ASBMR 27th ANNUAL MEETING OFFICAL PROGRAM

Friday, September 23, 2005

Posters Open 5:15 pm – 7:00 pm
Exhibits Open 5:15 pm – 7:00 pm

9:30 am – 12:00 pm
Bone and Mineral Complications of Chronic Kidney Disease (CKD) Symposium
Delta Ballroom

12:00 noon – 1:00 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D, E/F

1:00 pm – 2:00 pm
Clinical Roundtable/Case Conference
Presidential Ballroom South

2:00 pm – 3:30 pm
Mini-Symposium A:
The Periosteum –
A Surface for All Seasons
Delta Ballroom

Mini-Symposium B:
Secondary Causes of Osteoporosis
Presidential Ballroom South

3:45 pm – 5:15 pm
Mini-Symposium C: Of Mice and Men: Modeling Skeletal Disease in Genetically Engineered Mice
Delta Ballroom

Mini-Symposium D: Stress Fractures
Presidential Ballroom South

5:15 pm – 7:00 pm
Welcome Reception & Plenary Poster Session – *Ryman Exhibit Hall C*

7:00 pm – 8:00 pm
New Investigator/New Member/ First Time Attendee Reception
Washington B

Saturday, September 24, 2005

Posters Open 8:00 am – 6:00 pm
Exhibits Open 9:15 am – 4:30 pm

7:00 am – 8:00 am
New Investigator/New Member Breakfast - *Governor's Ballroom C/D*

8:00 am – 8:10 am
Welcome & Announcements
Delta Ballroom

8:10 am – 9:10 am
Gerald Aurbach Memorial Lecture
Delta Ballroom

9:10 am – 9:25 am - *Delta Ballroom*
(9:10 am) William F. Neuman Award Presentation
(9:15 am) Fuller Albright Award Presentation
(9:20 am) Gideon A. Rodan Excellence in Mentorship Award Presentation

9:25 am – 10:00 am
Break – *Ryman Exhibit Hall C*

10:00 am – 11:30 am
Plenary Orals
I Basic - *Presidential Ballroom South*
II Clinical/Translational - *Delta Ballroom*

11:30 am – 2:30 pm
Poster Session I – *Ryman Exhibit Hall C*
Odd: 11:30 am – 1:00 pm
Even : 1:00 pm – 2:30 pm

11:30 am – 12:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D, E/F

12:00 noon – 2:00 pm
Special Session for Allied Health Professionals
Governor's Ballroom North

12:30 pm – 1:30 pm
Clinical Roundtable/Case Conference
Presidential Ballroom South

Saturday, September 24, 2005 (Continued)

12:30 pm – 2:00 pm
Grant Writing Workshop
Governor's Ballroom C/D

1:30 pm – 2:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D, E/F

2:30 pm – 4:00 pm
Concurrent Oral Sessions
1) Osteoblasts I
Presidential Ballroom South
2) Cartilage – *Governor's Ballroom C/D*
3) BMPs, TGF-beta, Other Growth Factor and Cytokines
Presidential Ballroom A
4) Genetics of Bone and Mineral Disorder *Presidential Ballroom B*
5) Osteoporosis Epidemiology
Delta Ballroom
6) Osteoporosis-Pathophysiology
Governor's Ballroom North

4:00 pm – 4:30 pm
Break – *Ryman Exhibit Hall C*

4:30 pm – 6:00 pm
Concurrent State-of-the-Art Lectures
A) (Basic) – Epigenetics
Presidential Ballroom South
B) (Clinical) – Absolute Risk
Delta Ballroom

6:00 pm – 7:00 pm
ASBMR Annual Business Meeting
Governor's Ballroom C/D

Sunday, September 25, 2005

Posters Open 8:00 am – 6:00 pm
Exhibits Open 9:30 am – 4:30 pm

7:00 am – 8:00 am
ASBMR Minority Breakfast
Washington B

8:00 am – 9:30 am
Plenary Symposium I
Bone and Its Vasculature
Delta Ballroom

8:00 am – 9:30 am
Clinical Half-Day Sessions
Presidential Ballroom South

9:30 am – 9:35 am
Presentation of Frederic C. Bartter Award – *Delta Ballroom*

9:35 am – 10:00 am
Break - *Ryman Exhibit Hall C*

10:00 am – 11:30 am
Plenary Orals
I Basic - *Presidential Ballroom South*
II Clinical/Translational - *Delta Ballroom*

11:30 am – 2:30 pm
Poster Session II - *Ryman Exhibit Hall C*
Odd: 11:30 am – 1:00 pm
Even: 1:00 pm – 2:30 pm

11:30 am – 12:30 pm
The Art of Grant Reviewing
Jackson E/F

11:30 pm – 12:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D

12:00 pm – 2:00 pm
Clinical Half-Day Sessions
Presidential Ballroom South

12:30 pm – 2:00 pm
Biotechniques Workshop
Governor's Ballroom North

Sunday, September 25, 2005 (Continued)

12:30 pm -1:30 pm
The Role of Advocacy in Musculoskeletal Research Funding: Grassroots, NIH, Congress and the Public
Governor's Ballroom C/D

1:30 pm – 2:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D, E/F

2:30 pm – 4:00 pm
Concurrent Oral Sessions
7) Osteoblasts II – *Governor's Ballroom C/D*
8) Osteoclasts I – *Presidential Ballroom A*
9) Osteoporosis – Epidemiology
Presidential Ballroom South
10) Osteoporosis Treatment
Delta Ballroom
11) Bone Acquisition & Pediatric Bone Diseases – *Governor's Ballroom North*
12) Mechanical Loading & Exercise
Presidential Ballroom B

4:00 pm – 4:30 pm
Break - *Ryman Exhibit Hall C*

4:30 pm – 6:00 pm
Concurrent State-of-the-Art Lectures
A) (Basic) - Embryonic Sources of Skeletal Tissue – *Delta Ballroom*
B) (Clinical) - Bone Quality
Presidential Ballroom South

6:00 pm – 7:30pm
Women in Bone and Mineral Research Event – *Washington B*

8:30 pm – 11:30pm
ASBMR Social Event
General Jackson Showboat

ASBMR 27th ANNUAL MEETING OFFICAL PROGRAM

Monday, September 26, 2005

Posters Open 8:00 am – 6:00 pm
Exhibits Open 9:30 am – 4:30 pm

5:30 am – 7:15 am
Fun Run/Walk
Two Rivers Park

8:00 am – 9:30 am
Plenary Symposium II
Phosphate: From Bench to Bedside
Delta Ballroom

9:30 am – 9:35 am
Presentation of Shirley Hohl Service Award - *Delta Ballroom*

9:35 am – 10:00 am
Break – Ryman Exhibit Hall C

10:00 am – 11:30 am
Plenary Orals
I Basic - *Presidential Ballroom South*
II Clinical/Translational – *Delta Ballroom*

11:30 am – 2:30 pm
Poster Session III – *Ryman Exhibit Hall*
Odd: 11:30 am – 1:00 pm
Even: 1:00 pm – 2:30 pm

11:30 pm – 12:30 pm
Training and Career Development Awards: Minding Your Fs and Ks
Jackson E/F

11:30 pm – 12:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D

12:30 pm – 2:00 pm
Career Options for Scientists Workshop
Presidential Ballroom B

12:30 – 1:30 pm
Clinical Roundtable/Case Conference
Presidential Ballroom South

Monday, September 26, 2005 (Continued)

1:00 pm – 2:00 pm
Meet-the-International Grant Writers Session - *Canal A/B*

1:30 pm – 2:30 pm
Meet-the-Professor Sessions
Lincoln A,C,D,E &
Jackson A/B, C/D, E/F

2:30 pm – 4:00 pm
Concurrent Oral Sessions
13) Chrondocyte/Osteoblasts
Bayou C/D
14) Steroid Hormones
Presidential Ballroom South
15) Cancer and Bone
Presidential Ballroom B
16) Bone Acquisition & Pediatric Bone Diseases – *Presidential Ballroom A*
17) Osteoporosis – Epidemiology – *Delta Ballroom*
18) Osteoporosis – Pathophysiology
Governor's Ballroom North

4:00 pm – 4:30 pm
Break – Ryman Exhibit Hall C

4:30 pm – 6:00 pm
Concurrent Oral Sessions
19) Osteoclasts II – *Governor's Ballroom North*
20) Bone, Cartilage & Connective Tissue Matrix – *Bayou C/D*
21) Peptide Calciotropic Hormones
Presidential Ballroom South
22) Other Disorders of Bone and Mineral Metabolism
Presidential Ballroom A
23) Mechanical Loading & Exercising
Presidential Ballroom B
24) Osteoporosis Diagnosis & Treatment – *Delta Ballroom*

Tuesday, Sept. 27, 2005

8:00 am – 9:00 am
Louis V. Avioli Memorial Lecture
Delta Ballroom

9:00 am – 9:05 am
Louis V. Avioli Memorial Award
Delta Ballroom

9:05 am – 9:30 am
Break – *Delta Lobby B*

9:30 am – 11:00 am
Concurrent Oral Sessions
25) Osteoblasts III – *Bayou A/B*
26) BMPs, TGF-beta, Other Growth Factors and Cytokines & Others
Bayou E
27) Steroids/Hormones II – *Bayou C/D*
28) Genetics & Metabolic Bone Disease – *Canal C/D*
29) Cancer & Bone – *Canal A/B*
30) Osteoporosis – Diagnosis and Treatment – *Delta Ballroom*

11:30 am
ADJOURN

2005 ANCILLARY PROGRAM

Wednesday, September 21, 2005

The International Society for Clinical Densitometry (ISCD) – Sessions
7:30 am – 11:30 am
ISCD Bone Densitometry Course General Session
Bayou E

11:30 am - 5:30 pm
ISCD Bone Densitometry - Clinician Course Lectures
Jackson A/B

11:30 am - 5:30 pm
ISCD Bone Densitometry - Technologist Course Lectures
Jackson C/D

Thursday, September 22, 2005

The International Society for Clinical Densitometry (ISCD) - Sessions
7:30 am – 11:15 am
ISCD Bone Densitometry – Clinician Course Lectures
Jackson A/B

7:30 am – 11:45 am
ISCD Bone Densitometry –Technologist Course Lectures
Jackson C/D

11:45 am – 2:00 pm
ISCD Bone Densitometry – Clinician Exam
Jackson A/B

12:30 pm – 1:45 pm
ISCD Bone Densitometry – Technologist Exam
Jackson C/D

1:00 pm - 5:45 pm
ISCD Vertebral Fracture Assessment (VFA) Course
Tennessee Ballroom D/E

Friday, September 23, 2005

Working Groups
7:00 pm – 9:00 pm
Working Group on Rheumatic Disease and Bone
Bayou C/D

7:00 pm – 9:30 pm
Muscle and Bone Working Group
Canal E

7:00 pm – 9:30 pm
In Vivo Working Group
Canal A/B

7:00 pm – 9:30 pm
Nutrition and Bone Health Working Group
Canal C/D

7:00 pm – 10:00 pm
Vitamin D Working Group
Bayou E

7:15 pm – 10:00 pm
Working Group on Hormone-Receptor Interactions
Bayou A/B

Industry-Supported Symposia
7:00 pm – 9:30 pm
Optimizing Outcomes for Patients with Metabolic Bone Disease
Sponsored by Integrated Communications Corp.,and Medical Education Resources, Inc.
Supported by an educational grant from Novartis Pharmaceuticals Corporation
Tennessee Ballroom

7:00 pm – 9:30 pm
The Biology of Bone Loss: Advancing the Clinical Management of Osteoporosis
Sponsored by SciMed LLC and Postgraduate Institute for Medicine
Supported by an educational grant from Merck & Co., Inc.
Presentation Ballroom North

7:00 pm – 9:30 pm
New and Future Clinical Approaches to the Prevention of Fractures
Sponsored by The Endocrine Society
Supported by an educational grant from Pfizer, Inc.
Governor's Ballroom North

Saturday, September 24, 2005

Working Groups
7:00 pm – 9:00 pm
Non-Invasive Assessment of Trabecular Bone Microarchitecture Working Group
Canal A/B

7:00 pm – 9:00 pm
Working Group on Musculoskeletal Rehabilitation in Patients with Osteoporosis
Bayou E

7:00 pm – 9:30 pm
Molecular Biology & Pathology of Bone Working Group
Bayou A/B

7:00 pm – 9:30 pm
Working Group on Aging and the Human Skeleton
Canal C/D

7:00 pm – 10:00 pm
Biochemical Markers of Bone Turnover Working Group
Bayou C/D

Industry-Supported Symposia
7:00 pm – 10:00 pm

The RANK/RANKL/OPG Axis: A New Therapeutic Target for the Treatment and Prevention of Bone Loss
Sponsored by Health Science Center for Continuing Medical Education
Supported by an education grant from Amgen, Inc.
Tennessee Ballroom

7:00 pm – 10:00 pm
The Evolving Role of Vitamin D Analogs: Links between Bone Metabolism, Cardiovascular Health, and Long-Term Survival
Sponsored by the Albert Einstein College of Medicine
Supported by an educational grant from Abbott Laboratories
Presidential Ballroom North

2005 ANCILLARY PROGRAM

Sunday, September 25, 2005

Industry-Supported Symposia
6:00 am – 8:00 am
Parathyroid Hormone: A New Frontier in Bone Health
Sponsored by Postgraduate Institute for Medicine
Supported by an unrestricted educational grant from NPS Pharmaceuticals
Tennessee Ballroom

8:30 pm – 11:30 pm
ASBMR SOCIAL EVENT
General Jackson Showboat
Tickets Required

Monday, September 26, 2005

5:30 am – 7:15 am
ASBMR FUN RUN/WALK
Supported by Novartis Pharmaceuticals Corporation
Busing provided to Two Rivers Park

Working Groups
6:30 pm – 8:30 pm
Physical Activity and Falls Working Group
Bayou C/D

6:30 pm – 9:30 pm
Adult Bone and Mineral Working Group
Canal A/B

6:30 pm – 9:30 pm
Post Transplantation and Bone Disease Working Group
Bayou E

7:00 pm – 9:30 pm
Bone Remodeling and Stress Fracture Working Group
Canal C/D

7:00 pm – 10:00 pm
Pediatric Bone and Mineral Working Group
Bayou A/B

Monday, September 26, 2005 (Continued)

Industry-Supported Symposia
6:45 pm – 10:00 pm
Determinants of Fracture Risk Reduction: From Bench to Bedside
Sponsored by Photosound Communications Inc., and Postgraduate Institute of Medicine
Supported by an unrestricted educational grant from The Alliance for Better Bone Health (Procter & Gamble Pharmaceuticals and Aventis)
Tennessee Ballroom

7:00 pm – 9:30 pm
Expanding the Options of Bisphosphonate Therapy
Sponsored by Cerebrio and the University of Kentucky
Supported by an educational grant from Roche and GlaxoSmithKline
Governor's Ballroom C/D

2005 Abstracts

Twenty-Seventh Annual Meeting of the American Society for Bone and Mineral Research

Gaylord Opryland Resort and Convention Center
Nashville, Tennessee, USA
September 23-27, 2005

The Journal of Bone and Mineral Research (ISSN: 0884-0431) provides a forum for papers of the highest quality pertaining to all areas of the biology and physiology of bone, the hormones that regulate bone and mineral metabolism and the pathophysiology and treatment of disorders of bone and mineral metabolism. All authored papers and editorial news and comments, opinions, findings, conclusions or recommendations in the *Journal* are those of the author(s) and do not necessarily reflect the views of the *Journal* and its publisher, nor does their publication imply any endorsement. *The Journal of Bone and Mineral Research* is the official journal of the American Society for Bone and Mineral Research and is published monthly plus a special issue in September by the American Society for Bone and Mineral Research, 2025 M Street, N.W., Suite 800, Washington, DC 20036-3309, USA. Address reprint/ offprint inquiries to the Sheridan Press at US (717) 632-8448 x 8110. Periodicals postage paid in Washington, DC, and additional offices. POSTMASTER SEND ADDRESS CHANGES TO: *Journal of Bone and Mineral Research,* P.O. Box 2759, Durham, NC 27715, USA. 2005 Subscription Rates: U.S.: Personal $495.00; Institutional: $560.00; Canada/Mexico: Personal $515.00; Institutional $585.00; Overseas: Personal $570.00; Institutional: $605.00. Single issue $50.00. Subscription term is January - December.

Claims for missing issues will be serviced at no charge if received within six months of issue date {journal@jbmr.org, or fax (US) 919-620-8465}. Duplicate copies cannot be sent to replace issues not delivered because of failure to notify publisher of change of address. Please notify ASBMR of new address six (6) weeks in advance of moving date. All subscriptions are payable in advance in U.S. funds drawn on a U.S. bank. If not fully satisfied, notify publisher for a refund on all unmailed issues.

Address advertising and commercial reprint inquiries to Mr. Steve Kavalgian, Mill River Media LLC, 141 Boston Post Rd. Old Lyme, CT 06371-1303, USA; (860) 434-6889 (phone); (860) 434-9744 (fax); kavalgian@adelphia.net (e-mail). Advertisements are subject to editorial approval.

The Journal of Bone and Mineral Research is a Journal Club™ selection. The *Journal* is indexed by Index Medicus, Current Contents/Life Science,CABS (Current Awareness in Biological Sciences), Excerpta Medica, Cambridge Scientific Abstracts, Chemical Abstracts, Reference Update, ScienceCitation Index, and Nuclear Medicine Literature Updating and Indexing Service.

AMERICAN SOCIETY FOR BONE AND MINERAL RESEARCH (ASBMR)

OFFICERS

President: Sylvia Christakos, Ph.D.
President-Elect: Elizabeth Shane, M.D.
Past-President: Robert A. Nissenson, Ph.D.
Secretary-Treasurer: Marc K. Drezner, M.D.

COUNCIL

Daniel Bikle, M.D., Ph.D.	*Term expires 2006*	Sundeep Khosla, M.D.	*Term expires 2005*
Jane Cauley, Ph.D.	*Term expires 2006*	René Rizzoli, M.D.	*Term expires 2007*
John Eisman, M.B.B.S., Ph.D.	*Ex Officio*	Vicki Rosen, Ph.D.	*Term expires 2006*
Susan Greenspan, M.D.	*Term expires 2005*	Thomas Spelsberg, Ph.D.	*Term expires 2007*
Theresa Guise, M.D.	*Term expires 2007*	Gary Stein, Ph.D.	*Term expires 2005*

PAST PRESIDENTS

Louis V. Avioli, M.D.	*1979-1980*	Steven L. Teitelbaum, M.D.	*1992-1993*
Lawrence G. Raisz, M.D.	*1980-1981*	Henry M. Kronenberg, M.D.	*1993-1994*
Claude D. Arnaud, M.D.	*1981-1982*	Ernesto Canalis, M.D.	*1994-1995*
Stephen M. Krane, M.D.	*1982-1983*	John P. Bilezikian, M.D.	*1995-1996*
William A. Peck, M.D.	*1983-1984*	Gregory R. Mundy, M.D.	*1996-1997*
Paula H. Stern, Ph.D.	*1984-1985*	Michael Rosenblatt, M.D.	*1997-1998*
B. Lawrence Riggs, M.D.	*1985-1986*	Jane E. Aubin, Ph.D.	*1998-1999*
Norman H. Bell, 4M.D.	*1986-1987*	David Goltzman, M.D.	*1999-2000*
Gideon A. Rodan, M.D., Ph.D.	*1987-1988*	Robert Marcus, M.D.	*2000-2001*
John G. Haddad, Jr., M.D.	*1988-1989*	Robert R. Recker, M.D.	*2001-2002*
Armen H. Tashjian, Jr., M.D.	*1989-1990*	Clifford J. Rosen, M.D.	*2002-2003*
Frederick R. Singer, M.D.	*1990-1991*	Robert A. Nissenson, Ph.D.	*2003-2004*
Mark R. Haussler, Ph.D.	*1991-1992*		

PAST SECRETARY-TREASURERS

Norman H. Bell, M.D.	*1977-1985*	Steven R. Goldring, M.D.	*1997-2000*
Gregory R. Mundy, M.D.	*1985-1991*	Andrew F. Stewart, M.D.	*2000-2004*
Arnold J. Kahn, Ph.D.	*1991-1997*		

PAST COUNCILORS

Constantine Anast, M.D.	*1980-1982*	Hector F. DeLuca, Ph.D.	*1979-1980*
Claude D. Arnaud, M.D.	*1979-1980*	Marie Demay, M.D.	*2000-2003*
Andrew Arnold, M.D.	*1999-2002*	Richard Eastell, M.D., F.R.C.P.	*2000-2003*
Jane E. Aubin, Ph.D.	*1991-1994*	John Eisman, MBBS, Ph.D.	*1994-1997*
Roland Baron, D.D.S., Ph.D.	*1991-1994*	Murray J. Favus, M.D.	*1992-1995*
John P. Bilezikian, M.D.	*1987-1990*	David Feldman, M.D.	*1982-1986*
Dennis Black, Ph.D.	*2001-2004*	Lorraine A. Fitzpatrick, M.D.	*1998-2001*
Lynda F. Bonewald, Ph.D.	*1995-1998*	Francis Glorieux, M.D., Ph.D.	*1988-1991*
Arthur E. Broadus, M.D., Ph.D.	*1990-1993*	Julie Glowacki, Ph.D.	*1999-2002*
Ernesto Canalis, M.D.	*1989-1992*	Steven R. Goldring, M.D.	*1993-1996*
Janet M. Canterbury, M.D.	*1981-1984*	Ralph S. Goldsmith, M.D.	*1980-1983*
Sylvia Christakos, Ph.D.	*1989-1992*	David Goltzman, M.D.	*1984-1988*
Thomas L. Clemens, Ph.D.	*1998-2001*	Maxine Gowen, Ph.D.	*2000-2003*
Jack W. Coburn, M.D.	*1981-1984*	John G. Haddad, Jr., M.D.	*1982-1985*
David V. Cohn, Ph.D.	*1982-1985*	Mark R. Haussler, Ph.D.	*1982-1985*
Cary W. Cooper, Ph.D.	*1980-1981*	Hunter H. Heath III, M.D.	*1985-1988*
Steven R. Cummings, M.D.	*1996-1999*	Helen L. Henry, Ph.D.	*1985-1988*
Bess Dawson-Hughes, M.D.	*1996-1999*	Keith A. Hruska, M.D.	*1989-1992*

GENERAL INFORMATION

ASBMR MEETING LOCATION

All ASBMR 27th Annual Meeting sessions will take place in the Gaylord Opryland Resort and Convention Center, unless otherwise stated. The Gaylord Opryland Resort and Convention Center is located at 2800 Opryland Drive, Nashville, Tennessee, USA.

AUDIO- AND VIDEOTAPING

ASBMR expects that attendees respect each presenter's willingness to provide free exchange of scientific information without the abridgement of his or her rights or privacy and without the unauthorized copying and use of the scientific data shared during his or her presentation. In addition, ASBMR expects that attendees will respect Exhibitors' desires not to have their products or booths photographed or videotaped.

T**he use of cameras, audio-taping devices, and videotaping equipment is strictly prohibited within all Oral Scientific Sessions, the Exhibit Halls, and the Poster Sessions without the express written permission of the ASBMR.** Unauthorized use of the taping equipment may result in the confiscation of the equipment or the individual may be asked to leave the scientific session or Exhibit Hall. These rules are strictly enforced.

USE OF ASBMR NAME AND LOGO

ASBMR reserves the right to approve use of its name in all material disseminated to the media, public and professionals. ASBMR's name, meeting name, and meeting logo may not be used without permission. Use of the ASBMR logo is prohibited. Materials should be directed to ASBMR Executive Director Joan Goldberg. All ASBMR corporate supporters and exhibitors should share their media outreach plans with the ASBMR Executive Director before release.

No abstract presented at the ASBMR 27th Annual Meeting may be released to the press before its official presentation date and time. Press releases must be embargoed until one hour after the presentation.

ASBMR MEETING CONTENT AND EMBARGO POLICY

Abstracts submitted to the ASBMR 27th Annual Meeting are embargoed - that is, unavailable for public release in written, oral and electronic communications - until one hour after the abstract has been presented.

The ASBMR is sensitive to issues of commercial confidentiality and relevant aspects of the U.S. Securities and Exchange Commission (SEC) regulations. Therefore, the ASBMR reminds all readers that all must adhere to the U.S. Securities and Exchange Commission regulations and treat all scientific information as confidential until the embargo has been lifted - one hour after the abstract has been presented. Any reader of, or listener to, ASBMR Annual Meeting content may be viewed as an "insider" by the SEC due to knowledge of information included in abstracts, particularly clinical trial abstracts. SEC regulations may call for criminal penalties for using such information.

COPYRIGHT

DISCLAIMER

All authored abstracts, findings, conclusions, or recommendations contained herein are those of the author(s) and do not reflect the views of the American Society for Bone and Mineral Research or herein imply any endorsement. No responsibility is assumed, and responsibility is herby disclaimed, by the American Society for Bone and Mineral Research for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of methods, products, instructions, or ideas presented in the materials herein (2005 Abstracts). Independent verification of diagnosis and drug dosages should be made. Discussions, views and recommendations as to medical procedures, choice of drugs and drug dosages are the responsibility of the authors.

CONTINUING MEDICAL EDUCATION CREDITS

The Federation of American Societies for Experimental Biology (FASEB) is accredited by the Accreditation Council for Continuing Medical Education to sponsor continuing medical education for physicians. This activity has been planned and implemented in accordance with the Essential Areas and Policies of the Accreditation Council for Continuing Medical Education through the joint sponsorship of FASEB and the ASBMR

Category I Continuing Medical Education (CME) credits toward the American Medical Association's (AMA) Physician Recognition Award will be offered at this meeting. FASEB designates this educational activity for a maximum of 40 category 1 credits. Each physician should claim only those credits that he or she actually spent in the activity. CME application forms will be available in the On-Site Program book, which will be distributed at the meeting. There is a $45 application fee, payable to FASEB upon submission of the form.

Fax: ..... (301) 634-7007
E-mail: ..... pmcgovern@faseb.org

Meeting Objective

The ASBMR 27th Annual Meeting is designed to allow members to present new developments in education, research and clinical practice related to bone and mineral metabolism. The program objectives include updating attendees on the recent advances in osteoporosis and other diseases of bone and mineral metabolism, vitamin D and other steroids, peptide calciotropic hormones, mechanical loading and exercise, bone acquisition and pediatric bone disease, cartilage and connective tissue matrix, and growth factors.

As a result of their attendance, participants should have enhanced their knowledge of osteoporosis, other diseases of bone, basic bone biology and its correlation to mineral metabolism, as well as their ability to treat and care for their patients. Attendees should have developed a clearer understanding of the interrelationship among basic research, clinical research and patient care through the discussions that are expected to take place. The ASBMR 27th Annual Meeting program should produce an enhanced appreciation of the investigative, diagnostic and therapeutic aspects of metabolic bone disorders.

Target Audience

The program is designed for researchers, physicians, clinicians, and other allied health professionals with interests in endocrinology, physiology, cell biology, pathology, molecular biology, genetics, epidemiology, internal medicine, rheumatology, orthopedics, dentistry, nephrology, and pharmacology.

DISCLOSURE/CONFLICT OF INTEREST

The Federation of American Societies for Experimental Biology (FASEB) requires that audiences at FASEB-sponsored educational programs be informed of a presenter's (speaker, faculty, author, or contributor) academic and professional affiliations, and the disclosure of the existence of any significant financial interest or other relationship a presenter has with the manufacturer(s) of any commercial product(s) discussed in an educational presentation. This policy allows the listener/attendee to be fully knowledgeable in evaluating the information being presented. The Program will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.

All authors of submitted abstracts completed the disclosure statement in the online submission program. Invited speakers who are not required to submit an abstract received a form in the mail that they completed and returned.

Disclosure may include any relationship that may bias one's presentation or which, if known, could give the perception of bias. This includes relevant financial relationships of a spouse or partner. These situations may include, but are not limited to:

DISCLOSURE KEY

1. stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. research grants
3. employment (full or part-time)
4. ownership or partnership
5. consulting fees or other remuneration
6. non-remunerative positions of influence such as officer, board member, trustee, or public spokesperson
7. receipt of royalties
8. speaker’s bureau

For full-time employees of industry or government, the affiliation listed in the *2005 Abstracts* will constitute full disclosure.

Disclosures for invited speakers and abstract presenters are provided at the end of the session listing for invited speakers (see *On-Site Program* book) and directly after the body of an abstract for abstract submissions. If there is no conflict of interest or disclosure listed, this means that the invited speaker and/or abstract presenter indicated no conflicts to disclose.

The disclosure information will correspond to the key above. If disclosures are given, the company name, along with the respective disclosure relationship number will be listed (for example: Company Name, 2, 8.).

2005 ABSTRACTS BOOK

Supported by an unrestricted educational grant from Alliance for Better Bone Health (a collaboration between Procter & Gamble Pharmaceuticals and Aventis Pharmaceuticals, a member of the sanofi-aventis Group)

This *2005 Abstracts* book is distributed on-site at the Annual Meeting to all ASBMR members and non-member attendees. Non-member subscribers to *JBMR* will receive the *2005 Abstracts* book by mail. ASBMR members who do not attend the Annual Meeting will receive their copy of the *2005 Abstracts* book by mail following the meeting. The entire ASBMR Scientific Program (invited speaker sessions, lectures, and abstract-based oral and poster presentation information), as well as the 2005 Ancillary Program (Working Groups and Industry-Supported Symposia), are included in full detail in the On-Site Program book and on the ASBMR website at www.asbmr.org. **We encourage you to make use of the *2005 Abstracts* On-line that is accessible via the ASBMR website at www.asbmr.org. A complimentary hard copy of the *2005 Abstracts* book in PDF format will be available for download for all ASBMR members and pre-registered attendees via the ASBMR website as well.**

AWARD PRESENTATIONS

The following ASBMR Awards will be presented immediately following the morning Plenary Symposia and Plenary Lectures in the Delta Ballroom of the Gaylord Opryland Resort and Convention Center - the ASBMR Gideon A. Rodan Excellence in Mentorship Award, the Fuller Albright Award, the Louis V. Avioli Founders Award, the Frederic C. Bartter Award, the William F. Neuman Award, and the Shirley Hohl Service Award. Please refer to the schedule found in the inside cover of this book for award presentation times.

ASBMR VIRTUAL EXHIBIT HALL

The ASBMR Virtual Exhibit Hall (www.asbmr.org/LiveASBMREHall.com) showcases Exhibitors and their products, many of which are present at this year's ASBMR 27th Annual Meeting. Visitors to the ASBMR Virtual Exhibit Hall are able to learn more about Exhibitor's products and services, easily contact them for further information, and enjoy an Exhibit Hall experience at their leisure year-round.

CYBER CAFÉ

Supported by NPS Pharmaceuticals

The Cyber Café, located in the Exhibit Hall, has full Internet capability and enables attendees to search the Internet and check their email. The Cyber Café will be open during published Poster Hall hours.

NIH LOUNGE

Looking for another opportunity to ask U.S. National Institutes of Health and Center for Scientific Review staff about your grant proposal or idea? Plan to visit the Meet-the-NIH Lounge in the Ryman Chamber C of the Gaylord Opryland Resort and Convention Center and get your questions answered. Program staff from the National Institute and Musculoskeletal and Skin Diseases (NIAMS), the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), the National Cancer Institute (NCI), the National Institute of Dental and Craniofacial Research (NIDCR), National Institute on Aging (NIA), Center for Scientific Review (CSR), National Institute of Child Health and Human Development (NICHD), and more will be on-hand, by appointment, to meet with you. Be sure to sign up for open time slots on-site.

YOUNG INVESTIGATOR LOUNGE

All Young Investigator Annual Meeting attendees are cordially invited to drop by the Young Investigator Lounge located in the Ryman Chamber B of the Gaylord Opryland Resort and Convention Center. Expand your network of colleagues and make new friends.

ASBMR HALF-DAY SYMPOSIUM: BONE AND MINERAL COMPLICATIONS OF CHRONIC KIDNEY DISEASE (CKD)

This session will be held on Friday, September 23, 2005, from 9:30 am to 12:00 noon, in the Delta Ballroom of the Gaylord Opryland Resort and Convention Center. Several issues of critical importance to clinicians and researchers in the field will be discussed.

RECEPTION FOR NEW INVESTIGATOR/NEW MEMBER/FIRST TIME ATTENDEES

Sponsored by the ASBMR Membership Development Committee

We are inviting new members and attendees who would like to become affiliated with the ASBMR for a special event which will follow the ASBMR Welcome Reception and Plenary Poster Session. The reception will be held in the Washington B room. The purpose of this social event is to assist attendees with opportunities to meet other recent attendees. The event has been organized to promote interactions among new and junior investigators. Beverages will be available at regular prices ("cash bar").

NEW INVESTIGATOR/NEW MEMBER BREAKFAST

Sponsored by the ASBMR Membership Development Committee
Supported by an unrestricted educational grant from Merck & Co., Inc.

The New Investigator/New Member Breakfast will be held on Saturday, September 24, 2005, from 7:00 am to 8:00 am, in the Governor's Ballroom C/D of the Gaylord Opryland Resort and Convention Center. New Investigators (those early in their research careers) and new ASBMR members are invited to join the ASBMR Council, the Membership Development Committee and colleagues for an informational breakfast. Highlights will include opening remarks by the President of ASBMR, Dr. Sylvia Christakos, and an overview of the program planning by the Program Chairs Drs. Michael Econs and Pamela Robey. Program Directors from U.S. NIH Institutes and Centers, along with ASBMR member senior and junior scientists, will be available for discussion at specially marked tables. Attendees should look for table signs advertising a specialty or NIH Institute or Center of Interest. Or attendees can make their own signs to join with colleagues who have similar interests. Breakfast will be provided.

SPECIAL SESSION FOR ALLIED HEALTH PROFESSIONALS

Sponsored by the ASBMR Membership Development Committee
Supported by an educational grant from Amgen, Inc.

This session will be held on Saturday, September 24, 2005, from 12:00 noon to 2:00 pm, in Governor's Ballroom North of the Gaylord Opryland Resort and Convention Center. This special session is of interest to allied health professionals, first time meeting attendees, individuals new to the field, nurses, clinical research study coordinators, physical therapists and/or those seeking guidance in navigating through the extensive ASBMR program. An overview of the ASBMR 27th Annual Meeting will be given along with lectures on "Nomenclature for Osteoporosis Drugs" and "AMG 162." There is no additional fee or registration required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

GRANT WRITING WORKSHOP: TIPS ON GETTING FUNDED

Sponsored by the ASBMR Membership Development Committee

The Grant Writing Workshop will be held on Saturday, September 24, 2005, from 12:30 pm to 2:00 pm, in the Governor's Ballroom C/D of the Gaylord Opryland Resort and Convention Center. New investigators (those early in their research careers) and new members are invited to attend a workshop on the grant writing process, including advice on grantsmanship and the peer-review process. A panel discussion, based on questions and feedback from the audience, will be led by U.S. NIH representatives and experienced ASBMR members from academia, including an international representative. Funding source information and opportunities will be provided. This is a valuable opportunity for new investigators to gain helpful tips and information directly from these representatives and to become familiar with the different programs. There is no additional fee or registration required for this session, nor will food or beverages be served. However, attendees are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

BIOTECHNIQUES WORKSHOP: BIOLUMINESCENT IMAGING

Sponsored by the ASBMR Education Committee

This session will take place on Sunday, September 25, 2005, from 12:30 pm to 2:00 pm, in the Governor's Ballroom North of the Gaylord Opryland Resort and Convention Center. There is no additional fee or registration required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

THE ART OF GRANT REVIEWING

Sponsored by the ASBMR U.S. Center for Scientific Review(CSR) Task Force

This session will take place on Sunday, September 25, 2005, from 11:30 am to 12:30 pm, in the Jackson E/F room of the Gaylord Opryland Resort and Convention Center. This session, intended for investigators who are at an early to mid-stage of their career, will address the U.S. National Institutes of Health (NIH) grant review process and will provide insight into the skills needed to serve as an effective grant reviewer. Through this session and other activities, the ASBMR U.S. Center for Scientific Review (CSR) Task Force hopes to increase the pool of experienced investigators who would be willing to serve on study sections and review different types of bone-related grants, including basic, translational and clinical grants. The discussion at this informal, interactive session will be led by a panel of CSR Program Directors and previous NIH Grant Study Section Chairs. There is no additional fee but registration is required for this session. Tickets can be obtained from the Meet-the-Professor ticket desk in the Delta Lobby B. Food and beverages will not be served. However, you are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

CAREER OPTIONS FOR SCIENTISTS

Sponsored by the ASBMR Education Committee

The Career Options for Scientists Workshop will be held on Monday, September 26, 2005, from 12:30 pm to 2:00 pm, in the Presidential Ballroom B of the Gaylord Opryland Resort and Convention Center. This year's Career Options for Scientists Workshop is entitled "Perseverance Pays: Overcoming Nay Sayers to Get a Project on Track." While common, early career rejections and frustrations can be devastating to the morale and motivation of younger investigators. Three distinguished ASBMR members will give their perspective on how they have been able to overcome professional, personal, or career hurdles to complete important projects and advance professionally. This workshop targets basic scientists and clinical researchers in both academia and industry. It should be informative for attendees in all phases of their careers, but in particular for researchers who are in early phases of career development. There is no additional fee or registration required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

MEET-THE-INTERNATIONAL GRANT WRITERS

Sponsored by the ASBMR Membership Development Committee

This informal, interactive session is designed for international (non-U.S.) investigators seeking grant information and advice specific to their country or region. Attendees will have an opportunity to meet with grant writers from the various geographic areas identified including: Australia, Korea, Europe, Japan, United Kingdom, Central and South America. Information on international grant opportunities will be available. This session will be held on Monday, September 26, 2005, from 1:00 pm to 2:00 pm, in the Canal A/B room. There is no additional fee or registration required for this session. Please note that food and beverages are not served. However, you are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) the Gaylord Opryland Resort and Convention Center.

CLINICAL ROUNDTABLES/CLINICAL HALF-DAY

The Clinical Roundtable and Half-day sessions are informal sessions geared toward the practicing clinician, offering insight into treatment and diagnosis of bone diseases. These sessions will feature a focused discussion on topical issues of clinical relevance. The clinical roundtable on "What Is the Optimal Duration of Bisphosphonate Therapy?" and "Premenopausal Women with Low BMD" will be held on Friday, September 23, 2005, from 1:00 pm to 2:00 pm, in the Presidential Ballroom South of the Gaylord Opryland Resort and Conference Center. The session on "Acute Vertebral Fracture during a Seizure in a Patient on Long-Term Anticonvulsant Therapy - Is This Traumatic or Not?" and "Kidney Stones and Low Bone Mass" will be held on Saturday, September 24, 2005, from 12:30 pm to 1:30 pm, in the Presidential Ballroom South of the Gaylord Opryland Resort and Conference Center. The Clinical Half-Day sessions on "Steroid-Induced Osteoporosis" and Vertebroplasty/Kyphoplasty Point-Counterpoint: Pro and Con," will be held on Sunday, September 25, 2005 from 8:00 am to 9:30 am, in the Presidential Ballroom Sound of the Gaylord Opryland Resort and Convention Center. The Clinical Half-Day sessions on "Falls," "Vitamin D: Is There an Epidemic?" and "Pitfalls of Densitometry and Difficult Densitometry Cases" will be held on Sunday, September 25 2005, from 12:00 pm to 2:00 pm, in the Presidential Ballroom South of the Gaylord Opryland Resort and Conference Center. The session on "Osteogenesis Imperfecta (OI)" and "Bone Disease in Sick Children: What Standards Should Be Used?" will be held on Monday, September 26, 2005, from 12:30 pm to 1:30 pm, in the Presidential Ballroom South of the Gaylord Opryland Resort and Conference Center

MEET-THE-PROFESSOR SESSIONS

The Meet-the-Professor Sessions are a series of informal sessions designed to provide an opportunity for meeting attendees to interact with experts in an intimate setting and discuss specific clinical and research topics. This year the Meet-the-Professor program has been expanded in order to increase the number of attendees who are able to participate in these sessions. The schedule allows for many Meet-the-Professor sessions to be given twice during the program.

Interested individuals must sign up on-site for the sessions. Tickets are extremely limited and are required for admission. If you are interested in attending one of these sessions, we encourage you to sign up at your earliest convenience on-site at the Registration Desk in the Delta B Lobby at the Gaylord Opryland Resort and Convention Center. There is no additional fee required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area in the Exhibit Hall (Ryman Hall C) in the Gaylord Opryland Resort and Convention Center.

ASBMR MINORITY BREAKFAST

Sponsored by the ASBMR Minority Task Force

Minority attendees - and those who want to help further minority participation in the bone and mineral research field and in the ASBMR - are invited to a complimentary breakfast with the ASBMR Minority Task Force. The Minority Breakfast will be held on Sunday, September 25, 2005, from 7:00 am to 8:00 am, in Washington B room of the Gaylord Opryland Resort and Convention Center. Participants can learn about minority research and travel grants and other career development programs as well as discuss concerns and recommendations for new initiatives. Space is limited to 50 attendees. There is no additional fee. However, you will need to register for the breakfast onsite at the ASBMR 27th Annual Meeting Meet-the-Professor Session Registration desk. All attendees will automatically be registered for a special drawing for free tickets to the ASBMR Social Event!

THE WOMEN IN BONE AND MINERAL RESEARCH EVENT

Sponsored by the ASBMR Women in Bone and Mineral Research Committee
Supported by a grant from Aastrom Biosciences, Inc.

The Women in Bone and Mineral Research Event will be held on Sunday, September 25, from 6:00 pm to 7:30 pm in the Washington B room in the Gaylord Opryland Resort and Convention Center. There is a $35 registration fee ($15 for students/trainees) for this event. Light hors d'oeuvres and soft drinks will be served. A cash bar will be available.

THE ROLE OF ADVOCACY IN MUSCULOSKELETAL RESEARCH FUNDING: GRASSROOTS, NIH, CONGRESS AND THE PUBLIC

Sponsored by the ASBMR Advocacy Committee

This session will provide a brief overview of the current political research funding climate in the U.S., and the strategies used in advocating for increased funding and grassroots advocacy. The Advocacy 101 session will be held on Sunday, September 25, 2005, from 12:30 pm to 1:30 pm in the Governor's Ballroom C/D in the Gaylord Opryland Resort and Convention Center. Speakers and panelists include the Bone Coalition's advocate on Capitol Hill, Washington, DC, USA, ASBMR's representative on the Federation of American Societies for Experimental Biology (FASEB) Board, and ASBMR's Advocacy Committee Chair and ASBMR's Executive Director. Attendees will learn about the ASBMR advocacy program and how scientists can become more effective research advocates around the world. Attendees will receive materials to assist in advocacy, including fact sheets and tips on successful advocacy approaches.

WELCOME RECEPTION AND PLENARY POSTER SESSION

Supported by an educational grant from Merck & Co., Inc.

On Friday, September 23, 2005, from 5:15 pm to 7:00 pm, attendees and registered guests are invited to attend the ASBMR Welcome Reception and Plenary Poster Session in Exhibit/Poster in Ryman Hall C of the Gaylord Opryland Resort and Convention Center. Simply display your badge for admission. Guests may purchase a badge for $30 at registration, which will allow entrance to the Welcome Reception and Exhibit Hall.

ASBMR SOCIAL EVENT

On Sunday, September 25, 2005, from 8:30 pm to 11:30 pm, come cruise the Cumberland River with ASBMR aboard the General Jackson Showboat. The 300-foot-long General Jackson is an historic paddlewheel riverboat reminiscent of ones that cruised the Southern waterways in the 1800s. On board we'll enjoy light refreshments, drinks, music and, of course, a terrific dance band. The General Jackson boards across from the Gaylord Opryland Resort and Convention Center, but shuttle busing will be provided from the Presidential Portico f rom 8:15 pm - 9:00 pm. The boat sails promptly at 9:30 pm. Tickets are required for admission and must be purchased in advance for $30. If available tickets remain, they will be sold on-site at the ASBMR Registration Desk in the Delta Lobby B of the Gaylord Opryland Resort and Convention Center. Don't be late! There are no refunds for those who miss the boat!

ASBMR FUN RUN/WALK

Supported by Novartis Pharmaceuticals Corporation

Delegates and guests of the ASBMR 27th Annual Meeting will have an opportunity to participate in a 5 Km Fun Run/Walk. Whether participants choose to walk or run, they will find this event a terrific way to begin a busy day. There is no cost to participate. Drinks and snacks will be provided. There will be busing provided to Two Rivers Park, where the Fun Run/Walk will be held from 5:30 am to 7:15 am on Monday, September 26, 2005. Meet the shuttle bus at the Presidential Portico outside the Presidential Lobby of the Gaylord Opryland Resort and Conference Center promptly at 5:30 am.

DINE-AROUND RESTAURANT RESERVATION SERVICE

Explore the fabulous hometown flavor of Music City! Or dine at one of Nashville's dozens of four-star restaurants. ASBMR will have a Restaurant Reservations Desk available in the ASBMR Registration Area in the Delta Lobby B of the Gaylord Opryland Resort and Convention Center. You can make reservations for your small group, or if you're dining alone, we can help you make a small group reservation with other ASBMR attendees. For Friday, Saturday and Monday evenings, ASBMR has set aside tables at a variety of restaurants in several of the city's hottest nightspots. We'll bus you from the Gaylord Opryland Resort and Convention Center to your restaurant. After dinner, enjoy the city's nightlife and hop on the bus to return to the hotel. The shuttle busing is complimentary. All meal and entertainment costs will be charged to individual diners and club visitors.

FREE ASBMR DOWNTOWN SHUTTLE BUS

ASBMR is providing free shuttle buses to downtown Nashville during the times below each evening. The buses will pickup at the Presidential Portico outside of the Presidential Lobby of the Gaylord Opryland Resort and Convention Center. The return shuttles will pickup at the same locations where you were dropped off downtown. Attendees using the restaurant reservation service will use the same shuttles. Stop by the Restaurant Reservations desk in Delta Lobby B during registration hours for more information.

Thursday, September 22 5:00 pm - 12:00 midnight - 1 Location: Downtown/Riverfront Park

Friday, September 23 7:00 pm - 12:00 midnight - 3 Locations: Downtown/Riverfront Park, Vanderbilt Area and West End/Hillsboro

Saturday, September 24 7:00 pm - 12:00 midnight - 3 Locations: Downtown/Riverfront Park, Vanderbilt Area and West End/Hillsboro

Sunday, September 25 6:00 pm - 12:00 midnight - 1 Location: Downtown/Riverfront Park

Monday, September 26 6:00 pm - 12:00 midnight - 3 Locations: Downtown/Riverfront Park, Vanderbilt Area and West End/Hillsboro

HOTEL SHUTTLES

ASBMR is not providing a shuttle bus from the GuestHouse International Inn, the Radisson Hotel at Opryland, the Fairfield Inn by Marriott, the Best Western Suites Near Orpyland, the AmeriSuites, nor any of the hotels along Music Valley Drive. However, some of these properties have their own vans that will shuttle guests to the Gaylord Opryland Resort if the van is available. We encourage you to inquire at your specific hotel.

ASBMR is providing a shuttle from the Nashville Airport Marriott in the mornings and evenings. Additional shuttles may also be added for airport hotels within the official ASBMR block. Bus schedules will be provided in official ASBMR hotel lobbies as well as at the Information desk in Delta Lobby B at the Gaylord Opryland Resort.

REGISTRATION HOURS

All on-site registration will take place in the Delta Lobby B of the Gaylord Opryland Resort and Convention Center.

Thursday, September 22, 2005	9:00 am - 5:00 pm
Friday, September 23, 2005	7:00 am - 6:30 pm
Saturday, September 24, 2005	7:00 am - 5:30 pm
Sunday, September 25, 2005	7:00 am - 5:30 pm
Monday, September 26, 2005	7:30 am - 5:00 pm

EXHIBIT HALL HOURS

The Exhibit Hall is located in the Ryman Exhibit Hall C of the Gaylord Opryland Resort and Convention Center. For meeting attendees, lunch will be available for purchase in the hall during Exhibit hours

Friday, September 23, 2005	5:15 pm - 7:00 pm
Saturday, September 24, 2005	9:15 am - 4:30 pm
Sunday, September 25, 2005	9:30 am - 4:30 pm
Monday, September 26, 2005	9:30 am - 4:30 pm

ASBMR TELEPHONE NUMBERS

Management Office	Tel: (615) 458-0830
Registration Desk	Tel: (615) 458-0819
Media Office	Tel: (615) 458-0832
Media Office Fax	Fax: (615) 458-0816

SPEAKER READY ROOM

Supported by an unrestricted educational grant from Mission Pharmacal Company

Speakers must check into the Speaker Ready Room 24 hours in advance of their presentation. At that time, speakers may review their slides. The Speaker Ready Room is located in the Presidential Chamber A of the Gaylord Opryland Resort and Convention Center. Review of slides must occur at least 24 hours prior to your presentation. The Speaker Ready Room will be open during the following times:

Speaker Ready Room Hours

Thursday, September 22	12:00 noon – 5:00 pm
Friday, September 23	7:00 am – 5:30 pm
Saturday, September 24	7:00 am – 6:00 pm
Sunday, September 25	7:00 am – 5:30 pm
Monday, September 26	7:00 am – 5:30 pm
Tuesday, September 27	7:00 am – 11:00 am

SPEAKER LOUNGE

Supported by an unrestricted educational grant from the Alliance for Better Bone Health (a collaboration between Procter & Gamble Pharmaceuticals and Aventis Pharmaceuticals, a member of the sanofi-aventis Group)

The Speaker Lounge will be located in the Presidential Chamber B of the Gaylord Opryland Resort and Convention Center. The lounge provides a relaxing atmosphere for the oral presenters and invited speakers to rest, mingle with one another, and to catch up on office work. The room will be equipped with computers, fax, copier, phone/modem lines, snacks and beverages, sofas and chairs. The Speaker Lounge will be available from Friday, September 23 to Monday, September 26, from 7:00 am to 4:00 pm, and on Tuesday, September 27, from 7:00 am to 11:00 am.

POSTER SESSIONS

All poster sessions will be held in Ryman Hall C of the Gaylord Opryland Resort and Convention Center. Authors must be at their posters for 1½ hours of the designated poster sessions on Saturday through Monday and must be available to answer questions during this period. Authors of odd-numbered posters should be present from 11:30 am to 1:00 pm on their designated days. Authors of even-numbered posters should be present from 1:00 pm to 2:30 pm.

Poster numbers are listed in this 2005 Abstracts book prefixed with a letter that denotes the day of presentation, i.e., F (Friday), SA (Saturday), SU (Sunday), M (Monday). These letters are not posted on the boards. **Presenters should mount their posters on the board bearing their assigned numbers, disregarding the letter prefix. ASBMR accepts no liability for posters or poster materials and will not adjudicate disputes between abstract presenters.**

Plenary Poster presenters and Young Investigator Award recipients presenting posters should mount their posters on Friday, September 23, 2005, between 3:00 pm and 5:00 pm. Plenary Poster presenters and Young Investigator Award recipients presenting posters are expected to be present during the Welcome Reception and Plenary Poster Session on Friday, September 23, from 5:15 pm to 7:00 pm. Plenary Poster presenters and Young Investigator Award recipients presenting posters will follow the odd/even hours for presenters during Poster Session I on Saturday, September 24, 2005. Plenary Posters will remain posted until Saturday, September 24 at 6:00 pm. Young Investigator Award posters will remain posted for the duration of the meeting.

Please note that children 12 years of age and under will not be permitted in the poster area or the Exhibit Hall at any time.

Presenter Check-in:
Since only poster presenters are allowed in the Exhibit/Poster Hall during the below poster set-up hours, please go to the Poster Presenter Check-in Table to receive a security pass. The table will be located by the side entrance to Ryman Hall C2, which is accessed through Ryman Foyer B. To speed the check-in process, please have your poster board number ready.

NOTE: Posters remaining after Poster Dismantling times will be discarded.
Young Investigator Award Posters remain up through Monday, September 26.
Please adhere to these scheduled times to maximize interaction for other attendees:

ASBMR MEMBERSHIP

The ASBMR Exhibit Booth is #213 (see Exhibit Hall map, pullout map #2) in the Ryman Exhibit Hall C. Come by and meet the ASBMR staff, pick up information about the Society, check out the online version of the Journal of Bone and Mineral Research, and order copies of the 5th Edition of the Primer on Metabolic Bone Diseases and Disorders of Mineral Metabolism.

The ASBMR Membership Counter is located in the Registration Area in the South Lobby and will be prepared to accept 2006 ASBMR membership renewal payments.

ASBMR JOB PLACEMENT SERVICE

The ASBMR Job Placement Service is easily accessible year-round online. You can access the most up-to-date job and candidate listings using the ASBMR Job Placement Service Website. Simply submit your resume or job announcement using the online forms at www.asbmr.org. After your forms are submitted and payment is received, you will be able to use your self-assigned login name and password to access the Online Placement Service database anytime you wish.

Employers enrolled in the service will be entitled to display unlimited job announcements online and onsite at the meeting on the bulletin board located in the Registration Area of the Delta Lobby B of the Gaylord Opryland Resort and Convention Center. In addition, employers will have access to candidates' Curricula Vitae.

Employers and candidates may request further information by accessing the ASBMR Online Job Placement Service at www.asbmr.org.

ASBMR MEDIA OFFICE

The ASBMR Media Office will be in operation during the ASBMR 27th Annual Meeting to facilitate media-related activities during the meeting. The Media Office will be located in the Governor's Chamber D room in the Gaylord Opryland Resort and Convention Center.

Media Office - Hours of Operation

Friday, September 23, 2005	9:00 am - 5:00 pm
Saturday, September 24, 2005	8:00 am - 5:00 pm
Sunday, September 25, 2005	8:00 am - 5:00 pm
Monday, September 26, 2005	8:00 am - 5:00 pm
Tuesday, September 27, 2005	8:00 am - 11:00 am

SPECIAL NOTICES — SAFETY TIPS

- Remove your convention badge outside the meeting sites. Do not wear your badge outside or advertise that you're a visitor and not familiar with your surroundings.
- Walk with another person rather than alone. Avoid alleys, walkways between buildings, and deserted parking lots.
- Remain alert, be aware of your surroundings, and carry your handbag in front of you.
- While in your hotel room, always lock your door. Know where emergency exits are in your hotel.
- Place any valuables in a hotel safety deposit box rather than leaving them in your room or carrying them with you.
- Keep a copy of your passport and travel papers in a safe place.

DOES THE ASBMR HAVE YOUR EMAIL ADDRESS?

Next year all important ASBMR Annual Meeting materials will be found on the ASBMR Website… and we will broadcast email to everyone on our correspondence list early notice of the Call for Abstracts, Preliminary Program, Registration and Housing information, Abstracts Online, and more! **So you don't miss out** on early notices and regular updates, please send all your contact information to the ASBMR, including your email address.

American Society for Bone and Mineral Research
2025 M Street, NW, Suite 800
Washington, DC 20036-3309, USA

ANNUAL MEETING EVALUATION

The 2005 Annual Meeting Evaluation will be accessible online following the 27th Annual Meeting. An email will be sent to all meeting attendees who provided their email addresses at the time of registration. The email will provide a hyperlink to the online evaluation site. It will also be accessible via the ASBMR website at www.asbmr.org. We strongly encourage and welcome all attendees to provide us with feedback on the meeting. Your input is very important to us.

FUTURE ANNUAL MEETING DATES

September 15-19, 2006
ASBMR 28th Annual Meeting
Philadelphia, Pennsylvania, USA

September 16-20, 2007
ASBMR 29th Annual Meeting
Honolulu, Hawaii, USA

September 12-16, 2008
ASBMR 30th Annual Meeting
Montreal, Quebec, Canada

September 11-15, 2009
ASBMR 31st Annual Meeting
Denver, Colorado, USA

HOW THE PROGRAM WAS SELECTED

The 2005 ASBMR Program Co-Chairs and the President have spent close to two years in developing the scientific program for the 27th Annual Meeting. We very much appreciated the advice and suggestions of the previous Program Co-Chairs, Marie Demay, M.D., and Eric Orwoll, Ph.D., and Past-President Robert Nissenson, Ph.D., as we put the program together.

Dr. Ignarro Presents Aurbach Lecture

The basic format of the meeting, emphasizing short oral presentations and poster sessions, is the same as in past years. The meeting will begin with the Gerald D. Aurbach Memorial Lecture on Saturday, and we are very excited that Nobel Laureate Louis J. Ignarro, Ph.D., accepted our invitation to present our Society's most prestigious lecture.

Dr. Aubin Presents Avioli Lecture

The final day of the meeting will feature the Louis V. Avioli Memorial Lecture, to be presented this year by Jane E. Aubin, Ph.D. After considerable discussion with many ASBMR members, we selected topics for basic and clinical Mini-Symposia on Friday. Plenary Sessions on Saturday, Sunday and Monday, and State-of-the-Art Lectures on Saturday and Sunday, were selected by the Program Co-Chairs to cover emerging issues.

Program Features Innovations

There have been several changes in the 2005 program, however. One notable change is the expanded clinical sessions on Sunday. Also, based on the success of the clinical case conferences in 2004, the number of case conferences has been expanded from two to four sessions (Friday through Monday). To increase the opportunity for attendees to participate in the ever-popular Meet-the-Professor (MTP) sessions, we have greatly increased the number of MTP sessions available as well. Additionally, the number of Clinical MTPs has doubled and many faculty are giving two MTP sessions. Importantly, these changes have been made largely on the basis of participant survey results from the 2004 meeting. (The Program Committee carefully reviewed the 2004 survey results and took every comment into consideration.)

Handling Conflict of Interest

During the course of planning this year's meeting, the 2005 Program Committee and ASBMR staff experienced increased responsibilities in complying with the Updated Standards for Commercial Support of the U.S. Accreditation Council for Continuing Medical Education (ACCME). The ASBMR receives its Continuing Medical Education (CME) credits through the Federation of American Societies for Experimental Biology (FASEB), which is accredited by the ACCME. As the ability to provide CME for the ASBMR Annual Meeting is extremely important to the ASBMR, we have handled speaker potential conflicts of interest differently to comply with the updated standards. Current rules require not only disclosure of conflicts, but resolution of conflicts for all speakers, session chairs and Program Committee members. We would appreciate your comments on the post-meeting survey regarding how well these potential conflicts of interest were resolved.

Review and Selection of Abstracts, Awards

The categories for abstract submission were the same as in previous years, and authors were asked to identify up to three categories that best suited the content of their abstract. Each Program Co-Chair was responsible for reviewing abstracts self-identified as basic or translational/clinical. Slightly more than 1,800 abstracts were submitted, 41% basic and 59% translational/clinical, which is comparable to the distribution in 2004.

In consultation with the President, the Program Co-Chairs identified a Chair for each category and nine other reviewers. After abstract submission, the Co-Chairs reviewed all abstracts, and in some cases, reassigned them to other categories. The abstracts were reviewed "blindly" on a 5-point scale, and reviewers were instructed to refrain from reviewing abstracts in which they were in conflict. In addition, based on the ACCME's new requirements, reviewers were also asked to identify those abstracts in which commercial bias was evident. The scores were tabulated by Coe-Truman Technologies, ASBMR's abstract processing vendor; these scores were then used to select the oral program by the Program Co-Chairs and President, along with the President-Elect, Elizabeth Shane, M.D., and next year's Annual Meeting Co-Chairs, Andrew Arnold, Ph.D., and Susan Greenspan, M.D.

The over-arching principle in assembling the oral program was to select abstracts based on their scores, and then organize them into thematic sessions. The highest rated abstracts from the basic and translational/clinical (18 of each) submissions were selected for the plenary oral sessions. The next highest were selected for concurrent oral sessions; and highly ranked abstracts that were not selected for the oral program were assigned to the Plenary Poster Session on Friday evening. Slightly more than 12% of the submitted abstracts were assigned to the oral program, and each category had roughly similar representation on the oral program based on numbers of abstracts submitted, with only minor variation based on differences in the spread of scoring in the different categories.

This year, a separate "Late-Breaking" Abstract Session has not been designated in the program. This decision was made in consultation with Council, the Program Co-Chairs and the President. While there is an opportunity to submit late-breaking abstracts of broad interest where the findings were not available in time for submission by the regular abstract deadline, the abstract, if selected, will be assigned to a time slot at the end of a session that most closely matches its content. As stated in the Call for Abstracts, the merit of the late-breaking abstracts must reach or surpass the level of those selected for the regular oral program. Consequently, it is not known at the time of the Program Selection Meeting held in June whether or not abstracts that truly qualify will be submitted (Late-Breaking abstracts were due on July 20th). The time and location of any Late-Breaking Abstract that has been selected will be advertised, and an insert will be included in the ASBMR delegate bags.

The Society, assisted by corporate support, offers a number of awards, such as the ASBMR Young Investigator Award, the ASBMR Outstanding Abstract Award, the ASBMR Award for Outstanding Research in the Pathophysiology of Osteoporosis, and the ASBMR President's Book Award. As in previous years, these awardees have been selected based on abstract score and eligibility.

Thanks and Acknowledgments

We are extremely grateful to all of our colleagues and to the members who have provided us with a great deal of advice and many outstanding suggestions for speakers and topics. We also thank all of the scientific reviewers for the quality and timeliness of their efforts. And needless to say, not much would be possible without the support of the ASBMR Business Office Staff, Lizzy Koenst, (who left the ASBMR earlier in the year), Amy Werner, Yvette Dalka and Karen Hasson, and Judie Spalding of Coe-Truman Technologies (ASBMR's abstract processing vendor). It is because of all of the hard work and dedication of those involved that we feel that this is an outstanding scientific program. We hope that you enjoy it as much as we have putting it together!

Sincerely,

Sylvia Christakos, Ph.D., *President*
Pamela G. Robey, Ph.D., *Program Co-Chair*
Michael J. Econs, M.D., *Program Co-Chair*

WEDNESDAY, SEPTEMBER 21, 2005
DAY-AT-A-GLANCE

Time/Event/Location
All events will be held at the Gaylord Opryland Resort and Convention Center, unless otherwise noted.)

Ancillary Program - The International Society for Clinical Densitometry (ISCD)

7:30 am - 5:30 pm
ISCD Bone Densitometry - Clinician Course Lecture
Jackson A/B

7:30 am - 5:30 pm
ISCD Bone Densitometry - Technologist Course Lecture
Jackson C/D

THURSDAY, SEPTEMBER 22, 2005
DAY-AT-A-GLANCE

Time/Event/Location
(All events will be held at the Gaylord Opryland Resort and Convention Center, unless otherwise noted.)

DISCLOSURE/CONFLICT OF INTEREST

The Federation of American Societies for Experimental Biology (FASEB) requires that audiences at FASEB-sponsored educational programs be informed of a presenter's (speaker, faculty, author, or contributor) academic and professional affiliations, and the existence of any significant financial interest or other relationship a presenter has with the manufacturer(s) of any commercial product(s) discussed in an educational presentation. This policy allows the listener/attendee to be fully knowledgeable in evaluating the information being presented. The Program will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.

All authors of submitted abstracts completed the disclosure statement in the online submission program. Invited speakers who are not required to submit an abstract received a form in the mail that they completed and returned.

Disclosure may include any relationship that may bias one's presentation or which, if known, could give the perception of bias. These situations may include, but are not limited to:

DISCLOSURE KEY

1. stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. research grants
3. employment (full or part-time)
4. ownership or partnership
5. consulting fees or other remuneration
6. non-remunerative positions of influence such as officer, board member, trustee, or public spokesperson
7. receipt of royalties
8. speaker’s bureau

For full-time employees of industry or government, the affiliation listed in the *2005 Abstracts* will constitute full disclosure.

Disclosures for invited speakers and abstract presenters are provided at the end of the session listing for invited speakers and directly after the body of an abstract for abstract submissions. If there is no conflict of interest or disclosure listed, this means that the invited speaker and/or abstract presenter indicated no conflicts to disclose.

The disclosure information will correspond to the key above. If disclosures are given, the company name, along with the respective disclosure relationship number will be listed (for example: Company Name, 2, 8.).

Dkk Proteins Control Osteoblast Function and Bone Formation both *In Vitro* and *In Vivo*. G. Rawadi*[1], S. Roman-Roman[1], K. Boulukos*[2], F. Morvan*[3], P. Martin*[2], S. Pinho*[4], P. Pognonec*[2], P. Clément-Lacroix*[1], C. Niehrs*[4], R. Baron[5]. [1]In Vitro Pharmacology, Prostrakan, Romainville, France, [2]UMR CNRS 6548, Nice, France, [3]Yale University, New Haven, CT, USA, [4]DKFZ, Heidelberg, Germany, [5]Prostrakan, Romainville, France.

The Wnt/β-catenin signalling pathway has been demonstrated to play an essential role in bone biology. Loss of function mutations in the Wnt co-receptor LRP5, causes severe osteoporosis, while gain of function mutation in this same receptor leads to a high bone mass phenotype in both humans and mice. Wnt activity also regulates the expression and secretion of a number of Wnt-antagonizing proteins including Dickkopfs (Dkks). We have investigated the effect of Dkk1, Dkk2 and Dkk3 on osteoblast differentiation and bone formation both *in vitro* and *in vivo* through a knockout. First, overexpression of Dkk1 and Dkk2 proteins in rat primary osteoblasts results in complete inhibition of mineralized nodule formation. These inhibitory effects on osteoblast differentiation were also confirmed by measuring the expression of osteoblast differentiation markers such as alkaline phosphate and osteocalcin. Interestingly, Dkk1 and 2 overexpression increased adipocyte differentiation in the same cultures, as observed by red-oil staining and PPARγ expression. Unlike Dkk1 and 2, Dkk3 overexpression has no effect on osteoblast differentiation. Using purified recombinant murine Dkk proteins in M3CT3-E1 osteoblastic cells further supported our data. In fact, rmDkk1 inhibits spontaneous MC3T3-E1 cell mineralization as well as mineralization induced by the morphogenic proteins Sonic Hedgehog and BMP-2. In addition, rmDkk1 reduces alkaline phosphate expression in MC3T3-E1 cells. Our data clearly demonstrate that Dkk proteins are able to antagonize osteoblast differentiation and matrix mineralization *in vitro*. To analyze the role of Dkk1 *in vivo*, we gene rated *dkk1* knockout mice. While homozygous *dkk1*-deficient mice are embryonic lethal, heterozygous *dkk1* deficient mice are healthy, viable and develop normally. Importantly, structural, dynamic and cellular analysis of bone remodelling in $dkk1^{+/-}$ mice showed a strong increase in bone mineral density, an increased trabecular number and enhanced osteoblast activity with a marked increase in the Bone Formation Rate. Osteoblast number was significantly higher in $dkk1^{+/-}$ compared to wild type mice, whereas osteoclast number was not affected. We conclude that 1/ Dkk proteins, which antagonize the LRP5 and Wnt-dependent β-catenin pathway, regulate osteoblast differentiation, bone formation and bone mass in vivo and 2/ Heterozygous deletion of the gene encoding Dkk1 is sufficient to induce a high bone mass phenotype in mice.

Suppression of Dkk1 Is Not Essential for PTH-Mediated Activation of Canonical Wnt Signaling in Bone. J. Guo, E. Schipani, M. Liu*, F. R. Bringhurst, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Dkk1 acts as a negative regulator of canonical Wnt signaling by binding to and antagonizing activation of Lrp5/6. We have previously shown that PTH suppresses Dkk1 mRNA expression in osteoblasts ex vivo and that overexpression of Dkk1 leads to less trabecular bone in vivo. To explore whether the anabolic action of PTH on bone is mediated in part by canonical Wnt signaling, we examined the effect of overexpression of Dkk1 on the high bone mass caused by expression of a constitutively active PTHR in osteoblasts in vivo. Mice overexpressing Dkk1 under the control the mouse α1(I) collagen promoter (Dkk1 mice) were mated to Jansen transgenic mice that express a constitutively active PTHR under the control of the same promoter as in Dkk1 mice. As reported previously, Dkk1 mice had low bone mass in the metaphyseal region, while Jansen mice exhibited overproduction of trabecular bone at 6 weeks of age. Interestingly, the increase in trabecular bone characteristic of the Jansen phenotype was partly prevented in mice that expressed both transgenes in the same time, as shown by histology. To determine the effect of overexpression of Dkk1 on canonical Wnt signaling in osteoblasts, Dkk1 mice were mated to TopGal reporter mice that carry a bacterial β-galactosidase transgene responsive to canonical Wnt signaling. We observed that Dkk1 overexpression leads to decreased Wnt signaling in osteoblasts. These osteoblasts exhibited lower levels of TopGal-associated β-galactosidase activity, and quantitative RT-PCR revealed lower levels of TopGal mRNA and lower levels of mRNA encoding Axin2, a Wnt-target gene, in bones from these mice. However, the continued expression of Dkk1 in these mice, which was not suppressed by PTH, did not block PTH's ability to activate Wnt signaling. When PTH was given to the Dkk1 mice for 24 hr, expression levels of TopGal and Axin2 mRNAs were significantly elevated (both >2-fold). Similar findings were observed in MC3T3 cells stably co-transfected with mouse PTHR and a Wnt/β-catenin-dependent Topflash reporter gene. Reporter activity, determined by luciferase assay, in such stable cells was significantly suppressed by transient transfection with a mouse Dkk1 expression construct (50%) but was dramatically increased by PTH in a dose- and time-dependent manner. PTH still induced reporter activity despite the overexpression of Dkk1 in such stable cells. We conclude that PTH activates the Wnt pathway in bone, an action that may contribute to the anabolic action of PTH. Though PTH suppresses Dkk1 expression in osteoblasts, PTH still activates Wnt signaling even when Dkk1 expression is not suppressed in transgenic mice and cultured osteoblasts.

Hedgehog Signaling Interacts with Wnt/b-catenin Signaling in Controlling Endochondral Bone Formation and Synovial Joint Development. K. Mak*, L. Garrett-Beal*, Y. Yang*. Genetic Disease Research Branch, NHGRI/NIH, Bethesda, MD, USA.

Chondrocyte and osteoblast differention and synovial joint formation are key aspects of endochondral skeletal development.We have shown previously that Wnt/b-catenin signaling is required for osteoblast and chondrocyte differentiation from mesenchyme progenitors, and it is also required for proper progression of chondrocyte hypertrophy.Indian hedgehog (Ihh) signaling is also required for endochondral bone formation and controls chondrocyte proliferation and hypertrophy by forming a negative feedback loop with parathyroid hormone related peptide (PTHrP).To test the genetic interaction of Wnt and Ihh-PTHrP signaling in both osteoblast differentiation and chondrocyte maturation,we have generated mouse embryos with disrupted Wnt and Ihh signaling in the skeletal system.The floxed alleles of Patched (Ptc) and Smoothened (Smo) which encode receptors of Hedgehog (Hh) ligand were used to upregulate or inactivate Ihh signaling respectively.We used two different floxed b-catenin (an obligatory component of canonical Wnt signaling) alleles,Catnb or CatnbEx3, to produce inactivated or constitutively activated b-catenin respectively.Col2a1-Cre mouse was used to specifically mutate Ptc,Smo and b-catenin in all chondrocytes and some osteoblasts.We have found that in Ptcc/-;Col2a1-Cre mice, chondrocyte hypertrophy was significantly delayed whereas endochondral bone formation was greatly enhanced.Synovial joint fusion was observed,possibly due to Bone morphogenetic proteins (Bmps) upregulation.The Catnbc/-;Col2a1-Cre mice showed delayed chondrocyte hypertrophy and diminished bone formation.Synovial joint fusion was observed in some areas.Interestingly,in the Ptcc/-;Catnbc/-;Col2a1-Cre double mutant embryo,bone formation was greatly diminished,similar to that observed in Catnbc/-;Col2a1-Cre mutants,demonstrating that Hh signaling acts upstream of Wnt/b-catenin signaling in promoting osteoblast differentiation.In the cartilage of the double mutant embryo,however,delay of chondrocyte hypertrophy was more severe than either single mutant,indicating that Wnt/b-catenin and Ihh-PTHrP signaling act in parallel,but antagonistically with each other in controlling chondrocyte hypertrophy as the phenotypes of b-catenin loss of function mutants were enhanced by Ihh gain of function mutants. Lastly,synovial joint fusion was also greatly enhanced in the double mutant, indicating that Ihh signaling antagonizes with Wnt signaling in synovial joint induction too.The antagonistic activity of Ihh signaling is likely to be indirect due to Bmp-2,-4,-7 upregulation in the Ptcc/-;Col2a1-Cre embryo.

Msx2 Enhances Bone Mass Via Canonical Wnt Signals. S. Cheng, J. Shao, N. Charlton-Kachigian*, A. P. Loewy*, J. M. Pingsterhaus*, D. A. Towler. Div. of Bone and Mineral Diseases, Dept. of Med, Washington University School of Medicine, St. Louis, MO, USA.

Osteoblasts and adipocytes share a progenitor derived from the stromal cell lineage -- a progenitor possessing features of the pericytic microvascular smooth muscle cell. Since Msx2 promotes osteogenesis but suppresses adipogenic differentiation of vascular myofibroblasts, we studied effects of Msx2 on osteoblast physiology, implementing validated *in vitro* and *in vivo* models. In MC3T3-E1 osteoblasts and 10T1/2 mesenchymal cells, Msx2 stimulated proliferation via suppression of p27 and upregulation of cyclin D2. SFG-Msx2 transduced cells also expressed elevated levels of osterix (Osx), alkaline phosphatase (ALP), and bone sialoprotein (BSP) -- but not Runx2. ALP activity and Osx promoter activity (LUC reporter) were enhanced in cultures of SFG-Msx2 cells vs. SFG-LacZ controls, and Osx antisense oligonucleotide reduced Msx2 stimulation of ALP. Since canonical Wnts also stimulate bone formation, we examined the relationship between Msx2 and Wnt signaling. Msx2 upregulated multiple Wnt ligands, but down-regulated the expression of Dkk1, a Wnt inhibitor. β-catenin protein accumulation in Msx2 cells was increased, confirming activated canonical Wnt signaling. Moreoever, β-Catenin accumulated to a greater extent in the nuclei in cells adjacent to EGFP-Msx2 transfected cells vs. EGFP controls. Using the TCF/LEF optimal promoter construct TOPFLASH, we identified that transcription supported from this Wnt- responsive reporter was increased 2 fold when co-cultured with SGF-Msx2 transduced cells vs. SFG-LacZ controls. Restoring Dkk1 activity with either SFG-Dkk1 retrovirus or Dkk1 treatment (a) diminished Msx2-dependent upregulation of ALP activity, (b) inhibited ALP, Osx, and BSP mRNA accumulation; (c) upregulated PPARγ2; and (d) reversed the adipostatic effect of Msx2. To confirm these observations *in vivo*, we studied CMV-Msx2 transgenic (Tg) mice, a model validated in studies of Msx2-dependent craniosynostosis. Msx2 Tg mice exhibited increased bone mineral density and decreased body fat accumulation as compared to non-transgenic sibs. Osteoblasts from Msx2 Tg expressed higher mRNA levels of ALP, Osx, and BSP, and exhibited increased matrix calcification. Msx2 Tg bone marrow cells displayed elevated osteogenesis and suppressed adipogenesis in histological assays. Finally, as compared to TOPGAL+ mice (Wnt signaling-LacZ reporter mouse), osteoblasts from Msx2Tg+;TOPGAL+ siblings exhibited 5-fold enhanced LacZ staining. Thus, Msx2 regulates mesenchymal cell fate and body composition. Canonical Wnt signals that upregulate Osx expression mediate in part Msx2 pro-osteogenic actions.

Cartilage-Specific Over-Expression of Smurf2 Induces Osteoarthritis by Degradation of Phospho-Smad3. Q. Wu, Y. B. Lim*, K. Kim*, M. Zuscik, D. Chen, E. M. Schwarz, J. E. Puzas, R. J. O'Keefe, R. N. Rosier. Orthopaedics, University of Rochester, Rochester, NY, USA.

Articular cartilage in diarthrodial joints and nucleus pulposus of the intervertebral discs are tissues that are maintained by the activity of chondrocytes that facilitate matrix catabolism. During osteoarthritis (OA), the cartilage architecture in these tissues is degraded due to abnormal articular chondrocyte maturation. During the progression of OA, cartilaginous outgrowths and osteophytes are formed on the joint surface and periphery, which undergo endochondral ossification leading to further joint damage. Several lines of evidence have demonstrated that TGF-ß signaling is essential to maintain articular cartilage by preventing articular chondrocyte from undergoing inappropriate terminal maturation. Supporting this idea, over-expression of Smurf2, an E3 ubiquitin ligase that targets Smad1 and Smad2 for the proteasome degradation, leads to reduced TGF-ß signaling and accelerated chondrocyte maturation *in vitro*. We therefore hypothesized that over-expression of Smurf2 in cartilage *in vivo* will induce inappropriate chondrocyte maturation and cause OA. To test this hypothesis, we generated transgenic mice over-expressing Smurf2 under control of type II collagen promoter. We characterized the mice at 2, 4.5, and 6-8 months of age, and found an osteoarthritic phenotype in several diarthrodial joints and in the intervertebral disks. In the knee joints, the osteoarthritic changes included degenerated articular cartilage, chondro-osteophyte formation in periosteum, mineralization of the meniscus and ligaments, and sub-chondral sclerosis. The severity of these phenotypic changes progressed with aging. By 8 months, Smurf2 over-expressing mice had lost 80% of the articular cartilage in the knee, accompanied by severe clefting; chondrocyte cloning, hypertrophic differentiation and formation of marrow cavities within the meniscus and ligaments. To the mechanism of these phenotypes, we performed Smurf2 functional assays in chondrocytes derived from the neonatal mouse sternum. Among Smad1, Smad2 and Smad3 protein levels, only phospho-Smad3 is dramatically decreased in Smurf2-tg chondrocytes. Furthermore, this decrease can be partially rescued by application of a proteasome inhibitor, suggesting that Smurf2-mediated phospho-Smad3 degradation is proteasome dependent. Consistent with this data, TGF-ß promoter activity is inhibited in Smurf2-tg chondrocytes, and the promoter responsive activity for BMP is similar in Smurf2-tg chondrocytes with that of WT. Thus, cartilage-specific overexpression of Smurf2-induced OA is mediated by degradation of phospho-Smad3.

S100A1 and S100B, Transcriptional Target Molecules of SOX5, SOX6 and SOX9 (the SOX Trio), Inhibit Hypertrophic Differentiation and Calcification of Chondrocytes. T. Saito*, T. Ikeda, K. Nakamura, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine, University of Tokyo, Tokyo, Japan.

SOX9 not only stimulates chondrogenic differentiation, but also suppresses hypertrophic differentiation and calcification of chondrocytes, and its co-activators SOX5 and SOX6 enhance these actions, so that the combination (the SOX trio) is reported to provide signals for the regeneration of permanent cartilage. To identify transcriptional targets of the SOX trio in the inhibition of the terminal differentiation of chondrocytes, we screened the target molecules of the SOX trio by a microarray analysis using human mesenchymal stem cells (hMSC) in which the SOX trio was adenovirally introduced. Compared to the LacZ-introduced control, 603 genes were up-regulated by the SOX trio, among which two homologous genes in the S100 family, S100A1 and S100B, showed very strong increases. Real-time RT-PCR analysis confirmed that expressions of S100A1 and S100B were strongly induced by the SOX trio introduction, while weakly by SOX9 alone, in hMSC, human dermal fibroblasts, and other non-chondrogenic cell lines. In vivo expressions of S100A1 and S100B were shown by in situ hybridization to be localized in the pre-hypertrophic chondrocytes of the mouse growth plate, following the expressions of the SOX trio. Luciferase-reporter assay identified the core enhancer elements of the SOX trio within 40 bp and 32 bp regions in the proximal promoters of S100A1 and S100B, respectively, both containing the paired HMG binding motif surrounded by GC rich sequences, which is a typical feature of SOX9 enhancers. These regions strongly and selectively responded to the SOX trio introduction depending on their repeat numbers, indicating that S100A1 and S100B are direct transcriptional targets of the trio. To further investigate the functional contribution of S100A1 and S100B to chondrocyte differentiation, these molecules or their siRNA were retrovirally introduced into mouse chondrogenic ATDC5 cells that underwent hypertrophic differentiation and calcification in the presence of insulin. Overexpression of S100A1 and/or S100B reduced type X collagen and osteocalcin mRNA levels, and ALP and Alizarin red stainings. In the meantime, silencing of S100A1 and S100B markedly accelerated these markers, e.g., the type X collagen mRNA level to more than 20-fold. We thus conclude that S100A1 and S100B, novel transcriptional target molecules of the SOX trio, inhibit hypertrophic differentiation and calcification of chondrocytes. Elucidation of the molecular network related to these signalings will much benefit the regenerative medicine of permanent cartilage.

Hypoxia and HIF-1α Expression Enhance Osteolytic Bone Metastases in Breast Cancer. T. Hiraga[1], S. Kizaka-Kondoh*[2], K. Hirota*[3], T. Yoneda[1]. [1]Biochemistry, Osaka Univ Grad Sch Dent, Osaka, Japan, [2]COE, Radiation Oncology, Kyoto Univ Grad Sch Med, Kyoto, Japan, [3]Anesthesia, Kyoto Univ Grad Sch Med, Kyoto, Japan.

Hypoxia is a common feature of locally advanced solid tumors and is associated with malignant phenotype including resistance to anti-cancer therapies, recurrence, local invasiveness and distant metastasis. The transcription factor hypoxia-inducible factor-1α (HIF-1α) is a major regulator for cancer cells to adapt the hypoxia and is implicated in malignant progression of cancers. Hypoxia and HIF-1α expression are correlated with poor survival in cancer patients. However, the role of hypoxia and HIF-1α expression in bone metastasis has not been explored. Here, we studied whether hypoxia and HIF-1α expression contribute to the development of bone metastases using an animal model of human breast cancer. The MDA-MB-231 human breast cancer cells metastasized to bone following intracardiac inoculation showed accumulation of a hypoxic marker pimonidazole. These hypoxic MDA-MB-231 cells also exhibited nuclear HIF-1α expression. To verify the role of hypoxia in bone metastases, we tested the effects of the oxygen-dependent degradation domain of HIF-1α fused with HIV-TAT protein transduction domain and caspase-3 (TAT-ODD-Casp3) on bone metastases. This fusion protein is shown to selectively induce apoptosis in hypoxic tumor cells. Intraperitoneal administration of TAT-ODD-Casp3 reduced bone metastases in a dose-dependent manner. We next examined the role of HIF-1α in bone metastases by establishing MDA-MB-231 cells stably transfected with constitutively-active HIF-1α cDNA (MDA/CA-HIF). Bone metastases of MDA/CA-HIF were significantly increased accompanied with elevated number of CD31-positive blood vessels. Since the progression of osteolytic bone metastasis is thought to be due to the uncoupling between osteoclastic bone resorption and osteoblastic bone formation, we examined the effects of hypoxia and HIF-1α on the differentiation osteoblasts and osteoclasts. Hypoxia and CA-HIF overexpression markedly inhibited BMP2-induced osteoblastic differentiation and Runx2 expression in the pluripotent mesenchymal cells C3H10T1/2 and calcification in murine primary osteoblasts. On the other hand, hypoxia increased TRAP-positive osteoclast-like cell formation in spleen cell cultures in the presence of RANKL and M-CSF. In conclusion, these results suggest that tumor-associated hypoxia and HIF-1α expression promote the progression of bone metastases in breast cancer. Our results also suggest that hypoxia and HIF-1α play a role in the induction of osteolytic change in bone metastases through causing an uncoupling between bone resorption and formation.

Placental Calcium Transporter Gene (PMCA3) Expression Predicts Intra-Uterine Bone Mineral Accrual. R. Martin*[1], N. C. W. Harvey[2], S. R. Crozier*[2], M. K. Javaid[2], P. Taylor*[3], E. M. Dennison*[2], H. M. Inskip*[2], K. M. Godfrey*[2], C. Cooper[2], R. Lewis*[1]. [1]Centre for the Developmental Origins of Health and Disease, University of Southampton, Southampton, United Kingdom, [2]MRC Epidemiology Resource Centre, Southampton, United Kingdom, [3]Medical Physics and Bioengineering, Southampton General Hospital, Southampton, United Kingdom.

Evidence is accruing that the intra-uterine environment has a persisting influence on childhood skeletal growth, and predicts fracture risk in later life. We have previously demonstrated that placental calcium transport, partly determined by maternal 25-(OH) vitamin D status, may underlie this phenomenon. The aim of this study was to explore the relationship between expression of calcium transporters in the human placenta, and neonatal bone mineral accrual in the offspring. Tissue samples from 70 human placentae were rapidly frozen in liquid nitrogen and stored at -70 °C. A quantitative real time polymerase chain reaction was used to measure the mRNA expression of PMCA isoforms 1, 3 and 4, using beta-actin as a control gene. Neonatal whole body bone area, mineral content and density (BA, BMC, BMD) were measured within 2 weeks of birth using a Lunar DPX DXA instrument. Linear regression methods were used to explore the relationship between PMCA expression and neonatal bone mass. Full ethical approval was granted for this study. After controlling for beta-actin expression, PMCA3 mRNA expression predicted BA (p=0.02), BMC (p=0.04) [Figure], placental weight (p=0.04) and birth weight (p=0.006) of the neonate. In a multivariate model, the relationship between placental PMCA3 expression and neonatal BMC was independent of maternal height, and pre-pregnant fat stores, parity and calcium intake (p~0.05). Thus expression of the placental calcium transporter PMCA3 predicts neonatal whole body bone mineral content. This association may explain, in part, the mechanism whereby a mother's 25(OH)-vitamin D stores influence her offspring's bone mass. Further elucidation of this process may allow development of novel therapeutic strategies to optimise childhood bone mineral accrual and thus reduce osteoporotic fractures in future generations.

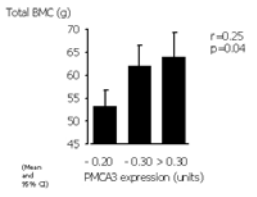

Figure: Neonatal whole body BMC (g) by thirds of PMCA3 expression, expressed relative to beta-actin (control).

A Comparison of Total Hip BMD as a Predictor of Fracture Risk: A Meta-Analysis. O. Johnell, J. A. Kanis, A. Oden*, H. Johansson*, C. Gluer, S. Fujiwara*, E. V. McCloskey, L. J. Melton, P. Delmas. Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom.

Meta-analyses of the predictive value of BMD on fracture risk have focussed on the use of DXA at the femoral neck. By contrast, many practice guidelines have favoured the use of total hip BMD, because of a smaller precision error. The aim of this study was to compare the performance characteristics of the two DXA sites. The hypothesis was that T-scores derived from either site would give comparable information on fracture risk. We studied 8,547 men and women from five prospective population-based cohorts, OPUS, Hiroshima, Sheffield, Rochester and OFELY with a total follow-up of 29,574 person years. The effect of BMD on fracture risk was examined using a Poisson model in each sex and cohort separately. The results of the different studies were then merged using weighted coefficients. BMD, both at the total hip and at the femoral neck, was a strong predictor of fractures in men and women and did not significantly differ, and the data were merged. For all fractures the risk ratio for 1 SD decrease of Z-score was 1.47 (1.36-1.58) for total hip vs 1.39 (1.28-1.50) for femoral neck. For all osteoporotic fractures the gradient of risk was 1.48 (1.36-1.61)) vs 1.44 (1.33-1.57), respectively, and for hip fractures was 2.17 (1.81-2.61) vs 2.33 (1.92-2.84) . There were no significant differences between the two hip measurements. In order to determine whether T-scores could be used interchangeably, we compared T-scores at the total hip and femoral neck using the NHANES database. When the Z-score was set a 0, T-scores at the two sites were fairly similar in women, but systematically lower at the femoral neck than at the total hip in men (Table).

Age	Men		Women	
	Femoral neck	Total hip	Femoral neck	Total hip
50	-0.21	0.40	-0.81	-0.51
55	-0.37	0.32	-0.98	-0.62
60	-0.51	0.14	-1.22	-0.93
65	-0.66	-0.04	-1.46	-1.22
70	-0.81	-0.21	-1.70	-1.50
75	-0.95	-0.38	-1.94	-1.79
80	-1.10	-0.55	-2.18	-2.07
85	-1.24	-0.72	-2.42	-2.36
90	-1.39	-0.89	-2.66	-2.64

We conclude that BMD measured at the total hip is a risk factor of substantial importance for fractures. The predictive ability was similar to measurement at the femoral neck. Whereas T-scores and Z-scores can be interchangeably used at the two BMD sites in women, this differs markedly in men. With this caveat, the two measurements can be used interchangeably in case finding models.

Substantial Trabecular Bone Loss Occurs in Young Adult Women and Men: A Population-Based Longitudinal Study. B. L. Riggs[1], L. J. Melton[2], A. L. Oberg*[3], E. J. Atkinson*[3], S. Khosla[1]. [1]Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA, [2]Clinical Epidemiology, Mayo Clinic College of Medicine, Rochester, MN, USA, [3]Biostatistics, Mayo Clinic College of Medicine, Rochester, MN, USA.

Conventional wisdom holds that bone loss begins in women at menopause (due to sex steroid deficiency) and in men later in life (due to age-related factors). However, the possibility of earlier bone loss has not been assessed longitudinally in population-based studies using highly precise technology capable of distinguishing trabecular and cortical bone. Thus, in an age- and sex-stratified random population sample (n = 671), we made between 2- and 4-consecutive annual measurements of trabecular (trab) bone at distal radius (DR) and distal tibia (DT) and cortical (cort) bone at proximal radius (PR) and proximal tibia (PT) by peripheral quantitative computed tomography (pQCT, Densiscan, Scanco AG, CV 0.5%). We excluded from analysis 97 subjects receiving HRT, SERM, or bisphosphonate therapy. Both premenopausal women and young men had substantial rates of trabecular bone loss but minimal or no cortical bone loss until middle life whereas postmenopausal women and men older than 50 yrs had, as expected, substantial continuing cortical and trabecular bone loss (Table 1). Assessment of changes in volumetric BMD (vBMD) by decade in both sexes showed that substantial trabecular bone loss began in the third decade whereas substantial cortical bone loss did not begin until middle life. The decrease in cortical vBMD beginning in middle age is consistent with increases in bone turnover induced by menopause in women or by declining free sex steroids in men. However, the onset of substantial trabecular bone loss in both sexes soon after completion of pubertal growth at a time when sex steroids levels are, by definition, “normal” indicates that current paradigms on pathogenesis of osteoporosis are incomplete and that further study is required.

Table 1. Changes in vBMD in %/yr (mean ± SD)

Group	DR-Trab	PR-Cort	DT-Trab	PT-Cort
Females				
Premenopausal	-0.67 ± 0.98**	-0.11 ± 0.51*	-0.53 ± 1.20**	-0.08 ± 0.44*

A School Curriculum Based Exercise Program Increase Bone Mineral Accrual in Boys and Girls during Early Adolescence-Four Years Data from the POP-Study (Pediatric Osteoporosis Prevention Study) - a Prospective Controlled Intervention Study in 221 Children. C. Linden, P. Gardsell*, H. Ahlborg, M. Karlsson. Orthopaedics, University Hospital Malmö, Malmö, Sweden.

The longest reported prospective controlled intervention study with exercise in growing children which evaluate the accrual of bone mineral span 20 months. The purpose of this study was to evaluate the effect of an exercise intervention program within the school curriculum during the first school years, to catch also children not specifically interested in exercise, and to present the so far longest controlled follow-up data of exercise during growth. A population based cohort including 73 healthy Caucasian boys (aged 7.8 ± 0.6 at baseline) and 48 girls (aged 7.7 ± 0.6) in the only school in the Bunkeflo society outside Malmö, Sweden, were included in a school curriculum with 40 minutes physical activity every school day. One hundred healthy age and gender matched children (52 boys and 48 girls) in three nearby schools served as controls. These children were assigned to the general Swedish curriculum of physical activity in these grades (60-90 min/w). Bone mineral content (BMC; g) were measured with dual X-ray absorbtiometry (DXA) at the lumbar spine (LS) and femoral neck (FN) before initiation of the intervention and then yearly for four years. The slope for each individual was estimated from the repeated measurements, and the annual changes calculated. Data is presented as mean ± SD. There were no differences in age, height, weight or BMC at baseline. In boys, the annual gain in BMC in the LS was greater in the intervention group in comparison with the controls during the 4 year follow-up, 7.0 ± 2.3 versus (vs.) 6.2 ± 1.5, $p<0.05$. In girls, a similar effect was seen in the LS 9.1 ± 4.1 vs. 7.1 ± 3.3 and in the FN 0.39 ± 0.20 vs. 0.29 ± 0.17, $p < 0.01$ respectively. The annual increase of the FN width (mm) was also greater in the intervention group, 1.23 ± 0.42 vs. 1.07 ± 0.49 in boys and 1.45 ± 0.91 vs. 1.03 ± 0.76 in girls, $p < 0.05$. The discrepancies remained after adjusting for differences in weight gain, height gain and pubertal development during the study, except for FN width in girls ($p=0.08$). A school based exercise program within the general curriculum during the first four school years seems to increase the accrual of bone mass and bone size. This is the first published intervention study that is population based and include the intervention within the school curriculum. Furthermore, it is so far the only intervention study that exceeds 20 months. Based on the data in this study it seems that increased time spent in physical education classes may increase peak bone mass and subsequently can be used as a prevention strategy for osteoporosis.

A 14-Year Longitudinal Study of the Relationship of Childhood Physical Activity to Adult Bone Mineral Content. A. D. G. Baxter-Jones*, C. A. Mundt*, R. L. Mirwald*, R. A. Faulkner, D. A. Bailey. College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

The purpose of this study was to investigate longitudinally the influence of childhood physical activity on bone mineral content (BMC) measured during the third decade of life. We previously showed, in this cohort of children, that maturational and size adjusted total body and femoral neck BMC were greater in active boys and girls compared to their inactive peers, one year after the attainment of peak BMC velocity. In the present analysis we analyzed data from 82 females and 65 males, between the ages of 18.2 and 27.5 years, who were longitudinally assessed from 1991-1997 and re-assessed from 2002-2005. Subjects were from the University of Saskatchewan’s Pediatric Bone Mineral Accrual Study. Physical activity and anthropometry were measured every 6 months during childhood and annually in adulthood. Dual-energy X-ray absorptiometry scans of the total body (TB), lumbar spine (LS), total hip (TH) and femoral neck (FN) (Hologic 2000, array mode) were collected annually. Ages at peak height velocity (PHV) and peak BMC velocity were identified using data collected over the growing years. A mean age- and gender-specific standardized activity (Z) score was calculated for each subject based on multiple yearly activity assessments. The childhood activity scores were used to identify active (top quartile), average (middle two quartiles), or inactive (bottom quartile) groups. Adult BMC values were averaged over a maximum of three years. At follow-up, the average age from PHV was 10.6 ± 3.4 years in females and 10.0 ± 2.2 years in males. Using two-way analysis of covariance (ANCOVA; covariates, years from PHV, average adult height and weight) for BMC, no significant interactions were found between sex and physical activity at any of the four sites ($p>0.05$). Significant gender and physical activity main effects were found for total body, total femoral hip, and femoral neck BMC ($p<0.05$). Lumbar spine BMC also showed a significant sex effect ($p<0.05$) however, there was no effect of physical activity at this site ($p>0.05$). We previously showed that the growing skeleton responded to increased everyday physical activity by increased bone mineral accrual. The present analysis suggests these changes persist into early adult life.

Hoxa10: A BMP2-Responsive Gene Activates Runx2 and Regulates Osteogenesis. M. Q. Hassan*, R. Tare*, A. J. van Wijnen, J. L. Stein*, G. S. Stein, J. B. Lian. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

Homozygous mice targeted for disruption of the gene encoding Hoxa10, a member of the abdominal B class of homeobox proteins, show an anterior homeotic transformation of lumber vertebrae and have severe fertility defects. Analysis of microarray gene profiles during BMP2 osteogenic induction of C2C12 myogenic cells identified Hoxa10 in a gene cluster together with Runx2, the transcription factor essential for bone formation. Because SMAD regulatory elements in the Runx2 gene have not been identified, we examined regulation of Runx2 by Hoxa10 as a mediator of BMP2 induced Runx2 gene expression. Hoxa10 binds specifically to the TTAT consensus core, rather than the classic ATTA homeodomain motif. Multiple putative TTAT motifs were identified within -1 kb of the Runx2 promoter. Overexpression of recombinant Hoxa10 protein in non-osseous and osteoblastic cells results in a 3-4 fold activation of Runx2. Deletion and site-directed mutagenesis studies confirmed a functional Hoxa10 site in the proximal promoter. By chromatin immunoprecipitation assay, we find that recruitment of Hoxa10 to the Runx2 promoter is maximal during the early stages of osteoblast differentiation from primary cells, and that Hoxa10 is not associated with the promoter in mature cells in a mineralized matrix. We next demonstrated the ability of Hoxa10 in MC3T3 cells to induce endogenous expression of markers of early osteoblast differentiation and observe that Runx2 and BSP mRNAs are increased by 2-3 fold within 24 hrs. The biological significance of this regulation was assessed in vivo. In situ immunohistochemistry of mouse bone sections confirmed the co-expression of Hoxa10 and Runx2 in long bone and vertebrae in hypertrophic chondrocytes and osteoblasts. These findings suggest Hoxa10 is linked to an early event in osteoblast differentiation. In conclusion, these studies identify Hoxa10 as a target of BMP2 signaling that results in activation of a lineage-specific transcription factor and other target genes. Thus, we propose that BMP2 induction of Hoxa10 and Hoxa10 activation of Runx2 are components of a regulatory cascade for the expression of genes promoting bone formation.

Involvement of Cbfb in the Cooperative Action of BMP and Runx2 Signalings on Osteogenic Differentiation. S. Ohba[1], T. Ikeda[1], F. Kugimiya[1], F. Yano[1], T. Fujita[2], T. Komori[3], T. Ogasawara[1], K. Nakamura*[1], T. Takato*[1], H. Kawaguchi[1], U. Chung[1]. [1]Univ. of Tokyo, Tokyo, Japan, [2]Setsunan Univ., Osaka, Japan, [3]Nagasaki Univ., Nagasaki, Japan.

Aiming at clinical application to bone regeneration, we previously developed a cell-based monitoring system for osteogenic differentiation, and found that the combination of BMP and Runx2 signalings induce this differentiation from various cell types including non-osteoblastic cells much more potently than either of them alone. We also showed that cell sheets of dermal fibroblasts stimulated by the combination, but not only one of them, induced bone formation in vivo in mouse critical-size bone defects. To learn the mechanism of the cooperative action of the two signalings, we investigated the involvement of Cbfb, a heterodimer partner of Runx2. Cultured calvarial cells derived from Cbfb-deficient mice failed to induce expression of ALP, osteopontin or osteocalcin as determined by real-time RT-PCR in response to infection of an adenovirus expressing constitutively active ALK6 and Runx2 (Ad-caALK6+Runx2), which was restored by an adenoviral reintroduction of Cbfb (Ad-Cbfb) to the level of the wild-type calvarial cell culture. To define the molecular interaction, we infected non-osteoblastic NIH3T3 cells with Ad-caALK6, Ad-Runx2, Ad-Cbfb or their combinations. Expression of osteocalcin mRNA was induced by Ad-caALK6+Runx2, but not by Ad-caALK6, Ad-Runx2, Ad-Cbfb, Ad-caALK6+Cbfb or Ad-Runx2+Cbfb, and the induction was enhanced by additional infection of Ad-Cbfb. Although Cbfb mRNA level was not altered by Ad-caALK6+Runx2, the protein level determined by immunoblot analysis was markedly increased by Ad-caALK6+Runx2 and Ad-Runx2 to the same extent. In the presence of lactacystin, a specific ubiquitin-proteasome inhibitor, the Cbfb protein level was increased without being affected by Ad-Runx2 or Ad-caALK6+Runx2, indicating that Runx2 protects Cbfb from being degraded by the ubiquitin-proteasome system. Although Runx2 and Cbfb were co-localized in the nucleus upon infection with Ad-caALK6+Runx2 or with Ad-Runx2 alone, immunoprecipitation analysis revealed that these two proteins bound to each other only upon infection with the former. In addition, chromatin immunoprecipitation analysis showed that Ad-caALK6+Runx2, but not Ad-Runx2, recruited Cbfb to the osteocalcin promoter (mOC-67/-471), whereas Runx2 was constantly recruited. These lines of results indicate that BMP and Runx2 signalings cooperatively induce osteogenic differentiation through regulation of Cbfb in the following ways: Runx2 increases the stability of the Cbfb protein; and BMP enhances formation of the Runx2-Cbfb complex and binding of the complex to the promoter.

