27	53

Management of osteoporosis in this population is not entirely consistent between Europe and other regions involved in GLOW. Use of bone-density testing and bone medications is lower in Europe than in other regions. Even in women with high FRACTURE Index scores, Europe appears to be more conservative than other regions in using medications.

**Bone Fragility Beyond Bone Mineral Density: A French Prospective Experience.** M. Rancier<sup>\*1</sup>, T. Maire<sup>\*1</sup>, V. Pascal-Vigneron<sup>\*1</sup>, L. Fiorani<sup>\*1</sup>, A. Bellou<sup>\*2</sup>, D. Mainard<sup>\*3</sup>, H. Coudane<sup>\*4</sup>, D. Mole<sup>\*5</sup>, G. Weryha<sup>1</sup>.

<sup>1</sup>Endocrinology, CHU Nancy-Brabois, Vandoeuvre, France, <sup>2</sup>Primary Care Department, Sau-Chu, Nancy, France, <sup>3</sup>Cot Chu, Nancy, France, <sup>4</sup>Atol Chu, Nancy, France, <sup>5</sup>CTO Clinique de Traumatologie, Nancy, France.

Osteoporosis is commonly discovered through fragility fractures. Strategic diagnosis sites are primary care units. During one year we have recorded all low energy fractures in patients attending the primary care department of the University Hospital of Nancy (France). Patients are 45 years old and over.

**Population:** 929 women (73.8 years  $\pm$  13.5), 365 men (65.4 years  $\pm$  14.3).

Complete exploration of osteoporosis was performed in 170 women and 72 men.

**Fractures:**

Women: 150 wrist; 283 femoral neck; 52 vertebra; 120 humerus; 19 pelvis; 302 other.

Men: 32 wrist; 99 femoral neck; 20 vertebra; 46 humerus; 14 pelvis; 133 other.

Fourteen double fractures; 2 triple fractures. 72% of patients experienced their first osteoporotic fracture.

**WHO classification status:** Data are summarized in table 1. 70 to 85% of patients don't have radiological osteoporosis according to the 1994 WHO definition, especially men. Data in table 2 show no influence of past fracture events. Sex difference exist at femoral site only.

**Fracture sites:** Patients with a femoral fracture have significantly lower Bone Mineral Density than those with a wrist or other fracture. In the subgroup of the previously fractured patients, no difference persists. In the subgroup with no past fracture, BMD at the femoral neck is significantly lower in femoral fractures than in all other sites. At lumbar spine, femoral and humeral fractures are associated with lower BMD (only significant for femur).

**Conclusion:** About one fourth of the patients over 45 years old treated for a low energy fracture have under a T-score under the -2.5SD threshold. Thus the imputability of bone mineral density in fragility fracture seems to be fewer than previously believed.

Table 1: WHO status according to sex and BMD site

WHO Status	Women Spine	Women Femoral	Men Spine	Men Femoral
Normal	24,1%	28,8%	34,7%	49,3%
Osteopaenia	46,5%	47,8%	41,7%	35,2%
Osteoporosis	29,4%	23,2%	23,6%	15,5%

Tables 2: WHO status repartition according to BMD site and past fractures

BMD site	Past fracture events	Normal	Osteopaenia	Osteoporosis
Spine	No	51 (30,2%)	77 (45,6%)	41 (24,2%)
Spine	Yes	15 (20,6%)	32 (43,8%)	26 (35,6%)
Femoral	No	60 (36,6%)	72 (43,9%)	32 (19,5%)
Femoral	Yes	22 (31,4%)	31 (44,3%)	17 (24,3%)

Khi Square non significant (spine and femoral)

**A Composite Bone Score with QCT Bone Measurements and Fracture History.** N. Rianon<sup>1</sup>, T. Lang<sup>2</sup>, G. Sigurdsson<sup>3</sup>, K. Siggeirsdottir<sup>\*4</sup>, G. Eiriksdottir<sup>\*5</sup>, S. Sigurdsson<sup>\*5</sup>, B. Jonsson<sup>\*6</sup>, V. Gudnason<sup>7</sup>, T. Harris<sup>\*1</sup>.

<sup>1</sup>LEDB, NIA, Bethesda, MD, USA, <sup>2</sup>Radiology, UCSF, San Francisco, CA, USA, <sup>3</sup>Medicine/Endocrinology & Metabolism, University of Iceland, Reykjavik, Iceland, <sup>4</sup>Development, Icelandic Heart Association, Kopavogur, Iceland, <sup>5</sup>Icelandic Heart Association, Kopavogur, Iceland, <sup>6</sup>Orthopedics, University Hospital, Malmo, Sweden, <sup>7</sup>Cardiovascular Genetics, University of Iceland, Reykjavik, Iceland.

The distributions of quantitative computerized tomography (QCT) measures of cortical and trabecular density, bone volume and cross-sectional area with age, gender and fracture history have been reported. How these measures aggregate and correlate with a standard BMD measure is unknown. We examined the gender-specific relationship of each QCT measures and a combined score with prevalent fractures for participants in the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-R) (mean age=77  $\pm$  6 for 2438 men & 3326 women). We contrasted the QCT measures with the relationship of QCT-derived DEXA-like BMD of total hip (TOBD) and fracture history.

Four QCT measures (standardized using gender specific Z-scores) were included in a composite score (Z4BS): vertebral trabecular BMD (VBMD); minimal cross sectional area of femur neck (MNCS); femur neck cortical thickness (volume/femur neck integral volume) (CorTh); and femur neck trabecular BMD (FNTB). Sum of the four Z scores of these measures was divided into quartiles. The lowest quartile indicated poor bone health; the middle two were combined together as moderate bone health; and the highest quartile indicated good bone health and this variable was used in age-adjusted logistic regression models. Fracture history was based on report of vertebral or wrist fracture at age 65 or older or hip fractures.

Mean BMI, height and weight were (respectively) 27  $\pm$  4, 1.8 meters  $\pm$  6, and 83 kg  $\pm$  13 in men; and 27  $\pm$  5, 1.6 meters  $\pm$  6, and 70 kg  $\pm$  13 in women. Fracture history demonstrated a negative association with Z4BS (p < 0.001 for both genders) as did all QCT measures (p < 0.001 both genders) except MNCS. However, except for MNCS, the QCT measures did

not differ significantly from each other in relation to fracture history.

The combined QCT measure was not a stronger correlate of fracture than TOBD and fracture. MNCS was not related to fracture history and had minimal impact on the Z score composite measure.

$\beta$  of Fracture History and QCT Bone Measurements (Males and Females)

## SU290

**Lean Body Mass is a Better Predictor of Bone Mineral Density than Leg Power or Grip Strength in Healthy Caucasian Adults--The Rancho Bernardo Study.** A. Afghani<sup>\*1</sup>, E. Barrett-Connor<sup>2</sup>. <sup>1</sup>Health Sciences, TUI University, Cypress, CA, USA, <sup>2</sup>Family & Preventive Medicine, University of California, San Diego, La Jolla, CA, USA.

Our aim was to investigate the associations between bone mineral density (BMD) and specific markers of muscular fitness (lean mass, leg power, and grip strength) in healthy Caucasian adults. 380 women and 284 men aged 46-80 years participated in this community-based study. Lean body mass (LBM) and BMD of the lumbar spine (L1-L4), total hip, and total body were measured using dual energy x-ray absorptiometry. Leg extensor power of each leg was measured 3 times by the Nottingham Power Rig; the mean of the dominant side was used in this study. Grip strength was measured in each hand by isometric dynamometry. Leg power (102 versus 191 watts, p<0.0001) and grip strength (22.5 versus 40 kg, p<0.0001) were lower in women than in men. Using Spearman correlations, in women, leg power and grip strength were associated with BMD at all sites (r=-0.20-0.35; p<0.001). In men, leg power (r=0.28; p<0.0001) and grip strength (r=0.19; p<0.005) were associated with hip BMD but not with spine BMD (r=0.10, p=0.09). Total body BMD in men was correlated with leg power (r=0.27; p<0.0001) and grip strength (r=0.23; p<0.0001). In stepwise multiple linear regression models adjusted for age, fat mass, leg power, and grip strength, LBM emerged as the strongest predictor of total body BMD, explaining 13% and 31% of the variance in women and men, respectively. Thus, leg extensor power and grip strength are significantly associated with hip and total body BMD but LBM was a better predictor of BMD than measured leg power or grip strength in both sexes.

**Relationship Between the Metabolic Syndrome and Bone Mineral Density in Korean Middle-Aged Women.** H. Choi<sup>1</sup>, Y. Lee<sup>\*2</sup>, I. Joo<sup>\*3</sup>, S. Kim<sup>\*1</sup>, H. Oh<sup>\*3</sup>.

<sup>1</sup>Department of Family Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>2</sup>Department of Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, <sup>3</sup>Department of Family Medicine, Kwandong University College of Medicine, Cheil General Hospital, Seoul, Republic of Korea.

**Background:** Bone mineral density (BMD) increases with body fat mass and obesity has a protective effect against osteoporosis. However, obesity-induced chronic inflammation is a key component in the pathogenesis of insulin resistance and the metabolic syndrome. It has been suggested that proinflammatory cytokines and low-grade systemic inflammation activate bone resorption and may lead to reduced bone mineral density (BMD). The objective of the current study was to determine the relationship between the metabolic syndrome and BMD.

**Methods:** This was a cross-sectional study of 510 premenopausal women and 788 postmenopausal women age of 40-78 years who had visited Health Promotion Center, Eulji University Hospital from March 2004 to May 2006. Medical history and lifestyle data were collected by a questionnaire and history taking. Basic physical examination and laboratory tests were performed after at least 12 hours of fasting. Spinal BMD was measured by dual-energy X-ray absorptiometry. The modified National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III) and the American Diabetes Association (ADA) criteria were used for the definition of the metabolic syndrome.

Analyses were adjusted for relevant covariates.

Results: Among 1,298 women, 453 (34.9%) had the metabolic syndrome. Women with the metabolic syndrome were significantly older ( $56.4 \pm 7.7$  vs.  $51.1 \pm 8.1$  years old respectively,  $P < 0.001$ ) and suffer from more of osteoporosis (24.3% vs. 18.2% respectively,  $P = 0.002$ ) than women without the metabolic syndrome. After adjusting for age, menopause status, smoking, alcohol and exercise, spine BMD was significantly lower among women with the metabolic syndrome ( $0.878 \pm 0.171$  vs.  $0.910 \pm 0.160$  g/cm<sup>2</sup> respectively,  $P = 0.007$ ). Adjusted spine BMD decreased with additional components of the metabolic syndrome, but women with all components (abdominal obesity, high blood pressure, high fasting glucose, high triglyceride, low high density lipoprotein) had higher spine BMD than women with two components. Conclusion: In middle-aged Korean women, the metabolic syndrome may be associated with reduced spine BMD.

**Normative Z-scores from the Canadian Multicentre Osteoporosis Study Youth Cohort.** W. Zhou<sup>\*1</sup>, C. Berger<sup>\*1</sup>, J. D. Adachi<sup>2</sup>, A. Papaioannou<sup>2</sup>, G. Ioannidis<sup>2</sup>, C. Webber<sup>2</sup>, S. Atkinson<sup>2</sup>, W. P. Olszynski<sup>3</sup>, J. P. Brown<sup>4</sup>, D. A. Hanley<sup>5</sup>, R. Josse<sup>6</sup>, N. Kreiger<sup>\*6</sup>, J. Prior<sup>7</sup>, S. Kaiser<sup>8</sup>, S. Kirkland<sup>8</sup>, D. Goltzman<sup>1</sup>, K. S. Davison<sup>4</sup>. <sup>1</sup>McGill Univ., Montreal, QC, Canada, <sup>2</sup>McMaster Univ., Hamilton, ON, Canada, <sup>3</sup>Univ. of Saskatchewan, Saskatoon, SK, Canada, <sup>4</sup>Laval Univ., Ste-Foy, QC, Canada, <sup>5</sup>Univ. of Calgary, Calgary, AB, Canada, <sup>6</sup>Univ. of Toronto, Toronto, ON, Canada, <sup>7</sup>Univ. of British Columbia, Vancouver, BC, Canada, <sup>8</sup>Dalhousie Univ., Halifax, NS, Canada.

The development of normative bone mineral density (BMD) data allows for the comparison of an individual's BMD to the healthy-population average. The International Society of Clinical Densitometry recommends the use of Z-scores, which are age- and sex-specific, when interpreting DXA results in children and adolescents. Therefore, the purpose of this study was to establish Z-scores for the Canadian population between the ages of 16-24 years. In the Canadian Multicentre Osteoporosis Study (CaMos) a cohort of 1001 males and females between the ages of 16-24 years were recruited to describe the natural history of bone development in this age group. Of the 1001 participants, 877 were white and 375 had previously experienced a fracture, of which 114 were classified as minimal trauma fractures. Further, more than 111 participants used inhaled glucocorticoids. There were no differences between the mean BMD of all white participants and the mean BMD in the minimal fracture or inhaled glucocorticoid user subgroups, so these groups were integrated and means and standard deviations (SD) of all white participants were used as our reference data to construct Canadian youth BMD Z-scores. Z-scores were derived for five skeletal sites using CaMos reference data by sex and for each age year. Since the majority of the data was normally distributed (85 of 90 groups; age by gender by site), z-score was defined as follows: (measured BMD - matched mean BMD)/matched SD. The figure presents the mean BMD values in the total hip BMD by sex, along with the upper bound of the 95% confidence interval. The mean (SD) total hip z-score by centre varied in young men from -0.42 (0.96) in Toronto to 0.29 (0.90) in Kingston and in women from -0.36 (1.00) in Vancouver to 0.33 (0.93) in Saskatoon.

In this study normal BMD data for the Canadian population between the ages of 16-24 years was established. This information will be valuable in helping to identify those individuals with very low BMD.

**Disclosures:** W. Zhou, None.

## SU293

**Socioeconomic Status, Bone Mineral Density Testing and Hip Fracture Rates in a Universal Health-care System.** O. S. Donescu<sup>1</sup>, D. Thiruchelvam<sup>\*2</sup>, G. A. Hawker<sup>3</sup>, S. B. Jaglal<sup>4</sup>. <sup>1</sup>Toronto Rehabilitation Institute at University of Toronto, Toronto, ON, Canada, <sup>2</sup>Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, <sup>3</sup>Division of Rheumatology, Department of Medicine, Women's College Hospital, Toronto, ON, Canada, <sup>4</sup>Department of Physical Therapy, University of Toronto, Toronto Rehabilitation Institute at University of Toronto, Toronto, ON, Canada.

The purpose of the study was to describe rates of hip fracture and BMD test utilization, by socioeconomic status (SES). This retrospective, observational cohort study used linked population-based administrative data from Ontario, Canada and SES geographical indicators from the 2001 Canadian Census. Individuals' postal codes determined residential neighborhoods average household income. The geographically based SES indicators based on median SES of all residents of a postal code were used as a proxy for individual SES. The Ontario population was divided into five groups of income ranges (quintiles) with 1 being the lowest and 5 being the highest.

Study subjects were individuals 40 years of age and older who had a hip fracture or underwent to BMD testing between April 1st, 2005 and March 31st, 2006 in Ontario. The study population included approximately 6 million individuals.

Analyses were stratified by age (40-64; 65-84 and 85-105 years old) and gender. There was a general trend of lower hip fracture rates in individuals with higher income, except in women 85 years and older (RR=1.14, 95% CI: 1.00-1.29). All trends were statistically significant ( $p < 0.01$ ), with the exception of that in men over 85 years old ( $p = 0.64$ ). Relative rates for individuals of highest SES ranged from 0.47 in men and women 40-64 years of age (95% CI: 0.30-0.64, and 0.31-0.62, respectively), to 0.91, 95% CI: 0.68-1.14 in men 85-105 years of age. A trend of higher rates of BMD test utilization was found among individuals of higher SES compared to individuals of lower SES in all age strata ( $p < 0.0001$ ). RR for individuals of highest SES ranged from 1.08 in men 40-64 years of age, 95% CI: 1.04-1.13 to 1.46 in men 85-105 years of age, 95% CI: 1.26-1.65.

Individuals of higher SES experience in general lower hip fracture rates and higher diagnostic testing rates, suggesting an inequality in access to care in a universal health-care system.

**Disclosures:** O.S. Donescu, None.

## SU294

**Prevalence of Osteoporosis and Osteopenia in Men and Women According to the Fragility Fracture Type: A Nationwide Swiss Survey.** O. Lamy<sup>1</sup>, N. Suhm<sup>\*2</sup>, K. Lippuner<sup>3</sup>. <sup>1</sup>Department of Internal Medicine, University Hospital, Lausanne, Switzerland, <sup>2</sup>Treatment Center for Musculoskeletal Diseases, University Hospital, Basel, Switzerland, <sup>3</sup>Osteoporosis Policlinic, University Hospital, Bern, Switzerland.

**Background:** The prevalence of a low BMD (T-score  $\leq -1$  SD) in postmenopausal women with a fragility fracture may vary from 70% to less than 50%. In one study (Siris ES. Arch Intern Med 2004; 164:1108-1112), the prevalence of osteoporosis was very low at 6.4%. The corresponding values in men are more rarely reported.

**Methods:** In a nationwide Swiss survey, all consecutive patients aged 50+ presenting with one or more fractures to the emergency ward, were recruited by 8 participating hospitals between 2004 and 2006. Diagnostic workup was collected for descriptive analysis.

**Results:** 3667 consecutive patients with a fragility fracture, 2797 women (73.8 $\pm$ 11.6 years) and 870 men (70.0 $\pm$ 12.1 years), were included. DXA measurement was performed in 1152 (44%) patients. The mean of the lowest T-score values was -2.34 SD in women and -2.16 SD in men. In the 908 women, the prevalence of osteoporosis and osteopenia according to the fracture type was: sacrum (100%, 0%), rib (100%, 0%), thoracic vertebral (78%, 22%), femur trochanter (67%, 26%), pelvis (66%, 32%), lumbar vertebral (63%, 28%), femoral neck (53%, 34%), femur shaft (50%, 50%), proximal humerus (50%, 34%), distal forearm (41%, 45%), tibia proximal (41%, 31%), malleolar lateral (28%, 46%), malleolar median (13%, 47%). The corresponding percentages in the 244 men were: distal forearm (70%, 19%), rib (63%, 11%), pelvis (60%, 20%), malleolar median (60%, 32%), femur trochanter (48%, 31%), thoracic vertebral (47%, 53%), lumbar vertebral (43%, 36%), proximal humerus (40%, 43%), femoral neck (28%, 55%), tibia proximal (26%, 36%), malleolar lateral (18%, 56%).

**Conclusion:** The probability of underlying osteoporosis or osteopenia in men and women aged 50+ who experienced a fragility fracture was beyond 75% in fractures of the sacrum, pelvis, spine, femur, proximal humerus and distal forearm. The medial and lateral malleolar fractures had the lowest predictive value in women, not in men.

## SU295

**Linkage and Association Study of Chromosome 1p36 with Bone Mineral Density in Southern Chinese.** H. Li\*, Q. Huang, A. Kung. The University of Hong Kong, Hong Kong, Hong Kong.

Chromosome 1p36 is a region that has previously shown good evidence of linkage to bone mineral density (BMD) in multiple studies. We aim to determine if 1p36 is linked to BMD variation in southern Chinese population by linkage analysis and to evaluate the association of the candidate genes at 1p36 with BMD by a gene-wide and tag SNP-based association study. Seven microsatellite markers with average inter-marker distance 4.3cM in 1p36 were genotyped in 1459 subjects from 306 southern Chinese families, which were ascertained through a proband with BMD Z-score  $\leq -1.28$  at either the lumbar spine or total hip. Multi-point linkage analysis was performed using the regression-based method implemented in the Merlin package. In the entire study population and female subjects, modest evidence of linkage to total hip BMD was observed at 18.04 cM (LOD = 1.762) and 17.07 cM (LOD = 1.83) respectively. Sub-group analysis in the 678 pre-menopausal women showed suggestive evidence of linkage to total hip BMD at 16.57 cM (LOD=2.93). Twenty-three tag SNPs (tSNPs) of four candidate genes (TNFRSF1B, PLOD, CNR2, and MTHFR) at 1p36 were genotyped in 1243 unrelated Chinese case-control subjects using the high-throughput Sequenom platform. The cases were individuals with low BMD (Z-scores  $\leq -1.28$ ) while the controls had high BMD (Z-score  $\geq +1.0$ ) at either the L1-4 lumbar spine or femoral neck. Allelic and genotypic associations were evaluated by Haploview and binary logistic regression implemented in SPSS respectively. Potential epistasis was tested by multifactor dimensionality reduction (MDR) and validated by conditional logistic regression. The PLOD rs7529452 (C385T; F98F) and MTHFR rs1801133 (C677T; A429E) showed significant genotypic and allelic associations with BMD at all skeletal sites measured ( $p = 0.04$ - $0.001$ ), and a promising two-locus gene-gene interaction for femoral neck BMD ( $p = 0.0013$ ; cross-validation consistency = 20/20; testing accuracy = 59.18%). The CNR2 rs2501431 (A592G; G155G) showed nominally significant allelic associations with trochanter BMD and hip BMD. Our results suggest that 1p36 is linked to BMD, and multiple genes at 1p36, individually or in combination, contribute to osteoporosis susceptibility in Chinese.

## SU296

**BMD Measurement by DXA after a Fragility Fracture Increases the Likelihood of Subsequent Osteoporosis Treatment.** A. W. Popp<sup>1</sup>, C. Semm<sup>\*1</sup>, N. Suhm<sup>\*2</sup>, O. Lamy<sup>3</sup>, K. Lippuner<sup>1</sup>. <sup>1</sup>Osteoporosis Polyclinic, University Hospital and University of Bern, Bern, Switzerland, <sup>2</sup>Treatment Centre for Musculoskeletal Diseases, University Hospital of Basel, Basel, Switzerland, <sup>3</sup>Department of Internal Medicine, University Hospital of Lausanne, Lausanne, Switzerland.

DXA is the reference method for the determination of BMD and the diagnosis of osteoporosis. Whether DXA measurement increases the likelihood of subsequent osteoporosis treatment is unknown.

In a nationwide Swiss survey, patients aged 50+ presenting with one or more fractures to the emergency ward, were recruited by 8 participating hospitals between 2004 and 2006, diagnostic workup and treatment patterns of underlying osteoporosis were collected for descriptive analysis.

In total, 4'966 consecutive male (N=1'368, mean age 69.0 yrs) and female (N=3'598, mean age 73.9 yrs) patients presented with a clinical fracture at one of the emergency wards. Of these patients, 3'667 were considered as having a fragility fracture and included in the survey.

According to predefined categories, 30.7% of the acute fractures occurred at the upper limbs (distal forearm or proximal humerus), 19.5% at the axial skeleton (spine including sacrum and ribs or pelvis), 26.4% at the lower limbs (femur or tibia) and 23.4% at another localization (including malleolar fractures).

Diagnostic workup data were available for 2615 (71.3%) patients. DXA measurement was performed in only 1152 (44.0%) of these patients. Forty-six percent of the patients had severe osteoporosis (BMD T-score  $\leq -2.5$  SD and one or more fragility fractures), 35.1% had osteopenia (T-score -1 to -2.5 SD), 14.4% were normal (T-score  $> -1$  SD), and 4.5% no available value.

The rate of subsequent treatment with a bone active substance (bisphosphonate, SERM, PTH, HRT, or calcitonin) alone or in combination with a calcium and/or vitamin D supplement was significantly higher in patients with compared to those without BMD measurement, i.e. 51.0% (463/ 908) vs. 10.8% (204/ 1889) in women, and 41.4% (101/ 244) vs. 3.2% (20/ 626) in men, respectively ( $p < 0.001$  by chi-square test).

BMD measurement by DXA vs. no BMD measurement lead to a fivefold increase in treatment with a bone active substance in women and to a more than tenfold increase in men, who presented with a fragility fracture.

The infrequent usage of BMD measurements by DXA in the routine diagnostic workup of fracture patients may contribute to explain underdiagnosis and undertreatment of osteoporosis in Switzerland, even in the high risk group of patients aged 50+ presenting with an acute fragility fracture.

**Disclosures:** A.W. Popp, None.

**Rate of Bone Loss is Greater in Young Adult Men than Women.** J. R. Shaffer<sup>1</sup>, C. M. Kammerer<sup>1</sup>, J. M. Bruder<sup>2</sup>, R. L. Bauer<sup>\*2</sup>, B. D. Mitchell<sup>3</sup>. <sup>1</sup>Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of Texas Health Science Center, San Antonio, TX, USA, <sup>3</sup>Division of Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, MD, USA.

Differences between sexes in rate and onset of bone loss, leading to differences in risk for osteoporosis, are well established in older populations. Bone loss in women is commonly thought to occur more rapidly and begin earlier (at menopause) than in men. However, recent studies have shown that substantial bone loss, particularly in trabecular bone, occurs in young adults of both sexes, but possible sex differences have not been well characterized. We examined percent change in bone mineral density (BMD) at several skeletal sites in participants of the San Antonio Family Osteoporosis Study.

Annual percent change in BMD of the femoral neck, total hip, lumbar spine, 1/3 radius, and ultradistal radius was calculated from DXA measurements taken at two time points, 5.6 years apart, in 327 young adult Mexican Americans (116 men, 211 women, ages 25-45 years at baseline). Because this sample contains related individuals, analyses were performed using maximum likelihood methods while conditioning on the familial dependence among participants. We tested whether percent change in BMD differed from zero in each sex, and whether percent change differed between men and women.

Young adult men lost BMD at the femoral neck, lumbar spine, and ultradistal radius (-0.47, -0.40, and -0.91 %/year, respectively;  $p < 10^{-4}$  for all) and gained BMD at the total hip and 1/3 radius (+0.23 and +0.28 %/yr, respectively;  $p < 0.02$  for both). Young women also gained BMD at the total hip and 1/3 radius (+0.69 and +0.68 %/yr;  $p < 10^{-10}$  for both), lost BMD at the ultradistal radius (-0.30 %/yr,  $p < 10^{-4}$ ), but had no change in femoral neck or lumbar spine BMD. However, at all skeletal sites, men experienced greater loss or smaller gain in BMD than women ( $p < 0.001$  for all). This sex difference in BMD change was also present after adjusting for age, interim menopause, body mass index (BMI), and interim change in BMI ( $p < 0.02$ ).

The loss of BMD at skeletal sites comprised of a substantial proportion of trabecular bone (femoral neck, lumbar spine, ultradistal radius) but not at sites that contain mostly cortical bone (1/3 radius) is consistent with other studies indicating that trabecular bone is lost from early adulthood, whereas cortical bone is lost later in life, and may be gained in young adults. The greater bone loss observed in young men versus young women challenges conventional wisdom regarding the sex-dependency of bone loss and subsequent risk of osteoporosis.

**Relationship between BMD of the Lumbar Spine and Knee Osteoarthritis in South Korean.** I. Park<sup>1</sup>, S. Cheon<sup>\*2</sup>. <sup>1</sup>Orthopedic Surgery, Kyungpook University Hospital, Daegu, Republic of Korea, <sup>2</sup>Orthopedic Surgery, 16th Korean Airforce Division, Yaecheon, Republic of Korea.

This is a post hoc analysis of prospective, nation-wide 13 multi-center study named "Risk Factors of Knee Osteoarthritis(OA) in Korean". Authors reviewed the relationship between BMD of the lumbar spine and knee OA in South Korean. One-hundred ninety South Korean from 40 to 64 year were evaluated by matching the age by 5 year interval. Over 65 year-old was excluded to rule out possibilities of natural aging process of knee OA. Knee OA group has 96 (male 14, female 82) persons, and control has 94 (male 24, female 70). Knee osteoarthritis was defined by both a clinical interview using OA scales of WOMAC TM 3.01 and Kellgren-Lawrence grade III or IV using bilateral posteroanterior, lateral, and tangential knee radiography. Erythrocyte sedimentation rate(ESR), cross-reacting protein(CRP), and RA factor were checked to exclude other arthritis. BMD of the lumbar spine was measured by DXA with consideration of precision error at each center. After correcting gender and age difference, there is a statistical inverse difference between the BMD of L3 spine and knee osteoarthritis by t-test ( $p=0.048$ ), and no statistical difference between whole L1-L4 spines and knee OA. But, there is a tendency that knee OA patients showed higher lumbar spine BMD than control group ( $p=0.067$ ). Knee OA group showed very strong statistical difference of higher ( $p=0.001$ ) BMI(body mass index) than control group and this may affect the tendency of higher BMD of lumbar spines in knee OA patients. Other factors also have impact the inverse relationship between BMD of lumbar spine and knee OA by other studies.

**Determinants of Trabecular and Cortical Volumetric Bone Mineral Density Differ in Men of African Ancestry.** Y. Sheu<sup>1</sup>, J. A. Cauley<sup>1</sup>, C. H. Bunker<sup>\*1</sup>, A. L. Patrick<sup>\*2</sup>, V. W. Wheeler<sup>\*2</sup>, C. L. Gordon<sup>\*3</sup>, C. M. Kammerer<sup>\*4</sup>, J. M. Zmuda<sup>1</sup>. <sup>1</sup>Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>The Tobago Health Studies Office, Scarborough, Trinidad and Tobago, <sup>3</sup>Radiology, McMaster University, Hamilton, ON, Canada, <sup>4</sup>Human Genetics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA.

Quantitative computed tomography (QCT) is a 3-dimensional imaging technique that distinguishes trabecular (TRAB) from cortical (CRT) bone and provides a measure of volumetric bone mineral density (vBMD). Few studies have examined the factors related to vBMD in men, especially in men of African ancestry. We evaluated comprehensively the relationship of TRAB and CRT vBMD (measured at the radius and tibia skeletal sites) with age, anthropometric, medical and behavioral factors in a large cohort of Afro-Caribbean men (n=1,901) aged 40 years and above from the Tobago Bone Health Study. Cross-sectionally, mean TRAB vBMD at both sites decreased significantly before age 50 (4-9%, p=0.01) and then remained constant or decreased slightly thereafter. In contrast, mean CRT vBMD decreased steadily with advancing age. In general, multiple linear regression analyses identified advanced age, smoking, and prostate cancer as major correlates of lower vBMD. Men with type 2 diabetes had higher vBMD, but the effect was much larger for TRAB versus CRT bone. Other relationships with covariates also differed between CRT and TRAB vBMD, and between skeletal sites. For example, body weight was positively correlated with TRAB vBMD but negatively correlated with CRT vBMD. Identified correlates for each site explained approximately 6-10% variation in TRAB vBMD and 13-16% variation in CRT vBMD. Our findings suggest that there are different age patterns and correlates for TRAB and CRT vBMD in men of African ancestry emphasizing the importance of examining the type of bone separately.

**Cortical Bone Mass and Structure in Older Afro-Caribbean and Caucasian Men.** Y. Sheu<sup>1</sup>, J. A. Cauley<sup>1</sup>, V. W. Wheeler<sup>\*2</sup>, M. Petit<sup>\*3</sup>, K. E. Ensrud<sup>3</sup>, A. L. Patrick<sup>\*2</sup>, C. H. Bunker<sup>\*1</sup>, C. L. Gordon<sup>\*4</sup>, L. M. Marshall<sup>5</sup>, E. S. Orwoll<sup>5</sup>, J. M. Zmuda<sup>1</sup>. <sup>1</sup>Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>The Tobago Health Studies Office, Scarborough, Trinidad and Tobago, <sup>3</sup>VA Medical Center & University of Minnesota, Minneapolis, MN, USA, <sup>4</sup>Radiology, McMaster University, Hamilton, ON, Canada, <sup>5</sup>Oregon Health & Sciences University, Portland, OR, USA.

In contrast to dual-energy x-ray absorptiometry (DXA), peripheral quantitative computed tomography (pQCT) measures cortical volumetric BMD (vBMD) and bone structure. Little is known about racial differences in pQCT measures of cortical bone mass and structure in men. We tested the hypothesis that racial differences in cortical bone mass and structure would be independent of differences in body size and composition by investigating data from 1150 Caucasian American men in the Osteoporotic Fractures in Men Study and 452 Afro-Caribbean men in the Tobago Bone Health Study. All men were aged 65 years and older. Cortical vBMD, cortical bone mineral content (BMC), total cross-sectional area (CSA), cortical thickness (THK), and section modulus (SM) at the radius and tibia were measured by pQCT (Stratec XCT-2000). Body fat and non-bone lean mass were measured by DXA (Hologic QDR 4500). Age, height, body fat and tibia length were higher in Caucasian than Afro-Caribbean men whereas radius length and prevalence of diabetes, smoking and physical activity were lower in Caucasians (all p<0.003). However, whole body lean mass did not differ between the two groups. After adjusting for these variables, cortical vBMD, BMC, SM and total CSA were significantly greater at both the radius and tibia in Afro-Caribbean than Caucasian men (Table). Cortical THK was greater in Caucasian men only at the tibia. However, racial differences were most apparent in SM and were relatively greater in Afro-Caribbean men at the weight-bearing tibia (+17%) than at the radius (+10%). Thus, compared with Caucasians, men of African ancestry have greater cortical bone mass which does not appear to be explained by differences in body size, composition, or physical activity. In addition, bone mass is distributed further from the central axis of the long bones leading to more favorable bone geometry in Afro-Caribbean men. Further studies are needed to identify the factors contributing to racial differences in measures of cortical bone structure in men.

	Radius		Tibia	
	Caucasian	Afro-Caribbean	Caucasian	Afro-Caribbean

**Effects of Exercise and Milk Intake on Bone in Adolescents.** K. Nawata<sup>\*1</sup>, M. Kodama<sup>\*1</sup>, T. Yamaura<sup>\*1</sup>, S. Yamamoto<sup>1</sup>, H. Ishida<sup>1</sup>, K. Uenishi<sup>1</sup>, M. Konishi<sup>2</sup>, Q. Zhou<sup>2</sup>. <sup>1</sup>Kagawa Nutrition University, Saitama, Japan, <sup>2</sup>GE Healthcare, Madison, WI, USA.

Adolescence is an important period for achieving adequate bone mass. The study was aimed at assessing how exercise and milk intake effected bone status in adolescents longitudinal observations. We measured bone status at the os calcis using quantitative ultrasound (QUS, GE Healthcare Achilles Insight TM) and assessed diet and other lifestyle factors using questionnaires annually for 5 years. All subjects (aged 12.6 ±0.6years) attending the first years were recruited for this study and follow-up to the after five years. In total, 226 boys and 180 girls students were observed every year. In boys, mean stiffness index (SI) was 82.0 at the first years and 114.5 at the after five years(increased 40.3±19.8%). Multiple regression analyses revealed that SI increased in boys significant positive related with the mean frequency of exercise in a week and mean daily milk intake during the 5 years (p<0.05); In girls, on the other hand, mean SI was 85.9 at the first year and 104.2 at the after 5 years (increased 22.6±18.9%). Multiple regression analyses revealed that the increase in SI in girls significant positive correlated with the mean frequency of exercise (p<0.05), but no significant correlation with mean daily milk intake (p>0.05). For the girls, analysis results revealed that, in those students who had SI below 78.0 (25 %) in the first year, their SI increased during following 5-year period had no significant relationship with the frequency of exercise, although there is a significant positive correlation with the frequency of milk intake. This longitudinal study indicate that frequent of exercise is important for bone growth in all adolescent boys and girls; Daily milk intake is important for adolescent boys and especially for low SI adolescent girls.

## SU302

**Volumetric Bone Parameters in Relation to Fracture History in Healthy Men at the Age of Peak Bone Mass.** H. Zmierzczak<sup>1</sup>, B. Lapauw<sup>\*2</sup>, Y. Taes<sup>\*2</sup>, S. Goemaere<sup>1</sup>, J. Kaufman<sup>2</sup>. <sup>1</sup>Unit for Osteoporosis and Metabolic Bone Diseases, Ghent University Hospital, Ghent, Belgium, <sup>2</sup>Endocrinology, Ghent University Hospital, Ghent, Belgium.

The present cross-sectional, population-based study investigates volumetric bone mineral density (vBMD) and bone geometry in relation to prevalent self-reported clinical fractures in a sib-pair setting of young healthy male subjects (n = 677) at the age of peak bone mass (25-45 yr).

Cortical bone parameters of the radius and tibia at the 66% site (2/3 of bone length from distal) of the dominant limbs were assessed using peripheral quantitative computed tomography (XCT2000, Stratec GmbH). Trabecular bone parameters of the radius at the non-dominant limb were assessed at the 4% site. Fracture history was obtained from patient recall. Differences in volumetric bone parameters between participants with an without prevalent fractures were investigated using linear mixed-effects modeling analyses, accounting for the interdependence of measurements within siblings. Subjects with diseases or clinical conditions, including hormonal and other laboratory parameters, known to affect bone metabolism, were excluded.

Thirty three % of the participants reported one or more fracture, of which 16% sustained wrist, 5% shoulder, 4% humerus, 7% lower limb and 1% rib fracture. Four participants reported a hip fracture (0.6%) after major trauma. Finger, toe and cranial fractures were excluded from the analysis. No differences in weight, height or age between participants with or without previous fracture were observed (all P > 0.35). Descriptives of volumetric bone parameters are given in the table below.

		With fracture (n=226)	Without fracture (n=451)	p
Radius	Trabecular vBMD (mg/cm <sup>3</sup> )	223 ± 39	231 ± 40	0.019
	Cortical vBMD (mg/cm <sup>3</sup> )	1095 ± 36	1103 ± 35	0.009
	Cortical thickness (mm)	2.47 ± 0.31	2.55 ± 0.32	0.001
	Periosteal circumference (mm)	48.3 ± 3.8	48.1 ± 3.7	0.324
Tibia	Cortical vBMD (mg/cm <sup>3</sup> )	1109 ± 24	1114 ± 24	0.022
	Cortical thickness (mm)	4.47 ± 0.60	4.55 ± 0.54	0.194
	Periosteal circumference (mm)	94.9 ± 5.5	94.7 ± 6.2	0.557

In conclusion, we found that healthy men with a history of fractures presented with lower trabecular and cortical vBMD, as well as with smaller cortical thickness at the radius. No differences in periosteal bone circumference were observed. The lower level of mineralization is associated with fracture history independently of bone size and might contribute to a greater future fracture risk. As diseases or clinical conditions affecting bone metabolism were excluded, the degree of mineralization is presumed to be determined by subclinical or genetic factors.

**Baseline Assessment of Osteoporosis Risk in Oklahoma Native American Women.** B. J. Smith<sup>1</sup>, M. Leyva<sup>\*2</sup>, C. E. Aston<sup>\*2</sup>, L. D. Stephens<sup>\*2</sup>, M. Z. Baker<sup>\*3</sup>. <sup>1</sup>Department of Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, <sup>2</sup>General Clinical Research Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA, <sup>3</sup>Department of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA.

Osteoporosis is estimated to afflict 1 out of 2 women over the age of 50 y. These estimates are based primarily on Caucasian populations with limited information on Native Americans. Native American women may be considered high risk for osteoporosis-related fractures due to lifestyle factors (e.g. physical activity, dietary calcium and vitamin D intake) in conjunction with the incidence of diabetes. This study was designed to begin to examine the prevalence of osteoporosis in Native American women and to assess various lifestyle factors and medical conditions that influence the rate of bone loss and consequent risk for osteoporosis. Native American women aged, 50+ years, who were eligible for services at Indian Health Clinics in the Oklahoma City area were recruited for the study. Participants underwent a baseline osteoporosis risk assessment (i.e. medical history, whole body, hip, spine and forearm DXA scans, anthropometrics and calcium intake assessment). Baseline demographic data (n=77) were: age (62 ± 9), BMI (29 ± 5), waist:hip ratio (0.9 ± 0.1), and years postmenopausal (15.0 ± 3.8). Self-reported osteoporosis was 14.3%, previous vertebral fractures (3.8%), hip fracture (3.8%), and wrist fractures (3.8%). Additionally, 28.6% of the study participants reported a previous history of type II diabetes and 46.8% of hypertension. Similar to other ethnic groups, increasing BMI appeared to be protective of BMD for the total hip, femoral neck and lumbar spine while women with a BMI < 24 were at greater risk of osteopenia and/or osteoporosis. Several weight related measures, such as BMI, were significantly positively correlated with BMD measures of the lumbar spine, femoral neck, and total hip, with waist circumference showing the largest correlations. Total hip T-scores appear to decline with age at a similar rate as Caucasian women and dietary calcium intake did not appear to influence this decline in BMD. Interestingly, protection of total hip BMD appeared to be afforded to individuals with hypertension and/or the combination of hypertension and type II diabetes over and above that afforded by increasing BMI. Based on these very preliminary results it appears that the risk for osteoporosis is very similar in Native American women compared to their Caucasian counterparts.

## SU304

**Negative Association between the Metabolic Syndrome and Bone Mineral Density in Korean Adults.** H. Y. Kim<sup>1</sup>, S. H. Lee<sup>\*2</sup>, H. K. Kim<sup>\*2</sup>, J. M. Koh<sup>2</sup>, G. S. Kim<sup>2</sup>. <sup>1</sup>Division of Endocrinology and Metabolism, University of Wonkwang College of Medicine, Sanbon Medica Center, Gunpo, Republic of Korea, <sup>2</sup>Division of Endocrinology and Metabolism, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

**Background:** Recently many studies suggested the relationship between osteoporosis and cardiovascular disease. The association between different diseases might have been attributable to common risk factors. Metabolic syndrome (MS) was composed of major risk factors of cardiovascular disease. There had been many contradictory reports about the association between each component of metabolic syndrome and bone mineral density (BMD). However, the combined effects of the metabolic syndrome on BMD had been reported rarely. The aim of this study was to determine the association between metabolic syndrome and bone mineral density in Korean adults.

**Methods:** We examined the association between metabolic syndrome and BMD in Korean men (n=1241) and postmenopausal women (n=1109). BMD was measured at the femoral neck and lumbar spine using dual energy X-ray absorptiometry. We made cross-sectional analysis of BMD for subjects with and without metabolic syndrome defined by NCEP-ATP III criteria.

**Results:** The prevalence of metabolic syndrome was 13.0% in men and 17.3% in women. After adjusting for age and BMI, femur neck BMD (FN-BMD) was lower among subjects with MS (0.801 ± 0.010 g/cm<sup>2</sup>; 0.692 ± 0.009 g/cm<sup>2</sup>) than those without (0.826 ± 0.004 g/cm<sup>2</sup>; 0.724 ± 0.004 g/cm<sup>2</sup>) in both men and women (P=0.019; P=0.001). No significant association was seen between MS and BMD at lumbar spine. In multiple regression analysis between each MS component and FN-BMD, waist circumference and glucose were associated with BMD. We found significantly lower FN-BMD in subgroups of abdominal obesity (P<0.001). With the presence of increasing component of MS, there was a significant trend toward lower FN-BMD (P=0.001). The adjusted log-transformed hsCRP level increased with more components. (P=0.002)

**Conclusions:** In Korean men and postmenopausal women, the metabolic syndrome was associated with lower FN-BMD. Among MS component, there was a significant negative association between FN-BMD and abdominal obesity. This association suggested the possibility that increased inflammation induced by visceral fat, somewhat different from total fat mass, might lead to reduced BMD.

## SU305

**Impact of Dietary Protein on Calcium Homeostasis and Nitrogen Excretion in the Presence and Absence of Potassium Bicarbonate.** L. Ceglia<sup>1</sup>, S. S. Harris<sup>1</sup>, S. A. Abrams<sup>2</sup>, H. M. Rasmussen<sup>\*1</sup>, G. Dallal<sup>\*1</sup>, B. Dawson-Hughes<sup>1</sup>. <sup>1</sup>Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA, <sup>2</sup>USDA Children's Nutrition Research Center, Houston, TX, USA.

There are conflicting data on whether dietary protein stimulates calcium absorption and few data on whether giving an alkaline salt to reduce the acid load that accompanies protein would alter the impact of dietary protein on calcium handling and muscle breakdown. In this study we determine the effect of dietary protein on calcium absorption, urinary calcium excretion (UCa), and urinary nitrogen excretion (UNi), and evaluate whether any effects seen are modulated by neutralizing the diet with potassium bicarbonate (KHCO<sub>3</sub>).

20 subjects age 54-82 were randomized to take KHCO<sub>3</sub> (up to 90 mmol/d, n=9) or placebo (n=11) for 41 days. All subjects gave written informed consent. After 2 weeks on treatment, all subjects went through 2 successive 10-d metabolic diet periods containing either low (0.5 g/kg) or high (1.5 g/kg) protein in random order, with a 5-d wash-out period between diets. Calcium intake throughout was 1200 mg/d. After each diet cycle, UCa, UNi, and net acid excretion (NAE) were collected over a 24-hr period, and fractional calcium absorption was measured using dual stable isotopes.

Table. UCa, UNi, and fractional calcium absorption after each diet in the 2 groups

	Placebo		KHCO <sub>3</sub>	
	Low Protein	High Protein	Low Protein	High Protein
UCa (mg)	105.2±42.1	154.7±83.0 <sup>a</sup>	99.0±38.7	134.5±70.3 <sup>a</sup>
UNi (mg)	4.3±0.8	13.6±2.4 <sup>a</sup>	5.6±2.5	12.1±3.5 <sup>a</sup>
Fractional Calcium Absorption (%)	16.6±7.2 <sup>b</sup>	17.2±5.8 <sup>c</sup>	23.7±6.3	23.5±10.0

Diet effect: <sup>a</sup> differs within group from low protein diet at P<0.05.

Treatment effect: differs within diet at <sup>b</sup> P<0.05, <sup>c</sup> P=0.099 (trend)

After each diet cycle, NAE levels revealed full neutralization by KHCO<sub>3</sub> (Placebo group: low protein 10.9±22.4 mmol/L, high protein 19.6±11.7 mmol/L; KHCO<sub>3</sub> group: low protein -20.6±7.8 mmol/L, high protein -12.7±9.0 mmol/L). These results in healthy older subjects confirm increases in calcium and nitrogen excretion with increasing protein in the diet, but do not confirm the previous observation that protein increases calcium absorption (1). These findings also suggest that KHCO<sub>3</sub> may enhance intestinal calcium absorption.

**Air Pollution Might Be a Neglected Risk-Factor of Hypovitaminosis D.** D. H. Manicourt<sup>\*</sup>, J. P. Devogelaer. Rheumatology Unit, St-Luc University Hospital, Brussels, Belgium.

By absorbing sunlight UVB, ozone, a common urban pollutant, might reduce cutaneous vitamin D photosynthesis. Therefore, we conducted a cross-sectional study that established the characteristics and percentage of subjects with serum 25-hydroxyvitamin D [25(OH)D] levels<30 ng/ml among postmenopausal housewives having outdoors activities either in Brussels city or in the countryside and consulting for low back pain. Parameters included dietary intakes, sun exposure index (SEI), levels of PTH, and femoral neck (FN) T-score. Among 249 women consulting for low back pain in June and July, 121 were free of conditions/drugs affecting bone/calcium metabolism, and were selected. Brussels-dwellers (n=52) and rural-dwellers (n=69) had similar mean age (65-67 year), body mass index (24 kg/m<sup>2</sup>) and vitamin D intakes (191-200 IU/day), but differed in mean SEI (113 versus 87;p<0.001) and prevalence of 25(OH)D <30 and <20 ng/ml (83% vs 42% and 46% vs 9%, respectively). In each group, SEI correlated positively with 25(OH)D, but ozone levels were 4-times greater in Brussels than in countryside. After adjusting for SEI, 25(OH)D was 2-times higher in rural-dwellers, and after adjusting for 25(OH)D, SEI was 3-times higher in Brussels-dwellers. In subjects with 25(OH)D<30 ng/ml, but not in subjects with higher 25(OH)D levels, the mean PTH was higher in those with a calcium intake 700 mg/day. FN T-score correlated positively with 25(OH)D and negatively with PTH.

It is concluded that air pollution is a neglected risk-factor of hypovitaminosis D known to compromise several health outcomes. As long as 25(OH)D is >30 ng/ml, calcium intake>700 mg/day is not mandatory for preventing high PTH levels.

## SU307

**Effect of Low Dose Vitamin K2 (MK-4) Supplementation on Bio-indices in Postmenopausal Japanese Women.** N. Koitaya<sup>\*1</sup>, J. Ezaki<sup>\*1</sup>, M. Nishimuta<sup>\*1</sup>, J. Yamauchi<sup>\*1</sup>, E. Hashizume<sup>\*2</sup>, K. Morishita<sup>\*2</sup>, S. Sasaki<sup>\*1</sup>, Y. Ishimi<sup>1</sup>.  
<sup>1</sup>Nutritional Epidemiology Program, National Institute of Health and Nutrition, Tokyo, Japan, <sup>2</sup>Healthcare Products Development Center, Kyowa Hakko Kogyo Co., LTD, Tsukuba, Japan.

It is well known that vitamin K is responsible for  $\gamma$ -carboxylation of peptide-bound glutamate (Glu) residues to produce  $\gamma$ -carboxyglutamate (Gla) in target proteins that are synthesized in limited number of tissues such as bone and vascular tissues.

Dietary vitamin K exists in 2 major forms: phyloquinone (PK) and menaquinones (MK-1 ~ MK-14). The adequate intake (AI) of vitamin K for women aged 30 years and more was set at 65  $\mu$ g/day in the Dietary Reference Intakes (DRIs) for Japanese, 2005. However, epidemiological studies reported that daily intake of vitamin K less than 109  $\mu$ g/day increased the risk of hip fracture in peri- and postmenopausal women. Furthermore, higher circulating vitamin K concentrations are required for OC  $\gamma$ -carboxylation in elderly people compared with younger people. In Japan, 45mg/day of MK-4 has been used for treatment of the patients with osteoporosis. On the other hand, it is not well known whether supplementation of low doses of MK-4 benefits bone metabolism in healthy postmenopausal women at a high risk of bone loss. Thus, the aim of this study is to examine the effects of an additional intake of 1.5mg/day MK-4 on bone metabolism and other indices in healthy postmenopausal women.

The study was performed as a randomized double blind placebo-controlled trial, participants aged 53-65 years randomly assigned to 2 groups, and supplemented with 1.5mg/day MK-4 or placebo in 2 soft capsules for 4 weeks (n=20 for each group). The serum concentrations of lipids, vitamin K, vitamin D, intact  $\gamma$ -carboxylated, and undercarboxylated serum osteocalcin (iOC, GlaOC and uOC, respectively); and urinary bone resorption markers were assessed at the baseline, 2 and 4 weeks. Intake of Natto which is fermented soybean containing MK-7 was restricted during the study period. The study was carried out according to the guidelines of the Declaration of Helsinki. The most marked effects of MK-4 intake were observed on serum OC concentrations. Serum GlaOC increased, and the uOC and the uOC/iOC ratio that indicates the degree of OC  $\gamma$ -carboxylation decreased significantly at 2 weeks compared with that at baseline in the MK-4 group. The serum uOC and uOC/iOC ratio in the MK-4 group were significantly lower than those in the placebo group at 4 weeks. These results suggest that supplementation with 1.5mg/day MK-4 accelerated the degree of OC  $\gamma$ -carboxylation. Thus, the additional daily intake of low dose MK-4 might be beneficial in the maintenance of bone health in postmenopausal women.

**Disclosures:** Y. Ishimi, None.

**Calcium Intake and Serum Bone Formation Markers Are Associated with the Functional Single Nucleotide Polymorphism in the Tissue-Nonspecific Alkaline Phosphatase Gene.** M. Goseki-Sone<sup>1</sup>, N. Sogabe<sup>\*1</sup>, N. Tsugawa<sup>\*2</sup>, R. Maruyama<sup>\*1</sup>, M. Kamao<sup>\*2</sup>, T. Okano<sup>2</sup>, T. Hosoi<sup>3</sup>. <sup>1</sup>Food and Nutrition, Japan Women's University, Tokyo, Japan, <sup>2</sup>Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, <sup>3</sup>Department of Advanced Medicine, National Center of Gerontology and Geriatrics, Aichi, Japan.

Osteoporosis is characterized by a low bone mass, the micro architectural deterioration of bone tissue, and an increasing risk of fracture in the elderly. The disease results from complex interactions between genetic and environmental factors such as nutrition. It seems to be important to maximize peak bone mass during youth, and so nutritional education targeted at accelerating and maintaining bone health is indispensable for young people. Tissue-nonspecific alkaline phosphatase (TNSALP) is suggested to be essential for bone mineralization. Recently, we identified polymorphisms of the *TNSALP* gene 787T>C (Y246H) associated with BMD among 501 postmenopausal women (JBMR, 20:773-782, 2005). In the present study, we attempted to examine the nutritional effects of the *TNSALP* genotype on serum markers of bone metabolism. The subjects were 60 healthy young male volunteers. Dietary nutrient intakes were determined by food records kept for 3 consecutive days. Serum concentrations of bone-specific ALP (BAP), ALP, intact osteocalcin (OC), 25(OH)<sub>2</sub>D<sub>3</sub>, 1 $\alpha$ , 25(OH)<sub>2</sub>D<sub>3</sub> were measured. All subjects were genotyped for the presence of the polymorphism (Y246H). There were no significant correlations between the levels of serum BAP, ALP, intact OC, 25(OH)<sub>2</sub>D<sub>3</sub>, 1 $\alpha$ , 25(OH)<sub>2</sub>D<sub>3</sub>, calcium and vitamin D intakes among genotypes. In all subjects, there was a significant positive correlation between the levels of BAP and 1 $\alpha$ , 25(OH)<sub>2</sub>D<sub>3</sub> (p<0.001). Interestingly, calcium intake was significantly correlated with the level of serum BAP or intact OC in 787T>C homozygotes (CC-type) (p<0.01), but not in heterozygotes (TC-type), nor in 787T homozygotes (TT-type). Our findings indicate the possibility that the osteoporosis-susceptibility gene *TNSALP* has nutritional effects on serum bone formation markers, and that gene-nutritional factor-related interactions potentially modulate the risk of osteoporosis.

**Dietary Patterns in Canadian Men and Women Ages 25 and Older: Relationship to Body Mass Index and Bone Mineral Density.** L. Langsetmo<sup>1</sup>, S. Poliquin<sup>\*1</sup>, D. Hanley<sup>2</sup>, J. Prior<sup>3</sup>, S. Barr<sup>\*3</sup>, T. Anastassiades<sup>4</sup>, T. Towheed<sup>4</sup>, D. Goltzman<sup>5</sup>, N. Krieger<sup>\*6</sup>. <sup>1</sup>CaMos, Montreal, QC, Canada, <sup>2</sup>University of Calgary, Calgary, AB, Canada, <sup>3</sup>University of British Columbia, Vancouver, BC, Canada, <sup>4</sup>Queen's University, Kingston, ON, Canada, <sup>5</sup>McGill University, Montreal, QC, Canada, <sup>6</sup>University of Toronto, Toronto, ON, Canada.

Previous research has shown that underlying dietary patterns are related to the risk of many different adverse health outcomes, but the relationship of these underlying patterns to skeletal fragility is not well understood. The objective of the study was to determine whether dietary patterns in men (ages 25-49, 50+) and women (pre-menopause, post-menopause) are related to bone mineral density (BMD) independently of other associated lifestyle variables and how this relationship is mediated by body mass index. This cohort study included 1928 men and 4611 women participants in the Canadian Multicentre Osteoporosis Study, a randomly selected population-based longitudinal cohort. Dietary patterns were assessed at year 2 and based on self-administered food frequency questionnaire. BMD was measured at year 5 by dual x-ray absorptiometry and calibrated using a phantom. We identified two underlying dietary patterns using factor analysis and then derived factor scores. The first factor score (nutrient dense or "Prudent") was most strongly associated with intake of fruits, vegetables, and whole grains. The second factor score (energy dense or "Western") was most strongly associated with intake of soft drinks, potato chips and French fries, certain meats (hamburger, hot dog, lunch meat, bacon, and sausage), and certain desserts (doughnuts, chocolate, ice cream). The energy dense factor score was associated with higher body mass index independently of other demographic and lifestyle factors. Body mass index was a strong independent predictor of BMD. For a fixed body mass index, each standard deviation increase in the energy dense score was associated with a BMD decrease of 0.009 (95% CI: 0.002, 0.016) g/cm<sup>2</sup> for men 50+ years old and 0.004 (95% CI: 0.000, 0.008) g/cm<sup>2</sup> for postmenopausal women, whereas there was no significant association in either group without the adjustment for body mass index. For a fixed body mass index, each standard deviation increase in the nutrient dense score was associated with a BMD increase of 0.012 (95% CI: 0.002, 0.022) g/cm<sup>2</sup> for men 25-49 years old. There was a positive association between an energy dense diet and higher body mass index, but this did not translate to positive association between an energy dense diet and BMD. Therefore, diet is related to BMD through multiple causal pathways.

**Relationship among Nutritional Status, Oxidative Stress and Bone Density in Institutionalized Elderly.** V. Mocanu<sup>\*1</sup>, O. Voroniu<sup>\*2</sup>, R. Haliga<sup>\*1</sup>, T. Oboroceanu<sup>\*1</sup>, R. Costan<sup>\*3</sup>, V. Luca<sup>\*1</sup>, C. Galesanu<sup>\*3</sup>. <sup>1</sup>Pathophysiology, University of Medicine and Pharmacy, Iasi, Romania, <sup>2</sup>Hygiene, University of Medicine and Pharmacy, Iasi, Romania, <sup>3</sup>Endocrinology, University of Medicine and Pharmacy, Iasi, Romania.

**OBJECTIVE:** Nutrition plays a role in health promotion and well-being, but there is still a lack of knowledge about nutrition-related risk factors in aging. The purpose of this project was to evaluate the link between nutritional status, pro/antioxidant balance and bone status in elderly subjects residing in a nursing home. **METHODS:** The subjects were 50 elderly people (36 females and 14 males aged 72.6 $\pm$ 7 years, mean  $\pm$  standard deviation SD, range 63-93). Their nutritional status was assessed by weight, height, albumin, transthyretin (prealbumin), C-reactive protein, 25OHvitamin D, glucose, cholesterol, total proteins, lymphocytes and count of CD4 and CD8, a 10 day food record combined with a food-frequency questionnaire; the MNA nutritional screening. Plasma malondialdehyde and erythrocyte reduced glutathione, catalase and superoxide dismutase were evaluated in elderly people as indices of the oxidative balance. Femoral neck and lumbar bone mineral density (BMD) were measured by DXA scan. **RESULTS:** The mean vitamin and mineral intake for participants met the RDAs except for calcium and vitamin D. The MNA scores have been found to be significantly correlated to nutritional intake (p < 0.01 for energy, carbohydrates, calcium, vitamin D), anthropometric and biological nutritional parameters (p < 0.01 for albumin, transthyretin, cholesterol, 25OHvitamin D). An MNA score between 17 and 23.5 can identify those persons with mild malnutrition in which nutrition intervention may be effective. A significant negative correlation (p < 0.05) between dietary intake of vitamin D and malondialdehyde and between dietary 25OH vitamin D and low bone density (p < 0.01) was observed. **CONCLUSION:** The results of the present study showed the potential impact of nutritional factors and oxidative stress on bone health in older adults.

**Increasing the Number of Steps Taken per Day Leads to a Greater Weight Loss and More Favorable Body Composition in Overweight Postmenopausal Women.** C. C. Douglas<sup>\*1</sup>, P. Liu<sup>1</sup>, H. Shin<sup>1</sup>, A. P. Crombie<sup>\*1</sup>, K. Humphrey<sup>\*1</sup>, O. J. Kelly<sup>1</sup>, G. R. Dutton<sup>\*2</sup>, J. Z. Ilich<sup>1</sup>. <sup>1</sup>Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, <sup>2</sup>Medical Humanities and Social Sciences, College of Medicine, Florida State University, Tallahassee, FL, USA.

Pedometers are inexpensive and simple tools that provide a specific and measurable assessment of the number of steps taken, or distance walked. Some clinical studies have demonstrated that pedometers could be used to assess activity of participants and relate it to various outcomes. Our purpose was to examine the relationship between pedometer-assessed activity and body composition in Caucasian overweight and obese postmenopausal women enrolled in a weight loss study for a period of 3 months. Participants at baseline included 45 early postmenopausal (from 2-10y) women, aged 56.0±3.2 y, with a BMI of 32.9±6.7 kg/m<sup>2</sup> (mean±SD). After enrollment, baseline measurements were recorded, and participants were assigned a low energy diet plan (consisting of a normal ratio of macronutrients), and were encouraged to increase number of steps/day. Each participant received a pedometer (Optimal Health Products) and was instructed how to use it and record the steps/day over a 7-day period. Analysis for the 3 months follow-up included only those participants who completed all baseline and 3-month measurements (n=32). Number of steps/day was recorded over seven days at baseline and 3 months. At baseline, the average number of steps/day was 6,941±3,468; only six (13.3%) participants exceeded the recommended 10,000 steps/day. Results showed significant negative correlation (Pearson's r ranging from -0.3 to -0.5) between number of steps/day and iDXA-analyzed trunk, android (abdominal), gynoid (hip) and total fat, all p's <0.05. ANCOVA, with age and energy intake (kcal) as the covariates, revealed significant difference in trunk fat and android fat, and BMI between participants divided in groups below and above mean number of steps/day, resulting in lower values in the group exceeding the mean number of steps/day (p's <0.05). After 3 months, the number of steps increased by 823±2855 steps/day; a 24% increase in activity from baseline. There was a 3.3±4.2 kg loss in body weight, representing a 3.9±5.3% weight loss for the group. Participants who lost 5 kg or more (n=11) of body weight demonstrated a significant increase in steps/day (vs. baseline) compared to those who lost <5 kg (p=0.05), even though energy consumption was similar between groups. We conclude that increasing the number of steps/day (even if the recommended level has not been reached) could help in weight loss and contribute to a more favorable body composition in this population.

## SU312

**Designing a Latino Osteoporosis Awareness Campaign.** K. Cody<sup>\*1</sup>, B. Tracewell<sup>\*1</sup>, A. Focil<sup>2</sup>, V. Lujan<sup>\*3</sup>, K. Campbell<sup>\*4</sup>, M. Wang<sup>\*5</sup>. <sup>1</sup>Foundation for Osteoporosis Research and Education, Oakland, CA, USA, <sup>2</sup>California Hispanic Osteoporosis Foundation, Oxnard, CA, USA, <sup>3</sup>La Clínica de la Raza, Concord, CA, USA, <sup>4</sup>Procter & Gamble, Irvine, CA, USA, <sup>5</sup>UC Berkeley Center for Weight and Health, Berkeley, CA, USA.

Hip fractures have doubled among California Latinos since 1983, while remaining unchanged or declining in other ethnic groups[1]. Despite prevention efforts, Latinos as a group do not take recommended actions to protect themselves from bone loss, osteoporosis and fractures.

In 2007, a partnership[2] formed to design and test effective messages and strategies for an osteoporosis awareness campaign for Latinos. These experts examined existing literature, identified education tools and dissemination strategies and tested them in focus group settings with 63 Latinos (56% females) ranging in age from 23 to 89 with a mean age of 58.

Literature shows that among Latinos there is a general fear of health testing ("fatalismo") that runs counter to preventive health care, making them particularly vulnerable to asymptomatic diseases. Good communication and experience with health care providers is critical.

Focus groups revealed a wide range of knowledge about osteoporosis, from those who have never heard the word "osteoporosis" to those who have been diagnosed with osteoporosis. Familiarity was usually due to family members or friends suffering with osteoporosis.

Focus groups reported that messages should be simple, positive, familial, hopeful and delivered in Spanish. Colored illustrations and graphics drew the most attention. Participants favored doctors as the first choice for delivering messages, followed by promotores, nurses or other clinic staff.

Preferred methods for message delivery were varied and included local Spanish-language radio and television programs, short videos with testimonials, "stories" with families about what to eat, and how to incorporate daily exercise. Other effective media was printed materials with illustrations, appealing graphics, and "bulletins" or colorful, "newsy" mailings to adults over 50.

Focus on the family was prevalent throughout the focus groups. Having someone in the family with osteoporosis and learning more about it raised interest in prevention.

**Interventions to Prevent Falls in the Community-Dwelling Elderly: A Systematic Review.** D. A. Butt<sup>1</sup>, O. Gajic-Veljanoski<sup>\*2</sup>, A. Cheung<sup>2</sup>. <sup>1</sup>Family & Community Medicine, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Osteoporosis, University Health Network, Toronto, ON, Canada.

The evidence for interventions to prevent falls in elderly has undergone much change with the publication of several recent trials. Our study assessed the effectiveness of various interventions in preventing falls in community-dwelling elderly by reviewing published randomized controlled trials, systematic reviews and meta-analyses.

We conducted a systematic search of Medline, EMBASE and all Evidence-Based Medicine Reviews (1950-January 2008). The bibliographies of relevant articles were also searched. The search words were: "community-dwelling", "elderly", "accidental falls" and "falls". All English-language articles in the elderly (age ≥ 65 years), living at home that provided the number of falls, number of fallers or fall-related injuries were included. Two independent reviewers extracted data on participants, interventions and falls outcomes, and rated the studies for quality based on established criteria.

We identified 546 abstracts and 27 studies met eligibility criteria for inclusion into our systematic review. These studies include 1 systematic review on interventions, 2 studies on multifactorial interventions (1 meta-analysis, 1 trial), 12 trials on exercise, 3 studies on withdrawal of drugs (2 meta-analyses, 1 trial), 4 studies on vitamin D (1 meta-analysis, 3 trials), 1 trial on cognitive-behavioural learning, 2 trials on correction of visual impairment and 2 studies on assistive devices (1 systematic review, 1 trial). Interventions that reduce falls in community-dwelling elderly include exercises (tai chi, relative risk (RR) 0.45-0.67), muscle strengthening (RR 0.77-0.80), gait and balance training (RR 0.54-0.69); home hazard assessment and modification in elderly at risk of falls (RR 0.59-0.66); gradual withdrawal of psychotropic drugs (RR 0.34); vitamin D supplementation in women (odds ratio (OR) 0.54-0.78); cognitive-behavioural learning in elderly at risk of falls (RR 0.69) and correction of cataracts via phacoemulsification in women (RR 0.66). There was insufficient evidence to support the use of multifactorial interventions and external hip protectors to reduce falls and the number of fallers in community-dwelling elderly. Exercise in visually impaired and older persons transitioning to frailty, and correction of visual impairment in elderly not at risk of falls increased the incidence of falls (RR 1.15-1.57) and fractures (RR 1.15-1.74).

Based on current evidence, there are a number of effective interventions for the prevention of falls in community-dwelling elderly. Health care professionals need to be better informed so that these interventions can be integrated into routine care to prevent falls and injuries in the elderly.

**Prevention of the Metabolic Syndrome together with Osteoporosis in Young Men: 4 Months Trial by Improvement of Diet and Physical Activity with Milk Intake.** T. Hirota<sup>1</sup>, I. Kawasaki<sup>\*1</sup>, H. Ikeda<sup>\*1</sup>, T. Aoe<sup>\*1</sup>, K. Hirota<sup>\*2</sup>. <sup>1</sup>Research Laboratory, Tsuji Academy of Nutrition, Osaka-city, Japan, <sup>2</sup>Obstetrics & Gynecology, Nissay Hospital, Osaka-city, Japan.

To assess strategy for prevention of not only osteoporosis but also the metabolic syndrome (MetS) in young men by increasing calcium intake with milk.

Thirty five male students (21±4 yr, BMI: 21.8±2.5) who voluntarily attended 4-mo study to decrease fat and increase muscle mass and bone mineral density (BMD) were randomly assigned to either an obligatory milk intake of 200 ml/day (milk group, n=19) or not (control group, n=16). All subjects had been educated for proper diet and physical activity and the diaries of meals and sports written by themselves had been constantly followed by dietitians. Body fat, lean mass, and bone mineral by dual energy x-ray absorptiometry and risk factors of MetS including blood pressure, fasting glucose, lipids and waist circumference were measured. Calcium intake by 3-day dietary record, vitamin D status by 25(OH)D (RIA), and intact PTH as serum calcium regulating hormone were determined.

Baseline calcium intake in the subjects was as low as 468 mg/day which were quite similar to the National Health and Nutrition Survey in Japanese young men. Total number of risk factors of MetS at baseline was 11 in control and 18 in milk groups. These risk factors were decreased to 10 and 8, respectively after 4-mo trial, however, such significant changes were observed only in milk group. Mean blood pressure was decreased and HDL-cholesterol and femoral neck BMD were increased significantly only in milk group, while their body weight, fat and lean mass were changed a little after 4-mo. Four subjects (1 in control and 3 in milk groups) out of 6 (2 in control and 4 in milk groups) who had two or more of MetS risk factors at baseline, became to the normal range of these risk factors after 4-mo.

Increased intake of milk which is the best source of calcium should help not only to increase BMD but also to decrease risks of MetS in young Japanese men whose calcium intake is much lower than Europeans and Americans.

## SU315

**Rosiglitazone-induced Change in Bone Mineral Density among African Americans with Type 2 Diabetes Mellitus or Impaired Glucose Tolerance.** S. W. Ing<sup>1</sup>, K. Osei<sup>\*1</sup>, T. Gaillard<sup>\*1</sup>, L. T. Sinnott<sup>\*2</sup>, R. D. Jackson<sup>1</sup>. <sup>1</sup>Internal Medicine, Ohio State University, Columbus, OH, USA, <sup>2</sup>Optometry, Ohio State University, Columbus, OH, USA.

**Purpose:** This was an exploratory study to assess BMD changes among African Americans with type 2 diabetes mellitus (T2DM) or impaired glucose tolerance (IGT) treated with rosiglitazone.

**Methods:** We retrospectively evaluated data from a cohort of African American subjects with T2DM or IGT treated with rosiglitazone 8 mg daily for 12 weeks. Body composition DXA scans (Lunar DPX) at baseline and 12 weeks were performed at the total body including subregions: arm, leg, trunk, pelvis, and spine. Serum total adiponectin concentrations at baseline and 12 weeks were also measured. For each subject, change in BMD and adiponectin levels over the 12 weeks was computed. An ordinary least squares regression was performed for each BMD location, with change in BMD as outcome and change in adiponectin level as predictor. We controlled for gender, age, baseline BMI, and group (T2DM or IGT) in these analyses.

**Results:** The study cohort consisted of 24 women and 4 men, mean age 50.1 years, 17 with T2DM and 11 with IGT, and mean BMI of 37 kg/m<sup>2</sup>. Short term precision using root mean square coefficient of variation by site was: total body 0.5%, arm 2.9%, leg 1.6%, trunk 1.6%, pelvis 3.4%, and spine 3.8%. Change in BMD (SD) by site was: arm +1.4% (4.6), leg +0.6% (3.6), trunk +0.5% (4.3), pelvis +0.2% (5.1), spine +2.4% (9.8) and total body +0.2% (2.0). All were statistically nonsignificant. Adiponectin significantly increased from baseline 7.7 mcg/ml (SD 4.3) to 15.5 (8.4). Baseline adiponectin correlated with baseline BMD at the leg ( $r = -0.49$ ,  $p < 0.05$ ). Regression analyses between adiponectin change (mcg/ml) and BMD change (mg/cm<sup>2</sup>) were nonsignificant, but point estimates of the regression parameters were negative at the arm (-1.3), trunk (-1.6), pelvis (-2.4), and spine (-3.5). After multiplying these estimates by the mean adiponectin increase (7.7 mcg/ml), mean (and percent) changes in BMD by body site were: arm -9.8 (-1.1%), trunk -12.4 (-1.2%), pelvis -18.6 (-1.4%), and spine -26.7 (-2.3%) mg/cm<sup>2</sup>, respectively.

**Conclusion:** Rosiglitazone therapy in middle aged African Americans with T2DM or IGT may not lead to short term decreases in BMD. Serum adiponectin concentration doubled and correlations between increase in adiponectin and change in BMD were nonsignificant, but the direction of this relationship was negative, suggesting that increasing adiponectin may be associated with bone loss in this population.

**Disclosures:** S.W. Ing, None.

## SU316

**Bone Is More Susceptible to Vitamin K Deficiency than Liver.** A. Kuwabara<sup>\*1</sup>, K. Tanaka<sup>1</sup>, N. Tsugawa<sup>\*2</sup>, M. Kamao<sup>\*2</sup>, M. Himeno<sup>\*1</sup>, Y. Ogawa<sup>\*1</sup>, M. Kishimoto<sup>\*1</sup>, M. Fukuda<sup>\*1</sup>, S. Kido<sup>\*1</sup>, T. Okano<sup>1</sup>. <sup>1</sup>Kyoto Women's University, Kyoto, Japan, <sup>2</sup>Kobe Pharmaceutical University, Kobe, Japan.

**Aim:** In most countries including Japan,  $\gamma$ -carboxylation of blood coagulation factors in the liver has been the basis for determining adequate intake (AI) for vitamin K. Recently, vitamin K is known to be an essential nutrient for preventing fracture. In this study, relative susceptibility of liver and bone to vitamin K deficiency was investigated in two study models.

**Study (1) Methods:** Elderly institutionalized subjects were evaluated for vitamin K status by measuring serum PIVKA (protein induced by vitamin K absence) -II and uOC (undercarboxylated osteocalcin) levels, as the sensitive markers for hepatic and skeletal vitamin K deficiency, respectively. Cut-off values were 28mAU/ml for PIVKA-II and 4.5ng/ml for uOC. **Results:** Serum PIVKA-II and uOC levels were 20.8 $\pm$ 5.9mAU/ml and 4.8 $\pm$ 3.3ng/ml, respectively. Serum PIVKA-II and uOC concentration exceeded the cut-off value in 8% and 47% of subjects, respectively. Median vitamin K intake was approximately 200 $\mu$ g, which more than 2.5 times higher than current Japanese AI.

**Study (2) Methods:** Patients with inflammatory bowel disease (IBD; 50 Crohn's disease; CD, 65 ulcerative colitis; UC) were evaluated for their BMD, urinary bone resorption marker (NTx), plasma vitamin D and K levels, serum parathyroid hormone (PTH), PIVKA-II and uOC levels, and their food intake. **Results:** BMD were generally decreased, most notably at radius. Urinary NTx excretion was elevated in most patients. CD patients had significantly lower vitamin D and K levels, significantly higher serum PTH, uOC and PIVKA-II concentrations than UC patients. Serum PIVKA-II and uOC levels were elevated in 18% and 80% of patients respectively, suggesting that bone is more vitamin K-deficient than liver. Plasma vitamin D and K levels correlated with fat intake, but not with their intake of these vitamins. Decreased plasma vitamin D and K concentrations were risk factors for radial low BMD by multiple regression analysis.

**Discussion:** In these two study models, the prevalence of elevated PIVKA-II was much higher than that of elevated uOC levels, suggesting that bone is much more susceptible to vitamin K deficiency. These differences are likely to arise from the anatomical reason such that vitamin K absorbed from the intestine is first delivered and utilized in the liver, then to extra-hepatic tissues including bone (first pass effect). These facts should be taken into account in determining the AI for vitamin K.

**Disclosures:** K. Tanaka, None.

## SU317

**Impaired Methylation Capacity Is Associated with Low Bone Mineral Density.** J. van Meurs<sup>1</sup>, N. Yazdanpanah<sup>\*1</sup>, C. Zillikens<sup>\*1</sup>, R. de Jonge<sup>\*2</sup>, F. Rivadeneira<sup>1</sup>, A. Hofman<sup>\*3</sup>, J. Lindemans<sup>\*2</sup>, H. Pols<sup>1</sup>, A. Uitterlinden<sup>1</sup>. <sup>1</sup>Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands, <sup>2</sup>Clinical Chemistry, Erasmus Medical Center, Rotterdam, Netherlands, <sup>3</sup>Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands.