Reconstitution of Runx2/Cbfa1 Null Cells Identifies Runx2 Domains Required for Osteoblast Differentiation. J. Bae*, R. Narla*, S. Gutierrez*, J. Pratap, J. L. Stein*, J. B. Lian, G. S. Stein, A. Javed. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

While it is well established that Runx2/Cbfa1 promotes osteoblast differentiation, the specific regions of the Runx2 protein required for induction of the osteogenic lineage remain to be identified. We approached this question by characterizing gene expression profiles and osteogenic activity of calvarial derived cells from Runx2 null mice reconstituted with wild type (WT) or deletion mutants of Runx2. Absence of Runx2 activity in these cells was confirmed by both in situ immunofluorescence microscopy and western blot analysis. Culturing these cells for 3 weeks in the presence or absence of osteogenic media (β-glycerol phosphate and ascorbic acid) did not stimulate osteoblastic gene expression. However, infection with adenovirus expressing WT-Runx2 at the proliferation stage robustly induced the normal program of osteoblast differentiation. Early markers such as collagen type-1 (Col-I) and alkaline phosphatase (AP) were induced (4-8 fold) at days 4 and 8. Genes representing mature osteoblast stages, Osteopontin (OP), Bone sialo protein (BSP), Runx2 and Osteocalcin (OC) were expressed in normal temporal order and were dramatically induced (18-36 fold) at later time points (days 8 and 12). Interestingly this pattern of gene expression was similar in cells infected with a mutant Runx2 protein that lacks 96 residues at the C-terminus (Runx2 Δ432); thus, the Groucho repressor and the C-terminal activation domain are dispensable for Runx2 osteogenic activity. Upon infection with a Runx2 mutant in which a further 41 aa were deleted (Runx2 Δ391), we find no osteoblast markers (AP, Col-I, OP, BSP, Runx2 and OC) were expressed and no osteogenic activity was observed. We note that the mutant Runx2 protein enters nucleus and can bind DNA and its expression was sustained through out the time course. Thus the 391-432 domain is a critical component of Runx2 osteogenic function. With the Runx2 null cell model, Runx2 and BMP2 dependent or independent events could be distinguished that can not be identified in other cell model systems because BMP2 strongly activate endogenous Runx2. Treatment of BMP2 alone could not induce the osteogenic program in these cells, while reconstitution of both BMP2 and Runx2 (WT or Δ432) signals in these cells, results in a 20-40 fold increased expression of osteogenic genes. However, the Runx2 Δ391 mutant with BMP2 fails to stimulate the normal osteoblast differentiation program. In conclusion, our studies demonstrate that: 1) the C-terminus of Runx2 is required to initiate the osteogenic differentiation program 2) BMP2 osteogenic activity requires Runx2.

1016

Functional Switching of Runx2 by Cdk6 and Cdk4 in Regulation of Osteoblast Differentiation. T. Ogasawara[1], H. Chikuda[1], S. Ohba[1], D. Chikazu[1], M. Katagiri*[1], F. Yano[1], K. Nakamura[1], U. Chung[1], K. Hoshi[1], T. Takato*[1], H. Okayama*[2], H. Kawaguchi[1]. [1]Sensory & Motor System Medicine, University of Tokyo, Tokyo, Japan, [2]Biochemistry & Molecular Biology, University of Tokyo, Tokyo, Japan.

Because a temporal arrest in the G1 phase of the cell cycle is known to be a prerequisite for cell differentiation, this study investigated the involvement of cell cycle factors such as cyclins, cyclin-dependent kinases (Cdks) and Cdk inhibitors (CKIs) that critically influence osteoblast differentiation. Of the G1 cell cycle factors, Western blot and RT-PCR analyses in the presence and absence of proteasome inhibitors revealed that Cdk6 expression was most strongly down-regulated via transcriptional repression during differentiation of MC3T3-E1 cells and primary mouse calvarial osteoblasts induced by BMP-2. Overexpression of Cdk6 in MC3T3-E1 cells inhibited the BMP-2-induced alkaline phosphatase (ALP) activity and osteocalcin expression, while overexpression of dominant negative (dn)Cdk6 or silencing of Cdk6 through RNA interference stimulated the osteoblast differentiation. Immunoprecipitation assay showed that not only Cdk6, but also Cdk4, bound to Runx2 in MC3T3-E1 cells. Although the Cdk6-Runx2 complex was predominant over the Cdk4-Runx2 complex in the control culture, the BMP-2 treatment caused a marked decrease of the former and an increase of the latter. Cdk4-Runx2 complex was shown by chromatin immunoprecipitation analysis to bind to the osteocalcin promoter (mOC-67/471), while Cdk6-Runx2 complex did not. The Cdk6 overexpression did not alter the expression level or the subcellular localization of Runx2, but markedly reduced the Runx2 binding to mOC-67/471 in parallel with the differentiation inhibition. To further examine the involvement of Cdk4 and Cdk6 in the Runx2 function, these molecules were transfected to C3H10T1/2 cells which expressed little endogenous Runx2. The Cdk4 co-transfection enhanced osteocalcin and ALP expression induced by the Runx2 transfection, which was stimulated by the dnCdk6 transfection. These results indicate that Cdk6 inhibits promoter-binding and transcriptional activities of Runx2 by binding to Runx2 competitively, while Cdk4 acts as a transcriptional co-activator of Runx2. It is concluded that the down-regulation of Cdk6 expression by differentiation stimuli leads to the decrease in Cdk6-Runx2 complex and the increase in Cdk4-Runx2 complex, both causing enhancement of the Runx2 transcriptional activity. Hence, the present study is the first to shed light on novel roles of the Cdks that control a functional switching of Runx2 in the regulation of osteoblast differentiation.

SOX9 Is a Potent Transcriptional Repressor for RUNX2 during Skeletogenesis. G. Zhou[1], E. Munivez*[2], Q. Zheng*[1], F. Elgin*[1], P. Fonseca*[1], Y. Chen*[2], E. Sebald*[3], D. Krakow*[3], B. Lee[2]. [1]Dept. of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]Dept. of Molecular and Human Genetics, Baylor College of Medicine, Howard Hughes Medical Institute, Houston, TX, USA, [3]Dept. of Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA.

Runt-domain transcription factor RUNX2 is essential for osteoblast differentiation and chondrocyte hypertrophy. However during mouse embryonic development it is also expressed early in mesenchymal condensations. Hence, antagonism of Runx2 is required to down regulate its expression and function in those condensates that are destined to differentiate into chondrocytes instead of osteoblast. But how this is achieved is still poorly understood. SOX9 is a HMG-box-containing transcriptional activator essential for chondrocyte condensation and cartilage formation. *SOX9* heterozygous mutations in humans cause severe skeletal malformation syndrome campomelic dysplasia. Since *Sox9* is expressed highly in chondrogenic mesenchymal cell condensations but absent in hypertrophic chondrocytes, we hypothesize that SOX9 also acts as a transcriptional repressor for osteoblast differentiation and chondrocyte hypertrophy via inhibition of RUNX2 activity. In this study, we demonstrate that SOX9 and RUNX2 directly interact with each other through their DNA binding domains. SOX9 decreased RUNX2 binding to its target sequence and severely repressed RUNX2 transactivation of its reporter constructs. To test the *in vivo* repressor function of SOX9 we have generated transgenic mice expressing *SOX9* in osteoblasts by utilizing a cell-type specific *Col1a1* promoter. The *Col1a1-SOX9* transgenic mice displayed generalized dwarfism. Von Kossa staining and alkaline phosphatase staining demonstrated that osteoblasts from transgenic mice were less active compared with wild-type mice. Expressions of osteoblast-related markers including *Runx2*, *Col1a1* were also downregulated in the long bones of transgenic mice as assayed by quantitative real-time RT-PCR. Furthermore, we correlated this observation in humans with campomelic dysplasia. Here, haploinsufficiency of SOX9 resulted in upregulation of a chondrocyte maturation marker *COL10A1*, a known transcriptional target of RUNX2. In summary, our results reveal a novel transcriptional repressor function of SOX9 during skeltogenesis. Understanding the interaction between these two key transcription factors will help us elucidate the transcriptional network governing cell fate commitment during skeletogenesis.

TNF Inhibits Osteoblast Function by Increasing Runx2 Degradation through Smurf1 E3 Ligase. H. Kaneki, D. Chen, R. Guo*, B. F. Boyce, L. Xing. University of Rochester, Rochester, NY, USA.

TNF and IL-1 stimulate osteoclastic bone resorption and inhibit osteoblastic bone formation, in part by inducing osteoblast (obl) apoptosis, but the molecular mechanisms by which they inhibit obl function are not well established. Ubiquitin-mediated proteasomal degradation has been implicated in the regulation of BMP and TGF-β signaling pathways in various cell types. The E3 ubiquitin ligase, Smad ubiquitin regulatory factor 1 (Smurf1), negatively regulates osteoblast differentiation by mediating proteasomal degradation of the BMP signaling proteins, Smads 1 and 5, and Runx2. To test the hypothesis that TNF or IL-1 inhibit obls by up-regulating Smurf1 E3 ligase and degrading these proteins, we first examined the effects of TNF and IL-1 on expression of Smurf1 in 2T3 and C2C12 obl precursor cells. TNF (7.5 ng/ml), but not IL-1 (1-20 ng/ml) increased expression of Smurf1 mRNA by 22±2-fold over control in a dose-dependent manner, an effect confirmed at the protein level by Western blotting. To determine if TNF or IL-1 induce Runx2 degradation, we transfected 2T3 and C2C12 cells with a FLAG-tagged Runx2 expression plasmid and treated them with TNF or IL-1. TNF, but not IL-1, significantly reduced transfected and endogenous Runx2 protein levels detected by anti-Flag and anti-Runx2 monoclonal antibodies, indicating that TNF induces Runx2 degradation. Proteasomal degradation of substrate proteins involves their ubiquitination. Therefore, we examined if ubiquitinated-Runx2 complexes could be detected in 2T3 cells treated with TNF. When Runx2 protein was immunoprecipitated, an ubiquitinated-Runx2 protein ladder was detected by Western blot in the presence of TNF. Treatment of cells with the proteasome inhibitor, MG-132, significantly increased TNF-induced Runx2 ubiquitination, indicating that TNF-induced Runx2 degradation is ubiquitin-proteasome-dependent. Next, to confirm if TNF-induced Runx2 degradation is Smurf1-dependent, we infected 2T3 cells with retrovirus expressing double stranded small interfering Smurf1 RNA to knock down expression of endogenous Smurf1. Smurf1 siRNA decreased TNF-induced Smurf1 expression by 92 % without changing the expression of other E3 ligases, such as Smurf2 and WWP1, and prevented TNF-induced Runx2 degradation. In addition, Smurf1 siRNA blocked TNF-induced inhibition of osteoblast marker gene expression (ALP 89±3 % vs. 45±2 %; Type I collagen 80±3 % vs. 35±2 %). In summary, TNF, but not IL-1, increases Smurf1 expression in osteoblasts and promotes ubiquitination and proteasomal degradation of Runx2 protein, which is blocked by Smurf1 siRNA. These findings indicate that TNF may inhibit bone formation by preventing BMP-mediated signaling in osteoblastic cells.

A Dual Role for Wnt in Chondrogenesis: Inhibition of Wnt/β-Catenin Signaling by DKK1 Promotes Initial Chondrogenesis of Mesencymal Stem Cell but Suppresses Chondrocyte Hypertrophy. G. Rawadi*, Z. Yang*, E. Susanto*, R. Ee*, H. Chan*, Y. Liu*, R. Baron. Prostrakan, Romainville, France.

The Wnt/β-catenin pathway has recently been reported in the regulation of chondrogenesis and chondrocyte differentiation. Dickkopf (DKK) proteins are inhibitors of Wnt/β-catenin signaling by antagonizing LDL-receptor related protein (LRP) 5 or 6 activity. The aim of this study was to investigate the effect of DKK1 on the differentiation process of murine limb bud-derived mesenchymal stem cells (MSC), to better understand the role of Wnt/β-catenin pathway in cartilage development. Micromass culture of MSC isolated from limb buds of 11.5d murine embryos was used as an ex-vivo model of chondrogenesis differentiation in culture. Cultured MSC undergo initial condensation, chondrogenesis, followed by hypertrophy differentiation and terminal maturation forming calcified cartilage matrix. The effect of recombinant Wnt3a and DKK1 on chondrogenesis was assayed by alcian blue staining of matrix formation, real-time PCR analysis of chondrocyte markers expression, alkaline phosphatase (ALP) activity and alizarin red mineralization staining. Wnt3a treatment of MSC resulted in suppression of initial condensation in a dose-dependent manner as demonstrated by a reduction of matrix formation and mRNA expression of early chondrocyte markers, type II collagen and aggrecan. In contrast, treatment with Wnt3a potentiated hypertrophy differentiation in chondrocytes already engaged in maturation, with enhanced ALP activity as well as increased expression of ALP and type X collagen mRNA. The dual effect of Wnt3a was further supported by the use of a specific GSKβ3 inhibitor, which mimics Wnt proteins and activates β-catenin signaling. In agreement with these observations, treatment of MSC with DKK1 enhanced the initial chondrogenesis process and significantly inhibited hypertrophy differentiation of matured chondrocytes. In addition, DKK1 antagonized the effect of exogenous Wnt3a on MSC differentiation; matrix formation suppressed by Wnt3a was reversed, and enhanced ALP activities inhibited. Finally, we analyzed the differentiation of MSC derived from both *Lrp5*$^{-/-}$ and *Dkk1*$^{-/-}$ mice and compared it to cells from wild-type littermate animals. The results confirmed that Wnt has a dual effect of chondrocytic differentiation. We conclude that early expression of Wnt3a retains mesenchymal stem cells in a pre-chondrocytic state whereas Wnt3a is later required for their differentiation into hypertrophic chondrocytes while the Wnt-signaling antagonist Dkk1 exerts opposite effects.

Canonical Wnt Signaling Mediates Chondrocyte Hypertrophy through the Runx 2 Transcription Factor. Y. Dong, E. M. Schwarz, R. J. O'keefe, H. M. Drissi. Orthopaedics, University of Rochester, Rochester, NY, USA.

Wnt secreted factors control limb morphogenesis in vivo. We investigated the molecular mechanisms underlying Wnt regulation of chondrocyte hypertrophy using the embryonic chick sternal chondrocyte model. RCAS viral over-expression Wnt8c and Wnt9a, upstream of ß-catenin, up-regulated collagen X (colX) and Runx2 thereby inducing chondrocyte hypertrophy, while Wnt5a, which utilizes the calcium pathway, inhibited the expression of colX and has no effect on Runx2 transcripts. Furthermore, Wnt8c and Wnt 9a strongly inhibited the early chondrocyte phenotypic gene, collagen II (col2) and Wnt 5a over-expression significantly enhanced col2 expression in these cultures. BMP-2 enhanced canonical wnt8c- and wnt9a-induced chondrocyte hypertrophy while over-expression of wnt5a inhibited BMP-2 induction of colX. Similarly, TGF-ß inhibited wnt8c- and wnt9a-induced expression of colX and Runx2, while it further potentates the inhibitory effect of wnt5a on colX. Interestingly, both BMP-2 and TGF-ß enhanced the expression of Col2 in wnt5a over-expressing cells. Over-expression of ß-catenin mimics the effect of wnt8c and wnt9a by up-regulating Runx2, colX, and alkaline phosphatase mRNA levels while it inhibits col2 and Sox9 transcription. Thus our results indicate that activation of the canonical ß-catenin wnt signaling pathway induces chondrocyte hypertrophy while the calcium pathway represses chondrocyte maturation. Our western blot analysis shows that ß-catenin also induces the protein levels of Runx2 in chondrocytes. To determine the transcriptional mechanisms by which this canonical signaling regulated chondrocyte hypertrophy, we investigated the effects of ß-catenin-TCF/LEF on Runx2 and type X collagen promoters which carry putative binding sites for TCF. Over-expression of TCF and ß-catenin using deletion mutants of the Runx2 promoter shows that the proximal 128 base pairs of this promoter is responsible for the wnt-mediated induction of Runx2. Similarly, over-expression of ß-catenin caused a significant transactivation of the ABC-640 and b2 chick type X collagen promoter. However mutant TCF binding site in Runx2 promoter -128 fragment leads a loss response of Runx2 promoter to ß-catenin. Mutation of TCF binding site in type X collagen promoter however did not change its activity. Finally, gel shift assay analyses determined the functionality of the TCF/LEF binding sites on the Runx2 promoter. Altogether we demonstrate that Wnt/ß-catenin signaling induces chondrocyte maturation at least partly through activation of Runx2 gene expression.

Activated Wnt Signaling in sFRP1 Null Mouse Alters Chondrocyte Differentiation *Ex Vivo*. T. Gaur*[1], L. Rich*[2], C. J. Lengner*[1], D. Ayers*[2], J. L. Stein*[1], G. S. Stein[1], P. V. N. Bodine[3], B. S. Komm[3], J. B. Lian[1]. [1]Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, [2]Department of Orthopedic Surgery, University of Massachusetts Medical School, Worcester, MA, USA, [3]Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA.

During chondrogenesis, mesenchymal cells condense and differentiate to a cartilage template for bone formation. Various Wnt proteins are implicated in positive and negative regulation of chondrocyte differentiation. Genetic ablation of sFRP1 (sFRP1 KO), an antagonist of Wnt signaling in mouse, promotes increased Wnt signaling and is characterized by a high bone mass phenotype in the adult. To examine chondrogenesis in these mice, we used mouse embryonic fibroblasts (MEFs) that undergo chondrocyte differentiation as micromass cultures and in the presence of BMP2, a regulator of chondrogenesis *in vivo*. We compared expression of marker genes during the chondrogenic differentiation time course (12 days) between WT and KO and with or without BMP2 treatment. In absence of BMP2, the levels of collagen type II are ~21 fold higher; collagen type X, a marker of chondrocyte hypertrophy is ~9 fold higher; and basal levels of Indian hedgehog, a marker for transition from chondrogenesis to osteogenesis is 3-5 fold higher in sFRP1 KO MEFs. These results demonstrate that sFRP1 KO MEFs could initiate chondrogenic differentiation in the absence of BMP2. In the presence of BMP2, the KO cells showed an increase in differentiation by alcian blue staining, consistent with the 12 fold higher expression of collagen II. However, Indian hedgehog was induced to ~160 fold in WT, but only 2 fold increase in KO and peak expression of collagen X and alkaline phosphatase is delayed in KO MEFs. These findings suggest a delay of *in vitro* terminal differentiation of hypertrophic chondrocytes in KO. This pattern of gene expression is consistent with the finding that sFRP1 is expressed at maximal levels from day 0 to 3, then suppressed during early differentiation when Collagen II is expressed in WT cells. sFRP1 is induced again at a late stage of hypertrophic chondrocytes and calcification (d9) when osteocalcin is expressed. Thus Wnt signaling is inhibited by sFRP1 prior to induction of chondrogenesis and at the hypertrophic stage. Our results suggest stage-specific roles of Wnt signaling during chondrogenesis which activates the initial recruitment of progenitor cells into the chondrocytic lineage. However, to reach the terminal differentiation of hypertrophic chondrocytes, attenuation of Wnt signaling is necessary. Thus, the sFRP1 KO model that exhibits constitutive Wnt signaling has identified key requirements for chondrogenesis.

Retinoids Activate Collagen X Gene Expression in Prehypertrophic Chondrocytes both by Direct Transcriptional Activation and by Stimulation of BMP Signaling. S. L. Adams, L. Lassová*, Z. Niu*, E. B. Golden*, A. J. Cohen*. Biochemistry, School of Dental Medicine, University of Pennsylvania, Philadelphia, PA, USA.

During endochondral bone formation, chondrocytes undergo a terminal differentiation process characterized by hypertrophy and by production of type X collagen (Col X), a protein found only in hypertrophic cartilage. Retinoids stimulate chondrocyte maturation *in vitro* and are essential for endochondral bone formation *in vivo,* and clinical use of synthetic retinoids can cause premature growth plate closure and growth retardation. Despite the well-documented importance of retinoids in regulating endochondral bone formation, the molecular mechanisms by which they mediate this process are largely unknown. We show that retinoids act both by directly stimulating transcription of the Col X gene and by stimulating production of bone morphogenetic proteins (BMPs). We have defined the direct activation mechanism by analysis of wild-type and mutated fragments of the Col X promoter ligated to a luciferase reporter gene and by electrophoretic mobility shift assays (EMSAs). Our studies show that stimulation of the Col X promoter by retinoic acid (RA) requires a distal region of the promoter (nucleotides -2618 to -2594) containing two overlapping RA response elements (RAREs) that share a 6-nucleotide half-site. EMSAs using antibodies against various retinoic acid receptors (RARs) showed that RARγ is the major receptor binding this compound RARE in cultured chondrocytes. Mutagenesis of the 6-nucleotide shared half-site abolished both RAREs, preventing binding of RARγ and abrogating stimulation of the promoter by RA. Thus RA activation of Col X transcription occurs in part by direct activation of the RARγ receptor, which acts as a ligand-activated transcription factor. However, the direct effects of retinoids on Col X transcription appear to be amplified by stimulation of BMP signaling. We used real-time polymerase chain reaction to show that RA induces a rapid ~30-fold stimulation of mRNAs encoding BMPs 2 and 6 and a lesser stimulation of BMP4 mRNA; BMPs were previously shown to stimulate Col X gene transcription. To determine the relative contributions of direct activation *versus* BMP-dependent activation of Col X by RA, we used a dominant-negative (DN) mutant of Smad 4, a constitutive component of the BMP signaling pathway; this mutant was shown previously to block BMP signaling (Lagna *et al*., *Nature* **383**, 832-836, 1996). The DN Smad 4 decreased stimulation of the Col X promoter from 19 fold to 3.5 fold, indicating that RA stimulation of BMP signaling contributes significantly to transcriptional activation of the Col X promoter during chondrocyte maturation.

Constitutive Activation of MKK6 in Chondrocytes of Transgenic Mice Inhibits Proliferation and Delays Endochondral Ossification. R. Zhang*[1], S. Murakami[2], F. Coustry*[1], Y. Wang*[1], B. de Crombrugghe*[1]. [1]Molecular Genetics, UT MD Anderson Cancer Center, Houston, TX, USA, [2]Orthopaedics, Case Western Reserve University, Cleveland, OH, USA.

To examine the role of the p38 MAPK pathway in endochondral ossification, we generated transgenic mice that express MKK6EE, a constitutively active mutant of MKK6, in chondrocytes. Four transgenic mouse lines showed a similar dwarf phenotype. Skeletal preparations showed shortened axial and appendicular skeletons. At 3 weeks of age, the average length of long bones was decreased by about 20-30% in transgenic mice. Histological examination of the growth plates of long bones revealed a reduced zone of hypertrophic chondrocytes and a delay in the formation of primary and secondary ossification centers. BrdU incorporation in growth-plate chondrocytes showed 43% and 58% reduction at postnatal days 9 and 21, respectively, indicating inhibition of proliferation. Consistent with these observations, *in situ* hybridization showed inhibition of positive regulators of proliferation, *Indian hedgehog, PTH/PTHrP* receptor, and *cyclin D1* and upregulation of a cell cycle inhibitor *p21* in chondrocytes of these mice. Since transgenic mice that express MKK6EE in chondrocytes showed phenotypes similar to those of mice that overexpress *SOX9* in chondrocytes, we examined Sox9 activity *in vivo* by generating mice harboring a Sox9-dependent reporter. We observed a 2-fold increase ($P < 0.05$) in the activity of this Sox9-dependent reporter in mice that express MKK6EE in chondrocytes without changes in Sox9 levels. Similarly, p38 signaling increased the transcriptional activity of Sox9 in COS7 cells and primary chondrocytes in transient transfection experiments. These observations are consistent with the notion that increased activity of Sox9 accounts at least in part for the phenotype caused by constitutive activation of MKK6 in chondrocytes. Activating mutations of FGFR3 cause the most common forms of human dwarfism, achondroplasia and thanatophoric dysplasia. Since p38 is activated by FGF in chondrocytes, it is possible that the anti-proliferative effects of Fgfr3 are at least in part mediated by p38. We previously generated transgenic mice that express a constitutively active mutant of MEK1 in chondrocytes. These mice showed an achondroplasia-like dwarf phenotype characterized by inhibition of hypertrophic chondrocyte differentiation; however, chondrocyte proliferation was not affected. Our observations strongly suggest that the ERK1/ERK2 and p38 MAPK pathways play distinct roles in endochondral ossification. We propose that both pathways contribute to the dwarfism caused by activating mutations in FGFR3 by different mechanisms.

Hypoxia Promotes Cartilage Matrix Synthesis via p38 MAPKinase and Suppresses Terminal Differentiation via HDAC4. M. Hirao*, N. Tamai*, A. Myoui*, N. Tsumaki*, N. Araki*, H. Yoshikawa. Dept. of Orthopaedics, Osaka University Graduate School of Medicine, Suita, Japan.

Cartilage is an avascular tissue that functions at a lower oxygen tension than do most other tissues. Under the hypothesis that oxygen tension plays an important role in chondrocyte differentiation and function, we investigated the influence of oxygen tension on chondrocyte biology using pluripotent mesenchymal cell line C3H10T1/2 and on endochondral ossification in 14.5E mice embryo forearm organ culture. 10T1/2 cells and embryo forearms were cultured in normoxia (O_2 20%) or hypoxia (O_2 5%) in the presence of rhBMP-2 (500ng/ml). 10T1/2 cells produced more abundant glycosaminoglican (GAG) in hypoxia than in normoxia. In parallel, type II collagen (*Col2a1*) gene expression was elevated by hypoxia, while type X collagen (*Col10a1*) gene expression was suppressed. In organ cultures, hypoxia promoted cartilage matrix synthesis as estimated by the area stained by Safranin O and suppressed *Col10a1* expression by *in situ* hybridization. These data indicate that hypoxia promotes cartilage matrix synthesis and suppresses terminal differentiation. To elucidate the mechanisms, we overexpressed inhibitory Smad6 but it did not alter the GAG induction by hypoxia. Hypoxia promoted matrix synthesis even in organ culture of *Smad6* transgenic mice. In contrast, p38MAPK inhibitor, FR167653 as well as dominant-negative MKK3 abolished hypoxia-induced matrix synthesis both *in vitro* and in organ culture. However, FR167653 did not rescue the reduced *Col10a1* gene expression by hypoxia. These data suggest that hypoxia-induced cartilage matrix synthesis is mediated by p38MAPK pathway but the suppression of terminal differentiation is under the regulation of other molecules. Recently, it was reported that histone deacetylase 4 (HDAC4) controls chondrocyte hypertrophy by repressing *Runx2* gene expression and transcriptional activity. We found that in 10T1/2 cells, hypoxia reduced *Runx2* gene expression and increased HDAC4 protein expression in nuclear extract but that it did not altered Sox9 expression, phosphorylation and transcriptional activity. When *Runx2* activity was augmented by overexpressing wild-type *Runx2*, *Col10a1* gene expression was not suppressed by hypoxia. Inhibition of HDAC4 using siRNA caused up-regulation of *Runx2* gene expression and its transcriptional activity, and restored *Col10a1* gene expression down-regulated by hypoxia. These data strongly suggest that HDAC4 plays a key role in the regulation of chondrocyte terminal differentiation by oxygen tension. Collectively, our data indicate that hypoxia promotes cartilage matrix synthesis via p38 MAPK and suppresses terminal differentiation via HDAC4.

Absence of BMP2 Results in Low Bone Mineral Density, Osteoarthritis, Spontaneous Fracture and Impaired Fracture Healing. K. Tsuji[1], B. D. Harfe*[2], K. Cox[1], M. Bouxsein[3], L. Gerstenfeld[4], A. Bandyopadhyay*[5], C. Tabin*[5], V. Rosen[1]. [1]Oral and Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, [2]Department of Molecular Genetics and Microbiology, University of Florida College of Medicine, Gainsville, FL, USA, [3]Beth Israel Daconess Medical Center, Boston, MA, USA, [4]Boston University, Boston, MA, USA, [5]Harvard Medical School, Boston, MA, USA.

Evaluating the importance of BMP2 in the skeleton is complicated by early embryonic lethality in mice lacking Bmp2, and by conservation of signaling pathways for osteogenic BMPs. To overcome these limitations, we established BMP2 conditional knockout mice (BMP2Prx1Cre) in which we inactivated Bmp2 only in the limb bud, effectively requiring the appendicular skeleton to form in the absence of BMP2. Here we report that BMP2Prx1Cre mice appear normal at birth but quickly develop pronounced defects in postnatal bone formation. At one week of age, the region specific expression of chondrocyte and osteoblast marker genes is conserved in limbs of BMP2Prx1Cre mice, but replacement of mineralized cartilage by bone and formation of secondary ossification centers are both significantly delayed. By week 2, the articular surfaces of the femur and tibia of BMP2Prx1Cre mice become increasingly fibrotic, and multiple spontaneous fractures are evident in femoral heads of BMP2Prx1Cre mice. At these sites, fracture callus formation is absent. As BMP2Prx1Cre mice age (17-28 weeks), they display significantly lower bone mineral density in appendicular skeletal elements compared to wild type and BMP2Prx1Cre heterozygous littermates. Spontaneous fractures that do not heal can be easily identified upon X-ray in these adult BMP2Prx1Cre mice. To test the bone repair capacity of adult BMP2Prx1Cre mice, we created transverse femur fractures in 30-week old mice and evaluated the time course of fracture repair. BMP2Prx1Cre mice showed no healing response at 10 or 21 days post fracture, in stark contrast to control mice where a robust healing response was evident by X-ray as early as day 10. Mice heterozygous for BMP2Prx1Cre showed an intermediate healing response, having little or no fracture callus on day 10, and a small callus on day 21. As a whole, our data are the first to indicate that locally produced BMP2 is absolutely required for normal postnatal bone formation and repair.

Targeted Deletion of BMP4 Causes Osteopenia in Adult Mice Supporting a Postnatal Role for BMP4 in Osteoblast Function and Bone Quality. D. Guo[1], W. Yang[2], M. Harris[2], J. Zhang[1], J. Feng[1], C. Anderson*[3], A. Lichtler[4], B. Hogan*[5], H. Kulessa*[6], S. Liu*[3], L. Quarles*[3], B. Kream[7], S. E. Harris[2]. [1]Oral Biology, UMKC, Kansas City, MO, USA, [2]Periodontics, UTHSCSA, San Antonio, TX, USA, [3]Kansas U Medical Center, Kansas City, KS, USA, [4]Genetics, U of Connecticut, Farmington, CT, USA, [5]Genetics, Duke U, Durham, NC, USA, [6]U of Vanderbilt, Nashville, TN, USA, [7]Genetics and Developmental Biology, U of Connecticut Medical Center, Farmington, CT, USA.

In our previous study, a conditional knock-out mouse model was generated to determine the function of Bone morphogenetic protein 4 (BMP4) in postnatal development. BMP4 was successfully conditionally deleted (BMP4cKO) in osteoblasts by crossing 3.6kb collagen 1a1 promoter Cre transgenic mice with mice with one BMP4 floxed allele and one null allele. The resulting phenotypes showed incomplete penetrance and were sorted into three subtypes according to age at time of death. Type I (30%) were embryonic lethal. Type II showed severe osteopenia, small size, and prematurely died from hydronephrosis between 10 and 35 days after birth. Type III that constituted 65% survive beyond 35 days and show osteopenia with no hydronephrosis and normal kidney function as measured by BUN, calcium and phosphate. We have now focused on the skeletal changes in type III BMP4cKO with normal kidney function. Bones from adult (older than 2 months) BMP4 cKO were radiographed and compared to their sex-matched littermate controls with one copy of the normal BMP4 gene. Bone mineral density (BMD) in 9 month old BMP4 cKO were 7-18% lower than their control littermates, with significant changes observed in forelimbs, spine, calvaria and mandibles. The extent of BMD reduction was similar to the changes in 12-day-old and 1-month-old BMP4cKO, which were averaged from a combination of type II and III mutants. By both X-ray radiography and histology, the spines of BMP4 cKO show the greatest decreases in BMD in 9 month old animals, indicating a greater sensitivity of the vertebrae to BMP4 deletion. MicroCT analysis also showed similar reduction of cortical thickness, trabecular number and connectivity, and ratio of bone volume / total volume in the femurs from these 9 month old animals (n=3). Both type II (with hydronephrosis), and type III (without hydronephrosis) show this same bone phenotype, with the spine showing the most dramatic loss of bone. We have now confirmed the loss of BMP signaling in these adult BMP4 cKO mouse by reduced Osterix expression and other downstream genes of BMP signaling using in situ hybridization. Hydronephrosis is not responsible for the reduced BMD in BMP4 cKO, thus establishing BMP4 as an important direct contributor to bone quantity and quality in adult animals.

BMP-6 Restores Bone in Osteoporotic Aged Rats and, Unlike Estradiol and PTH, Restores Trabecular Bone in Ovariectomized BMP-6 Knockout Mice. P. Simic*, J. Buljan-Culej*, I. Orlic*, F. Borovecki*, S. Vukicevic. Laboratory for Mineralized Tissues, Zagreb Medical School, Zagreb, Croatia.

Bone morphogenetic proteins (BMPs) induce new bone formation when applied locally. However, there is no evidence that a recombinant BMP, given systematically, can restore bone in an osteoporotic rat model. Rats were ovariectomized at 6 months of age and the therapy started 6 months later. Total body, lumbar spine and hind limbs BMD was measured at 6 and 12 weeks period. Within three months, BMD in BMP-6 treated rats reached the values of sham treated animals at hind limbs and lumbar spine. BMP-6 was most effective at the lowest dose of 1 g/kg 3 times weekly. In vivo measurements were subsequently confirmed by ex vivo BMD values, by pQCT, µCT and histomorphometry of distal femurs, and by biomechanical testing of long bones. In similar experiments BMP-7 was not effective, while estradiol was less effective, and did not have a synergistic effect with BMP-6. To further explore whether estradiol and PTH exerts their bone activity via BMP-6, Bmp-6 mutant and wild type mice were ovariectomized (OVX) and three weeks later treated for the next 6 weeks as follows: (1) sham, (2) OVX, (3) OVX + BMP-6 (10 µg/kg i.v. 3xweek), (4) OVX + 17ß-estradiol (E2) (50 µg/kg i.v. 3xweek) (5) OVX + PTH (75 µg/kg s.c. 3xweek). As revealed by µCT Bmp-6 -/- sham animals had decreased BV/TV and trabecular number as compared to wild type sham mice. Unlike in wild type mice, OVX , estradiol and PTH therapy did not influence the BMD and trabecular bone volume in Bmp-6 -/- mice. On the contrary, BMP-6 therapy increased BV/TV, trabecular number and trabecular thickness in Bmp-6 -/- OVX mice to higher values than in sham animals. Gene expression profiling using femur mRNA of BMP-6 treated animals revealed significantly changed expression of extracellular matrix, cell cycle, growth factor/cytokine and transcription factor related genes, including procollagen type IX, fibronection 1, IGF-1, EGF, cyclin D3, interleukins 12 and 17, respectively. Unlike estradiol and PTH, treatment with BMP-6 increased both osteoprotegerin and osteocalcin serum levels in wild type and Bmp-6 -/- OVX mice. In conclusion, we demonstrate for the first time that systemically administered BMP-6 exerts both anti-resorptive and anabolic effects on restoring bone in aged OVX rats. Moreover, in OVX Bmp-6 -/- mice BMP-6, but not estradiol and PTH, restores trabecular bone suggesting that both estradiol and PTH mediate at least partially their anabolic bone activity via BMP-6.

SARAb Regulates BMP-Induced Gene Expression in Xenopus and Human Osteoblast Differentiation. W. Shi[1], C. Chang*[2], C. Sun*[1], J. Yang*[1], S. Nie*[2], J. Wang*[1], X. Li*[1], X. Cao[1]. [1]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Cell Biology, University of Alabama at Birmingham, Birmingham, AL, USA.

Signals of Transforming growth factor beta (TGFβ) family are transduced by cytoplasmic Smad proteins. Smad Anchor for Receptor Activation (SARA) facilitates TGFβ and activin/nodal signaling through recruitment of Smad2/3 to early endosomes to present them to the receptor complex. However, no similar protein has been identified for bone morphogenetic protein (BMP)/Smad1 pathway. In this study, a novel FYVE domain protein was found to bind specifically to Smad1 but not Smad2 and enhance Smad1 phosphorylation and nuclear localization upon BMP stimulation, and was therefore named SARAb. Expression of a small interfering RNA (siRNA) against SARAb results in decreased Smad1 phosphorylation. Disruption of the membrane-anchoring FYVE motif by a point mutation leads to reduction of BMP-responsive gene expression in cells. These data thus show for the first time that BMP signaling also requires a SARA-like molecule. Furthermore, it was demonstrate that similar to the Drosophila SARA, SARAb contains a protein phosphatase-binding motif, which functions to negatively modulate BMP signals through receptor dephosphorylation. Since BMPs play diverse roles during early Xenopus development, especially in embryonic dorsoventral patterning, to investigate whether SARAb can modulate BMP signaling *in vivo*, we examined the effect of SARAb overexpression on BMP-dependent endogenous mesodermal marker expression. We injected BMP4 RNA with or without RNAs encoding SARAb or SARAb mutants in animal poles of two-cell stage embryos and dissected animal caps from injected embryos at blastula stages 8.5-9. The caps were incubated to gastrula stages before total RNA was extracted for reverse transcription (RT)-PCR assay for marker gene expression. Injection of SARAb with mutant phosphatase binding domain (F872A) enhanced expression of BMP downstream genes including Xbra, Xhox3 and Xwnt8, further supporting the notion that recruitment of PP1c by SARAb for receptor dephosphorylation is a part of the negative feedback loop, and blockage of recruitment of PP1c enhances BMP *in vivo* function. More significantly, we observed that injection of SARAb FYVE(C735S) mutant or Smad binding domain ΔSBD mutant led to inhibition of the marker gene expression. Our data suggest that SARAb can modulate endogenous BMP-responsive gene transcription. Taken together, our results suggest that SARAb is an important component of the BMP signaling pathway and is capable of recruitment of R-Smads and negative feedback regulation of the BMP signals.

Sclerostin Inhibits BMP-Stimulated Bone Formation by Antagonizing Wnt Signaling. R. L. van Bezooijen[1], A. Visser*[1], G. van der Horst*[1], M. Karperien[1], S. E. Papapoulos[1], P. ten Dijke*[2], C. W. G. M. Löwik[1]. [1]Endocrinology and Metabolic Diseases, Leiden University Medical Center, Leiden, The Netherlands, [2]Molecular Cell Biology, Leiden University Medical Center, Leiden, The Netherlands.

Sclerosteosis is a rare skeletal dysplasia characterized by progressive bone thickening due to increased bone formation. It is caused by deficiency of the *SOST* gene product sclerostin, a negative regulator of bone formation secreted by osteocytes. The mechanism by which sclerostin inhibits bone formation is unclear. Sclerostin is a member of the DAN family of glycoproteins that share the capacity to antagonize BMP activity. Sclerostin binds BMPs and antagonizes their bone forming action without any preference for specific BMPs. Sclerostin's mechanism of action, however, is distinct from other BMP antagonists, since it does not antagonize direct BMP-induced responses such as Smad phosphorylation and BMP reporter construct, BRE-luc, activation. We have previously suggested two possible mechanisms by which sclerostin may antagonize BMP-stimulated bone formation. First, sclerostin may need a BMP inducible co-factor to antagonize BMP signaling. We tested this hypothesis and found that sclerostin did not antagonize BMP-stimulated BRE-luc activity after BMP pretreatment for 48 hours, a time period that should have facilitated production of a co-factor. Second, sclerostin may inhibit BMP-stimulated bone formation by antagonizing another yet unknown BMP-inducible growth factor. Wnts, for example, cooperate with BMPs to stimulate bone formation and other DAN family members also antagonize Wnt activity. We found that BMPs activated the Wnt reporter construct TBE-luc in mouse mesenchymal KS483 cells and sclerostin completely antagonized this action. Similarly, it antagonized TBE-luc activation by constitutive active BMP receptors Alk2 and Alk6, showing that in the absence of ligand-mediated BMP signaling sclerostin still inhibited Wnt signaling. Subsequently, we studied whether sclerostin antagonized Wnt-stimulated TBE-luc activity. Sclerostin indeed antagonized activation of TBE-luc by expression constructs for Wnt1, Wnt3, and Wn3a. Remarkably, sclerostin did not antagonize recombinant human Wnt3a-induced TBE-luc activity. In conclusion, sclerostin does not antagonize early BMP signaling, but antagonizes BMP-stimulated Wnt signaling in osteoblastic cells. Furthermore, it antagonized Wnt1, Wnt3, and Wnt3a-induced signaling. These findings indicate that sclerostin, secreted by osteocytes, inhibits bone formation by antagonizing Wnt signaling in osteoblasts. High bone mass in sclerosteosis may, therefore, result from increased Wnt signaling due to the absence of sclerostin.

A Critical Point Mutation in the Runx2 Subnuclear Targeting Domain Abrogates Osteogenic Function by Blocking Integration of the BMP2 Signal. A. Javed, F. Afzal*, J. Bae*, S. Gutierrez*, S. K. Zaidi*, R. Devados*, M. Green*, A. J. van Wijnen, J. L. Stein*, G. S. Stein, J. B. Lian. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

The convergence of two regulatory pathways, BMP2 signaling and Runx2 transcriptional control, has been implicated as a requirement for bone formation *in vivo*. Genetic studies have shown that deletion of the Runx2 C-terminus which contains the Smad interacting domain (SMID) and the nuclear matrix targeting signal (NMTS) results in a complete loss of bone formation. We tested the hypothesis that Runx2 serves as a template for integration of the BMP signal by interacting with Smad. From a panel of nine point mutations within the SMID/NMTS domain of Runx2, we identified a critical triple mutant (tmRunx2) that abrogates Runx2-Smad physical association. This Runx2 mutant included a key tyrosine residue that is required for subnuclear targeting. Strikingly, mutation of this tyrosine alone did not affect formation of the Runx2-Smad complex. The tmRunx2, however, is deficient in its interactions with either BMP2 or TGFβ responsive Smads and cannot integrate the BMP2/TGFβ signal in promoter reporter assays. We next tested the ability of the wild type (WT) and tmRunx2 proteins to induce the program of osteoblast differentiation in a Runx2 null cell model. Cells were infected with WT and mutant Runx2 adenovirus and expression of a series of osteogenic markers was examined. The tmRunx2 exhibited a 30-40% reduction in activation of the COL-1, AP, OP, BSP, and OC marker genes compared to WT. Runx2 null cells are unresponsive to BMP2 treatment. When we examined integration of the BMP2 osteogenic signal by WT and mutant Runx2 proteins that retain Smad interaction, a robust induction of the osteoblast marker genes was observed. However, the tmRunx2 failed to activate the BMP2 induced osteogenic program. These studies demonstrate that the subnuclear targeting function and formation of a Smad-Runx2 osteogenic complex are functionally inseparable. Our results provide direct evidence for the role of nuclear architecture in organizing physiologically responsive BMP-Smad complexes as a mechanism that allows bone cell type-specific activity during osteogenesis.

Identification of Akp2 as a Gene that Regulates Peak Bone Mass in Mice. R. F. Klein, A. S. Carlos*, J. N. Kansagor*, D. A. Olson*, W. J. Wagoner*, E. A. Larson*, D. C. Dinulescu*, T. G. Munsey*, C. Vanek, D. L. Madison*, J. R. Lundblad*, J. K. Belknap*, E. S. Orwoll. Bone and Mineral Unit, Oregon Health & Science University, Portland, OR, USA.

The identification of genes underlying quantitative-trait loci (QTL) for complex diseases, such as osteoporosis, is a challenging and difficult task. We have previously identified a QTL on chromosome 4 (Chr 4) that is associated with variation in peak BMD in C57BL/6 (B6) and DBA/2 (D2) mice. Selective breeding was used to transfer the chromosomal fragment containing the Chr 4 QTL interval from D2 onto a B6 genetic background. Comparison of the resulting congenic (Cg) mouse strain with the background (Bgd) B6 strain established that a 65 megabase D2 genomic interval on Chr 4 in isolation confers increased peak whole body BMD (65.0 ± 0.6 mg/cm^2 *vs.* 61.2 ± 0.4 mg/cm^2, $p < 0.0001$) and femoral ultimate failure load (17.3 ± 0.8 N *vs.* 14.5 ± 0.5 N, $p < 0.01$). Examination of late pubertal animals (8-wk-old, when bone accrual rates are maximal) found serum alkaline phosphatase (ALP) activity reduced 43% (167 ± 8 U/L vs. 292 ± 11 U/L, $p < 0.0001$) in the B6 Bgd strain compared to the Cg strain but serum osteocalcin levels were similar. Bone histomorphometry revealed increased mineralizing surface, mineral apposition rates and bone formation rates in Cg mice when compared to the B6 Bgd mice. Sequencing of *Akp2* (which resides within the Chr 4 QTL and encodes ALP) identified an amino acid sequence variant at position 324 (B6 allele=Leu & D2 allele=Pro). This Pro residue is conserved in the homologous ALP genes of all vertebrates (human, rat, cow, dog, and cat) implicating an important functional role for this particular codon or region of the enzyme. Kinetic analysis of calvarial ALP from Chr 4 Cg and Bgd mice revealed no differences in enzymatic catalytic parameters. However, human osteoblastic U2OS cell cultures expressing the D2 ALP protein exhibited 50% more whole cell ALP activity, 70% more cell surface ALP activity and 4.8-fold more ALP activity in the conditioned medium compared to U2OS cell cultures expressing equivalent levels of the B6 ALP protein, suggesting that the B6 polymorphism may lead to aberrant intracellular processing and/or impaired cell surface localization of ALP. These results provide strong presumptive evidence that ALP is an important determinant of peak bone mass in laboratory mice. As the 1p36 chromosomal region harboring *TNSALP* (the human homolog of *Akp2)* has been linked to bone phenotypes relevant to osteoporosis in 3 different genome-wide linkage analyses, it is intriguing to consider that inherited differences in ALP activity may contribute to the natural variation in peak bone density and strength in human populations.

The Role of the Trps1 Transcriptional Repressor in Endochondral Bone Formation. D. Napierala[1], K. Sam*[2], Q. Zheng*[2], G. Zhou[2], R. A. Shivdasani*[3], B. Lee[1]. [1]Howard Hughes Medical Institute, Houston, TX, USA, [2]Baylor College of Medicine, Houston, TX, USA, [3]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, USA.

Mutations in the *TRPS1* gene cause tricho-rhino-phalangeal syndrome (TRPS), a dominantly inherited skeletal dysplasia characterized by short stature, hip dysplasia, cone-shaped epiphyses, premature closure of growth plates, and distinctive craniofacial appearance. During mouse skeletal development *Trps1* is highly expressed in chondrogenic mesenchymal condensations, prehypertrophic chondrocytes and perichondrium. Trps1 is a transcription repressor that contains nine zinc-fingers including GATA-type and Ikaros-type domains. To elucidate the role of Trps1 in skeletogenesis, we analyzed *Trps1* mutant mice deleted for the GATA DNA-binding domain. Heterozygous mutant mice have normal appearance except of the craniofacial abnormalities with the shortening of the snout and a sloped down nose. Homozygous *Trps1* mutant mice die shortly after birth. Alcian blue and alizarin red staining of skeletons of new-born homozygous mutant mice demonstrated delayed ossification of vertebrae and sternum, and significantly reduced maxilla and mandible. Histological analysis of growth plates showed the elongation of prehypertrophic and hypertrophic chondrocytes zone and delay in endochondral ossification, which is more pronounced in homozygous mutant mice. To analyze the expression of genes involved in endochondral ossification, we performed quantitative real-time PCR on mRNA isolated from humerus of wild type and *Trps1* heterozygous mutant mice. This analysis showed dramatic increase of expression of chondrogenic markers - *col10a1* and *col2a1* as well as elevated expression of *Runx2*. *Runx2* is a key transcription factor involved in osteoblast differentiation and chondrocyte maturation. To test the potential interaction of *Trps1* and *Runx2*, we performed cotransfection studies in ROS17 and COS7 cell lines. In COS7 cells, *Trps1* strongly represses *Runx2* transactivation of the target 6xOSE reporter, which responds only to *Runx2* transactivation. The 6xOSE reporter is also down regulated in the presence of *Trps1* in ROS17 cells expressing high levels of endogenous *Runx2*. Moreover, the bone-related promoter of *Runx2* contains several potential GATA consensus sequences. *In vitro* analyses showed that *Trps1* forms complexes with each of these elements in COS7 but not in ROS17 cell lines. Our data suggest that *Trps1* regulates the cartilage to bone transition during endochondral ossification and that could be partially through inhibition of expression of the *Runx2* gene as well as *Runx2* protein function.

A Knock-in Mouse Model for a Collagen Type X NC1 Domain Mutation Associated with Metaphyseal Chondrodysplasia Type Schmid (MCDS). M. H. Rajpar*, R. Eardley*, K. E. Kadler*, D. J. Thornton*, M. D. Briggs*, R. P. Boot-Handford*. Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

Metaphyseal chondrodysplasia type Schmid (MCDS) is an autosomal dominant disorder characterised by a shortened stature, waddling gait and *coxa vara*. Radiological findings include an irregular, widened growth plate and metaphyseal flaring. Numerous mutations in the collagen X gene (*COL10A1*) have been described in MCDS families, the majority of which are located in the C-terminal NC1 domain. Collagen X is synthesised by hypertrophic chondrocytes within the growth plate of developing bones. The disease mechanisms behind the pathology of MCDS remain controversial, with evidence for both a dominant interference effect, whereby the mutant protein interferes with the formation of normal homotrimers, and haploinsufficiency, where only 50% of the normal levels of collagen X are synthesised. Although a number of transgenic mouse *Col10a1* mutant models exist, there is currently no model which represents missense mutations causing the MCDS pathology in humans. We have utilised a gene targeting strategy to introduce the mouse equivalent of the MCDS N617K mutation into the mouse *Col10a1* gene. This mutation originally identified in an MCDS kindred, substitutes an asparagine residue for a lysine and is located on the outer surface of the NC1 homotrimer. A targeting construct containing the modified gene was integrated into the mouse genome using homologous recombination in R1 ES cells. Homologously recombined ES cells were identified, injected into blastocysts and implanted into pseudopregnant mice, resulting in high quality chimeric mice that have transmitted the mutation through the germline. Transgenic mice were analysed using x-ray imaging, monitoring of growth rate, bone measurements, skeletal preparations, histology, immunohistochemistry and RNA expression. Heterozygous offspring have no overt phenotype, displaying normal growth rates and fertility levels. Mice carrying two mutant alleles display a chondrodysplasic phenotype, characterised by reduced body weight and size, shortening of the long bones and dysplasia of the hip, and histologically, a disorganised growth plate. Expression of the mutant allele has been demonstrated by both RNA and immunohistochemical analyses. These results indicate that the mice carrying the N617K mutation have a phenotype reminiscent of that seen in the human condition, and will be used to investigate the disease mechanism underlying the pathology of MCDS.

Tamoxifen Induced Bone Morphological Protein Receptor 1A (*Bmpr1a*) Conditional Knockout Mice Display an Age-Dependent Phenotype in Long Bones Different from Calvariae. N. Kamiya*[1], L. Ye*[2], T. Kobayashi[3], H. M. Kronenberg[3], J. Feng[2], Y. Mishina*[1]. [1]LRDT, NIEHS/NIH, Research Triangle Park, NC, USA, [2]Oral Biology, School of Dentistry, University of Missouri-Kansas City, Kansas City, MO, USA, [3]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Three type I receptors, BMPRIA(Alk3), BMPRIB(Alk6), and ActRI(ALK2), are responsible for signaling of the bone morphogenetic proteins. However, it is unclear what common and unique features these receptors share during bone development and remodeling. We previously rescued an early embryonic lethality of regular *Bmpr1a* KO mice in a later osteoblast-specific manner using Osteocalcin(Og2)-Cre and floxed *Bmpr1a* mice. The mutant mice showed reduced bone mass up to 3 months after birth, but bone mass was increased as they aged due to reduced bone resorption. To further investigate the age-dependent roles of BMPRIA in bone development and remodeling, the Cre-ER^{TM} (a tamoxifen(TM) inducible Cre) mice were generated under the control of 3.2 kb type I collagen promoter. After TM injection into pregnant mice from day14 to day16, Cre activity was confirmed in osteoblasts and osteocytes in embryos at E18.5. A dramatic reduction of mineralization in long bone was observed in *Bmpr1a* CKO mice at E18.5. They showed thinner cortical and immature trabecular bone characters compared to littermates. The long bone cortex showed immature woven bone phonotype. On the other hand, calvaria of *Bmpr1a* CKO mice displayed a lamellar bone phenotype with large numbers of osteocytes at E18.5. Also, column formation of the growth plate was irregular. Interestingly, when TM was injected into newborn for three weeks, analysis of P21 showed more mature trabecular bone. Based on these observations, we propose that BMP signaling through BMPRIA is essential for early bone maturation and remodeling. Our results suggest that roles of BMPRIA are bone loci- and age-dependent, which may contribute to the diversity of bone shape and size.

Metabolic and Skeletal Consequences of a High Fat/Diabetogenic Diet on Bone Acquisition in a Congenic Mouse Strain with Altered Osteoblast Differentiation. C. Ackert-Bicknell, C. Marvin-Bivens*, J. Denegre*, L. Horton*, K. Shultz*, L. R. Donahue, W. Beamer, M. Bouxsein, C. Rosen. The Jackson Laboratory, Bar Harbor, ME, USA.

Congenic 6T mice were generated by backcrossing a 30 cM QTL region of Chr 6 from C3H/HeJ to C57BL/6(B6) 10 generations. Female 6T mice have low peak BMD, impaired bone formation due to decreased osteoblast (OB) differentiation, reduced liver and skeletal IGF-I, adipocyte infiltration in the marrow and liver, and more body fat vs B6. Three genes in the Chr6 QTL that can force a shift into the adipocyte lineage and alter OB differentiation show increased bone expression in 6T (i.e. *Klf15, Pparg, Alox 5)*. To test their effect on bone acquisition, we fed either a reference (NIH31) diet **(RD)** or a high fat/ sucrose diabetogenic diet (**HFD**) to female 6T and B6 mice post weaning for 13 wks. The diets consisted of the following: **RD**: protein:18%kcal, carbs: 71%kcal, Fat: 6%kcal, fiber: 5%; **HFD** protein:17% kcal, Carbs:51%kcal; Fat:32% kcal). At 16 wks, 6T mice fed **RD** had more hepatic fat droplets ($p<0.05$), lower vBMD ($p<0.01$), shorter femurs, decreased trabecular BV/TV ($p<0.01$), and reduced cortical thickness ($p<0.01$) vs B6 fed a **RD.** On a **RD**, 6T and B6 showed no differences in free fatty acids (FFA), calcium, triglycerides, (TG), insulin or glucose. But, on the **HFD** diet, B6 gained wt and increased body fat, had a rise in serum insulin ($p<0.05$), an elevated blood glucose (i.e. 200 mg/dL; $p<0.05$ vs **RD**), a decrease in IGF-I ($p<0.04$ vs **RD**) and greater free fatty acids. 6T mice on the **HFD** showed no change in body wt or fat, nor in any metabolic parameter (e.g. serum IGF-I, FFA,TG, serum insulin or glucose). In respect to bone, the **HFD** diet produced significant increases in trabecular BMD in 6T and B6 compared to the **RD** diet ($p<0.05$) such that 6T distal femoral BV/TV was fully rescued. On a **HFD** both strains had increases in periosteal circumference, while 6T had reduced femoral cortical BMD compared to **RD** fed 6T ($p<0.05$). B6 showed a significant reduction in femoral length on the **HFD** diet. In conclusion, 6T mice are protected from the insulin resistance/ diabetes syndrome in response to a **HFD** diet, a finding similar to the phenotype of the Pro12Ala mutation in the human *PPARG* gene. The **HFD** diet rescued the trabecular and periosteal, but not length or cortical phenotypes of 6T, without changing IGF-I. In the 6T mouse where OB differentiation is impaired and there is a shift into the adipocyte lineage, peak trabecular BMD can still be improved with a **HFD** diet. This suggests: 1) the OB and adipocyte differentiation programs *in vivo* are not mutually exclusive; 2) in 6T, the *Pparg* pathway is already activated;3) **HFD** diets can enhance peak BMD. Studies to identify the genes influencing acquisition of peak BMD and lineage allocation in 6T are ongoing.

Different Epigenetic Variants of Pseudohypoparathyroidism Type-IB Are Associated with Distinct Mutations of *GNAS*. M. Bastepe[1], A. Linglart*[1], L. F. Fröhlich[1], H. Jüppner[2]. [1]Endocrine Unit, Mass. General Hospital and Harvard Medical School, Boston, MA, USA, [2]Endocrine Unit and Pediatric Nephrology Unit, Mass. General Hospital and Harvard Medical School, Boston, MA, USA.

Pseudohypoparathyroidism type-Ib (PHP-Ib) is inherited only from maternal obligate carriers. The patients display genomic imprinting abnormalities of *GNAS*, including a loss of exon A/B methylation found in nearly all cases. We have previously identified, in multiple kindreds with autosomal dominant PHP-Ib (AD-PHP-Ib), a heterozygous 3-kb microdeletion in *STX16*, an apparently non-imprinted gene centromeric of *GNAS*. All the patients carrying this unique, maternally inherited 3-kb deletion show loss of exon A/B methylation without epigenetic defects at other *GNAS* differentially methylated regions (DMRs). Furthermore, in another AD-PHP-Ib kindred in whom affected individuals also display a loss of exon A/B methylation alone, we have identified a heterozygous 4.4-kb deletion within *STX16* that overlaps with the 3-kb deletion. Thus, in our cohort, 22 of the 23 patients who display isolated exon A/B defects carry mutations within *STX16*. In contrast, the remaining 21 sporadic and 2 familial PHP-Ib patients who show epigenetic defects at multiple *GNAS* DMRs, including exon A/B, do not appear to carry mutations within *STX16*. Recently, in the two familial cases with broad epigenetic defects, we have identified 4-kb and 4.7-kb deletions removing, in either case, the entire DMR containing exon NESP55 and exons 3 and 4 of its antisense transcript. After maternal transmission, each of the latter deletions causes loss of maternal *GNAS* imprints. However, similar large deletions at the NESP55 DMR have been excluded so far in all sporadic cases with broad methylation changes. Taken together, it appears that distinct genetic mutations lead to distinct epigenetic alterations within *GNAS,* which converge upon their phenotypic outcome, i.e. renal PTH-resistance. The latter is predicted to be affected by imprinting of exon A/B, which in turn determines expression of Gsα in renal proximal tubules. Based on the identified mutations, the region of overlap between the two *STX16* deletions (1.3 kb) likely contains a cis-acting element required for imprinting of maternal exon A/B, while the NESP55 DMR contains another cis-acting element required for imprinting of the entire maternal *GNAS* allele. The mutation(s) responsible for the *GNAS* defects in sporadic PHP-Ib cases remains to be determined. It may disrupt yet another imprinting control element, or alternatively, it is located in an entirely unlinked gene.

Comparison of Ten-Year Absolute Fracture Risk and WHO Risk Categorization in Menopausal Females. W. D. Leslie[1], K. Siminoski*[2], J. Brown*[3]. [1]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [2]Dept. of Radiology, University of Alberta, Edmonton, AB, Canada, [3]CHUL Research Centre, Laval University, Sainte-Foy, PQ, Canada.

There is increasing agreement that a risk-based approach to fracture risk assessment is preferable to risk categorization based upon bone mineral density (BMD) alone. How this might affect patient classification is unclear and needs to be clearly understood since there are large resource implications. We compared rates of high-risk classification in 17,053 women age 50 and older from a regional BMD program. This program maintains a large population-based database of clinical DXA results that has been previously described (JCD 2005;8:25-30). High-risk was designated according to 3 rules: femoral neck T-score -2.5 or below, minimum T-score (from L1-4, femoral neck, trochanter or total hip) -2.5 or below, or 10-year osteoporotic fracture risk (based upon age and femoral neck T-score) 20% or greater. The overall rates of high-risk categorization were 16.3%, 31.4%, and 20.3%, respectively (P<0.00001 for all pairwise comparisons). 10-year fracture risk resulted in a lower rate of high-risk designation in women age 50-60, exceeded femoral neck categorization after age 65-69, and exceeded minimum site categorization after age 75-79. The overall rate of high-risk categorization with 10-year fracture risk 20% or above is slightly greater than with femoral neck BMD alone and much less than with a minimum T-score approach. Use of different risk cutoffs grossly over-classified (5%, 10%, 15%) or under-classified (25%, 30%) high-risk when compared with the conventional T-score based BMD thresholds. In conclusion, the use of 10-year fracture risk with a 20% high-risk threshold appropriately accentuates the age-related increase in fracture risk. Compared with BMD alone, its effect would be to de-emphasize risk in early menopausal women while emphasizing risk in older women.

Long-Term Prediction of Incident Vertebral Fractures over 15 Years of Follow-Up: Data from the Study of Osteoporotic Fractures (SOF). M. C. Hochberg[1], L. Palermo*[2], J. Cauley[3], K. Ensrud[4], T. Hillier*[5], M. Nevitt[2], S. R. Cummings[6]. [1]Medicine, University of Maryland, Baltimore, MD, USA, [2]Epidemiology, University of California San Francisco, San Francisco, CA, USA, [3]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [4]Medicine, University of Minnesota, Minneapolis, MN, USA, [5]Medicine, Kaiser Permanente Health System, Portland, OR, USA, [6]Research, California Pacific Medical Center, San Francisco, CA, USA.

Prevalent vertebral fracture (VFx) is associated with an increased risk of incident VFx over a mean of 4 years; however, long-term predictors of incident VFx have not been examined. 2680 Caucasian women age 65 and above when they enrolled in SOF (mean [SD] 68.9 [3.3] years) had lateral lumbar and thoracic vertebral x-rays at baseline and a mean [SD] of 14.9 [0.7] years later (mean [SD] age 83.8 [3.3] years). Using vertebral morphometry, anterior (Ha), posterior (Hp) and mid-vertebral height (Hm) were measured. Prevalent VFx were considered present at baseline if any of the following ratios (Ha/Hp; Hm/Hp; Hp(i)/Hp(i-1) and Ha(i)/Ha(i-1); or Hp(i)/Hp(i+1) and Ha(i)/Ha(i+1)) was > 3 SDs below the "trimmed" mean. Incident VFx were defined as a decrease of at least 20% and 4mm in vertebral height at any level. Risk factors were measured at baseline except for bone mineral density (BMD) at the proximal femur; this was measured at the 1st follow-up visit 2 years after baseline. Multiple variable logistic regression analysis was used to estimate the odds ratio (95% confidence intervals) of incident VFx; all analyses were adjusted for baseline age and clinic. 492 (18.4%) of the 2680 women had an incident VFx during follow-up, including 164 (41.6%) of 394 with and 328 (14.3%) of 2286 without a prevalent VFx at baseline (aOR = 4.15 [95% CI: 3.28, 5.25], P < .001). Additional risk factors that were independently associated with incident VFx were included in the final multiple variable logistic regression model; results from this model are shown in the Table. There were no significant first-order interactions between prevalent VFx and any of these other risk factors. We conclude that having a prevalent VFx is associated with a 3 to 4-fold increased risk of developing an incident VFx among long-term survivors even after 15 years. fractures. Older women with prevalent VFx should receive treatment to decrease their long-term risk of incident VFx.

Factors Associated with Incident VFx (adjusted for all other variables in the table)

Variable	Odds Ratio (95% CI)
Prevalent VFx	3.21 (2.49, 4.14)
Age (per 5-years)	1.51 (1.29, 1.77)
Total Hip BMD (per SD)	1.65 (1.44, 1.88)
Nonspine Fx after age 50	1.40 (1.12, 1.76)
Fall in last 12 months	1.37 (1.09, 1.74)
Current smoker	1.44 (0.97, 2.14)
Body mass index (per SD)	0.89 (0.79, 1.01)

Osteoprotegerin Promoter Polymorphism, Bone Density and the Risk of Hip Fracture in Older Women. J. I. Oakley[1], J. M. Zmuda[1], S. P. Moffett[1], K. L. Stone[2], L. Y. Lui[2], J. Li*[3], J. A. Cauley[1], B. C. Taylor[4], T. A. Hillier*[5], W. Browner*[6], M. C. Hochberg*[7], G. Peltz*[8], S. R. Cummings[6]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Epidemiology and Biostatistics, University of California, San Francisco, CA, USA, [3]Human Genetics, Roche Molecular Systems, Alameda, CA, USA, [4]General Internal Medicine, Veterans Affairs Medical Center, Minneapolis, MN, USA, [5]Kaiser Permanente Center for Health Research Northwest/Hawaii, Portland, OR, USA, [6]Research Institute, California Pacific Medical Center, San Francisco, CA, USA, [7]Medicine and Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD, USA, [8]Roche Biosciences, Palo Alto, CA, USA.

Osteoprotegerin (OPG) is a soluble decoy receptor that blocks osteoclastic bone resorption. We performed genetic association analyses of an A163G promoter polymorphism at the OPG locus, bone mineral density (BMD) and the risk of incident fracture among 6695 women aged 65 years and older in the prospective Study of Osteoporotic Fractures (SOF). We confirmed 700 incident hip (366 femoral neck, 334 intertrochanteric) and 510 incident wrist fractures by review of medical records during 13.6 years of follow-up (91,249 person-years). BMD was measured by DXA (Hologic QDR). The OPG polymorphism was genotyped in the context of a multiplex PCR followed by allele-specific SNP detection with immobilized oligonucleotide probes in linear arrays. Women who were homozygous for the less common G allele had significantly lower BMD at the total hip than those who were homozygous for the wild-type A allele (G/G: 0.74±0.15 vs. A/A: 0.76±0.13; p=0.009). Similar reductions were observed for all sub-regions of the hip. Previous studies in the SOF cohort showed that family history of hip fracture predicts femoral neck but not intertrochanteric fractures. Thus, we analyzed the risk of these fractures separately by OPG genotype. Compared with A/A homozygotes, G/G homozygotes had an 82% greater risk of femoral neck fracture (RR: 1.82; 95% CI: 1.02-3.24) (p=0.04). In contrast, the OPG polymorphism was not significantly associated with intertrochanteric fractures (RR: 0.86; 95% CI: 0.35-2.08). The association between OPG genotype and femoral neck fracture was attenuated and no longer statistically significant after adjusting for the lower femoral neck BMD in women with the G/G genotype (RR: 1.46; 95% CI: 0.82-2.61). There were no significant associations between OPG genotype and risk of wrist fracture. Older women with the G/G genotype of the OPG promoter polymorphism, or a closely linked allelic variant, may have a lower hip BMD and an increased risk of femoral neck fracture.

Beta2 Adrenergic Receptor, Beta-Blockers and their Influence on Bone Mass in Humans: The Framingham Osteoporosis Study. S. Ferrari[1], S. Demissie*[2], D. Karasik[3], L. A. Cupples*[4], A. Imamovic*[5], J. Dupuis*[4], D. P. Kiel[3]. [1]Geneva Univ Hosp, Geneva, Switzerland, [2]BU Sch Pub Health & Prog Genom Applic, Boston, MA, USA, [3]Hebrew SeniorLife, Boston, MA, USA, [4]BU Sch Pub Health, Boston, MA, USA, [5]BU Dept Neurol, Boston, MA, USA.

Beta 2 adrenergic receptors (ADRB2) regulate bone turnover.Beta-blockers (BB) increase bone mass in mice, and have been associated with higher BMD in postmenopausal women, but this association has not been confirmed. Whether ADRB2 signaling influences bone mass in humans remains uncertain. We examined the association of ADRB2 polymorphisms with BMD at the spine (LS), femoral neck (FN), and troch (FT) by DXA and their interaction with BB in 776 females and 740 males from the Framingham Offspring Cohort. Six SNPs, including two missense substitutions (Arg16Gly and Gln27Glu) affecting ADRB2 down-regulation, were determined within three ADRB2 LD regions. Main and interaction effects ANCOVA models were used to analyze BB and ADRB2 effects on BMD, adjusting for sex, age and estrogen (in women) (model 1), additionally for height and BMI (model 2), and for cardiovascular diseases (CVD, model 3). Mean age (±SD) was 61.3 ± 9.1 yrs. 274 women and men used BB, including 63 using non-beta1 selective beta-blockers (NSBB). In men and women together, BB users had higher BMD at all sites (BB, P=0.0004-0.017; NSBB, P=0.004-0.05, model 1). After adjusting for height and BMI, these effects remained significant only at LS (BB, P=0.04; NSBB P=0.033, model 2), but not after adjusting for CVD (model 3). In women, but not in men, associations with BMD were found for the T>C SNP in LD region 1, G>A SNP in LD region 3, and Gln27Glu and Arg16Gly SNPs in LD region 2. In females significant interactions with BB occurred for ADRB2 genotypes in LD regions 2 and 3.

P values for ADRB2 genotype associations and interactions with BB on BMD in women (model 2)

	T>C Block 1	G>A Block 3	Gln27Glu Block 2	Arg16Gly Block 2
BMD	P assoc.	P assoc.	P assoc.	P assoc.
	P inter.	P inter.	P inter.	P inter.
FN	0.058	0.001	0.03	0.05
	ns	0.025	0.025	0.028
FT	0.035	0.005	0.08	0.068
	ns	0.01	0.002	.0016
LS	0.037	0.11	ns	ns
	ns	0.03	0.088	0.11

Further adjustment for CVD (model 3) did not alter these results. After excluding women on NSBB (n=31), haplotype analysis indicated that BMDand BUA decreased 1-3% at all sites per copy of the Arg16-Gln27 haplotype (freq 36%, $p<0.05$, model 3). In conclusion, evidence that ADRB2 genetic variation is associated with BMD in women supports a role of the adrenergic pathway in the regulation of bone mass in humans. Although doses of beta-blockers commonly used to treat CVD are unlikely to increase BMD overall, interactions between BB and ADRB2 polymorphisms suggest that BB might influence bone mass in distinct genotypic sub-groups.

Sex Hormone Levels and Risk of Falling in Community-Dwelling Older Persons: A Prospective Study. H. A. Bischoff-Ferrari[1], J. E. Orav*[2], B. Dawson-Hughes[3]. [1]Medicine, Brigham and Women's Hospital, Boston, MA, USA, [2]Biostatistics, Harvard School of Public Health, Boston, MA, USA, [3]Jean Mayer USDA Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA.

Background: Little is known how sex hormone levels affect the risk of falling in older persons. **Aim:** To prospectively assess the risk of falling in older men and women based on baseline sex hormone levels. **Methods:** 199 men and 246 women age 65 or older living at home were followed prospectively for 3 years after baseline assessment of estrone, estradiol, total testosterone, free testosterone, androstenedione, dihydroepiandrosterone (DHEA) and sex hormone binding globulin (SHBG). Falling at least once was the primary outcome using logistic regression analysis. All hormones were evaluated by gender, controlling for age, body mass index, baseline 25-hydroxyvitamin D levels, baseline physical activity, smoking, alcohol use, number of comorbid conditions, maximal follow-up and vitamin D plus calcium treatment. Testosterone and estrogen levels were also adjusted for SHBG. **Results:** In 3 years 49% of men and 57% of women suffered at least 1 fall. Men in the highest quartile of total testosterone (≥ 5.7 ng/ml) had a 78% decreased odds of falling compared to men in the lowest quartile with serum levels below 3.8 ng/ml (OR = 0.22; 95% CI [0.07,0.72]). Conversely, men in the top quartile of SHBG (≥ 65.5 ng/l) had a 3.9-fold increased odds of falling compared to those in the lowest quartile with serum levels below 41.1 ng/l (OR = 3.90; 95% CI [1.09,13.93]). Similar to men, women in the top quartile of testosterone levels (≥ 0.49 ng/ml) had a 66% decreased odds of falling compared to those in the lowest quartile with serum levels below 0.20 ng/ml (OR = 0.34; 95% CI [0.14,0.83]). While there was no effect of SHBG in women, women in the top quartile of DHEA (> 0.76 mcg/ml) had a 61% lower odds of falling compared to those in the lowest quartile with serum levels below 0.31 mcg/ml (OR = 0.39; 95% CI [0.16,0.93]. While there was a significant positive trend between higher testosterone levels and fall protection in both genders (men: p = 0.008; women: p = 0.03), there appeared to be a threshold effect with equally strong protection in the second, third and top quartile for SHBG in men and DHEA in women. Estrone, estradiol, free testosterone and androstenedione did not predict falling in men or women. **Conclusion:** Independent of other important risk factors of falling, higher total testosterone in both genders and higher DHEA levels in women appear to reduce the odds of falling by over 60%. On the other hand, high SHBG levels appear to increase the odds of falling in men almost 4-fold. Other sex hormones were not appreciably associated with falling in community-dwelling older persons.

Long Term Effects of a Randomised Controlled Trial (RCT) of Osteoporosis Screening on the Use of Medication and Fracture Risk. R. J. Barr*[1], A. Stewart*[1], D. J. Torgerson*[2], D. M. Reid[1]. [1]Medicine and Therapeutics, University of Aberdeen, Aberdeen, United Kingdom, [2]Health Economics, University of York, York, United Kingdom.

Osteoporosis is a common condition occurring in 1 in 2 women but current management is unsatisfactory because it is generally not introduced until a major fracture has occurred. Population screening programmes are one means to identify menopausal women with low bone mineral density (BMD) and an elevated risk of future fracture but require to be proven effective in a RCT. In 1993 a random sample of 4800 women aged 45-54 years living within 32km of Aberdeen, Scotland, was selected from a primary health care register. Subjects were randomised in equal numbers to screening (active (A)) or no screening (inactive controls (C)). Only the active women were assessed and those found to be in the lowest quartile of BMD were suggested to consider HRT treatment and informed about other lifestyle factors to reduce fracture risk. Nine years after randomisation a follow-up questionnaire was mailed to both groups to assess the effect of screening on the uptake of treatment and on the incidence of fractures. Response rates after 9 years were C=56.8% and A=59.7%. No significant differences between the groups were observed in: age, weight, height or self-reported general health, nor in self-reported disease states with the exception of hyperparathyroidism (C=0.5% A=1.1%, p=0.05). 52.4% of the active group reported taking HRT compared with 44.5% of the control group ($p<0.001$). No significant difference was observed in the mean duration of HRT use (C=86.0 months A=84.0 months p=0.58). Similarly the active subjects were significantly more likely to report current or past use of vitamin D, calcium, alendronate, etidronate or raloxifene than the control subjects (36.6% of the active group and 21.6% of the control group reporting to have taken some form of osteoporosis medication, excluding HRT, ($p<0.001$)). A significantly greater number of the active group not advised to take HRT at screening compared with the control group had taken HRT (49.7% vs 44.5%, p=0.017). This trend was repeated in the use of other osteoporosis medications. In a per protocol analysis of self-reported incident fractures a 23.7% reduction in fractures (of any site) in the active group was observed (RR=0.763 95%CI=0.579-1.006) which increased to 25.2% following adjustment for age, weight and height (RR =0.748, 95%CI=0.567-0.986). No significant difference was observed in the number of fallers (C=13.9% A=15.6%, p=0.202) or the rate of falls (C=0.28falls/year A=0.30falls/year, p=0.503). Screening for low bone density significantly increases the use of HRT and other treatment for osteoporosis and reduces fracture incidence.

FSH Directly Regulates Bone Mass: Implications for Understanding the Pathogenesis of Osteoporosis Due to Hypogonadism. L. Sun[1], Z. Zhang*[1], Y. Peng*[1], J. Iqbal*[1], S. Zaidi*[1], D. J. Papachristou*[2], H. Zhou*[1], A. C. Sharrow*[2], B. B. Yaroslavskiy*[2], L. Zhu*[1], A. Zallone*[3], M. R. Sairam*[4], T. R. Kumar*[5], L. Cardoso-Landa*[1], M. B. Schaffler[1], B. S. Moonga*[1], H. C. Blair[2], M. Zaidi[1]. [1]Medicine, Mt. Sinai School of Medicine and the Bronx VA GRECC, New York, NY, USA, [2]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [3]Medicine, University of Bari, Bari, Italy, [4]Medicine, Clinical Research Institute of Montreal, Montreal, ON, Canada, [5]Medicine, University of Kansas, Kansas City, KS, USA.

Hypogonadal bone loss is thought to arise solely from declining estrogen. Nonetheless, due to a loss of estrogenic feedback, pituitary-derived serum FSH levels increase. Here we report that FSH (ligand) and FSHβ receptor (FSHR) null mice have normal bone mass despite severe hypogonadism. Histomorphometry and micro-CT revealed that trabecular bone volume, cortical bone thickness and osteoclast resorption surfaces in null mice were not different from wild type littermates. Flow cytometry of bone marrow cells revealed no differences in osteoclast precursor populations. Together, the results establish that FSH is required for hypogonadal bone loss. Interestingly, bone mass was *increased* and osteoclast resorption surfaces decreased in haplo-insufficient $FSH\beta^{+/-}$ mice with intact ovarian function. This suggests that FSH acts on osteoclasts independently of estrogen. In parallel, we find that osteoclasts possess FSH receptors (FSHRs) coupled to the inhibitory G-protein, Gi; that FSH directly stimulates osteoclast formation, function and survival; and that these FSH-induced enhancements are Erk1/2- and Akt-mediated. Real time PCR, Western blotting, flow cytometry and confocal microscopy together revealed that FSHRs are present on both murine and human osteoclasts, but not on osteoblasts. FSH (3 to 100 ng/ml) stimulated RANK-L-induced osteoclast differentiation from hematopoetic stem cell precursors; no responses were observed with the related glycoprotein hormones LH and GnRH. FSH also stimulated Erk1/2 phosphorylation and c-fos nuclear translocation, both of which were pertussis toxin-inhibitable. In the pit assay, FSH (3 to 30 ng/ml) stimulated osteoclastic bone resorption; this likely resulted from the observed enhancements in actin ring formation (phalloidin staining) and acid secretion (lysotracker accumulation). Finally, FSH supported the survival of osteoclasts by enhancing Akt phosphorylation and reducing apoptosis (annexin V staining). Together, the results suggest that FSH, by stimulating osteoclastic bone resorption, contributes to the hypogonadal bone loss that has been attributed solely to declining estrogen. Potential therapeutic implications may eventually follow.

Purification and Characterization of Circulating Osteoblast Lineage Cells: Expression of Type I Collagen mRNA Is a Key Difference between these and Adherent Bone Marrow Stromal Cells. G. Z. Eghbali-Fatourechi, S. Khosla. Mayo Clinic, Rochester, MN, USA.

We recently reported on circulating osteoblastic cells in humans expressing osteocalcin (OCN) and/or bone alkaline phosphatase (BAP) (*NEJM, in press)*. To further characterize these cells, we first tested for co-expression of OCN, BAP, RANKL, and the hematopoietic/endothelial progenitor marker, CD34. Using flow cytometry, we found that 57% of OCN+ cells were BAP+, whereas only 29% of BAP+ cells were OCN+. 51% and 62% of OCN+ and BAP+ cells, respectively, were CD34+, while 57% and 43% of each were RANKL+. To obtain highly purified populations of human OCN+ and BAP+ cells, we performed sequential negative selection (resulting in removal of cells expressing hematopoietic or myeloid markers) followed by magnetic cell sorting (MACS) using monoclonal antibodies to OCN or BAP. The Figure shows flow cytometry histograms of cell numbers vs. fluorescence intensity using the OCN antibody following each selection step for OCN+ cells **(A)**. Cells isolated following this sequential enrichment were ~ 90% homogeneous for OCN or BAP expression **(B)**. These highly purified circulating OCN+ and BAP+ cells were analyzed for gene expression in comparison with a well characterized, adherent human bone marrow stromal cell line (hMS 2-15 [JBMR 13:205, 1998]). OCN+ and BAP+ cells expressed similar levels of OCN mRNA and ~50 fold higher AP mRNA levels as compared to hMS 2-15 cells. By contrast, hMS 2-15 cells expressed 500 and 100 fold higher mRNA levels for type 1 collagen α2 (col1α2) compared to BAP+ and OCN+ cells, respectively. The marked difference in col1α2 mRNA

levels in adherent bone marrow stromal vs. circulating osteoblastic cells suggests that adherence to extracellular matrix may be necessary for maximal expression of collagen by the circulating osteoblastic non-adherent cells. Consistent with our data, a previous report (J Cell Biol 153:1133, 2001) has demonstrated high levels of collagen type 1 but absent AP expression in circulating adherent osteoblastic cells, although non-adherent circulating osteoblastic cells were not examined in that study. Finally, our method for obtaining highly purified osteoblast lineage cells from human blood should greatly facilitate studies examining changes in gene and/or protein expression in these cells in patients with osteoporosis and other metabolic bone disorders.

Spontaneous Fractures in the Mouse Mutant *Sfx* Are Caused by Deletion of Gulonolactone Oxidase (GULO) Gene, Causing Vitamin C Deficiency: Evidence that Vitamin C Is a Critical Determinant of ATP Synthesis in Differentiating Osteoblasts. S. Mohan[1], A. Kapoor*[1], A. Singgih*[1], Z. Zhang*[1], T. Taylor*[1], H. Yu*[1], R. Chadwick[1], Y. Chung*[1], L. Donahue*[2], G. Crawford*[2], C. Rosen*[2], J. E. Wergedal[1], D. J. Baylink[1]. [1]JLP VAMC and LLU, Loma Linda, CA, USA, [2]Jackson Labs, Bar Harbor, ME, USA.

To identify the genetic basis for osteoporotic fractures, we utilized a mouse model that develops spontaneous fractures (*sfx*) at an early age. After weaning, the *sfx/sfx* mice exhibited impaired somatic growth, reduced motility, *sfx* and died at 6-8 wks of age while +/*sfx* mice were indistinguishable from +/+ mice. Femur and tibial BMD were reduced by 30% in *sfx* mice at 5 wks of age. Histomorphometric analyses of bones from *sfx* mice revealed that mineral apposition rate was decreased by >80%, implying reduced osteoblast (OB) activity in *sfx* mice. The *sfx* gene was fine mapped to a 2MB region containing 30 genes in chr. 14. We have identified the GULO gene (38146 bp region), involved in the synthesis of ascorbic acid (AA), is responsible for the *sfx* phenotype as treatment of *sfx* mice with AA rescues the phenotype (Mohan et al., JBMR, in press). To identify the molecular pathways that contribute to impaired OB cell function, we performed a microarray analysis using 20,000 mouse oligo probes to identify genes differentially expressed in the bones of *sfx*. We found expression levels of several genes related to mitochondrial energy metabolism were severely compromised in the bones of *sfx* mice. We next used bone marrow stromal (BMS) cells derived from *sfx/sfx* mice as an *in vitro* model to test if AA deficiency influences ATP synthesis. We found that BMS cells derived from *sfx* mice are able to form mineralized nodules only when treated with AA which was associated with several-fold increase in the expression levels of collagen, ALP and osteocalcin and an 8-fold increase ($P<0.001$) in cellular ATP levels. Because of the established importance of glycerol 3-phosphate (G3P) shuttle in the generation of ATP, we evaluated if AA regulates G3P shuttle. Accordingly, we found that 24 h AA treatment caused a 3-fold (P<001) increase in expression of cytosolic G3P dehydrogenase (G3PD1) in BMS cells derived from *sfx* mice. The expression levels of G3PD1 but not G3PD2 increased by 20-fold during *in vitro* differentiation of BMS cells into OBs in the presence of AA. Conclusions: 1) The *sfx* mouse has a mutation of the GULO gene, which leads to AA deficiency, impaired OB cell function and fractures in the affected mice; 2) AA may be required for ATP production, OB differentiation via a G3P shuttle; and 3) Adequate vitamin C uptake may be critical in attaining and maintaining peak BMD in humans as they lack GULO gene and are therefore completely dependent on diet for vitamin C.

Adipose Tissue Is a Negative Independent Predictor of Cortical Bone Size in Non-Weight Bearing Bones in Young Men; an Association Mediated by Leptin - *The GOOD Study*. M. Lorentzon, S. Movérare Skrtic, D. Mellström, C. Ohlsson. Center for Bone Research at the Sahlgrenska Academy, Departments of Internal Medicine and Geriatrics, Gothenburg University, Gothenburg, Sweden.

Adipose tissue (AT) is believed to exert a stimulatory effect on bone mass acquisition primarily due to increased mechanical loading on the bones. Due to the limitations of the DXA technique, the association between AT, leptin and volumetric BMD (vBMD) and size of the different bone compartments, i.e. cortical and trabecular bone, remains unknown. The aim of this study was to determine the role of AT and leptin as independent predictors of cortical bone size in weight bearing and non-weight bearing bones. We measured the cortical bone size and vBMD (at the diaphysis), trabecular vBMD (at the metaphysis) of the radius and tibia (pQCT), total body lean mass (DXA), total body AT (DXA), and serum leptin levels in 1068 men (age 18.9±0.6 yrs) included in the *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study. A multiple linear regression model, including age, height, total body lean mass, present physical activity, calcium intake, smoking, and total body AT, was used to determine the independent predictors of cortical bone size as well as cortical and trabecular vBMD of the non weight bearing radius and the weight bearing tibia. Total body AT was a negative independent predictor of cortical bone size (cortical cross sectional area (CSA): $\beta=-0.09$, $p<0.001$, and periosteal circumference (PC): $\beta=-0.07$, $p<0.01$) of the radius but a positive independent predictor of the cortical bone size of the tibia (cortical CSA: $\beta=0.06$, $p<0.01$, and PC: $\beta=0.08$, $p<0.001$). When leptin was added to this multiple regression model, leptin was found to be a negative independent predictor of the cortical CSA of both the radius ($\beta=-0.07$, $p=0.04$) and tibia ($\beta=-0.06$, $p=0.048$). Serum leptin levels were not associated with cortical or trabecular vBMD of the radius or tibia. After adding leptin to the multiple linear regression model, total body AT was no longer a negative independent predictor of any parameter of cortical bone size of the radius, but was still a positive independent predictor of the cortical bone size of the tibia, suggesting that leptin is a mediator of the negative association between adipose tissue and cortical bone size of the non-weight bearing bone. The present findings suggest that AT exerts a positive effect on cortical bone size in bones subjected to mechanical loading, while it influences cortical bone size negatively in the non-weight bearing bone. Our data indicate that the negative role of AT on cortical bone size of the non-weight bearing bone is mediated via serum leptin levels.

Regulation of Bone Formation by Adiponectin through Autocrine/ Paracrine and Endocrine Pathways. Y. Shinoda*, M. Yamaguchi*, N. Ogata, T. Akune, T. Kadowaki*, Y. Takeuchi, S. Fukumoto, K. Hoshi, U. Chung, K. Nakamura, H. Kawaguchi. Orthopaedic Surgery and Internal Medicine, University of Tokyo, Tokyo, Japan.

Accumulated evidence has shown that there is a common regulation of bone and adipose tissues. Leptin, a representative adipokine, has been reported to be a powerful inhibitor of bone formation. The present study investigated the regulation of bone metabolism by adiponectin, another representative adipokine, that is known to increase the sensitivity to insulin. We initially found by RT-PCR analysis that adiponectin and its receptors AdipoR1 and AdipoR2, but not leptin, were expressed in mouse calvarial primary osteoblasts (POB), M-CSF-dependent bone marrow macrophages, and osteoclasts, indicating that adiponectin can act on bone through an autocrine/paracrine pathway as well as an endocrine pathway. We then generated adiponectin-deficient (Ad-/-) mice and investigated the role of adiponectin in bone. These mice developed and grew normally, and showed no abnormality in bone mass or turnover as determined by radiological and histomorphometric analyses, implying an equivalent balance of the pathways above. In the cultures of POB derived from the Ad-/- mice, osteogenesis determined by ALP and Alizarin red stainings, but not osteoclastogenesis determined by TRAP staining, was markedly decreased compared to that in the wild-type culture, indicating a positive action of endogenous adiponectin through the autocrine/paracrine pathway on bone formation. To examine the endocrine action, we added recombinant adiponectin in the cultures of POB and marrow cells, and found that the direct action inhibited osteogenesis. However, in the presence of insulin or IGF-I, potent stimulators of bone formation, immunoprecipitation and immunoblotting analyses revealed that recombinant adiponectin enhanced the insulin/ IGF-I-induced phosphorylation of IRS-1 and Akt, the main signaling molecules, suggesting indirect stimulation on bone formation. We then examined the endocrine action in vivo by generating transgenic mice that overexpressed adiponectin driven by the serum amyloid P component promoter, so that the expression was limited to the liver. The mice showed no abnormality in bone mass or turnover, possibly due to an equivalent balance of the direct and indirect actions of circulating adiponectin. The lines of results indicate that adiponectin regulates bone formation in three distinct pathways: a positive action through the autocrine/paracrine pathway by locally produced adiponectin, a negative action through the direct pathway by circulating adiponectin, and a positive action through the indirect pathway by circulating adiponectin that enhances the insulin/IGF-I signaling.

Effects of Central Leptin Gene Therapy on Weight Reduction and Cancellous Bone Mass in Female Rats. U. T. Iwaniec, S. Boghossian*, M. G. Dube*, R. Torto*, R. R. Arzaga*, T. J. Wronski, S. P. Kalra*. University of Florida, Gainesville, FL, USA.

Obesity is one of the fastest-growing health problems worldwide, not only in adults but in children as well. Central leptin gene therapy (the delivery of the leptin gene into the hypothalamus for a sustained supply of the hormone in the brain) has the potential for long-term control of obesity as it has proven very effective in preventing age-associated increases in body weight in rats fed normal and high-fat diets. However, as hypothalamic administration of leptin has been shown to decrease bone mass in mice, osteopenia constitutes a potential adverse side-effect of leptin gene therapy. The objective of this study was to evaluate the effects of centrally administered, recombinant adeno-associated virus-leptin (rAAV-lep) gene therapy on bone in rapidly growing and sexually mature female Sprague-Dawley rats. Three-week old rats were implanted with cannulae in the 3rd ventricle and injected with either rAAV-lep (n=10) or rAAV-GFP (control vector encoding green fluorescent protein, n=10) and maintained on standard rat chow fed *ad lib* for 43 weeks. Proximal tibiae were then collected and processed for cancellous bone histomorphometry. rAAV-lep administration evoked a sustained decrease in body weight gain (33-35% lower in rAAV-lep than in rAAV-GFP rats) throughout the course of the experiment (Pediatr. Res. 52:189-98). At 43 weeks post-vector injection, cancellous bone

volume was 37% lower in rAAV-lep rats than in the rAAV-GFP rats (20±2.0% vs. 12.5±1.0%, mean±SE). In order to determine if similar changes were observed in sexually mature animals, 12-week old rats were implanted with cannulae and injected with either rAAV-lep or rAAV-GFP (4-6 rats/group). In the 1st experiment, the rats were maintained for 5 weeks, in the 2nd for 10 weeks, and in the 3rd for up to 86 weeks post-vector administration. Despite weight reductions of approximately 15% in rAAV-lep rats in comparison to rAAV-GFP rats at 5 and 10 weeks post-vector injection, significant differences in cancellous bone volume were not detected between the rAAV-lep and rAAV-GFP groups at either time point. In the 86-week study, a reduced body weight was maintained in the rAAV-lep in comparison to the rAAV-GFP rats for the duration of the experiment. However, significant differences in cancellous bone volume were likewise not detected between the two groups at termination of the study. We conclude that leptin gene therapy in rapidly growing rats results in sustained reductions in body weight as well as reduced peak bone mass. These data, however, suggest that increased hypothalamic leptin levels do not induce significant cancellous bone loss in adult female rats.

Continuous PTH Treatment Causes Bone Loss through Upregulated T Cell Localization to the Bone Surfaces. X. Wu, W. Qian*, M. Ryan, K. Page*, X. Yang*, F. Grassi, N. Weitzmann, R. Pacifici. Emory University, Atlanta, GA, USA.

PTH is known to stimulate osteoclast (OC) formation and activity but the involved mechanism is unknown. We have investigated the novel hypothesis that continuous PTH treatment causes bone loss by inducing T cells to secrete osteoclastogenic cytokines. 10 week old WT Bl6 mice, T cell deficient nude mice and nude mice subjected to T cell reconstitution by adoptive transfer of WT T cells one week before the initiation of the study, were treated with hPTH1-34 (40 μg/kg/day) delivered by sc osmotic pumps for 4 weeks. Weekly BMD measurements by PIXImus revealed that PTH caused a significant bone loss in WT mice and (- 5.2 %, $p<0.05$) in T cell replete nude mice (- 5.7 %, $p<0.05$), but not in T cell deficient mice (- 0.4 %, p = ns). In contrast, no significant bone loss was observed in all groups of intact mice or mice treated with vehicle. PTH also caused a significant increase in serum levels of CTX, a marker of bone resorption in WT mice and (20.7 % compared to baseline) in T cell replete nude mice (96.0 %,compared to baseline), but not in T cell deficient mice (0.5 % compared to baseline). No changes in CTX were observed in control groups. In a second experiment in which mice were treated with hPTH1-34, 80 μg/kg/day for 2 weeks. T cell deficient nude mice were completely protected against the increase in bone resorption and the bone loss induced by PTH. Furthermore, measurements of cortical vertebral bone volume (CBV) by μCT in samples harvested at sacrificed revealed CBV to be 8.4 % lower in WT mice treated with PTH as compared to WT intact mice and WT mice treated with vehicle. In contrast, all groups of T cell deficient nude mice had similar CBV values. Thus, the catabolic effect of PTH is mediated by T cells. Staining of longitudinal diaphyseal bone sections for TRAP (an OC marker) and CD3 (a T cell marker) revealed that in control mice T cell were concentrated in the endosteal BM region. In vehicle treated mice the endosteal BM area occupied by T cells was 3 fold higher along OC covered endosteal surfaces than naked surfaces, suggesting that T cells promote physiologic OC renewal. In contrast, after 2 weeks of PTH treatment, a time when new OC had already formed, the endosteal BM area occupied by T cells was only 1.4 fold higher along OC covered endosteal surfaces than along naked surfaces. These preliminary data suggest that T cells migrated to new areas where OC had yet to form. In summary, the finding that T cell mediates the catabolic effect of PTH on bone provides a new paradigm for T cells as an essential target of PTH in bone. The data also suggest that PTH induces bone loss by favoring the localization of T cells to endosteal surfaces available for remodeling.

Deletion of the Mid- and Carboxyl Regions of PTHrP Produces Growth Retardation and Early Senescence in Mice. D. Miao, H. Su*, B. He*, J. Gao, Q. Xia*, D. Goltzman, A. C. Karaplis. Medicine, McGill University, Montreal, PQ, Canada.

Previous studies have demonstrated the important biological role played by the NH_2-terminal end of PTHrP by interacting with the common PTH/PTHrP receptor. Other studies have suggested roles for the mid-region and carboxyl ends of the molecule in calcium and skeletal homeostasis. We and others have previously shown nuclear localization of PTHrP in multiple cell types and we previously identified a functional nucleolar localization sequence within the 87 to 107 region of the molecule. In the present study we examined the function of the mid- and carboxyl- regions ("C-terminal") of PTHrP *in vivo* by inserting a premature termination codon in the PTHrP gene and creating a "knock-in" (KI) mouse expressing PTHrP (1-84). Immunocytochemistry in mouse embryonic fibroblasts (MEFs) confirmed the absence of C-terminal PTHrP and the presence of N-terminal protein. Newborn PTHrP KI mice were morphologically normal but slightly smaller than wild-type littermates. Post-natally, however, KI mice failed to grow normally and developed an unstable gait, cachexia, reduced fat deposition, thin skin with hyperkeratosis of the epidermis, and osteoporosis. KI mice did not survive past 2 to 3 weeks of age. Serum calcium and PTH concentrations were normal. Skeletal growth retardation resulted from a reduction in both chondrocyte proliferation and differentiation and premature osteoporosis was caused by reduced osteoblastic bone formation in both trabecular and cortical bone associated with decreased expression of Cbfa1, alkaline phosphatase, type I collagen and osteocalcin. The proliferation of bone marrow cells was decreased in KI mice as demonstrated by BrdU incorporation and flow cytometry. Apoptotic cells in thymus and spleen were increased as demonstrated both by TUNEL assay and annexinV/propidium iodide staining. Increased expression of the senescence marker β-galactosidase was observed in tubules of the renal cortex of KI mice and both MEFs and tissues demonstrated markedly increased expression of senescence-associated tumor suppressor genes such as $p16^{INK4a}$. These results indicate that the C-terminal region of PTHrP exerts an important role in stimulating cell proliferation and preventing apoptosis by regulating tumor suppressor genes such as $p16^{INK4a}$ in a variety of tissues and that its absence produces a syndrome of early senescence.

Neurofibromin (Nf1) through its Expression in Osteoblasts, Controls Bone Formation and Bone Resorption. F. Elefteriou[1], D. M. Benson*[2], X. Liu*[3], L. Parada*[2], G. Karsenty[3]. [1]Cellular and Structural biology, UT Heath Science Center at San Antonio, San Antonio, TX, USA, [2]Center for Developmental Biology, University of Texas Southwestern Medical Center, Dallas, TX, USA, [3]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

Type I Neurofibromatosis (NF1) is an autosomal dominant disease caused by loss of function mutations in the tumor suppressor gene *Nf1* and that affects multiple organs. Patients affected by NF1 display, among other pathological conditions, bone abnormalities that include macrocephaly, scoliosis/kyphosis, pectus excavatum, and tibial pseusoarthroses, suggesting that neurofibromin, the product of the *Nf1* gene, is involved in bone development and/or homeostasis. To address the role of *Nf1* in osteoblasts, we crossed mice bearing a floxed allele of *Nf1* with transgenic mice expressing *Cre-recombinase* under the control of the osteoblast-specific *alpha1(I) collagen* promoter fragment to generate a mouse model of osteoblast-specific *Nf1* deletion ($Nf1_{ob}$-deficient mice). $Nf1_{ob}$-deficient mice were born at a normal mendelian ratio without gross anatomical abnormalities, thus excluding that *Nf1* plays an important role during bone development. In contrast, histomorphometric analyses revealed that absence of *Nf1* in osteoblasts resulted in an increase in bone mass and osteoid surface and volume as a result of an increase in the bone formation rate. These bone abnormalities were not accompanied by any mineral ion abnormalities. In agreement with these observations, *Nf1*-deficient osteoblasts synthesized more collagen and formed larger colonies than wild type (WT) osteoblasts *in vitro*. Altogether, these results indicate that neurofibromin regulates osteoblast proliferation and functions and thereby bone mass. In addition, bone resorption parameters such as the number of differentiated osteoclasts and the elimination of urinary deoxypiridinoline were increased in $Nf1_{ob}$-deficient mice compared to WT mice. An osteoblast/osteoclast co-culture assay revealed that *Nf1*-deficient osteoblasts supported osteoclast differentiation markedly better than WT osteoblasts, indicating that *Nf1* deletion in osteoblasts is responsible for the increase in bone resorption observed in $Nf1_{ob}$-deficient mice. Molecular analyses by real-time PCR using isolated populations of WT and *Nf1*-deficient osteoblasts revealed that *Rankl* expression was significantly up-regulated in *Nf1*-deficient osteoblasts. Thus, osteoblast-specific deletion of *Nf1* reveals that neurofibromin is a potent regulator of both arms of bone remodeling. Ongoing studies aiming at identifying the signaling pathways downstream of *Nf1* in osteoblasts will be presented at the meeting.

T-Cell Factor, Schnurri-2, Enhances Osteoblastic and Osteoclastic Function *In Vivo* as a Novel Transcriptional Modulator to Be Involved in Coupling in Bone Remodeling via its Link to BMP and RANKL Signaling. Y. Saita[1], T. Takagi*[2], K. Kitahara[1], M. Usui[1], Y. Ezura[1], K. Nakashima[1], H. Kurosawa*[3], S. Ishii*[2], M. Noda[1]. [1]Molecular Pharmacology, 21st COE Program, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Laboratory of Molecular Genetics, RIKEN Tsukuba Institute, Ibaraki, Japan, [3]Orthopedics, Juntendo University, School of Medicine, Tokyo, Japan.

Schnurri-2(Shn-2) is a large zinc finger protein, required for positive selection of thymocytes and for regulation of type 2 T helper cell differentiation via competitive binding to a consensus NFkB motif to inhibit promoter activity. Although immune systems and skeletal systems share critical signalings, little is known regarding the function of a Shn-2 in bone. Therefore we examine the function of Shn-2 in bone. Bone mineral density and bone mineral contents in long bones were significantly reduced in 12wk old Shn-2 knock out mice. Shn-2 deficiency also reduced cortical bone mass. The histomorphometrical analysis indicated Shn-2 deficiency suppressed mineral apposition rate and bone formation rate in cortical bone as well as cancellous bone. Furthermore RT-PCR analysis of the RNA taken from the long bone indicated that Shn-2 deficiency suppressed the levels of osterix as well as osteocalcin mRNA. Overexpression of Shn-2 in MC3T3E1 osteoblastic cells enhanced osteocalcin promoter activity. Interestingly Shn-2 enhanced the levels of a luciferase reporter expression via BMP response elements 12×GCCG as well as TGF-β response elements 3TP luciferase. In the presence of BMP or TGF-β, Shn-2 enhanced the GCCG or 3TP-luc activities more than BMP or TGF-β alone. TGF-β treatment enhanced Shn-2 gene expression in osteoblastic MC3T3E1 cells suggesting the presence of positive feedback. Similar to the suppression in osteoblastic activity in Shn-2 deficient mice, Shn-2 deficiency suppressed the number of osteoclasts in vivo. Osteoclastogenesis in vitro using bone marrow cells were also impaired in the absence of Shn-2. In RAW264.7 mouse monocytic cells, Shn-2 expresses at the basal state and treatment of RANKL enhanced the expression level of Shn-2. Thus, Shn-2 is an activator in both osteoblasts and osteoclasts. Interestingly trabecular bone volume was slightly increased in Shn-2 deficient mice, suggesting that reduction in osteoblastic activity

in Shn-2 deficient mice appears to be less than the reduction in osteoclastic activity. Overall, our data indicated that Shn-2 has the key role in the activation of both osteoblasts and osteoclasts and thus playing a pivotal role in each of the bone formation and bone resorption to be responsible for maintenance of coupling events in bone remodeling.