**OBJECTIVE:** A mildly elevated circulating homocysteine (Hcy) level is a new and potentially modifiable risk factor for osteoporotic fractures. It is not clear whether the Hcy toxicity effects are direct or if they are caused by disturbed levels of associated metabolites. One such associated factor might be aberrant methylation patterns, through which epigenetic control of gene transcription occurs. Dietary methionine is converted to S-adenosylmethionine (SAM). SAM serves as the major intracellular methyl donor in many transmethylation reactions in the cell. The demethylated product of the transmethylation reaction is S-adenosylhomocysteine (SAH), which is further converted to homocysteine. Chronic elevation in Hcy levels is associated with a parallel decreased SAM/SAH ratio, which leads to decreased methylation of DNA. This suggests that elevated Hcy levels may be an indirect indicator of decreased SAM/SAH ratio and compromised cellular methylation capacity. The aim of the current study was to examine the relation between methylation capacity as measured by circulating SAM/SAH ratio and bone parameters.

**METHODS:** We measured circulating homocysteine, SAM and SAH levels in serum of 500 women aged 65-75 years from the prospective population-based Rotterdam study. Association analysis was done between SAM/SAH ratios and femoral neck bone mineral density and fracture incidence.

**RESULTS:** Low SAM/SAH ratios were significantly correlated with high homocysteine levels, ( $r=0.21$ ,  $p<0.001$ ) and age ( $r=0.16$ ,  $p<0.001$ ), but not with height and weight.

Multiple linear regression analysis showed that low SAM/SAH ratios were associated with low BMD (standardized B=0.13,  $p=0.006$ ), independent of age and homocysteine levels. Quartile specific analysis showed that women with a SAM/SAH ratio in the highest quartile had a 0.3SD higher BMD compared to women in the lowest quartile. Similar analysis for Hcys levels showed no relation between BMD and hcy levels. In addition, fracture incidence was higher in women with SAM/SAH ratio in the lowest 3 quartiles compared to the highest quartile with borderline significance (1.6% vs 6%, Chi-square  $p=0.055$ , HR 3.6[0.9-15.3]). This increased fracture risk was independent of age, Hcys levels, and BMD. **CONCLUSION:** Low methylation capacity (SAM/SAH ratio) is associated to low BMD, independent of age and homocysteine levels. In addition, low SAM/SAH ratio show a strong trend towards a higher fracture risk independent of homocysteine levels, but this needs to be confirmed in a larger study.

## SU318

**Does Adiposity Affect Bone Strength Indices in Young Adult Black Females?** N. K. Pollock<sup>1</sup>, E. M. Laing<sup>1</sup>, M. W. Hamrick<sup>2</sup>, C. A. Baile<sup>1</sup>, R. D. Lewis<sup>1</sup>. <sup>1</sup>Foods and Nutrition, The University of Georgia, Athens, GA, USA, <sup>2</sup>Cellular Biology and Anatomy, The Medical College of Georgia, Augusta, GA, USA.

Some studies suggest that obesity may have a negative impact on bone health. Since obesity rates have been increasing among young adult black females, it is important to ascertain the impact of adiposity on bone in this racial group. To date, the relationship between adiposity and indices of bone strength in young adult black females has not been investigated. The purpose of this study was to compare tibial and radial bone measurements between two groups defined as having normal and high levels of body fat, while taking into consideration the muscle and bone relationship. Black females (N=44, aged 19.2 $\pm$ 1.2 years) participated in this cross-sectional study. Participants were divided into 2 groups on the basis of their percent body fat: normal-fat (less than 32% fat; n=29) and high-fat (greater than 32% fat; n=15). These classifications were selected based on levels of body fat associated with cardiovascular risk factors. Fat-free soft tissue, fat mass and % fat were measured using DXA. Tibial and radial bone measurements were assessed by peripheral quantitative computed tomography (pQCT) at the 4%, 20% and 66% sites from the distal metaphyses, which reflect trabecular bone, cortical bone and muscle cross-sectional area (MCSA), respectively. Data were analyzed using independent samples t-tests and ANCOVA. Unadjusted bone measures were not different between groups. After controlling for MCSA, the high- vs. normal-fat group had lower bone measures at the 20% site of the tibia (periosteal circumference and polar strength-strain index;  $P<0.05$ ). No differences were found at the adjusted radial bone measurements. Traditionally, excess adiposity is presumed to be advantageous for the skeleton. However, in this study, excess weight in the form of fat mass does not seem to provide additional benefits to cortical bone at a weight-loaded site in young adult black females.

## SU319

**Does Dietary Protein reduce Hip Fracture Risk in Elderly Men and Women? The Framingham Study.** D. Misra<sup>\*1</sup>, S. D. Berry<sup>1</sup>, K. E. Broe<sup>1</sup>, K. L. Tucker<sup>2</sup>, L. A. Cupples<sup>3</sup>, D. P. Kiel<sup>1</sup>, M. T. Hannan<sup>1</sup>. <sup>1</sup>IFAR, HSL, Boston, MA, USA, <sup>2</sup>Tufts Univ, Boston, MA, USA, <sup>3</sup>Boston Univ, Boston, MA, USA.

Although higher protein intake has been associated with higher bone mineral density (BMD), the effect of protein intake on fracture risk remains unclear. A few large studies have revealed an inverse relation between dietary protein intake and hip fracture risk in younger persons (<70y) but the relation between protein and hip fracture risk is unclear in individuals >70y. Thus, we examined the relation between protein intake and hip fracture among older men and women in the Framingham Study.

Our subjects included persons who attended Framingham exam 1988-89 and provided information on protein intake by 126-item Willett's Food Frequency Questionnaire (FFQ). Participant with missing or implausible FFQ energy intake (<600 and >4000 kcal) and those with prior hip fracture were excluded. Total protein intake (g/d) was energy-adjusted. Information was collected at baseline on the following covariates: age (y), sex, weight (lb) & height (cm) to calculate body mass index (BMI) and total energy intake (kcal). Femoral neck BMD (g/cm<sup>2</sup>) was also obtained with Lunar Dual photon absorptiometry using standard technique.

Hip fractures were ascertained and confirmed through interview and review of medical records through 12/31/05. Incidence rates were calculated for each protein quartile. Cox proportional hazard regression was used to examine the risk of hip fracture associated with energy-adjusted protein intake (in continuous and quartile forms) adjusting for age, sex, BMI and total energy intake.

Of the 946 participants (576 women and 370 men), mean age 75y, 100 incident fractures (80 women, 20 men) were identified over the 17-year follow-up. There was no reduction in risk of hip fracture per gram of energy-adjusted total protein intake (HR= 0.995, 95%CI 0.98-1.01). Reduction in risk of hip fracture across quartiles showed a protective trend but result was only borderline statistically significant (p=0.07), see table.

Energy-adjusted Protein Quartiles(mean.g/d)	Hazard Ratios	95% CI
Q1 46.5± 7.29	1	
Q2 59.6± 2.24	0.70	0.41-1.19
Q3 67.7± 2.43	0.56	0.32-1.0
Q4 82.7± 10.27	0.63	0.37-1.09

Hazard ratios were similar when femoral neck BMD was added to the model.

We found that high dietary protein may be associated with reduced risk of hip fracture in elderly men and women, but our study had limited power. Larger studies are needed to confirm this finding in elders.

## SU320

**Costs Associated with Non-hip, Non-vertebral (NHNV) Fractures in a Managed Care Setting.** K. Foley<sup>\*1</sup>, N. Shi<sup>\*1</sup>, G. Lenhart<sup>\*1</sup>, E. Badamgarav<sup>\*2</sup>.

<sup>1</sup>Thomson Healthcare, Cambridge, MA, USA, <sup>2</sup>Global Health Economics, Amgen Inc., Thousand Oaks, CA, USA.

NHNV fractures are the most common fractures, occurring 11 times more frequently in patients aged 50-64 yrs than in those aged ≥ 65 yrs. NHNV fractures are often followed by subsequent fractures at the same or new skeletal sites. To determine the economic and clinical burden associated with NHNV fractures, a retrospective claims analysis was conducted to evaluate rates of subsequent fractures following an initial NHNV fracture and associated incremental costs in a managed care setting.

Fully adjudicated medical claims from a research database were used to identify patients aged ≥ 50 yrs with a closed hip, vertebral, or NHNV fracture (including distal femur, pelvic, humerus, wrist, clavicle, and leg) between 07/01/2001 and 12/02/2004. The first observed fracture was the index fracture. Patients were continuously enrolled 6 mos before and 12 mos after the index fracture. A 1:1 control group was selected for each fracture category by matching on age, gender, region, and diagnostic cluster score ± 3 points. Subsequent new-site fractures were identified by ICD-9 codes; subsequent same-site fractures were identified by 2 consecutive fracture claims with same diagnosis ≥ 180 days apart. Multivariate regression modeling controlled for potential residual confounding factors. Incremental direct medical costs of NHNV fractures (fracture group minus control) in the 12 mos after the index fracture were estimated.

NHNV fractures occurred in 27,424 of 33,233 fracture patients aged 50-64 yrs and 40,690 of 73,945 fracture patients aged ≥ 65 yrs. Mean (SD) ages were 58.7 (4.0) yrs and 79.9 (7.5) yrs, respectively. The average adjusted incremental per-fracture cost associated with individual NHNV fractures was \$9,183 for patients aged 50-64 years and \$6,106 for patients aged ≥ 65 yrs. Overall, 31.3% of patients aged 50-64 yrs and 34.9% of patients aged ≥ 65 yrs had subsequent fractures within 12 mos of the index fracture. Subsequent fractures were associated with a 3-fold increase in incremental annual costs compared with initial fractures (Table).

Annual Incremental Cost of NHNV Fracture Treatment				
	Patients Aged 50-64 Years (N=27,424)		Patients Aged 65+ Years (N=40,690)	
	N	Incremental Cost	N	Incremental Cost
Annual cost of single NHNV fracture without a subsequent fracture	18,847	\$5,654	26,622	\$3,479
Annual cost of NHNV fracture with subsequent fractures	8,577	\$16,919	14,068	\$11,008

NHNV fractures are prevalent and can pose a substantial economic burden for managed care plans. NHNV fractures occur early in disease progression and more frequently in younger patients. This analysis suggests that avoiding initial fractures may be a factor in decreasing the rate of subsequent fractures and associated costs.

## SU321

**"Pathologic" Fractures: To Include or Exclude?** J. R. Curtis<sup>1</sup>, D. J. Becker<sup>\*2</sup>, M. Kilgore<sup>\*2</sup>, L. C. Gary<sup>\*2</sup>, R. Matthews<sup>\*3</sup>, M. A. Morrissey<sup>\*2</sup>, N. Patkar<sup>\*1</sup>, K. G. Saag<sup>1</sup>, A. H. Warriner<sup>\*4</sup>, E. Delzell<sup>\*3</sup>. <sup>1</sup>Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>Department of Health Care Organization and Policy, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>3</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>4</sup>Division of Endocrinology, Diabetes and Metabolism, University of Alabama at Birmingham, Birmingham, AL, USA.

**Introduction:** Analyses of osteoporosis-related fractures that use administrative claims data often exclude pathologic fractures (ICD-9 code 733.1x) due of concern that these are caused by a malignancy. We examined pathologic fracture diagnoses of the vertebrae and hip to evaluate their impact on fracture incidence estimates and to determine whether there was evidence for a malignancy.

**Methods:** We studied U.S. Medicare beneficiaries age ≥ 65 with part Medicare A+B and not HMO coverage with new fractures following a 12-month "clean" period with no fracture diagnoses. The ICD-9 diagnosis codes used were 733.13 (pathologic vert) and 805.2, 805.4 and 805.8 (non-pathologic vert); and 733.14 (pathologic hip) and 820.0, 820.2 and 820.8 (non-pathologic hip). We further examined the proportions of people with ≥ 1 inpatient or physician diagnosis of a malignancy in the prior year or 1 month following the fracture.

**Results:** We identified 69,867 individuals with a vertebral fracture diagnosis. Median age was 78 years; 77% women, 95% white. The proportion of persons with pathologic fracture diagnoses only, non-pathologic diagnoses only, and both are shown (Table). Each of these three groups constituted approximately one-third of fracture cases; the proportion with evidence for malignancy was approximately equal.

There were 90,039 persons with a hip fracture; median age was 80 years; 78% women, 93% white. Persons with pathologic fracture diagnoses accounted only for 1% of all hip fractures; the proportion of these with evidence for a malignancy was higher (51%) than for people with only non-pathologic hip fracture diagnoses (26%).

**Conclusion:** Among U.S. Medicare beneficiaries, only one-third to one-half of people with a pathologic fracture diagnosis of the vertebrae or hip had evidence for a malignancy. Particularly for vertebral fractures, excluding persons with pathologic fractures in epidemiologic analyses that utilize administrative claims data substantially underestimates the burden of fractures due to osteoporosis.

	Pathologic Diagnoses Only	Non-pathologic Diagnoses Only	Both Diagnoses
Spine (% of total spine fractures)	30	38	32
Proportion of these persons with ≥ 1 claim for malignancy	32	28	32
Hip (% of total hip fractures)	1	95	4
Proportion of these persons with ≥ 1 claim for malignancy	51	26	44

## SU322

**Prevalence of Vertebral Fractures in Aging Women Suffering from Hip Fracture.** M. Sosa<sup>1</sup>, Working Group on Osteoporosis<sup>\*2</sup>. <sup>1</sup>Medicine, University of Las Palmas de GC and Hospital University Insular, Las Palmas de Gran Canaria, Spain, <sup>2</sup>Osteoporosis Working Group, Sociedad Española de Medicina Interna, Spain.

**Background.** Fractures are the clinical complication of osteoporosis. There are no previous studies that describe the prevalence of vertebral fractures (VF) in patients admitted into a hospital due to a hip fracture (HF).

**Objective.** To study the prevalence of vertebral fractures in elderly women in the moment of their admission to the hospital due to a hip fracture.

**Method.** This is a cooperative, multicentric, case control study, performed in 21 different hospitals of Spain by the Working Group on Osteoporosis of the Spanish Society of Internal Medicine. A total of 143 elderly women with hip fractures comprised the case group. The control group consists of 138 elderly women admitted into other wards of the hospital due to other diseases with no relationship with osteoporosis. A questionnaire was administered and a lateral thoracic and lumbar X-ray was performed to assess vertebral fractures applying Genant's criteria.

**Results.** The mean age of the patients with HF was 79.8 ± 6.9 years and the mean age of the controls was 77.7 ± 8.9 years. Patients suffering from HF had less weight than controls (BMI: 25.9 ± 4.4 g/m<sup>2</sup> vs 27.7 ± 5.2 kg/m<sup>2</sup>, p = 0.002). Prevalence of VF was 62.6% in patients with HF, and 50% in controls (p = 0.039).

## ASBMR 30th Annual Meeting

Basal characteristics of the population studied			
	Hip fracture n= 143	Controls n= 129	p value
Age (years)	79.8 (6.9)	77.7 (8.9)	0.03
Weight (Kg)	63.5 (12.1)	67.0 (12.9)	0.02
Height (cm)	156.4(8.1)	155.5 (7.3)	0.33
BMI (Kg/m <sup>2</sup> )	25.9 (4.4)	27.8 (5.2)	0.002
Arm span (cm)	150.1 (16.0)	151.0 (10.4)	0.586

Comparison of some risk factors between hip fracture and controls				
	Hip fracture	Controls	p value	OR (95% CI)
Actual tobacco use	6.3%	7.2%	0.763	0.866 (0.341; 2.201)
Actual alcohol consumption	5%	5.8%	0.769	0.855 (0.302; 2.426)
Use of statins	18.9%	28.1%	0.081	0.597 (0.334; 1.068)
Use of hypnotics	42.3%	29.7%	0.029	1.731 (1.056; 2.837)
Previous falls	42.4%	38.8%	0.540	1.163 (0.717; 1.886)
Maternal history of Hip fracture	6.6%	5.6%	0.732	0.195 (0.431; 3.310)
Prevalence of vertebral fractures	62.6%	50.0%	0.039	1.673 (1.025; 2.731)

Conclusions. Elderly women admitted to a hospital due to hip fracture have a very high prevalence of previously undiagnosed VF. Indeed, elderly women admitted into the hospital because of other diseases also have a high prevalence of VF. These facts must be taken into account due to the morbidity and mortality of VF, that increases the HF morbidity and mortality.

**Disclosures:** M. Sosa, None.

## SU323

**Poor Peripheral Sensorimotor Nerve Function Is Associated with High Fall Risk.** K. A. Faulkner<sup>1</sup>, E. S. Strotmeyer<sup>1</sup>, S. Zivkovic<sup>\*2</sup>, J. Verghese<sup>\*3</sup>, J. Van Swearingen<sup>\*2</sup>, S. Studenski<sup>\*2</sup>, J. A. Cauley<sup>1</sup>. <sup>1</sup>Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, <sup>2</sup>University of Pittsburgh, Pittsburgh, PA, USA, <sup>3</sup>Albert Einstein College of Medicine, Bronx, NY, USA.

It is not known whether poor subclinical peripheral nerve function predicts falls. Participants were 377 community-dwelling men (mean age=76.8 years, SD=4.9), who were enrolled in the Osteoporotic Fractures in Men Study at the Pittsburgh clinic. Subclinical was defined as meeting electrodiagnostic criteria without clinical signs or symptoms. Electrophysiologically-detected peripheral nerve conduction was measured at the non-dominant sural sensory nerve (SNAP=amplitude in uV and DSL=distal sensory latency in ms) and bilaterally at the deep peroneal motor nerve (CMAP=amplitude in mV and DML=distal motor latency in ms) using the NC-stat® (NeuroMetrix, Inc.). DSL was available in 305 men with valid SNAP. Clinical signs, including loss of 10g monofilament detection on the worse toe and open sores, and 3 symptoms of peripheral neuropathy were assessed. Number of falls in two subsequent years were self-reported in postcard mailings every 4 months. Multivariate-adjusted (see footnote) Relative Risks of falling (RR) were calculated using Poisson regression models. The average fall rate during the study was 50.8/100 man-years. Fall rates were 113-486% higher among men in the middle and worst tertiles of non-dominant side DML compared to men in the best tertile (Table). Middle and worst tertiles of dominant-side DML were associated with 11-41% higher fall rates compared to men in the best tertile. Fall rates were 41% higher among men in the middle tertile of DSL compared to men in the best tertile. Among 210 men without clinical signs or symptoms, associations of poor dominant and non-dominant side DML and fall rates remained. Middle and worst tertiles non-dominant-side DML RRs were 5.69 (95% CI:3.40-9.53) and 2.13 (95% CI:1.23-3.72) and middle and worst tertiles dominant-side DML tertiles were 2.07 (95% CI:1.31-3.28) and 2.84 (95% CI:1.76-4.61), respectively (data not shown).

Table. Relative risks of falls (95%CI)\* according to tertile of peripheral nerve conduction, N=377.

	Best Tertile	Middle Tertile	Worst Tertile	P-Value
CMAP amplitude, non-dominant side	1.00 (Referent)	0.94 (0.73-1.21)	0.86 (0.66-1.12)	0.55
CMAP amplitude, dominant side	1.00 (Referent)	1.33 (1.01-1.77)	1.10 (0.83-1.47)	0.10
DML, non-dominant side	1.00 (Referent)	5.68 (3.40-9.53)	2.13 (1.23-3.72)	<.001
DML, dominant side	1.00 (Referent)	1.11 (0.84-1.48)	1.41 (1.08-1.84)	0.03
SNAP amplitude, non-dominant side	1.00 (Referent)	1.16 (0.87-1.55)	1.27 (0.95-1.70)	0.26
DSL, non-dominant side	1.00 (Referent)	1.40 (1.04-1.88)	1.04 (0.76-1.42)	0.05

\* Adjusted for age, height, muscle area, fat mass, diabetes, depressive symptoms, visual acuity, cognitive function (Teng 3MS), physical activity, use of anti-anxiety & antidepressant medications, use of anticonvulsants, dizziness, smoking, and alcohol consumption

Poor peripheral nerve function, particularly motor, is associated with high fall risk in older community-dwelling men, even in men without signs or symptoms of peripheral neuropathy. Electrodiagnostic evidence of poor peripheral nerve function may help us to identify older men at high fall risk.

**Disclosures:** K.A. Faulkner, None.

## SU324

**8 year Fracture & Mortality Outcomes of the Fracture Liaison Service That Provides Systematic Assessment for Prevention of Secondary Fractures to All Patients Age 50+ With New Low-trauma Fractures.** A. R. McLellan, M. Fraser<sup>\*</sup>. Medical Sciences, Western Infirmary, Glasgow, United Kingdom.

This study reports secondary fracture incidence & mortality in patients who, after presenting with a new fracture, were routinely offered assessment to reduce the incidence of

secondary fractures, during the first 8yr of the Fracture Liaison Service (FLS).

Cox proportional hazards was used to calculate hazard ratios & 95% CI for risk factors for occurrence of secondary fractures & mortality. 7505 women, age (mean(SD)) 73.3(12)yr & 2180 men, age 68.8(11.7)yr, with 11096 consecutive new low-trauma fracture presentations were assessed; index fractures were of radius/ulna, hip, humerus, ankle, hand/foot & 'other sites' in 29%, 24%, 13%, 9%, 10% & 15% resp. All were offered post-fracture assessment; 88% underwent assessment but 12% were too unwell or refused. 31% were treated with bisphosphonate (& calcium/vitD), 24% with calcium/vitD, 4% with other treatments & 41% received no treatment (incl. those who were unwell or refused).

11% sustained ≥1 further fracture: of these, 21% occurred within 6months(mo.) of the index fracture, and 35% & 58% occurred within 12 & 24mo. After adjustment for gender, cumulative fracture history, socioeconomic status, alcohol intake, femoral neck (FN) T-score & site of index fracture, treatment with bisphosphonates was associated with reduced HR for secondary fracture (0.64 (0.51 to 0.80)); this was not seen for other treatment groups. Occurrence of secondary fractures was associated with greater cumulative fracture history e.g. 1, 2 or 4 fractures were associated with HR (95%CI) of 2.24 (1.02 to 4.91), 3.05 (1.35 to 6.90) & 3.70 (1.37 to 11.49), with alcohol excess (1.84 (1.42 to 2.39)), socioeconomic deprivation (most v least deprived) (1.40 (1.13 to 1.74)), site of original fracture - in particular, the group of 'other sites' (1.33(1.03 to 1.72)) & FN T-score (0.68 (0.61 to 0.74)).

20% of patients died: 41% of these died within first 12mo. of index fracture. Male gender was associated with doubling of mortality risk (2.03 (1.66 to 2.48)). Mortality risk was also associated with age (1.07(1.06 to 1.08)), FN T-score (0.77 (0.70 to 0.84)), smoking (1.67 (1.38 to 2.03)), alcohol excess (1.61 (1.22 to 2.11)), socioeconomic deprivation (most v least deprived) (1.43 (1.14 to 1.80)) & whether the index fracture was managed as an inpatient (v outpatient) (1.26 (1.06 to 1.50)).

A systems-based approach, such as our FLS, can achieve delivery of routine post-fracture assessment for fracture secondary prevention in 88% of patients with new fractures. Use of bisphosphonates protects against secondary fractures. Groups at greater risk of secondary fractures & mortality have been identified; the remaining challenge is how their outcomes can be improved.

**Disclosures:** A.R. McLellan, None.

## SU325

**Trauma Type of Non-hip, Non-vertebral Fractures in Postmenopausal Women Being Treated for Osteoporosis in Europe.** C. Roux<sup>1</sup>, C. Cooper<sup>2</sup>, S. Ortolani<sup>3</sup>, A. Díez-Pérez<sup>\*4</sup>, R. Horne<sup>\*5</sup>, N. Franchimont<sup>6</sup>, V. Easton<sup>\*7</sup>, N. Freemantle<sup>\*8</sup>. <sup>1</sup>Département de Rhumatologie B, Hospital Cochin, Paris, France, <sup>2</sup>MRC Epidemiology Resource Centre, University of Southampton, Southampton, United Kingdom, <sup>3</sup>Istituto Auxologico Italiano, Milan, Italy, <sup>4</sup>Dept. de Medicina, Hospital del Mar, Barcelona, Spain, <sup>5</sup>Practice & Policy, The School of Pharmacy, University of London, London, United Kingdom, <sup>6</sup>Amgen (Europe) GmbH, Zug, Switzerland, <sup>7</sup>Biostatistics, Amgen Ltd, Cambridge, United Kingdom, <sup>8</sup>University of Birmingham, West Midlands, United Kingdom.

Recent evidence challenged the notion that fractures due to high trauma are not osteoporotic fractures (JAMA 2007;298(20):2381). We examined this assertion by analyzing fracture history data from 2117 European women being treated with active osteoporosis treatments who are enrolled in an ongoing study. The Prospective Observational Scientific Study Investigating Bone Loss Experience in Europe (POSSIBLE EU<sup>®</sup>) is being conducted in primary care centers in France, Germany, Italy, Spain and the United Kingdom. Fracture history data were collected at study start. Physicians coded all fractures according to 22 different locations (or Other and Unknown). Fractures, excluding those of the face, skull, fingers or toes, are described and characterized by location (hip, vertebral, and nonhip/nonvertebral [NHNV]), type of trauma according to physician (major: falling off ladder to car accident; minor: no to mild trauma), and timing of fracture relative to reported age at menopause (pre- vs post-menopausal). These women had a median age of 69 years (median time since menopause, 20 years). Of 859 women who had experienced fractures, 577 (67%) and 281 (33%) had 1 and ≥ 2 fractures, respectively. Of 1291 reported fractures, most (71%) were NHNV, versus 22% vertebral and 7% hip; most occurred after menopause (Table). 25-39% of postmenopausal fractures occurred after major trauma (Table).

Table. Summary of Fracture Type by Trauma Type

Fracture Type	Trauma Type According to Physician	Number of Premenopausal Fractures	Number of Postmenopausal Fractures
Hip	Minor	2	48
	Major	1	29
Spine	Minor	1	166
	Major	6	54
NHNV	Minor	76	414
	Major	61	254

Note: 105 fractures had missing data related to date of menopause, trauma type or location

In summary, based on interim results from this study of postmenopausal women receiving active osteoporosis treatment, NHNV fractures are common, but occur more frequently after menopause. Actual relatedness of fractures to trauma may be questioned, especially as perception of trauma may be affected by patient age. These results suggest that the notion of attributing fracture to a trauma type may be non-essential in the osteoporosis population.

## SU326

**High Mortality in Male Nursing Home Residents with Hip Fracture.** S. D. Berry, E. J. Samelson, M. Bordes\*, K. E. Broe, D. P. Kiel. Heb SenLife, Boston, MA, USA.

Prior studies have demonstrated mortality following a hip fracture is greater in men compared to women. It remains unclear whether this gender difference is independent of pre-fracture characteristics or peri-operative and post-fracture complications, especially among frail elders. Therefore, our study is the first to compare all-cause mortality in male and female nursing home residents with a hip fracture. We also examined whether specific peri-operative and post-fracture complications predict mortality in this frail population. Participants included 196 residents (154 women, 42 men) of Hebrew Rehabilitation Center, a 725-bed long-term care facility in Boston, MA, who experienced a hip fracture between 1999-2006 and were followed until death, relocation, or June 30, 2007. Hip fractures were identified by federally mandated incident reports, and vital status was determined from an administrative database. Fractures and deaths were confirmed by medical records. Pre-fracture characteristics including age, sex, functional status (ADL short scale), dementia (Cognitive Performance Scale), co-morbidities (anemia, arrhythmia, coronary disease, congestive heart failure (CHF), cancer, diabetes, emphysema) and BMI (kg/m<sup>2</sup>) were collected from the Minimum Data Set, a federally mandated assessment of nursing home residents. Peri-operative complications (Acute Myocardial Infarction, CHF, delirium, and infection) and 6-month post-operative complications (delirium, pressure ulcer, pneumonia, and UTI) were determined from physician notes. We examined the bivariate association between each peri-operative and post-fracture complication and mortality individually using Cox proportional hazards models. Variables that were significant at  $p \leq 0.1$  and pre-fracture characteristics were included in multivariate models. The mean age of participants was 89.0 yrs ( $\pm 6.3$  yrs). During a median follow-up of 1.3 yrs, 146 participants (112 women, 34 men) died. In multivariate models, male residents were twice as likely to die compared to females (HR=1.9, 95% CI 1.2, 3.0). Post-operative complications of pressure ulcer and pneumonia were associated with a 70% increase in mortality in men and women (combined results: pressure ulcer, HR=1.7, 95%CI 1.2, 2.6; pneumonia, HR=1.7, 95% CI 1.1, 2.7). Individual peri-operative complications were not associated with mortality, nor were the 6-month complications of delirium and UTI. In conclusion, male nursing home residents with a hip fracture had greater mortality compared to females, even after accounting for pre-fracture status, peri-operative complications, and post-fracture complications. Post-fracture prevention of pressure ulcers and timely treatment of pneumonia may help to reduce mortality in this frail population.

**Disclosures:** S.D. Berry, None.

## SU327

**Incidence and Costs of Proximal Humerus and Wrist Fractures in Women in France.** M. Maravic\*<sup>1</sup>, P. Taupin\*<sup>2</sup>, P. Landais\*<sup>2</sup>, C. Roux<sup>3</sup>. <sup>1</sup>DIM, Hôpital Léopold Bellan, Paris, France, <sup>2</sup>SBIM, Hôpital Necker, Paris, France, <sup>3</sup>Rheumatology, Hôpital Cochin, Paris, France.

Fracture of the proximal humerus (PHF) is one of the most frequent fractures related to osteoporosis, with substantial morbidity. An increased risk of mortality has been described in the year following this fracture. The aim of this study was to describe the hospital incidence rate of PH fracture, the inpatient costs, and the outcome of these patients, as compared to patients suffering from wrist fracture (WF).

**Patients and methods:** Data are from the French National hospital database; in this database, all patients hospitalized in the country for fractures are registered. We selected in years 2002 and 2006 female patients hospitalized for medical or surgical treatment of upper humerus fracture, or distal radius fracture, and excluded patients with a concomitant diagnosis for cancer. We described the number of hospitalizations, the incidence, the type of entry and exit of hospital, and the inpatients costs in 2006.

**Results:** The data were reported in the following table.

	PHF	WF
Number of hospitalizations in 2002/2006	10 888 / 11432	30 772 / 30 889
Incidence in 2002 / 2006 *	568 / 597	1 580 / 1 613
Increase with age-group 2001 / 2006 °		
30-49	66 / 60	347 / 318
50-69	395 / 435	1 640 / 1 780
> 69 years	1 825 / 1 906	3 960 / 3 960
Entry from home (2006)	95%	97%
Outcomes (2006)		
Home	66%	90%
Rehabilitation	25%	7%
Other care	6%	2%
Living in institution	2%	1%
Death	1%	0%
Inpatients costs (euros 2006)	42 739 508	69 162 264

\*Incidence per million, °  $p < 0.0001$

**Conclusion:** In contrast to the reported data about the decrease of hip fractures incidence, the incidence of PHF and WF did not decrease in France between 2002 and 2006 in women. Whatever the type of fractures or the year studied, the incidence increased with age, stressing the role of the underlying osteoporosis. The inpatient cost was higher for PHF than for WF.

**Disclosures:** M. Maravic, None.

## SU328

**Proximal Humerus Fractures in Men. Epidemiology and Costs.** M. Maravic\*<sup>1</sup>, P. Taupin\*<sup>2</sup>, P. Landais\*<sup>2</sup>, C. Roux<sup>3</sup>. <sup>1</sup>DIM, Hôpital Léopold Bellan, Paris, France, <sup>2</sup>SBIM, Hôpital Necker, Paris, France, <sup>3</sup>Rheumatology, Hôpital Cochin, Paris, France.

In contrast to intensive research into hip and vertebral fractures, little is known about proximal humerus (PH) fractures in men. The aim of this study was to describe the incidence and cost of these fractures and short-term outcome of men with PH fractures.

**Patients and methods:** Data are from the French National hospital database; in this database, all patients hospitalized in the country for fractures are registered. We selected in years 2002 and 2006 male patients ( $\geq 30$  years) hospitalized for medical or surgical treatment of upper humerus fracture, and excluded patients with a concomitant diagnosis of cancer. We described the number of hospitalizations, the incidence in 3 aged-groups, the number of associated diagnoses, the type of entry and exit of hospital, and the inpatients cost in 2006.

**Results:** 3 689 and 3 805 fractures were registered in 2002 and 2006. The incidence rate was 216 and 223 per million in 2002 and 2006 respectively. In 2006, the incidence rate was 110, 233 and 553 in age-group 30-49, 50-69 and  $>69$  years, respectively. This incidence increased significantly with age ( $p < 10^{-4}$ ). The mean of associated diagnoses were  $1.33 \pm 1.92$ ,  $1.69 \pm 2.14$  and  $2.18 \pm 2.53$  in the 3 aged-group, respectively ( $p < 10^{-4}$ ). In 2006, 96% of patients came from home; however, only 74% returned home directly, 17% were transferred to rehabilitation centre, 7% to other type of care, 1% in institution and 1% died. The inpatients costs in 2006 was 14 564 849 euros.

**Conclusion:** The incidence of PH in men did not decrease between 2002 and 2006. The increase with age, especially in the age group upper 69 years, outlined the role of underlying osteoporosis. This increased incidence had consequences in terms of inpatients costs.

**Clinical Outcome in Elderly with Proximal Femur or Humerus Fractures in an Orthogeriatric Rehabilitation Unit.** G. A. Carmona\*, R. Rizzoli, P. Ammann. Division of Bone Disease, WHO Collaborating Centre, Dpt of Rehabilitation and Geriatrics, Geneva University Hospitals/Faculty of Medicine, Switzerland.

Benefits of orthogeriatric intervention in recovery following a fracture of the proximal femur in the elderly are well documented. Whilst fractures of the proximal humerus are associated with a marked decrease in functional independence, the influence of orthogeriatric intervention in elderly who have sustained a proximal humerus fracture is still poorly documented. We performed a retrospective observational study in patients admitted to an orthogeriatric unit between 2002 and 2006, for a hip fracture (HIP#, n=291) or proximal humerus fracture (HUM#, n=73). The rehabilitation program, administered by an interdisciplinary team, integrated walking/balance exercises, muscle strengthening and daily life-training activities. Functional capacity during rehabilitation was evaluated by the Functional Independence Measure (FIM) score at admission (median: 11 days after fracture), after two weeks, and just prior to discharge (median: 33 days observation time). To further evaluate functional outcomes, we separated the functional motor items (MOTOR FIM) into upper and lower limb items (UPPER and LOWER FIM). Values are means  $\pm$  SD and differences were tested using Students' t-test. At admission, age and all motor functional independence scores were significantly higher in patients with HIP# vs. HUM# (83.3  $\pm$  7 vs. 81.5  $\pm$  7 yrs,  $p=0.04$ ; MOTOR FIM: 38.2  $\pm$  11 vs. 33.6  $\pm$  11,  $p=0.002$ ; UPPER FIM: 18.9  $\pm$  4 vs. 12.8  $\pm$  4,  $p<0.0001$  and LOWER FIM: 16.6  $\pm$  6 vs. 12.9  $\pm$  4,  $p<0.0001$ ). At discharge, there was a significant overall gain with HIP# and HUM# (FIM: 24.1  $\pm$  16 vs. 25.9  $\pm$  13,  $p=0.4$ ; MOTOR FIM: 20.6  $\pm$  12 vs. 23.3  $\pm$  11,  $p=0.12$ ; UPPER FIM: 5.3  $\pm$  5 vs. 8.7  $\pm$  5,  $p<0.0001$  and LOWER FIM: 6.5  $\pm$  5 vs. 9  $\pm$  5,  $p<0.0001$ ). For upper and lower limbs the gain was significantly higher for HUM#. The kinetics of MOTOR FIM increases differed between the groups; in the HIP# the functional gain was significantly higher during the first two weeks, while those in HUM# group improved constantly throughout the observation period. Similar trends were observed for the other parameters tested. A functional performance gain was observed for both types of fracture independently of cognitive status (Mini-Mental State score of less or more than 24). This study indicates that an orthogeriatric rehabilitation program improves the functional performance of elderly who have sustained hip or humerus fractures independently of cognitive level. The kinetics of these positive effects differ in the second half of the recovery period with an increase significantly higher in humerus fractured patients.

## SU330

**Evaluation of Bone Mineral Density Following an Education Intervention on Osteoporosis Offered to Women after a Fragility Fracture.** L. Bessette<sup>1</sup>, J. P. Brown<sup>1</sup>, S. Jean<sup>\*2</sup>, S. K. Davison<sup>1</sup>, M. Beaulieu<sup>\*3</sup>, M. Baranci<sup>\*4</sup>, L. Ste-Marie<sup>5</sup>. <sup>1</sup>CHUL Research Centre, Quebec, QC, Canada, <sup>2</sup>Institut national de santé publique du Québec, Quebec, QC, Canada, <sup>3</sup>Merck Frosst, Kirkland, QC, Canada, <sup>4</sup>sanofi-aventis, Laval, QC, Canada, <sup>5</sup>University of Montreal, Montreal, QC, Canada.

The objective of this analysis was to evaluate the rate of bone mineral density (BMD) testing by dual-energy x-ray absorptiometry (DXA) 12 months following an osteoporosis (OP) education intervention offered to women  $\geq 50$  years who suffered a fragility fracture within the past year.

Three educational tools were developed: a 15-minute video, written material on OP targeted to the participants, and written documentation on OP targeted to physicians. Information was based on the 2002 Clinical Practice Guidelines for the Diagnosis and Management of Osteoporosis in Canada. Six to eight months after the fracture event, women who suffered a fragility fracture were contacted by phone and offered to be randomized into one of three educational groups: A) The control group (no intervention); B) the documentation group (written documents for the participants and the physician); or C) the video group (both the video and the documentation for the participants and the physician). Women randomized into groups B and C were invited to consult their treating physician with the written documentation. The BMD testing rate was evaluated during a phone interview 12 months after the intervention. The current analysis was completed only with participants who had no diagnosis and treatment for OP at randomisation.

Of 894 women, 850 (95%) accepted to be randomized. Of these, 546 (64%) (mean age: 61.7 years) were without OP diagnosis and treatment. Ninety-six percent of these 546 women were contacted and completed the phone questionnaire 12 months after randomization. In group B, 84% read the document and 58% gave the document to their physician. In group C, 87% read the document and/or saw the video and 61% transmitted the document to their physician. The BMD testing rates 12 months after the intervention were 24% in group A compared to 32% in both groups B and C. For the women randomized to one groups B and C, 60% consulted their physicians with the Osteoporosis Canada Guidelines for the Diagnosis, Prevention and Treatment of Osteoporosis. When isolating those participants randomized to both groups B and C and who consulted their treating physician with the documents, the BMD testing rate increased to 40%.

An intervention targeting the patient increased the rate of BMD testing in the group of participants who provided this documentation to their doctors.

**Genome-wide Association Study Identified RTP3 as a Novel Gene for Bone Strength.** L. Zhao<sup>1</sup>, X. Liu<sup>\*2</sup>, Y. Liu<sup>\*2</sup>, L. Wang<sup>\*3</sup>, Y. Liu<sup>\*2</sup>, H. Yan<sup>\*3</sup>, J. Liu<sup>\*2</sup>, D. Xiong<sup>\*1</sup>, F. Pan<sup>\*3</sup>, Z. Tang<sup>\*4</sup>, T. Yang<sup>\*3</sup>, X. Chen<sup>\*4</sup>, Y. Guo<sup>\*3</sup>, S. Lei<sup>\*4</sup>, R. R. Recker<sup>1</sup>, H. Deng<sup>2</sup>. <sup>1</sup>Osteoporosis Research Center, Creighton University Medical Center, Omaha, NE, USA, <sup>2</sup>School of Medicine, University of Missouri - Kansas City, Kansas City, MO, USA, <sup>3</sup>School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, China, <sup>4</sup>Laboratory of Molecular and Statistical Genetics, College of Life Sciences, Hunan Normal University, Changsha, China.

Femoral bone geometry is an important determinant of bone strength and predictor of hip fracture, the most severe osteoporotic fracture. Genome-wide association has been approved to be an efficient and feasible approach to identify genetic factors for complex disorders. Here we report the first genome-wide association study on femoral bone geometry, examining ~500,000 SNPs in 1,000 Caucasians. A common variant rs7430431 in the RTP3 (receptor transporting protein 3) gene was identified in strong association with BR (buckling ratio) ( $P=1.61E-07$ ), an index for bone structural instability, and CT (cortical thickness) ( $P=1.92E-06$ ). Haplotype analysis indicated that the block containing rs7430431 had highly suggestive association with BR ( $P=5.76E-05$ ). Subjects carrying the C allele of rs7430431 had, on average, 9.8% higher BR than those carrying the alternative T allele ( $P=3.00E-05$ ), thus suffering higher hip fracture risk. In addition, most SNPs of the RTP3 gene achieved highly suggestive association with both BR and CT ( $P \leq 0.001$ ). To verify our findings in another ethnic group and to assess the relevance of the RTP3 gene to hip fracture risk, we tested the association of the SNPs of the RTP3 gene with osteoporotic hip fracture in a Chinese sample composed of 360 hip fracture patients and 340 healthy controls. Significant association ( $P=0.001$  and  $P=0.003$ ) between two SNPs (rs10514713 and rs883739) of the gene and hip fracture was found and hence substantiated the importance of RTP3 to bone strength. These observations, combined with potential functional relevance of RTP3 to bone development, suggest that RTP3 is a novel candidate gene for bone strength.

**Recognition and Treatment of Male Osteoporosis is Low.** J. LaFleur<sup>\*1</sup>, C. McAdam-Marx<sup>\*1</sup>, S. Pickard<sup>\*2</sup>, J. Nebeker<sup>\*2</sup>. <sup>1</sup>Department of Pharmacotherapy, University of Utah, Salt Lake City, UT, USA, <sup>2</sup>Division of Clinical Epidemiology, University of Utah, Salt Lake City, UT, USA.

**Background:** The prevalence of osteoporosis among males over age 50 in the US ranges from 3% of Hispanics and 4% of Blacks to 7% of White and Asian men. The expected rate of fragility fractures for males over age 50 is 25% in their remaining lifetimes. In secondary osteoporosis, bisphosphonates have been shown to reduce the risk of these fractures by 67-81%.

**Purpose:** The purpose of this analysis was to characterize the disease burden of osteoporosis and fragility fractures, treatment rates, and the prevalence of risk factors in male veterans.

**Methods:** We used Veterans Health Administration clinical datasets for veterans treated in the US rocky mountain region to create a cohort of males over the age of 49 who received care during the calendar years of 2005 and 2006. We identified the proportions of patients with documented osteoporosis or fragility fracture and, of those, the proportions who were treated and untreated. The prevalence of well-known clinical risk factors and their associated fracture rates were also documented.

**Results:** 115,012 males age 50 and over received care. The mean age of the cohort was 67.1 (SD 10.6). Among the 38% with recorded race information, 92.7% were Caucasian. Among the 74% with recorded body mass index (BMI), 3.6% were underweight and 30.6% were normal weight. An osteoporosis diagnosis was reported in only 1.9% of patients. The prevalence of fragility fracture during the two-year period was 1.3%. Among those that had a fragility fracture, only 6.3% had a prescription for an oral bisphosphonate, compared to 74.0% of patients with a documented osteoporosis diagnosis.

Overall, the incidence of fracture over a median follow-up of 2.8 years was 2.1/1000 person-years (PY). The incidence was increased significantly in patients with a prior vertebral fracture (83.0/1000 PY,  $p<0.001$ ), hip fracture (76.1/1000 PY,  $p<0.001$ ), or wrist fracture (59.7/1000 PY,  $p<0.001$ ). The incidence was lower in patients being treated with a bisphosphonate (7.3/1000 PY) compared to patients with untreated osteoporosis (43.7/1000 PY,  $p=0.048$ ).

**Conclusions:** In the rocky mountain region, the proportion of male veterans diagnosed with osteoporosis is less than a third of the national rate, suggesting low levels of recognition. Moreover, only a small fraction of veterans with fragility fractures appear to be receiving oral bisphosphonates, the current standard of care for men.

**Changes in Histomorphometric Parameters after Menopause: A Prospective Study.** L. A. G. Armas, J. M. Lappe, R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Menopause is the event in women's lives most closely linked to bone loss and subsequent risk of osteoporosis and attendant fractures late in life. This study was designed to determine bone tissue- and cell- level changes in bone remodeling that occur with rapid bone loss at menopause.

Fifty healthy premenopausal white women (mean age  $49.4 \pm 1.9$  yrs) had a transilial bone biopsy after tetracycline labeling on entry into study and returned for a 2<sup>nd</sup> biopsy 12 months after their last menses. The biopsy specimens were fixed, embedded, sectioned, and evaluated. Measured and calculated variables in trabecular bone histomorphometry used here are described by Parfitt.

Analysis of within-subject change in variables in the 50 women who experienced normal menopause was done by paired t-test. Structural variables were not significantly different between pre and post menopausal females except osteoid volume was significantly higher in the postmenopausal females. Most of the surface based data (eroding surface (ES/BS), osteoclast surface (OcS/BS), osteoblast surface (ObS/BS), mineralizing surface (MS/BS), and mineral apposition rate (MAR)) were significantly higher in the postmenopausal women.

The dynamic variables were calculated based on perimeter measurements that included double label plus half the single label. The bone formation rate and activation frequency (AcF) were higher in postmenopausal females. The formation period (FP), remodeling period (RmP), mineralization lag time (Mlt), and off time (OfT) was shorter for postmenopausal women.

The changes in dynamic variables seen by histomorphometry during menopause reflect the increased rate of bone remodeling during estrogen deficiency.

Table 1 Dynamic data (based on double label plus half single label surface)

Variable	N	Premenopausal Median CI)	Postmenopausal Median CI)	Paired T test P value
BFR/BV %/yr	48	6.6 (0.84 - 23.6)	13.4 (3.2 - 39.5)	0.0001
FP yr	48	0.76 (0.16 - 6.3)	0.37 (0.17 - 1.6)	0.001
RP yr	48	0.14 (0.02 - 1.7)	0.14 (0.04 - 0.64)	NS
RmP yr	48	0.92 (0.26 - 6.8)	0.53 (0.22 - 2.2)	0.002
Mlt days	48	48.6 (6.4 - 213.2)	26.2 (10.8 - 89.1)	0.001
OfT days	48	-19.5 (-309.1 - - 2.3)	-13.1 (-95.5 - -2.8)	0.013

**Predictive Capacity of Biochemical Markers of Bone Turnover and Endogenous Hormones for Osteoporosis in Men: Ten-year Follow-up of a Japanese Cohort.** N. Yoshimura<sup>1</sup>, H. Oka<sup>\*1</sup>, S. Muraki<sup>2</sup>, T. Akune<sup>\*2</sup>, H. Kawaguchi<sup>3</sup>, K. Nakamura<sup>3</sup>. <sup>1</sup>Dept of Joint Disease Research, 22nd Century Medical and Research Center, the University of Tokyo, Tokyo, Japan, <sup>2</sup>Dept of Clinical Motor System Medicine, 22nd Century Medical and Research Center, the University of Tokyo, Tokyo, Japan, <sup>3</sup>Dept of Orthopaedic Surgery, the University of Tokyo, Tokyo, Japan.

Although social and economic impacts of male osteoporosis (OP) are increasing worldwide, there is little understanding of the etiology or epidemiology due to the lack of longitudinal data on this disorder. This study aimed at exploration of the incidence and evaluation of the predictive capacity of biochemical markers of bone turnover (BTMs) and endogenous hormones for the male OP in residents of a rural population in Japan followed for 10 years. Two-hundred subjects aged 40-79 years with 50 men in each generation (40-49, 50-59, 60-69 and 70-79) were randomly selected in 1992 from the full list of residents born in 1913-1952. Baseline BMD of the lumbar spine and proximal femur was measured by DXA in 1993, 1996, 2000 and 2003. Serum intact OC, total OC, ALP, BAP, PICP, PINP, ICTP, serum and urinary CTX, NTX, urinary PYR, DPD, serum free testosterone (FT), estradiol and intact parathyroid hormone were measured in the initial survey. One-hundred and fifty-three out of 200 men (76.5%) who had been initially recruited completed a 10-year follow-up. Rates of change of BMD at lumbar spine and femoral neck were 0.26%/y and 0.16%/y over the first three years, and those over 10 years were 0.08%/y and -0.03%/y, respectively. Incidence of OP at the lumbar spine and femoral neck over 10 years were 23.8/10,000 person years and 17.1/10,000 person years, respectively. According to multivariate regression analysis utilizing the rate of change of BMD as an objective factor, and each BTM and endogenous hormone as an explanatory factor after adjusting for age and body mass index (BMI), the mean values of PYR and FT were significantly related to the rate of change of BMD during the first three years (PYR and BMD at lumbar spine; beta 0.20, R<sup>2</sup> 0.05, P<0.01, FT and BMD at femoral neck; beta 0.21, R<sup>2</sup> 0.05, P<0.01), while none of the values of BTMs or endogenous hormones could predict the bone loss during 10 years. Then, after the analysis of Cox proportional hazards model adjusted for age and BMI, serum levels of PINP correlated with incidence of OP at lumbar spine and FT was significantly related to incidence of OP at femoral neck (PINP vs. +1 standard deviation (SD); hazard ratio (HR) 1.86, 95% confidence interval (CI) 1.13-3.07; FT vs. +1SD; HR 0.25, 95%CI 0.08-0.80). We conclude that the serum levels of PYR and FT could be the useful predictor for bone loss within three years and PINP and FT for future occurrence of the male OP.

**Disclosures:** N. Yoshimura, None.

**Influence of Sex Hormones on Bone Mineral Density in Middle Aged and Elderly Men.** S. R. Pye<sup>\*1</sup>, S. Boonen<sup>2</sup>, H. Borghs<sup>\*2</sup>, D. Vanderschueren<sup>2</sup>, J. E. Adams<sup>3</sup>, K. A. Ward<sup>3</sup>, G. Bartfai<sup>\*4</sup>, F. Casanueva<sup>\*5</sup>, J. D. Finn<sup>\*6</sup>, G. Forti<sup>\*7</sup>, A. Giwercman<sup>\*8</sup>, I. T. Huhtaniemi<sup>\*9</sup>, K. Kula<sup>\*10</sup>, M. Punab<sup>\*11</sup>, A. J. Silman<sup>\*1</sup>, E. C. Wu<sup>\*6</sup>, T. W. O'Neill<sup>1</sup>. <sup>1</sup>ARC Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, <sup>2</sup>Katholieke Universiteit Leuven, Leuven, Belgium, <sup>3</sup>Department of Imaging Science and Biomedical Engineering, The University of Manchester, Manchester, United Kingdom, <sup>4</sup>University of Szeged, Szeged, Hungary, <sup>5</sup>University of Santiago de Compostela, Santiago de Compostela, Spain, <sup>6</sup>Department of Endocrinology, The University of Manchester, Manchester, United Kingdom, <sup>7</sup>University of Florence, Florence, Italy, <sup>8</sup>Lund University, Malmö, Sweden, <sup>9</sup>Imperial College, London, United Kingdom, <sup>10</sup>University of Lodz, Lodz, Poland, <sup>11</sup>University of Tartu, Tartu, Estonia.

Serum sex hormones particularly estrogen are known to be associated with bone mass in men. Most studies have been in cohorts of elderly men with fewer data including middle age subjects. Moreover the relative role of age related changes in total versus free or bioavailable fractions of sex hormones on bone health remains unclear. The aim of this study was to determine the influence of sex hormones on bone mineral density (BMD) in middle aged & elderly European men.

Men aged between 40 & 79 years were recruited from population registers in two European centres (Manchester, UK; Leuven, Belgium). 400 subjects (100 in each of the four decades of interest) from each centre were invited to attend for dual energy X-ray absorptiometry (DXA) of the hip & spine (Hologic QDR 4500 & Discovery). Fasting blood samples were assayed for serum testosterone (T), estradiol (E2) & sex-hormone binding globulin (SHBG) by electrochemoluminescence immunoassays (Roche Diagnostics, Germany). Free & bioavailable (bio) T & E2 levels were derived using mass action equations & association constants. Height & weight were measured in all subjects. Associations between BMD at the spine and hip and sex hormones were assessed using linear regression with adjustments for age, height, weight & centre.

753 men, mean age 60.1 years (SD=10.9) were included in the analysis. Higher levels of total E2 were associated with increased BMD at the total hip ( $\beta$  per 10 pmol/l change = 0.004; 95% CI 0.001, 0.007) & lumbar spine ( $\beta$  per 10 pmol/l change = 0.006; 95% CI 0.001, 0.010). Similar associations were observed with free & bio E2. Total T was unrelated to BMD, but higher levels of free & bio T were associated with increased BMD at the total hip ( $\beta$  per 10 pmol/l change in free T = 0.001; 95% CI 0.000, 0.003 &  $\beta$  per nmol/l change in bio T = 0.005; 95% CI 0.000, 0.010 respectively). SHBG was unrelated to BMD at any site.

In this population survey of middle aged and elderly European men, higher levels of E2 and free T were associated with increased bone mass at the hip and spine.

**Menopausal and Postmenopausal Women Have Significantly Higher Bone Resorption and Oxidative Stress Parameters than Premenopausal Women.**

E. S. Mackinnon<sup>\*1</sup>, A. V. Rao<sup>\*2</sup>, R. G. Josse<sup>\*1</sup>, L. G. Rao<sup>1</sup>. <sup>1</sup>Department of Medicine, St. Michael's Hospital, Toronto, ON, Canada, <sup>2</sup>Department of Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

We have previously shown that oxidative stress is associated with an increased risk of osteoporosis (Osteoporos Int., 2007;18(1):109-15). Based on these results, we extended our cross-sectional study to include premenopausal, menopausal and postmenopausal women in order to confirm whether oxidative stress correlates with bone resorption and predicts the risk for osteoporosis in these women. A total of 108 women, aged 25-70, were recruited (Research Ethics Board approved, St. Michael's Hospital, Toronto). None of the participants were on medications for diabetes, high blood pressure or osteoporosis. Fasting blood samples, dietary records from the preceding seven days and the following information was collected: age, menopausal status, height, weight and blood pressure. Fasting blood samples were assayed for the bone resorption marker cross-linked aminoterminal N-telopeptide (NTx), lipid peroxidation (TBARS) and protein oxidation (where low protein thiols indicates higher oxidation). Participants were stratified into three groups: premenopausal (n=27), menopausal (n=27), and postmenopausal (n=54) women. One-way ANOVA and the Bonferroni Multiple Comparison test were used to determine differences in bone resorption and oxidative stress parameters between groups. Within groups, Pearson Correlation was used to determine whether bone resorption was associated with oxidative stress. As shown in the table below, bone resorption and oxidative stress parameters were significantly higher in menopausal and postmenopausal women than those in premenopausal women. Furthermore, a high bone resorption was significantly correlated with a lower protein thiols (higher protein oxidation) in both menopausal ( $r = -0.2711$ ,  $p < 0.05$ ) and postmenopausal women ( $r = -0.4202$ ,  $p < 0.05$ ). In conclusion, our results provide further confirmation that oxidative stress is important in the development of osteoporosis. Therapeutic agents such as the antioxidant lycopene, which can inhibit oxidative stress, may be beneficial for the prevention of osteoporosis.

Parameters	Mean $\pm$ SEM (p value vs. PR)		
	Premenopausal women (PR)	Menopausal women (M)	Postmenopausal women (PM)
NTx (nM BCE)	16.3 $\pm$ 1.0	23.8 $\pm$ 1.5 (p<0.001)	20.8 $\pm$ 1.0 (p<0.05)
Protein Thiols* ( $\mu$ M)	537.8 $\pm$ 12.3	456.2 $\pm$ 18.9 (p<0.05)	459.8 $\pm$ 15.6 (p<0.01)
TBARS (nmol/ml)	4.8 $\pm$ 0.2	7.8 $\pm$ 0.6 (p<0.001)	8.9 $\pm$ 0.3 (p<0.001)

\*low protein thiols = high protein oxidation

## SU337

**Bone Mineral Density and Body Composition in Postmenopausal Women with Psoriasis and Psoriatic Arthritis.** P. G. Pedreira<sup>\*</sup>, M. M. Pinheiro<sup>\*</sup>, V. L. Szejnfeld<sup>\*</sup>. Reumatology, São Paulo University, São Paulo, Brazil.

**BACKGROUND:** Patients with psoriatic arthritis (PsA) have local and systemic bone loss. Besides, they may have low lean mass related to chronic inflammation, immobilization and joint impairment. Psoriasis (Ps) can affect joints in 5 to 8%, with increased concentrations of TNF- $\alpha$  and IL-6 which enhance bone resorption. However, it is not known if osteoporosis or sarcopenia is more frequent in PsA or Ps patients.

**OBJECTIVE:** To compare bone mineral density (BMD) and body composition (BC) measurements in Ps and PsA patients.

**METHODS:** This a cross-sectional study in 47 Ps postmenopausal women and 39 PsA postmenopausal women. All patients performed dual X-ray absorptiometry (DXA) at lumbar spine, total femur and total body (GE-lunar DPX, MD+). Besides, the patients performed cutaneous and articular evaluation with specific instruments (PASI, HAQ and DAS28) as well answered a questionnaire that included details about lifestyle, habits, gynecological factors, previous fracture, concomitant diseases and medications. Spine fractures were evaluated using lumbar and thoracic spine X-ray. Secondary osteoporosis and patients using mobility devices were excluded.

**RESULTS:** Age, body mass index (BMI) and BMD at lumbar spine, total femur and total body were similar in Ps and PsA patients. However, vertebral and femoral osteoporosis was significantly more frequent in PsA than Ps patients. PsA patients had significantly total lean mass lower than Ps patients. Moreover, sarcopenia was three times more frequent in PsA than Ps patients. PsA patients presented higher total fat mass than Ps patients, but fatty distribution (android shape) was not different between the groups. Our results are listed in table below.

	PsA (N = 39)	Ps (N = 47)	P
Age (years)	61 ± 8	61 ± 9	NS
BMI (kg/m <sup>2</sup> )	29.03 ± 3.72	28.9 ± 5.48	NS
Lumbar Spine BMD (g/cm <sup>2</sup> )	1.060 ± 0.2	1.050 ± 0.1	NS
Total Femur BMD (g/cm <sup>2</sup> )	0.940 ± 0.1	0.920 ± 0.1	NS
Total Body BMD (g/cm <sup>2</sup> )	1.120 ± 0.1	1.110 ± 0.1	NS
Spine			
Osteopenia (%)	30.8	29.8	NS
Osteoporosis (%)	17.9	12.8	<0.05
Femur			
Osteopenia (%)	35.9	46.8	<0.05
Osteoporosis (%)	7.7	4.2	<0.05
Total Lean Mass (kg)	35.34 ± 3.96	37.46 ± 5.00	0.01
Android Shape (%)	61.5	61.7	NS
Fat Mass (%)	45.9	43.4	0.02

BMI: Body Mass Index; BMD: Bone Mineral Density; PsA: Psoriatic Arthritis; Ps: Psoriasis

**CONCLUSIONS:** Although Ps and PsA patients present high prevalence of low bone mass, there was no significant difference between them. PsA patients had lower lean mass and higher fat mass than Ps patients. These findings in PsA patients may be related to more risk to disability, osteoporotic fractures, metabolic syndrome and cardiovascular diseases.

## SU338

**Self Reported Weight At Birth Predicts Measures of Femoral Size but Not Volumetric BMD in Elderly Men: MrOS.** M. Javai<sup>1</sup>, L. Lui<sup>2</sup>, P. Cawthon<sup>2</sup>, T. Lang<sup>3</sup>, N. Lane<sup>3</sup>, E. Orwoll<sup>4</sup>, E. Barrett-Conner<sup>5</sup>, M. Nevitt<sup>3</sup>, C. Cooper<sup>1</sup>, S. Cummings<sup>2</sup>. <sup>1</sup>The Botnar Research Centre, Oxford, United Kingdom, <sup>2</sup>CPMC, San Francisco, CA, USA, <sup>3</sup>UCSF, San Francisco, CA, USA, <sup>4</sup>OHSU, Portland, OR, USA, <sup>5</sup>UCSD, San Diego, CA, USA.

**Purpose:** The mechanism for poor intrauterine growth leading to adult hip fracture is unclear. We report the association between birthweight and hip geometry and bone density in community-dwelling elderly men.

**Methods:** Of baseline recorded data, we used self-reported birthweight, measured height, weight and quantitative computed tomography (QCT) measurements of femoral neck axis length, cross sectional area (CSA) and volumetric BMD (vBMD) among the participants in the Osteoporotic Fractures in Men (MrOS), a cohort study of US men ages 65 years and older. Neck axis length was measured as the distance between the minimum (femoral neck [FN]) and maximum CSA. CSA was derived from the area within the periosteal boundary. The neck shaft angle was calculated from the FN and shaft angles. Of the 3786 men with QCT data, 1831 (48.3%) reported birth weight. We compared men with birthweight < 7 pounds (low birthweight (LBW); n=501) and ≥ 9 pounds (high birthweight (HBW); n=262) with those weighing 7-8.9 pounds (medium birthweight, referent group; n= 1,068) using linear regression models adjusting for current age, height and BMI.

**Results:** The mean age of the 1831 men with both birthweight and QCT measurements was 73 yrs (SD 5.9).

The HBW men had a longer femoral neck and this remained statistically significant after adjusting for adult BMI but was of borderline significance (p=0.06) after also adjusting for adult height. LBW men also had a longer neck than the referent group after adjusting for current height and BMI (p=0.009). FN cross sectional area was reduced in LBW men by 0.25 SD (p<0.001) and this remained significant after adjusting for both current height and BMI. Neck shaft angle was not predicted (p>0.1) by birth weight. Neither cortical nor trabecular vBMD at the femoral neck were associated with birth weight.

**Conclusions:** These findings support the hypothesis that the skeletal envelope, but not density, is set, in part, at birth. LBW men have a longer femoral neck than expected for their cross sectional area. Additional research describing the relationship between the early developmental factors and lifetime fracture risk should be pursued; such research may inform primary preventative strategies for fracture prevention

**Relationship between reported birth weight and QCT measures of bone strength in cohort elderly men**

Legend: Unadjusted Mean (95% CI) shown; P values from regression models adjusted for age, height and BMI with referent medium birth weight group (\* p<0.05, \*\* p< 0.01)

## SU339

**Casual Decomposition of Risk Factors in Osteoporosis Burden.** Z. Hamidi<sup>1</sup>, R. Majdzadeh<sup>2</sup>, A. Soltani<sup>3</sup>, B. Larijani<sup>4</sup>. <sup>1</sup>Endocrinology and Metabolism Research Centre of Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, <sup>2</sup>Public Health School of Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Osteoporosis is an extending problem in the world and priority setting of prevention efforts and researches about it, is necessary.

In our study we calculated the Generalized Impact Fraction (GIF) index and avoidable burden of Osteoporosis related to "low calcium intake, smoking, reduced sun Exposure, low physical activity, low BMI and systemic glucocorticoid therapy. These risk factors, all can be intervened. Data about prevalence, casual effect and counterfactual prevalence of any of above risk factors obtained from different Iranian (and if needed Non-Iranian) studies that contained best qualified evidences that was attainable.

When counterfactual prevalence considered 0% (theoretical minimum risk), GIFs of smoking, low calcium intake, reduced sun Exposure, low physical activity, low BMI and systemic glucocorticoid therapy, was 0.038, 0.038, 0.110, 0.290, 0.211 and 0.020, respectively. When appropriate feasible minimum risk was considered as counterfactual prevalence, GIF of smoking, low calcium intake, low physical activity, and systemic glucocorticoid therapy, was 0.019, 0.010, 0.290 and 0.007.

Interventions that reduce low physical activity are at the priority of osteoporosis prevention strategies. Of course cost-effectiveness and practicality of any intervention must be appreciated.

**Disclosures:** Z. Hamidi, None.

## SU340

**Fragility Fractures and Health Status in a Multinational Cohort. The Global Longitudinal Registry of Osteoporosis in Women.** C. Cooper<sup>1</sup>, J. Adachi<sup>2</sup>, F. A. Anderson<sup>3</sup>, J. Compston<sup>4</sup>, J. C. Netelenbos<sup>5</sup>, J. Pfeilschifter<sup>6</sup>, S. Silverman<sup>7</sup>, R. Dedrick<sup>8</sup>, S. Adami<sup>8</sup>. <sup>1</sup>Southampton General Hospital, Southampton, United Kingdom, <sup>2</sup>St. Joseph's Hospital, Hamilton, ON, USA, <sup>3</sup>UMASS Medical School, Worcester, MA, USA, <sup>4</sup>University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, <sup>5</sup>VU University Medical Center, Amsterdam, Netherlands, <sup>6</sup>Medizinische Klinik I, Lutherhaus, Essen, Germany, <sup>7</sup>David Geffen School of Medicine, Los Angeles, CA, USA, <sup>8</sup>University of Verona, Verona, Italy.

The purpose of this study was to examine baseline self-rated health among women with and without prevalent fractures.

The Global Longitudinal registry of Osteoporosis in Women (GLOW) is an observational follow-up study of women aged ≥55 years recruited by 540 primary physician practices (17 sites, 10 countries). Practices typical of each region were identified through primary care networks organized for administrative, research or educational purposes. All non-institutionalized women visiting the practice within the prior 2 years were eligible. Self-administered questionnaires were mailed, with a 2:1 over-sampling of women ≥65 years. Data on occurrence of prior fractures since age 45 at any of 10 bone locations were collected. Respondents rated their overall health on a 5-point scale, from "excellent" to "poor," and completed EQ-5D, a generic instrument that captures 5 dimensions of health status (mobility, self-care, usual activities, pain/discomfort, anxiety/depression).

Among 47,786 women, 23% reported ≥1 fracture since age 45. Site-specific prevalence varied from 5.8% (wrist) to 0.4% (pelvis). Prevalence of "fair" or "poor" self-rated health was 21% for women without fractures vs 41% for those with multiple fractures (range 24% for wrist to 42% for spinal fracture). Mean EQ-5D scores were significantly higher in women without fractures (0.78 vs 0.74 or 0.65 of a possible score of 1.00), and tended to indicate greater impairment for those who had had fractures to spine, hip, and clavicle. All mean scores for those with fractures were significantly different from means for subjects without fractures (P<0.0001).

Table. Overall self-rated health status and fracture history (age standardized). \*P<0.05

	No fracture 77%	Any 1 fracture 17%	Multiple fractures 6%
Subjects			
EQ-5D: "Any problems"			
Mobility	27%	33%	50%
Self care	6%	9%	18%
Usual activities	26%	32%	50%
Pain	68%	74%	83%
Anxiety	40%	44%	53%
EQ-5D, mean (standard deviation)	0.78 (0.21)	0.74 (0.24)	0.65 (0.29)
SF-36: "Any limitations"			
Vigorous activity	79%	83%	89%
Moderate activity	39%	48%	63%
Bathe or dress self	11%	15%	25%
Health "fair" or "poor"	21%*	27%	41%

Women who have sustained fractures after age 45 reported poorer health status than contemporaries without fractures, particularly women with fractures of the spine, hip and pelvis.

### Risk Factors for Low BMD in Healthy Men Age 50 Years or Older: A Systematic Review. C. C. Kennedy<sup>1</sup>, A. Papaioannou<sup>1</sup>, A. Cranney<sup>2</sup>, G. Hawker<sup>3</sup>, J. P. Brown<sup>4</sup>, S. M. Kaiser<sup>5</sup>, W. D. Leslie<sup>6</sup>, C. J. M. O'Brien<sup>\*7</sup>.

<sup>1</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>2</sup>Medicine & Clinical Epidemiology, University of Ottawa, Ottawa, ON, Canada, <sup>3</sup>Medicine and Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Medicine, Université Laval, Quebec, QC, Canada, <sup>5</sup>Medicine, Dalhousie University, Halifax, NS, Canada, <sup>6</sup>Medicine & Radiology, University of Manitoba, Winnipeg, MB, Canada, <sup>7</sup>Radiology, Brantford General Hospital, Brantford, ON, Canada.

Research to date has largely focused on the diagnosis and management of osteoporosis in postmenopausal women. The objective of this systematic review was to evaluate the evidence regarding risk factors for low bone mineral density (BMD) and bone loss in healthy men age 50 years or older.

Our population of interest was men age 50 years or older. The search was carried out on several databases via the OVID search interface between January 1990 and January 2006. The three main search concepts were bone density, densitometry and risk factors. Only observational studies that used dual energy x-ray absorptiometry (lumbar spine or proximal femur) were included. We were interested in factors that could be assessed in primary practice via clinical history; Studies investigating osteoporosis associated with diseases or medications were excluded. Trained reviewers assessed methodological quality and an individual grade ('Good', 'Fair', 'Poor') was assigned to each study based on the United States Preventive Services Task Force (USPSTF) rating system. Studies assigned a grade of 'Poor' were excluded.

The search strategy identified 642 relevant abstracts. In total, 25 articles from 18 different studies met both the inclusion and quality criteria. Sample sizes ranged from 137 to 5995 with a median of 458. Consistent risk factors were: age, smoking, low weight, physical/functional limitations and previous fracture. In longitudinal studies, physical activity and alcohol were not predictive of bone loss; in cross-sectional studies, there was inconsistent evidence. The evidence was inconsistent or weak for: calcium, muscle strength, family history of fracture/osteoporosis, and height/height loss.

This systematic review highlights several easily assessed risk factors for low BMD and bone loss in healthy men. This data will assist policy makers and primary care physicians in assessing which men over age 50 should be referred for bone densitometry.

### Distribution of Risk Factors for Fracture in Women With and Without a Fracture History: A Regional Comparison. The Global Longitudinal Registry of Osteoporosis in Women. J. D. Adachi<sup>1</sup>, P. Sambrook<sup>2</sup>, A. Diez-Perez<sup>3</sup>, J. Compston<sup>\*4</sup>, F. Hooven<sup>\*5</sup>, J. C. Netelenbos<sup>5</sup>, N. B. Watts<sup>7</sup>, R. Dedrick<sup>\*8</sup>, C. Roux<sup>\*8</sup>.

<sup>1</sup>Medicine, St. Joseph's Hospital - McMaster University, Hamilton, ON, USA, <sup>2</sup>University of Sydney-Royal North Shore Hospital, Sydney, Australia, <sup>3</sup>Hospital del Mar, Barcelona, Spain, <sup>4</sup>University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, <sup>5</sup>UMASS Medical School, Worcester, MA, USA, <sup>6</sup>VU University Medical Center, Amsterdam, Netherlands, <sup>7</sup>University of Cincinnati, Cincinnati, OH, USA, <sup>8</sup>Hopital Cochin, Paris, France.

The aim of this study was to compare the prevalence of risk factors for fracture in 3 regions in women with and without report of prior fracture, in a large cohort of women aged  $\geq 55$  years.

The Global Longitudinal registry of Osteoporosis in Women (GLOW) is an observational follow-up study of 50,226 women aged  $\geq 55$  recruited through 540 primary physician practices (17 sites, 10 countries). Practices typical of each region were identified. All non-institutionalized patients visiting the practice within the prior 2 years were eligible. Self-administered questionnaires were mailed, with 2:1 over-sampling of those aged  $\geq 65$ . Reminder postcards and second surveys were sent to enhance participation; in some sites patients were followed-up by telephone. Follow-up questionnaires will be sent at 12-month intervals for 5 years.

Among women who reported a history of fracture after age 45, 41% required their arms to rise from sitting versus 32% of those without a history of fracture. Overall, 28% of women with a history of fracture reported cortisone use vs 23% in those without a fracture history. Women in the US with a fracture history were more likely to report being on cortisone (39%) than European women with a fracture history (18%) (Table). Of the women in Australia and Canada without a fracture history, 5.6% reported drinking  $>14$  alcoholic drinks/week vs 3.4% of European women and 2.4% of US women. When comparing the 3 regions, all variables were highly significantly different ( $P < 0.0001$ ) except for weight  $< 125$  lb in women with a fracture history ( $P < 0.05$ ).

Table. Age-standardized prevalence of risk factors for fracture.

Risk factor (%)	History of fracture (n=11,893)			No history of fracture (n=38,333)		
	Can/Aust (n=1448)	Europe (n=5494)	USA (n=4951)	Can/Aust (n=4936)	Europe (n=16,965)	USA (n=16,432)
Maternal hip fracture	15	13	16	12	11	12
Weight $< 125$ lbs (57 kg)	18	19	15	15	18	14
Current smoker	7.8	11	9.2	8.6	10	7.6
Arms used to assist from sitting	41	38	46	32	29	34
Parental fracture	18	17	20	15	13	15
Cortisone (ever taken)	28	18	39	24	13	32
Alcoholic drinks ( $> 14$ /week)	6.4	3.3	2.1	5.6	3.4	2.4
Rheumatoid arthritis	12	15	11	9.0	12	8.8

In this international "real-world" population of women, self-reported risk factors for fracture varied widely by both geographic region and by history (vs no history) of fracture.

## SU343

### The Development of a Point-of-care Clinical Decision Support Tool for Osteoporosis Disease Management. M. Kastner<sup>\*1</sup>, D. Lottridge<sup>\*2</sup>, J. Li<sup>\*2</sup>, S. E. Straus<sup>\*3</sup>.

<sup>1</sup>Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Mechanical and Industrial Engineering, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Medicine, University of Calgary, Calgary, AB, Canada.

**Purpose:** To develop a prototype tool that can support clinical decision making in osteoporosis disease management (OP-DM) at the point of care.

**Methods:** Key findings from a systematic review of randomized trials assessing OP-DM interventions were used to develop a conceptual design of the tool. We then conducted a qualitative study of focus groups with family physicians and general internists to develop a working prototype of the tool. The goal of the focus groups was to assess which features, functions, format, and evidence are important to include in the tool; and to discuss barriers to using such a tool in clinical practice. Focus groups were audiotaped and transcribed verbatim. 2 reviewers independently coded data using a combination of grounded theory methodology and verbal protocol analysis.

**Results:** 4 focus groups (n=17) were needed to achieve saturation of themes (mean age range 47-55 years, 76% men). Using an iterative model, the OP-DM tool was modified from analysis of the first focus group, which informed changes to the tool for subsequent focus groups. Barriers identified were related to the accuracy and feasibility of extracting BMD test results and medications from the risk assessment questionnaire, and the need to include well-balanced information in the patient education sheet. Suggestions for modifying the prototype included the addition of a percentile graph showing patients' 10-year absolute risk for fractures, and ensuring that the tool takes no more than 5 minutes to complete. The resulting working prototype is multi-targeted (patients, physicians, and clinic nurses), and includes 3 components: 1) an osteoporosis risk assessment questionnaire filled out by eligible patients on a Tablet PC in the examination room while waiting for their physician; 2) a one-page sheet outlining appropriate OP-DM recommendations according to guidelines made available for physicians at the point of care in print or via an EMR system; 3) a customized educational sheet given to patients soon after they complete the questionnaire, which includes their 10-year absolute risk for fractures, and tailored osteoporosis information about their diagnosis and treatment recommendations.

**Conclusions:** We developed a comprehensive OP-DM prototype that may aid physicians in their clinical decision making at the point of care. Next steps include conducting usability testing with all end users of the tool, and a pilot study to evaluate the tool in 3 family practice settings.