The RUNX2 Transcription Factor Regulates Ribosomal RNA Gene Expression for Osteoblast Growth and Differentiation. D. W. Young, M. Galindo*, X. Yang*, J. Underwood*, J. Pratap, J. L. Stein*, J. B. Lian, J. A. Nickerson*, A. J. van Wijnen, G. S. Stein. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

Skeletal development as well as osteoblast cell growth and function require stringent control of ribosomal biogenesis. Genetic alterations that deregulate ribosome production (e.g., Treacher Collins Syndrome) result in craniofacial bone defects and growth retardation. Here we investigated whether ribosomal RNA biosynthesis is regulated by the bone-related RUNX2 transcription factor that controls the proliferative potential of osteoprecursors and osteogenic lineage commitment. We find that reduction of Runx2 levels in human Saos-2 cells by siRNA activates rRNA transcription, indicating that ribosomal gene production is indeed Runx2 responsive. Furthermore, a bioinformatics analysis reveals the presence of multiple Runx binding elements within regulatory regions of rRNA genes. We therefore performed chromatin immunoprecipitation (ChIP) analysis and establish that Runx2 directly associates with ribosomal RNA genes. Both immunofluorescence and immunoelectron microscopy reveal that a subset of Runx2 is localized to nucleoli where ribosomal genes reside and ribosomal biogenesis occurs. Interestingly, we find that during the mitotic silencing of gene expression Runx2 is localized at chromosomal foci that are associated with active chromatin at nucleolar organizing regions and co-localize with the RNA polymerase I transcription factor, Upstream Binding Factor (UBF1). Using cell synchronization strategies and ChIP assays, we demonstrate that the association of Runx2 with rDNA is a cell cycle regulated process that is modulated during the mitosis to G1 and G0/G1 transitions. Functional linkage between Runx2 and ribosomal gene expression is further established by enhanced ribosomal RNA synthesis in primary cells isolated from the calvarial tissue of Runx2 null mice compared with wild-type Runx2 counterparts. Notably, induction of Runx2 in uncommitted mesenchymal cells directly represses ribosomal biogenesis, and this repression of ribosomal gene expression by Runx2 is associated with cell growth inhibition and expression of osteoblast-specific genes. Taken together our findings establish that Runx2 not only controls osteoblast lineage commitment, but also acts as a suppressor of cell growth by inhibiting rRNA synthesis. Our findings elucidate a novel mechanism by which ribosomal biogenesis is coordinately controlled by the Runx2 transcription factor to support osteoblast differentiation and skeletal development.

Fibronectin Serves as an Essential Template for Assembly of Multiple Bone Matrix Proteins, and Is Essential for TGF-β Deposition, Matrix Stability, and Normal Mineralization. Q. Chen[1], P. Sivakumar[1], J. Zhao*[1], B. J. Rongish*[2], A. Czirok*[2], V. Dusevich*[1], M. R. Dallas*[1], D. M. Peters*[3], D. F. Mosher*[3], S. L. Dallas[1]. [1]Univ. of Missouri, Kansas City, MO, USA, [2]Univ. of Kansas Med Cntr, Kansas City, KS, USA, [3]Univ. of Wisconsin, Madison, WI, USA.

Fibronectin (FN) is an extracellular matrix (ECM) glycoprotein important for cell adhesion, migration and matrix assembly. Disruption of fibronectin in primary osteoblasts impairs mineralization. To gain further insight into the role of FN in bone, we have performed dynamic imaging of ECM assembly in living osteoblasts and have used fibroblasts from E6.5 FN-null embryos as a FN deficient cell model. When differentiated with BMP2, these cells express terminal osteoblast markers, yet fail to mineralize without addition of exogenous FN. We hypothesized that FN regulates mineralization by controlling assembly and stability of multiple bone ECM molecules. Immunostaining showed that type I collagen, fibrillin-1, latent TGFβ binding protein 1 (LTBP1), decorin, biglycan and perlecan were initially colocalized with FN. Assembly of these ECM components was severely impaired in FN null cells, as shown by immunostaining, TEM and Western blotting, even though synthesis/secretion was unaffected. We also found an 80% reduction in TGFβ1 deposition into the ECM of FN null cells. Rescue experiments showed that mineralization, assembly of bone ECM components and TGFβ deposition were rescued by full length FN but not by FN fragments that do not form fibrils, including a 160kDa RGD-containing fragment. This suggests that integrin signaling alone is insufficient to rescue these pathways. Although optimal mineralization occurred when FN was continually present, the critical period was between days 6 and 10. Dynamic imaging in living osteoblasts using fluorescent probes to ECM molecules showed that the ECM fibrillar networks were highly dynamic. Not only was FN required for initial assembly of these ECM proteins, but the continued presence of FN was required for their continued assembly and to maintain matrix stability. When FN null cells were grown on a preformed matrix or overlayed with a collagen gel, mineralization was rescued, suggesting that the key event for mineralization is collagen deposition. Sequential assembly of bone ECM components was suggested by studies with Mov13 cells lacking α1(I) collagen. Assembly of fibrillin-1, LTBP1, perlecan and decorin was normal in these cells but biglycan was impaired. These data suggest that a major mechanism by which FN controls mineralization is by orchestrating the sequential assembly of multiple bone ECM components, maintaining ECM stability and regulating incorporation of growth factors, such as TGFβ, into bone matrix.

MRI Based Virtual Bone Biopsy Detects Large One-Year Changes in Trabecular Bone Architecture of Early Postmenopausal Women. G. A. Ladinsky*, B. Vasilic*, A. M. Popescu*, B. Zemel*, A. C. Wright*, H. K. Song*, P. K. Saha*, H. Peachy*, P. J. Snyder*, F. W. Wehrli. University of Pennsylvania, Philadelphia, PA, USA.

Estrogen depletion following menopause is accompanied by bone loss and architectural deterioration of trabecular bone (TB); hormone replacement therapy (HRT) protects against such bone loss. Here we provide an update on preliminary data from the first *in vivo* detection of such skeletal changes in an ongoing study involving early postmenopausal women, half of whom are getting HRT and half of whom are not (controls). Images of the distal radius and tibia were acquired by means of a MRI-based virtual bone biopsy at 137x137x410 μm^3 voxel size with bone volume fraction maps generated using subvoxel processing to yield a final voxel size of 62x62x103 μm^3. These images were then binarized, skeletonized and subjected to 3D digital topological analysis (DTA). Skeletonization converts rods to curves and plates to surfaces. Parameters quantifying scale included BV/TV and Tb.Th while DTA parameters included the volume densities of curve voxels (CURV), surface voxels (SURF) and profile edges (PE, ends of structures intermediate between surfaces and curves) and composite parameters included the surface/curve ratio (S/C) and erosion index (EI, ratio of parameters expected to increase with osteoclastic resorption divided by those expected to decrease). Images were collected at baseline and 11-13 months with preliminary results presented for 29 control and 17 HRT subjects that afforded images of adequate quality. Scale parameters at the tibia were not significant while DTA parameters PE, CURV, S/C, EI provided highly significant changes (P<0.0001-0.003) ranging from 8.0 to 9.5% in control subjects but little or no significant change was observed in the HRT group. Similarly, DEXA BMD in the spine (hip) decreased 2.7% (1.4%) in controls (P<0.0001-0.001) (though less than DTA parameters) but not in HRT subjects. These findings, not previously observed *in vivo*, are consistent with the known protective effects of HRT ensuring maintenance of a more plate-like TB architecture. This work suggests that MRI-based *in vivo* micromorphometry of trabecular bone shows promise as a tool for monitoring osteoporosis treatment. (Sponsors: NIH R01AR41443, T32DK07006 & Novartis)

Finite Element Biomechanical Analysis of the PTH and Alendronate (PaTH) Study: PTH Increases Vertebral Strength by Altering both Average Density and Density Distribution. D. M. Black[1], R. P. Crawford*[2], L. Palermo*[3], J. P. Bilezikian[4], S. Greenspan[5], T. M. Keaveny[6]. [1]UC San Francisco, San Francisco, CA, USA, [2]O.N. Diagnostics, LLC, Berkeley, CA, USA, [3]Epidemiology and Biostatistics, UC San Francisco, San Francisco, CA, USA, [4]Columbia University, New York, NY, USA, [5]University of Pittsburgh, Pittsburgh, PA, USA, [6]Mechanical Engineering and Bioengineering, UC Berkeley, Berkeley, CA, USA.

QCT-based finite element models biomechanically integrate all information in the QCT scans to provide measures of bone strength (Biomechanical CT or BCT). In this pilot study, we applied BCT to measure changes in vertebral strength in 20 randomly selected post-menopausal women treated with PTH (1-84) 100mcg sq daily for one year in the PaTH study, a randomized trial comparing PTH or alendronate alone and together. We also measured strength changes in the trabecular region by virtually "peeling away" the outer 2 mm of each vertebra (which includes the cortex), and also quantified the role of intra-vertebral density variation by virtually removing such variations. The results for areal spine BMD (DXA), volumetric density (QCT) and BCT are shown below. On average, PTH increased overall vertebral strength by almost 30% at one year. The strength of the trabecular region was increased by almost 50% more than overall vertebral strength. When all densitometric variations within each vertebra were virtually removed, vertebral strength increased by only 15%, about half the total increase in strength. Taken together, these results indicate that about half the overall increase in vertebral strength can be attributed to an *average* increase in bone density, and the remaining half of the effect is due to alterations in the *distribution* of bone density within the vertebra. This is the first study to use BCT clinically to investigate longitudinal changes in bone strength during treatment

for osteoporosis. BCT provides insight into the biomechanical implications not only of changes in overall bone density but also in changes in density distribution after PTH administration to human subjects. These biomechanical strength effects of the treatment are not appreciated by DXA or QCT alone.

	Baseline	12 Month	% Change
BMD L1-L4 (g/cm^2)	0.79 ± 0.12	0.84 ± 0.13	6.9 ± 5.0
QCT integral density (g/cm^3)	0.14 ± 0.02	0.16 ± 0.03	14.9 ± 13.0
QCT trabecular single slice (g/cm^3)	0.80 ± 0.02	0.10 ± 0.03	27.4 ± 28.4
BCT vertebral strength (N)	4521 ± 1042	5715 ± 1335	28.8 ± 25.9
BCT trabecular strength (N)	2234 ± 665	3084 ± 978	42.4 ± 38.2
BCT strength averaged-density (N)	3322 ± 523	3806 ± 600	15.4 ± 13.8

*all % changes (mean ± SD) were significant (baseline vs. 12 month, p<0.05).

Bone Mineral Density (BMD) Measurement and Prediction of Fractures in Older Women: Is More Better? T. A. Hillier[1], K. L. Stone[2], J. R. Rizzo*[1], K. L. Pedula*[1], J. A. Cauley[3], M. Hochberg[4], S. R. Cummings[2]. [1]Center for Health Research, Kaiser Permanente, Portland, OR, USA, [2]San Francisco Coordinating Center, CPMC Research Institute and UCSF, San Francisco, CA, USA, [3]U of Pittsburgh, Pittsburgh, PA, USA, [4]U of Maryland, Baltimore, MD, USA.

Whether repeat BMD measurement adds additional benefit beyond the initial BMD measurement in prediction of non-traumatic fractures in older women is unknown. We measured total hip DXA BMD in 4,124 participants in the Study of Osteoporotic Fractures with a mean age of 72 years (SD 4) in 1989-90, and 8 years later (Hologic 1,000). We validated incident non-traumatic hip and non-spine fractures by radiology reports during 5 years of >98% follow-up. In addition, 2,193 of these women had lateral spine x-rays in 1991-2, then 6.5 years later. Incident spine fractures were defined morphometrically by >20% and at least 4 mm decrease in vertebral height at any level. We analyzed the association between fractures and (a) Initial (iBMD), (b) Follow-up BMD (fuBMD), (c) iBMD plus change between i and fu BMD (i+chgBMD). After the fuBMD measurement, 877 women suffered an incident non-traumatic non-spine fracture, 275 of which were hip fractures. In addition, 345 women developed a morphometric spine fracture. After adjustment for age and weight change, the risk of incident fracture was similar with either iBMD or fuBMD (per unit SD decrease in total hip) in prediction of non-spine (HR 1.5-1.6), spine (OR 1.7-1.8), or hip fracture (HR 2.0-2.2), p<0.001 for all models. Receiver-operator characteristic (ROC) curves revealed similar area under the curve (AUC) in fuBMD or i+chgBMD compared to initial BMD for non-spine fractures (0.65 for all models), spine fractures (0.67-0.68), or hip fractures (0.73-74;Figure). Further stratification by initial BMD group t-score (normal, osteopenic, osteoporotic) did not reveal much improvement in AUC for the repeat BMD measure compared to the initial BMD. Our results indicate, that for the average older post-menopausal woman age 65 or older, repeat BMD measurement may provide little additional benefit in predicting osteoporotic fractures beyond the initial BMD.

Growth in Infancy and Childhood Predicts Hip Fracture Risk in Late Adulthood. M. K. Javaid[1], J. G. Eriksson*[2], T. Forsen*[2], E. Kajantie*[2], C. Osmond*[1], D. J. P. Barker*[1], C. Cooper[1]. [1]Bone and Joint, MRC ERC Southampton, Southampton, United Kingdom, [2]Diabetes and Genetic Epidemiology, The National Public Health Institute, Helsinki, Finland.

Peak bone mass has been shown to account for up to 60% of the variation in adult bone mass. We have previously demonstrated that poor late childhood growth predicts adult hip fracture. We now wish to further explore the relationship with early childhood growth and adult fracture risk, and test to what extent this is mediated by differences in proximal femoral densitometry. Maternity, school and welfare records were electronically linked with hospitalization and mortality records in Helsinki, Finland, and 8,760 individuals (4,130 women) born in the University Central Hospital Helsinki between 1934-1944 were identified. These individuals all had birth weight and length recorded as well as weight and height at varying intervals during infancy and while at school. Hip fractures were identified from the hospitalization and mortality records using ICD-10 codes. In a sub-sample, 190 women with complete birth, infant and childhood records underwent DXA of the lumbar spine and proximal femur using a Hologic QDR 4500 DXA instrument. From the 8,760 individuals identified, 6,101 (2,825 women; mean age 56 yr (SD 4.4yrs) had regular measurements available enabling growth curves to be derived. From these individuals, 31 hip fractures were identified. Of the childhood predictors of fracture risk, the standard deviate (z) score change in indices of body build (years 1-12) were strongly associated with adult hip fracture risk. Thus those in the lowest quarter of the distribution of weight (BMI) gain (z score change <-0.78) had a 6.4 fold increase in hip fracture risk (p=0.008) compared with those in the highest quarter of this distribution (z score change >+0.69). The increased risk was present in both men and women. In the sub sample of 190 women who underwent bone mineral measurement, an equivalent change in BMI z-score during childhood was only associated with 0.11 SD decrease in aBMD and 0.33 SD decrease in bone area at the proximal femur. We have been able to demonstrate that poor growth during early childhood is associated with an increased risk in hip fracture; however, the mechanism for this appears to be explained only in part by the association between measures of early growth and adult bone size and areal density.

Glutamine Repeat Mutations Define a New RUNX2 Related Syndrome with Decreased Femoral Neck BMD, Decreased Calcaneal Ultrasound and Increased Risk of Osteoporotic Fracture. A. Stephens*[1], J. Doecke*[1], S. H. Ralston[2], R. Prince[3], G. C. Nicholson[4], N. A. Morrison[1]. [1]School of Medical Science, Griffith University, Gold Coast, Australia, [2]Rheumatic Diseases Unit, University of Edinburgh, Edinburgh, United Kingdom, [3]Department of Endocrinology and Diabetes, University of Western Australia, Perth, Australia, [4]Department of Medicine, Geelong Hospital, University of Melbourne, Geelong, Australia.

RUNX2 is an essential transcription factor required for osteoblast differentiation and cartilage formation. Haplo-insufficiency of RUNX2 leads to cleidocranial dysplasia (CCD) a skeletal disorder characterized by gross skeletal dysgenesis. A notable feature of the RUNX2 protein is the polyglutamine and polyalanine (23Q/17A) domain coded by a repeat sequence. Such repeat sequences are subject to high mutation rates through strand slippage during replication. Since none of the known mutations causing CCD map in the glutamine repeat region, we hypothesised that Q-repeat mutations would exist at high frequency and may be related to a more subtle bone phenotype than the morphological abnormalities of CCD. We screened 3600 subjects derived from three normal populations for Q-repeat mutations. A total of 28 subjects were identified who were heterozygous for a wild type allele and were carriers of Q variants: (deletions 15Q, 16Q, 17Q, and extensions 30Q). 12 of the 28 Q variant carriers had osteoporotic fracture. BMD data were available for each of the populations and were expressed in the form of Z-scores around the appropriate age-adjusted mean. Collectively, Q-repeat variants presented with significantly decreased femoral neck BMD (p=0.0006) with an effect of -0.56SD in BMD attributable to a single copy of the Q-variant in the presence of a wild type allele. Broadband ultrasound attenuation (BUA) and speed of sound (SOS) measured in the calcaneus were available on 18 Q-variant subjects. Q-variants displayed significantly decreased BUA (p=0.006) with an effect of -0.65SD. To understand the mechanism via which the Q-repeat deletions and expansions were conferring decreased BMD and BUA, the transactivation function of the 16Q and 30Q alleles were analyzed using a RUNX2 reporter gene assay. 16Q and 30Q alleles were capable of transactivating target reporter plasmids but at levels significantly lower compared to wild type (23Q). Our analysis has identified a new class of functionally relevant RUNX2 variants in the Q repeat that influence BMD and fracture. Q-variants occur at the relatively high frequency ~0.8%, meaning that more than 2 million people in the US may be affected.

Chronic High-Dose Glucocorticoids Are Associated with Increased Cortical Bone Mass and Minimal Trabecular Deficits in Children with Nephrotic Syndrome. M. B. Leonard, R. M. Herskovitz*, K. M. Howard, J. M. Burnham, B. S. Zemel. Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Glucocorticoids (GC) suppress bone formation and impair growth. However, we recently reported that chronic high-dose GC therapy for childhood nephrotic syndrome (NS) was associated with increased whole body bone mineral content (BMC) and normal spine BMC, as measured by DXA (New Engl J Med, 2004). GC-induced obesity exerted a protective effect on BMC. The objective of this study was to use peripheral quantitative computed tomography (pQCT) to assess trabecular volumetric BMD (vBMD) and cortical dimensions in children treated with GC for NS. PQCT (Stratec XCT 2000) measurements of the tibia were obtained in 63 prevalent NS subjects (42M/21F) and 308 healthy controls (148M/160F), ages 5 to 21 yr. Trabecular vBMD was measured at the 3% distal site. Cortical BMC, periosteal (PERI) and endosteal (ENDO) circumferences, and cross-sectional moment of inertia (CSMI) were measured at the 38% mid-shaft. Height and BMI were converted to age and sex specific z-scores using national reference data. Sex-specific regression models were used to generate z-scores for trabecular vBMD relative to age and cortical measures relative to tibia length. NS subjects had lower height z-scores (-0.17 $\pm$ 0.81 vs. 0.23 $\pm$ 0.87, $p < 0.01$) and higher BMI z-scores (0.88 $\pm$ 1.01 vs.0.12 $\pm$ 0.89, $p < 0.0001$), compared with controls. PQCT results are summarized in the Table. Trabecular vBMD was marginally lower in subjects with NS ($p = 0.08$); on average, vBMD was at the 40th percentile for age in NS. Cortical BMC, PERI and CSMI were all significantly greater in NS compared with controls (all $p< 0.001$). Adjustment for BMI z-score eliminated the group differences in cortical dimensions, e.g. adjusted mean CSMI z-score = 0.25 (95% CI: -0.4, 0.53, $p = 0.09$) in NS. After adjustment for BMI z-score, trabecular vBMD was significantly lower in NS (mean z-score: -0.43; 95% CI -0.73, -0.12, $p < 0.01$), compared with controls. These pQCT data confirm that GC therapy is associated with marginal deficits in trabecular vBMD and significantly greater cortical BMC, periosteal dimensions and CSMI in children with NS. The GC-induced obesity ameliorated trabecular vBMD deficits and was associated with greater cortical BMC and dimensions. GC-induced obesity may counteract the suppressive effects of GC on bone formation.

pQCT Z-scores in Subjects with Nephrotic Syndrome and Healthy Controls

	Trab vBMD	Cortical BMC	Cortical PERI	Cortical ENDO	Cortical CSMI
Controls	0.00 $\pm$ 1.03	0.00 $\pm$ 0.99	0.00 $\pm$ 1.03	0.00 $\pm$ 1.06	0.00 $\pm$ 1.02

Polycystin-1: A Novel Mechanosensor in Osteoblast/Osteocytes Coupled to *Runx*2. Z. Xiao[1], S. Zhang*[1], J. Mahlios*[1], J. Calvet*[1], L. Bonewald[2], L. Quarles[1]. [1]University of Kansas Medical Center, Kansas City, KS, USA, [2]University of Missouri, Kansas City, MO, USA.

Osteocytes and osteoblasts are the key mechanotransducing cells in bone, but the molecular mechanisms mediating responses to mechanical strain are uncertain. Polycystin-1 (PC1), a transmembrane G-protein coupled receptor, functions as a putative flow-responsive mechanosensor complexed with polycystin-2 (PC2), a receptor-activated calcium channel, in renal epithelial cilia. Mutations of PKD1, the gene coding for PC1, cause autosomal dominant polycystic kidney disease (ADPKD). PC1 is also expressed in embryonic mesenchyme and neural crest tissues, which give rise to endochondral and intramembranous bone and mice lacking *Pkd1* have abnormal skeletogenesis. These observations raise the possibility that PC1 might be an important mechanosensor in the skeleton. To investigate the function of PC1 in bone, we evaluated *Pkd1*^{m1Bei} mice, which have an inactivating missense point mutation (T to G at 9248bp) that is embryonic lethal in homozygotes. Alizarin red and alcian blue staining of E14.5 and 15.5 *Pkd1*^{m1Bei} null embryos showed delayed calcification consistent with the reported role of PC1 in skeletal development. More importantly, we observed a 7% reduction in BMD of the femur as assessed by dual energy x-ray absorptiometry (DEXA) in 6-week-old *Pkd1*^{m1Bei} heterozygous mice, indicating that reduction of PC1 expression leads to osteopenia postnatally. To determine if PC1 and PC2 transcripts are expressed in osteoblasts and osteocytes, we performed RT-PCR with specific primers for PC1 and PC2 using RNA from MC3T3-E1 osteoblasts and MLO-Y4 osteocytes. We found that both PC1 and PC2 transcripts are highly expressed in both cell types. In addition, MC3T3-E1 and MLO-Y4 cells expressed transcripts for polaris, a protein present in cilia, consistent with the presence of cilia in osteoblasts/osteocytes. Activation of PC1 signaling can be achieved by overexpression of the C-terminus of PC1. To assess the function of PC1 on *Runx*2 promoter activity in osteoblasts, we transiently co-transfected MC3T3-E1 osteoblasts with two mouse C-terminal PC1 constructs, PC1-LT containing the C-terminal 222 aa of PC1 or PC1-HT containing the C-terminal 193 aa of PC1 and the 1.4 kb *Runx*2 P1 luciferase promoter/reporter construct. Overexpression of either PC1-LT or PC1-HT in this osteoblastic cell line resulted in a 3-4 fold increase of the P1 promoter activity of *Runx*2, an essential transcription factor controlling osteoblastogenesis. These findings suggest that PC1 is part of a mechanosensing complex in bone that allows osteoblasts/osteocytes to sense and transduce mechanical forces into anabolic cell signals leading to new bone formation.

Enhancement of Bone Formation by Small Molecule Compounds that Disrupt Dkk-LRP5/6 Interaction. P. Liu[1], Y. Zhang[1], X. Li*[2], J. Zheng*[3], D. Wu*[1]. [1]University of Connecticut Health Center, Farmington, CT, USA, [2]Enzo Biochem, Farmingdale, NY, USA, [3]St. Jude Hospital, Memphis, TN, USA.

Both human and mouse genetic evidence indicates that the canonical Wnt signaling has an important role in bone formation. Our study of the mechanism underlying the high bone mass mutation of Wnt coreceptor LRP5 (G171V) suggests that this mutation reduces Dkk1-mediated antagonism. This finding allows us to hypothesize that disruption of the interaction between LRP5 and Wnt antagonist Dkk may lead to an increase in bone formation. To identify small molecules that can disrupt the interaction, we used an innovated approach that combines structural and molecular biology, "*in silico"* virtual screening, and biological assays. We first mapped the Dkk-binding domain on LRP5 by using site-directed mutagenesis. Based on the deduced structure of this Dkk-binding domain, computer-based "*in silico*" virtual screening of small molecule compound libraries was performed. The first-round screen yielded 50 candidate compounds, and we were able to obtain 17 of them for testing their ability to inhibit Dkk binding to LRP5. Three of the compounds showed inhibitory effects on Dkk binding, and they share a common structural core. A second-round screening for compounds that contain this basic structural core was then carried out. We obtained and tested 19 of top ranked compounds and found that one of them (IIC8) was able to reverse Dkk-mediated inhibition of Wnt signaling at low uM concentrations. The third-round virtual screening was carried out based on the structure of IIC8 and yielded a compound (IIIC3) that can reverse Dkk-mediated antagonism of Wnt signaling at the high nM range. Both IIC8 and IIIC3 are able to block the binding of Dkk1-AP to LRP5 or LRP6. To test their effects on bone formation, IIC8 and IIIC3 were injected locally at mouse calvaria. Both compounds showed strong stimulatory effects on bone formation.

Severely Reduced Bone Mass with Defective Osteoblastogenesis in N-Cadherin Heterozygous/Cadherin-11 Null Double Mutant Mice. C. Donsante*, A. Di Benedetto*, G. Mbalaviele, R. Civitelli. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

We have previously shown that targeted expression of a dominant negative truncated form of N-cadherin (Ncad) delays acquisition of peak bone mass in mice and retards osteoblast differentiation. However, heterozygous Ncad$^{+/-}$ mice are normal (homozygous loss of Ncad is embryonically lethal) and cadherin-11 (Cad11) null mice are only modestly osteopenic. To determine the specific roles of the two major osteoblast cadherins, we introduced an Ncad null allele in a Cad11 null background to generate double Ncad$^{+/-}$/Cad11$^{-/-}$ mutant mice. These mice are viable, although they are obtained at lower than expected Mendelian frequency. Whole body bone mineral density by DEXA was significantly lower in the double mutants relative to both wild type (wt) and Cad11$^{-/-}$ mice, a difference detectable at 2 months and increasing with age (-10.1±6.3% and -12.6±6.4% vs. wt and Cad11$^{-/-}$, respectively at 6 months). Ncad$^{+/}$;Cad11$^{/}$ double mutants were also significantly smaller (body weight -20.7±10.5% and -19.7±10.6% vs. wt and Cad11$^{-/-}$) and had reduced percent body fat, after 2 months of age. Contact radiographs of isolated tibiae and femurs showed shorter length, rarefied trabecular pattern, cortical thinning and tubulation of diaphyses in Ncad$^{+/-}$/Cad11$^{-/-}$ relative to wt mice; while Cad11$^{-/-}$ bones were modestly osteopenic. Bone histomorphometry confirmed decreased bone mass (BV/TV: 14.6±4.8% vs. 11.4±3.1%) and osteoblast surface (ObPm/BPm: 35.3±11.5% vs. 14.8±7.2%) in the double mutants relative to wt mice, respectively, with no difference in osteoclast number. In vitro mineralization was reduced >50% in Ncad$^{+/-}$/Cad11$^{-/-}$ relative to wt calvaria cells, but it was actually slightly more intense relative to Cad11$^{-/-}$ osteoblasts. However, the number of colony forming units-fibroblasts isolated from the bone marrow of double mutants was reduced about 60% relative to both wt and Cad11$^{-/-}$ cells, suggesting a decreased number of mesenchymal stem cells in the double mutants. Finally, in association with decreased cadherin abundance, total and nuclear β-catenin was significantly reduced in post-confluent Ncad$^{+/-}$/Cad11$^{-/-}$ calvaria cells, and to a greater extent than in Cad11$^{-/-}$ cells, relative to wt. Thus, single Ncad allele loss in a Cad11 null background causes a far more severe osteopenic phenotype than either independent mutation, attended by defective osteoblastogenesis and reduced mesenchymal stem cell pool. Ncad and Cad11 serve overlapping, though not identical roles in development of peak bone mass, in part via modulation of β-catenin abundance.

Canonical Wnt Signaling Controls Osteoblast or Chondrocyte Differentiation from Mesenchymal Progenitor Cells during Skeletogenesis. T. F. Day*, X. Guo*, L. Garrett-Beal*, Y. Yang*. National Human Genome Research Institute, Bethesda, MD, USA.

Vertebrate skeletal development starts from mesenchymal condensations, from which chondrocytes and osteoblasts are differentiated. During intramembranous ossification mesenchymal progenitor cells differentiate directly into osteoblasts, whereas in endochondral ossification they first differentiate into chondrocytes. Since we found that the β-catenin mediated canonical Wnt signaling activity is upregulated in early osteogenic condensations, we tested whether the canonical Wnt signaling controls osteoblast and chondrocyte differentiation from mesenchymal progenitors during vertebrate skeletal development. Mice with a floxed β-*catenin* allele *(catnby*) were crossed with *Dermo1-Cre* to ablate β-*catenin* in

mesenchymal condensations prior to osteoblast and chondrocyte differentiation. The *catnby$^{c/c}$;Dermo1-Cre* mouse embryos exhibited ectopic chondrocyte differentiation at the expense of osteoblasts where osteoblasts normally differentiate during both intramembranous and endochondral ossification. To further test the function of canonical Wnt signaling in osteoblast and chondrocyte differentiation, we isolated mesenchymal cells from the *catnby$^{c/c}$* embryonic calvarium and limb buds at 12.5 dpc. Calvarial cells were cultured under osteogenic conditions whereas limb bud cells were used for micromass cultures. The cultures were infected by a *Cre*-adenovirus to inactivate β-*catenin*. Inactivation of β-*catenin* in calvarial cultures led to loss of bone nodules and ectopic cartilage nodule formation, while in micromass cultures cartilage nodule formation was greatly increased. These results indicate that the canonical Wnt signaling plays a decisive role in controlling chondrocyte versus osteoblast formation when mesenchymal progenitor cells differentiate. We then tested the interaction of Wnt/β-catenin signaling with other signaling pathways mediated by PI3K, BMP2 and FGF, which also regulate chondrocyte and osteoblast differentiation. BMP2 promoted osteoblast differentiation in wild-type calvarial cultures as well as chondrocyte differentiation in β-*catenin* inactivated cultures, whereas the BMP antagonist Noggin inhibited both bone and chondrocyte nodule formation in wild-type and β-*catenin* inactivated cultures respectively. In addition, the PI3K inhibitor LY294002 and FGF8 not only inhibited osteoblast differentiation in wild-type cells, they also inhibited chondrocyte differentiation in cells with inactivated β-*catenin*. This data indicates that the BMP, PI3K, and FGF signaling pathways act independent of the canonical Wnt pathway in controlling osteoblast and chondrocyte differentiation.

Adult Bone Marrow Derived Mesenchymal Stem Cell (MSC) Migration in Response to a Fracture Regeneration Cue. K. S. Shimer*[1], B. Landis*[2], L. O'Rear*[1], S. Aakula*[2], L. Longobardi*[1], D. Jansen*[3], H. Moses*[2], A. Spagnoli[1]. [1]Pediatrics, Vanderbilt University Medical Center, Nashville, TN, USA, [2]Vanderbilt University Medical Center, Nashville, TN, USA, [3]Biomedical Engineering, Vanderbilt University, Nashville, TN, USA.

The *in vivo* regenerative ability of MSC is a fascinating but still poorly understood process. Our understanding of MSC recruitment into damaged tissues is minimal because of the limitations of the systems used for tracking the donor cells into the recipient. To determine the recruitement capacity of systemically administered MSC to a fracture repair site we engineered MSC with a luciferase reporter (MSC-luc) and tracked the MSC-luc migration using bioluminescence imaging (BLI). MSC were cultured from the bone marrow of syngeneic FVB WT mice and infected during the exponential growth phase with an Adenovirus-firefly luciferase-green flourescent protein reporter (luc-GFP). Mice (age 8-12 weeks, n=3) tibias were pinned and fractured and MSC-luc-GFP were then injected into their tail veins. Fracture site was confirmed via CT imaging. Every day for a total of 7 days the mice were given an IP injection of luciferin followed by BLI. To quantify the MSC that migrated to the fracture site, we FACS sorted the MSC-luc-GFP positive cells. A serial dilution of MSC-luc-GFP were placed into a 6 well dish and BLI was performed after adding luciferin to each well to create a curve to correlate signal intesity with cell number. Due to the attenuating effects that tissues have on BLI signal intensity, a isotropic light-emitting bead was used to define an attenuation factor between *in vitro* and *in vivo* imaging signals. The skin over the fracture site was found to decrease the signal by 29.2%. When this attenuation factor was applied to our *in vivo* signal data and then correlated with the *in vitro* signal vs. cell number curve, we found that at least 4,787 ± 389 MSC ($p<0.05$) migrated to the fracture site and was significant compared to the contralateral unfractured leg. Longitudinal migration patterns revealed that MSC resided in the lungs for one day then moved to liver and brain on day 2. MSC dispersed on day 3 with no foci other then the brain and by day 4 were shown to migrate to the fracture site, where they resided for the time study period. Our data provides critical information about the real time migrational pattern of MSC in response to a fracture repair cue. In particular, we found that MSC travel through the capillary beds of lung, liver and brain before being recruited to the fracture site. Understanding MSC migration will help delineate the actual MSC dose in real time that migrates to the sites of injury. Further studies will determine if the strength of these healed fractures through biomechanical testing.

Administration of CD34-Positive Cells Contributes to Osteogenesis and Vasculogenesis for Functional Bone Healing. T. Matsumoto[1], A. Kawamoto*[1], R. Kuroda*[2], M. Ishikawa*[1], H. Iwasaki*[1], S. Lee[2], A. Oyamada*[1], K. Sadamoto*[1], M. Horii*[1], H. Nishimura*[1], S. Murasawa*[1], M. Kurosaka*[2], T. Asahara*[1]. [1]Stem Cell Translational Research, Kobe Institute of Biomedical Research and Inovation / RIKEN Center for Developmental Biology, Kobe, Japan, [2]Department of Orthopedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan.

Recently, neovascularization has been reported to play a critical role in the process of fracture healing. Adult human peripheral blood CD34+ cells, an endothelial/hematopoietic progenitor cell-enriched cell population, also have been reported to differentiate into osteoblasts in vitro over a decade ago. However, therapeutic potential of CD34+ cells for fracture healing is still unknown. We performed a series of experiments to prove a reasonable hypothesis that functional fracture healing may be supported by osteogenesis and vasculogenesis via regenerative plasticity of CD34+ cells. Peripheral blood CD34+ cells were isolated from total mononuclear cells (MNCs) of adult human volunteers using a magnetic cell sorting system. PBS, $1x10^5$ MNCs or $1x10^5$ CD34+ cells were intravenously transplanted after creating femoral fracture with the periosteum cauterizing of nude rats (n=12 in each group). Marked recruitment of CD34+ cells, not MNCs, labeled with Qdots were observed around fracture site by fluorescence microscopy at day seven. RT-PCR and immunohistochemical staining at the peri-fracture site demonstrated molecular and histological expression of human specific markers for endothelial cells (CD31, VE-cadherin) and osteoblasts (osteocalcin, collagen1A1) two weeks after CD34+ cell transplantation. Necropsy examination at week two disclosed augumentation of capillary density (CD34+, 1187.5±79.3; MNC, 562.5±36.6; PBS, 532.5±49.3/mm^2 respectively. $P<0.01$ for CD34+ vs MNC or PBS) and osteoblastic density (CD34+, 468.0±25.3; MNC, 321.6±28.8; PBS group, 141.6±14.0/mm^2 respectively. $P<0.01$ for CD34+ vs MNC or PBS). Frequency of fracture healing with the bridging callus assessed by radiological and histological examinations was 66% four weeks, and 100% eight weeks after CD34+ cell transplantation, while all fractures in other groups fell into nonunions at week eight. Biomechanical assessment by three point bending test at week eight revealed significantly functional healing by CD34+ cell transplantation compared to other groups. In conclusions, systemic administration of human peripheral blood CD34+ cells to immunodeficient rats subjected to femoral fracture induces osteogenesis as well as vasculogenesis in the peri-fracture zone and provides a favorable environment for bone healing and remodeling, followed by their functional recovery.

Chondrocytes Support Osteoclast Formation by Expressing RANKL, a Process Controlled by 1α, 25-dihydroxyvitamin D_3. R. Masuyama*, I. Stockmans*, S. Torrekens*, K. Moermans*, C. Maes*, R. Bouillon, G. Carmeliet. Laboratory of Experimental Medicine & Endocrinology, KUL, Leuven, Belgium.

1α, 25-dihydroxyvitamin D_3 (VD) is required for normal mineral and bone metabolism mainly by regulating active intestinal calcium transport after weaning. The vitamin D receptor (VDR) is however already expressed during early endochondral bone development. To investigate the function of VD in this process we generated mice with chondrocyte-specific inactivation of VDR by mating VDR$^{flox/flox}$ to transgenic mice expressing Cre-recombinase under control of collagen 2 (Ovchinnikov *et al. Genesis.* 2000). As a result, VD treatment of cultured epiphyseal chondrocytes induced Cyp24 gene expression only in VDR$^{flox/flox}$/Col2Cre$^-$ cells ($p<0.00005$, vs vehicle), but not in VDR$^{flox/flox}$/Col2Cre$^+$ chondrocytes. VDR$^{flox/flox}$/Col2Cre$^+$ mice were viable and showed normal growth. At 8 weeks, bone mass, measured by pQCT and histomorphometry, and dynamic bone parameters were similar between the genotypes. However, at pre-weaning stages (day15 and neonatal), histological analysis revealed an increased bone mass in VDR$^{flox/flox}$/Col2Cre$^+$ tibia ($p<0.036$), which was associated with decreased osteoclast surface to bone surface at day15 ($p<0.022$) and reduced osteoclast number at the growth plate in neonatal mice ($p<0.019$) compared to VDR$^{flox/flox}$/Col2Cre$^-$ mice. In addition, the initial invasion of blood vessels and osteoclasts in embryonic day (E) 15.5 tibia was delayed in the VDR$^{flox/flox}$/Col2Cre$^+$ mice. Length of mineralization after culturing E15.5 metatarsals for 4 days was significantly smaller in VDR$^{flox/flox}$/Col2Cre$^+$ mice. These data suggest that VD regulates in chondrocytes the expression of genes involved in osteoclast formation. Accordingly, VD (10^{-8}M) treatment increased RANKL gene expression 40 fold in primary epiphyseal chondrocytes derived from VDR$^{flox/flox}$/Col2Cre$^-$ mice, whereas this effect was lacking in VDR$^{flox/flox}$/Col2Cre$^+$ chondrocytes. Furthermore, TRAP positive multinuclear cells were formed when primary VDR$^{flox/flox}$/Col2Cre$^-$ chondrocytes were cocultured with splenocytes derived from either genotype and treated with VD but not when VDR$^{flox/flox}$/Col2Cre$^+$ chondrocytes were used. In conclusion, VDR expression in chondrocytes contributes to timely osteoclast formation during early endochondral bone development by regulating RANKL expression.

A RANK Cytoplasmic Motif, PFQEP$^{369-373}$, Plays a Predominant Role in Mediating Osteoclast Survival by Activating Akt and its Downstream Signaling Molecule AFX. W. Liu*[1], S. Wang*[1], S. Wei*[1], L. Sun[2], X. Feng[1]. [1]Pathology, Univ. of Alabama at Birmingham, Birmingham, AL, USA, [2]Medicine/Endocrinoiogy, Mount Sinai chool of Medicine, New York, NY, USA.

RANKL, a member of the TNF family, is a crucial cytokine regulating osteoclast formation, function and survival. RANKL exerts its effect by activating its receptor RANK, which recruits various intracellular signaling molecules via specific motifs in its cytoplasmic tail. Previously, we reported the identification of three functional RANK cytoplasmic motifs (Motif 1: PFQEP$^{369-373}$; Motif 2: PVQEET$^{559-564}$ and Motif 3: PVQEQG$^{604-609}$) and demonstrated that Motif 2 and Motif 3 are more potent than Motif 1 in mediating osteoclast formation and function. In the present study, we examined the role of the three motifs in osteoclast survival. Our osteoclast survival assays demonstrated that Motif 1, in contrast to its minimal role in osteoclast formation and function, plays a predominant role in maintaining osteoclast survival. Moreover, while Motif 2 and Motif 3 are very potent in osteoclast formation and function, they exert a moderate effect on osteoclast survival. Given that RANKL has been shown to be able to activate Akt, which is a critical mediator of cell survival in a variety of cell types, we investigated the role of these motifs in activating Akt signaling pathway. Our data demonstrated that Motif 1, but not Motif 2 and Motif 3, is able to stimulate Akt activation (phosphorylation). Our previous study has shown that all three motifs are capable of activating NF-κB, which is also a mediator of osteoclast survival. Thus, Motif 1 mediates osteoclast survival by activating both Akt and NF-κB pathways while Motif 2 and Motif 3 do so by activating NF-κB only. Since it has been established that Akt utilizes distinct downstream pathways

such as GSK3β, FKHR, BAD and AFX to regulate cell survival, we then investigated which downstream signaling pathway(s) is activated by Akt to promote osteoclast survival. By using antibodies against phosphorylated GSK3β, FKHR, BAD and AFX, we demonstrated that RANKL only stimulates AFX phosphorylation, indicating that the AFX pathway is the key pathway activated by Akt to modulate osteoclast survival. Taken together, we conclude that Motif 1 plays a predominant role in mediating osteoclast survival and Motif 1 does so by activating Akt and NF-κB pathways. Moreover, Akt exerts its effect on osteoclast survival by activating its downstream signaling molecule AFX.

K63-Linked Polyubiquitin Chains Catalyzed by the E3 Ligase TRAF6 Are Required for RANK Signaling and Osteoclast Formation. B. Lamothe*, W. K. Webster*, B. G. Darnay. Experimental Therapeutics, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA.

RANK plays a central role in the maintenance of the bone homeostasis by regulating the differentiation and activation of osteoclasts. The binding of RANKL to its receptor results in the recruitment of TRAF6, which activates the NF-kB, JNK, p38, and MAPK pathways. The RING domain of TRAF6 is required for its ability to signal, most likely by functioning as an E3 ubiquitin ligase, which together with the ubiquitin conjugating enzyme complex Ubc13/Uev1A catalyzes the synthesis of a unique polyubiquitin chain linked through lysine-63 (K63). Thus, TRAF6-mediated polyubiquitination acts as a trigger to activate the stress kinase pathways. Here we present evidence that RANK induces rapid K63-linked ubiquitination of TRAF6, which is blocked by a catalytically inactive Ubc13. The ability of RANK to activate NF-kB and JNK is abolished by ectopic expression of a RING finger mutant of TRAF6 devoid of autoubiquitination activity, or a catalytically inactive Ubc13. Previous studies indicated that the zinc finger protein A20, a protein known to interact with TRAF6 and RIP, prevents NF-kB activation by TNF, IL-1, and LPS. Additionally, recent evidence suggests that A20 possess both E3 ubiquitin ligase activity and deubiquitinating activity. Similar to LPS, RANKL induced the rapid, transient upregulation of A20 in RAW264.7 cells. In addition, ectopic expression of A20 inhibited RANKL- and RANK-induced NF-kB and JNK activation, which suggests that the deubiquitinating enzyme A20 tightly controls RANKL responses. To address the functional significance of the E3 ligase activity of TRAF6 in osteoclastogenesis, we infected RAW264.7 cells with a retrovirus that encodes for TRAF6 or the RING domain mutant of TRAF6. We observed that wild-type TRAF6, but not the RING domain mutant of TRAF6, caused RANKL-independent upregulation of NFATc1 and osteoclast differentiation. In addition, we have identified the lysines on TRAF6, which are involved for its auto-ubiquitination and are thus able to dissect the role of K63-linked polyubiquitin chain on TRAF6 and its ubiquitin ligase activity to activate downstream signaling pathways. To this end, we are actively pursuing the downstream targets of the E3 ligase activity of TRAF6 for K63-linked polyubiquitination, such as TAB2 and NEMO. The identification of TRAF6 substrates will provide the missing link by which ubiquitination initiates the activation of NF-kB and JNK by RANKL. Thus, we present the first evidence that the E3 ligase activity of TRAF6 is required for RANK signaling and programming osteoclast progenitors to become fully differentiated and active osteoclasts.

RANKL Induced iNOS/NO Acts as a Negative Feedback Inhibitor during Osteoclastogenesis via an NF-kB and IFN-β/Stat1 Signaling Pathway. H. Zheng, X. Yu, P. A. Collin-Osdoby, P. A. Osdoby. Department of Biology, Washington University, St Louis, MO, USA.

RANKL is essential for osteoclast (OC) formation and binds RANK to trigger multiple signals (ERK, p38 MAPK, JNK, NF-kB). We showed that RANKL also induces iNOS mRNA, protein and NO release during OC differentiation. Inhibitors of iNOS/NO augmented RANKL-induced OC formation and bone resorption, and OC development and resorption were greater in marrow cultures of iNOS-/- vs. iNOS+/+ mice. Thus, NO is an autocrine negative feedback signal regulating RANKL-mediated OC development in murine RAW 264.7 and primary bone marrow cells. Here, we investigated signal mechanisms by which RANKL induces iNOS/NO to restrain OC formation using selective inhibitors, blocking antibodies, and marrow cells from normal, IFN receptor-/-, or Stat-1-/- mice. Inhibitors of NF-kB (PDTC), p38 MAPK (SB203580), or ERK1/2 (PD98059) blocked both OC formation and iNOS/NO induction in murine pre-OC, indicating they are required for both RANKL-induced OC formation and iNOS/NO negative feedback regulation. In contrast, JNK inhibition (SP600025) blocked only OC formation and RANKL activation of JNK was not needed for the NO negative feedback mechanism. Because IFN β was shown to be a RANKL-induced negative feedback signal during OC development, and IFN β can induce iNOS/NO in other cells, we investigated if RANKL induced IFN β and downstream phosphorylation of Stat-1 was involved in RANKL stimulated iNOS/NO and restrained OC formation. We found that: 1) RANKL induced IFN β (by 30') and P-Stat-1 (by 4 h), 2) RANKL stimulation of P-Stat-1 and iNOS/NO (but not IFN β) required new protein synthesis, was mimicked by exogenous IFN β and was inhibited by neutralizing Ab to IFN β thereby enhancing OC formation, and 3) NF-kB inhibition blocked RANKL induced IFN β. Moreover, marrow cells from mice deficient in the IFN β receptor component IFNAR1 (IFNAR1-/-) or Stat-1-/- exhibited little iNOS/NO response to RANKL and generated more OC vs. marrow cells from IFNAR1+/+ or Stat-1+/+ mice. These and other findings conclusively demonstrate that the novel autocrine negative feedback pathway triggered by RANKL during OC development involves NF-kB activation, followed by IFN β induction, IFN-R signaling, P-Ser of Stat-1, and induction of iNOS mRNA, protein, and NO release. Specifically interfering with RANKL-mediated IFN β or Stat-1 activation prevents iNOS/NO induction, enhances OC formation and bone resorption, and suggests a novel target for therapeutic intervention to diminish bone loss in skeletal pathologies characterized by elevated RANKL and OC bone resorption.

SDF-1 Promotes the Transendothelial Migration of Circulating Human CD14$^+$ Monocytes and Osteoclast (OC) Precursors, Resulting in Greater RANKL-Induced OC Formation and Bone Resorption. L. Kindle, L. Rothe, M. Kriss*, P. A. Osdoby, P. A. Collin-Osdoby. Department of Biology, Washington University, St Louis, MO, USA.

OC precursors (pre-OC) of the monocytic lineage reside in the bone marrow and peripheral circulation, from which they may be recruited to sites for development and resorption of bone during normal skeletal remodeling or pathological bone erosion. A functional relationship exists between the bone microvasculature and areas of active resorption; however, little is known about how circulating pre-OC are recruited into bone and directed to sites for their OC differentiation and function. Chemokines are key signals regulating cell trafficking. SDF-1 is a chemokine highly produced by bone stromal and endothelial cells that acts as a normal homing signal for hematopoietic cells via their expression of the receptor CXCR4. SDF-1 is also highly produced by inflamed synoviocytes in arthritic joints, and a selective CXCR4 antagonist inhibits OC numbers and bone loss in murine arthritis. Previously, we showed that SDF-1 chemoattracts pre-OC from human peripheral blood mononuclear cells (hPBMC), leading to greater RANKL-induced OC formation and bone resorption. Here, we investigated if SDF-1 is also important for pre-OC recruitment via stimulating their transendothelial migration (TEM) through a human microvascular endothelial cell (HMVEC) barrier using a transwell model. TEM of hPBMC into the lower chambers was increased > 2-fold by 10 nM SDF-1 and led to greater OC and resorption pit formation after M-CSF + RANKL culture of the migrated cells. SDF-1 stimulated TEM was inhibited (~65%) by HMVEC pretreatment with neutralizing antibodies to the key endothelial cell adhesion molecules ICAM-1, VCAM-1, and PECAM-1. HMVEC expressed modest SDF-1 mRNA and protein levels, and they efficiently took up and displayed on their surface exogenously supplied SDF-1 that stimulated hPBMC TEM. Because pre-OC derive from the CD14$^+$ monocyte fraction of hPBMC, and CD14$^+$ cells expressed CXCR4, we examined CD14$^+$ TEM to SDF-1. Like hPBMC, CD14$^+$ TEM was increased 2-fold by SDF-1 and led to 2-fold higher OC and bone pit formation after their M-CSF + RANKL culture. Furthermore, hPBMC that had undergone TEM to SDF-1 were enriched for pre-OC, suggesting preferential recruitment from the mixed hPBMC population. We conclude that SDF-1 may be a key signal provided by bone endothelial and stromal cells that has multiple roles in OC biology, including recruitment of circulating pre-OC through the endothelial barrier into the marrow and directing the chemotactic navigation of pre-OC to appropriate stromal sites for their differentiation and function during normal bone remodeling or pathological bone destruction.

TNF Promotes Osteoclast Precursor Mobilization to the Blood by Inhibiting SDF-1 Production by Bone Marrow Stromal Cells. Q. Zhang, Z. Yao, R. Guo*, E. M. Schwarz, T. Bushnell*, B. F. Boyce, L. Xing. University of Rochester, Rochester, NY, USA.

Osteoclasts (ocls) differentiate from circulating ocl precursors (OCPs) and are essential effector cells for focal bone erosion in chronic inflammatory arthritis. TNF is a potent ocls stimulator that increases circulating OCPs numbers by enhancing their egress from the bone marrow. Stromal cell derived factor 1 (SDF-1) and its receptor, CXCR4, play a critical role controlling homing and mobilization of hematopoietic stem and progenitor cells, but it is not known if they serve this function in OCPs mobilization or if TNF might affect it. To investigate this question, we first examined the effect of TNF on expression of SDF-1 in stromal cells from TNF transgenic (TNF-Tg) arthritic and wt mice. Stromal cells from TNF-Tg mice expressed significantly lower SDF-1 than wt mice (0.4±0.1 vs 1±0.05 ng/ml, measured by ELISA). Administration of TNF to wt mice decreased marrow SDF-1 levels (0.2±0.03 ng/ml vs 0.74±0.07 in PBS-treated mice) and resulted in a 8-fold increase in blood OCPs (CD11b$^+$/Gr-1$^{-/lo}$ cells: 2.6±0.2 x10E6/ml vs 0.3±0.02 x10E6/ml in PBS-treated mice). *In vitro*, TNF significantly lowered SDF-1 mRNA levels and protein production (2.4±0.8 ng/ml vs 6.9±0.9 ng/ml in PBS-treated cells) by ST2 stromal cells. To determine if OCPs express functional CXCR4, wt OCPs were cultured in a transwell/ osteoclastogenesis assay. OCPs migrated toward an SDF-1 gradient in a dose-dependent manner and the cells that migrated differentiated with M-CSF and RANKL treatment into ocls (Trap +ve cells: 0±0/well in PBS-attracted cells vs 71±5 multinucleated cells/well and 118±15 mononucleated cells/well in SDF-1 (100ng/ml)-attracted cells). We observed no change in CXCR4 levels on OCPs from TNF-Tg mice or TNF-treated bone marrow OCPs. Pre-treatment of OCPs with TNF did not affect the rate of migration towards the SDF-1 gradient. To determine if TNF-mediated cell mobilization is specific for myeloid/ocl precursors, the frequency of other cell types in the blood of TNF-Tg and wt mice was compared using combinations of cell surface markers. Except for the 8-fold increase in CD11b$^+$/Gr-1$^{-/lo}$ myeloid/ocl precursors, there was no alternation in the frequency of B220+ B cells, CD3+ T cells, or Lin-/Sca1+/c-Kit+ stem cells in TNF-Tg mice. In summary, TNF inhibits SDF-1 production by bone marrow stromal cells without affecting OCP migration or expression of CXCR4. Since stromal cells hold hematopoietic cells in the marrow by SDF-1/CXCR4 interaction, we propose that TNF promotes OCP egression to the blood stream and thus facilitates their subsequent mobilization in chronically inflamed joints by reducing bone marrow stromal expression of SDF-1.

Correlates of Femoral Neck Trabecular and Cortical Volumetric Bone Mineral Density (vBMD): The Osteoporotic Fractures in Men Study, MrOS. J. Cauley[1], T. Blackwell[2], J. M. Zmuda[1], D. C. Bauer[2], R. Fullman[2], K. E. Ensrud[3], K. L. Stone[2], E. Barrett-Connor[4], E. S. Orwoll[5]. [1]U of Pittsburgh, Pittsburgh, PA, USA, [2]UCSF, San Francisco, CA, USA, [3]U Minnesota, Minneapolis, MN, USA, [4]UCSD, San Diego, CA, USA, [5]Oregon Health & Science University, Portland, OR, USA.

Correlates of areal BMD (aBMD) are well established, but whether these same factors correlate with vBMD is unknown. The objective of the current cross-sectional analysis is to determine the correlates of femoral neck trabecular and cortical vBMD in 3,671 men, mean age 73.6y + 5.9 and to compare them to those of aBMD. BMD was measured by QCT at 6 clinical centers; aBMD was measured by DXA. Demographic, history and lifestyle information was obtained by interview and height and weight by examination. All models were adjusted for clinic site, age, and race. To express the strength of the associations, % differences (95% CI) were calculated from multivariable linear regression models using the formula (beta * unit/mean BMD). Units were chosen to approximate 1 Standard Deviation (SD). Multivariable models explained 14%, 21%, and 20% of the overall variance in trabecular and cortical vBMD and aBMD, respectively. In general, the associations were stronger for trabecular than cortical vBMD, Table. Race and diabetes were the strongest positive predictors and history of non-trauma fracture, the strongest negative predictor. Past smoking, history of kidney stones, and corticosteroid use were associated with >5% lower trabecular vBMD and Parkinson's disease, >5% lower cortical vBMD. In general, the direction of the association of each characteristic with aBMD and vBMD were similar although the magnitude differed across variables. Identification of these correlates could help to identify men at risk for fracture and improve our understanding of fracture etiology.

Table: Multivariable Correlates of Femoral Neck aBMD and vBMD: % difference in BMD per unit (95% CI) in the characteristic

	Unit/ Referent	aBMD	Trabecular vBMD	Cortical vBMD
Age	5y	NS[+]	-6.3 (-8.3, -4.3)	NS[+]
Race	White			
Black		11.3 (8.9, 13.8)	31.8 (21.8, 41.8)	3.6 (1.8 ,5.5)

Spinal Loading and Vertebral Strength: A Population-Based Study Using QCT. M. L. Bouxsein[1], B. L. Riggs[2], L. J. Melton[2], J. Muller*[1], E. J. Atkinson*[2], A. L. Oberg*[2], S. Khosla[2]. [1]Orthopedic Surgery, Beth Israel Deaconess Medical Center, Boston, MA, USA, [2]Mayo Clinic, Rochester, MN, USA.

Whereas spine BMD by DXA is widely used to predict vertebral fracture risk, approaches that incorporate better estimates of vertebral strength combined with spine loading may improve the identification of those at high risk for fracture. As a first step towards this goal, we studied an age-stratified sample of 375 women (W) and 325 men (M), aged 21 - 97 yrs. QCT was used to measure lumbar vertebral bone density (vBMD, mg/cm^3) and cross-sectional area (CSA, cm^2). Vertebral strength (VStr, Newtons, N) in compression was estimated from vBMD and CSA using engineering beam theory and in vitro mechanical testing data (Crawford et al, 2003). Individual height, weight and sex were incorporated into a biomechanical model to estimate the compressive load applied to the lumbar vertebra (VLoad, N) during bending forwards with a 10 kg weight in the hands. The factor of risk for fracture (Φ) was defined as VLoad/VStr (theoretically fracture occurs when Φ>1). **Results**: VStr was 22 to 54% higher in M than W at all ages (p<0.001), and declined over life significantly more in W (-40%) than in M (-25%, p=0.03). VLoad was on average 9% higher in M than W (p< 0.001). Thus, Φ was lower (ie, decreased risk of fracture) in M than W at all ages (-12.5% to -24.6%, p<0.001), and worsened with age more in W than M (+57% vs +35%, p = 0.006). The proportion of individuals in which fracture was predicted to occur increased with age, as Φ exceeded 1.0 in 8.2% and 1.6% of W and M below age 50, compared to 34.5% and 10.8%, respectively, above age 50. Among those over age 50, persons with Φ > 1 were older, shorter (W only), had lower vBMD and VStr, and higher CSA (M only) and VLoad compared to those with Φ < 1 (p=0.03 - 0.001, Table). In conclusion, our findings, which represent the first population-based study incorporating estimates of vertebral strength and loads, demonstrate that 1) the age- and sex-differences in the 'factor of risk' mirror the reported prevalence of vertebral fracture, and 2) individuals at high risk for vertebral fracture have both lower vertebral strength and greater vertebral loads. These data provide strong rationale for future studies comparing DXA with Φ as predictors of fracture risk. Table 1. Characteristics of individuals over age 50 according to their "factor of risk" value.

Effects of Gender and Age on Bone Microstructure at the Wrist: A Population-Based *In Vivo* Bone Biopsy Study. S. Khosla, B. L. Riggs, A. L. Oberg*, E. J. Atkinson*, L. McDaniel*, J. M. Peterson*, L. J. Melton. Endocrine Research Unit, Mayo Clinic College of Medicine, Rochester, MN, USA.

Although changes in bone microstructure contribute to fracture risk independently of BMD, it has not heretofore been possible to assess this non-invasively in population-based studies. Thus, we used high resolution 3D-pQCT imaging (voxel size, 89 μm, Scanco AG) to define, in a random sample of women (F, n = 322) and men (M, n = 254) age 21 to 97 yrs, gender and age effects on bone microstructure at the wrist. Relative to young F (age 20-29 yrs, n = 17), young M (n = 18) had higher values for trabecular bone volume/tissue volume (BV/TV, by 26%, P = 0.002), trabecular thickness (TbTh, by 27%, P < 0.001), bone area (BA, by 50%, P < 0.001), and endocortical area (EnA, by 55%, P < 0.001), but similar values for trabecular number (TbN), trabecular separation (TbSp), and cortical thickness (CTh). Shown in the Table are the percent changes as a function of age (20-90 yrs), correlation with age (R), and comparisons of slopes (F vs. M) in these parameters.

Variable	Women		Men		P-value (F vs. M)
	% Ch	R	% Ch	R	
BV/TV	-27[c]	-0.27[c]	-25[c]	-0.37[c]	0.629
TbN	-14[c, NL]	-0.29[c]	+9[NL]	-0.04	<0.001
TbTh	-14[c, NL]	-0.22[c]	-25[c, NL]	-0.40[c]	0.052
TbSp	+24[c]	+0.30[c]	-4[b, NL]	+0.16[a]	<0.001
BA	+11[b]	+0.15[b]	+13[b]	+0.19[b]	0.243
EnA	+26[c]	+0.25[c]	+22[c]	+0.24[c]	0.410
CTh	-52[c, NL]	-0.58[c]	-37[c, NL]	-0.42[c]	0.005

[a]P < 0.05; [b]P < 0.01; [c]P < 0.001; NL, non-linear relationship with age.

More detailed analyses revealed that, whereas changes in TbN, TbTh, and TbSp were similar in F and M after age 50 yrs, there were clear differences in these changes in F vs. M aged 20-49 yrs. Thus, in M aged 20-49 yrs, TbN increased by 18% (P < 0.001), TbTh decreased by 28% (P < 0.001), and TbSp decreased by 12% (P < 0.001), consistent with a conversion of trabecular plates to rods, and these changes offset age-related decreases in TbN and increases in TbSp in M after age 50 yrs. By contrast, TbN and TbSp remained stable in F aged 20-49 yrs, and TbTh decreased by 13% (P = 0.02), with further decreases in TbN and TbTh and increases in TbSp after age 50 yrs, consistent with microstructural damage. Conclusions: 1) Relative to F, M begin adult life with a more plate-like, and thus stronger, trabecular microstructure; 2) This, combined with virtually no change over life in TbN or TbSp in M as compared to significant decreases in TbN and increases in TbSp in F likely contributes to lower life-long risk of fractures in M and to their virtual immunity to age-related increases in wrist (Colles') fractures; and 3) High resolution 3D-pQCT analyses of bone microstructure is a powerful new tool that will greatly enhance clinical assessment of fracture risk.

The Effect of Cyclooxygenase-2 Inhibitors on Bone Mineral Density: Results from the CaM*os* Study. J. B. Richards*[1], L. Joseph*[2], D. Goltzman[1]. [1]Endocrinology, McGill University, Montreal, PQ, Canada, [2]Epidemiology and Biostatistics, McGill University, Montreal, PQ, Canada.

In animal models the inhibition of prostaglandin E2 production, through the use of cyclooxygenase-2 (COX-2) inhibitors, has been demonstrated to decrease load-induced bone formation but also to prevent menopause-associated bone loss. We hypothesized that COX-2 use would be associated with a lower bone mineral density (BMD) in men, but may conversely be associated with a higher BMD in post-menopausal women not using estrogen supplementation. To date the effect of COX-2 specific inhibitors on human bone mineral density has not been described. We tested these hypotheses using a multi-centered randomly selected population-based cohort of 1934 male (mean and [SD] 64.1 [13.6] years) and 4556 post-menopausal female (mean and [SD] 75.1 [6.3]) subjects. To test these hypotheses we used standard linear regression techniques. Compared to the rest of the

cohort, daily COX-2 users (males n=121, females n=337) were more likely to be older, have a higher body mass index (BMI), and carry a diagnosis of osteoarthritis or rheumatoid arthritis. When compared to non-users, men using daily COX-2 inhibitors had a lower BMD at all hip sites and a trend towards a lower BMD at lumbar spine. Females COX-2 users, not taking estrogen supplementation, were found to have a higher BMD than non-users. In the presence of exogenous estrogen this protective effect of COX-2 inhibitors was lost. These effects generally persisted after adjustment for confounders (age, BMI, number of ovulatory cycles (in females), calcium intake, previous fracture, osteoarthritis, rheumatoid arthritis, lupus, education level and centre). In addition, we found a linear relationship between COX-2 dose and these aforementioned effects. Our findings suggest that daily use of COX-2 inhibitors may decrease BMD in men, but conversely may increase BMD in women not using estrogen supplementation. These results support the hypotheses that COX-2 inhibition may prevent both load-induced bone formation and estrogen-withdrawal mediated bone loss. Men who previously used daily COX-2 inhibitors, who have other risk factors for low BMD, may benefit from BMD testing to assess their future fracture risk. COX-2 inhibition may however have utility in post-menopausal women if bone selective analogs can be developed.

Percent Change in BMD: COX-2 Users vs. Non-Users (95% CI) Adjusted Analysis

Time Trends in Mortality Following Hip Fracture. A. B. Araujo[1], Y. Wang*[2], L. M. Brass*[2], H. M. Krumholz*[2], J. H. Lichtman*[2]. [1]New England Research Institutes, Watertown, MA, USA, [2]Yale University School of Medicine, New Haven, CT, USA.

There are between 250,000-300,000 hip fractures in the U.S. annually. Nearly 20% of hip fracture patients die with one year of fracture. The impact of changes in population demographics, increasing hip fracture incidence, and advances in hip fracture management on post-fracture mortality outcomes is unclear since there are limited data on time trends in mortality among hip fracture patients. To address this issue, we obtained data for all U.S. Medicare fee-for-service claims for hip fracture (ICD-9-CM code: 820.0-820.9) between 1992 and 1999 to examine time trends in the 1-year mortality rate following hip fracture. Rates were estimated in the cohort overall and by age, gender, and race/ethnicity. Expected death rates were calculated for each year between 1992 and 1999 for each 5-year age, gender, race/ethnic group from National Center for Health Statistics data. Time trends in mortality following hip fracture were evaluated with Poisson regression, which yields estimates of the standardized mortality ratio (SMR) for fracture patients relative to the general population. Information on age, race/ethnicity (black, white, other), and gender was obtained from the Medicare Denominator File. A total of 1,929,797 qualifying hip fractures among patients 65 y or older were identified between 1992 and 1999. The mortality rate in the cohort overall was 20.5%, and rose significantly from 18.4% in 1992 to 22.8% in 1999. During the same period, the underlying mortality in the population increased 9.6%. As a result, the SMR increased from 2.01 to 2.29 (an increase of 13.5%) over the time period. The time trend in SMRs was more pronounced (p=.0039) among younger age groups but showed no variation (p=.9542) with gender-race/ethnic group. Changes in comorbidity and hospital length of stay did not explain the rise in SMRs. These findings are of great concern given the expected increase in the U.S. elderly population over the next few decades.

Projections of Osteoporosis Fractures and Costs by Skeletal Site in the USA. A. Tosteson[1], D. Solomon[2], A. B. King*[3], B. Dawson-Hughes[4], R. Burge*[3], J. Wong*[5]. [1]Dartmouth College Medical School, Hanover, NH, USA, [2]Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA, [3]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [4]Tufts University, Boston, MA, USA, [5]Tufts University School of Medicine, Boston, MA, USA.

Osteoporosis is characterized by a loss of bone strength, leading to an increased risk of fracture (Fx). In the United States, over 10 million people have osteoporosis, and an additional 34 million have osteopenia. Demographic changes and lifestyle factors may lead to increases in Fx and costs across multiple skeletal sites. The aims of the study were to estimate osteoporosis Fx incidence and costs by Fx type in the USA. A Fx incidence based Markov model of OP was used to estimate osteoporosis-related Fx and costs by skeletal site for the U.S. population aged 50-99 years. Fracture types included Hip, Vertebral, Forearm/wrist, Pelvic, and Other (non-pathologic clavicle, humerus, carpal, tibia, fibula, femur). Hip Fx incidence rates (ICD-9 820.xx, closed only; trauma cases excluded) were calculated from national hospital discharge data; clinical incidence rates for all other Fx types were obtained from published studies. Unit costs of Fxs were obtained from database estimates and from published studies. Annual Fxs and costs were projected through 2025 using U.S. Census Bureau population data. In 2005, total incident osteoporotic Fxs and related costs are predicted to exceed 2.05 million and $16.9 billion, respectively, in the U.S. Non-vertebral Fxs account for 73% of total Fxs and 94% of costs. Hip Fxs comprise 14% of Fxs and 71% of costs in 2005. All other non-vertebral Fxs account for 59% of incident Fxs and 22% of costs. Incidence per 10,000 population (aged 50-99) is 77 for Other Fxs, 63 for Vertebral, 45 for Wrist, 34 for Hip, and 15 for Pelvic. Assuming no change, by 2025 total incident Fxs are predicted to increase by 48% to over 3 million, while costs grow to over $25.2 B (49%).

Site	2005 Fx (000s)(%)	2005 $Costs M (%)	2025 Fx (000s) (% Growth)	2025 $Costs M (% Growth)
Vertebral	547 (27)	1,076 (6)	831 (52)	1,650 (53)
Hip	296 (14)	12,059 (71)	447 (51)	18,000 (49)
Wrist	397 (19)	535 (3)	571 (44)	757 (41)
Pelvic	135 (7)	873 (5)	210 (56)	1,401 (60)
Other	675 (33)	2,371 (14)	976 (45)	3,461 (46)
Total	2,050	16,915	3,036 (48)	25, 268 (49)

Projections for 2005 reveal that 73% of the 2.05 million clinical fractures and 94% of costs are non-vertebral. Fracture incidence and costs are expected to increase dramatically to over 3 million and $25.2 billion per year by 2025 due to anticipated demographic changes. Osteoporosis intervention programs should consider the impact of fracture on the total skeleton, not only at vertebral and hip sites.

Effects of PTH Rechallenge 1 Year after the First PTH Course in Patients on Long-Term Alendronate. F. Cosman, J. W. Nieves, M. Zion*, N. Barbuto*, R. Lindsay. Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

We performed a randomized clinical trial in 126 women, who had been treated for osteoporosis with alendronate for at least 1 year (mean 3.2 years) and assigned to remain on alendronate and receive daily PTH(1-34) 25 mcg/d, cyclic PTH(1-34) 25 mcg/d, given in 3 month on/3 month off cycles, or alendronate alone. After the active drug treatment period of 15 months, subjects were followed on continued alendronate for 12 subsequent months and then invited to participate in an observational extension protocol where all subjects were offered daily PTH(1-34) therapy for an additional 15 months. Of the 108 subjects who completed the original 15 month clinical trial, 82 completed the 12-month follow-up period and of those, 43 agreed to participate in the extension study. Here we present experience on the first 24 subjects, representing 13 subjects from the original daily PTH group and 11 subjects from the original cyclic PTH group. During the 12 month interval between the PTH challenge and the PTH rechallenge, biochemical indices returned to pre-PTH treatment baseline levels and there was no significant decline in BMD from the peak seen after the 15 month first PTH course. Since all subjects in both the original daily and cyclic PTH groups received the same PTH dose for the first 3 months, data from the PTH groups were combined for the 3-month biochemical bone turnover analyses. Also, as there were no significant differences in BMD response at 15 months between the daily and cyclic PTH groups during the first PTH challenge, the two PTH groups were pooled for the BMD analysis. Effects of PTH on bone turnover over the first 3 months of the PTH rechallenge were compared to the bone turnover effects of the first PTH challenge at the same time point. Effects of the PTH rechallenge on BMD of the lumbar spine at 15 months were compared to those seen at the same time during the first PTH challenge. Serum osteocalcin increased by 77.9±10% during the initial PTH challenge and by 75.6±23% during the PTH rechallenge at 3 months. Urine N-telopeptide increased by 102±52 % during the initial PTH challenge and by 124±55% during the PTH rechallenge at 3 months. Spine BMD increased by 5.3±1.2% during the first PTH challenge and by 4.3±0.7% during the PTH rechallenge at 15 months. The results suggest that, in patients on long-term ongoing alendronate therapy, rechallenge with PTH, after a 12 month interval off PTH, stimulates increases in bone formation, resorption and BMD similar to those seen during the first course of PTH administration. Patients who remain at high risk of fracture despite a first course of PTH therapy might benefit from a second discrete PTH course given 12 months later.

Safety and Efficacy of PTH(1-84) at 18 and 24 Months in Women with Postmenopausal Osteoporosis Receiving Hormone Therapy: Results from the POWER Study. I. Fogelman*[1], C. Christiansen*[2], T. Spector*[3], W. Fraser*[4], J. Fordham*[5]. [1]Guy's, Kings and St Thomas' Hospital Medical School, London, United Kingdom, [2]Center for Clinical and Basic Research, Ballerup, Denmark, [3]St Thomas' Hospital, London, United Kingdom, [4]Royal Liverpool University Hospital, London, United Kingdom, [5]The James Cook University Hospital, London, United Kingdom.

PTH(1-84) reduces the incidence of vertebral fractures and increases BMD in women with postmenopausal osteoporosis. Adding PTH(1-84) to the therapeutic regimen of women with low BMD who are on stable HRT may provide additional benefits. The Prevention of Osteoporosis in Women on Estrogen Replacement (POWER) trial was a randomized, double-blind, placebo-controlled, multi-center study involving 180 women (mean age, 58.8 years; mean years postmenopausal, 12.6) with low BMD (LS T-scores ≤-2.0) who had received HRT for ≥6 months. Patients were randomized to daily injections of PTH(1-84) 100 µg/d + HRT (n=90) or HRT alone (n=90). Subjects received calcium (700-1050 mg/d) and vitamin D (800 IU/d). An increase in LS BMD was seen in both groups at Months 18 and 24; however, a statistically significant increase in subjects receiving

PTH(1-84) + HRT compared with HRT alone was seen at Months 18 (6.42%, p<0.001) and 24 (6.53%, p<0.001). In the PTH(1-84) + HRT group statistically significant increases over baseline of 7.9% and 8.6% (p<0.001) were seen at Months 18 and 24. At the femoral neck (FN), PTH(1-84) + HRT treatment resulted in a statistically significant increase in BMD of 2.27% relative to the increase observed with HRT alone (0.47%; p=0.024). There was a statistically significant increase in bone specific alkaline phosphatase (BSAP) of 97.7% at Month 12 and of 115.1% at Month 24 for PTH(1-84) when compared with placebo at Months 12 (18.5%, p=0.01) and 24 (28.7%, p=0.009). Similarly, a PTH(1-84)-associated increase in N-telopeptide (NTx) of 65.0% at Month 12 for PTH(1-84) compared with placebo (2.3%, p<0.0001) was maintained at Month 24 (69.2% vs 24.3%, p=0.0049). There was no significant change in these values in subjects on HRT alone. The incidence of vertebral and non-vertebral fractures in this study population was very low and the impact of PTH(1-84) on clinical fracture is difficult to assess. Adverse events (AEs) were similar in the HRT and PTH(1-84) + HRT groups; serious AEs occurred in 17.8% and 26.7% of subjects, respectively. Hypercalcemia was 2.2% and 14.4% respectively in the HRT and the PTH(1-84) + HRT groups. Combined PTH(1-84) + HRT therapy was associated with statistically significant increases in LS and FN BMD and other surrogates that indicate anabolic activity when compared to HRT alone. PTH(1-84) in combination with HRT was well tolerated and safe.

Risedronate and Alendronate Similarly Suppress Remodeling and Increase Microdamage in Beagles after 1 Year of Treatment at Clinical Doses. M. R. Allen[1], K. Iwata*[1], R. Phipps[2], D. B. Burr[1]. [1]Anatomy & Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Procter and Gamble Pharmaceuticals, Inc., Mason, OH, USA.

One year of bisphosphonate treatment at 5-6x the post-menopausal osteoporosis (PMO) clinical dose suppresses cancellous bone remodeling by 90%, increases microdamage and reduces toughness in the lumbar vertebrae of normal beagles. The current study was designed to determine if bisphosphonates given at lower doses would result in lower levels of remodeling suppression and less microdamage accumulation. One-year-old female beagles were randomized into seven groups (n = 12/group) and treated daily for 1 year with oral doses of vehicle, risedronate (RIS; 0.05, 0.1, or 0.5 mg/kg/day) or alendronate (ALN; 0.1, 0.2, or 1.0 mg/kg/day). The 1:2 ratio of each of the three risedronate to alendronate doses was based on clinical dosing (= dose equivalents). The lower two doses of each compound correspond approximately to the daily PMO clinical dose on a mg/kg basis while the highest dose was 5-6x the clinical dose. Bone remodeling, microdamage, and mechanical properties of lumber vertebrae were quantified. Cancellous bone activation frequency (Ac.f) was dose-dependently suppressed by RIS ($p < 0.05$) by -40%, -66%, and -84% compared to vehicle-treated animals. There was no dose-response in remodeling suppression for ALN; all three doses reduced Ac.f similarly (-65%, -71%, and 76%) compared to vehicle ($p < 0.05$). At the lowest dose-equivalent, RIS suppressed Ac.F. significantly less than ALN; there was no difference at the other two dosing equivalents. Cancellous bone crack surface density (Cr.S.Dn) was significantly increased (3-4x) compared to controls with the lower 2 doses of each drug. The high dose of each drug increased Cr.S.Dn by >5x, significantly higher than lower doses. There was no difference in Cr.S.Dn between RIS and ALN at dose equivalents. The relationship between Ac.f and Cr.S.Dn was similar for both ALN and RIS (both $r^2 = 0.22$; $p < 0.003$). Both RIS and ALN significantly increased vertebral stiffness; there was no effect on other extrinsic or intrinsic mechanical properties. In summary: 1) risedronate dose-dependently suppressed cancellous bone remodeling while alendronate suppressed remodeling similarly at all three doses, 2) both RIS or ALN similarly increases microdamage accumulation (3-4x at PMO clinical dose levels and >5x at 5-6x clinical dose levels) without significant negative effects on mechanical properties.

Sclerostin Monoclonal Antibody Treatment of Osteoporotic Rats Completely Reverses One Year of Ovariectomy-Induced Systemic Bone Loss. K. Warmington*[1], M. Ominsky[1], B. Bolon*[2], R. Cattley*[1], P. Stephens*[3], A. Lawson*[3], D. Lightwood*[3], V. Perkins*[3], H. Kirby*[3], A. Moore*[3], M. Robinson*[3], P. J. Kostenuik[1], W. S. Simonet[1], D. L. Lacey[1], C. Paszty[1]. [1]Amgen Inc, Thousand Oaks, CA, USA, [2]GEMpath Inc, Cedar City, UT, USA, [3]Celltech R and D Ltd, Slough, United Kingdom.

Genetic data and gene expression analysis in humans and mice, along with pharmacological data generated in rodents, point at the secreted protein sclerostin as playing a key role in controlling bone mass throughout life. Sclerostin negatively regulates the anabolic output of the osteoblast lineage, and thus the absence of sclerostin results in increased bone formation and high bone mass. To explore the therapeutic potential of sclerostin as a target for the treatment of postmenopausal osteoporosis, 6 month-old female rats were ovariectomized (OVX), allowed to lose bone for 1 year, and were then treated with a sclerostin neutralizing monoclonal antibody (Mab). Bone mineral density (BMD) was determined *in vivo* by DXA and *ex vivo* by Micro-CT. Bone loss, at 1 year post-OVX, was similar at various skeletal sites with a ~ 12% decrease in BMD compared to age-matched, sham-operated controls. Five weeks of Mab treatment led to statistically significant increases in BMD in lumbar vertebrae (26 %), whole leg (16 %), femoral metaphysis (28 %) and femoral diaphysis (9%) compared to vehicle treated controls. These increases in BMD were similar to the increases seen in the PTH treated-group. Micro-CT analysis of the femur showed that sclerostin inhibition led to improved trabecular architecture [increased BV/TV (118%), BMD (64%), trabecular number (50%), trabecular thickness (57%)] and cortical geometry [increased cortical thickness (26%) and decreased endosteal circumference (14%)]. At the five week timepoint, serum TRAP-5b (an osteoclast-specific resorption marker) was statistically significantly decreased in the Mab-treated rats (43 % vs vehicle). This decrease in TRAP-5b suggests that the sclerostin pathway, in addition to controlling osteoblasts, may also affect osteoclasts, perhaps by modulating osteoblast expressed OPG and RANKL levels. Gross observation, serum clinical chemistry, hematological analysis, and histopathological analysis revealed no abnormalities associated with pharmacological inhibition of sclerostin. In summary, very impressive increases in BMD were achieved in a rat model of post-menopausal osteoporosis (PMO) after five weeks of treatment with a sclerostin-neutralizing Mab. These data suggest that inhibition of sclerostin may be useful in humans for building bone in the clinical setting of PMO, even in cases where osteoporosis has progressed to the point where significant bone loss has already occurred.

Effects of Parathyroid Hormone 1-84 on Cortical and Trabecular Bone at the Hip as Assessed by QCT: Results at 18 Months from the TOP Study. C. E. Bogado[1], J. R. Zanchetta[1], A. Mango*[1], A. L. Mathisen*[2], J. Fox*[2], M. K. Newman*[2]. [1]Clinical Research, IDIM, Buenos Aires, Argentina, [2]NPS Pharmaceuticals, Salt Lake City, UT, USA.

Treatment with PTH increases trabecular bone mineral density (BMD), but its effects on mixed trabecular and cortical bone sites, like the hip, are less well established. We used quantitative computed tomography (QCT) to assess the effects of treatment with parathyroid hormone 1-84 (PTH) on volumetric (v) trabecular (Tb), cortical (Ct) and integral (Int; Tb+Ct) BMD, bone mineral content (BMC) and bone volume (BV) at the total hip and femoral neck of postmenopausal women with osteoporosis. The QCT study consisted of 122 women from the TOP study (BMD T score ≤-2.5 at the lumbar spine, total hip or femoral neck) who were randomly assigned to daily injections of PTH (100 μg; n=62) or placebo (n=60). The mean percent change from baseline for Placebo and PTH subjects is shown in the Table below.

	Total Hip			Femoral Neck		
	Placebo	PTH	p-value	Placebo	PTH	p-value
vTbBMD	-0.21	4.99	<0.001	-0.42	4.11	0.006
vTbBMC	-1.06	2.91	0.003	-2.56	7.80	0.003
TbBV	-0.83	-1.29	0.604	-1.46	3.34	0.074
vCtBMD	3.25	-1.41	0.001	1.22	-0.91	0.278
vCtBMC	-4.74	0.04	0.040	1.74	8.22	0.116
CtBV	-7.17	1.83	0.003	0.01	11.17	0.043
vIntBMD	-0.21	4.50	<0.001	1.37	3.37	0.178
vIntBMC	-1.06	2.91	0.003	0.23	7.25	0.032
IntBV	-0.83	-2.10	0.258	-1.61	4.26	0.041

The increase in vTbBMD at total hip and femoral neck in PTH-treated subjects was due primarily to an increase in vTbBMC; there was no significant change in TbBV at either site. In contrast, CtBV increased significantly in the PTH group at both hip regions. However, because the increase in vCtBMC was smaller than the increase in bone volume, there was a decrease in vCtBMD that was significant at the total hip, but not at the femoral neck. To our knowledge this is the first placebo controlled study of the effects of PTH treatment on vBMD at the hip using QCT. Daily administration of PTH for 18 months increases integral and volumetric trabecular BMD and BMC, and cortical bone volume. We found only a modest decrease in volumetric cortical BMD, which was not significant at the femoral neck region. These results are consistent with changes observed in PTH-treated osteopenic rhesus monkeys in which increases in integral vBMD and vBMC at these regions translated into significant increases in bone strength.

The Effects of Strontium Ranelate on Bone Remodeling and Bone Safety Assessed by Histomorphometry in Patients with Postmenopausal Osteoporosis. M. E. Arlot, P. Delmas, B. Burt-Pichat*, J. P. Roux*, N. Portero*, P. J. Meunier. INSERM Unit 403, C. Bernard University, Lyon, France.

Strontium ranelate (SR), a novel antiosteoporotic drug, has been found in pre-clinical studies to stimulate bone formation and to decrease bone resorption, rebalancing bone turnover toward formation. As shown in the SOTI and TROPOS clinical studies, SR 2g/day is safe and effective in postmenopausal women with osteoporosis in reducing the risk of fractures (vertebral -41% and hip in osteoporotic women aged 74 years or more -36%). The objectives of our study on transiliac bone biopsies were a) to assess the mechanism of action of strontium ranelate at the cell or bone tissue level and b) to evaluate bone safety. Transiliac bone biopsies were obtained in a subset of the SOTI, TROPOS and STRATOS patients at baseline, 1, 2, 3, 4 or 5 years from the start of a treatment with either SR 2g/day or placebo. All patients received calcium and vitamin D supplementation. The analysis compared the pooled data from 1 to 5 years in patients treated with SR (treated; n: 49) with the pooled data from placebo plus baseline data obtained for patients in SR group (untreated; n: 87). Histomorphometric parameters were measured at both cancellous, endosteal and cortical envelopes. The positive effects of SR on bone formation were confirmed by a significant higher osteoblastic surfaces (Ob.S/BS) in treated as compared to untreated (+38%; p=0.047) and by a significant greater Mineral Apposition Rate (MAR) in cancellous and cortical bone (+8%; p=0.008, +11%; p=0.033, respectively). At the tissue level, there was no significant change in activation frequency. The effects on resorption consisted of a trend towards lower endosteal eroded surfaces, endosteal and cancellous osteoclast surfaces and osteoclast number (-14, -6%, -9%, -9%, NS, respectively,). With

the higher Ob.S/BS in treated, it was expected to also observe higher osteoclast surfaces, which was not the case, confirming the dual mode of action of SR. In terms of safety parameters, the cancellous osteoid thickness was found to be significantly lower in treated (p=0.007), the MAR was significantly higher in treated with no change in osteoid volume and mineralization lag time. These results demonstrate that primary mineralization rate is not impaired, but on the contrary stimulated by SR.All these findings indicate the stimulating effects of strontium ranelate on the osteoblastic population and MAR and a moderate decrease in bone resorption. They are in agreement with the increase of biochemical markers of formation and the decrease of those of resorption shown in clinical studies and confirm the dual mode of action of strontium ranelate, rebalancing the bone metabolism in favor of formation.

SHP2 Mutations that Cause Noonan Syndrome May Lead to Disorganized Chondrogenesis. N. Namba[1], K. Takahashi*[1], E. Ogura*[2], M. Kawai*[1], S. Kogaki*[1], H. Tanaka[2], K. Ozono[1]. [1]Pediatrics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan, [2]Pediatrics, Okayama University Graduate School of Medicine and Dentistry, Okayama, Japan.

Noonan syndrome (NS) is an autosomal dominant disorder characterized by unusual facial features, proportionate short stature, skeletal anomalies, and congenital heart defects. Recently, mutations in the *PTPN11* gene, which encodes the protein tyrosine phosphatase SHP2, have been reported to account for approximately 50% of NS. SHP-2 is a ubiquitously expressed protein composed of 2 amino-terminus SH2 domains (N-SH2 and C-SH2) followed by a protein tyrosine phosphatase (PTP) domain. Though the identified mutations have been postulated as gain-of-function changes, we have reported that this may not necessarily be the case. We have now extended our study to 4 other mutants. COS-1 cells were transfected with WT or mutant SHP2 and tested for phosphatase activity. While PTP activity was increased in D61N, E139D, and Y279C SHP2, it was lower than that of WT in Q510E SHP2. Deletion of the SH2 domains that allosterically inhibit the PTP domain had no effect suggesting that the Q510E mutation attenuates enzyme activity *per se* rather than affinity between the domains. To investigate how these changes in SHP2 function might affect chondrogenesis, we introduced WT, C459S (dominant negative), and two of the mutants, D61N and Q510E SHP2 into ATDC5 chondrogenic cells using adenoviral vectors. When BrdU incorporation was assayed in the presence of serum, mutations that decreased PTP activity diminished DNA synthesis. Interestingly, when the assay was done in serum/growth factor free conditions, mutant SHP2s upregulated DNA synthesis regardless of phosphatase activity, suggesting that adhesion-mediated signaling may be involved. Since fibroblast growth factors (FGFs) play a key role in chondrogenesis, we next evaluated FGF-2 (5 ng/ml) induced MAPK activity by immunoblotting and detection with anti-phospho-ERK1/2 and anti-ERK1/2 antibodies. Mutations associated with low PTP activity reduced ERK activation. We also examined cell spreading and actin organization since adhesion-mediated signaling could be altered as indicated above. Transfected cells were trypsinized and replated on coverslips for 60 min followed by staining with Alexa Fluor 546 phalloidin. D61N SHP2 induced cell spreading and stress fiber formation while the contrary occurred with Q510E SHP2. Taken together, these results suggest that SHP2 mutations perturb crosstalk between growth factor-mediated and adhesion-mediated signals, possibly leading to disorganized chondrogenesis.

Phenotypic Expression of a PTHR1 Null Mutation in Homozygous and Heterozygous States. B. Gérard*[1], M. Vibert*[2], D. Menzies*[3], J. Ragage*[2], G. Bertrand*[1], D. Prié*[4], B. Grandchamp*[1], C. Silve[4]. [1]Hôpital Bichat, Service de Biochimie Hormonale et Génétique, Paris, France, [2]Hôpital Ste Croix, Metz, France, [3]Centre de Pathologie, Metz, France, [4]Faculté de Médecine Xavier Bichat, INSERM U426, Paris, France.

Blomstrand lethal chondrodysplasia (BLC) is a rare autosomal recessive disorder resulting from inactivating mutations in the PTH/PTHrP receptor (PTHR1) gene. Although the developmental defects in bone, tooth and breast have been characterized in detail, important aspects of the disease, including the cause of death, remain undefined, and no phenotypic abnormalities resulting from a heterozygous PTHR1 null mutation have been reported. Analysis of a new family with an inactivating mutation in PTHR1 has shed new light on these areas. PTHR1 gene analysis in the propositus revealed the presence of a homozygous 10 kb deletion encompassing P2 and P3 promoter regions, the first translated exon and most of the first intron. This large deletion, which precludes PTHR1 transcription, was present in the heterozygous state in both parents. At delivery (29 weeks), the infant was severely hydropic, but had normal cardiac activity. Radiological and histological analysis of the skeleton confirmed the diagnosis of BLC. A striking reduction in bone marrow space was noted, due to the extreme shortness of the long bones and coarse and much widened trabaculae. Residual islands of haematopoietic tissue demonstrated erythroblastosis. Important extramedullary haematopoiesis in liver was present, and associated with hepatosiderosis. Iron deposition was lobular and diffuse, with a periportal to pericentral gradient, a feature reminiscent of dyserythropoiesis. Except for evidence of right ventricular hypertrophy, no cardiac defects were present. In view of recent evidence that both osteoblast differentiation and signalling through PTHR1 regulate the development of stromal and hematopoeitic stem cells, the association of marrow dysplasia, extramedullary hematopoiesis and hepatosiderosis are consistent with the possibility that foetal anaemia resulting from abnormal erythrogenesis may contribute to the lethality of BLC. Both parents had hyperphosphatemia (mother: 1.45; father: 1.74; normal: 0.80-1.40 mM) and increased maximal renal phosphate reabsorption (1.6, and 1.8; respectively, normal: 0.7-1.4 mM), despite serum PTH (bio intact 1-84) values that were normal or increased. Serum calcium concentration and urinary calcium excretion were normal. The failure of PTH to adequately inhibit phosphate reabsorption in the parents suggests that heterozygous inactivation of PTHR1 is sufficient to impair the PTH response of proximal renal tubular cells.

The Recovery of Bone Mass after Weaning in Mice Is Associated with Increased Rates of Bone Formation and Decreased Rates of Bone Resorption. L. Ardeshirpour, J. N. VanHouten*, P. R. Dann*, J. J. Wysolmerski. Internal Medicine (Endocrinology), Yale University, New Haven, CT, USA.

Mammalian reproduction triggers a remarkable cycle of skeletal catabolism and anabolism. Lactation is associated with the loss of significant amounts of bone, a deficit, which is fully repaired after weaning. In fact, the recovery of bone mass post weaning represents the most rapid accrual of bone during adult life. The purpose of this study was to characterize maternal bone and mineral metabolism upon weaning in mice. Twelve-week-old CD-1 mice were allowed to become pregnant and deliver. On day 12 of lactation, pups were removed to initiate weaning. Serial DEXA scans from mid-lactation to 4 weeks after weaning revealed a progressive increase in bone mineral density (BMD). Compared to mid-lactation, by 4 weeks post weaning, BMD increased by 37% in the spine, 27% in the femur and 25% in the whole body. Remarkably, BMD started to increase as early as 3 days post weaning and statistically significant differences were seen by day 7 at the spine, day 10 at the femur and day 14 when total body BMD was assessed. Histomorphometry revealed a trend towards increased trabecular volume and significant increases in trabecular thickness by day 28 post weaning. Levels of urinary collagen C-telopeptide (CTx) decreased and remained low during the post-weaning period, suggesting that the elevated rates of bone resorption seen during lactation are promptly suppressed after weaning. In contrast, plasma osteocalcin levels, which were already elevated during lactation, increased further at day 3 post weaning, suggesting that bone formation rates are augmented following weaning. Histomorphometry studies in trabecular bone confirmed these changes in biochemical markers. Osteoclast numbers declined significantly, immediately after weaning. Osteoblast numbers were variable, but dynamic histomorphometry revealed an increase in bone formation rates. Interestingly, the mice were hypercalcemic 3 days after weaning, but calcium levels returned to the normal range by 1 week. Circulating PTH and PTHrP levels did not change during this time. In conclusion, upon weaning, maternal bone density increases rapidly in mice. This is accompanied by a decrease in rates of bone resorption and an increase in rates of bone formation. These findings provide the basis for further investigation of the molecular mechanism underlying the transition from bone loss to bone gain following the cessation of suckling.

The Effect of Pamidronate Discontinuation in Children and Adolescents with Moderate to Severe Osteogenesis Imperfecta. F. Rauch, C. Land, C. Munns, R. Travers, F. Glorieux. Shriners Hospital, Montreal, PQ, Canada.

Treatment with cyclical intravenous pamidronate is beneficial to children and adolescents with moderate to severe forms of osteogenesis imperfecta (OI). However, it is unclear at present how long the therapeutic effect persists after treatment discontinuation. In this study we therefore followed the course of 42 OI pediatric patients (19 girls) in the two years after stopping pamidronate. They had received the drug for an average duration of 5.1 years and were 13.2±5.0 years (mean±SD) old when treatment was discontinued. Expressed as a percentage of the result expected in age- and sex-matched healthy subjects, the bone resorption marker urinary NTx/creatinine increased from 45±21% to 72±33% during the first two years after pamidronate was stopped ($P < 0.001$ by ANOVA). However, NTx/creatinine at the two-year time point was still significantly lower than in healthy subjects or in untreated OI patients of the same age ($P < 0.001$). Lumbar spine bone mineral content increased by 12% in the two years following pamidronate discontinuation, whereas volumetric bone mineral density (vBMD) remained unchanged. Expressed as a percentage of the result expected in age- and sex-matched healthy subjects, lumbar spine vBMD decreased from 101±13% to 96±12% ($P = 0.02$). The study population sustained a total of 27 radiologically confirmed lower extremity fractures during the last two years of pamidronate treatment, whereas 18 such fractures occurred in the two years after discontinuation of therapy. These observations suggest that bone turnover recovers slowly after pamidronate is discontinued but is still suppressed after a drug-free interval of two years. Lumbar spine vBMD is maintained and fracture incidence does not increase within two years after stopping treatment.

Bone Mineral Density of Relatives of Individuals with Osteogenesis Imperfecta. L. A. DiMeglio[1], L. Ford*[2], C. McClintock*[2], M. Peacock[2]. [1]Pediatrics, Section of Pediatric Endocrinology, Indiana University, Indianapolis, IN, USA, [2]Medicine, Indiana University, Indianapolis, IN, USA.

Most cases of Osteogenesis Imperfecta (OI) are attributable to mutations in the genes for type I collagen (COL1A1 or COL1A2). Severe cases are often due to missense mutations that result in an abnormal collagen that interferes with the formation of collagen triple helices whereas mild cases are generally due to "null" mutations that reduce the amount of collagen produced. However, phenotype has wide variability and the relationship between genotype and phenotype is poor, even in family members with the same mutation. The reasons for this phenotypic variability remain uncharacterized. A striking phenotype in OI is decreased Bone Mineral Density (BMD). To examine if BMD is a potential marker for OI in families, we measured BMD in 70 relatives (45 parents, 21 siblings, 4 children) of 29 index patients with OI. 43 relatives had a first-degree family member with mild OI (Type I); 27 had relatives with severe OI (Type III or IV). Three parents and one daughter of individuals with Type I OI had an established diagnosis of OI. Relatives ranged in age from 5 to 69 years, with a mean age of 33 years. Relatives of individuals with Type I OI had lower mean BMD Z-scores of the lumbar spine than those with Type III OI (-0.56 v. 0.32, $p<0.02$), and trended toward lower total body Z-scores (0.03 v. 0.64, $p<0.07$) and lower femoral neck z-scores (-0.46 v. 0.18, $p<0.07$). These relationships were maintained even when the data from the 4 individuals with known OI were excluded. Six parents had total body z-scores of > +2. Surprisingly, 5 of these parents had children with severe OI. Although there was no correlation between the total body z-scores of index patients and of their relatives for type I patients ($p=0.3$), there was a strong **negative** correlation between total body z-scores of individuals with severe OI and those of their relatives ($r =-0.62$, $p<0.05$), indicating that affected individuals with severe OI had relatives with high bone mineral densities. Since type I OI is often inherited in an autosomal dominant fashion, one would anticipate as many as 50% of relatives would also carry an abnormal collagen gene. Mean BMDs that are low for age in these relatives, therefore, as we have documented, would be expected. Type III and IV OI are believed to be predominately sporadic mutations. The cluster of parents with high BMDs with children with severe OI, and the negative correlation between family members' BMDs and probands' BMDs are, therefore, unexpected and as of yet unexplained. The results suggest that in subjects with severe OI there are interactions between the genetic defects in collagen genes and genes that promote high bone mass.

Effects of Pamidronate on Bone Modeling, Bone Remodeling and Degree of Mineralization of Bone from Children with Osteogenesis Imperfecta. G. Boivin[1], P. Chavassieux[1], V. Forin*[2], G. Pinto*[3], P. J. Meunier[1]. [1]INSERM Unité 403, Faculty of Medicine R. Laennec, University C. Bernard Lyon1, Lyon, France, [2]Hospital Trousseau, Paris, France, [3]Hospital Necker, Paris, France.

Osteogenesis imperfecta (OI) is characterized by a bone fragility with a low bone mass, an alteration of the trabecular connectivity and a frequent increased bone remodeling (Rauch et al. 2000 Bone 26 :581-9). Treatment with bisphosphonates has been proposed. Intraveinous pamidronate leads to increase bone mass and decrease bone remodeling in children with OI (Rauch et al. 2002 J Clin Invest 110:1293-99). The degree of mineralization, rarely measured was increased in untreated OI (Boyde et al. 1999 Calcif Tissue Int 64:185-90) and normal after pamidronate (Weber et al. 2004 J Bone Miner Res 19 suppl. 1:S99). Our purpose was to evaluate, using bone histomorphometry and quantitative microradiography, the effects of pamidronate in iliac bone biopsies from 38 children (17 boys and 21 girls, 10 ± 5 yrs old) with OI (type I, III ou IV) treated for 2 years (IV cumulative dose of 9 mg/kg/yr before the age of 3 years and 8.5 mg/kg/yr after this age), and daily supplementation in vitamin D (1200 UI) and calcium (250-500 mg). Compared to age-matched controls (Glorieux et al. 2000 Bone 26:103-9) untreated OI showed significant ($p<0.0001$) decreased cortical thickness, BV/TV and trabecular number, and increased trabecular separation. Bone turnover appeared significantly augmented (activation frequency : +77%, $p<0.001$) with increase in osteoid parameters, a delay in the mineralization without defect of primary mineralization. After 2 years of pamidronate, bone mass (cortical thickness +55%, $p=0.008$, BV/TV +59%) was increased with an improvement of trabecular connectivity. Bone remodeling was significantly ($p<0.05$) decreased (mineralizing surfaces, activation frequency). After pamidronate, the mean degree of mineralization was slightly increased (+4.6%). Compared to adult controls (Boivin & Meunier 2002 Calcif Tissue Int 70:503-11), degree of mineralization of bone was slightly decreased in untreated OI. In conclusion, these results confirm the decrease of bone remodeling and a positive bone tissue balance of modeling after 2 years of pamidronate in children with OI. The augmentation of BMD (+66%, $p<0.001$) in OI after pamidronate (Forin et al. Joint Bone Spine in press) is due to a strong increase in bone mass associated with a sligth improvement of the degree of mineralization.

Role of Estrogen Receptor Beta in Mechanotransduction. L. K. Saxon*, A. G. Robling, C. H. Turner. Orthopaedic Research, Indiana University, Indianapolis, IN, USA.

Animal studies and longitudinal observations of women show that estrogen suppresses periosteal bone formation and continues to do so when combined with exercise. The discovery of estrogen receptors (ER) α and β have aided understanding of how estrogen and mechanical loading influence cortical bone formation. We hypothesized that the antagonistic effect of estrogen on the periosteum, when combined with mechanical loading, is due to signaling through ERβ. To investigate this 60 male and 60 female WT and $ER\beta^{-/-}$ mice were randomly assigned to either high, moderate or low mechanical loaded groups. The right ulnae of each mouse were subjected to in vivo loading for 60 cycles/day using a 2 Hz haversine waveform, for 3 consecutive days. Fluorochrome labels were injected 2 and 7 days after beginning loading and mice were sacrificed on day 12. Strain gauges were used to measure the mechanical strain applied per load on the medial periosteal surface of the loaded ulna from a subgroup of mice from each group. Differences between periosteal bone formation rate (BFR/BS $\mu m^3/um^2$ per year) in the loaded (right) versus nonloaded (left) ulna were measured using standard bone histomorphometry. Bone formation induced by mechanical loading was not different among the male WT and $ER\beta^{-/-}$ mice. In contrast, a difference in rBFR/BS was apparent between female WT and $ER\beta^{-/-}$ mice; periosteal bone formation was 5 times greater in female $ER\beta^{-/-}$ mice compared to WT for the same mechanical strain ($p<0.05$). These data suggest that removal of ERβ signaling makes long bones more sensitive to mechanical loading. The results appear to support our hypothesis that estrogen inhibits exercise-induced periosteal bone formation via a signaling pathway that activates ERβ. Because differences in loading responsiveness was detected in female $ER\beta^{-/-}$ and WT mice, but not in the male mice, it appears as though the ligand needs to be present for ERβ to be activated and potentially decrease the osteogenic response to mechanical loading. In conclusion, we found that female mice with a null mutation of ERβ formed more periosteal bone in response to mechanical loading. These results suggest that ERβ signaling suppresses periosteal bone formation.