**Disclosures:** M. Kastner, None.

This study received funding from: CIHR.

**Multinational Comparison of Bone Health in Women 55 Years of Age and Older. The Global Longitudinal Registry of Osteoporosis in Women.** P. Delmas<sup>1</sup>, S. Adams<sup>2\*</sup>, F. A. Anderson<sup>3</sup>, S. Gehlbach<sup>3</sup>, J. Pfeilschifter<sup>4</sup>, P. Sambrook<sup>5</sup>, S. Silverman<sup>6</sup>, R. Dedrick<sup>3</sup>, C. Roux<sup>7</sup>, R. Lindsay<sup>8</sup>. <sup>1</sup>Hôpital Edouard Herriot, Lyon, France, <sup>2</sup>University of Verona, Verona, Italy, <sup>3</sup>UMASS Medical School, Worcester, MA, USA, <sup>4</sup>Lutherhaus, Essen, Germany, <sup>5</sup>University of Sydney-Royal North Shore Hospital, Sydney, Australia, <sup>6</sup>David Geffen School of Medicine, Los Angeles, CA, USA, <sup>7</sup>Hopital Cochin, Paris, France, <sup>8</sup>Helen Hayes Hospital, New York, NY, USA.

The purpose of this study was to compare bone health among women ≥55 years of age from 3 geographic regions.

Practices typical of each region were identified through primary care networks organized for administrative, research or educational purposes. All non-institutionalized patients visiting each practice within the prior 2 years were eligible. Self-administered questionnaires were mailed, with 2:1 over-sampling of women ≥65 years of age. Follow-up questionnaires will be sent at 12-month intervals for 5 years.

The study population comprises 50,187 women from 716 physician practices in Europe, USA and Canada/Australia. Twenty-four percent of women reported at least 1 fracture occurring after age 45: 18% had a single fracture and 6.0% had 2 or more. The most frequently reported fracture was of the wrist (8.8%) followed by the ankle (6.3%; Table). Overall, 10.9% of fractures affected weight-bearing bones of the lower body, which are associated with greater levels of disability. Twelve percent of women said that their mothers had sustained a hip fracture. Across study sites, age-adjusted prevalence of previous fractures ranged from 22% in the USA to 25% in Europe. Wrist fractures were reported by 10% of women in Europe but only 7.1% of US women; hip fracture reports were highest in Europe (2.1%) and lowest in Canada/Australia (1.4%).

Table. Women reporting fracture by geographic region (age-adjusted)

Fracture site (%)	Europe N=22,459	USA N=21,344	Canada/Australia N=6384
Clavicle	1.6	1.2	1.4
Arm	3.2	2.9	2.6
Wrist	10	7.1	8.7
Spine	2.9	1.8	2.0
Rib	4.6	3.9	4.1
Hip	2.1	2.0	1.4
Pelvis	1.0	1.2	0.8
Ankle	5.7	6.9	6.1
Upper leg	1.0	1.1	0.6
Lower leg	2.5	2.6	2.2
Upper body	18	14	16
Lower body	11	12	9.9

Fracture incidence data gathered in subsequent years of the GLOW study will provide a better assessment of whether there is significant variation in the incidence of certain fracture types between regions. This study will also provide the opportunity to assess variation in quality-of-life outcomes according to type of fracture and region.

## SU345

**Comparison between Logistic Regression and Artificial Neural Networks for Vertebral Fracture Risk Assessment: Analysis from GISMO Lombardia Database.** M. Bevilacqua<sup>1</sup>, E. Grossi<sup>2\*</sup>, G. Gandolini<sup>3</sup>, M. Massarotti<sup>4</sup>, I. Chiodini<sup>5</sup>, M. Longhi<sup>6</sup>, L. Pietrogrande<sup>7</sup>, I. Santi<sup>8</sup>. <sup>1</sup>Endocrinology Unit, Sacco Hospital, Milan, Italy, <sup>2</sup>Centro Diagnostico Italiano, Milan, Italy, <sup>3</sup>Rheumatology Unit, IRCCS Don Gnocchi, Milan, Italy, <sup>4</sup>Rheumatology Unit, IRCCS Humanitas, Rozzano (Milan), Italy, <sup>5</sup>Endocrinology and Diabetology Unit, IRCCS Policlinico, Milan, Italy, <sup>6</sup>Rheumatology Unit, IRCCS Galeazzi, Milan, Italy, <sup>7</sup>San Paolo Hospital, University of Milan, Milan, Italy, <sup>8</sup>Pio Albergo Trivulzio Geriatrics Institute, Milan, Italy.

**Background** -Artificial neural networks (ANNs) are computer algorithms inspired by the highly interactive processing of the human brain. When exposed to complex data sets ANNs can learn the underlying laws that associate different variables to a definite outcome.

**Aims** - A cooperative Italian database of 490 osteoporotic women described by 39 variables was analysed to evaluate the capacity of ANNs to recognise patients with (VF<sup>+</sup>, n= 214) or without (VF, n= 276) vertebral fracture on the basis of classical bone osteoporotic risk factors, and other common clinical information

**Method** - The performance of ANN and LR (logistic regression) were assessed by calculating the percentage of correct identifications of VF<sup>+</sup> and VF patients (sensitivity and specificity, respectively) and the prediction accuracy (arithmetic mean between sensitivity and specificity) using a rigorous and homogeneous training and testing protocol typically employed with ANNs.

**Results** - The results showed that ANNs can be trained to identify VF<sup>+</sup> and VF subjects

more accurately than logistic regression. Using all information available, the prediction accuracies of the ANNs and LR providing the best results were 49.57 % and 53.96%, respectively. When the ANNs were allowed to choose the relevant input data automatically (TWIST system-Semeion), 27 variables were selected among 39. Using this set of variables as input data, the performance of the ANNs in the classification task reached an overall prediction accuracy of 75% (Table 1).

Age, BMI, menopause age, smoking, alcohol use, schooling, hypertension, milk and yogurt intake resulted to be the most relevant variables for the best performing model.

**Conclusions** - ANNs technology is highly promising in the development of accurate diagnostic tools designed to recognize patients at high risk of vertebral fracture.

**Table 1** - Summary of model classifications performances

Model	Sensitivity	Specificity	Overall accuracy
LR	44.26%	54.88%	49.57%
ANNs	63.70%	44.21%	53.96%
ANNs (selected var)	75.00%	75.00%	75.00%

## SU346

**Is the Association between Hypertension and Bone Osteoporotic Fracture Expressing a Real Interdependence? Clues from GISMO Lombardia Database.** G. Gandolini<sup>1</sup>, E. Grossi<sup>2\*</sup>, M. Bevilacqua<sup>3</sup>, M. Massarotti<sup>4</sup>, I. Chiodini<sup>5</sup>, M. Longhi<sup>6</sup>, L. Pietrogrande<sup>7</sup>, I. Santi<sup>8</sup>. <sup>1</sup>Rheumatology Unit, IRCCS Don Gnocchi, Milan, Italy, <sup>2</sup>Centro Diagnostico Italiano, Milan, Italy, <sup>3</sup>Endocrinology Unit, Sacco Hospital, Milan, Italy, <sup>4</sup>Rheumatology Unit, IRCCS Humanitas, Rozzano (Milan), Italy, <sup>5</sup>Endocrinology and Diabetology Unit, IRCCS Ospedale Maggiore Policlinico, Milan, Italy, <sup>6</sup>Rheumatology Unit, IRCCS Galeazzi, Milan, Italy, <sup>7</sup>San Paolo Hospital, University of Milan, Milan, Italy, <sup>8</sup>Pio Albergo Trivulzio Geriatrics Institute, Milan, Italy.

**Background** - The interaction between osteoporosis (OP) and arterial hypertension (AH) is a controversial issue in clinical epidemiology. Various alterations of calcium metabolism have been described in AH; such alterations can cause decreased bone mass, the principal determinant of fracture. On the other hand patients with AH are frequently treated with beta-blockers, thiazides or angiotensin converting enzyme inhibitors which have a beneficial effect on bone mass. This is currently considered one of the possible explanation about the lower incidence of bone fracture in AH in some clinical trials.

**Aim** - To assess the association between AH and vertebral bone fracture (VF) with a novel statistical approach based on non linear mapping in addition to traditional statistics.

**Methods** - We have addressed this issue carrying out a data mining procedure on a cooperative Italian database, composed by of 490 OP women described by 39 variables (214 with VF and 276 without VF). We studied the association between AH and VF with two approaches: Principal Component Analysis (PCA), a linear statistical analysis, and a new non linear mapping method (PST, Semeion Institute).This algorithm is able to perform a multidimensional scaling of variables finding out their optimal spatial distribution in bidimensional space, and identifying emerging natural clusters.

**Results** - Prevalence of AH in the whole group was 35.7%. The prevalence of AH was higher in the subgroup with VF: 41.1% (C.I 95% = 34.52% - 47.69%) than in the subgroup without VF: 31.5% (C.I 95%= 26.02% - 36.98%). In the overall study group as in the subgroup with VF the mean T-score of AH subjects resulted almost equal to that of non-AH subjects. A natural clustering of AH and VF was observed with PCA (at least in 1<sup>st</sup> and 2<sup>nd</sup> component projection) and with PST algorithm as well. With PST algorithm the association among these variables was unquestionable and remained unaffected by increasing progressively the number of clusters, pointing out the existence of a real interdependence among these two conditions.

**Conclusions** - Further work is required to explain the possible mechanisms of the interdependence between AH and OP, given the complexity of variables associations.

**Disclosures:** M. Bevilacqua, None.

## SU347

**Prospective Observational Study of Osteoporosis Medication Use in Postmenopausal Women in the European Union (POSSIBLE EU®): Characteristics, Health Status and Quality of Life at Baseline.** N. Freemantle<sup>\*1</sup>, C. Cooper<sup>2</sup>, R. Horne<sup>\*3</sup>, S. Kakad<sup>\*4</sup>, V. Easton<sup>\*5</sup>, L. Martinez<sup>\*6</sup>.  
<sup>1</sup>Health Care Evaluation Group, University of Birmingham, Birmingham, United Kingdom, <sup>2</sup>MRC Epidemiology Resource Centre, University of Southampton, Southampton, United Kingdom, <sup>3</sup>Practice & Policy, University of London, London, United Kingdom, <sup>4</sup>Amgen Ltd, Uxbridge, United Kingdom, <sup>5</sup>Amgen Ltd, Cambridge, United Kingdom, <sup>6</sup>Société Française de Médecine Générale, Issy les Moulineaux, France.

POSSIBLE EU® is an ongoing, observational cohort study that describes the characteristics of postmenopausal (PMO) women being treated for osteoporosis by primary care physicians (PCPs), their behaviors, and attitudes towards treatment. 196 primary care centers in France, Germany, Italy, Spain and the United Kingdom are involved. During routine visits, eligible women who gave consent were enrolled into 1 of 3 cohorts based on osteoporosis therapy status: Inception (initiate therapy at enrolment); Switch (change to alternative therapy at enrolment); or Established (continue on same therapy as prior 12 months). PCPs and patients provide data at enrolment and at quarterly intervals for 12 months. For this interim analysis, complete baseline (BL) data are available for 2117 women; 1432 had BL patient-reported outcome data (Table). Of 1432 patients, 29% currently smoke or are exsmokers; >50% report drinking alcohol; 15% report falling in the past month; and 74% had a family history of fracture. Only 14 women reported living in assisted care facilities; the rest live alone or with spouse, family, or others. These women represent a severely osteoporotic population based on T-score and fracture history (Table). QOL measured by EuroQol - 5 dimensions (EQ-5D) and Osteoporosis Assessment Questionnaire - short Version (OPAQ-SV) are lower than observed previously for the age group and population in clinical trials of fracture prevention (Arthr Rheum. 2001;44:2611; JBMR. 2000;15:1384) (Table). Most patients reported moderate to severe pain (Table). 84% of patients on treatment at BL report taking bisphosphonates. Overall, data from this interim analysis indicate PMO women in Europe being treated with osteoporosis medication live in the community and report severe osteoporotic disease, pain and low QOL. Future data from this study should provide insight into the "real world" management of osteoporosis in Europe, outside of the clinical trial setting.

	All Patients (N=2117)	Inception (N=1120)	Established (N=654)	Switch (N=343)
Age (years), median (25 <sup>th</sup> , 75 <sup>th</sup> quartiles)	69.0 (61.0, 76.0)	69.0 (60.0, 76.0)	70.0 (62.0, 76.0)	70.0 (63.0, 78.0)
Diagnosis of osteopenia/osteoporosis, %/%	30.6% / 68.0%	36.3% / 62.3%	21.9% / 76.9%	29.1% / 69.2%
History of any fracture before baseline, %	41.2%	38.0%	44.6%	45.2%
Minimum T-score <sup>a,b</sup> at diagnosis, median (25 <sup>th</sup> , 75 <sup>th</sup> quartiles)	-2.7 (-3.3, -2.2)	-2.7 (-3.2, -2.2)	-2.8 (-3.4, -2.4)	-2.7 (-3.3, -2.2)

**Assessment of The 10-Year Risk of Fracture in Italian Postmenopausal Women Using BMD and Clinical Risk Factors: A Multicenter Study.** M. Pedrazzoni<sup>1</sup>, A. Giusti<sup>2</sup>, A. Barone<sup>\*2</sup>, G. Girasole<sup>\*3</sup>, G. Pioli<sup>4</sup>, G. Passeri<sup>\*1</sup>, E. Palummen<sup>\*2</sup>, G. Bianchi<sup>\*3</sup>. <sup>1</sup>Internal Medicine, University of Parma, Parma, Italy, <sup>2</sup>Gerontology, Galliera Hospital, Genoa, Italy, <sup>3</sup>Rheumatology, Colletta Hospital, Arenzano, Italy, <sup>4</sup>Gerontology, Santa Maria Hospital, Reggio Emilia, Italy.

The aim of this study was to estimate the absolute risk of fracture in a cohort of postmenopausal women using the Italian FRAX™ charts recently published (<http://www.shef.ac.uk/FRAX/chart.htm>) based on femoral neck BMD and 3 internationally validated clinical risk factors (CRFs: prior history of fragility fracture, family history of fracture, current smoking). Postmenopausal women from 3 osteoporosis centers of Northern Italy (Arenzano, Genoa, Parma) answered a standardized questionnaire to assess smoking habits, history of fragility fractures and fractures in first-degree relatives. Glucocorticoid treated subjects were excluded since, according to Italian guidelines, the management of these subjects depends only on dosage and duration of steroid use. BMD measurements at the femoral neck were

obtained by DXA; T-scores were calculated based on NHANES reference values. The 10-year risk of fracture was computed by linear interpolation of the FRAX™ charts as a function of age, femoral T-score and number of CRFs.

The overall population consisted of 9280 women (mean age 64; range: 50-90). The mean femoral neck T-score was -1.7 (range: from -4.0 to +1.0). The proportion of women with 0, 1, 2 and 3 prevalent CRFs was 69.7%, 27.0%, 3.3% and 0.1%, respectively. The median 10-year risk was 8.8% for osteoporotic fracture (clinical spine, hip, forearm and humerus) and 2.4% for hip fracture. 25% of subjects had a 10-year risk greater or equal to 13.6% for osteoporotic fracture and 5.5% for hip fracture. In women younger than 65 years the median 10-year risk of osteoporotic fracture was 5.9% (range: from 2.7% to 45%); in contrast, in older women the median 10-year risk was 13.6% (range: from 4.3% to 60.2%). The respective figures for hip fracture were 1.1% (0.01-30.6%) and 5.5% (0.3-51.2%). The addition of CRFs greatly amplified risk stratification as compared to age and BMD: from 8.8% the median risk increased to 12.6%, 17.6% and 33.3% with 1, 2 and 3 CRFs, respectively. The integration of CRFs, age and BMD using the FRAX™ charts enhances the assessment of fracture risk. Further prospective studies are needed for validation.

## SU349

**Smoking is an Independent Predictor of Low Bone Mineral Density, Prevalent Vertebral Fractures and Incident Fractures in Elderly Men.** Mr OS Sweden. H. Jutberger<sup>\*1</sup>, M. Lorentzon<sup>1</sup>, Ö. Ljunggren<sup>2</sup>, M. Karlsson<sup>3</sup>, E. Orwoll<sup>4</sup>, C. Ohlsson<sup>1</sup>, D. Mellström<sup>1</sup>. <sup>1</sup>Centre for Bone Research at the Sahlgrenska Academy, University of Göteborg, Sweden, Göteborg, Sweden, <sup>2</sup>Dep of Medical Sciences, University of Uppsala, Sweden, Uppsala, Sweden, <sup>3</sup>Dep of Ortopaedics, Malmö University Hospital, Sweden, Malmö, Sweden, <sup>4</sup>Bone and Mineral Research Unit, Oregon Health and Sciences University, Portland, OR, USA, Portland, OR, USA.

Smoking is considered to be a risk factor for osteoporosis and fractures in women, but is unclear in men. The aim of this study was to examine the effect of smoking for bone mineral density, prevalent vertebral fractures and incident fractures in elderly men.

We studied 3014 men, aged 69 - 80 years, in the Swedish part of Mr OS (centres in Göteborg, Malmö and Uppsala). The international Mr OS questionnaire was used. Standardized BMD was measured with calibrated scanners (Lunar Prodigy and Hologic 4500 A). In the two centres Göteborg and Malmö 1395 men had an X-ray of the thoracic and lumbar spine at baseline.

9 per cent were current smokers, 54 per cent were ex-smokers and 37 per cent were never-smokers. 226 men (17 per cent) had one or more X-ray verified vertebral fracture. Current smoking was an independent negative predictor of standardized BMD in total hip, femoral neck, trochanter and lumbar spine when using linear regression models. Prevalent fractures among smokers are presented in fig.1. Risk for vertebral fractures among smokers: OR 1.77 (1.172-2.686). Adjusted for lumbar-BMD, ( $p < 0.05$ ). During the three first years after baseline 209 X-ray verified fractures occurred. Fracture risk in smokers was calculated with Cox proportional hazard ratio and is presented in table 1.

We conclude that tobacco smoking in elderly men is an important predictor for low bone mineral density, prevalent vertebral fractures and incident fractures, especially vertebral fractures and hip fractures.

**Fig 1. Prevalent vertebral fractures (%)**

**Table 1. Risk for incident fracture. Cox prop. HR**

Fracture (N=209)	HR 1.76 (1.171-2.642)
Non-vertebral osteoporotic fracture (N=83)	HR 2.16 (1.191-3.909)
Vertebral fracture Clin. & X-ray verified (N=67)	HR 2.72 (1.482-5.001)
Hip fracture (N=38)	HR 3.27 (1.491-7.158)

## SU350

**The Association of Stiffness Index and Cross-Linked N-Telopeptides of Type I Collagen (NTx) with Any Clinical Fractures Differs with Age and Gender.** A. Yasuyo, K. Aoyagi. Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

The purpose of this cross-sectional study was to evaluate associations of calcaneal stiffness index and cross-linked N-telopeptides of type I collagen (NTx) with fractures among Japanese community-dwelling people  $\geq 40$  years old. Subjects comprised 453 men with a mean ( $\pm$ standard deviation (SD)) age of  $66.8 \pm 10.0$  years (range, 40-91 years) and 897 women with a mean age of  $65.9 \pm 9.8$  (range, 40-87 years). Calcaneal stiffness index was obtained using quantitative ultrasound measurements. Urinary NTx divided by creatinine was measured for 263 men and 534 women for whom urine samples were available. Information on previous fractures after 45 years old (due to minor or moderate trauma) was obtained by questionnaire. Stiffness index showed significant negative correlations with age and urinary NTx in both genders. When adjusted for age, Pearson's partial correlation coefficient between stiffness index and urinary NTx was -0.27 ( $p < 0.001$ ) for men and -0.19 ( $p < 0.001$ ) for women. Among all subjects, 39 men (8.6%) and 147 women (16.4%) reported at least one clinical fracture. Among women, fracture prevalence significantly increased with age ( $p < 0.001$ ), while no significant association was observed between age and fracture prevalence among men. Associations of stiffness index and urinary NTx with fractures were examined using logistic regression analysis, adjusting for age. Among younger women ( $< 65$  years), urinary NTx was significantly associated with fracture, whereas stiffness index was not. Age-adjusted odds ratios (ORs) for fracture were 0.70 (95% confidence interval (CI), 0.45-1.10) for stiffness index (per 1 SD decrease) and 1.66 (95%CI, 1.04-2.65) for urinary NTx (per 1 SD increase). In contrast, among older women ( $\geq 65$  years), stiffness index was significantly associated with fracture, whereas urinary NTx was not. Age-adjusted ORs were 1.32 (95%CI, 1.04-1.67) for stiffness index and 0.94 (95%CI, 0.71-1.24) for urinary NTx. However, neither stiffness index nor urinary NTx was significantly associated with fracture among men in both age groups. These results suggest that increased bone turnover appears to be an important risk factor for fracture among younger women, while bone mass appears important among older women. Although stiffness index significantly correlated with urinary NTx in both men and women, the impact of stiffness index and urinary NTx on risk of fracture may differ substantially with age and gender. When assessing fracture risk, age- and gender-specific approaches for interpreting and applying bone mass measurements or bone turnover markers to individuals would be desirable.

**Fractures of the Spine and Hip Increase the Risk of Death in Canadians.** G. Ioannidis<sup>1</sup>, A. Papaioannou<sup>1</sup>, N. Akhtar-Danesh<sup>\*1</sup>, W. M. Hopman<sup>\*2</sup>, T. Anastassiades<sup>3</sup>, J. C. Prior<sup>4</sup>, L. Pickard<sup>1</sup>, K. S. Davison<sup>4</sup>, C. C. Kennedy<sup>4</sup>, W. P. Olszynski<sup>5</sup>, D. Goltzman<sup>6</sup>, E. Papadimitropoulos<sup>7</sup>, J. P. Brown<sup>4</sup>, L. Thabane<sup>\*1</sup>, A. Gafni<sup>\*1</sup>, R. G. Josse<sup>8</sup>, D. A. Hanley<sup>9</sup>, J. D. Adachi<sup>1</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada, <sup>2</sup>Queen's University, Kingston, ON, Canada, <sup>3</sup>University of British Columbia, Vancouver, BC, Canada, <sup>4</sup>Laval University, Ste-Foy, QC, Canada, <sup>5</sup>University of Saskatchewan, Saskatoon, SK, Canada, <sup>6</sup>McGill University, Montreal, QC, Canada, <sup>7</sup>Eli Lilly and Company, Toronto, ON, Canada, <sup>8</sup>Toronto University, Toronto, ON, Canada, <sup>9</sup>Calgary University, Calgary, AB, Canada.

Utilizing data from the Canadian Multicentre Osteoporosis Study (CaMos) we evaluated the association between new fractures and mortality over a 5-year period in a cohort of women and men from across Canada. A total of 7753 participants, 2187 men and 5566 women over the age of 50 years participated in this prospective study. New fractures were based on self-reports and included hip, vertebral, rib, forearm, pelvic, and others. The fracture groups were subdivided based on timing of the fracture: during the 1st, 2nd, 3rd or 4th/5th year; those without incident fracture were the reference. Multivariable Cox proportional hazards analyses were conducted to examine the association between the time to incident fracture and time to death. Hazard ratios and 95% confidence intervals (CI) were calculated. During the 5-years of follow-up, 636 (8.3%) participants died. Of these, 239 (11.1%) were men and 397 (7.2%) were women. For men, the adjusted results showed that the hazard ratio was 6.1 (95% CI: 1.4, 26.9) indicating a higher hazard for death in men with hip fracture during the 1st year compared with men without hip fractures. For women, the hazard ratio was 2.9 (95% CI: 1.0, 8.2) showing higher mortality for those with a hip fracture during the 1st year of follow-up as compared with women without these fractures. Also for women with vertebral fractures, the hazard ratios were 3.5 (95% CI: 1.1, 11.4) and 3.8 (95% CI: 1.5, 9.5) for those occurring during the 1st and 2nd year of follow-up, respectively. In conclusion, hip and vertebral fractures contribute importantly to deaths in Canadians. Thus, interventions that reduce fracture rates should be implemented to decrease mortality.

**Very High Frequency of Poor Vitamin D Status in French Women with Bone Fragility.** F. E. Levy-Weil<sup>\*1</sup>, D. Sitruk-Khalfon<sup>\*2</sup>, S. Djennane<sup>\*1</sup>, C. Rosenberg<sup>\*1</sup>, Y. Nourmamod<sup>\*2</sup>, C. Cormier<sup>3</sup>, J. C. Souberbielle<sup>\*4</sup>. <sup>1</sup>Rheumatology Department, Centre Hospitalier Victor Dupouy, Argenteuil, France, <sup>2</sup>Biochemistry Laboratory, Centre Hospitalier Victor Dupouy, Argenteuil, France, <sup>3</sup>Rheumatology Department, Hopital Cochin APHP Université Paris-Descartes, Paris, France, <sup>4</sup>Physiology Laboratory, Hopital Necker-Enfants Malades, Paris, France.

Vitamin D is an important determinant of bone health. Inadequate vitamin D status might raise the risk of osteoporotic fracture by increasing bone loss from secondary hyperparathyroidism and by its direct effect on muscle strength.

The aim of this study was to determine and to compare the prevalence of vitamin D deficiency and its level of severity in post-menopausal osteopenic or osteoporotic French women with and without any fracture.

We measured serum 25-hydroxyvitamin D (25OHD) concentration in 261 women with a low bone density and/or a prevalent low trauma fracture seen consecutively in our unit from January 2006 to March 2008. History of secondary osteoporosis was excluded. 129 patients had at least one prevalent fracture while 132 had no prevalent fracture. As described among the recent literature, regarding its optimal benefit on multiple health outcomes, we used 30 ng/mL (75nmol/mL) as the cut-off point defining vitamin D inadequacy. Vitamin D status was categorised in four groups: normal (25OHD $>30$ ng/mL), moderate insufficiency (20ng/mL $<25$ OHD $<30$ ng/mL), severe insufficiency (10ng/mL $<25$ OHD $<20$ ng/mL) and deficiency (25OHD $<10$ ng/mL). Data are presented as median (interquartile range) for continuous variables, and as % (n/total) for nominal variables.

Women with prevalent fracture were significantly older than those without fracture [68 years (59-75) versus 62 years (57-70);  $p < 0.001$ ] and had a moderately, but significantly lower 25OHD serum level [15 ng/mL (9-22) versus 18.4 ng/mL (11.0-24.9);  $p < 0.01$ ]. Only 5 patients in each group had a 25OHD level above 30ng/mL. The proportion of women with a 25OHD concentration  $< 10$  ng/mL was not different in both groups [27.9% (36/129) in women with fracture versus 19.7% (26/132) in those without fracture] but more women with a previous fracture had a 25OHD level  $< 20$  ng/mL [67.4% (87/129) versus 53.8% (71/132);  $p < 0.05$ ]. There was no correlation between age and 25OHD neither in the whole population nor in each separate group.

This study confirms that vitamin D inadequacy is highly prevalent in French women with bone fragility. Adequate vitamin D supplementation may thus significantly improve bone health in this population.

## SU353

**Femoral Neck and Trochanteric Fractures and Vitamin D.** M. J. Davis<sup>\*</sup>, F. H. N. Budden. Medicine, St. Joseph's Health Centre, Toronto, ON, Canada.

The relevance of the femoral neck and trochanteric fracture is reviewed in relation to age, sex, serum calcium, albumin, and 25OH vitamin D3 in patients with a "fractured hip". The charts and laboratory results of 127 in-patients, admitted to an orthopaedic unit in a community hospital in 2007, were reviewed electronically.

Mean age was 80.56 years, median age 82 years and range 51-98 years. 94, 74% were women and 33, 26% were men. 37, 29% had femoral neck fractures and 90, 71% had trochanteric fractures. 29 women, 78% and 8 men, 22% had femoral neck fractures. 65 women, 73% and 25 men, 27% had trochanteric fractures.

Not all of the patients had blood work done. Blood work was done post-operatively. 112 patient had serum calcium and albumin measured. Mean serum calcium was 2.16 mmol/L, median 2.17 mmol/L and range 1.82-2.44 mmol/L. Normal range is 2.20-2.60 mmol/L. No patient was hypercalcemic. Serum albumin mean was 29.7 g/L, median 30.5 g/L, and range 15-41 g/L. Normal range is 35-50 g/L. 70 patients had 25OH vitamin D3 measured with the mean 36.39 nmol/L, median 32 nmol/L and range  $< 12$ -92 nmol/L. 25OH vitamin D3 deficiency is less than 25 nmol/L, insufficiency is 25-75 nmol/L and an adequate level is above 75 nmol/L. 5 patients had a 25OH vitamin D3 level greater than 75 nmol/L. The lowest monthly average 25OH vitamin D3 was 22.2 nmol/L in March.

These patients were old which is a risk for any fracture, particularly the "fractured hip". Women had femoral neck and trochanteric fractures three times more often than men. The femoral neck fracture is considered the paradigm of osteoporotic fractures while the trochanteric fracture is rarely mentioned. A trochanteric fracture was three times more frequent than a femoral neck fracture. The trochanter is large and strong relative to the femoral neck. In the orthopaedic literature, trochanteric fractures are associated with poorer functional outcome and higher morbidity and mortality than the femoral neck. The low serum albumin may reflect their poor nutritional status pre-operatively but also is decreased by trauma and the surgical procedure. Except for 5 patients, all were either 25OH vitaminD3 deficient or insufficient. This reflects their low vitamin D3 state pre-admission but the vitamin D3 level drops post-operatively due to a decrease in the D binding protein. The few younger men had lower vitamin D3 levels than the older men, possibly caused by poor nutrition. The patients with femoral neck fractures had lower vitamin D3 levels than the trochanteric fractures.

This was a retrospective study fraught with problems: a small number of subjects with incomplete laboratory investigations. This study raised more questions to be answered Question: "Is the femoral neck fracture associated more with vitamin D3 deficiency while the trochanteric fracture is related more to "pure" osteoporosis?"

**Disclosures:** F.H.N. Budden, None.

## SU354

### Questionnaire-based Osteoporosis Risk Assessment in a Rural Area Primary Care Setting. H. Schober<sup>1</sup>, M. Lüder<sup>2\*</sup>, K. Biebler<sup>3</sup>, R. Andresen<sup>4</sup>.

<sup>1</sup>Internal Medicine, City Hospital Südstadt Rostock, Teaching Hospital of University of Rostock, Rostock, Germany, <sup>2</sup>General Practice Wolgast, Wolgast, Germany, <sup>3</sup>Biometry Center, Ernst Moritz Arndt University Greifswald, Greifswald, Germany, <sup>4</sup>Department of Radiology, Hospital Güstrow, Teaching Hospital of University of Rostock, Güstrow, Germany.

Osteoporosis represents a major health problem. Major risk factors include age and diminished bone density. Recommendations for bone mass measurement are based on the patients' history. The aim of the present study was to evaluate the proportion of patients at risk of osteoporosis as identified by a questionnaire in a primary care setting.

Patients (n=1500) presenting to a general practitioner in a rural area were offered a questionnaire, resulting in 737 complete data sets (508 females/229 males) for analysis. Questions were related to estrogen deficiency (menarche, menopause, amenorrhoe, pregnancy), increased fracture susceptibility (fractures at age > 40 ys), parental fractures, specific diseases (asthma, rheumatoid arthritis, hyperthyroidism), drug therapy (heparin, coumarin, steroid), diet, and physical activity. Results for every question were scored in increments of ten (maximal score 2,325 points). Points were not assigned to patient's age. Patients suffering from overt osteoporosis were used as control group.

Scores varied between 15 and 822. Females demonstrated significantly higher scores compared to males (p<0.04). Among controls with established osteoporosis, 61.3 % achieved scores exceeding 200 points, and 43.4 % more than 250 points. Using the latter criterion as risk threshold, 13.5 % (66 females/28 males) of the study population was identified. Part of these patients underwent bone density measurement (QCT) which revealed osteoporosis in 54 % and osteopenia in 25 %, respectively. This investigation established an overall proportion of questionnaire-based patients with osteoporosis to 10.3 %. All of these patients were older than 64 years.

Using a questionnaire, 13.5 % of patients presenting to a general practitioner in a rural area could be identified of being at risk for osteoporosis. After bone density analysis, this number was corrected to 10.3 %. A questionnaire-based approach to osteoporosis risk assessment is a simple and potentially useful tool in detecting patients at risk for osteoporosis.

### The Relationship Between Clinical Risk Factors for Osteoporosis and BMD in Women Aged Less than 50 Years. M. S. Surdhar\*, I. Fogelman, G. M. Blake, M. L. Frost. Osteoporosis Screening & Research Unit, King's College London, London, United Kingdom.

Currently there are no clear guidelines on how to identify, diagnose or treat premenopausal women who may be at risk of osteoporosis or early bone loss. The aim of this study was to investigate the relationship between clinical risk factors for osteoporosis and BMD in a large group of women aged less than 50 years to identify which risk factors have the greatest impact on BMD. This will provide important information to facilitate DXA referral decisions in the premenopausal population. The study population consisted of 552 women aged less than 50 years. 432 were found to have one or more of the following risk factors (i) a history of atraumatic fracture; (ii) a BMI less than 20kg/m<sup>2</sup>; (iii) X-ray osteopenia; (iv) a medical condition known to influence bone metabolism; (v) current use of therapy known to influence bone metabolism; (vi) a family history of osteoporosis; (vii) Premature menopause before age of 45 years; (viii) Amenorrhoea greater than 6 months duration. BMD was measured at the lumbar spine (LS), femoral neck (FN) and total hip (THIP) using DXA. Multivariate regression analysis was used to calculate the Z-score decrements associated with each of the eight clinical risk factors. A significant difference in LS, FN and THIP BMD between those with and without risk factors was observed (p<0.001). Fifteen percent of women with clinical risk factors had a T-score equal to or less than -2.5 compared to 1% of those without risk factors. Z-score decrements associated with each risk factor are shown in the table.

Table: Z-score decrements associated with each clinical risk factor

	LS BMD	FN BMD	THIP BMD
History of fracture	-0.61 (0.15)**	-0.62 (0.14)**	-0.57 (0.12)**
BMI less than 20	-0.63 (0.15)**	-0.79 (0.13)**	-0.79 (0.12)**
X-ray osteopenia	-0.56 (0.40)	-0.05 (0.36)	-0.06 (0.31)
Medical condition	-0.09 (0.15)	-0.08 (0.13)	-0.05 (0.11)
Therapy	-0.20 (0.12)	-0.18 (0.11)	-0.10 (0.09)
Family history	-0.13 (0.11)	-0.12 (0.10)	-0.09 (0.09)
Early menopause	-0.22 (0.12)	-0.03 (0.11)	-0.04 (0.10)
Amenorrhoea	-0.43 (0.13)**	-0.29 (0.11)*	-0.26 (0.10)*
No risk factors	0.19 (0.09)	0.17 (0.08)	0.13 (0.07)

\* p = <0.05 vs. no risk factors; \*\* p = <0.001 vs. no risk factors.

The lowest Z-scores were found in those women with history of an atraumatic fracture, a BMI less than 20 and a history of amenorrhoea for both spine and hip BMD. This study may aid in the identification of younger women aged less than 50 years who should be referred for osteoporosis screening using DXA.

## SU356

### No Fracture Is a Poor Predictor of Fracture Risk. A. Hoiseth. Sentrum Rtg., Oslo, Norway.

Fractures are reported to be an independent risk factors for new fractures. However, as early as in 1994 a group of experts (WHO technical report on osteoporosis) commented that many first fractures occur too late in life to be useful as risk predictors. We address the associations between earlier in life fractures and fractures occurring in age group 66-75 and age >75. Fracture data (age at fracture, fracture types and fracture sequela) were recorded in two cohorts of women (N=5138 and 8731) at routine bone densitometry (DXA). Results were considered "significant" when the two cohorts agreed. Results are presented as pooled for the two cohorts. Fractures were grouped as number of fractures and fracture types. More than 3 fractures were recorded as 3 fractures. The fractures were classified as: 'Femoral', at least a femoral fracture; 'Vertebral', at least a vertebral fracture but no femoral fractures and 'Other', one or more fractures but no femoral or vertebral fractures (results not presented). Age at first fracture was classified as 'Early', before age 50; 'Middle-age', between age 50 and 65 and 'Late', after age 65. **Results** There was an increasing frequency of cases with first fractures with increasing age: Of those aged 66-75, respectively 30.0%, 39.7% and 30.3% had an Early, Middle-age and Late first fracture. For cases >75 the values were 18.2%, 23.8% and 57.9%. Those with Late first fracture reported the smallest number of fractures: In age group 66-75, 40.0% with an Early first fracture had suffered one fracture only as compared to 70.3% for those with a Late first fracture. The respective values for cases aged >75 were 29.1% and 62.7%. The fractures were somewhat more severe in those with a late first fracture: In age group 66-75, 9.6% of the cases with an Early first fracture suffered a Femoral fracture and 13.3% a Vertebral fracture, with a Middle-age first fracture the values were respectively 15.3% and 8.8% and with a Late first fracture 23.5% and 10.6%. The respective values for cases aged >75 were 18.8% and 13.6%; 13.0% and 14.4%; 22.6% and 16.0%. Cases with a late in life first fracture reported a higher frequency of sequela: In age group 66-75 10.0% with an Early first fracture reported a sequela as compared to 19.8% in those with a Late first fracture. In cases >75 the values were 17.3% and 25.2%. **Conclusion** Our results support the view held by the WHO-report from 1994. A large proportion of first fractures occur too late in life for using previous fractures as a predictor for later fractures; having had no fracture early in life does not imply low late in life fracture risk. Although those with early fractures had the largest number of life-time fractures, those with late in life first fractures suffered the most severe fractures. Excluding cases with no "previous" fractures for further fracture risk assessment, for example by DXA, may substantially underestimate real fracture risk.

## SU357

### Reduced Renal Function Is Associated with Increased Rates of Bone Loss At The Hip And Spine: The Canadian Multicentre Osteoporosis Study. S. A. Jamal<sup>1</sup>, D. A. Hanley<sup>2</sup>, J. Prior<sup>3</sup>, A. Papaioannou<sup>4</sup>, R. G. Josse<sup>1</sup>, D. Goltzman<sup>5</sup>. <sup>1</sup>Medicine, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Medicine, University of Calgary, Calgary, AB, Canada, <sup>3</sup>Medicine, University of British Columbia, Vancouver, BC, Canada, <sup>4</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>5</sup>Medicine, McGill University, Montreal, QC, Canada.

The relationship between renal function and rates of bone loss is unclear.

We determined the association between changes in BMD at the total hip, femoral neck and lumbar spine over 5 years and estimated glomerular filtration rate (eGFR) among men and women aged 50 and older participating in CaMos.

We restricted our analyses to men and women aged 50 and older in whom serum creatinine was measured at baseline. We calculated the eGFR using the Cockcroft-Gault formula. We calculated the percent change in BMD at the total hip, femoral neck and lumbar spine over 5 years. We used linear regression to determine the annualized percent change in BMD per 10 mL/min/1.73m<sup>2</sup> of eGFR. Results are stratified by gender, and adjusted for baseline BMD, and creatinine.

Data on 191 men and 444 women was available for analysis. The mean age of women was 58.7 (±11.7) years, the mean body weight 64.4 kg (±12.9) kg and the creatinine at study entry was 74.3 (±13.3) mmol/L. Men were slightly older 57.7 (±13.0) years, weighed more: 77.9 (±12.3) kg and had a higher creatinine at baseline: 92.8(±16.6) mmol/L. Among women, for each 10 mL/min/1.73m<sup>2</sup> decrease in eGFR femoral neck BMD decreased by 1.6% (95% Confidence Interval: 0.76 to 2.42), total hip BMD decreased by 1.7% (95% CI: 0.84 to 2.5) and spine BMD decreased by 1.3 (95% CI: 0.44 to 2.1). In contrast among men, there was no significant decrease in femoral neck BMD 0.54% (95% CI: -0.9 to 1.98), total hip BMD (0.5%; 95% CI: -0.95 to 1.94), or lumbar spine BMD 0.4% (95% CI: -0.94 to 1.84).

Our findings indicate that among women, but not men, there is a strong and consistent decrease in BMD at the hip and spine with worsening renal function based on the eGFR. One potential explanation for the lack of relationship between bone loss and eGFR in men is the small sample size and the small change in BMD over time. Our findings, together with those of others, highlight the importance of renal function as a risk factor for bone loss and fracture.

## SU358

**Are There Any Ethnic Differences in Bone Mineral Density in a Lupus Cohort?** A. Costinescu\*<sup>1</sup>, I. Moldovan\*<sup>2</sup>. <sup>1</sup>University of Medicine and Pharmacy, Bucharest, Romania, <sup>2</sup>Loma Linda University, Loma Linda, CA, USA.

The purpose of this study is to determine if there are any differences in bone mineral density (BMD) between Hispanic and Caucasian patients in a lupus cohort. The charts of one hundred Hispanic and fifty Caucasian patients with SLE (systemic lupus erythematosus) were reviewed. Twenty Hispanic (previously presented in an abstract) and nine Caucasian women that had their BMD assessed by dual X-ray absorptiometry (DXA) were identified. The patients were divided into pre- and post menopausal status and the Hispanics were compared to the Caucasians within the two groups. Statistical analysis was performed using the student t-test. Clinical determinants of BMD that were recorded included age, height, weight, body mass index (BMI), duration of disease, SLE disease activity index (SLEDAI) at the time of the DXA scan, SLE damage index (SLICC), steroid treatment as well as use of immunosuppressive and osteoporosis medications. There was no statistically significant difference between the Hispanic and Caucasian pre- and postmenopausal groups in terms of age, average BMI, duration of SLE, average SLEDAI score and average prednisone dose. BMI results for Hispanic women were in the range of overweight as opposed to the Caucasian patients, who had BMI within normal range. Four Hispanic premenopausal and five postmenopausal patients were obese, as opposed to one Caucasian obese patient in each group. The Hispanic premenopausal women had statistically significant ( $P=0.001$ ) more damage from lupus by SLICC score. Overall, seventeen Hispanic patients (85%) were taking glucocorticoids, but only five (25%) were taking medications for osteoporosis, including bisphosphonates, calcium and vitamin D. In the Caucasian population, six patients (67%) were on glucocorticoids, and five (55%) out of nine patients were on medications for osteoporosis. Our analysis showed that the postmenopausal Caucasian women were found to have a statistically significant lower BMD at the hip, as compared to the Hispanic ones. Neither the spine, nor the femoral neck sites examined showed any significant difference for Hispanics versus Caucasians within the respective groups. However, 15% of the Hispanic patients were found to be osteoporotic and 30% were osteopenic as opposed to 33% and respectively 55% of the Caucasians. In conclusion, this small study suggests that the Caucasian lupus women are more prone to osteopenia and osteoporosis, especially after menopause, when compared to the Hispanic patients. The role of higher BMI observed in our Hispanic patients, in preserving bone mass is yet to be determined. Larger studies are needed to better define the distinct characteristics of the two ethnic populations that are affected by lupus.

## SU359

**Carotid Plaque Causes Low Spinal Bone Mineral Density in Korean Postmenopausal Women with Diabetes.** D. Byun, J. Kim\*, M. Roh\*, J. Mok\*, Y. Kim\*, H. Park\*, C. Kim\*, S. Kim\*, K. Suh\*, M. Yoo\*. Endocrinology, Soonchunhyang University Hospital, Seoul, Republic of Korea.

**Background:** Recent studies suggest a possible pathogenic linkage between the osteoporosis and atherosclerosis which closely related with diabetes. Both atherosclerosis and osteoporosis are independent predictors of cardiovascular disease (CVD) events, and may share common regulatory mechanisms. In this study we want to show the relationship between bone mineral density (BMD) and atherosclerotic parameters in Korean postmenopausal women with diabetes.

**Methods:** Total 60 postmenopausal women with diabetes were enrolled in the study. We measured pulse wave velocity (PWV), carotid intima-media thickness (IMT) and carotid plaque as a atherosclerotic parameters. We also checked anthropometric and serologic including HbA1C, C-peptide, lipid profiles and bone markers. The lumbar spine, femur neck and total hip BMD was measured using dual-energy X-ray absorptiometry (DXA).

**Results:** From multiple linear regression analyses of all the study subjects, lumbar spine, femur neck and total hip BMD were significantly decreased according to age ( $r^2 = -0.288$ ,  $p=0.028$ ,  $r^2 = -0.358$ ,  $p=0.003$ ,  $r^2 = -0.297$ ,  $p=0.023$  respectively). Serum calcium, aortic PWV, and mean IMT were significantly increased according to increase of age ( $r^2 = 0.386$ ,  $p=0.012$ ,  $r^2 = 0.396$ ,  $p=0.002$ ,  $r^2 = 0.297$ ,  $p=0.024$  respectively). From bivariate analyses, the lumbar spine, femur neck and total hip BMD showed a negative correlation with duration of diabetes ( $r^2 = -0.307$ ,  $p=0.019$ ,  $r^2 = -0.284$ ,  $p=0.03$ ,  $r^2 = -0.259$ ,  $p=0.05$  respectively). Lipid profile, IMT, PWV were not correlated with BMD. The prevalence of carotid plaque in our study was 30%. Only the patients with presence of plaque showed significantly decreased lumbar spine BMD compare to those with absence of plaque ( $p=0.048$ ). Patients with presence of carotid plaque also showed significant relationship with increased duration of DM ( $p=0.033$ ) and aortic PWV ( $p=0.001$ ) compare to patients with absence of carotid plaque.

**Conclusion:** Out of many atherosclerotic risk factors, carotid plaque causes low spinal BMD and has significant relationship with high serum calcium level, increased aortic PWV and increased duration of DM.

## SU360

**Vertebral Fracture in Men: Level of Trauma, Bone Mineral Density and Lean Body Mass.** S. F. Evans\*, C. A. Sharp\*, M. W. J. Davie. Charles Salt Research Centre, Robert Jones & Agnes Hunt Orthopaedic Hospital NHS Trust, Oswestry, United Kingdom.

Low trauma vertebral fracture (LTVF) in men is associated with low lean body mass (ALMI) and low bone density (BMD). Recent data suggest that men with high trauma fracture also have low BMD. We have investigated whether men with high trauma vertebral fracture (HTVF) have low ALMI and low BMD.

Men with clinical vertebral fracture (referred with symptoms) were categorised as having low trauma (fall from no more than standing height or no discernible trauma;  $n=59$ ; age  $63 \pm 13$ yr) or high trauma (fall from more than standing height  $n=30$ ; age  $60 \pm 12$ yr). Control subjects ( $n=180$ ; aged 16-84yr) with no fracture and no significant medical history were taken from a larger study of osteoporosis in men. BMD (L2-4=LS; Femoral neck=FN) and ALMI  $\{=(\text{sum of lean in all four limbs})/\text{Ht}^2\}$  were measured by DXA (Hologic QDR4500). T scores were established from control men aged 20-39yr and Z scores from appropriate age groups. Differences were established by Chi square or by the Binomial test. The study was approved by the local research ethics committee.

Results are shown in the Table.

	Low trauma VF			High traumatic VF		
	LS-BMD	FN-BMD	ALMI	LS-BMD	FN-BMD	ALMI
<b>T score</b>	-1.36	-1.83	-0.69	-0.98	-1.58	-0.27
% with < T-2.5	15	28	2	7	17	0
<b>Z score</b>	-1.28	-1.15	-0.51	-0.93	-0.90	-0.14
% Z score < ZERO	91	88	66	77	87	52

The proportion of patients with BMD T score less than -2.5 did not differ between groups. In both groups there were significantly more men with BMD Z score values below zero at both FN and LS sites (Binomial test,  $p<0.01$ ), deficits at both sites being similar for both LTVF and HTVF. ALMI was significantly low in LTVF but not HTVF. Men with vertebral fracture have low BMD irrespective of degree of trauma but low ALMI is a feature of low trauma VF only. This suggests that ALMI may influence the risk of minor trauma in leading to a vertebral fracture.

## SU361

**A Computer-based Measure Using Normalized Heights Predicts Vertebral Fracture Independent of BMD in Post-menopausal Women.** A. Ghosh\*<sup>1</sup>, M. Bruijine\*<sup>2</sup>, P. Pettersen\*<sup>3</sup>, M. Karsdal\*<sup>1</sup>, D. Leeming\*<sup>1</sup>, C. Christiansen\*<sup>1</sup>, M. Nielsen\*<sup>2</sup>. <sup>1</sup>Nordic Bioscience, Herlev, Denmark, <sup>2</sup>University of Copenhagen, Copenhagen, Denmark, <sup>3</sup>Center for Clinical and Basic Research, Ballerup, Denmark.

Baseline deformity in the vertebral shape plays an important role in spine fracture risk assessment for post-menopausal women. Since they are discrete, most of these measures can not be used in progressive monitoring of fracture risk. Building on these methods a novel computer based continuous vertebral fracture risk measure is proposed. The most deformed (maximum difference in heights) one among T12-L5 vertebrae for each of the individuals in the study was chosen. To adjust for the variation due to the physical size of the subjects, the three vertebral heights (anterior, posterior and middle) were normalized to unit average. The risk for an individual to sustain a fracture was computed using a probability measure derived from a quadratic classifier based on the minimum and the maximum of the normalized heights.

There were 72 healthy elderly women in the study, of which 36 maintained skeletal integrity (Group 1) and 36 sustained at least one fracture in the lumbar spine over a 7.5-year study period (Group 2). The two groups were carefully matched for age ( $65.8 \pm 1$  vs.  $64.6 \pm 1.3$ ), BMI ( $25.1 \pm 0.63$  vs.  $24.8 \pm 0.63$ ), spine BMD ( $0.83 \pm 0.02$  vs.  $0.83 \pm 0.03$ ), smoking habits (8 vs. 7), and physical activity at baseline. The quadratic classifier to compute the continuous measure of the fracture risk was built using the subjects at baseline and to separate test from training, the fracture risks for the baseline subjects were calculated in a leave-one-out fashion.

Separating the future fractures based on baseline measurements, the area under the ROC curve was 0.76. At baseline, the means of the fracture risk for Group 2 and Group 1 were significantly different ( $0.6 \pm 0.03$  vs.  $0.4 \pm 0.04$ ,  $p < 10^{-3}$ ). A fracture further increased the risk measure ( $0.9 \pm 0.03$  vs.  $0.6 \pm 0.03$ ,  $p < 10^{-7}$ ) in Group 2, whereas no statistically significant change was detectable in Group 1 between baseline and follow up ( $0.4 \pm 0.04$  vs.  $0.5 \pm 0.04$ ,  $p=0.06$ ). The increase in the risk in Group 1 from baseline to follow up was consistent with the clinical findings that the fracture risk increases with age. Defining high/low risks as above/below the median measurements the proposed method yields significantly larger odds ratio compared to the traditional height ratios (7 vs. 3.3), justifying the choice. The continuous nature of the measure also enables us to assess the severity of risk.

We envisage that the method will lead to efficient prediction of vertebral fracture facilitating: (a) early diagnosis, (b) decrease in the required sample size for studies, and (c) easier assessment of the efficacy of fracture preventing drugs.

**Muscle Power and Tibial Bone Strength in Older Women.** M. C. Ashe, T. Y. L. Liu-Ambrose\*, D. M. L. Cooper\*, K. M. Khan, H. A. McKay. Centre for Hip Health, Vancouver, BC, Canada.

Previous literature has highlighted the importance of strength training on bone outcomes in older women. However, to our knowledge, there are no reports that investigated the relation between muscle power and bone strength for this age group. Therefore, the purpose of this study was to assess the association between muscle power and tibial bone strength in older women aged 65-75 years. Seventy-four community-dwelling healthy older women aged 65-75 years were recruited. Muscle power and strength (one repetition maximum; 1RM) of bilateral leg extension was measured using Keiser air-pressure resistance equipment (Keiser Sports Health Equipment, Fresno, California). Participants were asked to wear a waist-mounted ActiGraph (GT1M ActiGraph, LLC, Fort Walton Beach, FL) accelerometer to objectively record physical activity for 7 days. In addition, participants were asked to recall physical activity in the previous 7 days using the Physical Activity Scale for the Elderly (PASE) self-report questionnaire. Peripheral quantitative computed tomography (pQCT) was used to measure tibial mid-shaft (50% site) bone strength (strength-strain index, section modulus). We used Pearson correlations and multi-level linear regression to investigate the associations between muscle performance and bone strength. Muscle power contributed 6.6% ( $p=0.007$ ) of the variance for bone strength-strain index and 8.9% ( $p=0.001$ ) of the variance of section modulus in older women after accounting for age, height, weight and self-report physical activity (PASE). Moderate-vigorous physical activity (MVPA) as recorded by accelerometry was significantly related to muscle power in the lower extremity ( $r=0.260$ ;  $p=0.041$ ). There were no significant associations between muscle strength (1RM) in the lower extremity and bone strength or MVPA. In this cross-sectional investigation, muscle power significantly contributed to estimated bone strength and was associated with MVPA in healthy community dwelling older women. Further investigation is necessary to determine whether power training will prove to be a more effective stimulus for bone strength than conventional strength training.

**High Sex Hormone Binding Globulin (SHBG) Levels in Older Patients with Acute Hip Fracture Are Correlated with Worse Function and Increased Bone Resorption.** A. Egli<sup>\*1</sup>, B. Dawson-Hughes<sup>2</sup>, R. Theiler<sup>\*3</sup>, H. Staehelin<sup>\*4</sup>, J. Henschkowski<sup>\*1</sup>, H. A. Bischoff-Ferrari<sup>1</sup>. <sup>1</sup>Rheumatology, University of Zurich, Zurich, Switzerland, <sup>2</sup>Tufts University, Boston, MA, USA, <sup>3</sup>Rheumatology, Triemli StadtSpital, Zurich, Switzerland, <sup>4</sup>Geriatrics, University of Basel, Basel, Switzerland.

**Background:** Previous studies suggested that higher SHBG levels are associated with an increased hip fracture risk and that higher testosterone levels may reduce the odds of falling among men and women age 65 and older. **Aim:** To study the correlation of serum testosterone and SHBG with function (timed up & go test) and bone resorption (urinary deoxypyridinolin = DPD) within 1 to 2 weeks after hip fracture surgery. **Results:** Mean age was 86 year ( $\pm 6.9$ ), 79% women, and 69% admitted from home. These are baseline data from the ongoing Zurich hip fracture trial with vitamin D including 173 patients with acute hip fracture. Total testosterone serum levels were above the laboratory detection threshold ( $> 0.1$  nmol/l) in 33 of 36 men and in 57 of 135 women. Mean total testosterone levels were  $5.16 (\pm 4.51)$  nmol/l in men and  $0.60 (\pm 0.41)$  nmol/l in women. We did not find significant univariate correlations between total testosterone and function or DPD in men or women. Mean serum SHBG levels were  $47.9 (\pm 17.4)$  nmol/l in men and  $58.4 (\pm 20.0)$  nmol/l in women. Among men and women, higher SHBG levels correlated with slower performance in the timed up&go test (men:  $r = 0.49$ ,  $p = 0.01$ ; women:  $r = 0.35$ ,  $p < 0.0001$ ). Similarly, higher SHBG levels were correlated with higher urinary DPD excretion in men ( $r = 0.37$ ,  $p = 0.03$ ) and women ( $r = 0.18$ ,  $p = 0.02$ ). In the multivariate model, a higher SHBG level was significantly associated with slower performance in the timed up&go test ( $p = 0.001$ ) independent of age, gender, type of dwelling, serum 25(OH)D level, and body mass index. Apart from SHBG level, only female gender was associated with slower test performance (0.03). Furthermore, in the second multivariate model, a higher SHBG level was significantly associated with higher DPD excretion ( $p = 0.03$ ) independent of age, gender, type of dwelling, serum 25(OH)D level, and body mass index. Adding testosterone to both multivariate models did not change significance of SHBG and testosterone had no independent effect. **Conclusion:** Higher SHBG levels in patients with acute hip fracture are independently associated with worse function and increased bone resorption during acute care after hip fracture surgery. Total testosterone levels were low in men with acute hip fracture, and did not correlate with function or DPD excretion in men or women early after hip fracture surgery.

**Effects of Neurological Impairment and Functional Mobility on Bone Mineral Density Following Stroke: A Pilot Study.** N. M. Wysocki\*, S. H. Saxon\*, P. Supanwanid\*, Y. Wang\*, R. L. Harvey\*, E. J. Roth\*, T. J. Schnitzer. Physical Medicine and Rehabilitation, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

Stroke patients have a 2-4 fold increased risk of hip fracture compared to the general population, primarily on the paretic side. Decreased bone mineral density (BMD) on the paretic side may be an important risk factor. However, the relationship between BMD and stroke related motor impairment and functional mobility is not known. The purpose of this study was to investigate the relationship between bone mineral density (BMD), neurological impairment, and functional limitations in stroke patients and to identify risk factors for osteoporosis in this population. A cross-sectional study design was used; a convenience sample of 33 stroke patients was recruited from an outpatient rehabilitation clinic. Descriptive data including demographics and clinical history were collected. Patients answered a questionnaire regarding functional status, and motor function was assessed by trained physicians using the motor components (questions 4-7) of the NIH stroke scale (NIHSS), (possible score 0 - 21). BMD was measured using dual energy X-ray absorptiometry (DEXA). ANOVA was used to compare BMD between patients with differing walking ability and neurological impairment. Paired t-test was used to compare BMD between the paretic and non-paretic hip. The patients' mean age was  $58.4 \pm 14.5$  years; there were 19 male and 14 female patients; time post-stroke was  $6.3 \pm 6.3$  years. Patients with more severe neurological impairment (higher sum NIHSS) had lower BMD at the paretic total hip ( $r = -0.396$ ,  $p = 0.027$ ) and non-paretic total hip ( $r = -0.469$ ,  $p = 0.007$ ). Patients with limited walking ability had lower BMD and Z-score at both the paretic and non-paretic total hip ( $p = 0.014$  and  $p = 0.035$ , respectively). BMD and Z-score were significantly decreased in the paretic vs. non-paretic limb at the hip ( $t = 3.31$ ;  $p = 0.002$ ). The majority of patients (73%) had decreased BMD at the paretic hip compared to age matched normals (average z-score,  $-1.22$  at paretic hip). Of note, most patients in this study were not being treated for low bone mass or osteoporosis. Only 3% of patients were being treated with a bisphosphonate, 12% with vitamin D supplements, and 15% with calcium supplementation. In conclusion, this study suggests that severe neurological impairment and reduced walking ability are associated with low BMD following stroke and that the BMD in the paretic lower limb is more affected than the nonparetic leg. This study highlights the effect that disuse and function can have on BMD and reinforces the importance of addressing bone health and osteoporosis risk in stroke patients.

**Genetic Variation in IL6 and LRP5 Is Associated with Osteoporosis in the Marshfield Clinic Personalized Medicine Project: Evidence for Interaction with Smoking.** P. Giampietro<sup>1</sup>, C. McCarty<sup>\*2</sup>, B. Mukesh<sup>\*2</sup>, F. McKiernan<sup>1</sup>, D. Wilson<sup>1</sup>, A. Shuldiner<sup>\*3</sup>, J. Levasseur<sup>\*3</sup>, L. Ivacic<sup>\*2</sup>, T. Kitchner<sup>\*2</sup>, N. Ghebranious<sup>\*2</sup>. <sup>1</sup>Marshfield Clinic, Marshfield, WI, USA, <sup>2</sup>Marshfield Clinic Research Foundation, Marshfield, WI, USA, <sup>3</sup>University of Maryland School of Medicine, Baltimore, MD, USA.

Osteoporosis is a complex disease mediated by genetic and environmental factors. A nested case-control study within the Marshfield Clinic Personalized Medicine Research Project was performed to assess the relative impact of cigarette smoking, statin use, genetic polymorphisms, and one-way interaction of these factors on the development of osteoporosis in post-menopausal women. Genotyping of 14 SNP alleles corresponding to VDR, ESRI, COL1A1, IL-6, TGF- $\beta$ , ApoE and LRP5 genes, was performed on 309 postmenopausal Caucasian females with osteoporosis (DXA T-scores  $\leq -2.5$  (spine, femur or radius) or history of low energy fracture) and 293 matched controls without osteoporosis (T-scores  $> -2.5$ ). The ethnic composition of the sub population studied was 99.7% Caucasian with predominant German ancestry. Cases differed from controls with respect to BMI (cases:  $32.9 \pm 6.7$  vs. controls:  $26.9 \pm 5.0$ ;  $p < 0.001$ ), mean age ( $70.4 \pm 9.4$  vs.  $61.6 \pm 8$  years,  $p < 0.001$ ) and smoking (70.2% cases 'never smoked' vs. 60.1% controls;  $p = 0.02$ ) but not statin use. SNPs were chosen based upon known function consequences or prior evidence for association in other studies and were genotyped using MALDI-TOF. The IL6-C634G (rs1800796) C allele of the promoter region was found to be associated with osteoporosis (odds ratio (OR) for CC + CG = 2.51 (95% CI=1.33, 4.75;  $p = 0.0047$ ), independent of statin use or smoking status.) This finding replicates the association of rs1800796 with osteoporosis reported by Ota et al. (J Hum Genet 2001; 46: 267-272) in a Japanese population. However, we found the opposite allele associated with osteoporosis suggesting the causative variant may be on a different haplotype in the two populations. On stratification for smoking, an association with LRP5 (C135242T) and osteoporosis emerged (OR 2.8 in smokers with the A/G allele (95% CI= 1.1, 7.0  $p = 0.03$ ), suggesting a role for an environmental interaction in this association. In conclusion, we provide evidence for a role of genetic variation in IL6 and LRP5 in osteoporosis risk in Caucasian women, the latter manifest only in smokers.

## SU366

**Establishing Healthy Body Composition Values with DXA.** M. K. Oates<sup>\*1</sup>, D. W. Oates<sup>\*1</sup>, H. S. Barden<sup>2</sup>, D. Ergun<sup>2</sup>. <sup>1</sup>Mary Oates M.D. Inc, Santa Maria, CA, USA, <sup>2</sup>GE Healthcare, Madison, WI, USA.

There is considerable interest for body composition reference data for healthy adults. Protocols for collecting reference data should be restricted to subjects with few, if any, medical conditions affecting general health and body composition, and should encompass a wide variety of body shapes and sizes. We are collecting male and female reference data of healthy subjects following a protocol that excludes subjects who have or have had medical conditions including, but not restricted to: coronary heart disease, diabetes, kidney disease, liver disease, HIV, cancer, eating disorders, hypertension under 50 years of age, surgical procedures for obesity, BMI less than 18 or greater than 40, and surgical implants. In addition, we excluded subjects who were dieting, did not exercise at least 3x a week, consumed >2 alcohol drinks/day, had smoked within the past 6 mo., or were professional athletes. We are reporting preliminary body composition results (age 18-59 years) measured with dual-energy X-ray absorptiometry (DXA) using Lunar iDXA or Lunar Prodigy (GE Healthcare). Average female and male age, height, weight, and BMI were 40.7 and 31.9 years, 164.5 and 179.4 cm, 63.8 and 82.6 kg, and 23.8 and 25.6 kg/m<sup>2</sup>, respectively. 117 women and 85 men were measured on the iDXA; 118 different women and 79 different men in a separate study were measured on the Prodigy. Mean %fat values by decade for iDXA and Prodigy were not significantly different between densitometers, except for male values that differed for age 18-29, due to more younger subjects measured with Prodigy. Lean Mass Index (LMI), defined as lean mass/height<sup>2</sup> may be useful to compare and identify muscular density of individuals of similar body BMI or %fat (Figure).

Age (yrs)	Male and Female %Fat by Age			
	Female iDXA %Fat Mean (sd)	Female Prodigy %Fat Mean (sd)	Male iDXA %Fat Mean (sd)	Male Prodigy %Fat Mean (sd)
18-29	28.3 (6.6)	27.4 (8.5)	19.8 (5.5)	13.2 (7.6)*
30-39	31.8 (8.1)	29.6 (10.0)	22.3 (6.1)	21.8 (7.4)
40-49	30.6 (7.6)	31.9 (9.6)	20.8 (6.1)	18.6 (9.3)

**Hormonal Influences on Volumetric Bone Density and Geometric Properties in Obesity.** D. Sukumar<sup>\*1</sup>, Y. Schluskel<sup>\*1</sup>, H. Ambia-Sobhan<sup>\*1</sup>, C. Gordon<sup>2</sup>, T. Stahl<sup>\*3</sup>, S. Schneider<sup>\*3</sup>, S. A. Shapses<sup>1</sup>. <sup>1</sup>Nutritional Sciences, Rutgers University, New Brunswick, NJ, USA, <sup>2</sup>McMaster University, Hamilton, ON, Canada, <sup>3</sup>University Medicine & Dentistry of NJ, New Brunswick, NJ, USA.

Obesity is associated with an altered hormonal milieu and a higher bone density. We examined how body mass index (BMI) influences trabecular and cortical bone in women by examining hormones such as parathyroid hormone (PTH), estradiol (E2), vitamin D (25 OH D) and bone markers. We measured trabecular and cortical bone parameters including volumetric bone mineral density (vBMD), bone mineral content (BMC), geometric properties, polar moment of inertia (Ip) and stress strain index (SSI). We examined 174 women (ages 24-70 years) with extreme differences in BMI (18-57 kg/m<sup>2</sup>). Data was categorized by the four definitions of BMI (Figure) and assessed by analysis of variance in the pre- and post-menopausal women. Not surprisingly, all women with a BMI >35 kg/m<sup>2</sup> had higher trabecular BMC, vBMD, cortical BMC, area and thickness, periosteal circumference, Ip and SSI in comparison with normal weight women. Interestingly, premenopausal women with a high BMI (> 35 kg/m<sup>2</sup>) showed a lower cortical vBMD (p <

0.05) than leaner women (Figure) that may be explained by the higher serum PTH (R = 0.60, p<0.0001) and urinary pyridinoline (R = 0.38, p< 0.01). In contrast, BMI did not influence cortical BMD in postmenopausal women, but this may be due to the positive association between serum estrogen and PTH (R = 0.51, p < 0.01) that was analyzed in a subset of the postmenopausal women (n=56). Estrogen associated with obesity in postmenopausal women (R= 0.61, p < 0.001) may be preventing a catabolic effect of PTH on bone. An altered hormonal milieu associated with obesity may influence cortical bone although the role of other adipokines and hormones remain to be investigated.

**Radiation-Induced Bone Loss: Description of Dose, Time Course, Age, Strain and Sex Variables.** L. C. Bowman<sup>\*1</sup>, E. W. Livingston<sup>\*1</sup>, J. S. Willey<sup>1</sup>, M. E. Robbins<sup>\*2</sup>, J. D. Bourland<sup>\*2</sup>, T. A. Bateman<sup>1</sup>. <sup>1</sup>Bioengineering, Clemson University, Clemson, SC, USA, <sup>2</sup>Radiation Oncology, Wake Forest University School of Medicine, Winston-Salem, NC, USA.

Cancer patients have an increased fracture risk resulting from atrophy after radiotherapy. Factors contributing to bone loss are poorly understood. The aim of these studies was to characterize a murine model of radiation-induced bone loss. Our goal was to describe how absorbed dose; animal age, strain, and sex; and time course early after exposure can influence trabecular bone parameters. Dose: 10-wk old female C57BL/6 (B6) mice received 2, 4, or 6 Gy X-rays (140 kVp)(n=5/group). Lower bone volume fraction (BV/TV; microCT analysis; proximal tibia) was observed 2-wks post-irradiation in all groups vs. non-irradiated control (2 Gy, -42%; 4 Gy, -39%; 6 Gy, -44%)(P<0.05). Deterioration of trabecular microarchitecture was also indicated by lower trabecular number and connectivity (P<0.05). No differences were observed between doses. 2 Gy was the lowest dose to produce bone loss without an effect on body mass. This dose was thus used in subsequent studies. Time Course: 20-wk-old female B6 mice were irradiated (n=12/group) and euthanized after either 7 or 14 days. Lower BV/TV (day 7, -32%; day 14, -42%) was observed at both time points (P<0.05). Based on these data, 2-wks after irradiation was used for subsequent studies. Age: Skeletally immature (9-wk old) and mature (19-wk old) female B6 mice were irradiated (n=6/group). BV/TV was lower in both immature and mature mice (9 wk, -42%; 19 wk, -35%) compared with age-matched controls (P<0.001). Strain 1: 19-wk old female B6 and BALBc mice were irradiated (2 Gy) and compared to strain-matched, non-irradiated controls (n=6/group). Irradiated B6 mice had lower BV/TV (-38%) vs. control (P<0.001). BALBc mice exhibited a non-significant decline in BV/TV (-17%, P=0.07). Strain 2: 13-wk-old female B6 and DBA/2 (DBA) mice were irradiated and compared with strain-matched, non-irradiated controls (n=6/group). BV/TV was lower for irradiated mice (B6, -35%; DBA, -29%)(P<0.01). Sex: 14-wk old male and female B6 mice were irradiated (n=6/group). Irradiated mice had lower BV/TV (male, -35%, P<0.05; female, -28%, P<0.01) vs. sex-matched, non-irradiated controls. In these murine studies, bone loss occurred early after exposure to moderate doses of X-rays across a broad range of conditions, including strain, age, sex, and absorbed dose. These changes occurred without a change in body mass. The consistent early skeletal response to radiation across murine strains and conditions facilitates the development of a robust animal model to study the cellular and molecular cause of atrophy after irradiation.

**Obesity Is Associated with Higher BMD, Lower Bone Resorption and Slower Hip Bone Loss: Are these Associations Mediated by Adipokines?** J. Finigan, F. Gossiel\*, D. M. Greenfield\*, R. A. Hannon, R. Eastell. University of Sheffield, Sheffield, United Kingdom.

It is known that obesity is associated with a reduced risk of spine and hip fractures, higher BMD, lower bone turnover markers and slower rates of bone loss. It has also been observed that adipocyte-derived hormones, or adipokines, are altered in obesity: leptin is increased and adiponectin is decreased. The aim of this study was to investigate whether the bone differences associated with obesity are mediated by adipokines.

A population-based cohort of women 50-85 years old took part in a 10-year observational study with visits at 0, 2, 5, 7 and 10 years. Height, weight, fasting blood and urine samples, and BMD by DXA at the lumbar spine (LS), total hip (TH) and total body (TB) were measured at the 5-year visit. The annual percentage rate of change in BMD at TH was calculated for each subject from the regression line through all their available BMD results over a period of 5, 7 or 10 years. We identified 67 women with normal body mass index (BMI 18-25) and 34 obese women (BMI >30), excluding any subjects who were diabetic or taking HRT. We measured markers of bone resorption S-CTX (Elecsys, Roche; n=98) and U-NTX (Vitros Eci, Orthoclinical Diagnostics; corrected for creatinine, n=85), and also adiponectin (n=88) and leptin (n=87) (ELISA, R&D Systems), with log-transformation of the results.

There was no difference in age between obese and normal subjects, but in obese subjects BMD was higher at all sites ( $p<0.001$ ), CTX was lower ( $0.333 \pm 0.469$  ng/ml,  $p=0.016$ ) although NTX was no different ( $p>0.9$ ), and TH bone loss was slower ( $0.38 \pm 0.71$  %/yr,  $p=0.032$ ) compared to normal subjects. The obese women also had higher leptin ( $294.9 \pm 84.1$  pg/mL,  $p<0.001$ ) and lower adiponectin ( $124.6 \pm 162.7$  ng/mL,  $p=0.023$ ) than the normal subjects.

Leptin and adiponectin were associated, directly and inversely respectively, with TH BMD ( $p=0.006$ ,  $p=0.045$ ). Higher leptin was also associated with a lower rate of TH bone loss ( $p=0.024$ ). These associations were independent of BMI group and CTX, and for leptin, of NTX. There was no significant correlation between leptin or adiponectin and either resorption marker, even when adjusted for BMI group, although within the normal group only, leptin correlated with CTX ( $r=0.3$ ,  $p=0.031$ ).

We conclude that obesity is associated with higher BMD, lower bone resorption and slower rates of bone loss. Although the altered adipokine levels in obese women are associated with high BMD, they are not strongly associated with bone turnover or rates of hip bone loss and so are unlikely to mediate the effects of obesity on bone.

**Baseline Characteristics of Women Taking Part in an Osteoporosis Intervention: the Primary Care Osteoporosis Risk of Fracture Screening (POROS).** D. Schneider\*, K. Worley\*, K. Campbell\*, M. Steinbuch\*. <sup>1</sup>La Jolla, La Jolla, CA, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA.

In clinical practice, perimenopausal and early postmenopausal women are not systematically assessed for fracture risk. The Primary Care Osteoporosis Risk of Fracture Screening (POROS) study is a prospective 24-month observational study designed to examine the impact of a 3-step osteoporosis/osteoporosis screening program in the primary care setting within a large, diverse patient population of women 50-64 years of age.

The screening consisted of 3 sequential steps: Step 1: Fracture risk assessment questionnaire. Subjects with no risk factors were assigned to receive usual care, and subjects with  $\geq 1$  risk factor for fracture were randomized to intervention or non-intervention with 4:1 allocation. Step 2: Urine NTx test for intervention group. Step 3: If NTx result was  $>50$ , hip and spine DXA were done. Subjects' physicians received results and submitted a baseline case report form (CRF) to document intention for prevention and disease management strategies. The subjects will be observed through self-administered questionnaires at baseline, 1, 6, 12, and 24 months to assess health behaviors, treatment initiation, fractures, and resource utilization.

This report summarizes the baseline demographics and fracture risk factors of 2919 women enrolled in the study from 7 medical groups in the Western United States. A total of 1025 women had no risk factors. The intervention group consisted of 1514 women and the non-intervention 380. The mean age for all groups was 56 years and approximately 70% were White. Approximately 80% were postmenopausal and 35% had previously used hormone therapy. There were significantly more Hispanic women (28%) in the no risk factors group compared to both the intervention (23%) and the non-intervention groups (22%). The subjects were educated with 73% having at least some college.

Of the 8 risk factors assessed, BMI  $< 24$  kg/m<sup>2</sup> was most frequent at 42%. Others included previous fracture (15%), mother or father with hip fracture (20%), weight  $\leq 125$  pounds (19%), current smoker (11%), need arms to assist self in standing up from chair (37%), drinks 3+ alcoholic beverages per day (7%), rheumatoid arthritis (17%), and recent corticosteroid use (3%).

POROS will provide data on the effectiveness of utilizing a sequential screening program to identify younger women at high risk of fracture in a primary care setting.

## SU371

**Fracture Risk in Young Patients with Chronic Diseases.** M. L. Bianchi<sup>1</sup>, M. Biggioggero<sup>\*1</sup>, C. Limonta<sup>\*1</sup>, C. Colombo<sup>\*2</sup>, L. Ghio<sup>\*2</sup>, A. Edefonti<sup>\*2</sup>, F. Corona<sup>\*2</sup>, G. Nebbia<sup>\*2</sup>, L. Morandi<sup>\*3</sup>. <sup>1</sup>Bone Metabolism Unit, Istituto Auxologico Italiano IRCCS, Milano, Italy, <sup>2</sup>Clinica Pediatrica, Università di Milano, Milano, Italy, <sup>3</sup>Istituto Neurologico Besta, Milano, Italy.

To estimate the risk of fragility fractures is important in the decision about implementing preventive treatment strategies in patients with bone metabolism problems and low bone mass. There is strong evidence to consider BMD an independent predictor of the risk of fragility fractures in adults with osteoporosis. Accordingly, we did a prospective 5-year study to evaluate if BMD could be used to estimate the risk of fractures also in children affected by chronic diseases potentially affecting bone.