Osteocyte Apoptosis and the Loss of Bone Mineral and Strength Induced by Tail Suspension in Mice Is Entirely Caused by Reduced Mechanical Strains, whereas OsteoblastApoptosis Is Due to Endogenous Glucocorticoid Actions. J. Aguirre, L. Plotkin, K. Vyas*, S. Stewart*, C. O'Brien, A. Parfitt, R. Weinstein, S. Manolagas, T. Bellido. Endocrinology, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Mechanical stimulation of osteocytic cells in vitro prevents their apoptosis via an integrin/Src/FAK signaling pathway leading to ERK activation. Conversely, reduction of mechanical forces in vivo increases the prevalence of osteocyte apoptosis; and this event precedes temporally, and is spatially associated with, osteoclast-mediated resorption and the loss of mineral and strength induced by tail suspension in mice. Unloading also induces an early increase in osteoblast apoptosis, which is associated with reduced osteoblast number and osteoid perimeter reflecting decreased bone formation. The bone fragility induced by administration of glucocorticoids to mice and humans is also accompanied by an increased prevalence of osteocyte and osteoblast apoptosis; and skeletal unloading by tail suspension has been shown to increase endogenous corticosterone in mice and rats. To determine the potential contribution of endogenous glucocorticoid action to the bone changes induced by unloading, we tail-suspended transgenic mice overexpressing 11β-hydroxysteroid dehydrogenase type 2 under the control of the murine osteocalcin promoter (OG2-11β-HSD2 mice) (n=10-12/group). This genetic manipulation deflects glucocorticoid action in osteoblasts and osteocytes by a pre-receptor mechanism involving conversion of biological active glucocorticoids to their inert 11-keto metabolites. We found that tail suspension induced a similar increase in the prevalence of cortical and cancellous osteocyte apoptosis in OG2-11β-HSD2 mice compared to wild type littermates after 7 days, which remained elevated up to 28 days. Likewise, the increased osteoclast number and the decreased cortical width, spinal BMD and vertebral strength found after 28 days of unloading were similar in bone of transgenic and wild type mice. Remarkably, the increase in apoptotic osteoblasts and the decrease in serum osteocalcin observed at 7 days in wild type mice were abrogated in OG2-11β-HSD2 mice. These findings indicate that the early increase in osteoblast apoptosis and reduced bone formation induced by tail suspension is due to the action of endogenous glucocorticoids. On the other hand, the increase in osteocyte apoptosis followed by loss of BMD and strength is entirely due to reduced mechanical loading confirming that physiological levels of strains maintain osteocyte viability.

A 3D Model of Osteocyte Gene Expression in Response to Mechanical Loading - Correlation of DMP1 Gene Expression in Osteocytes with Local Strain. S. Kotha*[1], S. Gidla*[1], J. Gluhak-Heinrich[2], M. Schaffler*[3], S. Harris[4], L. Bonewald[1]. [1]Oral Biology, Univ of Missouri, Kansas City, MO, USA, [2]Univ of Texas Health Science Center, San Antonio, TX, USA, [3]Mount Sinai School of Medicine, New York, NY, USA, [4]UTHSCSA, San Antonio, TX, USA.

The osteocyte is thought to act as a mechanotransducer, translating strain signals into a biological response. It is not known if osteoctyes respond as a population or individually in response to local strains. In this study, mRNA expression of Dentin Matrix Protein 1

(DMP1), a mechanically responsive gene highly expressed in osteocytes, was used as a readout to characterize this response. The goal of this study was to generate a 3-dimensional model based on finite element analysis (FEA), correlating gene expression in osteocytes to their local strain environment. FEA was conducted on ulnae from 6 month old female Sprague Dawley rats and validated by strain gage measurements. Right ulnae were loaded at 4Hz, 20N until 30% loss in whole bone stiffness. Left ulnae served as contralateral controls. DMP1 expression was assayed 2 days after loading by quantitative in situ hybridization using P^{32} labeled RNA probes. Gene expression was evaluated in seven transverse sections, spaced 0.75mm apart at the ulnar mid-shaft. Gene expression in osteocytes was correlated to local (continuum level) strains as determined from FEA. DMP1 expression in loaded ulnae was 2 fold higher than controls. Within bone sections, the pattern of gene expression per osteocyte was highly correlated to local strain magnitude in both loaded (DMP1: r^2= 0.72; p< 0.02) and control (DMP1: r^2= 0.61; p< 0.03) ulnae, regardless of whether strains were tensile or compressive. Our 3D model of gene expression showed that the longitudinal pattern of DMP1 gene expression (i.e. along the length of the ulna) was also correlated to peak compressive strain in both the loaded (DMP1: r^2= 0.65 ; p< 0.02) and control (DMP1: r^2= 0.63; p< 0.03) ulnae. The highest expression of DMP1 occurred in locations where new bone formation is predicted. **Together, these data suggest that osteocytes can respond globally (i.e. as a population) to increased strain, and that the response of individual osteocytes is also correlated with its local strain environment.** Refinements to this 3D model will allow incorporation of, any mechanoresponsive gene, biological response, and study of molecular mechanisms.

Repetitions of Mechanical Loading Potentiate Bone Cellular Responses by a Mechanism Involving NMDA Type Glutamate Receptors. E. A. Bowe*, T. M. Skerry. Department of Medicine, University of Sheffield, Sheffield, United Kingdom.

It has been shown that mechanical loading is a more potent stimulus to bone if instead of a single daily period of loading, the same number of cycles are divided into shorter separate loadings. This suggests that bone cells have the ability to memorise effects of loading and to modify their responses to subsequent loads in accordance with previous load history. Such a system functions in the CNS, where synaptic plasticity, the ability of previous synaptic events to potentiate or depress subsequent responses, underlies learning and memory. Specifically, Long Term Potentiation (LTP) involves interactions between different glutamate receptors and post-synaptic proteins at the synapse. Previously we have shown that the necessary components for LTP are expressed by osteoblasts, and are involved in responses to loading. The studies reported here were to determine whether a previous loading event potentiates bone cell responses to subsequent load and if so, whether an LTP like mechanism was involved. We loaded ROS 17/2.8 cells cyclically using a four point bending device (peak strain 3400με at 1Hz) for one or two 10 minute loading periods, 1 hour apart, with or without the competitive NMDA type glutamate receptor antagonist AP-5 (50M). Before the second loading period, AP5 was throughly washed off the cells. Cells were harvested 10 minutes after the last load for mRNA analysis. Real time RT-PCR was performed to measure changes in cFOS, JUNB and FOS-1 expression, which are immediate early genes involved in differentiation. A single 10 minute period of cyclic strain caused a significant increase in cFOS mRNA ($p<0.001$) that was unaffected by the presence of AP-5. Cells that experienced two intervals of strain showed a further significant ($p<0.004$) increase in cFOS expression compared with cells loaded once. This increased response to a second loading period was abolished when AP5 was present for either one or both of the loading periods, in which case cFOS levels were then not different from cells that had experienced just one period of strain. Equivalent changes were not detected in JUNB or FOS-1 mRNA. In cells subjected to one or two fluid flow regimens with and without AP-5, there was no difference between one and two flow periods, whether AP-5 was added or not. These data provide compelling evidence that the potentiation induced *in vivo* by divided loading events occurs *in vitro*, and that its mechanism involves NMDA receptor-mediated signalling. This suggests that an LTP-like process is functional in bone. Since it is known that in the CNS, LTP is enhanced by estrogen, subtle changes in bone's LTP could account for post-menopausal reductions in the osteogenic effects of habitual activity.

Potential Role of α5 Integrin as a Mechanosensor in the Opening of Hemichannels for the Release of Prostaglandin in Response to Mechanical Stress. P. P. Cherian[1], A. J. Siller-Jackson*[1], S. Burra[1], S. Gu*[1], L. F. Bonewald[2], E. Sprague*[3], J. X. Jiang[1]. [1]Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, [2]Oral Biology, School of Dentistry, University of Missouri, Kansas City, MO, USA, [3]Radiology, University of Texas Health Science Center, San Antonio, TX, USA.

Mechanosensing osteocytes express large amounts of the gap junction-forming protein, connexin (Cx) 43, yet gap junctions are only active at the small tips of their dendritic processes, suggesting another function for Cx43. Previous studies have shown that both primary osteocytes and the osteocyte-like MLO-Y4 cells respond to fluid flow shear stress (FFSS) by releasing intracellular prostaglandin E_2 (PGE_2). MLO-Y4 cells were exposed to FFSS at 16 dynes/cm^2 in the absence and presence of the gap junction inhibitors 18 β-glycyrrhetinic acid (β-GA) and carbenoxolone, and Cx43 antisense. We observed that cells plated at lower densities release more PGE_2 than cells plated at higher densities (>20X) in response to FFSS. This response was significantly reduced by Cx43 antisense and by β-GA and carbenoxolone, even in cells without physical contact. Inhibitors of other channels, such as the purinergic receptor $P2X_7$ and the prostaglandin transporter PGT, had no effect on PGE_2 release. These results suggest that Cx43-hemichannels are involved in the release of PGE_2 in response to FFSS. Indeed, FFSS induced the opening of hemichannels in primary osteocytes and MLO-Y4 cells, and this opening was inhibited by an antibody specific for Cx43-hemichannels. To identify the potential mechanosensor responsible for the opening of hemichannels, immunolocalization of tethering molecules was examined. Co-localization of Cx43 was observed with α5 integrin, but not with vinculin, paxillin, or focal adhesions. Cx43 and α5 integrin co-localized not only on the cell surface, but also throughout the cell body and cell processes, becoming more prominent in flow conditions. With FFSS, Cx43 protein migrates to the plasma membrane with an increase in hexametric forms of Cx43 on the cell surface as Cx43 located at the cell surface was more resistant to Triton-X-100 extraction with FFSS, suggesting the formation of detergent-insoluble protein plaques, similar to previously reported for gap junctional plaques. Together, these results suggest FFSS induces the translocation and assembly of Cx43 in the membrane surface along with α5 integrin and that un-apposed hemichannels formed by Cx43 serve as a novel portal for the release of prostaglandin in response to mechanical strain.

Identification of Transient Receptor Potential Vanilloid 4 (TRPV4) to Be Mechanosensitive Channel that Mediates Bone Loss Due to Unloading. F. Mizoguchi*[1], A. Mizuno*[2], H. Kondo[1], Y. Ezura[1], K. Nakashima[1], M. Suzuki*[2], N. Miyasaka*[3], M. Noda[1]. [1]Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Pharmacology, Jichi Medical School, Tochigi, Japan, [3]Department of Medicine and Rheumatology, Tokyo Medical and Dental University, Tokyo, Japan.

Mechanosensing is one of the major determination paths for biological events. Transient receptor potential vanilloid 4 (TRPV4) is a Ca^{2+} permeable nonselective cation channel and it has been implicated in Ca^{2+} dependent signal transduction in several tissues, including brain, vascular endothelium and skin. TRPV4 has been suggested to be a channel that plays a role to sense heat, hyposmolality and pressure. Recently, TRPA1, a family member of TRP, was found to be mechanosensitive transduction channel in vertebral hair cells (Nature 2004). Mechanical stress also plays an important role in the maintenance of bone mass, as exemplified by the rapid loss of bone due to unloading in bed ridden patients to lead to osteoporosis. Such rapid events could be mediated by ionic movements through channels. In endothelial cells, cation channels have been suggested to sense shear stress. However, it has not been yet fully understood how bone senses the mechanical stress as no definite mechanosensitive cation channel has been discovered in bone. We examined whether TRPV4 is a sensor of mechanical stress in bone and if it is involved in the bone loss by using $TRPV4^{-/-}$ mice subjected to tail suspension, a model of unloading. Unloading for two weeks by tail suspension resulted in reduction in the secondly trabecular bone volume in wild type by about 40% as reported previously. In sharp contrast, there were no decreases in $TRPV4^{-/-}$ mice subjected to tail suspension. Body weight at the end point of two weeks of tails suspension was comparable between loaded mice and tail-suspended mice regardless of the genotype. As we usually see that primary spongiosa is a sensitive site for unloading, we also measured trabecular bone mass in this area. The height of the primary spongiosa was reduced by about 40% in wild type mice. Again TRPV4 deficiency blocked such suppression in the height of the primary spongiosa even after two weeks tail suspension. These results indicate that TRPV4 serves a mechanosensitive channel in bone as it was identified in hair cells and this would be one of the important mechanisms that regulate bone homeostasis.

Ablation of the Androgen Receptor in Mineralizing Osteoblasts Results in Late-Onset Loss of Trabecular Bone. A. J. Notini*[1], J. F. McManus*[1], A. J. Moore*[2], M. L. Bouxsein[3], V. Glatt*[3], B. E. Kream[4], H. A. Morris[2], J. D. Zajac[1], R. A. Davey[1]. [1]Medicine, University of Melbourne, Austin Health, Heidelberg, Australia, [2]Hanson Institute, Adelaide, Australia, [3]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, [4]Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Androgens stimulate bone formation and help maintain bone mass. However, the mechanisms by which androgens act on bone remain poorly defined. The aim of this study was to investigate the role of the androgen receptor (AR) in osteoblasts using osteoblast-selective AR knockout (ob-ARKO) mice. Mice with a floxed exon 3 of the AR gene were bred with Col 2.3-Cre transgenic mice, in which Cre recombinase is expressed in mineralizing osteoblasts. The skeletal phenotype of male ob-ARKO mice was assessed by histomorphometry and quantitative microcomputed tomography (microCT) at 6-, 12- and 32-weeks of age (n=8 per group). Wild-type, AR floxed and Col 2.3-Cre male littermates were used as controls. Data were analyzed by one-way ANOVA and Tukey's Post Hoc Test. Ob-ARKO males had normal body weight and femur length compared to controls. MicroCT analysis of the 5th lumbar vertebral body demonstrated that ob-ARKO mice had a decrease in trabecular number (Tb.N)($p<0.01$) and an increase in trabecular thickness (Tb.Th)($p<0.05$) compared to control mice at 12- and 32-weeks of age, suggesting increased bone turnover. This resulted in a reduction in trabecular bone volume (BV/TV)($p<0.05$) in ob-ARKO mice compared to controls at 32-weeks of age. The effects observed in ob-ARKO mice were accompanied by a reduction in connectivity density ($p<0.01$) and an increase in trabecular separation (Tb.Sp)($p<0.01$) compared to control mice at 12- and 32-weeks of age, suggesting a reduction in bone quality. MicroCT analysis of the distal femoral metaphysis also demonstrated a reduction in Tb.N ($p<0.05$), connectivity density ($p<0.01$) and an increase in Tb.Sp ($p<0.05$) in ob-ARKO mice compared to controls at 32-weeks (but not 12-weeks) of age. There was no effect on cortical thickness in ob-ARKO mice. We are currently performing dynamic histomorphometry, and measuring bone turnover markers and hormone levels in urine and serum samples collected from ob-ARKO and control mice. In summary, these findings demonstrate that inactivation of the AR, specifically in mineralizing osteoblasts in mice, results in increased bone turnover and decreased structural integrity of the bone, leading to a reduction in trabecular BV/TV in the vertebra at 32-weeks of age. Our data provides evidence of a role for androgens in the maintenance of trabecular bone volume directly via the AR in mineralizing osteoblasts.

Estrogens Control the Birth and Apoptosis of Bone Cells in Mice in Which ERα Cannot Interact with DNA (ERα$^{NERKI/-}$). S. Kousteni, M. Almeida, L. Han, A. Warren*, V. Lowe*, S. C. Manolagas. Div. Endocrinol., Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas Med. Sci., Little Rock, AR, USA.

Studies with 4-estren-3α,17β-diol (estren), a synthetic ligand of the ERα or the AR that simulates the nongenotropic effects of estrogens on osteoblast/osteocyte apoptosis but has minimal effects on classical transcription, have suggested that the classical genotropic actions of sex steroid receptors are dispensable for their bone protective effects, but essential for their effects on reproductive tissues. To test this hypothesis directly, a knock-in mouse model in which one endogenous ERα allele has been replaced by a mutant form of ERα which lacks DNA binding activity and classical ERE-mediated transcription (ERα NERKI; Jakacka et al., Mol Endo 16:2188, 2002) was crossed with a heterozygote knock-out mouse model of the ERα gene (Dupont et al., Development 127:4277, 2000). We anticipated that the progeny of such a cross, designated ERα$^{NERKI/-}$, should allow signaling of the ERα only through non-ERE pathways. We report that, as compared to 3 month-old wt control mice, ERα$^{NERKI/-}$ mice of the same age had an atrophic uterus (weighing 4-fold less) and much lower mRNA expression (3-fold) of the ERE-dependent Complement 3 (C3) gene, as measured by Real-time PCR. Further, ovariectomy (ovx) reduced uterine weight in the wt control but not in the ERα$^{NERKI/-}$; and E_2 replacement administered by daily subcutaneous injections (30 ng/g) for 5 days was effective in restoring uterine weight in the wt control but not in the ovx ERα$^{NERKI/-}$ mice. However, 1 h following injection of E_2 to either wt controls or ERα$^{NERKI/-}$ mice we detected (by Western Blot analysis) an increase in the phosphorylation of ERK and the ERK-regulated transcription factors Elk-1 and C/EBPβ in vertebral lysates from both types of mice. On the other hand, 1 h treatment of ovx ERα$^{NERKI/-}$ mice with E_2 induced phosphorylation of Smad1, 5 and 8, but this effect was absent in the wt controls. Osteoclastogenesis assayed in *ex vivo* bone marrow cultures was upregulated in both wt and ERα$^{NERKI/-}$ ovx mice. Moreover, in *ex vivo* bone marrow and calvaria cell cultures derived from the ERα$^{NERKI/-}$ mice E_2 (10^{-8} M) increased apoptosis of mature osteoclasts and protected calvaria-derived osteoblastic cells from etoposide-induced apoptosis, as effectively as in wt controls. We conclude that estrogens do indeed regulate the birth and death of bone cells via ERE independent mechanisms; and kinase-mediated (nongenotropic) actions of the ER, in the absence of perhaps counter regulatory classical ERE-mediated actions, may activate signaling pathways that promote osteoblast commitment and differentiation.

The 1,25-Dihydroxyvitamin D/Vitamin D Receptor System Is Required for the Catabolic Effect of PTH but not its Anabolic Action. R. Samadfam, D. Miao, Q. Xia*, G. N. Hendy, D. Goltzman. Calcium lab, McGill, Montral, PQ, Canada.

PTH administered intermittently is known to have an "anabolic" effect, i.e., to increase bone formation whereas continuous infusion of PTH produces predominantly a bone resorptive or "catabolic" response. We examined the effect of the 1,25-dihydroxyvitamin D [1,25$(OH)_2D_3$]/vitamin D receptor(VDR) system on these responses by administering PTH to wild-type mice, to mice with targeted deletion of the 1α(OH)ase enzyme [1α(OH)ase-/-], and to mice with targeted deletion of the VDR [VDR-/-]. Mice were maintained on a "rescue" diet high in calcium (2%), phosphorus (1.25%) and lactose (20%) from after weaning to 2 months of age. We and others have previously shown that mice on this diet exhibit normal serum PTH, calcium and phosphorus concentrations. We have also reported that 1α(OH)ase-/- and VDR-/- animals on this diet exhibit reduced bone formation and trabecular bone volume suggesting a requirement for the vitamin D system for baseline bone formation. To examine the effect of deficiency of the vitamin D system on the anabolic effect of PTH, we treated animals with either vehicle, PTH (1-34) 80 µg/kg per day or PTH 80 µg/kg three times a day for 8 weeks. PTH 80 µg/kg once daily produced an increase in bone density in both wild-type and mutant mice and PTH 80 µg/kg three times a day produced an even more robust effect. Histologic analysis demonstrated increases in trabecular bone and in osteoblast numbers. The response was slightly less in mutant mice than in wild-type mice reflecting the requirements for the 1,25$(OH)_2D_3$ for baseline bone formation. We then examined the catabolic effect of PTH in wild-type and mutant mice by infusing PTH (1-34) 140 µg/kg/day for 2 weeks using Alzet osmotic minipumps. The continuous infusion of PTH resulted in a significant decrease in bone density which was evident as early as one week after infusion into wild-type animals. In contrast infusion of PTH into mutant mice increased bone density, particularly in the lumbar spine and increased trabecular bone volume. The data indicate that the 1,25$(OH)_2D_3$/VDR system is not required for the anabolic effect of PTH but that the catabolic effect of PTH may be significantly dampened by reduced 1,25$(OH)_2D_3$/VDR activity. The catabolic action of PTH may therefore be dependent on an intact 1,25$(OH)_2D_3$/VDR system and may be converted to an anabolic action by modulating this system.

The Pituitary Hormone, FSH, Directly Enhances Osteoclast Formation and Survival. Z. Zhang*[1], L. Sun[1], Y. Peng*[1], J. Iqbal*[1], S. Zaidi*[1], D. J. Papachristou*[2], H. Zhou*[1], A. C. Sharrow*[2], B. B. Yaroslavskiy*[2], L. Zhu*[1], A. Zallone[3], M. R. Sairam*[4], T. R. Kumar*[5], L. Cardoso-Landa*[1], M. B. Schaffler[1], B. S. Moonga*[1], H. C. Blair[2], M. Zaidi[1]. [1]Medicine, Mt. Sinai School of Medicine and the Bronx VA GRECC, New York, NY, USA, [2]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [3]Medicine, University of Bari, Bari, Italy, [4]Medicine, Clinical Research Institute of Montreal, Montreal, ON, Canada, [5]Medicine, University of Kansas, Kansas City, KS, USA.

Post-menopausal bone loss is accompanied not only by declining estrogen, but also by elevated FSH levels. Nonetheless, a direct effect of FSH on bone cells has never been investigated. Here, we report for the first time that FSH directly stimulates the formation and survival of osteoclasts. We find that RANK-L-induced osteoclast formation from either bone marrow or RAW cell precursors is enhanced significantly in the presence of FSH at levels found in circulation (3 to 100 ng/ml). This was paralleled by a significant increase in the expression of the osteoclast differentiation markers TRAP, calcitonin receptor and VEGFc. These effects were strongly potentiated when the FSH receptor (FSHR) was over-expressed in adenovirus-infected RAW cells, and were lost in FSHR null osteoclast precursors; together the results establish that FSH effects are mediated *via* an osteoclastic FSHR. The effects of FSH on osteoclastogenesis remained intact in TSH receptor (TSHR) null cells, ruling out cross-reactivity between FSH and the TSHR, which is also present on the osteoclast. In parallel studies, FSH promoted the survival of osteoclast precursors and mature osteoclasts. In RAW264.7 cells, effects of FSH on early apoptosis were demonstrated by the dose-dependent reduction in the camptothecin-induced annexin V^{high}/PI^{low} cell population. In the absence of RANK-L and M-CSF, FSH caused a concentration-dependent increase in the number of surviving mature osteoclasts generated from bone marrow or RAW264.7 cells. Finally, FSH enhanced the phosphorylation of Akt1, a key anti-apoptotic kinase, as well as the MAP kinases Erk1 and Erk2 at 30 and 60 minutes post stimulation. This was paralleled by an increased nuclear localization of c-fos at 30 minutes. Consistent with a role for c-fos in mediating the osteoclastogenic and anti-apoptotic actions of FSH, basal c-fos levels were reduced in FSHR null osteoclasts compared with wild type cells. We conclude therefore that FSH acts directly on osteoclasts to promote their formation and survival. Increased circulating FSH levels accompanying ovarian failure may thus contribute to the bone loss that has been attributed traditionally to declining estrogen.

Glucocorticoid Induced Osteoporosis Requires the Glucocorticoid Receptor in Osteoblasts and Does Not Depend on DNA Binding of the Receptor. J. Tuckermann[1], A. F. Schilling[2], M. Priemel*[2], B. Stride*[3], M. Kirilov*[3], T. Wintermantel*[3], F. Tronche*[4], M. Amling[2], G. Schuetz*[3]. [1]Tissue Specific Hormone Action, Institute of Molecular Biotechnology, Jena, Germany, [2]Experimental Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany, [3]Molecular Biology of the Cell I, German Cancer Research Centre, Heidelberg, Germany, [4]Collége de France, Paris, France.

Osteoporosis is a severe adverse effect observed during glucocorticoid therapy. The physiological mechanism remains poorly understood. Glucocorticoids (GC) could influence bone homeostasis by lowering calcium levels, impact on the release of sex hormones and on hormones of the growth axis or by acting directly on bone cells. GC exert their effects by binding to the glucocorticoid receptor (GR) which in turn regulates gene expression by binding to GC responsible elements in the promoter region of target genes or by interacting with and thus interfering with other transcription factors. To address the cellular and molecular role of GR function in GC induced osteoporosis we analyzed the effect of GC on bone in mice with osteoblast specific and DNA binding deficient GR mutations. For the osteoblast specific deletion of the GR we generated transgenic mice carrying the cre recombinase gene under the control of regulatory sequences of the runx2 gene. In runx2-cre mice cre expression and recombination of loxP-sites occurs in cells of the osteoblastic lineage. These mice were crossed with GRloxP mice ($GR^{runx2cre}$). To study the DNA binding independent function of the GR we investigated the mechanism of GC induced osteoporosis in function selective GR mutant mice (GR^{dim}). In wildtype mice prednisolone treatment for two weeks strongly inhibited the bone formation leading to lower bone mass. In contrast in $GR^{runx2cre}$ mice bone formation was not affected by prednisolone treatment and thus bone mass was maintained. This indicates that GC action on bone is mediated by direct effects of the GR in osteoblasts. To determine, if this action depends on DNA binding of the GR, we treated GR^{dim} mice with prednisolone. These mice responded to GC with a strong inhibition of bone formation. This results in a low bone mass phenotype, which was similar to that what we observed in wildtype mice. In summary, GC exert their bone deleterious effects primarily via the glucocorticoid receptor in osteoblasts and the DNA binding function of the GR is not required. These results define the critical cell type and provide insights into the molecular mechanism of GC induced osteoporosis. They could help to design GC therapies with less bone related adverse effects.

Lack of Oxytocin in KO Mice Results in a Denser Appendicular Skeleton. Role of the Hormone as Autocrine-Paracrine Enhancer of Osteoblast and Osteoclast Activity. G. Colaianni*[1], R. Tamma*[1], N. Patano*[1], C. Camerino*[1], G. Montemurro*[1], M. Strippoli*[1], A. Di Benedetto*[1], S. Colucci*[1], M. Grano*[1], L. Sun*[2], M. Zaidi[2], A. Zallone[1]. [1]Human Anatomy and Histology, University of Bari, Bari, Italy, [2]Mount Sinai Medical School, New York, NY, USA.

Oxytocin (OT) is a well known hypothalamic hormone, whose effects in recent years have been demonstrated to be more widespread than previously believed. Oxytocin receptors (OTRs) are expressed by osteoblasts, mature osteoclasts and by their precursors. Here we show that oxytocin is an estrogen-controlled autocrine-paracrine short life peptide that turns on cell activity in bone, stimulating pulses of bone resorption and formation. OTRs are up-modulated by an estradiol pre-treatment. As simultaneous result, RNA for oxytocin also becomes evident in osteoblasts and osteoclasts, indicating local synthesis of the hormone. The effects of estrogen stimulation are reversed after 12-24 hours. OTR stimulation elicits in both cell kinds calcium increase and ERK activation within 5' from OT treatment, back to basal levels after 20'. OT strongly stimulates proliferation in growing osteoblast cultures and in blood-derived macrophage population. In more differentiated osteoblasts OT, as seen by Western Blot and RT-PCR, reduces the expression of osteoprotegerin and induces a RANK-L increase. This effect is reversed after 24 hours. Osteoclastogenesis is strongly enhanced: in the presence of MCSF and RANK-L, OT added to the medium gives rise to a higher number of TRAP-positive cells. By real time PCR a significant increase of Cathepsin K and Beta-3 expression is evident. Bone resorption activity is, however, decreased by 40% in the first 48 hour after OT stimulation, but is thereafter back to control levels. All together these results indicate that the Oxytocin acts as an estrogen-mediated switch that keeps up bone cell activity, stimulating proliferation of both cell kinds. Oxytocin KO mice have been generated and, while normally developed at birth, mature mice show a denser appendicular skeleton and a reduced mineralization of the skull. This preliminary observation can suggest that the overall effect in vivo of the lack of oxytocin is a reduced bone turnover, resulting in a reduced resorption of vertebrae and long bones and insufficient formation in the skull. Experiments with KO cells are under way. Oxytocin role can be relevant in particular during the final period of pregnancy and after parturition when a high level of circulating calcium is necessary for the mineralization of the baby skeleton and for lactation, and could also be an important switch that keeps high the bone turnover level.

Mutations in the PLEKHM1 Gene Cause Autosomal Recessive Osteopetrosis in Rat and Human. L. Van Wesenbeeck*[1], P. R. Odgren[2], A. Frattini*[3], P. Moens*[4], C. MacKay*[2], E. Van Hul*[1], J. Timmermans*[5], R. Jacobs*[4], B. Peruzzi*[6], A. Teti[6], A. Villa[3], W. Van Hul[1]. [1]Center of Medical Genetics, University of Antwerp, Wilrijk, Belgium, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA, [3]Instituto di Tecnologie Biomediche Avanzate, Segrate, Italy, [4]Pediatric Orthopaedics, Catholic University of Leuven, Leuven, Belgium, [5]Laboratory of Cell Biology and Histology, University of Antwerp, Antwerp, Belgium, [6]Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

The osteopetroses are a genetically heterogeneous group of bone disorders characterized by a reduction in bone resorption resulting in an overall increase in skeletal mass. Several forms have been described in both human and animals. The incisors absent (ia) rat displays a generalized skeletal sclerosis and a delay in tooth eruption due to numerous dysfunctional osteoclasts. In order to elucidate the gene responsible for the osteopetrotic phenotype of the ia rat, we previously performed segregation analysis and delineated a 4.7 cM region on rat chromosome 10q32.1, in which the disease-causing gene is located (Van Wesenbeeck et al, 2004). Sequencing analysis of the genes located in this interval resulted in the identification of a deletion of 1 nucleotide in the plekhm1 gene in ia rats, resulting in a frameshift mutation followed by additional unrelated amino acids and a premature stopcodon. We also performed mutation analysis of the entire coding sequence of the PLEKHM1 gene in patients diagnosed with various forms of osteopetrosis and identified a splice site mutation in the human PLEKHM1 gene in 1 family diagnosed with the intermediate type of osteopetrosis associated with chondrolysis of the hip. Expression analysis demonstrated that the plekhm1 gene is ubiquitously expressed. Immunohistochemistry experiments clearly show the expression of the plekhm1 protein in bone tissue. We also performed GFP fluorescence experiments and showed that the plekhm1 protein is localized intracellularly. So far, the role of the plekhm1 protein in bone metabolism has not been elucidated. However, the presence of a RUN and a Pleckstrin Homology domain suggests that the plekhm1 protein is linked to small GTPase signaling. Indeed, it has been shown that several members of the small GTPase superfamily play a role in osteoclast functioning (Coxon et al 2003). These findings implicate for the first time that the plekhm1 protein has a role in osteoclast functioning and, more generally, in the bone resorption process.

Analysis of the Biochemical Mechanisms for the Endocrine Actions of FGF23. X. YU[1], O. A. Ibrahimi*[2], R. Goetz*[2], F. Zhang*[3], S. I. Davis*[1], H. J. Garringer[1], R. J. Linhardt*[3], D. M. Ornitz*[4], M. Mohammadi*[2], K. E. White[1]. [1]Indiana University School of Medicine, Indianapolis, IN, USA, [2]New York University School of Medicine, New York, NY, USA, [3]Rensselaer Polytechnic Institute, Troy, NY, USA, [4]Washington University Medical School, St. Louis, MO, USA.

Studies aimed at understanding the pathophysiology of several human disorders have collectively revealed that fibroblast growth factor-23 (FGF23) is a physiological regulator of renal phosphate reabsorption and vitamin D production. FGF23 is largely produced in bone, and unlike other FGFs, which are paracrine and autocrine factors, circulates in the bloodstream to the kidney where it ultimately acts within the proximal tubule to control mineral metabolism. Presently, it is unknown which of the seven principal FGF receptors (FGFRs) transmits FGF23 biological activity. Herein, we performed surface plasmon resonance (SPR) to comprehensively characterize FGF23 receptor binding specificity. We found that FGF23 specifically bound the 'c' splice isoforms of FGFR1-3 as well as FGFR4 with affinities of 200-700 nM, but did not bind the FGFR1-3 'b' splice forms. To provide biological evidence for the binding specificity of FGF23, we used an FGFR-based mitogenic assay. Consistent with our SPR data, in the presence of heparin, a glycosaminoglycan (GAG) cofactor required for FGF activation of FGFRs, FGF23 only activated FGFR1c (235% of control), 2c (243%), 3c (294%), and 4 (318%). The fact that FGF23 possesses modest receptor affinity and endocrine action led us to hypothesize that FGF23 may exhibit preferences for subsets of GAGs to produce biological activity within target tissues. We therefore assayed a library of in-house prepared GAGs for the ability to promote FGF23 activity. Of significance, highly sulfated and longer GAG species, with specific chemical backbones, were capable of synergizing dose-dependent FGF23 activity. Using opossum kidney (OK) cells, a model for kidney proximal tubule cells, FGF23 inhibited sodium-phosphate cotransporter Npt2a mRNA expression in a dose and time dependent manner. Removal of cell surface GAGs abolished the effects of FGF23, and only exogenous highly sulfated GAG was capable of restoring FGF23 activity, suggesting that OK cells naturally express specific GAGs permissive for FGF23 action. Based upon these results, we propose that the unique endocrine actions of FGF23 involve escape from FGF23-producing cells, circulation to the kidney, and signaling through multiple FGFRs in the presence of specific, highly sulfated GAGs. Our biochemical findings provide important insights into the molecular mechanisms by which disregulated FGF23 signaling leads to disorders of hyper- and hypophosphatemia.

Osteoblasts Are the Physiologically Relevant Site of *PHEX/Phex* Mutation in X-Linked Hypophosphatemia (XLH). B. Yuan[1], M. Takaiwa[1], T. L. Clemens[2], M. K. Drezner[1]. [1]University of Wisconsin, Madison, WI, USA, [2]University of Alabama, Birmingham, AL, USA.

Cloning of the *PHEX* gene from the *HYP* region of Xp22.1 in patients with XLH and identification of *PHEX/Phex* mutations in >2/3 of affected patients tested and in *hyp*-mice established that defects in *PHEX/Phex* underlie XLH. However, although *PHEX/Phex* expression occurs primarily in cells of the osteoblast lineage, increased osteoblast specific *Phex* expression in transgenic *hyp*-mice fails to rescue the disease phenotype, including abnormal renal phosphate transport and hypophosphatemia. Despite contrary physiological evidence, including secretion of putative phosphate transport inhibitory activity by *hyp*-mouse osteoblasts *in vitro*, these data suggest abnormal *Phex* expression at sites other than bone/osteoblasts underlies XLH. To definitively explore this paradox, we created mice with global *Phex* knockout ($Phex^{-/-}$) and conditional osteocalcin (OC) promoted inactivation of *Phex* in osteoblasts ($OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$) to establish if abnormal *Phex* in osteoblasts alone may underlie the *HYP* phenotype. We found $Phex^{-/-}$ mice exhibit ubiquitous absence of the *Phex* gene in tissues such as brain, lung, muscle, bone, kidney and heart. In contrast, $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ mice have absence of the *Phex* gene only in bone. Subsequently, we compared biochemistries of normal, *hyp*-, $Phex^{-/-}$ and $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ mice. Serum calcium was similar in $Phex^{-/-}$ (8.3±0.4 mg/dl), $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ (7.9±0.1 mg/dl) and *hyp*-mice (8.3±0.1 mg/dl) and insignificantly different from that in normal mice (8.4±0.1 mg/dl). In contrast, serum phosphorus in $Phex^{-/-}$ (3.3±0.2 mg/dl), $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ (3.5±0.2 mg/dl) and *hyp*-mice (4.1±0.2 mg/dl) was significantly less ($p<0.01$) than in normal mice (7.1±0.4 mg/dl), albeit *hyp*-mice had a significantly greater ($p<0.05$) level than the knockouts. More importantly, the renal brush border membrane phosphate transport in $Phex^{-/-}$ (146.8±10.9 pmol/mg protein/10s) and $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ mice (134.3±8.6 pmol/mg protein/10s) was comparable and significantly less ($p<0.001$) than in normal mice (246.7±13.8 pmol/mg protein/10s) but no different than in *hyp*-mice (120.7±10.4 pmol/mg protein/10s). The abnormal renal phosphate transport in the $Phex^{-/-}$ and $OC\text{-}Cre\text{-}Phex^{\Delta flox/\Delta flox}$ mice occurred due to increased bone production (>7 fold) and serum levels of FGF-23 and consequent decreased kidney membrane Npt2 protein, a mechanism identical to that in *hyp*-mice. These data provide compelling evidence that aberrant *Phex* function in osteoblasts alone is sufficient to underlie the biochemical phenotype in *hyp*-mice, establishing osteoblasts as the physiologically relevant gene mutation site in XLH.

Homozygous Loss-of-Function Mutation in the Renal Sodium-Phosphate Co-Transporter NaPi-IIc (SLC34A3) Leads to Isolated Renal Phosphate-Wasting in a Large Consanguineous Kindred with Hereditary Hypophosphatemic Rickets with Hypercalciuria. C. Bergwitz[1], N. M. Roslin*[2], J. C. Loredo-Osti*[2], M. Tieder*[3], H. Abu-Zahra*[1], M. Fujiwara*[2], K. Morgan*[2], H. S. Tenenhouse[2], H. Jüppner[1]. [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Research Institute of the McGill University Health Centre, McGill University, Montreal, PQ, Canada, [3]Tel Aviv University, Tel Aviv, Israel.

Hereditary hypophosphatemic rickets with hypercalciuria (HHRH) is an autosomal recessive disorder. Affected individuals show renal phosphate (Pi)-wasting leading to rickets/osteomalacia, but contrary to patients with XLH or ADHR, HHRH individuals show elevated 1,25(OH)2D3 leading to absorptive hypercalciuria. We performed a genome-wide linkage scan using genomic DNA from a consanguineous Bedouin kindred with HHRH (Tieder et. al. 1985) and showed that 8 of 10 affected individuals were homozygous at marker D9S1838; all parents were heterozygous. The two affected individuals, heterozygous at D9S1838, became homozygous at marker D9S1826, while three other HHRH patients were now recombinant, making it likely that the genetic defect leading to HHRH resides between markers D9S1826 and D9S1838. A novel microsatellite marker, CB9 (Chr.9:137208898), showed homozygosity for all affected individuals, but heterozygosity for all available parents, indicating linkage to chromosome region 9q34. SLC34A3, which encodes the type IIc sodium-Pi co-transporter, NaPi-IIc, was an obvious candidate gene, since it is normally expressed in the brush border membrane of proximal tubular cells, where most filtered Pi is reabsorbed. Nucleotide sequence analysis of SLC34A3 (13 exons and introns) revealed a homozygous frameshift mutation, c.227delC. This mutation disrupts a StuI site which allowed us to independently confirm this homozygous mutation in all affected individuals while all available parents were heterozygous; the mutation was, furthermore, absent in 94 chromosomes from healthy controls. The c.227delC mutation is predicted to cause complete loss of function of NaPi-IIc, and as such is the first description of a genetic defect in humans leading to a primary impairment in renal Pi reabsorption. Our findings, furthermore, emphasize the importance of NaPi-IIc in humans since lack of functional NaPi-IIc protein in patients with HHRH results in severe renal Pi-wasting, leading to hypophosphatemia, an up-regulation of the renal 1-alpha hydroxylase, elevated serum 1,25(OH)2D concentrations and absorptive hypercalciuria.

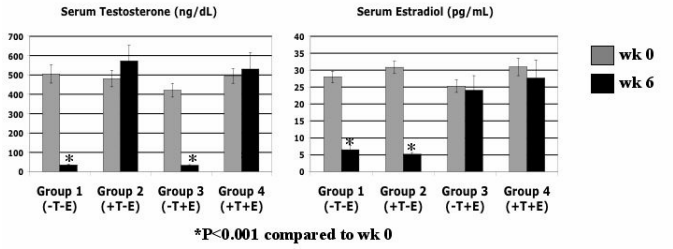
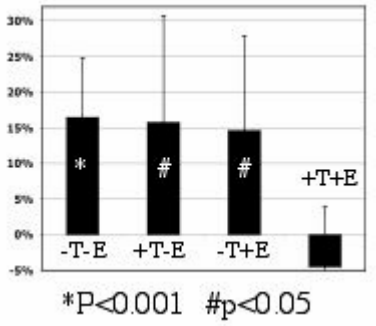
Effects of Selective Testosterone and Estradiol Withdrawal on Skeletal Sensitivity to Parathyroid Hormone in Men. B. Z. Leder[1], J. S. Finkelstein[1], M. Miller*[1], S. Comeaux*[1], R. Cohen*[1], H. Lee*[2]. [1]Endocrine, Massachusetts General Hospital, Boston, MA, USA, [2]Biostatistics, Massachusetts General Hospital, Boston, MA, USA.

Gonadal steroid withdrawal increases bone turnover and causes bone loss in men, but the underlying mechanisms are not yet defined. We previously reported that gonadal steroid deprivation increases the skeletal sensitivity to the bone resorbing properties of PTH in men but it is not known if this effect is mediated by the absence of androgens, estrogens, or both. To make this determination, we randomized 58 men (age 20-45) to receive combinations of a GnRH analog, aromatase inhibitor, and hormone add-back therapy to produce the following groups: Group 1 (testosterone (T) and estradiol (E) deficient, n=16), Group 2 (T sufficient but E deficient, n=12), Group 3 (T deficient but E sufficient, n=14), and group 4 (T and E sufficient, n=16). 24-hour PTH infusions were performed before and 6 wk after hormonal manipulation. Serum NTX and OC were measured every 6 hours during the PTH infusions. The changes in gonadal steroid levels in each group are shown below.



***P<0.001 compared to wk 0**

Mean (SD) NTX levels measured prior to PTH infusion did not change in the eugonadal group but increased by 24% (17%) in group 1 (-T-E, P<0.001), by 16% (20%) in group 2 (+T-E, P=0.011), and by 11% (22%) in group 3 (-T+E, P=0.045). Serum NTX increased during PTH infusions in all groups at all time points (P<0.001). In the eugonadal group, the increase in PTH was the same at wk 0 and wk 6, whereas in all the other groups, the PTH-induced increase in serum NTX was greater at wk 6 compared to wk 0 (see figure).



Serum OC fell during PTH infusions in all groups and at all time points (P<0.001), but no differences were observed between wk 0 and wk 6 in any group. We conclude that the selective suppression of testosterone, estradiol, or both increases the skeletal responsiveness to the bone resorbing effects of PTH in men. Moreover, there does not appear to be a large additive effect of combined hormonal deprivation compared to the withdrawal of each hormone individually.

The Leptin Receptor Strongly Influences Bone Structure and Strength: Results from a Genome-Wide Screen in Rats. C. H. Turner[1], I. Alam[1], Q. Sun[1], J. Li[2], R. K. Fuchs[2], H. J. Edenberg*[3], D. L. Koller[4], T. Foroud[4], M. J. Econs[4]. [1]Biomedical Engineering, Indiana University, Indianapolis, IN, USA, [2]Anatomy, Indiana University, Indianapolis, IN, USA, [3]Biochemistry, Indiana University, Indianapolis, IN, USA, [4]Molecular Genetics, Indiana University, Indianapolis, IN, USA.

Previously, we identified two inbred strains of rats which differ greatly in bone mass and strength. These rat strains, F344 and LEW, were used to map quantitative trait loci (QTL) for skeletal phenotypes. A genome-wide screen was conducted on a 2nd filial (F2) population of 595 rats derived from F344 and LEW progenitors. The screen identified a QTL on chromosome (Chr) 5 that affected femoral and vertebral bone strength. At the Chr 5 locus, rats homozygous for F344 alleles had 8% greater femoral strength, 12% greater femoral moment of inertia, and 4% greater vertebral cross-section, than rats homozygous for LEW alleles. We subsequently extracted RNA from femurs from 4 wk old rats, and analyzed gene expression using the Affymetrix U34 rat genome array. Of the 31,099 putative genes on the array, 20,028 were expressed in the rat femur. Six genes on Chr 5 were differentially expressed in F344 compared to LEW, including the leptin receptor (*Lepr*). Real time PCR analysis confirmed that *Lepr* was expressed 11-fold higher ($p<0.0001$) in F344 femurs compared to LEW femurs. To test whether *Lepr* is linked to bone strength parameters, we genotyped the 595 rats in our F2 population using a

microsatellite marker that falls within an intronic region of the *Lepr* gene (D5Wox39). We found that variation at D5Wox39 explained 7.8% to 8.4% of the total variance in femoral structure and strength and that this marker accounted for the entire variance explained by the Chr 5 QTL. We then examined the effect of inactivating the *Lepr* in rats using the Zucker fa/fa rat model, which has an inactivating mutation of *Lepr*. At 5 months of age, Zucker fa/fa rats had bones with reduced cross-sectional size and strength. Zucker fa/fa rats had 17% lower femoral strength, 12% lower femoral moment of inertia, 41% lower vertebral strength, 17% lower vertebral cross-section, and 37% lower vertebral areal BMD ($p<0.0001$ for all tests), compared to lean controls (fa/Fa or Fa/Fa). Consequently, lack of a functioning *Lepr* in Zucker fa/fa rats negatively affected bone strength and structure. In our F2 population, rats with F344 alleles had higher expression of *Lepr* and greater bone strength compared to rats with LEW alleles. Our observations suggest a positive association between *Lepr* expression and bone strength. In addition, polymorphisms in the *Lepr* appear to exert strong influences on femoral and vertebral structure and strength.

Competitive Recruitment of β-catenin by BMP-2 to Smad-Containing Complexes from Tcf/Lef-Dependent Transcriptional Machinery. V. Salazar*, R. Civitelli, G. Mbalaviele. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

β-catenin is necessary for bone development and maintenance. We have previously shown that stabilized β-catenin synergizes with BMP-2 in inducing osteogenic differentiation from uncommitted, multipotent C3H10T1/2 cells. We studied the mechanisms of this interaction using 3 constitutively stabilized β-catenin mutants, *mut*GSK3 (all 4 deactivating phosphorylation sites mutated to alanine), ΔN90 and ΔN151 (N-terminal truncation), which were retrovirally transduced into C3H10T1/2 cells. While all these mutants stimulated Tcf/Lef transcription, though with different potency [*mut*GSK3 > (ΔN90 ΔN151)], only *mut*GSK3 or ΔN90, but not ΔN151, were able to stimulate alkaline phosphatase activity in C3H10T1/2 cells in the absence of BMP-2 (6-, 6-, 1.5-fold stimulation, respectively). However, all mutants synergized with BMP-2 for alkaline phosphatase induction (10-, 10-, 4-fold stimulation by *mut*GSK3, ΔN90 and ΔN151, respectively). Nonetheless, even in the absence of exogenous BMP-2, the specific inhibitor of BMPs, Noggin, dose-dependently inhibited alkaline phosphatase activity induced by constitutively active β-catenin mutants, implying that endogenously produced BMPs participate in and are required for β-catenin osteogenic activity. We also detected rapid dephosphorylation of endogenous β-catenin within 10 minutes of BMP-2 exposure, an event required for transcriptional activity. Co-immunoprecipitation demonstrated a dramatic increase of β-catenin/Smad4 association upon BMP-2 stimulation, coincident with β-catenin and Smad4 nuclear translocation, indicating β-catenin participation in Smad-containing complexes. Interestingly, neither did BMP-2 activate a Tcf/Lef reporter system (TOPflash), nor did active β-catenin mutants transactivate a Smad binding element (SBE-Luc). However, when the endogenous canonical β-catenin signaling was activated by lithium chloride (a GSK3 inhibitor), TOPflash activity was reduced >75% in the presence of BMP-2. Conversely, lithium chloride almost completely prevented BMP-2 activation of SBE-Luc. Furthermore, a constitutively stabilized but transcriptionally defective C-terminus truncated β-catenin mutant abrogated SBE-Luc stimulation by BMP-2 (100-600 ng/ml), and decreased >80% BMP-2 induction of alkaline phosphatase. Thus, BMP-2 competitively recruits β-catenin to Smad-containing transcriptional complexes, at the expense of Tcf/Lef transcriptional machinery. These results demonstrate that β-catenin osteogenic action proceeds via novel, "non-canonical" mechanisms.

Beta-Catenin Promotes Growth Plate Chondrocyte Differentiation and Maturation. M. Chen, Y. Yan, Y. Dong, H. Drissi, D. Chen, R. J. O'Keefe. Orthopaedics, University of Rochester, Rochester, NY, USA.

Chondrocyte maturation is a multi-step process essential for endochondral bone formation. Several growth factors regulate chondrocyte differentiation, including BMPs and Wnts. Wnt signaling was investigated in cartilage tissues and cells obtained from TopGal transgenic mice, which have the beta-catenin-responsive 3XTCF element driving the lacZ transgene. LacZ staining was present in 14.5 and 16.5 dpc embryos and in new born (P4) TopGal transgenic mice in proliferating and hypertrophic chondrocytes. To investigate the role of Wnt/beta-catenin signaling in chondrocyte differentiation, primary mouse sternal chondrocytes were isolated from neonatal TopGal mice. Treatment with Wnt3a increased the expressions of *BMP-2* (2-fold), *BMP-4* (2-fold) and *colX* (3-fold) after 3 days of exposure. While BMP-2 did not alter lacZ activity in chondrocytes derived from TopGal transgenic mice, it stimulated *colX*, *MMP13*, *alkaline phosphatase* and *VEGF*. To determine the role of Wnt3a/beta-catenin on chondrocyte maturation, C5.18 chondrocytes were transfected with beta-catenin expression plasmid or treated with recombinant Wnt3a. Wnt3a and beta-catenin stimulated the BMP reporter, 12XSBE-Luc, by 2.5 and 5-fold, respectively, and induced the expression of *colX*. Addition of noggin completely blocked the Wnt3a and beta-catenin-*colX* induction and BMP reporter activity. These results demonstrate that Wnt/beta-catenin induces chondrocyte differentiation in a BMP signaling-dependent manner. Experiments demonstrated expression of the natural intracellular inhibitor of beta-catenin signaling, inhibitor of beta-catenin/TCF4 (ICAT) in chondrocytes. ICAT over-expression in C5.18 chondrocytes reduced beta-catenin-induced Top-flash activity (60%). Transgenic mice targeting the ICAT transgene to cartilage using the 1.0kb type II collagen promoter (Col2-Flag-ICAT) were developed. Seven Col2-ICAT founder mice were identified and two independent transgenic lines produced and transgene expression was observed in cartilage tissues. Radiograph analysis showed retarded limb development with Col2-ICAT transgenic mice being 20-50% smaller than littermate controls. While 2-week-old wild-type mice had a well-developed secondary epiphyseal centers of ossification, chondrocyte maturation was completely absent in the epiphysis of Col2-ICAT transgenic mice, demonstrating a marked delay in chondrocyte maturation. The growth plate demonstrated thickening of the proliferating region and reduced width of the hypertrophic chondrocyte region. These results demonstrate that beta-catenin signaling induces BMP signaling and is required for chondrocyte maturation.

Deletion of DMP1 Results in Osteomalacia and Abnormalities in the Osteocyte Lacuno-Canalicular System - Rescue by Re-expression of DMP1 in the Osteoblast Lineage but not by High Phosphate Diet. Y. Lu[1], H. F. Rios[1], D. Nicolella[2], S. Kotha[1], S. Zhang*[1], Y. Xie*[1], L. Ye[1], J. D. Eick[1], L. Bonewald[1], J. Q. Feng[1]. [1]Oral Biology, School of Dentistry, UMKC, Kansas City, MO, USA, [2]Mech and Matls Engr, SW Res Ins., San Antonio, TX, USA.

Deletion of Dentin Matrix Protein 1 (DMP1) results in a severe osteomalacia-like phenotype, with a dramatic increase in osteoid seam thickness. Mineralization is defective as evidenced by diffuse fluorochrome labeling throughout the matrix. By immunogold labeling and immunostaining, DMP1 was shown to be highly expressed in osteocytes in normal bone and to localize specifically along the walls of the canaliculi. To gain further insights into the mechanisms for these osteocyte and mineralization abnormalities, the osteocyte lacuno-canalicular system in wild type and *Dmp1* KO mice was analyzed using procion red injection, atomic force microscopy, TEM, backscatter SEM, and resin casted SEM techniques. These experiments showed that the osteocyte lacunae in *Dmp1* KO mice, in both the long bones and alveolar bone, were twice as large, rounded and less ellipsoid compared to lacunae in wild-type mice. The osteocyte canaliculi in these KO mice were disorganized, reduced in number with loss of the lamina limitans, resulting in collapse of the canalicular space. Dendrite membrane surfaces appeared buckled and ridged. To distinguish from other conditions of osteomalacia such as Vitamin D resistant rickets, and to determine whether DMP1 functions in a local or systemic manner, a diet enriched in calcium, phosphorus, and lactose was fed to *Dmp1* KO mice from weaning until two months of age. In contrast to several other models of osteomalacia, including 25 hydroxyvitamin D 1 α hydroxylase KO and VDR KO mice, this diet failed to rescue the mineralization defect in *Dmp1* KO mice. To determine if re-expression of DMP1 in the osteoblast lineage would rescue the KO phenotype, 5 independent transgenic lines overexpressing DMP1 driven by a 3.6 kb rat type 1α1 collagen promoter were generated for crossing with *Dmp1* KO mice. Re-expression of DMP1 using this promoter rescued the phenotype by 1 month of age. High DMP1 protein expression was confirmed in both osteoblasts and in osteocyte canaliculi in the rescued mice. Interestingly, no phenotype was observed when DMP1 was overexpressed on a normal background. Together these data show that DMP1 is an extracellular matrix protein essential for establishment of normal osteocyte and lacuno-canalicular morphology. These findings identify DMP1 as a critical local regulator of mineral incorporation into osteoid and highlight its unique role in the molecular pathway for mineralization in bone.

Overexpression of the Zinc Transporter ZIP1 Induces an Osteogenic Phenotype in Mesenchymal Stem Cells. A. Gupta, M. A. Khadeer*, S. N. Sahu*, G. Bai*. Biomedical Sciences, University of Maryland, Baltimore, MD, USA.

Zinc (Zn) is an essential trace element that is involved in diverse metabolic and signaling pathways. Zn deficiency is associated with retardation of bone growth. Zn is relatively abundant in bone, and can be detected as free/loosely-bound Zn ions in both osteoid and in matrix vesicles produced by osteoblasts. Zn is thought to exert a direct effect on bone mineralization by its action on nucleation and mineral growth. Zn is also an important component of alkaline phosphatase (ALP) and several metalloproteases. Previous *in vitro* studies have suggested a direct effect of Zn on both proliferation and differentiation of osteoblast-like cells. However, the mechanisms for uptake of Zn into osteoblasts have not been examined in detail. Several families of Zn transporters have previously been characterized in mammalian cells, which function in either uptake, intracellular sequestration or efflux of Zn. The Zrt/Irt-like protein (ZIP) family of transporters mediates uptake of Zn into most mammalian cells, whereas the cation diffusion family (CDF) of transporters is involved primarily in Zn efflux. In the current study, we have examined Zn transport in osteoprogenitor cells, and have attempted to define a functional role for a Zn transport mechanism in osteogenic differentiation. We have identified at least two Zn transporters in both human mesenchymal stem cells and osteoblastic cells, namely the ubiquitous Zn transporter, ZIP1 and LIV-1, previously characterized to be expressed in breast cancer. The subcellular localization of both these Zn transporters suggested both plasma membrane and diffuse cytoplasmic distribution. During the process of osteogenic differentiation of pleuripotent mesenchymal stem cells, both Zn uptake and the expression of ZIP1 were increased. Adenoviral-mediated overexpression of ZIP1 in mesenchymal stem cells resulted in manifestation of an osteogenic phenotype in the absence of osteogenic culture conditions. The induction of an osteogenic lineage was associated with increased expression of osteopontin, Cbfa1/Runx2, bone sialoprotein, and collagen type 1. A siRNA-mediated reduction of ZIP1 protein expression in mesenchymal stem cells caused decreased Zn uptake, and inhibition of osteoblastic differentiation under osteogenic culture conditions. Finally, following overexpression of ZIP1 in mesenchymal stem cells, DNA microarray analysis revealed differential regulation of genes associated with proliferation of osteoprogenitor cells and osteoblast differentiation. In conclusion, these studies provide important insights into the role of a plasma membrane Zn transporter in initiation of an osteogenic lineage from mesenchymal stem cells.

Parathyroid Hormone Regulation of Notch Signaling during Osteoblastic Maturation. L. M. Bevelock*, X. Li*, C. Boumah, N. C. Partridge. Physiology & Biophysics, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ, USA.

The Notch signaling pathway plays a critical role in many cell differentiation processes. Our laboratory first identified that parathyroid hormone (PTH) increased the expression of Jagged1, a ligand of the Notch signaling pathway, in UMR 106-01 osteoblastic cells. We hypothesized that Jagged1 stimulates the proliferation of preosteoblasts, while inhibiting their further differentiation, overall resulting in bone growth. The objective of this study was to characterize the regulation of Jagged1 by PTH both *in vitro* and *in vivo* and to determine the effect of Jagged1 stimulation on osteoblastic proliferation and maturation. Parathyroid hormone (1-34, 10^{-8} M) treatment of UMR 106-01 osteoblastic cells increased Jagged1 mRNA expression eightfold 2 h after treatment, as determined by real-time RT-PCR. The increase in Jagged1 mRNA persisted for 8 h of PTH treatment. This increase in Jagged1 mRNA expression translated into increased Jagged1 protein expression. We also found that injections of hPTH(1-34; 8 ug/100g) daily for 5 d in three-month old female rats increased Jagged1 mRNA levels fourfold in the femoral metaphyses. These results demonstrate that PTH increases Jagged1 mRNA levels both *in vitro* and *in vivo*. The upregulation of Jagged1 by PTH in osteoblastic cells is a primary response since it does not require *de novo* protein synthesis. The PKA inhibitor, H-89, abolished PTH's stimulation of Jagged1 mRNA, while the PKC inhibitor, GF109203X, mildly inhibited PTH's stimulation of Jagged1 mRNA, demonstrating that PTH's stimulation of Jagged1 mRNA occurs primarily via the PKA pathway. To stimulate Notch signaling, Jagged1 protein was immobilized on cell culture dishes upon which rat primary calvarial osteoblasts were grown. Cell cycle analyses demonstrated that Jagged1 stimulated proliferation of rat primary calvarial osteoblasts; 20.7% of proliferating calvarial osteoblasts treated with Jagged1 entered the cell cycle, compared to 16.0% of the control cells (p=0.0002). Jagged1 treatment strongly inhibited expression of mRNAs for matrix metalloproteinase-13, alkaline phosphatase, osteocalcin and Runx2 by 7-, 3-, 120-, and 7-fold, respectively, in differentiating primary osteoblasts. These results suggest that Jagged1 stimulates proliferation of osteoblasts, while inhibiting their further differentiation. PTH stimulation of Jagged1 on the mature osteoblast may result in increased signaling by Jagged1 to preosteoblasts through Notch to increase their proliferation and suspend their differentiation, resulting in overall bone growth. The increase in the preosteoblast pool may be one mechanism by which intermittent injection of PTH increases bone mass.

Adipocytes in ΔFosB Overexpressing Mice Accumulate Less Fat Independent of the Osteoblast Phenotype. G. C. Rowe*[1], L. Neff*[2], W. Horne[2], R. Baron[2]. [1]MCDB, Yale University, New Haven, CT, USA, [2]Orthopaedics, Yale School of Medicine, New Haven, CT, USA.

Osteoblasts and adipocytes share a common mesenchymal precursor and several observations have suggested an inverse relationship between differentiation in the two lineages. Overexpression of ΔFosB, a naturally occurring alternative splice form of the FosB transcription factor, upregulates osteoblast differentiation and bone formation, leading to osteosclerosis. In vivo, the expression of ΔFosB under the control of the enolase 2 promoter (NSE) results in both an increase in bone mass and a decrease in adipose tissue mass, supporting the hypothesis of an inverse relationship between the two cell lineages. However, further studies have shown that the bone mass increase was independent of the fat phenotype, since no difference in adipose mass occurred when ΔFosB was expressed under the control of the osteoblast-specific osteocalcin promoter (OG2). To determine if the decreased fat mass was due to a decrease in the number of adipocytes that differentiate from mesenchymal precursors or to a decrease in the ability of adipocytes to accumulate fat, resulting in a decrease in adipocyte size, we compared epididymal fat pads from the NSE-ΔFosB and OG2-ΔFosB mice. However, the adipocytes within the epididymal fat pads of the NSE-ΔFosB were significantly smaller than those of the control littermates. Detailed analysis of the adipose tissue revealed that the decrease in adipose mass was directly proportional to the decrease in cell size. To determine if this decrease in adipocyte size was restricted to the epididymal fat, we examined the subcutaneous fat from the skin in the abdominal region. The size of the subcutaneous adipocytes was also reduced in the NSE-ΔFosB mice, giving rise to a thinner skin, that was due solely to the decrease in adipocyte size and not to differences in the epidermal or dermal layers. These differences in adipocyte cell size were absent in the OG2-ΔFosB mice, reinforcing the observation that the osteoblastic phenotype is independent of the adipocytic phenotype. Thus, the results indicate that decreased adipocyte size may, at least in part, explain the reduced fat mass observed in the ΔFosB mice and confirm that this decrease in fat is indeed independent of the increased bone. We conclude from this study and from the analysis of the OG2-ΔFosB mice that the enhancement of osteoblast differentiation by ΔFosB does not hamper the differentiation of mesenchymal cells into the adipocytes, making it unlikely that the decrease in fat observed in these animals is due to increased osteoblast differentiation. Instead, these results suggest a direct and osteoblast-independent effect of ΔFosB on the ability of individual adipocytes to accumulate lipids.

Increased Thymic T Cell Output Accounts for 50% of the Acute Bone Loss Induced by Ovariectomy. M. Robbie Ryan, W. Qian*, M. N. Weitzmann, R. Pacifici. Endocrinology, Metabolism and Lipids, Emory University, Atlanta, GA, USA.

Ovariectomy (ovx) induced bone loss is prevented by neutralization of IL-7, an estrogen regulated factor required for T lymphopoiesis and T cell homeostasis. Previous studies have revealed that ovx induced IL-7 causes bone loss by increasing the size of T cell pool producing the osteoclastogenic cytokine TNF. One mechanism by which ovx stimulates T lymphopoiesis is an IL-7 dependent increase in thymic T cell output, but the relative contribution of the thymus to ovx induced bone loss remained unclear. To determine if the IL-7 dependent expansion of T cells that occurs following ovx is due to an expansion of the existing T cell pool or due to de novo T cell production in the thymus, thymectomies (THX) were performed. Eleven-week-old C57BL6/J mice were either sham THX or THX, and one week later were ovx or sham operated and treated with neutralizing IL-7 antibody M25 or with irrelevant antibody for 4 weeks. Total body bone mineral density measurements by DEXA showed that THX/ovx mice lost ~50% less bone that sham THX/ovx mice. Furthermore, in vivo IL-7 neutralization completely prevented bone loss both in euthymic and THX ovx mice. These findings demonstrate that neutralizing IL-7 prevents bone loss due to both the thymic dependent and independent mechanisms of ovx induced bone loss. FACS analysis revealed that while ovx induced a significant increase in both the number of CD4+ T cells and in the number of activated (CD4+CD69+ and CD4+CD25+) T cells in the BM of THX mice, ovx caused a 5 fold higher change in sham THX/ovx mice. Similarly, there was a significant increase in the number of CD4+TNF+ T cells in the BM following ovx, but this was 3 fold lower than the sham THX/ovx group. The induction of T cell activation and TNF production was completely prevented by IL-7 neutralization. In vivo BrdU proliferation studies revealed a significant reduction in the number of proliferating naïve T cells in the THX/ovx group, whereas proliferation of memory T cells following ovx remained elevated. Together this data indicates that de novo T cell production contributes to approximately 50% of the T cell pool involved in ovx induced bone loss. Furthermore, this data indicates that even in the absence of the thymus, the peripheral T cell pool is able to expand and produce TNF in response to IL-7 and estrogen deficiency. Thus, the disruption of both T cell and bone homeostasis induced by ovx is mediated by IL-7 and due to both the thymic and extra thymic effects of this cytokine. We conclude that IL-7 is a pivotal upstream target through which estrogen regulates immune functions critical for bone homeostasis. Modulation of either IL-7 activity or thymic function may thus represent a novel therapeutic approach for osteoporosis.

The Estrogen Receptors (ERα and ERβ) Play an Essential Role in Osteocyte Mechanotransduction: Requirement of Membrane Localization and Caveolin-1, but not DNA Binding. J. Aguirre, L. Plotkin, K. Vyas*, S. Kousteni, C. O'Brien, S. Manolagas, T. Bellido. Endocrinology, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Mechanical stimulation prevents osteocyte apoptosis via a mechanism that requires activation of ERKs. However, cells lacking both ER α and β can not exhibit the ERK-activating effect of mechanical stimulation. Because of evidence that the ligand binding domain (E) of ERα is sufficient to mediate estrogen-dependent anti-apoptosis via an extranuclear non-genotropic mechanism, we investigated here whether ERα, ERβ, as well as their respective E domains are sufficient to mediate ERK activation induced by mechanical stimuli; and, whether the subcellular localization of the receptors alters this response. Expression of ERα and ERβ was knocked-down in MLO-Y4 osteocytic cells by small interference RNAs for the receptors, followed by rescue with wild type or ER mutants, along with ERK2 fused to a fluorescent protein to allow quantification of nuclear ERK accumulation. Receptor silencing and expression of receptor mutants were confirmed by Western blotting and real time PCR, respectively. Cultures were then subjected to biaxial stretching using a Flexercell Strain Unit (10 min at 5% elongation). Cells in which endogenous ERα and ERβ were silenced fail to exhibit nuclear ERK2 accumulation induced by mechanical stimulation by mechanical stimulation, whereas cells silenced for the non-essential protein lamin A/C remained responsive. Stretch-induced nuclear ERK2 accumulation was recovered in ERα/ERβ-silenced cells by transfecting ERα, ERβ, as well as Eα or Eβ; or by transfecting an ERα mutant (L525A) which does not bind estrogens. In addition, the response to stretching in ERα/ERβ-silenced cells was recovered by transfecting Eα targeted to the plasma membrane, but not by Eα targeted to the nucleus. Furthermore, transfection of an ERα mutant that exhibits decreased localization at the plasma membrane (S522A), or an unpalmitoylable ERα mutant with impaired plasma membrane localization and inability to interact with caveolin-1 (C447A), failed to confer ERK activation in response to stretching. These findings indicate that: a) both ERα and ERβ are able to mediate the ERK-activating function of mechanical stimulation; b) the ligand binding domain of each receptor is sufficient to confer responsiveness to mechanical stimuli, albeit in a ligand-independent fashion; and c) both plasma membrane localization of the ERα and its interaction with caveolin-1 are required for mechanotransduction.

Smad4 Induce Apoptosis by Inducing Bim Alternative Splicing as an ERα Cofactor. Q. N. Li, L. Wu*, D. Oelschlager*, C. Stockard*, W. Grizzle*, N. Wang*, M. Wan, H. Chen*, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Estrogens regulate differentiation and maintenance of reproductive, skeletal, cardiovascular and neural tissues by activating their estrogen receptors (ERs). Antiestrogen compounds such as SERMs regulate ER function by recruiting different co-factors. To examine their molecular mechanisms, we have identified that Smad4, a common signal transducer in BMP/TGF-β signaling, functions as a transcription ERα corepressor, and antiestrogen ligands, not by β-estradiol, induce the interaction of endogenous ERα with Smad4. To examine the function of the interaction, we examined the effect of Smad4 on apoptosis in 2 ERα positive (ERα+) cell lines (MCF-7 and T47D) and 2 ERα negative (ERα-) cell lines (MDA-231 and -468), and the results showed that Smad4 induced apoptosis only in ERα+ cells and not in ERα- cells. Western blot data demonstrated that Smad4 induces proapoptosis marker expression including Bim, Bax and Cytochrome c release in ERα+ cells. Bim is the BH3-only protein resides upstream in the apoptosis pathway. We found that Smad4 induces expression three alternative spliced isoforms at both protein and mRNA levels, and splice variants of human Bim mRNA were confirmed with DNA sequence analysis. The spliced short form Bim, the most potent inducer, is sufficient to induce apoptosis. These results indicate that Smad4 induces apoptosis in ERα+ cell by induction of Bim splicing. To further confirm that ERα is required, we expressed ERα siRNA in MCF-7 cells, which significantly reduced Smad4-induced Bax expression, Cytochrome c release and apoptosis. Smad4 was able to induce apoptosis in MDA-231 cells with acquired ERα expression. Finally, we examined the mechanism of Smad4-induced apoptosis *in vivo*. MCF-7 and MDA-231 cells were transfected with Smad4 or GFP, and were inoculated in nude mice. The tumor sizes of MCF-7 cells with Smad4 are only one tenth of those expressing GFP, and Tunnel assays showed apoptosis positive cells were significantly induced in Smad4 tumor xenograft compared with its GFP control. Whereas in MDA-231, tumor sizes in Smad4 transfected cells are not significantly different from GFP cells. Western blot and immunihistochemical staining of the tumor xenografts for apoptotic biomarkers showed that Smad4 expression induced pro-apoptosis expression including Bim, Bax and Cytochrome c release, but induction of these pro-apoptotic markers was not observed in nude mice bearing MDA-231 tumor xenografts. In summary, we characterized a novel mechanism that Smad4, an ERα cofactor, induces apoptosis by induction of Bim slicing, which may help to understand the diverse biological function of estrogen and serve as a potential drug target.

Regulation of Vitamin D Receptor Subcellular Trafficking. J. Barsony[1], K. Prufer*[2]. [1]National Institutes of Health and Georgetown University, Bethesda, MD, USA, [2]Department of Biological Sciences, Louisiana State University, Baton Rouge, LA, USA.

Previously we demonstrated that the vitamin D receptor (VDR) rapidly shuttles between the cytoplasm and the nucleus, and that the kinetics of nuclear import and export are influenced by the ligand, calcitriol. To elucidate the mechanisms of VDR trafficking, we continue to define segments of VDR that interact with the nuclear import receptors (nuclear localization sequence, NLS) and nuclear export receptors (NES) using mutational analysis. Moreover, we seek to understand the physiological importance and regulation of VDR trafficking in osteoblasts and osteoclasts. Confocal microscopy showed steady-state localization of VDR, and fluorescence recovery after photobleaching (FRAP) experiments indicated the kinetics of nuclear import and export. Deletion analysis and site-directed mutagenesis targeted potential NLSs of GFP-VDR to evaluate direct nuclear import, targeted leucine-rich regions to identify an interaction site for the crm-1 export receptor, and targeted coactivator, corepressor, and heat shock protein 70 (hsp70) binding regions to evaluate the influence of these protein partners on VDR nuclear import and export. Transcriptional activities of wild type and mutant receptors were assessed by luciferase reporter assays. Mutation of the R54 of VDR to glutamic acid abolished nuclear import, whereas mutation of R54 to glycine allowed import, suggesting that this NLS interacts with importin beta. A deletion preventing hsp70 binding precluded hormone-dependent nuclear accumulation of GFP-VDR, as did mutations in the AF-2 region preventing coactivator binding. We identified the N-CoR binding site of VDR by homology analysis and found that a mutation in this region (I242R) inhibits Crm-1 mediated VDR export. The crm-1 mediated export of NCoR required the binding of HDAC3, which has a well-defined NES. Taken together with the finding that the crm-1 inhibitor leptomycin B only prevents the export of unliganded VDR, these data indicate that the export of the unliganded VDR is indirect, requires assembly of the corepressor complex in the cytoplasm. TOR signaling regulates protein synthesis and cell proliferation, therefore nutrient deprivation and treatment with a specific TOR inhibitor, rapamycin, have profound effects on osteoblast functions. We found that nutrient deprivation or rapamycin facilitated calcitriol-induced nuclear import of GFP-VDR and increased transcriptional activities of VDR in ROS17/2.8 osteoblastic cells. Our findings provide new insight into the mechanisms of VDR subcellular trafficking and reveal the regulation of VDR import and transcriptional activities by the nutrient sensing TOR signaling pathway.

Several Nuclear Hormone Receptors Interact with DNA-PK in Common to Exert nVDRE-mediated Transcriptional Inhibition of the PTHrP Gene. T. Okazaki, T. Fujita. Endocrine unit, Internal Medicine, University of Tokyo school of Medicine, Tokyo, Japan.

We reported that both $1,25(OH)_2$ vitaminD_3 (abbreviated as D3) and 17β estradiol (E2) repressed PTHrP expression in human breast cancer MCF7 cells. We proposed that recruitment of HDAC2 (histone deacetylase2) as well as the catalytic subunit of DNA-dependent protein kinase (DNA-PKcs) to the chromatinized nVDREm, a half site of DR-3 type DNA element in the PTHrP promoter region, is required in this process. On the assumption that the mechanism of gene inhibition by the liganded nuclear hormone receptors is somewhat conserved, we examined whether other nuclear hormones affect PTHrP gene expression. Here, by using RT-PCR, we report that dexamethasone, progesterone and dihydrotestosterone inhibit transcription of the endogenous PTHrP as well nVDREm-containing reporter genes by 40~70% in MCF7 cells. Such inhibition was recognized as early as 2h after administration of 10 nM of each hormone and lasted at least 12h, which was similar to the repression by D3 and E2. Chromatin immunoprecipitation (ChIP) assay revealed that each hormone, respectively, recruited HDAC2 as well as DNA-PKcs to the nVDREm DNA element in a sequence-specific manner. DNA-PKcs remained tethered to the nVDREm region at least for 12h since its first appearance 30min after hormone treatment. Then, we found that transcriptional repression of the PTHrP gene by each hormone was abrogated by the treatment of the cells with inhibitors of either HDAC (trichostatin A) or DNA-PKcs (high concentration of wortmannin). Introduction of the regulatory subunit of DNA-PK, p70 Ku antigen, in the anti-sense orientation into MCF7 cells decreased the amount of Ku70 protein by about 50%. In these cells, transcriptional repression of the endogenous PTHrP as well nVDREm-containing reporter genes by these nuclear hormones was almost completely abrogated. As expected, ChIP assay revealed that hormone-dependent recruitment of DNA-PKcs to the chromatinized nVDREm was also inhibited in these cells. So far, we were able to confirm hormone-dependent interaction between DNA-PK and VDR/ERα/R, respectively, by using IP (immunoprecipitation)-Western assay. The effects of other nuclear hormone receptor ligands such as triiodothyronine, all-trans/9-cis retinoic acids and troglitazone are currently under investigation. Taken together, we raise a possibility that in order to exert nVDREm-mediated gene inhibition, several nuclear hormones utilize conserved transcriptional machinery in which the interaction between nuclear hormone receptors and DNA-PK plays crucial roles.

PTH/Forskolin Induces Selective VDR DNA Binding to the Osteopontin Gene Promoter in the Absence of 1,25(OH)2D3 and Suppresses the Gene's Transcriptional Output. S. Kim, N. K. Shevde, J. W. Pike. Biochemistry, University of Wisconsin- Madison, Madison, WI, USA.

The vitamin D receptor (VDR) is a transcription factor that mediates the actions of 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) through association with target genes. Historical as well as more recent chromatin immunoprecipitation studies (ChIP) support the idea that this process is initiated through a ligand-dependent VDR activation event. This event promotes the formation of VDR/RXR heterodimers as well as subsequent DNA binding to specific regulatory elements located within the promoter regions of vitamin D responsive genes. The bound VDR/RXR then serves to recruit coregulatory complexes necessary for downstream transcriptional activation. In the present series of experiments, we explored the possibility that VDR might also impact the activity of target genes in the absence of 1,25(OH)2D3, particularly under conditions that might modulate either the level or the activity of the unliganded VDR. Of the many agents that regulate the VDR gene, perhaps the most profound is PTH and/or forskolin. Indeed, we show that the treatment of mouse MC3T3-E1 cells with forskolin leads to both a rapid and dose-dependent increase in VDR mRNA and a dramatic 8-fold increase in VDR protein. That this effect of PTH/forskolin could impact the activity of vitamin D target genes was supported by the interesting observation using ChIP analysis that forskolin treatment selectively increased the association of the VDR with the osteopontin gene promoter but not that for Cyp24 in intact cells. Surprisingly, forskolin-induced VDR binding was not accompanied by co-localization of RXR, although the recruitment of this VDR partner was observed upon treatment with 1,25(OH)2D3. The absence of RXR suggested the possibility that unliganded VDR might function to suppress rather than to induce osteopontin transcription. To explore this, we treated calvarial osteoblasts derived from either wildtype or VDR-null mice with forskolin for periods up to 24 hours and assessed OPN mRNA abundance using RT-PCR. Forskolin suppressed OPN gene expression in a time-dependent fashion in wildtype calvarial cells but not in those from VDR-null mice. These results suggest that factors such as forskolin (and PTH) can induce the binding of unliganded VDR to at least one vitamin D target gene (OPN). In the absence of RXR, however, VDR appears capable of suppressing rather than inducing gene expression. Further studies will be required to assess the nature of the VDR suppressing unit, and to determine whether OPN gene binding is due to VDR upregulation or to a PKA-induced modification.

Role of Acid-Sensing TRPV1 in Bone Pain Associated with Cancer Colonization in Bone. H. Wakabayashi*[1], S. Wakisaka*[2], T. Hiraga[1], T. Sakurai*[1], M. Tominaga*[3], T. Yoneda[1]. [1]Biochem, Osaka Univ, Suita, Japan, [2]Oral Anat, Osaka Univ, Suita, Japan, [3]Okazaki Inst Integrat Biosci, NINS, Okazaki, Japan.

Bone pain is one of the major complications that affects QOL of cancer patients with bone metastases. Although the precise mechanism of bone pain is still unclear, the widely-known clinical observations that specific inhibitors of bone resorption bisphosphonates (BPs) reduce bone pain suggest a potential role of osteoclasts that play a central role in bone metastases. Osteoclasts dissolve bone minerals by releasing protons through the vacuolar type proton pump (V-H+-ATPase), thereby inducing acidosis, which is a well-known cause of pain. Recent studies have shown that acidosis directly activates the transient receptor potential channel-vanilloid subfamily member 1 (TRPV1) that converts pain signals into electrochemical signals and transduces them to the central nervous system. Here, we studied the role of TRPV1 in the induction of bone pain associated with cancer colonization in bone. Histological examination showed that TRPV1 was expressed together with calcitonin gene-related protein (CGRP)-positive sensory neurons in periosteum, cortical bone and bone marrow and dorsal root ganglion (DRG). To study the role of TRPV1, we established an animal model of cancer-induced bone pain by inoculating the Lewis lung cancer cells into tibiae in syngeneic wild-type (WT) and TRPV1-deficient (TRPV-/-) mice. In WT mice, tumor-inoculated tibiae showed hyperalgesia, decreased grip force and increased flinching compared with control tibiae, suggesting increased bone pain. The BP alendronate significantly reduced the hyperalgesia, increased grip force and decreased flinching. A specific inhibitor of the V-H+-ATPase bafilomycin A1 also showed the identical effects, suggesting a critical role of protons released by osteoclasts in bone pain. TRPV1-immunoreactive fibers were increased in tumor-inoculated bone compared with control bones. In contrast to WT mice, there were no differences in the hyperalgesia and grip force between bones with and without cancer cells in TRPV1-/- mice. Flinching of tumor-inoculated hind-limbs in TRPV1-/- mice was significantly less than WT mice. Number of c-Fos immunoreactive neurons in spinal dorsal horn (laminae I/II, L3-5) was greater in WT mice than TRPV1-/- mice. Consistent with these in vivo results, the F-11 rat DRG-like cells transfected with TRPV1 showed elevated and sustained c-Fos expression in response to acid. In conclusion, our results suggest that TRPV1 activation in the sensory neurons innervating bone by the acidic microenvironment created by bone-resorbing osteoclasts plays a critical role in cancer-induced bone pain.

Ral Activation Promotes Prostate Cancer Metastasis to Bone. J. Yin, M. Chock*, M. Oberst*, Y. Ward*, K. Kelly*. National Institute of Health/ National Cancer Institute, Bethesda, MD, USA.

Ras activation has been linked to the progression of many cancer types including prostate cancer. To determine if Ras plays a causal role in prostate cancer metastasis and the contribution of Ras effector pathways to the development of metastasis, we expressed oncogenic RasV12 and effector domain mutants in a human prostate cancer cell line DU145 and assessed their metastatic ability in a mouse metastasis model. Our experiments show that, following intracardiac injection, DU145 expressing oncogenic RasV12 metastasized to multiple organs including bone, brain and adrenal glands. Mice bearing DU145/RasV12 cells developed metastasis within 6-8 week. However, mice bearing DU145 empty vector control cells rarely developed metastases even with extended observation time (3 months). Ras activates multiple pathways; three well characterized Ras downstream pathways are Raf-MEK, phosphatidylinositol-3 kinase (PI3K) and Ral guanine nucleotide exchange factors (RalGEFs). We further investigated the contribution of these pathways to the development of metastasis using Ras effector domain mutants that specifically activate one of the pathways. Ras12VS35, Ras12VC40 and Ras12VG37 activate Raf-MEK pathway, PI3K pathway, and RalGEFs pathways respectively. We found that each downstream pathway produced a distinct metastatic phenotype in our mouse model. DU145 cells expressing Ras12V35S and Ras12V40C produced mainly brain metastasis and very few bone metastases. However, DU145/Ras12V37G caused mainly bone metastasis. The bone metastases in this model involve long bones and spine, and are osteolytic with osteoblastic components. Since bone is the major metastatic site of prostate cancer, we focused on the major downstream pathway of Ras12V37G, the RalGEFs. To determine if RalGEFs mediate the development of bone metastasis, RlfCAAX, a RalGEF that constitutively activates the Ral pathway, was expressed in DU145 cells. Mice inoculated with DU145/RlfCAAX expressing cells developed long bone and spine metastases in 6 weeks. Furthermore, blocking the RalGEF pathway by expressing a dominant negative RalB protein (RalBN28) in DU145/Ras12V37G inhibited the development of metastasis and increased the survival rate compared with DU145/ Ras12V37G alone. These results suggest that Ras activation promotes bone metastasis by activating the Ral pathway. Prostate cancer metastasis is a multi-step and multi-factor process, and our findings indicate that activation of Ras may play a major role in promoting prostate cancer metastasis. Furthermore, specific activation of the RalGEF pathway promotes the development bone metastasis.

Targeting Myeloma Bone Marrow Microenvironment by GammadeltaT Cells. M. Abe, T. Hara*, H. Shibata*, T. Hashimoto*, S. Ozaki*, S. Kido, D. Inoue, T. Matsumoto. Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan.

Multiple myeloma (MM) is characterized by devastating bone destruction and immune suppression leading to tumor escape and susceptibility to infection. MM develops and expands in a manner dependent on bone marrow (BM) microenvironment. We and others have demonstrated a vicious cycle between tumor expansion and bone destruction based on complex cellular interaction between MM cells and the BM microenvironment, providing a rationale for therapeutic strategies targeting the MM BM microenvironment. Aminobisphosphonate (N-BP), a potent anti-resorptive agent, can be recognized by human gammadeltaT cell receptors, and has a potential to expand gammadeltaT cells, which exert potent anti-myeloma effects. Although clinical application of gammadeltaT cells is underway in MM, their impact on BM microenvironment is unknown. In the present study, we explored the effects of the gammadeltaT cells on bone cells as well as co-cultures of MM cells and bone cells. GammadeltaT cells were expanded (30- to 100-fold increase) from peripheral blood mononuclear cells (PBMC) upon stimulation with N-BP (1microM) and IL-2 for 2 weeks. The gammadeltaT cells added exogenously were found to densely adhere to PBMC-derived preOCs and OCs as well as RPMI8226 MM cells and destroy them more than a half. Of note, the gammadeltaT cells almost completely annihilated them within 12 hours in the presence of N-BP and IL-2. Cytotoxic effects of N-BP and IL-2 were not significant. Interestingly, the gammadeltaT cells showed only minor effects on the viability of normal lymphocytes and BM stromal cells at day 4 and the colony formation of hematopoietic progenitor cells (BFU-E and CFU-GM). Thus, OC lineage cells as well as MM cells are highly susceptibile to gammadeltaT cells in an N-BP-inducible fashion. As we previously reported, growth and survival of MM cells and their resistance to anti-cancer agents are potently enhanced by co-existing OCs, plus MM cells support OC survival. GammadeltaT cells also exerted potent cytotoxic effects on both RPMI8226 cells and OCs in the presence of N-BP and IL-2 even in the co-culture settings. Furthermore, gammadeltaT cells migrated towards factors derived from the tumor bone lesions, osteopontin and MIP-1alpha, produced mainly by the BM microenvironment (especially OCs) and MM cells, respectively. These results suggest that gammadeltaT cells expanded by N-BP and IL-2 are able to target MM cells and OCs in the MM BM microenvironment, thereby inhibiting tumor expansion along with bone destruction. Therefore, gammadeltaT cells may provide a novel and promising therapeutic approach against MM.

Dkk1 Modulates Osteoclastogenesis and Bone Resorption: Implications for Myeloma Bone Disease. B. O. Oyajobi[1], A. Gupta*[1], A. Flores*[2], C. Wideman*[1], C. Shipman[1], G. R. Mundy[1], I. R. Garrett[2]. [1]Univ Texas Hlth Sci Ctr, San Antonio, TX, USA, [2]OsteoScreen, San Antonio, TX, USA.

The two current concepts of myeloma bone disease are of (i) localized osteolysis; (ii) generalized osteopenia with bone loss adjacent to 'nests' of tumor cells. In the murine 5TGM1 model of myeloma bone disease, we find localized osteolysis together with generalized osteopenia, determined by histomorphometry and bone scintigraphy (99mTc-MDP uptake), distinct from tumor cells. Similar preliminary data consistent with a generalized suppression of bone formation have been suggested in human studies. Although the mechanism underlying the generalized osteopenia in myeloma is unknown, it is likely to involve a circulating mediator. Our notion is that Dkk1, a circulating antagonist of canonical Wnt signaling overexpressed in patients with myeloma bone disease (Tian et al., 2003), plays an important role in this generalized osteopenia. Transgenic mice overexpressing Dkk1 exhibit an osteopenic phenotype. We hypothesize that, in addition to its effects on bone formation, Dkk1 also affects osteoclastogenesis, acting to uncouple bone resorption from formation. To test this hypothesis, we examined (i) effects of Dkk1 in ex vivo bone organ cultures that reflect 'coupling'; (ii) effects of Dkk1 and Wnt-3a (to activate Wnt signaling) on osteoclastogenesis in vitro. In neonatal mouse calvarial cultures, Dkk1 (100ng/ml) strongly inhibited new bone formation stimulated by a combination of BMP-2 and Wnt-3a. Exposure of calvariae to IL-1alpha (0.1nM) for 24 hrs stimulates osteoclastic bone resorption over a 4 day period, which is then followed by a wave of new bone formation from day 4 through day 7, assessed histomorphometrically. Dkk1 dose-dependently abrogated the IL-1-induced new bone formation assessed morphologically. Next, we examined the effect of Dkk1 in mouse whole bone marrow cultures in which 1,25(OH)2D3 robustly induces formation of TRAP+ multinucleated osteoclasts (Ocl). Ocl formation was significantly augmented in the presence of Dkk1 (100-500 ng/ml). In contrast, Wnt-3a (10-100ng/ml) inhibited Ocl formation dose-dependently. More importantly, Dkk1 reversed the inhibitory effect of Wnt-3a, inducing Ocl formation 3-fold greater that in the presence of D3 alone. Together, our data indicates that Dkk1 has the potential to promote osteoclastogenesis while concomitantly blocking bone formation. In myeloma patients with elevated Dkk1 levels, this would exacerbate the local bone disease and potentially be responsible for the generalized osteopenia. Therapeutic strategies aimed at reducing Dkk1 expression in the tumoral bone microenvironment, such as proteasome inhibition, would be beneficial in such patients.

Blocking DKK1 Activity in Primary Myeloma-Bearing SCID-rab Mice Is Associated with Increased Osteoblast Activity and Bone Formation, and Inhibition of Tumor Growth. S. Yaccoby*, F. Zhan*, B. Barlogie, J. D. Shaughnessy*. Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

We have previously demonstrated that multiple myeloma (MM) cells produce DKK1 and that DKK1 inhibits differentiation of osteoblast precursors in vitro (Tian et al. *NEJM* 2003). This is thought to result in an uncoupling process that may lead to induction of lytic bone destruction in MM. The aim of this study was to test the role of DKK1 in our novel SCID-rab model for primary MM. In this system rabbit bones were implanted S.C. in unconditioned SCID mice. Following 6 weeks, primary MM cells were injected directly into the implanted bone. MM cells from >85% of patients (n>50) were successfully engrafted, grew exclusively in the implanted bone and produce typical disease manifestations including increased osteoclast activity, reduced osteoblast numbers and induction of osteolytic bone disease (Yata & Yaccoby, *Leukemia* 2004). In this study, SCID-rab mice were engrafted with MM cell-expressing DKK1 (assessed by global gene expression profiling) from 7 patients. Following establishment of MM growth, as monitored by weekly measurement of human monoclonal immunoglobulins in mice sera and radiographically, mice were injected subcutaneously into the surrounding area of the implanted bone with neutralizing antibody (AB) against DKK1 (polyclonal AB: n=4, 50 µg/injection/2 days; monoclonal AB: n=3, 100 µg/injection/day) or vehicle, for 4-6 weeks. Whereas bone mineral density (BMD) in control mice was reduced by 3.4%±3.3% from pre-treatment levels, BMD in mice treated with anti-DKK1 was increased by 8.8%±6.8% from pre-treatment levels ($p<0.04$). The bone anabolic effect of DKK1 could also be visualized on x-ray radiographs. Histological examination revealed that myelomatous bones of anti-DKK1-treated mice had increased numbers of osteocalcin-expressing osteoblasts (45±5 vs. 16±2 per mm bone in controls, $p<0.02$) and reduced number of multinucleated TRAP-expressing osteoclasts (5±3 vs. 13±2 per mm bone in controls, $p<0.004$). Whereas in control mice tumor burden was increased in all experiments, anti-DKK1 treatment was associated with reduced tumor growth from pre-treatment levels in 4 of 7 experiments. Overall, tumor burden in control and anti-DKK1-treated mice was increased by 373%±141% and 162%±62% from pre-treatment levels, respectively ($p<0.02$). We conclude that DKK1 is a key player in myeloma bone disease and that blocking DKK1 activity in myelomatous bones reduces osteolytic bone resorption, increases bone formation and helps control myeloma progression. Our data also suggest that anti-DKK1 treatment may be useful for treating osteoporosis.

TGF-Beta Stimulates IL-6, PDGF-AA, and VEGF in Renal Cell Carcinoma Bone Metastasis. M. Doucet*, S. Kominsky, D. Nell*, K. Weber. Department of Orthopaedic Surgery, Johns Hopkins University, Baltimore, MD, USA.

TGF-β is a multifunctional cytokine, which has potent growth promoting effects on advanced cancers. We have shown that TGF-βRI and TGF-βRII are expressed in human RCC bone metastasis and are functional in human bone-derived RCC cell lines (RBM-IT4, RMB23, RBM21A, RBM17C). Since bone is the most abundant repository for TGF-β in the human body, we examined whether TGF-β plays a role in promoting the growth of RCC bone metastasis. We generated transgenic RBM1-IT4 cells stably expressing a dominant-negative (DN) TGF-βRII. RBM1-IT4, empty vector control cells, and two clones (DN1 and DN2) that showed a 46% reduction in TGF-β signaling were injected into the tibiae of athymic nude mice. Digital radiography showed that mice injected with DN2 cells had a significantly decreased incidence of bone lesions ($p<0.05$) and osteolysis ($p<0.001$) relative to parental cells while those injected with DN1 cells had no detectable lesions ($p<0.001$). Further, tumor growth, assessed by tumor weight and H&E staining, was significantly decreased in mice injected with DN1 and DN2 cells compared to parental cells ($p<0.05$). Since TGF-β treatment of RBM1-IT4 cells had no effect on cell proliferation as determined by MTT assay, we examined the ability of TGF-β to induce cytokines involved in cell growth, angiogenesis, and bone resorption. TGF-β stimulated increased secretion of IL-6 (x = 2.3-fold), VEGF (x = 1.3-fold), and PDGF-AA (x = 1.8-fold) from bone-derived RCC cells as determined by ELISA. Correspondingly, IHC analysis showed that IL-6, VEGF, and PDGF-AA were expressed in 8/9, 18/18, and 2/2 cases of human RCC bone metastasis. TGF-β-induced production of other growth promoting and bone resorptive factors, such as IL-8, TNF-α, and IL-1β was not observed. IL-6 is a multifunctional cytokine that has the ability to regulate cell proliferation and bone resorption. We found that IL-6 receptor (gp80) mRNA was expressed in 13/13 cases of human RCC bone metastasis and 4/4 bone-derived RCC cell lines. Further, gp80 protein expression was found in 16/16 cases of human RCC bone metastasis and RBM1-IT4 tumors established in the mouse tibia by IHC analysis. IL-6 treatment of bone-derived RCC cell lines stimulated STAT3, JNK, PI3K, and ERK signal transduction pathways by Western analysis. Interestingly, IL-6 stimulation of bone-derived RCC cells increased SMAD2/3 phosphorylation in response to TGF-β as determined by Western analysis, suggesting the possible potentiation of TGF-β signaling by IL-6. Taken together, these data suggest that TGF-β may play a substantial role in promoting the growth of RCC bone metastases and concomitant bone destruction, possibly involving the induction of cytokines IL-6, VEGF, and PDGF-AA.

Determinants of Bone Geometry, Density and Strength in Growing Bone. H. M. Macdonald*[1], S. A. Kontulainen[2], M. A. Petit[3], H. A. McKay[2]. [1]Human Kinetics, University of British Columbia, Vancouver, BC, Canada, [2]Orthopaedics, University of British Columbia, Vancouver, BC, Canada, [3]Kinesiology, University of Minnesota, Minneapolis, MN, USA.

The determinants of bone mass as measured by DXA have been studied extensively in children. Less is known about the influence of body and muscle size, maturity, ethnicity, physical activity and calcium intake on the 3-dimensional properties of bone during growth. Thus, our objective was to use pQCT to identify determinants of bone geometry, density and strength at 3 sites of the tibia in boys and girls. We measured height, tibial length and weight of 440 children (225 boys, 215 girls) aged 9-11 years (Tanner stage I-III). Ethnicity, physical activity and calcium intake were determined by questionnaire. We used pQCT (XCT-2000) to measure total bone cross-sectional area (ToA, mm^2) and total density (ToD, mg/cm^3) at the distal tibia (8%) with which we calculated a bone strength index (BSI, mm^3) as [ToA * $(ToD)^2$]. We measured ToA, cortical area (CoA, mm^2), cortical density (CoD, mg/cm^3) and strength-strain index (SSI, mm^3) at two shaft sites [midshaft (50%), proximal two-thirds (66%)] and muscle cross-sectional area (MCSA, cm^2) at the 66% site. We used multiple regression to identify significant predictors of bone outcomes. Compared to girls, boys were significantly heavier (37.9 vs 36.1kg, $p < 0.05$) and had greater MCSA (34.3 vs 33.1 cm^2, $p < 0.05$). Boys were also more physically active and had a higher calcium intake. All bone outcomes were 5-15% greater for boys ($p < 0.05$) except CoD which was not significantly different between sexes. For boys and girls, leg length explained the most variance in bone geometry and strength at the distal and shaft sites (20-64%) and was a weak predictor of density at all sites (1-6%). After adjusting for leg length, MCSA accounted for 13-20% of the variance in ToA, ToD and BSI at the distal tibia, 9-17% of the variance in ToA, CoA and SSI at both shaft sites and only 2-5% of the variance in CoD. Physical activity explained 5-8% of the variance in ToD and BSI at the distal site in both sexes and 1-2% of the variance in ToA, CoA and SSI at the shaft sites in boys only. Calcium was a weak predictor (1-4%) of ToD and BSI at the distal site and CoA, CoD and SSI at the shaft sites in boys only. Ethnicity explained less than 2% of the variance in ToA and CoA at the midshaft in girls only (Caucasian > Asian) and maturity was not a significant determinant of bone outcomes in either sex. Our data suggest that body size and MCSA explain most of the variance in tibial bone geometry, strength and total density but not cortical density in boys and girls. Higher physical activity levels and calcium intake among boys may explain why these factors influenced bone outcomes to a larger extent in boys.

RANKL Inhibition Decreases Femoral Head Deformity Following Ischemic Necrosis of the Femoral Head in Immature Pigs. S. Morgan-Bagley*[1], P. Kostenuik[2], H. Kim[1]. [1]Shriners Hospital for Children, Tampa, FL, USA, [2]Metabolic Disorders Research, Amgen, Inc., Thousand Oaks, CA, USA.

Legg-Calve-Perthes disease is a common pediatric hip disorder caused by ischemic necrosis of the femoral head. Osteoclastic bone resorption during the repair process has been shown to result in a flattening of the infarcted head that often leads to premature osteoarthritis. OPG is a soluble decoy receptor that inhibits osteoclastogenesis and bone resorption by neutralizing RANKL, a TNF member that is critical for osteoclast formation, function and survival. The therapeutic potential of RANKL inhibitors to inhibit bone resorption and preserve the structural integrity of the femoral head following ischemic necrosis has not been investigated. The purpose of this study was to investigate the effectiveness of recombinant OPG-Fc in the prevention of femoral head deformity in a large animal model of ischemic necrosis. In 10 piglets, ischemic necrosis was surgically induced by placing a ligature around the femoral neck. Two weeks later, OPG-Fc or PBS was administered subcutaneously to 5 animals per group for 6 wks. The animals were euthanized at 8 wks. Radiographic and histomorphometric assessments were performed on the femoral head. Western blot analysis for OPG and RANKL was performed on the bone from distal femoral condyle. The antiresorptive effects of OPG-Fc were monitored by measuring serum NTx. Radiographic assessment showed significantly greater preservation of the femoral head in the OPG-Fc group compared to PBS control ($p=0.03$). Epiphyseal quotient, the ratio of epiphyseal height to diameter, was significantly higher in the OPG group (0.39 ± 0.05) vs PBS controls (0.24 ± 0.06). Histomorphometry revealed a significant decrease in the number of osteoclasts ($p<0.0001$) present in the OPG group (1.8 ± 2.2/mm^2) vs PBS controls (35.6 ± 6.7/mm^2). Femoral epiphyseal bone volume (BV/TV) was significantly higher in the OPG group (16.5 ± 2.1) vs PBS controls (1.3 ± 2.6, $p< 0.0001$). The area of fibrovascular tissue where all trabecular bone had been resorbed was significantly reduced by OPG ($p<0.001$ vs PBS controls). Western blot analysis showed an increase in OPG and a decrease in RANKL in the OPG group compared to saline group. Serum NTx levels were reduced by 93% in the OPG group vs. saline controls ($p=0.01$ and 0.005 at 3 and 8wks respectively). To our knowledge, this is the first study to demonstrate the efficacy of recombinant OPG-Fc in pigs. These data are also the first to show that RANKL inhibition prevents femoral head deformity following ischemic necrosis. RANKL inhibitors may therefore represent a novel and promising therapeutic approach to inhibit bone resorption and thereby preserve the structural integrity of infarcted bone.

Age at Pubertal Growth Spurt Is a Strong Independent Predictor of Both Trabecular and Cortical BMD in Young Adult Swedish Men - *The GOOD Study*. J. M. Kindblom, M. Lorentzon, E. Norjavaara*, Å. Hellqvist*, S. Nilsson*, D. Mellström, C. Ohlsson. Center for Bone Research at the Sahlgrenska Academy, Department of Internal Medicine, Gothenburg University, Gothenburg, Sweden.

A large part of adult bone mass is acquired during puberty. However, the role of the time of pubertal growth spurt for adult bone mass is unclear. The aim of the present study was to investigate the influence of age at pubertal growth spurt for adult cortical and trabecular bone mass. Detailed growth charts from birth up to 18-20 years of age were available for 549 men participating in the *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study. Peak Height Velocity (PHV; occurring two years after the initiation of puberty) was calculated using the infancy-childhood-pubertal growth model. The time of PHV was then correlated with cortical and trabecular bone phenotypes analysed at 18-20 years of age, using peripheral quantitative computerized tomography (pQCT). Environmental factors were assessed through questionnaires. The independent predictive role of time for PHV was assessed through linear regression, including time of PHV, age at pQCT analyses, height, weight, calcium intake, smoking and physical activity. Trabecular BMD, measured, in the distal metaphyseal area of the tibia revealed that time of PHV was a strong negative predictor of trabecular BMD (β = -0.187, $p<0.0001$). Cortical bone analyses in the diaphyseal region of the tibia showed that time of PHV was an independent strong negative predictor of cortical BMD (β = -0.337, $p<0.0001$) and a positive predictor of cortical endosteal circumference (β = 0.213, $p=0.006$). Cortical periosteal circumference remained unchanged. We next compared the subjects with early puberty (EP, the 15% with earliest PHV, 12.0 ± 0.4 years of age) with those with late puberty (LP, the 15 % with latest PHV, 15.2 ± 0.5 years of age). Subjects with EP had higher trabecular (9.8 ± 1.3%, $p< 0.001$) and cortical BMD (1.9 ± 0.2%, $p< 0.001$) than those with LP. Moreover, subjects with EP had decreased endosteal circumference (-5.7 ± 1.2%, $p= 0.003$) but unchanged periosteal circumference (- 1.8 ± 0.7 %, NS) compared with those with LP. Thus, the time of puberty is a strong independent predictor of both trabecular and cortical BMD in young Swedish men and subjects with LP displayed an endosteal cortical expansion. Our study indicates that late puberty might be a risk factor for the development of low bone mass later in adult life. Further studies are required to determine if time of puberty is a determinant of trabecular and cortical BMD in elderly men.

Children with Bone Fragility Fractures Have Reduced Bone Mineral Areal Density at the Forearm and Hip and Higher Percent Body Fat. S. L. Mobley*[1], E. Ha*[1], J. D. Landoll*[1], N. E. Badenhop-Stevens*[1], A. Clairmont*[1], P. Goel*[2], V. Matkovic*[1]. [1]Bone and Mineral Metabolism Laboratory, The Ohio State University, Columbus, OH, USA, [2]Department of Statistics, The Ohio State University, Columbus, OH, USA.

Bone fragility fractures in children are very common during the pubertal growth spurt. We previously showed a reduced volumetric bone mineral density of the radius in children with distal forearm fracture due to low to moderate trauma (Landoll et al. J Bone Min Res 19:S87, 2004). We now present anthropometry data as well as bone mineral areal density measurements at several skeletal regions of interest in a group of children with (N=458) and without (N=398) forearm fracture (60% males, 40% females). Bone mineral areal density of the proximal and distal radius , hip, spine, and total body were measured by DXA (GE-Lunar DPX-IQ). For case subjects, measurements of the forearm were made on the non-fractured arm. For control subjects, measurements were made on the matching (dominant vs. non-dominant) arm. The results of the measurements are presented in the table.

Variable	Fracture group Mean (± SE)	Control group Mean (± SE)	Significance P
Age	11.3 (0.1)	11.3 (0.1)	0.755
Height cm	149.7 (0.7)	149.0 (0.7)	0.510
Weight kg	47.4 (0.8)	44.5 (0.8)	0.011
Body fat kg	11.687 (0.449)	9.476 (0.387)	0.0002
% Body Fat	24.0 (0.5)	21.0 (0.5)	0.0001
TBBMC kg	1.634 (0.030)	1.598 (0.030)	0.393
Spine BMD g/cm2	0.83 (0.007)	0.84 (0.009)	0.269
Femur neck BMD g/cm2	0.86 (0.007)	0.89 (0.008)	0.0001
Femur trochanter BMD g/cm2	0.75 (0.006)	0.78 (0.007)	0.015
Proximal radius BMD g/cm2	0.522 (0.004)	0.531 (0.004)	0.112
Distal radius BMD g/cm2	0.299 (0.003)	0.308 (0.003)	0.031

The above results show bone deficits in children with bone fragility fracture, not only at the forearm but also at the hip. The above results may be important in the view of rising obesity in children as well as fracture rate.

Fractures in Puberty - Causes and Implications in Old Age. M. Suuriniemi*[1], H. Suominen[1], H. Kröger[2], S. Cheng[1]. [1]Univ. JKL, Jyväskylä, Finland, [2]Univ. KU, Kuopio, Finland.

The aetiology of the large increase in the incidence of arm fractures during puberty and their relationship to the risk of osteoporosis in older age are unclear. The purpose of this study was to investigate the differences in bone properties and metabolism between girls with and without fractures during their early pubertal period. The subjects were 258 healthy 10-13-yr-old girls with Tanner stage I-III. Bone properties of the total body, total proximal femur, femoral neck, lumbar spine, distal radius, tibia shaft, and calcaneus were measured using different bone assessment modalities (dual-energy X-ray absorptiometry, peripheral quantitative computed tomography, scanning calcaneal ultrasonometry, and axial transmission ultrasonometry). Also, serum growth hormone, insulin-like growth factor-1, insulin-like growth factor-binding protein-3, estradiol, testosterone, sex hormone-binding glubulin, leptin, parathyroid hormone, 25-hydroxyvitamin D, aminoterminal propeptide of type 1 collagen, osteocalcin, bone-specific alkaline phosphatase, and tartrate-resistant acid phosphatase isoenzyme 5b were analysed. Dietary intakes, physical activity, family history of osteoporosis, and fracture history were determined by questionnaires. The fractures were further confirmed by medical records including X-ray photographs. The fractures occurred during ages 10-13-yr and not caused by severe trauma were included in the analysis. Our results showed that each of the 11 fractures concerned the arm; 6 of them occured 2-12 months before and 5 of them 2-19 months after the bone assessments. Girls with fractures had significantly larger cross-sectional area (269±22 vs 225±43 mm^2, $p=0.001$) but smaller volumetric bone mineral density (242±32 vs 290±36 mg/cm^3, $p<0.001$) of the radius, as well as higher activity of the bone-specific alkaline phosphatase (147±47 vs 119±33 U/L, $p=0.012$), than girls without a fracture history. No differences were found between girls who fractured before and those who fractured after the bone assessments. Noteworthily, the fractured girls also had 4.8 times higher relative risk of having a family member with osteoporosis ($p=0.015$), compared to their non-fractured counterparts. These findings suggest that the increased incidence of arm fractures during the adolescent growth spurt may be accounted for the inability of mineral accrual to keep pace with the great increase in bone size of the arm. Furthermore, the fractured girls may share some common genetic factors with their family members, which predispose them to high bone turnover, posing complications on the bone modeling and remodeling. Pubertal fractures should thus be considered as a true risk for future postmenopausal osteoporosis.

Bone Mass at the Lumbar Spine in Young Adults: Late Effects of Very Low Birth Weight. C. M. Smith[1], N. P. Wright*[2], J. Wales*[3], C. MacKenzie*[2], R. Primhak*[3], R. Eastell[1]. [1]Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, [2]Sheffield Children's Hospital, Sheffield, United Kingdom, [3]Dept of Child Health, University of Sheffield, Sheffield, United Kingdom.

A low peak bone mass (PBM) is an established risk factor for fracture in later life. Prepubertal children who were born with very low birth weight (<1500g, VLBW) have reduced bone mass compared to children born at full term. However, this reduced mass appears to be appropriate for their reduced body size, suggesting no reduction in bone strength during childhood. The effect of VLBW on PBM is unknown. A low bone mass in this population may become increasingly important as more VLBW infants survive into adulthood. PA lumbar spine bone mass was measured, using dual energy x-ray absorptiometry (Hologic Discovery), in 62 young men and women (age 21 -25 years); 36 born VLBW, 26 normal birth weight controls (C). There were 20 and 18 women, and 16 and 8 men in the VLBW and C groups respectively. Bone volume (BV) and volumetric bone density (bone mineral apparent density, BMAD) were estimated, using Carter's method (1997). Standard deviations scores (SDS), adjusted for age, height and weight, were calculated. The VLBW and C groups were compared using unpaired t-tests. Height and weight were not significantly different between the VLBW and C groups. Lumbar spine bone mineral density (BMD) was significantly reduced in the VLBW group. Mean (SD) BMD ZSc (Hologic output, adjusted for age only) was -0.68 (0.95) and -0.09 (0.99), $p = 0.02$, in the VLBW and C groups respectively. There were no differences in BV SDS. BMAD SDS (mean, SD) was reduced in the VLBW group (-0.49 (0.93), $p = 0.04$). PBM is reduced in VLBW young adults. This deficit is the result of reduced volumetric density, whereas bone size is normal. The deficit is still apparent after adjusting for differences in body size. Previous studies have suggested that VLBW children have reduced bone mass that is appropriate for bone and body size. We speculate that our results may suggest a deviation from normal bone mass accrual during puberty in VLBW individuals, which results in bones of normal size, but of reduced density. This reduced PBM may have implications for future fracture risk in VLBW individuals.

High Bone Turnover Predicts Mortality in the Frail Elderly: A Prospective Cohort Study. C. Chen*[1], P. Sambrook[1], L. March*[1], I. Cameron*[1], R. Cumming*[2], J. Simpson*[2], M. Seibel[3]. [1]Institute of Bone & Joint Research, University of Sydney, Sydney, Australia, [2]School of Public Health, University of Sydney, Sydney, Australia, [3]ANZAC institute, University of Sydney, Sydney, Australia.

Osteoporotic fractures are associated with accelerated bone turnover and excess mortality. In a prospective cohort study of 1112 elderly subjects, we assessed whether the rate of bone turnover is a direct predictor of mortality. Baseline data from elderly subjects (mean +/- SD age: 86 +/- 6.9 yrs; 21% male) living in residential care facilities were analysed. Parameters included: age, gender, co-morbidity, incident hip fractures, serum aminoterminal propeptide of type I collagen (PINP), carboxyterminal telopeptide of type I collagen (CTX), intact parathyroid hormone (PTH), serum 25 hydroxyvitamin D (25OHD). Serum calcium, phosphate and creatinine were measured in a randomly selected subgroup of 448 subjects (40%). Over a median follow-up of 817 (range: 4 - 2028) days , a total of 559 (50.3%) subjects died. In univariate analyses, time to death was significantly ($p< 0.05$) associated with age (HR 1.62, per 10 yrs), gender (HR 1.33, male vs. female), comorbidity (HR 0.31, mild vs. severe illness), hip fracture (HR 2.26, yes vs no), log serum creatinine (HR 1.67), log PTH (HR 1.29), log CTX (HR 1.50) and log PINP (HR 1.32). These associations remained unchanged when adjusted for serum creatinine levels. Mortality rates/ person/ year continuously increased with increasing serum CTX or PINP concentrations (highest quintile vs. lowest quintile, CTX: 32.4 vs 16.5%, PINP: 30.5 vs. 20.0%). In multivariate analyses adjusting for age, gender, comorbidity, 25OHD, PTH and hip fracture status, both bone turnover markers remained significantly associated with all cause time to death: log CTX, HR 1.27 (95%CI 1.11-1.47, $p<0.001$), log PINP, HR 1.21 (95%CI 1.06-1.39, $p= 0.007$). For individual causes of death, bone turnover markers were associated with deaths from cardiac and cerebrovascular causes, but not infections. We conclude that in the frail elderly, high bone turnover predicts death independent of age, gender, comorbidity, renal function, serum PTH levels and hip fracture status.

Vitamin D Deficiency and Neuromuscular Performance in the Longitudinal Aging Study Amsterdam (LASA). I. S. Wicherts*[1], N. M. Schoor Van*[1], A. J. P. Boeke*[1], P. Lips[2]. [1]EMGO, VU University Medical Center, Amsterdam, The Netherlands, [2]Endocrinology, VU University Medical Center, Amsterdam, The Netherlands.

Vitamin D deficiency is common in the elderly. Recently vitamin D deficiency has been implicated as a cause of decreased physical performance and falls. The aim of this study was to determine whether lower serum 25-hydroxyvitamin D (25(OH)D) is associated with lower neuromuscular performance. The study was done within the framework of the Longitudinal Aging Study Amsterdam (LASA), a follow-up study in a representative sample of the older Dutch population which started in 1992. Subjects were 656 men and 695 women aged 65 years or older on January 1, 1996 (mean age ± SD: 75.5 ± 6.6 yr). In 1995-1996, data were collected on physical performance and vitamin D status. Neuromuscular performance was measured by the sum of the following tasks: 5 chair stands, a walking test and tandem stand, each scored in seconds and classified from 1 to 4 points according to quartiles of the distribution. The total performance score, representing muscle strength and balance, ranged from 0 to 12. Multivariate regression analysis, adjusted for age, gender and Conclusions:body mass index (BMI), was used to examine the association between vitamin D status and neuromuscular performance. Serum 25(OH)D (mean ± SD) was 53.3 ± 24.0 nmol/l. Serum 25(OH)D was ≤ 25nmol/l in 152 (11.3%) persons, 25-50 nmol/l in 486 (36.0%) persons, 50 -75 nmol/l in 449 (33.2%) persons, and > 75 nmol/l in 232 (17.2%) persons. Scores on chair stands, walking test and tandem stand each showed significant improvement with increasing serum 25(OH)D ($P<0.001$). The total performance score was 4.9 when 25(OH)D ≤25nmol/l, 6.82 when 25(OH)D was 25-50 nmol/l, 8.10 when 25(OH)D was 50- 75 nmol/l and 8.72 when 25(OH)D > 75 nmol/l. The change in total performance score with increasing serum 25(OH)D was significant for all steps. When adjusting for age, gender and BMI, the performance score increased significantly with serum 25(OH)D up till 50 nmol/l ($P< 0.005$). In conclusion, a low serum 25(OH)D was significantly associated with lower neuromuscular performance up to a threshold of 50 nmol/l.

Ethnic Diversity in Volumetric Bone Density and Geometry in Older Men: The Osteoporotic Fractures in Men Study (MrOS). J. M. Zmuda[1], B. K. S. Chan*[2], L. M. Marshall*[2], J. A. Cauley[1], T. F. Lang[3], K. E. Ensrud[4], C. E. Lewis*[5], M. L. Stefanick*[6], E. Barrett-Conner*[7], E. S. Orwoll[8]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Oregon Health and Science University, Portland, OR, USA, [3]University of California, San Francisco, CA, USA, [4]VAMC and University of Minnesota, Minneapolis, MN, USA, [5]University of Alabama, Birmingham, AL, USA, [6]Stanford University, Palo Alto, CA, USA, [7]University of California, San Diego, CA, USA, [8]Oregon Health and Sciences University, Portland, OR, USA.

Bone mineral density (BMD) is not the only determinant of bone strength and fracture risk. The structural geometric properties of bone, such as the size, thickness, shape and spatial distribution of bone mass, also influences bone strength. Ethnic differences in bone geometry may have important effects on fracture epidemiology, but remain poorly defined. To address this, we characterized volumetric BMD (vBMD) and cross-sectional area (CSA) in 3,158 men aged 65+ from 6 geographic regions in the US who are enrolled in the Osteoporotic Fractures in Men Study (MrOS). Race/ethnicity was self-reported. BMD (g/cm^3) and CSA (cm^3) were derived from volumetric quantitative computed tomography scans of the femoral neck (FN) and lumbar spine (LS). Analyses were adjusted for age, height, weight and geographic area. Ethnic differences in vBMD were apparent in both the trabecular and cortical bone compartments at both skeletal regions (Table). FN and LS vBMD were greatest in African Americans (AA). FN and LS CSA were lowest in AA and greatest in Caucasians (CA). These ethnic differences in vBMD and geometry might contribute to at least some of the ethnic difference in hip and vertebral fracture epidemiology.

Femoral and Vertebral BMD and Geometry by Ethnicity

Ethnic Group	CA	AA	AS	HA
No. of men	2786	168	117	87
FN Cortical BMD	.524	.541	.520	.525
FN Trabecular BMD	.069	.094	.093	.079
FN CSA	12.7	12.3	12.5	12.6
LS Trabecular BMD	.109	.140	.117	.113
LS CSA	11.9	11.1	11.7	11.7

All $p<0.01$ for differences by ethnic group adjusted for age, weight, height, geographic region. CA, Caucasian American; AA, African American; AS, Asian American; HA, Hispanic American;

Fracture in Childhood and Adolescence: a New Risk Factor for Osteoporosis? S. L. Ferrari, T. Chevalley, J. Bonjour, R. Rizzoli. Div. of Bone Diseases, Geneva University Hospital, Geneva, Switzerland.

Traumatic fractures affect nearly one out of two children, with a peak incidence concomitant to peak height velocity (PHV). Its has been hypothesized that bone fragility at that age results from a transient deficit in bone mineral accrual relative to bone size. Whether a low bone mass persists beyond the period of PHV however remains unknown. Bone mineral content (BMC) was longitudinally assessed by DXA at both fractured and non-fractured sites in a cohort of 125 females who were followed over 8.5 yrs, from pre-puberty to pubertal maturity (mean age ± sem, 16.4 ± 0.1 yrs). During this period, 58 fractures occurred in 41/125 girls (cumulative incidence, 46.4%), 48% of all fractures affecting the forearm and wrist. Girls with and without fractures had similar height, weight and BMI, as well as mean calcium intake (>900 mg/d), at all time points. Before puberty and at the time of PHV, BMC values at the proximal radius (33% Rad.) tended to be lower in those with fractures ($p=0.066$ by non-parametric tests). However, as these girls reached pubertal maturity, BMC at the ultradistal radius (UD Rad.), femur trochanter (FT) and lumbar spine (LS) were all significantly lower in girls with fractures, whereas BMC at femur neck (FN) and diaphysis (F.Dia) were not (Table).

	BMC (G) FRACTURES (41)	BMC (G) CONTROLS (84)	P VALUE (Mann-Whitney U)
LS	42.67 ±1.08	45.39 ± 0.85	0.020
FN	4.55 ± 0.09	4.69 ± 0.08	NS
FT	5.91 ± 0.15	6.36 ± 0.14	0.034
F. Dia	52.67 ± 1.25	51.49 ± 1.03	NS
UD Rad.	1.35 ± 0.04	1.44 ± 0.03	0.019
33% RAd.	1.81 ± 0.03	1.89 ± 0.03	NS

Moreover, compared to girls without fractures, BMC gain throughout puberty was significantly less in fractured girls at LS (-8.0%, $p = 0.015$) and UD Rad. (-12.0%, $p = 0.006$), and approached significance at FT (-8.4%, $p = 0.064$) and 33% Rad. (-6.0%, $p = 0.09$), without differences in height and weight gain. BMC values at all sites were highly correlated between pre-puberty and pubertal maturity ($R=0.54$ at FT to 0.81 at LS) and within-trait correlations between mature daughters and their mothers led to heritability estimates ranging 80%-90% for hip, spine and 33%Rad. BMC, but only 36% for UD Rad. BMC. In summary, female children with fractures have lower BMC gain and lower bone mineral mass when they reach pubertal maturity, particularly at sites containing predominantly trabecular bone. Taken together with the evidence of tracking for bone mass during growth and the strong contribution of genetic factors therein, these observations suggest that a history of fracture in childhood and adolescence may be a marker for genetically determined low peak bone mass and osteoporosis later in life.

High IGFBP-2 Levels Are Associated with an Increased Risk of Osteoporotic Fractures in Elderly Men. C. Meier[1], T. V. Nguyen[2], J. R. Center[2], M. J. Seibel[1], J. A. Eisman[2]. [1]Bone Research Program, ANZAC Research Institute, University Sydney, Sydney, Australia, [2]Bone and Mineral Research Program, Garvan Institute of Medical Research, St. Vincent's Hospital and UNSW, Sydney, Australia.

Serum IGFBP-2 levels increase with advancing age, are inversely associated with bone mineral density (BMD) and are positively correlated with bone resorption rates. We examined the relationship between serum IGFBP2 and fracture risk in community-dwelling men. This case-cohort control study included 139 men, aged 71 ± 5.3 yrs (mean±SD) who had been prospectively followed in the Dubbo Osteoporosis Epidemiology Study for a median of 6.3 yrs (range, 2-13 yrs). During this period, 38 men had incident low-trauma non-vertebral fractures (cases), while 101 men had no fractures (controls). Femoral neck BMD, markers of bone resorption (ICTP) and formation (PINP), and serum levels of IGF-I, IGFBP-2, IGFBP-3 were measured at baseline. In the entire sample, IGFBP-2 was negatively correlated with femoral neck BMD ($r= -0.21$; $p= 0.01$) and positively correlated with age ($r=0.34$; $p<0.001$). Men with a subsequent fracture had higher baseline IGFBP-2 levels and higher baseline ICTP levels than men without a fracture. There were no significant differences in IGF-I, IGFBP-3 between cases and controls. In univariate logistic regression analysis, increased fracture risk was associated with higher IGFBP-2 (odds ratio [OR] 1.9; 95%CI 1.3-2.9) or higher ICTP levels (OR 2.3; 95% CI 1.5-3.5). After adjusting for age and femoral neck BMD, the effect of IGFBP-2 remained statistically significant (OR 1.73; 95%CI: 1.1-2.7). However, with the introduction of ICTP, the OR associated with IGFBP-2 reduced to 1.4 (95% CI: 0.8-2.3). In conclusion, these results suggest that IGFBP-2 predicts fracture risk in men independent of BMD and age, and this association is possibly mediated through an association between IGFBP-2 and bone resorption.

Short-Term and Long-Term Absolute Risk of Fracture by Bone Mineral Density and Age in Women and Men. N. D. Nguyen, H. Alhborg, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Residual lifetime risk of fracture (RLRF) is a preferred absolute-risk approach of assessment fracture risk in an individual, because it takes into account the risk of mortality of the individual. Although bone mineral density (BMD) is the best predictor of fracture risk, the RLRF for various BMD levels is not known due to lack of long-term longitudinal data. The present study was undertaken to estimate the RLRF in elderly men and women by age and BMD level. A sample of 1358 women and 859 men aged 60+ years as at 1989 of Caucasian background who have participated in the Dubbo Osteoporosis Epidemiology Study were studied. The participants have been followed for 15 years (1989-2004), and all fractures were recorded and confirmed by X-ray and personal interview. Traumatic and pathological fractures and fractures of skull, cervical spinal or digits were excluded from the analysis. During the follow-up period, all-cause mortality was also recorded. Bone mineral density at the femoral neck was measured by dual energy X-ray absorptiometry (GE-LUNAR) at baseline. Short-term (10-year) and RLRF from the age of 50 were estimated by the survival analysis with left truncation using the Cox's proportional hazards model taking into account the competing risk of death. During the follow-up period, 496 women and 180 men had sustained at least one fracture, and 465 women and 374 men had died. After adjusting for the competing risk of death, the RLRF (from the age of 50) was 54% (95% CI: 48-59) in women and 32% (23-36) in men. In women, the 10-year risk of fracture increased from 16% (12-21) among those aged 60-69 yr to 49% (40-61) among those aged 80+. In men, the 10-year risk also increased from 11% (5-17) among those aged 60-69 yr to 26% (13-38) among those aged 80+. The risk of fracture, as expected, increased with reduced BMD levels. In women with BMD T-scores≤-2.5, the 10-year and RLRF were 31% (19-44) and 71% (66-79), respectively; among men with the same BMD levels, the 10-year and RLRF risk of fracture was 30% (2-56) and 47% (35-77), respectively. For a given BMD level, the 10-year risk and RLRF also increased with advancing age, such that by the age of 70 and above, there was no significant difference in 10-year risk or RLRF between women with T-scores≤-2.5. Thus, in Caucasian population, the residual lifetime risk of any fracture from the age 50 is 1 in 3 men and 1 in 2 women. The presence of low BMD increased the risk to 1 in 2 men and 7 in 10 women. These estimates provide a means to communicate the risk of fracture to an individual patient, and can be used to promote identification of high-risk individuals and target for treatment in the population.

Akt1 in Osteoblasts and Osteoclasts Contributes to the Maintenance of Bone Mass and Turnover. N. Kawamura, F. Kugimiya, R. Suzuki*, K. Tobe*, T. Kadowaki*, K. Nakamura, U. Chung, H. Kawaguchi. Orthopaedic Surgery and Metabolic Diseases, University of Tokyo, Tokyo, Japan.

The phosphoinositide-dependent serine-threonine protein kinase Akt has been proposed to be involved in regulation of bone metabolism in vitro. This study initially confirmed that Akt was phosphorylated in isolated mouse calvarial primary osteoblasts (POB) by stimulation of insulin / IGF-I or BMP-2, and in M-CSF-dependent bone marrow macrophages (BMMϕ) and the BMMϕ-derived mature osteoclasts by stimulation of M-CSF. Among the three isoforms of Akt, Akt1 was shown to be most strongly expressed in the cells above by real-time RT-PCR. We then generated Akt1-deficient (-/-) mice and investigated the role of Akt1 in bone. Although Akt1-/- mice developed normally without abnormalities of major organs except for 10-20% decrease in body size as compared to wild-type (+/+) littermates, they exhibited significant decreases in both trabecular and cortex bone volume at 4-16 weeks of age by bone densitometry, 3D-μCT and pQCT analyses. Histomorphometric analysis of the proximal tibiae at 8 weeks revealed that parameters of both bone formation (Ob.S/BS, MAR & BFR/BS) and resorption (N.Oc/B.Pm & ES/BS) were lower in -/- mice than in +/+ mice. Cultured -/- POB showed markedly reduced differentiation and matrix synthesis determined by Alizarin red / von Kossa stainings and mRNA levels of osteogenesis markers such as COL1A1, ALP, BSP, osteopontin and osteocalcin. These decreases in -/- POB were restored to the +/+ POB levels by adenoviral reintroduction of Akt1. Runx2 adenovirally introduced into +/+ POB bound to and activated the osteocalcin promoter determined by chromatin immunoprecipitation and luciferase-reporter assays, respectively, both of which were markedly suppressed in -/- POB. After serum deprivation, cell survival rate was lower, and caspase-3 activity was higher in -/- POB than in +/+ POB; both were restored by Akt1 or Bcl-XL introduction. Osteoclastogenesis in co-culture of POB and bone marrow cells were reduced when either POB or marrow cells were derived from -/- mice. Furthermore, RANKL mRNA level in -/- POB, osteoclastogenesis from -/- BMMϕ in the presence of soluble RANKL, and survival of the -/- BMMϕ-derived mature osteoclasts were decreased. We conclude that Akt1 deficiency leads to low turnover osteopenia through dysfunctions of osteoblasts and osteoclasts: the former through decreased transcriptional activity of Runx2 and increased susceptibility to mitochondria-dependent apoptosis; and the latter through suppressed RANKL expression in osteoblasts and defects in differentiation / survival of osteoclastic cells. Akt1 was shown to play a pivotal role in the maintenance of bone mass and turnover.

The Pathogenesis of Age-Related Bone Loss in Mice Involves Increased Production of PPAR γ-Activating Oxidized Lipids Derived from the Lipoxygenase Alox15. R. L. Jilka, R. A. Wynne*, X. Chen, S. Stewart*, L. Xu*, J. J. Thaden*, R. S. Weinstein, S. S. Manolagas. Depts. of Endo/Metab, Biostatistics, and Geriatrics, University of Arkansas for Medical Sciences, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Age-related bone loss is characterized by a decrease in osteoblast number, but the underlying mechanism is unknown. It was recently shown that the level of expression of the lipoxygenase Alox15, and PPARγ, are determinants of bone mass in mice; and that Alox15, as well as reactive oxygen species (ROS), oxidize polyunsaturated fatty acids to generate PPARγ ligands. Moreover, activation of PPARγ with rosiglitazone causes bone loss in mice associated with increased marrow adipocytes, reduced osteoblasts and bone formation rate, and increased osteoblast apoptosis. PPARγ ligands also inhibited osteoblast differentiation and increased apoptosis of osteoblast progenitors. Therefore, we hypothesized that age-related bone loss is due at least in part to an increase in Alox15- and ROS-derived oxidized lipid ligands. Elsewhere in this meeting, we report that vertebral and femoral BMD declines by ~16% between 15 and 31 months of age in female C57BL/6 mice, and that this decline is associated with increased oxidative stress, increased osteoblast apoptosis and decreased bone formation rate. Here, we report that the bone content of oxidized lipid ligands of PPARγ, including 12- and 15-HETE and 13-HODE, increased by ~2-fold with advancing age in these mice, as determined by mass spectrometry. Moreover, transcript levels of Alox15 and PPARγ in bone increased progressively with age by 10-30 fold. The role of Alox15 was further examined using marrow cultures from 5-6 month old DBA/2 mice bearing an Alox15 allele characterized by high levels of expression, as compared to cells from C57BL/6 mice bearing the wild type allele or congenic DBA/2 mice bearing the C57BL/6 wild type allele. As expected, cells from DBA/2 mice exhibited a 30-50-fold increase in Alox15 expression, and this corresponded with a 2-fold reduction in osteocalcin expression as compared to wild type controls. Addition of the Alox15 substrates linoleic and arachidonic acid (20μM each) further reduced osteocalcin expression in cultures from DBA/2 mice, but had no effect on cultures from wild type controls. Taken together, these findings support the contention that PPARγ is increasingly activated by lipid peroxidation products with advancing age, secondary to elevated levels of ROS and Alox15. This results in bone loss due to increased adipogenesis at the expense of osteoblasts, and increased apoptosis of osteoblasts and their progenitors.

Caspase-2 Deficient Mice Have an Age-Associated Increase in Osteoclastic Bone Resorption and Bone Turnover. Y. Zhang*, S. S. Padalecki, B. Grubbs*, B. Goins*, A. Soundararajan*, B. Story*, G. R. Mundy, B. A. Herman*. UT Health Science Center, San Antonio, TX, USA.

Caspase-2 is a cysteine protease that is an important regulator of apoptosis. Osteoclast apoptosis is a critical determinant of bone resorption, and drugs such as bisphosphonates that stimulate osteoclast apoptosis result in an inhibition of bone resorption. Accordingly, we examined the role of Caspase-2 in osteoclastic bone resorption and bone turnover using a genetic murine model lacking Caspase-2. A comparative study was performed on Caspase-2 deficient mice and wildtype mice over the course of their lifespan. Age-related phenotypes appeared earlier in the Caspase-2 null mice compared to wildtype mice, including an increase in kyphosis and a decrease in whole body bone mineral density

(BMD). We hypothesized that these differences were due to an increase in bone resorption and bone turnover in aged Caspase-2 deficient mice compared to wild-type controls. To characterize the age-related skeletal phenotype of Caspase-2 deficient mice, we performed BMD studies on these mice and controls. In addition, we performed ^{99m}Tc-MDP MicroSPECT to assess the state of bone turnover in Caspase-2 null and wildtype mice. Additionally, quantitative bone histomorphometry was performed on the spines of these mice to assess trabecular bone volume, osteoclast number and osteoblast number. In addition to a decrease in whole body BMD, Caspase-2 null mice also exhibited a significantly lower BMD of the femur compared to wildtype controls at 22-24 months of age. Quantitative region of interest measurements of ^{99m}Tc-MDP MicroSPECT studies of Caspase-2 deficient mice and wildtype mice showed a generalized increase in bone turnover in the Caspase-2 deficient mice. Biodistribution studies of ^{99m}Tc-MDP uptake performed at sacrifice on individual tissues confirmed this increase in bone turnover, particularly in the hind limbs of the Caspase-2 deficient mice. Histological analysis of the spines of Caspase-2 null mice revealed a significant decrease in trabecular bone volume and an increase in osteoclast number along the trabecular bone surface compared to wildtype controls. There was no difference in the number of osteoblasts per mm of bone surface. This work provides evidence for an in vivo physiological role for Caspase-2 in regulating bone resorption and bone turnover. Since the total body BMD decreased only in aged animals, these data support the hypothesis that Caspase-2 plays an important role in the regulation of osteoclastic bone resorption and bone turnover during aging and may be an important molecular target for the prevention of the increased bone turnover associated with age-related osteoporosis.

Elimination of Classical (ERE) ERα Signaling Causes Osteopenia and Deficits in Bone Mass Acquisition in Male Mice. F. A. Syed, D. G. Fraser*, S. Khosla. Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA.

Estrogen receptor (ERα) mediates its effects either via the classical pathway requiring ERE binding or through non-classical, non-ERE pathways (e.g., AP-1 sites). Generation of mice with a wildtype ERα allele (ERα$^+$) and an ERα allele with a knock-in mutation abolishing the classical pathway [non-classical ERα knock-in, NERKI (Mol. Endo 16: 2188, 2002)] provides an opportunity to study the effects of this mutation on bone. Since heterozygous female mice are infertile, it is not possible to generate homozygous NERKI/NERKI mice. Therefore, ERα$^+$/NERKI males were mated with ERα$^+$/ERKO(-) females to generate ERα$^+$/ERα$^+$, ERα$^+$/NERKI and ERα$^-$/NERKI mice in the F1 generation. The ERα$^-$/NERKI mice have one deleted ERα allele and a NERKI allele and signal exclusively through the non-classical pathway. We compared the in vivo bone phenotype of the ER$^-$α/NERKI males to their ERα$^+$/ERα$^+$ and ERα$^+$/NERKI littermates at 6, 12, 20 and 25 weeks of age. Spine and femur BMD were assessed by DXA and tibial trabecular and cortical bone parameters were assessed by pQCT. ERα$^-$/NERKI mice had reduced serum IGF-I levels and shorter bones. Spine and femur BMD were significantly reduced in both the ERα$^+$/NERKI and ER$^-$α/NERKI mice at all time points (P<0.01 and P<0.02 vs WT, respectively). In contrast to female NERKI mice of comparable age, the ERα$^+$/NERKI and ERα$^-$/NERKI mice had lower tibial trabecular BMD as compared to their ERα$^+$/ERα$^+$ littermates at 12 weeks and this deficit was maintained at further time points. Cortical BMD and thickness at the tibial metaphysis and diaphysis were also significantly reduced in the ERα$^-$/NERKI mice; the ERα$^+$/NERKI mice also displayed a similar pattern except that at 20 and 25 weeks, their BMD at the metaphysis was not reduced. Periosteal circumference was significantly reduced in ERα$^+$/NERKI and ERα$^-$/NERKI mice (P<0.05 vs WT) at all time points, with the reduction being greater in the ERα$^-$/NERKI mice (P<0.05 vs ERα$^+$/NERKI). Endosteal circumferences were decreased in the ERα$^-$/NERKI but not in the ERα$^+$/NERKI male mice from 12 weeks of age onwards. This is in contrast to female ERα$^-$/NERKI mice, where an increase in endosteal circumference was observed. Our results suggest that the attenuation or absence of classical ERE signaling leads to a reduction in both trabecular and cortical bone parameters and to a significant decrease in periosteal bone apposition which is offset by lower endosteal bone expansion in growing male ERα$^-$/NERKI bones. These patterns of bone growth seem to be different from female ERα$^-$/NERKI mice in which trabecular bone is maintained and there is increased endosteal bone expansion. These gender differences on the consequences of loss of ERE signaling require further study.

Estrogen Dependent Chromatin Remodeling at CIITA *In Vivo*: a Model for Estrogenic Suppression of Inflammatory Bone-Wasting Genes. E. Benasciutti[1], L. Oliva[1], W. Reith*[2], S. Cenci[1]. [1]Dibit,San Raffaele Scientific Institute, Milan, Italy, [2]University of Geneva Medical School, Geneva, Switzerland.

Estrogen (E)-mediated anti-inflammatory effects are crucial in bone homeostasis. Among bone-wasting factors, E suppresses inflammatory cytokines (IL-1β, TNFα and IL-6) and the key immune regulator MHC class II transactivator (CIITA). While stimulation of target genes by E is well characterized and relies on chromatin remodeling to transactivate promoters, whether gene suppression by E occurs via chromatin dynamics has never been asked. We explored the mechanism by which E suppresses CIITA by chromatin immunoprecipitation (ChIP) and real time quantitative PCR on cross-linked samples of primary purified BMM from ovariectomized (ovx) and sham operated mice. We observed a profound hyperacetylation of histones H3 and H4 on the whole CIITA regulatory region, in conditions of E deficiency. Interestingly, within H3, promoter IV (the main CIITA inducible promoter) displays a selective hyperacetylation of lysine 9 (K9) and hypermethylation of K4, two modifications known to direct gene expression. Furthermore, E-dependent histone hyperacetylation at pIV is not associated with increased recruitment of the coactivators CBP and p300, suggesting that a distinct E-regulated histone acetyltransferase, specific for H3, is required to modify chromatin structure at this site. To test whether histone acetylation plays a causal role in CIITA regulation by E, we tested the specific histone deacetylase inhibitor trichostatin A (TsA) on primary BMM. TsA significantly increased the capacity of IFNγ to induce MHCII expression in cells from sham mice to the level observed in those from ovx mice, suggesting a central role for histone acetylation in the regulatory effect of E on CIITA expression. ChIP for acetylated H3 and H4 in primary BMM revealed that E treatment *in vitro* directly suppresses IFNγ-induced histone acetylation at the CIITA regulatory region. Moreover, a dynamic analysis revealed that E suppresses the early induction of CIITA by IFNγ, mediated mainly by pIV, but not the sustained induction, operated by pI. Attesting to a central role of pIV in mediating E driven suppression of CIITA *in vivo*, we observed that pIV null BMM are resistant to E-operated CIITA suppression. Altogether, our data: (i) demonstrate that histone acetylation is causally involved in the mechanism by which E suppresses CIITA; (ii) describe an E-dependent histone code underlying CIITA overexpression; (iii) identify pIV as a key target of E-dependent CIITA suppression. Our data provide a framework for identifying molecular mediators whereby E suppresses inflammatory, bone wasting genes.

Oxidative Stress Induced Dendritic Cell-Dependent T Cell Activation. A Novel Mechanism by Which Estrogen Deficiency Causes Bone Loss. F. Grassi, M. Robbie-Ryan, W. Qian*, K. Page*, R. Pacifici. Dep of Medicine, Division of Endocrinology, Metabolism and Lipids, Emory University, Atlanta, GA, USA.

Two novel mechanisms have recently been proposed to explain how estrogen (E) prevents bone loss. The finding that the anti oxidant N-Acetyl Cysteine (NAC) protects against ovariectomy (ovx)-induced bone loss have led to the hypothesis that the key effect of E is that of blocking the generation of reactive oxygen species (ROS), but the mechanism linking ROS to bone loss is still unclear. Studies in the nude mouse have shown that ovx causes bone loss by promoting T cell activation and the T cell production of osteoclastogenic factors through stimulation of antigen presentation (AP), but the involved mechanism is unknown. Among the cellular functions controlled by redox-signaling, is the maturation and activity of dendritic cells (DC), the most potent AP cells. Therefore, we asked whether ovx activates AP by promoting oxidative stress and weather activation of DC is the mechanism by which ROS cause bone loss. We found that ovx increases DC expression of MHCII molecule by 2 fold, and DC specific AP by 5 folds in the bone marrow (BM), while it had no effect in other lymphoid organs. When cocultured with T cells from intact donors, DC from the BM of ovx, but not sham operated, mice also increased T cell production of TNF and RANKL by 2-3 folds. Spleen or lymph nodes DC from all groups had no effects. To investigate the role of ROS in DC activation, 12-week old mice where ovx or sham operated and treated with NAC (100 mg/Kg/day i.p.) or vehicle for 4 weeks. We found that NAC treatment significantly protected against ovx-induced bone loss. Furthermore, NAC treatment also prevented 80% of the ovx-induced increase in DC mediated AP, thus leading to a 70% prevention (p<0.05) of the ovx induced increase in the number of BM activated CD4+ and CD8+ T cells. Furthermore, levels of TNF were strikingly regulated by NAC as the ovx-induced increase in both total BM TNF and T cell-secreted TNF was completely prevented by NAC treatment. We conclude that the mechanism by which oxidative stress causes bone loss in ovx mice is by inducing AP by DC, events which stimulate T cell activation and T cell TNF production. The data also show that ovx induces T cell activation by promoting a BM specific increase in the maturation and activity of DC with a mechanism involving increased ROS generation. Thus both oxidative stress and T cell activation are required for ovx to cause bone loss.

Direct Measurement of Actin Dynamics Demonstrates that Actin Turnover Is Src Kinase-Dependent in Osteoclasts Podosomes. O. Destaing*[1], A. Sanjay[2], W. Horne[1], P. De Camilli*[3], R. Baron[1]. [1]Cell biology, School of Medicine, New Haven, CT, USA, [2]Temple university, Philadelphia, PA, USA, [3]Howard Hughes Medical Institute, School of Medicine, New Haven, CT, USA.

Podosomes constitute a characteristic organisation of actin that is essential for osteoclast (OC) attachment, migration and function. Confocal videomicroscopy and FRAP analysis have shown that podosomes contain a central column of actin which undergoes constant turnover at a rate of about 2-4 minutes. Moreover, the central column of F-actin is surrounded by a dynamic cloud of diffusely organized F-actin. The proto-oncogene c-Src is essential for bone resorption and for actin organisation in OCs. Src-/- OCs do not form a peripheral ring of podosomes, have a defect in migration and fail to resorb bone efficiently. Although previous studies have suggested that Src deletion alters podosome assembly/disassembly and/or actin turnover, no study has explored the dynamics of the actin cytoskeleton organization in live Src-/- OCs. In this report, we used videomicroscopy of living OCs micro-injected with actin-GFP to address this question. After plating, Src-/- OCs formed few podosomes and the surrounding cloud of F-actin was decreased. In addition, Src-/- OCs failed to spread and presented an accumulation of dorsal ruffles. Also, Src-/- OCs plated on apatite collagen complex (ACC), a mineralized extracellular matrix coating mimicking the bone surface, failed to form a sealing zone or degrade the ACC. The podosome life span was markedly increased in the Src-/- OCs, while the rate of actin polymerization in the podosome core was decreased. Thus, Src controls both the formation

and disassembly of the F-actin core. Re-expression of avian Src or a constitutively activated form of Src (SrcY527F) induced the formation of numerous podosomes and the reappearance of the surrounding F-actin cloud and restored the dynamic characteristics of the podosome, confirming that the changes in podosome dynamics were a consequence of the lack of Src. Finally, we determined which domain of Src was necessary for the regulation of actin turnover at podosomes in OCs. The rescue of the altered actin organization in Src-/- OCs required Src kinase activity, as the K295M (kinase dead) and K295M Y527F (kinase dead and fully open) mutants failed to rescue the actin dynamics phenotype. In contrast, deletion of either the SH2 or the SH3 domain, leaving intact their kinase activity, also rescued the Src-/- OC phenotype, at least in part.This first direct confocal videomicroscopic analysis of actin turnover in Src -/- OCs podosomes demonstrates that Src promotes osteoclast migration and bone resorption by regulating the assembly, actin polymerization and disassembly of podosomes.

Impaired Recruitment of Csk into Lipid Rafts due to Decreased Cbp Expression Leads to Elevated c-Src Kinase Activity and Bone Resorption in Osteoclasts. T. Matsubara[1], F. Ikeda[1], K. Hata*[1], M. Okada*[2], R. Nishimura[1], T. Yoneda[1]. [1]Biochem, Osaka Univ Grad Sch Dent, Osaka, Japan, [2]Oncogene Res, Res Inst Microbial Disease, Osaka Univ, Osaka, Japan.

The tyrosine kinase c-Src, which plays an indispensable role in ruffled border formation and bone resorption, is constitutively increased in osteoclasts compared to other tissues and cells. The molecular mechanism underlying increased c-Src activity in osteoclasts is unknown. c-Src activity is negatively regulated by c-terminal c-Src kinase (Csk). Recently, Csk binding protein (Cbp) has been identified and shown to recruit Csk into lipid rafts where c-Src and cytoskeleton regulatory proteins also co-localize. The finding led us to examine weather Cbp is involved in elevated c-Src activity in osteoclasts. To approach this, we first examined the expression levels and subcellular localization of c-Src, Csk and Cbp in osteoclasts. Western blot analyses demonstrated that c-Src was expressed in a highly activated state in lipid rafts in osteoclasts. Of note, Csk expression was marginal in lipid rafts despite that overall cellular Csk expression was as high as other tissues and cells. Consistent with this, cellular Cbp expression was very low. These results suggest that low Cbp expression leads to reduced Csk recruitment to lipid rafts in osteoclasts. To examine this, we introduced Cbp into osteoclast-like cells formed in spleen cell cultures using the adenovirus technology. Cbp increased Csk recruitment to lipid rafts through a physical interaction between Cbp and Csk and suppressed c-Src activity in a dose-dependent manner. Furthermore, we found that introduction of Cbp markedly inhibited the formation of actin ring and resorption pits on dentine slices. These results suggest that the relationship between c-Src, Csk, and Cbp is critical to osteoclastic bone resorption. We next studied the regulatory mechanism of Cbp expression in osteoclasts. Undifferentiated RAW 264.7 cells expressed substantial levels of Cbp. Induction of osteoclastic differentiation of RAW 264.7 cells with soluble RANKL decreased Cbp expression. Furthermore, overexpression of TRAF6 and NFAT2 induced the osteoclastic differentiation of RAW264.7 cells with marked inhibition of Cbp expression. These results collectively suggest that activation of RANKL signaling regulates Cbp expression via TRAF6 and NFAT2 in association with osteoclastic differentiation. In conclusion, our results suggest that impaired recruitment of Csk to lipid rafts due to reduced Cbp expression leads to constitutively elevated c-Src activity in osteoclasts. They also suggest that Cbp expression in osteoclasts is modulated according to the state of RANKL-induced osteoclastic differentiation.

Osteoclast-Specific Inactivation of the Integrin-Linked Kinase (ILK) Inhibits Bone Resorption. T. Dossa*[1], A. Arabian[1], S. Dedhar*[2], G. D. Roodman[3], R. St-Arnaud[1]. [1]Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada, [2]Department of Biochemistry and Molecular Biology, University of British Columbia, Vancouver, BC, Canada, [3]Bone Biology Center, University of Pittsburgh, Pittsburgh, PA, USA.

Bone resorption requires the adhesion of osteoclasts to extracellular matrix (ECM) components, a process mediated by the $\alpha_v\beta_3$ integrin. Following engagement with the ECM, integrin receptors signal via multiple downstream effectors, including the Integrin-Linked Kinase (ILK). In order to characterize the physiological role of ILK in bone resorption, we generated mice with an osteoclast-specific ILK gene ablation. Mice with one inactivated ILK allele ($ILK^{+/-}$) were mated with TRAP-Cre transgenic mice. Progeny from this cross (TRAP-Cre;$ILK^{+/-}$) was bred to mice homozygous for a floxed ILK allele ($ILK^{fl/fl}$) to yield mutant mice with ILK-deficient osteoclasts (TRAP-Cre;$ILK^{-/fl}$). The mutant animals thus had one ILK allele inactivated in all tissues, and both alleles disrupted in osteoclasts. Mutant mice appeared phenotypically normal, but histomorphometric analysis of the proximal tibia revealed an increase in bone volume (24%) and trabecular thickness (44%). Osteoclastogenesis, assessed by TRAP staining of bone sections or in vitro cultures, was not affected. Indeed, osteoclast-specific ILK ablation was associated with an increase in osteoclast number both in vitro (12%) and in vivo (35%). Primary cultures of osteoclasts were generated on synthetic calcium phosphate discs and the mutant cells displayed a decrease in resorption activity (87%). We also measured decreased serum concentrations of the C-terminal telopeptide of collagen, a marker of osteoclastic activity, in mice with ILK-deficient osteoclasts. Our results show that ILK is important for the function, but not the differentiation, of osteoclasts. The characterization of the molecular mechanisms responsible for the observed phenotype will identify novel pathways regulating bone resorption.

Extracellular Acidification Acts on Ovarian Cancer G Protein-Coupled Receptor 1 (OGR1) to Enhance Osteoclast Survival through an NFAT-Independent, Protein Kinase C-Dependent Pathway. A. Pereverzev*[1], S. V. Komarova[2], G. B. Tremblay[3], S. J. Dixon[1], S. M. Sims*[1]. [1]CIHR Group in Skeletal Development and Remodeling, University of Western Ontario, London, ON, Canada, [2]Faculty of Dentistry, McGill University, Montreal, PQ, Canada, [3]Alethia BioTherapeutics, Montreal, PQ, Canada.

For at least 85 years, acidosis has been recognized to have detrimental effects on the skeleton. We have recently reported that acidification and RANK ligand induce signals in osteoclasts that converge on the Ca/calcineurin/NFAT pathway to stimulate resorption (Proc. Natl. Acad. Sci. USA 102: 2643-8, 2005). Moreover, expression of the proton sensing receptor OGR1 was strongly induced during *in vitro* osteoclastogenesis from RAW 264.7 cells, with corresponding increases in acid-induced elevation of cytosolic free Ca concentration ([Ca]i). Here, we first assessed whether acid-induced elevation of [Ca]i in osteoclasts is mediated by OGR1. [Ca]i of fura-2-loaded osteoclasts was monitored by microspectrofluorimetry. Acid-induced rise of [Ca]i was suppressed in osteoclast-like cells derived from RAW 264.7 cells in which OGR1 RNA was specifically depleted using siRNA. Moreover, acid-induced elevation of [Ca]i in authentic rat osteoclasts was significantly inhibited by the OGR1 antagonist Cu. These data support an essential role for the proton sensing receptor OGR1 in mediating acid-induced Ca signaling in osteoclasts. Next, we examined effects of activation of OGR1 on osteoclast survival. Survival of authentic rat osteoclasts after 18 h was markedly enhanced by acidification of the culture medium, from 40 ± 10% at pH 7.6 to 83 ± 4% at pH 7.0. Osteoprotegerin had no effect on the enhanced survival induced by acidification, but inhibited that elicited by RANK ligand. Addition of Cu or chelation of intracellular Ca with BAPTA abolished the effect of acidification on survival, consistent with the involvement of OGR1. Surprisingly, inhibition of NFAT translocation with the cell-permeable peptide inhibitor 11R-VIVIT did not affect the increase in survival induced by acidification; however, it did significantly suppress the increase in survival induced by RANK ligand. On the other hand, the protein kinase C (PKC) inhibitor bisindolylmaleimide I, but not its inactive analog, abolished the effect of acidification on survival, implicating PKC signaling. Thus, extracellular acidification acts directly through OGR1 to enhance osteoclast survival through an NFAT-independent, PKC-dependent pathway. Increased osteoclast survival would contribute to bone loss in systemic acidosis and local acidosis associated with inflammatory and neoplastic bone diseases.

Parathyroid Hormone Stimulates Osteoblastic Expression of Monocyte Chemotactic Protein-1 to Recruit Pre/Osteoclasts. X. LI*[1], L. Qin[2], N. Partridge[1]. [1]Physiology & Biophysics, UMDNJ-Robert Wood Johnson Medical School and Graduate School of Biomedical Sciences, Piscataway, NJ, USA, [2]Physiology & Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

Parathyroid hormone (PTH) is the major hormone regulating bone remodeling via its actions on both bone formation and resorption. Inhibition of bone resorption blunts PTH's anabolic effects indicating that activated resorption is a prerequisite for the *in vivo* anabolic effect of PTH. The molecular basis of osteoclast activation involved in PTH's anabolic effects is not well deciphered. Since PTH signals via its receptor on osteoblasts, osteoclasts are impacted by PTH indirectly via osteoblasts. Microarray with Affymetrix Rat 230A chips of femoral metaphyseal RNA from 3-month-old female rats injected with hPTH (1-34) at 80ug/kg/d or vehicle for 14d identified a highly significant association between the stimulation of monocyte chemotactic protein-1 (MCP-1) and PTH's anabolic effect. The stimulation of MCP-1 by PTH was extraordinary both *in vivo* and *in vitro* and depended on the PKA pathway. Realtime RT-PCR showed that MCP-1's mRNA in RNA isolated from femora of rats injected with PTH for 1, 3, 7 or 14d increased to 32, 35, 54 or 224-fold respectively 1h after the last PTH injection, declining to basal levels within 2h. In UMR 106-01 cells, MCP-1 mRNA reached its peak (25-fold) at 90-min and MCP-1 protein was maximal in the cell media by ELISA, 2h after PTH treatment. We further confirmed MCP-1 stimulation is a dose-dependent primary response to PTH *in vitro*. MCP-1 is a potent chemokine for monocytes, and its *in vivo* expression pattern after PTH injection leads us to propose that MCP-1 recruits and activates pre/osteoclasts as part of PTH's anabolic effects. Studies with the mouse monocyte cell line RAW 264.7 showed that MCP-1 potently recruits osteoclastic monocyte precursors and facilitates RANKL-induced osteoclastogenesis. In the presence of RANKL, MCP-1 significantly increased TRAP mRNA (15-fold) and the number and size of TRAP-positive multinuclear osteoclasts in a dose dependent manner (increased by 15, 39 and 75% with 20, 50 and 100 ng/ml MCP-1 respectively). In chemotaxis experiments, both recombinant MCP-1 and conditioned media from UMR 106-01 cells treated with PTH for 2h had strong chemotatic effects on RAW cells and TRAP-positive multinuclear osteoclastic cells. Our model suggests that PTH-induced osteoblastic expression of MCP-1 is involved in osteoclast recruitment and differentiation at the stage of multinucleation of osteoclast precursors and provides a rationale for increased osteoclast activity in PTH's anabolic effects in addition to RANKL stimulation to initiate enhanced bone remodeling.

Dynamin GTPase- and Src-Dependent Regulation of Pyk2 Phosphorylation in Osteoclasts. A. Bruzzaniti, L. Neff*, W. Horne, R. Baron. Orthopaedics, Yale University School of Medicine, New Haven, CT, USA.

Signaling from the Pyk2-Src-Cbl protein complex is essential for the dynamics of podosomes, which mediate osteoclast (OC) attachment, migration and bone resorption. Accordingly, deletion of any of these genes leads to decreased OC motility, and to osteopetrosis in $Src^{-/-}$ and $Pyk2^{-/-}$ mice. While much is known about Pyk2-Src-Cbl complex assembly, the factors that promote the disassembly of this complex are unknown. We have previously shown that the GTPase Dynamin (Dyn) is localized to podosomes and interacts in a Src-sensitive manner with Cbl and is involved in podosome actin remodeling in OCs. Moreover, overexpression of the dominant-negative, GTP-binding mutant DynK44A slows actin turnover in podosomes and decreases bone resorption *in vitro*. Since Pyk2 is activated by Ca^{2+} mobilization following integrin engagement and has been implicated in cytoskeletal reorganization, we examined the potential interactions between Dyn and Pyk2. We report that Dyn colocalizes with Pyk2 in the podosome actin ring and forms a complex with Pyk2. The interaction of Dyn or DynK44A with Pyk2 involved the proline-rich domain of Dyn and the N-terminal region of Pyk2 but not the kinase activity of Pyk2. Importantly, phosphorylation of Pyk2 at Tyr402, a residue that is autophosphorylated upon Pyk2 activation and forms the binding site for the Src SH2-domain, was dramatically decreased by Dyn but not DynK44A. Although Dyn-Pyk2 complex formation was not dependent on Src's adaptor function, Src was required for the inhibition of Tyr402 phosphorylation by Dyn. Thus, once activated by integrin engagement via an increase in intracellular Ca^{2+}, Pyk2 is autophosphorylated at Tyr402, recruiting and activating Src at attachment sites. Our study shows that Dyn is also recruited by Pyk2, possibly in the same Src- and Cbl-containing complex. Furthermore, the recruitment of Dyn leads to the Src- and Dyn GTPase-dependent decrease in the phosphorylation of Pyk2 at Tyr402, potentially leading to the dissociation of Src and/or decreased Src and Pyk2 kinase activities. In conclusion, we propose that a dynamic intermolecular interaction exists between Dyn and the Cbl-Src-Pyk2 complex which affects downstream signaling, leading to changes in podosome turnover and OC function.

Aberrant Bone Formation in Mice Over-Expressing Specific VEGF Isoforms in Cartilage. C. Maes[1], J. J. Haigh*[2], A. Chan*[2], K. Haigh*[2], R. Bouillon[3], G. Carmeliet[3], A. Nagy*[4]. [1]Legendo, K.U.Leuven, Leuven, Belgium, [2]Vascular Cell Biology Unit, VIB, Ghent, Belgium, [3]Legendo, K.U.Leuven, Leuven, Belgium, [4]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

Previous loss-of-function studies revealed multiple roles of VEGF and its isoforms (VEGF120, 164 and 188) in bone development and repair. Accordingly, the potential use of VEGF in bone pathology is being explored. To determine the in vivo consequences of increased VEGF, we employed a gain-of-function approach. The 3 VEGF-isoforms were conditionally targeted to the Rosa-26 locus and over-expressed in collagen 2-expressing tissue. Q-RT-PCR verified that the total VEGF mRNA level was comparably upregulated, by 70-85%, in each of the mutants as compared to WT mice. Therefore, these models enable a direct comparison of the different isoforms on cartilage/bone formation. Skeletal staining of newborn mice showed that cartilage specific over-expression of VEGF164 or VEGF188, but not of VEGF120, impaired growth and resulted in short and misshapen limbs. To elucidate the mechanism, embryonic stages were investigated. In VEGF164 over-expressing mutants, no defects in cartilage development were observed by histomorphological analysis, BrdU marking, and collagen 2 and 10 in situ hybridization (ISH). However, the perichondrium was thickened with increased accumulation of TRAP+ cells and CD31+ blood vessels and strongly enhanced MMP-9 immunoreactivity. This was followed by premature and/or excessive invasion and erosion of the diaphyseal cartilage. Concomitantly, osteoblastogenesis seemed enhanced, as suggested by the presence of numerous BrdU+ cells in the perichondrium, strong Runx2 ISH signal, and increased osteocalcin staining. Yet, bone collar formation was severely impaired. In contrast, excessive bone formation occurred within the diaphysis, showing a dramatic re-orientation and increase of bony structures and blood vessels. This led to marked widening of the diaphyses and bowing of the long bones. A comparable phenotype was seen in VEGF188 over-expressing mice although it started later than in VEGF164 mutants, consistent with the more persistent localization of VEGF188 within the epiphysis, as revealed by ELISA. Notably, only VEGF164 mutants showed dramatic systemic edema, underscoring the importance of isoform selection for therapeutic use in terms of specificity and safety. Together, these findings reveal the capacity of VEGF to affect the coupling of bone collar formation and cartilage invasion during development and highlight the power of VEGF as a stimulator of bone formation. Importantly, our data show that application of VEGF, e.g. in fractures or osteoporosis, must be associated with careful monitoring of the new bone structure.

Chondrocyte-Specific Disruption of Insulin-Like Growth Factor (IGF)-I Expression Reduces Bone Density and Bone Size in Mice. K. E. Govoni[1], S. K. Lee*[1], Y. S. Chung*[1], R. R. Behringer*[2], J. E. Wergedal[1], D. J. Baylink[1], S. Mohan[1]. [1]MDC, JLP VAMC, Loma Linda, CA, USA, [2]MD Anderson Cancer CTR, Houston, TX, USA.

IGF-I is an important regulator of BMD and bone size, two important determinants of bone strength. IGF-I actions on bone are known to be mediated via endocrine and local autocrine/paracrine mechanisms. In mice in which liver production of IGF-I was disrupted, no changes in BMD or bone size were observed, suggesting that bone derived IGF-I may be more important than circulating IGF-I in regulating peak BMD and bone size. To test this hypothesis, we used the well established Cre-lox approach to disrupt IGF-I in chondrocytes. Type 2α1 collagen-Cre mice were crossed with IGF-I loxP mice to generate Cre+ (IGF-I disruption) or Cre- (control), loxP homozygous mice. Bone parameters were measured by DXA at 2, 4, 8, and 12 wks of age and pQCT at 12 wks. Cre and IGF-I expression were determined by real-time RT-PCR at 2 and 12 wks. Cre expression was greater in metaphysis and cartilage than diaphysis and calvaria tissue of Cre+ mice. Compared with Cre+ mice, IGF-I expression in Cre- mice was 1.7 and 2.0 fold greater in metaphysis and cartilage, respectively at 2 wks ($P < 0.01$) and 1.4 fold greater in the diaphysis at 12 wks ($P < 0.05$). A reduction ($P < 0.05$) in body length and skeletal parameters was observed in Cre+ mice at 4 wks and these deficits were maintained through 12 wks.

Age (weeks)	2	4	8	12
Body weight	105 ± 6	93 ± 5	90 ± 4*	91 ± 5*
Body length	100 ± 3	93 ± 2*	93 ± 1*	93 ± 1*
Total body BMC	109 ± 10	86 ± 4*	87 ± 4*	89 ± 3*
Total body BMD	101 ± 2	95 ± 1*	96 ± 2*	95 ± 1*
Total body bone area	106 ± 8	90 ± 3*	91 ± 3*	94 ± 2*

Values are % of Cre- mice (mean ± SE); n = 16 mice per group (except 2 wks); * ($P < 0.05$)

Interestingly, bone size, measured by pQCT, was reduced 7% in both the vertebrae ($P < 0.01$) and femur ($P < 0.05$) of Cre+ mice at 12 wks. To investigate the role of chondrocyte derived IGF-I in mediating rapid bone accretion during puberty, we compared the rate of gain in skeletal parameters during this period. We found that gain in body length and total body BMC and BMD were reduced by 30%, 16%, 18%, respectively ($P < 0.05$), in Cre+ mice between 2 and 4 wks. Conclusions: 1) targeted disruption of IGF-I in chondrocytes results in decreased BMD, bone size, bone length, body weight, and IGF-I expression in bone, 2) chondrocyte derived IGF-I is involved, in part, in mediating rapid bone accretion that occurs during puberty, but not during the first 2 wks of postnatal growth, 3) our data are consistent with the hypothesis that bone derived IGF-I may be more critical than endocrine IGF-I for attainment of peak BMD and bone size in mice.

Temporal Control of Gene Deletion in the Cartilage Using a Tamoxifen Inducible Cre Transgenic Mouse. M. J. Hilton, F. Long. Internal Medicine - Division of Bone and Mineral Diseases, Washington University School of Medicine - St. Louis, St. Louis, MO, USA.

Understanding of gene function in particular biological processes, such as specific stages of skeletal development, is often hampered by the early lethality or developmental arrest caused by gene deletion using conventional means. Here taking advantage of the Cre-loxP technology, we have created and characterized a Cre transgenic line that allows for temporal control of gene deletion in both the embryonic and postnatal skeleton. Specifically, the transgene expresses under the collagen a1 (II) (Col2a1) promoter/enhancer a tamoxifen (TM) activatable Cre recombinase (Col2Cre-TM). By crossing with the Rosa26LacZ reporter mice (R26R) which allowed for the expression of LacZ following Cre activation, we demonstrated that following intraparitoneal injections of TM at various time points, Cre activity was detected in distinct cell populations. In particular, early injection of TM at E8.5-E10.5 into the pregnant female resulted in Cre activity progressing through the limb cartilage elements in a proximal to distal fashion, reflecting the temporal activation of the Col2a1 promoter in the limb skeleton. Injection of TM at E11.5 showed strong Cre activity in chondrocytes, the perichondrium, as well as the joint capsules. Importantly, injections at E12.5 or later showed a near complete restriction of Cre activity to proliferating and prehypertrophic chondrocytes. Similarly, injection of TM in postnatal day 10 pups (P10) resulted in highly specific Cre activity in both the growth plate chondrocytes as well as the articular chondrocytes. Additionally, injection of TM at sub-threshold concentrations induced Cre activity within small clusters of chondrocytes (clones), which allowed for clonal analysis. Finally, in preliminary experiments, by removing Smoothened (Smo) at either E11.5 or P10 using the Col2Cre-TM line, we demonstrated a clear defect in chondrocyte development, consistent with the critical role of Ihh signaling in skeletal development. In summary, the Col2Cre-TM transgenic mouse line provides a useful tool in studying both embryonic and postnatal endochondral bone development.

The Hedgehog Signaling Molecule Gli2 Regulates Both BMP-2 and PTHrP Expression in the Growth Plate. M. Zhao, J. A. Sterling*, M. Qiao*, B. O. Oyajobi, S. E. Harris, G. R. Mundy. Cellular and Structural Biology, University of Texas Health Science center at San Antonio, San Antonio, TX, USA.

Both PTHrP and BMP2 have been demonstrated to have important physiological roles in chondrocyte maturation at the growth plate. There clearly needs to be coordination between these growth regulatory cytokines at this site. We propose that the zinc finger protein, Gli2, which mediates Hedgehog (Hh) signaling, is responsible for this coordination. We have previously found that Gli2 is a powerful activator of BMP2 gene expression in osteoblasts. In an experiment using TMC23 cells, a clonal growth plate chondrocyte cell line, we found that these cells express all Gli family members, Gli1, Gli2 and Gli3, and the Ihh receptors, Ptc1, Ptc2 and Smo. We examined the effects of the Gli family on PTHrP expression and the chondrocytic phenotype in TMC23 cells, since these molecules mediate Hh signaling, and Ihh is known to influence PTHrP expression in growth plate chondrocytes. We found that Gli2 is the only member of the Gli family that markedly up-regulates PTHrP promoter activity, and this effect was dramatically diminished by Gli2 siRNA. Cytochemistry, RT-PCR and immunoassay have shown that overexpression of Gli2 in TMC23 cells elevated the synthesis of proteoglycans and the gene expression of Sox9 and collagen II. DNA analysis including EMSA indicated that the effect of Gli2 on the PTHrP promoter is likely indirect. We have also investigated the effects of Gli2 on BMP2 gene expression in chondrocytes. We found that overexpression of Gli2, but not Gli1 and Gli3, markedly enhances BMP2 promoter activity and BMP2 mRNA level in TMC23 cells determined by promoter reporter assay and real time PCR, which was largely blocked by Gli2 siRNA. Deletion studies and EMSA of the BMP2 promoter have demonstrated that three Gli binding sites in the promoter are required for the direct transactivation of Gli2. However, in a separate experiment, we found that the incubation of TMC23 cells with BMP2 did not affect PTHrP promoter activity, suggesting that Gli2 stimulates PTHrP expression in chondrocytes independent of its effect on the BMP2 pathway. Further, we examined the cartilage phenotype and the expression of BMP2 and PTHrP in Gli2 knockout mice. We found that $Gli2^{-/-}$ mice, with lower bone mass, had severe cartilage defects including significantly expanded proliferating and hypertrophic zones of the growth plates, and both BMP2 and PTHrP expression were dramatically reduced in these areas. These findings suggest: Ihh mediates effects on chondrocytes through the signaling molecule Gli2; stimulation of Gli2 on expression of BMP2 and PTHrP are direct and indirect respectively; the effects of Gli2 on PTHrP are independent of the effects on BMP2.

***Dlx2* Stimulates the Murine Chondrocyte Maturation *In Vitro* and *In Vivo*.** Y. Zhang*[1], M. Zuscik[2], D. Chen[2], R. Rosier[2], E. Schwarz[2], H. Drissi[2], R. O'Keefe[2]. [1]Orthopaedics/Pathology and Laboratory Medicine, University of Rochester, Rochester, NY, USA, [2]Orthopaedics, University of Rochester, Rochester, NY, USA.

Although BMP-2 strongly promotes chondrocyte maturation, the molecular mechanisms and downstream effectors of these events remain under investigation. *Dlx2* gene expression is induced by BMP-2 in immortalized human chondrocytes. *Dlx2* -/- mice have craniofacial and cartilage defects. However, comprehensive studies of the function of *Dlx2* during chondrocyte maturation have not been performed. In these studies, the function of *Dlx2* was examined *in vitro* in murine TMC-23 cells and in primary murine sternal chondrocyte (PSC) and *in vivo* by generating cartilage specific *Dlx2* transgenic mouse. Using real-time RT-PCR, the expressions of the *Dlx* genes (1-6) were examined after 24 and 48 hours of BMP-2 treatment in TMC-23 and PSC. While all *Dlx* genes are expressed, the highest baseline levels were observed for *Dlx2* and *Dlx5*. In TMC-23 cells, BMP-2 treatment for 24 hours caused induction in *Dlx1* (3-fold), *Dlx2* (8-fold), *Dlx5* (3-fold), and *Dlx6* (3-fold) compared to the control, and similar increases were maintained after 2 days of BMP-2 treatment. In PSC, BMP-2 stimulated *Dlx1* (3-fold) and *Dlx2* (2-fold) expressions at 24 hours, and induced *Dlx5* (3.5-fold) and *Dlx6* (3-fold) at 48 hours. Using pLenti vector, *Dlx2* was over-expressed in PSC. Three days after infection, *Dlx2* significantly promoted the expressions of *colX* (4 folds) and *osteocalcin* (5 folds), and repressed *col2* (2 folds). However, *Dlx2* had no effect on *VEGF*, *MMP9*, and *MMP13*. *Dlx2* over-expression also stimulated alkaline phosphatase activity (3-folds). A gain of function approach was used to determine if the *Dlx2* was directly involved *colX* induction. In 293T cells, *Dlx2* enhanced activity (3.5-fold) of the murine type X collagen promoter (4 kb). The type X collage promoter contains two *Dlx2* consensus binding sequences at approximately -100 and at -1300 bp. Site-directed mutagenesis of the first TAAT motif significantly reduced reporter gene activity following *Dlx2* co-transfection. A 1.0kB *col2* promoter was used to drive *Dlx2* expression in cartilage tissues *in vivo*. Transgenic mice are significantly smaller than the wild type mice and have multiple skeletal malformations, including rib cage, spine, dental tissue, and craniofacial components. These results demonstrate that *Dlx2* is a downstream target of BMP signaling in chondrocytes, stimulates chondrocyte maturation, and induces expression of the type X collagen promoter.

Inactivation of Nek1 Protein Kinase Signaling in Kat2J Mice Leads to Skeletal Defects. S. L. Abboud[1], A. Singh*[1], K. Woodruff*[1], M. Roudier*[2], M. MacDougall*[1], D. Riley*[1], Y. Chen*[1]. [1]University of Texas Health Science Center, VA Hospital, San Antonio, TX, USA, [2]SkeleTech. Inc, Bothwell, WA, USA.

Nek1 was originally identified as a mammalian ortholog of never in mitosis A (NIMA), a protein kinase that controls mitosis and cell cycle progression in fungi. Mammalian Nek1 has dual serine-threonine and tyrosine kinase activity and is essential for responding to DNA damage and preventing aberrant apoptosis via the intrinsic mitochondrial pathway. We have discovered that Nek1 is normally expressed in growth plate cartilage, osteoblasts and osteocytes during murine postnatal development and declines with age. In the spontaneous mutant kat2J/Nek1-/- mice, absence of Nek1 leads to dwarfism, facial dysmorphism and polycystic kidney disease. However, the precise biologic effect of Nek1 deficiency on skeletal tissues is unknown. To address this issue, the skeletal phenotype of kat2J/Nek1-/- mice was analyzed. Mutant mice showed stunted growth 10 days after birth, were half the weight of wild type (wt) littermates and developed abnormal craniofacial features including rounded skull, shortened midface and malocclusion of the mandible. Compared to wt, kat2J/Nek1-/- mice had skeletal defects characterized by altered chondrogenesis and osteogenesis. Radiographs of mutants at 3 weeks showed shortened long bones and an osteoporotic-like phenotype with decreased cortical thickness compared to wt. Kat2J/Nek1-/- femurs by microCT showed a malformed epiphysis and distorted growth plate and, by pQCT, the bone mineral density was decreased. Histologic preparations and histomorphometry of femurs demonstrated a widened, less organized growth plate, decreased bone volume with few thin trabeculae and decreased osteoblasts in mutants compared to wt. Alizarin red and alcian blue staining also indicated defects in ossification as early as postnatal day 1. To determine whether skeletal changes in kat2J/Nek1-/- were associated with altered cell survival, assays for apoptosis were performed. By TUNEL analysis, increased apoptosis was observed in growth plate chondrocytes of mutant mice. Bone marrow stromal/osteoblast cells isolated from mutants also showed increased apoptosis and loss of mitochondrial membrane potential, which were rescued by re-expression of wt Nek1 via an adenoviral vector. Results show for the first time that absence of Nek1 increases apoptosis within skeletal tissues and leads to defects in growing bone. Nek1 likely maintains cartilage/bone cell homeostasis and prevents aberrant apoptosis during the rapid phase of postnatal growth. Further elucidation of the downstream target molecules for Nek1 may provide unique strategies for enhancing skeletal growth and restoring bone loss.

Interactions between PTHrP and BMP Signaling during Mammary Gland Development. J. R. Hens[1], P. R. Dann*[1], J. P. Zhang*[1], S. E. Harris*[2], J. J. Wysolmerski[1]. [1]Internal Medicine, Yale University, New Haven, CT, USA, [2]Periodontics, The University of Texas at San Antonio, San Antonio, TX, USA.

Parathyroid hormone-related protein (PTHrP) directs mesenchymal cell fate choices that are critical for the proper development of the embryonic mammary gland. In mice that lack PTHrP or its receptor, the mammary mesenchyme fails to develop and the morphogenesis of the mammary bud is arrested. In contrast, over-expression of PTHrP in keratinocytes in K14-PTHrP transgenic mice leads to the conversion of the ventral dermis to mammary mesenchyme. Our aims in this study were to understand how PTHrP modulates mesenchymal cell fate decisions and to discern why the effects of PTHrP over-expression are limited to the ventral surface of the embryo. Using a BMP-4/lac Z "knock-in" mouse, we found that prior to embryonic day 15 (e15), BMP-4 was strongly expressed in the ventral mesenchyme in a pattern approximating that portion of the ventral epidermis affected by PTHrP overexpression. Therefore, we examined whether changes in PTHrP expression in the embryonic mammary bud and epidermis altered mesenchymal BMP signaling. Wild-type (WT) embryos demonstrated intense nuclear staining for phospho-SMAD 1,5 and 8 in the mammary mesenchyme, suggesting that these cells were targets of BMP-signaling. Phospho-SMAD staining was reduced in PTHrP and PTH1R knockout mammary buds and was inappropriately present in the ventral dermis of K14-PTHrP embryos. We confirmed this change in BMP signaling by examining SMAD phosphorylation in WT and K14-PTHrP ventral skins by Western blot. We also examined whether PTHrP could modulate BMP signaling in mesenchymal cell lines in vitro. We treated C3H10T1/2 and C2C12 cells with BMP2 or BMP4 in the presence or absence of PTHrP and found that PTHrP augments SMAD phosphorylation in these cell lines. Finally, it has been shown that disruption of the gene encoding the homeobox transcription factor, MSX2, in mice partially phenocopies the mammary defects seen in PTHrP and PTH1R knockout mice. Given this observation and given the fact that MSX2 is a BMP-responsive gene, we examined the expression of MSX2 by in situ hybridization in our models of PTHrP over and under expression. In PTHrP and PTH1R knockout mice, MSX2 expression was absent from mammary mesenchyme and in K14-PTHrP mice MSX2 was ectopically expressed in the ventral dermis. These data suggest that PTHrP signaling alters mesenchymal cell fate in the mammary bud by modulating BMP signaling and inducing the expression of MSX2.

Nuclear Targeting of PTHrP and Cellular Proliferation: A Central Role for $p27^{kip1}$ in Molecular Control of the Cell Cycle. N. M. Fiaschi-Taesch[1], K. R. Ubriani*[1], K. K. Takane*[1], B. M. Sicari*[1], B. Law*[2], A. F. Stewart[1]. [1]Medicine, Endocrinology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Pharmacology, University of Florida, Gainesville, FL, USA.

Parathyroid hormone-related protein (PTHrP) contains a classical bipartite nuclear localization signal. Nuclear targeting of PTHrP has been associated with proliferation in osteoblasts, chondrocytes, breast and prostate cancer cells, and arterial vascular smooth muscle cells (VSMC). In the arterial wall, PTHrP is markedly upregulated in response to angioplasty, and is associated with arterial re-stenosis. Overexpression exacerbates arterial re-stenosis, and, conversely, knockout of the PTHrP gene is associated with deceleration of VSMC proliferation in vivo. The mechanism of nuclear PTHrP-induced cellular proliferation is therefore of interest in VSMC as well as in other cell types. Here, we explore the entire G1/S proteome in nuclear-targeted VSMC. Nuclear PTHrP is associated with an increase in phospho-pRb, and release of G1/S arrest. This pRb phosphorylation is associated with stable levels of cdk's 2, 4 and 6, the D cyclins, cyclins A and E, p15, p16, p18, p19 and p21. In striking contrast to the other members of the G1/S proteome, p27kip1 is markedly reduced, and this is associated with a dramatic increase in cdk-2/cyclin A/E kinase activity. Adenoviral replacement of $p27^{kip1}$ normalizes proliferation rates, confirming that $p27^{kip1}$ loss is responsible for the increase in VSMC proliferation in PTHrP-nuclear-targeted VSMC. $p27^{kip1}$ mRNA levels are near normal in nuclear-PTHrP-expressing VSMC, suggesting that $p27^{kip1}$ loss is regulated at the protein level. This was confirmed using the proteasome inhibitor, MG132, which resulted in normalization of $p27^{kip1}$. Cycloheximide degradation studies confirm that $p27^{kip1}$ half-life is markedly reduced in nuclear-targeted PTHrP-expressing cells. Further, nuclear PTHrP overexpression leads to phosphorylation of $p27^{kip1}$ on Thr^{187}, a well known signal for $p27^{kip1}$ degradation. Finally, $p27^{kip1}$ is known to be degraded by ubiquitination in other cell types, with cullin-1, skp-1 and skp-2 being critical members of the E3-ligase complex. Cullin-1 and skp-2, but not skp-1 are markedly upregulated in nuclear PTHrP-expressing cells, and are likely candidates for the mediators of nuclear targeted PTHrP-induced p27 degradation. The current observations define a novel "PTHrP-$p27^{kip1}$ axis" that regulates cell cycle proliferation by nuclear-targeted PTHrP in VSMC and potentially other cell types as well. This axis is a potential target for therapeutic manipulation of the arterial response to injury, and possibly in cell types of skeletal origin as well.

Increased PTH Anabolic Effects in a Mouse Model Expressing a Phosphorylation-Deficient PTH/PTHrP Receptor (pdPTH1R). G. S. Bounoutas*, H. Tawfeek*, A. Abou-Samra. Endocrine, Massachusetts General Hospital, Boston, MA, USA.

In a variety of animal models it has been shown that intermittent PTH administration increases bone mineral density (BMD) whereas continuous PTH infusion decreases BMD. We have hypothesized that the differential anabolic responses of the two modalities of PTH administration may be secondary to their differential effects on PTH1R internalization and desensitization. We have recently described a pdPTH1R mouse model, in which a pdPTH1R was knocked into the locus of the PTH1R gene using homologous recombination, and have shown that this mouse model exhibits a sustained increase in plasma cyclic AMP level after subcutaneous PTH administration. In this study we used the pdPTH1R mouse model to examine the hypothesis that PTH1R phosphorylation is important for the anabolic response to intermittent PTH administration. We first backcrossed the pdPTH1R mouse into the C57/B6J background for 6 generations. Twelve-week-old WT and pdPTH1R male mice (7 mice per group) were injected 5 times/week with 40 g/kg PTH(1-34). Body weight, bone mineral density, and bone mineral content were measured at 2, 6, and 10 weeks. BMD increased over the experiment period by 3.1%±2.7 and 0.5%±3.3 in WT and pdPTH1R mice, respectively. Compared to vehicle-treated animals, PTH administration increased BMD by 6.2%±2.7 ($p = 0.03$) and 8.4%±2.8 ($p = 0.0002$) in WT and pdPTH1R mice, respectively. PTH administration resulted in a ~2-fold increase in the rate of BMD growth in WT mice and a ~16-fold increase in BMD growth in the pdPTH1R mice. The data thus show that PTH1R phosphorylation is not required for the anabolic effects of PTH, and that the bone anabolic effects of PTH is greater in pdPTH1R mice than in WT mice.

NHMF1 Switches Extracellular Signal-Regulated Kinase Signaling by the PTH Receptor. B. Wang*[1], W. B. Sneddon[1], Y. Yang*[1], P. A. Friedman[2]. [1]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Dept. of Pharmacology and Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Parathyroid hormone (PTH) binds its cognate G-protein-coupled receptor (PTH1R) and results in several signaling events involving adenylyl cyclase/protein kinase A and phospholipase C/protein kinase C pathways. Many cellular effects of PTH depend on the activation of the mitogen-activated protein kinases (MAPK) ERK1 and ERK2 (ERK 1/2). Na/H exchange regulatory factor 1 (NHERF1) is a cytoplasmic protein that can regulate PTH-mediated PTH1R internalization in kidney tubule and osteoblastic cells and restore PTH-mediated increases of intracellular calcium in OKH cells. However, the effect of NHERF1 on PTH activation of ERK1/2 is unknown. The objective of the present study was to determine if NHERF1 regulates PTH-dependent ERK1/2 activation. To address this problem, we engineered a cell system expressing the PTH1R, where NHERF1 could be induced. Chinese hamster ovary (CHO) cells, which have negligible endogenous PTH1R or NHERF1 expression, were stably transfected with pcDNA4-NHERF1, pcDNA6/TR and pcDNA3.1(+)-PTH1R-HA. Tetracycline (8-100 ng/ml) induced dose-dependent increases of NHERF1 expression. NHERF1 blocked PTH(1-34) (10^{-10}-10^{-8} M)-induced ERK1/2 activity. NHERF1 also blocked PTH(7-34)-stimulated ERK1/2 activity. Different levels of NHERF1 induced by various concentrations of tetracycline in the CHO cell system blocked both PTH(1-34) and 7-34-induced ERK1/2 phosphorylation. The requirement for PDZ domain interaction between NHERF1 and the PTH1R for ERK1/2 stimulation was examined with a PTH1R containing a mutated PDZ recognition sequence. NHERF1 and wild-type or mutant PTH1R, where the terminal methionine 593 was replaced by alanine (M593A), were cotransfected in wild-type CHO cells. Stimulation of ether wild-type or mutant receptor by PTH(1-34) (10^{-8} M) induced ERK1/2 phosphorylation. NHERF1inhibited activation of ERK1/2 by wild-type PTH1R but had no effect on the mutant receptor. In conclusion, PTH(1-34) and 7-34 activate ERK1/2. NHERF1 blocks PTH1R-stimulated ERK1/2 activation by both PTH(1-34) and 7-34, thereby switching ERK signaling by the PTH receptor. This regulatory effect of NHERF1 depends on its binding to the carboxyl terminal PTH1R PDZ-binding domain.

Global Knock-Down of the Calcitonin Receptor (CTR) Results in Decreased Trabecular Bone Volume in Young Female Mice. R. A. Davey[1], J. F. McManus*[1], A. J. Moore*[2], M. W. S. Chiu*[1], A. M. Axell*[1], A. J. Notini*[1], H. A. Morris[2], D. M. Findlay[3], J. D. Zajac[1]. [1]Medicine, Austin Health, University of Melbourne, Heidelberg, Victoria, Australia, [2]Hanson Institute, Adelaide, South Australia, Australia, [3]Orthopaedics and Trauma, University of Adelaide, Adelaide, South Australia, Australia.

To investigate the physiological control of bone resorption and formation by calcitonin (CT), we have generated a global calcitonin receptor (CTR) knock-down (KD) mouse model using the Cre-loxP system. CTR-loxP mice were generated using embryonic stem cell technology. Exons 13 and 14 of the CTR, which encode the seventh transmembrane domain and C-terminus, were targeted for deletion. CTR KD mice were generated by breeding the CTR-loxP mice with CMV-Cre mice, which express Cre ubiquitously. We have demonstrated Cre-mediated deletion of exons 13 and 14 of the CTR in the bones of CTR KD mice and estimate the deletion to be greater than 90% at the mRNA level compared to controls using northern analysis. Male and female heterozygous (het) CTR-lox controls, het CTR KDs and homozygous (hom) CTR KDs were studied at 6, 12 and 24 weeks of age. Distal femora were prepared for quantitative histomorphometry using established resin embedding techniques. Trabecular bone volume (BV/TV %) was decreased in female hom CTR KD mice at 6 weeks of age ($P<0.05$) (hom CTR KD: 21.3 ± 2.4, het CTR-lox control: 34.5 ± 3.7, het CTR KD: 32.7 ± 2.8). This was associated with a decrease in trabecular number ($P<0.05$), while trabecular thickness and mineral apposition rate were unaffected, suggesting increased bone resorption. Osteoclast surface was unchanged in female hom CTR KDs suggesting that the increase in bone resorption observed in the hom CTR KD female mice may be a result of increased osteoclast activity and/or lifespan with no change in the number of osteoclasts. We are currently assessing the formation, activity and lifespan of osteoclasts derived from bone marrow cells of hom CTR KD mice in vitro. No changes were observed in serum calcium, serum total protein or intact PTH levels in female CTR KD mice. No changes in any of the bone histomorphometric variables were observed in hom CTR KD males at 6 weeks of age. Serum calcium however was decreased in male hom CTR KD mice compared to het CTR-lox controls and het CTR KDs ($P<0.05$), while serum total protein and intact PTH levels were unaffected.In conclusion, we have demonstrated that global knockdown of the CTR results in decreased trabecular bone volume in young female mice and that this bone loss is associated with increased bone resorption. These data suggest that the role calcitonin plays in regulating bone cell turnover is greater in young female mice than males.

Uncovering the Physiologic Function of Calcitonin Using Genetically Modified Mouse Models. A. Voss*[1], S. Liese*[1], M. Priemel[1], P. Catala-Lehnen*[1], A. F. Schilling[1], C. Mueldner*[1], M. Haberland*[1], J. M. Rueger*[1], R. B. Emeson*[2], R. F. Gagel[3], T. Schinke[1], M. Amling[1]. [1]Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany, [2]Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, [3]Department of Endocrine Neoplasia and Hormonal Disorders, University of Texas, Houston, TX, USA.

The peptide hormone calcitonin (CT) is produced by thyroidal C-cells and is well known for its inhibitory action on bone-resorbing osteoclasts. However, the physiologic significance of this action is still under debate, since it was difficult to explain why thyroidectomy does not result in osteoporosis and why high circulating CT levels associated with medullary thyroid carcinoma fail to trigger osteopetrosis. Moreover, the high bone mass phenotype of three months old Calc1-deficient mice suggested a previously unknown physiologic function of CT as an inhibitor of bone formation. We have now extended this analysis to older Calc1-deficient mice and compared their phenotype to alpha-CGRP-deficient mice, since the loss of the Calc1 gene results in the lack of CT and alpha-CGRP. Consistent with our previous findings we observed a high bone mass phenotype of Calc1-deficient mice at several ages ranging from 3 to 18 months, whereas alpha-CGRP-deficient mice were osteopenic. Surprisingly, the high bone mass

phenotype of the Calc1-deficient mice at 12 months of age was accompanied by a specific increase of bone resorption parameters compared to wildtype controls (OcS/BS: 8.6 ± 1. 5 % vs. 1.9 ± 0.6 %; urinary Dpd crosslinks (nM/nM creatinine): 41.7 ± 12.4 vs. 18.9 ± 7.7). Consistent with their high bone mass (BV/TV: 16.5 ± 1.6 % vs. 13.1 ± 1.0 %) we also observed an increased bone formation rate in Calc1-deficient mice compared to wildtype controls (BFR/BS (µm3/µm2/year): 135.1 ± 18.7 vs. 99.7 ± 17.8), despite the absence of alpha-CGRP that leads to decreased bone formation. These results demonstrate that Calc1-deficient mice develop a phenotype of high bone turnover with age. This severe phenotype is accompanied by hyperostotic lesions that were observed in more than 20 % of the Calc1-deficient mice at 12 months of age, but never in wildtype controls or in alpha-CGRP-deficient mice. Taken together, these data uncover a physiologic function of CT as a regulator of bone turnover affecting both bone resorption and bone formation. This dual action of CT may explain the conflicting results obtained by measuring bone densities in human patients with altered CT levels.

MEPE-ASARM-Peptide Associated Mineralization Defects in X-Linked Hypophosphatemic Rickets (hyp) Is Corrected by Protease-Inhibitors. P. S. N. Rowe[1], N. Matsumoto*[2], O. D. Jo*[2], R. N. J. Shih*[2], M. Roudier*[1], J. Harrison*[1], N. Yanagawa*[2]. [1]University of Texas HSC, San Antonio, TX, USA, [2]UCLA, Sulpeveda, CA, USA.

MEPE and osteoblastic-proteases are elevated in the hyp-osteoblast. This leads to increased release of a small protease-resistant MEPE-peptide (ASARM-peptide), a potent inhibitor of mineralization and phosphate-uptake. Since our previous studies showed: (1) cathepsin-B cleaves MEPE releasing ASARM-peptide and (2) hyp-osteoblast cells hyper-secrete cathepsin-D, an activator of cathepsin-B, our aims were to: 1. Determine whether cathepsin-inhibitors correct the mineralization defect *in-vivo* (reduce peptide-release) and 2. Determine whether hyp-bone ASARM-peptide levels are elevated? Normal-littermates and hyp-mice (n=6) were subcutaneously injected once a day for 4 weeks with: 1. pepstatin (non-specific inhibitor of cathepsin-D), 2. CAO74 (specific inhibitor of cathepsin-B) and 3. vehicle. Animals were then sacrificed, bones removed and detailed histomorphometry, pQCT, uCT and immunohistochemistry (ASARM-antibodies) carried out. As expected, Goldner-staining of "vehicle-group" hyp-femurs revealed extensive regions of unmineralized-osteoid, widened epiphyses and disruption of the growth-plate. In contrast, hyp-animals treated with protease-inhibitors showed marked and significant improvement in all histomorphological parameters for endosteal/periosteal-bone and growth plate. The mineralization-apposition-rate (um/day), bone-formation-rate/ bone-surface referent (um^3/um^2/year) and mineralization-surface as a percentage of bone-surface (%) were normalized by protease-treatment. Moreover, the growth-plate-width (>42%, P=0.002), osteoid-thickness (>40%, P=0.002) and cortical-area (>40%, P=0.003) were significantly and markedly improved. Also, high-resolution pQCT density-maps of metaphyseal and diaphyseal regions confirmed major and significant increases of mineralized-bone in protease-inhibitor treated hyp-animals. This was confirmed further by uCT (figure 1).

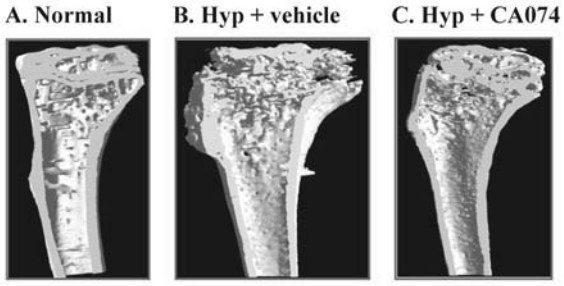

Figure 1: micro-computed-tomography (uCT) of tibiae.

Finally, the growth-plate and cortical-bone of hyp-femurs contained a massive accumulation of osteoblast-derived ASARM-peptide(s). Thus, *in-vivo* administration of cathepsin-inhibitors likely reduces ASARM-peptide release and improves bone-mineralization and architecture in hyp-mice.

Vitamin D Dependent Functions of Fgf-23 *In Vivo*. D. Sitara[1], R. St-Arnaud[2], R. G. Erben[3], M. S. Razzaque*[1], B. Lanske[1]. [1]Oral & Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, [2]Genetics Unit, Shriners Hospital, Montreal, PQ, Canada, [3]Dept. of Natural Sciences, University of Veterinary Medicine, Vienna, Austria.

FGF-23 has been identified as the circulating phosphaturic factor associated with renal phosphate wasting leading to rickets and osteomalacia, as found in patients with autosomal dominant hyposphophatemic rickets, oncogenic osteomalacia, and X-linked hyposphosphatemia. We recently reported the generation of *Fgf-23* null animals resulting in a phenotype including growth retardation, severe hyperphosphatemia, increased serum ALP activity and $1,25(OH)_2D_3$ concentrations, abnormal bone mineralization, and tissue calcifications. A similar phenotype has been reported in patients with familial tumor calcinosis, caused by inactivating mutations in the FGF-23 gene. In the current study we studied the expression of *Fgf-23* postnatally by *lacZ* staining of various adult tissues of *Hyp/Fgf-23*$^{+/-}$ and *Hyp/Fgf-23*$^{-/-}$ mice, and were able to detect strong signals in all bones. We also investigated whether part of the abnormal *Fgf-23* null phenotype is due to the increased $1,25(OH)_2D_3$ levels. Thus, we established a new mouse model in which we eliminated vitamin D dependent mechanisms in *Fgf-23* null mice by generating double mutant animals which were deficient for both *Fgf-23* and 1α (OH)ase, the enzyme that converts the inactive form of vitamin D to the active form. Our data demonstrate for the first time that deleting the *1α hydroxylase* gene from *Fgf-23* null mice reverses the severe hypersphosphatemia to hyposphosphatemia, suggesting that regulation of phosphate homeostasis by *Fgf-23* is at least partly vitamin D-dependent. In addition to the biochemical measurements, we performed routine histological analysis and analyzed the mineralization pattern of the long bones of *Fgf-23*$^{-/-}$, 1α (OH)ase$^{-/-}$, and Fgf-23$^{-/-}$/1α (OH)ase$^{-/-}$ double mutant animals, by von Kossa staining on methylmetacrylate sections and Alizarin Red S staining on full body skeletons. Our findings suggest that Fgf-23$^{-/-}$/1α (OH)ase$^{-/-}$ double mutant mice resemble the phenotype of 1α (OH)ase$^{-/-}$ single knock-out animals as they exhibit ricketic appearance such as a wider growth plate with an expansion of hypertrophic chondrocytes, and a decrease in mineral deposition. Alizarin staining of all compound mutant skeletal elements clearly illustrated that the abnormal nodule formation previously observed in many *Fgf-23* null bones had completely disappeared indicating that $1,25(OH)_2D_3$ must have caused these features. We are currently measuring proliferation and apoptosis rates and are evaluating the expression of skeletal marker genes by *in situ* hybridization.

Structural Survey of FGF23. H. J. Garringer*, S. I. Davis*, T. E. M. Larsson, X. Yu, K. E. White. Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA.

Fibroblast growth factor-23 (FGF23) is a secreted factor required for normal phosphate and vitamin D metabolism. Our previous studies identified FGF23 mutations responsible for the heritable human disorders autosomal dominant hypophosphatemic rickets (ADHR) and tumoral calcinosis (TC) which alter the structure and processing of the encoded polypeptide. The objective of the present study was to isolate FGF23 domains central to its intracellular processing and secretion. In this regard, wild type and R176Q ADHR mutant FGF23s, were truncated by C-terminal deletions of 20, 38, and 52 residues, as well as by an N-terminal deletion of 25 residues. These truncated FGF23 species were transiently transfected into HEK293 cells and the conditioned media and cellular lysates were assessed for FGF23 expression. Western analyses of the media revealed the presence of all C-terminally truncated wild type and R176Q mutant FGF23s of the predicted sizes, whereas no signal was found in the corresponding lysates. Conversely, media from the cells transfected with the N-terminal deletion produced no FGF23 signal by Western analysis, whereas the corresponding lysates were positive. Although western analysis indicated that the N-terminally truncated FGF23 was retained within the cell, ELISA specific to the C-terminal domains of FGF23 showed that C-terminal protein fragments were present in the media, indicating that this mutant was cleaved by intracellular proteases and secreted. As expected, the C-terminally truncated proteins containing the R176Q mutation were more stable than their wild type counterparts. We recently demonstrated that an FGF23 mutation responsible for the TC phenotype, serine to glycine at residue 71 (S71G), results predominantly in the secretion of C-terminal FGF23 fragments. To understand substitutions tolerated at S71, we replaced S71 with corresponding residues conserved in other FGFs at the homologous position. A conserved threonine substitution (S71T) resulted in processing and secretion similar to wild type FGF23. In contrast, an asparagine substitution (S71N) resulted in complete intracellular retention of FGF23, and no secreted fragments. These findings indicate that S71N FGF23 is either resistant to, or not exposed to intracellular proteases, and does not enter the secretive pathway. In conclusion, our results indicate that the FGF23 C-terminus is not central to FGF23 processing. However, N-terminal domains of FGF23 are critical for processing, exemplified by the fact that the S71N mutant is capable of 'uncoupling' FGF23 production and secretion.

Successful Transplantation of Infantile Hypophosphatasia Using Bone Fragments and Cultured Osteoblasts. R. Cahill*[1], S. Perlman*[2], S. Mumm[3], W. H. McAlister*[4], M. P. Whyte[5]. [1]Pediatric Research Institute, St. Louis, MO, USA, [2]All Children's Hospital, St. Petersburg, FL, USA, [3]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, [4]St. Louis Children's Hospital, St. Louis, MO, USA, [5]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA.

Hypophosphatasia (HPP) is a rare heritable form of rickets featuring deficiency of the "tissue non - specific" isoenzyme of alkaline phosphatase (TNSALP) due to deactivating mutation of the *TNSALP* gene. *Infantile* HPP (I-HPP) often leads to respiratory death in infancy. There is no established medical treatment. However, an 8-month-old with I-HPP who underwent bone marrow transplantation (BMT) in 1997 had temporary improvement of her skeleton and lasting clinical and radiographic improvement 13 months later after receiving marrow cells expanded *ex vivo*. We used a unique approach for a second patient with likely fatal I-HPP. She was admitted to the ICU at age 5 months with a typical presentation of I-HPP; failure to thrive, bone pain, hypercalcemia, low alkaline phosphatase (18 IU/L) and demonstrated progressive skeletal demineralization. She carried 2 *TNSALP* missense defects: G571A, Glu174Lys (usually associated with "childhood" HPP) and A1289G, Asn413Ser (unique). Reported preclinical studies to improve osteoprogenitor engraftment included placement of bone intraperitoneally or directly into

bone. Hence, at age 9 months, after a reduced conditioning regimen, she received T-cell depleted bone marrow from her HLA-mismatched (4/6) father and, 17 days later, donor bone fragments; 2 intraperitoneally and 2 near the iliac crest. On day +28, cultured osteoblast-like cells and additional bone marrow and T-cells from the donor were infused. At +3.5 months, bone pain improved, radiographic progression of demineralization halted, and new bone appeared. At 20 months pBMT, without any evidence of donor engraftment in the periphery, PCR of male marker SRY sequences was performed on patient bone marrow and adherent cells from a bone biopsy specimen. Evidence of donor cells (SRY+) was found only in cultured bone cells. Now, 6 years post-procedure, she is well but has small radiolucencies in long bones, normal growth plates, and bone mineral density resembling mild "childhood" HPP. We postulate that despite absence of peripheral engraftment or correction in biochemical changes of HPP, sufficient TNSALP activity from donor stromal cells in proximity to sites of mineralization largely reversed the clinical and radiographic features of I-HPP.

Effect of Parathyroidectomy in Asymptomatic Primary Hyperparathyroidism: Preliminary Results of a Prospective Randomized Study. E. Ambrogini*[1], L. Cianferotti*[1], E. Vignali[1], F. Cetani[1], A. Picone*[1], G. Viccica*[1], P. Miccoli*[2], A. Pinchera*[1], C. Marcocci[1]. [1]Endocrinology and Metabolism, University of Pisa, Pisa, Italy, [2]Surgery, University of Pisa, Pisa, Italy.

Asymptomatic primary hyperparathyroidism (PHPT) is a disorder, usually not progressive, and therefore, according to the 1991 NIH Consensus Development Conference, most patients can be followed-up without parathyroidectomy (PTX). On the other hand there is evidence that also patients with mild PHPT can benefit from PTX. Aim of the present investigation was to compare in a 2-year, prospective, randomized study the effect of PTX *vs* no treatment in patients with asymptomatic PHPT. The primary endpoint was the change in lumbar spine bone mineral density (BMD). Secondary endpoints were: BMD changes at femur and distal radius, markers of bone turnover, quality of life (assessed by the SF-36 and SCL-90 questionnaires), echocardiography parameters, complication of surgery, and progression of the disease in the untreated group. Forty-nine patients (45 women and 4 men) with sporadic PHPT, who did not meet the NIH guidelines for PTX, have been enrolled so far: 24 underwent PTX and 25 were not treated. We report herein the results in 39 patients (19 treated with PTX and 20 untreated) who completed the one-year follow-up. At baseline the 2 groups were similar for age (63.0 ±7,4 vs 64.3 ±6,8 yrs), biochemical parameters (calcium, PTH, urinary calcium, renal function), vitamin D status and markers of bone turnover (B-ALP, osteocalcin, U-CTX, S-CTX), BMD at lumbar spine, total femur and distal radius. Patients were evaluated every 6 months. One patient had persistent PHPT after surgery and was excluded from the analysis. In the PTX-treated group lumbar spine and total femur BMD increased after one year by 4.4% and 1.6%, respectively, whereas in the untreated group they decreased by 1.6% and 2.8 %, respectively. The % changes were significantly different between the two groups ($p= 0.002$ at both sites). No clinically meaningful changes in any of the SF-36 and SCL-90 scores were observed in the two groups during follow-up. Five of the 20 untreated patients (33 %) had *de novo* appearance of at least one of the NIH criteria for surgery: worsening of hypercalcemia (n=1), hypercalciuria (n=3), nephrolitiasis (n=1), cortical BMD below -2 Z-score (n=1) and clinical vertebral fracture (n=1). No complication of surgery were observed. In conclusion, our preliminary data suggest that PTX may be advantageously performed in patients with asymptomatic PHPT since treated patients had significantly improved BMD at lumbar spine and femur compared to untreated ones, and conservative follow-up was associated with a progression of the disease in about one third of patients.

Prevalence of Vitamin D Depletion (-D) among Subjects Seeking Advice about Management of their Primary Hyperparathyroidism (PHPT). N. Parikh[1], T. Eskridge*[1], J. Hill*[1], A. Bhan*[2], M. Honasoge[2], D. Rao[1]. [1]Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA, [2]Bone & Mineral Metabolism, Henry Ford Hospital, Detroit, MI, USA.