Our total study sample includes 1,000 children/adolescents (508 F, 492 M, age 2-19 years) affected by different chronic diseases (renal diseases, systemic connective diseases, cystic fibrosis, liver diseases, Duchenne Muscular Dystrophy). In this sample, 71% of the subjects sustaining at least one low-trauma fracture had a vertebral BMD Z-score of  $-2$  or less.

We recently completed a 5-year follow-up of 579 of these patients (277 F, 302 M, age 3-18 years). In all patients, vertebral and total body (TB) BMC and BMD were measured with DXA (Hologic); vertebral BMD was adjusted for bone size to calculate BMAD.

During the follow-up, 126 (21.8%) patients had one or more fractures for minor trauma. The average vertebral Z-score was  $-2.6 \pm 1.7$ ; in 83 cases (65.9%), the Z-score was  $<-2$  and in the remaining 43 (34.1%) between  $-2$  and  $-0.9$ .

A Z-score  $<-2$  at baseline was significantly associated with an increased risk of fractures in the following 5 years ( $p<0.001$ ). For each 1 SD decrease in TB-BMD there was a 2.1-fold increase in the risk of a limb (mainly forearm) fracture; and for each 1 SD decrease in vertebral BMAD, there was a 2.8-fold increase in the risk of a vertebral fracture.

We also observed that a previous fracture was independently associated with an increased risk (1.8-fold) of a new fracture. The use of steroids, independently of the cumulative dose, doubled the risk of fractures in subjects with a Z-score  $<-1.5$ .

Contrary to the previous reports that, among healthy children and adolescents, boys had more fractures than girls, we did not find any gender differences for fragility fractures in chronically ill children. Also, while in healthy subjects the higher incidence of fractures was observed during adolescence, age and puberty were not associated with an increased risk of fractures in our sample.

In conclusion, our study shows that in young patients affected by chronic diseases, BMD, previous fractures and steroid use are independently related to an increased risk of fractures over 5 years.

## SU372

**The Bone-Building Effects of the Oral Calcium-Sensing Receptor Antagonist, Ronacaleret, in Ovariectomized Rats.** S. J. Hoffman\*, C. A. Capriotti\*, J. A. Vasko\*, X. Liang\*, G. B. Stroup\*, L. N. Casillas\*, R. W. Marquis\*, S. Kumar. GlaxoSmithKline, Collegeville, PA, USA.

Short-term antagonism of calcium-sensing receptors (CaR) on parathyroid cells transiently releases endogenous parathyroid hormone (PTH(1-84)), which stimulates bone formation. This study investigated the bone-building effects of ronacaleret (SB-751689), a CaR antagonist under investigation as an oral treatment for osteoporosis, in ovariectomized (OVX) rats.

Sprague Dawley virgin female rats aged 10.5 months were divided into 8 groups of 9 or 10 animals: 2 groups underwent ovariectomy or sham surgery and were euthanized 6 weeks after surgery to provide baseline data; 2 control groups (OVX or sham) received oral vehicle (1% methylcellulose); 3 OVX groups received oral ronacaleret, 30, 60 or 120 mg/kg; and the final OVX group received PTH(1-34) subcutaneously at  $1 \mu\text{g/kg}$  (a dose previously shown to be comparable to PTH(1-84) release after oral administration of ronacaleret). All treatments were given once daily for 8 weeks from day 43 post-surgery.

Peak plasma levels ( $C_{\text{max}}$ ) of ronacaleret increased dose dependently after oral administration during week 8 (858, 1338 and 3259 ng/ml, for the 30, 60 and 120 mg/kg doses, respectively). However, the effect of ronacaleret on PTH(1-84) release was less dose dependent ( $C_{\text{max}}$  33, 66 and 68 pM, respectively). In comparison, the  $C_{\text{max}}$  of PTH(1-34) was 27 pM. At 2 h postdose, the 2 highest doses of ronacaleret dose dependently and significantly ( $p<0.05$ ) increased plasma ionized calcium levels compared with baseline measurement.

Ovariectomy induced significant bone loss in the lumbar spine and the proximal tibia. Only PTH(1-34) significantly reduced bone loss in the lumbar spine as measured by dual-energy X-ray absorptiometry (DXA) ( $p<0.05$  compared with OVX controls at week 10), although DXA is unable to discriminate between trabecular and cortical bone. In contrast, histological analysis revealed significant increases in bone formation rates and osteoid perimeter at the lumbar spine with ronacaleret, 120 mg/kg ( $p<0.01$ ). At the proximal tibia, loss of trabecular bone mineral density was reduced by the 2 highest doses of ronacaleret and PTH(1-34) ( $p<0.01$ ). For the distal tibia, treatment outcome varied when different analyses were applied, but overall cortical bone loss was reduced with ronacaleret. Ovariectomy significantly increased the markers of bone turnover, urinary deoxypyridinoline and plasma osteocalcin, but treatment with ronacaleret and PTH(1-34) did not significantly decrease their levels.

Thus, oral administration of ronacaleret in OVX rats stimulates PTH(1-84) release which leads to reduced trabecular and cortical bone loss.

## SU373

**The Anabolic Skeletal Effects of a Growth Hormone-Derived Peptide (AOD9604) in the Ovariectomized Rat Model of Osteoporosis.** I. Kamikowski<sup>\*1</sup>, R. Renlund<sup>\*2</sup>, M. D. Grynpas<sup>3</sup>. <sup>1</sup>Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

A synthetic human Growth Hormone (hGH) 16-AA C-terminus peptide, AOD9604 (AOD, Tyr-hGH171191), has been shown to modulate fat metabolism and is currently being developed as a novel weight-loss drug. However, hGH is known to affect both adipocytes and osteoblasts, which suggests that AOD may also affect bone. Previously, it has been shown that AOD can prevent OVX-induced bone loss and fragility. This study focuses on the ability of AOD to rebuild the bone lost during ovariectomy (OVX) in a rat model of osteoporosis. Nine month-old female rats were ovariectomized and left without treatment for 12 weeks in order to lose bone. The OVX rats were divided into an untreated control group (N=13) and three groups treated with increasing doses of AOD (0.01 mg/kg/day [N=13], 0.03 mg/kg/day [N=14], 0.25 mg/kg/day [N=14]) administered orally by gavage for 12 weeks. An additional sham-OVX operated group (N=15) served as a negative control. The two control groups were given vehicles by gavage as per the AOD treated groups. Following sacrifice, dual energy x-ray absorptiometry (DXA) was used to determine femoral and vertebral Bone Mineral Density (BMD). Three-point bending, torsion, femoral neck fracture and vertebrae compression tests were used to evaluate femoral and vertebral mechanical properties. DXA results showed no significant increase in BMD following AOD administration. However, vertebral compression showed a dose-dependent increase in ultimate stress and elastic modulus. In three-point bending, the highest dose of AOD (0.25 mg/kg/day) caused a significant ( $p<0.05$ ) decrease in ultimate stress while the lowest dose of AOD (0.01 mg/kg/day) caused a significant ( $p<0.05$ ) increase in shear stress following torsion testing. Future work includes assessing mineralization changes, through back-scattered electron imaging and microhardness testing, and structure and remodelling changes, through static and dynamic histomorphometry. In conclusions, our results suggest that AOD had differential effects on cortical and trabecular bone and, despite the lack of AOD effect seen with DXA, mechanical tests indicate AOD administration resulted in a dose dependent restoration of vertebral bone strength.

## SU374

**Inhibition of PPAR $\gamma$ 2 by BADGE and Vitamin D in Male Mice Increases Osteoblastogenesis and Inhibits Bone Matrix Mineralization Leading to Osteomalacia.** G. Duque<sup>1</sup>, D. Rivas<sup>2</sup>, J. Ong<sup>\*2</sup>, W. Lee<sup>\*3</sup>, J. E. Henderson<sup>3</sup>. <sup>1</sup>Nepean Clinical School-University of Sydney, Penrith, Australia, <sup>2</sup>Lady Davis Institute-McGill University, Montreal, QC, Canada, <sup>3</sup>JTN Wong Laboratories-McGill University, Montreal, QC, Canada.

Bone marrow fat infiltration is a prevalent feature in people with age-related bone loss, which correlates inversely with bone formation and positively with high expression levels of peroxisomal proliferator-activated receptor gamma 2 (PPAR $\gamma$ 2). Inhibition of PPAR $\gamma$ 2 thus represents a potential therapeutic approach for age-related bone loss. In this study, we examined the effect of PPAR $\gamma$ 2 inhibition on bone in skeletally mature C57BL/6J male mice. Four-month-old mice were treated with a PPAR $\gamma$ 2 antagonist, bisphenol-A-diglycidyl ether (BADGE) (30 mg/Kg/day, IP) alone or in combination with 1,25(OH)2D3 (18 pmol/24 h, SC) for 6 wk. Micro computed tomography and bone histomorphometry indicated that mice treated with both BADGE + 1,25(OH)2D3 had significantly increased bone volume and improved bone quality compared with mice treated with either BADGE or 1,25(OH)2D3 alone ( $p<0.001$ ). This phenotype occurred in the absence of alterations in osteoclast numbers or eroded surfaces. The BADGE-treated mice exhibited classic signs of osteomalacia including increased osteoid length and width in association with broad, diffuse tetracycline bands with low fluorescence intensity. All of the treated groups showed a significant increase in circulating levels of bone formation markers without changes in bone resorption markers ( $p<0.001$ ) and parathyroid hormone (PTH), Ca+ and P+ remained normal. The effects were more pronounced in mice treated with BADGE + 1,25(OH)2D3. Ex-vivo cultures of bone marrow cells from treated mice showed significantly higher level of osteoblastogenesis, reduced adipogenesis and a reduction in fat volume ( $p<0.01$ ). These changes were accompanied by increased expression of osteocalcin and Runx2 protein and a decrease in PPAR $\gamma$ 2 nuclear activation complex. Taken together, these observations demonstrate that inhibition of PPAR $\gamma$ 2 in adult male mice decreased marrow fat and enhanced bone formation. The presence of osteomalacia in the absence of high levels of PTH or low levels of either calcium or vitamin D, suggests that BADGE may influence bone mineralization by an alternate pathway.

## SU375

**Cannabinoid Receptor Ligands Rescue Bone Loss and Stimulate Fracture Healing.** O. Ofek<sup>\*1</sup>, A. Bajayo<sup>\*1</sup>, E. Melamed<sup>\*1</sup>, Y. Gabet<sup>\*1</sup>, E. Shohami<sup>\*2</sup>, R. Mechoulam<sup>\*3</sup>, I. Bab<sup>1</sup>. <sup>1</sup>Bone Laboratory, The Hebrew University of Jerusalem, Jerusalem, Israel, <sup>2</sup>Pharmacology, The Hebrew University of Jerusalem, Jerusalem, Israel, <sup>3</sup>Medicinal Chemistry and Natural Products, The Hebrew University of Jerusalem, Jerusalem, Israel.

A number of studies have recently demonstrated the presence of cannabinoid receptors in osteoblasts, osteoclasts and skeletal sympathetic nerve terminals. Cannabinoid receptor null mice have a low bone mass phenotype and cannabinoid ligands, which activate the Gi-protein coupled receptors CB1 and CB2, are capable of attenuating ovariectomy (OVX)-induced bone loss. CB1 is mainly neuronal whereas CB2 is preferentially expressed in peripheral tissues. Using models for testing the reversal of OVX-induced bone loss and stimulation of fracture healing we show here that cannabinoid receptor agonists have a net bone anabolic activity. In the OVX model, mice were left untreated for 6 weeks postoperatively. Combined  $\mu$ CT/histomorphometric analysis indicated that during this time the trabecular bone volume density (BV/TV) in the lumbar vertebrae and distal femoral metaphyses stabilized at respective 25% and 40% lower levels compared to sham-OVX controls. This was followed by a 6-week i.p. administration of the CB2-specific agonist HU-308, at 20 mg/Kg/day. This treatment resulted in a 35% rescue of the OVX-induced bone loss, mainly by stimulating bone formation and augmenting the trabecular thickness. The magnitude of this effect is comparable to that of PTH(1-34) in a similar experimental setting. To assess the effect of cannabis abuse on fracture healing, adult male rats were treated chronically with a mixture of tetrahydrocannabinol (THC) and cannabidiol, the most abundant constituents of marijuana and hashish. Administration of these cannabinoids, each at 5 mg/Kg/day, commenced immediately after standardized femoral pinning and mid-diaphyseal fracturing.  $\mu$ CT assessment carried out after 2 weeks showed 37% increase in the BV/TV of the newly formed mineralized callus, accompanied by 32% increase in trabecular number and, particularly important, 52% stimulation of the trabecular connectivity density. Additional experiments in MC3T3 E1 and primary osteoblast cultures suggest that the effects of CB1/CB2 agonists like THC and of CB2 specific agonists like HU-308 and AM1241 are mediated by a Gi-protein - Erk1/2 pathway, but not p38. Together, these results portray cannabinoid receptor agonists as potent bone anabolic agents. Further studies characterizing the skeletal activity of selective CB2 agonists are advocated for the rescue of skeletal deficits, since this receptor is not involved in the well established cannabinoid psychotropic effects and control of energy metabolism.

**A Soluble Activin Receptor Type IIA Fusion Protein, ACE-011, Increases Bone Mass by Stimulating Bone Formation and Inhibiting Bone Resorption in Cynomolgus Monkeys.** S. Lotinun<sup>1</sup>, R. J. Fajardo<sup>\*2</sup>, R. S. Pearsall<sup>3</sup>, M. L. Boussein<sup>2</sup>, R. Baron<sup>1</sup>. <sup>1</sup>Harvard School of Dental Medicine and Harvard Medical School, Boston, MA, USA, <sup>2</sup>Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, <sup>3</sup>Accelaron Pharma, Cambridge, MA, USA.

Activin A, a member of the TGF- $\beta$  superfamily, has been shown to inhibit osteoblast differentiation and stimulate osteoclastogenesis *in vitro*. An antagonist to activin, a soluble form of extracellular domain of the activin receptor type IIA (ActRIIA) fused to the Fc domain of murine IgG has been shown to have an anabolic effect on bone in mice. The present study was designed to test human ActRIIA-IgG-Fc (ACE-011) in non-human primates to determine if the increased bone mass was due to an increase in bone formation, a decrease in bone resorption or both. Young, female Cynomolgus monkeys were injected subcutaneously with either 10 mg/kg ACE-011 or vehicle biweekly for 3 months. PIXImus, pQCT and micro-CT analysis demonstrated that ACE-011 improved bone density and microarchitecture in the axial and appendicular skeleton. Mechanical testing indicated a higher vertebral compressive strength in ACE-011-treated monkeys compared to vehicle-treated controls. To further characterize the mechanism by which ACE-011 increased bone mass and strength, histomorphometry analysis of distal femur, femoral midshaft, femoral neck and 12<sup>th</sup> thoracic vertebrae was evaluated. Compared to vehicle, ACE-011 significantly increased cancellous bone volume (87%,  $p<0.001$ ) with a 36% ( $p<0.05$ ) increase in trabecular thickness, 40% ( $p<0.01$ ) increase in trabecular number and 50% ( $p<0.05$ ) decrease in trabecular separation at distal femur. Interestingly, ACE-011 induced a 154% ( $p<0.01$ ) increase in bone formation rate, 75% ( $p<0.05$ ) increase in mineralizing surface and 43% ( $p<0.05$ ) increase in mineral apposition rate. Monkeys treated with ACE-011 had greater osteoblast surface and a decrease in osteoclast surface, with only modest changes in bone biochemical marker data. No differences were observed in parameters of cortical bone at the midshaft of the femur. Similar to distal femur, ACE-011 treatment led to an increase in cancellous bone volume, bone formation rate and osteoblast surface at the femoral neck. Similar trends were observed in thoracic vertebrae with an increase in cancellous bone volume (32%,  $p=0.09$ ), bone formation rate (77%,  $p=0.12$ ) and osteoblast surface (49%,  $p=0.19$ ) and significantly decreased osteoclast surface (72%,  $p<0.05$ ). These data demonstrate that ACE-011 is a dual anabolic-antiresorptive compound, improving cancellous bone volume by promoting bone formation and inhibiting bone resorption. Thus, soluble ActRIIA fusion protein may be useful in the prevention and/or treatment of skeletal fragility.

**Inhibition of Bone Loss and Muscle Atrophy by Dihydrotestosterone in a Mouse Hindlimb Disuse Model.** Y. Qin<sup>1</sup>, A. Ali<sup>\*1</sup>, S. Judex<sup>1</sup>, Q. Zeng<sup>\*2</sup>, V. Krishnan<sup>\*2</sup>, Y. L. Ma<sup>2</sup>. <sup>1</sup>Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, <sup>2</sup>Eli Lilly Research Laboratories, Indianapolis, IN, USA.

Musculoskeletal adaptations to microgravity and functional disuse have significant physiological effects leading to skeletal complications, i.e., bone loss and muscle atrophy. Generally hormone is considered to be a key regulator of skeletal formation and/or inhibition of loss, e.g., androgen hormone is essential for increasing and maintaining muscle mass during functional disuse. The objective of the study was to investigate the role of androgen on bone and muscle during a course of hindlimb suspension in the presence of Dihydrotestosterone (DHT), an active form of testosterone. 34 adult female BALB mice were randomly separated to 4 groups: 1) control vehicle, no suspension, 2) control vehicle, hind limb suspension (HLS), 3) DHT 2mg/kg/d sc, hind limb suspension, 4) baseline control, for 3 weeks. Whole body and wet muscle weight were measured. Bone mass was assessed by pDEXA. Longitudinal body weight data showed significant reduction in body weight in the HLS control group, while DHT treatment attenuated the body weight loss in HLS mice in the first week and completely restored the body weight to the non suspension group by end of the study. Suspension decreased hind limb muscle mass in soleus (-34%), gastrocnemius (-23%), and quadriceps muscles (-26%) ( $p < 0.05$ ), while the DHT group protected the muscle wet weight loss with an increasing trend in all muscle groups ranging from 3% to 12%. HLS reduced BMD and BMC in whole femur (-20%, -21%,  $p < 0.01$ ), mid-diaphysis (-11%, -9%,  $p < 0.05$ ), and distal femoral regions, (-25%, -25%,  $p < 0.01$ ). DHT treatments partially protected BMD and BMC in whole femur (+14%), mid-diaphyseal femur (+7%), and distal femur (21%, 25%) when compared to HLS control. Our data suggested that Dihydrotestosterone protected against the muscle atrophy and bone loss in the functionally disused model of hindlimb suspension.

**Effects of Statins on eNOS and BMP2 in Osteoblasts.** M. M. Moore, J. R. Edwards, G. E. Gutierrez, G. R. Mundy. Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA.

Statins stimulate osteoblast differentiation, bone formation, and enhance fracture healing. Although they have been shown to increase BMP2 transcription, the mechanism by which they do this is unclear. We hypothesize that the activation of endothelial nitric oxide synthase (eNOS) in osteoblasts may be responsible, since statins have been shown to increase eNOS expression in endothelial cells, and eNOS null mice have a bone phenotype that is the mirror image of statin-treated mice (Armour et al, 2001). To determine if statins increase eNOS mRNA expressed in bone cells, a pre-osteoblastic cell line, 2T3, was incubated with osteoblastic medium in the presence or absence of 5µM lovastatin. Lovastatin caused a maximal 3-fold increase in eNOS mRNA after 19 days of culture, although there was a steady significant increase after day 5. In the same cells, BMP2 mRNA was increased 25-fold after 19 days in culture, with a steady and significant increase after day 2. Lovastatin also increased mineralized bone nodule formation and alkaline phosphatase activity after 11 days in culture. Although control cultures also demonstrated an increase in BMP2 and eNOS mRNAs, and an increase in mineralized bone nodule formation and alkaline phosphatase activity, this occurred more rapidly in the lovastatin-treated osteoblasts, and to a greater extent. In the untreated cultures, these effects were not seen before 10 days of culture. We conclude that lovastatin hastens osteoblast differentiation in 2T3 osteoblastic cells, as evidenced by more rapid expression of eNOS mRNA, BMP2 mRNA, alkaline phosphatase activity and mineralized bone nodule formation, and causes increases in each of these parameters compared with osteoblasts cultured in control media for the same time period. These data are consistent with effects of statins to sequentially increase BMP2 and eNOS expression in osteoblasts.

**Rapid Optical Imaging of Bone Formation Responses in the Rodent Skeleton.** K. Petrosky\*, M. Pegurri\*, A. Studer\*, M. Merdes\*, R. Kneuer\*, H. Gremlich\*, M. Kneissel. Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland.

Changes in bone formation are monitored by biomarker or histomorphometric readouts. Biomarker readouts are rapid, but do not provide information about changes in local bone turnover. Histomorphometry allows for detailed analyses in regions of interest, but is time consuming. In the present studies we monitored rapidly local bone forming activity by near-infrared fluorescence (NIRF) imaging, using a NIRF bisphosphonate derivative homing to bone and binding to hydroxyapatite. First 6-month-old female OF1 mice ( $n = 6$  / group) were administered twice daily 33, 100, or 300 nM hPTH(1-34) sc. onto the calvaria to induce local bone formation. Animals received either alizarin and calcein on day 5 and 12 respectively for classical histomorphometry or 0.1 mg/kg of Cy5.5 labeled pamidronate at day 7 and 8. A time-domain small animal optical imager (GE eXplore Optix) was used for *in vivo* detection of NIRF signal in their calvaria 4 hours after the second application of the NIRF probe. We observed a dose-related increase in fluorescent signal in PTH treated calvarias which reached significance at the 100 nM dose. Histomorphometric evaluation revealed that bone formation rates were increased at the calvaria surface, but not in the underlying marrow cavities. Pooled bone formation rates of the two compartments corresponded to NIRF signal changes

observed in PTH treated calvarias. Histology confirmed presence of the NIRF probe at mineralizing fronts. We proceeded to systemic PTH treatment of 11-month-old female OF1 mice and 9-month-old female Wistar rats ( $n = 8$  / group). Animals received daily sc. 6 (rats only), 25 or 100 microg/kg of hPTH(1-34) or vehicle for 14 days. Animals were administered iv. 0.1 mg/kg of the bisphosphonate derivative on day 13 and 14. The animals were sacrificed 6 hours after the second application for excision of hind limbs and lumbar spine. *Ex vivo* measurements demonstrated a dose-related increase in NIRF signal in the distal femur and the proximal tibia of PTH treated mice. Increases were significant and reached about two-fold in animals treated with the highest dose. A similar increase was observed in the lumbar spine. In rats significant increases in NIRF signal were observed from 25 microg/kg onwards in the proximal tibia, while in the spine a significant increase was already detectable in animals treated with 6 microg/kg PTH. In summary we were able to monitor bone formation responses triggered by local or systemic anabolic treatment at various skeletal sites in rodents. The results suggest that bone formation responses can be quantified rapidly *in vivo* by the use of this optical imaging technology.

**Intermittent PTH Administration Increases Bone Mass and Strength in Aged Mice by Antagonizing Oxidative Stress-induced Osteoblast Apoptosis via ERK-mediated Attenuation of p66<sup>shc</sup> Phosphorylation.** R. L. Jilka, M. Almeida, L. Han, R. S. Weinstein, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

The cellular and molecular mechanisms of the anabolic effect of intermittent PTH in animal models have been largely investigated at peak adult bone mass. However, it is unknown whether similar mechanisms underlie the effectiveness of PTH in young and old subjects. C57BL/6 mice lose bone mass and strength with advancing age and these changes are associated with increased oxidative stress and increased osteoblast apoptosis. Based on this and extensive evidence that oxidative stress induces osteoblast apoptosis in a cell autonomous manner, we compared the effects of intermittent PTH administration on bone mass, strength, and prevalence of osteoblast apoptosis in 6 versus 26 month old female C57BL/6 mice; and also examined the effects of PTH on H<sub>2</sub>O<sub>2</sub>-induced apoptosis of osteoblastic cells *in vitro*. Prior to treatment, old mice exhibited the expected reductions in vertebral and femoral bone mass, and cancellous bone volume, as compared to young mice as determined by DEXA and microCT. These changes were associated with reduced vertebral and femoral strength. Moreover, the prevalence of osteoblast apoptosis in vertebral cancellous bone was 30% in old mice, as compared to 9% in young mice. Daily injections of 100 ng/g PTH(1-34) for 28 days increased femoral and vertebral BMD, vertebral bone volume, femoral cortical thickness, and indices of bone strength in both young and old mice; and in the latter reversed all these parameters to levels that approached or exceeded those seen in the untreated young ones. More important, PTH reduced the prevalence of apoptotic osteoblasts in cancellous vertebral bone by 2- and 3-fold in young and old animals respectively; in the latter to the level of the untreated young animals. Consistent with the *in vivo* findings, 1 h pretreatment of murine calvaria cells or the osteoblastic cell line OB-6 with 50 nM PTH prevented apoptosis induced by H<sub>2</sub>O<sub>2</sub>. The anti-apoptotic effect of the hormone was associated with a striking attenuation of the H<sub>2</sub>O<sub>2</sub>-induced phosphorylation of p66<sup>shc</sup>, a redox enzyme that generates mitochondrial H<sub>2</sub>O<sub>2</sub> to trigger mitochondria swelling and apoptosis. The reduction in H<sub>2</sub>O<sub>2</sub>-induced p66<sup>shc</sup> phosphorylation was reproduced by dibutyl-1-cAMP (100 µM) and was abrogated by the MAP kinase inhibitor PD98059. Collectively, these results demonstrate that PTH can reverse age-related bone loss, in part, by a previously unappreciated action of the hormone that involves ERK-mediated attenuation of p66<sup>shc</sup> phosphorylation, which counteracts the apoptotic effects of oxidative stress on osteoblasts.

**Combination of Flaxseed and Estrogen Benefits Bone Health in the Ovariectomized Rat Model of Postmenopausal Osteoporosis.** S. M. Sacco\*, J. M. Jiang\*, S. Reza-Lopez\*, D. W. Ma\*, W. E. Ward<sup>1</sup>. <sup>1</sup>Nutritional Sciences, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Department of Human Health and Nutritional Sciences, University of Guelph, Guelph, ON, Canada.

The unanticipated increase in risk of stroke reported by the Women's Health Initiative stimulated interest in newer formulations of estrogen therapy (ET) that contain lower-than-standard doses and alternative modes of delivery. Moreover, many postmenopausal women are consuming natural health products such as flaxseed (FS) to relieve menopausal-like symptoms and to improve overall health. FS is an oilseed rich in lignans and n-3 polyunsaturated fatty acids (PUFA) that may modulate bone metabolism through their estrogen-like or anti-inflammatory properties, respectively. Whether FS enhances or interferes with ET is unknown. This study determined the effect of 10% FS, standard dose (SD) ET, low dose (LD) ET, and their combination on bone mineral and biomechanical bone strength in ovariectomized (ovx) rats. Ovx rats were treated for 12 weeks with 1) basal diet (negative control); 2) 10% FS diet; 3) SD ET implant (25 µg, 90 day release); 4) LD ET implant (13 µg, 90 day release); 5) FS + SD; 6) FS + LD. A sham-operated group was included as a positive control. Femurs and lumbar vertebrae (LV) were analyzed for bone mineral density (BMD) by densitometry and biomechanical strength testing using a material testing system. Total fatty acid composition of tibias and LV3 were measured to determine if n-3 PUFA from FS are incorporated into bone. FS + LD and FS + SD resulted in higher BMD ( $p < 0.05$ ) and peak load ( $p < 0.05$ ) in the LV compared to the negative control while FS alone was neither beneficial nor detrimental to bone mineral and strength. SD ET and LD ET were

intermediate to negative control and combination groups. No effects on bone mineral or strength in femurs were observed. FS feeding resulted in higher relative levels of n-3 PUFA ( $p < 0.05$ ) including  $\alpha$ -linolenic acid and eicosapentaenoic acid, and lower relative levels of n-6 PUFA including linoleic acid and arachidonic acid in tibias and LV compared to all other groups. Linoleic acid in LV3 tended to be inversely associated with LV bone mineral content ( $r = -0.323$ ,  $p = 0.063$ ) indicating that the altered fatty acid composition by FS may not be the primary modulator of bone metabolism in ovx rats. In summary, FS combined with LD ET provided the greatest protection against ovariectomy-induced bone loss, and this benefit is site-specific to vertebrae with no benefit to long bones. FS feeding resulted in higher incorporation of n-3 PUFAs in both tibias and LV but the lack of association between fatty acid composition and bone outcomes suggest that the lignans may be primarily responsible for positive outcomes of combined ET and FS intervention.

**Short-term Effect of Zoledronic Acid on the Superficial Vascularisation of Membranous Bone Sites: An Intravital Study on Rat Calvarium.** J. Paccou<sup>\*1</sup>, M. Vieillard<sup>\*1</sup>, G. Penel<sup>\*2</sup>, B. Duquesnoy<sup>\*1</sup>, B. Cortet<sup>1</sup>. <sup>1</sup>Hopital Roger Salengro, Lille, France, <sup>2</sup>Faculté de Chirurgie Dentaire, EA 4032., Lille, France.

**Introduction:** The superficial vascularisation is of great importance in membranous bone healing process. A new rat calvarium intravital model was developed to study the short-term effect of a single high-dose zoledronic acid infusion on the superficial angiogenesis.

**Materials and methods:** Eighteen adult Sprague Dawley male rats were used. Optical bone chambers were implanted under general anaesthesia, with an optical window in contact with the bone tissue surface. A digital camera was used for the acquisition of photographs of the vascular network. Photographs were analysed using Aphelion<sup>®</sup> software to determine vascular density (VD). This was defined as the ratio of blood vessel pixels to all other pixels in the region of interest. The rats were randomly distributed between two groups. Nine rats were injected with 400  $\mu$ g/kg of zoledronic acid (Z) (ZOMETA<sup>®</sup>, Novartis, Switzerland) and nine other rats were injected with physiologic saline solution (PSS). Photographs were taken just before the infusion (T0), 2 hours after the start of infusion (T120), and then at days 2, 3 and 5.

**Results:** During the fifteen days prior to infusion, a decrease in vascular density was observed in both groups, corresponding to the bone healing process. No statistical difference was observed between the two groups at T0 just before infusion ( $p = 0.38$ ). An early dissociation between the PSS group and the Z group was observed after infusion. A decrease in vascular density was observed in the Z group until the fifth day. No statistical differences were observed at T120 and day 2. Statistical differences were observed between Z and PSS groups at day 3 ( $p = 0.009$ ) and day 5 ( $p = 0.0005$ ).

**Discussion:** A rat calvarium intravital model was used to study the effect of a slow infusion of zoledronic acid on vascular density during the bone healing process. A decrease in vascular density was observed during the five-day follow up when compared to the infusion of physiologic saline solution. The decrease in vascular density was probably due to a vasoconstrictor effect. As our model was a static model with no hemodynamic measurements, extrapolation of these results is difficult. The exact mechanism accounting for the hemodynamic effect of zoledronic acid has yet to be elucidated. A better understanding of the molecular mechanisms underlying the actions of zoledronic acid on blood vessels is necessary.

**Conclusion:** For the first time, this study demonstrates a short-term effect of a zoledronic acid infusion on vascular density at a membranous bone site. The observed decrease in vascular density is presumably linked to a vasoconstriction mechanism. Larger and longer trials are required to assess this hypothesis.

**Changes of Bone Metabolism in Immunosuppressant, FK506 Treated Rats.** H. Wakabayashi<sup>1</sup>, J. Kanda<sup>1</sup>, E. Katayanagi<sup>\*1</sup>, A. Takahashi<sup>\*2</sup>, K. Onodera<sup>\*3</sup>. <sup>1</sup>Clinical Pharmacotherapy, Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan, <sup>2</sup>Clinics of Dentistry for the Disabled, Tohoku University Dental Hospital, Sendai, Japan, <sup>3</sup>Pharmacotherapy, Yokohama College of Pharmacy, Yokohama, Japan.

Immunosuppressant drugs like FK506 (tacrolimus), cyclosporine are widely used for solid organ transplantation. However, immunosuppressant drugs also have severe side effects. One of prominent side effects is an induction of osteoporosis. In the present study, we investigated the effects of short-term administration of immunosuppressant drug, FK506 (tacrolimus) on bone metabolism (bone mineral density, bone vitamin K analogs, serum osteocalcin and calcium, and serum tartrate-resistant acid phosphatase). Male Wistar rats (6 week-old) were administered orally with the dose of FK506 (6 mg/kg) every day for 2 weeks. For the control group of rats, physiological saline was administered in the same manner. FK506-treated group showed the significant decreases in bone mineral density (BMD) and bone vitamin K analog (MK-4) in compared with the control group. Whereas these significant decreases were prevented by the injection of sodium risedronate hydrate (5 mg/kg).

**Efficacy and Safety of Monthly Oral Ibandronate in Postmenopausal Women with Low Bone Density.** M. A. Bolognese<sup>1</sup>, M. R. McClung<sup>\*2</sup>, F. Sedarati<sup>\*3</sup>, R. R. Recker<sup>\*4</sup>, P. D. Miller<sup>\*5</sup>. <sup>1</sup>Bethesda Health Research, Bethesda, MD, USA, <sup>2</sup>Oregon Osteoporosis Center, Portland, OR, USA, <sup>3</sup>Roche, Nutley, NJ, USA, <sup>4</sup>Osteoporosis Research Center, Omaha, NE, USA, <sup>5</sup>Colorado Center for Bone Research, Lakewood, CO, USA.

Monthly oral ibandronate has been shown to increase bone mineral density (BMD) and reduce bone turnover in clinical trials of women with postmenopausal osteoporosis. For some patients, bisphosphonate therapy may be useful to prevent the progression of low bone density (osteopenia) to osteoporosis. This study investigated the efficacy and safety of treatment with monthly oral ibandronate (150 mg) in postmenopausal women with low bone density. PREVENTION was a 1-year, double-blind, placebo-controlled, randomized study, which enrolled ambulatory postmenopausal women aged 45-60 years with baseline lumbar spine (LS) BMD T-score  $< -1.0$  and  $> -2.5$  and baseline proximal femur BMD T-score  $> -2.5$ . The relative change from baseline (%) in mean LS BMD at 1 year was the primary endpoint (intent-to-treat population). Treatment groups were compared using a two-way ANOVA model, which adjusted for independent factors including baseline LS BMD T-score, and time since menopause. Changes in proximal femur and serum C-terminal telopeptide of type 1 collagen (sCTX) were assessed as secondary endpoints. Adverse events and safety laboratory parameters were monitored continuously. Calcium and vitamin D supplements were provided to all participants. This study enrolled a total of 160 women; 77 received monthly ibandronate and 83 received placebo. Participants treated with ibandronate achieved larger increases in LS BMD after 1 year compared with patients receiving placebo (3.7% vs -0.4% [difference of 4.1%,  $P < 0.0001$ ], after adjustment for baseline LS BMD T-score, and time since menopause). The mean relative change in total hip BMD was 1.5% for women receiving ibandronate and -0.9% in women receiving placebo. After 3 months, median sCTX levels were reduced by over 55% in the ibandronate group compared with ~4% in the placebo group. Monthly ibandronate was well tolerated and the incidence of adverse events was similar between treatment groups. The most common treatment-related adverse events in patients receiving ibandronate were dyspepsia (5.2%), myalgia (5.2%), and influenza-like illness (5.2%). Treatment of appropriate patients with monthly ibandronate therapy may prevent bone loss in women with low bone density.

This study received funding from: Roche and GlaxoSmithKline.

## SU385

**Effects of Vitamin K2 and Risedronate on Bone Formation and Resorption, Osteocyte Lacunar System and Porosity in the Cortical Bone of Glucocorticoid-Treated Rats.** J. Iwamoto<sup>1</sup>, H. Matsumoto<sup>\*1</sup>, T. Takeda<sup>\*1</sup>, X. Liu<sup>\*2</sup>, J. K. Yeh<sup>2</sup>. <sup>1</sup>Department of Sports Medicine, Keio University School of Medicine, Tokyo, Japan, <sup>2</sup>Department of Medicine, Winthrop-University Hospital, Mineola, NY, USA.

The purpose of the present study was to examine the effects of vitamin K2 and risedronate on bone formation and resorption, the osteocyte lacunar system and porosity in the cortical bone of glucocorticoid (GC)-treated rats. Forty-nine female Sprague-Dawley rats, 3 months of age, were randomized into five groups according to the following treatment schedule: age-matched control, GC administration, and GC administration with concomitant administration of vitamin K2, risedronate, or vitamin K2 + risedronate. At the end of the 8-week experiment, classical bone histomorphometric analysis was performed and the osteocyte lacunar system and porosity were evaluated on the cortical bone of the tibial diaphysis. GC administration decreased percent cortical bone area and increased percent marrow area as a result of decreased periosteal bone formation and increased endocortical bone erosion, and increased cortical porosity. Vitamin K2 prevented a reduction in periosteal bone formation, but did not affect percent cortical bone and marrow areas. Risedronate prevented a reduction in periosteal bone formation and an increase in endocortical bone erosion, resulting in prevention of alterations in percent cortical bone and marrow areas. Both vitamin K2 and risedronate increased viable osteocyte density and lacunar occupancy, and prevented a GC-induced increase in cortical porosity. Vitamin K2 and risedronate had additive effects on viable osteocyte density and lacunar occupancy and a synergistic effect on cortical porosity. The present study showed the efficacy of vitamin K2 and risedronate for bone formation and resorption, the osteocyte lacunar system and porosity in the cortical bone of GC-treated rats.

**Disclosures:** J. Iwamoto, None.

## SU386

**The Bisphosphonate, Pamidronate, Suppresses the Pro-inflammatory Response in a Mouse Model of Osteogenesis Imperfecta (OI) as Well as Normal (NL) Littermates.** A. I. Leet<sup>1</sup>, Y. Ni<sup>\*2</sup>, T. Kazarian<sup>\*1</sup>, A. Jain<sup>\*2</sup>, N. S. Fedarko<sup>\*2</sup>. <sup>1</sup>Orthopedic Surgery, Johns Hopkins University, Baltimore, MD, USA, <sup>2</sup>Geriatrics, Johns Hopkins University, Baltimore, MD, USA.

Historically, OI patients have had a history of massive blood loss during surgery, but in a recent clinical study, we found no evidence of this increased blood loss during femoral surgery. Many children in our study were being treated with bisphosphonates and we hypothesized that bisphosphonates had an anti-inflammatory effect. We used an animal model of OI to test whether pamidronate (Aredia) could suppress cytokine release.

OIM, carrier and NL mice were used to measure pro-inflammatory cytokines including IL- $\beta$ , TNF $\alpha$ , INF $\gamma$ , and IL-6, IL-8, IL-10, & IL-12. A tibia fracture model was used to study the differences in pro-inflammatory response between OIM and NL mice at 15, 30, 60, 120, & 480 min. from fracture.

OIM (OI) and normal (NL) mice were treated with no drug (0) or Aredia (Novartis) at 0.12mg/kg x 4 doses (LD). A high dose group (HD) was given 10 x this dose, which proved highly toxic over the treatment course; thus, only baseline data could be obtained. Fractures were created using a closed model with a 3-point bend applied to the tibia. At a planned time point after the fracture, 1 ml of blood per animal were collected via facial bleeding and the blood was spun to separate out the serum layer used for assay. Assays of the pro-inflammatory markers were performed via ELISA using a 96 well, 7 chamber multiplex plate (MSD Inc.).

Baseline means in pg/ml for cytokines are shown in the table below. Pamidronate suppressed the pro-inflammatory response in all pro-inflammatory markers. The underlined values all had  $p < .05$  on ANOVA non-parametric analysis comparing the means within each genotype.

	NL 0	NL LD	NL HD	OI 0	OI LD	OI HD
IL-1 beta	19.4	16.6	16.7	<u>23.4</u>	<u>5.2</u>	<u>2.6</u>
IL- 6	18.1	9.2	10.9	30.9	15.9	12.0
IL- 8	<u>94.8</u>	<u>27.6</u>	<u>36.8</u>	98.1	53.9	46.3
IL- 10	<u>38.1</u>	<u>14.8</u>	<u>17.3</u>	49.5	27.1	20.5
IL- 12	<u>55.1</u>	<u>9.7</u>	<u>0</u>	84.3	75.6	0
INFgamma	0.9	0.6	0.1	<u>3.7</u>	<u>2.5</u>	<u>1.3</u>
TNF	<u>4.0</u>	<u>1.40</u>	<u>1.3</u>	<u>9.2</u>	<u>1.1</u>	<u>2.8</u>

The fracture data also showed that pamidronate suppressed the pro-inflammatory markers over the first 8 hours from a fracture. The suppressive effect seemed greater in OI than in NL mouse serum.

The bisphosphonate, pamidronate, seems to have an anti-inflammatory effect in both NL and OI mice. This may explain why patients have less blood loss after fracture or surgery than historically reported. More study is necessary as to when bisphosphonates should be given after fractures or osteotomies to avoid interference with bone healing.

## SU387

**Risedronate Has a More Rapid Onset of Remodeling Suppression than Alendronate in Rabbit Vertebral Trabecular Bone.** M. R. Allen<sup>1</sup>, R. J. Phipps<sup>2</sup>, A. S. Koivuniemi<sup>\*1</sup>, M. C. Koivuniemi<sup>\*1</sup>, D. B. Burr<sup>1</sup>. <sup>1</sup>Anatomy & Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Procter and Gamble Pharmaceuticals, Mason, OH, USA.

In a retrospective observational study, risedronate-treated patients had significantly lower incidence of hip and non-vertebral fractures in the first year on therapy than alendronate-treated patients [Silverman et al. 2007]. The goal of this study was to test the hypothesis that risedronate suppresses bone remodeling significantly more quickly than alendronate after the initiation of drug treatment. Four month old female rabbits (n = 32) were divided into four groups and treated with vehicle (VEH), low or high dose risedronate (RIS, 1.2 or 2.4  $\mu$ g/kg), or alendronate (ALN, 2.4  $\mu$ g/kg) subcutaneously 3x/week for 5 weeks. The lower RIS dose and the ALN dose were consistent, on a mg/kg basis, with those used for treatment of post menopausal osteoporosis; the higher RIS dose served as a mg equivalent to the ALN dose. Rabbits received weekly injections of fluorochromes to label actively forming bone surfaces according to the following schedule: tetracycline (week 1), alizarin (week 2), calcein (week 3) and xylenol orange (week 4). Rabbits were euthanized five days after the final label and the fourth lumbar vertebra was processed for histological assessment. The percentage of trabecular bone surface covered with each of the fluorochrome labels was measured to determine the level of active bone formation over time. The amount of labeled bone surface at week 1 was not significantly different among groups. Relative to the amount of labeled surface at week 1, there was significantly less percent labeled surface at weeks 2 and 3 in RIS1.2 (-8%) and RIS2.4 (-11%) groups compared to both VEH and ALN; there was no difference between VEH and ALN. At week 4 only the RIS1.2 group was significantly different from VEH and ALN. These results show that at doses equivalent to those used clinically for treatment of postmenopausal osteoporosis, risedronate exerts a more rapid onset of remodeling suppression compared to alendronate in vertebral trabecular bone.

## SU388

**Monthly Intravenous Zoledronate Suppresses Tissue-Level Remodeling Significantly More Than Daily Oral Alendronate in the Mandible and Rib of Skeletally Mature Female Dogs.** M. R. Allen, D. J. Kubek<sup>\*</sup>, D. B. Burr. Anatomy & Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Bisphosphonate treatment significantly reduces bone loss and skeletal metastases in cancer patients partly through its suppression of bone remodeling. The bisphosphonate doses currently used for cancer treatment greatly exceed those used for post-menopausal osteoporosis and while these different regimens produce similar levels of remodeling suppression when measured using systemic biomarkers, there are no data concerning their effects on regional bone remodeling. The goal of this study was to use histology to compare tissue-level remodeling suppression at various bone sites between the most commonly used cancer and osteoporosis treatment regimens. One-year-old intact female beagles were treated for 3 months with vehicle (VEH), alendronate (ALN; 0.2 mg/kg/day) or zoledronic acid (ZOL; 0.06 mg/kg/month). ALN was administered orally each day while VEH and ZOL were administered intravenously every 4 weeks via a 15 minute infusion. These doses and treatment regimens are consistent, on a mg/kg basis, with those used for the treatment of post-menopausal osteoporosis (ALN) and cancer (ZOL). Animals were sacrificed 4 weeks following the last infusion of ZOL. The extent of intracortical bone remodeling in the mandible (subdivided into alveolar and non-alveolar regions), rib, and tibia was quantified as the number of labeled osteons normalized to bone area. Compared to VEH, intracortical bone remodeling was significantly reduced in ZOL-treated animals within the alveolar bone of the mandible (-92%), the non-alveolar bone of the mandible (-83%) and the rib (-85%). These reductions of remodeling in ZOL-treated animals also were significantly lower than ALN-treated animals at each of these three analysis sites (-56%, -55%, and -57%, respectively). Levels of intracortical remodeling were not significantly different between ALN and VEH at any of the sites and there was no difference in the number of labeled osteons among any of the treatment groups in the tibia. Comparing these data to previous experiments in our laboratory shows that the level of remodeling suppression in animals treated with three-months of ZOL was 50% greater in mandibular alveolar bone compared to animals treated for three years with oral alendronate. Based on these results, we conclude that monthly intravenous zoledronate, at doses consistent with those used for cancer treatment, reduces tissue-level intracortical bone remodeling in the mandible and rib significantly more than oral alendronate at doses used for osteoporosis.

**Sites of Femoral Fractures in the Fracture Intervention Trial (FIT) of Alendronate and Its Long-term Extension (FLEX).** D. C. Bauer<sup>\*1</sup>, D. M. Black<sup>\*1</sup>, H. Genant<sup>\*1</sup>, A. de Papp<sup>2</sup>, A. Santora<sup>\*3</sup>, E. Rosenberg<sup>\*2</sup>, K. Ensrud<sup>\*4</sup>, S. R. Cummings<sup>\*5</sup>. <sup>1</sup>UCSF, San Francisco, CA, USA, <sup>2</sup>Merck & Co., Inc., North Wales, PA, USA, <sup>3</sup>Merck & Co., Inc., Rahway, NJ, USA, <sup>4</sup>University of Minnesota, Minneapolis, MN, USA, <sup>5</sup>CPMC, San Francisco, CA, USA.

Recent reports suggest subtrochanteric or proximal diaphyseal fractures of the femur may occur in patients receiving oral bisphosphonates, but the epidemiology of these fractures is less well understood compared to other femur fractures. No placebo controlled studies have specifically investigated the relationship between such fractures and use of bisphosphonates. The Fracture Intervention Trial (FIT, n=6459) and the FIT Long-term Extension (FLEX, n=1099) were randomized, placebo-controlled, double-blind studies of

alendronate (ALN) in postmenopausal women. FIT examined 5-10 mg ALN or placebo (PBO) daily in women with low BMD, in cohorts with or without vertebral fractures, for 3-4.5 years. In FLEX, ALN-treated women from FIT were re-randomized to 5 mg ALN, 10 mg ALN, or PBO daily for an additional 5 years to examine the effects of ALN discontinuation on BMD. Femur fractures were centrally adjudicated and categorized by the UCSF Coordinating Center as femoral neck, intertrochanteric, hip:other, or femoral shaft based on review of X-ray reports or radiographs. Subtrochanteric fractures were not specifically noted. Time to first hip or femoral shaft fracture in the ALN and PBO groups was analyzed using Cox models (Table). In FIT, hip fracture risk was lower in the ALN group (0.9% vs. 1.4%). Most hip fractures were coded as femoral neck or intertrochanteric, but 2 hip fractures were captured as hip:other (both PBO), and 5 femoral shaft fractures without further sub-categorization were recorded. In FLEX, hip fracture risk was similar among ALN and PBO groups (3.0% in both); 1 hip fracture was captured as hip:other (PBO) and 3 femoral shaft fractures in 2 women (ALN) were recorded. A blinded review of available source documents to more precisely identify atypical hip and shaft fractures is underway, but our analysis is limited by the small number of events and wide CI. Large epidemiologic studies and meta-analysis of treatment trials will be required to better describe the epidemiology of non-hip femoral fractures in osteoporotic patients and to determine the potential relationship with long-term bisphosphonate treatment.

Table. Patients with hip and femoral shaft fracture events.

Fracture Site	FIT			FLEX		
	ALN (n=3236)	PBO (n=3223)	RH (95% CI)	ALN* (n=662)	PBO (n=437)	RH (95% CI)
Any Hip	30	46	0.6 (0.4, 1.0)	20	13	1.0 (0.5, 2.1)
Femoral neck	16	31	0.5 (0.3, 0.9)	10	7	0.9 (0.4, 2.5)
Intertrochanteric	14	13	1.1 (0.5, 2.3)	10	5	1.3 (0.5, 3.9)

## SU390

**The Prevalence of Subtrochanteric Fractures in Patients Older than 50 Years Presenting with a Clinical Vertebral or Non-vertebral Fracture.** A. Boonen<sup>\*1</sup>, D. Wakefield<sup>\*2</sup>, K. Huntjens<sup>\*3</sup>, S. van Helden<sup>\*4</sup>, P. Geusens<sup>1</sup>. <sup>1</sup>Internal Medicine/Rheumatology, University Maastricht, Maastricht, Netherlands, <sup>2</sup>University Aberdeen, Aberdeen, United Kingdom, <sup>3</sup>University Maastricht, Maastricht, Netherlands, <sup>4</sup>Surgery, University Maastricht, Maastricht, Netherlands.

Several case series have suggested a link between bisphosphonate (BP) therapy and atypical fractures of the femoral diaphysis. However, in none of the studies the prevalence of these fractures nor the total number of screened patients were documented. Only one study mentioned the proportion of patients on alendronate. We carried out a review of all consecutive patients older than 50 years presenting with a clinical fracture in the context of the osteoporosis and fracture clinic of the hospital.

In total, 3412 patients presented with a clinical vertebral or non-vertebral fracture over a period of 3 years, of whom 2520 consulted the fracture nurse and 892 did not participate in the fracture prevention program. X-rays of all femur fractures (n=558) were reviewed and 31 cases of subtrochanteric fractures were identified. Of the 29 in whom medication intake at the time of fracture could be verified, 2 (7%) were on treatment with BPs at the time of fracture. One patient on daily alendronate since 18 months had a spiral fracture, one patient on generic alendronate since unknown time had a transverse fracture (of 45°). The only patient with a horizontal transverse fracture (of 0°) had a history of metastatic breast carcinoma without radiographic evidence of bone metastasis at the fracture site and had no previous treatment with BPs. Eight of the 57 patients with a hip prosthesis for osteoarthritis had a periprosthetic femur fracture, of whom one patient used BP at the time of fracture. Of patients who participated in the program, 111 (4%) reported to have BP treatment at the time of fracture (odds ratio for subtrochanteric fracture when on BP compared to not on BP: 1.6; 95% confidence interval: 0.4-6.9). Most subtrochanteric fractures (75%) were the result of a simple fall. We conclude that subtrochanteric fractures represent <1% of all clinical vertebral and non-vertebral fractures in patients older than 50 years presenting with a clinical fracture. More >90% of subtrochanteric fractures were found in patients not taking BPs at the time of fracture, indicating that in most patients with a subtrochanteric fracture other mechanisms than low bone turnover associated with intake of BPs are needed to explain their presence.

## SU391

**Comparison of the Effects of Ibandronate Alone with Ibandronate in Combination with SNAC on Bone Density and Bone Strength in Ovariectomized Rats.** R. Samadfam<sup>1</sup>, S. Y. Smith<sup>1</sup>, A. Varela<sup>1</sup>, T. Pfister<sup>2</sup>, F. Bauss<sup>3</sup>. <sup>1</sup>Bone Research, Charles River Laboratories, Senneville, QC, Canada, <sup>2</sup>F. Hoffmann-La Roche Ltd, Basel, Switzerland, <sup>3</sup>Roche Diagnostics GmbH, Penzberg, Germany.

Oral bioavailability of bisphosphonates is low (~1%). Increasing bioavailability would allow either a lower dose than currently used, or keeping the dose while increasing the dosing-free interval. The purpose of this study was to compare the effects of two different dose formulations of Ibandronate (IBN) with or without an absorption enhancer, sodium N-[8-(2-hydroxybenzoyl)amino]caprylate (SNAC), on bone parameters. Seven week old Sprague-Dawley CD rats were assigned to 10 groups of 10 females/group. All animals were ovariectomized (OVX), with the exception of one group which underwent sham surgery. One day after surgery, animals were given a weekly dose of vehicle, IBN or IBN+SNAC by gavage for 10 weeks. Doses for IBN alone treated animals were 1, 3, 10, and 30 mg/kg/dose. In SNAC+IBN treated animals, doses for IBN were 0.2, 0.6, 2 and 6 mg/kg/dose. The doses of IBN for IBN+SNAC groups were based on the expectation that SNAC increases AUC and Cmax by about 2 and 4-5 fold respectively. Ratio IBN:SNAC was 1:30. Bone mass, architecture and strength were analyzed by means of bone mineral density, biomechanical analyses, and histomorphometry.

In lumbar vertebrae, IBN alone or in combination with SNAC increased bone mass dose-dependently compared to controls, however, group mean comparisons indicated that IBN/SNAC treated animals had lower BMD compared to their corresponding IBN alone groups. These increases correlated with increases in vertebral bone strength parameters obtained from compression analyses. Femoral BMD was also dose-dependently increased however this did not translate into increases in bone strength parameters for the 3-point bending due to the effect of IBN on bone geometry in young growing rats.

Both formulations of IBN (with or without SNAC) resulted in dose-dependent increases in BV/TV, Md.V/TV, Tb.Th, Tb.N and osteoclast surface and decrease in Tb.Sp at the proximal tibia metaphysis. The effects of IBN alone on the evaluated histomorphometric parameters were generally superior to those of IBN/SNAC when compared to their corresponding IBN dose groups. Relative potency estimation analyses based on a linear model revealed an approx. 2-fold increase in the pharmacodynamic efficacy of oral IBN by SNAC. However, it remains to be determined whether bioavailability and renal excretion of IBN are similar throughout the tested dose range, and whether non-linear calculations including these parameters would justify translation into clinical use.

**Alendronate Affects Cross-talk of Osteoclasts and Osteoblasts *in vivo*.** E. Shimizu<sup>1</sup>, J. Tamasi<sup>\*2</sup>, N. C. Partridge<sup>1</sup>. <sup>1</sup>Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, <sup>2</sup>Clinical Discovery Technologies, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ, USA.

Bisphosphonates are potent inhibitors of osteoclastic bone resorption and are valuable therapeutic agents in the treatment of postmenopausal osteoporosis, osteitis deformans, and bone metastasis with or without hypercalcemia. Although it has recently been discovered that bisphosphonates are associated with osteonecrosis of the jaw (ONJ), the pathophysiological mechanism of ONJ is not clear. Since bisphosphonates inhibit the functions of osteoclasts, osteoclast feedback to osteoblasts may also be ablated, and thus inhibit normal physiological bone remodeling and turnover resulting in ONJ. Our hypothesis is that bisphosphonates indirectly regulate the functioning of osteoblasts via feedback from osteoclasts to osteoblasts. To investigate this, adult mice were injected with alendronate (10 ug/100 g/week) for 8-weeks. We found that alendronate significantly stimulated BMD and inhibited osteoclast marker genes such as TRAP, cathepsin K and NFAT2 in femurs. We also found that alendronate increased osteoprotegerin (OPG) gene expression and decreased the ratio of receptor activator of nuclear factor-kB ligand (RANKL) to OPG. Thus, alendronate also indirectly suppressed osteoclast differentiation via the osteoblast. Alendronate may also affect ligands produced by osteoclasts which act on receptors on osteoblasts. We investigated ephrin ligands and eph receptors, and found that alendronate increased ephrin B1, and Eph B1, B3, B6 in femurs. Next, we examined if alendronate affected osteoblastic function. Alendronate suppressed expression of bone sialoprotein (BSP) and osteonectin (ON) in both femurs and bone marrow osteoblastic cells from mice which had received alendronate. In addition, the same cells had increased Eph B1 and B3. We investigated if alendronate directly affected osteoblastic differentiation using primary cultures of osteoblasts. Alendronate at a high concentration (10 uM) suppressed bone mineral nodule formation and osteocalcin gene expression but did not affect other genes. Thus, alendronate, through its effects on the osteoclast, appears to regulate expression of ephrin B1 which may then regulate and act through the Eph B1, B3, B6 receptors on the osteoblast to suppress osteoblast differentiation.

**Improved Bone Mass After Co-administration of Strontium Ranelate and Risedronate in a Rat Model of Osteoporosis using “in-vivo” Micro-CT.** M. R. Doschak, C. T. Lee\*, M. D. Jones\*, G. Li\*, J. Foster\*, M. J. M. Duke\*. Pharmacy & Pharmaceutical Science, University of Alberta, Edmonton, AB, Canada.

Antiresorptive therapy is often initiated retrospectively, after the significant loss of both bone mass and trabecular connectivity. Despite slowing further bone loss, antiresorptive agents have limited capacity for increasing bone mass. Furthermore, increases in bone mass can only occur where pre-existing trabecular connections remain. Thus, we tested if prospective combination antiresorptive-anabolic drug therapy would improve bone mass and trabecular connectivity in a rat model of osteoporosis.

Twenty 6-month old female rats were randomly assigned to one of five groups (n=4/group): 1) Ovariectomized (OVX) untreated controls, 2) Strontium ranelate (Protos™) treated (STR; 308 mg/kg qd p.o.), 3) Risedronate-treated (RIS; 0.06 mg/kg q3.5d s.c.), 4) Combined STR-RIS, and 5) Sham-operated (SHAM). Each rat was imaged at baseline using “in-vivo” micro-CT to assess bone mass and bone mineral density (BMD). Antiresorptive drug interventions (either STR or RIS) were also initiated at time-zero and continued to the same endpoint of 5 months post-OVX, and assessed longitudinally with “in-vivo” micro-CT at monthly intervals. At the experimental endpoint, rat tibiae were dissected free of soft tissues and tested for mechanical strength to failure in 3-point flexural analyses, then incinerated in a muffle-furnace and the ash used to assess calcium and strontium content by Instrumental Neutron Activation Analysis (INAA).

Results confirmed significant loss of bone mass in OVX rats as measured with “in-vivo” micro-CT, particularly during the first 2 months. Both RIS dosed groups significantly slowed the further loss of bone mass over untreated OVX controls, however, only the combined STR-RIS group resulted in a significant increase in bone mass compared to all groups (bar the sham-operated controls). Micro-CT based histomorphometric analyses of trabecular bone was significantly correlated with bone strength measurements from mechanical testing. INAA accurately measured bone strontium content, and the relationship with BMD positive bias was explored.

We conclude that the co-administration of bone antiresorptive and anabolic drugs in a prospective regimen during the pathogenesis of Osteoporosis significantly improved bone mass over either agent alone as a monotherapy.

**Alfacalcidol Ameliorates Bone Dynamics in Senescence-accelerated SAMP6 Mice and in Fracture Repair Rat Model.** A. Shiraishi\*, S. Sakai\*, M. Mihara\*. Product Research Dept., Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Alfacalcidol (1 $\alpha$ (OH)D<sub>3</sub>: ALF), the prodrug of calcitriol, is an inhibitor of bone resorption in estrogen-deficient high-turnover osteoporosis rat model. In this study, we assessed the effects of ALF on the bone loss in low-turnover osteoporosis using senescence-accelerated SAMP6 mice and on the processes of fracture repair using rat model. <Exp.1> Four month-old male SAMP6 mice were received ALF (0.1 or 0.2 $\mu$ g/kg, p.o. 5 times/week) administration for 6 weeks. Micro-CT analysis revealed that ALF treatment dose-dependently increased the bone volume (BV/TV), trabecular number (Tb.N) and connectivity density (Conn.D) at trabecular region of proximal tibia and the bone area of cortical tibia. Histomorphometrical analysis indicated that, in trabecular and endocortical bone, ALF markedly suppressed bone resorption parameters such as ES/BS and N.Oc/BS. <Exp.2> Wistar rats at three months of age were either sham operated or ovariectomized (OVX) and divided into three groups: SHAM control, OVX control, ALF (0.1 $\mu$ g/kg, p.o. 5 times/week) groups. Treatment began immediately after the surgery. Three weeks after ovariectomy, bilateral osteotomies were performed on the femoral midshaft and fixed with intramedullary wires. Fracture calluses were excised at twelve weeks after fracture. Callus sizes were not different among all groups. ALF treatment did not show significant effect on the progression of fracture repair. The ratio of lamellar to woven bone in ALF-treated group was similar to sham control group. In ALF-treated group, BMD at fracture region was significantly higher than vehicle control group. Moreover, the mechanical properties at fracture site in ALF-treated group were higher than those in vehicle control group (max load: 149.7 vs. 119.5 N, stiffness: 260.3 vs. 166.5 N/mm, respectively). Histomorphometrical analysis revealed that ALF increased bone formation (BFR/BS) at fracture site, while suppressed bone resorption (ES/BS) at normal site of femoral midshaft. In conclusion, ALF ameliorated bone dynamics in senescence-accelerated SAMP6 mice and in fracture repair rat model.

**Effect of Skin Color and Oral Vitamin D Supplementation on Serum 25(OH) Vitamin D in Adolescent Girls.** C. Y. Park\*<sup>1</sup>, K. M. Hill\*<sup>1</sup>, A. E. Elble\*<sup>1</sup>, B. R. Martin\*<sup>1</sup>, M. Peacock\*<sup>2</sup>, C. M. Weaver\*<sup>1</sup>. <sup>1</sup>Dept of Foods and Nutrition, Purdue University, West Lafayette, IN, USA, <sup>2</sup>Dept of Medicine, Indiana University School of Medicine, Indianapolis, IN, USA.

Sunlight exposure and skin pigmentation are important determinants of serum 25(OH) vitamin D (s25D) levels. We investigated these relationships while minimizing UVB exposure and controlling diet in adolescent girls in Indiana. Forty-four girls (25 white, 13 Asian, 2 black, 2 Hispanic, 2 mixed) aged 11-14y participating in a metabolic balance study during the summer were monitored for skin color and s25D for 7 weeks. Skin color was measured by reflectance (Minolta CM-2600d) and these values were used to calculate individual typology angle (ITA), a measurement of skin pigmentation. The forehead and forearm were measured for facultative skin color (color of skin where light-induced pigmentation occur), and the upper inner arm for constitutive skin color (photo-protected skin color). S25D was assessed by RIA. Subjects were provided with sunscreen (sun protection factor  $\geq 15$ ) and 200 IU/d vitamin D in a controlled diet. During the last 4 weeks, 14 girls were given 1000 IU/d vitamin D<sub>3</sub>. At baseline, higher ITA (less pigmentation) predicted higher levels of s25D in the forehead (Figure). At 7 weeks, ITA decreased from baseline in the upper arm only. S25D increased in all subjects, but the increase in vitamin D supplemented girls was significantly greater than non-supplemented girls (p<0.01). Although facultative skin color predicted s25D levels at baseline, changes in skin color were not associated with change of s25D levels, regardless of vitamin D supplementation.

**Vitamin D Concentrations of Healthy Children Living in the Calgary Health Region.** C. A. Stoian\*, J. K. Mah\*, R. G. Cox\*, D. K. Stephure, M. Lyon\*. University of Calgary, Calgary, AB, Canada.

Vitamin D deficiency results in rickets in children and osteomalacia in adults. The purpose of our study was to examine the vitamin D status among healthy children aged 2 to 13 years living in Southern Alberta, Canada.

The data in this study was collected prospectively from healthy children 2 to 13 years of age who presented consecutively at the Alberta Children's Hospital for elective surgery from December 2005 to December 2006. Data collected from children eligible to enter the study and for whom informed consent was obtained included child's weight, height, age, gender, ethnicity, use of vitamin supplements, physical activity, time spent outdoors, and medications used on a regular basis. Each child's dietary intake was assessed using the Harvard Service Food Frequency Questionnaire. Measurements of blood concentrations were performed according to manufacturer's specifications: serum 25 hydroxyvitamin D (25(OH) D) and parathyroid hormone (DiaSorin); total calcium, phosphate, albumin and creatinine (Ortho Clinical Diagnostics), and alkaline phosphatase (Rosche). Demographic data were available for 1862 subjects. Serum 25(OH) D concentrations were available for 1442 subjects, of whom 862 (59.78%) were boys and 580 (40.22%) were girls. The mean age of subjects for whom serum 25(OH) D concentrations were known was 6.09 years (SD = 2.85 years). There was no statistical difference for age or sex between the study group and the group without laboratory data. Seventy five children (5.2%) were found to be vitamin D deficient, defined as serum 25(OH)D concentrations  $\leq 37.5$  nmol/L. Suboptimal vitamin D (serum 25(OH)D concentrations  $\leq 80$  nmol/L) was determined in 689 subjects (47.78%). Only 22 subjects (1.53%) were found to have severe vitamin D deficiency (serum 25(OH) D concentrations  $\leq 20$  nmol/L). More subjects were vitamin D deficient in the older age group (9 to 13 years) compared to the younger age groups (2 to 4.99 years and 5 to 8.99 years): 11.24%, 3.93% and 3.83%, respectively. There was no statistical difference between boys and girls with respect to vitamin D deficiency status. Children in the vitamin D deficient group spent significantly less hours outdoor compared to those whose serum 25(OH)D concentrations were greater than 37.5 nmol/L (p value = 0.005). During winter the mean  $\pm$  standard deviation of serum 25(OH) D

concentrations were significantly lower ( $77.98 \pm 37.34$  nmol/L) when compared with values obtained during summer ( $96.42 \pm 37.50$  nmol/L).

In our study vitamin D deficiency was less prevalent than reported by other authors. Children who do not participate in outdoor activities regularly throughout the year or those who do not have sufficient vitamin D intake from dietary sources should receive appropriate vitamin D supplementation to ensure optimal bone health.

## SU397

### The Comparative Antifracture Efficacy of N-containing Bisphosphonates.

M. C. Hochberg, Medicine, University of Maryland, Baltimore, MD, USA.

**Background:** Four N-containing bisphosphonates (BPs), alendronate (ALN), ibandronate (IBAN), risedronate (RIS) and zoledronic acid (ZOL), are approved for the treatment of women with postmenopausal osteoporosis (PMO). While several head-to-head studies have compared the efficacy of some of these BPs using surrogate outcomes (changes in bone mineral density and bone turnover markers), no head-to-head trials have been designed to compare antifracture efficacy.

**Objective:** To estimate the comparative antifracture efficacy of N-containing BPs.

**Methods:** Data on the antifracture efficacy of the N-containing BPs in women with PMO were abstracted from several sources: the updated 2008 Cochrane systematic reviews by Wells and colleagues provided data on radiographic vertebral (VFX), non-vertebral (non-VFX) and hip fracture reduction for ALN and RIS; the pivotal phase III trial and individual patient meta-analysis by Harris and colleagues provided data for VFX and non-VFX reduction for IBAN, respectively; and the pivotal phase III trial provided data for VFX, non-VFX and hip fracture reduction for ZOL. For both ALN and RIS, the analysis was limited to results of secondary prevention (treatment) trials that used the daily doses of 10 mg and 5 mg, respectively. For IBAN, data on VFX for the daily dose of 2.5 mg and non-VFX reduction for the high-dose cumulative exposure group of 150 mg monthly or 3 mg IV every 3 months, respectively, were used in the analysis. The method of adjusted indirect comparisons (Bucher et al: J Clin Epidemiol 1997;50:683-91) was used to calculate the estimated relative risk (RR) and 95% confidence intervals (CI) for hypothetical head-to-head studies; statistical significance is inferred if the CI does not include unity.

**Results (Table):** There were no significant differences in estimated antifracture efficacy between ALN, RIS and IBAN for either VFX or non-VFX; between ALN, RIS and ZOL for non-VFX including hip fractures; or between IBAN and ZOL for non-VFX. ZOL appeared to be more efficacious for reduction in VFX than ALN, RIS and IBAN.

**Conclusions:** These data, derived using the method of adjusted indirect comparisons (Level 2A evidence), suggest that ZOL may be more efficacious than other N-containing BPs for reduction in risk of new radiographic VFX. Head-to-head RCTs would be needed to confirm this finding. There were no significant differences, however, in estimated efficacy for reduction in either non-VFX or hip fractures.

Relative Risk (95% Confidence Intervals) for Incident Fractures: Adjusted Indirect Comparisons			
Drug Comparison	Vertebral Fracture	Non-vertebral Fracture	Hip Fracture
ALN vs RIS	0.90 (0.66, 1.24)	0.96 (0.78, 1.19)	0.63 (0.34, 1.20)
ALN vs IBAN	1.14 (0.72, 1.83)	1.17 (0.77, 1.77)	N/A
ALN vs ZOL	1.83 (1.28, 2.55)	1.04 (0.82, 1.31)	0.80 (0.40, 1.58)
RIS vs IBAN	1.27 (0.80, 2.00)	1.21 (0.82, 1.80)	N/A
RIS vs ZOL	2.04 (1.49, 2.77)	1.08 (0.90, 1.30)	1.25 (0.83, 1.89)
IBAN vs ZOL	1.60 (1.01, 2.55)	0.89 (0.59, 1.34)	N/A

## SU398

**Zoledronic Acid Treatment of Osteoporosis: Effects in Men.** D. A. Johnson<sup>\*1</sup>, M. I. Williams<sup>\*1</sup>, J. LaFleur<sup>\*2</sup>, R. A. Adler<sup>1</sup>. <sup>1</sup>Endocrinology, McGuire VAMC, Richmond, VA, USA, <sup>2</sup>University of Utah College of Pharmacy, Salt Lake City, UT, USA.

Although clinical trials of zoledronic acid have shown excellent bone mineral density increases and fracture risk reductions, there is always concern that results cannot be generalized to other populations. We have used zoledronic acid 4 mg infusions off-label for patients intolerant to or non-adherent to oral bisphosphonate therapy for osteoporosis. We previously reported that routine laboratory measurements of the bone resorption marker NTx found that NTx was often suppressed for > 12 months. We have experience with treatment of a heterogeneous group of approximately 100 patients and report here the results in 41 men who have had bone density measurements before and after at least one infusion.

Bone mineral density was measured by a Hologic Discovery densitometer and changes in spine, total hip, and total forearm were determined. All patients had monitoring of renal function, serum calcium, and 25-hydroxyvitamin D levels. Vitamin D was replaced in all subjects before infusion.

In this group, the number of infusions varied from 1 to 4, but the average was two. The average time between bone density measurements was 3.1 years. Patients did not receive additional infusions until the NTx level returned to the low normal range. Thus, the interval between infusions was usually more than one year.

In the spine, the average increase of BMD was 3.99%, and the average increase in the total hip was 1.77%. The total forearm is the default setting on the Hologic densitometer. Thus, the average change in the forearm was a decrease of 0.74%, although some men showed an

increase in the forearm.

When the data are expressed per year, the increase in the spine was 1.47% and the increase in the hip was 0.59%. Overall, 82% of men demonstrated an increase in the spine, 71% an increase in the total hip and 42% an increase in the forearm. In our population, 66% of patients had been prescribed oral bisphosphonates or intravenous pamidronate before receiving zoledronic acid. As might be expected, larger increases in spine (5.5% naive group v. 1.4% bisphosphonate exposed group) occurred in the bisphosphonate naive patients.

Thus, in a real world setting of a heterogeneous group of men with osteoporosis, there was a change in bone density similar to what has been reported in men receiving oral bisphosphonates. Further studies are underway to analyze suppression of NTx with change in BMD.

**Disclosures:** R.A. Adler, Novartis 2, 3, 4.

## SU399

**Atypical Osteoclast Phenotype after Long-Term Alendronate Therapy for Osteoporosis: A Paired Bone Biopsies Report.** N. Dion, J. L. Petit\*, L. G. Ste-Marie. Saint-Luc Hospital, Research Centre of the Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, QC, Canada.

Bisphosphonates (BPs) have been the preferred agents for the treatment of osteoporosis for almost 10 years. The paradigm for the last years was that by decreasing bone resorption and promoting osteoclast apoptosis, BP treatment reduces bone turnover and allows more complete secondary mineralization leading to a lower risk of fractures. We present the cases of 4 patients (1 woman and 3 men) with osteoporosis treated for 6 or 8 years with alendronate (ALN). As expected, ALN treatment increased significantly bone mineral density which gradually led to a plateau after 3 to 4 years of treatment. To evaluate bone turnover at the tissue level, we compared bone histomorphometric results of trans-iliac bone biopsies (Bx) performed in each patient before (pre-ALN) and after 6 or 8 years of ALN (ALN+). Before ALN treatment, all patients had moderate to high turnover osteoporosis characterized by low trabecular bone volume (BV/TV) with normal or high bone formation activity and normal or high bone resorption surfaces (ES/BS). After ALN therapy, BV/TV increased or remained unchanged whereas matrix synthesis was drastically reduced as shown by the suppression of the bone formation rate (BFR/BS) when compared to pre-ALN Bx. No significant difference for ES/BS and for the number of osteoclast per bone perimeter (N.Oc/B.Pm) was observed in ALN+ Bx comparing to the pre-ALN Bx (cf table). As reported recently by Weinstein R.S. et al., and Dempster D.W. et al., (ASBMR 2007, abstract 1058 and 1096, respectively) in Bx of patients on ALN therapy, we observed, in all ALN+ Bx, giant multinucleated osteoclasts which were occasionally detached from bone surfaces and/or adjacent to shallow Howship's lacunae. Surprisingly, most of the osteoclasts observed in ALN+ Bx, showed an intense positive reaction to tartrate resistant acid phosphatase (N.OcTRACP+/B.Pm =  $0.39 \pm 0.09$  / mm). Our results emphasize that long-term ALN therapy does not induce a decrease in the number of osteoclasts as an increased apoptosis would suggest (if not compensated by an increase in osteoclastogenesis). The development of a new phenotype of giant osteoclasts positively active for TRACP could involve an unknown compensatory mechanism to BP treatment. Further studies are needed to better explain this phenomenon and explore its relevance to clinical response to BP treatment.

	Pre-ALN	ALN+	P-value (paired t-test)
BFR/BS ( $\mu\text{m}^3/\mu\text{m}^2/\text{y}$ )	47.8 $\pm$ 8.7*	6.2 $\pm$ 3.2	0.01
ES/BS (%)	8.0 $\pm$ 1.2	7.4 $\pm$ 1.7	0.85
N.Oc/B.Pm (/mm)	0.30 $\pm$ 0.04	0.32 $\pm$ 0.07	0.78

**Reduced Osteoclastogenesis and RANKL Expression in Marrow from Women Taking Alendronate.** B. Eslami<sup>\*1</sup>, S. Zhou<sup>1</sup>, M. S. LeBoff<sup>2</sup>, J. Glowacki<sup>1</sup>. <sup>1</sup>Orthopedic Surgery, Brigham and Women Hospital, Boston, MA, USA, <sup>2</sup>Division of Endocrinology, Brigham and Women Hospital, Boston, MA, USA.

Osteoporosis is a major public health problem and bisphosphonates such as Alendronate (AL) are commonly used for prevention of fracture and treatment of osteoporosis. Little is known about the effects of AL on human marrow cells and regulation of osteoclast differentiation. The first study tested the hypothesis that marrow from women taking AL generates fewer osteoclasts and expresses less RANKL compared with women not taking AL. The second study tested the hypothesis that treatment of the stromal fraction of marrow with AL would alter expression of genes that regulate osteoclastogenesis.

Marrow was obtained as discarded tissue during total hip replacement for osteoarthritis in postmenopausal women. For the first study, low-density immature bone marrow cells (LDBMC) from 4 subjects taking AL at the time of surgery (+AL) were matched with LDBMC from 5 untreated subjects (-AL) and cultured  $\pm$  25 ng/ml M-CSF to stimulate osteoclast differentiation. After two weeks, expression of CAT-K, RANKL, OPG and M-CSF was evaluated relative to expression of a housekeeping gene. For the second study, adherent marrow stromal cells (MSCs) from 10 subjects (-AL) were treated with AL ( $10^{-5}$ ,  $10^{-7}$  and  $10^{-9}$  M) and 25 ng/ml M-CSF. Expression of OPG and MCSF was assessed at 1, 3, and 5 days.

In the first study with unfractionated LDBMC, the +AL samples showed lower basal expression of the osteoclast marker gene Cat-K (8%,  $P=0.015$ ) and the pro-osteoclastogenic regulatory gene RANKL (17%,  $P=0.027$ ) than the -AL samples. As expected, M-CSF significantly increased Cat-K in both +AL (8.8 fold,  $P=0.028$ ) and -AL (2.9 fold,  $P=0.028$ ); nevertheless, Cat-K expression remained lower in cells from +AL subjects (24%,  $P=0.015$ ) than from -AL. There were no significant differences in expression of OPG and M-CSF.

In the second study with adherent MSCs, AL ( $10^{-9}$  M) upregulated OPG expression in a subset 4 of 10 samples ( $P=0.009$ ), by an average of  $52\% \pm 34$ . The responsive cells differed from the non-responsive ones in that they showed a constitutive increase in M-CSF production, perhaps reflecting different states of differentiation or genetic features. These results indicate that in addition to AL's inhibition of osteoclastic bone resorption, AL may directly inhibit osteoclastogenesis by affecting the key regulatory genes in stromal cells. Furthermore, these studies affirm the usefulness of human marrow cultures to explore the clinical effects of therapeutic interventions at the cellular level.

**Do Physicians Who Practice Together Provide Similar Osteoporosis Care?**

J. R. Curtis<sup>1</sup>, J. Xi<sup>\*1</sup>, T. Arora<sup>\*1</sup>, A. G. Silver<sup>\*2</sup>, C. Colon-Emeric<sup>\*3</sup>, A. O. Westfall<sup>\*4</sup>, E. Delzell<sup>\*5</sup>, K. G. Saag<sup>1</sup>. <sup>1</sup>Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>2</sup>The Carolinas Center for Medical Excellence, Cary, NC, USA, <sup>3</sup>Department of Medicine, Duke University, Durham, NC, USA, <sup>4</sup>Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, USA, <sup>5</sup>Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA.

**Introduction:** Patients' receipt of prescription osteoporosis therapies (OP Rx) is likely to be influenced by their physician's prescribing patterns. Additionally, if physicians in contiguous practices influence one another's prescribing, successful quality improvement interventions need to target at the practice level rather than at individual physicians.

**Methods:** To address this issue in two high risk populations we examined receipt of OP Rx in: 1) long term glucocorticoid (GC) users in a large U.S. healthcare organization and 2) nursing home (NH) residents with prior fracture or osteoporosis. A common practice setting was defined as doctors who practiced at the same address or in the same nursing home. Hierarchical linear modeling (HLM) and alternating logistic regression (ALR) evaluated the relationship between OP Rx and the common practice setting and the individual physician and are reported as cluster-specific odds ratios and intra-class correlation coefficients (ICCs).

**Results:** Among 6281 long term GC users treated by 2096 doctors in 1295 practices, the proportion receiving OP Rx was 24%. Among 1447 NH residents in 350 nursing homes treated by 67 physicians, the proportion receiving OP Rx was 33%. The relationship between OP Rx and clustering at the physician practice and individual physician level is shown in the Table. There was no significant relationship between receipt of OP Rx and physician practice or nursing home after accounting for the significant effect of the individual physician.

**Conclusion:** In long term glucocorticoid users and NH residents with prior fracture, physicians practicing together were not more likely to prescribe osteoporosis prescription medications than those who did not. Osteoporosis quality improvement interventions can likely ignore the effect of physician groups and common practice settings and maximize power by targeting individual physicians.

Relationship Between OP Rx & Clustering at the Practice Setting and Individual Physician

	Cluster OR (95% CI)	Adjusted* Cluster OR (95% CI)	Adjusted* ICC
<b>Glucocorticoid users</b>			
Physician group practice effect	1.22 (0.88 - 1.69)	1.16 (0.86 - 1.57)	0.03
Individual Physician effect	1.56 (1.34 - 1.82)	1.53 (1.32 - 1.77)	0.08
<b>Nursing home residents</b>			
Nursing home effect	1.06 (0.94 - 1.20)	1.07 (0.94 - 1.22)	0.02
Individual Physician effect	1.22 (1.00 - 1.49)	1.24 (1.02 - 1.51)	0.05

**Effect of 10-Year Fracture Risk Tool Results on Likelihood of Bisphosphonate Prescribing.** B. Ettinger<sup>1</sup>, K. Cody<sup>\*2</sup>, C. Gross<sup>3</sup>. <sup>1</sup>University of California, San Francisco, CA, USA, <sup>2</sup>Foundation for Osteoporosis and Education (FORE), Oakland, CA, USA, <sup>3</sup>AVIYA Clinical Res and Dev, Orinda, CA, USA.

Previous research has shown that likelihood of prescribing osteoporosis drugs was affected by the way clinical data were presented.\* Several fracture risk assessment tools have recently been posted on web sites. To evaluate the effect of fracture data presentation from one of these tools (FRC®; [www://riskcalculator.fore.org](http://www.riskcalculator.fore.org)), we designed a comparison study among attendees of two national scientific meetings.

In September-October 2007, 213 surveys were completed by attendees at the annual meetings of the North American Menopause Society (NAMS), non-osteoporosis experts, largely OB/GYN practitioners, and of the American Society for Bone and Mineral Research (ASBMR), osteoporosis experts. Respondents all reported prescribing bisphosphonates (BP) and being familiar with bone densitometry. Enthusiasm for prescribing BP was rated for each of 3 postmenopausal women (70% or more likelihood of prescribing was set as the threshold). By random assignment, half of those surveyed were provided with only case descriptions (including T-scores) while half were also given a fracture risk assessment graphic and numerical display of fracture risk. Three hypothetical cases were presented: patient A with established osteoporosis; patient B, an osteopenic, younger woman at low fracture risk; patient C, older, but not obviously osteoporotic, with several clinical risk factors that led to high fracture risk. Our hypotheses related to cases B and C; that FRC would reduce prescribing in Case B and would increase prescribing in Case C.

BP treatment for Case A was universally chosen as likely (90-100%), regardless of the type of report (case information only 96.3%; FRC 92.3%). In Case B, the likelihood of prescribing BP fell 60% (from 11.9% to 4.8%) when the FRC was provided. In Case C, the likelihood of prescribing BP increased 21% (from 57.8% to 70.2%) when FRC was provided. Responses of those surveyed at ASBMR differed from those surveyed at NAMS in regard to Case B; NAMS respondents markedly reduced likelihood of BP prescribing (from 22% to 4%;  $p=.004$ ) when fracture risk was provided while ASBMR respondents voted very low (0-6%) likelihood whether or not the fracture risk was provided.

Enthusiasm for treating postmenopausal women with BP varies depending on clinical risk profile and can be further modified by addition of fracture risk information. The FRC tool yielded greatest effect in reducing likelihood of prescribing BP to a younger osteopenic woman by practitioners who were generalists (OB/GYN largely) and less effect was found among bone experts.

**Once-A-Month (OAM) Risedronate 150 mg Reduced Vertebral Fracture Risk at One Year in a Historical Control Analysis.** N. Watts<sup>1</sup>, A. Klemes<sup>2</sup>, L. Wagner<sup>\*2</sup>, J. Brown<sup>3</sup>.

<sup>1</sup>University of Cincinnati Bone Health & Osteoporosis Center, Cincinnati, OH, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA, <sup>3</sup>Rheumatology and Bone Diseases Research Group, Sainte-Foy, QC, Canada.

The anti-fracture efficacy of new osteoporosis therapies is evaluated in randomized placebo controlled trials. The inclusion of a placebo arm in subsequent studies of other dosing regimens may be limited by practical or ethical considerations. In these cases, an historical control group can be a viable alternative. In a recent active-controlled study, OAM risedronate 150 mg demonstrated increases in bone mineral density (BMD) that are non-inferior to those seen with the risedronate 5 mg daily dose, which has proven anti-fracture efficacy.

To assess the anti-fracture efficacy of this new regimen, fracture data collected in the active controlled study of 150 mg of risedronate was analyzed using matched historical control data from previous placebo-controlled trials with identical baseline characteristics. Women in the OAM study were matched with placebo patients in the Vertebral Efficacy of

Risedronate Therapy (VERT) trials for age, years since menopause, BMD, and prevalent vertebral fractures. An historical active treatment group was also constructed from the 5 mg daily arm of the VERT trials for comparison with the 5 mg daily and 150 mg OAM treatment groups in the OAM study.

Over one year new vertebral fractures occurred in 1.4% of the risedronate 5 mg daily group from the OAM study (n = 642) and 1.4% of the 150 mg OAM group (n = 650), in 5% of the historical placebo patients (n = 101, matched from 988) and 2% of the risedronate 5 mg daily patients (n = 99 matched from 979) in the VERT studies. New vertebral fracture risk at 12 months was reduced by 72% in the 150 mg OAM group compared with the historical placebo group (RR 0.27; 95% CI, 0.08 to 1.07, P = 0.032), similar to the 1-year risk reduction observed in the VERT trials of risedronate 5 mg daily (61-65%). OAM risedronate appears as effective as the 5 mg daily dose in reducing the risk of new vertebral fractures in the first year of treatment when a historical placebo control group is used. The use of appropriate historical control data is an alternative to assess fracture effects in osteoporosis trials for which placebo-controlled data are not available.

**Treating Osteoporosis in the Elderly: An Environmental Scan of Nursing Home Prescribing in Ontario, Canada.** A. Papaioannou<sup>1</sup>, C. C. Kennedy<sup>1</sup>, G. Campbell<sup>2</sup>, L. M. Giangregorio<sup>3</sup>, J. Ma<sup>4</sup>, J. D. Adachi<sup>1</sup>. <sup>1</sup>Medicine, McMaster University, Hamilton, ON, Canada, <sup>2</sup>Medical Pharmacies Group, Hamilton, ON, Canada, <sup>3</sup>Kinesiology, University of Waterloo, Waterloo, ON, Canada, <sup>4</sup>Mathematics and Statistics, McMaster University, Hamilton, ON, Canada.

In 2005, the provincial health ministry in Ontario, Canada launched the Osteoporosis Strategy as a comprehensive approach to preventing and managing osteoporosis. For the Long Term Care (LTC) component, the major objective is to develop and deliver knowledge translation tools aimed at improving care processes to reduce falls and fragility fractures in elderly LTC residents. To understand the current level of treatment for osteoporosis in LTC, we partnered with a large pharmacy provider that delivers pharmacy care to over 35,000 residents in long term care homes across Ontario, Canada.

In this analysis, we examined 15 LTC homes (N=3,132 residents) from across the province. Means (standard deviation, SD) and proportions were computed as appropriate. The impact of age and gender on prescribing rates were examined in linear regression analysis.

The mean age of the study sample was 83 years; approximately 66% were women. The overall rate of prescribing was 29% for calcium, 38% for vitamin D, and 18% for bisphosphonates (alendronate, risedronate, or etidronate). Of residents prescribed calcium, the mean daily dose was 922 mg (SD 438). Of residents prescribed vitamin D, the mean daily dose (including multi-vitamins) was 923 IU (SD 773). As displayed in Figure 1, there was considerable prescribing variation between homes. Bisphosphonate use ranged from 7-31%; vitamin D use from 11-62%; and calcium use from 16-44%. Age and gender did not significantly impact the prescribing rates amongst the homes.

The variation in prescribing rates between homes likely represents the previous lack of standardized guidelines and academic detailing for prescribing in nursing homes. The aim of the provincial-wide Osteoporosis strategy in Long Term Care, is to educate physicians and front-line staff and deliver tailored knowledge translation tools to all LTC homes in Ontario. It is hoped this initiative will increase appropriate use of calcium, vitamin D, and bisphosphonates for all elderly residents, irrespective of region.

Black<sup>2</sup>. <sup>1</sup>Univ. of Sheffield, Sheffield, United Kingdom, <sup>2</sup>UCSF, San Francisco, CA, USA, <sup>3</sup>Katholieke Univ. Leuven, Leuven, Belgium, <sup>4</sup>CPMC Res Institute & UCSF, San Francisco, CA, USA, <sup>5</sup>Hôpital Edouard Herriot Pavillon, Lyon, France, <sup>6</sup>Univ. of Pittsburgh, Pittsburgh, PA, USA, <sup>7</sup>Savient Pharmaceuticals, East Brunswick, NJ, USA, <sup>8</sup>Hospital Ramos Mejía, Buenos Aires, Argentina, <sup>9</sup>La Colletta Hospital, Genova, Italy, <sup>10</sup>Osteoporosis Research Centre, Vancouver, BC, Canada, <sup>11</sup>Chinese Univ. of Hong Kong, Prince of Wales Hospital, Shatin NT/Hong Kong SAR, China, <sup>12</sup>Centro TIEMPO, Buenos Aires, Argentina, <sup>13</sup>Novartis Pharmaceuticals, East Hanover, NJ, USA, <sup>14</sup>Novartis Pharma AG, Basel, Switzerland.

We have reported that lumbar spine (LS) bone mineral density (BMD) increases by 6.7% after 3 yrs of zoledronic acid 5 mg (ZOL) given as a 15-minute infusion annually to women with postmenopausal osteoporosis (Black et al, NEJM 2007). Such increases not only reflect an increase in the density of the lumbar vertebral bodies but also any change in the calcification of the aorta or density of the posterior processes of the vertebrae, neither of which are likely to contribute to the strength of the vertebral body. Changes in the vertebral body alone can be studied by quantitative computed tomography (QCT). We planned a substudy of HORIZON-PFT, a 3 yr, double-blind, placebo-controlled trial of women with postmenopausal osteoporosis randomized to a 15-minute infusion of ZOL or placebo at baseline, 12 and 24 months. This substudy included 233 women (mean age 74 yrs) who had QCT of the LS at baseline; 180 had evaluable LS QCT data at 36 months. LS BMD (L1-4) was measured by DXA at baseline, Months 6, 12, 24 and 36 and by QCT (L1-2) at baseline and Month 36 using a bone mineral reference phantom of hydroxyapatite. LS QCT was analyzed to give similar regions of interest to DXA, namely total integral AP- and lateral-BMD estimates. Between-group difference for change in LS BMD by DXA was intermediate between that for spinal BMD anteroposterior (AP) and lateral views DXA-like (Table). Neither % change in spine BMD AP nor lateral-BMD decreased with placebo (Table). In conclusion, once-yearly ZOL increases BMD of the vertebra as measured by DXA and vertebral body as measured by QCT by similar amounts compared to placebo.

Variable	Least square mean ( $\pm$ SD) ZOL	Least square mean ( $\pm$ SD) Placebo	% change from baseline P-value
BMD (DXA)	8.81 $\pm$ 5.63 (n=67)	1.83 $\pm$ 6.75 (n=68)	<0.0001
BMD AP view DXA-like	5.98 $\pm$ 6.51 (n=92)	0.31 $\pm$ 7.77 (n=88)	<0.0001
BMD lateral view DXA-like	9.80 $\pm$ 12.03 (n=92)	1.44 $\pm$ 11.22 (n=88)	<0.0001

## SU406

**The Premenopausal Reference Ranges of Bone Turnover Markers and the Effect of Bisphosphonates in Korean Postmenopausal Women.** D. Chung, J. Chung\*, D. Cho\*, M. Chung\*. Internal Medicine, Chonnam National University Medical School, Gwangju City, Republic of Korea.

High bone turnover after menopause or in various conditions is related to increased bone loss and risk of osteoporotic fracture. Bisphosphonates rapidly reduce the bone turnover rate and significantly decrease fragility fracture. However, although it is clinically very rare, oversuppression of bone turnover can cause mineralization defect and atypical fracture. Therefore, adequate suppression of bone turnover is very important to maintain normal bone quality and to prevent fracture. Many clinical trials report that bisphosphonates decrease the bone turnover rate to premenopausal range without oversuppression. In this study, we investigated the reference levels of bone turnover markers in Korean premenopausal women (N=160) without any disease or drug history affecting bone metabolism. Serum CTX and osteocalcin levels in this group are 0.277 $\pm$ 0.135 ng/ml and 16.87 $\pm$ 5.74 ng/ml, respectively. In postmenopausal women (N=269), the levels are significantly increased to 0.518 $\pm$ 0.312 ng/ml (p=0.000 vs premenopausal women) and 25.57 $\pm$ 10.89 ng/ml (p=0.000 vs premenopausal women), respectively. In postmenopausal osteoporotic women using bisphosphonates (10 mg/day or 70 mg/week for alendronate and 35 mg/week for risedronate) at least more than 6 months (N=51), serum CTX level was significantly lower (0.124 $\pm$ 0.090, p=0.000) than premenopausal reference range. However, osteocalcin level (17.59 $\pm$ 11.31, p=N.S.) was similar to that of premenopausal women. These results indicate that bone resorption marker, CTX, is more significantly suppressed than usual premenopausal level in Korean postmenopausal women with bisphosphonates. The meaning of this kind of change of bone turnover should be interpreted with caution, and due to small number of cases of bisphosphonate users in this trial, further studies would be needed to clarify or define more appropriate suppression ranges of bone turnover rate.

## SU407

**Effect of Risedronate on Bone Density in Hematopoietic Stem Cell Transplant Patients: A Prospective, Randomized, Double-Blind Placebo-Controlled Trial.** K. Baek<sup>\*1</sup>, G. Kim<sup>\*1</sup>, M. Kim<sup>\*1</sup>, D. Lim<sup>\*1</sup>, S. Lee<sup>\*1</sup>, J. Han<sup>1</sup>, H. Kim<sup>\*1</sup>, K. Oh<sup>\*2</sup>, M. Kang<sup>\*1</sup>. <sup>1</sup>Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, <sup>2</sup>Department of Endocrinology and Metabolism, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

**Background:** Osteoporosis is a relatively common complication after hematopoietic stem cell transplantation (HSCT). To our current knowledge, there has been no randomized controlled study on the effect of oral bisphosphonates on bone mineral density (BMD) after HSCT.

**Subjects and Methods:** We conducted a double-blind, randomized controlled trial comparing risedronate (35 mg/week) with placebo in patients receiving HSCT at the Catholic Hematopoietic Stem Cell Transplantation Center. 121 patients were enrolled prior to HSCT from September 2005 until February 2008. All received combined calcium and vitamin D supplementation and were followed for 12 months. Primary outcome variables were BMD changes at the spine and total hip at the end of the follow-up period. Secondary variables were the changes of bone turnover markers.

**Results:** Data from 55 patients who were enrolled until March 2007 were analyzed. 36 patients (65.45%) completed the study until March 2008. The risedronate group and the placebo group consisted of 16 and 20 patients, respectively. The major causes of dropout were infection and disease relapse (n=10), loss to follow-up (n=4), and patient withdrawal due to gastrointestinal discomfort (n=2). Patients treated with risedronate demonstrated significantly less bone loss at the lumbar spine (-0.7 vs. -6.46%, P=0.05) during a 1-yr longitudinal follow-up. Notably, serum 1-CTP levels showed a significant decrease in the risedronate-treated patients (P<0.001).

**Conclusion:** Risedronate significantly attenuated bone loss in HSCT patients. This effect was most prominent in the lumbar spine.

**Disclosures:** K. Baek, None.

## SU408

**Fracture Risk with Once-Monthly Oral Ibandronate Compared with Weekly Bisphosphonates: Primary and Sensitivity Analyses from the eValuation of Ibandronate Efficacy (VIBE) Database Fracture Study.** S. T. Harris<sup>1</sup>, W. A. Blumentals<sup>\*2</sup>, S. A. Poston<sup>\*3</sup>, S. L. Silverman<sup>4</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, CA, USA, <sup>2</sup>Roche, Nutley, NJ, USA, <sup>3</sup>GlaxoSmithKline, Research Triangle Park, NC, USA, <sup>4</sup>Cedars-Sinai Medical Center/UCLA, Beverly Hills, CA, USA.

The VIBE study compared fracture risk between patients treated with once-monthly and weekly oral bisphosphonates (BPs).

Women ≥45 years old, newly prescribed once-monthly oral ibandronate or weekly oral alendronate or risedronate, adherent for ≥90 days, and without malignancy or Paget's disease were included. Data were censored at fracture, 12 months after BP initiation, end of health plan enrollment, BP brand switch, regimen switch, or treatment discontinuation. Fracture risk was compared using Cox regression models and adjusted for potential confounding factors. The analysis was repeated for weekly alendronate or risedronate patients separately compared with ibandronate patients. Sensitivity analyses were conducted excluding patients with codes in the pre-index period for each of the following: estrogen or non-estrogen osteoporosis medications, glucocorticoids, fractures, GI medications, and glucocorticoids and/or osteopenia. Additional analyses varied the requirement for adherence to treatment.

The primary analysis included 7,354 patients receiving once-monthly ibandronate and 56,837 patients receiving weekly BPs (alendronate 35,865, risedronate 20,972). Mean age was 60.14 years for ibandronate patients and 60.54 years for weekly BP patients. The risks of hip fracture, nonvertebral fracture (NVF) and all fractures were not significantly different between groups (rate of all fractures 1.51% for weekly BPs, 1.40% for ibandronate, adjusted hazard ratio [HR] 0.82, p=0.052), but the risk of vertebral fracture was statistically lower in the ibandronate group (0.24% vs 0.11%, adjusted HR 0.36, p=0.006). Similarly, the risks of hip fracture or NVF were not significantly different between ibandronate and alendronate or risedronate, but the risk of vertebral fracture was significantly lower for ibandronate than either weekly BP (alendronate p=0.004, risedronate p=0.014). In all sensitivity analyses, there were no significant differences between groups in the risks of hip fracture or NVF. The risk of vertebral fracture was statistically lower in the ibandronate group, except when non-adherent patients were included in the analysis.

In this study, patients treated with oral once-monthly ibandronate or weekly BPs had a similar risk of hip fracture or NVF during the first year of treatment. The risk of vertebral fracture was lower for ibandronate patients, though the clinical implications of these findings require further exploration and validation.

## SU409

**Quarterly Intravenous Ibandronic Acid in the Community Setting in England - Cost-effective Healthcare Delivery for Osteoporosis Patients.** S. Venkatachalam<sup>1</sup>, R. Suchitra<sup>\*1</sup>, C. Molloy<sup>\*2</sup>, J. McPeake<sup>\*2</sup>, S. Darrington<sup>\*2</sup>, D. Lloyd<sup>\*2</sup>, T. Price<sup>1</sup>. <sup>1</sup>Rheumatology, Cannock Chase Hospital, Cannock, United Kingdom, <sup>2</sup>South Staffordshire Primary Care Trust, Cannock, United Kingdom.

Oral bisphosphonates are the mainstay in the treatment of osteoporosis. Intolerance due to upper gastrointestinal side-effects and their complex administration regime do not help patient compliance. They are inappropriate for patients with cognitive impairment or dysphagia. Intravenous (IV) Disodium Pamidronate in hospital, is an option for these patients, but unlicensed. IV Ibandronic acid is a licensed alternative and lends itself for delivery in the community.

We provide Rheumatology and Osteoporosis services for a population of 500,000 over 5 sites. We had 200 patients receiving IV Disodium Pamidronate quarterly as day cases at the base hospital. Each infusion lasted over an hour and cost \$600. Patients from outreach clinics had to travel far. In contrast, IV Ibandronic acid injection takes less than a minute, costs only \$300, enables rapid turnover of patients and allows more time for education. The annual cost of IV Ibandronic acid for 200 patients delivered by the community team is \$240,000 compared to \$500,000 for IV Disodium Pamidronate in hospital. Community delivery of IV Ibandronic acid has resulted in considerable savings.

We have treated 250 patients with quarterly IV Ibandronic acid in the community over a year. We had very few adverse events which include acute phase reaction, phlebitis and dyspepsia in about 2% of our patients. We have performed about 50 injections at home for patients with difficulties in access. The strength of the service is in delivering care by community nurses and clinicians working together.

IV Ibandronic acid is a safe treatment in the community and ensures compliance. Our innovative service enables effective treatment closer to the patient's home and saves considerable resources for the local health economy.

**Measurement Equivalence of Osteoporosis-Specific and General Quality of Life Instruments in Aboriginal and Non-aboriginal Women.** L. M. Li<sup>\*1</sup>, C. Metge<sup>\*2</sup>, W. D. Leslie<sup>3</sup>. <sup>1</sup>Community Health Sciences, University of Manitoba, Winnipeg, MB, Canada, <sup>2</sup>Pharmacy, University of Manitoba, Winnipeg, MB, Canada, <sup>3</sup>Medicine, University of Manitoba, Winnipeg, MB, Canada.

This study assessed the psychometric equivalence of osteoporosis-specific and general health-related quality of life (HRQOL) instruments in two ethnic groups. The assessment of HRQOL is challenging because individuals with different cultural or socio-demographic characteristics may not interpret questions about their well-being or functional status in the same way.

A total of 258 Aboriginal and 181 non-Aboriginal women were recruited to the First Nations Bone Health Study from rural and urban sites in the province of Manitoba, Canada. The mini-Osteoporosis Quality of Life Questionnaire (mini-OQLQ) and the Medical Outcomes Study Short Form 36 (SF-36) instrument were administered to study participants by trained interviewers. Confirmatory factor analysis (CFA) techniques were used to test different forms of measurement equivalence in the two groups using likelihood ratio tests and other goodness of fit indices. The analyses were conducted using LISREL software.

The CFA results showed that the weakest forms of measurement invariance, configural and metric invariance, were satisfied for the mini-OQLQ instrument, indicating that Aboriginal and non-Aboriginal women have the same conceptualization of osteoporotic quality of life and the concepts have equivalent meaning in the two groups. However, two more stringent forms of equivalence, scalar and complete measurement invariance, were not satisfied. For the SF-36, all forms of measurement invariance were satisfied.

Evidence of measurement invariance is necessary to make valid comparisons between groups on HRQOL measures. This study concluded that measurement equivalence was not demonstrated for the disease-specific quality of life measure but was supported for the general quality of life measure. Ethnicity appears to influence responses about the effect of osteoporosis on one's life. The cross-cultural validation methodology adopted in this study could be applied to data from other HRQOL instruments, other ethnic groups, or groups defined by differences on other characteristics such as age, sex, or type of disease.

## SU411

**Rehabilitation after Clinically-diagnosed Osteoporotic Vertebral Fracture: Results of a Pilot Study.** K. M. Shipp, E. Hegedus<sup>\*</sup>, C. F. Pieper<sup>\*</sup>, H. White<sup>\*</sup>, J. K. Richardson<sup>\*</sup>, T. J. Weber, H. Hoening<sup>\*</sup>. Duke University, Durham, NC, USA.

The objectives of this pilot study were 1) to assess feasibility and safety and 2) to derive estimates of treatment effects for the outcomes of a physical-therapist delivered mobility training intervention designed to control pain and maintain function during recovery from a new vertebral fracture (VF). Participants were 6 independently-living, cognitively robust older women with back pain ≥ 4 on visual analog scale and diagnosis of new osteoporotic

vertebral fracture (confirmed by MRI indicating edema in the vertebral body or new fracture, in comparison with previous radiographs, within one spinal level of the area of back pain). Recruitment occurred via referral by geriatricians and endocrinologists at a tertiary medical center. The women were randomly allocated to usual care (UC, n=2) or the rehabilitation intervention (INT, n=4). The intervention included up to 7 1-hour individual, in-home visits over 1 month focused on finding and maintaining neutral spine alignment during transitional movements (sit to stand, bed mobility) and functional activities (brushing teeth, lifting, getting in and out of a car, walking). In addition, subjects were provided with a four-wheeled walker and instructed to push down on the handles with their arms while walking to assist in keeping the trunk upright. Baseline, 1-month and 3-month follow-up measures of pain, osteoporosis-specific quality of life, and physical function were assessed. Differences between groups were analyzed using an exact permutation test on ranked change scores. The mean age was 84.5 years, with mean number of vertebral fractures 3.2 and mean number of medical problems 5. All subjects completed the study. No falls, fractures (including radiographically-identified VF), or serious adverse events occurred in either arm during the study. Compared to the UC subjects, the INT subjects displayed a trend (p=0.067) toward improvement in pain (81% decrease INT vs. 4% increase UC), the symptom scale (119% increase INT vs. 35% increase UC -- higher score is better) and combined physical and activities of daily living scales (65% increase INT vs. 18% increase UC -- higher score is better) of the Osteoporosis Quality of Life Questionnaire. Physical performance did not change in either group. The trends in pain reduction and better self-reported physical function indicate that this mobility training rehabilitation intervention is worthy of further study and can be adequately powered with a small sample size.

**Women with Severe Osteoporosis Treated with rhPTH(1-34) (teriparatide) Improve Quality of Life Regardless of Incident Fractures: 18 Month Results from the European Forsteo® Observational Study (EFOS).** B. Langdahl<sup>1</sup>, Ö. Ljunggren<sup>2</sup>, W. Lems<sup>3</sup>, J. B. Walsh<sup>4</sup>, C. Barker<sup>5</sup>, A. Fahrleitner-Pammer<sup>6</sup>, D. Karras<sup>7</sup>, G. Rajzbaum<sup>8</sup>, F. Jakob<sup>9</sup>, A. Kutahov<sup>5</sup>, F. Marin<sup>5</sup>. <sup>1</sup>Univ Hosp, Århus, Denmark, <sup>2</sup>Univ Hosp, Uppsala, Sweden, <sup>3</sup>VU Univ Hosp, Amsterdam, Netherlands, <sup>4</sup>St James's Hosp Trinity College, Dublin, Ireland, <sup>5</sup>Lilly Res Ctr, Windlesham, United Kingdom, <sup>6</sup>Med Univ, Graz, Austria, <sup>7</sup>Veterans Admin Hosp, Athens, Greece, <sup>8</sup>St Joseph Hosp, Paris, France, <sup>9</sup>Julius-Maximilians-Univ, Würzburg, Germany.

**AIM:** To describe the influence of incident fractures in changes in health related quality of life (HRQoL) in postmenopausal women with osteoporosis treated with teriparatide for 18 months in the European Forsteo® Observational Study (EFOS). **PATIENTS AND METHODS:** Prospective, observational study in female patients with osteoporosis from 8 European countries. Treatment with teriparatide was for up to 18 months. Clinical vertebral and non-vertebral fragility fractures were recorded at follow-up visits. HRQoL was measured using EQ-5D. **RESULTS:** 1648 women were enrolled for a total of 1924.7 women-years follow-up. 138 women (8.8%) sustained a total of 168 incident fractures (38.7% clinical vertebral, 61.3% non-vertebral) over 18 months (821 fractures /10,000 women-years). Median duration of treatment was 540 and 533 days in Incident Fracture (IF) and No Fracture (NF) groups, respectively. Mean EQ-5D Health State Values (HSV) and Visual Analogue Scale (VAS) showed significant increase in both groups (NF and IF) from baseline to 18 months (HSV p values = < 0.001; VAS p values = < 0.001). After 18 months the HSV in the NF group exceeded the values in the IF group (p = 0.053). Over the duration of treatment women in NF group had a higher increase in VAS than those with IF (p<0.001) (Figure). Women in NF group compared to IF group more frequently reported "no problems" across all domains of EQ-5D. The largest improvement was reported in the EQ-5D sub-domains of usual activities and pain/discomfort. **CONCLUSION:** Women being prescribed teriparatide in the EFOS cohort suffer from severe osteoporosis with significant impact on their HRQoL. Women in EFOS showed clinically significant improvement in HRQoL regardless of fracture during treatment.

**Back Pain is Reduced in Postmenopausal Women with Severe Osteoporosis Treated with rhPTH(1-34) (teriparatide) Regardless of Incident Fractures: 18 Month Results from the European Forsteo® Observational Study (EFOS).** Ö. Ljunggren<sup>1</sup>, A. Fahrleitner-Pammer<sup>2</sup>, A. Kutahov<sup>3</sup>, J. B. Walsh<sup>4</sup>, B. Langdahl<sup>5</sup>, F. Jakob<sup>6</sup>, W. Lems<sup>7</sup>, G. Rajzbaum<sup>8</sup>, C. Barker<sup>3</sup>, D. Karras<sup>9</sup>, F. Marin<sup>3</sup>. <sup>1</sup>Univ Hosp, Uppsala, Sweden, <sup>2</sup>Med Univ, Graz, Austria, <sup>3</sup>Lilly Res Ctr, Windlesham, United Kingdom, <sup>4</sup>St James's Hosp Trinity College, Dublin, Ireland, <sup>5</sup>Univ Hosp, Århus, Denmark, <sup>6</sup>Julius-Maximilians-Univ, Würzburg, Germany, <sup>7</sup>VU Univ Hosp, Amsterdam, Netherlands, <sup>8</sup>St Joseph Hosp, Paris, France, <sup>9</sup>Veterans Admin Hosp, Athens, Greece.

**AIM:** To describe the differences in back pain (BP) in postmenopausal women with osteoporosis with or without incident fracture treated with teriparatide for 18 months in the European Forsteo® Observational Study (EFOS). **PATIENTS AND METHODS:** Prospective, observational study in women with osteoporosis from 8 European countries. Treatment with teriparatide was for up to 18 months. Clinical vertebral and non-vertebral fragility fractures were recorded at follow-up visits. BP was measured using a 100 mm Visual Analogue Scale (VAS) ranging from no BP (0) to worst possible BP (100), and a BP questionnaire. **RESULTS:** 1648 women were enrolled for a total of 1924.7 women-years follow-up. 138 women (8.8%) sustained a total of 168 incident fractures (38.7% clinical vertebral, 61.3% non-vertebral) over 18 months (821 fractures /10,000 women-years). A reduction of BP was observed in both groups - with and without incident fracture - after 18 months (p values < 0.001). Patients in the No Fracture (NF) group had a greater decrease (improvement) in back pain VAS (-27 mm) than those in the Incident Fracture (IF) group (-18.5 mm) (p<0.001) (Table). A reduction of frequency and severity of back pain in the NF group exceeded the values in the IF group (Figure). **CONCLUSION:** Patients being prescribed teriparatide in the EFOS cohort suffer from severe osteoporosis with frequent and severe back pain. Patients in EFOS showed clinically significant reduction in frequency and severity of back pain regardless of fracture during treatment.

Back pain VAS in patients with back pain, mean±SD		
Back Pain VAS (mm)	IF Group	NF Group
Baseline	59.3 ± 25.0	57.6 ± 26.8
3 months	46.3 ± 23.5	42.5 ± 25.2
6 months	44.0 ± 22.9	37.6 ± 25.5
12 months	40.6 ± 25.0	33.9 ± 25.7

## SU414

**Improvement in Quality of Life among Women Treated with Risedronate: Experience from a 2-Year Randomized Controlled Study.** D. Gold<sup>1</sup>, N. Borisov<sup>2</sup>, M. Steinbuch<sup>\*2</sup>, D. Brixner<sup>\*3</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC, USA, <sup>2</sup>Procter & Gamble Pharmaceuticals, Mason, OH, USA, <sup>3</sup>University of Utah, Salt Lake City, UT, USA.

Well-proven fracture prevention of bisphosphonate treatment should result in improved quality of life (QoL) for patients on therapy. This study assessed QoL utilities as measured by 5-dimensional EuroQol (EQ-5D) questionnaire among postmenopausal osteoporotic (PMO) women at baseline and throughout 2-year risedronate treatment and compared follow-up data to baseline measures.

The sample included PMO women with or without prevalent vertebral fracture who were treated for 2 years with risedronate either 5mg daily or 75 mg on 2 consecutive days per month. For the purpose of this study, both treatment arms were combined in a single treatment cohort. EQ-5D (US scoring) was collected at baseline, 12 and 24 months of treatment. The baseline QoL utility values were compared to 12-month and 24-month values by age groups and fracture history. Each dimension of EQ-5D (mobility, self-care, usual activities, pain, and anxiety) was also explored among selected groups.

Of 1,229 treated women in the study, 1,213 (99%) completed the EQ-5D questionnaire during the study period and were included in the analysis. Mean (SD) age of the study subjects was 65 (8). The mean (SD) baseline utility was reported at 0.83 (0.15); this utility is consistent with US average for females in the same age group (Fryback, 2007). Mean baseline utility decreased with age (0.84 vs. 0.83,  $p=0.06$ , <65 vs. 65-74; 0.84 vs. 0.82,  $p=0.08$ , <65 vs. ≥75), history of vertebral fracture (0.81 vs. 0.84,  $p=0.001$ ), and BMI ≥30 (0.77 vs. 0.84,  $p<0.001$ ). Overall, mean QoL utility showed improvement over the course of the treatment (Figure 1). Women with prevalent vertebral fracture reported significantly higher level of utility at 24-month of treatment vs. baseline (Figure 2) and improvements in all 5 dimensions of the EQ-5D. Two-year treatment with risedronate significantly improved QoL as measured by the overall utility score and 5 dimensions of EQ-5D among PMO women. The greatest impact on QoL was observed among women with previous vertebral fracture.

## SU415

**In Osteoporotic Other than in Healthy Bone, Thoracolumbar Fractures Spare the Adjacent Discs.** T. R. Blatter<sup>\*</sup>, C. Josten<sup>\*</sup>. Trauma & Reconstructive Surgery, Leipzig University, Leipzig, Germany.

**Introduction:** In fractures of the thoracolumbar spine, adjacent discs typically are disrupted. It is uncertain, however, whether this pathomechanism is true as well for patients with generalized osteoporosis. As a theoretical alternative, fractures in the osteoporotic spine might spare the adjacent discs (due to minor set off-trauma?, preexistent sclerosis of discs?). Cognition of the true mechanism will have immediate impact on the surgical technique, as an undisrupted disc does not have to be addressed by discectomy and thus an anterior reconstruction will be dispensable.

**Method:** We compared 2 groups of patients. Inclusion criteria for the first group were: age ≤40, adequate trauma, thoracolumbar vertebral body fracture types A3 acc. to Magerl (1). Initially, posterior short segment instrumentation was performed. Patients were readmitted 5-7 weeks later for secondary anterior reconstruction (disc-/corpectomy, cage-interposition). Prior to anterior reconstruction, native X-rays and CT-scans were performed to screen for radiographic signs of posttraumatic disc alterations. Inclusion criteria for the second group were: age ≥60, osteoporosis (t-score ≤-2.5; DEXA), adequate trauma, thoracolumbar vertebral body fractures of the above types. After posterior short segment instrumentation (Sextant, Medtronic) with cement-augmentation of pedicle screws and balloon-kypheoplasty (Kyphon) of the fractured vertebra, native X-rays and CT-scans were performed 5-7 weeks after trauma. These again were screened for radiographic signs of posttraumatic disc alterations.

**Results:** In group 1, 8 patients (average age 34) with traumatic burst fractures (Th8-L3) were included. In group 2, 20 patients (average age 74) with traumatic burst fractures (Th10-L5) were included. In contrast to group 1, the latter patients suffered from osteoporosis (average t-score 2.9). Prior to anterior reconstruction, all 8 patients of group 1 clearly showed signs of vacuum-phenomena in the affected discs at 5-7 weeks after trauma. In contrast, none of the 20 patients in group 2 showed radiographic signs of secondary disc alteration.

**Conclusion:** In generalized osteoporosis, adjacent discs to burst fractures do not show radiographic signs of posttraumatic alterations. This finding has immediate impact on the surgical procedure; with this subgroup - other than in the healthy young - an anterior reconstruction with disc-/corpectomy is not necessary. For these cases, we favor posterior short segment instrumentation with cement-augmentation of pedicle screws in combination with balloon-kypheoplasty of the fractured vertebra.

**Electronic Medical Record Based "ALERT System" improved Diagnosis and Treatment of Osteoporosis in Orthopaedic Out-Patient Clinic.** C. Lee<sup>\*1</sup>, S. Moon<sup>1</sup>, N. Sul<sup>\*1</sup>, K. Yang<sup>\*1</sup>, J. Lee<sup>\*1</sup>, E. Moon<sup>\*1</sup>, S. Park<sup>\*1</sup>, H. Kim<sup>\*1</sup>, J. Jahng<sup>\*1</sup>, H. Lee<sup>\*1</sup>, H. Chun<sup>\*2</sup>, I. Kwon<sup>\*3</sup>. <sup>1</sup>Orthopaedic Surgery, Yonsei University, Seoul, Republic of Korea, <sup>2</sup>Mechanical Engineering, Yonsei University, Seoul, Republic of Korea, <sup>3</sup>School of Dentistry, Kyung Hee University, Seoul, Republic of Korea.

Under-diagnosis and under-treatment of osteoporosis is world wide phenomenon, especially in orthopaedic practice. Various interventions resulted in less dramatic improvement in diagnosis and treatment of osteoporosis. Electronic medical record (EMR) proved to be an efficient tool for medical practice. In this study, EMR based reminder for bone mineral density (BMD) measurement "ALERT" in orthopaedic out patient clinic (OPC) was tested prospectively. Rate of diagnosis and treatment of osteoporosis was compared before and after "ALERT". All patients in OPC (age above 50 years) were included from 1 month before and after ALERT program initiation. Before ALERT, 599 patients visited while 659 patients visited to OPC after ALERT. ALERT criteria were set according to National Osteoporosis Diagnosis Guideline. Rates of BMD measurement and prescription of osteoporotic medication were assessed. Before ALERT only 29% of female patients from whom were eligible for BMD screening, underwent BMD. After ALERT reminder 61% of those were screened with BMD. Only 11% of male patients from whom were eligible for BMD, underwent BMD before ALERT. After ALERT reminder, 58% of those were screened with BMD. In female and male patient combined, BMD screening increased from 23% to 60% after ALERT reminder in EMR. Also proportion of the patients who underwent medical treatment of osteoporosis increased from 9% to 31% after ALERT reminder. EMR based ALERT system definitely increased diagnosis and treatment of osteoporosis in orthopaedic OPC. Therefore EMR based ALERT system can be best solution for world wide under-diagnosis and under-treatment of osteoporosis in orthopaedic field.

**Gastrointestinal Side Effects in Postmenopausal U.S. Women on Osteoporosis Therapies: 6-month Findings from the POSSIBLE US<sup>TM</sup> Study.** C. Woo<sup>1</sup>, G. Gao<sup>\*1</sup>, S. Wade<sup>\*2</sup>, M. Hochberg<sup>3</sup>. <sup>1</sup>Amgen Inc., South San Francisco, CA, USA, <sup>2</sup>Wade Outcomes Research and Consulting, Salt Lake City, UT, USA, <sup>3</sup>University of Maryland, Baltimore, MD, USA.

Gastrointestinal (GI) side effects have been observed among osteoporosis (OP) patients receiving therapy, which may lead them to switch or discontinue treatment. The impact of GI side effects on treatment satisfaction and health-related quality of life (HRQOL) is not well-known.

In the Prospective Observational Scientific Study Investigating Bone Loss Experience (POSSIBLE US<sup>TM</sup>), women on osteoporosis therapies are followed for 2 to 3 years, with data collected every 6 months by self-administered questionnaire. To understand the impact of GI side effects on women new to (n=1483) or stable on (n=1861) pharmacologic OP therapy, we examined patient report of GI side effects overall and by drug class (bisphosphonate users vs non-bisphosphonate users), and the association between GI side effect reporting and treatment satisfaction and HRQOL.

About 20% of new or stable patients reported ≥ 1 GI side effect over 6 months of follow-up (TABLE). Overall, bisphosphonate users were more likely to report any GI side effect than non-bisphosphonate users at entry [age adj. OR (95% CI) 2.0 (1.66, 2.40)] and month 6 [1.4 (1.18, 1.62)]. Adjusting for age at entry, drug class, number of comorbidities and concomitant medications, women who reported any GI side effect at entry were 8% (23% vs 15%) more likely to discontinue or switch agents by month 6 than women who reported no GI side effects at entry (adj OR = 1.71, 95% CI: 1.33, 2.21). Of women continuing on the same agent at month 6, 44% reported taking antacids, H2 blockers, or proton pump inhibitors. Women new to OP therapy and with GI side effects at entry reported lower mean treatment satisfaction scores (Treatment Satisfaction Questionnaire for Medication Global dimension: 55.0 vs 64.1,  $p=0.002$ ) and lower mean HRQOL (EQ-5D Current Health State: 78.3 vs. 82.2,  $p=0.054$ ) at month 6, than those who did not report GI side effects at entry.

Among postmenopausal U.S. women on OP therapies, GI side effects are common and associated with lower HRQOL, lower treatment satisfaction, and higher rates of discontinuation of or switching pharmacologic OP agents

GI side effects at entry & month 6 in patients new to & stable on pharmacologic OP therapies				
	New Entry n = 1483 %	New Month 6 n = 1127 %	Stable Entry n = 1861 %	Stable Month 6 n = 1608 %

**Functionality Outcomes Including Brisk Walking Speed Are Associated with Bone Mineral Density in Postmenopausal Women.** K. Humphrey\*, P. Liu, H. Shin, C. C. Douglas\*, A. P. Crombie\*, O. J. Kelly, L. B. Panton\*, J. Z. Ilich. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

Functionality is the measurement of one's ability to perform simulated daily tasks and can be assessed by measuring strength, endurance, flexibility, agility and balance. Functionality outcomes may be related to an individual's overall health status and physical conditioning. Our purpose was to examine the relationship between various aspects of functionality and bone mineral density (BMD) in Caucasian overweight and obese postmenopausal women. BMD of the total body, femur (neck, Ward's triangle, trochanter, shaft, total) and forearm (radius and ulna at ultradistal and 1/3 distance) were measured by iDXA (GE Medical Systems, Madison, WI). Participants included 37 early postmenopausal (from 2-10 y) women, aged 54.7±3.8 y, with a body mass index (BMI) of 31.3±4.8 kg/m<sup>2</sup> (mean±SD). Participants completed functionality tests including: 8 meter normal and brisk walks, normal and brisk step length, handgrip strength assessment, and the chair-stand test. In multiple regression models containing age, and BMI, brisk walk speed was significantly associated with BMD of all femoral sites (except the trochanter), and total body (adjusted R<sup>2</sup> range, 16%-25%; P<0.05). Normal walk speed and step length were not related to the BMD of any skeletal site of the femur or total body. Handgrip strength was significantly associated with forearm BMD at most of the sites (adjusted R<sup>2</sup> range=13-21%, P less than or equal to 0.05). Trends for associations were observed between the chair stand and femoral BMD (significant for shaft only; adjusted R<sup>2</sup> range=12-14%). We conclude that functionality performance is related to BMD of various skeletal sites. Conditioning with regard to these functionality measures may be beneficial in osteoporosis prevention.

## SU419

**Quality of Life in Mexican Hip Fractures Patients Using EUROQOL (EQ-5) After Discharge from Hip Fracture and 6 Months of Followup.** P. Clark<sup>1</sup>, F. Carlos<sup>\*1</sup>, E. Ramirez<sup>\*2</sup>, A. Camacho<sup>\*1</sup>, F. Franco-Marina<sup>\*2</sup>. <sup>1</sup>Clinical Epidemiology Unit, IMSS-Faculty of Medicine UNAM, Mexico City, Mexico, <sup>2</sup>Epidemiología y Socio-medicina, Instituto Nacional de Rehabilitación, Mexico City, Mexico.

**Objective:** To identify trajectories in Health related quality of life (HRQOL) observed between months 1 and 6 after initial discharge in treated and surviving hip fracture Mexican patients.

**Methods:** Hip fracture patients attending 5 Mexico City public and private hospitals were identified and observed between months 1 and 6 after initial discharge.

The Euroqol questionnaire was applied to each individual to gather information on their HRQOL during the first, third and sixth month after initial hip fracture discharge from the hospital. In 72% of the individuals this assessment was retrospective and performed during the sixth month after initial discharge.

Eq5d score valuations were obtained for each time period using the UK values assigned to each health state. Five EUROQOL trajectories in these patients were visually identified: a) Continuous HRQOL improvement during the 6 month observation period, b) EarlyHRQOL improvement concentrated on the first 3 months after discharge, c) Delayed HRQOL improvement mainly occurring between the third and the sixth month after discharge, d) Same HRQOL over the observation period and e) HRQOL worsening over the study period.

Predictors related to these trajectories included: age, gender, marital status, Eq5d score at the first month, type of surgery, co-morbidities and hospital readmissions. Data were analyzed through a multinomial logistic regression model which also included a term indicating whether the HRQOL assessment was either prospective or retrospective.

**Results:** 136 treated and surviving hip fracture patients were analyzed. Of them 78.6% showed an improvement in their Eq5d scores over the observation period (38.9% a continuous improvement and 37.5% an early improvement). Only 8.1% showed a worsening in their HRQOL over the observation period and 12.5% maintained during the observation the same HRQOL. Statistically significant results that follow come from the final multivariate model. Prospective interviews were more frequent in the trajectories showing continuous improvement or worsening HRQOL. Persons showing the same or worsening trajectory over the observation period had an older average age than those showing any of the three improving trajectories. Persons with worsening or delayed improvement trajectories had a better Eq5d score at the start of observation. Patients treated by partial or total hip replacement tended to show more frequently the same or worse HRQOL over the study period, whereas those receiving an open or closed hip screw tended to show more frequently a continuous or early improvement.

**Disclosures:** P. Clark, None.

## SU420

**The Association Between Falls and Health-Related Quality of Life (HRQoL).** J. McFetridge<sup>\*1</sup>, E. Barrett-Connor<sup>2</sup>, S. G. Sajjan<sup>\*3</sup>, T. Fan<sup>\*3</sup>, P. D. Miller<sup>4</sup>, S. S. Sen<sup>\*3</sup>, E. S. Siris<sup>5</sup>. <sup>1</sup>Lehigh University, Bethlehem, PA, USA, <sup>2</sup>University of California, San Diego, La Jolla, CA, USA, <sup>3</sup>Merck & Co., Inc, Whitehouse Station, NJ, USA, <sup>4</sup>Colorado Center for Bone Research, Lakewood, CO, USA, <sup>5</sup>Columbia University Medical Center, New York, NY, USA.

To assess the association between falls and HRQoL in women age 50 - 99 who participated in the National Osteoporosis Risk Assessment (NORA) Survey, 152,065 women completed the baseline and one-year follow-up NORA surveys. HRQoL was assessed by SF-12 Physical (PCS) and Mental Component Summary (MCS) scores. Information on self-reported falls and associated medical care for the 12 months prior to 1st follow-up survey was collected. Three groups were formed: falls not resulting in medical care (doctor's visit, emergency room) and/or fracture (Group I), falls resulting in medical care without fracture (Group II), and falls resulting in fracture (Group III). Group least squares means of PCS and MCS at the one-year follow-up survey were adjusted for key factors (age, ethnicity, BMD T-score, education, BMI, fractures prior to baseline and baseline health status). Differences by fall status for the entire cohort, as well as by age group (50-64 yrs vs. 65-99 yrs) were determined. Statistical significance of the interaction effect of age and fall status on PCS and MCS was also examined. A total of 28,887 patients [group I (n=19,303), group II (n=6,407), group III (n=3,177)] reported having a fall during the one year between surveys. For both age groups, with all fall types, women with fall had poorer PCS than those who had not fallen with a general pattern of PCS worsening with increasing fall severity (see table). The interaction between age group and fall status was not significant. A significant association was also found between MCS and falls (data not shown), but it was inconsistent and of a lesser magnitude. Falls even in absence of resultant fracture was associated with a lower HRQoL. The association between recent fall in the past year and HRQoL was similar for older and younger postmenopausal women. These findings highlight the importance of falls in postmenopausal women of all ages.

Fall group	Differences of Least Squares Means for PCS		
	All patients	50-64 yrs	65-99 yrs
Group I	-1.8469*	-1.7145*	-1.9792*
Group II	-3.8959*	-3.9813*	-3.8104*
Group III	-4.4390*	-4.3454*	-4.5327*

\* Differences of least squares means versus the no fall group: p < 0.0001

**Superiority of Alfacalcidol over Plain Vitamin D in Men with Osteoporosis: A Prospective, Observational, Single Center, Two Year Trial on 214 Patients.** J. D. Ringe<sup>1</sup>, P. Farahmand<sup>\*1</sup>, E. Schacht<sup>2</sup>. <sup>1</sup>Medical Clinic 4, Klinikum Leverkusen (Univ. of Cologne), Leverkusen, Germany, <sup>2</sup>ZORG (Zurich Osteoporosis Research Group), Zollikerberg, Switzerland.

**Background:** Due to pleiotropic actions on bone, gut, muscle and other target tissues alfacalcidol is an interesting drug for treating osteoporosis and preventing falls. Within studies on glucocorticoid-induced osteoporosis always men have been treated with this active D-hormone prodrug, but there is no pure male study in the literature. Therefore we conducted a study to compare the efficacy of alfacalcidol versus plain vitamin D in patients with established male osteoporosis.

**Methods:** For ethical reasons and to simulate practical conditions we selected in a pair-wise manner 107 patients with established male osteoporosis and prevalent vert. fxs (group A) and 107 patients without prevalent vert. fxs (group B). Group A we treated with 1mcg alfacalcidol + 500 mg calcium daily and group B with 1000 I.U. vitamin D + 1000 mg calcium daily for two years.

With this design we are comparing two groups with a different risk at onset. Due to the prevalent vert. fxs and lower average BMD values there is a higher risk for incident fractures in group A. The scientific question is whether despite these differences the therapeutic results in group A are not inferior or even superior. BMD was measured at the lumbar spine and at the femoral neck with dual energy x-ray absorptiometry (LUNAR) and lateral x-rays of the spine were taken, both annually and observer blind.

**Results:** After 2 years we found significantly higher increases for LS-BMD (+3.2 vs. +0.8%) and TH-BMD (+1.9 vs. -0.9%) in group A and B resp. 18 incident falls were reported in the alfacalcidol group and 38 in the group treated with plain vitamin (p = 0.04). There were significantly lower rates of patients with new vert. and non-vert.-fxs in group A than in group B (-48% for each type of fractures; p = 0.035 and p = 0.004 resp.) Concerning the incidence of new non-vert fxs we found out that there was a relation to renal function in the two groups. The advantage for alfacalcidol was mainly due to a higher non-vert, fall-related fxs reducing potency in patients with a creatinine-clearance below 60ml/min. (Odds ratio: 5.652; p = 0.002). There were no SAE and no deterioration of renal function in both groups.

**Conclusion:** Despite the higher risk profile of the patients in the alfacalcidol group at onset alfacalcidol showed a higher therapeutic efficacy in terms of BMD, falls and fractures. One important advantage of alfacalcidol may be that it works in vitamin D deplete and replete patients and also in those with mild to moderate deterioration of renal function.

**Vitamin D<sub>3</sub> Treatment of Elderly People - Twice a Day or Every Four Months? A Comparative Study of Efficacy and Safety of Two Oral Dosages with Same Annual Dose of 292000 Units.** V. V. Välimäki<sup>1</sup>, T. Pekkarinen<sup>2</sup>, S. Aarum<sup>1</sup>, U. Turpeinen<sup>3</sup>, E. Hämäläinen<sup>3</sup>, E. Löyttyniemi<sup>4</sup>, M. J. Välimäki<sup>1</sup>.

<sup>1</sup>Department of Medicine, Division of Endocrinology, Helsinki University Central Hospital, Helsinki, Finland, <sup>2</sup>Department of Internal Medicine, Helsinki University Central Hospital, Vantaa, Finland, <sup>3</sup>Department of Clinical Chemistry, Helsinki University Central Hospital, Helsinki, Finland, <sup>4</sup>Department of Statistics, University of Turku, Turku, Finland.

This randomized, double blind two-arm parallel vitamin D<sub>3</sub> supplementation trial compared efficacy and safety of two oral dosages of vitamin D<sub>3</sub> resulting in equal annual dose of 292,000 IU.

Forty women aged 69.3-78.8 years were randomly assigned to either vitamin D<sub>3</sub> 400 IU twice daily (Daily) or vitamin D<sub>3</sub> oil 97333 IU every four months (Every 4 months) for one year. All received one gram calcium supplementation daily. Serum 25OHD<sub>3</sub> in relation to the target levels of 50-75 nmol/l, serum PTH, and serum type I procollagen aminoterminal propeptide (PINP) were followed as efficacy parameters and serum and urine calcium and different measures of renal function as safety parameters.

The 25OHD<sub>3</sub> concentration differed between the study groups over time (P<0.0001), and increased more in the Daily group than in the Every 4 months group with the increases in mean values from baseline to 12 months being 16.4 nmol/l (P<0.0001) and 3.9 nmol/l (P=0.142), respectively. One hundred percent and 47% in the Daily group and 67% and 28% in the Every 4 months group had 25OHD<sub>3</sub> concentration above 50 nmol/l and 75 nmol/l at the end of the study, respectively. PTH levels did not show any seasonal perturbation in either group. Serum PINP levels declined similarly in both groups over time (P<0.0001). Serum ionized calcium levels remained stable and did not differ between the groups. 24-hour urinary calcium excretion rose (P<0.0001 for time) similarly in the study groups, the increases in mean values from baseline to 12 months being 1.21 mmol (P<0.0001) in the Daily group and 0.58 mmol in the Every 4 months group (P=0.040). Renal function fluctuated (P<0.0001) but did not worsen over time in either group in terms of serum creatinine, cystatin C, or creatinine clearance.

In terms of serum 25OHD<sub>3</sub> concentrations daily treatment was more efficient than four monthly treatment, but to increase adherence to supplementation the latter is still worth developing e.g. by shortening the dosing interval to 3 months. Both treatments increased urinary excretion of calcium, but did not worsen renal function.

## SU423

**Anti-fall Efficacy of Oral Supplemental Vitamin D and Active Vitamin D.** J. Henschkowski<sup>1</sup>, B. Dawson-Hughes<sup>2</sup>, H. B. Staehelin<sup>3</sup>, A. E. Stuck<sup>4</sup>, J. E. Orav<sup>5</sup>, A. Egli<sup>1</sup>, H. A. Bischoff-Ferrari<sup>1</sup>.

<sup>1</sup>Rheumatology, University of Zurich, Zurich, Switzerland, <sup>2</sup>Jean Mayer USDA HNRCA, Tufts University, Boston, MA, USA, <sup>3</sup>Geriatrics, University of Basel, Basel, Switzerland, <sup>4</sup>Geriatrics, University of Bern, Bern, Switzerland, <sup>5</sup>Biostatistics, Harvard School of Public Health, Boston, MA, USA.

**Background:** Results from fall prevention trials with supplemental vitamin D have been mixed and trials varied by dose, type of vitamin D (D<sub>3</sub> = cholecalciferol or D<sub>2</sub> = ergocalciferol), and quality of fall assessment. A possible differential benefit of supplemental versus alpha-hydroxylated vitamin D (active D) has not been established.

**Aim:** We performed a meta-analysis on the efficacy of supplemental vitamin D in preventing falls among older individuals (age 65+) and compared the pooled effects from supplemental and active vitamin D trials.

**Studies included:** The primary analysis included double-blind RCTs with prospective fall assessment of oral vitamin D with or without calcium supplementation compared to calcium or placebo.

**Results:** Supplemental vitamin D: 8 RCTs (n=2426) met our inclusion criteria. For supplemental vitamin D, heterogeneity was observed for dose of vitamin D (low-dose: 200-600 IU / day versus higher dose: 700 IU + / day; p -value 0.017) and achieved 25-hydroxyvitamin D level (< 60 nmol/l versus ≥ 60 nmol/l; p-value = 0.003). Higher dose supplemental vitamin D reduced the relative risk (RR) of a fall by 19% (pooled RR=0.81; 95% CI, 0.71-0.92; n = 1921 from seven trials) and effects were most pronounced (26%) with D<sub>3</sub> (pooled RR = 0.74; 95% CI, 0.58-0.93; n= 946). Falls were not reduced by low dose supplemental vitamin D (pooled RR = 1.10, 95% CI, 0.89-1.35) or by achieved serum 25-hydroxyvitamin D concentrations less than 60 nmol/l (pooled RR = 1.34, 95% CI, 0.98-1.84).

Active vitamin D: 2 RCTs, (n= 624) met our inclusion criteria. Active vitamin D in a dose of 1µg 1αCalcidiol or 0.5 µg Calcitriol per day reduced fall risk by 22% (pooled RR = 0.78; 95% CI, 0.64-0.94).

**Conclusion:** Supplemental vitamin D in a higher dose of at least 700 IU reduced the risk of falling among older individuals by at least 19% and to a similar degree as active D. Low dose supplemental vitamin D of 600 IU or less, or supplementation resulting in serum 25-hydroxyvitamin D concentrations of less than 60 nmol/l may not reduce the risk of falling among older individuals.

## SU424

**Vitamin D Deficiency Is Associated with Diminished Quality of Life Based on Qualeffo-41 Questionnaire Analysis.** P. M. Camacho<sup>1</sup>, A. M. Mazhari<sup>1</sup>, B. Sexton<sup>1</sup>, P. Sapountzi<sup>1</sup>, J. Sinacore<sup>2</sup>.

<sup>1</sup>Endocrinology, Loyola University Medical Center, Maywood, IL, USA, <sup>2</sup>Preventive Medicine, Loyola University Medical Center, Maywood, IL, USA.

Vitamin D deficiency leads to bone loss, fractures, bone pain and muscle weakness. Vitamin D deficient individuals frequently report an improvement in pain, muscle strength, mood and sense of well-being when treated with vitamin D, translating to a better quality of life. We describe the partial results of an ongoing prospective study that aims to determine the effect of vitamin D deficiency on health-related quality of life.

The Qualeffo-41 questionnaire is a quality of life survey validated for patients with osteoporosis. It contains questions in five domains: pain, physical function, social function, general health perception and mental function. The scores are expressed on a 100-point scale, with 0 corresponding to the best and 100 being the worst health related quality of life.

Individuals evaluated at Loyola Osteoporosis and Metabolic Bone Disease Center for osteopenia and osteoporosis were screened for vitamin D deficiency. Patients with 25 OH Vitamin D (25OHD) level <20 ng/ml were enrolled in the vitamin D deficient group (VDG) and those with 25 OHD > 20 ng/ml were enrolled in the control group (CG). When the study was initiated in 2004, vitamin D deficiency was defined as 25 OHD < 20 ng/ml. 36 patients (6 male and 30 female) were enrolled in the VDG and 24 patients (all female) in the CG. The mean age in years for the VDG was 58 +/- 13 versus 60 +/- 11 in the CG (p=0.406). The mean 25 OHD in the VDG was 14.78 +/- 4.47 versus 38.04 +/- 12.08 in the CG (p<0.0005). Intact PTH was 61.90 +/- 33.31 in the VDG versus 36.30 +/- 13.24 in the CG (p=0.001). Spine BMD in the VDG was 1.105 gm/cm2 +/- 0.229 versus 0.915 +/- 0.271 in the control group (p=0.012) and mean T scores were -.85 +/- 1.93 and -1.55 +/- .338, respectively, (p=0.19). Femoral neck BMD and T scores were not statistically different.

The mean total score was significantly higher in the VDG at 34.5 +/- 15.9 versus 22.4 +/- 12.3 in the CG (p=0.003). 4 out of 5 domains showed significantly higher scores in the VDG compared to the CG; general health perception (p<0.0005), physical function (p=0.005), pain (p=0.020) and social function (p=0.012). Mental function was not significantly different between the 2 groups. There was an inverse correlation between the total score and vitamin D levels r=-.371 (p=0.004), when corrected for age. There was no correlation between the total score and LS and FN BMD and T scores.

Our study clearly shows that vitamin D deficient individuals suffer from diminished quality of life, independent of the severity of bone loss. Future results of this ongoing study will determine if correction of the deficiency will lead to a significant improvement.

## SU425

**Effect of Vitamin D<sub>2</sub> or Vitamin D<sub>3</sub> Supplementation on Serum 25(OH)D.**

N. Binkley, D. Gemar, A. Woods\*, J. Engelke\*, R. Ramamurthy, D. Krueger, M. K. Drezner. Osteoporosis Clinical Research Program, University of Wisconsin-Madison, Madison, WI, USA.

Ergocalciferol (D<sub>2</sub>) has been assumed less effective than cholecalciferol (D<sub>3</sub>) in maintaining serum 25-hydroxyvitamin D [25(OH)D]. However, data supporting this are limited and a recent report challenges this assumption. The effect of oral vitamin D dosing on circulating 25(OH)D concentration depends on absorption, subsequent metabolism, and the impact on pre-existing circulating 25(OH)D<sub>3</sub> concentration. However, data evaluating the effect of vitamin D<sub>2</sub> administration on circulating 25(OH)D<sub>3</sub> concentration are limited and existing studies of short duration. This study investigates the effects of long-term administration of vitamin D<sub>2</sub> or vitamin D<sub>3</sub> on circulating levels of 25(OH)D<sub>2</sub>, 25(OH)D<sub>3</sub> and total 25(OH)D. In this year-long randomized, double-blind trial, community-dwelling adults age 65+ were randomly assigned to receive daily (1,600 IU) or once-monthly (50,000 IU) vitamin D<sub>2</sub> or vitamin D<sub>3</sub>. Serum for 25(OH)D measurement by HPLC was obtained at baseline and immediately before monthly dosing at months 1, 2, 3, 6, 9 and 12. All 25(OH)D measurements for each individual were performed in a single HPLC run to minimize assay variability. Study enrollment (total n = 64) was completed in summer 2007; preliminary data for the first 17 study completers (13 women/4 men) are reported here. Baseline mean (± SD) age, BMI and 25(OH)D were 73.5 (4.7) years, 24.9 (4.7) kg/m<sup>2</sup> and 28.8 (11.2) ng/ml respectively. At one year, a greater increase in mean total 25(OH)D was observed with vitamin D<sub>3</sub> than with vitamin D<sub>2</sub> whether dosed daily (16.2 vs. 8.6 ng/ml) or monthly (7.9 vs -0.9 ng/ml). As expected, the increase in total 25(OH)D, seen with vitamin D<sub>3</sub> dosing, reflects an increase (p < 0.05) in 25(OH)D<sub>3</sub>; 19.4 and 8.6 ng/ml for daily and monthly dosing respectively. Similarly, vitamin D<sub>2</sub> administration raises 25(OH)D<sub>2</sub>; 19.6 and 18.7 ng/ml for daily and monthly dosing respectively. However, with vitamin D<sub>2</sub> dosing, a reciprocal decrease (p < 0.01) in 25(OH)D<sub>3</sub> of approximately the same magnitude as the increase in 25(OH)D<sub>2</sub>, results in minimal or no increase in total 25(OH)D. Substantial between-individual variability exists in 25(OH)D response to identical vitamin D<sub>2</sub> and vitamin D<sub>3</sub> doses. Serum and 24-hour urinary calcium concentrations were unchanged over 12 months for all groups.

These preliminary results suggest that, over the course of one year, the long-term effects of vitamin D<sub>2</sub> administration on total 25(OH)D are largely negated by a reduction in the circulating 25(OH)D<sub>3</sub> concentration. Thus, vitamin D<sub>3</sub> appears a more effective treatment than vitamin D<sub>2</sub> to increase serum 25(OH)D.

**Disclosures:** N. Binkley, None.

## SU426

**The Effects of 50,000 IU of Vitamin D<sub>2</sub> Twice per Month on Circulating 25-Hydroxyvitamin D and Calcium Levels.** S. M. Pietras\*, B. K. Obayan\*, M. H. Cai\*, M. F. Holick. Vitamin D, Skin and Bone Research Laboratory, Endocrine Section, Department of Medicine, Boston University School of Medicine, Boston Medical Center, Boston, MA, USA.

**Purpose:** Knowledge about the many physiologic functions of vitamin D is growing. Vitamin D is important for muscle and skeletal health and may have a role in reducing the risk of malignancies, autoimmune and cardiovascular diseases. To date there have been no long-term studies using pharmacologic dosing to maintain vitamin D sufficiency. Here we report our experience treating patients with 50,000 IU of vitamin D<sub>2</sub> twice a month for up to six years. **Methods:** Retrospective chart review of patients seen in a specialty bone clinic. Data collected included serum 25(OH) D values, calcium (Ca) and parathyroid hormone (PTH) levels. **Results:** 90 patients qualified. We found a significant improvement in 25(OH) D values with a mean value prior to treatment of 23.1 +/- 9.5 ng/mL, compared to 46.4 +/- 18.0 ng/mL at the final visit during the review period (p<0.001). 9% of patients were vitamin D sufficient (25(OH) D ≥ 30 ng/mL) at the initiation of treatment, compared with 82% at the final visit (p<0.001). After an initial improvement during the first 6 months (serum 25(OH) D levels increased to approximately 35 ng/mL) levels remained stable over time. 43 patients were initially treated with 50,000 IU of vitamin D<sub>2</sub> weekly for 8 weeks prior to starting maintenance therapy with twice monthly vitamin D. Mean values for Ca and PTH did not significantly change. 13 patients with primary or tertiary hyperparathyroidism were included in the review, and when analyzed separately the Ca levels in these patients did not significantly change (mean initial value 10.3 +/- 0.9 mg/dL, mean final value 10.2 +/- 0.7 mg/dL, p=0.89), nor did the PTH values (mean initial value 176.7 +/- 263.5 pg/mL, final value 168.5 +/- 120.3 pg/mL, p=0.88). **Conclusion:** Treating patients with 50,000 IU of vitamin D<sub>2</sub> twice per month is an effective method to prevent the recurrence of vitamin D deficiency and maintain serum levels in what is now considered to be the preferred range for health.

**Graph 1: Status of Vitamin D Sufficiency: Initiation of Treatment vs. Final Visit**  
 Vitamin D deficiency: 25(OH) D levels <20 ng/mL. Vitamin D insufficiency: 25(OH) D levels 20-29.9 ng/mL. Vitamin D sufficiency: 25(OH) D levels ≥ 30 ng/mL.

**Disclosures:** *S.M. Pietras, None.*

## SU427

**What Is Your Patient's Vitamin D Status? Clinical Consideration of Variability in a 25(OH)D Measurement.** N. Binkley, D. Krueger, J. Engelke\*, M. K. Drezner. Osteoporosis Clinical Research Program, University of Wisconsin-Madison, Madison, WI, USA.

Clinicians are increasingly obtaining 25(OH)D measurements and using this value to recommend vitamin D supplementation. However, a 25(OH)D measurement, like all laboratory tests, is impacted by assay and biologic variability. An additional source of variability for many laboratory tests, including 25(OH)D, is lack of standard calibrators. Finally, it is logical that assaying 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub> separately to determine total 25(OH)D increases measurement error. Despite the above, it is our impression that clinicians may not consider 25(OH)D measurement variability when prescribing high-dose vitamin D treatment. The purpose of this report is to raise clinician awareness to potential variability in 25(OH)D measurement and suggest how to confront this reality. 25(OH)D assay variability was investigated using 3 serum controls, containing differing amounts of 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub>, measured 49 times over 14 months for routine quality assurance. Between-lab variability was explored (data previously reported) by sending 16 specimens to 2 clinical laboratories for 25(OH)D measurement. Biologic variability is reported for 3 volunteers in whom blood was obtained weekly for 16 weeks following substantial sun exposure. Finally, the possibility that specimens containing both 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub> produce greater variability in total 25(OH)D was explored. Two samples with total 25(OH)D near 30 ng/ml, one comprised of only 25(OH)D<sub>3</sub>, the other with nearly equal amounts of 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub>, are being measured weekly. In the 3 QC sera, 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub> were evaluated separately; the mean values ranged from 15.1 to 91.1 ng/ml with 95% confidence intervals from +/-1.9 to 4.7%.

Between-laboratory bias for the 2 clinical labs was 4.4 ng/ml (~15% at 30 ng/ml). Combining these sources of variability, a single 25(OH)D result may vary by ~20%. As such, a single value of "30 ng/ml" is between 24 and 36 ng/ml. Similarly, a value of "25 ng/ml" may be 31 ng/ml, while a value of 33 ng/ml may be 27 ng/ml. Day-to-day biologic variability appears minimal, although seasonal variability was observed with a decline in 25(OH)D of 15-30% over 16 weeks in the fall/winter.

In conclusion, based on assay and between-lab variability, a single reported 25(OH)D result is likely within 20% of the "true" value. It is possible that serum containing both 25(OH)D<sub>2</sub> and 25(OH)D<sub>3</sub> will have even greater variability. Clinicians are well advised to consider this variability when applying any cutpoint approach, e.g., 30 ng/ml, to define optimal vitamin D status. In patients with borderline vitamin D status, e.g., 25-35 ng/ml, a conservative approach to vitamin D repletion, rather than prescription of high-dose vitamin D<sub>2</sub>, seems appropriate.

## SU428

**A Randomised Controlled Trial of the Effects of Vitamin D Supplementation upon Muscle Function in Adolescent Girls.** K. A. Ward<sup>1</sup>, G. Das<sup>2\*</sup>, J. L. Berry<sup>3</sup>, S. A. Roberts<sup>4\*</sup>, J. E. Adams<sup>1</sup>, Z. Mughal<sup>5</sup>. <sup>1</sup>Clinical Radiology, University of Manchester, Manchester, United Kingdom, <sup>2</sup>Paediatrics, Central Manchester Primary Care Trust, Manchester, United Kingdom, <sup>3</sup>Medicine, University of Manchester, Manchester, United Kingdom, <sup>4</sup>Health Methodology Research Group, University of Manchester, Manchester, United Kingdom, <sup>5</sup>Paediatric Medicine, Central Manchester and Manchester Childrens University Hospitals NHS Trust, Manchester, United Kingdom.

Myopathy is the major clinical symptom of hypovitaminosis D. As part of a double blind, randomised controlled trial of vitamin D supplementation we measured muscle power and force at baseline and follow-up. We hypothesised that after 12 months vitamin D supplementation muscle power would increase more in the supplemented group than in the placebo group.

73 of the original 99 girls screened for the trial had 25(OH)D levels < 15ng/ml. All girls had baseline muscle measurements using jumping mechanography and hand-held dynamometry. Muscle measurements were repeated after 12 months vitamin D supplementation (4 doses 150 000IU Ergocalciferol). A single two legged jump (2LJ), multiple one leg jumps (1LJ) and grip strength measurements were performed.

69 girls (94%) completed the trial; reasons for loss to follow up are leaving school (n=3) and starting treatment for clinical symptoms of 25(OH)D deficiency. Differences between groups were tested using ANCOVA adjusting for baseline weight, log baseline 25(OH)D and baseline measurement. Exploratory analyses of whether vitamin D level affected response to supplementation was performed after splitting baseline 25(OH)D level into tertiles (< 5.5ng/ml, 5.51 - 6.95 ng/ml, >6.95 ng/ml); ANOVA tested difference between groups.

At follow up 25(OH)D status was 22.4ng/ml (SD 3.6, range 13.8 to 29.2) in the active group and 6.3 ng/ml (SD 2.6, range 2.4 to 13.2) in controls. There were no significant differences between the vitamin D treated group and controls for any of the parameters studied in the lower or upper limb. Muscle power, but not force, increased in the supplementation group with lowest baseline 25(OH)D levels (p = 0.057).