There is growing concern about vitamin D depletion (-D) in the US population in general and in patients with bone and mineral disorders in particular. We reported a high prevalence of -D in a large cohort (>3500) of osteoporosis (OP) patients. Such information is lacking in PHPT patients. This is relevant because calcium (Ca) and vitamin D intakes are restricted based on intuition that it might aggravate hypercalcemia, but the rationale for such practice is not well founded. On the contrary, it may worsen the degree of HPT. Therefore, we assessed the prevalence of -D (serum 25-OHD ≤15 ng/ml) in all PHPT patients seen between Jan 2000-Dec 2004. We excluded patients with known causes for -D, and all non-whites and non-blacks. Serum Ca, creatinine (Cr), and PTH were measured in all patients. 559 PHPT patients were seen during the 5y; 456 women (72%); 296 whites (53%); mean age 65 ± 13y. In the entire cohort, the prevalence of -D was 28% (159/559) and 47% (263/559) with 250OHD ≤15 and ≤20 ng/ml cut-offs respectively; the rates remained relatively constant during the 5y by either criterion: 20, 33, 23, 24, and 21% and 45, 57, 47, 42, and 37% respectively and were higher than in OP patients. PTH correlated directly with Ca ($r=0.34$; $p<0.001$) and inversely with 25-OHD ($r= -0.34$; $p<0.001$) but not with age or Cr (data not shown). Serum 25-OHD was influenced by PTH and age, (multiple regression analysis; $p<0.001$ and $=0.02$ respectively), but not Ca or Cr. Based on the differences in slopes of PTH on 25-OHD between OP and PHPT cohorts, we found an effect of high PTH on 25-OHD level, most likely due to accelerated turnover leading to conditional - D in PHPT patients. Conclusions: In this largest study of its kind in the US, we found unacceptably high prevalence of -D in unselected PHPT patients and an additional "stress" on vitamin D nutrition. Our findings have important clinical implications in medical and surgical management of PHPT. Since -D promotes adenoma growth and modifies disease expression, attention to Ca and vitamin D nutrition is essential in PHPT patients. The current pervasive practice of restricting Ca and vitamin D intake in PHPT patients is unwarranted: to paraphrase Fuller Albright…*for all practical purposes bone disease does not develop if the patient drinks milk sufficient to avoid negative Ca balance*. Finally, our findings in these 2 large cohorts imply that either the prevailing educational efforts are ineffective or the foods and supplements do not contain adequate amounts of vitamin D or both. The dichotomy between what is recommended and what is practiced needs urgent attention.

Inhibin A Reduces Bone but not Muscle Loss in Hindlimb Suspended Mice. D. S. Perrien[1], N. S. Akel[1], L. J. Suva[1], E. Dupont-Versteegden[2], D. Gaddy[1]. [1]Department of Physiology and Biophysics and Center for Orthopaedic Research, UAMS, Little Rock, AR, USA, [2]Department of Geriatrics, UAMS, Little Rock, AR, USA.

Inhibin A (InhA) overexpression protects mice from hypogonadal bone loss via a mechanism that stimulates osteoblast activity and possibly differentiation, without effects on bone resorption. Bone loss during disuse is thought to occur due to a reduction in bone formation suggesting anabolic agents such as InhA may prevent the ensuing osteopenia. In addition, myostatin, a potent suppressor of muscle mass, utilizes the Activin/TGFβ signaling pathways and hence may be antagonized by InhA. This led to the hypothesis that regulated InhA overexpression would prevent both bone and muscle atrophy in hindlimb suspended (HS) mice. This idea was tested using 6-month-old male mice harboring a Mifeprisone (MFP)-inducible human InhA transgene. Mice were assigned to one of 3 treatment groups Con-Veh, HS-Veh, or HS-Inh (MFP-induced). At the time of suspension, a time release pellet containing MFP was subcutaneously implanted in all HS-Inh mice, while a placebo pellet was implanted in mice assigned to the Veh groups. HS mice were suspended by the tail at a 30° head-down angle while Con-Veh mice were individually housed in standard cages for three weeks. The volume and architecture of trabecular bone in the proximal tibial metaphysis was measured by e*x vivo* μCT. HS-Veh mice had significantly lower trabecular BV/TV (Con-Veh 0.175 ±0.069; HS-Veh 0.115 ±0.026; $p<0.05$) and deteriorated architectural properties including decreases in connectivity density, trabecular number and thickness and corresponding increase in separation ($p<0.05$ vs Con-Veh). In contrast, these measures were not significantly different between Con-Veh and HS-Inh mice. Moreover, the trabecular number in HS-Inh mice (5.28 ±0.36 mm^{-1}) was significantly greater than that of HS-Veh (4.68 ±0.51 mm^{-1}; $p<0.05$ vs HS-Inh) demonstrating that InhA overexpression reduced the loss of bone volume and prevented the decrease in trabecular number induced by HS. As expected, lower hindlimb muscle weight-to-body weight ratio (triceps surea) decreased with HS (Con-Veh 4.59+/-0.21 mg/g; HS-Veh 3.95+/-0.26; $p<0.001$) which was not prevented in InhA treated animals (HS-Inh 4.12+/-0.26; $p<0.001$ vs Con-Veh; NS vs. HS-Veh). Similar results were observed for the soleus muscle (Con-Veh 0.215 ±0.018 mg/g; HS-Veh 0.140 ±0.025 mg/g; $p<0.001$), while InhA overexpression had no effect on the atrophy (HS-Inh 0.143 ±0.011 mg/g; $p<0.001$ vs Con-Veh; NS vs. HS-Veh). Together these data demonstrate that InhA overexpression prevents bone, but not muscle loss during HS, further expanding its role as a potent bone anabolic agent.

Mechanical Loading during Growth Has Long-Term Benefits to Skeletal Health. S. J. Warden[1], R. K. Fuchs[2], A. B. Castillo[3], C. H. Turner[3]. [1]Department of Physical Therapy, Indiana University, Indianapolis, IN, USA, [2]Department of Anatomy and Cell Biology, Indiana University, Indianapolis, IN, USA, [3]Department of Biomedical Engineering, Indiana University, Indianapolis, IN, USA.

A disparity exists between when the skeleton is most responsive to exercise (pre-puberty) and when it is most prone to low-trauma fracture (late adulthood). The aim of the current study was to investigate whether bone changes induced by mechanical loading during growth are preserved with subsequent long-term detraining in an animal model. The right forearms of 5-wk-old female Sprague-Dawley rats were mechanically loaded 3 days/wk for 7 wks using the ulna axial loading model. Left ulnas served as internal controls and were not loaded. Adaptation to the loading program was determined within-animal prior to and after the completion of the loading program using *in vivo* DXA and pQCT. Following completion of the loading program, animals were subsequently detrained (restricted to home-cage activity) for 32 weeks, during which time periodic *in vivo* measurements were performed. Mechanical loading induced significant adaptation of the ulna, without influencing longitudinal growth. Loaded (right) forearms had 4.0% and 4.2% greater aBMD and BMC on DXA than contralateral non-loaded (left) forearms, respectively (all $P<0.01$). Similarly, on pQCT the loaded ulnas had 5.3% and 4.3% greater BMC and cortical area than the contralateral ulnas, respectively (all $P<0.02$). The largest effect was observed for the minimum second moment of area (I_{MIN}) which was 27.8% greater in loaded ulnas ($P<0.001$). Each of these loading-induced changes were maintained during detraining (all $P<0.05$). In particular, all (100%) of the absolute difference in I_{MIN} between loaded and non-loaded ulnas was maintained with 32 wks detraining (see figure). This data indicates that mechanical loading during growth may have lasting benefits on the skeleton. Loading predominantly induced an adaptation in bone structure (increase in I_{MIN}). This change persisted for more than six months of detraining after only 7 wks of loading. I_{MIN}

represents the resistance to bending and is significantly correlated with bone strength in the rat ulna (r^2=0.76). Thus, our data suggests that exercise-induced loading during growth may have lasting benefits on bone strength.

Skeletal Recovery Following Long-Duration Spaceflight Missions as Predicted by Preflight and Postflight Dual X-ray Absorptiometry (DXA) Scans of 49 Crewmembers. J. D. Sibonga[1], H. J. Evans*[2], H. Sung*[1], E. R. Spector*[2], V. S. Oganov*[3], A. V. Bakulin*[3], L. C. Shackelford*[4], A. D. LeBlanc[1]. [1]Division Space Life Sciences, Universities Space Research Association, Houston, TX, USA, [2]Wyle Laboratories, Houston, TX, USA, [3]Institute of Biomedical Problems, Moscow, Russian Federation, [4]NASA Johnson Space Center, Houston, TX, USA.

The weightless condition of spaceflight accelerates bone loss in crewmembers. At NASA Johnson Space Center (JSC), measurement of bone mineral density (BMD) by DXA is part of the astronaut medical evaluation requirements to monitor spaceflight effects on the skeleton. DXA scans performed before and after flight provide an opportunity to evaluate skeletal recovery in astronauts who return to a 1 g environment after long-duration spaceflight missions (4- 6 months). To increase the power of this analysis, the JSC lab was given access to BMD data of cosmonauts who served on the Russian MIR (n=22) and on the International Space Station (ISS) (n=8) together with data from 12 astronauts who served on ISS. We used BMD data from these 42 crewmembers to predict the skeletal response of 7 astronauts on the NASA MIR who provided multiple post-flight scans in a study of bone recovery. The deficit between pre- and postflight BMD, for every postflight scan performed on a crewmember, was plotted as a function of Days-after-Landing, as determined by the difference between landing date and the date of the postflight scan. The best fit of the data appeared to be an exponential function. A computed half-life, analogous to the decay of a radioisotope, was used to describe the number of days at which there was 50% recovery of bone lost during spaceflight. The "Recovery Half-lives" for lumbar spine, pelvis, total hip, femoral neck, trochanter and calcaneus were approximately six months. The fitted data from the multiple postflight scans of the 7 Mir astronauts fell within 95% confidence boundaries generated from the 42 international crewmembers indicating the predictive value of the original fitted data for skeletal recovery. In conclusion, the recovery half-lives for specific skeletal sites suggest that it will take more than 12 months before there is sufficient restoration of preflight BMD at these sites in crewmembers flown on missions of 4-6 months.

Recovery of Proximal Femoral Density and Geometry after Long-Duration Spaceflight. T. F. Lang[1], A. LeBlanc[2], H. Evans*[3], Y. Lu*[1]. [1]Radiology, University of California, San Francisco, San Francisco, CA, USA, [2]Life Sciences, Universities Space Research Association, Houston, TX, USA, [3]Wyle Laboratories, Houston, TX, USA.

Bone atrophy is a well-known medical consequence of long-duration spaceflight. Recent studies have demonstrated the regional extent and compartmental distribution of this loss, but there is little information on skeletal recovery after prolonged weightlessness. To address this, we used volumetric quantitative computed tomography (vQCT) to measure changes, in crew of the International Space Station, of proximal femoral cortical and trabecular bone that occurred 12 months after flights lasting 4-7 months. 14 subjects were imaged with a helical vQCT protocol (80 kVp, 280 mAs 3mm slice thickness, pitch=1) at three time points: pre-flight, post-flight and 12 months after mission completion. In the total femur hip region, we measured integral volumetric BMD (iBMD), integral BMC (iBMC), integral tissue volume (iVOL), trabecular BMD (tBMD), cortical BMD (cBMD) and cortical volume (cVOL). As a bone size measure, we also quantified the minimum femoral neck cross-sectional area (minCSA). For each measure, we computed the mean percentage bone loss incurred over the flight, the mean percentage change during the recovery period, and the ratio of the 12 month post-mission measurement to preflight values. The paired t-test determined whether the inflight and postflight changes were non-zero, and whether the 12-month to pre-flight ratio was different from 1. Results are tabulated below for the hip. Total femur iBMC, but not iBMD or tBMD, recovered to its pre-flight value. Recovery of bone mass involved increases in both bone density and bone size. We found incomplete recovery of BMD in the hip in the year after long-duration spaceflight. As shown by increased minCSA and iVOL, the proximal femur appears to adapt to resumed load bearing by periosteal apposition.

Femoral Osteocytes Are not Subject to Hypoxia in the Hindlimb Suspended Mouse. H. Y. Stevens, D. R. Meays*, J. A. Frangos. La Jolla Bioengineering Institute, La Jolla, CA, USA.

The enhancement of fluid flow in bone by means of mechanical loading induces an adaptive, osteogenic response. It is still unclear whether this remodeling activity is a result of increased shear stress *per se*, improved transport of chemical factors or streaming potentials generated at bone surfaces via fluid flow. The presence of high levels of osteocyte hypoxia, in an invasive avian ulna disuse model, relative to loaded control bone, would suggest that the supply of oxygen is limited in unloaded bone. This study investigated whether osteocytes in the non-invasive murine hindlimb suspension model of disuse osteopenia are subject to hypoxia. We measured levels of hypoxia in femora of mice that had been hindlimb-suspended (unloaded) or unsuspended (loaded) for 10 days (n = 7), and in the same animals observed the effect of increased IFF, via femoral vein ligation, on hypoxic fraction. In another group of animals, arterial occlusion was effected via femoral artery ligation and levels of hypoxia studied at day 1 and 4 (n = 3). Fluorescent immunolocalization of hypoxia inducible factor-1 alpha (HIF-1α) within osteocyte nuclei of midshaft cryostat sections, was used as an index of upregulation of hypoxia transcription factor. The fraction of osteocytes positive for HIF-1α was calculated from nine fields of view under the 40 X objective. Osteocyte viability and osteoclastic activity along bone surfaces were assessed in arterially-occluded bones by LDH and TRAP activity, respectively. Unloaded bone osteocytes were not hypoxic (1.2 ± 0.2 (% ± S.E.M.)) when compared to loaded controls (1.6 ± 0.2, p = 0.3) and increased IFF, via venous ligation, did not alter these levels significantly (unloaded 0.9 ± 0.2; loaded 1.3 ± 0.4, p = 0.3). Arterially-occluded femora demonstrated a significant level of osteocyte hypoxia compared to sham-operated limbs at 1 day (occluded 11.8 ± 1.7; sham 3.7 ± 0.4, $p < 0.05$) and 4 days after ligation (occluded 10.3 ± 2.0; sham 3.0 ± 1.0, $p < 0.05$). However, TRAP activity was not elevated in the arterially-occluded hypoxic femur compared to the sham-operated limb, suggesting little association between hypoxic osteocyte occurrence and osteoclastic activity in this study. Assessment of LDH-positive osteocytes (viable cells) indicated that osteocyte death (approx 20%) had occurred in both femoral artery-occluded and sham-operated femora between day 1 and day 4, and therefore arterial ligation likely compromised blood supply to the contra-lateral limb. These results support the concept that osteocytes in unloaded bone are not oxygen- limited and that IFF-driven bone formation, seen in the hindlimb suspended mouse is not chemotransport-related but likely mediated by fluid shear stress itself.

MuRF1, which Induces Denervation-Dependent Protein Degradation in Muscle, Is Involved in Unloading-Induced Bone Loss. H. Kondo[1], H. Sorimachi*[2], S. Takeda*[3], M. Noda[1]. [1]Molecular Pharmacology, Medical Research Institute, 21st Century COE Program, Tokyo Medical and Dental University, Tokyo, Japan, [2]Graduate School of Agricultural and Life Sciences, University of Tokyo, Tokyo, Japan, [3]Molecular Therapy, National Institute of Neuroscience, Tokyo, Japan.

MuRF1 is a muscle RING finger protein which is involved in IKKB NFkB activation dependent muscle wasting induced by denervation (Cell 2004). Since MuRF1 is involved in muscle wasting and its expression is enhanced in the muscle of mice subjected to tail suspension (TS)(Science 2001), MuRF1 involvement in similar protein degradation in bone loss due to unloading was examined in this paper. We conducted TS using MuRF1 KO mice and wild type (WT) control mice. TS induced reduction in the weight of soleus muscle. However, MuRF1 deficiency totally prevented such loss of weight in soleus muscle. Bone mineral content (BMC) analysis indicated that BMC was significantly reduced in WT mice due to unloading. In contrast, MuRF1 deficiency suppressed such reduction in BMC. This was observed both in femora and tibiae. These data indicated that unloading induced osteopenic signals would be dependent on MuRF1. Cortical bone mass in the mid shaft of femur was reduced by TS in WT mice. Again in contrast, such reduction in the cortical bone mass in the femur was no longer observed even after TS in MuRF1 deficient mice. Similarly, the thickness of the cortical bone was reduced by TS in WT mice but the reduction was attenuated by MuRF1 deficiency. MuRF1 deficiency alone reduced about 30% of the cancellous bone volume compared to WT mice in loaded control groups. Unloading caused about 60% reduction cancellous bone volume (BV/TV) in WT mice. Compared to WT, TS-induced bone loss was reduced to about 30% in MuRF1 deficient mice. Thus the magnitude of TS-induced reduction in cancellous bone was reduced in MuRF1 deficient mice compared to WT ($p<0.05$). These data indicated that the ring finger protein, MuRF1, which is involved in protein degradation through ubiquitination in muscle, could affect bone mass at basal levels as well as bone loss due to unloading.

Reduced Mineralization Density of Bone in Premenopausal Women with Idiopathic Osteoporosis. P. Roschger[1], I. Manjubala*[2], J. G. Hofstaetter[1], E. Shane[3], M. A. Donovan*[3], J. Fleischer*[3], D. Dempster[4], P. Fratzl*[2], K. Klaushofer[1]. [1]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 4th Medical Dept., Hanusch Hospital, Vienna, Austria, [2]Max Planck Institute of Colloids and Interfaces, Dept. of Biomaterials, Potsdam, Germany, [3]College of Physicians and Surgeons, Columbia University, New York, New York, NY, USA, [4]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

The syndrome of idiopathic osteoporosis (IOP) is characterized by the development of fragility fractures in otherwise healthy, young individuals, in whom no contributing etiology can be identified. In a recent case-control study of premenopausal women with IOP (JCEM 2005 Epub doi: 10.1210/jc.2004-2042), we observed that the cases were characterized by lower spine bone mass (Z score +/-SD, -2.1 +/-1 vs 0.0 +/-0.8; $p<0.05$) and histomorphometric evidence of reduced bone formation (MS/BS 42% lower than controls; p=.02). Neither of these findings would be expected to result in such marked skeletal fragility in young subjects. However, the amount of mineral embedded in the collagenous matrix to form the collagen/mineral nano-composite of bone plays a pivotal role in defining its intrinsic mechanical properties (e.g. E-modulus). Therefore, we evaluated the integrity of the bone material itself. Using quantitative backscattered electron imaging (qBEI), the bone mineralization density distribution (BMDD) of trabecular bone in biopsies of patients with IOP (n=9) and age-matched healthy premenopausal women (n=15) was determined. The mean (CaMean) and typical (CaPeak) calcium content, the variation of calcium content (CaWidth) and the percentage of low mineralized matrix (CaLow) were measured to characterize the BMDD. A small but significant reduction in degree of mineralization in the cases (CaMean -3.0%, $P<0.05$ and CaPeak -2.7%, $P<0.05$) compared to the control group was detected, while the other BMDD parameters, CaWidth and CaLow, were not significantly different. The moderate decrease in mineralization density alone might not be sufficient to explain bone fragility. However, the decrease in mineralization was an unexpected finding with respect to the low bone turnover reported in the cases. One would have expected the contrary, namely an increase in degree of mineralization, because low bone turnover permits prolonged secondary mineralization in a larger number of bone packets, resulting in a higher mineral content. This finding suggests that in IOP, changes in the mineralization process itself might occur, which are most likely based on alterations of the organic matrix, and which, in turn, might contribute to increased fragility.

Risk-Equivalent Z-Scores for DXA and Other Techniques Based on a Systematic Review. C. C. Glüer. Med. Physik, Klinik f. Diag. Radiologie, UK S-H, Kiel, Germany.

The WHO diagnostic T-Score criterion of -2.5 is not applicable to techniques other than DXA. There is a need for risk criteria that can be used across techniques and which are suited to define intervention criteria based on absolute fracture risk. An approach based on Z-Scores is presented. 1) Estimates of absolute and relative risk were compiled from SOF, EVOS/EPOS and the Rotterdam study. 2) Z-Score model. The most relevant predictors of fracture risk are age, bone mineral density (BMD) and prevalent vertebral fractures(prVFx). A factorial model of absolute risk using Z-Scores separates the impact of these three factors, described by relative risk (RR): AbsRisk=AbsRisk (woman age 70) x RR(age) x RR(Z-Score) x RR(prVFx). 3) Systematic review of gradients of risk for non-DXA techniques. Standardized risk or odds ratios per SD (sRR) derived from prospective studies or cross-sectional studies in which DXA was also measured, were accepted. Evidence was rated according to the Oxford Center for Evidence Based Medicine Criteria. 4) Risk equivalent Z-Scores for these techniques. In the factorial model, risk-equivalent Z-Scores for a non-DXA technique are given by: Z-Score(non-DXA) = ln(sRR(DXA)) / ln(sRR(non-DXA)) x Z-Score(DXA). For weighted combined risk of vertebral and hip fracture Z-Score intervention levels were calculated for 2 scenarios: a) absolute risk equivalent to current DXA T-score=-2.5 (WHO) and b) absolute risk fixed at level equivalent to DXA T-Score=-2.5 at age 70 (fixed). 1)&2) For a Western European woman aged 70 the absolute 10-year risk of hip fracture is 6.3% doubling every 6.3 years of age, with sRR = 2.4 for total femur BMD, and RR of 1.8 and 0.9 if vertebral fractures are present or absent; for vertebral fractures the absolute 10-year risk is 12.2% doubling every 8.1 years of age, with a gradient of risk of 1.9 for total femur BMD, RR of 3.3 and 0.8 if vertebral fractures are present or absent. 3) In the systematic review, 106 articles met the evidence criteria and 43 techniques/variables were graded. 4) The table lists Z-Score intervention levels for scenarios a) (WHO) and b) (fixed) along with level of evidence.

Method (level of evidence)	prVFx	WHO 60yrs	WHO 70yrs	WHO 80yrs	fixed 60yrs	fixed 70yrs	fixed 80yrs
DXA BMD tot. femur (A)	yes	0.4	0.6	0.7	-1.1	-0.7	-0.4
DXA BMD tot. femur (A)	?	-1.1	-0.7	-0.4	-2.0	-0.7	0.6
DXA BMD tot. femur (A)	no	-1.2	-0.9	-0.7	-2.2	-1.0	0.2
QUS calc Stiffn. Index (B)	?	-1.3	-0.9	-0.6	-2.3	-0.9	0.4

The model allows to estimate absolute risk and calculate intervention levels for different techniques and differently defined intervention levels in a consistent fashion. It can be expanded by interaction terms and more risk factors once robust data become available.

Inadequate Vitamin D Status Despite Abundant Sun Exposure. N. Binkley[1], R. Novotny[2], D. Krueger[1], T. Kawahara-Baccus*[1], Y. G. Daida*[2], D. Gemar[1], G. Lensmeyer*[3], M. K. Drezner[1]. [1]University of Wisconsin Osteoporosis Clinical Research Program, Madison, WI, USA, [2]Human Nutrition, Food and Animal Sciences, University of Hawaii at Manoa, Honolulu, HI, USA, [3]Laboratory Medicine, University of Wisconsin, Madison, WI, USA.

Lack of sun exposure is widely accepted as the cause of epidemic vitamin D inadequacy worldwide. However, a number of studies find that some individuals with seemingly adequate UV exposure have a low serum 25-hydroxyvitamin D (25OHD) concentration. Existing data are confounded by imprecision of the 25OHD assays employed and a lack of assurance that UV exposure was optimal. Therefore, we compared 25OHD status in a group of 100 adults in Honolulu, HI (latitude 21°) with self-reported habitually high sun exposure (3 or more hours, 5 days per week) to that in 174 adults in Madison, WI (latitude 43°), measuring 25OHD with a precise HPLC assay, the results of which correlate well with those obtained by tandem mass spectroscopy (r^2=0.9). In the HI group, dietary vitamin D intake and sun exposure were determined by questionnaire and skin color by reflectance colorimetry. The HI population (33 women/67 men) and the WI population (94 women/80 men) had similar age (24.1±0.7 vs. 23.9±0.3 years) and BMI (23.5±0.4 vs. 23.1±0.2). Sun exposure of the HI adults was 21.4±1.5 hours/week. As anticipated, serum 25OHD was higher ($p<0.001$) in the HI than WI population (31.4±1.0 vs. 18.3±0.8 ng/ml). Surprisingly, the highest 25OHD concentrations were virtually identical in the HI (62.0 ng/ml) and WI (62.3 ng/ml) populations. Moreover, serum 25OHD concentration in the HI group was unrelated to hours of sun exposure or skin color. Additionally, the range of 25OHD levels in the HI population (12-62 ng/ml) broadly overlapped that of the WI population (5-62 ng/ml), suggesting that the vitamin D inadequacy undoubtedly present in the WI population likewise is manifest in the sun-exposed HI population. In fact, serum 25OHD was ≤20 ng/ml in 10% of the HI population, despite sun exposure without use of sunscreen of 23.1±4.9 (range 6-50) hours/week. These data suggest that variable responsivity to UVB radiation is evident among individuals, causing some to have inadequate vitamin D status despite abundant sun exposure. Though counter-intuitive, this possibility is evolutionarily feasible, as the high calcium intake of early humans may have allowed maintenance of optimal calcium balance despite seemingly inadequate vitamin D status. Finally, as the maximal 25OHD concentration produced by natural UV exposure appears to be ~65-70 ng/ml, clinicians prescribing high-dose vitamin D treatment are well-advised to avoid using such therapy in amounts or duration that increase serum 25OHD concentration above this range.

Patients with Hip Fracture Exhibit Bone Micro-Architectural Deterioration Compared to Patients with Colle's Fracture as Assessed with *In Vivo* High Resolution 3D Micro-pQCT. European Advanced Detection of Bone Quality(ADOQ) Study. M. Zouch*, B. Gerbay*, T. Thomas, L. Vico, C. Alexandre. LBTO, INSERM 366, Saint-Etienne, France.

Osteoporosis is a bone fragility disease due to both low bone mineral density (BMD) and architectural deterioration. However, 3D architectural changes are poorly documented in fractured patients. Therefore, within the European ADOQ Study, we conducted a preliminary survey using a novel 3D pQCT device (XTreme CT, Scanco Medical, Zurich, Switzerland) in post-menopausal women with either hip fracture (HF, n=29; age: 76.1±12.5 yo), Colle's fracture (CF, n=15; age: 70.0±12.2 yo) or no fracture (C, n=30; age: 71.4±5.7 yo). No statistical significant difference in age was observed between the three groups. Measurements were performed up to 6 weeks after fracture. Total Hip BMD (H-BMD) was measured with DEXA (Delphi , QDR 4500, Hologic). Quantitative 3D densitometric parameters in mg/cm^3 (Total Bone Density: D100, Cortical Density: DCort and Trabecular Density: DTrab) and qualitative micro-architectural parameters (Trabecular Bone Volume, BV/TV, %, Trabecular Number, Tb.N, /mm, Trabecular Thickness, TbTh, mm, Trabecular Separation, Tb.Sp, mm and Cortical Thickness, C.Th, mm) were analyzed at weight-bearing (distal tibia) and non weight-bearing (distal radius) sites. Results were adjusted for BMI since body weight was lower in the HF group. As expected, H-BMD and D100 were significantly reduced at both sites in HF and CF as compared to C. Surprisingly, in CF, we observed a significant decrease in radial DCort as compared to C (31.2±5.3 vs 36.9±6.3; $p<0.05$) while no cancellous microarchitectural differences were observed at both sites. In contrast, in HF, we observed a significant lower tibial DTrab (5.0±2.0 vs 6.4±1.8; $p<0.01$) and tibial BV/ TV (42 ± 17.10^{-4} vs 53 ± 15.10^{-4} ; $p<0.01$) as compared to C. In addition, architectural parameters were impaired, with higher Tb.Sp and lower C.Th than in C, at both the radial (467 ± 261.10^{-4} vs 276 ± 107.10^{-4}; $p<0.001$ and 277 ± 139.10^{-4} vs 344 ± 85.10^{-4}; $p<0.05$) and tibial sites (380 ± 230.10^{-4} vs 231 ± 53.10^{-4}; $p<0.001$ and 248 ± 137.10^{-4} vs 346 ± 118.10^{-4}; $p<0.01$), respectively. In conclusion, 3-D analysis suggests that CF are mainly related to local cortical low mineral density whereas HF are associated with a combination of both trabecular and cortical quantitative and qualitative damages occuring in both weight-bearing and non weight-bearing bones. Further studies are needed to understand the mechanisms leading to such differences which could explain the different responses to therapy observed in these peripheral sites.

AAE581, a Novel Cathepsin K Inhibitor, Protects against Ovariectomy-Induced Bone Loss in Non-Human Primates, in Part by Stimulation of Periosteal Bone Formation. C. Jerome[1], M. Missbach*[2], R. Gamse*[2]. [1]SkeleTech, Bothell, WA, USA, [2]Novartis Institutes for BioMedical Research, Basel, Switzerland.

This study was designed to evaluate the effects of AAE581, a highly potent and specific small molecule inhibitor of the osteoclastic enzyme cathepsin K, on bone biomarkers, mass, strength, and histology in the ovariectomized non-human primate model of postmenopausal osteoporosis. Eighty ovariectomized female cynomolgus monkeys (*Macaca fascicularis*) were dosed orally twice daily with vehicle or AAE581 at 3, 10, or 30 mg/kg for 18 months. Twenty sham-ovariectomized animals (SHAM) received vehicle. Serum and urine samples for bone biomarker analysis, DXA measurements of spine and femur, and pQCT measurements of femur neck were collected at baseline and then at 3 or 6 month intervals. Vertebra, femur neck and mid-femur were subjected to biomechanical testing and histomorphometric analysis at 18 months. All groups were compared to ovariectomized control, with $p<0.05$ considered significant. Serum and urinary biomarkers of bone resorption and formation were significantly increased by ovariectomy. Medium and high doses of AAE581 reduced resorption markers (serum and urinary NTx) to sham levels or below, while maintaining elevation of formation markers (serum osteocalcin and BSAP) above SHAM. BMD and BMC of lumbar spine and femur were significantly lower in ovariectomized than in SHAM animals, and were significantly increased to levels comparable to (spine), or even greater than (femur) SHAM by all 3 doses of AAE581. Femoral neck total BMD was significantly increased to levels greater than SHAM by AAE581 treatment, due to improved BMD in both trabecular and cortical compartments. Vertebral maximum load and stiffness were significantly increased by high dose AAE581, vertebral ultimate strength and elastic modulus by medium and high doses. Vertebral and femoral midshaft BMC were significantly correlated to maximum load. Some (low dose) or most (medium and high dose) histomorphometric indices of bone turnover in vertebra and femoral neck were significantly decreased by AAE581. In contrast, periosteal bone formation rates were significantly increased at both sites by mid and high doses and in mid-femur by low and medium doses of AAE581. In conclusion, AAE581 improved bone mass and strength accompanied by the expected inhibition of bone turnover at most sites, and also had a unexpected stimulatory effect on periosteal bone formation.

Cyclic PTH Stimulates Bone Formation in the Murine Lumbar Vertebrae with A Magnitude Comparable to that Produced by Daily PTH. A. Iida-Klein[1], S. S. Lu[1], F. Cosman[2], D. W. Dempster[1], R. Lindsay[2]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

In humans, a regimen of repeated 3-month cycles of hPTH[1-34]-on and off (cyclic PTH) was found to be as effective as daily injections of hPTH[1-34] (daily PTH) in increasing vertebral bone mineral density (BMD) at 15 months (*Cosman et al.,* ASBMR, 2003). In mice, an alternating one-week-on and off regimen of daily injections of hPTH[1-34] (cyclic PTH) has been shown to increase femoral BMD, strength and cortical width, as effectively as the daily PTH when improved BMD, strength and cortical width are calculated as a function of the amount of PTH administered (*Iida-Klein et al.,* Endocrine Society, 2005). In order to further explore the potential of cyclical PTH administration, we performed histomorphometric analyses of vertebral bones from 20-week-old female C57BL/J6 mice treated with the following regimens: 1) daily injections with vehicle for 7 weeks (control), 2) daily injections with hPTH[1-34] (40 μg/kg/day) for 7 weeks (daily PTH) and 3) daily injections with hPTH[1-34] (40 μg/kg/day) and vehicle alternating weekly for 7 weeks (cyclic PTH). Calcein (10 mg/kg) was injected at 10, 9, 3 and 2 days prior to euthanasia. Histomorphometry was performed on the cancellous and cortical bone of the 2nd lumbar vertebra**.** Cyclic PTH produced significant increases in BV/TV, trabecular width and number, trabecular osteoblast and osteoclast perimeters, cortical width, mineral apposition rate and bone formation rate, with magnitudes comparable to those of daily PTH (Table 1). Importantly, while the anabolic response was similar in magnitude with both regimens, the total amount of PTH delivered in the cyclic regimen was over 40 % less than that in the daily regimen. The current study supports the potential use of cyclic PTH regimens for the treatment of osteoporosis. Such an approach would have obvious financial benefits and may also improve adherence to PTH therapy.

Table 1 Histomorphometric Analyses of Vertebral Bones

		Lumbar Vertebra		
	Unit	**Control**	**Daily PTH**	**Cyclic PTH**

Skeletal Defects in R*ingelschwanz* Mutant Mice Reveal that Lrp6 Is Involved in Bone Resorption and Essential for Proper Bone Mass Aquisition. T. Kubota*[1], T. Michigami[2], C. Kokubu*[3], A. Suzuki*[2], N. Sakai*[1], S. Nakajima[1], K. Imai*[4], K. Ozono[1]. [1]Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan, [2]Department of Environmental Medicine, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, [3]Center for Advanced Science and Innovatiion, Osaka University, Osaka, Japan, [4]GSF-Nationai Resaerch Center for Environment and Health, Neuherberg, Germany.

Although accumulating studies have shown that low-density lipoprotein receptor-related protein 5 (LRP5) is a key regulator in bone homeostasis, the role of LRP6, another co-receptor for Wnt ligands, in bone metabolism has not been fully elucidated. Here, we present evidence that Lrp6 is involved in bone resorption and required for bone acquisition, using a mouse model with a hypomorphic allele of *Lrp6*. We previously reported that a novel spontaneous mutation *ringelschwanz* (*rs*) in the mouse was caused by a point mutation in *Lrp6*, leading to an amino acid substitution R886W. Homozygous *rs/rs* mice exhibited malformations of vertebral column and spina bifida in the lumbo-sacral region, oligodactyly, and delayed ossification of digits at birth. A genetic complementation test has revealed that *rs* is a hypomorphic *Lrp6* allele. Primary fibroblasts isolated from *rs/rs* mice could not efficiently transduce signals through the Wnt/β-catenin pathway. In the present study, we have further analyzed the bone phenotype in *rs/rs* mice. pQCT analyses on tibiae from 9 and 26-week-old mice revealed the decrease in trabecular density, cortical area, periosteal circumference and endosteal circumference in *rs/rs* mice in both sexes. Bone histomorphometry in 26-week-old female mice showed that bone volume and trabecular number were decreased in *rs/rs* compared with wild-type mice. Unexpectedly, eroded surface was increased in *rs/rs* mice. The cellular basis underlying this low bone mass phenotype in *rs/rs* mice was then studied using primary osteoblasts isolated from the calvariae. The *Rankl* mRNA expression level was markedly increased in osteoblasts from 7-week-old *rs/rs* mice, although it was unaltered in osteoblasts from neonatal *rs/rs* mice. There was no obvious difference in the expression levels of *Opg*, *Lrp6*, and *Lrp5*. The proliferation analyzed by MTS assay and the mineralization *in vitro* were not impaired in osteoblasts from 7-week-old *rs/rs* mice. In summary, *Lrp6* mutant *rs/rs* mice showed the low bone mass phenotype associated with increased bone resorption, and the *Rankl* mRNA expression level was markedly increased in *rs/rs* osteoblasts. These results indicate that Wnt signaling via Lrp6 is involved in bone resorption through osteoblasts.

Caveolin-1 Deficient Mice Have Bigger Bones. J. Rubin[1], Z. Schwartz[2], K. Wong*[2], L. Wang*[2], M. Drab*[3], D. Smith*[4], H. Jo*[4], B. D. Boyan[2], T. Gross[5]. [1]Emory & VAMC, Decatur, GA, USA, [2]Georgia Tech, Atlanta, GA, USA, [3]Max Planck, Dresden, Germany, [4]Emory Univ, Atlanta, GA, USA, [5]Univ Washington, Seattle, WA, USA.

Caveolin-1 associates with signaling molecules in caveolae of the plasma membrane. It can be predicted that in the absence of caveolin-1 that many signaling pathways will be dysregulated. Caveolin-1 null mice in a C57/B6 background ("Cav-1 null") are viable and fertile, but smaller, leaner and have hyperproliferative lungs and vascular abnormalities. We evaluated the effect of caveolin-1 deficiency on the skeleton. Using micro-CT, we observed clear differences in both cortical and trabecular bone in the morphology of male Cav-1 null femurs by 6 wk of age through at least 9 wk compared to C57 wild type mice. At 7.5 wk, cortical bone area at the femoral mid-diaphysis was increased by 84% ($p=0.0003$) compared to wild type mice. The increased cortical bone area was achieved through a 44% increase in periosteal area ($p=0.0016$), which more than compensated for the 20% increase in endocortical area ($p=0.06$). Trabeculae of the distal femoral metaphysis and epiphysis of Cav-1 null mice demonstrated similar phenotypic alterations compared to wild type mice. Metaphyseal BV/TV was significantly elevated (metaphysis: 340% more than control, $p=0.005$), trabecular thickness increased (metaphysis: +34%, $p=0.02$), and trabecular spacing was diminished (metaphysis: -36%, $p=0.004$). Dynamic histomorphometry supported increased bone formation in both compartments, but also showed decreased trabecular MAR and BFR as well as cortical MAR (59, 52% and 32% of wt, all $p<0.05$). The skeletal phenotype implies that there has been increased bone formation due to either increased osteoblast proliferation or function; the decreased MAR at 7.5 wk, however, implies that the increased bone formation occurred at an earlier time or, less likely, that osteoclast activity is decreased. That still growing 7.5 wk Cav-1 null skeletons are ~25% larger than those of 16 wk C57 mice ensures a non-transient phenotype. Since the caveolin-1 scaffold can function to inactivate or damp incoming signals it is possible that an osteoprogenitor response to hormonal/mechanical stimuli is enhanced in its absence. Deciphering the etiology of the large bones in this transgenic will require evaluation at several time points, as well as generation of a bone specific Cav-1 knockout, since dysregulation of signaling networks in the global knockout may arise from non-skeletal sources.

Overexpression of ZFP 521 (MC-33), a 30 Zinc-Finger ΔFosB-Interacting Protein, Induces an Increase in Bone Volume and Bone Formation Rates in Transgenic Mice. M. Wu*, F. Morvan*, J. Zhang*, L. Neff*, W. Philbrick*, W. C. Horne, R. Baron. Cell Biology, Yale University, New Haven, CT, USA.

A cell autonomous effect of overexpressed ΔFosB on osteoblast differentiation and bone formation leads to a severe and progressive osteosclerosis in transgenic mice. We previously identified ZFP 521 (formerly MC-33) as a novel ΔFosB-interacting protein in a yeast two-hybrid screen of an osteoblast library. ZFP 521 is a 180 kDa protein with 30 C2H2 Kruppel-like zinc fingers, which localizes to the nucleus. In adult mice, ZFP 521 was strongly expressed in brain, heart, lung, and skeletal muscle and at lower levels in fat, spleen, kidney and liver. ZFP 521 is expressed at high levels in primary calvarial osteoblasts. *In situ* hybridization studies demonstrated that ZFP 521 mRNA was expressed during bone development in mesenchymal condensations, in the preosteoblastic layers, and in the growth plate. *In vitro*, ZFP 521 mRNA was downregulated by osteogenic (BMP-2) or adipogenic agents (indomethacin, hydrocortisone and IBMX). Further, transient transfection of ZFP 521 into C3H10T1/2 and MC3T3-E1 cells suppressed the Δ2ΔFosB-induced increase in Runx2 expression, and stable overexpression in the same cells reduced alkaline phosphatase activity to background. In addition, ZFP 521 inhibited the activation of Runx2 and osteocalcin promoters by Runx2 in luciferase assays. In order to examine the *in vivo* role of ZFP 521, we generated transgenic mice that overexpressed ZFP 521 under the control of either the enolase 2 (NSE) or the osteocalcin (OG2) promoter. ZFP 521 overexpression *in vivo* resulted in a two-fold increase in bone volume with an increase in osteoblast number and osteoid volume. Dynamic bone formation parameters such as mineral apposition rate and bone formation rate were increased by three-fold. Von Kossa staining of *ex vivo* cultures of primary osteoblasts from OG2-ZFP 521-overexpressing mice demonstrated an increase in nodule formation and mineralization. In contrast, cultures of primary osteoblasts from NSE-ZFP 521 mice exhibited decreased nodule formation and mineralization. Given that 1/ The OG2 promoter is activated late in osteoblast differentiation; 2/ The exogenous NSE promoter is activated both early and late; 3/ Runx2 exerts opposite effects on early and late stages of osteoblast differentiation and 4/ ZFP 521 represses Runx2 transcriptional activity, we propose that ZFP 521 acts as a Runx2 repressor, inhibiting early stages of osteoblast differentiation while favoring osteoblast differentiation and bone formation when expressed during later stages.

The Transcription Factor EBF-1 Regulates Osteoblast and Adipocyte Development. D. G. T. Hesslein*[1], Y. Xi[1], S. Zhou*[1], C. M. Gundberg[1], R. Grosschedl*[2], J. A. Lorenzo[3], D. G. Schatz*[1], M. C. Horowitz[1]. [1]Yale University, Howard Hughes Medical Institute, New Haven, CT, USA, [2]Max-Planck Institute, Freiburg, Germany, [3]University of Connecticut, Farmington, CT, USA.

A regulatory network comprised of transcription factors control B cell fate specification. Two of these factors, PU.1 and Pax5, also regulate osteoclast development. Early B Cell Factor-1 (EBF-1) is another member of this network that has been shown to be essential for B cell differentiation. Interestingly, EBF-1-/- mice are runted and have a reduced life span. We analyzed the bone phenotype of EBF-1 homozygous mutant (-/-) and wild-type (+/+) mice by histomorphometry and biochemistry. Spleen and bone marrow cells (BM) were used as sources of osteoclast precursors. Tibia from -/- mice had a striking increase in osteoblasts lining bone surfaces (>85%), at both 4 and 12 weeks of age ($p<.01$). Consistent with this was a 29% increase in osteoid thickness and a 185% increase in the bone formation rate ($p<.001$). This correlated with a 2 fold increase in serum osteocalcin ($p<.001$). However, in vitro proliferation and alkaline phosphatase activity of -/- osteoblasts did not differ from control. In contrast, osteoclast number was similar in 4 week-old +/+ and -/- mice; however, at 12 weeks the number of osteoclasts was more than twice that of controls ($p<.0001$). Culture of BM from 4 week-old -/- but not 12 week-old mice with M-CSF + RANKL consistently yielded less osteoclasts than controls. These data correlated with a 72% increase in bone volume at 12 weeks of age ($p<.01$). The most striking aspect of the EBF-1-/- bones was the presence of adipocytes, which filled the marrow space. Unusually, adipocytes also filled the marrow space in the secondary center of ossification. Like the increased number of osteoblasts, the adipocytes in the marrow were present at both 4 and 12 weeks of age. Oil-red-O staining confirmed the increased fat deposition in BM smears. Increased adiposity was also seen histologically in the liver but not the spleen of -/- mice. Importantly, EBF-1 mRNA was expressed in preconfluent, confluent and post confluent wild-type osteoblasts and in adipocytes. These data imply that the increased bone mass in mutant mice resulted from an increase in the number of osteoblasts and not from insufficient or defective osteoclasts. Loss of EBF-1 caused a pronounced, site-specific change in adipogenesis and fat deposition. Therefore, EBF-1-/- mice may be a new model of lypodystrophy. The phenotype of EBF-1-/- mice is distinct from that of either PU.1 or Pax5 deficient mice. The expression of EBF-1 in osteoblasts and in adipocytes and the distinct bone phenotype in EBF-1-/- mice identifies EBF-1 as a novel regulator of osteoblast and adipocyte development.

The Homeoprotein Engrailed-1 Has Pleiotropic Functions in Calvarial Intramembranous Bone Formation. R. A. Deckelbaum[1], A. Majithia*[1], T. Booker*[1], J. E. Henderson[2], C. A. Loomis*[1]. [1]Pathology, New York University, New York, NY, USA, [2]Centre for Bone & Periodontal Research, McGill University, Montreal, PQ, Canada.

Recent studies have identified a growing number of homeodomain transcription factors as critical regulators of cranial intramembranous bone formation. Our unpublished observations have suggested a possible role for the homeoprotein Engrailed-1 (En1) in craniofacial development. In the present study we aimed to define the craniofacial expression of *En1* and investigate its regulatory functions during skull vault ossification. Using a *lacZ* reporter mouse strain, we show that *En1* expression initiates at embryonic day 11.5 (E11.5) within the skeletogenic mesenchyme of the primordial frontal and parietal bones, and subsequently expands into all facial and cranial vault mesenchyme. During overt osteogenesis (E14.5-E18.5) *En1* is expressed by calvarial osteoblasts and cells of the suture mesenchyme. Neonatal *En1*$^{-/-}$ mice exhibit generalized calvarial bone hypoplasia and sutural patency, displaying prominent posterior-frontal foramina. Micro computerized tomography (microCT) analysis confirms that calvarial bones of *En1* mutants are osteopenic (BV/TV: Wt=3.460 ±0.4033, n=8; *En1*$^{-/-}$=2.205 ±0.3031, n=6; $p=0.0301$), exhibit increased trabecular spicule separation (Tb.Sp.: Wt=0.7007 ±0.05129, n=8; *En1*$^{-/-}$=0.8362 ±0.02945, n=6; $p=0.0448$), and show reduced osteoid mineralization. Assessment of osteogenic differentiation in vivo and in cultured calvarial osteoblasts indicates that *En1* regulates the onset of *osteopontin* and *osterix* expression and is later essential for the osteoblastic expression of *bone sialoprotein* and *osteocalcin*. In addition, BrdU incorporation analysis suggests a role for *En1* in regulating sutural osteoprogenitor proliferation. Ongoing studies are beginning to unravel a regulatory interplay between *En1* and the FGF/MAPK signaling pathway in osteoblasts. To examine the possibility that the calvarial osteopenia in *En1* mutants may result in part from increased bone resorption we performed histomorphometric analysis of TRAP^{+} osteoclasts. Significantly, we observed increased numbers of osteoclasts in *En1*$^{-/-}$ calvariae that were also more widely distributed by comparison to their wt counterparts. Consistent with this observation, we show that *En1*-null osteoblasts upregulate the expression of receptor activator of NFkB ligand (RANKL) while maintaining normal *osteprotegrin* expression. In summary, this study identifies *En1* as a novel cell-autonomous modulator of calvarial osteoblast differentiation, which also plays a non cell-autonomous role in regulating osteoclast recruitment and/or activation.

Regulation of Osteoblast Differentiation by Dlx5 in Transgenic Mice. H. Chin*[1], H. Li*[1], C. L. Wang*[2], A. C. Lichtler[1]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Transgenic Core Facility, Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan Republic of China.

The *Dlx5* gene encodes a DNA-binding homeobox protein, which acts as a transcription factor and is expressed in many developing tissues. Previous studies have shown that Dlx5 induces osteoblast differentiation *in vitro,* Dlx5 knockout mice show delayed calvarial ossification, and that blocking Dlx gene signaling inhibits induction of many of the genes induced by BMPs in osteoblastic cells. These results indicate that activation of Dlx5 is probably an important event for cells entering the osteogenesis pathway. To explore the role of Dlx5 in regulating osteoblast differentiation *in vivo*, we generated transgenic mice over-expressing *Dlx5* using the bone-directed 1.7 kb and 3.6 kb rat type I collagen promoters. The 1.7 kb promoter drives expression primarily in differentiating osteoblasts, while the 3.6 kb promoter is expressed at earlier stages of osteoblast lineage progression, as well as other type I collagen expressing cells. Most *Col1(1.7)-Dlx5* mice die perinatally due to difficulties in breathing, and the survivors usually have generally mild phenotypes. The bones are generally well ossified, but are significantly malformed. On the other hand, *Col1(3.6)-Dlx5* mice are grossly smaller with severe bone phenotypes. *Col1(3.6)-Dlx5* mice usually suffer from malocclusion and twisted axial bones. Whole mount Alizarin Red and Alcian Blue staining of the mutant mice revealed multiple bone morphogenesis defects, including rib and vertebrae patterning abnormalities, craniofacial and long bone abnormalities, inner ear defects, and teeth problems. Comparing *Col1(3.6)-Dlx5* mice to the wildtype by histology, the trabecular bone is significantly reduced and the growth plate is less organized. In summary, our data demonstrate that overexpression of *Dlx5* significantly interferes with the development of axial bones, and can lead to a low bone mass phenotype in long bones. These bone phenotypes may be due to improper induction of osteoblast differentiation. Further analysis will focus on histology and histomorphometry, to evaluate the hypothesis that early expression of Dlx5 causes premature induction of osteoblast differentiation leading to insufficient numbers of mature osteoblasts, while later expression of Dlx5 promotes osteoblastic differentiation.

Smurf1 Mediates Runx2 Degradation through a Smad6-Dependent Mechanism. R. Shen, M. Chen, R. J. O'Keefe, D. Chen. Orthopaedics, University of Rochester, Rochester, NY, USA.

Runx2 is a bone-specific transcription factor that plays a critical role in bone development, postnatal bone formation, and chondrocyte maturation. In previous studies, we discovered that the E3 ubiquitin ligase Smurf1 mediates Runx2 degradation in an ubiquitin-proteasome-dependent manner. Over-expression of Smurf1 in osteoblasts inhibits osteoblast differentiation. In transgenic mice in which Smurf1 transgene is targeted to osteoblasts using the murine type I collagen promoter (2.3 kb), bone formation and osteoblast function are inhibited, demonstrating that Smurf1 plays an important regulatory role in osteoblast function and bone formation. In the present studies, we investigate the molecular mechanism by which Smurf1 mediates Runx2 degradation. Smurf1 is a Hect domain E3 ubiquitin ligase and interacts with the PY motif of substrate proteins. A conserved PY motif has been identified in all Runx family members. To determine if Smurf1 induces Runx2 degradation through direct binding to Runx2, we created a mutant Runx2 with a PY motif deletion and found that Smurf1 retained its activity to induce Runx2 degradation even when the PY motif of Runx2 is deleted. These results suggest that Smurf1 mediates Runx2 degradation through an indirect mechanism. It has been reported that Smurf1 interacts with Smads 1, 5, 6 and 7 and Smads 1 and 5 also interact with Runx2. We then determined if Smads 1 and 5 mediate Smurf1-induced Runx2 degradation and found that Smads 1 and 5 had no effect on Smurf1-induced Runx2 degradation. Although Smads 6 and 7 bind Smurf1 and co-localize with Smurf1 in the nucleus, it is not known if Smads 6 and 7 interact with Runx2 and mediate Runx2 degradation. We performed immunoprecipitation (IP) assays and found that Smad6 but not Smad7 interacts with Runx2. Smad6 enhances Smurf1-induced Runx2 ubiquitination and degradation in a dose-dependent manner and the effect of Smad6 on Runx2 degradation is completely abolished by the proteasome inhibitor PS-1, indicating that Smad6-mediated Runx2 degradation is ubiquitin-proteasome-dependent. These results demonstrate that Smurf1-mediated Runx2 degradation is Smad6-dependent and this degradation can serve as a negative regulatory mechanism for BMP-Smad-Runx2 signaling pathway.

Involvement of MT1-MMP and ADAM10 in RANKL Shedding. A. Hikita[1], I. Yana*[2], M. Seiki*[2], K. Nakamura[1], S. Tanaka[1]. [1]Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan, [2]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Receptor activator of NF-κB ligand (RANKL) is a member of tumor necrosis factor family cytokines, which plays essential roles in osteoclast differentiation and activation. RANKL is a type II integral transmembrane glycoprotein and known to undergo proteolytic release from the plasma membrane. Several proteinases such as tumor necrosis factor α converting enzyme (TACE), membrane-type1 matrix metalloproteinase (MT1-MMP) and a disintegrin and metalloproteinase (ADAM) 19 have been shown to possess RANKL shedding activity, but no definite RANKL shaddases have been identified yet. To identify molecules implicated in RANKL shedding, we developed an assay system using plasmids encoding SEAP (secreted placental alkaline phosphatase) fused with partial cDNA of mouse RANKL containing stalk region. The RANKL-SEAP plasmid was transfected into 293T cells together with various MMP and ADAM expression vectors, and the RANKL-shedding activity of these proteinases was detected as alkaline phosphatase activity in the supernatants. Among these proteinases, MT1-MMP and ADAM10 had relatively strong RANKL shedding activity. Soluble RANKL was recovered by osteoprotegerin-Fc, and subjected to Western blotting analysis with anti-RANKL antibody. Soluble RANKL was detected as two bands, suggesting that the cleavage occurred at two different sites. Introduction of RNA interference (RNAi) of MT1-MMP and ADAM10 resulted in the disappearance of the lower molecular weight band, and the reduction in the higher molecular weight band, respectively. Suppression of RANKL shedding with RNAi in osteoblasts resulted in an increase in the level of membrane-bound RANKL, and promoted osteoclastogenesis in co-cultures with spleen cells. In addition, osteoblastic cells obtained from MT1-MMP-deficient mice induced osteoclast differentiation in cocultures more efficiently than normal osteoblasts. In conclusion, at least two RANKL shedding enzymes with different cleavage sites exist, and MT1-MMP and ADAM10 are possible candidates of RANKL sheddase in osteoblastic cells. Further analyzing the role of these protainases using knock-out mice will lead to clarification of the biological and pathological meaning of RANKL shedding in vivo.

Osteoblast Specific Overexpression of Human Interleukin-7 Rescues the Bone Phenotype of Interleukin-7 Deficient Female Mice. S. Lee[1], J. Kalinowski*[1], D. J. Adams[2], H. L. Aguila*[3], J. A. Lorenzo[1]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA, [3]Immunology, University of Connecticut Health Center, Farmington, CT, USA.

Interleukin-7 (IL-7) is a potent stimulator of B and T lymphocytes and a direct inhibitor of *in vitro* osteoclastogenesis in murine bone marrow cultures. We previously reported that IL-7 deficient (KO) mice had significantly decreased trabecular bone mass and increased *in vitro* osteoclast (OCL) formation compared to wild type (WT) mice. To determine if the alteration in bone mass and osteoclast formation in KO mice can be rescued, we crossed KO mice with mice that had targeted IL-7 production in osteoblasts (Tg). Tg mice contained a transgene, which used the rat 2.3 kb Col1A1 promoter to drive human IL-7 expression. We found an increase in early B cells ($B220^+/IgM^-$) in the bone marrow of Tg mice (WT = 21.3%, Tg = 48.9%), which is a known effect of IL-7. In contrast, KO mice had minimal bone marrow B-lymphopoiesis (KO=2.1%). However, KO mice that overexpress IL-7 in bone (KO/Tg) had normal early B cells development (KO/Tg=22.6%). To explore if the effect of IL-7 was limited only to bone, we examined the T cell populations in the thymus of these mice. Thymic cellularity was not affected by the IL-7 transgene but was decreased in KO mice (WT=19.0±0.82; Tg=14.5±1.50; KO=0.18±0.09; KO/Tg=0.17±0.18) confirming the specificity of IL-7 production in Tg mice. Micro-CT analyses of 8-9 week old male and female mice showed significant differences in trabecular bone mass only in KO females, which had a 24% decreased ($p<.05$) in this parameter (WT= 10.1±0.7%; KO=7.7±0.8%). KO/Tg mice had trabecular bone mass equivalent to that of WT (KO/Tg=9.6±0.6%). To investigate if locally produced IL-7 had effects on OCL formation *in vitro*, we cultured bone marrow cells from WT, KO and KO/Tg with M-CSF and RANKL for 4 days. Bone marrow cultures from KO mice showed increased osteoclast formation in cells from both males and females (45% to 51% increase, $p<.01$) compared to WT littermate cells. However, bone marrow cells from KO/Tg mice showed OCL formation both in males and females that was similar to that seen in WT cells (WT=293±9; KO=428±119; KO/Tg=288±13 in males, WT=201±8; KO=304±9; KO/Tg=194±11 in females). These findings demonstrate that targeted expression of IL-7 in osteoblasts rescues the bone phenotype of IL-7 KO mice. In addition, in KO mice bone mass differed from that of WT only in females. These results likely reflect both a direct inhibitory effects of IL-7 on osteoclastogenesis *in vivo* and gender-specific differences in responses to IL-7.

Disclosures: ***S. Lee****, None.*

Cardiotrophin-1 Regulates Osteoclast Formation and Function in an Essential Manner Distinct from other gp130 Cytokines. N. A. Sims[1], J. M. W. Quinn[2], H. Saleh*[2], T. Martin[2]. [1]Department of Medicine at St. Vincent's Hospital, The University of Melbourne, Fitzroy, Australia, [2]St. Vincent's Institute, Fitzroy, Australia.

The gp130 family of cytokines, (IL-6, IL-11, CNTF, Oncostatin M, LIF and Cardiotrophin-1 (CT-1)) all signal by forming a receptor complex including the common gp130 receptor subunit. Previous work has shown that gp130 is required for normal osteoclastogenesis; in gp130 null mice there is a dramatic reduction in trabecular bone mass due to increased osteoclast generation in vivo and in vitro, which contrasts with the stimulatory effects of gp130 family members on cultured osteoclasts. Mice rendered null for IL-11R, IL-6 and LIF-R all have unique bone phenotypes, which suggest distinct signaling pathways induced by the cytokine-specific receptor complexes formed. In this study, we examined the skeletons of CT-1 null mice to determine its unique contribution to normal bone structure and bone cell function. In adult males, CT-1 null mice demonstrated a significant increase in trabecular bone volume measured by histomorphometry (increased by 229%) and trabecular BMD by pQCT (increased by 31%) compared with wild type controls. Histomorphometric markers of bone formation were unchanged by the CT-1 null mutation. The increase in bone mass was associated with an increased number of osteoclasts, and these were abnormally large. Osteoclast surface and number were approximately doubled and the amount of bone surface covered by each osteoclast was significantly elevated. However, these large osteoclasts appeared to be functionally impaired, suggested both by the increased bone mass, and by an increase in cartilage remnants within the trabecular bone of the CT-1 null mice. The increased osteoclastogenesis observed in CT-1 null mice appeared to be cell-lineage specific. Stimulation of CT-1 null bone marrow cultures with RANKL and M-CSF led to a significant elevation in osteoclast number in comparison with wild type marrow. As observed in vivo, the osteoclasts generated were larger, and with more nuclei than osteoclasts generated from wild type mice. This phenotype is distinct from knockouts of all other gp130 family members described to date. CT-1 is therefore essential for normal osteoclastogenesis and osteoclast function, and is unique in its actions on gp130 signaling. The high bone mass observed with CT-1 gene ablation in the presence of increased osteoclastogenesis suggests that inhibition of CT-1 signaling may provide a unique therapeutic target for inhibiting bone resorption.

Over-Expression of Dkk-1 in Osteoblasts Reduces Bone Mass but Does not Alter the Anabolic Response to Intermittent PTH Treatment in Mice. G. Q. Yao, J. J. Wu*, N. Troiano*, M. Bartkiewicz, B. H. Sun, K. Insogna. Yale University, New Haven, CT, USA.

Gain-of-function mutations in LRP5 increase bone mass in part by conferring resistance to the inhibitory actions of Dkk-1. Increased expression of Dkk-1 by malignant plasma cells has been reported as the basis for reduced bone formation in multiple myeloma. These findings suggest that Dkk-1 suppresses bone formation *in vivo*. PTH is a potent anabolic agent, but the cellular mechanism by which it increases bone mass is unknown. We sought to determine if Dkk-1 and PTH interact in regulating bone mass. PTH treatment of primary murine osteoblasts for 24 hours reduced Dkk-1 expression by 90% as quantified by real-time PCR. To directly determine whether Dkk-1 modulates PTH's anabolic response *in vivo*, we engineered transgenic (TG) mice expressing murine Dkk-1 under the control of the 2.3-kb rat collagen alpha-1 promoter. We studied one of two transgenic lines in which Dkk-1 expression was increased 4- to 5-fold over endogenous levels. Using DEXA, we found that TG mice had significantly reduced bone mass (-7.3%), which was accompanied by reduced histomorphometric parameters of bone formation (reduced OV/TV, ObS/OS

and NOb/TAR). Trabecular thickness and number were significantly reduced and TbSp was increased as compared to control animals. Treatment of TG and wild-type (WT) littermates with 95 ng/g body-weight of h(1-34) PTH for 34 days resulted in comparable increases in bone mass at all skeletal sites. In the spine, bone mass increased by 9% in the PTH-treated WT mice and by 2% vehicle-treated WT mice. In TG mice the increases were 17%, and 4% respectively. PTH induced increases in bone density in the femur and the body as a whole were also comparable in TG and WT animals. We conclude that: (1) Continuous exposure to PTH *in vitro* suppresses Dkk-1 expression in primary murine osteoblasts. Whether this occurs with intermittent PTH treatment *in vivo* is under investigation. Since PTH has been reported to suppress the rat collagen 1 promoter *in vitro* it is possible that it also suppressed the transgene in our mice. (2) Over-expression of Dkk-1 in osteoblasts *in vivo* suppresses bone formation and reduces bone mass, consistent with the conclusion that Dkk-1 is an important negative regulator of bone mass. (3) The anabolic response to PTH is unaltered in TG mice that over-express Dkk-1 in osteoblasts. Whether this reflects the site of expression of Dkk-1 or the ability of intermittent PTH to circumvent or overcome the negative regulatory effects of Dkk-1 on bone anabolism is an important area for further study.

Abnormal Axial Skeleton in TGF-Beta Type I Receptor-Deficient Mice. K. Torigoe*[1], M. Ishijima[1], T. Nakamura*[1], N. Haruyama*[2], A. B. Kulkarni*[2], S. Karlsson*[3], Y. Yamada*[1]. [1]NIDCR, CDBRB, Molecular Biology Section, NIH, Bethesda, MD, USA, [2]NIDCR, CDBRB, Functional Genomics Section, NIH, Bethesda, MD, USA, [3]Molecular Medicine and Gene Therapy, Lund University, Lund, Sweden.

Transforming growth factor beta (TGF-β) initiates its diverse cellular responses during development and pathogenesis by binding to a specific cell surface complex consisting of TGF-β type I (TβrI/Alk5) and type II (TβrII) receptors, and activating downstream signaling through Smad and MAPK proteins. TGF-β has been implicated in the growth and differentiation of chondrocytes. For example, TGF-β transduces its signal through a MEK-ERK-Elk1 pathway to regulate chondrocyte proliferation. TGF-β induces aggrecan expression in chondrogenic cell lines. While TGF-β enhances chondrocyte proliferation, it inhibits the terminal differentiation of chondrocytes and helps them remain in the prehypertrophic stages. In response to TGF-β, ATF2 is phosphorylated via the activation of p38 MAP kinase. The phosphorylated ATF2 cooperates with Smad3 to inhibit the rate of chondrocyte maturation. To study the role of TGF-β signaling in cartilage development and disease, we have created cartilage-specific conditional knockout mice for TGF-β receptor type I by mating floxed-*TβrI* mice with *Col2a1cre* transgenic mice which express cre recombinase specific to cartilage under the control of the type II collagen promoter and enhancer. The conditional knockout mice with the cartilage-specific *TβrI* deficiency were perinatally lethal. We found that in the mutant mice, development of the axial cartilage in the spine and skull was impaired, while appendicular cartilage was relatively normal. The upper portion of the vertebrae was more severely disorganized and herniated than the lower portion. The formation of intervertebral disks was defective, and segmentation of the upper vertebrae was disrupted. Although chondrocytes were differentiated, histological staining indicated significantly reduced extracellular matrix and GAG (glycosaminoglycan) levels in mutant vertebral cartilage than wild-type cartilage. Perichondrium cells migrated into cartilage at the herniation site, suggesting a reduced strength of mutant cartilage. Mechanical force may cause the position-dependent and disproportionate abnormality of the vertebrae. Currently, the molecular mechanisms that cause axial skeleton defects are under investigation.

Temporal Deletion of the Hepatic IGF-I Gene at 4 weeks of Age Has a Dramatic Effect on Acquisition of Cortical and Trabecular Bone. S. Yakar[1], D. LeRoith[1], C. Rosen[2], M. Bouxsein[2]. [1]NIDDK, Bethesda, MD, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

Earlier studies established that circulating IGF-I was related to BMD. Using the *Cre-Lox P* technology, we generated liver-specific IGF-I gene deleted mice (LID) with a 75% reduction in circulating IGF-I, but no change in skeletal IGF-I expression. At 12 wks of age, LIDs had reduced: femur length, periosteal circumference, femoral cross sectional area and cortical thickness vs controls. Since peak cortical BMD is attained between 4-8 wks, we sought to determine how low circulating IGF-I during maximal bone accrual could affect trabecular and cortical compartments. We generated a tamoxifen (Tx) inducible LID mouse (i-LID/Cre) which carries two floxed alleles of the IGF-I gene and the Cre recombinase under the antitrypsin 1α promoter; this promoter can be induced by Tx injection. Control mice (i-LID) carry the floxed alleles of the IGF-I gene but do not express the Cre recombinase; hence injection of Tx should not lower serum IGF-I. Blood was drawn before Tx injections, at 4 wks and at 8 wks; bones and livers were harvested. Hepatic IGF-I mRNA was assessed by RNAse protection assay to confirm IGF-I gene recombination in iLID/Cre injected with Tx. Serum IGF-I are noted:

Strain n	Tamoxifen	4 wk serum IGF-I	8 wk serum IGF-I p vs 4wk
i-LID 4	-	394+14 ng/ml	304+28.4 ng/ml p=0.10
i-LID +Tx 6	+	351+10 ng/ml	219+10 ng/ml p=0.05
i-LID/Cre+Tx 4	+	380+15 ng/ml	46.0+2.4 ng/ml p<0.0001

No differences in bone length were observed. Total mid-femoral cross-sectional area was greater in i-LID>i-LID+Tx >i-LID/Cre+Tx (p=0.007 and p=0.05 respectively).Cortical thickness was also lower in i-LID/Cre+Tx than the other two groups (p<0.02). Tx alone slightly reduced IGF-I and total cortical area. Surprisingly, femoral BV/TV was ordered exactly the opposite of the cortical parameters: i-LID/Cre+Tx>i-LID> iLID+Tx; p< 0.005; as such, there was a 40 % increase in trabecular BV/TV in i-LID/Cre+Tx mice vs controls (i-LID) treated with Tx. In sum, 1) temporal deletion of the liver IGF-I gene causes a marked decline in circulating IGF-I; 2) 4 wks after reducing serum but not skeletal IGF-I, there is a significant reduction in cortical bone area and thickness; and 3) trabecular bone volume fraction increases in response to very low serum IGF-I, a phenotype similar to IGF-I null mice. In conclusion, this unique system in which serum, but not skeletal IGF-I can be manipulated in mice, establishes the importance of circulating IGF-I during peak bone acquisition. The mechanism driving increased trabecular BMD in IGF-I deficient mice needs further study.

Direct (IGF-1 Independent) Actions of Growth Hormone in Osteoblasts Identified through Cre/Lox Disruption of the IGF-1 Receptor. D. J. DiGirolamo*[1], A. Mukherjee*[1], Y. Wang*[1], X. Liu*[1], S. J. Frank*[2], T. L. Clemens[1]. [1]Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, USA.

Growth hormone (GH) is one of the most important factors controlling bone growth and mass, yet the cellular targets and mechanisms of action of GH in bone remain unclear. The principal difficulty in studying GH action is the fact that GH stimulates insulin-like growth factor-1 (IGF-1) production, making it impossible to distinguish actions due to GH versus those resulting indirectly through IGF-1. To define *direct* actions of GH in bone, we utilized mice which lack the IGF-1 receptor (ΔIGF-1R) in osteoblasts, developed using Cre/Lox recombination. Growth hormone treatment of bone marrow stromal cells from wild type mice promoted the formation of CFU-OB and inhibited adipogenic markers, whereas stromal cells from ΔIGF-1R mice failed to differentiate normally. To examine signaling and function of GH in mature osteoblasts, calvarial osteoblasts from mice homozygous for the floxed IGF-1 allele (IGF-$1^{flox/flox}$) were infected with adenoviral vectors expressing Cre (Adeno-Cre). Knockdown of the IGF-1R mRNA (>90%) was accompanied by a near elimination of IGF-1 stimulated IRS-1 phosphorylation but retention of GH mediated JAK-2/STAT-5 phosphorylation. Growth hormone induced JAK-2/STAT-5 activation was consistently greater in osteoblasts with an intact IGF-1R, suggesting that although the receptor is not required for GH signaling, its presence may allow GH to activate its signaling pathways more effectively. To identify GH actions, we compared the effects of GH and IGF-1 on proliferation (MTT) and staurosporine induced apoptosis (TUNEL and Bax expression). In these studies, the ability of GH to increase osteoblast proliferation was abolished by removal of the IGF-1R, suggesting that GH increases osteoblast proliferation primarily by inducing IGF-1 production. In contrast, GH inhibited apoptosis even in cells lacking the IGF-1R, demonstrating that the anti-apoptotic actions of GH do not require IGF-1 signaling. However, the anti-apoptotic effect of GH was more pronounced in cells expressing the IGF-1R consistent with the idea that GHR and IGF-1R act in a synergistic fashion. In conclusion, these studies identify, for the first time, *direct* actions of GH on osteoblasts and validate a model system for further study of the GH/IGF-1 axis in bone.

Cooperative Signaling by Fibroblast Growth Factor Receptor 1 and 2 Is Required for Craniofacial Development. H. Kanazawa[1], K. Yu*[1], I. H. Hung*[1], A. Jacob*[1], J. M. Partanen*[2], D. M. Ornitz*[1]. [1]Molecular Biology and Pharmacology, Washington University Medical School in St. Louis, St. Louis, MO, USA, [2]Institute of Biotechnology, University of Helsinki, Helsinki, Finland.

Many craniosynostosis syndromes are caused by mutations in Fibroblast Growth Factor Receptors (FGFR) 1 and 2. In addition to craniofacial abnormalities, these patients often have short stature and malformations of the hands and feet. Although FGFR1 and FGFR2 each have important roles in skeletal development and are expressed in partially overlapping patterns, redundancy between these receptors is poorly defined. To address the combined affect of loss of function of both genes on craniofacial development, we have generated *Fgfr1/Fgfr2* double conditional knockout mice (DCKO) with *Dermo*1-cre and *Wnt*1-cre targeting alleles. *Dermo-1* cre DCKO mice have a much more severe phenotype than either single receptor conditional knockout. Significantly in *Dermo-1* cre DCKO mice, the frontal bones were much smaller and the sagittal suture was greatly expanded. These mice also had a hypoplastic squamous bone, missing tympanic rings, shortened or truncated zygomatic arch, and a shortened and malformed mandible. In contrast, temporal bones of DCKO mice were relatively normal. By whole mount in situ hybridization the expression level of *Osteopontin* in E16.5 and E.17.5 calvaria was elevated in *Dermo-1* cre DCKO in the frontal bone area compared to controls. These data suggested a specific role of FGFR1 and 2 signaling on cranial neural crest cells that contribute to cranial bones. Then thus generated *Wnt1*-cre DCKO mice to analyze the impact of FGFR 1 and 2 signaling on cranial neural crest cells. *Wnt*1-cre DCKO mice revealed a very dramatic phenotype: the frontal bone was very small, and the facial region was severely truncated. In conclusion, FGFR 1 and 2 signaling shows significant redundancy and preferentially affects cranial neural crest-derived cells.

RANKL/RANK Expression Is Essential for TNF-Induced Joint Erosion and Inflammation *In Vivo*, but not for TNF-Induced Osteoclast Formation *In Vitro* where NF-kB Expression Is Essential. L. Xing, Z. Yao, Q. Zhang, P. Li, E. Schwarz, B. Boyce. University of Rochester, Rochester, NY, USA.

Two major controversies regarding the RANKL/RANK pathway in TNF-mediated erosive bone loss are: 1) must osteoclast (ocl) precursors be primed by RANKL before TNF can induce them to form ocls; and 2) does this pathway regulate not only osteoclastogenesis, but also inflammation in TNF-induced arthritis? To address the first issue, we treated spleen cells from either RANKL-/- or RANK-/- mice with TNF and M-CSF and found that both formed numerous TRAP+ ocls (65±1 and 69±14/well, vs 90±12 from wt cells). These ocls expressed calcitonin receptors and resorbed bone slices (pits area: 0.52±0.02 and 0.6±0.1 mm^2 in TNF- vs 0±0 in PBS-treated cells)**.** In contrast, TNF did not induce ocls from splenocytes from NF-κB p50/p52-/- mice, but when NFAT 1 or 2 was over-expressed in these cells by retroviral infection, ocls formed in response to TNF (61±5 and 71±17 ocls/well, for NFAT1 and 2, vs 0±0 for GFP-infected cells). To address the second issue, we crossed RANKL-/- and RANK-/- mice with TNF transgenic mice to generate RANKL-/-/TNF and RANK-/-/TNF hybrid mice. As expected, the RANKL-/-/TNF (n=6) or RANK-/-/TNF (n=3) mice had no ocls or joint erosion identified histologically, but surprisingly did not have joint inflammation (synovial membrane area: 0.03±0.02 mm^2 in RANKL-/-/TNF vs 0.97±0.24 in TNF-Tg mice, vs 0±0 mm^2 in wt mice) after 4.5 month of age. In contrast, RANKL+/-/TNF or RANK+/-/TNF littermates all had joint inflammation and bone erosion. Serum TNF levels (by ELISA) were significantly decreased in RANKL/TNF hybrids compared to TNF-Tg mice (74±25.7 pg/ml vs 173±32, P<0.05). Consistent with this finding, RANK:Fc treatment of TNF-Tg mice (n=8) significantly reduced not only bone erosion, but also the joint inflammation area measured histologically: (0.15±0.13 mm^2 in RANK:Fc- vs 1.2±0.5 in PBS-treated mice) and blood TNF concentrations (47±2.5 pg/ml vs 85±5.3, P<0.05). In contrast, in the acute arthritis model induced by serum transfer, joint inflammation of similar severity developed in RANK-/- mice as in wt littermates, despite the lack of ocls and bone erosion (n=3/genotype). We conclude that 1) TNF induces ocl formation from both RANKL and RANK knockout splenocytes in vitro through an NF-κB/NFAT-dependent mechanism and 2) RANKL-/-/TNF/or RANK-/-/TNF hybrid mice do not have joint erosion or inflammation because the RANKL/RANK pathway is critical for TNF-induced joint inflammation, perhaps through regulation of TNF production by RANK expressing cells in vivo. Thus, inhibitors of RANKL may have efficacy in reducing inflammation in joints of patients with TNF-induced arthritis as well as inhibiting bone resorption.

Glucocorticoid Excess Disrupts the Canalicular Circulation: Potential Mechanism of the Disparity between Bone Density and Strength in Glucocorticoid-Induced Osteoporosis and Osteonecrosis. R. S. Weinstein, J. J. Goellner*, D. Jia, R. S. Shelton*, A. M. Parfitt, S. C. Manolagas. Div. of Endo/Metab, Center for Osteoporosis, Central Arkansas Veterans Healthcare System, Univ of Arkansas for Med Sci, Little Rock, AR, USA.

Patients treated with glucocorticoids suffer vertebral fractures in the presence of higher lumbar bone mineral density (BMD) than is found in patients with fractures due to postmenopausal osteoporosis, indicating that the adverse effects of glucocorticoids on bone may be due, in part, to abnormalities separate from the decline in bone mass. In addition to BMD, contributions to bone strength are also made by several other characteristics including bone size, architecture, osteocyte viability and the quality of the mineral, matrix and fluid phases. To investigate these other contributions, we examined *in vivo* spinal BMD by DEXA and *ex vivo* vertebral compression strength in adult mice receiving prednisolone pellets for 28 days compared to control mice implanted with placebo pellets. We found that the slope of the relationship between vertebral strength and spinal BMD in the control animals was significantly different from that in the prednisolone group, indicating a glucocorticoid-induced deterioration in bone quality similar to that found in patients with glucocorticoid-induced osteoporosis. Consistent with this resemblance, the prednisolone-treated mice developed a decreased rate of bone formation and an increased prevalence of osteoblast and osteocyte apoptosis, findings characteristic of glucocorticoid-induced osteoporosis. To determine the effects of the glucocorticoid excess on the fluid phase of bone, 0.3 mL of 1.6% procion red (a metabolically inert aqueous tracer, MW 300-400) was injected into a tail vein 2 hours before necropsy. In 5 um thin, longitudinal sections of undecalcified bone viewed under epifluorescent light, procion red was abundantly detected in the osteocytic lacunae and canaliculi of the mice receiving placebo pellets but was severely diminished in the animals receiving prednisolone. Interruption of the lacunocanalicular system would prevent delivery of nutrients and osteotrophic signals that are important to osteocyte survival. Therefore, disruption of the canalicular circulation could be a pathogenetic factor in glucocorticoid-induced osteocyte apoptosis. Furthermore, changes in the quality of the bone matrix and mineral that follow the decrease in canalicular circulation and increase in osteocyte apoptosis may be responsible for the disparity between bone density and strength in glucocorticoid-induced osteoporosis and osteonecrosis.

Androgen Receptor Transgenic Mice Have Decreased Body Fat, Reduced Adipogensis and an Increased Osteoblast Differentiation Program. K. M. Wiren[1], A. S. Toombs*[1], A. M. Matsumoto[2], X. Zhang[1]. [1]VA Medical Center and Oregon Health & Science University, Portland, OR, USA, [2]VA Puget Sound Health Care System and University of Washington, Seattle, WA, USA.

The direct effects of androgen signaling on bone are demonstrated in transgenic mice with enhanced androgen sensitivity, using androgen receptor (AR) under the control of the 3.6-kb α1(I)-collagen promoter (AR-tg). Male AR-tg mice show a complex anabolic bone phenotype with no change in circulating steroid levels. Since androgens are known to influence body composition, we hypothesized that targeted overexpression of AR in bone marrow stromal cells (MSCs) could alter lineage commitment to bone, fat and muscle. Body composition was analyzed by DXA, fat depot weights and adipogenesis in response to 5α-dihydrotestosterone (DHT) in MSC cultures. Gene expression was evaluated with qRT-PCR analysis. Male AR-tg 6 month old mice showed significantly increased BMC/body weight ($P < 0.01$), percentage lean mass ($P < 0.001$) but reduced percentage fat mass ($P < 0.001$) by DXA. Fat pad dissection from male AR-tg versus littermate controls showed significantly reduced white adipose tissue in visceral ($P < 0.05$) and gonadal ($P < 0.01$) fat, with no effect in brown fat. AR-tg expression was targeted to bone, with the highest expression in calvaria but ~100-1000 fold lower in mature fat, muscle, skin, kidney, liver, and spleen. Fresh marrow isolates showed AR-tg expression; only males showed reduced PPARgamma expression. Since androgen is hypothesized to influence body composition through modulation of MSC lineage allocation, we investigated adipogenic differentiation in MSC cultures. MSC were grown to confluence, then switched to adipogenic media. AR-tg MSC DHT-treated cultures showed dramatic inhibition of adipogenesis assessed by Oil Red O staining, with greater inhibition of PPARgamma expression versus controls. M2-10B4 stromal cell cultures also showed reduced Oil Red O after DHT treatment. Conversely, osteoblast differentation was enhanced assessed by alkaline phosphtase activity. Thus, male AR-tg mice have decreased adiposity, increased lean mass and increased osteoblast differentiation due to enhanced androgen signaling without systemic androgen treatment. These results are consistent with late-onset obesity observed in global AR null animals and provide *in vivo* confirmation of the hypothesis that AR in MSCs directs lineage allocation. Further analysis will be important to define the distinct contributions of androgens to the maintenance of healthy body composition, and may identify regulatory pathways responsible for the deleterious consequences of hypogonadism and aging on central fat accumulation, muscle weakness and declining bone mass.

Estradiol Recovers Hepatic IGF-I Gene Expression in Growth Hormone Resistant Mice through Activation of the JAK-STAT Pathway. K. Venken*[1], F. Schuit*[1], L. Van Lommel*[1], K. Tsukamoto*[1], J. J. Kopchick*[2], K. Coschigano*[2], C. Ohlsson[3], S. Movérare*[3], S. Boonen[1], R. Bouillon[1], D. Vanderschueren[1]. [1]K.U.Leuven, Leuven, Belgium, [2]Ohio University, Athens, OH, USA, [3]Gothenburg University, Gothenburg, Sweden.

We previously observed that estradiol (E_2) therapy (0.03 µg/day via subcutaneous implants) in orchidectomized (orx) male mice with disrupted growth hormone receptor (GHRKO) (6-10 weeks) increased hepatic and serum insulin-like growth factor-I (IGF-I). The E_2-induced increase in serum IGF-I was associated with a rescue of longitudinal and radial skeletal growth. The aim of this study was to investigate the molecular basis of the E_2-induced increase in hepatic IGF-I expression in GHRKO mice. Genome-wide mRNA expression profiles in the liver of orx GHRKO and orx wild-types (WT), treated with or without E_2, were studied using Affymetrix 430 2.0 arrays (45037 probesets). Our filtering strategy was based upon transcripts that were altered in orx GHRKO versus orx WT, *and* that showed an inverse change after E_2 treatment in orx GHRKO. IGF-I (represented by 4 probesets) and IGF binding protein, acid labile subunit (IGFBP, ALS) (1 probeset) mRNA expression was almost completely abolished in orx GHRKO (signal log ratio (SLR) -5.4 and -5.2 vs orx WT, resp., $P<0.000001$), but was partly restored after E_2 therapy (SLR +4.4 and +3.8 vs orx GHRKO, resp., $P<0.0005$). Interestingly, in the absence of the GHR, estrogen receptor alpha (2 probesets) and prolactin receptor (PrlR) (5 probesets) mRNA expression was significantly downregulated in orx GHRKO (SLR -1.6 and -3.9 vs orx WT, resp., $P<0.0001$), indicating that GHR signaling is critical for the integrity of other major receptor signaling systems in the liver. Moreover, E_2 induced a full compensation for this multi-receptor deficit in GHRKO (SLR +2.1 and +4.0 vs orx GHRKO, resp., $P<0.00005$). As the full recovery of PrlR expression suggested a compensation of a putative mechanism involving the JAK-STAT pathway, STAT5 activation (through phosphorylation) was measured. Phosphorylated STAT5, assessed by Western blotting, was significantly increased in E_2-treated GHRKO (+240% vs orx GHRKO), indicating that STAT5 activation contributed to the enhanced IGF-I gene expression. To date, GH is the only hormone known to induce hepatic IGF-I expression through activation of the JAK-STAT pathway. Here we demonstrate that, in the absence of a functional GHR, the JAK-STAT pathway is activated by estrogen, indicating a novel mechanism of stimulation of hepatic IGF-I production. Therefore, estrogen or estrogen-like compounds (e.g. SERMs) merit investigation as potential IGF-I secretagogues to restore serum IGF-I levels in GH/IGF-I deficient and/or GH resistant conditions.

Retinoblastoma-Binding Protein 1, a Novel Estrogen Receptor-Regulated Gene, Plays a Role in the Suppression of Osteoblastic Proliferation. D. G. Monroe[1], F. J. Secreto[1], M. Subramaniam[1], J. R. Hawse[1], B. J. Getz*[1], S. Khosla[2], T. C. Spelsberg[1]. [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Estrogen (E2) is involved in mediating many important functions relevant to osteoblast cells (OBs). We and others have demonstrated that E2 inhibits cell proliferation by acting specifically through ERα and not ERβ, in U2OS human osteosarcoma and hFOB cell lines. Using a combination of microarray and RT-PCR analysis of 2 hr E2-treated U2OS-ERα or-ERβ cell lines, we identified retinoblastoma binding protein 1 (RBBP1) as a major E2-regulated gene. RBBP1 is a transcriptional repressor that functions by interacting with the retinoblastoma (Rb)/HDAC complex, important tumor suppressors involved in repressing E2F-dependent gene transcription, thus inhibiting cell proliferation. RBBP1 mRNA levels increase after 2hr of E2 treatment in both ERα- and ERβ-expressing lines, however sustained increases in RBBP1 are only observed with ERα . We further demonstrate that E2-dependent regulation occurs in mouse primary calvarial OBs and in ERα-expressing Hs578T breast cancer cells, suggesting that E2 regulation of RBBP1 may be of more general importance in divergent tissues and animal species. Examination of the RBBP1 genomic sequence revealed an estrogen response element (ERE) within the first intron of RBBP1, which was confirmed to bind ERs using gel shift and chromatin immunoprecipitation assays. EREs were also discovered in the mouse and chicken genomic RBBP1 sequences, which also bind ERs, demonstrating an evolutionary conservation of RBBP1 regulation by E2. Furthermore, 35S-Met labeling/IP experiments in the ERα and ERβ lines suggests that the Rb/HDAC corepressor complex exists at higher concentrations in the E2-treated ERα line compared to the ERβ line. This suggests a model whereby a sustained increase in expression of RBBP1 through E2-bound ERα, stimulates the nucleation of the Rb/HDAC complex, thereby inhibiting cell proliferation. Flow cytometry analysis was performed to determine the extent of the G1 cell population in ERα and ERβ lines. E2 treatment resulted in a significant increase (22%) of ERα cells in the G1 phase of the cell cycle, whereas no change was observed in ERβ cells. We are currently examining siRNA knockdown of RBBP1 to determine whether RBBP1 is directly involved in suppression of E2- and ERα-dependent OB proliferation. These data support our hypothesis that RBBP1 is involved in ERα-specific decreases in cellular proliferation by stalling the cells in G1 of the cell cycle.

SWI/SNF Chromatin Remodeling Complexes Cooperate with the Vitamin D Receptor and C/EBP Beta in the Regulation of 25-Hydroxyvitamin D_3 24-Hydroxylase Transcription. Q. Shen*, P. Dhawan*, S. Christakos. Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

The mammalian SWI/SNF related complexes facilitate gene transcription by remodeling chromatin using the energy of ATP hydrolysis. SWI/SNF is implicated in regulating differentiation as well as in transcriptional activation stimulated by estrogen, glucocorticoid and retinoic acid receptors. Each SWI/SNF complex contains one of two homologous ATPases, Brahma (Brm) and Brahma/related gene 1 (Brg-1). Little is known about their specialized functions and what role they may have in vitamin D receptor (VDR) mediated transcription. We demonstrate that SWI/SNF complexes contribute to transcriptional activation by VDR and cooperate with VDR and C/EBP beta in the regulation of 25-hydroxyvitamin D_3 24-hydroxylase (24(OH)ase) transcription. In MC3T3-E1 osteoblastic cells that contain endogenous VDR, we found that the N-terminal region of Brg-1 (Brg-1-N) and mutant Brm, that can act as dominant negative inhibitors, significantly inhibited $1,25(OH)_2D_3$ induction of 24(OH)ase transcription (3- 6 fold). The effect was not specific for 24(OH)ase transcription since a similar inhibition of $1,25(OH)_2D_3$ induced transcription was observed in MC3T3-E1 cells using the mouse osteopontin (OPN) promoter (-777/+79) or a construct containing multiple copies of the OPN vitamin D response element (VDRE) upstream of the minimal thymidine kinase (tk) promoter. Mutant Brm or Brg-1-N had no effect on the activity of the tk promoter. Using the Brm and Brg-1 deficient cell lines SW-13 and C33-A and the 24(OH)ase promoter, Brm was found to facilitate VDR mediated activation of 24(OH)ase transcription (4- 7 fold) without being essential. In VDR transfected COS-7 cells, mutant Brm inhibited C/EBP beta enhancement of VDR mediated 24(OH)ase transcription, suggesting cooperativity between VDR, the SWI/SNF complex and C/EBP beta in regulating 24(OH)ase transcription. C/EBP beta enhancement of VDR mediated transcription was not observed using the OPN promoter, the VDRE tk promoter construct or the 24(OH)ase promoter with the C/EBP site mutated. GST pull down assays indicate that Brm associates with C/EBP beta and immunoprecipitation assays indicate that Brg-1 is capable of associating with VDR. Chromatin immunoprecipitation (ChIP) using MC3T3-E1 cells showed the association of SWI/SNF as well as C/EBP beta with the 24(OH)ase promoter. Together these studies reveal a role for SWI/SNF in VDR mediated transciption and suggest that the interaction between C/EBP beta and SWI/SNF may also be an important determinant in the C/EBP beta mediated enhancement of 24(OH)ase transcription.

siRNA against 25-OHD_3 1α-Hydroxylase Inhibits Local Production of $1,25-(OH)_2D_3$ and Prevents 25-OHD_3 Induced Growth Inhibition of Cancer Cells *In Vitro* and *In Vivo*. D. C. Huang[1], X. F. Yang*[1], J. S. Rhim*[2], R. L. Horst[3], R. Kremer[1]. [1]Department of Medicine, Royal Victoria Hospital and Mcgill University, Montreal, PQ, Canada, [2]Center for Prostate Disease Research, Uniformed Services, University of the Health Sciences, Bethesda, MD, USA, [3]USDA, Agriculture Research Service, National Animal Disease Center, Ames, IA, USA.

Extra-renal expression of the 1 α-hydroxylase enzyme which catalyzes the conversion of 25-hydroxyvitamin D_3 to 1α, 25-dihydroxyvitamin D_3 may play an important autocrine/paracrine antiproliferative function. In the present study, we used a small interfering double-stranded RNA (siRNA) to knockdown 1α-hydroxylase in two cancer cell lines previously shown to express this enzyme. A hairpin oligonucleotide sequence corresponding to the N-terminal region of the 1α-hydroxylase gene was cloned into the siRNA vector. Transfection of this plasmid into the human amelanotic melanoma cell line A375 and the human prostate cancer cell lines FNC267B1-*ras* led to a dramatic decrease in the conversion of 25-OHD_3 to $1,25-(OH)_2D_3$. We then examined the effect of substrate 25-OHD_3 on parameters of growth and differentiation in both 1α-hydroxylase knockdown cell lines and compared them to the same parameters in the corresponding wild type control cell lines transfected with vector alone. Addition of 25-OHD_3 (10^{-6} M) to wild type cells inhibited growth by 28±5% in A375 cells ($p<0.001$) and by 36±6% in the human transformed prostate cell line FNC267B1 ($p<0.001$). In contrast, no significant growth inhibition was observed in both knockdown A375 and FNC267B1 cell lines in the presence of 25-OHD_3 (10^{-6} M). This growth inhibitory effect was further analyzed *in vivo* following subcutaneous injection of 1α-hydroxylase knockdown or wild type cells in severely compromised immunodeficient (SCID) mice. Alzet osmotic mini-pump containing 25-OHD_3 were implanted two days before tumor cell transplantation to deliver a constant infusion of 25-OHD_3 (2000 pM/24h) or vehicle. Circulating 25-OHD_3 concentrations were at least 10 fold higher in 25-OHD_3 treated animals as compared to vehicle treated animals without significant changes in circulating calcium levels. A significant inhibition of tumor growth was observed in mice transplanted with wild type A375 or FNC267B1 control cells treated with 25-OHD_3 as compared to vehicle ($p<0.001$). In contrast no tumor reduction was observed in mice transplanted with siRNA knockdown cells. In summary our data demonstrate that local conversion of 25-OHD_3 to $1,25-(OH)_2D_3$ inhibits tumor growth in both melanoma and prostate cancer cells. These data therefore suggest potential therapeutic cancer applications for the non-calcemic vitamin D precursor 25-OHD_3.

PTH and 1,25-Dihydroxyvitamin D_3 Each Independently Exert Skeletal Anabolic Effects and Improve Mineral Ion Homeostasis in Mice which Are Homozygous for both the 1α-Hydroxylase and PTH Null Alleles. Y. Xue, A. C. Karaplis, G. N. Hendy, D. Goltzman, D. Miao. Medicine, McGill University, Montreal, PQ, Canada.

Parathyroid hormone (PTH) and 1,25-Dihydroxyvitamin D_3 ($1,25-(OH)_2D_3$) directly affect calcium and skeletal homeostasis, and each exerts important regulatory effects on the other. To identify whether PTH and $1,25-(OH)_2D_3$ can exert skeletal effects and regulate mineral ion homeostasis in an independent manner in vivo, double knockout (double KO) mice, which are homozygous for both the 1α-hydroxylase and PTH null alleles, were treated with vehicle or PTH 1-34 peptide (0.2 µg) or $1,25-(OH)_2D_3$ (0.02 µg) per mouse per day subcutaneously starting from day 4 until 14 days of age. At day 14, we compared the PTH or $1,25-(OH)_2D_3$ treated double KO mice to the vehicle-treated double KO mice and the vehicle-treated wild-type mice. Serum calcium rose from 1.23 ±0.03 mmol/L (43% of wild type) in untreated double KO mice to 2.08 ±0.04 mmol/L (73% of wild-type) and 1.97±0.05 mmol/L (69% of wild-type) in PTH- and $1,25-(OH)_2D_3$-treated double KO mice, respectively. Messenger RNA and protein levels of the renal calcium transporters, TRPV5, calbindin-D_{28K}, calbindin-D_{9K} and NCX1 were down-regulated in the kidney of vehicle-treated double KO mice relative to wild-type, but were up-regulated by either PTH or $1,25-(OH)_2D_3$ administration. Epiphyseal volume, chondrocyte proliferation and differentiation, and cartilaginous matrix mineralization were all increased after 10 days of exogenous PTH or $1,25-(OH)_2D_3$ administration to the double KO mice, but the effect on the epiphysis was greater with $1,25-(OH)_2D_3$. As a result of these positive effects long bone length increased with both treatments. The exogenous PTH and $1,25-(OH)_2D_3$ administration also stimulated appositional osteoblastic bone formation at both trabeculae and cortices, in a manner independent of each other, however, the effect was greater with PTH. Treatment with PTH and $1,25-(OH)_2D_3$ both increased osteoblast number and type I collagen deposition in bone matrix. Consistent with these observations, expression levels of the osteoblastic genes, Cbfa1, ALP, type I collagen and osteocalcin were all up-regulated following 10 days of PTH or $1,25-(OH)_2D_3$ administration to the double KO mice. The number of TRAP positive osteoclasts in bone increased relative to the vehicle-treated double mutants but were still less in the PTH- or $1,25-(OH)_2D_3$-treated double mutants than in vehicle-treated wild-type mice. These results indicate that PTH and $1,25-(OH)_2D_3$ can increase serum calcium concentrations and exert skeletal anabolic effects independent of each other.

Novel Regulation of 25-Hydroxyvitamin D_3 24-Hydroxylase (24(OH)ase) Transcription by Glucocorticoids: Cooperative Effects of the Glucocorticoid Receptor, C/EBP beta and the Vitamin D Receptor in 24(OH)ase Transcription. P. Dhawan*, X. Peng*, S. Christakos. Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

Glucocorticoid induced bone loss has been proposed to involve direct effects on bone cells as well as alterations in calcium absorption and excretion. Since vitamin D is important for the maintenance of calcium homeostasis, in the present study the effects of glucocorticoids on vitamin D metabolism through the expression of 24(OH)ase, an enzyme involved in the catabolism of $1,25(OH)_2D_3$, were examined. Injection of 7 week old male vitamin D replete mice with dexamethasone (dex; 2mg/kg body weight for 5 days) resulted in a signficant induction in 24(OH)ase mRNA in kidney (3.4 ± 0.4 fold), indicating a regulatory effect of glucocorticoids on vitamin D metabolism. Recent evidence has indicated cooperative effects between the transcriptional activator, C/EBP beta and the vitamin D receptor (VDR) in the regulation of 24(OH)ase transcription. In the presence of ligand bound VDR, C/EBP beta enhances 24(OH)ase transcription and this enhancement is mediated by a C/EBP binding site at -395/-388 in the 24(OH)ase promoter. Whether glucocorticoids can affect 24(OH)ase transcription is not known. Here we demonstrate for the first time a glucocorticoid receptor (GR) dependent enhancement of $1,25(OH)_2D_3$ induced 24(OH)ase transcription. Transfection studies indicated that in the absence of $1,25(OH)_2D_3$ activation, treatment with dex alone (10^{-8}M- 10^{-6}M) of GR transfected COS-7 cells did not affect 24(OH)ase transcription. However dex treatment of GR and VDR transfected COS-7 cells potentiated $1,25(OH)_2D_3$ induced 24(OH)ase transcription (4-5 fold). In addition GR and dex treatment potentiated the C/EBP beta mediated enhancement of VDR mediated 24(OH)ase transcription (2-3 fold) and immunoprecipitation assays indicated that GR can interact with C/EBP beta. A glucocorticoid response element was not present in the rat 24(OH)ase promoter (-671/+74). Using the rat 24(OH)ase promoter (-671/+74) with the C/EBP beta site mutated, GR mediated potentiation of $1,25(OH)_2D_3$ induced 24(OH)ase transcription was inhibited, suggesting functional cooperation between C/EBP beta and GR in the regulation of 24(OH)ase transcription. These findings indicate a novel mechanism whereby glucocorticoids can alter VDR mediated 24(OH)ase transcription through a functional interaction between GR and C/EBP beta that results in an enhanced ability of C/EBP beta to cooperate with VDR in the regulation of 24(OH)ase. In addition, these results suggest that glucocorticoid mediated alterations in vitamin D metabolism may contribute to glucocorticoid induced bone loss.

Abnormal Renal Phosphate Transport Underlies the Aberrantly Regulated 25-Hydroxyvitamin D-1α-Hydroxylase (1-OHylase) Activity in *Hyp*-Mice. M. Takaiwa, B. Yuan, Y. Xing*, R. Achyutharao*, M. K. Drezner. University of Wisconsin, Madison, WI, USA.

Abnormal vitamin D metabolism in *hyp*-mice is due primarily to aberrant regulation of renal $1,25(OH)_2D$ production. We demonstrated that such defective regulation results from abnormal 1-OHylase mRNA translation in the cells of the proximal convoluted tubule. Hence, despite normal up-regulation of mRNA transcripts in *hyp*-mice in response to hypophosphatemia and PTH, these stimuli fail to substantially alter renal 1-OHylase protein content and consequently enzyme activity in the mutants. Whether this abnormality is due to a circulating phosphatonin (FGF-23) or to the direct/independent effects of abnormal phosphate transport in the renal proximal convoluted tubule, and the resultant changes in the intracellular milieu, remains unknown. Thus, to address the cause of the abnormal vitamin D metabolism, we created C57BL/6J transgenic (*KAP-Npt2*) mice and mated them with *hyp*-mice to produce transgenic *KAP-Npt2 hyp*-mice. Due to *Npt2* over-expression and enhanced renal Na^+-dependent phosphate transport, the serum phosphorus concentration in the *KAP-Npt2 hyp*-mice (6.6±0.7 mg/dl) was no different from normal (7.2±0.6 mg/dl) but significantly greater ($p<0.001$) than in *hyp*-mice (4.5±0.4 mg/dl). Subsequently, we compared P- and PTH-stimulated 1-OHylase mRNA (RT-PCR), protein (Western) and enzyme activity in 8-12 week old male C57BL/6J normal and transgenic *KAP-Npt2 hyp*-mice. In concert with a normal serum phosphorus concentration under basal conditions, the *KAP-Npt2 hyp*-mice reset production of $1,25(OH)_2D$ and, unlike *hyp*-mice, exhibited normal abundance of 1-OHylase mRNA transcripts (1.3±0.5 vs 1.0±0.1 fold), as well as normal amounts of 1-OHylase protein (1.2±0.5 vs 1.0±0.1 fold) and enzyme activity (6.5± 0.5 vs 5.5±0.3 fmoles/mg protein/min), consistent with normal 1-OHylase mRNA translation. Moreover, in response to PTH stimulation, the *KAP-Npt2 hyp*-mice displayed not only normal up-regulation of 1-OHylase mRNA transcripts (9.5±0.3 vs 9.7±0.5 fold), as in *hyp*-mice, but, in contrast, normal enhancement of 1-OHylase protein (1.6±0.1 vs 1.6±0.2 fold) and enzyme activity (13.0±1.0 vs 14.9±1.5 fmoles/mg protein/min), again consistent with normal mRNA translation. Normalization of vitamin D metabolism in the *KAP-Npt2 hyp*-mice occurred despite maintenance of an elevated serum FGF-23 level comparable to that in *hyp*-mice. These observations provide compelling evidence that the abnormal regulation of renal $1,25(OH)_2D$ production in *hyp*-mice is secondary to the direct effects of abnormal phosphate transport in the renal proximal tubule and undoubtedly resultant changes in the intracellular milieu that regulate mRNA translation.

Osteoclasts from ADOI Patients Are Completely Normal *In Vitro* Indicating that Osteoblasts with a Aain of Function in LRP5 Loose their Ability to Support Osteoclastogenesis. K. Henriksen[1], J. Gram*[2], P. Høegh-Andersen*[1], S. Schaller*[1], J. Bollerslev[3], M. A. Karsdal[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Ribe County Hospital, Esbjerg, Denmark, [3]Department of Medical Endocrinology, National University Hospital, Oslo, Norway.

Patients harbouring mutations in the LRP5 protein have either Autosomal Dominant Osteopetrosis type I (ADOI) or Osteoporosis-Pseudoglioma Syndrome (OPPG), depending on whether the mutations lead to a gain or a loss of function. This proves that LRP5 is a central regulator of bone metabolism. Increased activity of LRP5 leads to increased osteoblast activity further leading to increased bone mass. ADOI patients have significantly reduced levels of osteoclasts, indicating that either LRP5 has a function in osteoclasts or that ADOI osteoblasts fail to support normal osteoclastogenesis. To investigate whether the defect in osteoclasts from ADOI patients is endo-or exogenous we isolated CD14+ monocytes from 5 patients with a T253I mutation causing ADOI and from age and sex-matched controls and compared their ability to generate mature multinuclear resorbing osteoclasts, when treated with RANKL and M-CSF. We found that monocytes from ADOI patients differentiate into osteoclasts at the same rate as control monocytes. By comparison of expression of osteoclast markers, cathepsin K, TRACP, ClC-7 and MMP-9 by Western-blot, we found no differences between ADOI and control osteoclasts undergoing differentiation. In alignment, the ability of ADOI osteoclasts to form actin rings was not impaired. By immunolocalization of Cathepsin K, TRACP, MMP-9 and ClC-7, we found normal localization in gradients towards the resorption lacuna as expected. We investigated the ability of the ADOI osteoclasts to resorb bone and we found that they resorb bone as efficiently as their control counterparts as investigated by CTX-I collagen release from bone slices, and pit area measurements. In ADOI patients, we analysed the effect of the thyroid hormone T_3 *in vivo* to test whether the lowered number of osteoclasts had an effect on the induction of bone turnover, presented as increases compared to baseline values of osteocalcin and CTX-I in serum. We found that induction of bone formation was normal. In contrast, we found that the increase in bone resorption was reduced to 40% ($p<0.05$) in ADOI patients compared to controls. In conclusion, LRP5 mutations do not affect osteoclast function *in vitro*. In contrast, osteoclast resorption *in vivo* is impaired. We speculate that ADOI mutations alter the osteoblastic phenotype towards a bone forming phenotype, and that these bone-forming osteoblasts possess a lower potential for supporting osteoclast function.

Expression of TAF_{II}-17 and IL-6 in Osteoclast (OCL) Precursors Is Sufficient for Formation of Pagetic-like OCL. N. Kurihara[1], K. Yamana*[2], G. D. Roodman[3]. [1]Medicine-Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Bone and Calcium Metabolism, Teijin Institute for Bio-Medical Research, Tokyo, Japan, [3]Medicine-Hematology/Oncology, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Osteoclasts (OCL) from patients with Paget's Disease (PD) differ from normal OCL. Pagetic OCL have increased nuclear number, hyper-sensitivity to $1,25\text{-}(OH)_2D_3$ and RANKL, increased bone resorbing capacity and increased rate of OCL formation in vitro. However, the mechanism responsible for these abnormalities is unclear. Bone marrow cells from patients with PD express measles virus nucleocapsid protein (MVNP) transcripts, and expression of the MVNP gene in normal OCL precursors results in formation of OCL that express the abnormal characteristics of OCL from Paget's patients. Further, both OCL from PD patients and OCL precursors transduced with the MVNP gene also secrete large amounts of IL-6 and a VDR binding peptide, TAF_{II}-17. TAF_{II}-17 enhances the $1,25\text{-}(OH)_2D_3$ responsivity of OCL precursors. We hypothesized that MVNP increased IL-6 production by OCL, which in turn upregulated expression of TAF_{II}-17, and enhanced $1,25\text{-}(OH)_2D_3$ responsivity of pagetic OCL precursors. Therefore, we determined the capacity of TAF_{II}-17 to induce $1,25\text{-}(OH)_2D_3$ hyper-responsivity and expression of a pagetic phenotype in normal OCL precursors in vitro. TAF_{II}-17 or MVNP was transfected into normal human marrow cells, which were then treated with 10^{-11} to 10^{-8}M $1,25\text{-}(OH)_2D_3$, and the number and characteristics of the OCL formed were determined. TAF_{II}-17 transfected cells formed increased numbers of OCL that were hyper-responsive to $1,25\text{-}(OH)_2D_3$, but did not demonstrate RANKL hyper-responsivity, increased numbers of nuclei per OCL or produce high levels of IL-6 (47±1 pg/ml vs. 269±11 pg/ml, TAF_{II}-17 vs. MVNP transduced cells). We then treated TAF_{II}-17 transduced OCL precursors with low concentrations of $1,25\text{-}(OH)_2D_3$ and 100 pg/ml IL-6. TAF_{II}-17 transduced OCL precursors treated with IL-6 and $1,25\text{-}(OH)_2D_3$ formed OCL that had increased numbers of nuclei per OCL, a markedly increased bone-resorbing capacity and increased responsivity to RANKL, similar to OCL formed by MVNP transduced OCL precursors. These results demonstrate that TAF_{II}-17 by itself can increase VDR mediated gene transcription and the sensitivity of OCL precursor cells to $1,25\text{-}(OH)_2D_3$, but in addition, increased production of IL-6 by OCL precursors is required for formation of pagetic-like OCL.

Differential Activity of Human RUNX2 P2 Promoter Alleles Associated with Deciles of BMD Show an Allele-Specific DNA-Protein Interaction in Osteoblast Nuclear Extracts. J. D. Doecke*[1], C. J. Day*[1], A. Stephens*[1], G. C. Nicholson[2], N. A. Morrison[1]. [1]School of Medical Science, Griffith University, Gold Coast, Australia, [2]Department of Medicine, Geelong Hospital, University of Melbourne, Geelong, Australia.

We hypothesized that by taking subjects from the extremes of a population, we would specifically find alleles related to the bone mineral density trait, if such alleles exist for any particular target gene. We tested this idea using RUNX2, the well known osteoblast transcription factor. From a population of 1300 subjects the age-weight adjusted femoral neck bone mineral density (BMD) was ranked and the upper and lower deciles taken to represent the adjusted extremes. After adjusting and ranking, the two groups (n=130 each) were not significantly different for age or weight. In these 260 subjects, we identified 19 allelic variations within the RUNX2 gene and promoter (P1 and P2), and characterized these novel variations with respect to BMD strata by genotype using dHPLC. A general linkage disequilibrium (LD) analysis of RUNX2 showed that LD drops off with physical distance, as expected. Within the P2 promoter were three polymorphic nucleotides for which the minor alleles were over represented in the upper decile of BMD. These alleles are in complete LD with each other and represent a haplotype block that is significantly associated with increased BMD. Constructs made from the "normal" and the "high BMD" alleles were cloned upstream of otherwise identical luciferase constructs. Despite there being only 3 nucleotide differences between the two constructs, when transfected into osteoblast-like cells the high BMD allele construct showed significantly greater P2 promoter activity than the normal allele. Comparative homology studies showed that the high BMD alleles were the major forms in other animals (dog, rat, mouse, chimp), suggesting that the human normal BMD alleles represent the evolutionary change. The rat sequence was identical to the human high BMD allele, permitting an analysis of DNA-protein interactions in the well characterized ROS17/2.8 rat osteoblast cell line. These data showed abundant nuclear factor binding to one the three polymorphic sites in the human normal BMD allele that does not occur in the high BMD allele (and rat sequence). The data suggest that the high BMD allele does not interact with a factor that otherwise binds strongly to the normal human allele. Since the high BMD allele had higher P2 promoter activity, the binding activity may be a repressor that limits the expression of the normal allele. In any event, the nuclear factor is a candidate for the allele-specific regulation of the RUNX2 promoter.

PlexinD1, Is a Plexin Family Member Being Expressed in Central Nervous System and Endothelium, and Is Involved in the Skeletal Patterning in the Development of Bone. T. Kanda[1], Y. Yoshida*[2], K. Nakashima*[1], Y. Ezura[1], M. Noda[1]. [1]Molecular Pharmacology, 21st COE program, Medical Research Institute, Tokyo medical and Dental University, Tokyo, Japan, [2]Department of Biochemistry and Molecular Biophysics, Howard Hughes Medical Institute, Columbia University., New York, NY, USA.

Plexin family members are characterized by their large, single-pass transmembrane protein domain with homology to the scatter factor receptors encoded by MET gene. Plexins in the conjunction with the neuropilins are the receptors for semaphorins. These ligand-receptor signaling systems have been first identified to be involved in axonal guidance. In addition to the central nervous system, PlexinD1 is expressed in the endothelial cells. The signaling by semaphorin 3E and PlexinD1 controls the positioning of endothelial cells and the patterning of the developing vasculature in the mouse (Science 2005). As both the central nervous system and vascular systems are closely associated with the control of skeletal systems, we examined the effects of PlexinD1 deficiency on the skeletal development. PlexinD1 deficiency specifically altered the axial skeletal elements. Within the axial skeletal elements, vertebral body development was severely impaired and fragmentations or loss of the vertebral body was observed in PlexinD1-null mice. This was observed almost entirely from the caudal to rostral ends of the vertebral columns. Interestingly, although the vertebral body was fragmented, segmental pattern was intact and rib cages as well as the transverse processes was almost fully preserved. Therefore, PlexinD1 deficiency specifically affects the vertebral body formation. Although the fragmentation was occurring, the total body mineral density was not affected by the deficiency of PlexinD1. Interestingly, such of differences were specifically within the central axis since limb bones were more or less normal in PlexinD1 knockout mice. In order to access the role of PlexinD1 in adult bones in relationship to the osteogenesis, we have conducted bone marrow ablation experiments using adult wild type mice and heterozygous PlexinD1 knockout mice. Ablation causes new bone formation in the bone marrow within 10 days and the levels of newly formed bone at the growth plate area as well as bone marrow area were similar between the wild type and heterozygous knockout mice. These data indicated that PlexinD1 is specifically involved in the formation of precise patterning of vertebral body development of skeletal systems.

Large Scale Prospective Meta-Analysis of BMD and Fracture in Relation to *COLIA1* Sp1 Polymorphism: The GENOMOS Study. S. H. Ralston[1], A. G. Uitterlinden[2], S. Balcells*[3], M. L. Brandi[4], A. H. Carey*[5], B. L. Langdahl[6], R. Lorenc[7], X. Nogues[8], B. Obermayer-Pietsch[9], J. Reeve[10], D. M. Reid[11], H. A. Pols[2], N. M. van Schoor*[12], J. P. A. Ioannidis*[13]. [1]University of Edinburgh, Edinburgh, United Kingdom, [2]Erasmus University, Rotterdam, The Netherlands, [3]University of Barcelona, Barcelona, Spain, [4]University of Florence, Florence, Italy, [5]Oxagen, Didcot, United Kingdom, [6]University of Aarhus, Aarhus, Denmark, [7]CMHI, Warsaw, Poland, [8]Hospital del Mar, Barcelona, Spain, [9]University of Graz, Graz, Austria, [10]University of Cambridge, Cambridge, United Kingdom, [11]University of Aberdeen, Aberdeen, United Kingdom, [12]Vrije Universiteit, Amsterdam, The Netherlands, [13]Department of Hygiene and Epidemiology, University of Ioannina, Ioannina, Greece.

A Sp1 binding site polymorphism in *COLIA1* has been suggested to be a genetic marker of osteoporosis. We conducted a prospective meta-analysis of individual level data from nine European centres and 26,242 study subjects in relation to spine and hip BMD and bone fractures. No between-centre heterogeneity was observed for any outcome in any genetic contrast (except modest heterogeneity for spine BMD) and Hardy Weinberg Equilibrium was met for all centres. There were no BMD differences in “GG” homozygotes vs. “GT” heterozygotes, but “TT” homozygotes had lower BMD than “GG” and “GT” at the spine (21 mg/cm^2 [95% CI, 0 to 41]; p=0.043) and hip (25 mg/cm^2 [16 to 34]; p<0.001). The BMD association was unaltered after adjustment for age, height, weight, HRT use and menopausal status. In the study group as whole, 6,498 subjects gave a history of bone fracture, of which 3,742 were considered low-trauma fractures. There were 2,380 vertebral fractures, and 2,550 incident fractures (403 incident vertebral fractures). The Sp1 polymorphism was not associated with fracture overall; odds ratio [95% CI] per T allele =1.02 [0.96-1.08] or with prevalent vertebral fracture; odds ratio = 1.05 [0.93-1.19]. However, for incident vertebral fracture, Sp1 alleles were associated with risk in females; OR = 1.34 [1.04-1.73], (p=0.011) per copy of the T allele, independent of BMD, and unaltered in adjusted analyses. We conclude that the COL1A1 Sp1 polymorphism is associated with BMD and with incident vertebral fractures independent of BMD. No association with prevalent fractures was observed. The large sample size makes the study statistically robust, but the association we observed with BMD and fracture was modest illustrating that single genetic markers make a limited contribution to assessing fracture risk. Our study demonstrates the value of adequately powered studies in quantitating effects of common genetic variants on complex disease.

Gene Search for Femoral Neck Cross-Sectional Geometry. D. H. Xiong, H. Shen*, R. R. Recker, H. W. Deng. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Bone geometry is a critical determinant of bone strength, which is highly heritable and is the ultimate intrinsic determinant of fracture risk. To search the underlying genes influencing bone geometry, we performed both genetic linkage and association analyses here. In 4,251 subjects from 471 pedigrees, we genotyped 410 microsatellite markers (~8.9 cM apart) across the whole human genome and performed linkage analyses for five bone geometry parameters at the femoral neck (FN): cross-sectional area (CSA), cortical thickness (CT), endocortical diameter (ED), sectional modulus (Z), and buckling ratio (BR). Significant linkage was found on chromosome 20q11 for CT (LOD = 4.07), 20q13 for BR (LOD = 3.49), and Xq25 for CT (LOD = 3.90). We also identified 13 suggestive linkage signals for the studied geometry traits. Interestingly, three genomic regions seem to be linked with multiple FN geometry traits such as 20q11-13 for CSA, BR and CT (LOD = 2.63, 3.49 and 4.07, respectively), 3q26-27 for CSA and CT (LOD = 2.01 and 2.09, respectively), and 1p12 for CT and CSA (LOD = 1.86 and 2.32, respectively). Given the significant linkage evidence and the exceptionally large sample size adopted, our data strongly support 20q11-13 as a promising region harboring FN geometry quantitative trait loci (QTLs). The association between the estrogen receptor alpha (ER-alpha) gene and FN geometry was tested due to the well-known important physiological effects of estrogen on bone mass and bone remodeling in both genders. We genotyped and tested seven single nucleotide polymorphisms (SNPs) and their haplotypes of the ER-alpha gene in relation to the FN bone geometry parameters in 405 Caucasian nuclear families. Significant association was detected between SNP4 *(rs1801132*) in exon 4 and ED in both single locus analyses (P = 0.005) and haplotype analyses (P = 0.031). Subjects carrying allele G at SNP 4 had 2.70% smaller ED than non-carriers (data were adjusted by age, sex, weight and height). In addition, SNP5 (*rs932477*) in intron 4 is associated with both CT and BR (single locus analyses: P = 0.035 and 0.041, respectively; haplotype analyses: P = 0.010 and 0.004, respectively). Similar patterns of association were shown in subgroup analyses stratified by sex, with no apparent sex-specific effects. In summary, we identified several highly significant genomic regions such as 20q11-13 that may contain major QTLs underlying variation in FN bone geometry and suggested that the ER-alpha gene may have modest genetic effects on variation in femoral neck geometry. This study represents an important step toward identifying genes underlying bone geometry (and thus bone quality) and ultimately the risk of osteoporotic fracture.

Moving between Mouse and Humans to Identify a Candidate Gene on Chromosome 10 that Affects Serum IGF-I, Bone Turnover, and Bone Mineral Density. Y. Hsu[1], K. Delahunty*[2], T. Niu*[1], H. Terwedow*[1], J. Lorenzo[3], B. Kream[3], J. Brain*[1], W. Beamer[2], X. Xu[1], C. Rosen[2]. [1]Population Genetics, Harvard Sch. of Public Health, BOSTON, MA, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]University of Connecticut Health Center, Farmington, CT, USA.

IGF-I is an important growth factor for skeletal remodeling. Several lines of evidence from mice inbred strains and humans suggest that serum IGF-I and BMD are related. We previously identified 4 QTL for the serum IGF-I in F2 mice derived from C3H x B6 crosses. Congenic mice were subsequently generated for two of these QTL (Chr 6 and 10). Those strains were found to have corresponding differences in IGF-I and volumetric BMD (vBMD) in females only. The Chr 10 congenic (10T) exhibited higher serum IGF-I, significantly greater skeletal IGF-I expression and 8% greater vBMD with evidence of increased turnover by histomorphometry versus B6. In vitro, 10T stromal cells showed greater AP staining, and had enhanced osteoclast generation after exposure to RANKL and mCSF versus B6 ($p<0.01$). SNP block haplotyping using databases localized candidate genes to a <2cM region, very close to the IGF-I gene. To test whether polymorphisms in the IGF-I gene are associated with serum IGF-I and BMD in humans, we examined haplotype tagging SNPs using an extreme case control analysis derived from 13,000 Chinese men and women: 521 controls with extreme high hip BMD were matched with 519 extreme low hip BMD cases. Covariates were adjusted by gender- and menopause-specific regression for age, weight, physical activity, and smoking. We noted that serum IGF-I was negatively associated with total body and hip BMD in postmenopausal women ($p<0.01$). The ORs for extreme low hip BMD were significantly associated with three LD SNPs (ORs ranging from 2.1-5.1, $p<0.01$- $p< 0.05$) for postmenopausal women. The SNP located in 3' UTR region was also significantly associated with low serum IGF-I but only in postmenopausal women ($p<0.05$). Among women, there was a strong trend downwards in serum IGF-I concentrations related to the presence of osteoporosis; i.e. controls 104±5 ng/ml, Cases: 92±3, Osteoporosis by T-score: 86±3, Osteoporotic fractures: 80±7; $p<0.01$. In summary, studies in congenic mice narrow the Chr 10 QTL to a region that includes the IGF-I gene. Studies in humans suggest that polymorphisms in the IGF-I gene are causally associated not only with expression of IGF-I but also with the acquisition of peak bone mass. Further subline analysis and haplotyping in the mouse will identify whether the 3'UTR region of the IGF-I gene is critical for regulating bone turnover and peptide expression. Moving between mouse and humans provides an ideal and complementary means for evaluating genomic function and its implications.

Combined Bisphosphonate and Endothelin a Receptor Antagonist Treatment More Effectively Reduces Prostate Cancer Growth in Bone than either Alone. K. S. Mohammad[1], C. McKenna*[1], A. Mison*[1], M. Niewolna*[1], R. Vessella*[2], E. Corey*[2], T. A. Guise[1]. [1]Internal Medicine/ Endocrinology, University of Virginia, Charlottesville, VA, USA, [2]Urology, University of Washington Medical Center, Seattle, WA, USA.

Osteoblastic bone metastases are common in prostate cancer and cause significant morbidity. Endothelin-1 (ET-1) secreted by prostate cancers stimulates osteoblastic responses via the endothelin A receptor (ETAR). ETAR blockade reduces bone metastases in animal models as well as in men with prostate cancer. Osteoclastic bone resorption also contributes to the pathophysiology of osteoblastic metastases. Resorption markers are increased and bisphosphonate antiresorptive drugs reduce skeletal morbidity in patients with osteoblastic disease. We hypothesized that osteolysis contributes to skeletal morbidity in patients with prostate cancer, as much as pathologic bone formation. We used an animal model of osteoblastic prostate cancer to test the effect on tumor growth in bone of osteoblast inhibition with ETAR receptor antagonist (atrasentan) or osteoclast inhibition with bisphosphonate (zoledronic acid ZA), as single agents or in combination. Male nude mice were inoculated with LuCaP 23.1, a xenograft that secretes prostate specific antigen (PSA) and ET-1. Mice were treated with vehicle, atrasentan (20mg/kg/day), ZA (5ug/kg, 3X/week) or the combination, starting one week before tumor inoculation and continuing for 24 weeks. Tumor progression was followed by radiographs and serum PSA concentrations. Mice treated with atrasentan or ZA alone had less osteoblastic response on x-ray compared to vehicle ($p<0.05$) but did not differ from each other. The combination of atrasentan and ZA was significantly more effective than vehicle or single treatments ($p<0.01$). PSA concentrations were similar between the vehicle and single treatment groups but were significantly lower in mice treated with both atrasentan and ZA. Histomorphometric analysis of bone demonstrated markedly less tumor burden in bone ($p<0.001$) as well as new bone area ($p<0.05$) in mice treated with the combination of atrasentan and ZA compared with those treated with vehicle or ZA. Single agent treatment with atrasentan was associated with a greater reduction in tumor burden and new bone area than treatment with ZA alone. The data suggest that osteoblast and osteoclast activities cooperate to drive the progression of prostate cancer growth in bone. Thus, combination therapy targeting the two major bone cell types should be an effective treatment for osteoblastic bone metastases.

Reduced Bone and Lung Metastases of 4T1 Mouse Breast Cancer in Osteopontin Null Mice. A. Hiraki*, N. Hashimoto*, P. Williams*, M. Bunegin*, T. Yoneda. Division of Endocrinology, Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

A secreted phosphoglycoprotein osteopontin (OPN) is produced in various types of human cancers and has been implicated in tumorigenesis, local invasiveness and distant metastases. Recent studies have reported that tumor-produced OPN plays a role in bone metastases in human breast and prostate cancers. However the role of host-derived OPN in metastasis of these cancers to bone, in which OPN is abundant, and non-bone sites is unclear. It is also unclear whether OPN plays a specific role in bone metastases. To study these, we developed a syngeneic orthotopic model of metastasis in which inoculation of the 4T1 mouse breast cancer cells in mammary fat pad in female Balb/c mice caused metastases in bone and lung. The 4T1 cells were stably transfected with firefly luciferase cDNA (4T1/luc) for quantitative assessment of tumor burden. Western blot analyses showed that 4T1 cells produced substantial amounts of OPN. Introduction of an anti-sense-OPN cDNA in 4T1 cells (4T1/ASOPN/luc) markedly inhibited OPN production and reduced metastases to bone and lung compared to empty-vector-transfected 4T1 cells (4T1/EV/luc). These results show that tumor-produced OPN plays an important role in distant metastases in 4T1 breast cancer. To examine the role of host-derived OPN in distant metastasis, we inoculated 4T1/EV/luc and 4T1/ASOPN/luc into syngeneic female OPN-deficient (OPN-/-) mice compared with wild-type (WT) mice. Tumor formation of 4T1/EV/luc and 4T1/ASOPN/luc at the orthotopic site did not differ between WT and OPN-/- mice. In contrast, 4T1/EV/luc metastases to bone and lung were decreased in OPN-/- mice compared with WT mice. Similarly, 4T1/ASOPN/luc metastases to bone and lung were also reduced in OPN-/- mice. To understand the mechanism underlying reduced distant metastases in OPN-/- mice, adherence, proliferation and apoptosis of 4T1 cells in plates coated with varying concentrations of OPN were examined. We found that the attachment and growth of 4T1/EV/luc and 4T1/ASOPN/luc cells in OPN-coated plates were greater than non-coated plates. The effects were dependent on OPN concentration. Furthermore, these cells displayed decreased apoptosis in OPN-coated plates. These results suggest that host-derived OPN contributes to the stimulation of arrest and colonization and protection from apoptosis of metastatic cancer cells in target organs. Taken together, our results using OPN-/- mice suggest that not only tumor-derived but also host-derived OPN is critical to bone and lung metastases in breast cancer. The results also suggest that OPN plays an important role in non-bone metastases as well as bone metastases.

Inhibition of Epidermal Growth Factor Receptor Signaling Abrogates Humoral Hypercalcemia of Malignancy in a Mouse Model of Human Lung Squamous Cell Carcinoma. G. Lorch*[1], P. F. Koltz*[2], Y. M. Cho*[2], R. L. Konger*[2], K. S. Nadella*[1], J. L. Gilmore*[2], R. E. Toribio*[1], T. J. Rosol[1], J. Foley[2]. [1]Veterinary Biosciences, The Ohio State University, Columbus, OH, USA, [2]School of Medicine, Indiana University, Indianapolis, IN, USA.

Dysregulation of the erbB family of receptors and the epidermal growth-factor (EGF) family of peptide hormones plays an important role in the progression of human lung squamous cell carcinoma (SCC). Lung SCC is frequently associated with humoral hypercalcemia of malignancy (HHM) due to over production of parathyroid hormone-related protein (PTHrP). It has been reported that EGF induces PTHrP transcription through epidermal growth factor receptor (EGFR) signaling, likely involving the ras/Mek/Erk pathway in keratinocytes. The purpose of this study was to evaluate EGFRs' contribution to PTHrP expression and resulting HHM in the human lung SCC cell line, RWGT2. RWGT2 cells produce HHM when grown as a xenograft in nude mice. Using western blot analysis, we found that RWGT2 SCC express high levels of EGFR and moderate levels of erbB3. We identified that RWGT2 SCC produce the EGF-related growth factors amphiregulin, TGF-α and heparin binding-EGF by Q-RT-PCR. Amphiregulin mRNA levels were 1000-fold greater than the other two factors. To test the relationship between EGFR activity and PTHrP gene expression in RWGT2 SCC, we treated the cells for 6 hours with 1μM of EGFR tyrosine kinase inhibitors (TKI) PD153035 and ZD1839 (gefitinib) and measured PTHrP mRNA levels by Q-RT-PCR. Treatment with each TKI resulted in significant reductions (60%) of PTHrP/GAPDH mRNA ratios, suggesting that a substantial portion of PTHrP mRNA in RWGT2 cells was due to EGFR signaling. The *in vivo* relationship between EGFR and PTHrP gene expression was investigated using a xenograft RWGT2 HHM model. Hypercalcemic mice with total Ca^{2+} concentrations ≥12 mg/dl were treated with 200mg/kg of gefitinib for 3 consecutive 24-hour periods. Plasma calcium was measured at 6, 24, 52, and 78 hrs after the first treatment. Calcium concentrations were significantly reduced at all time points when compared to pretreatment and control values ($p<0.05$). All gefitinib-treated HHM mice had normal calcium concentrations at 78 hrs. Plasma PTHrP concentrations in gefitinib-treated mice were significantly reduced (50%) when compared to untreated mice with RWGT2 xenografts at 78 hrs ($p<0.05$). In conclusion, autocrine activation of PTHrP gene expression is mediated through the EGFR in this cell line. Moreover, inhibition of the EGFR pathway in an HHM model by administration of an anilinoquinazoline demonstrates for the first time that EGFR is a potential target for antihypercalcemic therapy in patients with lung SCC-associated HHM.

SD-208, a Small Molecule Inhibitor of Transforming Growth Factor β Receptor I Kinase Reduces Breast Cancer Metastases to Bone and Improves Survival in a Mouse Model. E. G. Stebbins*[1], K. S. Mohammad[2], M. Niewolna*[2], C. R. McKenna*[2], A. P. Mison*[2], F. Schimmoller*[1], A. Murphy*[1], S. Chakravarty*[1], S. Dugar*[1], L. S. Higgins*[1], D. H. Wong*[1], T. A. Guise[2]. [1]Scios, Inc., Fremont, CA, USA, [2]Division of Endocrinology, University of Virginia, Charlottesville, VA, USA.

Breast cancer commonly metastasizes to and destroys bone to cause pain and fracture. Substantial data support central roles for bone-derived transforming growth factor-beta (TGF-β) and tumor-derived osteolytic factors such as parathyroid hormone related peptide (PTHrP) in a vicious cycle of local bone destruction in osteolytic metastases. TGF-β, stored in bone matrix and released in active form during osteoclastic resorption, stimulates PTHrP production by tumor cells. PTHrP in turn mediates bone destruction by stimulating osteoclasts. A dominant negative mutant of the type II TGF-β receptor inhibited TGF-β-induced PTHrP secretion *in vitro* and development of bone metastases in an MDA-MB-231 experimental metastasis model. These studies provided proof of principle to support a role for TGF-β blockade in the treatment of breast cancer bone metastases. SD-208, a small molecule inhibitor of TGF-β receptor I kinase (TGF-βRI), inhibits signaling downstream of the TGF-β receptor. The *in vivo* efficacy of SD-208 was evaluated in an experimental metastasis model using the breast carcinoma cell line MDA-MB-231. Pre-treating nude mice with SD-208 (0.3 and 1 mg/ml added to drinking water) reduced the rate of osteolytic bone destruction, as assessed by computerized image analysis of radiographs, and prolonged survival. In mice with established bone metastases, SD-208 (20 and 60 mg/kg po qd administered via oral gavage) reduced osteolytic lesion area and prolonged survival compared to vehicle control. To dissect the mechanism regulating these *in vivo* therapeutic benefits, the effects of SD-208 were analyzed in cultured MDA-MB-231 cells. SD-208 did not affect cell proliferation. However, SD-208 inhibited TGF-β-induced smad2/3 phosphorylation as well as decreased production of TGF-β-stimulation of osteolytic factors, IL-11, PTHrP, and growth promoting factor, connective tissue growth factor (CTGF). It also reduced TGF-β secretion from MDA-MB-231 cells, suggesting possible autocrine effects of TGF-β on the cancer cells. Taken together, these data indicate that therapeutic targeting of TGF-β may decrease the osteolytic bone metastases due to breast cancer by blocking tumor production of osteolytic and growth-promoting factors such as IL-11, PTHrP and CTGF.

Inhibiting $p62^{ZIP}$ Expression Decreases OCL Formation by Blocking the Effects of RANKL and TNF-α. N. Kurihara[1], T. Honjo[1], J. J. Windle[2], G. D. Roodman[3]. [1]Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, Virginia Commonwealth Univ., Richmond, VA, USA, [3]Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Osteolytic bone destruction occurs in up to 80% of patients with multiple myeloma (MM), and plays a critical role in promoting tumor growth. RANK ligand (RANKL), IL-6 and TNF-α production is increased in the marrow microenvironment in MM patients and have been implicated in this process. Recently, a new member of the RANKL signaling pathway, $p62^{ZIP}$, has been identified. $p62^{ZIP}$ plays a critical role in NF-κB activation induced by TNF-α, RANKL and IL-1 and is involved in multiple signaling pathways that can enhance tumor cell survival and bone destruction. It is our hypothesis that inhibiting $p62^{ZIP}$ expression will profoundly diminish osteolytic bone destruction and myeloma growth by blocking the effects of RANKL and IL-6 produced in the tumor-bone microenvironment in response to TNF-α. Therefore, we used $p62^{ZIP}$ -/- mice to determine the role of $p62^{ZIP}$ on OCL formation and the capacity of p62-/- stromal cells to support OCL formation by normal spleen cells treated with $1,25(OH)_2D_3$ or PTHrP. Spleen or marrow cells from p62-/- and p62+/-mice were treated with RANKL or TNF-α to induce OCL formation and assess NF-κB gene reporter activity. OCL formation and NF-κB gene reporter activity in p62-/- mice were markedly decreased at low concentrations of RANKL and TNF-α compared to p62+/- OCL precursors. Expression of RANKL mRNA and protein in cultured marrow stromal cells from these mice showed that similar levels of RANKL mRNA were detected in both normal and p62-/- stromal cells treated with $1,25-(OH)_2D_3$, or PTH-rp for 48 hours. Conditioned media from marrow stromal cells treated with vehicle (media alone), $1,25-(OH)_2D_3$, PTH-rp, TNF-α or IL-6 for 7 days showed that $1,25-(OH)_2D_3$ induced similar maximal RANKL levels in the conditioned media (1089±689 pg/ml for p62+/- and 1161±567 pg/ml for p62-/-, mean ± SD respectively). In contrast, in cultures treated with 100 pg/ml TNF-α, RANKL levels were significantly decreased in p62-/- stromal cell cultures (775±391 vs. 114±9 pg/ml, mean ± SD). We then tested stromal cells from p62-/- mice for their capacity to support osteoclastogenesis by normal spleen CFU-blast. OCL formation was significantly decreased in cocultures of p62-/- stromal cells treated with PTH-rp, IL-6 and TNF-α. These results demonstrate that p62 plays an important role in OCL formation induced by inflammatory cytokines that are upregulated in the marrow microenvironment in patients with myeloma. They further suggest that blocking p62 signaling may markedly reduce OCL formation in myeloma patients.

Osteonecrosis of the Jaw in Patients Receiving Intravenous Bisphosphonate Therapy. A. O. Hoff, B. Toth*, K. Altundag*, V. Guarneri*, A. Nooka*, K. Desrouleaux*, M. Klein*, A. Adamus*, G. Sayegh*, A. Worthing*, R. F. Gagel, G. N. Hortobagyi*. University of Texas MD Anderson Cancer Center, Houston, TX, USA.

Advances in treatment modalities for metastatic bone disease (MBD) have resulted in a dramatic change in the outcome of cancer patients (pts). Part of this progress has occurred with the introduction of bisphosphonate (BP) therapy. Studies have shown that BPs significantly reduce the number and delay the onset of skeletal-related events such as fractures, cord compression and hypercalcemia. Although the efficacy of these drugs is well documented, there have been recent reports of osteonecrosis of the jaw (ONJ) occurring in pts receiving BP. This is a preliminary report of our 2239 patient records reviewed to date. To estimate the frequency, understand the clinical presentation and to identify risk factors for development of ONJ we have initiated a retrospective review of pts treated with intravenous (IV) BP at our Institution from January 1994 to December 31, 2003. A total of 4032 treated pts have been identified through the Pharmacy database. Patients diagnosed with ONJ at the dental oncology clinic are also reviewed. ONJ was defined as exposed non-healing bone with/without pain of at least 3-6 months duration. Among 2239 records reviewed to date, we have identified 29 pts with ONJ [estimated frequency (EF): 1.3%]. Fourteen of these pts have multiple myeloma (MM) (14/309, EF: 4.5%), 14 have metastatic breast carcinoma (MBC) (14/1147, EF 1.2%). One or more potential predisposing factors were identified in several pts: dental extraction prior to development of ONJ (12), mandibular exostosis (7), trauma (2), and periodontal disease (10). The time from starting BP therapy to the diagnosis of ONJ, defined as time to event (TTE), ranged from 4 to 65 months (mean TTE: 40 months). Thirteen patients were treated with pamidronate (PA) and zoledronic acid (ZA), 7 patients with ZA, 8 patients treated with PA and, 1 patient treated with alendronate and PA. The mean cumulative dose of PA was 2092 mg (range: 360-3610 mg), ZA was 53 mg (range: 28-96 mg). Pts were treated with aggressive oral hygiene, salicept or sodium bicarbonate oral rinse, debridement of necrotic bone and antibiotics when infection was detected. In conclusion, ONJ is a significant but relatively uncommon event observed in patients with MBC and MM treated with IV BP. The pathogenesis and etiology are still unclear but a combination of factors, possibly including chronic bisphosphonate therapy, exposure to extensive chemotherapy agents and steroids as well as a traumatic oral event, seem to be important in its evolution.

Dickkopf's Are Expressed by Breast Cancer Cell Lines and Regulated by PTHrP. K. D. Hausler*. Bone, Joint and Cancer, St. Vincent's Institute, Melbourne, Australia.

Dickkopf (Dkk) proteins have been shown to bind to LRP-5 and prevent Wnt signalling, a pathway involved in bone formation. We have investigated the role of the Wnt pathway in breast cancer growth in bone using a candidate gene approach. We determined mRNA expression levels of secreted frizzled-related proteins (sFRP's), Dkk's and other Wnt pathway molecules using MCF-7 human breast cancer cell lines. MCF-7, vector control cell lines and several clonal cell lines overexpressing PTHrP, which induce greater osteolytic damage *in vivo* than parental MCF-7 cells, were found to express components of the Wnt pathway. Notably, the cell lines overexpressing PTHrP had increased Dkk-2 mRNA expression relative to vector control and parental MCF-7 cells.We investigated the association between Dkk-2 and PTHrP mRNA in MCF-7 cells using recombinant and synthetic peptides corresponding to various portions of PTHrP.C-terminal region of PTHrP (107-139aa), but not N-terminal sequences (1-34 and 1-108aa), were found to upregulate both Dkk-2 and Dkk-3 mRNA's 4-fold in MCF-7 and MCF-10A (mammary epithelial) cell lines. There was no effect of any fragments of PTHrP on Dkk-1 mRNA. We established that there is an active canonical Wnt signalling pathway present in MCF-7 cells by measuring translocation of β-catenin to the nucleus (immunocytochemistry) and activation of Tcf/Lef gene transcription (luciferase reporter) in the presence of either LiCl (GSK3βinhibitor) or recombinant Wnt3a. To determine the effect of Dkks upon osteoclast formation, we used recombinant Dkk-1 and found that this inhibits osteoclast formation *in vitro*. sFRP-1, another inhibitor of the Wnt pathway, also inhibited osteoclast formation. Both sFRP-1 or Dkk-1 was able to dose dependently inhibit osteoclast formation in either osteoblast/bone marrow co-cultures, or RANKL+M-CSF-treated bone marrow cultures. The action of Dkk-1 and sFRP-1 to limit osteoclast formation may be explained by their ability to inhibit Wnt signaling (canonical, canonical and non-canonical respectively), suggesting that Wnt signaling is involved in osteoclastogenesis. Combined these data suggest that Dkk's produced by breast cancers may influence the proposed vicious cycle of destruction characteristic of breast cancer growth in bone in an autocrine manner, particularly since PTHrP, a driver of osteolysis, regulates expression of Dkk's. In addition, there may be paracrine actions of Dkk's on resident osteoclast and osteoblast cells.

Inhibition of RhoA GTPase and p42/44 MAPKs Triggers Osteosarcoma Cell Apoptosis Independently of BMP-2 Signaling. O. Fromigué*[1], S. Bouvet*[1], E. Haÿ*[1], A. Jacquel*[2], D. Modrowski[1], P. Auberger*[2], P. J. Marie[1]. [1]Laboratory of Osteoblast Biology and Pathology, Inserm U606, Paris, France, [2]Faculty of Medicine Pasteur, Inserm U526, Nice, France.

Osteosarcoma is the most common primary bone tumor in young adults. Despite improved prognosis, resistance to chemotherapy remains responsible for failure of osteosarcoma treatment. The identification of signals that promote apoptosis in osteosarcoma cells may provide clues to develop new therapeutic strategies for chemoresistant osteosarcoma. We previously showed that BMP-2 induces apoptosis in human osteosarcoma cells through activation of BMP receptor IB (BMPR-IB). Here, we investigated whether statins that promote BMP-2 expression in osteoblasts, may induce human osteosarcoma cell apoptosis through activation of BMP signaling. Lipophilic statins (atorvastatin, simvastatin and cerivastatin, kindly provided by Bristol-Myers-Squibb, USA) strikingly induced caspases-dependent-apoptosis in both BMPR-IB-expressing (SaOS2) and BMPR-IB-deficient (OHS4) human osteosarcoma cells, whereas the hydrophilic statin pravastatin had no effect. Statin-induced caspase-3 activity occurred earlier (7-24 h) than BMP-2 protein expression which increased at 72 h. The statin-induced apoptosis was not prevented by overexpression of noggin, a potent BMP antagonist and was not associated with increased Runx2, alkaline phosphatase and osteocalcin mRNA levels. The proapoptotic effect of statins was abolished by mevalonate and geranylgeranylpyrophosphate, but not farnesylpyrophosphate, indicating the involvement of small GTPases Rho proteins. Lipophilic statins rapidly induced RhoA cell membrane relocalization to the cytosol and inactivation of RhoA activity with a time course consistent with activation of caspase-3, which implicates RhoA in human osteoasarcoma cell death induced by statins. The inhibition of RhoA activity induced by statins resulted in decreased phosphorylation of the survival pathway p42/p44-MAPKs and decreased expression of the anti-apoptotic protein Bcl-2, whereas Bax, Bim and survivin were not affected. Constitutively active RhoA, but not wild type RhoA, rescued phospho-p42/p44-MAPKs and Bcl-2 levels and abolished statin-induced apoptosis, which establishes a key role for RhoA in controlling osteosarcoma cell apoptosis. The data provide the first evidence in osteosarcoma cells that inhibition of RhoA GTPase activity by statins is sufficient to induce irreversible apoptosis by a BMP-2-independent mechanism mediated by inhibition of the p42/p44-MAPKs-Bcl-2 survival pathway, and support the concept that osteosarcoma cell apoptosis can be induced independently of commitment to cell differentiation.

Influence of Estrogen Status and Alendronate on Periosteal Bone Formation in the Ilium of Adult Women. S. J. Bare*[1], S. Recker[1], R. Recker[1], D. Kimmel[2]. [1]Creighton University, Omaha, NE, USA, [2]Merck & Co., West Point, PA, USA.

The trabecular (Tb) envelope of transilial biopsy (TIBx) specimens is most often studied. TIBxs also contain periosteal [Ps] and endocortical [Ec] envelopes. The Ps and Ec envelopes may reflect unique hormonal/treatment effects on bone remodeling. Our purpose is to quantitate the influence of hormonal status change or alendronate (ALN) on the Ps and Ec envelopes of adult women. One unstained section from each of two levels of TIBx's of 42 healthy women (1-7yrs pre-menopause [peri] and at 1yr after last menses [post]); and 137 post-menopausal osteoporotic (PMO) women treated with placebo (PBO), ALN (10mg/d), hormone replacement (HRT), or HRT+ALN for 2yrs, was examined for: total (BS), and double (2XL)-fluorochrome labeled surface, and mineral apposition rate (MAR), in Ps and Ec envelopes. 2XL/BS was calculated omitting subjects lacking 2XL. Paired t-test was used for the first group (* P<.05; peri vs. post) (+ P<.05; Ps vs. Ec); two-factor ANOVA was used for the latter.

Table 1a Transmenopausal Women (N=42)

Envelope	Surface (mm)	% with 2XL	2XL/BS (%)	MAR (μm/d)
Ps/Peri	30±4	14	1.24±1.15	0.76±0.26 (6)
Ps/Post	34±4	33*	1.14±1.14	0.99±0.47 (14)
Ec/Peri	34±5	91	6.12±4.64+	0.88±0.19 (38)
Ec/Post	38±4	93	5.65±4.00	0.97±0.22 (39)

Table 1b. Effect of HRT and ALN (N=137)

Ps/PBO	30±9	38	1.36±1.06	0.86±0.36 (18)
Ps/ALN	32±6	29	0.75±0.58	0.86±0.35 (7)

Ec/HRT	30±10	61*	3.68±3.92*	0.71±0.24 (19)
Ec/ALN+HRT	33±9	12**	1.26±1.31*	0.58±0.25 (4)

Based on 2XL/BS and percentage of subjects with 2XL, the Ps envelope had a much lower bone formation rate than the Ec envelope both peri- and post-menopause. The percentage of women with Ps 2XL doubled transmenopausally, without a change at the Ec envelope. 2XL/BS in each envelope was constant. In PMO biopsies the Ps envelope again had a lower percentage of subjects with 2XL and lower 2XL/BS than the Ec envelope. HRT reduced the percentage with 2XL at both envelopes, while ALN reduces that percentage only at the Ec envelope. Both HRT and ALN reduce 2XL/BS at the Ec envelope. **Conclusion:** The TIBx Ps envelope forms bone much more slowly than the Ec envelope. HRT slows bone formation at both envelopes, while ALN does so only at the Ec envelope. These data suggest that estrogen deficiency onset is accompanied by increased periosteal expansion. They further suggest that ALN permits periosteal expansion to continue unabated, while HRT inhibits it.

Preventing the First Vertebral Fracture in Postmenopausal Women with Low Bone Mass Using PTH(1-84): Results from the TOP Study. S. L. Greenspan*[1], H. G. Bone*[2], T. B. Marriott*[3], J. R. Zanchetta*[4], M. P. Ettinger*[5], D. A. Hanley*[6], M. K. Drezner*[7], P. D. Miller*[8]. [1]University of Pittsburgh, Osteoporosis Prevention and Treatment Center, Pittsburgh, PA, USA, [2]Michigan Bone and Mineral Clinic, Detroit, MI, USA, [3]NPS Pharmaceuticals, Salt Lake City, UT, USA, [4]IDIM and USAL University, Buenos Aires, Argentina, [5]The Regional Osteoporosis Center, Stuart, FL, USA, [6]University of Calgary, Calgary, AB, Canada, [7]University of Wisconsin Medical School, Madison, WI, USA, [8]Colorado Center for Bone Research, Lakewood, CO, USA.

The occurrence of a first vertebral fracture may produce significant immediate morbidity, but clinical trials and population studies have also shown a vertebral fracture increases the risk of more vertebral fractures; these fractures have adverse implications for patients' long-term health. Reducing risk of first fracture in women with osteoporosis is an important goal. The Treatment of Osteoporosis with PTH (TOP) study, an 18-month, multinational, randomized, double-blind, placebo-controlled trial, assessed the effect of recombinant human PTH(1-84) on vertebral fracture incidence in postmenopausal women with osteoporosis. Analysis was by intent to treat (ITT), which included all randomized subjects with evaluable spine X-rays at 18 months. Subjects included postmenopausal women with low bone mass without (n=2056) and with (n=471) prevalent vertebral fracture (PVF) at baseline. Bone density criteria for entry without PVF were lumbar spine T-scores of ≤-3.0 (age 45-54 years), or ≤-2.5 (≥55 years). All subjects received calcium (700 mg/d) and vitamin D (400 IU/d) supplements. At 18 months, the incidence of vertebral fractures (total ITT) was 3.37% in placebo-treated subjects vs 1.32% in PTH(1-84)-treated subjects, a relative risk reduction (RRR) of 61%. In the ITT group without PVF, the incidence of new (first) vertebral fracture was 2.08% (placebo) and 0.67% (PTH(1-84)), a RRR of 68% (95% CI: 0.14-0.75, p=0.006). In the ITT group with a PVF, the incidence of new vertebral fracture was 8.94% (placebo) and 4.24% (PTH(1-84)), a 53% RRR (95% CI: 0.23-0.98, p=0.040). In general, PTH(1-84) therapy was well tolerated, with headache, dizziness, and nausea occurring with higher frequency in the PTH(1-84)-treated group than in the placebo-treated group. Although the incidence of hypercalcemia was higher (28.3% vs 4.7% in the placebo group), this led to discontinuation of therapy in only 0.5% of the PTH(1-84)-treated group (ITT). We conclude that PTH(1-84) therapy significantly reduces the incidence of vertebral fractures, and, in particular, significantly decreased the risk of first vertebral fracture in a population of postmenopausal women with osteoporosis defined by BMD.

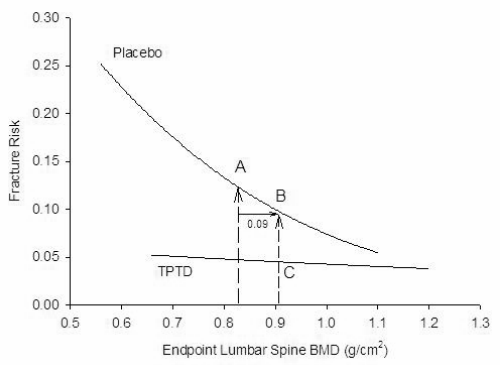
Change in Bone Mineral Density (BMD) and Fracture Risk Reduction in Teriparatide-Treated Women with Osteoporosis. P. Chen*[1], P. D. Miller[2], P. D. Delmas[3], D. A. Misurski*[1], J. H. Krege[1]. [1]Eli Lilly and Company, Indianapolis, IN, USA, [2]Center for Bone Research, University of Colorado, Denver, CO, USA, [3]Hopital Edouard Herriot, Claude Bernard University of Lyon, Lyon, France.

Changes in BMD account for a relatively small proportion of fracture risk reduction in patients treated with antiresorptive drugs.[1-3] The relationship between teriparatide (TPTD)-mediated increases in lumbar spine (LS) BMD and the risk of new vertebral fractures was assessed using data from the Fracture Prevention Trial. Postmenopausal women with osteoporosis (n=1637) were randomized to placebo or TPTD 20 or 40 mcg/day for a median 19 months.[4] LS BMD was assessed at baseline and 18 months. Vertebrae whose fracture status changed were removed from the present analysis. Baseline and endpoint lateral spine x-rays were assessed using a visual semiquantitative technique.[5] Both baseline BMD and BMD change were contributors to fracture risk. The mean increase in TPTD-treated patients was 0.09 g/cm^2. This increase was similar across tertiles of baseline BMD. Fracture risk was assessed using a logistic regression model. Factors included in the model were endpoint BMD, treatment (pooled TPTD versus placebo), and treatment-by-BMD interaction. All were statistically significant ($p < 0.05$). Compared to placebo, fracture risk was lower in the TPTD group for all endpoint BMD values, and the absolute risk reduction was significantly different across the range of endpoint BMD values (Figure).



In the figure, A-B and A-C represent fracture risk reductions associated with a 0.09 g/cm^2 increase in BMD alone and in response to TPTD, respectively. The proportion of TPTD-

mediated fracture risk reduction attributable to the increase in BMD can be estimated by (A-B)/(A-C). For "A" values from 0.7 to 0.9 g/cm^2, the proportion of TPTD-mediated fracture risk reduction attributable to a 0.09 g/cm^2 increase in BMD ranged from 30 to 41%, respectively. The remainder of vertebral fracture risk reduction with TPTD was due to improvements in other non-BMD determinants of bone strength.

Indications for Spinal Radiography in Postmenopausal Women. L. Ferrar[1], D. Felsenberg*[2], C. Roux*[3], D. M. Reid*[4], C. C. Gluer*[5], G. Armbrecht*[2], T. Blenk*[2], R. Eastell[6]. [1]Division of Clinical Sciences (N), University of Sheffield, Sheffield, United Kingdom, [2]Free University, Berlin, Germany, [3]Descartes University, Paris, France, [4]University of Aberdeen, Aberdeen, United Kingdom, [5]University Hospital, Schleswig Holstein, Kiel, Germany, [6]Division of Clinical Sciences (N), University of Sheffield, UK, Sheffield, United Kingdom.

Prevalent vertebral fracture is a powerful predictor of future fracture risk. The aim of this analysis was to evaluate a range of risk factors that could be used as indicators for referral for spinal radiography. The study subjects were postmenopausal women participating in a population-based study of osteoporosis (n = 2374). Vertebral fractures (VFs) were identified from spinal radiographs (vertebral height ratio < 0.80 and differential diagnosis by radiologist) in 378 women. Risk factors tested were older age (≥65 and ≥70 years), height (stature) loss≥4 cm since age 25 years, history of low-trauma non-vertebral fracture (non-VF), bone mineral density (BMD) T score ≤-2.5 (spine or total hip) and corticosteroid use (≥5 mg/day for ≥6 months). These were tested individually for discrimination of women with VFs (chi-squared test), then together by logistic regression (with separate analyses for the 2 age thresholds). Receiver Operator Characteristic (ROC) analysis was used to evaluate the discrimination of women with VF by one or more of the significant risk factors from the logistic regression model. For individual risk factors, odds ratios for VF were 4.0 and 2.9 (T ≤-2.5 at hip and spine), 1.9 (history of non-VF), 1.9 and 1.8 (age≥65 and ≥70 years), 1.6 (height loss ≥4 cm) and 0.9 (corticosteroid use). Significant risk factors from logistic regression were BMD T score ≤-2.5 (hip or spine), history of non-VF and age (≥65 or ≥70 years). Results for analysis of one or more significant risk factors are shown below in the table. Only 131 (35%) of women with VF would have been diagnosed with osteoporosis on the basis of BMD measurements alone.

	One or more significant risk factor		
	Age excluded	Including age ≥65 years	Including age ≥70 years
VF-positive [negative] (n)	211 [628]	304 [1262]	274 [1034]
Sensitivity [specificity] (%)	56 [69]	80 [37]	73 [48]
Positive predictive value	25.1	19.4	20.9
Odds ratio	1.6	2.4	2.5
Area under curve	0.62	0.59	0.60
95% CI	0.60, 0.64	0.57, 0.61	0.58, 0.62

We conclude that referral for VFA on the basis of axial BMD T score ≤ -2.5, history of low trauma non-vertebral fracture or age ≥65 years could identify around three-quarters of postmenopausal women with vertebral fracture.

GLP-2 Administration Attenuates Nocturnal Bone Resorption in Postmenopausal Women: A 14-Day Study. D. B. Henriksen[1], P. Alexandersen*[2], B. Hartmann[1], C. Adrian*[1], I. Byrjalsen*[3], J. J. Holst*[4]. [1]Sanos Bioscience A/S, Herlev, Denmark, [2]Center for Clinical and Basic Research A/S, Vejle, Denmark, [3]Nordic Bioscience A/S, Herlev, Denmark, [4]Medical Physiology, University of Copenhagen, Copenhagen, Denmark.

The gastrointestinal hormone, glucagon-like peptide-2 (GLP-2) has been suggested to be involved in an entero-osseous axis, which coordinates bone resorption in response to nutrient intake. We have located the GLP-2 receptor on osteoclasts and shown that GLP-2 exposure to osteoclasts in culture leads to a dose related reduction in bone resorption. Likewise, subcutaneous injection of GLP-2 in healthy postmenopausal women results in a dose related reduction in bone resorption as assessed by fragments derived from collagen type I, (CTX-I). Bone formation, as assessed by osteocalcin, was unaffected by the exogenous GLP-2 treatment. The objective of the study was to investigate whether the previously found single-dose effects of GLP-2 on the biochemical markers of bone turnover persist and are reproducible during continued daily administration. Nocturnal increase in bone resorption reflects the highest activity level of the osteoclasts. The current study was designed to evaluate the effect of exogenous GLP-2 on bone turnover in healthy postmenopausal women after one daily administration of GLP-2 at bedtime (10 p.m.) during a 2-week treatment period. This was a randomised, double-blind, placebo-controlled, parallel group, and dose-ranging study in 60 healthy postmenopausal women. Twenty subjects were randomised to each treatment group to receive treatment with daily doses of 1.6 or 3.2 mg of GLP-2, or placebo. We found an acute and sustained reduction of bone resorption after GLP-2 injection as compared to placebo for both 1.6 and 3.2 mg groups. This effect was similar at Day 1 and Day 14. The baseline normalised area under the curve ($AUC_{0\text{-}6h}$) for the 6-hour profile of s-CTX was highly statistically significant different from placebo (P<0.0001) for both 1.6 and 3.2 mg GLP-2 groups and there were no statistically significant difference in the effect between Day 1 and Day 14. Thus, the effect seen at Day 1 was sustained after 14 days of treatment with GLP-2. Bone formation (osteocalcin) level was unaffected by treatment with GLP-2. The drug substance was well tolerated and none of the subjects developed antibodies against GLP-2. No serious adverse events were reported by the investigators, which could be attributed to the GLP-2 drug substance. In conclusion, these observations suggest that GLP-2 might be useful as a pharmacological agent for the un-coupling of the bone turnover processes. Further studies are warranted to determine the putative anti-osteoporotic effect of GLP-2.

RANKL Inhibition Improves Cortical Bone Geometry by Stimulating Periosteal Bone Formation in Orchiectomized Rats. X. Li, Z. Geng*, S. Kaufman*, H. L. Tan*, S. Morony*, M. Grisanti*, K. Hoffmann*, M. Ominsky, P. J. Kostenuik. Amgen, Thousand Oaks, CA, USA.

In cynomolgus monkeys, the RANKL inhibitor, OPG, increases cortical thickness and periosteal circumference. This periosteal expansion increases bone strength index by virtue of improvements in the cross-sectional moment of inertia (CSMI). The mechanism by which RANKL inhibition leads to cortical expansion is unclear. We examined the effects of OPG on cortical geometry and periosteal bone formation in a model of cortical osteopenia caused by androgen ablation**.** Three-month-old rats were either sham-operated (Sham) or orchiectomized (ORX). ORX rats were treated with PBS or OPG (10 mg/kg, twice/week SC, n=10-11/group) beginning immediately after the surgery. Periosteal and endocortical diameters at the femoral shaft were collected in a blinded manner from digital X-rays after 6 weeks of treatment. PBS-treated ORX rats had 9% and 12% decreases in periosteal and endocortical diameters, respectively (p<0.01 vs Shams). These changes resulted in a 27% decrease in CSMI (p<0.01 vs Shams). OPG-treated ORX rats had significantly greater periosteal (6%) and endocortical diameters (8%) than PBS-treated ORX rats. These OPG-induced changes led to a 16% increase in CSMI (p=0.06 vs PBS-ORX rats). Dynamic histomorphometry of the femoral shaft provided mechanistic insights into these geometric changes. Orchiectomy led to a significant (38%) reduction in periosteal bone formation rate (BFR) and a significant increase (133%) in endocortical BFR. These changes would contribute to reductions in periosteal and endocortical diameters. OPG caused a significant (33%) increase in periosteal BFR and a significant (142%) reduction in endocortical BFR. These changes returned periosteal and endocortical diameters in ORX rats to levels similar to Shams. OPG also caused significant improvements in cancellous bone. PBS-ORX rats had significant (67%) reductions in bone volume (BV/TV) at the distal femur. OPG treatment significantly reduced osteoclast surface by 67% and increased BV/TV by 107%. DXA showed that OPG increased distal femur BMD by 18% (p<0.05 vs PBS-ORX). In summary, androgen ablation in rats results in significant cortical and cancellous osteopenia. Cortical osteopenia was associated with reduced periosteal bone formation and a reduced CSMI. OPG treatment prevented these changes and restored cortical and cancellous bone mass to Sham levels. These data suggest that OPG improves cortical bone geometry and increases CSMI by stimulating periosteal apposition. RANKL inhibition therefore appears to be a promising therapeutic approach for preventing the loss of both cortical and trabecular bone after androgen ablation.

Age- and Dose Dependent Effects of Hormone Replacement Therapy on Fracture Risk on the Population Level. P. Vestergaard, L. Rejnmark, L. Mosekilde. The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark.

Purpose: To assess the fracture preventive effects of hormone replacement therapy in different age groups and in different dosages in postmenopausal women. Methods: Population based case-control study. Cases were all women who sustained any fracture during the year 2000 in Denmark (n=64,548). For each case, three controls (n=193,641) matched on age were randomly drawn from the background population. Exposure was use of hormone replacement therapy (HRT) from 1996 to 2000. Adjustments were made for socio-economic factors, comorbidity, and use of other bone active drugs. The effect of HRT dose was examined by stratifying for average daily dose (DDD: defined daily dose). Results: A fracture reduction was only seen in women aged ≥50 years. A fracture risk reduction was seen in women using ≥0.3 DDD/day, i.e. in women using less than the recommended daily dose (1 DDD/day). The risk reduction for any fracture was larger in women aged ≥60 years (0.3-0.99 DDD/day: OR=0.77, 95% CI: 0.73-0.82, ≥1 DDD/day: OR=0.61, 95% CI: 0.56-0.67) than in women aged 50-59 years (0.3-0.99 DDD/day: OR=0.92, 95% CI: 0.85-0.99, ≥1 DDD/day: OR=0.77, 95% CI: 0.70-0.84). Larger risk reductions were seen for Colles' fractures (age 50-59 years: OR=0.64 for 0.3-0.99 DDD/day, and OR=0.57 for 1≥ DDD/day, age ≥60 years: OR=0.52 for 0.3-0.99 DDD/day, and OR=0.40 for ≥1 DDD/day). For hip fractures the risk reduction was as follows: age 50-59 years: OR=0.56 for 0.3-0.99 DDD/day, and OR=0.48 for ≥1 DDD/day, age ≥60 years: OR=0.77 for 0.3-0.99 DDD/day, and OR=0.64 for ≥1 DDD/day. Upon adjustment for socio-economic variables, comorbidity, and use of other bone active drugs, the risk reduction was even larger. Conclusions: Hormone replacement therapy posses a large fracture-reducing potential at population level even at dosages lower than usually recommended. This may be useful when trying to tailor estrogen-based therapies not associated with an increased risk of breast cancer and other adverse effects. The risk reduction was larger with advancing age for any fracture and Colles' fracture, while the opposite was the case for hip fractures. Differences in distribution of trabecular and cortical bone may be responsible for this.

Connexin43 Is Required for a Full Osteoanabolic Response to Parathyroid Hormone. D. Chung[1], R. Civitelli[2]. [1]Internal Medicine, Chonnam National University Med. Sch., Gwangju, Republic of Korea, [2]Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

Parathyroid hormone (PTH) is currently used as anabolic therapy for osteoporosis, although its mechanism of action is not fully clarified. Previous in vitro work suggests that PTH action on bone cells requires connexin43 (Cx43) gap junctional communication. To test the role of Cx43 in PTH anabolic response we used mice with a selective osteoblast ablation of the Cx43 gene, obtained using a *Cx43^{flox}* allele and a 2.3 kb fragment of the α_1*(I) collagen* promoter to drive Cre in osteoblasts (Col-Cre). Adult (5- to 8-month-old) mice of three genotypes, *Cx43$^{+/flox}$* (wild type equivalent), *Cx43$^{-/flox}$* (heterozygous equivalent) and *Col-Cre:Cx43$^{-/flox}$* (conditional knockout) were injected subcutaneously (5 days a week for 4 weeks) with either vehicle (saline) or 40 μg/kg b.w. PTH (1-34) (teriparatide, Eli-Lilly; n=12 or more per group). Untreated *Col-Cre:Cx43$^{-/flox}$* mice develop low peak bone mass, attended by delayed osteoblast differentiation, and remain osteopenic with age. After 4 weeks of PTH treatment, whole body bone mineral content increased rapidly and progressively in the *Cx43$^{+/flox}$* group (12.5±4.7% vs. baseline), an effect significantly attenuated in *Col-Cre:Cx43$^{-/flox}$* mice (6.7±5.3%), whereas *Cx43$^{-/flox}$* exhibited an intermediate response (9.3±4.6%). While this attenuated response was overcome by PTH 80 μg/kg b.w. in *Cx43$^{-/flox}$* mice, a full response was never obtained with higher doses of PTH in *Col-Cre:Cx43$^{-/flox}$* mice. Attenuation of PTH anabolic action was associated with reduced mineral apposition rate in *Col-Cre:Cx43$^{-/flox}$* relative to *Cx43$^{-/flox}$* and *Cx43$^{+/flox}$* mice (tibia: 0.4±0.3, 1.5±0.2, 1.6±0.5 μm/day; spine: 0.4±0.2, 1.2±0.1, 1.7±0.2 μm/day, respectively). Other histomorphometric parameters of osteoblast activity were similarly reduced in osteoblast Cx43-deficient mice, whereas no evidence of increased osteoclast activity was noted in any genotypes. Regional DEXA analysis revealed that attenuation of PTH response in *Col-Cre:Cx43$^{-/flox}$* mice was far more pronounced in the lumbar spine (primarily trabecular) than in the whole femur (primarily cortical). Consistent with these findings, 3-D vertebral bone mass by μCT was lower in PTH treated *Col-Cre:Cx43$^{-/flox}$* relative to *Cx43$^{-/flox}$* and *Cx43$^{+/flox}$* mice (499.0±51.0, 517.6±32.6, and 561.6±46.3 g/cm^3). In conclusion, lack of Cx43 in osteoblasts hinders the bone anabolic effect of PTH. This resistance is the consequence of failure to mount a full osteoblast response to the hormone, which is more apparent in trabecular than in cortical bone. Thus, osteoblast Cx43 has an instrumental role in the mechanism of PTH osteoanabolic action in vivo.

Paternal Skeletal Size Predicts Neonatal Bone Mineral Accrual. N. C. W. Harvey[1], M. K. Javaid[1], P. Taylor*[2], S. R. Crozier*[1], E. M. Dennison*[1], H. M. Inskip*[1], K. M. Godfrey*[1], C. Cooper[1]. [1]MRC Epidemiology Resource Centre, Southampton, United Kingdom, [2]Medical Physics and Bioengineering, Southampton General Hospital, Southampton, United Kingdom.

We have previously demonstrated that maternal body build and lifestyle factors predict neonatal bone mineral accrual. However, the paternal determinants of neonatal bone mass remain little known. In this study we explored the relationship between a father's bone mass and that of his offspring. 280 pregnancies were recruited from the Southampton Women's Survey, a unique, well established cohort of women, aged 20-34 years, who had been assessed before and during early and late pregnancy. The neonates underwent whole body DXA within 20 days of birth; at this time the fathers were invited to undergo a whole body DXA scan using an Hologic Discovery instrument. Multivariate regression methods were used to explore the parental determinants of neonatal bone mass. Full ethical approval was given for this study. After adjustment for the father's age, and the baby's gestational age, sex and age at DXA scan, there were highly significant positive associations between baby's whole body bone area (BA), bone mineral content (BMC), and bone mineral density (BMD), and the corresponding indices in the father (p=0.009, 0.001, 0.03 respectively- table 1). When mother's height, body composition (fat mass estimated from skin folds), smoking, and calcium intake were included in multivariate regression models of father's DXA indices, the associations for paternal variables remained statistically significant (BA: p=0.02, BMC: p=0.002, BMD: p=0.04). Thus father's skeletal size predicts skeletal size in the offspring, independently of the mother's body build and lifestyle. These data point to the importance of considering paternal genotype in studies exploring the developmental origins of adult osteoporotic fracture. Table 1

		Baby

Effects of Skeletal and Sexual Maturation on Trabecular and Cortical Density of the Peripheral Skeleton. B. Zemel[1], H. Kalkwarf[2], M. Leonard[1], J. Shepherd[3], S. Mahboubi*[1], M. Frederick*[4], K. Winer*[5]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Cincinatti Children's Medical Center, Cincinatti, OH, USA, [3]University of California San Fransisco, San Fransisco, CA, USA, [4]Clinical Trials & Survey Corporation, Baltimore, MD, USA, [5]National Institue of Child Health and Human Development, Rockville, MD, USA.

Determining the effects of maturational processes on bone density compartments is important for understanding the factors that influence the development of the adult skeleton. It may also reveal growth-related periods of vulnerability in healthy children. This study describes the relations between sexual and skeletal maturation and trabecular and cortical volumetric BMD (mg/cm^3) in the distal radius and tibia, as measured by peripheral quantitative computed tomography in a subset healthy children, 6 to 17 years of age, from the multi-center Bone Mineral Density in Childhood Study. 159 children (43% black, 51% female) were evaluated at baseline and 12 months. Trabecular BMD was measured at the 3% radius and tibia sites. Cortical BMD was assessed at the 30% radius and 38% tibia sites. Bone age was evaluated by hand-wrist x-ray and sexual maturation by physical exam. Self-identified race was coded as black vs non-black. Mixed effects models were used to evaluate the effects of skeletal and sexual maturation on BMD. Polynomial terms were included to account for the distinct increase in cortical BMD that occurred at older ages. Overall, bone age was a better predictor of cortical BMD than chronological age. R^2 values for tibia cortical BMD increased from 0.19 to 0.31 for males and from 0.61 to 0.70 for females when bone age was used. R^2 values for radius cortical BMD increased from 0.37 to 0.40 for males and from 0.70 to 0.78 for females when bone age was used. Tibia cortical BMD models with bone age were improved by the addition of race for females (R^2=0.76), and race and testes size for males (R^2=0.45). Radius cortical BMD for males was best explained by bone age and race for males (R^2 =0.46), and for females, just by bone age. Radius trabecular BMD was best explained by testes size and black ethnicity for males (R^2=0.06), and by race for females (R^2=0.15). Tibia trabecular BMD was best explained by chronological age in males (R^2=0.09) and breast stage and black ethnicity for females (R^2=0.34). These findings demonstrate that (1) cortical BMD changes developmentally, with a rapid increase in late adolescence; (2) bone age is a better predictor of cortical BMD than chronological age; (3) skeletal maturation explains a greater amount of variance in BMD for females compared to males; and (4) the effects of puberty on trabecular and cortical BMD may be site and gender dependent.

Bone Mass Accrual Is Modulated by IGF-I and Muscle Mass in Pubertal Girls: A Two Year Follow-Up Study. R. Zhao*[1], M. Alen*[1], A. Mahonen*[2], S. Sipilä*[1], T. Finni*[1], R. Wang*[3], U. Kujala*[1], S. Cheng[1]. [1]Univ. of Jyväskylä, Jyväskylä, Finland, [2]Univ. of Kuopio, Kuopio, Finland, [3]Shanghai Institute of Physical Education, Shanghai, China.

The study aim was to investigate whether bone mass/density is associated with increased serum insulin-like growth factor-I (IGF-I) and muscle mass/size in 258 healthy Finnish girls (age 11-13 yrs). Bone cross-sectional area (BCSA), mineral content (BMC), density (BMD), muscle cross-sectional area (MCSA), and muscle mass (MM) were assessed using peripheral quantitative computed tomography (pQCT) at left lower leg (including fibula and tibia), and IGF-I by radioimmunoassay at the baseline, 12 months and 24 months. We found that IGF-I increased rapidly up to the menarche and decreased thereafter (hierarchical mode analysis taking into account growth). IGF-I correlated with BMC (r=0.29, p<0.001) and BMD (r=0.19, p=0.049) before menarche, but not after menarche (multilevel regression). The speed of growth of MCSA, MM, BCSA, and BMC tended to slow down after menarche, but BMD was continuously increased. BCSA and BMC correlated with MCSA and MM significantly both before (r=0.30, p<0.001; r=0.28, p=0.016, respectively) and after menarche (r=0.21, p=0.033; r=0.23, p=0.03, respectively). The effect of IGF-I on bone mass and density seems to be stronger prior to menarche, while muscle mass is associated with bone mass and size accrual during whole puberty.

Sex Hormone-Related Polymorphisms as Predictors of Adult Stature in Swedish Men - ***The GOOD Study.*** M. Lorentzon, D. Mellström, C. Ohlsson. Center for Bone Research at the Sahlgrenska Academy, Departments of Internal Medicine and Geriatrics, Gothenburg University, Gothenburg, Sweden.

The regulation of longitudinal bone growth depends primarily on genetic factors, hormone status (thyroid hormones, GH/IGF-I and sex steroids), and environmental determinants such as nutrition. Androgens and estrogens are crucial for longitudinal bone growth and skeletal maturation in males. However, the relationship between polymorphisms in genes of the sex hormone system and adult stature remains unclear. The aim of the present study was to investigate the importance of sex hormone-related polymorphisms for the attainment of adult stature and skeletal proportions (the axial and appendicular skeleton) in 1068 men (age 18.9±0.6 yrs) included in the Gothenburg Osteoporosis and Obesity Determinants (GOOD) study. We investigated, in a systematic manner, 18 previously described sex hormone-related polymorphisms (1-5 polymorphisms in each gene; sex steroid synthesis - *aromatase/CYP19, CYP17, 5-α-reductase*; sex steroid degradation - *CYP1A1, CYP1B1, COMT*; in the receptors for estrogens - *ERα and ERβ* and for androgens - *AR*; and in the sex hormone binding protein - *SHBG*). Two of these polymorphisms were clearly associated with final height: (1) the repeat sequence (CAG) polymorphism in the first exon of the AR and (2) the repeat sequence (TAAAA) polymorphism in the 5' promoter region of SHBG. The length of the tibia (appendicular skeletal site), sitting height (axial skeletal site) and final height were measured using standardized equipment. The $(CAG)_n$ polymorphism in the AR and the $(TAAAA)_n$ polymorphism in SHBG were determined using an ABI 3730 sequencer. The repeat number of the AR polymorphism has previously been shown to be inversely correlated to the AR activity. Our results reveal that the repeat number of the $(CAG)_n$ polymorphism of the AR was inversely correlated to height (r= -0.07, p=0.02), sitting height (r= -0.07, p=0.04) and tibia length (r= -0.07, p=0.04), but not with serum sex hormone levels. The SHBG repeat polymorphism was clearly associated with serum levels of SHBG (r= -0.13, p<0.0001), total testosterone (r= -0.08, p=0.01) and with length of the tibia (r= -0.08, p=0.02), sitting height (r= -0.09, p<0.01) and adult stature (r=-0.08, p=0.02). Our results indicate that a high CAG repeat number in the AR (resulting in lower AR activity) or a high TAAAA repeat number of the SHBG gene (resulting in lower SHBG levels) negatively influences final height as a result of both reduced axial and appendicular skeletal growth. In conclusion, our screening of most of the known major sex-steroid-related polymorphisms, identified two genetic polymorphisms associated with final height in men.

DLX5 Is Responsible for Cooperative Interactions between BMPs and RUNX2. M. Phimphilai*[1], H. Roca*[2], R. T. Franceschi[3]. [1]Biological Chemistry; Metabolism, Endocrinology and Diabetes, University of Michigan, Ann Arbor, MI, USA, [2]Periodontics, Prevention and Geriatrics, University of Michigan, Ann Arbor, MI, USA, [3]Periodontics, Prevention and Geriatrics; Biological Chemistry, University of Michigan, Ann Arbor, MI, USA.

BMPs are potent osteogenic factors that stimulate osteoblast differentiation and bone formation. BMPs are known to induce expression of RUNX2/CBFA1 and DLX5 transcription factors. Because overexpression of RUNX2 induces osteoblast-related genes and mineralization, as well as facilitates bone formation by non-osteoblast cell lines, it has been proposed that this factor mediates actions of BMPs in stimulating osteoblast differentiation. However, BMP treatment of calvarial-derived cells from *Cbfa1*-deficient mice still leads to modest induction of osteoblast markers suggesting that some actions of BMPs are independent of RUNX2 (Komori et al, 1997, Cell 89:755). Previous worked from our laboratory showed that adenovirus-mediated overexpression of RUNX2 and BMP2 synergistically stimulated osteoblast differentiation. In this study, we examine this synergy in greater detail and explore downstream signaling events responsible for the complementary function between these two factors. BMP blocking antibodies and Noggin dramatically inhibited RUNX2-dependent induction of osteoblast differentiation markers (ALP, OCN and BSP). Moreover, recombinant human BMP2 synergistically enhanced RUNX2 actions. Our results indicate that BMP activity is necessary for RUNX2-dependent transcription and that RUNX2 and BMPs cooperatively interact to stimulate osteoblast differentiation. Interestingly, the ability of BMP2 to stimulate downstream signal transduction pathways (Smad 1,5,8 and p38, JNK and ERK MAPK pathways) was not affected by RUNX2. In contrast, BMP2 and RUNX2 synergistically induced DLX5 expression and this induction preceded induction of *Ocn* and *Bsp* genes. ChIP assays revealed that DLX5 preferentially associated with chromatin in the vicinity of RUNX2 binding sites in both *Bsp* and *Ocn* promoters only when both genes were transcriptionally active. A co-immunoprecipitation assay detected a physical interaction between RUNX2 and DLX5. Site-specific mutagenesis studies on the *Bsp* promoter demonstrated functional cooperativity between the RUNX2 site and adjacent DLX5 binding site in MC3T3-E1 cells. Taken together, our results suggest that DLX5 functions in concert with RUNX2. In conclusion, RUNX2 and BMPs cooperatively function in stimulating osteoblast differentiation and the orchestrated function between RUNX2 and DLX5 may lead to the functional cooperativity between these two factors.

BMP Antagonist Caf1, which Suppresses BMP-Induced Bone Formation and MAR, Is Expressed in Chondrocytes, Ovary and Brain. K. Oikawa[1], T. Nakamura*[2], M. Usui[1], I. Ishikawa*[3], T. Yamamoto*[2], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]University of Tokyo, Tokyo, Japan, [3]Periodontology, Tokyo Medical and Dental University, Tokyo, Japan.

Bone mass is determined based on the interactions among stimulators and suppressors for bone formation and bone resorption. Caf1 (CCR4- associated factor 1) is a transcription factor (Nature Genetics, 2004) which associates with Tob. Tob antagonizes BMP actions in vivo (PNAS 2004, Cell 2000). Like Tob, Caf1 suppressed BMP-induced bone formation in vivo, the levels of mineral apposition rate, bone formation rate, BMP-induced alkaline phosphatase expression in vitro and nodule formation activities in vitro. Moreover, Caf1 deficiency preserved bone mass even after ovariectomy, indicating that Caf1 is involved in bone mass determination as a BMP antagonist in adult bone in the ovariectomized mice. We have further examined the localization of the Caf1 expression using LacZ makers in Caf1 knockout mice and observed that Caf1(LacZ) expression in bone as well as the growth plate cartilage. Within the cartilaginous tissues, LacZ expression could be observed in articular chondrocytes as well as proliferating, prehypertrophic, and hypertrophic chondrocytes in long bone. LacZ expression in Caf1 knockout mice was also observed in mandibular bone suggesting the role of Caf1 in bone in oral tissue. Interestingly, Caf1 was also highly expressed in brain especially in the cortical regions in embryos and adult mice. Since Caf1 deficiency reduces bone loss due to ovariectomy, we tested whether Caf1 is expressed in endocrine system. Although uterus weight was reduced similarly by ovariectomy in both wild type and Caf1 knockout mice, Caf1 (LacZ) was highly expressed in ovary. Within the ovary, Caf1 (LacZ) is expressed at low levels in most of the cells. However, highest Caf1 expression based on the LacZ staining was observed in oocytes. These data indicate that Caf1 is involved in the adult bone mass determination by antagonizing BMP activities in osteoblastic cells while it is also expressed highly in chondrocytes as well as extraskeletal tissues including brain and ovary suggesting its multiple roles in the mediation of a neuronal and endocrine signaling that may be linked to bone signaling.

Vascular Calcification (VC) Stimulated by Chronic Kidney Disease (CKD) Is Reversible Linked to Stimulation of Skeletal Modeling. G. Saab*[1], S. Mathew*[2], L. Chaudhary[2], K. A. Hruska[2]. [1]Internal Medicine, Washington University, St. Louis, MO, USA, [2]Pediatrics, Washington University, St. Louis, MO, USA.

VC is an important cause of morbidity and mortality in CKD, for which no therapy is available. We have shown that CKD stimulates neointimal and medial VC in low density lipoprotein receptor deficient (LDLR-/-) mice fed high fat/cholesterol diets over a 12 week course from 10 to 22 weeks of age. In the studies reported here, VC was allowed to develop for the 12 week period and treatment with BMP-7, 10 mcg/kg, or vehicle injected intraperitoneal once weekly from 22 to 28 weeks was begun. The hypothesis was that BMP-7 would reverse VC produced by CKD in this model. CKD was induced in 10 week old LDLR-/- mice by cautery of the right kidney followed by left nephrectomy, and animals were randomized into groups. One CKD group fed high fat/cholesterol was sacrificed at 22 weeks to determine baseline aortic calcification. At 28 weeks the aorta was removed, desiccated and calcium content determined using a cresolphthalein complexone method, (Sigma, St. Louis, MO). Renal function assessed by the serum BUN was 19±3mg/dl in wild type mice, 21±6 in sham operated mice, and similar between the CKD groups, 64±25mg/dl. In CKD high fat fed BMP-7 treated animals the serum PO4 was 10.1±0.02mg/dl before treatment and 6.2±0.02 at sacrifice. Ca, PTH, cholesterol and glucose levels were not affected by treatment. Skeletal histomorphometry revealed the adynamic bone disorder in the CKD high fat vehicle treated animals. Calcein labeled surfaces and adjusted apposition rates indicative of increased BMU's were stimulated by BMP-7 therapy. There was no increase in renal PO4 excretion. Finally, treatment with BMP-7 decreased aortic calcification in both the sham operated animals fed high fat and in animals with CKD by 40 and 45% respectively ($p<0.05$ for both). Groups of animals treated with CaCO3 to directly decrease the serum phosphorus were employed in the same protocol to further analyze the effect of serum phosphorus reduction. These groups demonstrated about 50% of the reduction in vascular calcification observed with the BMP-7 treatment. We conclude that there is a pathological link between abnormal bone mineralization and vascular calcification mediated in part by high phosphorus environments. By increasing skeletal deposition of phosphate, BMP-7 reduces serum PO4 which in turn inhibits vascular calcification. Thus, BMP-7 may represent a novel therapy for vascular calcification and renal osteodystrophy.

Osteoblastic Differentiation of Human Aortic Vascular Smooth Muscle Cells (VSMC) and Mineralization *In Vitro*. S. Mathew*, T. Geurs*, K. A. Hruska. Pediatrics, Washington University, St. Louis, MO, USA.

In patients with chronic kidney disease calcification of the aortic tunica media is associated with a high risk of adverse clinical events. Evidence has accumulated suggesting that vascular calcification (VC) is a regulated process akin to bone formation. Currently, no therapy is available for VC. Recently, we have shown that BMP-7 inhibits VC in a murine model of the metabolic syndrome and CKD with atherosclerosis and arteriosclerosis. Furthermore, a marker of the osteoblastic lineage, osteocalcin was inhibited by BMP-7 in the VMSC *in vivo*. Our central hypothesis is that BMP-7 will restore the differentiated phenotype of VSMC and inhibit calcification. To analyze the mechanism of BMP-7 action, we established a model of human calcifying VSMC obtained from the aortas of cadaver organ donors with atherosclerosis by increasing media phosphorus (Pi) from 1 to 2 mM. High Pi induced BMP-2, MSX2 and Cbfa1 expression. Osterix and osteocalcin expression and matrix mineralization followed by days 7 to 14. The mineralization was due to hydroxyapatite nodules. High Pi decreased matrix Gla protein levels, along with markers of the contractile VSMC phenotype. Treatment with BMP-7 dose dependently prevented calcification by VSMC. Cbfa1, MSX2, Osterix and Osteocalcin expression were inhibited by BMP-7 in a similar dose response as mineralization. Matrix Gla protein levels were induced by BMP-7. The earliest osteoblast specific transcription factor, Cbfa1, was expressed and regulated by phosphorus and decreased with BMP-7. Since Cbfa1, MSX2 and osterix are critical transcription factors for bone formation as demonstrated by mice deficient in any of the three proteins *in vivo*, we conclude that the mechanism of BMP-7 action is through inhibition of osteoblastic specific gene transcription. This is the first demonstration that BMP-7 inhibits calcification stimulated by VSMC *in vitro* by inhibition of the calcifying cell phenotype through downregulation of osteoblast specific genes despite upregulation of the same transcriptional program in human bone marrow stromal cells.

Mineral Nucleation within Biomineralization Foci Requires Serine Protease Activation of Bone Acidic Glycoprotein-75. N. T. Huffman*[1], D. Lovitch[2], R. J. Midura[3], J. P. Gorski[1]. [1]Molecular Biology and Oral Biology, Univ. of Missouri-Kansas City, Kansas City, MO, USA, [2]Oral Biology, Univ. of Missouri-Kansas City, Kansas City, MO, USA, [3]Biomedical Engineering, Cleveland Clinic and Foundation, Cleveland, OH, USA.

We have shown that nucleation of mineral crystals within developing primary bone and in common osteoblastic culture models occurs within supramolecular, extracellular, matrix vesicle containing complexes termed biomineralization foci (BMF). Proteomic analysis of laser captured BMF indicates specific enrichment of a 50 kDa fragment of bone acidic

glycoprotein-75 (BAG-75), which is also extractable from primary bone and present in serum. BAG-75 is a BMF biomarker. We hypothesized that proteolytic cleavage of BAG-75 into bioactive fragments may be required both for its uptake into BMF and its proposed function as an initiator of nucleation. To test this hypothesis, we first analyzed a series of protease inhibitors for their effect on mineralization in UMR 106 osteoblastic cultures. UMR cells mineralize rapidly over a 24 h culture period in the presence of ß-glycerophosphate (BGP) (64 to 88 h after plating). Inhibitors were therefore present during the entire 24 h mineralization period. Of the inhibitors tested, only AEBSF [4-(2-aminoethyl)-benzenesulfonyl fluoride hydrochloride] (0.1-0.4 mM) was found to completely block mineralization, as determined by quantitation of Alizarin red S staining. Parallel studies with a cell proliferation assay demonstrate this was not due to an effect on viability. In contrast, 100 μM antipain, 10 μM E-64, 100 μM elastatinal, 10 μM GM 6001, 100 μM leupeptin, 100 μM Pefabloc PL or 3 µg/ml aprotinin were all without effect. Although spherical BMF-like structures were visible by bright field microscopy in AEBSF-treated cultures, they failed to stain for BAG-75 suggesting a failure in uptake of BAG-75. This was not due to reduced synthesis of BAG-75 as an 8-fold increase in BAG-75 was detected in the culture media. In contrast, cell layer fractions from control BGP-treated cultures contained a 20 kDa fragment of BAG-75 which was absent from AEBSF-treated cultures. The size and bone sialoprotein content of BMF was also decreased by AEBSF. Direct fluorescent assays of total protease activity revealed about 10% of the activity in mineralizing UMR cultures was inhibitable by AEBSF. Our results demonstrate for the first time that initial nucleation of mineral within BMF can be blocked by serine protease inhibitor AEBSF. Mechanistically, AEBSF prevents BAG-75 fragmentation with the result that final assembly of BMF is inhibited. We hypothesize that mineralization within BMF is a sequential process requiring serine protease-catalyzed activation of BAG-75.

CNP/Guanylyl Cyclase B (GC-B) System Regulates Endochondral Ossification - The Analysis of GC-B Null Mice. Y. Komatsu, A. Yasoda*, N. Tamura*, Y. Nakatsuru*, H. Arai*, K. Nakao*. Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.

C-type natriureteic peptide (CNP) regulates the endochondral ossification by binding guanylyl cyclase B (GC-B) expressed on the proliferative and prehypertrophic chondrocytes in the growth plate. We recently reported that the GC-B$^{-/-}$ mice exhibit the dwarfism with short body length and extremities, exactly same as CNP$^{-/-}$ mice. Furthermore, in the rare autosomal recessive genetic skeletal abnormality, known as acromesomelic dysplasia, type maroteaux, the missense mutations of GC-B were also reported. To investigate the function of CNP/GC-B system in endochondral ossification, we studied the interaction between CNP/GC-B system and FGFR-3, whose constitutive activation is responsible for achondroplasia, using GC-B$^{-/-}$ mice. The naso-anal lengths of GC-B$^{-/-}$ mice were 60 to 70% of wild type littermates at 4 to 10 weeks of age. Histologically, GC-B-/- mice display striking narrowing of the growth plate of vertebrae and long bones. In situ hybridization revealed that both prehypertrophic and hypertrophic chondrocytes layers, expressing type II and type X collagens, respectively, were narrowed, but the normal columnar organization of the growth plate was maintained. The CNP-dependent production of cGMP was undetected in the tibia from GC-B$^{-/-}$ mice. The 8-bromo-cGMP dose-dependently inhibited the induction of ERK phosphorylation induced by FGF18 without changing the level of FGFR-3, although it did not affect the phosphorylation of STAT-1 in the tibia from both GC-B$^{-/-}$ mice and wild type littermates. CNP did not show any effect either on ERK or STAT-1 phosphorylation in those of GC-B$^{-/-}$ mice. These results explain one of the molecular mechanisms of the growth stimulating action of CNP/GC-B system in the growth plate chondrocytes.

A 300 bp of Mouse Col10a1 Distal Promoter Element Is Sufficient to Mediate Its High-level Tissue-Specific Expression in Hypertrophic Chondrocytes *In Vivo*. Q. Zheng*[1], B. Keller*[1], G. Zhou[1], D. Napierala[2], Y. Chen*[2], A. Parker*[3], B. Lee[2]. [1]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]Howard Hughes Med. Inst., Houston, TX, USA, [3]Respiratory and Inflammation Res. Area, Astrazeneca, Cheshire, United Kingdom.

Type X collagen gene (*Col10a1*) is specifically expressed in hypertrophic chondrocytes, the terminal stage of chondrocyte differentiation during cartilage development. Identification of the cis-regulatory element and its binding factors for tissue-specific mouse *Col10a1* expression in hypertrophic chondrocytes is thus essential for understanding the mechanisms that specify endochondral ossification and underlie the molecular pathogenesis of skeletal dysplasia. We have previously reported that 4kb *Col10a1* promoter containing Runx2 elements can specifically drive weak reporter gene (*LacZ*) expression in the lower hypertrophic zone of transgenic mice. Here we report generation of additional transgenic mouse lines harboring various *Col10a1* promoter/intronic fragment (Tg-10 kb) or distal *Col10a1* element (Tg-6kb and Tg-4.6kb) driving *LacZ* as reporter. High-level tissue-specific reporter expression was observed in these transgenic mice. These results correspond well with more recent mouse genetics study which demonstrated that 4.6 kb murine *Col10a1* promoter containing conserved enhancer (-4377 to -3865 bp) allows tissue-specific expression of *lacZ* reporter gene in hypertrophic cartilage in vivo. To clarify the contribution of this *Col10a1* distal element to its tissue-specific expression, transgenic mouse lines using two copies of the putative enhancer element (-4.6 to -3.9 kb) upstream of the *Col10a1* basal promoter driving LacZ as reporter (Tg-2xEnh) have been established and showed similar tissue-specific expression pattern. More recently, we have generated transgenic founder mice carrying reporter construct containing four copies of highly conserved 300 bp fragments within the *Col10a1* distal promoter region (-4.3 kb to -4.0 kb) upstream of the same *Col10a1* basal promoter. These Tg-4x300 founder mice show similar tissue-specific reporter/*LacZ* expression pattern to that of the Tg-4.6 kb, Tg-6 kb, Tg-10 kb and Tg-2xEnh mice. These data together suggest that this 300 bp highly conserved element must contain the major enhancer sufficient for tissue-specific *Col10a1*/reporter expression throughout the hypertrophic zone. Further localization of the cis regulatory element within this region and its binding factors will ultimately help to identify possible signaling pathways relevant to skeletal development and therefore has the potential for therapeutic targets with preventive or curative value of related bone/cartilage disorders.

F032

Runx1, 2 or 3 Regulates Chondrocyte Differentiation with Different Efficacy and Induction of Runx in Intervertebral Disk Leads to Disk Degeneration. S. Takeda[1], J. Ozdemir*[2], S. Sato*[1], Y. Aso[3], A. Kimura*[3], K. Shinomiya*[1], G. Karsenty[2]. [1]Dept. of Orthopedics, 21COE, Tokyo Medical and Dental University, Tokyo, Japan, [2]Dept. of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [3]Dept. of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan.

Runx2 together with Runx3 has been shown to accelerate chondrocyte hypertrophy. However, it was uncertain if there is any difference in their ability inducing chondrocyte differentiation in vivo. To address that question, firstly we compared the expression of Runx2, 3 and the other member of Runx family Runx1 by in situ hybridization. Runx2 was expressed in prehypertrophic and hypertrophic chondrocytes strongly in the early stage of embryogenesis but declined thereafter. Runx3 was also expressed in prehypertrophic and hypertrophic chondrocytes and its expression level was unchanged throughout the embryogenesis. Runx1 was temporarily expressed in mesenchymal condensation. Secondly, we generated transgenic mice (tg) expressing Runx1, 2 or 3 in non-hypertrophic chondrocyte using α1(II) collagen promoter. All Runx3 tg and most of the Runx2 tg died perinatally due to ectopic cartilage calcification. While, all Runx1 tg and some Runx2 tg survived and developed kyphosis and scoliosis by 3months. Histologically, intervertebral disk of Runx1 and Runx2 tg mice showed ectopic hypertrophic chondrocyte differentiation, characterized by type X collagen immunoreactivity. In human patients' intervertebral disk (IVD) degeneration, ectopic chondrocyte differentiation is documented. Therefore, we tested if weight loading, a most common cause of IVD degeneration, induces Runx expression, which may cause chondrocyte hypertrophy. Indeed, weight loading of the IVD by compression for a day significantly increased Runx expression. These results demonstrated that all of Runx genes control chondrocyte differentiation, albeit with different efficacy, and indicated that induction of Runx in IVD causes IVD degeneration.

Chondrocyte-Specific Deletion of Indian Hedgehog *(Ihh)* in Postnatal Life. Y. Maeda*[1], M. Nguyen*[2], S. Mackem*[2], B. Lanske[1]. [1]Oral and Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, [2]National Cancer Institute, Bethesda, WA, USA.

Indian hedgehog (*Ihh*) has been shown to be essential for osteoblast differentiation and chondrocyte proliferation/differentiation during endochondral bone formation. *Ihh* null animals exhibit severe skeletal abnormalities and die early during midgestation or latest at birth. We recently discovered that targeted deletion of *Ihh* from only chondrocytes using the *cre/loxP* gene technology led to a similar abnormal phenotype with perinatal death. The early lethality of both animal models does not allow to study the physiological role of Ihh in endochondral bones in postnatal life. We, therefore, generated a new mouse model in which ablation of the *Ihh* gene from chondrocytes can be induced in a temporal-specific manner. To selectively ablate the *Ihh* gene from chondrocytes in the postnatal skeleton, floxed *Ihh* animals were mated with mice in which the *collagen type 2 (α1)* promoter drives a transgene coding for a fusion protein between *Cre* recombinase and an estrogen receptor with a point mutation in its ligand-binding domain *(ER*).* This point mutation in the fusion protein *(CreER*)* allows induction of *Cre* recombinase by tamoxifen (4-hydroxytamoxifen = 4-OHT), but not by estradiol. Injection of tamoxifen can, therefore, be used to induce ablation of the *Ihh* gene at any desired time point. We first tested and validated the consistent specificity and efficiency of postnatal *Cre* excision after tamoxifen injection in *Rosa26cre* indicator mice. A single dose of 2.0 mg 4-OHT was injected intraperitoneally (ip) into 2-week old (p14) *col2-CreER*-Rosa26* indicator mice. Mice were sacrificed at 1, 4, 7 and 14 days after 4-OHT injection and *lacZ* expression was examined by X-gal staining. Exposure to 4-OHT induced *Cre*-mediated recombination starting at 1 day after injection. Strong and specific lacZ staining was observed in growth plates of digits, long bones, ribs, vertebrates and tail, articular surfaces of long bones and palatal suture in the skull. Subsequently, we generated *col2CreER*-floxed Ihh* animals and injected them at p1 and p14 with 0.2 mg and 2.0 mg 4-OHT, respectively. We are currently analyzing the phenotype of these mutant animals to study the physiological role of Ihh in chondrocytes of the postnatal skeleton. These investigations provide a new system in which we can examine for the first time the functions of Ihh after birth.

HCN2 Ion Channels Regulate Bone Development, Mass and Strength. T. Notomi[1], A. Ludwig*[2], G. Reilly*[3], F. B. Hofmann*[2], T. M. Skerry[1]. [1]School of Medicine & Biomedical Sciences, Univ. of Sheffield, Sheffield, United Kingdom, [2]Dept. of Pharmacology and Toxicology, Technical Univ. of Munich, Munich, Germany, [3]Dept. of Engineering Materials, Univ. of Sheffield, Sheffield, United Kingdom.

Hyperpolarization-activated cation currents (Ih) contribute to various physiological properties and functions in the Central Nervous System (CNS) and heart, including the generation of spontaneous rhythmic activity and setting of resting membrane potential. Recent reports also suggested that Ih affect synaptic transmission and Long-Term Potentiation (LTP) in the brain. Four subunits of the Hyperpolarization-activated and Cyclic Nucleotide gated nonselective cation channels (HCN), which generate Ih, have been cloned in the brain and heart. Since numerous neuronal signaling processes have been shown to have functions in bone, we investigated the expression and function of HCNs in the skeleton. Three HCN subtypes, HCN2, HCN3 and HCN4, were identified in whole murine bone (C3H, 12wk old) by RT-PCR and immunoblotting, qualitatively HCN2 was the most abundant. To investigate functions of HCN *in vitro*, mouse bone marrow cells (BMC) were cultured under osteogenic conditions in the presence or absence of the Ih inhibitor ZD7288 (50μM). Inhibition of Ih prevented the normal expression of all osteoblastic markers by BMCs, suggesting that HCNs is a key component in osteoblastic differentiation *in vitro*. To determine the physiological role of HCN, mice lacking the HCN2 gene were analyzed. In knockout mice, the body weight was reduced by 30-35% and femoral and tibial bone length and wet weight was significantly reduced compared to wild type (WT) mice ($p<0.05$). Peripheral computed tomography(pQCT) measurements showed that in the proximal tibia the trabecular bone mineral density (BMD) and area in HCN2-/- mice were significantly less than that in WT mice (BMD, 266.4±23.3 vs. 366.8±17.3 mg/ccm; Area, 1.47±0.09 vs. 2.03±0.11 mm^2; $n=5$, $p<0.05$). In the cortical area of mid-femur, both cortical bone BMD and area in HCN2-/- mice was also significantly less than that in WT mice(BMD, 278.5±17.0 vs. 333.2±17.2 mg/ccm; Area, 0.80±0.03 vs.1.04±0.02 mm^2; $n=5$, $p<0.05$). Three point bending tests revealed that the HCN2 null mice had significantly reduced bone strength compared to WT mice (18.0±0.76 vs. 23.5±0.96 N; $n=5$, $p<0.05$) even after correction for bone weight (1.14±0.12 vs. 1.39±0.06 N/mg; $n=5$, $p<0.05$). These findings demonstrate a novel signaling pathway that impacts on bone architecture and strength. It is not yet clear whether this effect is due to a direct role of HCN2 in regulating cation currents in osteoblasts or some form of rhythmic activity or an effect mediated through other systems such as LTP.

Wdr5, a BMP-2 Induced Gene, Interacts with Ihh and Wnt Signaling Pathways during Endochondral Bone Formation. F. Gori, L. Friedman*, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Among the local signaling pathways known to play a role in endochondral bone formation is the BMP pathway. We identified a novel BMP-2-induced gene, named BIG-3 and recently renamed Wdr5, that is developmentally expressed in osteoblasts and chondrocytes and that dramatically accelerates the program of chondrocyte and osteoblast differentiation *in vitro*. To investigate whether Wdr5 has a functional role during endochondral bone formation, we generated transgenic mice overexpressing Wdr5 under the control of the 2.4-kb fragment of the mouse α (1) I collagen promoter. The targeted expression of Wdr5 to osteoblasts led to an overall bigger skeleton at embryonic day 14.5 compared to wild-type littermates. Histological analyses at 14.5 dpc demonstrated that the humeri of transgene positive embryos were longer than those isolated from wild type littermates. Interestingly, while no difference was observed in the length of the zone of proliferating chondrocytes, the hypertrophic layer was expanded in transgene positive embryos compared to wild type littermates. The expression domain of osteopontin, a marker of terminally differentiated chondrocytes was expanded and the expression of type I collagen was stronger and more extensive in the bone collar of humeri isolated from transgene positive embryos compared to wild type littermates, demonstrating accelerated chondrocyte differentiation and maturation of the bone collar, respectively. Using TOPGAL mice that express a TCF/β-catenin-responsive β-galactosidase transgene, we showed that Wnt signaling was activated earlier in the osteoblasts of the bone collar of Wdr5 transgenic mice compared to wild type littermates. The expression of Ihh and its receptor Ptc-1 were also investigated to address the hypothesis that Wdr5 expressed in the bone collar interacts in a paracrine fashion with the Ihh signaling pathway in regulating chondrocyte differentiation. The expression levels and domains of Ihh and Ptc-1 were decreased in the humeri of transgene positive embryos compared to their wild type littermates. These findings indicate that Wdr5 plays a regulatory role in endochondral bone formation. Targeted overexpression of this novel protein to osteoblasts results in acceleration of osteoblast differentiation, likely mediated by the Wnt signaling pathway. The acceleration of chondrocyte differentiation and maturation suggests that Wdr5 expressed in the bone collar has paracrine actions on chondrocyte differentiation, likely mediated by the Ihh/PTHrP signaling pathway.

Tight Skin (Tsk) Mutant Mice Exhibit a Definitive Skeletal Phenotype. T. Barisic-Dujmovic*[1], I. Boban*[1], D. J. Adams*[2], S. H. Clark[1]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Department of Orthopedic Surgery, University of Connecticut Health Center, Farmington, CT, USA.

The tight skin (Tsk) mutation is an autosomal dominant located on mouse chromosome 2, and is associated with an intragenic duplication of the fibrillin 1 gene. Fibrillin 1 is an extracellular macromolecule, and it is known that fibrillin molecules join with each other to form structurally complex microfibrils. The Tsk phenotype includes a tightness of skin, lung emphysema, myocardial hypertrophy, enlarged skeleton and kyphosis. While the skin, lung and heart features of the Tsk mutation have been the subject of many studies the skeletal phenotype has largely been ignored. We have shown that Tsk mice have a bone phenotype similar to that of patients with Marfan syndrome (MFS). The clinical signs in Marfan syndrome are mainly musculoskeletal (thoracic malformations, spinal abnormalities, tall stature), ocular and cardiovascular (aorta aneurysm, aortic dissection). Despite the fact that mutations in the fibrillin 1 gene have been identified in many Marfan patients, the pathogenesis of Marfan syndrome is not understood. Similar to Marfan patients, Tsk mice display spinal abnormalities and have decreased bone mineral density. In addition Tsk mice have significantly longer bodies and femurs. To further assess the Tsk bone phenotype we used μCT imaging analysis of femurs from Tsk versus normal 2 and 4-month old mice. Cortical and trabecular bone volume were significantly decreased (13% and 39%, respectively) in Tsk femurs. Trabecular thickness, number, connectivity, and surface area were significantly lower in Tsk mice, with an increase in trabecular spacing. Based on these observations we hypothesized that osteoblast differentiation might be impaired in Tsk mice and that this impairment could be associated with a decrease in the expression of bone differentiation markers. To examine this hypothesis marrow stromal cultures (MSC) from Tsk and normal mice were evaluated, showing decreased expression of osteocalcin in Tsk MSC. Staining with xylenol orange for mineral revealed decreased numbers of mineralized nodules in MSC from Tsk mice. Further MSC cultures were analyzed using an osteoblast specific marker pOBCol2.3GFP. These data showed a decreased number of GFP positive nodules in Tsk compared to normal. Taken together, these results suggest that fibrillin 1 as an important factor in osteoblast differentiation. Moreover, since transforming growth factor β (TGF-β) has been implicated in the pathogenesis of both MFS and the Tsk mutation, Tsk mice provide a good model to study interactions between fibrilllin 1 glycoprotein and TGF-β.