There were no overall differences in muscle power between the treated group and controls despite improvements in 25(OH)D status. There were no changes in force, perhaps reflecting that these girls had completed growth prior to the study. The improvement in power in girls taking supplementation in the lowest tertile of baseline 25(OH)D was through increased jumping velocity (p = 0.012). These data support the clinical observation of loss of proximal muscle function at the very lowest levels of 25(OH)D. The implications of this loss of function upon skeletal growth and development remain to be determined.

## SU429

**Which is the Best Oral High-Dose Vitamin D<sub>3</sub> Regimen for Postmenopausal Women with Hypovitaminosis D?** S. R. Mastaglia\*, M. Seijo\*, A. Bagur, J. Somoza\*, B. Oliveri. Sección Osteopatías Médicas, Hospital de Clínica. Universidad de Buenos Aires, Buenos Aires, Argentina.

Hypovitaminosis D is a common problem in postmenopausal and elderly people. Intermittent administration of vitamin D is being studied as a means to ensure compliance with the supplementation regimen and to ensure adequate levels. The aim of this study was to assess the effectiveness and safety of two high-dose oral intermittent vitamin D<sub>3</sub> regimens. Sixteen healthy postmenopausal women aged 58.4±5.0 years (X±SD), with 25OHD <20ng/ml, not receiving any treatment known to affect bone metabolism were recruited. They were randomly assigned to one of two groups: Group 1 receiving a single 100,000IU dose of cholecalciferol (D<sub>3</sub>) and Group 2 receiving an additional similar dose on day 45. Serum calcium, phosphorus, bone alkaline phosphatase, iPTH and urinary Calcium/creatinine were measured at baseline (previous to D<sub>3</sub> administration), and at 45 and 90 days. Average 25OHD levels rose from 14.5±4.3 ng/ml at baseline to 20.1±3.0 ng/ml at day 45 (p<0.004), and to 24.7±5 at day 90 (p<0.001 vs. baseline) in all the patients. When divided according to regimen both groups had similar values at 45 days (G1=20.0±4 and G2:20.2 ± 2ng/ml) Group 1 maintained vitamin D levels between day 45 and 90 (23.0±4 ng/ml; ns); only 9% reached 25OHD levels ≥30ng/ml. Group 2 showed a significant increase in 25OHD levels between day 45 and 90 (28.5±3 ng/ml; p<0.04). Forty percent of women had 25OHD levels ≥30ng/ml. No significant differences in the remaining biochemical parameters were observed between groups at any time point and all the values were within the reference range for postmenopausal women. A single oral 100,000IU dose of cholecalciferol is safe but not sufficient. A second similar dose administered at 45 days improves 25OHD levels but is still not enough for healthy postmenopausal women with hypovitaminosis D to reach adequate 25OHD levels.

\* Group 2: baseline vs. 45 days; p<0.01  
# Group 1 vs. Group 2 at 90 days; p<0.003

## SU430

**A Single Dose of 100,000IU D<sub>3</sub> Appears to be Insufficient to Achieve Desirable Levels of 25OHD in Patients with Hypovitaminosis D.** A. Bagur<sup>1</sup>, M. V. Ferro<sup>\*1</sup>, D. González<sup>\*2</sup>, M. C. Fernández<sup>\*1</sup>, B. Oliveri<sup>1</sup>, M. S. Parisi<sup>1</sup>. <sup>1</sup>Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, <sup>2</sup>Sección Osteopatías Médicas, Centro de Osteopatías Médicas, Buenos Aires, Argentina.

Hypovitaminosis D is a major worldwide public problem. Correction of vitamin D is important for prevention of osteoporosis since bone loss and fractures have been linked with vitamin D deficiency. The aim of the study was to evaluate the response and safety to a unique vitamin D<sub>3</sub> dose (100,000 IU) in patients with low 25OHD levels. Ninety three clinical records from patients who received this unique dose of vitamin D<sub>3</sub> for hypovitaminosis D were reviewed. Inclusion criteria were: 25OHD levels below 32 ng/ml, 25OHD determinations at baseline and after 1 to 3 months of treatment, performed at the same laboratory, and normal serum calcium. Thirty eight out 90 had the inclusion/exclusion criteria defined, and all of them were women. We excluded 55 clinical records, 34 due to uncompleted data, 3 because the samples were made in different laboratories and 15 did not have 25OHD determinations after the first dose of vitamin D<sub>3</sub>. The mean age ± 1SD was 63.3 ± 9.6 years, 35 of them were postmenopausal and 3 premenopausal women. Laboratory tests were: serum calcium, phosphate, 25OHD, bone alkaline phosphatase, CTX, iPTH and urine 24hs calcium at baseline and post treatment. Subjects were divided in three groups according to baseline 25OHD: 0-10, 11-20 and 21-31 ng/ml. At baseline 2 patients (5.3%) had values between 0 to 10, 19 (50%) between 11 to 20 ng/ml and 17 (44.7%) between 21 to 31 ng/ml. The 25OHD levels post 1 to 3 months dose of vitamin D were: nobody had values under 10 ng/ml, 2 (5.3%) were between 11 to 20 ng/ml, 17 (44.7%) between 21 to 31 ng/ml and 19 (50%) had 25 OHD levels above 32

ng/ml.

There were not cases of hypercalcemia or hypercalciuria after treatment.

One or two new doses of vitamin D were prescribed in patients who did not reach optimal levels of vitamin D with the first treatment (this analysis was pending to complete all the data).

**Conclusion:** A unique dose of 100,000 IU D<sub>3</sub> was safe but insufficient since only 50% of patients reached the recommended 25OHD levels at the first 3 months of treatment. Additional doses have to be recommended to obtain normal levels in patients who continued with hypovitaminosis D.

## SU431

**Efficacy of the Vitamin D Supplementation in Patients with Hypovitaminosis D and Secondary Hyperparathyroidism.** E. Casado, M. Larrosa<sup>\*</sup>, I. Vázquez<sup>\*</sup>, C. Orellana<sup>\*</sup>, M. García-Manrique<sup>\*</sup>, J. Gratacós<sup>\*</sup>. Rheumatology, Hospital Sabadell, Sabadell, Spain.

**Purpose:** To analyze which proportion of patients with hypovitaminosis D and secondary hyperparathyroidism normalize PTH levels after on month of treatment with calcidiol. To analyze if the chronic treatment with vitamin D (calcidiol or cholecalciferol) is useful to maintain compensated the hyperparathyroidism of these patients.

**Methods:** Prospective, open-label study, with systematic inclusion of all patients with hypovitaminosis D (25(OH)D<sub>3</sub> < 25 ng/ml) and secondary hyperparathyroidism (PTH < 65 pg/ml), who were attended in the Rheumatology out-patient clinic during a two-year period. Patients with a suspected primary hyperparathyroidism or with renal failure were excluded. All the included patients were treated with calcidiol (16000 IU/week) during the first month (64000 IU). During the follow up the patients were randomized in two groups of treatment: calcidiol (16000 IU/3 weeks) or cholecalciferol (800 IU/day). 25(OH)D<sub>3</sub> and PTH levels were analysed after the first month of treatment with calcidiol, and after 3 months of the two-branch treatment.

**Results:** 61 patients with hypovitaminosis D and secondary hyperparathyroidism were included (53 female, 8 male). Mean age 74.5±7.8 years (45.5-88). The mean 25(OH)D<sub>3</sub> levels were 16.9±5.5 ng/ml and the PTH 101.6±44.5 pg/ml. After the first month of treatment with 64000 IU of calcidiol 61/61 (100%) of the patients normalized the 25(OH)D<sub>3</sub> levels (mean 88.9±26.1 ng/ml), although only 32/61 (52.5%) patients compensated the secondary hyperparathyroidism, with a mean of PTH 67.1±33 pg/ml (44.9±11.5 in the group who normalized the PTH levels vs 92.5±31.3 in the group who didn't). After 3 months of treatment with vitamin D we observed a decrease in the 25(OH)D<sub>3</sub> levels (61.8±24.4 ng/ml) and increase in the PTH levels (71.7±30.2 pg/ml), with 58% of patients with secondary hyperparathyroidism. Of the 32 patients that normalized PTH levels after the first month of treatment 39% had a high PTH after 3 months of treatment with vitamin D. We didn't find any difference between calcidiol or cholecalciferol respecting their efficacy to maintain PTH levels in the normal range after 3 months of treatment (40% and 38.5% of the patients treated with calcidiol and cholecalciferol failed to maintain normal PTH levels). **Conclusions:** The induction treatment with calcidiol 64000 IU/month is useful to normalize vitamin D levels in patients with hypovitaminosis D, but it seems insufficient to compensate the secondary hyperparathyroidism that have some of these patients. The long-treatment with vitamin D seems to be also unsuccessful to maintain PTH levels in the normal range in this population. <!--presmeth-->

**Red Flags Are Missed in the Prevention of Hip Fractures: Baseline Results of the Zurich Hip Fracture Trial.** H. A. Bischoff-Ferrari<sup>1</sup>, H. B. Staehelin<sup>\*2</sup>, B. Dawson-Hughes<sup>3</sup>, A. Platz<sup>\*4</sup>, U. Can<sup>\*4</sup>, S. Looser<sup>\*1</sup>, B. Bretschner<sup>\*5</sup>, R. Theiler<sup>\*5</sup>. <sup>1</sup>Rheumatology, University of Zurich, Zurich, Switzerland, <sup>2</sup>Geriatrics, University of Basel, Basel, Switzerland, <sup>3</sup>Tufts University, Boston, MA, USA, <sup>4</sup>Traumatology, Triemli StadtSpital, Zurich, Switzerland, <sup>5</sup>Rheumatology, Triemli StadtSpital, Zurich, Switzerland.

**Background:** From 1-2005 to 12-2007, we recruited 173 patients age 65 and older with acute hip fracture and a Folstein mini mental score of at least 15 into an ongoing double-blind RCT with vitamin D. 69% of hip fracture patients were admitted from home and 31% from institutions, 79% were women. Mean age was 86 year (± 6.9).

**Aim:** We present results from 3 self-reported "red flag" questions answered 3 to 7 days after the acute hip fracture that should have triggered vitamin D supplementation prior to the hip fracture event.

**Results:** Upon admission to acute care, only 12% of hip fracture patients enrolled had any dose of vitamin D including multivitamin formulations. Mean 25(OH)D was 31.3 nmol/l (± 19) in hip fracture patients admitted from home and 33.3 nmol/l (± 23) in those from institutionalized care. 51% of hip fracture patients admitted from home and 54% admitted from institutions had severe vitamin D deficiency (25(OH)D of less than 30 nmol/l). 48% of hip fracture patients admitted from home and 51% of those admitted from institutions reported that they had a previous fracture outside the hip prior to the acute hip fracture event. Of those admitted from home, 29% reported that they had fallen rarely and 20% that they had fallen repeatedly in the last 6 month prior to the acute hip fracture event. Similarly, of those admitted from institutions, 27% reported that they had fallen rarely and 34% that they had fallen repeatedly in the last 6 month prior to the acute hip fracture event. Furthermore, 33% of those admitted from home and 24% from institutions reported that

they felt weakness in their legs 6 months prior to their acute hip fracture event.

**Conclusion:** Vitamin D supplementation for the prevention of falls and fractures is recommended in several guidelines, however, according to our data collected between 2005 and 2007, guideline practice is still low. The positive report of red flags including previous fractures, previous falls, and muscle weakness is common in patients with acute hip fracture and may help increase guideline practice in older individuals.

### Wintertime Vitamin D Supplementation Inhibits Seasonal Variation of Calcitropic Hormones and Maintains Bone Turnover In Healthy Men. H. T. Viljakainen<sup>\*1</sup>, M. Väisänen<sup>\*1</sup>, V. Kemi<sup>\*1</sup>, T. Rikkinen<sup>2</sup>, H. Kröger<sup>3</sup>, E. K. A. Laitinen<sup>\*4</sup>, C. Lamberg-Allardt<sup>1</sup>.

<sup>1</sup>Department of Applied Chemistry and Microbiology, division Nutrition, University of Helsinki, Helsinki, Finland, <sup>2</sup>Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, <sup>3</sup>Department of Surgery, Kuopio University Hospital, Kuopio, Finland, <sup>4</sup>Department of Obstetrics and Gynaecology, Helsinki University Central Hospital, Helsinki, Finland.

Vitamin D is suggested to have a role in the coupling of bone resorption and formation. The association between bone mineral density (BMD) and vitamin D status is evident among men. Compared with women, men are believed to have more stable bone turnover, and thus, are considered less susceptible to the seasonal variation of calcitropic hormones. We examined whether seasonal variation exists in calcitropic hormones, bone remodelling markers and BMD in healthy men. Furthermore, we determined which vitamin D intake is required to prevent this variation.

Subjects (N=54) comprised healthy Caucasian men aged 21-49 years, with a mean (SD) habitual dietary intake of vitamin D of 6.6 (5.1) µg/d. This was a 6-month double-blinded vitamin D intervention study, in which subjects were allocated to three groups of 20 µg (800 IU), 10 µg (400 IU), or placebo. Randomization was performed (by age, weight, initial S-25-OHD status and dietary intake of vitamin D) into three groups. The trial lasted from November to April, altogether 26 weeks. Fasting blood samplings were collected six times for analyses of serum 25-OHD, PTH, BALP and TRACP. Radial volumetric BMD was measured at the beginning and end of the study with pQCT.

Wintertime variation was noted in S-25-OHD, PTH and TRACP (p<0.001, p=0.012 and p<0.05, respectively), but not in BALP or vBMD in the placebo group. Until the 20-week time point, vitamin D supplementation increased the S-25-OHD concentration dose-dependently, the mean dose-response being 1.55 (1.24) nmol/l/µg. Supplementation inhibited the winter elevation of PTH (p=0.035), decreased the BALP concentration (p=0.044), but did not affect TRACP.

Healthy men are exposed to wintertime decrease in vitamin D status that impacts PTH concentration. Ratio of TRACP/BALP and their correlation illustrate the coupling of bone remodelling in a robust way. The coupling was maintained in vitamin D supplemented groups, but not in the placebo group. Although the results concerning radial vBMD hardly showed a tendency towards benefit, our study supports the prevailing data of the benefits of vitamin D. A total intake of 17 µg of vitamin D is required to prevent season-related changes both in calcitropic hormones and in bone turnover among healthy men.

## SU434

### The Efficacy and Safety of Short Term Treatment with Different Doses of Cholecalciferol on 25-Hydroxy Vitamin D Levels in Postmenopausal Females with Osteoporosis. H. C. Hoeck<sup>\*1</sup>, B. Li<sup>\*2</sup>, P. Qvist<sup>\*2</sup>. <sup>1</sup>CCBR, Aalborg, Denmark, <sup>2</sup>Nordic Bioscience, Herlev, Denmark.

The study was performed on the baseline data from a cohort of 433 ambulatory postmenopausal females (mean age 68.5 y) screened between March 2007 and March 2008 for participation in an osteoporosis study. Main inclusion criteria was a DEXA-scanning demonstrating osteoporosis as defined by a T-score below - 2.5 SD or between - 1.0 and - 2.5 SD and at least one osteoporotic fracture. An amendment included a new FDA guideline to change the lower acceptable limit of 25-hydroxy vitamin D (25(OH)D) for inclusion to 60 nmol/L. Subjects with a 25(OH)D < 60 nmol/L were allowed to be substituted with vitamin D and the biochemistry retested. This study reports on the efficacy and safety of oral treatment with 25 µg (N=22; mean age: 70.6 y), 50 µg (N=19; mean age: 66.7 y), 75 µg (N=19; mean age: 68.7 y), 100 µg (N=41; mean age: 70.0 y) or 200 µg (N=30; mean age: 66.9 y) of cholecalciferol daily for 10 days. In the group of subjects treated with 25 µg of cholecalciferol daily 25(OH)D increased significantly from 32.4±2.7 nmol/L (mean±SEM) to 50.8±2.9 nmol/L. In the groups treated with 50 µg, 75 µg, 100 µg and 200 µg of vitamin D3 daily 25(OH)D concentrations increased significantly from 46.7±2.8 nmol/L to 65.8±2.6 nmol/L, from 41.6±2.7 nmol/L to 67.4±2.9 nmol/L, from 46.7±1.4 nmol/L to 64.4±2.2 nmol/L and from 42.1 ± 2.0 nmol/L to 71.2 ± 2.8 nmol/L respectively (P < 0.001 for all groups). Seventy-one, 37, 37, 40 and 27 %, respectively, had a 25(OH)D level below 60 nmol/L in response to the five different doses of cholecalciferol. In the 25 µg, 100 µg and 200 µg group s-calcium increased within the reference range (P<0.006) whereas PTH only decreased in the 25 µg group (P=0.004). Apart from a significant increase in alkaline phosphatase (AP) in the 50 µg group (P=0.003) and in creatinine in the 200 µg group (P=0.023) no changes in AP or creatinine was observed in any of the other groups (P>0.1). No adverse events were observed during treatment with any dose of vitamin D. In conclusion, 10 days of treatment with 25 µg, 50 µg, 75 µg, 100 µg or 200 µg of vitamin D3 was safe and increased 25(OH)D levels significantly although

responses were variable. In order to increase in 25(OH)D levels above 60 nmol/L in all subjects our data indicate that the treatment period should be extended beyond 10 days rather than to increase the daily dose of vitamin D3 further. Future strategies for correction of vitamin D insufficiency on a short term basis should take this information in to consideration.

### Male and Female Cynomolgus Monkey Models of Osteoporosis: Comparative In Vivo Data. N. Doyle<sup>\*1</sup>, S. Y. Smith<sup>1</sup>, K. A. Veverka<sup>2</sup>, <sup>1</sup>Charles River Laboratories, Senneville, QC, Canada, <sup>2</sup>GTx, Inc, Memphis, TN, USA.

Osteoporosis in women is often a consequence of menopause while in men it can be associated with hypogonadism or a consequence of androgen deprivation therapy for patients with prostate cancer. Ovariectomized (OVX) and orchidectomized (ORX) aged non-human primates are proposed surgically-induced models to evaluate drugs for the treatment or prevention of osteoporosis. Data from Sham and gonadectomized (OVX and ORX) animals were derived using the same instruments and assays and compared. The effects of OVX/ORX were monitored *in vivo* for 16 months using DXA, pQCT and biochemical markers of bone turnover. Cynomolgus monkeys aged ≥ 9 years old from both sexes (13 to 15 females/group [previously reported in Bone 2003, 32:45-55] and 20 males/group) were obtained from established colonies in the USA or Mauritius and assigned to two groups by whole body bone mineral content for each gender. The effects of OVX and ORX were evident for all *in vivo* parameters measured as early as 4 months following gonadectomy when compared to Sham controls and baseline values. Relative to controls, decreases were obtained in lumbar spine DXA BMD of 10 and 9%, and 11% and 16% at the femoral neck, for females and males, respectively. Decreases in trabecular BMD measured by pQCT at the proximal tibia were also similar (-17 to 20%) for both sexes. Over the study period, endosteal circumference was increased for both OVX and ORX animals compared to Sham whereas the changes in periosteal circumference (and total slice area) were minimal. Increased endosteal resorption for gonadectomized animals resulted in decreases in cortical thickness of the tibial diaphysis of 5 to 6%. Biochemical markers were elevated with maximal levels noted after 4 to 8 months for males (up to 6 X higher) and 8 to 12 months for females (up to 3 X higher). Body weights for females were unaffected by OVX, however for males body weight decreased by 20% in the first 4 months following ORX and then stabilized. This was associated with a decrease in muscle area measured by pQCT of -18% compared to baseline. In conclusion, both OVX and ORX were associated with bone activation as evidenced by increases in biochemical markers of bone turnover and loss of bone mass measured by densitometry techniques. Tibial cortical thinning attributed to endosteal expansion was observed in both sexes. In males, bone loss may be secondary to the loss of muscle mass following ORX. These data support the use of both genders as models of osteoporosis in the preclinical evaluation of potential bone anabolic or anti-catabolic agents.

### Osteoporosis in the Aging Males after Hip Fracture. W. Misiorowski<sup>\*</sup>, M. Rabijewski<sup>\*</sup>, W. Zgliczynski<sup>\*</sup>. Endocrinology Dept., Medical Centre for Postgraduate Education, Warsaw, Poland.

While most studies of osteoporosis have focused on postmenopausal women, older men are also at increased risk of fragility fractures. However, yet even with a comprehensive evaluation, approximately 40% of men with osteoporosis have no identifiable risk factor or cause.

**Objective:** The aim of the study was to determine risk factors or cause of osteoporosis in males after hip fracture.

**Material and methods:** We studied 97 men, aged 69 to 89 years old, recently after low-trauma hip fracture. Bone mineral density (BMD) of nonfractured hip was measured using DXA. The serum calcium, PTH-intact, 25-OHD3, LH, FSH, testosterone and estradiol levels were measured.

**Results:** 53 men (59.5%) were current smokers, next twelve had smoked previously. 9% reported no alcohol intake, while 15 men had a history of alcohol abuse. Previous nontraumatic vertebral fracture was reported by 15 men. Nearly all of the men were categorized as osteoporotic at the nonfractured hip defined as BMD Tscore -2.5 or less. 51.7% of the subjects had hypovitaminosis D (25-OHD < 20 ng/ml). Testosterone deficiency (< 3.5 ng/ml) was found in 42 hip fracture men (47.2%). In next thirteen serum testosterone was in low normal limits (3.5 to 4.0 ng/ml), however T/LH index was below 1.0.

**Conclusions:** Gonadal deficiency appears to be an important and heretofore understudied risk factor for hip fracture in men. Other important risk factors are smoking and hypovitaminosis D. Prevention of hip fractures in men may involve early recognition and treatment of testosterone deficiency.

**Disclosures:** W. Misiorowski, None.

## SU437

**Acute Change in Serum Ionized Calcium Directly Affects Bone Formation Independent of PTH Action During Hemodialysis.** S. Yano<sup>1</sup>, T. Yamaguchi<sup>1</sup>, K. Suzuki<sup>2</sup>, M. Sumi<sup>3</sup>, Y. Himeno<sup>3</sup>, T. Sugimoto<sup>1</sup>. <sup>1</sup>Department of Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan, <sup>2</sup>Otsuka Clinic, Izumo, Japan, <sup>3</sup>Himeno Clinic, Izumo, Japan.

Serum ionized calcium (iCa) and parathyroid hormone (PTH) levels are known to be dynamically changed during hemodialysis (HD) session. However, little is known about the effects of their acute changes on bone metabolism during HD. In this study, we addressed effects of changes in serum Ca and PTH on bone formation during HD session. In 100 patients undergoing maintenance HD therapy, blood samples were obtained before and after 4hr HD session to measure serum iCa, whole (w) and total (t) PTH, and procollagen type-1 amino-terminal propeptide (PINP, a bone formation marker). Ca concentration in dialysate was 3.0 mEq/l in 50 patients and 2.5 mEq/l in the rest patients. wPTH and tPTH levels were significantly increased after HD session (183 to 211 pg/ml and 289 to 314 pg/ml, respectively,  $p < 0.0001$ ) with concomitant elevation in serum iCa level (2.57 to 2.76 mEq/l). On the other hand, serum PINP levels were significantly decreased during HD session (416 to 355 ng/ml). Simple regression analysis showed that change in serum iCa ( $\Delta$ iCa) was negatively and significantly correlated with change in wPTH ( $\Delta$ wPTH) ( $r = -0.566$ ,  $p < 0.0001$ ) and with change in tPTH ( $\Delta$ tPTH) ( $r = -0.550$ ,  $p < 0.0001$ ) during HD session, and that % change in PINP was positively and significantly correlated with  $\Delta$ iCa ( $r = 0.298$ ,  $p < 0.0001$ ), and negatively and significantly with  $\Delta$ wPTH ( $r = -0.337$ ,  $p = 0.0006$ ). When multiple regression analysis was performed with  $\Delta$ iCa and  $\Delta$ wPTH as independent variables and % change in PINP as a dependent variable,  $\Delta$ iCa, but not  $\Delta$ wPTH, was selected as an index affecting % change in PINP ( $p < 0.0001$ ). The present study suggests that during HD session, although acute change in serum iCa negatively correlates with that in PTH, increase in iCa itself might directly augment bone formation independent of PTH action.

**Disclosures:** S. Yano, None.

**Hemodialysis Patients Rapidly Lose Their Bone Minerals After 60 Years of Age.** M. Ohsawa<sup>1</sup>, K. Itai<sup>1</sup>, K. Tanno<sup>1</sup>, K. Kato<sup>2</sup>, Y. Fujishima<sup>2</sup>, R. Konda<sup>2</sup>, T. Fujioka<sup>2</sup>, T. Onoda<sup>1</sup>, K. Sakata<sup>1</sup>, F. Yamauchi<sup>3</sup>, M. Fujishima<sup>4</sup>. <sup>1</sup>Hygiene and Preventive Medicine, Iwate Medical University, Morioka, Japan, <sup>2</sup>Department of Urology, Iwate Medical University, Morioka, Japan, <sup>3</sup>Division of Internal Medicine, San-ai Hospital, Morioka, Japan, <sup>4</sup>Division of Urology, San-ai Hospital, Morioka, Japan.

End-stage renal disease is commonly accompanied by abnormal mineral metabolism and abnormal bone metabolism. The purpose of this study is to determine age-specific mean levels of bone mineral density (BMD) and annual changes in BMD among adult Japanese hemodialysis patients. A total of 84 hemodialysis patients (66 men and 18 women) were enrolled. BMD was re-measured in each patient at least six months after initial examination. Densitometry of radial bone was evaluated using dual-energy X-ray absorptiometry (DXA) with DCS-600EX (Aloka Japan). Patients were divided into 4 age-specific groups (20-49, 50-59, 60-69, 70 years or older). Annual percent change in BMD was estimated in each patient. Mean levels of the latest BMD, the latest T score (expressed as percent of YAM), and annual percent changes in BMD were determined in each age group. Mean levels of BMD, T score, and % changes in BMD in each group were shown in the Table. Mean levels of BMD, and T score were low among hemodialysis patients aged 60 years or older. Annual changes of their BMD were -2.1% in 20-50's and -2.8% in 60's and -5.9% in 70's or older. These data suggest that hemodialysis patients rapidly lose their bone minerals after 60 years of age.

Mean levels of BMD, percent of YAM, and annual change of BMD				
Age-group	(subjects)	BMD (g/cm <sup>2</sup> )	% of YAM	Change of BMD (%/year)
20-49	(n=11)	0.657 $\pm$ 0.127	87.5 $\pm$ 14.8	-2.0
50-59	(n=18)	0.719 $\pm$ 0.069	94.0 $\pm$ 8.6	-2.1
60-69	(n=27)	0.572 $\pm$ 0.134	76.7 $\pm$ 14.4	-2.8
$\geq 70$	(n=28)	0.551 $\pm$ 0.164	73.6 $\pm$ 18.8	-5.9

**Kidney Dysfunction Disturbs Collagen Maturation in Adynamic Bone Disease as Assessed by Confocal Laser Raman Spectroscopy.** Y. Iwasaki<sup>1</sup>, H. Yamato<sup>2</sup>, M. Fukagawa<sup>3</sup>. <sup>1</sup>Health Sciences, Oita University of Nursing and Health Sciences, Oita, Japan, <sup>2</sup>Development, Kureha Special Laboratory Co, Ltd., Fikushima, Japan, <sup>3</sup>Nephrology & Dialysis center, Kobe University, Kobe, Japan.

Adynamic bone disease (ABD), which is a major type of renal osteodystrophy, is highly prevalent in chronic kidney disease. ABD has lowered bone formation and is associated with increased fracture rates, and brittle calcium control. However, it still remains unknown why fracture rates increases in ABD. On the other hand, we have already established an ABD model in rats. In addition, we reported that the low turnover bone was induced by uremic toxin which accumulated in blood associated with reducing renal function, because of the toxic effect of uremic toxin to osteoblast. In the present study,

evaluating the bone quality of ABD, we evaluated the mineral-matrix ratio and a couple of matrix-related parameters by confocal laser raman spectroscopy. As for the ABD model, after male SD rats underwent thyroparathyroidectomy (TPTx), they underwent 5/6 nephrectomy (Nx) or sham operations. These rats were continuously infused with rat PTH and injected with L-thyroxine subcutaneously to maintain physiological levels. Therefore TPTx-Nx rats can simulate ABD, because of their low turnover bone associated with the suppression of renal function. Groups were ABD (TPTx-Nx) and control (TPTx-sham). Recently, it has become easier to obtain spectroscopic properties from bone with a laser raman spectroscopy system (Nicolet Almega XR, Thermo Fisher Scientific Co.). We can get much information about the matrix in bone and we can also evaluate local change of bone contents by this system. Concerning As the results, mineral-matrix [PO4/Amid I] ratio, hydroxyl proline-proline [Hypro/pro] ratio, and a parameter of collagen crosslink in ABD revealed lower values compared with control. Particularly, Hypro/pro and collagen crosslink in ABD were 12% and 21% to control respectively. From the histomorphometry, the osteoblast surface and mineral apposition rate were decreased in ABD. The bone formation rate in ABD reduced to 8% of control. The bone mineral density of tibial metaphysis and diaphysis were not significantly different between the two groups. These results suggest that kidney dysfunction inhibits collagen maturation and suppressed bone turnover. Those matrix changes affect bone fragility and could lead to increase fracture risk without bone loss.

**Disclosures:** Y. Iwasaki, None.

**Serum Ionic Fluoride Levels among Hemodialysis Patients are Positively Associated with Levels of Serum Phosphate and Intact PTH.** K. Tanno<sup>1</sup>, M. Ohsawa<sup>1</sup>, K. Itai<sup>1</sup>, T. Onoda<sup>1</sup>, K. Sakata<sup>1</sup>, K. Kato<sup>2</sup>, Y. Fujishima<sup>2</sup>, R. Konda<sup>2</sup>, T. Fujioka<sup>2</sup>, F. Yamauchi<sup>3</sup>, M. Fujishima<sup>3</sup>, A. Okayama<sup>4</sup>. <sup>1</sup>Department of Hygiene and Preventive Medicine, Iwate Medical University, Morioka, Japan, <sup>2</sup>Department of Urology, Iwate Medical University, Morioka, Japan, <sup>3</sup>San-ai Hospital, Morioka, Japan, <sup>4</sup>The First Institute of Health Service, Japan Anti-Tuberculosis Association, Tokyo, Japan.

We previously reported that serum ionic fluoride (SIF) levels were extremely higher in adult hemodialysis patients than in normal controls. The aim of this study is to clarify whether excess levels of serum fluoride in hemodialysis patients are associated with abnormal bone and mineral metabolism. A total of 83 hemodialysis patients (65 men and 18 women) were enrolled. Bone mineral density (BMD) in the radius was evaluated using dual-energy X-ray absorptiometry (DXA) with DCS-600EX (Aloka Japan). Blood sampling was performed at the beginning of the dialysis session. Serum calcium (Ca) and phosphate (P) levels were determined by enzymatic assays. Levels of intact parathyroid hormone (iPTH) were determined by Electrostatic Controlled Linear Inchworm Actuator (ECLIA). SIF levels were determined by the flow injection method with an ion selective electrode. Patients were divided into tertile groups according to SIF levels. Sex- and age-adjusted mean levels of Ca (mg/dL), logarithm transformed P (geometric mean, mg/dL), logarithm transformed iPTH (geometric mean, pg/mL) and BMD (g/cm<sup>2</sup>) were calculated in each group. Mean age of patients was 65.8 years. Crude mean SIF level was 60.9  $\mu$ g/L. SIF levels were positively related to serum P levels and iPTH levels after sex and age adjustment. However, SIF levels were not related to serum Ca levels and BMD. (See table) These findings suggest that elevated SIF levels reflect activated bone mineral metabolism due to hyperphosphatemia and hyperparathyroidism.

	Sex- and age-adjusted mean level (95% CI) of each variable by the tertile groups according to SIF			trend P
	T1	T2	T3	
Range of SIF, $\mu$ g/L	30.3-47.7	48.0-58.2	59.1-487.8

**Kidney Disease is Associated with Abnormal Cortical Geometry Independent of Age and Gender.** T. L. Nickolas<sup>1</sup>, E. A. Stein<sup>1</sup>, V. Thomas<sup>1</sup>, H. F. Eisenberg<sup>1</sup>, D. J. McMahon<sup>1</sup>, M. B. Leonard<sup>2</sup>, E. Shane<sup>1</sup>. <sup>1</sup>Medicine, Columbia University, New York, NY, USA, <sup>2</sup>Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Chronic kidney disease (CKD) and osteoporosis (OP) are highly co-prevalent in the elderly. Although both CKD and OP result in increased fracture risk, the mechanisms of bone fragility may differ. Both CKD and aging are associated with secondary hyperparathyroidism, which has catabolic effects on cortical (Ct) bone. Estrogen deficiency, which affects both postmenopausal women and, to a lesser extent, older men, may have a greater impact on trabecular (Tb) bone. High resolution quantitative CT (HRpQCT) (XtremeCT, Scanco Medical AG, resolution 82  $\mu$ m) provides discrete measures of Ct and Tb microarchitecture in vivo. To assess the effects of CKD on Ct and Tb bone, we are conducting a cross-sectional study in older adults across a spectrum of kidney function. We hypothesized that Ct bone abnormalities

would predominate in patients with more advanced CKD.

To date, we have evaluated 76 subjects (33 women), ages 50-88. The MDRD formula was used to estimate GFR (eGFR), based upon serum creatinine, age, gender and race. 19 subjects were on dialysis and 27 had an eGFR > 60 mL/min. Among the rest, the median eGFR was 31 mL/min (range, 15-58). Univariate analyses demonstrated that abnormal Tb microstructure (low density, bone volume fraction, Tb number, thickness and increased separation) were significantly associated with female gender. Decreased Ct thickness and density were significantly associated with lower eGFR and older age. Multiple linear regression was used to determine the relationship between HRpQCT microarchitectural parameters and eGFR, adjusted for age and gender. Both Ct density and thickness were correlated with eGFR and age. Tb microarchitecture parameters remained associated with female gender (Table 1).

HR-pQCT Measurements	MDRD $\beta$ -coefficient	se	p-value	Age $\beta$ -coefficient	Se	p-value	Gender (female) $\beta$ -coefficient	se	p-value
Cortical Density (mg HA/cm <sup>3</sup> )	0.0013	0.0004	0.003	-0.0046	0.001	0.001	-0.0232	0.03	0.3
Cortical Thickness ( $\mu$ m)	0.0033	0.001	0.01	-0.0112	0.004	0.01	-0.2149	0.08	0.01
Trabecular Density (mg HA/cm <sup>3</sup> )	-0.0004	0.002	0.8	-0.0055	0.005	0.2	-0.3035	0.09	0.002
Trabecular Volume (%)	-0.0004	0.002	0.8	-0.0056	0.005	0.2	-0.3026	0.09	0.002
Trabecular Number (n/mm)	-0.0005	0.001	0.6	-0.0021	0.003	0.5	-0.1690	0.07	0.01
Trabecular Thickness ( $\mu$ m)	0.0001	0.001	0.9	-0.0033	0.003	0.2	-0.1320	0.05	0.02
Trabecular Separation ( $\mu$ m)	0.0006	0.001	0.6	0.0029	0.004	0.5	0.2080	0.07	0.01
Trabecular Separation Standard Deviation ( $\mu$ m)	0.0007	0.002	0.7	0.0054	0.007	0.4	0.3581	0.1	0.01

These data confirm that low kidney function is associated with lower Ct thickness and density, independent of age and gender. The data also confirm that female gender is associated with alterations in Tb microarchitecture and lower Ct density, independent of kidney function and age. Alterations in both Ct and Tb structure likely contribute to the increased risk of fragility fracture observed in patients with CKD and end stage kidney disease. Further studies are required to elucidate the pathogenesis of these microarchitectural abnormalities and their relationship to bone strength.

**Albuminuria, 25-Hydroxyvitamin D, 1,25-Dihydroxyvitamin D, and intact Parathyroid Hormone in Older Adults: The Rancho Bernardo Study.** S. K. Jassal<sup>\*1</sup>, M. Chonchol<sup>\*2</sup>, D. von Muhlen<sup>\*3</sup>, E. Barrett-Connor<sup>3</sup>. <sup>1</sup>Medicine, UCSD & VASDHS, San Diego, CA, USA, <sup>2</sup>Medicine, UCHSC, Denver, CO, USA, <sup>3</sup>Family & Preventive Medicine, UCSD, La Jolla, CA, USA.

**Purpose:** Mild declines in estimated glomerular filtration rate (eGFR < 60mL/min/1.73m<sup>2</sup>) are associated with decreased serum levels of 25-hydroxyvitamin D (25(OH)D) and 1,25-dihydroxyvitamin D (1,25(OH)<sub>2</sub>D) and increased intact parathyroid hormone (iPTH); treatment with 1,25(OH)<sub>2</sub>D reduces albuminuria. However, the association between albuminuria, an earlier marker of kidney dysfunction, and these three mineral metabolites has not been investigated.

**Methods:** A cross-sectional study of community dwelling, older adults (411 men and 662 women) from Southern California evaluated in 1997-1999. Serum levels of 25(OH)D, 1,25(OH)<sub>2</sub>D and iPTH and urine albumin and creatinine were measured on morning specimens.

**Results:** Mean age was 75 years; mean eGFR 74mL/min/m<sup>2</sup>, and median urine albumin/creatinine ratio (ACR) 6mg/g. Median serum levels of 25(OH)D, 1,25(OH)<sub>2</sub>D, and iPTH were 40ng/mL, 29pg/mL, and 46pg/mL, respectively and median serum levels by ACR quartile are shown in the Figure. In unadjusted analyses, there was a significant inverse association between increasing quartile of urine ACR and 25(OH)D (p for trend=0.001) and direct association with iPTH (p=0.004), but not 1,25(OH)<sub>2</sub>D (p=0.295). After adjusting for age alone, or multiple covariates including age, sex, body mass index, eGFR, systolic blood pressure, and fasting plasma glucose (Table), only iPTH continued to be significantly associated with urine ACR quartiles (age only, p = 0.04; all covariates p= 0.028). In a subset of 893 participants without diabetes, there was no significant association between any marker of mineral metabolism and ACR quartile.

**Conclusions:** ACR was independently associated with iPTH but not 25(OH)D or 1,25(OH)<sub>2</sub>D, in community dwelling older participants in Southern California. This association was not found in those without diabetes.

Adjusted mean levels of 25(OH)D, 1,25(OH) <sub>2</sub> D and iPTH by quartile of ACR					
Adjusted* mean by ACR quartile (mg/g)	1 ≤3.3	2 3.4-6.3	3 6.3-14.2	4 ≥14.3	p for trend

**Postprandial Hyperphosphatemia Is a Novel Risk Factor for Cardiovascular Disease by Involving Endothelial Dysfunction.** E. Shuto<sup>\*1</sup>, Y. Taketani<sup>1</sup>, R. Tanaka<sup>\*1</sup>, A. Tanimura<sup>\*1</sup>, T. Uebanso<sup>\*1</sup>, M. Isshiki<sup>\*2</sup>, N. Harada<sup>\*3</sup>, H. Yamamoto<sup>1</sup>, Y. Nakaya<sup>\*3</sup>, E. Takeda<sup>1</sup>. <sup>1</sup>Department of Clinical Nutrition, University of Tokushima Graduate School, Tokushima, Japan, <sup>2</sup>Department of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan, <sup>3</sup>Department of Nutrition and Metabolism, University of Tokushima Graduate School, Tokushima, Japan.

Hyperphosphatemia is closely associated with progress of cardiovascular disease and mortality in end-stage renal disease patients. It has been well known that hyperphosphatemia causes vascular calcification. Furthermore, recently overintake of phosphorus (P) has been speculated a risk of cardiovascular disease (CVD) in healthy persons as well as chronic kidney disease patients. We have hypothesized that hyperphosphatemia may also contribute to the progress of atherosclerosis on early-stage chronic kidney disease by involving endothelial dysfunction. Previously, we reported that high P-loading increased production of reactive oxidative species and decrease nitric oxide (NO) availability in endothelial cells. In this study, we investigated the effect of dietary P-loading on endothelial function in healthy male volunteers. Eleven healthy male volunteers were alternately served either P400 meal (400mg P/meal) or P1200 meal (1200mg P/meal), and measured biochemical markers in the blood and flow-mediated dilation (%FMD) of brachial artery before and at 2h after the meal ingestion (double-blinded crossover study). While serum P level significantly increased at 2h after P1200 meal ingestion, %FMD significantly decreased (P<0.001), but not after P400 meal ingestion. Negative correlation was detected between %FMD and serum P. All other biomarkers were within normal range in the preprandial and postprandial status, and above changes were dependent on serum P level. Additionally, we investigated the effect of high P-loading on the endothelium-dependent vasodilation by using rat aortic ring. Correspondingly high P-loading significantly decreased endothelium-dependent vasodilation in the rat aortic ring. These results suggest that dietary P-loading can cause endothelial dysfunction in human as well as animal model. This may offer an additional explanation of the relationship between higher serum P level and CVD risk or mortality as epidemiologically observed. This study was approved by Ethics Committee of our university hospital and by Animal Experimentation Committee of our university.

**A Therapy with Alfacalcidol Leads to a Significant Increase in Muscle Power and Balance.** L. C. Dukas<sup>\*1</sup>, E. Schacht<sup>2</sup>, M. Runge<sup>\*3</sup>. <sup>1</sup>Acute Geriatric University Clinic, Kantonsspital Basel, Basel, Switzerland, <sup>2</sup>ZORG Zurich Osteoporosis Research Group, Zurich, Switzerland, <sup>3</sup>Aerpah Klinik, Esslingen, Germany.

In an open prospective study we investigated the effect of Alfacalcidol (Bondiol®) on muscle power and balance in German patients with a Creatinine Clearance of <65ml/min., diagnosed to be at an increased risk of falls. Therefore patients underwent 3 monthly, different muscle power and balance tests for 6 months. Here we present the results for the Timed-Up and Go test (TUG).

The performance in the TUG was assessed as follows: the ability to successfully perform the TUG (<12sec.) (A), non successful performance in the TUG (>12sec.) (B), and the inability to perform the TUG (C), a non successful performance of the TUG being associated with an increased risk of falls. 261 patients (17.6% men and 82.4% women / mean age: 75.9 years / mean BMI: 26.3kg/m<sup>2</sup>) participated in this study.

Controlled for age, gender and BMI, a treatment with Alfacalcidol was associated with a significantly increased performance in the TUG (p<.0001): after 6 months the number of patients who successfully performed the TUG was significantly increased from 29.9% of the population to 51.7% (from N=78 to 135), a significant 73% increase. Also in group C we observed a significant improvement, corresponding to 12.8% decrease in the number of patients who at baseline were not able at all to perform the TUG. The mean time for the TUG performance was significantly diminished by 2.0sec. from 16.1sec at baseline to 14.1sec after 6 months.

We conclude therefore that a treatment with Alfacalcidol increases muscle power and balance as measured with the TUG. The number of patients who at baseline did not successfully perform the TUG and were therefore at an increased risk of falls, was diminished considerably under the treatment with Alfacalcidol.

For the practitioner the TUG is a validated test to monitor the risk of falls under the treatment with Alfacalcidol and therefore to document the therapeutic success of the treatment with Alfacalcidol.

Significant Improvement in TUG Performance under a 6 month therapy with Alfacalcidol			
TUG performance	at baseline	after 3 month	after 6 month
unable (N)	47	46	41

## SU445

**Serum Intact PTH of 100 to 150 pg/ml Is Associated with Greatest Survival in Maintenance Hemodialysis Patients.** M. Rambod<sup>\*1</sup>, S. Sprague<sup>2</sup>, K. Kalantar-Zadeh<sup>\*1</sup>. <sup>1</sup>Nephrology and Hypertension, Los Angeles BioMedical Research Institute, Torrance, CA, USA, <sup>2</sup>Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

**Background:** The Kidney Disease Outcome Quality Initiative (KDOQI) guidelines recommended intact (i) PTH of 150 to 300 pg/ml as the target range for maintenance hemodialysis (MHD) patients (pts) is higher than the normal iPTH (<65 pg/ml). We hypothesized that lower than the KDOQI recommended iPTH range is associated with greatest survival in MHD pts. **Methods:** We examined the 5-yr (10/01-1/07) mortality-predictability of iPTH in 748 MHD pts after multivariate adjustment for case-mix (Model 1) and also for serum albumin, phosphorus and interleukin-6 levels (Model 2). **Results:** Pts, 54±15 yrs old, including 45% women, 32% Blacks and 55% diabetics, with median dialysis vintage of 20 months, had a median iPTH of 247 pg/ml (inter-quartile range: 159-408 pg/ml). During the 5-yr follow-up, 228 pts died. Cox proportional regression calculated hazard ratio (HR) and 95% confidence intervals for all-cause mortality across increments of serum PTH were lowest for iPTH between 100 and 150 pg/ml (Table & Figure).

Death Hazard Ratio (Ref: iPTH 300-600 pg/ml)				
Death hazard ratio (95% CI)	<100 pg/ml	100-149 pg/ml	150-199 pg/ml	200-249 pg/ml
Model 1	0.75 (0.48-1.18)	0.44 (0.26-0.75)	0.51 (0.31-0.83)	0.83 (0.53-1.31)
Model 2	0.72 (0.45-1.17)	0.52 (0.29-0.92)	0.61 (0.37-1.01)	0.87 (0.55-1.38)

**Conclusion:** Serum PTH level below the KDOQI range appears associated with the greatest survival in MHD patients even after controlling for case-mix, nutritional status and inflammation.

**Disclosures:** M. Rambod, None.

## SU446

**Association of the Marker of Adynamic Bone Disease with Malnutrition-Inflammation Complex in Hemodialysis Patients.** M. Rambod<sup>\*1</sup>, S. Sprague<sup>2</sup>, K. Kalantar-Zadeh<sup>\*1</sup>. <sup>1</sup>Medicine/Nephrology, Harbor-UCLA, Torrance, CA, USA, <sup>2</sup>Medicine/Nephrology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL, USA.

**Background:** In maintenance hemodialysis (MHD) patients, the adynamic bone disease, which is associated with adverse outcomes, is believed to be more likely when serum intact PTH (iPTH) level is below 150 pg/ml (as compared to the recommended target range of 150-300 pg/ml). We hypothesized that serum iPTH<150 pg/ml is associated with higher risk of malnutrition and inflammation in MHD patients. **Methods:** In 748 MHD patients of a 5-year cohort (10/01-12/06) we examined the association of serum iPTH with pro-inflammatory markers and the "malnutrition-inflammation score" (MIS), which is a score between 0 [normal] and 30 [most abnormal], consisting of 7 components of the Subjective Global Assessment of nutrition, and serum albumin, transferrin and body mass index (Am J Kidney Dis 2001; 38:1251-63). **Results:** Patients were 54±15 yrs (mean±SD) old and included 45% women, 32% Blacks and 55% diabetics, with a median dialysis vintage of 20 months. The mean, median, and inter-quartile (IQ) range of 4 relevant variables were: MIS: 4.9 [median: 4, IQ: 2-6]; interleukin-6 (IL-6): 17.5 [7.4, 4.1-14.3] ng/ml, C-reactive protein (CRP): 5.8 [3.7, 1.5-7.6] mg/L, and tumor-necrosis factor-α (TNF-α): 9.1 [6.0, 4.1-9.2] ng/ml. The MIS was higher (worse) in patients with lower serum iPTH (p=0.003) (Figure 1).

High levels of pro-inflammatory markers were associated with iPTH <150 pg/ml (compared to 150-300 pg/ml) (Figure 2 & Table).

Table - Odd Ratios of PTH<150 pg/ml in 460 pts with PTH<300 pg/ml

	IL-6>=5 (pg/ml)	CRP>=15 (mg/L)	TNF-alpha >=6 (pg/ml)
Unadjusted	1.44 (0.95-2.18)	1.99 (1.03-3.86)	1.56 (1.06-2.30)
Case-mix adjusted	1.49 (0.94-2.36)	1.91 (0.93-3.90)	1.66 (1.08-2.54)
Fully adjusted	1.58 (0.93-2.69)	2.01 (0.90-4.49)	1.68 (1.05-2.67)

**Conclusion:** Low serum iPTH<150 pg/ml, the presumed marker of adynamic bone disease, may be another facet of the malnutrition-inflammation-complex syndrome in MHD patients.

**Disclosures:** M. Rambod, None.

## SU447

**Osteopenia in Chronic Kidney Disease: Effects of Phosphate Overload.** E. G. Gracioli\*, L. M. dos Reis\*, D. G. Batista\*, R. M. A. Moysés\*, V. Jorgetti, K. R. Neves\*. Nephrology, University of São Paulo, São Paulo, Brazil.

Calcium, phosphate (P), parathormone (PTH) and calcitriol metabolism disturbances are commonly seen in chronic kidney disease (CKD) and are involved in the pathogenesis of renal osteodystrophy. It is difficult to understand the role of each one separately, since small serum variations are capable of triggering compensatory mechanisms that try to re-establish their normal concentrations. We evaluated the isolated effect of P on bone of CKD rats, kept on a fixed PTH infusion, altering the P content in their diet. Fifty-five male wistar rats were submitted to parathyroidectomy and 5/6 nephrectomy (Nx). PTH activity was restored by an osmotic minipump in continuous infusion of 1-34 rat PTH (0.022µg/100g/hour-PTHn or 0.11µg/100g/hour-PTHh) or were sham-operated and received vehicle. P content (low P- LP= 0.2%; high P- HP= 1.2%) differentiated diets. We divided the groups as follow: sham; shamLP; PTHnNxLP; PTHhNxLP; shamHP; PTHnNxHP; PTHhNxHP. After 2 months, biochemistry and bone histomorphometry were analyzed. The Nx groups that were fed a P-rich diet presented higher P levels, as well as lower levels of calcium than those that were fed a diet poor in P. Histomorphometric analysis revealed that the rats were fed a P-rich diet (shamHP; PTHnNxHP; PTHhNxHP) presented lower trabecular volume (BV/TV) than their counterparts. This effect was minimized in the animals that received a high PTH infusion. **CONCLUSIONS:** P overload was associated with a decrease in trabecular bone volume. In those animals that received a high PTH infusion, this effect was minimized. Our findings demonstrated that P overload is hazardous to bone architecture and that uremia requires higher PTH levels to keep the bone integrity. The molecular basis of the effect of P overload on bone should be elucidated in further studies.

**Comparison of 1,25-dihydroxyvitamin D<sub>2</sub> and Calcitriol Effects in an Adenine-induced Model of CKD Reveals Differential Control Over Serum Calcium and Phosphate.** C. Helvig\*, D. Cuerrier\*, A. Kharebov\*, B. Ireland\*, J. Kim\*, K. Ryder\*, M. Petkovich. Cytochroma Inc., Markham, ON, Canada.

Calcitriol and related synthetic analogs have been used extensively in the clinic to control secondary hyperparathyroidism (SHPT) associated with chronic kidney disease (CKD) with the goal of minimizing the impact of disturbances of mineral metabolism and chronic elevation of parathyroid hormone levels on bone. Replacement therapy using active hormone can alter mineral balance leading to hypercalcemia and phosphatemia resulting in soft tissue mineralization. With the goal of identifying compounds with reduced toxicity, we have identified 1,25-dihydroxyvitamin D<sub>2</sub> (1,25-(OH)<sub>2</sub>D<sub>2</sub>) as a promising therapeutic candidate with efficacy equal to that of calcitriol, but without the same level of toxicity.

For the testing of different vitamin D compounds, we established a model of experimental CKD based on feeding rats a diet containing 0.75% adenine for 4 weeks.

This is the first time that this model has been used to compare the effects of 1,25-(OH)<sub>2</sub>D<sub>2</sub> and calcitriol, a drug currently used in the treatment of CKD to control PTH levels, on plasma PTH, serum alkaline phosphatase, serum calcium and phosphorus and gene regulation in order to find potential differences between these two vitamin D compounds. Moreover, metabolism and the effect on gene regulation such as intestinal alkaline phosphatase (IAP) of 1,25-(OH)<sub>2</sub>D<sub>2</sub> and calcitriol was investigated *in vitro*.

We have shown that 1,25-(OH)<sub>2</sub>D<sub>2</sub> is as potent as calcitriol in decreasing plasma PTH levels. Serum calcium and phosphorus were elevated after treatment with both compounds, however 1,25-(OH)<sub>2</sub>D<sub>2</sub> required higher doses than calcitriol to reach significant elevation of serum calcium and phosphorus. In general, as shown by the animal weight gain and survival, 1,25-(OH)<sub>2</sub>D<sub>2</sub> was found to be less toxic than calcitriol. Using human intestinal microsomes, 1,25-(OH)<sub>2</sub>D<sub>2</sub> was more susceptible than calcitriol to metabolism. In Caco-2 cells, 1,25-(OH)<sub>2</sub>D<sub>2</sub> differentially regulated IAP and CYP24. These studies implicate metabolism as an important mechanism to differentiate 1,25-(OH)<sub>2</sub>D<sub>2</sub> from calcitriol. Thus, we have shown that 1,25-(OH)<sub>2</sub>D<sub>2</sub> is equally potent compared to calcitriol to decrease plasma PTH levels *in vivo*. However, 1,25-(OH)<sub>2</sub>D<sub>2</sub> was shown to be less toxic than calcitriol possibly due to greater instability in the intestine. This study demonstrates that 1,25-(OH)<sub>2</sub>D<sub>2</sub> could offer an advantage over calcitriol for the treatment of SHPT associated with CKD.

**Disclosures:** C. Helvig, None.

## SU449

**Osteopenia in Chronic Kidney Disease: Effects of Calcium Overload.** L. M. dos Reis\*, D. G. Batista\*, E. G. Gracioli\*, A. O. Magalhães\*, V. C. N. Gouveia\*, K. R. Neves\*, R. M. A. Moysés\*, V. Jorgetti. Nephrology, University of São Paulo, São Paulo, Brazil.

The use of calcium (Ca) salts to control phosphorus (P) retention has long been recognized as a key component in the clinical management of chronic kidney disease (CKD). However, some concerns had arisen because Ca salts were linked to PTH over suppression and vascular calcification. In addition, the direct effects of Ca on bone were rarely evaluated because Ca use is always associated with a decrease in PTH and in P. We studied the isolated role of Ca in bone tissue of CKD animals, maintained on a fixed PTH infusion, fed with different Ca content in their diet. Thirty four male Wistar rats were submitted to parathyroidectomy (PTX) and 5/6 nephrectomy (Nx). PTH activity was restored by an osmotic minipump in continuous infusion of 1-34 rat PTH (0.022µg/100g/hour) or were sham-operated and received vehicle. Ca content was differentiated in diets (low Ca-LCa = 0.02%; high Ca-HCa = 1.2%). We divided the groups as follows: Sham, ShamLCa, ShamHCa, NxLCa and NxHCa. After 2 months, biochemical and bone histomorphometry were performed. Animals in ShamLCa group presented higher PTH levels as well as lower Ca than their counterparts. Nx groups that were fed a high Ca diet presented higher Ca levels, as well as lower P than those fed with low Ca. Histomorphometric analysis showed that Ca restriction was associated with a mineralization defect whereas Ca overload was associated with a decrease in bone trabecular volume.

In conclusion, despite a better control of serum P and a maintained PTH level, Ca overload presented an osteopenic effect, suggesting that it should be used with caution, either in CKD or in the general population.

**The Protective Actions of Vitamin D Analogs in the Vascular Calcification of Chronic Kidney Disease (CKD).** S. Mathew\*, F. Strebeck\*, K. A. Hruska. Pediatrics, Washington University, St. Louis, MO, USA.

Careful analysis of the scientific literature leads to the strong conclusion that the dose response curve for vitamin D receptor activation (VDRA) is biphasic. Vitamin D intoxication, a well-known clinical situation, involves dermal calcification by VDRA. However, VDRA is required for normal physiology as demonstrated by genetic studies in mice rendered deficient of  $1\alpha$ -hydroxylase or the vitamin D receptor. Furthermore, correction of calcitriol deficiency has been shown to have efficacy in clinical medicine. The importance of the biphasic dose response curve for vitamin D receptor activators is called into focus by recent observational studies that suggest exposure to VDRA, paricalcitol and hectorol, improve survival and cardiovascular outcomes in dialysis patients. In examining vascular calcification, an important component of cardiovascular morbidity and mortality in ESKD, several studies suggest that VDRA stimulates vascular calcification. Here we report that lower doses of the VDRA are protective in atherosclerotic vascular calcification stimulated by CKD in high fat fed mice due to the effects of the VDR to inhibit osteoblastic gene expression, including inhibition of aortic RUNX2, MSX2 and osterix expression. Studies in vitro demonstrate that low dose VDRA inhibit calcifying vascular smooth muscle cell cultures by decreasing osteoblastic gene transcription whereas higher doses fail to do so, thereby becoming permissive for the actions of oxidant injury. Furthermore, in mice with high levels of vascular calcification, VDRA stimulates bone formation rates, and in vitro, stimulate, not inhibit, osteoblastic function of bone marrow derived progenitors. The basis of these differential actions of VDRA in vascular versus skeletal osteoblastic cells lies in the cell fate step in differentiation to the contractile vascular smooth muscle cell. The mechanism of the actions of low-dose VDRA are shown in the studies reported here. Through activation of vascular smooth muscle cell differentiation, osteoblastic differentiation is repressed and vascular calcification is inhibited. We conclude that at low appropriate doses VDRA is protective against cardiovascular calcification in CKD.

**Reduction of Bone Mineral Density in the Patients with Rheumatoid Arthritis Is More Remarkable at Proximal Femur than at Lumbar Spine.** N. Hisanori\*, F. Hagiwara\*, S. Tohma\*. Department of Rheumatology, Sagami-hara National Hospital, Sagami-hara, Kanagawa, Japan.

**Objective:** Rheumatoid arthritis (RA) patients have different rates of bone mass loss at different bone sites during RA progression, with different mechanisms operating at each site. Here, we measured the bone mineral density (BMD) of the lumbar spine and proximal femur in RA patients to determine which site is more affected by RA prevalence. **Methods:** We recruited 675 Japanese RA patients and 156 gender-matched non-RA patients with connective tissue disease (CTD) as controls. BMD in the lumbar spine and proximal femur were measured by dual energy X-ray absorptiometry. These measurements were performed before treatment with a bone antiresorptive agent; either a bisphosphonate or estrogen. **Results:** BMD Z scores in the proximal femur were significantly lower in RA patients than in non-RA/CTD patients, while those for the lumbar spine did not differ significantly between the two groups of patients. The RA patients were divided into four groups based on Steinbrocker's disease stage and functional classification, and the differences between the mean BMD Z scores in the femur were statistically significant among these groups ( $p < 0.001$ ), decreasing progressively as disease stage and functional class increased from 1 to 4. In contrast, the lumbar spine BMD Z score did not show a significant difference among these groups. Disease duration of RA showed a significantly stronger correlation with BMD Z scores in the femur than those for the lumbar spine, while CRP, ESR and anti-agalactosyl (AG) IgG antibody levels exhibited significant correlations with the proximal femur BMD Z score, but not with that of the lumbar spine. Furthermore, multiple regression analysis confirmed a significant and independent association of RA stage, class, CRP and anti-AG IgG antibody levels with the BMD T score in the femoral neck, but not that in the lumbar spine. **Conclusion:** Our results suggest that BMD reduction is preferentially observed in the proximal femur in RA patients through an RA-associated mechanism.

**Relationship between Low Bone Mass and Aortic Valve Sclerosis in Korean Men and Women.** H. Choi\*<sup>1</sup>, Y. Rhee\*<sup>1</sup>, S. Kim\*<sup>2</sup>, N. Chung\*<sup>1</sup>, E. Lee\*<sup>1</sup>, S. Lim\*<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Department of Internal Medicine, Kwandong University College of Medicine, Goyang, Republic of Korea.

**Background:** Aortic valve sclerosis and low bone mass are both diseases of old age. Many studies have reported that osteoporosis or low bone mass is related to cardiovascular disease or vascular calcification. The aim of this study was to assess the relationship between aortic valve sclerosis and low bone mass in Korean men and women.

**Methods:** A total of 165 men and 97 women who visited Severance Hospital for medical checkups were included in this study. Each subject's bone mineral density (BMD) was measured by dual energy X-ray absorptiometry, and aortic valve sclerosis was assessed using transthoracic echocardiography.

**Results:** Among the 262 subjects, 61 had aortic valve sclerosis. The mean age of participants with and without aortic valve sclerosis was  $62.9 \pm 6.8$  yr and  $52.8 \pm 7.6$  yr, respectively. The prevalence of osteopenia and osteoporosis was higher in participants with aortic valve sclerosis (52.5% in subjects with aortic valve sclerosis, 36.8% in subjects without aortic valve sclerosis). Inversely, the prevalence of aortic valve sclerosis increased as BMD T-scores decreased. Based on logistic regression analysis of cardiovascular risk factors including age, male gender, BMI, smoking, hypertension, hypercholesterolemia, diabetes, and BMD T-score  $< -1.5$ , the independent predictors of aortic valve sclerosis were age (OR 1.23, 95% CI 1.14 - 1.30;  $p < 0.001$ ), male gender (OR 3.06, 95% CI 1.20 - 7.82;  $p = 0.019$ ), hypertension (OR 3.09, 95% CI 1.43 - 6.68;  $p = 0.004$ ), and BMD T-score  $< -1.5$  (OR 3.24, 95% CI 1.02 - 10.30;  $p = 0.046$ ).

**Conclusions:** Low bone mass might have an additional role to age, male gender, and hypertension in calcification of the aortic valve. Patients with low bone mass should be further evaluated for the presence of aortic valve sclerosis and related cardiovascular diseases.

## SU453

**Association between Vascular Calcification and Low Total Femur Bone Mineral Density in Elderly People Community-Dwelling.** C. F. Danilevicius\*<sup>1</sup>, J. B. Lopes\*<sup>1</sup>, L. Takayama\*<sup>1</sup>, V. F. Caparbo\*<sup>1</sup>, I. R. S. Oliveira\*<sup>2</sup>, M. E. Kuroishi\*<sup>2</sup>, P. R. Menezes\*<sup>3</sup>, M. Scazufca\*<sup>3</sup>, E. Bonfa\*<sup>1</sup>, R. M. R. Pereira\*<sup>1</sup>. <sup>1</sup>Rheumatology Division, University of São Paulo, São Paulo, Brazil, <sup>2</sup>Radiology, University of São Paulo, São Paulo, Brazil, <sup>3</sup>Preventive Medicine, University of São Paulo, São Paulo, Brazil.

The aim of this study was to determine the possible association of aortic abdominal calcification and bone mineral density (BMD) in elderly people community-dwelling. One thousand and forty-one subjects ( $\geq 65$  years-old) were selected in a well established elderly community in the São Paulo city. Lateral lumbar X-rays were analyzed for the presence of abdominal aortic wall calcification in the region corresponding to the first through fourth lumbar vertebrae. The severity of the anterior and posterior aortic calcification was graded individually on a 0-3 scale for each lumbar segment (total: 0-24). BMD were evaluated using DXA-HOLOGIC. Spearman's correlations were used to analyze the presence of aortic calcification ( $\geq 5$  score) with the following variables: anthropometric and clinical parameters, BMD and laboratorial biochemical data. Logistic regression analysis was done with the variables that show significance in the Spearman's correlation. Sixty hundred and eighty-one patients (65.41%) presented any calcification and the mean score was  $7.67 \pm 5.94$ . Of these patients, 61.23% had five or more aortic abdominal calcification score. Spearman analysis showed a significant correlation between the presence of aortic abdominal calcification (score  $\geq 5$ ) and the following parameters: age ( $r = 0.236$ ,  $p < 0.001$ ), height ( $r = -0.100$ ,  $p = 0.001$ ), weight ( $r = -0.093$ ,  $p = 0.003$ ), current and previous tobacco ( $r = 0.123$ ,  $p < 0.001$ ), falls ( $r = 0.069$ ,  $p = 0.026$ ), fragility fracture ( $r = 0.103$ ,  $p = 0.001$ ), diabetes mellitus ( $r = 0.093$ ,  $p = 0.003$ ), arterial hypertension ( $r = 0.118$ ,  $p < 0.001$ ), cardiovascular event ( $r = 0.093$ ,  $p = 0.003$ ), phosphorus ( $r = 0.131$ ,  $p < 0.001$ ), PTH ( $r = 0.083$ ,  $p = 0.01$ ), femoral neck BMD ( $r = -0.132$ ,  $p < 0.001$ ), total femur BMD ( $r = -0.148$ ,  $p < 0.001$ ), total body BMD ( $r = -0.130$ ,  $p < 0.001$ ) and lean mass ( $r = -0.141$ ,  $p < 0.001$ ). Logistic regression analysis revealed that the presence of aortic abdominal calcification was positively associated with age (OR=1.086, CI= 1.058-1.114,  $p < 0.001$ ) and negatively associated with total femur BMD in elderly people community-dwelling (OR=0.149, CI= 0.062-0.357,  $p < 0.001$ ). The demonstration of a positive correlation between low bone mineral density in total femur and advanced aortic calcification in a large elderly people community-dwelling reinforces previous hypothesis of a common physiopathological mechanisms underlying these two conditions.

**Influence of Hip Flexor or Knee Extensor Muscle Strength on Spinal Sagittal Alignment or Falls.** Y. Kasukawa, N. Miyakoshi, M. Hongo, H. Noguchi, K. Kamo, H. Sasaki, Y. Shimada\*. Department of Orthopedic Surgery, Akita University, Akita, Japan.

We have previously reported that decreased back extensor strength, decreased mobility of lumbar spine, and increased spinal inclination could represent risk factors for falls in patients with osteoporosis. However, muscle strength of lower extremity, which is hip flexor or knee extensor muscle, may influence the spinal sagittal alignment and mobility or the incidence of falls. The purpose of this study was to evaluate whether hip flexor or knee extensor muscle strength may influence the sagittal alignment or mobility of spine or the incidence of falls. Subjects comprised 26 elderly people (mean age, 73 years; range, 60-82 years, 11 male and 15 female) participated in physical check-up. Angles of thoracic or lumbar kyphosis and mobility of the thoracic or lumbar spine were measured in the upright position and at maximum flexion/extension using a computer-assisted device (SpinalMouse). Spinal inclination reflecting spinal sagittal alignment was also evaluated using SpinalMouse. Bilateral grip strengths were measured using a handgrip dynamometer. The bilateral hip flexor or knee extensor muscle strength was measured using portable dynamometer (PowerTrackII). Correlation of the muscle strength of lower extremity and the sagittal alignment or mobility of spine was analyzed. Then subjects were divided into 2 groups: subjects with a history of falls, fear of falling, or need for support when walking (Fall group, n=13; 5 men, 8 women); and subjects with no such history (Non-fall group, n=13; 6 men, 7 women). There was no significant correlation of hip flexor or knee extensor muscle strength and thoracic, lumbar, thoracic+lumbar spinal alignment or mobility. The hip flexor or knee extensor muscle strength also did not show significant correlation with spinal inclination or its mobility. Mean grip strength and mean knee extensor muscle strength, but not hip flexor muscle strength, were 43% (p<0.01) and 10% (p<0.05) lower in the Fall group than in the Non-fall group. These results of this study suggest that hip flexor and knee extensor muscle strength had no significant effect on spinal sagittal alignment and mobility. The muscle strength of lower extremity was decreased in the elderly patients with history of falls in the present study.

## SU455

**Determinants of low BMD in HIV infected postmenopausal women.** M. T. Yin<sup>1</sup>, D. Ferris<sup>2</sup>, D. McMahon<sup>1</sup>, S. Cabral<sup>1</sup>, H. Eisenberg<sup>3</sup>, J. Laurence<sup>3</sup>, V. K. Thomas<sup>3</sup>, S. Creemers<sup>3</sup>, E. Shane<sup>1</sup>. <sup>1</sup>Columbia University, NY, NY, USA, <sup>2</sup>Bronx Lebanon Hospital Center, NY, NY, USA, <sup>3</sup>Weill Medical College, NY, NY, USA.

Several studies have reported low BMD and abnormal mineral metabolism in association with HIV infection and its therapy. Although postmenopausal (PM) minority women constitute a growing segment of the HIV+ population in the US and may be at higher risk for osteoporosis and fracture than younger HIV+ men and women, little is known about their skeletal status. We therefore measured BMD by DXA in 101 HIV+ and 102 HIV- PM women from New York. Serum levels of pro-resorptive cytokines (TNF- $\alpha$ , RANKL, IL-6), 25OHD, parathyroid hormone (PTH), estrone (E), bone alkaline phosphatase (BAP) and N-telopeptide (NTX) were also measured. HIV+ women were younger (57 $\pm$ 6 vs 61 $\pm$ 6 yrs, p<0.0001) and had lower BMI (27.5 $\pm$ 5.9 vs 30.2 $\pm$ 5.8 kg/m<sup>2</sup>, p=0.001) but were of similar race/ethnicity (66% Hispanic, 34% African American) as HIV- women. Mean CD4 count was 509 $\pm$ 309 cells/mm<sup>3</sup> and 78% were on antiretrovirals (ARVs). T scores were lower in HIV+ than HIV- women at the lumbar spine (LS; -1.82 $\pm$ 0.1 vs -1.26 $\pm$ 0.1, p=0.0008), total hip (TH; -0.95 $\pm$ 0.1 vs -0.49 $\pm$ 0.1, p=0.0008) and femoral neck (FN; -1.30 $\pm$ 0.1 vs -0.9 $\pm$ 0.1, p=0.007). More HIV+ women had T scores <-1.0 at the LS (75% vs 60%, p=0.03), FN (63% vs 44%, p=0.006) and TH (48% vs 28%, p=0.003). Prevalence of osteoporosis (T score <-2.5) in HIV+ and HIV- at the LS (25% vs 18%, p=0.22), TH (5% vs 1%, p=0.10), and FN (12% vs 7%, p=0.22) and self-reported fracture at any site (10% vs 7%, p=0.51) were similar between groups. In a multivariate model, HIV+ status remained negatively associated with LS T score (partial correlations r=-0.17, p=0.02) and TH T score (partial correlations r=-0.15, p=0.03) after adjustment for age, weight, and other predictors such as alcohol, calcium and multivitamin supplementation. Serum BAP, NTX and TNF- $\alpha$  were higher and PTH and E lower in HIV+ women than controls (Table), while serum 25OHD and IL-6 were similar. Cytokine levels did not correlate with BMD at any site, but estrone was positively associated with FN, TH and 1/3 radius even after adjustment for BMI. Among the HIV+ women, BMD did not correlate with ARV exposure. In conclusion, BMD is significantly lower and prevalence of osteopenia is higher in PM HIV+ than HIV- women. Although HIV status is an independent predictor of BMD, it appears not to be mediated by upregulation of pro-resorptive cytokines or ARV exposure.

	HIV+ (N=100)	HIV- (N=102)	P value
Osteocalcin (ng/ml)	6.6 $\pm$ 0.3	6.0 $\pm$ 0.2	0.09
BAP (U/L)	38.2 $\pm$ 1.8	30.6 $\pm$ 1.2	0.0008
NTX (nmol/BCE/L)	21.3 $\pm$ 1.1	16.5 $\pm$ 0.6	0.0001
IL-6 (ng/ml)	2.6 $\pm$ 0.3	2.3 $\pm$ 0.3	0.45
TNF- (pg/ml)	40.4 $\pm$ 2.6	30.1 $\pm$ 1.5	0.0008
RANKL (nmol/L)	57.3 $\pm$ 1.8	58.7 $\pm$ 2.5	0.65
Intact PTH (pg/ml)	34.8 $\pm$ 1.7	42.9 $\pm$ 1.9	0.002
Estrone	24.7 $\pm$ 1.1	30.8 $\pm$ 1.8	0.004

## SU456

**Type 1 Diabetes Is Associated with Lower Bone Mineral Density in Premenopausal Women But Not in Middle-aged Men - DIOS-Study.** T. Neumann<sup>1</sup>, A. Sämann<sup>2</sup>, S. Lodes<sup>1</sup>, M. Kiehnopf<sup>3</sup>, S. Franke<sup>1</sup>, C. Hemmelmann<sup>4</sup>, U. Müller<sup>5</sup>, G. Hein<sup>1</sup>, G. Wolf<sup>2</sup>. <sup>1</sup>Internal Medicine III, Rheumatology/ Osteology, Friedrich-Schiller-University, Jena, Germany, <sup>2</sup>Internal Medicine III, Nephrology, Friedrich-Schiller-University, Jena, Germany, <sup>3</sup>Institute of Clinical Chemistry and Laboratory Diagnostics, Friedrich-Schiller-University, Jena, Germany, <sup>4</sup>Institute of Medical Statistics, Computer Sciences and Documentation, Friedrich-Schiller-University, Jena, Germany, <sup>5</sup>Internal Medicine III, Endocrinology, Friedrich-Schiller-University, Jena, Germany.

It is assumed that type 1 diabetes mellitus (T1DM) is associated with an increased fractures risk. The aim of this study was to investigate the association between T1DM and bone mineral density (BMD) in comparison with non-diabetic healthy controls. A single-centre, cross sectional study of men and premenopausal women with T1DM was designed. Age, gender and body-mass index (BMI) were matched in the healthy control group. Investigation of BMD (lumbar spine, total hip, femoral neck and whole body), parameters of bone metabolism and bone-related clinical data were performed.

A total of 128 patients with T1DM and 77 non-diabetic controls were studied. BMD was significantly lower in females with T1DM compared with female healthy controls (total hip 0.999g/cm<sup>2</sup> vs. 1.077g/cm<sup>2</sup>, P<0.05; femoral neck 0.945g/cm<sup>2</sup> vs. 0.999g/cm<sup>2</sup>, P<0.05; total body 1.154g/cm<sup>2</sup> vs. 1.191g/cm<sup>2</sup>, P<0.05). However, BMD was not different in male patients compared to healthy men. C-terminal telopeptide of type I collagen (CTX), osteocalcin, parathormone, 25-hydroxyvitamin D and 1.25-dihydroxyvitamin D were significantly lower in male with T1DM compared to healthy controls. Females with T1DM had significantly lower osteocalcin and 25-hydroxyvitamin D but higher alkaline phosphatase compared with healthy women.

In multiple linear regression models for female participants, BMI was the strongest predictor of BMD. T1DM, reported fractures and CTX were inversely associated with BMD. Diabetes-related complications as neuropathy, nephropathy and retinopathy did not predict BMD. Participants with T1DM of all investigated ages reported more fractures but this did not reach statistical significans.

Our data suggest, that bone loss associated with T1DM is more pronounced in women than in man. Bone turn-over was lower in T1DM but did not explain differences in BMD. BMI and history of fractures were strong predictors of BMD and should be considered in risk estimation.

**Histomorphometric Evaluation in an Experimental Model of Hepatic Osteodystrophy.** F. A. Pereira, I. Facincani\*, L. N. Z. Ramalho\*, L. M. dos Reis\*, V. Jorgetti. Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.

Hepatic Osteodystrophy is an important co-morbidity of chronic liver disease. Conflicting results have been previously obtained about the predominating bone disease in this situation. Some data indicating that it is osteomalacia and others osteoporosis with different degrees of bone remodeling activity. The aim of this study was to evaluate bone remodeling. Twenty-nine Wistar rats were divided into two groups: Sham Group (SG n=15) and Hepatic Cholestasis Group (HCG n=14). HCG animals were submitted to bile-duct obstruction for induction of hepatic cholestasis. Thirty days after surgery the animals were sacrificed and blood samples, fragments of liver tissue and the right tibia were collected. The data of histomorphometric analysis showed that trabecular volume (BV/TV) was significantly smaller in HCG compared to SG: (HCG = 16.8  $\pm$  5.2 vs SG = 26.4  $\pm$  4.1 % p = 0.0001). The trabecular thickness (Tb.Th) and number of trabeculae (Tb.N) were significantly lower in HCG compared to SG. (Tb.Th: HCG = 33.5  $\pm$  4.6 vs SG=44.9  $\pm$  18.6  $\mu$  m p=0.01; Tb.N: HCG = 4.9  $\pm$  1.0 vs SG = 6.3  $\pm$  1.3 /mm p = 0.004). Trabecular separation (Tb.Sp) was significantly greater in HCG compared to SG. (Tb.Sp: HCG= 181.5  $\pm$  72.0 vs SG=124.7  $\pm$  34.4  $\mu$  m p=0.002). Dynamic histomorphometric parameters that express bone mineralization such as mineral apposition rate (MAR) and adjusted appositional rate of bone mineralization rate (Aj.AR) were significantly lower in HCG compared to SG: (MAR: HCG = 0.5  $\pm$  0.2 vs SG = 0.7  $\pm$  0.3  $\mu$  m/d p = 0.01; Aj.AR: HCG = 0.13  $\pm$  0.12 vs SG = 0.06  $\pm$  0.02  $\mu$  m/d p = 0.006). The mineralization lag time (Mit) as significantly longer in HCG compared to SG. (HCG = 78.7  $\pm$  64.4 vs GC = 41.6  $\pm$  27.0 days p = 0.02). The present results suggest that, in addition to a bone mass reduction, hepatic cholestasis is associated with a disorder of bone mineralization in rats. The definition of the pattern of osteometabolic disease in hepatic cirrhosis is fundamental for an appropriate treatment planning.

**Disclosures:** F.A. Pereira, None.

**Cortical and Trabecular Microarchitecture in HIV-Infected Postmenopausal Women.** A. D. Shu<sup>1</sup>, M. T. Yin<sup>1</sup>, D. Ferris<sup>\*2</sup>, D. J. McMahon<sup>1</sup>, H. Eisenberg<sup>\*1</sup>, V. K. Thomas<sup>\*1</sup>, S. Cabral<sup>\*1</sup>, E. S. Shane<sup>1</sup>.<sup>1</sup>Columbia University Medical Center, New York, NY, USA, <sup>2</sup>Bronx-Lebanon Hospital, Bronx, NY, USA.

Several studies have reported low BMD in association with HIV infection and its therapy. Although postmenopausal (PM) minority women are a growing segment of the HIV positive (HIV+) population in the United States, and may be at higher risk for osteoporosis and fracture than younger men and women with HIV/AIDS, little is known about their skeletal status. We measured BMD by DXA in 101 HIV+ and 102 HIV- PM Hispanic and African American women residing in New York and in a subset (39 HIV+ and 57 HIV-), we assessed cortical (Ct) and trabecular (Tb) microarchitecture by HRpQCT (Xtreme CT; Scanco Medical AG; resolution 82 µm) at the radius (RAD) and tibia (TIB). We excluded women with known osteoporosis, metabolic bone disease and serum Cr > 2.5 mg/dL.

HIV+ subjects were younger ( $56 \pm 6$  vs  $60 \pm 7$  yrs,  $p = 0.009$ ), had lower BMI ( $29 \pm 6$  vs  $31 \pm 7$ ,  $p = 0.006$ ), but were similar with regard to race/ethnicity, history of fracture (15% vs 11%,  $p = 0.48$ ), use of glucocorticoids, estrogen and anti-epileptic drugs. Of HIV+ subjects, 77% were on antiretroviral therapy (ARV).

Despite their younger age, HIV+ women (Table) had lower BMD at the total hip (TH) and femoral neck (FN) than HIV- women. By HRpQCT, when compared to premenopausal (PreM) women, both groups of PM women had lower Ct thickness, and Tb bone density, bone volume and number, and higher Tb separation and standard deviation of Tb separation reflecting inhomogeneity of the Tb network. However, the HIV+ and HIV- PM women did not differ from each other by any HRpQCT measure at the RAD or TIB (data not shown). When we limited the analysis to subjects with low BMD (T-score < -2), the HIV+ and HIV- groups (N = 21 and 23) remained similar.

In summary, despite their younger age, HIV+ PM women had lower hip BMD than HIV- PM women. When compared to premenopausal controls, Ct and Tb microstructural deterioration was similar in HIV+ and HIV- PM women, even though the HIV+ was younger than the HIV- group. These results suggest earlier deterioration of bone microarchitecture in PM HIV+ women.

**Table:** DXA and Radius HRpQCT for HIV+ and HIV- PM women (mean  $\pm$  SD) along with PreM reference values

	Our study			PreM reference
	HIV+ N = 39	HIV- N = 57	p-value	N = 26

**Plasma Osteocalcin is Inversely Related to Fat Mass and Plasma Glucose in Elderly Swedish Men.** J. M. Kindblom<sup>1</sup>, C. Ohlsson<sup>1</sup>, O. Ljunggren<sup>\*2</sup>, M. K. Karlsson<sup>\*3</sup>, A. Tivesten<sup>\*1</sup>, U. Smith<sup>\*1</sup>, D. Mellstrom<sup>1</sup>.

<sup>1</sup>Internal Medicine, Sahlgrenska Academy, Gothenburg, Sweden, <sup>2</sup>Uppsala University, Department of Medical Sciences, Gothenburg, Sweden, <sup>3</sup>Department of Clinical Sciences, Clinical and Molecular Osteoporosis Research Unit, Lund and Malmö, Sweden.

The osteoblast-derived protein osteocalcin has recently been shown to affect adiposity and glucose homeostasis in mice, suggesting that the skeleton via an endocrine mechanism influences energy metabolism. The aim with the present study was to investigate the relationship between plasma osteocalcin and parameters reflecting fat mass and glucose homeostasis in humans.

Fasting levels of plasma osteocalcin, plasma glucose, serum insulin and lipids were analysed in elderly men ( $75.3 \pm 3.2$  years) in the Gothenburg part (all subjects n = 1010, non-diabetic n = 857 and diabetic n = 153) of the MrOS Sweden study. Fat mass and lean mass were analysed using dual energy X-ray absorptiometry.

Diabetic subjects had lower plasma osteocalcin (-21.7 %,  $p < 0.001$ ) than non-diabetic subjects. For both all subjects and non-diabetic subjects, plasma osteocalcin was clearly inversely related to BMI, fat mass and plasma glucose ( $p < 0.001$ ), while it was not associated with height or lean mass. Plasma osteocalcin explained a substantial part (6.3%) of the variance in plasma glucose while it associated moderately with serum insulin. Multiple linear regression models adjusting for serum insulin and fat mass demonstrated that plasma osteocalcin was an independent negative predictor of plasma glucose ( $p < 0.001$ ).

We herein, for the first time in humans, demonstrate that plasma osteocalcin is inversely related to fat mass and plasma glucose. Although one should be cautious with mechanistic interpretations of cross-sectional association studies, our human data support recently published experimental studies, revealing endocrine functions of osteoblast-derived osteocalcin on glucose and fat homeostasis.

**A Possible Role for the T<sub>H</sub>17 System in a Mouse Model of Ankylosing Spondylitis.** G. Thomas<sup>1</sup>, T. Glant<sup>\*2</sup>, M. Brown<sup>1</sup>.

<sup>1</sup>Dimanatina Institute, University of Queensland, Woolloongabba, Australia, <sup>2</sup>Rush University Medical Center, Chicago, IL, USA.

Ankylosing spondylitis (AS) is a common inflammatory arthritis with an incidence similar to that of rheumatoid arthritis (RA)(0.5%). Characteristic clinical features are inflammatory back pain, asymmetric peripheral arthritis, enthesitis, and anterior uveitis. The condition primarily affects the spine and sacroiliac joints of the pelvis, causing pain and stiffness and eventual fusion. Unlike 'seropositive' forms of arthritis like RA in which inflammation leads to bone and joint erosion, in AS initial erosion is followed by relentless new bone formation leading to joint fusion. This process is very poorly understood. Although anti-TNF drugs produce improvements in acute inflammation in AS, there are no treatments which induce remission or retard the progressive joint fusion that inevitably occurs in the disease. Thus there is an urgent need for new effective therapies.

AS is a highly heritable condition and our group has recently demonstrated a genetic association between the *IL23r* gene and AS. IL23R is the specific subunit of the receptor complex for the cytokine IL-23 which has been shown to be a key regulatory factor in the development of the recently discovered T<sub>H</sub>17 effector T-cell subset. T<sub>H</sub>17 cells are characterised by production of the pro-inflammatory cytokine interleukin 17 (IL-17), which has been shown to play a key role in a number of mouse models of autoimmune diseases such as multiple sclerosis, colitis, arthritis and psoriasis.

We have established the proteoglycan induced spondylitis (PGISp) mouse model of AS in our laboratory. Inflammation is induced in BALB/c mice by 3 injections of a human cartilage crude proteoglycan extract which initially induces peripheral inflammation but is then followed by sacroiliitis and vertebral inflammation, disc destruction and eventual ankylosis. Mice were stopped 12 weeks after the initial proteoglycan injection and spines and peripheral joints collected for histological and RNA analysis. Spleens were also collected to measure immune cell responses. Significant peripheral inflammation was seen in >90% of the mice analysed. Similarly almost 100% penetrance of axial inflammation was seen with massive disc destruction in the vertebrae. The potential role of T<sub>H</sub>17 cells was assessed by determining the proportion of T<sub>H</sub>17 and T<sub>H</sub>1 cells in the spleen by measuring IL-17 and interferon gamma (IFNγ). PGISp-affected mice showed significant increases in the numbers of IL-17+ve T<sub>H</sub>17 cells with a corresponding decrease in IFNγ+ve T<sub>H</sub>1 cells resulting in a 3-fold increase in the T<sub>H</sub>17/T<sub>H</sub>1 cell ratio.

Thus we have demonstrated altered T<sub>H</sub>17 activity in a mouse AS model supporting our genetic findings. Further studies will elucidate the potential of anti-T<sub>H</sub>17 therapies in AS.

**Reduced Serum Osteocalcin and Sex Hormone Binding Globulin in Men with Type II Diabetes.** N. D. Nguyen, J. R. Center, J. A. Eisman, T. V. Nguyen.

Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Serum osteocalcin (OC), a 49-amino acid bone matrix protein, has recently been shown to be associated with diabetes in mice. However, it is unknown whether the association is present in men. Therefore, this study sought to examine the contribution of OC to the susceptibility of type II diabetes in men.

Serum OC, sex hormone binding globulin (SHBG), 25(OH)D, and PTH were measured by radioimmunoassay in 443 men aged 60+ at baseline (1989) in the Dubbo Osteoporosis Epidemiology Study. The men's health status, including fracture and diabetes, had been monitored between 1989 and 2007. Bone mineral density (BMD), clinical risk factors, and lifestyle factors had also been obtained at baseline and subsequent biannual visits.

During the follow-up, 41 men (or 9%) reported to have type II diabetes. Although the two groups of men were similar in age ( $69 \pm 7$  years, mean  $\pm$  SD) men with diabetes had greater body mass index (BMI,  $27 \pm 4$  vs  $26 \pm 3$ ), greater weight ( $83 \pm 13$  vs  $78 \pm 12$ ), 22% lower in log OC ( $1.46 \pm 0.59$  vs  $1.71 \pm 0.52$ ) and 15% lower in log SHBG ( $3.72 \pm 0.56$  vs  $3.89 \pm 0.40$ ), with p-values < 0.05. There was no significant difference in log estradiol ( $4.13 \pm 0.72$  vs  $4.21 \pm 0.55$ ) or log of 25(OH)D ( $4.24 \pm 0.30$  vs  $4.25 \pm 0.32$ ) between the men with and without diabetes. In multivariable analysis, after adjusting for BMI and smoking, the risk of diabetes was increased with each SD lower in osteocalcin (OR 1.52, 1.10-2.09) and SHBG (1.37, 1.00-1.87). Approximately 15% of the liability to diabetes was accounted for by osteocalcin and 13% by SHBG.

Thus, these data suggest that lower osteocalcin and SHBG were associated with an increased risk of type 2 diabetes in men. The use of serum OC and SHBG may help improve the prognostic accuracy of type II diabetes in men.

**Bone Histomorphometry in Patients with Crohn's Disease.** A. Oostlander<sup>\*1</sup>, N. Bravenboer<sup>1</sup>, P. Holzmann<sup>\*1</sup>, J. van der Woude<sup>\*2</sup>, G. Dijkstra<sup>\*3</sup>, A. van Bodegraven<sup>\*4</sup>, P. Lips<sup>1</sup>. <sup>1</sup>Endocrinology, VU University Medical Center, Amsterdam, Netherlands, <sup>2</sup>Gastroenterology and Hepatology, Erasmus Medical Center, Rotterdam; on behalf of the ICC, Netherlands, <sup>3</sup>Gastroenterology and Hepatology, University Medical Center Groningen, Groningen; on behalf of the ICC, Netherlands, <sup>4</sup>Gastroenterology, VU University Medical Center, Amsterdam; on behalf of the ICC, Netherlands.

Inflammatory bowel disease (IBD) is associated with an increased prevalence of osteoporosis. Etiopathogenesis of bone loss in IBD-patients is complex, multifactorial and partly unclear. In this study we evaluated bone mass and structure by histomorphometry in iliac crest bone obtained from patients with Crohn's disease.

A subset of 14 patients with quiescent Crohn's disease (CD) from a randomized, double blind, placebo-controlled trial were analyzed in this study. The group comprised 9 women and 5 men, aged 23-56 years (mean 39 years). All had a lumbar spine and/or total hip bone mineral density with a T-score of -1 to -2.5 SD. Patients with current corticosteroid treatment and metabolic bone diseases were excluded. Disease activity (CDAI), C-reactive protein (CRP) and Alkaline Phosphatase (ALPase) levels were determined. Transiliac bone biopsies were obtained at baseline. Five micrometer undecalcified sections were stained with Goldner's Trichrome and Tartrate-resistant Acid Phosphatase (TRAP). Bone histomorphometry was performed automatically using NIS-Elements and according to the ASBMR nomenclature.

Total CDAI ranged from 0 to 194 (mean 83), CRP levels varied from 1 to 15 mg/L (mean 5 mg/L), and ALPase levels were between 52 and 88 U/L (mean 67 U/L). Histomorphometric analysis of bone biopsies of 14 patients with quiescent CD showed a mean bone volume of 19.8% (95% CI: 8.6-30.9). Trabecular thickness was 117.3 µm (69.4-165.3), trabecular number 1.7/mm (0.9-2.5), and trabecular separation 499.0 µm (233.1-764.9). Relative osteoid volume was 1.3% (0.0-3.6) and osteoid thickness 6.5 µm (3.6-9.5). The number of TRAP positive osteoclasts was 0.4/mm<sup>2</sup> (0.0-0.8). Trabecular bone volume correlated well with femoral neck BMD (p=0.025). Correlation with clinical and biochemical parameters of Crohn's disease showed a borderline positive association between osteoclast number and disease activity (p=0.074).

Comparison of our data to histomorphometric data from obduction material of age-matched men reveals similar structural parameters<sup>1</sup>. However, osteoid volume as well as thickness tend to be lower in patients with CD. We conclude that bone mass and structure in patients with quiescent Crohn's disease is quite normal, whereas bone formation is slightly impaired. Furthermore, bone resorption seems to be associated with disease activity.

**Morphological Atherosclerosis Calcification Distribution (MACD) Index is a Strong Predictor of Cardio-Vascular Death and Include the Predictive Power of BMD.** C. Christiansen<sup>1</sup>, M. Karsdal<sup>1</sup>, M. Ganz<sup>\*2</sup>, E. Dam<sup>\*1</sup>, M. Nielsen<sup>\*2</sup>. <sup>1</sup>Nordic Bioscience, Herlev, Denmark, <sup>2</sup>Department of Computer Science, University of Copenhagen, Copenhagen, Denmark.

Aortic calcification is a major risk factor for cardiovascular disease (CVD) related deaths. We investigated the relation between mortality and aspects of number, size, morphology and distribution of calcified plaques in the lumbar aorta and BMD of postmenopausal women. 308 women aged 48 to 76 were followed for 8.3±0.3 years and CVD deaths were recorded. BMD and several aortic calcification markers were computed: number, morphology, distribution, from outlines of the calcified plaques in lumbar X-rays. These markers were compared to BMD, SCORE card, Framingham score, and the Aortic Calcification Severity score - AC24. AC24 adjusted by age, waist circumference, and triglyceride levels (ATW) predicted mortality in postmenopausal women (CVD p=0.03, All-cause p=0.006). The SCORE card and the Framingham score resulted in mortality odds ratios (MOR) of 5.0 and 5.2 - defining high risk as ≥6 and ≥18, respectively. BMD and BMD adjusted for ATW was lower in the group of deceased than in survivors (p<0.001) and negatively correlated to calcification markers in survivors (R<sup>2</sup> = 0.27, p<0.001). All scores based on the calcification geometry provided highly significant predictions. The number of calcified deposits (NCD) was a significant predictor even after adjustment by the AC24 score (p=0.002). The AC24 score adjusted by NCD had no predictive value (p=0.53). The high risk patients (NCD ≥ 13) had MOR 12. The morphological atherosclerosis calcification distribution (MACD) index provided MOR 20 which was significantly higher than AC24 and any single or multivariate metabolic/physical marker. BMD correlates with AC24 among CVD dead patients (p=0.03) unlike MACD (p=0.43). The recent MACD-index provides a unique combination of morphology and distribution of aortic calcifications, factors that in a combination increase the biological relevance of the index by emphasizing that smaller plaques with a spread elongated morphology have a larger growth potential and thereby subsequent rupture potential. It includes the predictive power of BMD unlike the AC24 index. Thereby, in the current cohort with a long term follow-up the MACD-index is a convincingly strong predictor of CVD mortality, with an odds ratio of 20, of postmenopausal death related to CVD events

**Bone Quality in Chinese American and Caucasian Women.** M. D. Walker<sup>1</sup>, C. Go<sup>\*1</sup>, J. Udesky<sup>\*1</sup>, D. J. McMahon<sup>\*1</sup>, G. Liu<sup>\*2</sup>, J. P. Bilezikian<sup>1</sup>. <sup>1</sup>Medicine, College of Physicians and Surgeons, Columbia University, New York, NY, USA, <sup>2</sup>Medicine, New York Downtown Hospital, New York, NY, USA.

Chinese Americans have low rates of hip fracture (fx) despite lower areal bone density (aBMD) by dual x-ray absorptiometry (DXA) compared to other racial groups. Aspects of bone quality, other than aBMD, may influence fx risk. These include bone size, volumetric bone density (vBMD), microarchitecture, mineralization density, crystallinity, & bone turnover. Data regarding these indicators of bone quality in Chinese American (CH) women could be helpful in understanding their low rates of hip fx. The goal of this study is to compare vBMD, bone size, as well as microarchitectural, structural & remodeling features of bone in CH and Caucasian (CA) women using DXA, central quantitative computed tomography (cQCT), high resolution peripheral QCT (HRpQCT), calciotropic hormones, bone turnover markers, & analysis of bone biopsies.

Data are presented for the first 15 women. The CH (n=7) and CA (n=8) groups did not differ in age (33 ± 3 vs. 34 ± 4 yrs; p=0.4), BMI (22 ± 2 vs. 24 ± 7 kg/m<sup>2</sup>; p=0.4), tobacco or alcohol use, family history of osteoporosis, oral contraceptive use, daily calcium (732 ± 197 vs. 1094 ± 635 mg; p=0.2) or vitamin D intake (295 ± 135 vs. 555 ± 435 IU; p=0.2). Serum 25-hydroxy vitamin D levels were lower in the CH group (29 ± 7 vs. 42 ± 13 ng/dl; p=0.03), but there was no difference in PTH levels (32 ± 11 vs. 31 ± 15 pg/ml; p=0.8). CH women tended to be less physically active (Baecke index 1.1 ± 0.5 vs. 1.5 ± 0.5; p=0.07) & spent less time outside (time outside score 2.2 ± 0.4 vs. 3.0 ± 1.1 p=0.06).

In the subset of women who have completed all tests (n = 7), aBMD did not differ for the lumbar spine (1.079 ± 0.05 vs. 1.065 ± 0.121 g/cm<sup>2</sup>; p=0.9), total hip (0.898 ± 0.047 vs. 0.977 ± 0.231 g/cm<sup>2</sup>; p=0.6), femoral neck (0.786 ± 0.059 vs. 0.844 ± 0.173 g/cm<sup>2</sup>; p=0.6) or 1/3 radius (0.666 ± 0.032 vs. 0.684 ± 0.045; p=0.6). There were no differences in HRpQCT indices at the radius. At the tibia, however, there was significantly greater trabecular thickness (Tb.Th) (0.098 ± 0.00 vs. 0.079 ± 0.01 mm; p=0.002) & a trend toward greater average total vBMD in the CH (382 ± 8 vs. 316 ± 47 mgHA/cm<sup>3</sup>; p=0.07) versus the CA group. There was no difference in cortical bone density, cortical thickness, trabecular bone density, trabecular bone volume/tissue volume, trabecular # or trabecular spacing.

Despite lower vitamin D levels, CH women did not differ from CA women of similar weight in aBMD, Tb.Th & average vBMD at the tibia, but not the radius, were greater in CH than CA women. The greater Tb.Th among CH women is of unclear clinical significance as this is a calculated variable. These data may provide insight into differences between Chinese Americans and Caucasians in a loaded bone, which could be important in understanding disparities in risk of hip fx.

**Fluoride Effects on Bone Formation, Mineralization and Mechanical Properties Are Influenced by Genetics.** M. Mousny<sup>\*1</sup>, S. Omelon<sup>\*2</sup>, L. Wise<sup>\*2</sup>, E. T. Everett<sup>3</sup>, M. Dumitriu<sup>\*2</sup>, D. P. Holmyard<sup>\*2</sup>, X. Banse<sup>\*1</sup>, J. P. Devogelaer<sup>4</sup>, M. D. Grynpas<sup>2</sup>. <sup>1</sup>Orthopaedic Research Laboratory, Catholic University of Louvain, Brussels, Belgium, <sup>2</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, <sup>3</sup>Department of Pediatric Dentistry and The Carolina Center for Genome Sciences, University of North Carolina, Chapel Hill, NC, USA, <sup>4</sup>Arthritis Unit, Catholic University of Louvain, Brussels, Belgium.

**Introduction:** The purpose of this study was to assess the effect of increasing fluoride (F<sup>-</sup>) doses on bone properties in inbred mouse strains in order to study the influence of genetic background.

**Materials and Methods:** Three inbred mouse strains with different susceptibilities to developing dental fluorosis (A/J a "susceptible" strain, SWR/J an "intermediate" strain, 129P3/J a "resistant" strain) were studied. Bone F<sup>-</sup> concentrations were determined. Bone mineral density (BMD) was evaluated through DEXA. Mechanical properties of cortical and trabecular bone were determined. Bone microarchitecture was quantified with microcomputed tomography and strut analysis. Bone formation was evaluated by static histomorphometry. Bone mineralization was quantified with Back Scattered Electron imaging (BSE) and powder X-ray diffraction. Microhardness measurements were taken from cortical and trabecular bone.

**Results:** Concordant with increasing F<sup>-</sup> dose were significant increases of F<sup>-</sup> bone concentration in all 3 strains. F<sup>-</sup> treatment had little effect on BMD. Mechanical testing showed significant alterations in "bone quality" in A/J, moderate alterations in SWR/J and no effect in 129P3/J. F<sup>-</sup> treatment had no significant effect on bone microarchitecture. Each strain demonstrated a significant increase in osteoid formation. The bone mineralization profiles showed a non-significant increase towards higher mineralization with increasing F<sup>-</sup> dose. Powder X-ray diffraction showed significantly smaller crystals for 129P3/J, and increased crystal width with increasing F<sup>-</sup> dose for all strains. There was no effect on bone microhardness.

**Conclusion:** Genetic factors may contribute to the variation in bone response to fluoride exposure. The increased crystal cross-section with increasing F<sup>-</sup> dose correlates with most of the decreased mechanical properties. An increase in bone F<sup>-</sup> might affect the mineral-organic interfacial bonding and/or bone matrix proteins. The smaller bone crystallites of the resistant strain may indicate a stronger organic/inorganic interface, reducing crystallite growth rate and increasing interfacial mechanical strength.

**Disclosures:** M. Mousny, None.

## SU466

**Correlation of Hip Geometry and Bone Density with Fragility Fracture in Japanese Postmenopausal Women.** M. Ito<sup>1</sup>, M. Uetani<sup>\*1</sup>, N. Wakao<sup>\*2</sup>, A. Harada<sup>\*3</sup>. <sup>1</sup>Radiology, Nagasaki University, Nagasaki, Japan, <sup>2</sup>Orthopaedic Surgery, Nagoya University, Nagoya, Japan, <sup>3</sup>Restorative Medicine, National Center for Geriatrics & Gerontology (NCGG), Oobu, Japan.

We investigated the characteristics of three-dimensional hip geometry and bone mineral density (BMD) in Japanese women in relation to fragility fracture using clinical CT. We also investigated structural factors relating to femoral neck (NECK) vs. trochanteric (TRO) fractures. Age-related changes in BMD and geometry of the proximal hip were studied in 208 postmenopausal women. The fracture study included 37 women with hip fracture (mean age: 75.9 years old) and 49 age-matched control women (79.4 years). We compared 20 women with NECK fracture (83.0 years) and age-matched 19 with TRO fracture (85.6 years). CT scanners used were Aquilion 16 (Toshiba) and Somatom 64 (Siemens) at Nagasaki University Hospital (NU) and NCGG, respectively. The reference phantom was B-MAS200 (Fjirebio Inc, Japan) containing hydroxyapatite at 0, 50, 100, 150 and 200 mg/cm<sup>3</sup>. The scanning condition are adjusted as much as possible; 120kV, 250mA, reconstruction thickness 0.5 mm at both institutes, and spatial resolution 0.625x0.625 mm at NCGG and 0.652x0.652 mm at NG. QCT PRO software (Mindways, USA) was used to analyze data for BMD, bone mass and areas in total, cortical and trabecular regions, and cortical thickness (CoTh), curvature, distance to center of bone mass (dist to CM), perimeter in cross-sectional femoral neck (CSFN). Hip axis length (HAL), neck shaft angle (NSA) and neck width, and biomechanical parameters such as cross-sectional moment of inertia (CSMI) and buckling ratio (BR) were also obtained. The shape of CSFN changed with aging; CoTh in superior, but not in inferior, region decreased significantly, maximal dist to CM increased, and curvature decreased. Women with hip fracture had a significantly lower total and cortical BMD, smaller cortical area and larger total and trabecular areas than those without hip fracture. Women with hip fracture had a significantly larger NSA, longer HAL, smaller curvature, lower CSMI and higher BR than those without fracture. The results of multiple regression analysis revealed that neck BMD was the strongest predictor of hip fracture among single parameters (coefficient of determination (CD)=26.4%), and adding geometrical parameters to neck BMD increased CD (43.0%). We also found that women with TRO fracture had a significantly lower cortical BMD, larger trabecular area, smaller NSA and lower BR than those with NECK fracture. We conclude that important parameters related to fragility fracture can be detected using clinical CT, that neck BMD is the strongest predictor of hip fracture, and that combination of BMD and geometrical data is useful for fracture risk assessment.

**Disclosures:** M. Ito, None.

## SU467

**Prediction of Trabecular Level Microdamage and Bone Fracture Through Local Strain.** P. J. Thurner<sup>\*1</sup>, R. Jungmann<sup>\*2</sup>, R. Tang<sup>\*3</sup>, G. Schitter<sup>\*2</sup>, D. Vashishth<sup>\*3</sup>, P. K. Hansma<sup>\*2</sup>. <sup>1</sup>School of Engineering Sciences, University of Southampton, Southampton, United Kingdom, <sup>2</sup>University of California Santa Barbara, Santa Barbara, CA, USA, <sup>3</sup>Rensselaer Polytechnic Institute, Troy, NY, USA.

The diagnosis of bone fracture risk in individuals is still mostly based on measurements of bone mineral density (BMD). Since diagnosis from BMD alone can carry large errors, additional parameters are necessary to reliably diagnose bone quality. One route to achieve this is the simulated mechanical evaluation of trabecular bone structures using finite element analyses (FEA) on acquired 3D data sets. To ensure meaningful results, such approaches need to include valid damage models predicting the occurrence of microdamage and fracture at certain thresholds, which weaken the structure. Here we present the results of a key experiment providing a first damage model by linking whitening in bone, seen during loading, to microdamage and involved local strains at the level of a single trabecula.

Rod-like trabeculae were excised from a proximal bovine femur and imprinted with a point grid using an ink jet printer. The trabeculae were tested in three-point bending, capturing force-displacement data and high-speed video images. Local strain fields on the sample surfaces were calculated using a custom digital image correlation algorithm. The average elastic modulus of (1.9±0.9) GPa was obtained from force-displacement data using the Euler-Bernoulli equation. For validation, experimental local strain patterns were compared to ones from a linear elastic FEA. After testing, trabeculae were subjected to basic fuchsin labeling, embedded and sectioned for microdamage analysis.

Whitening initiated on the tension side on loaded trabeculae in the form of a growing ellipsoid zone and faded upon formation of a macro-crack. At this point a whitened zone in front of the propagating crack tip appeared. Using basic fuchsin labeling, we find that whitening and microdamage occurrence are highly correlated, and that the size of cracks range from sub-μm to the μm range. Of the experimentally determined local strains, the tensile strain in x-direction, along the long axis of the samples, correlated best with the detected ellipsoidal whitening zone. The average tensile strain in x-direction at whitening onset was determined to be (1.9±0.1)% and the highest tensile strain just prior to failure was determined to be (12±6)%. Qualitatively, experimentally determined local strains agreed well with FEA. Quantitative values from experiments were generally lower due to the nonlinear properties of bone.

Based on our results and comparison to previous reports, we propose a brittle damage model for trabecular bone, asymmetric in tension and compression, with microdamage originating at tensile strains of 1.9%.

**Thermoreversible Pluronic F108 Gel as a Universal Tissue Immobilization Material for Micro-Computed Tomography Analyses.** E. Atti<sup>\*1</sup>, S. Tetradis<sup>1</sup>, C. E. Magyar<sup>\*2</sup>, J. K. Armstrong<sup>\*3</sup>. <sup>1</sup>UCLA School of Dentistry, Los Angeles, CA, USA, <sup>2</sup>David Geffen School of Medicine at UCLA, Los Angeles, CA, USA, <sup>3</sup>Keck School of Medicine, USC, Los Angeles, CA, USA.

Micro-computed tomography (μCT) provides high-resolution 3-D images and quantitative architectural and density data for whole animal and tissue specimens. Despite remarkable developments in μCT technology, facilitating its commonplace use today, little attention is paid to the development of a reliable method for single and multiple sample immobilization for an individual acquisition run. Pluronic F108 is a water-soluble 14 kDa block copolymer that forms a thermoreversible gel in aqueous solution at a concentration >20% (w/w). A 30% solution of Pluronic F108 in water has a gelation temperature of 17 °C, below which it is a free-flowing viscous fluid, and at room temperature is a firm, optically-clear gel. In this study, the use of a 30% solution of Pluronic F108 (polymer) in water was compared to two common techniques for sample immobilization for μCT analyses: polyethylene spacer (PE) and wet gauze in ethanol. Mice tibiae were excised, fixed in buffered formalin and stored in 70% ethanol. Tibiae were immobilized using polymer by half-filling a scanning tube with cold polymer liquid, allowing the polymer to gel at room temperature and inserting the tibiae into the gel in the desired orientation. The tube was then filled with cold polymer liquid and allowed to gel. The same tibiae were also immobilized using PE or wet gauze in ethanol. Tibiae were scanned using a Scanco-40 scanner with a voxel-isotropic resolution of 12 μm and an X-ray energy of 55 KVP and 72 UA. Background homogeneity was qualitatively assessed using the scout view. For the same anatomical site between the three methods, quantitative architectural and density parameters measured were total volume, bone volume and volume fraction, trabecular number, thickness and spacing, connectivity density, degree of anisotropy, structure model index and bone mineral density. In the scout view, a homogeneous background was observed for polymer, whereas heterogeneous backgrounds were observed for PE and gauze (air bubbles). For architectural and density parameters measured, comparable values for each parameter were obtained with all three immobilization techniques. The advantages of Pluronic F108 gel were the ease of sample orientation, homogeneous medium, clarity of scout views, absence of air bubbles and lack of pressure on the specimen. The use of Pluronic F108 gel provides a rapid and simple technique to reliably immobilize excised bone samples in the desired orientation that does not interfere with quantitative measurements, and may be applicable to immobilize any hard or soft tissue samples for μCT and other analytical techniques.

**Changes in Volumetric Bone Density and Bone Strength at the Tibial Midshaft in Boys and Girls 12-17 Years of Age.** Y. Ahamed<sup>\*1</sup>, D. M. L. Cooper<sup>\*2</sup>, M. Burrows<sup>\*1</sup>, S. Braid<sup>\*1</sup>, H. A. McKay<sup>1</sup>. <sup>1</sup>Orthopaedics, Family Practice, Centre for Hip Health and Musculoskeletal Research, University of British Columbia, Vancouver Coastal Health Research Institute, Vancouver, BC, Canada, <sup>2</sup>Anatomy and Cell Biology, University of Saskatchewan, Saskatoon, SK, Canada.

The greater incidence of fragility fractures in older women compared to men may be related to sex-specific patterns of bone strength development during growth. We recently compared adaptation at the periosteal and endosteal surfaces of the tibial midshaft in boys and girls during puberty. Although all children increased bone size through periosteal apposition, boys had substantially larger bones than girls ( $p < 0.001$ ). Similarly, the magnitude of endosteal apposition during adolescence was greater for girls ( $p < 0.001$ ). Given the greater contribution of geometry, as compared with density to bone strength, in theory, men would better resist structural failure as they have significantly larger but less dense bones, on average. Bone density, bone mineral content, bone size, and shape all contribute to bone strength but their relative contribution to bone strength in boys versus girls is largely unknown. Thus, our objective was to compare a) how volumetric bone density (vBMD) at the tibial midshaft is accrued in boys and girls across 6 years of growth and b) to compare sex differences in bone strength accrual. We hypothesized that girls would exhibit greater gains in vBMD compared with boys across adolescence; whereas, boys would exhibit greater gains in bone strength. Participants were 89 girls and 93 boys followed for 6 years as part of the longitudinal Healthy Bones Study. Participants were 12.0 years ( $\pm 0.55$ ) at baseline (2001) and 17.7 years ( $\pm 0.58$ ) at follow-up (2007). Peripheral QCT (Stratec XCT 2000) was utilised to acquire a 2.5 mm mid-diaphyseal slice of the left tibia at both time points. Stratec XCT 5.50 program with a threshold of 480 mg/cm<sup>3</sup> was used to process the grayscale pQCT images to determine cortical density (CoD, mg/cm<sup>3</sup>) and strength strain index (SSI, mm<sup>3</sup>). We utilized a mixed linear model to compare the rate of change of the selected bone outcomes between the sexes. Sex-specific comparisons showed no significant differences for change in CoD ( $p = 0.904$ ) across the years of adolescent growth and significantly greater differences for change in SSI for boys ( $p < 0.001$ ). The magnitude of these differences was 1.3% for CoD and 54.7% for SSI. Between the sexes, girls demonstrated significantly greater gains in CoD as compared with boys ( $p < 0.001$ ) whereas boys demonstrated significantly greater gains in SSI ( $p < 0.001$ ). Thus, although both boys and girls enhance their bone strength as they mature, the specific adaptation favors bone strength in boys.

**An Investigation of the Fatigue Behaviour of Rabbit Tibiae: Effects of Sex and Age.** T. L. Willett<sup>1</sup>, J. Wang<sup>\*2</sup>, M. D. Grynpas<sup>1</sup>. <sup>1</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, <sup>2</sup>Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Stress fractures in bone are the result of cyclic loading during intensive exercise but do not result solely from fatigue of the bone material. Stress fractures are most prevalent in athletes and army recruits and are more common in females and younger adults. Investigations in animal models have been done using rats and rabbits but age and sex have received little attention. The objective of this study is to investigate sex differences in the fatigue behaviour of tibiae from pubescent (4 months) and mature (12 months) rabbits ex vivo, establishing baseline material fatigue behaviour for a new rabbit model.

To date, tibiae from six male and seven female New Zealand White rabbits (age 4 months) have been tested. Prior to fatigue testing, the bones were scanned with both DEXA and CT scans to measure diaphyseal bone mineral density (BMD) and cross-sectional geometry respectively. The tibiae were loaded in 3-point bending using an Instron 8511 mechanical testing machine. The load was applied at the mid-diaphysis on the posterior-medial surface. Tests were performed under load control at 2Hz with load levels corresponding to initial peak-to-peak strain levels ranging from 3000 to 6000 microstrains with a strain at minimum load of approximately 500 microstrain. Tensile strain due to bending was accurately measured using a strain gauge bound to the anterior-lateral surface of the mid-diaphysis. During the testing, load, displacement, strain, time and cycle count (N) were acquired using a HBM Spider8 data acquisition system.

Diaphyseal BMD was not detectably different between the sexes. As a first comparison of the fatigue behaviour, peak-to-peak strain (S) versus log transformed number of cycles to failure (log(N)) curves were compared between the sexes using linear regression techniques at the 95% confidence level. The S-log(N) curves for the males (n=12) and females (n=12) at 4 months of age were not detectably different ( $p > 0.05$ ). A sex difference in the S-log(N) curves was not detected, perhaps, because the 4-month old rabbits had not yet completed skeletal maturation and any sex differences had not yet fully developed or due to variability between animals. Further analysis of the fatigue behaviour will be presented. Based on the literature, we expect that mature animals will display differences from both the younger group and between the sexes.

**Subject-specific Mechanical Properties of Trabecular Bone Using a Low-dose Imaging.** E. Sapin<sup>\*1</sup>, K. Briot<sup>2</sup>, S. Kolta<sup>2</sup>, C. Roux<sup>2</sup>, W. Skalli<sup>\*1</sup>, D. Mitton<sup>\*1</sup>. <sup>1</sup>Biomechanics Laboratory, ENSAM - Arts et Métiers ParisTech, Paris, France, <sup>2</sup>Rheumatology Department, Paris-Descartes University, Cochin Hospital, Paris, France.

Subject-specific finite-element models to predict failure load are based on quantitative computed tomography (QCT). Relationships between the Young's modulus (E) of vertebral trabecular bone and bone mineral density (BMD) assessed by QCT have been proposed in order to evaluate subject-specific vertebral stiffness. However, QCT is not adapted to analyse the whole spine for osteoporotic patients' follow-up because of the important radiation dose. Towards further in vivo applications, this study aims at evaluating the mechanical properties of the vertebral trabecular bone using a low-dose X-ray device.

Nineteen vertebrae (from T10 to T12; 7 females and 12 males;  $69 \pm 13$  years old) were considered. Biplanar X-rays were obtained using the EOS® system (the radiation dose is ten times lower than a conventional X-rays [2]) with a dual-energy modality to evaluate antero-posterior BMD (AP-BMD in g.cm<sup>-2</sup>) and lateral BMD related to the vertebral width (LAT-BMD in g.cm<sup>-3</sup>). A cylindrical sample was extracted from each vertebral body and tested in axial compression until failure to assess the Young's modulus (E) and the ultimate stress ( $\sigma_{max}$ ).

E was significantly related to AP- and LAT- BMDs ( $r^2 = 0.68$  - SEE=107.7MPa and  $r^2 = 0.53$  - SEE=125.6 MPa respectively;  $p < 0.01$ ). Significant relationships with  $\sigma_{max}$  were also found (AP-BMD:  $r^2 = 0.50$  - SEE=1.24 MPa; LAT-BMD:  $r^2 = 0.64$  - SEE=1.15 MPa;  $p < 0.01$ ).

These values are consistent with BMD assessed using QCT [1] and even better than previous study considering BMDs evaluated using dual X-ray absorptiometry [3]. This study showed that subject-specific mechanical properties of cancellous bone can be predicted from low-dose imaging. It is a first step towards subject-specific models using low-dose imaging to predict vertebral strength of osteoporotic patients.

**Peripheral Quantitative Computed Tomography (pQCT) Predicts Vertebral Fractures in Osteoporotic Postmenopausal Women.** K. D. Stathopoulos<sup>\*1</sup>, E. Metania<sup>\*1</sup>, P. Katsimbri<sup>\*1</sup>, T. Kaplanoglou<sup>\*1</sup>, N. Kordalis<sup>\*1</sup>, E. Efsthopoulos<sup>\*2</sup>, P. N. Soucacos<sup>\*1</sup>, G. Skarantavos<sup>1</sup>. <sup>1</sup>Department of Bone Metabolic Diseases, 1st Orthopedic clinic, University of Athens, "Attikon" University Hospital, Athens, Greece, <sup>2</sup>2nd Department of Radiology, University of Athens, "Attikon" University Hospital, Athens, Greece.

**Purpose** was to compare results of tibial pQCT measurements, in order to estimate differences in volumetric densities and geometric properties of the bone, between osteoporotic postmenopausal women with vertebral fractures of the thoracic spine and postmenopausal osteoporotic women without such fractures.

**For material and methods**, we examined retrospectively medical records of 50 osteoporotic postmenopausal women from a total of 1246 treated as outpatients in our department. Patients were separated in 2 groups: Group A (n=24, mean age 72.0y) had  $\geq 1$  osteoporotic fractures of the thoracic spine and Group B (n= 26, mean 68.6y) had no such fractures. Inclusion criteria: 1) age > 50y, 2) postmenopausal status > 2 years 3) DEXA (Spine or Hip) T-scores < -2.5 SD to define osteoporosis, 4) positive (Group A)/negative (Group B) x-rays for vertebral fracture (loss of anterior/central height of > 30% of the vertebral body) and 5) no previous use of bone anabolic agents (estrogens, teriparatide, parathormone). Exclusion criteria: secondary osteoporosis' conditions (glucocorticoid-induced or other), bone metabolic diseases, high-energy vertebral fractures, previous tibia fracture and malignancy. We compared tibial pQCT measurements at the 4%, 14% and 38% of tibia length sites between the 2 groups and performed statistical analysis of our results (t-test, ANOVA).

**Results:** there were no statistical differences between the 2 groups concerning age (p=0.197), time of menarche (p=0.729) or menopause (p=0.196), and tibia length (p=0.102). Trabecular density at the 4% site was significantly lower (p=0.016) in the fracture group (mean 146.521) than in the non-fracture group (mean 166.803). Subcortical density at the 14% site was lower in the fracture group (mean 658.83 vs 695.23 in the non-fracture group) but the results were not statistically significant (p=0.343). Patients with  $\geq 2$  vertebral fractures had lower trabecular densities than patients without fracture (p=0.020) or patients with 1 vertebral fracture (p=0.284). Finally, patients with vertebral fractures had lower total area (p=0.097), trabecular area (p=0.098) and cortical area (p=0.075) and lower cortical thickness (p=0.047) at the 4% site.

Our **conclusion** was that trabecular density on tibial pQCT was significantly lower in osteoporotic women with vertebral fractures than in non-fractured ones. pQCT technology may be helpful in recognizing women of high risk for osteoporotic vertebral fractures.

**Effects of a High G Environment on Bone Mineral Density in UK Fast-Jet Trainee Pilots.** D. Pearson<sup>\*1</sup>, J. P. Greeves<sup>2</sup>, S. E. Day<sup>\*2</sup>, J. Adams<sup>3</sup>, B. Horton<sup>\*1</sup>, D. Green<sup>\*1</sup>, D. Hosking<sup>1</sup>. <sup>1</sup>Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, <sup>2</sup>QinetiQ Ltd, Farnborough, United Kingdom, <sup>3</sup>Manchester University, Manchester, United Kingdom.

Pilots ejecting from fast-jet aircraft are susceptible to vertebral fractures, particularly at T12/L1. Reduced bone mineral density (BMD) is a risk factor for vertebral fracture. Pilots training on the Hawk T1 aircraft experience G forces ranging between -4 and +8 G, in different axes, that might confer potential positive effects on vertebral BMD. The purpose of this study was to examine the effect of high G training on lumbar spine BMD in fast-jet trainee pilots.

Twenty-five male fast-jet trainee pilots (mean (1SD) age 25.4 (3.1) y; height (1.80 (0.07) m; body mass 79.7 (8.0) kg) starting Advanced Flying Training (AFT) on the Hawk T1 trainer volunteered to take part. BMD at the lumbar spine (L1-L4), total hip, femoral neck and the whole body, and body composition were measured at the start (baseline) and during the final week (follow-up) of AFT. The duration of training ranged between 2.7 and 4.7 months, and pilots flew 60 (20) h. Lumbar spine, total hip and femoral neck BMD was also measured in 12 size-matched male controls (age 27.3 (6.9) y; height 1.80 (0.06) m; body mass 80.7 (8.7) kg) on two occasions, six months apart. Scans were performed using a Hologic® QDR 4500.

Pilots were significantly younger than controls (P<0.01), but no significant differences in lumbar spine, total hip or femoral neck BMD were shown at baseline between the two groups (P>0.05). Lumbar BMD did not change between baseline and follow-up in pilots (1.107 (0.115) vs 1.102 (0.114) g·cm<sup>2</sup>) or in controls (1.138 (0.141) vs 1.149 (0.157) g·cm<sup>2</sup>) (P>0.05). A significant decrease in total hip BMD between baseline and follow-up was observed in pilots (1.121 (0.132) vs 1.110 (0.131) g·cm<sup>2</sup>; P<0.05) but not in controls (P>0.05). No significant change occurred in femoral neck BMD in either group (P>0.05), or in whole body BMD and body composition in pilots.

These findings suggest that exposure to high G training does not alter mineralisation at the lumbar spine, and, therefore, may not offer protective effects against vertebral fracture in pilots ejecting from fast-jet aircraft. The effect of longer-term G exposure on BMD should be investigated. The mechanism for the significant reduction in BMD detected at the hip in pilots is uncertain, but might be explained by reduced levels of leisure time physical activity during AFT.

**Comparison of Voxel-Based and Smooth Finite Element Models to Predict Damage Accumulation in Vertebral Bodies.** Y. Chevalier<sup>\*</sup>, D. Pahr<sup>\*</sup>, P. K. Zysset. Institute of Lightweight Design and Structural Biomechanics, Vienna University of Technology, Vienna, Austria.

**Slipped Discs** are a common cause of low back pain. The aim of this study was to compare the results of two different modeling approaches to predict damage accumulation in vertebral bodies. A voxel-based finite element model (FEM) and a smooth FEM were used to simulate the mechanical behavior of a vertebral body under compression. The results of the two models were compared in terms of damage accumulation. The voxel-based FEM showed higher damage accumulation than the smooth FEM. This is due to the fact that the voxel-based FEM takes into account the local geometry of the vertebral body, while the smooth FEM uses a simplified geometry. The results of this study show that the voxel-based FEM is more accurate in predicting damage accumulation in vertebral bodies.

**Indication** of the model results is shown in the figure. The results of the two models are compared in terms of damage accumulation. The voxel-based FEM shows higher damage accumulation than the smooth FEM. This is due to the fact that the voxel-based FEM takes into account the local geometry of the vertebral body, while the smooth FEM uses a simplified geometry. The results of this study show that the voxel-based FEM is more accurate in predicting damage accumulation in vertebral bodies.

**Changes in Chemical, Mechanical, and Structural Properties of Lamellar Bone during Young Adulthood.** V. Bornikolas<sup>\*1</sup>, M. Ruppel<sup>\*1</sup>, L. Miller<sup>2</sup>, S. Judex<sup>1</sup>. <sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, <sup>2</sup>Brookhaven National Laboratories, Upton, NY, USA.

Despite clear evidence that factors pertaining to the quality of a bone may greatly influence its mechanical behavior, the precise identity of the underlying matrix components is unclear. Here, using the young adult rat skeleton, relations between chemical, mechanical, and structural properties were determined. Femurs of female Sprague-Dawley rats were harvested at 2mo, 4mo, and 5mo of age (n=4 each) and subjected to in situ chemical Fourier transform infrared microspectroscopy (FTIRM) analysis, static and dynamic nano-indentation, as well micro- and nano-computed tomography. All measurements were performed at anterior, posterior, medial, and lateral strips of the middiaphysis that spanned the entire cortex between the endocortical and periosteal surfaces. Preliminary data showed that the degree of mineralization, as indicated by the phosphate to protein ratio, increased between 2mo and 5mo of age. Interestingly, this increase was spatially highly-site specific and focal in nature (Fig. 1). Spatial correlations were performed site-specifically between the chemical, mechanical, and structural measurements. Together, these data indicate a great degree of site-specificity by which the diaphyseal rat femur alters its matrix properties, a characteristic that can be exploited for identifying chemical and structural components that modulate bone's mechanical behavior.

Figure 1: Map of the phosphate to protein ratio imaged at the posterior aspect of 2m old (left), 4m old (middle), and 5m old (right) rat femur. Brighter areas indicate higher levels of mineralization.

**Neonatal Exposure to Soy Isoflavones Attenuates Deterioration of Bone Tissue in Female but Not Male Mice After Cessation of Sex Steroid Production.** J. Kaludjerovic\*, W. E. Ward. Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

Isoflavones, abundant in soy foods such as soy protein-based infant formula, are structurally similar to estrogen and thus, may have the potential to elicit estrogen-like activity. Infants consuming soy protein-based infant formulas are exposed to substantial levels of soy isoflavones during developmental stages of life that are sensitive to environmental disturbances. Previous investigation from our laboratory has demonstrated that neonatal exposure to soy isoflavones, at levels similar to that of infants consuming soy protein-based infant formula, results in higher bone mineral density (BMD) and greater bone strength in female CD-1 mice at young adulthood. The primary objective of this study was to determine if the higher BMD and greater bone strength observed at 4 months of age from early exposure to soy isoflavones provides protection against the deterioration of bone tissue that occurs after the withdrawal of endogenous sex steroid production. Male and female mice (n=8-12 pups/group/gender) were randomized to subcutaneous injections of daidzein (DAI, 2 µg/d), genistein (GEN, 5 µg/d), DAI+ GEN (7 µg/d), diethylstilbestrol (DES, positive control, 2 µg/d), or corn oil (CON) from postnatal day one to five. At 4 months of age, mice were either ovariectomized (females) or orchidectomized (males) and were followed to 8 months of age. BMD and biomechanical bone strength were assessed at the femur and lumbar vertebrae to determine the effects of early isoflavone exposure on skeletal sites that differ in the proportion of cortical and trabecular bone. Females treated with DAI, GEN, DAI+GEN or DES had higher (p<0.05) lumbar vertebrae (LV1-LV3) bone mineral content (BMC) and BMD compared to the CON group. These improvements resulted in stronger vertebrae that were more resistant to fracture, as the peak load of LV2 was higher (p<0.05) in the DAI and DAI+GEN groups compared to CON. Similar trends were observed at the femur with DAI and DAI+GEN providing the greatest protection against the deterioration of bone tissue that occurs after the decline of endogenous sex steroid production. Among males, the effects of early exposure to isoflavones on bone metabolism were not significantly different from the CON group. In conclusion, short-term neonatal exposure to isoflavones provides protection against the deterioration of bone tissue postovariectomy in females but not postorchidectomy in males. The greatest protection resulted from treatment with DAI, either alone or in combination with GEN. Future research is required to elucidate the mechanisms by which early exposure to soy isoflavones modulates bone metabolism.

**Bone Size, Volumetric Bone Density in relation to Fat Mass in Healthy Young Men at age of Peak Bone Mass.** Y. E. Taes\*, B. Lapauw\*, S. Goemaere\*, H. Zmierzak\*, J. Kaufman\*. <sup>1</sup>Endocrinology, Ghent University Hospital, Ghent, Belgium, <sup>2</sup>Unit for Osteoporosis and Metabolic Bone Diseases, Ghent University Hospital, Ghent, Belgium.

This study was performed to assess the individual contribution of lean and fat mass on volumetric trabecular and cortical bone parameters.

We recruited 677 healthy male siblings at the age of peak bone mass (25-45 yrs) in a cross-sectional, population-based study. Trabecular and cortical bone parameters of the radius and cortical bone parameters of the tibia were assessed using peripheral quantitative computed tomography (pQCT). Lean and fat mass were determined using DXA. Cross-sectional associations between cortical, trabecular bone parameters and fat or lean mass were investigated using linear mixed-effects modeling analyses to account for family structure.

Positive univariate associations between height, body weight, lean or fat mass and bone size as determined by pQCT are observed. After controlling for age, weight and height, lean mass remains a strong positive determinant of cortical bone area, as well as cortical thickness and periosteal circumference, both at the radius ( $\beta = 0.26-0.91$ ;  $P < 0.003$  to  $0.0001$ ) and the tibia ( $\beta = 0.58-0.93$ ;  $P < 0.0001$ ). At the radius trabecular area ( $\beta = 0.70$ ;  $P < 0.0001$ ) and density ( $\beta = 0.19$ ;  $P = 0.03$ ) relate positively with lean mass. Fat mass is negatively associated with cortical bone area, cortical thickness and periosteal circumference, both at the radius ( $\beta = -0.33$  to  $-0.88$ ;  $P \leq 0.0001$ ) and the tibia ( $\beta = -0.59$  to  $-0.93$ ;  $P < 0.0001$ ) as well as with trabecular area ( $\beta = -0.65$ ;  $P < 0.0001$ ) at the radius, after correction for age, height and weight/lean mass. Cortical density is positively associated with fat mass ( $\beta = 0.18$  to  $0.20$ ;  $P = 0.01$  to  $0.03$ ) and inversely with lean mass ( $\beta = -0.25$  to  $-0.28$ ;  $P = 0.001$  to  $0.006$ ).

In conclusion, we found that lean mass is as expected a strong positive determinant of bone size at both the radius and tibia in healthy men at the age of peak bone mass, consistent with the model of bone adaptation to applied muscle force. After controlling for age, weight or lean mass and height, fat mass is negatively associated with cortical and trabecular bone size and positively with cortical density. Though no conclusion about the underlying mechanism can be drawn from this study, these findings could be explained through the mechanostat model of bone adaptation, programming of the mesenchymal stem cell or adipocyte-related factors.

## SU478

**Non-Enzymatic Glycation Alters Collagen Fibrillar Structure and Energy Dissipation Characteristics.** A. A. Poundarik\*, D. Vashishth. Biomedical Engg., Rensselaer Polytechnic Institute, Troy, NY, USA.

The ability of bone to resist fracture is determined not only by bone mineral density and architecture but also by the quality of its extracellular matrix (ECM) [1]. Post translational modifications including non enzymatic glycation (NEG), resulting from the formation of advanced glycation endproducts (AGEs), have been shown to alter the bone's ECM including collagen [2]. Because collagen is the principal structural protein in bone providing ductility, the accumulation of AGEs in collagen may increase bone fragility by altering its ultrastructure and energy dissipation characteristics.

Here we used atomic force microscopy (AFM) to study the effect of glycation on the fibrillar structure of collagen and on interfibrillar energy dissipation characteristics. Acid solubilized rat tail collagen was precipitated in vitro and incubated to obtain fibrils with 67nm D-periodicity. A 1.5M ribose solution was used to glycate [3] the collagen. Control (C) and glycated (G) collagen were imaged for topography using AC 160 cantilevers ( $k=40N/m$ ,  $f_c=300kHz$ ). Fibril diameter (D) was measured using section analysis (N=8). Force measurements on these samples (pulling rate of 5µm/sec) were carried out in PBS under ambient conditions using Olympus Biolever ( $k=0.025N/m$ ). As a measure of energy dissipation during deformation of collagen, area under the force-distance curves (A) was quantified (N=5). Data was assessed using non-parametric Mann-Whitney Rank Sum Tests. Fluorescence based AGE content was measured using established protocol [3]. AGEs increased three fold in the glycated samples with values being in the physiological range (p<0.05). Compared to the control sample, fibril diameter ( $D_c=363\pm40.4nm$ ) of glycated collagen showed a significant (p<0.001) reduction ( $D_g = 88.3\pm13.5nm$ ). Area under curve (energy dissipation) comparison between the two groups was also statistically significant (p=0.022) with the mean dissipation value for the glycated fibrils ( $A_g=4.216E-15\pm4.059E-15Nm$ ) being about an order of magnitude smaller than that of the control ( $A_c=3.014E-14\pm2.014E-14Nm$ ).

In conclusion, non-enzymatic glycation alters collagen fibrillar structure and reduces energy dissipation. Collagen in bone is responsible for providing ductility and absorbing energy thereby reducing fracture propensity. Known accumulation of AGEs due to diabetes and aging may consequently manifest as a degradation of bone matrix properties and an increased risk of fracture. Further studies are needed to investigate the molecular origin of these changes.

**Transmenopausal Changes In the Trabecular Bone Intrinsic Properties.** B. J. Polly<sup>\*1</sup>, J. A. Turner<sup>\*1</sup>, M. P. Akhter<sup>2</sup>, R. R. Recker<sup>2</sup>. <sup>1</sup>Engineering Mechanics, University of Nebraska, Lincoln, NE, USA, <sup>2</sup>Medicine, Creighton University, Omaha, NE, USA.

Bone fragility related to post-menopausal osteoporosis in women leads to atraumatic fractures of skeletal sites. Three-dimensional bone architecture has been reported previously. However, little is known about the intrinsic material strength changes during the transmenopausal period. The general hypothesis for this work is that measured variables describing trabecular bone intrinsic material properties are affected by change in hormonal status at menopause soon after final menses, such that indentation modulus and hardness will decline. Minimal data exist describing intrinsic material properties in human transilial bone biopsies representing transmenopausal period. Paired transilial biopsies specimens (n= 6 pairs) were used from a previously reported study in which bone biopsies were obtained from women on entry (pre-menopausal and >age 46), and at 12 months past the last menstrual period. Trabecular bone intrinsic properties were obtained using the nanoindentation technique (Hysitron, MN). Embedded bone biopsies were prepared with a flat and smooth surface by grinding with 600, 800, and 1200 grit sand papers and then polished with 1 micron and 0.25 micron diamond slurry (Buehler, IL). At least 20 indents per biopsy were made on trabecular sites using a Berkovich indenter tip. Indentation modulus was determined from the load displacement diagram using the Oliver-Pharr method. The loading and unloading sections were each 10 seconds, with loading rates of 600  $\mu\text{N/s}$  and -600  $\mu\text{N/s}$  respectively. The hold section was 10 seconds at the maximum force of 6,000  $\mu\text{N}$ . Paired t-tests were used to compare pre- and post-menopausal trabecular bone intrinsic properties. BV/TV (published micro-CT data, Table) decreased during transmenopausal period. There is no significant change between pre- and post menopausal bone specimens in their indentation modulus and hardness. Data from additional paired bone biopsies will allow us to document differences in trabecular bone intrinsic material properties. One limitation of this study is that the previously used bone biopsies were embedded in Methyl methacrylate, which may influence the measured intrinsic properties of bone. We expect that intrinsic material properties will be different in unembedded bone biopsies thus reflecting any true decline in skeletal quality during the transmenopausal period.

Mean $\pm$ SD	Pre	Post
BV/TV % (3D micro-CT)	28.3 $\pm$ 7.1	24.9 $\pm$ 7.4 <sup>a</sup>
Indentation modulus (GPa)	16.8 $\pm$ 2.0	17.1 $\pm$ 3.7
Indentation Hardness (GPa)	0.60 $\pm$ 0.06	0.64 $\pm$ 0.12

**Non-invasive In Vivo Raman Spectroscopy in Mice.** K. A. Dooley<sup>\*1</sup>, M. V. Schulmerich<sup>\*1</sup>, J. M. Kreider<sup>\*2</sup>, J. H. Cole<sup>1</sup>, S. A. Goldstein<sup>2</sup>, M. D. Morris<sup>1</sup>. <sup>1</sup>Chemistry, University of Michigan, Ann Arbor, MI, USA, <sup>2</sup>Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA.

Bone fragility is associated with changes in composition that are metrics of bone quality. Currently, no *in vivo* techniques are available for assessing the composition contributions to bone quality in animals used in the laboratory for studying disease states. We have developed a non-invasive Raman spectroscopic fiber optic probe to acquire bone spectra through the skin of mice and other small animals. The objective of this study was to investigate our ability to measure bone composition parameters non-invasively in mice. Strains of mice were selected to mimic the variation seen in a healthy human population. For all transcutaneous measurements, an approved protocol was followed. Mice were anesthetized, and hair was removed using a depilatory agent. Glycerol was applied to increase skin transparency. Plastic wrap was then placed over the limb, and water irrigation was used to prevent thermal damage. Multiple spectra were acquired on each tibia. The small size of the mouse limbs required great care in positioning the fiber optic probe to obtain valid results. Following transcutaneous measurements, the mice were sacrificed, overlying tissues were removed, and spectra of the exposed bone were collected for validation. Bone spectra were separated from spectra of overlying tissue using multivariate methods. The mineral/matrix ratio and mineral crystallinity, metrics of bone quality, were subsequently calculated. Both measures of mineral content and matrix content obtained transcutaneously were in good agreement with the values obtained from exposed bone. Our results demonstrate that important composition contributions to bone quality can be determined via transcutaneous measurements in mice. Preliminary measurements on rat and canine limbs demonstrate that this approach to *in vivo* spectroscopic measurement of bone quality is easily adapted to these larger animals with only minor changes in the placement and spacing of optical fibers.

## SU481

**Estimation of Relative Stiffness Contributions of Cortical and Trabecular Compartments by MRI-based Finite Element Analysis.** C. S. Rajapakse<sup>\*1</sup>, J. F. Magland<sup>\*1</sup>, M. J. Wald<sup>\*1</sup>, B. Vasilic<sup>\*1</sup>, X. H. Zhang<sup>\*2</sup>, X. E. Guo<sup>2</sup>, F. W. Wehrli<sup>1</sup>. <sup>1</sup>University of Pennsylvania, Philadelphia, PA, USA, <sup>2</sup>Columbia University, New York, NY, USA.

Whole bone stiffness has contributions from both cortical and trabecular bone (TB). The relative stiffness contribution of the two compartments can be estimated using finite element (FE) analysis. However, such estimations have been impractical due to the computational complexity. To estimate overall stiffness, a fast, custom-designed FE algorithm was developed. MR images of 30 whole cross-section distal tibia specimens of approx. 20mm length from 15 donors (ages 55-85 years) were obtained with 3D FLASE (spin-echo) pulse sequence in a 1.5T whole-body scanner, with 128 slices acquired at 160  $\mu\text{m}^3$  isotropic voxel size. Cortical, TB, and combined regions were manually selected to generate three data sets for each specimen. The FE analysis was then performed on the basis of inverted grayscale bone volume fraction (BVF) maps. The tissue properties were assumed to be linear elastic and isotropic with Poisson's ratio 0.3 and Young's modulus 13GPa, and the Young's modulus of each bone voxel was weighted by the corresponding BVF value. Simulated compression was applied along the principal loading (i.e. the bone's longitudinal) direction, and the stiffness was obtained by comparing the surface forces to the applied compression. Total computation time was around 75 hours for all 90 simulations on a dual quad-core system with 28GB of RAM. Figure 1a shows the relative stiffness contributions from cortex and TB for 15 specimens. The trabecular compartment was found to contribute 32 $\pm$ 12% to overall stiffness. Also noted from Figure 1a is the greater strength of the whole bone relative to the sum computed for each compartment. Such a relationship is also evident from Figure 1b in which whole-bone stiffness is plotted versus the sum from each compartment. The data show that whole-bone FE now is possible and can provide new insight into compartmental contributions to overall mechanical behavior in practical computation times on dedicated laboratory computer systems.

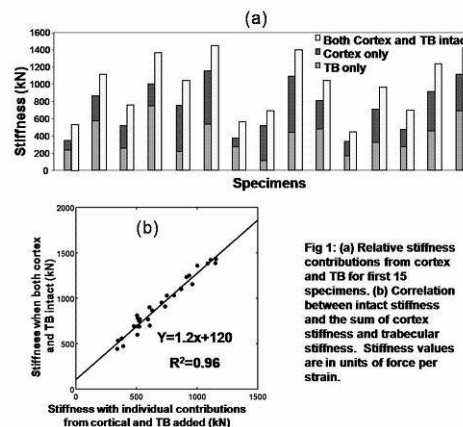

Fig 1: (a) Relative stiffness contributions from cortex and TB for first 15 specimens. (b) Correlation between intact stiffness and the sum of cortex stiffness and trabecular stiffness. Stiffness values are in units of force per strain.

**Vitamin D Insufficiency: Seasonal Variation in Healthy 6-12 year old African American and Caucasian Children.** K. Rajakumar<sup>1</sup>, M. F. Holick<sup>2</sup>, K. Jeong<sup>\*3</sup>, Y. Lin<sup>\*4</sup>, T. C. Chen<sup>2</sup>, F. Olabopo<sup>\*5</sup>, M. Haralam<sup>\*5</sup>, A. Nucci<sup>\*5</sup>, S. B. Thomas<sup>\*6</sup>, S. L. Greenspan<sup>7</sup>. <sup>1</sup>Pediatrics, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, <sup>2</sup>Medicine, Boston University School of Medicine, Boston, MA, USA, <sup>3</sup>Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA, <sup>4</sup>Medicine & Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA, <sup>5</sup>Children's Hospital of Pittsburgh, Pittsburgh, PA, USA, <sup>6</sup>Center for Minority Health, University of Pittsburgh, Pittsburgh, PA, USA, <sup>7</sup>Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

**Background:** Data characterizing the vitamin D (Vit D) status of healthy young school age children in the United States are limited.

**Objective:** To estimate the seasonal variation of vit D insufficiency in healthy 6-12 year old pre- and early adolescent African American (AA) and Caucasian (C) children residing in Pittsburgh, PA (latitude: 40.4N) and examine risk factors for vit D insufficiency.

**Design:** Serum 25-hydroxyvitamin D (25(OH)D), parathyroid hormone (PTH), calcium (Ca), phosphorus, albumin, and dietary intake of vit D and calcium were assessed during summer (June through September) and/or winter (December through March). Vit D deficiency was defined as serum 25(OH)D <20 ng/mL and insufficiency as 20 - <30 ng/mL. Serum 25(OH)D was measured by liquid chromatography tandem mass spectrometry (LC-MS/MS).

**Results:** A total of 123 children (mean age (yrs): 9.1 $\pm$ 1.7 [SD], AA: 93 [75%], C: 30 [25%], male: 72 [58%]) were enrolled during August, 2006 through September, 2007 and assessed during summer (N=116) and winter (N=72).

	Summer		Winter	
	AA (N=87)	C (N=29)	AA (N=57)	C (N=15)
Vit D Insufficient†	17(20%)	2(7%)	21(37%)	0(0%)*
BMI (Kg/M <sup>2</sup> )	19.4±3.9	17.1±2.1*	19.2±3.5	16.9±1.8*
Diet Vit D (IU/day)	308±178	410±193*	330±158	322±230
Diet Ca (mg/day)	1303±665	1321±457	1405±658	1221±454
25(OH)D (ng/mL)	39±11.4	48.8±14.7*	35.4±11.4	42.1±10.9*
PTH (pg/mL)	38.2±22.3	26.7±26.5*	36.6±20.2	23.3±8.9*

\*p<0.05, †: 2 subjects with vit D deficiency during summer and winter are included as vit D insufficient.

In a multivariate model, race (AA) and season (winter) were significant predictors of low serum 25(OH)D levels and low dietary intake of vitamin D was a predictor of higher PTH levels. AA children were 8 times more likely than C children to be vit D insufficient, odds ratio (CI): 8.4 (1.71, 41.3).

**Conclusion:** Vit D insufficiency was significantly greater during winter among pre-and early adolescent AA children compared to C children residing in the Northeast. Compared to C children, AA children had lower 25(OH)D and higher PTH in summer and winter. The benefits of optimizing the vitamin D status of young school age children need to be explored further.

**Advanced Vertebral Compression at Diagnosis among Children with Acute Lymphoblastic Leukemia.** L. M. Ward<sup>1</sup>, M. Matzinger<sup>\*1</sup>, N. Alos<sup>2</sup>, S. Atkinson<sup>3</sup>, C. Clarson<sup>\*4</sup>, R. Couch<sup>\*5</sup>, E. Cummings<sup>\*6</sup>, F. H. Glorieux<sup>7</sup>, R. Grant<sup>\*8</sup>, J. Halton<sup>\*1</sup>, B. Lentle<sup>\*9</sup>, H. Nadel<sup>9</sup>, C. Rodd<sup>7</sup>, K. Siminoski<sup>\*5</sup>, D. Stephure<sup>\*10</sup>, S. Taback<sup>\*11</sup>, N. Shenouda<sup>\*1</sup>, F. Rauch<sup>7</sup>, and the Canadian STOPP Consortium<sup>\*12</sup>. <sup>1</sup>Univ of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Univ de Montréal, Montréal, QC, Canada, <sup>3</sup>McMaster Univ, Hamilton, ON, Canada, <sup>4</sup>Univ of Western Ontario, London, ON, Canada, <sup>5</sup>Univ of Alberta, Edmonton, AB, Canada, <sup>6</sup>Dalhousie Univ, Halifax, NS, Canada, <sup>7</sup>McGill Univ, Montréal, QC, Canada, <sup>8</sup>Univ of Toronto, Toronto, ON, Canada, <sup>9</sup>Univ of British Columbia, Vancouver, BC, Canada, <sup>10</sup>Univ of Calgary, Calgary, AB, Canada, <sup>11</sup>University of Manitoba, Winnipeg, MB, Canada, <sup>12</sup>Canadian Pediatric Bone Health Working Group, Ottawa, ON, Canada.

Vertebral compression is a serious complication of childhood acute lymphoblastic leukemia (ALL). The frequency and pattern of vertebral fractures, as well as their relationship to bone mineral density and other clinical indices, have not been systematically studied. We evaluated spine health in 186 newly diagnosed children (age (mean±SD) 6.6±4.1 years; 108 boys) with ALL (precursor B cell: N=167; T cell: N=19), who were enrolled in a national bone health research program. Patients were assessed within 30 days of diagnosis, including lateral thoracolumbar spine x-ray and bone densitometry. Vertebral morphometry was carried out by the Genant semi-quantitative method. Thirty-seven patients (20%) had a total of 118 grade 1 or more prevalent vertebral compression fractures (80 thoracic, 68%; 38 lumbar); back pain occurred in 18/37 (49%). The frequency of spine fractures per patient was as follows: 1 to 2 fractures, 22/37 patients (59%); 3 to 7 fractures, 8 patients (22%); 8 or more fractures, 7 patients (19%). The T6/T7 and T12/L1 vertebrae were most commonly affected (21 and 17% of fractures, respectively). Seventy-nine percent (93/118) of fractures were mild (grade 1), 18 (15%) moderate (grade 2) and 7 (6%) severe (grade 3). Minimal vertebral changes (15-20% loss in height, grade 0.5) were noted in an additional 17 patients. Children with grade 1 or more vertebral compression had reduced lumbar spine areal bone mineral density (LS aBMD) z scores compared to those without (mean±SD, -1.7±1.4 vs. -0.8±1.2; P < 0.001). Among the clinical indices including age, gender, height, body mass index, leukemia sub-diagnosis and risk, white blood count, calcium/vitamin D intake, physical activity and LS aBMD z score, only spine BMD was associated with vertebral compression. For every 1 standard deviation reduction in LS aBMD z score, the odds for fracture increased 2.1-fold (95% CI 1.5, 3.0). Whether the children with vertebral fractures in this study will undergo rebuilding of the vertebral bodies and restitution of bone mass with ALL treatment remains under study.

**Accuracy of Cobb Angle Measurement with iDXA.** P. Markwardt\*, H. S. Barden, D. Ergun. GE Healthcare, Madison, WI, USA.

The diagnosis and monitoring of scoliosis, a medical condition characterized by lateral curvature of the spine, relies on accurate measurement of spinal curvature. The Cobb angle, the standard method of quantifying this curvature, is generally measured by hand from anteroposterior (AP) spine radiographs. The angle is determined by first locating the vertebra (apex vertebra) that is laterally displaced furthest from the centerline of the spine, and then locating the vertebrae at either end of the curve with the least lateral displacement from the center line and maximum end plate tilt. The Cobb angle is defined as the angle between the intersection of two lines, or lines perpendicular to them, drawn parallel to the superior endplate of the end vertebra above and the inferior endplate of the end vertebra below the apex vertebra.

AP images of an aluminum spine phantom were acquired with iDXA (GE Healthcare - Lunar) and analyzed with version 12.0 software. The spine geometry option was used to calculate Cobb angles for all combinations of vertebral ROIs from C1 to L5. ROIs were manually positioned over the C1 superior endplate and the C2-L5 inferior endplates. iDXA software automatically calculated the Cobb angle for each set of endplates. A protractor (Starrett No. 12) was used to measure phantom end-plate angles. iDXA values were compared to measured values. Results showed a very close relationship ( $R^2 = 0.998$ ) between iDXA-measured and protractor-measured Cobb angles, with slope of the regression not significantly different from identity. The mean difference and absolute mean difference between expected and measured angle was -0.01 degree and 0.53 degree, respectively. We conclude that Cobb angles measured from vertebral end plates on an aluminum spine phantom were measured accurately with iDXA. Similar results were shown for quantifying degree of kyphosis on lateral iDXA scans.

**25-HydroxyVitamin D Levels in Children with Chronic Kidney Disease (CKD) as Measured by Tandem Mass Spectrometry.** H. E. Price\*, C. B. Langman, F. Ali\*, E. R. Brooks\*, F. B. Vicente\*. Division of Kidney Diseases, Children's Memorial Hospital, Chicago, IL, USA.

Vitamin D is one of 3 hormones regulating calcium, phosphorus and bone homeostases. Human biology allows two forms: vitamin D3 (cholecalciferol) and vitamin D2 (ergocalciferol) to be used. Vitamin D3 is produced in the skin, while dietary vitamin D is derived from animal sources (D3) and from plant sterols (D2). In the liver, cyp2R1 produces 25(OH)D from either form, and both are subsequently converted to 1,25(OH)<sub>2</sub>D in the kidney. Circulating [25(OH)D] is the most sensitive measure of vitamin D nutritional status, since it has a half-life of ~3 weeks. Hypovitaminosis D is a common problem in individuals with chronic kidney disease (CKD), and is manifested by calcium malabsorption, 2<sup>o</sup> hyperparathyroidism, muscle weakness, and osteomalacia. Evidence-based medicine (EBM) guidelines have provided rationale for its supplementation in advancing CKD. In this study, we measured 25(OH)D in 97 children (7-19 years) with CKD and in 39 of their healthy siblings (6-21 years) utilizing Tandem Mass Spectrometry (TMS) methodology. 25(OH)D was subdivided into measured 25(OH)D2 and 25(OH)D3. Results are reported in ng/mL. 25(OH)D in children with CKD ranged from 6.7 to 114 (mean = 40.1, SD=20.3). These values differed from, and were greater than, their siblings group which ranged from 8.8 to 49.9 (X= 22.0, SD=8.7, p<0.001). Further in CKD, 25(OH)D2 (X= 5.8) was higher than in siblings who had no measurable 25(OH)D2 (p<0.001). In CKD, 25(OH)D3 was greater (X=34.2) compared to siblings (X=22.0, p<0.001). 19/97 children with CKD were receiving oral D2 and 8 were receiving oral D3 supplementation. Comparisons of mean 25(OH)D in CKD without supplementation as compared to the siblings showed that the CKD group were higher (30.4 vs. 22.0, respectively, p<0.001). In conclusion, and differently than we have reported for the decade prior to EBM recommendations for vitamin D supplementation, children with CKD were 25(OH)D sufficient while their healthy siblings were not. Many of the CKD children were receiving supplementation with oral D2 or D3, and the TMS methodology allowed for measurement of both these forms of 25(OH)D. Therefore, due to the accuracy of measuring 25(OH)D2 and D3 using TMS, we found that children with CKD may have normal levels of 25(OH)D, likely due to supplementation, while healthy children continue to remain below the recommended levels of nutritional vitamin D adequacy. Attention should be paid to the entire family of patients with CKD for adequacy of vitamin D nutrition. Further study is now needed to determine if there are additional factors, perhaps an increase in cyp2R1, which may regulate 25(OH)D levels in children with CKD.

## SU486

**Bone Status Evaluation in Pre-Pubertal Children with Cystic Fibrosis.** N. Haddad\*<sup>1</sup>, M. Howenstine\*<sup>1</sup>, M. Peacock\*<sup>2</sup>, L. A. DiMeglio\*<sup>1</sup>. <sup>1</sup>Pediatrics, Indiana School of Medicine, Indianapolis, IN, USA, <sup>2</sup>Medicine, Indiana School of Medicine, Indianapolis, IN, USA.

**Background:** Osteoporosis is a sequela of cystic fibrosis (CF) and is multi-factorial. No study has comprehensively assessed bone metabolism in young children with CF. Yet identification of factors contributing to early osteoporosis onset would permit development of prophylactic interventions.

**Objective:** To characterize bone mineral density (BMD) & bone metabolism in a group of pre-pubertal children with CF. Unaffected pre-pubertal siblings (sibs) were enrolled as controls.

**Methods:** Heights, weights, & pubertal assessments were done. Fracture & steroid history was collected by questionnaire. Serum calcium, phosphorus, PTH, 25-vitamin D, & markers of bone turnover & resorption were measured after an overnight fast. BMD & % body fat were measured using dual X-ray absorptiometry (DXA, Prodigy GE). Bone age radiographs were obtained.

**Results:** 20 CF patients (pts) & 20 unaffected sibs (45% males) were enrolled. 39 pts had genetic analyses. Nine CF pts were homozygous for Δ508 mutations, 10 had other mutations or were compound heterozygotes for Δ508 mutations. 12 sibs were heterozygous for Δ508 mutations, 3 were heterozygous for other mutations, & 5 had no mutation detected. Mean age was 6.9 ± 1.8 yr (range 4.2-10.1). Pts & sibs had comparable ages, bone ages, & gender distributions. CF pts had normal bone ages. 2 CF pts & 1 sib had a prior fracture. Five CF pts & 2 sibs had received a course of steroids during the prior year. CF pts had lower total body less head BMD Z-scores than sibs (-0.53±0.78 vs 0.32±1.48, p<0.05). CF pts also had lower % body fat, height, weight, sitting height & BMI than sibs (all p<0.05). One CF pt & her sib had BMD Z-scores < -2.0. BMD z-scores were not lower in older children. There were no differences in Ca, Phos, PTH, vitamin D, bone resorption (NTX/Cr, DPD/Cr) or formation (alkaline phosphatase (AP), bone AP, osteocalcin) between groups. CF pts homozygous for Δ508 mutations had significantly lower BMD Z-scores, shorter sitting heights, & lower % body fat and had lower AP & bone AP. Sibs heterozygous for Δ508 mutations did not differ from other unaffected sibs.

**Conclusions:** Young CF pts have normal calcium & vitamin D status & no evidence of increased bone resorption or decreased bone formation. They do have lower BMD compared to sib controls but this appears due to smaller body size. However, CF pts homozygous for Δ508 mutations did have some suggestion of worse bone status. Since CF pts were smaller than their sibs, & had lower BMD for age, optimizing nutrition will be an important component of their future bone health. Particular attention to strategies directed toward optimizing bone health (improved nutrition, physical activity) may be warranted for CF children homozygous for Δ508 mutations.

**Disclosures:** N. Haddad, None.

## SU487

**Is it Time to Update Normative Values for Ionized Calcium and Urine Calcium:Creatinine Ratios in Healthy Canadian Infants?** S. Gallo\*<sup>1</sup>, H. Weiler\*<sup>1</sup>, K. Trussler\*<sup>1</sup>, C. Vanstone\*<sup>1</sup>, A. Sharma\*<sup>2</sup>, J. Mitchell\*<sup>2</sup>, A. Khamessan\*<sup>3</sup>, M. L'Abbe\*<sup>4</sup>, C. Rodd\*<sup>2</sup>. <sup>1</sup>Dietetics and Human Nutrition, McGill University, Montreal, QC, Canada, <sup>2</sup>Montreal Children's Hospital, McGill University Health Center, Montreal, QC, Canada, <sup>3</sup>Euro-Pharm International Canada Inc., Montreal, QC, Canada, <sup>4</sup>Bureau of Nutritional Sciences, Health Canada, Ottawa, ON, Canada.

There is a paucity of information on normal plasma ionized calcium (iCa) and urine calcium:creatinine ratios (Ca:Cr) in Canadian infants. Both changing technology and a lack of appropriate reference data in healthy infants complicate the interpretation of critical laboratory values, even as physicians are being asked to assess asymptomatic infants with hypercalcemia. We measured iCa and urine Ca:Cr ratios as part of a clinical trial to assess vitamin D<sub>3</sub> dose response in healthy, term, breastfed infants randomized to 4 vitamin D<sub>3</sub> treatment groups (400, 800, 1200 and 1600 IU). Infants (30 boys, 24 girls) were recruited at their 2 week paediatrician visit from clinics located in the Montreal area. Study visits were conducted between 1 and 12 months of age at the Mary Emily Clinical Nutrition Research Unit of McGill University. Blood and urine samples from each visit were analyzed in the clinical laboratory of the Montreal Children's Hospital for iCa (Radiometer Analyzer, Radiometer, Copenhagen, DE) and urine Ca:Cr (Beckman CXI Analyzer, Beckman Instruments, Fullerton, CA). The effects of gender, vitamin D dose, and time were assessed by repeated measures ANOVA. Data are presented up to 3 months of age. Neither gender nor vitamin D dose were significant predictors of iCa. A significant time effect was noted (p<0.02) with a decline in iCa with age (Table 1), localized by post-hoc testing to the comparison of 1 and 3 month mean values. Neither gender, vitamin D dose, nor time were significant predictors of urine Ca:Cr. Adding iCa values to the model as a predictor revealed no further relationship between urine Ca:Cr and iCa levels. For those infants with persistently elevated levels, there were no ECG changes (n=5) or renal ultrasound changes (n=6) consistent with hypercalcemia/hypercalciuria. These data represent reference values for healthy term Canadian infants and suggests that it may be time to re-examine normative calcium values in such children.

Table 1: Mean ± SE [Range]. Ionized calcium and urine calcium:creatinine ratio from 1-3 months of life.

Time Point	Ionized Ca++ (mmol/L)	Urine Ca:Cr (mmol/mmol)
1 mo (n=54)	1.40 ± 5.0 × 10 <sup>-3</sup> [1.29, 1.52]	1.79 ± 0.14 [0.24, 4.23]
2 mo (n=46)	1.40 ± 6.0 × 10 <sup>-3</sup> [1.32, 1.48]	1.84 ± 0.19 [0.31, 5.07]
3 mo (n=40)	1.39 ± 6.0 × 10 <sup>-3</sup> [1.31, 1.46]	1.83 ± 0.14 [0.90, 4.02]

## SU488

**Use of Bone Biomarkers as an Endpoint in a Pediatric Study of Alendronate.** E. von Scheven\*<sup>1</sup>, C. M. Gordon\*<sup>2</sup>, D. Wypij\*<sup>2</sup>, M. Chagomerana\*<sup>2</sup>, J. Shepherd\*<sup>3</sup>, M. Wertz\*<sup>1</sup>, L. Bachrach\*<sup>4</sup>. <sup>1</sup>Pediatrics, UCSF, San Francisco, CA, USA, <sup>2</sup>Pediatrics, Harvard University, Boston, MA, USA, <sup>3</sup>Radiology, UCSF, San Francisco, CA, USA, <sup>4</sup>Pediatrics, Stanford University, Stanford, CA, USA.

We previously demonstrated significant gains in bone mineral density (BMD) in an alendronate trial for children with inflammatory diseases receiving glucocorticoid (GC) therapy. In this substudy we aimed to identify correlations between bone turnover markers and the observed densitometric gains in BMD.

We completed a randomized, placebo-controlled, double-blind multi-center trial of weekly alendronate (N=12) versus placebo (N=11) in children (83% female, mixed ethnicity, age 8-18 yrs with Lupus, vasculitis, juvenile dermatomyositis, Crohn's disease, and juvenile idiopathic arthritis). All subjects received calcium carbonate and vitamin D supplements for 18 months. Treated subjects demonstrated greater improvement of spinal BMD Z-score, spinal BMD, and bone mineral apparent density by dual energy x-ray absorptiometry. Markers of bone formation (serum bone alkaline phosphatase [ALP, chemiluminescent immunoassay] and osteocalcin [OC, radioimmunoassay]) and bone resorption (urine N-telopeptide/creatinine ratio [NTX, competitive inhibition ELISA]) were determined at baseline and 18 months. All assays were performed at Esoterix, Inc. T-tests, Wilcoxon rank sum tests and multi-variable linear regression models were utilized to compare groups.

At baseline, groups were matched for age, gender, Tanner stage, ethnicity, height, underlying disease, disease severity, concurrent medications, and vitamin D level. There were no significant group differences at baseline for ALP, OC, NTX or the ALP/NTX ratio. However the OC/NTX ratio was greater for subjects randomized to alendronate than placebo (0.04 ± 0.02 vs 0.02 ± 0.01, p=0.03). The percent change of ALP, OC, NTX, ALP/NTX ratio and OC/NTX ratio at 18 months was variable, and ranged from -61.3% to 534.8% for ALP, -73.6% to 882.7% for OC, -73.6% to 882.7% for NTX, -82.4% to 1168.1% for OC/NTX, and -35.4% to 151.6% for ALP/NTX ratio. Subjects receiving placebo demonstrated greater percent increases in ALP (28.9 ± 127.6% vs 26.17 ± 205.8%) which approached significance (p=0.07). No other treatment group differences were observed, even after controlling for age, gender, gains in height and weight, or GC dose. The observed change of BMD did not correlate with bone biomarkers, even after controlling for confounders.

In contrast to results from studies in adults, we found ALP, OC and urine NTX to be poor predictors of response to therapy among children with inflammatory diseases receiving alendronate. Efforts to identify alternative surrogate markers of skeletal response in this pediatric population are warranted.

**Normal Reference Values for Quantitative Ultrasound Bone Densitometry of the Calcaneus in Chinese Children and Adolescents.** H. Xu<sup>1</sup>, J. Li<sup>1\*</sup>, Q. Wu<sup>2</sup>, J. XIANG<sup>3</sup>, H. S. Barden<sup>4</sup>, Q. Zhou<sup>5</sup>. <sup>1</sup>Department of Nuclear Medicine, The First Affiliated Hospital, Jinan University, Guangzhou, China, <sup>2</sup>Medical College, Jinan University, Guangzhou, China, <sup>3</sup>Jiaxing 1st Hospital, Jiaxing, China, <sup>4</sup>GE Healthcare, Madison, WI, USA, <sup>5</sup>GE Healthcare, Shanghai, China.

Bone mass accumulated during childhood and adolescence is a primary determinant of fracture risk and osteoporosis in late adulthood. Due to quantitative ultrasound (QUS) densitometry's radiation-free, low-cost, simple, and portable advantages, it is adaptable to large-scale surveys. Normal calcaneal QUS of Chinese adults has already been determined and used in screening for osteoporosis and for evaluation of fracture risk. In China, pediatric QUS utility is currently limited, due to lack of reference data. Thus, an ethnicity-matched pediatric reference database needs to be established for use in Chinese children. A total of 1048 healthy children and adolescents (512 boys, 536 girls) from Guangzhou (n = 605) and Jiaxing (n = 443) aged from 5-18 years were examined with a Achilles densitometer (GE Healthcare, Lunar). Measurements on the left heel included speed of sound (SOS), broadband ultrasound attenuation (BUA), and a calculated stiffness index (SI). The Achilles densitometer has been shown to provide good precision for SI (1.8%), SOS (0.4%) and BUA (2.9%). Our results found that there were no significant differences for SI between males and females, except in the age range of 16 to 17 years. A steady increase of BUA, SOS, and SI was seen with increasing age, body height and weight in both sexes. In conclusion, our data can be used as normal reference values for children and adolescents in China. Further studies in children with disorders influencing bone metabolism are anticipated.

## SU490

**Differences in Bone Mineral Content at the Lumbar Spine and Proximal Femur in SA Children of different Ethnic groups.** L. K. Micklesfield<sup>1</sup>, S. A. Norris<sup>1</sup>, L. van der Merwe<sup>2\*</sup>, E. V. Lambert<sup>3</sup>, J. Pettifor<sup>1</sup>. <sup>1</sup>Department of Paediatrics, University of Witwatersrand, Johannesburg, South Africa, <sup>2</sup>Biostatistics Unit, Medical Research Council, Cape Town, South Africa, <sup>3</sup>Department of Human Biology, University of Cape Town, Cape Town, South Africa.

We have shown despite differences in size and age, whole body BMC is greater in SA children of mixed ancestral origin than in black and white US and SA children. To further investigate differences between ethnic groups within SA, we compared lumbar spine (LSBMC), proximal femur (PFBMC) and femoral neck (FNBMC) BMC in black (SAB; n=263) and white (SAW; n=73) children from Johannesburg, and in children of mixed ancestral origin (SAM; n=64) from Cape Town. SAW and SAB groups were slightly older (SAW: 9.5 ± 0.3; SAB: 9.6 ± 0.3; SAM: 9.3 ± 0.6 years) and heavier than the SAM group. There was no significant difference in mean body weight between the girls, however SAM boys were lighter than the other two groups. In what follows, "adjusted" indicates that comparisons between means were adjusted for age and height. Unadjusted LSBMC was lower in SAM boys compared to SAW boys, however this difference was not significant after adjustment. Unadjusted LSBMC was significantly lower in SAW girls compared to SAM girls, and remained so after adjustment. After adjustment, the following pattern was significant for LSBMC between the girls: SAM>SAB>SAW. The same pattern was significant for unadjusted and adjusted FNBMC in the girls, as well as in the boys after adjustment. Unadjusted PFBMC was not different between the boys in the three groups, however SAM girls had significantly higher PFBMC than SAW and SAB girls. After adjustment, SAM boys and girls had significantly higher PFBMC than their SAB and SAW counterparts. In addition, PFBMC was significantly higher in SAB boys than SAW boys. There was no difference between SAW and SAB girls for unadjusted or adjusted PFBMC. Best predictors were selected for BMC at the 3 sites from linear models containing the following: gender, height, weight, age, birth weight and ethnic group. Linear models containing the best predictors accounted for 40-59% of the variance at these sites. Birth weight contributed significantly to the models for LSBMC and PFBMC. Ethnicity, height and weight were significant contributors to BMC at all 3 sites. It is well established that black South African adults and children have higher FNBMD than SA whites, but the finding of higher BMC in children of mixed ancestral origin is of interest, as this ethnic group has not been studied previously.

**Infantile Hypercalcemia: Relationship of Dietary Intake of Calcium and Vitamin D to Serum and Urine Levels.** E. Assor<sup>\*</sup>, C. Grasemann<sup>\*</sup>, K. T. Parker<sup>\*</sup>, E. B. Sochett. Hospital for Sick Children, Toronto, ON, Canada.

Mild hypercalcemia in infants is a common diagnostic problem seen in the calcium bone clinic at HSC. A specific cause is infrequently found and most children are designated as having idiopathic hypercalcemia of infancy. As close to referral as practicable, a formal dietary assessment focusing on intake of calcium and vitamin D is obtained by a registered dietitian (RD). We have reviewed this experience to establish whether there is a relationship between dietary intake of calcium and vitamin D (expressed as a percentage of DRI for age) and their respective serum and urinary levels. Nineteen patients with a mean age of 13.8 month (range 0.6 - 40 months) have been evaluated over the last 2-3 years. A specific cause for the hypercalcemia was identified in only four (2 Williams syndrome, 2 Subcutaneous fat necrosis). All patients were formally assessed by the same RD. Average duration between the patients first clinic visit to dietary assessment was 3.8 months (range -3 - 25 months). Assessment was based on food records completed by the family and reviewed with the RD. At time of assessment, 3 patients were receiving vitamin D and 1 patient received a multivitamin containing both calcium and vitamin D. Nine patients (47%) were consuming a regular infant/toddler diet, 5 patients (26%) were on solids and formula, 2 (11%) were on formula and breast fed and 2 (11%) were on formula only. One patient (5%) was on solids and breast fed. Mean dietary calcium was 152 % of DRI for age (range 14% - 322 %). Mean dietary vitamin D was 270 IU (135% of DRI for age, range 0% - 350%). Mean ± SD for serum calcium, 25 OH vitamin D, PTH and urinary Ca/creatinine ratio were 2.75 ± 0.14 mmol/l, 65 ± 16 nmol/l, 23.5 ± 15 ng/l and 1.35 ± 1.23 respectively. There was no correlation between dietary calcium and serum calcium, between dietary calcium and urinary calcium/creatinine ratio nor between dietary vitamin D intake and 25 OH vitamin D levels. Despite increased intakes, neither dietary calcium nor vitamin D appears to play a causative role in mild hypercalcemia of infancy. DRI for vitamin D in infants need to be revised.

**Disclosures:** E. Assor, None.

## SU492

**Forearm pQCT Measurements in Males with Duchenne Muscular Dystrophy.** J. Landoll<sup>1\*</sup>, W. King<sup>2\*</sup>, J. Kissel<sup>2\*</sup>, V. Matkovic<sup>1</sup>. <sup>1</sup>Bone and Mineral Metabolism Laboratory, Ohio State Univ., Columbus, OH, USA, <sup>2</sup>Department of Neurology, Ohio State Univ., Columbus, OH, USA.

Duchenne Muscular Dystrophy (DMD) is the most common childhood muscular dystrophy. Studies using dual energy x-ray absorptiometry (DXA) have shown that patients with DMD have low areal bone mineral density (BMD) as compared to the general population of the same age and that the deviation from normal increases with age. There is a question of whether these patients require bone modifying medications (e.g., bisphosphonates) to mitigate this apparently decreased bone mineral density. However whether the deviation from normal reflects a true deficit in bone mineral density or may be related to geometric parameters (due to the relatively small size of DMD patients) inherent in areal bone density analyses, is unclear. This ongoing study examines the volumetric bone mineral density of DMD boys (n=23, age 7-17 y., average 11.4 y.) using pQCT of the forearm. Volumetric bone mineral density measurements of the non-dominant radius at the distal (4%) and proximal sites (33%) were performed using a pQCT (Stratec XCT-2000) densitometer. Preliminary results are compared to a population of healthy male individuals (n=189, age 7-17 y., average 11.7 y.). The average total cross-sectional area of the distal site (177 ± 50 mm<sup>2</sup>) is significantly lower than that for the control group (294 ± 75 mm<sup>2</sup>; p<0.001). The average total bone mineral density and trabecular bone mineral density at the distal site for the DMD group (254 ± 65, 127 ± 34 mg/cm<sup>3</sup>, respectively) is significantly lower than the control group (300 ± 34, 214 ± 32 mg/cm<sup>3</sup>, respectively; p<0.002). The average cortical area at the proximal site is significantly lower than the controls (40 ± 7 vs. 63 ± 17 mm<sup>2</sup>, respectively; p<0.001); however, the average cortical density is significantly higher than that of the control population (1147 ± 67 vs. 1092 ± 33 mg/cm<sup>3</sup>, p<0.002). These data show that boys with DMD do have smaller bones. They suggest that there is a real deficit in volumetric bone mineral density at the distal forearm site which is rich in trabecular bone whereas the bone mineral density at the proximal site (cortical bone) is normal. This information may determine the risk for bone fragility fractures in DMD patients and may influence prevention programs.

## SU493

**Age at Menarche Associated with Bone Strength in Girls: An X-treme CT Study.** M. Burrows<sup>1</sup>, D. Liu<sup>\*1</sup>, Y. Ahamed<sup>\*1</sup>, S. Braid<sup>1</sup>, H. A. McKay<sup>2</sup>. <sup>1</sup>Dept of Orthopaedics, University of British Columbia, Vancouver, BC, Canada, <sup>2</sup>Dept of Orthopaedics and Family Practice, University of British Columbia, Vancouver, BC, Canada.

Late menarche is a determinant of low bone mineral density in women and a strong risk factor for fracture (1). This could be due to either; 1) years of exposure to estrogen (women experiencing early menarche have higher years of exposure to estrogen); or 2) body habitus associated with early menarche (higher body mass index) (2). Our aim was to assess the influence of age at menarche on bone strength in girls. Participants were 77 girls; Age  $16.2 \pm 1.3$  yrs; Height  $161.2 \pm 6.5$  cm; Weight  $55.2 \pm 8.6$  kg; Age at menarche  $12.3 \pm 1.4$  yrs. They were assessed for physical activity using the physical activity questionnaire (PAQ), and total calcium intake using a food frequency questionnaire. We assessed maximal force production (Fmax, N/kg) using the Leonardo force platform (Novotech, Medical). We utilised X-tremeCT (Scanco Medical, 110 slices, 82µm) to assess bone strength at the 8% site of the non dominant distal tibia. Images were segmented using Image Processing Language (IPL, Scanco Medical) as per the manufacturer's *in-vivo* protocol. We assessed total area (ToA, mm<sup>2</sup>) and total bone mineral density (ToD, mg/cm<sup>3</sup>) and calculated bone strength index as ToA x ToD<sup>2</sup> (BSI, mg<sup>2</sup>/mm<sup>4</sup>) (3), which served as our dependent variable (DV). We developed a linear regression model based on relationships between the DV and the predictor variables (PV) and on association between DV and selected predictors using bivariate correlation. Our model included age at menarche as PV and age, height, weight, Fmax, physical activity and calcium intake as control variables (SPSS, v15.0). The age at menarche model (p=0.013) explained 33% of variance in BSI (Table 1), with ToD rather than ToA underpinning the relation between BSI and age at menarche. Although our findings suggest that timing of maturity may relate to bone strength longitudinal data are required to more adequately assess this relationship.

**Three Unrelated Patients with a Unique Spondylo-Epi-Metaphyseal Dysplasia.** M. B. Bober<sup>1</sup>, W. Mackenzie<sup>\*2</sup>, L. Nicholson<sup>\*1</sup>, C. I. Scott<sup>\*1</sup>. <sup>1</sup>Division of Genetics, AI duPont Hospital for Children, Wilmington, DE, USA, <sup>2</sup>Department of Orthopedics, AI duPont Hospital for Children, Wilmington, DE, USA.

We present three males currently ages 5 (Patient 1), 17 (Patient 2) and 23 years (Patient 3) with disproportionate short stature of short limbed type with rhizomelia. Radiographic evaluations demonstrate mild spinal involvement with thoracic platyspondyly, anterior notching of the lower thoracic vertebrae and lumbar lordosis. There is absent lumbar interpediculate widening. The lower extremities demonstrate metaphyseal widening of the long bones most notably at the distal femora. The epiphyses were small and irregular throughout. The iliac wings showed a wide lateral flare and the acetabulum was mildly dysplastic. The hands were brachydactylic with phalangeal shortening more distally than proximally. The metacarpals are short and broad. Ossification is age appropriate. No cervical spine instability or rib changes were noted. Clinically, the children have a strikingly similar facial appearance with outgoing and pleasant personalities. The scalp hair is of normal texture and distribution with a blonde color. Upper eyelid fullness is present and the iridae are blue. The nose is relatively short with a tall broad philtrum. The lower lip is full. The external ears had normal structure and position. The mandible was not prognathic, but appeared prominent in the AP view with a pointed chin. The teeth are all within normal limits. The children have mild pectus carinatum. Ligamentous laxity was present in all children. All three children had significant patellar instability with spontaneous subluxation. Patients 1 and 2 both underwent surgery to correct this abnormality. Patient 2 had a cleft palate and bifid uvula. Patient 2 and 3 have significant learning abnormalities with FSIQ (WISC-III) of Patient 2 49 and Patient 3 58.

**Newborn Infant Bone Mineralization is Affected by Their Umbilical Cord Length.** G. M. Chan, D. Wright\*. Pediatrics, University of Utah, Salt Lake City, UT, USA.

Activity has been demonstrated in promoting bone mass in infants and adults. The effect of activity on the fetal bone mass has not been studied. One of the major restrictions to fetal activity may be the length of the umbilical cord. We hypothesized that the newborn with a shortened umbilical cord may have low bone mineralization because of decreased fetal movement or activity. We investigated seven healthy newborn term infants with shorten umbilical cords and 15 control term infants. Mothers with pre-eclampsia or hypertension, chorioamnionitis or prolonged ruptured of membranes were excluded from the study. Mother's age, parity, infants' gender and birth and placenta weights were recorded. The umbilical cord length and diameter were measured as well as the newborn's tibial speed of sound (SOS). Speed of sound measurements (Sunlight Omnisense 7000P instrument) were obtained at the tibial midshaft and reflected the tibial cortical thickness and bone mineral density. Measurement reproducibility was  $0.8 \pm 0.6\%$  (mean  $\pm$  SD) for repeat speed of sound measures in the same (n = 20). There were no differences between the two groups in mother's age ( $24.6 \pm 5.8$  v  $25.8 \pm 3.3$  years), parity ( $2 \pm 1$  v  $2 \pm 1$ ), infant's gender (29% females v. 47% females), birth weights ( $3320 \pm 451$  v  $3409 \pm 452$  g) or placental weights ( $521 \pm 69$  v  $588 \pm 105$  g). Umbilical cord diameters were also similar,  $1.1 \pm 0.3$  v  $1.1 \pm 0.2$  cm. However, there was a difference in the cord length between the two groups,  $46 \pm 2$  v  $57 \pm 4$  cm (Mann Whitney, P<0.001). The newborn infants with the shorter umbilical cord also had lower tibial SOS compared to controls,  $3006 \pm 96$  v  $3235 \pm 304$  m/sec (Mann Whitney, P<0.05). Tibial SOS was related to the infant's umbilical cord length (r = 0.57, P<0.01) but not to infant's birth weight, gender, umbilical cord diameter, maternal age, or placenta weight. In conclusion, newborn infants with a short umbilical cord length have lower bone mineralization.

**Randomized Dose Comparison of Pamidronate in Children with Types III and IV Osteogenesis Imperfecta: 3 vs 6 Month Cycles.** J. C. Marini<sup>1</sup>, M. K. Abukhaled<sup>\*1</sup>, H. L. Cintas<sup>\*2</sup>, A. A. Obafemi<sup>\*1</sup>, J. F. Troendle<sup>\*3</sup>, A. D. Letocha<sup>\*1</sup>, J. C. Reynolds<sup>\*4</sup>, S. Paul<sup>\*2</sup>. <sup>1</sup>Bone and Extracellular Matrix Branch, National Institute of Health. National Institute of Child Health & Human Development., Bethesda, MD, USA, <sup>2</sup>Rehabilitation Medicine, National Institute of Health. Clinical Center, Bethesda, MD, USA, <sup>3</sup>Biometry and Mathematical Statistics Branch, National Institute of Health. National Institute of Child Health & Human Development., Bethesda, MD, USA, <sup>4</sup>Nuclear Medicine, National Institute of Health. Clinical Center, Bethesda, MD, USA.

Controlled trials of bisphosphonates in children with osteogenesis imperfecta (OI) demonstrated significant increases in vertebral BMD, height and area, while effect on fracture rate is controversial. However, high cumulative doses of pamidronate in children are associated with significant side effects such as impaired bone modelling, delayed fracture healing, and decline in bone material quality. The purpose of this study was to determine whether the vertebral benefits of q3m infusion cycles could be attained on q6m cycles, with a lower cumulative dose. Twenty-seven children with types III and IV OI were randomly assigned to receive 1mg/kg/3d IV pamidronate in q3 or q6 month cycles. All patients had serial spine radiographs, L1-L4 DXA, and musculoskeletal and function testing. L1-L4 DEXA increased significantly after 1 year of q3m cycles, with average change in z-score = +1.41 SD, but did not improve significantly with further treatment. In the q6m group, the average change in DEXA was not significant. Repeated measures analysis of DEXA z-scores yielded a z-score rate change of 0.064 SD/m for q3 vs 0.036 SD/m for q6 group (p=0.13). T12-L4 vertebral area and percent central compression were determined from radiographs. On repeated measures analysis, there was significant improvement of q6m group average L1-L4 and T12-L2 vertebral height (p=0.05, 0.01) and area (p=0.002, 0.006). The rate of improvement of the q3 group did not differ from the q6m for L1-L4 area or height (p=0.52, 0.86) or T12-L2 area or height (p=0.28, 0.77). Neither group of OI children had significant improvement in fracture incidence, manual muscle testing or BAMF motor scores after two years. It is noteworthy that the response to treatment was highly variable in each treatment group. For individual OI children, the improvement in vertebral area did not correlate with change in DEXA z-score. We concluded that equivalent gains in vertebral height and area are obtained with q6m and q3m pamidronate cycles. Both cycle interval and total number of cycles should be limited to minimize cumulative bisphosphonate dose in pediatric OI bone.

### Large Osteoclasts in Pediatric Osteogenesis Imperfecta Patients Receiving Intravenous Pamidronate. M. Cheung\*, F. H. Glorieux, F. Rauch. Shriners Hospital for Children, Montreal, QC, Canada.

Intravenous pamidronate is widely used to treat children with moderate to severe osteogenesis imperfecta (OI). Changes in the appearance of osteoclasts have previously been noted in children receiving pamidronate and have been interpreted as signs of toxicity. In the present study we analyzed osteoclast parameters in paired iliac bone specimens before and after two to four years of cyclical intravenous pamidronate therapy in 44 pediatric OI patients (age range: 1.4 to 17.5 years; 21 girls). During pamidronate treatment, average osteoclast diameter and the mean number of nuclei present per osteoclast increased by 18% ( $P = 0.02$ ) and 43% ( $P = 0.001$ ), respectively. The percentage of osteoclasts with no visible attachment to a bone surface was similar before (2%) and after (3%) pamidronate treatment ( $P = 0.30$ ). The number of samples containing large osteoclasts (LOC, diameter more than 50  $\mu\text{m}$ ) increased from 6 (14%) before treatment to 23 (52%) after pamidronate therapy ( $P < 0.001$  by chi square test). Post-treatment samples containing LOC had a greater core width ( $P = 0.04$ ) and higher cancellous bone volume per tissue volume ( $P < 0.001$ ), because cancellous bone volume had increased more during pamidronate treatment ( $P < 0.001$ ). Osteoclast number and surface were higher in samples with LOC, but there was no difference in cancellous bone formation parameters. The presence of LOC was independent of OI type, type of collagen type I mutation, lumbar spine bone mineral density and other clinical or biochemical measures. Thus, the presence of LOC may indicate greater sensitivity to bisphosphonates leading to greater core width and increased bone volume per tissue volume. No evidence was found that the presence of LOC is associated with adverse clinical events.

### Effect of Bone Marrow Transplantation (BMT) in a Child with Malignant Infantile Osteopetrosis. C. Tau<sup>1</sup>, M. Bondue<sup>1,2</sup>, C. Mautalen<sup>3</sup>, C. Casco<sup>3</sup>, E. Fradinger<sup>4</sup>, E. Pellisa<sup>4</sup>, R. Staciuk<sup>2</sup>, C. Figueroa<sup>2</sup>. <sup>1</sup>Metabolismo Cálculo y Óseo, Endocrinología, Hospital de Pediatría Garrahan, Buenos Aires, Argentina, <sup>2</sup>Trasplante de Medula Ósea, Hospital de Pediatría Garrahan, Buenos Aires, Argentina, <sup>3</sup>Centro de Osteopatías Médicas, Buenos Aires, Argentina, <sup>4</sup>Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina.

Infantile osteopetrosis (IO) is an hereditary sclerosing bone disease caused by osteoclast dysfunction, defective bone resorption and modeling. Hematopoietic stem cell transplantation (HSCT) is the only curative therapy. A girl with IO was seen at 4.5 months of age. She was born at term from consanguineous parents. At 1 month she had upper respiratory tract infection and required a blood transfusion for anemia. Height was -2.7 (z-score), she had protruding eyes, bilateral nystagmus, hepatosplenomegaly, audio and visual evoke response were absent. Bone marrow biopsy showed myelofibrosis and osteosclerosis. X-rays showed dense bones, generalized sclerosis, lack of corticomedullary differentiation, rickets, flaring of metaphyses of long bones, sclerosis of skull base. Since 2 months of age she was treated with methylprednisone 1 mg/kg/day and vitamin D 1000 IU/day was added at month 5 of life. Biochemical studies showed hypocalcemia (SCa) 8.1 mg/dl, hypophosphatemia (SP) 2.8 mg/dl, elevated bone alkaline phosphatase (BAP) 787 IU/L and PTH 173 pg/ml, low serum 25OHD (8 ng/ml), low hemoglobin (9.4 g/dl), uCa/uCr was 0.22 mg/mg, urinary CrossLaps (uCTX) and D-pyridoline (D-pyr) were low (590 ug/mmolCr and 16 nmol/mmolCr respectively). At the age of 5 months, she underwent an identical sibling BMT. Busulfan (16 mg/kg) and cyclophosphamide (200 mg/kg) were used as conditioning. She received  $8.93 \times 10^8/\text{kg}$  nucleated cells. Neutrophils count was  $>500/\text{mm}^3$  on day 20 and platelet count was  $>50,000/\text{mm}^3$  on day 47. The evolution after the BMT was uneventful. Forty months after the transplantation, a sustained hematological and immunological recovery was observed. SCa and SP normalized by day 19. SCa and SP increased by day 30 (10.8 mg/dl and 6.5 mg/dl respectively) but were asymptomatic. An impressive increment of uCTX and D-pyr was observed (uCTX was 4733 by day 15 and 8716 ug/mmolCr by day 42. D-pyr was 87 by day 42, 68 by month 6, 32 by month 9 and 24 nmol/mmolCr one year after BMT). Serum 25OHD was normal 2 months after BMT (39 ng/ml). BAP decreased to 520 by month 2, to 455 by month 6 and 163 IU/L 2 years after BMT. X-rays taken 6 months after BMT showed normal bones. Growth and hearing improved but no her visual acuity. We conclude, that BMT performed in this child with IO improved bone markers, radiological signs of rickets and bone sclerosis. Early referral for consideration of HSCT is mandatory in IO to reverse neurological damage.

### Teriparatide Treatment in a Young Man with Idiopathic Juvenile Osteoporosis Diagnosis. M. S. Parisi, A. Bagur, B. Oliveri. Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina.

Idiopathic Juvenile Osteoporosis (IJO) diagnosis is based on the exclusion of other diseases causing severe demineralization and fractures in childhood. A 27y old man, diagnosed with IJO, was treated with Teriparatide 18m. He was healthy until 14y old, when knees and ankle pain developed, and suffered femoral and humerus fractures. On presentation (18y) he uses crutches because of lumbar, knees, and ankle pain.

Rx: compression fractures of all vertebral bodies, genu varum, and aseptic necrosis of right femoral neck. L2L4BMD (DXA) Z-score was -7.3. Bone scan was unspecific with multiple areas of hypercaptation. Lab tests were normal, except for high bone alkaline phosphatase (BALP). Bone biopsy showed osteoporosis features, histomorphometry evidenced reduced osteoblast (Ob) and erosion surfaces, and negative double label tetracycline (TC).

He received calcium (Ca) and vit D 12m, and bisphosphonates for 2 y, that were suspended when he suffered a humeral fracture, and bone biopsy showed an increase in osteoid surface, still reduced bone volume and osteoblast surface, and without double label TC. However, bone pain diminished and BMD increased. Thereafter he continued on Ca/vit D 5y. Teriparatide (20ug/d), vit D2 (800IU/d), and Ca (0.5g/d) treatment was indicated based on the evidence of reduced Ob activity. The patient signed an informed consent approved by the Hospital Ethical Committee. Follow up: serum Ca, phosphate, BALP, iPTH, 25OHD, cross laps (CTX), osteocalcin (BGP), creatinine, uric acid, hemogram, hepatogram; and urinary Ca and creatinine at 0, 1, and every 3m. BMD and Rx every 6m; and bone biopsy and bone scan at 0, and 18m.

At baseline bone volume, osteoid surface, and osteoid thickness were in the normal range, with a low % single label TC; Ob surface persisted reduced. With Teriparatide, bone pain disappeared. Lab tests were normal, except for BALP (table 1). L2L4 BMD increased 19.9%, from 0.592 to 0.710g/cm<sup>2</sup>. Bone scan areas of hypercaptation disappeared. Bone biopsy results are pending. A caryotype informed a Robertsonian translocation (13.14). Molecular studies in progress.

Teriparatide produced clinical, densitometric and centellographic improvement. The response to treatment could sustain the hypothesis of an Ob defect. The abnormal caryotype suggests the possibility of an existing gene mutation.

Table 1

	CTX (ng/L)	BGP (ng/ml)	BALP (IU/L)
Normal Values	14-450	24-70	31-95
Months 0	278	35	111
6	357	42	84
12	283	54	96
18	334	60	100

### Vitamin D Supplementation in Breast Fed Infants: A Prospective Trial-Recruitment Problem Encountered Along the Way. T. Ponnappakkam, E. Bradford\*, R. C. Gensure. Pediatrics, Ochsner Clinic Foundation, New Orleans, LA, USA.

Exclusive breast feeding of newborns is more common because of the well documented benefits to mother and baby; however, there are concerns if the breast milk has sufficient vitamin D to prevent rickets. Anticipating this, the American Academy of Pediatrics (AAP) recommends universal vitamin D supplementation (200 IU/day) from 2 months of age, but there are few studies to support these recommendations. We are therefore conducting a study to compare vitamin D supplementation with placebo control in breastfed children. After obtaining approval from the Ochsner Institution Review Board (2006-186A) normal newborns (breast milk intake  $>50$  percent of total) were randomized into three study groups: no supplementation, 200 IU per day from 2 months, and 200 IU per day from birth. Blood samples and questionnaires are collected at birth, two, four, and six months of age. Our goal was to recruit 450 patients in 2 years; however, after one year only 42 patients were recruited (6 patients have completed the study). We screened 757 infants from July 2007-December 2007. 408 (53%) were breastfed post partum. 94% of these mothers were approached, only 5% agreed to participate in our study. The major reasons given for not wanting to participate are: not interested in a research study (26.5%), not willing to give a daily medication (10.3%); not breastfeeding at least 50% of the time (8.6%), and not wanting blood tests (5.9%). Retention among the recruited patients was also very low, with 66% dropping out in the first 2 months. The most common reason for dropping out of the study was cessation of breastfeeding. The blood samples collected so far in our study were analyzed for calcium, phosphorus, parathyroid hormone, 25-hydroxyvitamin D, alkaline phosphatase, and osteocalcin (cord blood at birth). There was no apparent difference in the levels of any of these measurements between the placebo and vitamin D treated groups at any time point; however, we do not yet have sufficient power in the study to support a negative conclusion. One case of rickets and one case of hypervitaminosis D has been reported by the pediatric endocrinologist at Ochsner, neither patient was enrolled in the study. A retrospective chart review of pediatric practices at Ochsner revealed that only 5% of breastfed infants receive vitamin D supplementation, revealing that there is poor compliance with the AAP recommendations. We recommend that the health care professionals should educate mothers of the importance of vitamin D and inform them of the current recommendations until future research can determine whether or not vitamin D supplementation is required to prevent rickets.

**Differential Effects of Growth Hormone and 1 Alfa Calcidiol on Cancellous and Cortical Bone in Hypophysectomized Rats.** A. A. Chaudhry<sup>\*1</sup>, M. Castro-Magana<sup>\*1</sup>, X. Q. Liu<sup>2</sup>, J. F. Aloia<sup>3</sup>, J. K. Yeh<sup>2</sup>. <sup>1</sup>Pediatric Endocrinology, Winthrop University Hospital, Mineola, NY, USA, <sup>2</sup>Metabolism laboratory, Winthrop University Hospital, Mineola, NY, USA, <sup>3</sup>Endocrinology, Winthrop University Hospital, Mineola, NY, USA.

Growth hormone deficiency in children causes severe growth retardation, Vitamin D deficiency and osteopenia. We investigated whether 1 alfa calcidiol alone or in combination with growth hormone can improve bone formation. Forty hypophysectomized Sprague-Dawley female rats (HX) at the age of 8 weeks (body weight in the range of 190-220 gm) were divided into 4 groups; HX, HX+ alfa calcidiol (oral 0.1 ug/kg daily), HX+GH (0.66 mg/0.2 ml SC daily), HX + GH + alfa calcidiol. Ten intact rats were used as controls. Total duration of treatment was 4 weeks. All rats received calcein (10 mg/kg) subcutaneously at day 19 and day 26 to label new bone formation. Data was analyzed using one-way ANOVA with group comparison and two-way ANOVA for treatment interactions. Results showed that GH increased body weight, femoral bone length, bone area, bone mineral content and bone density while alfa calcidiol only increased bone mineral content and bone density. In cortical bone, GH increased both periosteal and endocortical bone formation rate (BFR) resulting in a significant increase in cortical area (85.4±1.89 % vs HX 81.5±1.81 %, mean±SD, P<0.05). While alfa calcidiol suppressed endocortical eroded surface % without a significant effect on either periosteal or endocortical BFR resulting in a non-significant increase in cortical area (83.1±1.61%, ns). In cancellous bone both GH (7.97±1.95%) and alfa calcidiol (9.29±3.65%) increased cancellous bone area % (P<0.05) as compared to the HX group (4.55±1.33%). However GH effect was primarily due to increase in BFR while alfa calcidiol effect was primarily due to suppression of cancellous bone turnover in the HX rats. The combination of GH and alfa calcidiol had no additive effect on cancellous bone area (9.32±3.11%, interaction F value = 2.11, P = 0.155), but a negative interaction was observed on the cortical area (84.1±1.50%, interaction F value = -6.89, P<0.013). In conclusion, the increase in cortical and cancellous area percentage by GH is due to increase in BFR whereas alfacalcidol increased cortical and cancellous bone area percentage by primarily suppressing bone turnover. Hence, there is a differential anabolic effect of GH and alfa calcidiol on cortical and cancellous bone in HX rats.

Cortical and cancellous bone group comparison				
Group	Cortical Area %	periosteal BFR (mcm/d)	Cancellous Area %	Cancellous BFR (mcm/d)
HX	81.47±1.81	9.71±6.56	4.55±1.33	49.0±12.6
HX+Alfa	83.07±1.61	6.79±6.16	9.29±3.65	20.6±6.1
HX+GH	85.35±1.89	288±64.5	7.97±1.96	74.1±11.8
HX+Alfa+GH	84.11±1.50	269±59.5	9.32±3.11	48.9±10.5

**Interaction of Combined Intervention of Parathyroid Hormone and Growth Hormone on Trabecular and Cortical Bone Formation and Resorption in the Hypophysectomized Rats.** M. N. Guevarra<sup>\*1</sup>, M. Castro-Magana<sup>\*1</sup>, X. Q. Liu<sup>2</sup>, J. F. Aloia<sup>3</sup>, J. K. Yeh<sup>2</sup>. <sup>1</sup>Pediatric Endocrinology, Winthrop University Hospital, Mineola, NY, USA, <sup>2</sup>Metabolism Laboratory, Winthrop University Hospital, Mineola, NY, USA, <sup>3</sup>Endocrinology, Winthrop University Hospital, Mineola, NY, USA.

Growth hormone deficiency in pediatrics results in short stature and osteopenia. We postulated that growth hormone (GH) and parathyroid hormone (PTH) combination would result in an improvement of the bone formation. Forty hypophysectomized Sprague Dawley female rats (HX) at age 8 weeks were divided into four groups; HX, HX+PTH (62.5 ug/kg, SC daily), HX+GH (0.66mg/0.2ml, SC daily), and HX+PTH+GH. Ten intact rats were used as control. The total duration of the experiment was 4 weeks. Data was analyzed using One-way ANOVA with group comparison and Two-way ANOVA for treatment interaction. Results showed that GH increased body weight, femoral bone length, bone area, bone mineral content (BMC) and the bone density (BMD) whereas, PTH increased BMC and BMD without a significant increase in the body weight, femoral bone length, and bone area. The F value of the Two-way ANOVA showed that the combined treatment of GH and PTH had a synergistic effect on increasing BMD (F = 4.85, P<0.05). In cortical bone GH increased cortical area (85.5±1.89%, mean ± SD) significantly as compared to the HX (81.5±1.81%, P<0.05). The increase is primarily due to increased periosteal bone formation rate (BFR) without a significant effect on the endocortical BFR and the eroded surface %. PTH administration resulted in non-significant increase in cortical area (83.7± 2.05%, P = 0.087) since PTH increased only endocortical BFR without a significant effect on the endocortical eroded surface% nor the periosteal BFR as compared to the HX group. The result of combined intervention showed no additive effect in the cortical area (85.3±1.83%), in periosteal BFR and endocortical BFR. However, it showed a synergistic effect on suppression of endocortical eroded surface % (F value = 4.67, P = 0.037). In trabecular bone GH increased BFR with a statistic non-significant increase in the trabecular area (7.97±1.96% vs HX 4.55±1.33, P = 0.079) whereas PTH increased trabecular BFR with a significant increase in the trabecular area (15.98±5.68, P<0.05) as compared to the HX. The result of combined intervention shows an additive effect on increasing the trabecular area (24.03±5.56%). In conclusion, either PTH or GH treatment alone is able to enhance cortical and trabecular bone formation and bone density in the hypophysectomized rats. The combination treatment of PTH and GH has synergistic effect on increasing bone density and additive effect on increasing trabecular bone mass.

## SU503

**Bone Health Impairment in Children with Chronic Calcium and Vitamin D Deficiency due to Nutritional Allergies.** C. Grasemann<sup>\*</sup>, K. T. Parker<sup>\*</sup>, E. Assor<sup>\*</sup>, E. B. Sochett. Hospital for Sick Children, Toronto, ON, Canada.

Environmental allergies are a known but infrequently reported cause of nutritional rickets in children. We present here four children (3 boys, 1 girl, 5.3 - 13.6 yrs) with severe environmental allergies referred to the calcium bone clinic at HSC for further evaluation of rickets. Referrals were made based on abnormal x-rays in all cases. X-rays had been taken for: femur fracture, planned dental surgery, knee pain and work up of short stature. At presentation, three of the children had several clinical stigmata of rickets and had been symptomatic from leg deformities and bone pain for a period of 0.6 - 3 yrs. Biochemical evaluation at time of diagnoses showed:

	Calcium (mmol/L)	Phosphorus (mmol/L)	25-Hydroxy Vit.D (nmol/l)	PTH (ng/L)	Total Alkaline Phosp. (U/L)
Mean	1.92	1.18	14	468	1060
range	1.25 - 2.35	0.85 - 1.12	<10 - 32	49 - 948	191 - 2957

3 patients showed radiological characteristics of rickets and one decreased bone mineralization. Z-scores for Bone Mineral Density were - 2.7 and -2.9 in the two older children. Nutritional allergies included a wide variety of foods including milk, fish, nuts and beans. Dietary intakes were severely restricted by the families based on anxiety about allergic reactions. None of the three patients with rickets had been seen by a recognized allergy specialist. None were receiving supplementation with calcium or vitamin D. Clinic treatment recommendations included 4000 - 8000 UI of Vitamin D, 0.6 - 2mcg of Calcitriol and 750 - 1200 mg of Calcium per day. Biochemical evaluation after 6 months of treatment showed:

	Calcium (mmol/L)	Ca/Crea Ratio (Urin)	25-Hydroxy Vit.D (nmol/l)	PTH (ng/L)	Total Alkaline Phosp. (U/L)
Mean	2.42	0.074	55.5	101	438.5
range	2.33 - 2.48	0.05 - 0.09	32 - 84	26 - 241	164 - 1110

In conclusion, children with severe environmental allergies are at an increased risk for bone health impairment if not treated with adequate vitamin D and calcium supplements. Given, the high degree of self management in these families and fear of allergic reactions, there seems to be an under-recognized subgroup of patients at risk of rickets/osteomalacia. On treatment, the repair process is prolonged, whether due to compliance or due to the severity of the demineralization. Physicians taking care of these patients need to encourage and monitor calcium and vitamin D supplementation.

**BONE DESTINY - A One Step Fracture Risk Predictor for Clinicians.** W. G. Bensen<sup>1</sup>, W. Bensen<sup>\*2</sup>, K. A. Beattie<sup>\*1</sup>, A. Papaioannou<sup>\*1</sup>, W. Wong Pack<sup>\*1</sup>, M. Larche<sup>\*1</sup>, J. D. Adachi<sup>3</sup>. <sup>1</sup>Dept. of Medicine, McMaster University, Hamilton, ON, Canada, <sup>2</sup>None, Hamilton, ON, Canada, <sup>3</sup>Dept. of Medicine, St. Joseph's Healthcare - McMaster University, Hamilton, ON, Canada.

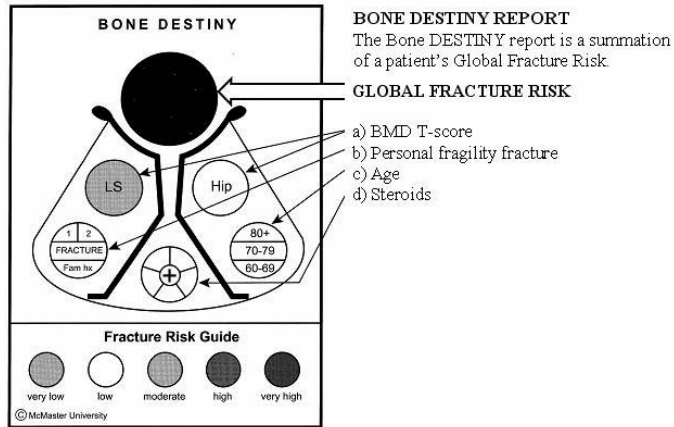

**Purpose:** To create a simple fracture risk predictor tool for clinicians that combines bone mineral density (BMD) with other risk factors for fracture in a way that is simple, easy to interpret and meaningful to patients.

**Methods:** BMD alone is an inadequate predictor of overall fracture risk and results expressed in T-scores often do not synapse a treatment response. In addition, T- scores often do not activate patients or doctors to initiate or adhere to therapy. Because BMD values do not take into account other risk factors for fracture, including previous fragility fracture and steroid use, many patients with significant fracture risk are not on treatment to prevent future fractures. Thus, "DESTINY" was created as an integrated model; a one-step fracture risk predictor that expresses BMD and overall fracture risk after taking into account age, BMD, previous fragility fracture and steroid use. This model uses 5 treatment specific colour zones which are easily recognizable and treatment-impelling to health care professionals.

**Results:** Destiny was designed over a two-year period as a cost-neutral, one-step program that integrates data input to a hand-held computer with BMD from a DEXA scanner to expresses fracture risk.

**Figure 1.** Bone DESTINY report

1. Technicians, while conducting DEXA scanning, input previous fragility fracture, steroid use, age and BMD into a hand-held computer model that is uploaded into a software program that produces a diagrammatic (DESTINY) report.2. The DESTINY report is colour coded by fracture risk where green=very low risk, yellow=low risk, orange=moderate risk, red=high risk and purple = very high risk (Figure 1).3. The reporter sees both BMD and DESTINY while dictating.4. DESTINY reports are easily understood by family physicians and other clinicians who arrange follow-up appointments guided by treatment zones.5. The report can also be shown to a patient to express their actual fracture risk. **Conclusion:** Bone DESTINY, a one-step fracture risk predictor tool, has been used successfully in over 10,000 patients in the greater Hamilton area. DESTINY reports conveying integrated fracture risk results through a colour-coded diagram are simple to interpret and explain to patients and have been positively received within the medical community.

**Anti-myeloma Effects of Osteoblasts Is Mediated Through Production of Small Leucine-rich Proteoglycans.** X. Li\*, A. Pennisi\*, S. Yaccoby. Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

We have previously demonstrated that while osteoclasts support multiple myeloma (MM) growth, osteoblasts have negative impact on growth of MM cells from a subset of patients, indicating that MM bone disease drives tumor progression. Main small leucine-rich proteoglycans SLRPs such as decorin and lumican which are essential for proper bone remodeling have been shown to inhibit growth of various tumors and their expression level is inversely correlated with tumor progression. The aim of the study was to investigate the role of decorin in the anti-MM effects of osteoblasts. We confirmed at the molecular and protein levels that in contrast to mesenchymal stem cells (MSCs) and osteoclasts, osteoblasts express and produce high level of decorin. We also found that normal but not MM plasma cells express decorin and that decorin expression tends to be lower in patient's osteoblasts than in donors' osteoblasts. Recombinant decorin was rapidly internalized by MM cells, directly induced upregulation of p21<sup>waf</sup> and apoptosis in primary MM cells. In co-culture with osteoclasts recombinant decorin inhibited growth of primary MM cells in 6 of 9 experiments by 47±10% (p<0.007). Co-culture of MM cells with osteoclasts in the presence of osteoblast's conditioned media resulted in reduced MM cell survival (n=5, p<0.002), an effect that was partially but significantly attenuated by decorin neutralizing antibody (5 µg/ml, n=5, p<0.01). Down-regulation of decorin by lentiviral-containing decorin siRNA in osteoblasts resulted in increased survival of MM cells in MM-osteoblast co-cultures (p<0.03). In contrast, overexpression of decorin in MSCs reduced MSCs-induced MM cell survival by (p<0.04). We also demonstrated that decorin significantly attenuated MM-induced tube formation by HUVECs in a matrigel assay (p<0.001), and effectively inhibited differentiation of human osteoclasts (p<0.01). Immunohistochemical analysis revealed reduced decorin level in myelomatous bones engrafted with primary MM cells and marked increased levels following treatment with osteoblast activating agents such as bortezomib, PTH and anti-DKK1, providing a possible molecular mechanism for anti-MM efficacy of these agents. We conclude that mature osteoblasts express high level of decorin which exerts the anti-MM effects directly and indirectly through inhibition of angiogenesis and osteoclastogenesis. Increasing endogenous or exogenous SLRPs in myelomatous bones are safe approaches to control MM and its associated bone disease.

## M002

**An Impaired Oxidative Stress Defense Mechanism May Reduce Bone Stiffness in Diabetic Charcot Neuroarthropathy.** K. A. Witzke<sup>1</sup>, A. I. Vinik<sup>2</sup>, H. K. Parsons<sup>2</sup>, G. Pittenger<sup>2</sup>. <sup>1</sup>Kinesiology, California State University, San Marcos, CA, USA, <sup>2</sup>Internal Medicine, Eastern Virginia Medical School, Norfolk, VA, USA.

**BACKGROUND:** Charcot neuroarthropathy is a serious consequence of prolonged neuropathy causing low-trauma foot fractures in up to 3% of diabetics. Charcot may be related to the overexpression of the cytokine receptor activator of NFκB ligand (RANKL)/osteoprotegerin (OPG) pathway, central to the processes regulating bone turnover. The advanced glycation end-product (AGE)/RAGE pathway may activate RANK and oxidative stress known pathogens in diabetic neuropathy. AGEs accumulating in diabetic collagen may also promote osteoblast apoptosis contributing to deficient bone formation. This study evaluated differences between type 2 diabetics with and without Charcot, and controls, with respect to: 1) bone remodeling, 2) RANKL/OPG, 3) RAGE, and 4) bone stiffness. **METHODS:** 80 males (aged 55.3±9.0y) [30 healthy controls (C), 30 type 2 diabetics with peripheral neuropathy (DN), and 20 age-matched type 2 diabetics with Charcot arthropathy (CA)] provided fasting blood samples evaluated for sRANKL, OPG, sRAGE, cross-linked N-telopeptides of type I collagen (NTx), and osteocalcin. Calcaneal bone stiffness was measured using quantitative ultrasound (QUS). **RESULTS:** sRANKL was similar between groups, but OPG was higher for DN (p=0.017) and somewhat higher for CA (p=0.067) compared to C, suggesting OPG is more related to diabetes/neuropathy than to Charcot specifically. NTx was similar but osteocalcin was much higher for CA than either DN or Controls. Protective sRAGE levels decreased with worse neuropathy, where DN levels were 54% lower, and CA levels were 86% lower than C (Table 1). sRAGE was positively correlated with calcaneal bone stiffness, where those with lowest sRAGE also had the lowest bone stiffness and resistance to fracture (r=0.35, p<0.006). **CONCLUSION:** These data suggest DN patients have impaired oxidative stress defense mechanisms and this capacity is markedly worse in CA. CA may indeed experience AGE-mediated osteoblast apoptosis, thereby limiting bone repair, which may be independent of the RANKL/OPG pathway. Administration of exogenous sRAGE may be a viable therapy for those at risk for Charcot.

**Table 1. Inflammation, oxidative stress, bone biomarkers, and bone stiffness**

**Fat Suppresses Osteoblast Differentiation by Soluble Factors That Induce Apoptosis.** S. Urs<sup>1</sup>, S. A. Bornstein<sup>1</sup>, M. Kawai<sup>1</sup>, M. C. Horowitz<sup>2</sup>, G. Duque<sup>3</sup>, A. C. Brown<sup>4</sup>, D. Roopenian<sup>5</sup>, C. J. Rosen<sup>1</sup>. <sup>1</sup>Research Institute, Maine Medical Center, Scarborough, ME, USA, <sup>2</sup>Yale University, New Haven, CT, USA, <sup>3</sup>University of Sydney, Penrith, Australia, <sup>4</sup>Bar Harbor Biotechnology, Trenton, ME, USA, <sup>5</sup>The Jackson Laboratory, Bar Harbor, ME, USA.

Low bone mass, reduced IGF-I, and increased marrow fat are noted with aging, caloric restriction, steroid and TZD use. In this study, we hypothesized that adipocytes secrete factors that influence IGF-I and inhibit osteoblast (OB) differentiation, potentiating the reciprocal relationship between marrow fat and BV/TV. To test that, we cultured marrow stromal cells (MSCs) from Swiss Webster mice in the lower part of a 2 chamber system separated by an insert that allowed only soluble factors from an upper chamber containing 500 mg fat isolated from peri-renal and visceral depots (PRVF), minced then rinsed in PBS and plated with MEMα. Fat was changed every 3 days (d) and CM assayed for IGF-I, osteocalcin, adiponectin and leptin. MSCs were grown for 7d in 10% FCS, switched to βGP and ascorbic acid for an additional 11 d in the lower chamber. Cells were stained at d10 and d14 for alkaline phosphatase (ALP). With PRVF in the upper chamber, the # of ALP+ colonies in the lower chamber was reduced by 60% vs MSCs without fat at both days (p<0.0003). Osteocalcin from MSCs co-cultured with PRVF was suppressed by 80% vs MSCs with no fat; but adiponectin, leptin and IGF-I in CM did not differ. Co-culture of fat and MSCs without an insert produced identical results: i.e. reduced ALP+ cells. To understand the failure of OB differentiation, we did qRT-PCR using a 384 well array to examine differentially regulated genes induced by PRVF. Runx2, BMP2, DMP1, Osterix and Osteocalcin were suppressed by 5 fold when MSCs were co-cultured with PRVF (p<0.0001). PTH1R was reduced 50 fold by PRVF (p<1.0 x 10<sup>-6</sup>) and IGF-I was reduced 30 fold (p<0.002). In contrast, TNF, VEGFα, IL-6 and IL-11 were up-regulated 10 fold (p<0.01). TNF, IL-1, IL-6 and VEGFα were also increased in the CM. TUNEL staining revealed an increase in MSC apoptosis. qRT-PCR for apoptosis genes revealed *Igf1* was the most highly suppressed gene (i.e. 24-40 fold at both days, p<0.002) and *Igf1bp3* the most highly expressed (30 fold, p<0.0001). Two pro-apoptotic genes (*Bnip*, *Unc5b*) were up regulated (p<0.05), while one anti-apoptosis gene, *Pawr*, was suppressed 10 fold at d10 and 14 (p<0.007). Thus, intra-abdominal fat produces a soluble factor that inhibits OB differentiation by activation of an apoptosis program involving *Igf1* and *Igf1bp3*. We conclude that age-related changes in bone mass and marrow fat may be due to release of adipokines or fatty acids within or outside the marrow milieu. Low IGF-I may be a permissive factor for enhancing marrow adipogenesis, but future studies are needed to define the function of marrow fat.

## M004

**Brief Pulsing Electromagnetic Field Exposure Differentially Effects Cell Cycle in Proliferating and Confluent Osteoblasts.** B. S. Margulies<sup>1</sup>, J. A. Spadaro<sup>2</sup>. <sup>1</sup>Animal Biology, University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA, USA, <sup>2</sup>Orthopedic Surgery, S.U.N.Y. Upstate Medical University, Syracuse, NY, USA.

**Introduction:** Making electromagnetic stimulation of bone cells into a more reliable clinical agent will require understanding the mechanism by which these responses occur. The objective of this experiment was to examine the cell cycle phase distribution and metabolic activity in MC3T3-E1 osteoblast-like cells after treatment with either a nitric oxide synthase inhibitor (NOSi) or calmodulin inhibitor (CAMi) prior to a single PEMF exposure in both low density and ~confluent cultures with treatment. Our hypothesis was that a brief PEMF exposure would alter the relative distribution of cells in different phases of the cell cycle and metabolic activity, and that the NOSi and CAMi would alter the PEMF effects. **Methods:** MC3T3-E1 mouse osteoblasts (ATCC) were seeded in 24 well plates at 2x10<sup>4</sup> cells/well (low density) and 2.5 x 10<sup>5</sup> cells/well (~confluent). A single PEMF or sham control treatment was applied for 30 minutes. The magnetic waveform was similar to that used clinically and consisted of bursts of short, asymmetric pulses repeated at 15 Hz, with peak amplitudes of 2 mT. Cultures were supplemented with the general NOSi LMMNA or the CAMi calmidazolium 1 hour prior to treatment. Cell cycle phases were assayed with flow cytometry while metabolic activity was assayed with the reduced-mitotracker dye (Invitrogen). **Results:** Results showed that in confluent cultures, PEMF appeared to reduce the transition from G<sub>0</sub>/G<sub>1</sub> to S and G<sub>2</sub>/M phase (p<0.05). In the low-

density cultures the PEMF exposure appeared to promote the transition from S-phase to G<sub>2</sub>/M by 10% (p<0.05). In both cases CAMi and NOSi altered these effects. PEMF also transiently decreased mitotracker staining, while NOSi and CAMi shifted the mitotracker staining. The sham-treated cells were identical in distribution to incubator control cultures and viability was not affected. **Discussion:** These findings suggest that PEMF may have effects on the pathways controlling the cell cycle. Previous studies have speculated that calcium signaling is responsible for transmitting the PEMF effect. A number of reports have suggested that calcium signaling may play an important role in the cell cycle through the following: The stimulation of  $\beta$ -catenin and calmodulin inhibition resulting in increased p21 and cells remaining in G<sub>0</sub>/G<sub>1</sub>. The current work would seem to support a similar mechanism, however, though this remains to be confirmed.

## M005

**Osteoblasts Apoptosis Is Mediated Through Glycogen Synthase Kinase 3 $\beta$ .** S. Yun<sup>\*1</sup>, H. Yoon<sup>\*1</sup>, S. Yi<sup>\*1</sup>, S. Jeong<sup>\*2</sup>, Y. Chung<sup>1</sup>. <sup>1</sup>Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea, <sup>2</sup>Medical Genetics, Ajou University School of Medicine, Suwon, Republic of Korea.

Mechanisms controlling the survival of osteoblast cells are critical during bone development and diseases.

In osteoblasts, glycogen synthase kinase-3 (GSK3) is a bone mass regulator in Wnt signaling pathway, which alters markers of osteogenesis, chondrogenesis, and adipogenesis. In this study, we found that genotoxic stress promoted apoptotic signaling through GSK3 $\beta$  in osteoblast cell line (CH310T1/2 cells) derived from mouse embryonic mesenchymal stem cells. Etoposide induced genotoxic stress and apoptosis. The protein expression of phosphorylation on serine-9 in GSK3 $\beta$  was decreased time-dependently that meant activation of GSK3  $\beta$ . To investigate the apoptosis by etoposide, we examined the caspase-3 activity, the key apoptosis mediator of apoptosis, and the protein expression of cleaved PARP, the caspase-3 substrate. Both of them were markedly increased. However, LiCl, a specific GSK3 inhibitor antagonized those effects dose-dependently. Moreover, the plant extract, which had protective effects in osteoblasts apoptosis was also related with GSK3 $\beta$  activity.

These data suggest that genotoxic stress may be able to enhance the osteoblasts survival by inhibition of GSK3, which maybe involved in osteoblasts function by regulation of apoptosis.

This research was supported by the "GRRC" Project of Gyeonggi Provincial Government, Republic of Korea.

## M006

**Functional Role of Odd-Skipped Related 2 in Preosteoblastic Cells.** S. Kawai, M. Yamauchi, A. Amano\*. Department of Oral Frontier Biology, Osaka University Graduate School of Dentistry, Suita-Osaka, Japan.

Zinc-finger transcription factor Odd-skipped related 2 (Osr2) is one of the regulators in osteoblast proliferation and bone formation. We previously reported its regulatory role using dominant-negative Osr2 transgenic mice. The transgenic mice revealed the characteristic features, including 1) delayed mineralization in calvarial and cortical bone tissues, 2) distinctly increased radiolucency in soft X-ray analysis, 3) reduced staining intensities with alcian blue and alizarin red in the skull and skeletal elements, and 4) markedly thinner parietal and cortical bones. Differentiation and proliferation of alveolar osteoblasts of transgenic mice were also found to be highly attenuated. In addition, Osr2-deficient mice revalidated that Osr2 play a critical role in the secondary palate development. In this study, we further analyzed the functional role of Osr2 in preosteoblastic cells in detail. At first, we analyzed an epigenetic regulation on Osr2 expression by multipotent mesenchymal C3H10T1/2 cells. Osr2 expression was remarkably upregulated by serum starvation as well as confluent culture, whereas the expression was downregulated to basal level following the serum re-addition. DNA methylation of Osr2 promoter was analyzed with the sodium bisulfite sequencing method. Consequently, the Osr2 promoter was demethylated in serum starvation as well as confluent growth arrest. Moreover, histone acetylation on Osr2 promoter was also analyzed with the chromatin immunoprecipitation. The histones on Osr2 promoter was acetylated in serum starvation as well as confluent culture. Secondly, we analyzed downstream target genes of Osr2 with microarray profiling. Osr2 overexpressing adenovirus was constructed and infected to C3H10T1/2 cells. Total RNAs were prepared and analyzed with Affymetrix mouse genome 430 2.0 arrays. As a result of array classification analysis of downstream genes, the genes in Wnt signaling pathway were regulated by Osr2. Our study indicates that Osr2 expression is regulated by epigenetic modification of DNA and histones. These findings demonstrate that Osr2 play an important role in cell cycle regulation through Wnt signaling pathway.

**Strontium Ranelate Protects Osteoblasts from Apoptosis Independently of the Calcium Sensing Receptor.** O. Fromiguet, A. Barbara\*, E. Hay\*, P. J. Marie\*. Osteoblast biology and pathology laboratory, Inserm U606 & University Paris, 7, Hôpital Lariboisiere, Paris Cedex 10, France.

Several clinical trials have established that strontium ranelate is a new treatment for postmenopausal osteoporosis. We previously showed that strontium ranelate promotes murine osteoblastic cell proliferation in part through activation of the calcium sensing receptor (CaSR). Recent studies have shown that bone formation is controlled by osteoblast survival. Moreover, osteoblast apoptosis was found to be increased in osteoporosis. In this study, we hypothesized that strontium ranelate may have a beneficial effect on osteoblast survival through activation of the CaSR. To test this hypothesis, primary mouse calvaria pre-osteoblasts were isolated from wild type (CaSR<sup>+/+</sup>) and CaSR null (CaSR<sup>-/-</sup>) mice by collagenase digestion. Cell cultures were used for determination of apoptosis using the Apopercut assay using a dye that is selectively imported by cells undergoing apoptosis. We tested the effect of strontium ranelate on apoptosis induced by IL-1  $\beta$  and TNF $\alpha$  which are pro-inflammatory cytokines that are known to induce osteoblast apoptosis. Treatment with IL-1 $\beta$  or TNF $\alpha$  (5 ng/ml, 24 hrs) increased apoptosis in both CaSR<sup>+/+</sup> and CaSR<sup>-/-</sup> murine calvaria osteoblasts. Strikingly, the addition of strontium ranelate (1-5 mM) blunted apoptosis induced by IL-1 $\beta$  or TNF $\alpha$ , and this effect occurred in both CaSR<sup>+/+</sup> and CaSR<sup>-/-</sup> osteoblasts. Furthermore, we showed that strontium ranelate (3, 5 and 10 mM) blunted osteoblast apoptosis induced by serum deprivation (0.5 %). Western blot analysis showed that strontium ranelate increased phospho-P13K and phospho-Akt levels in CaSR<sup>+/+</sup> and CaSR<sup>-/-</sup> osteoblasts, suggesting the involvement of these pro-survival signaling cascade in the observed anti-apoptotic effect. These results indicate that 1) strontium ranelate protects primary osteoblasts from apoptosis induced by inflammatory cytokines or serum deprivation in mouse calvaria osteoblasts, 2) The CaSR is not essential for the anti-apoptotic effect of strontium ranelate in osteoblasts and 3) The protective effect of strontium ranelate on osteoblast apoptosis involves activation of PI3K/Akt signaling in osteoblasts. These data indicate that strontium ranelate protects osteoblasts from apoptosis and that this protective effect of strontium ranelate on osteoblast apoptosis could involve additional receptor in addition to the calcium sensing receptor.

## M008

**Importance of Melastatin-like Transient Receptor Potential 7 and Magnesium in the Stimulation of Osteoblast Proliferation and Migration by Platelet-Derived Growth Factor.** E. Abed\*, R. Moreau\*. Sciences biologiques, Université du Québec à Montréal, Montréal, QC, Canada.

Bone is a dynamic tissue continuously being remodeled throughout life. Bone tissue is removed from the skeleton by osteoclasts and a novel bone matrix is added by osteoblasts. Normally, both resorption and formation processes are in balance and maintain skeletal strength and integrity. In this regard, adequate osteoblast proliferation, migration, differentiation and secretory function are essential both for adequate formation and for resorption processes, and thereby for the maintenance of bone remodeling equilibrium. Disturbances of this equilibrium may lead to decreased bone mass with associated increase in bone fragility and susceptibility to fracture (osteoporosis). Epidemiological studies have mentioned a link associating insufficient dietary magnesium intake in humans with low bone mass and osteoporosis. Here, we have investigated the importance of magnesium and melastatin-like transient receptor potential 7 (TRPM7), a calcium and magnesium channel, in the stimulation of osteoblast proliferation and migration by platelet-derived growth factor (PDGF), a known factor for the regulation of bone remodeling. We observed that the stimulation by PDGF of cell proliferation and migration was significantly reduced under culture conditions of low extracellular magnesium concentrations. The gene expression of TRPM7 by osteoblasts was increased by PDGF in a time-dependent manner. The reduction of TRPM7 expression by specific interfering RNA prevented the stimulation of proliferation and migration by PDGF. Our results indicate that extracellular magnesium and TRPM7 are important for PDGF-induced human osteoblast proliferation and migration which suggests that magnesium deficiency, a common condition among the general population, may lead to inadequate bone formation resulting in the development of osteoporosis.

**Lentiviral Short Hairpin RNA Mediated Inhibition of Glutaredoxin 5 Expression Induces Apoptosis via a Mechanism Involving Increased ROS and Cardiolipin Oxidation, and Reduced Superoxide Dismutase Activity.** G. R. Linares, W. Xing, K. Govoni, S. Mohan. JLP VAMC and LLU, Loma Linda, CA, USA.

Oxidative stress poses detrimental effects on bone by depleting antioxidants, activating osteoclasts, and inhibiting osteoblast (Ob) cell functions. Therefore, it is important to understand components of defense mechanisms to combat oxidative stress in bone. We recently found that Glutaredoxin 5 (Grx5), a member of an antioxidant enzyme family, which functions to maintain cellular redox homeostasis, is highly expressed in bone, induced by growth hormone and modulates Ob apoptosis and ROS production in MC3T3-E1 cells. In the present study, we sought to determine the molecular mechanism by which Grx5 protects against oxidative stress induced apoptosis by utilizing short hairpin RNA (shRNA) and to examine the effect of long term inhibition of Grx5 on Ob apoptosis. Lentiviral Grx5 shRNA infection of MC3T3-E1 cells reduced Grx5 expression by 72 % ( $P < 0.01$ ) in comparison to non-target shRNA control. Cytotoxicity induced by TNF- $\alpha$ , a known inducer of ROS, increased by 3.5-fold ( $P < 0.05$ ) in Grx5 shRNA treated cultures in comparison to shRNA control. Since caspase dependent apoptosis is a major mechanism by which TNF- $\alpha$  and  $H_2O_2$  induce apoptosis, we examined the consequence of Grx5 inhibition on caspase activity induced by these agents. In the presence of  $H_2O_2$  and TNF- $\alpha$ , caspase activity of Grx5 shRNA cells increased by 3.6-fold ( $P < 0.05$ ) and 2.3-fold ( $P < 0.05$ ) in comparison to shRNA control cells, respectively. We next evaluated the effects of ROS on oxidation of cardiolipin since it is known to modulate cytochrome c dependent activation of caspase. In the presence of  $H_2O_2$ , cardiolipin oxidation was significantly higher (2-fold increase,  $P < 0.001$ ) in Grx5 shRNA cells compared to shRNA control cells. Grx5 deficiency reduces formation of Fe-S cluster and thereby increases levels of free iron, a competitive inhibitor of manganese superoxide dismutase (Mn-SOD), which is a key mitochondrial ROS scavenger. Accordingly we found that Mn-SOD activity was reduced in Grx5-deficient Obs. If the increased caspase activity caused by ROS-induced cardiolipin oxidation is caused by reduced Mn-SOD activity, excess Mn should reverse the effect of Grx5 deficiency on Ob apoptosis by rescuing Mn-SOD activity. Accordingly, we found that 200  $\mu$ M  $MnCl_2$  rescued the increased caspase activity by  $H_2O_2$  in Grx5 shRNA treated Ob cultures ( $2504 \pm 44.9$  vs.  $3940 \pm 102.2$  RLU;  $P < 0.001$ ). Our findings are consistent with the hypothesis that Grx5 is an important determinant of Ob cell functions and acts via a molecular pathway that involves regulation of ROS production, cardiolipin oxidation, caspase activity, Fe-S cluster formation, and Mn-SOD activity.