Wnt/ß-Catenin Signaling Play Pivotal Roles in Synovial Joint Induction and Chondrocyte Maturation. X. Guo*, T. F. Day*, X. Jiang*, L. Garrett-Beal*, L. Topol*, Y. Yang*. Genetic Disease Research Branch, NIH/National Human Genome Research Institute, Bethesda, MD, USA.

Wnt signaling is one of the key signaling pathways in regulating skeletal development. To understand the molecular and cellular mechanism of Wnt signaling, we have used molecular genetic approaches to dissect the role of ß-catenin-mediated canonical Wnt signaling in vivo in two important skeletal development processes: synovial joint induction and endochondral bone formation. We have generated a floxed allele of *ß-catenin* mutant mouse, *Catnby$^{c/c}$* which allows us to block the canonical Wnt signaling in a tissue-specific manner by crossing the *Catnby$^{c/c}$* mice with *Col2a1-Cre* or *Dermo1-Cre* mice. Cre activity is detected in all chondrocytes and some osteoblasts in *Col2a1-Cre* mice whereas in *Dermo1-Cre* mice, Cre activity is detected in early mesenchymal condensations prior to chondrocyte or osteoblast differentiation. We found previously that some *Wnts* such as *Wnt14* signals through the canonical Wnt pathway in regulating skeletal development. Removal of *ß-catenin* in *Catnby$^{c/c}$; Dermo1-Cre* mice embryos resulted in synovial joint fusion, ectopical chondrocyte differentiation and diminished osteoblast differentiation. Conversely, in *Col2a1-Wnt14* transgenic embryos, synovial joint is ectopically induced, chondrocyte differentiation is inhibited and osteoblast differentiation is enhanced. These results demonstrate that the Wnt/ß-catenin signaling is necessary and sufficient for synovial joint induction and plays a pivatol role in endochondral bone formation. Interestingly, Wnt signaling appears to be required at different developmental stages for endochondral ossification. In the early mesenchymal condensation, Wnt signaling inhibits chodrocyte differentiation, but is required for osteoblast differentiation. In the differentiated chondrocytes, Wnt signaling promotes chondroctye maturation. The onset of chondroctye hypertrophy is normal in both *Catnby$^{c/c}$; Col2a1-Cre* and *Catnby$^{c/c}$; Dermo1-Cre* mice. However, the progression to the most mature chondrocytes which express *VEGF*, *MMP13* and *MMP9*, is significantly delayed in these mice. Conversely, in some *Col2a1-Wnt14* transgenic line where initial chondrocyte differentiation is not inhibited, expression domains of *VEGF, MMP13* and *MMP9* are greatly expanded. These data indicate that Wnt/ß-catenin signaling promotes endochondral bone formation through distinct mechanisms at different developmental stages: at early stage, it is required for osteoblast to differentiate from mesenchymal progenitor cells and later in hypertrophic chondrocytes, it promotes endochondral ossification by promoting the final maturation of hypertrophic chonodrocytes.

Altered Sensory Sensitivities in Osteocalcin Null Mutant Mice. P. Buckendahl, Y. K. Kim*, L. A. Pohorecky*. Center of Alcohol Studies, Rutgers University, Piscataway, NJ, USA.

Osteocalcin (OC) is a small, extracellular mineral-binding protein synthesized almost exclusively by osteoblasts and deposited along with bone mineral during formation. OC synthesis is regulated by glucocorticoids (GC) as well as numerous other hormones. A relatively consistent amount of newly synthesized OC is released to circulation (pOC), influenced not only by bone formation but also by physical and environmental stimuli such as those that increase GC and decrease plasma Ca^{++}. Acutely stressful stimuli (fear, isoflurane anesthesia, restraint immobilization) in humans, monkeys, and rats increase pOC within minutes, while pain (surgery), cold exposure, or anxiety (anticipation of surgery, novel environment, mild restraint) more slowly decrease pOC over periods of hours to days. These responses may be related to GC or to as yet undetermined sympathetic neural factors. OC has been immunolocalized to nociceptive cells of rat dorsal root ganglia and in taste sensors in glossopharyngeal ganglia. Because these responses generally also involve mobilization of Ca^{++}, and because of the affinity of OC for Ca^{++}, we hypothesized that it could be involved in sensing or modulating sensory stimuli. To begin to confirm this hypothesis, we compared OC null mutant (KO, n=9) and wild-type C57BL/6 (WT, n=9) mice, progeny of heterozygous littermate parents. Unlike WT, KO mice have no OC in plasma or bone. We tested behavior in the open field (± EtOH), thermal sensitivity (52.5 °C ± EtOH), paw sensitivity to Von Frey fibers (0.16 to 2 g force), and light/dark exploration. Basic open field locomotion and center/periphery preference did not differ between KO and WT. However, following EtOH injection (1 g/kg i.p.), mice differed significantly in relation to light intensity, with WT spending more time in lower light intensity areas than KO. WT also spent more time in the dark side of a light/dark box than did KO. Although WT and KO did not differ in response to hot plate test, WT were more sensitive to Von Frey fibers. The apparent contradiction in the latter findings may relate to differences in pain/touch receptors in the paw and associated ganglia. These findings suggest a novel and unique involvement of OC in sensory responses. Whether that results from pOC or from in situ synthesis remains to be determined.

Crtap Is Required for Prolyl 3-Hydroxylation of Fibrillar Collagens and Loss of its Function Causes Severe Kyphoscoliosis and Osteoporosis in Mice. R. Morello*[1], T. K. Bertin*[1], Y. Chen*[1], P. Castagnola*[2], D. R. Eyre*[3], B. F. Boyce*[4], B. Lee[5]. [1]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]National Institute for Cancer Research, Genoa, Italy, [3]University of Washington, Seattle, WA, USA, [4]University of Rochester Medical Center, Rochester, NY, USA, [5]Howard Hughes Medical Institute, Houston, TX, USA.

Recently we described the isolation and characterization of a novel protein, Crtap, differentially expressed in chicken hypertrophic chondrocytes compared to proliferating chondrocytes in vitro. We isolated the mouse ortholog and demonstrated its expression in chondrocytes, osteoblasts and osteoclasts by in situ hybridization and RT-PCR. To understand its function, we generated mutant mice by homologous recombination. Heterozygous Crtap+/- mice were asymptomatic. Crtap null mice were generated and northern hybridization analysis of total embryo RNA confirmed the absence of Crtap mRNA. The null mice are born viable at the expected Mendelian ratios and, although smaller, they show no obvious abnormalities at birth. However, by 3-4 months of age they begin to develop a moderate kyphosis that becomes pronounced at 6 months of age. Faxitron analyses confirmed the deformity of the spine at the thoracic level and, most importantly, it revealed severe generalized osteoporosis affecting both cortical and trabecular bone. Histological analysis confirmed the severe osteoporosis and showed abnormal proliferating chondrocytes in the growth plate. Bone histomorphometry demonstrated approximately 50% decrease of axial and appendicular BV/TV compared to wild type mice, normal osteoblast and osteoclast numbers, but low mineral apposition and bone formation rates. Importantly, Crtap null mice have defective osteoid formation. Moreover, because Vranka JA et. al (2004) showed that Crtap co-purifies with prolyl 3-hydroxylase, we analyzed tryptic digested, cyanogens bromide derived peptides from types I and II collagen isolated from Crtap null mice tissues using tandem mass spectrometry. Interestingly, the single prolyl 3-hydroxylation modification known to exist in these collagen chains was completely absent. The altered post-translation modification of fibrillar collagens together with defective osteoid formation suggest a critical role of prolyl 3-hydroxylation for proper bone matrix formation and point to a key role for Crtap during skeletal development and bone mass acquisition. Moreover, these data point to a novel pathophysiologic mechanism leading to a new type of collagenopathy perhaps in the osteogenesis imperfecta spectrum of disorders.

Expression of Mechanosensitive, Prochondrogenic Genes: A Link between Mechanical Stimulation and Tissue Differentiation. M. Tagil*[1], R. Rajani*[2], P. Bahra*[2], X. Cao*[2], D. Fischer*[2], R. Thompson*[2], J. Astrand*[1], P. Aspenberg*[3], K. Hankenson[2]. [1]Dep of Orthopedics, Lund University Hospital, Lund, Sweden, [2]University of Michigan, Ann Arbor, MI, USA, [3]Dep of Orthopedics, Linkoping University Hospital, Linkoping, Sweden.

Introduction We have developed an experimental bone chamber model in the rat. When hydrostatic pressure is applied, cartilage forms while bone forms without mechanical stimulation. To better understand chondroinduction secondary to mechanical load, we investigated morphologic changes at early time points following load, and used gene expression analysis to determine mechanosensitive genes. **Material and Methods** *Surgery*: Four groups of four Sprague Dawley rats had a non-loaded chamber implanted in one leg and a loaded chamber in the other. The tissue inside the loaded chamber was loaded by 2 MPa, in three second cycles, twenty times, twice a day. *Morphological analysis*: The rats were euthanized after 1, 3, 5 and 7 days of loading/non loading. Specimens were scanned using microCT and bone volume fraction and bone length were measured. The specimens were stained with H&E or safranin-O/fast green *Gene expression analysis*: Another 12 male rats at each time point were operated, loaded and harvested at 1, 3, 5, or 7 days. RNA was harvested using Qiagen RNAeasy. Affymetrix rat expression array 230 2.0 was hybridized with the eight samples and fluorescence signal detected. Microarray data was examined for genes exhibiting a minimum two-fold change in loaded vs unloaded specimens. DNA-Chip Analyzer (dCHIP) Software was used to filter genes showing a minimum 2.3 fold change in loaded vs unloaded specimens. To validate the array data, RNA was reverse transcribed and analyzed using qPCR. **Results** By d5, cartilage is evident in the mesenchyme overlying the bone, and by d7 has started to undergo endochondral ossification. The 20 most prevalent genes for unloaded and loaded specimens showed strong agreement. In addition to ribosomal proteins, hexokinase, and the cytoskeleton components beta-actin and vimentin, a number of genes related to bone formation were in the top 20, including collagens type I, III, and V, BSPII, osteopontin, and osteocalcin. Overall, over 2000 genes showed increased expression in loaded vs unloaded specimens at one of the days. **Discussion** Loading induced chondrogenic genes, as noted by increases in type II collagen, WISP2, and TSP4 on d5 and d7, as well, as a significant 5-fold induction of type X collagen on d7. Genes that may be associated with mechanoresponsiveness that leads to chondrogenesis are revealed by changes in d1 and d3 expression. Two likely candidates are cytokine receptor-like factor 3 (CRL3) and aldose reductase-like protein.

Action of Prostaglandin E2 (PGE2) via EP4 Receptor Is Critical for Osteolysis due to Bone Metastasis of Cancer. M. Takita*[1], M. Inada[1], T. Maruyama[2], C. Miyaura[1]. [1]Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, [2]Ono Pharmaceutical Co. Ltd., Osaka, Japan.

Bone metastasis of cancer induces osteolysis with increased bone resorption, but the mechanism of bone loss due to the presence of cancer cells is not fully understood. We have found that prostaglandin E2 (PGE2) acts mainly on EP4 receptor, one of the PGE receptor subtypes (EP1, EP2, EP3 and EP4), in osteoblasts to induce the receptor activator of NF-kB ligand (RANKL) expression to stimulate bone resorption. Expression of cyclooxygenase-2 (COX-2) and RANKL mRNA was elevated in bone with cancer metastasis, but the roles of PGE2 and its receptor EP4 in bone metastasis are not clear up to the present. In this study, we made a model of osteolytic bone metastasis by injecting mouse malignant melanoma B16 cells into the left heart ventricle of C57BL/6 mice and examined the effects of EP4 antagonist, a selective inhibitor of EP4 receptor, on bone loss due to cancer metastasis. When mice were injected with B16 cells from the left heart ventricle, metastatic regions accompanying severe bone loss were detected in femurs and tibiae 12 days after the injection. Bone mineral density (BMD) in the femur with metastasis was significantly decreased because of the enhancement of bone resorption compared with that in the control femur without metastasis. We measured the level of PGE2 in bone marrow supernatant collected from femurs with or without metastasis, and found that PGE2 in bone marrow from the femur with metastasis was elevated compared with that in the control. When EP4 antagonist was orally administered to C57BL/6 mice injected with B16 cells, osteolysis due to bone metastasis in femurs was suppressed, and the decrease in BMD was restored to the control level. In vitro, cell-to-cell contact between fixed-B16 cells and osteoblasts induced the expression of RANKL in osteoblasts. Adding fixed-B16 cells to the cocultutes of bone marrow cells and osteoblasts induced osteoclast formation without any bone-resorbing factor, suggesting that cell-to-cell interaction between osteoblasts and tumor cells could induce osteoclastogenesis and osteolysis in bone with cancer metastasis. PGE2 produced by host osteoblasts after contact with cancer cells may induce bone resorption by mechanisms via EP4 receptor expressed in osteoblasts. Therefore, EP4 antagonist may be a candidate for therapy for cancer accompanied by bone metastasis.

TGF-β Stimulation of PTHrP Expression in Breast Cancer Cells Is Regulated by Gli2. J. A. Sterling, L. Z. Sun*, B. Grubbs*, M. Zhao, B. O. Oyajobi, S. S. Padalecki, G. R. Mundy. Cellular and Structural Biology, UTHSCSA, San Antonio, TX, USA.

Some cancer cells, particularly squamous cell carcinomas, express parathyroid hormone-related peptide (PTHrP) in large amounts, and as a consequence cause increased bone resorption and hypercalcemia. Others, such as breast cancers, express PTHrP in the bone metastatic site as a consequence of stimulation of the cancer cells by bone-derived TGF-*β*. To understand why some cancer cells over-express PTHrP, we investigated the notion that cancer cells may hijack the Hedgehog (Hh) signaling pathway which regulates PTHrP expression physiologically in the growth plate. We have found that the Hh signaling molecule Gli2 enhances PTHrP expression in tumor cells that metastasize to bone. This stimulation is specific to Gli2, and not Gli1 and Gli3. Furthermore, we have found that several osteolytic and/or hypercalcemic human cancers which produce PTHrP also express Gli2, while 5 non-osteolytic cancers that do not produce PTHrP do not express Gli2. Mice inoculated via intracardiac injections with MDA-MB-231 breast cancer cells over-expressing Gli2 exhibited enhanced tumor induced osteolysis, as determined by histomorphometry and radiography, compared to empty vector control tumor bearing mice. These data indicate that Gli2 stimulates PTHrP and subsequent osteolysis in breast cancer that has metastasized to bone. To determine if Gli2-stimulated PTHrP expression is dependent on TGF-*β* signaling in breast cancer bone metastases, we utilized MDA-MB-231 cells stably transfected with a dominant negative TGF-*β* receptor type II (dnRII) and thus without intact TGF-*β* signaling. We found Gli2 was able to stimulate PTHrP promoter activity in these cells. In addition, using PTHrP luciferase constructs with the Smad binding site mutated, Gli2 also stimulated PTHrP promoter activity. Thus, TGF-*β* signaling is not required for Gli2 stimulation of PTHrP. To determine if TGF- *β*regulates Gli2 expression, MDA-MB-231 and MDA-MB-435 breast cancer cells were treated with TGF-*β*. TGF-*β* stimulated Gli2 protein expression by Western blot after only 30 min of treatment. By real-time PCR Gli2 expression was induced approximately 3-fold. These data indicate that Gli2 is regulated downstream of TGF-*β*, suggesting that the TGF-*β*-mediated increase in PTHrP production is mediated through Gli2. These data suggest Gli2 as a molecular target for drugs in metastatic breast cancer, and that inhibiting Gli2 expression in breast tumors that have metastasized to bone may disrupt the vicious cycle of TGF-*β* stimulation of PTHrP in advanced breast cancer.

c-Src Inhibition Decreases Breast Cancer-Induced Lethality and Incidence of Metastases in Nude Mice. C. Di Giacinto*[1], D. Fortunati*[1], I. Recchia*[1], A. Angelucci*[1], M. Susa*[2], D. Fabbro*[2], A. Teti[1], N. Rucci[1]. [1]Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy, [2]Novartis Pharma, Basel, Switzerland.

We investigated the involvement of c-Src in the development of breast cancer metastases. Balb-c nu/nu mice were intracardiacally injected with the human breast cancer cells MDA (MDAMB231), or with MDA cells stably transfected with c-Src wild type ($MDASrc^{WT}$) or c-Src kinase-dead dominant negative ($MDASrc^{DN}$) constructs. Similar progression and incidence of cachexia and mortality was observed in animals injected with MDA or $MDASrc^{WT}$ cells. In contrast, neither cachexia nor lethality was noticed in mice injected with $MDASrc^{DN}$ cells. X-ray analysis showed 57% and 71% incidence of bone metastases in MDA- and in $MDASrc^{WT}$ cell-injected mice, respectively, while in $MDASrc^{DN}$ cell-injected mice the onset of bone metastases was delayed, reaching only 25% at the end of experiment. In the latter, the incidence of soft tissue lesions was also reduced (MDA/$MDASrc^{WT}$ 85%, $MDASrc^{DN}$ 25%). In subcutaneous xenografts, tumor weight was increased in $MDASrc^{WT}$ (0.54 g ± 0.068) and decreased in $MDASrc^{DN}$ (0.15 g ± 0.04) relative to MDA cells (0.34 g ± 0.034) and the expression of the proliferation marker Ki67 changed accordingly ($MDASrc^{WT}$ 15%, $MDASrc^{DN}$ 2%, MDA 4%). MDA cell-injected mice were treated with 100 mg/kg/day of the c-Src inhibitor CGP76030, and showed an analogous reduction in cachexia, lethality and soft tissue metastases *vs* control animals. In untreated mice, osteolytic lesions appeared earlier, progressively increasing up to 57% incidence, while in treated mice the incidence was again 25%. In vitro, c-Src inhibition caused a concentration- and time-dependent reduction of MDA cell proliferation, adhesion, spreading and migration. Furthermore, it significantly inhibited bone marrow osteoclast formation and bone resorption. Treatment with c-Src inhibitor reduced osteoblast proliferation and increased the expression of alkaline phosphatase and of the osteoclast inhibitory cytokines GM-CSF and IL-12. Accordingly, IL-12 levels were reduced after osteoblast treatment with conditioned media (CM) from $MDASrc^{WT}$. Treatment of bone marrow cultures with CM from $MDASrc^{WT}$ and $MDASrc^{DN}$ cells stimulated osteoclast differentiation and increased endothelial cell activity to a similar extent as the MDA CM, suggesting that paracrine factors directly affecting these cell types are not altered. c-Src inhibitor treatment did not directly affect endothelial cell migration or invasion. In conclusion, we demonstrated a role for c-Src in the development of *in vivo* metastases, and identified a potential therapeutic target which could also reduce cachexia and lethality.

Prostate Cancer Cells Promote Osteoblastic Bone Metastases through Wnts. C. L. Hall[1], A. Bafico*[2], S. Aaronson*[2], E. T. Keller[1]. [1]Urology, University of Michigan, Ann Arbor, MI, USA, [2]Oncological Sciences, Mount Sinai School of Medicine, New York, NY, USA.

Prostate cancer (CaP) produces painful osteoblastic bone metastases through unknown mechanisms. CaP cells are known to produce a variety of potentially osteoblastic factors; however, identification of an osteoblastic factor using an *in vivo* CaP cell model has not been demonstrated to date. Wnts are a family of proteins that are necessary for bone development and are antagonized by endogenous proteins including Dickkopf-1 (DKK-1). We therefore examined whether CaP cells mediate osteoblastic activity through Wnts using DKK-1 as a tool to modify Wnt function. A variety of Wnt mRNAs were found to be expressed in CaP cell lines and Wnt mRNA expression was increased in primary CaP compared to non-neoplastic prostate tissue. In addition, osteolytic PC-3 cells expressed abundant message for the Wnt inhibitor DKK-1. To determine whether DKK-1 expression masked Wnt osteoblastic activity, osteolytic PC-3 cells were transfected with shRNA to DKK-1. Decreasing DKK-1 enabled PC-3 cells to induce osteoblastic activity, including alkaline phosphatase production and mineralization, in murine bone marrow stromal cells. Another CaP cell line, C4-2B, induces osteoblastic lesions *in vivo*. To determine if Wnts contribute to C4-2B's ability to induce osteoblastic lesions, C4-2B cells were transfected with a DKK-1 expression vector to block Wnt activity. The cells were then injected in the tibiae of mice and allowed to grow for 12 weeks. The expression of DKK-1 converted the C4-2B cells from an osteoblastic to a highly osteolytic tumor. Taken together, these data demonstrate that Wnts contribute to the mechanism through which CaP induces osteoblastic activity.

Bone Resorption Sites: Targets for Skeletal Colonization by Tumor Cells? R. J. Majeska[1], L. J. Silbert*[1], I. H. Gelman*[2], M. B. Schaffler[1]. [1]Leni and Peter W. May Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, [2]Roswell Park Cancer Institute, Buffalo, NY, USA.

Bone is a preferred site for prostate cancer (CaP) metastasis. Once tumor cells enter bone from the circulation, development of metastatic lesions is facilitated locally by growth/survival factors produced or released from matrix during bone resorption. However, it is not clear whether bone resorption or formation may also target the initial tissue colonization of bone by tumor cells. Here we tested the hypothesis that CaP cells in the circulation preferentially colonize bone near sites of ongoing formation and resorption. A human prostate cell line (LNCaP) was transfected to express GFP constitutively (LNCaP-GFP), and highly expressing cells were selected by flow cytometric sorting. Under IACUC-approved protocols, young male nude mice were treated for 6 days with the bisphosphonate risedronate (RIS, 0.2 mg/kg, sc) to inhibit bone resorption or with PBS vehicle. One day later, mice received 105 LNCaP-GFP cells in 0.1 ml by iv (tail) or intracardiac injection. After 24, 48 or 72h, animals were euthanized and proximal tibiae fixed in fresh 4% buffered paraformaldehyde, decalcified with EDTA and processed for histology. The distance between each fluorescent tumor cell and the nearest bone surface was measured, and the surfaces were characterized as either forming, resorbing or quiescent by standard histological criteria. We found that 24h after injection in control mice, 54% of all tumor cells were closest to active surfaces (24% forming, 30% resorbing), while 46% were nearest to quiescent surfaces; by contrast, forming, resorbing and quiescent surfaces accounted for 16%, 25% and 58% of total bone surfaces, respectively. This indicates preferential localization of tumor cells near sites of tissue activity. Similar distributions were seen at 48 and 72h post-injection. In addition, over 91% of cells near forming and resorbing sites were within 25μm of bone surfaces, while only 56% of cells were this close to quiescent surfaces. When bone resorption was suppressed with RIS, almost no tumor cells were seen near active or inactive resorption sites; however, total tumor cells per section also declined from 4.2 ± 0.9 to 2.0 ± 0.6 in RIS-treated animals. In summary, these data indicate that the initial colonization of skeletal tissues in mice by circulating prostate cancer cells appears to occur preferentially near sites of active bone formation/resorption. The findings also raise the possibility that factors produced locally near sites of resorption may have more widespread effects on the earliest stages of tumor cell invasion in bone.

Non-Isomerised C-Telopeptides of Type I Collagen (αCTX): A Sensitive Indicator of Metastatic Bone Disease. D. Leeming*[1], M. Koizumi*[2], B. Li*[1], I. Byrjalsen*[1], L. Tanko*[3], P. Qvist[1], C. Christiansen[3]. [1]Nordic Bioscience, Herlev, Denmark, [2]Cancer Institute Hospital, Tokyo, Japan, [3]Centre for Clinical & Basic Research, Ballerup, Denmark.

Purpose: To investigate the usefulness of measurement of urinary *α*CTX (C-telopetide of type I collagen) for detection of metastatic bone disease of different origin, and the pathogenic role of the OPG/RANKL system. Methods: Participants were 161 cancer patients; 90 breast cancer (45 with bone metastasis), 29 lung cancer (15 with bone metastases), and 42 prostate cancer (17 with bone metastases). Presence of bone metastases was determined by Tc99m scintigraphy and the skeletal involvement was graded according to the Soloway score; 1: <6 metastases, 2: 6-20 metastases, 3: >20 metastases but no super-scan, 4: superscan (i.e. >75% of ribs, vertebrae and pelvic being affected). For control purposes, 309 subjects without history or presence of cancer disease

were also included. Urine samples were collected and assessed for αCTX (Nordic Bioscience Diagnostics). Serum samples were analyzed for circulating OPG and RANKL (Immunediagnostic AG). Results: Cancer patients with bone metastases revealed significantly increased levels of αCTX compared with cancer patients without bone metastases. There was a significant association between number of metastases and αCTX levels (r=0.39, p=0.001). Furthermore, as shown in Fig. 1, αCTX increased with the severity of skeletal involvement as expressed in Soloway score. Presence of bone metastases was associated with increased level of αCTX for all cancer types (Fig 2). Serum OPG, RANKL, OPG/RANKL measurements indicated no significant differences between cancer patients with and without bone metastases, and there were no association between the level of these bone regulatory factors and number of bone metastases. RANKL/OPG ratios were significantly elevated in patients with diagnosed cancer compared with controls, independent of cancer-type. Conclusions: αCTX could be a convenient indicator of the presence and extent of metastatic bone involvement in cancer patients. The accelerated bone resorption seems to involve OPG secretion from tumor cells, yet the RANKL/OPG ratio offers little information regarding skeletal involvement.

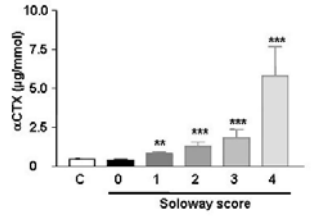

Figure 1. Means of αCTX in C:controls (white) and cancer patients without (black) and with (grey) bone metastases.

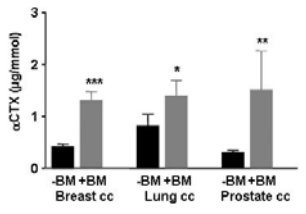

Figure 2. Means of αCTX in cancer patients without (black) and with (grey) bone metastases (analysis stratified for cancer type).

Site-Discordance of Osteoporosis Categorization in Menopausal Females. W. D. Leslie. Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada.

The modest correlation in bone mineral density (BMD) between different measurement sites inevitably leads to potential discordance in classifying patients based upon the conventional cutoff T-score ≤-2.5. Some groups recommend patient diagnosis based upon lowest site (ISCD), while others recommend a hip site (IOF). The number of osteoporotic sites may also be important as some groups have reported that this correlates with fracture risk. Our objective was to describe the pattern of site-discordance in a large population-based database of clinical DXA results from a regional BMD program (JCD 2005;8:25-30). Analysis was based upon 17,053 women age 50 and older with complete measurements of L1-4, femoral neck, trochanter and total hip. We calculated the number of sites with T-score ≤-2.5, T-score mean, range (max-min) and discordance index (difference between lowest site and mean of the 3 remaining sites). Of 5,350 patients osteoporotic by ISCD (at least one site with T ≤-2.5), almost half (2,530 [47%]) were abnormal at only a single site. Most of these (1,650 of 2,530 [65%]) were abnormal at L1-4 only and would be classified non-osteoporotic by IOF. The range and discordance index were highest for a single abnormal site (P<0.00001), suggested that the low value may be an outlier. The expected early spinal bone loss did not adequately account for single-site discordance (mean age 66±8 for abnormal L1-4 vs. 68±10 for abnormal hip). Age correlated only weakly with T-score range or discordance index ($r^2 \leq 0.01$). In conclusion, site-discordance is common and markedly affects patient categorization when different diagnostic criteria are used. Fracture outcomes data are needed to see if a single abnormal site improves or degrades the gradient of risk for fracture.

# Sites T ≤-2.5	Mean T (SE)	Range T (SE)	Discordance Index (SE)
0 (N=11,703)	-0.79 (.01)	1.25 (.01)	0.82 (.01)
1 (N=2,530)	-2.00 (.01)	1.56 (.01)	1.22 (.01)
2 (N=920)	-2.49 (.01)	1.20 (.02)	0.83 (.02)
3 (N=770)	-2.77 (.01)	1.33 (.03)	0.78 (.02)

The Cross Section Geometry of The Femoral Neck. L. Yang*, E. V. McCloskey, R. Eastell. Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom.

The calculation of biomechanical properties of the femoral neck (FN) from DXA is based on the assumption that it is circular in cross-section (CS). A recent study (Seeman et al, M099, ASBMR Annual Meeting, 2004) showed that the FN was ellipsoid in CS. The purpose of this study was to obtain a detailed description of the CS geometry of the FN along its axis. We evaluated the baseline-visit CT scans of both proximal femurs of 27 women (mean age 81, range 65 to 86 yr) with osteoporosis who were recruited at a single centre participating in the HORIZON Study. Additional slices were generated by linear interpolation of the CT number so the voxel size was reduced from 0.96×0.96×3 to 0.96×0.96×1 mm. The images were segmented by semi-automatic intensity thresholding and the CT number converted to vBMD using a phantom. A voxel was considered full of bone tissue if vBMD≥1.05 g/cm^3 and cortical if vBMD>0.5025 g/cm^3. The FN axis line was placed manually and the neck CS defined along the axis at 1.5 mm intervals. Nonlinear least-square regression was used to fit the CS to a circle and an ellipse. All the parameters were normalised along the length from the femoral head centre to the distal neck using cubic spline interpolation, and their mean and SD calculated. From the femoral head centre to distal FN the CS geometrical area, bone area, moment of inertia and modulus decreased and then increased. The lowest mean value for geometrical area was 7.1±0.8 cm^2 (at 65% FN length) and for the bone area was 1.4±0.2 cm^2 (40% to 60% FN length). The mean modulus about the anterior-posterior (AP) and medial-inferior to lateral-superior (MI-LS) axes were lowest at 38% (670±169 mm^4) and 54% (666±143 mm^4) FN length respectively. The CS shapes fitted better to an ellipse than to a circle for all CSs. The principal axes of the ellipse were not parallel to the anatomical axes in the distal half of the FN, they were increasingly internally rotated and reached a plateau of 23° at 80% FN length. From 5% to 45% FN length, the MI-LS axis was the short axis of the ellipse, significantly (p<0.05) shorter than the AP axis, but the difference was small. From 60% FN length onwards, the MI-LS axis was significantly (p<0.05) and increasingly longer than the AP axis, over 20% longer from 80% FN length onwards. The circularity assumption lead to a significant (p<0.05) under-estimation of the average vBMD in CS in the distal half of the FN, less than 80% of the actual vBMD from 65% FN length onwards. Cortical bone was found only in the CSs of the distal half FN and this could be due to the partial volume effect. In conclusion, the FN is ellipsoid in CS, and the ellipsoid size and orientation change along the FN axis. The circularity assumption can lead to large errors in estimating CS biomechanical properties, especially in the distal half of the FN.

Fracture Risk Assessment Using a Local versus an International Reference Database. A. Arabi[1], R. Baddoura[2], H. Awada*[2], N. J. Khoury*[3], S. Haddad*[4], G. Ayoub*[2], G. El-Hajjfuleihan[1]. [1]Internal Medicine, American University of Beirut, Beirut, Lebanon, [2]Rheumatology, Saint Joseph University, Beirut, Lebanon, [3]Diagnostic Radiology, American University of Beirut, Beirut, Lebanon, [4]Radiology, Saint Joseph University, Beirut, Lebanon.

Dual-energy X-ray absorptiometry (DXA) is the accepted method for measurement of bone mineral density (BMD). The IOF recommends the measurement of hip BMD, using the universal NHANES reference database. However, in many countries local databases are used without validation of such an approach. The aim of this study was to assess the ability of BMD measurements, using the WHO criteria (T-score≤-2.5), to identify subjects with prevalent vertebral fractures, using either the local or the NHANES databases. 460 non-Western Caucasian subjects, aged 65-85 years, were randomly recruited from a large metropolitan area, based on geographical maps. BMD at the hip were measured by DXA, using Hologic device. Local and Western derived T-score were calculated, using gender matched local or NHANES databases[1-2]. Lateral radiographs of the thoraco-lumbar spine were assessed using the semi-quantitative method of Genant[3]. Mild fractures were excluded. The sensitivity, specificity, PPV, NPV and area under the ROC, of BMD measurements to identify subjects with vertebral fracture, were computed using STATA v7. 56 women (19%) and 18 (12%) men had at least one vertebral fracture. When the Western database was used, 33% of women and 23% of men had osteoporosis at the hip. When the Local database was used, these percentages were 13% and 2% respectively.

Table. Sensitivity, specificity, PPV, NPV and area under the ROC, for BMD measurements of the hip, using the Western or local database, to predict the presence of vertebral fracture

	women N=301		Men N=159	
	Western	Local	Western	Local
Sensitivity	52	25	38	11
Specificity	71	89	79	99
PPV	30	35	20	66
NPV	86	83	90	89
ROC	0.61	0.57	0.59	0.55

In both genders, the sensitivity and the area under the ROC for detecting patients with prevalent vertebral fractures were higher when the Western database was used, but the NPP and the PPV did not differ between the 2 databases. Similar results were obtained when the analyses were done in the overall group (data not shown) Our study suggests that the use of a local database decreases the ability of DXA to identify subjects with prevalent vertebral fractures. It validates the IOF recommendation favoring the use of universal standardized databases, over local database[4].

Importance of the AP Spine View for the Reliability and Accuracy of Vertebral Fracture Assessment Compared to Radiography. J. T. Schousboe[1], K. E. Wilson[2], C. R. DeBold*[1]. [1]Park Nicollet Clinic & Institute, Minneapolis, MN, USA, [2]Hologic, Inc., Bedford, MA, USA.

Prevalent radiographic vertebral deformity is a powerful risk factor for incident fractures, yet the majority of these deformities are clinically unapparent. Imaging of the spine with a densitometer (vertebral fracture assessment, VFA) can detect these deformities, but the utility of the AP view in VFA and how scoliosis affects the performance of VFA is not fully established. To estimate the effect of scoliosis on the accuracy of VFA compared to x-ray and the utility of the AP view, we obtained lateral thoracic and lumbar spine radiographs and AP and lateral VFA images on 203 women age 65 and older who had been referred for bone densitometry. Both sets of images were evaluated for prevalent vertebral deformity consistent with fracture according to the

semiquantitative method of Genant. by two readers blinded to each other's readings. Each reader was also blinded to his own x-ray readings when evaluating VFA's. Reader 2 (JTS) evaluated the AP image for scoliosis. Considering all 203 participants, sensitivity of VFA for those with one or more grade 2 or 3 vertebral deformity was 63% for reader 1 (CRD) and 78% for reader 2. However, if subjects with moderate or severe scoliosis as graded by the VFA AP view were excluded (14 of 205), the sensitivity for those with grade 2 or 3 deformities was 87% for reader 1 and 93% for reader 2. A strategy of AP and lateral VFA followed by selective radiography in those with a grade 2 deformity (for confirmation) or those with moderate or severe scoliosis on the AP view showed excellent agreement with x-ray, as shown in the following table for reader 1 (values for reader 2 in parentheses).

	Radiography Negative	Radiography Positive	Totals
Absorptiometry Strategy Negative	185 (188)	2 (1)	187 (189)
Absorptiometry Strategy Positive	2 (1)	14 (13)	16 (14)
Totals	187 (189)	16 (14)	203

The kappa statistic for agreement between the two strategies was 0.864 (95% CI 0.794 - 0.934) for reader 1 and 0.923 (95% CI 0.853 - 0.993) for reader 2. The VFA strategy would require follow-up radiographs for 26 (12.8%) according to reader 1 and for 25 (12.3%) according to reader 2. VFA can detect those with grade 2 or 3 radiographic vertebral deformity very accurately, especially if the AP view is also obtained and follow-up radiographs are obtained for those with scoliosis and no obvious grade 3 fracture.

Trabecular and Cortical Bone Structure in Glutocorticoid-Steroid Induced Osteoporosis. B. Hyun*[1], G. Blumenkrantz*[1], D. C. Newitt[1], S. Majumdar[1], N. Lane[2]. [1]MQIR, Department of Radiology, UCSF, San Francisco, CA, USA, [2]Department of Medicine, UCD, Davis, CA, USA.

Subjects treated with glucocorticoids (GCs) fracture at higher bone mass than postmenopausal osteoporotic (PMO) women. Since GCs increase bone resorption and decrease bone formation, we hypothesize that changes that alter trabecular architecture with GC use differ from the PMO state. The purpose of this study was to evaluate trabecular bone (TB) and cortical bone (CB) structure in the distal radius using high-resolution MRI in subjects with GC induced bone loss (n = 13, mean age 53.4 ± 14.4 yrs, mean GC dose 6.7 mg/day, for 5 yrs.) compared to PMO fracture group (n=27, mean age 59.2 ± 3.2 yrs)(1). Methods: HR-MR images were obtained at 1.5 T (GE) using a gradient echo sequence at a spatial resolution of 156 x 156 x 500 µm. Trabecular and cortical regions of the distal radius were segmented, and bone measurements were calculated using semi-automatic in-house developed routines written in IDL (RSI, Boulder, CO). The TB region was segmented into bone and marrow components and measures such as App BV/TV (volume fraction), App TbN (trabecular number), App TbTh (trabecular thickness), and App TbSp (trabecular spacing) were calculated. TB measurements were calculated from the segmented trabecular regions and then averaged over two 5 mm slabs starting 7 mm from the endplate. The CB volume and average thickness was measured and also normalized for bone size in a 10 mm region 20 mm from the endplate. Results: The mean trabecular structure measures are shown in Table 1. When a subset (n = 8, mean age = 48.9 ± 15.2 yrs) was compared to the PMO subjects, the GC group had lower App BV/TV (-18.1%) App TbN (-3.3%,), App TbTh (-15.8%), and higher trabecular spacing (+13.9%) in a 5 mm region that was 7 mm from the endplate. In the next 5 mm consecutive region, 12 mm from endplate, the GC group had lower App BV/TV (-23.2%), App TbN (-5.9%), App TbTh (-19.4%), and higher TbSp (+15.1%) than the PMO fracture group. Cortical volumes and thicknesses of the GC group were on average larger, 7.9% and 21.5% respectively, than the PMO group. These results suggest that GCs do alter TB architecture more than PMO state. However, CB appears less involved with low doses of GCs. Additional analysis to determine whether GCs alter CB and TB structure both at the hip and calcaneus is underway.

		GCS Induced Osteoporosis	Post-Menopausal Osteoporotic Fracture (1)	p value
Averaged 5 mm region 7 mm from the endplate	App BV/TV	0.300 ± 0.049	0.366 ± 0.042	<0.001
	App TbN	1.604 ± 0.156	1.659 ± 0.177	0.325
	App TbSp	0.444 ± 0.078	0.390 ± 0.072	0.046
	App TbTh	0.186 ± 0.016	0.221 ± 0.053	<1.5E-06
Averaged 5 mm region 12 mm from the endplate	App BV/TV	0.273 ± 0.058	0.355 ± 0.053	<0.003
	App TbN	1.502 ± 0.208	1.596 ± 0.260	0.229
	App TbSp	0.503 ± 0.129	0.437 ± 0.020	0.215
	App TbTh	0.180 ± 0.018	0.223 ± 0.020	<2.0E-07

Role of Cortical Shell in Vertebral Strength Assessment. S. K. Eswaran*[1], A. Gupta*[1], M. F. Adams*[2], T. M. Keaveny[1]. [1]Mechanical Engineering, University of California at Berkeley, Berkeley, CA, USA, [2]Columbia University, New York, NY, USA.

One key issue in clinical non-invasive strength and fracture risk assessment for the spine is the relative biomechanical roles of the cortical shell vs. trabecular bone, an issue that remains poorly understood. To gain new insight into this issue, we developed high-resolution micro-CT based finite element models at 60-µm spatial resolution for 13 cadaveric thoracic vertebrae (age range: 54-87 years, 74.6±9.4 years). The shell was explicitly identified using custom image-processing routines, and three sets of models were analyzed under uniform compressive loading using high-performance supercomputers: the intact vertebral body; a "no-shell" model in which the shell was virtually removed; and a "shell-only" model, consisting of only the removed shell. From this, we could extract the relative biomechanical roles of the cortical shell and trabecular bone. Results indicated that the shell mass fraction (cortical shell mass divided by total mass) ranged from 21%-39%, indicating that the shell represents a substantial portion of the bone material in the vertebral body even though the average shell thickness was only 0.38±0.06 mm**.** As expected, the maximum load taken by the shell in a vertebra occurred at the narrowest section of the vertebra, and across vertebra, this varied between 41%-66%. The maximum load taken by the trabecular bone within a vertebra, which typically occurs close to the endplates, ranged across vertebrae from 68%-92%. The reduction in vertebral stiffness due to the virtual removal of the shell ranged from 38%-68%, and depended more on the shell mass fraction (R^2=0.93, p<0.0001) than on trabecular bone volume fraction (R^2=0.42, p<0.02). Taken together, these findings establish that the biomechanical role of the thin cortical shell in the vertebral body is substantial, and is maximum at the mid-section where the vertebra is narrowest. The role of the trabecular bone can also be substantial and is greatest near the endplates. It follows then that non-invasive densitometric assays of vertebral strength should include measures of both cortical and trabecular bone density. If trabecular bone density alone is to be monitored, the most relevant regions for sampling are near the endplates and not at the center since it is precisely in the central section that the trabecular bone has least influence on overall structural behavior.

Predicting Hip Fracture in a Sub-Group of Subjects from the Study of Osteoporotic Fractures Using Automated Structural Measurements of Proximal Femur in Pelvic Radiographs. D. Steines*[1], C. Arnaud[1], S. Liew[1], R. Vargas-Voracek[1], D. C. Bauer[2], S. R. Cummings[2], P. Hess[1]. [1]Imaging Therapeutics, Foster City, CA, USA, [2]S.F. Coordinating Center, CPMC Research Institute and UC San Francisco, San Francisco, CA, USA.

Factors other than bone mineral density (BMD), such as trabecular structure (TS) and cortical bone thinning (CBT), contribute to fracture. We analyzed whether fracture cases could be differentiated from controls without fracture using automated TS and CBT surrogate measurements of proximal femur from pelvic radiographs using novel imaging analysis technology. Examples of such measurements include the density of micro-structure in principal tensile regions and measurement of the shaft and neck cortical bone thickness and width. Pelvic radiographs from a subgroup of 400 women participating in the Study of Osteoporotic Fractures (SOF) were used in the analysis. A sample of 108 prevalent controls at end of follow-up and 97 hip fracture subjects with radiographs performed close to the time of fracture were chosen based on available BMD measurements as well as minimum acceptable image quality and patient positioning as graded by two different observers. TS and CBT measurements were combined into two separate micro and macro classification indexes respectively using likelihood ratios. The classification performance of each of these indices and in combination with body mass index (BMI) and BMD was evaluated using receiver operating characteristic (ROC) curves with a leave-one-out cross-validation scheme. The corresponding areas under the ROC curves and mean values with 25%, 50% and 75% percentiles for the parameters from control and fracture cases are summarized in the table below.

Parameters Analyzed	Area Under ROC Curve (%)	Sensitivity at 80% Specificity (%)	Control Cases Mean Value (1st, 2nd and 3rd quartiles)	Fracture Cases Mean Value (1st, 2nd and 3rd quartiles)	p-value t-test for difference in means
(Macro+Micro)+BMD	88	80	NA	NA	NA
(Macro+Micro) index	86	76	5.29 (-1.18,4.61,10.5)	-8.47 (-11.11,-6.8,-2.32)	<0.001
BMD	81	68	0.8 (0.72,0.80,0.89)	0.64 (0.57,0.64,0.7)	<0.001
Macro index only	74	53	3.17 (-0.17,0.91,3.75)	-0.18 (-2.4,-0.8,0.74)	0.0252
Micro index only	73	52	-0.37 (-2.86,-0.29,2.5)	-5.74 (-8.7,-3.57,-1.7)	<0.001
BMI	60	28	26.48 (23.0,26.3,29.5)	24.85 (22.2,24.4,27.1)	0.0046

The combined macro and micro structural measurements had a higher AUC than BMD alone (86% vs. 81%, p-value<0.001). The best performance (AUC=88%) was obtained when macro and micro indexes were combined with BMD suggesting the presence of added complementary information. Further optimization and generalization verification of these results is needed using a broader population sample since only prevalent controls were considered. Nonetheless, these results indicate that this new technology has the potential of improving the prediction of hip fracture risk based on classification of macro and micro-structural measurements from standard pelvic radiographs.

Prediction of Non-Vertebral Fracture Risk in 5201 Postmenopausal Women by Quantitative Ultrasound of the Calcaneus: 36-Month Final Results from the ECOSAP Prospective Study. A. Díez-Pérez[1], J. González-Macías[2], J. Vila*[3], F. Gómez-Martín*[4], T. Guerrero*[5], G. Rodríguez-Roca*[6], J. J. Montero*[7], M. A. Fortea*[8], I. Nieto*[9], P. Arqueros*[10], F. Marín[11]. [1]Dept. Internal Medicine, H. del Mar, Barcelona, Spain, [2]Dept. Internal Medicine,, H.U. Valdecilla, Santander, Spain, [3]IMIM, Barcelona, Spain, [4]C.S. Guayaba, Madrid, Spain, [5]C.S. Fuensanta, Sevilla, Spain, [6]C.S. Puebla de Montalbán, Madrid, Spain, [7]A.B.S. Ronda Prim, Mataró, Spain, [8]C.S. Campanar, Valencia, Spain, [9]C.S. Rochapea, Navarra, Spain, [10]C.S. Ciudad Jardín, Almería, Spain, [11]Medical Research, Eli Lilly and Company, Madrid, Spain.

Several prospective studies have shown that bone quantitative ultrasound (QUS) variables are predictive of osteoporotic fractures with a similar magnitude to DXA. ECOSAP is a 3-year prospective study to evaluate the ability of calcaneus QUS and several clinical risk factors of osteoporosis and fractures to predict the non-vertebral fracture risk in women ≥ 65 years . 5201 women aged 72.3±3.5 years (mean±SD) were assessed with a Sahara® equipment. Women were selected using non-probabilistic sampling of consecutive cases regardless of the reason for consultation in 58 Primary Care Centers across Spain. At baseline, 1042 women (20.1%) presented a history of fragility fracture in adulthood (>35 years). We report here the final study results. 4453 women (87,3%) have completed the 36-month final visit, with a total follow-up of 15,282 women/ years. A total of 369 non-vertebral fragility fractures in 317 women were reported. A Cox proportional hazard regression analysis with non-vertebral fractures as the dependent variable was performed. Independent variables included were all those with a p-value < 0.15. The final model consisted of age, history of falls, prevalent fractures, and family history of fractures. The hazard rates (and 95% CI) per SD decrease of each QUS parameter after adjusting for them are shown in the Table.

Type of fracture (number)	All non-vertebral (n=317)	Forearm (n=111)	Hip (n=52)	Humerus (n=51)
BUA	1.34 (1.18;1.52)	1.33 (1.08;1.65)	1.67 (1.22;2.30)	1.33 (0.98;1.81)
SOS	1.21 (1.09;1.34)	1.30 (1.12;1.50)	1.25 (0.99;1.57)	1.19 (0.90;1.55)
QUI	1.32 (1.17;1.50)	1.48 (1.19;1.84)	1.50 (1.08;2.08)	1.33 (0.97;1.82)
Estimated heel BMD	1.33 (1.17;1.51)	1.48 (1.19;1.85)	1.54 (1.11;2.14)	1.35 (0.98;1.86)
Estimated heel BMD (T-score)	1.30 (1.16;1.47)	1.44 (1.17;1.76)	1.56 (1.14;2.13)	1.35 (1.00;1.82)

The 3-year final results of the ECOSAP study show that QUS of the heel is a predictor of overall non-vertebral osteoporotic fractures, and of hip, forearm and humerus in a cohort of elderly Spanish women included regardless their bone mass status.

A Model to Predict Hip Fracture in Elderly Women by Using Clinical Factors and QUS: The Combined "SEMOF + EPIDOS" Prospective Cohort. D. Hans[1], C. Durosier*[1], A. M. Schott*[2], C. Ruffieux*[3], P. J. Meunier[4], R. Rizzoli[5], J. Cornuz*[3], M. A. Krieg[3]. [1]Nuclear Medicine, Geneva University Hospital, Geneva - 14, Switzerland, [2]Medical Information, Hospices Civils of Lyon, Lyon, France, [3]Outpatient Clinic, Lausanne University Hospital, Lausanne, Switzerland, [4]Inserm U 403, Edouard Herriot Hospital,, Lyon, France, [5]Bone Diseases, Geneva University Hospital, Geneva - 14, Switzerland.

A European report deplores that only a marginal percentage of women at high risk of osteoporotic fracture are diagnosed. Studies have shown that heel bone ultrasound (HBU) could be useful as a pre-screening method. The SEMOF study group recently demonstrated that the association between QUS with other risk factors improved the prediction of women at high risk for non vertebral fractures. The aim of our study is to develop a mega model combining EPIDOS and SEMOF to predict hip fracture using a simple score. We built a data base "EPIMOF" (12960 women aged 70 to 97 years) by grouping the SEMOF (Swiss) and EPIDOS (French) prospective multi-centre cohorts. At baseline, all the women had been measured by the HBU Achilles+ (GE-Lunar), and examined for their risks for osteoporosis thanks to questionnaires. During a mean follow-up period of 3.2 ± 0.9 years (± SD), 307 women reported a hip fracture. While all clinical and QUS factors were tested using a Cox model, only significant ones were used in the building of a score of risk. The principle of this score is based on the coefficients of the Cox model to give a weight to each independent predictor. We fixed the score threshold corresponding to a "high risk" of hip fracture so that the specificity was 80% and the score threshold corresponding to a "low risk" so that the sensitivity was 80%. The independent predictors of hip fracture we kept to calculate the score of risk are the following : stiffness index (SI, in 3 classes), age (in classes), fracture history and weight (more or less than 59 kg). 53.4 % of the women who reported a fracture were at high risk at baseline and 57.7 % of the women who didn't report a fracture were at low risk at baseline. Concerning SI alone, the corresponding percentages were 57.3% and 23%, respectively. 6.3 % of the women who were at high risk at baseline reported a hip fracture and 99.1 % of the women who were at low risk at baseline didn't report a fracture. Concerning SI alone, the corresponding percentages were 4.8 % and 99.2 %, respectively. In conclusion, associating heel bone ultrasound with clinical risk factors clearly improve the detection of elderly women at low risk of hip fracture. The score allows to exclude women at low risk with more assurance. Current cost-effective analysis is underway to further validate such an approach for pre-screening.

Five-Year Change in Bone Mineral Density Is Heritable in Mexican Americans: The San Antonio Family Osteoporosis Study. J. R. Shaffer*[1], C. M. Kammerer[1], J. Bruder*[2], R. L. Bauer*[2], B. D. Mitchell[3]. [1]U. Pittsburgh Grad. School Public Health, Pittsburgh, PA, USA, [2]U. Texas Health Science Center, San Antonio, TX, USA, [3]U. Maryland School of Medicine, Baltimore, MD, USA.

Acquisition of peak bone mass and subsequent rate of bone loss predict risk of osteoporosis. While numerous studies have documented the high heritability of peak bone mass acquisition, the genetic contribution to bone loss is largely unknown. We investigated the extent to which genes and environmental factors influence change in hip, spine, and radius bone mineral density (BMD) over time using data on 18 extended Mexican American families comprising 261 females, and 167 males, ages 18 to 78. DXA measurements of areal BMD of the hip, spine and radius were obtained at two time points, baseline and follow-up (3 to 7 years later, median = 5.5 years) and used to determine one-year change in BMD. Then, using maximum likelihood methods, we estimated the heritability of baseline BMD, follow-up BMD, and one-year change, after controlling for the effects of age, sex, and BMI. As expected, the proportion of variation due to genetic effects, the residual heritability, was significant and similar at baseline and follow-up, respectively, for hip (0.58 ± 0.10 vs. 0.51 ± 0.11), spine (0.54 ± 0.11 vs. 0.56 ± 0.11), and radius (0.26 ± 0.09 vs. 0.29 ± 0.10). Because most bone loss takes place later in life, we estimated heritability of BMD change in a subset of 176 individuals who were > 45 years of age at baseline. BMD decreased in these older individuals by an average of 0.0135, 0.005, and 0.003 g/cm^2 per five years, respectively, at hip, spine, and radius. Residual heritability of the one-year change in BMD at these sites, respectively, was 0.39 ± 0.20 (p = 0.009), 0.46 ± 0.22 (p = 0.007), and 0.45 ± 0.25 (p = 0.02). Thus, genetic factors may account for up to 40% of the variability in BMD change, whereas the variance explained collectively by age, sex, and BMI was about 30% for the spine, and < 5% for hip, and radius. While other unknown factors are also important, our estimates show that variation in one-year change of BMD, like peak BMD, is largely due to genetic factors. To the best of our knowledge, this is the first study to demonstrate the heritability of change in BMD, identifying the additional role of genetic factors affecting longitudinal loss of BMD in conjunction with those affecting acquisition of peak BMD. Furthermore, the magnitude of the heritability of BMD change indicates that subsequent linkage analyses to locate genes that affect BMD loss should be fruitful.

CAST Chromosome 1 QTL Is Complex and Contains Three BMD Loci and One Bone Size Locus: Evidence from Subcongenic Lines. B. Edderkaoui[1], D. J. Baylink[2], W. G. Beamer*[3], K. L. Shultz*[3], N. Dunn*[1], J. E. Wergedal[2], S. Mohan[2]. [1]JLP VAMC, Loma Linda, CA, USA, [2]JLP VAMC and LLU, Loma Linda, CA, USA, [3]Jackson Labs, Bar Harbor, MI, USA.

BMD is an important component of bone strength and a recognized predictor of risk for osteoporotic fracture. Elucidating the genetic basis for BMD variation could lead to identification of potential preventive measures against developing osteoporosis. Genome wide-linkage analysis using C57BL/6J(B6)-CAST/EiJ (CAST) intercross revealed the presence of quantitative trait locus (QTL) responsible for BMD variations in Chr 1. Our goal was to delineate the chromosome interval harboring this QTL by using subcongenic lines of mice. The B6.CAST-1T congenic line, which carries the CAST segment covering the whole QTL region in Chr 1, was previously generated to confirm the effect of this QTL on femoral vBMD (Beamer et al., 2003). Ten subcongenic lines were generated after several backcrossing of the initial B6-CAST-1T congenic with the B6 mice. 16-week-old female mice were characterized. Three sublines carrying non-overlapping CAST segments showed significant change of femoral vBMD compared to B6 control mice. This provided evidence for the presence of 3 genes within the initial QTL capable of regulating BMD independently. Phenotypic characterization of the remaining sublines, which carried over-lapping regions, confirmed the presence of at least three loci (BMD1-1, BMD1-2 and BMD1-3) responsible for vBMD variation in Chr 1 QTL. Sublines carrying CAST segment that covered the first two loci (BMD1-1 and BMD1-2) showed significantly greater femur vBMD (5-12%) compared to B6 mice. However, sublines carrying *cast* alleles within BMD1-3 locus showed significantly reduced femur vBMD compared to B6 mice (6%). Correlation analysis showed that femur vBMD phenotype had a strong negative correlation with endosteal perimeter (r=-0.8; P=0.003), and a strong positive correlation with cortical thickness among the ten sublines (r=0.97; P<0.001). These data provide evidence that the three genes in Chr 1 may influence the vBMD phenotype by affecting endocortical bone formation and/or bone resorption. In addition to the vBMD loci, the proximal region of BMD1-2 locus contains bone size (BS) QTL. The significantly greater periosteal in the two sublines covering this region was lost after adjustment for body weight (BW). In contrast, none of the vBMD QTL was affected by BW adjustment. In Conclusion: 1) the initial vBMD QTL in Chr 1 is the result of three separate QTLs which affect vBMD both positively and negatively. 2) The three loci influence femur vBMD primarily by increasing or reducing the endosteal perimeter. 3) A genetic locus associated with BW and BS phenotypes was found within the BMD QTL in Chr 1.

An Update on N-Ethyl-N-Nitrosourea (ENU) Induced Mutation Screen for Musculoskeletal Phenotypes in Mouse. A. Srivastava, S. Mohan, D. J. Baylink. JLP VAMC and LLU, Loma Linda, CA, USA.

Chemical mutagenesis followed by screening for abnormal phenotypes in the mouse holds great promise as a method for revealing gene function. Earlier, we have described a mouse N-ethyl-N-nitrosourea (ENU) mutagenesis program incorporating a genome-wide screen of one-generation dominant (F1) as well as three-generation recessive (F3) recessive mutations affecting musculoskeletal disorders in mouse model. Abnormal phenotypes are identified as ±2-3SD units different from control mice. The mutant mice were progeny tested to determine whether their abnormality is inheritable with a bimodal segregation of offspring in expected 1:1 or 1:3 Mendelian ratios, in dominant and recessive screens, respectively. We have screened approximately 2000 F1 and F3 mice. We observed more than 60 quantitative phenodeviants in primary screen, confirmed more than 30 phenodeviants in secondary screen, and tested approximately 30 phenodeviants for inheritable phenotypes. So far six musculoskeletal phenodeviants have been confirmed in multiple litters and are currently undergoing positional cloning.

Mutant Mouse ID	Genetic Screen	Major Phenotype	# Affected Mice (# of Progeny Screened)
917	Dominant	10-13% Lower total body bone area in males, females not affected	68 (165)
12137	Dominant	11-12% Higher Total Body Bone Density (BMD) and 12-14% Higher Bone Mineral Content (BMC)	56 (132)
12184	Dominant	11-14% Higher BMD, 15-20% Higher Trabecular BMD at Proximal Femur & Lumbar Vertebrae	45 (102)
B24	Recessive	13-14% Higher BMD and 14-15% Higher BMC	29 (86)
B29	Recessive	20-30% Low Bone Markers and 8-10% Higher Total Body BMD	6 (30)
B54	Recessive	9-14% Higher BMD, 14% Higher BMC	26 (85)

We have identified chromosomal location of a bone size mutant (ID 917) to a proximal region (12 cM) of chromosome 4. A high bone density mutant (ID12184) shows major locus on distal Chr 4 that regulates bone density. In conclusion, this program has identified mutants with significant differences in BMD, BMC and bone size, which would facilitate future discovery of major gene(s) that regulate BMD and other relevant skeletal phenotypes. In addition, the larger phenotypic variations in the mutant mice compared to QTL effects (~5%) and the availability of mutant mice for phenotypic characterization and gene expression without the need to develop congenic mice would increase the efficiency of gene identification process.

Mapping an ENU Mutant with High Bone Density Reveals a Major Locus on Distal Region of Chromosome 4. A. Srivastava, S. Mohan, V. Chest*, J. E. Wergedal, D. J. Baylink*. JLP VAMC and LLU, Loma Linda, CA, USA.

Using ENU mutagenesis approach to reveal gene function, we have identified a mutant with increased bone density in a dominant screen in C57BL/6J (B6) mice. Data from 16-week old progeny produced (total number of pups n=102) from this mutant mice showed that mean total body bone mineral density (BMD) was 9-13% higher ($p<0.001$, n=45) and total body bone mineral content (BMC) was 10-14% higher ($p<0.01$), as compared to age and sex matched wild type (WT) controls. The total body bone area was not significantly affected. In addition to bone density, the lean body mass determined by DEXA was 8-17% higher in mutant progeny. Volumetric bone density measured in tibia and femur by pQCT was 4-7% higher at midshaft region, as compared to WT mice. To determine the chromosomal location of the ENU mutation, we bred mutant B6 mice with C3H/HeJ (C3H) mice in an intercross breeding to generate 137 B6C3H F2 mice for a low-resolution (using 66 markers) QTL mapping. Body weight adjusted total body bone density and total body bone mineral content determined by DEXA were used as phenotypes. Data from female (n=67) and male (n=70) C3HB6 F2 mice were combined for QTL analysis. Interval mapping of BMD indicated a major peak with LOD score of 8.1 (genome wide significance value $p<0.00001$) on Chr 4 (70 cM). Similarly, interval mapping of BMC trait indicated a major peak with LOD score of 4.6 ($p=0.000024$) on Chr 4 (55 cM). In conclusion, we report identification and characterization of an ENU mutant with approximately 10% higher bone density, and QTL mapping of mutant mice indicates locus on distal Chr 4 that regulates bone density. Further studies on positional cloning will reveal the mutant gene that contributes to higher bone density in mutant B6 mice.

Isolation of a Gene Affecting Bone Mass on Rat Chromosome 4 Using Congenic Rats. I. Alam[1], L. Lumeng*[2], L. G. Carr*[2], C. H. Turner[1]. [1]Orthopaedic Surgery, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA, [2]Medicine, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA.

Several epidemiological studies showed an association between moderate alcohol intake and elevated bone mineral density. It is possible that gene regulating bone mass co-segregate with genes regulating the alcohol preference trait. Previously, we determined bone mass and strength phenotypes in three different alcohol-preferring rat lines. We observed that alcohol-preferring (P) rats have significantly higher bone mass and strength compared to alcohol-non-preferring (NP) rats, both in long bones and lumbar vertebra. Genetic mapping in P/NP rats has identified a major quantitative trait locus (QTL) on chromosome (Chr) 4 for alcohol preference. Also, a QTL linked to bone structure was identified at the same location, which suggests Chr 4 QTL harbor genes regulating both bone mass and alcohol preference. To further study the effects of the Chr 4 QTL, we created reciprocal congenic strains (P.NP and NP.P) by introgressing the Chr 4 QTL region of one inbred strain (donor) into the genetic background of another inbred strain (recipient). Bone phenotypes, i.e. bone mineral content (BMC) by DXA and volumetric bone mineral density (vBMD) by pQCT, in P/NP and P.NP/NP.P rats at 3 months were measured in long bones and lumbar vertebrae. P.NP rats had significantly lower (4 - 10%, $p<0.05$) normalized BMC (BMC/body weight) in the femur, tibia, and lumbar 1-6 vertebrae compared to P rats. Also, P.NP had significantly lower (14 - 17%, $p<0.0005$) total and trabecular vBMD at proximal tibia. The cortical vBMD at tibial midshaft did not differ between these rats, suggesting that the low BMD phenotype was due mostly to reduced trabecular bone. These results indicate that transfer of the QTL region of Chr 4 from NP rats to P rats significantly decreases bone mass in these congenic rats, suggesting that the Chr 4 QTL harbors a gene or genes that affect bone mass. The most likely candidate gene in this region is neuropeptide Y (NPY). The P.NP rats had decreased bone mineral density, increased body weight, and decreased alcohol preference, which are all associated with increased production of NPY. Our results suggest that some genes regulating bone mass do co-segregate with the genes affecting alcohol preference in congenic P.NP rats. Consequently, congenic P.NP rat model will be a valuable model for identifying some novel genes regulating bone biology.

Genetic Architecture of Bone Strength Related Traits in Weight-Bearing versus Non-Weight-Bearing Bones: The Tobago Family Study. X. Wang*[1], C. M. Kammerer[1], V. Wheeler*[2], A. L. Patrick*[2], J. A. Cauley*[1], C. H. Bunker*[1], J. M. Zmuda[1]. [1]U. of Pittsburgh, School of Public Health, Pittsburgh, PA, USA, [2]Tobago Health Studies Office, Tobago, Trinidad and Tobago.

Populations of African ancestry have lower osteoporotic fracture risk than other ethnic groups, but the number of affected individuals is expected to increase dramatically in the future due to demographic changes and the number of African individuals at increased risk. In sharp contrast to our understanding of osteoporosis in Caucasians, there is a paucity of information about skeletal health in non-white populations, and particularly among those of African heritage. Using preliminary data on 238 women and 166 men aged 18 and older (mean 43 years old) from 8 large, multigenerational Afro-Caribbean families with a mean family size >50 individuals (range from 21 to 112), we dissected the genetic architecture of bone strength related phenotypes measured by peripheral quantitative computed tomography (pQCT) (including cortical and trabecular volumetric BMD, endosteal and periosteal circumferences, and cortical thickness for the distal and proximal tibia and non-dominant radius). Heritabilities were estimated after accounting for age, gender and their interaction. The majority of measured traits were moderately to highly heritable (H2r, 20% to 71%). H2r estimates were several-fold higher for trabecular than cortical BMD at both the radius and tibia (0.66±0.10 versus 0.25±0.09 for radius and 0.71±0.10 versus 0.33±0.09 for tibia). The genetic correlation (r_g) between trabecular BMD at the radius and tibia (0.86±0.05) was high and similar to that for cortical BMD at these regions (0.87±0.08) indicating that common genes may regulate cortical and trabecular volumetric BMD between different anatomical sites. However, the genetic correlation between cortical and trabecular BMD in the radius (or in the tibia) was not significantly different from 0 (0.31±0.20 for both). We provide the first comprehensive genetic epidemiologic analysis of bone strength related traits measured by pQCT in human families and the first analysis of these traits in extended families of African heritage. The low genetic correlation between trabecular and cortical BMD implies that linkage analyses should reveal different genes influencing each of these bone traits.

F114

Genetic and Gender Regulation of Femoral Density and Size in Congenic Strains for Mouse Distal Chromosome 1. W. G. Beamer, K. L. Shultz, K. M. Delahunty*, L. G. Horton*, H. F. Coombs*, C. L. Ackert-Bicknell, L. R. Donahue, C. J. Rosen. The Jackson Laboratory, Bar Harbor, ME, USA.

Genetic analyses of F2 females from C57BL/6J (B6) and C3H/HeJ (C3H) inbred strains revealed at least 8 QTL for femoral vBMD measured by pQCT. Chromosome (Chr) 1 showed the highest LOD score and accounted for the largest fraction of vBMD variation. A B6.C3H-1T congenic strain carrying a large genomic segment from C3H confirmed the QTL presence. Nested congenic sublines were developed from the 1T congenic to

accurately map bone regulatory loci and test for possible gender differences. Femurs were isolated from groups (18-35) of 4 mo old female and male B6 progenitor and congenic mice homozygous for segments of distal Chr 1. Data acquired by SA Plus pQCT instrument included total femoral mineral and volume, metaphyseal trabecular mineral and volume, mid-diapyseal cortical thickness, plus endosteal and periosteal perimeters. Body weights and femur lengths differed among the sublines, thus bone data were adjusted for effects of body mass and skeletal size prior to statistical comparisons with B6 data. Six of 14 congenic sublines span the most distal 22 Mb region of Chr 1 with informative overlapping sequences. Comparison of subline bone parameters with B6 in the region from 169.93-172.01 Mb showed: 1) reduced trabecular vBMD in females and increased trabecular vBMD in males; 2) unchanged femoral length in females but reduced in males. Comparison of bone parameters in the region from 173.54-177.51 Mb showed: 1) females increased total femoral vBMD, mineral, volume, and both endosteal and periosteal perimeters; 2) males had unchanged femoral vBMD and decreased total mineral; 3) female femoral length was unchanged but reduced in males. Body weight declined for both sexes in chromosomal regions proximal and distal to, but not within, the 173.54-177.51 Mb region carrying the female vBMD regulation. PIXImus DEXA data showed the BMC for total body and lumbar spine confirmed the pQCT data for total mineral in females and males for the 173.54-177.51 Mb region. Whole bone mRNA was examined for gene expression by the Affymetrix 430 v2 chip. There are 115 genes in the distal 22 Mb region, 13 of which were differentially expressed. There are 14 genes in the 173.54Mb-177.42Mb region containing the QTL regulating increased female vBMD, four of which were differentially expressed, two were up-regulated (*Ifi202b, Ifi203*) and 2 were down-regulated (*Spna1, Fmn2*). These alterations in gene expression are being tested by real time PCR for validation in independent bone samples. These data confirm sex specific pathways for acquisition of peak bone mass, reveal compartment specific effects, and imply caution is warranted when generalizing findings across gender.

Molecular Basis of Heritable Forms of Osteoarthritis. L. J. Gleghorn*[1], R. Ramesar*[2], P. Beighton*[2], G. Wallis*[1]. [1]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom, [2]Department of Human Genetics, University of Cape Town, Cape Town, South Africa.

Osteoarthritis (OA) is a common, painful, debilitating disease that results in the progressive degeneration of the articular cartilage of synovial joints. Spondyloepiphyseal dysplasia - type Kimberley (SEDK) is a rare heritable skeletal dysplasia characterised by short stature, a stocky build and severe premature OA. This autosomal dominant disorder has been identified in a multi-generation family in South Africa. The aim of this study was to elucidate the molecular basis of SEDK in this family in order to gain an insight into the aetiology and pathogenesis of similar and more common forms of OA. Genetic linkage analysis was used to refine the SEDK disease locus to a 7cM region of chromosome 15q26.1. Candidate genes for the disorder were identified within this region on the basis of function and expression and then screened for mutations by direct sequencing. Screening of the aggrecan gene (*AGC1*), that encodes a major structural component of cartilage, identified a 1 bp insertion in the sequence of exon 12 that segregated with the disorder in the SEDK family. This mutation causes a frameshift plus a premature termination codon that predicts the synthesis of a truncated aggrecan core protein containing an abnormal sequence of 213 amino acids and lacking functionally important C terminal domains. This is the first *AGC1* mutation identified to cause a human disorder. *AGC1* mutations have however been identified to cause lethal recessive forms of skeletal dysplasia in the mouse and chick. Collectively these *AGC1* mutations establish an important role for aggrecan in both skeletogenesis and cartilage homeostasis. It is likely therefore that *AGC1* mutations cause as yet uncharacterized human forms of early onset osteoarthritis and studies to identify such mutations are underway. Further, studies are will be carried out to examine the molecular consequences of *AGC1* mutations on normal development and disease processes.

LRP 6 Variants Determine Fracture Risk in Elderly Men. J. van Meurs*[1], M. Jhamai*[1], A. Hofman*[2], J. van Leeuwen[1], H. Pols[1], A. Uitterlinden[1]. [1]Internal Medicine, Erasmus MC, Rotterdam, The Netherlands, [2]Epidemiology, Erasmus MC, Rotterdam, The Netherlands.

Recent work identified Wnt-signaling to control postnatal bone formation, with a pivotal role for the Wnt co-receptor LRP5. A closely related homologue of LRP5, LRP6, is also capable to act as a co-receptor for Wnt ligands and was recently shown to be important in bone metabolism in mice(Kokubu et al, Development 2004). We here studied association of an amino-acid variant of the LRP6 gene (Ile1062Val) with bone parameters and fracture risk in 6373 participants of a large prospective population-based cohort of elderly subjects. In addition, we studied interaction between Ile1062Val and LRP5 Ala1330Val, which has previously been implicated in osteoporosis, and the Arg324Gly variation in secreted frizzled related protein 3 (sFRP3) that was found previously to influence the ability to antagonize Wnt-signaling (Loughlin et al, PNAS 2004) and reduce the vertebral fracture risk in older women (Zmuda et al, ASBMR 2003). In men, carriership of the Val-allele (f=20%) of the I1062V polymorphism in LRP6 was associated with increased height (p=0.04) and increased vertebral body size (p=0.01). Male carriers of the Val-allele of the LRP6 polymorphism had a 60% increased risk (p=0.01) for fragility fractures. We found an additive effect of the LRP6 and LRP5 variants with respect to fracture risk. While male carriers of a single LRP6 or LRP5 risk allele had a fracture risk of 1.5, carriers of both risk alleles had a 2.4 times increased risk (p=0.004) for fragility fractures compared to the reference group. A similar trend was seen in women, however not reaching significance. In addition, we found a very significant interaction between the LRP6 and sFRP-3 variants. Either LRP6 or sFRP-3 risk allele carriers had 50% increased risk, while double risk allele carriers had a trend towards lower risk (p interaction term= 0.06 for males and 0.002 in females) All the relations were independent of age, height, weight or BMD. In conclusion, in men the V-1062 variant of the LRP6-gene is associated with frame-size and fracture risk. An additive effect was seen for fracture risk between the LRP5 and 6 variants, while the sFRP-3 variant interacts with the LRP6 variant to reduce fracture risk.The Ile1062Val polymorphism in LRP6 lies within a domain that is predicted to form a structure resembling a propeller with 6 blades. These domains have been implicated in binding of Wnts and Wnt-inhibitors. Alignment of close homologues of LRP6 showed a strong evolutionary conservation of the 1062 Isoleucine, which is strong evidence for functional importance of this residue. Further experiments are needed to elucidate the effects of this variant on function of the LRP6-protein.

Haplotype Polymorphisms of the Calcium-Sensing Receptor Gene and their Association with the Renal Stone Phenotype in Primary Hyperparathyroidism. A. Scillitani*[1], V. Guarnieri*[1], C. Battista*[1], S. De Geronimo*[2], L. Muscarella*[1], I. Chiodini*[1], M. Cignarelli*[3], S. Minisola[2], F. Bertoldo*[4], C. Francucci*[5], N. Malavolta*[6], A. Piovesan*[7], L. D'Agruma*[1], D. Cole[8]. [1]Casa Sollievo Sofferenza, San Giovanni Rotondo, Italy, [2]Un, Roma, Italy, [3]Un, FG, Italy, [4]Un, VR, Italy, [5]Un, AN, Italy, [6]Un, Bo, Italy, [7]Un, TO, Italy, [8]University, Toronto, ON, Canada.

Three clustered SNPs in exon 7 of the *CASR* gene (A986S, R990G, Q1011E) have been associated with variation in extracellular calcium levels in Caucasian populations, both individually and in haplotype combination. Looking for parallel associations in primary hyperparathyroidism (PHPT), we recruited 237 subjects with well-characterized sporadic PHPT [41 males 57 ± 15 yr (M ± SD) and 196 females age 58 ± 13 yr] for comparison with 433 controls recruited from a blood donor clinic. In all subjects, we measured serum calcium, albumin, PTH and in PHPT subjects we measured calcium/creatinine clearance (Cl_{Ca}/Cl_{Cr}), BMD by DEXA at spine and femur, and assessed kidney stones by ultrasonography. In all subjects, the 3 *CASR* SNPs were genotyped by direct sequencing. Frequencies of the four different haplotypes (ARQ, SRQ, AGQ, ARE) we observed did not deviate from that expected with Hardy-Weinberg equilibrium. The SRQ haplotype was significantly more common in patients (125/474 or 26.4% of chromosomes) than in controls (170/866 or 19.6% of chromosomes), without significant differences in the other haplotypes (χ^2= 8.39 p= 0.038). SRQ frequency showed a significant trend with disease status (F=7.48 p=0.006), when SRQ copy number was assessed, consistent with a co-dominant effect. There was no significant association between CASR haplotype and BMD. There was a significant association of haplotype with the kidney stone phenotype (χ^2= 15.2 p= 0.0017). In the stone- former sub-group, the SRQ haplotype was underrepresented (50/242 or 20.7% of chromosomes vs 66/210 or 31.4% of non-stoneformer chromosomes) and the AGQ overrepresented (6.6% vs 0.95% of non-stoneformer chromosomes). The association between renal stones in PHPT and presence of AGQ haplotype was significant (χ^2 = 9.73 p=0.002) and robust to logistic regression analysis that corrected for age, sex, PTH and Cl_{Ca}/Cl_{Cr} (p=0.015). PHPT subjects bearing at least one copy of the AGQ haplotype had an odds ratio of 3.8 (95% confidence interval: 1.29-11.2) for the presence of stones. Our data indicate that SRQ haplotype is significantly associated with PHPT and that AGQ haplotype within the PHPT patient population is significantly associated with renal stones in PHPT. Patients bearing this haplotype have a 3.8-fold increased risk for this complication, suggesting that it may be a useful predictor of clinical outcome

Contribution of Microsomal Prostaglandin E Synthase-1 (mPGES-1) in Fracture Healing and Osteoarthritis. K. Yamakawa[1], S. Kamekura[1], M. Murakami*[2], I. Kudo*[2], S. Uematsu*[3], S. Akira*[3], K. Nakamura*[1], H. Kawaguchi[1]. [1]Orthopaedic Surgery, Univ. of Tokyo, Tokyo, Japan, [2]Showa Univ., Tokyo, Japan, [3]Osaka Univ., Osaka, Japan.

Among three isozymes of prostaglandin E synthase (PGES), the terminal enzyme in the biosynthesis of PGE_2 that shows anabolic and catabolic regulation of bone and cartilage metabolism, only microsomal PGES-1 (mPGES-1) is the inducible enzyme functionally coupled with cyclooxygenase (COX)-2. We previously reported that mPGES-1 deficient (-/-) mice showed less sensitivity to pain, lower inflammation, and less inflammatory bone resorption with no effect on physiological condition. This study further investigated the involvement of PGES in two skeletal pathological conditions, bone fracture healing and osteoarthritis (OA), using mouse experimental models. As the fracture model, a transverse osteotomy was created at the tibia in 8-week-old male -/- and the wild-type (+/+) littermates (n=10 / genotype). X-ray analysis of +/+ mice showed that callus formation was detected at 1 week and all fractures were united with bony bridging by 3 weeks after the surgery. Among the three PGES isozymes, only mPGES-1 was shown to be up-regulated following the osteotomy in the callus cartilage and periosteum in +/+ mice by real-time RT-PCR and immunohistochemical analyses. In contrast, 5 out of 10 -/- mice remained in a nonunion state at 3 weeks and the other 5 showed much weaker union with smaller callus: the average volume and mineral content was about half those of +/+ callus. Histologically, the number of both mesenchymal cells and chondrocytes associated with intramembranous and endochondral ossification, respectively, were markedly decreased in the -/- callus at 1 week, while type X collagen- or TUNEL-positive chondrocytes were normally visible. These defects were restored to the +/+ levels by injection of an adenovirus vector carrying the mPGES-1 gene into the fracture site 2 days after the surgery. OA was induced by

medial ligament transection and menisectomy in the knee joints of 8-week-old male mice. Although the three isozymes of PGES were immunohistochemically detected in the joint cartilage of +/+ mice, the expressions did not change during OA progression. Both cartilage destruction and osteophyte formation were similar in +/+ and -/- mice during 14 weeks of observation. We thus conclude that mPGES-1 notably contributes to fracture healing by inducing cell proliferation at the early stage, but not to OA pathogenesis. An inhibitor of mPGES-1 is expected to be a highly selective agent against several disorders, and might replace COX-2 inhibitors whose fatal adverse events have recently been pointed out; however, it should be cautiously applied to patients with bone fracture.

Prevention of Osteoporosis in Ovariectomized Mice Deficient in Platelet-Activating Factor Receptor (PAF): The Autocrine/Paracrine Action of PAF on Osteoclasts not via Osteoblasts. H. Hikiji[1], S. Ishii*[2], H. Shindou*[2], T. Takato*[1], T. Shimizu*[2]. [1]Oral and Maxillofacial Surgery, University of Tokyo, Bunkyo-ku, Tokyo, Japan, [2]Biochemistry and Molecular Biology, University of Tokyo, Bunkyo-ku, Tokyo, Japan.

Platelet-activating factor (PAF, 1-*O*-alkyl-2-acetyl-*sn*-glycero-3-phosphocholine) is a potent phospholipid mediator with various biological activities including platelet activation via activation of a G protein-coupled PAF receptor. PAF is produced in diseases associated with bone resorption such as gingival inflammation or arthritis. However, little is known about the functions of PAF in bone metabolism. We used PAF receptor-deficient mice to define the role of PAF in the process of bone resorption following ovariectomy, a model of postmenopausal osteoporosis. Dual X-ray absorptiometry and histomorphometry clarified that bone resorption was markedly attenuated in PAF receptor-deficient mice, indicating that PAF links estrogen depletion and osteoporosis in vivo. Osteoclasts had higher activity of acetyl-CoA:lyso-PAF acetyltransferase, an important enzyme for PAF biosynthesis, than osteoblasts. TNF-α/IL-1β increased the enzyme activity in osteoclasts. Northern blot analysis revealed that osteoclasts, but not osteoblasts, expressed the PAF receptor mRNA. Consistently, PAF raised the $[Ca^{2+}]_i$ level in osteoclasts but not in osteoblasts. PAF receptor stimulation prolonged the survival of osteoclasts in vitro. Furthermore, the treatment of osteoclasts with a PAF receptor antagonist, WEB2086, reduced the survival rate and the Ca resorption activity. We also obtained similar results with osteoclasts from PAF receptor-deficient mice. In the organ culture study, bone resorption in dissected calvariae was significantly suppressed by the PAF receptor antagonist treatment and the genetic PAF receptor deficiency. Taken together, our results suggest that through the inflammatory cytokines, estrogen depletion enhances PAF production as a unique autocrine/paracrine factor for osteoclast functions. Inhibition of PAF function might develop a new strategy to prevent postmenopausal bone loss, without disturbing actions of osteoblasts.

Smad1 Inhibits the Prostate Cancer Cell Growth as an Androgen Receptor Co-Repressor Induced by Prostate-Derived Factor (PDF). T. Qiu*, X. Shen*, X. Cao. Pathology, University of Alabama at Birmingham, Birminham, AL, USA.

Prostate-derived factor (PDF) is a member of the TGF-/BMP superfamily that is expressed specifically in prostate and placenta. The expression of PDF is androgen-dependent. Subcutaneous implantation of recombinant PDF induced cartilage formation and the early stages of endochondral bone formation, indicating that PDF has a functional relationship to the bone morphogenetic protein (BMP). However, little is known about PDF signaling and its function. Here we report that for the first time Smad1 acts as androgen receptor (AR) co-repressor and PDF induces the interaction between AR and Smad1 by stimulating phosphorylation of BMP specific Smad1, not TGF-β Smads, indicating that PDF's activity is similar to BMPs. To investigate function of Smad1 as the AR transcriptional co-repressor, we examined the effects of phosphorylated Smad1 on propstate cell growth. We found that induction of Smad1 phosphorylation by constitutive BMPRI receptor (ALK6) inhibited the growth of AR^+ LNCaP cells, but not AR^- PC3 cells with cell proliferation assays. Interestingly, siRNA AR abolished the inhibition in LNCaP cells, and stably expression of AR in PC3 resumed Smad1 ability in inhibition of cell growth, indicating that Smad1-mediated inhibition is AR dependent. We then examined the potential interaction of Smad1 with AR in immunoprecipitation assay. Our results demonstrated that PDF/BMP or ALK6 induced interaction between endogenous Smad1 and AR. Noggin and mutation of Smad1 phosphorylation site (G419S) blocked the interaction. To directly visualize the Smad1-AR association in vivo, we employed yellow fluorescent protein-based protein-fragment complementation assays. The Smad1 was observed coupling with AR and accumulating in nuclei of the living cells upon androgen or PDF/BMP stimulation. Finally, we examined the effect of Smad1 on AR DNA binding activity in gel shift and chromatin immunoprecipitation assays. We found that Smad1 and AR formed complexes on the androgen response DNA element. Smad1 is recruited by AR to the endogenous prostate-specific antigen (PSA) promoter and represses the PSA expression at both mRNA and protein levels. PSA is an important clinical diagnostic marker for prostate tumor progression. Thus, we characterized a novel mechanism in which Smad1, induced by PDF/BMP, inhibits prostate cell growth by balancing androgen mitogenic activity. Our findings provide a BMP/Smad1 based potential therapeutic target for the treatment of prostate cancer, and improve anti-androgen treatment for prostate patients.

Inhibition of Bone Formation by Activated T Lymphocytes Is Partly Mediated through Interferon-γ. S. Varghese[1], N. Wyzga*[2], F. Sylvester*[2]. [1]Saint Francis Hospital and Medical Center, Hartford, CT, USA, [2]Connecticut Children's Medical Center, Hartford, CT, USA.

Osteopenia is common among patients suffering from inflammatory diseases. Since activation of T lymphocytes occurs in inflammatory diseases, we hypothesized that factors produced by activated T cells may decrease bone formation. We isolated T lymphocytes from 5-wk-old C57BL/6J male mice and activated them in vitro by culturing in the presence of anti-CD3ε and -CD28 antibodies for 4 to 7 days. T cell conditioned medium (TCM) was collected and used as a source of activated T cell-derived factors. Bone marrow stromal cells, a source of osteoblast precursors, were harvested from femurs of 5- to 7-wk-old C57BL/6J male mice and cultured for 10 days to allow settling of adherent cells and colony formation. Stromal cells were then cultured under osteoblastogenic conditions and treated with up to 10% resting or activated TCM for 1 to 3 wks. Bone formation was assessed by measuring mineralized nodule formation and markers of the osteoblast phenotype alkaline phosphatase and osteocalcin. Bone formation occurred in stromal cells exposed to resting TCM whereas it was inhibited in cultures exposed to activated TCM. Activated T cells secreted 6 to 450 ng/ml of interferon-gamma (IFN-γ) (n =6), and varying levels of IFN-γ in TCM suggested different degrees of T cell activation. We tested the direct effects of IFN-γ in stromal cells and found that IFN-γ inhibited bone formation at >0.5 ng/ml. Therefore, we postulated that the inhibitory effects of activated T cells on bone formation are mediated through IFN-γ. To test the role of IFN-γ in mediating the T cell effects on bone formation, we either blocked IFN-γ in activated TCM with an IFN-γ neutralizing antibody prior to testing TCM in stromal cells from wild-type mice or directly tested activated TCM in stromal cells from IFN-γ receptor null mice. The inhibitory effect on bone formation by a TCM, obtained from a modestly activated T cell preparation containing 6 ng/ml of IFN-γ and tested at 10%, was obliterated in stromal cells from IFN-γ receptor null mice. However, the inhibitory effect on bone formation by a TCM, obtained from a highly activated T cell preparation containing ~450 ng/ml of IFN-γ and tested at 1%, persisted even after blocking the IFN-γ effect suggesting that additional T cell factors that can inhibit bone formation may also be present in TCM from highly activated T cells. From these observations, we conclude that IFN-γ partly mediates the inhibitory effects of activated T cells on bone formation, although other factors are also involved. The inhibitory effects of T cell-derived factors, particularly IFN-γ, on bone formation may contribute to bone loss associated with inflammatory diseases.

A Dishevelled-Smad1 Interaction Links Wnt/β-catenin and BMP Signaling Pathways in Osteoblast Progenitors. Z. Liu*, Y. Tang*, D. J. DiGirolamo*, X. Cao, T. L. Clemens. Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Genetic evidence from both humans and mice suggest that the Wnt/β-catenin and BMP signaling pathways are essential for osteoblast development and differentiation. Upon binding of the Wnt ligands, activated Frizzled receptors then signal through Dishevelled (Dvl) which in turn stabilizes β-catenin and promotes nuclear translocation. In addition, previous studies suggest that BMPs, acting through Smads, can antagonize Wnt signaling to slow proliferation and promote osteoblast differentiation. In this study, we investigated the mechanisms responsible for crosstalk between Wnt/β-catenin and BMP-Smad signaling pathways. We first tested for interactions in 293T cells transfected with individual Smads (1-8) and Wnt pathway components using immunoprecipitation assays. These studies revealed a specific interaction between Smad1 and Dvl-1 which was dependent on the presence of Wnt3a or BMP-2. Under unstimulated conditions, Smad1 and Dvl-1 were co-immunoprecipitated. Addition of BMP-2 transiently disrupted the Smad1/Dvl-1 interaction with re-assembly occurring within 5h. In contrast, when cells were exposed to both Wnt3a and BMP-2, there was an enhanced accumulation of the Smad-Dvl complex over the same time course. This suggested that BMP signaling might restrict β-catenin activation through binding of Smad1 to Dvl-1. Consistent with this observation, in the absence of BMP-2, the Wnt3a induced disassembly of Smad1 and Dvl-1 coincided temporally with nuclear accumulation of β-catenin, whereas, stimulation of cells with both ligands resulted in decreased nuclear β-catenin levels. To assess the functional consequences of this interaction, we measured the activity of a Wnt responsive luciferase reporter (Topflash) in C3H10T1/2 and ST2 cells transfected with Smad1 and Dvl-1. Treatment with Wnt3a, but not BMP-2, stimulated luciferase activity, whereas co-stimulation with both Wnt3a and BMP-2 markedly reduced reporter activity. Furthermore, in C3H10T1/2 cells, Wnt3a induced proliferation was markedly attenuated by co-treatment with BMP-2. In conclusion, these results provide a potential mechanism whereby BMP-2 antagonizes Wnt signaling in osteoblast progenitors by promoting an interaction between Smad1 and Dvl-1 which restricts β-catenin activation.

Tumor Expression of RANKL and BMPs Influences the Formation of Metastatic Lung Cancer in Bone. A. Conduah*[1], B. T. Feeley*[1], N. Q. Liu*[1], S. Dubanett*[2], W. C. Dougall*[3], J. R. Lieberman[1]. [1]Orthopaedic Surgery, UCLA, Los Angeles, CA, USA, [2]Internal Medicine, UCLA, Los Angeles, CA, USA, [3]Amgen, Seattle, WA, USA.

The formation of a metastatic lesion in bone is a multi-step process and the cytokines expressed by tumor cell lines determine the type of metastatic lesion formed. The human non-small-cell-lung cancer (NSCLC) cell line A549 which produces a mixed osteoblastic and osteolytic lesion was used in this study. Using RT-PCR we determined that A549 cells produce mRNA for the production of cytokines that influence the formation of osteoblastic lesions (BMP-2, -4, and -6) and osteolytic lesions (RANKL, IL-6, and TNF-α). The purpose of this study was to determine if blockade of osteoclast activity (RANK:Fc) and BMP expression (Noggin) would result in a reduction of the formation of a mixed bone lesion in a murine model of metastasis. We examined our treatments in an intra-tibial injection model. There were 5 treatment groups each consisting of 10 SCID mice. Animals were treated with either A549 cells alone (Group I), A549 cells plus RANK:Fc (Group II), A549 cells transduced with vector that over expressed noggin (Group III), A549 cells and both RANK:Fc and noggin over expression (Group IV), and A549 cells transduced with an empty vector to control for viral transduction. Tumor size calculation, radiographic analyses, and histomorphometric analysis were performed at 4 and 8weeks. Animals in Groups II and III had significantly smaller tumor volumes compared to controls ($p<0.01$) and combination treatment (Group IV) led to the smallest tumor volume. Furthermore, treatment with A549 cells alone led to a mixed osteolytic/osteoblastic lesion, overexpression of noggin (Group III) led to a smaller, predominantly lytic lesion, treatment with RANK:Fc (Group II) led to an even smaller, predominantly blastic lesion, and combination treatment led to no visible lesion (Figure 1). In conclusion, we have demonstrated that a lung cancer cell line that induces a mixed bone lesion which secretes factors that stimulate both osteoclast (RANKL) and osteoblast (BMP) activity. When only one of these pathways was blocked the other lesion type became predominant. When both pathways were blocked lesion formation was significantly inhibited. These findings suggest that multi-modal therapy may be necessary to successfully treat metastatic bone disease.

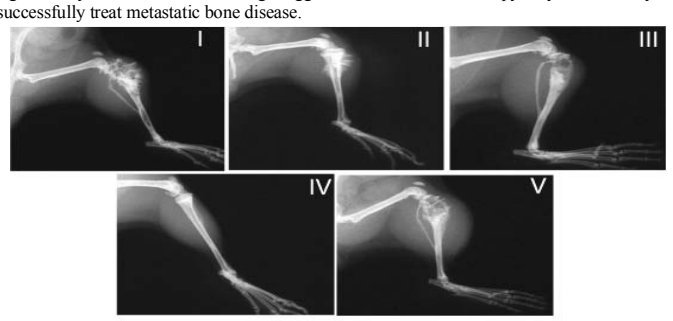

Figure 1. Radiographs of mice tibias at 8 weeks after intra tibial injection. Group I-A549 cells alone. Group II-A549 cells+RANK:Fc. Group III-A549 cells+Noggin. Group IV A54 cells+RANK:Fc+Noggin. Group V-A549 cells +empty vector.

Osteoglophonic Dysplasia Defines Novel Roles for FGFR1 in Bone Formation and Mass. E. G. Farrow*[1], T. E. M. Larsson[1], S. I. Davis*[1], X. Yu[1], E. Imel*[2], M. J. Econs[2], A. C. Lichtler[3], P. Pitukcheewanont*[4], L. Mascarenhas*[4], Y. Gutierrez*[4], K. Condon*[5], D. B. Burr[5], J. K. Hartsfield*[6], P. Beighton*[7], K. E. White[1]. [1]Med. and Molec. Genetics, Indiana Univ. Schl. of Med., Indianapolis, IN, USA, [2]Medicine, Indiana Univ. Schl. of Med., Indianapolis, IN, USA, [3]Univ. of Connecticut Health Center, West Hartford, CT, USA, [4]USC Keck Schl. of Med., Los Angeles, CA, USA, [5]Anat. & Cell Biol., Indiana Univ. Schl. of Med., Indianapolis, IN, USA, [6]Dept. Oral Facial Devel., Indiana Univ. Schl. of Dentistry, Indianapolis, IN, USA, [7]Univ. of Cape Town Med. Schl., Cape Town, South Africa.

The Fibroblast growth factors (FGFs) and their receptors (FGFRs) are central for many skeletal processes. Osteoglophonic dysplasia (OD, OMIM #166250) is a 'crossover' disorder that possesses phenotypes associated with activating FGFR1 and FGFR2 mutations, such as craniosynostosis, as well as with FGFR3 mutations, such as dwarfism. OD patients also present with non-ossifying metaphyseal bone lesions, and some patients have increased levels of FGF23, which inversely correlate with serum phosphate concentrations. We previously discovered that activating mutations in highly conserved residues (Y374C, N330I, and C381R) comprising the ligand binding and transmembrane domains of FGFR1 lead to OD. The patients with the Y374C and the C381R mutations had severe disease courses. We have identified two additional OD patients that have the N330I (ligand binding domain) and C381R (transmembrane domain) mutations. Besides craniosynostosis and dwarfism, both C381R patients have high metaphyseal lesional burden, giant cell granuloma of the gingava, and hypophosphatemia with elevated serum FGF23 levels (110 and 250 pg/ml, normal mean 28 pg/ml). To gain insight into FGFR1 function in the skeleton, we expressed FGFR1 carrying the Y374C OD mutation under the regulation of the osteoblast-specific 2.3 kb type I (α1) collagen promoter in a transgenic mouse model. A severely affected founder mouse was produced, but it expired prior to mating. This animal had low trabecular (299 vs 344 mg/cm^3) and cortical (1333 vs 1415 mg/cm^3) BMD, as determined by pQCT in the proximal tibiae. Radiographic analyses revealed severe, generalized osteopenia, and histological analyses demonstrated widened metaphyses with irregularities of the trabeculae, and decreased cortical thickness. In summary, we have confirmed that OD is caused by mutations in FGFR1, and expressing an OD FGFR1 mutant in osteoblasts results in low BMD and disturbed skeletal structure. Taken together, our results demonstrate that FGFR1 has critical functions in both cranial and long bone development, and that continuous activation of FGFR1 in osteoblasts may be a negative regulator of BMD.

F140

Characterization of FGF23/VDR Double Deficient Mice. T. Shimada*[1], H. Hasegawa*[1], I. Urakawa*[1], Y. Yamazaki*[1], J. Yasutake*[1], K. Oono*[1], T. Fujita[2], S. Fukumoto[2], T. Yamashita[1]. [1]Pharmaceutical Research Laboratories, KIRIN Brewery, Takasaki, Gunma, Japan, [2]Department of Internal Medicine, The University of Tokyo Hospital, Tokyo, Japan.

The findings that FGF23 null mice demonstrated abnormal elevations in serum phosphate and 1,25-dihydroxyvitamin D_3 (1,25D) concentrations supported a significant role of FGF23 in the phosphate and vitamin D metabolism. However, FGF23 null mice also exhibited other multiple defects such as abnormal glucose and lipid metabolism, growth retardation, histological changes in some organs including bone, and impaired renal function. These abnormal phenotypes still leave two possibilities; they were caused by the absence of undefined roles of FGF23 or secondary by sustained high serum phosphate or 1,25D levels. In our preliminary study, feeding with low phosphate diet decreased serum phosphate level, but did not affect most other defects in FGF23 null mice. Therefore, hyperphosphatemia itself is not a likely cause for those severe phenotypes. To evaluate the contribution of excess 1,25D action in FGF23 null mice to their abnormal phenotypes, we developed FGF23/VDR double deficient mice (*Fgf23*$^{-/-}$*Vdr*$^{-/-}$).The phenotypes of the mice with double heterozygous targeted alleles for Fgf23 and Vdr genes were completely normal. In contrast, the gross appearance of double KO mice was closely similar to that of VDR KO mice. Severe growth retardation observed in FGF23 KO disappeared in double KO (FGF23 KO; <10 g B.W. vs. double KO; >20g B.W.). Double KO mice showed almost normal life span maintaining normal serum BUN levels, while FGF23 KO suffered from short life span due to impaired renal failure. Serum glucose and cholesterol levels were also normal in double KO. Serum parameters for mineral metabolism of double KO were almost same as those in VDR KO mice characterized by low phosphate and calcium, and extremely high 1,25D and PTH levels. Bone histology of double KO mice demonstrated typical features of rickets as observed in VDR KO mice. However, the ratio of osteoblast surface/bone surface in double KO was much less than that in VDR KO mice and rather similar to that of FGF23 KO mice. Since the previous studies reported that the recombinant FGF23 functioned in VDR KO mice, FGF23 seems to regulate serum phosphate and vitamin D levels via VDR-independent action. However, the conserved phenotypic similarity between FGF23/VDR double KO mice and VDR KO mice indicates that excess 1,25D action caused other multiple defects in FGF23 KO except for the decreased number of osteoblasts.

Endogenous FGF2 Is Critically Important in PTH Induction of Bcl2, Phosphorylation of CREB and Runx2 Nuclear Accumulation in Osteoblasts. D. Agas*[1], M. G. Sabbieti*[1], L. Xiao[2], T. Naganawa[2], M. M. Hurley[2]. [1]Morf. and Comp. Biochem. Sciences, University of Camerino, Camerino, Italy, [2]Medicine, University of Connecticut Health Center, Farmington, CT, USA.

PTH and FGF2 both stimulate bone formation through possible mechanisms including enhanced differentiation of osteoblast (OB) precursors, increased activity of existing OB and reduced OB apoptosis. PTH increases FGF receptor-1 and FGF2 expression in OBs and the anabolic response to PTH is significantly reduced in Fgf2-/- mice. The goal of this study was to examine whether candidate factors implicated in the anabolic response to PTH were modulated in Fgf2-/- OBs. PTH and FGF2 prolong OB lifespan by increasing the survival gene Bcl-2 and decreasing the pro-apoptotic gene Bax. Runx2, which is absolutely required for differentiation of OB precursors and modulates the activity of mature OBs, is regulated by both PTH and FGF2. To assess the role of Bcl2/Bax and Runx2 in the reduced anabolic response to PTH in Fgf2-/- mice, these factors were measured by Western blot analysis and immunohistochemistry in cultured bone marrow stromal OBs from Fgf2+/+ and Fgf2-/- mice. PTH induced a 2.6-fold increase in the Bcl2/Bax protein ratio in Fgf2+/+ but not Fgf2-/- OBs. PTH increased Bcl2 in Fgf2-/- OB after FGF2 pre-treatment. Western blot analysis showed that PTH increased Runx2 protein expression in Fgf2+/+ but not Fgf2-/- OBs. Treatment with FGF2 restored the PTH responses in Fgf2-/- OBs. In contrast to PTH, forskolin treatment induced a marked increase in Runx2 protein in both Fgf2+/+ and Fgf2-/- OBs. By immunohistochemistry, FGF2 increased nuclear localization of Runx2 in OBs of both genotypes but PTH treatment induced nuclear accumulation of Runx2 only in Fgf2+/+ OBs. PTH and FGF2 act via activation of the protein kinase A and cAMP response element binding proteins (PKA/CREBs) as well as mitogen activated protein kinase (MAPK/ERK1/2) pathways to regulate Runx2 expression. Western blot analysis showed that PTH produced a similar increase in phospho-ERK1/2 levels in Fgf2+/+ and Fgf2-/- OBs. However, PTH increased phospho-CREB levels in Fgf2+/+ but not Fgf2-/- OBs. These data suggest that endogenous FGF2 is important in PTH effects on phospho-CREB, Bcl-2 and Runx2 levels as well as nuclear accumulation of Runx2. Reduced expression of these factors may contribute to the reduced anabolic response to PTH in the Fgf2-/- mice. Our results strongly indicate that the anabolic PTH effect is dependent in part on FGF2 expression.

The Effects of PAPP-A Deletion on the Murine Skeleton. S. J. Tanner, C. A. Conover. Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

The insulin-like growth factors (IGFs) are of undisputed importance in bone physiology. The effects of IGFs on bone cells are numerous and include stimulation of proliferation, increased expression of type I collagen, and suppression of osteoblast apoptosis. IGF activity is modulated by a number of regulatory molecules, including the six IGF binding proteins (IGFBPs 1-6). All of the binding proteins are expressed by bone cells *in vitro*, although IGFBP-4 is especially abundant in bone and inhibits IGF-I from interacting with its receptor. The binding proteins themselves are subject to regulation, thought mainly to be accomplished through proteolysis. In the case of IGFBP-4, this function is performed by pregnancy-associated plasma protein-A (PAPP-A), which cleaves IGFBP-4 at a single site mid-molecule, thereby increasing the local bioavailability of previously bound IGF-I. Recent work in our lab has resulted in the generation of a PAPP-A knockout (KO) mouse. Because PAPP-A is highly expressed by osteoblasts *in vivo* and *in vitro*, we are testing the hypothesis that deletion of PAPP-A has a negative impact on bone cell function and bone quality. Peripheral quantitative computed tomography (pQCT) was performed on the femoral midshaft of PAPP-A KO and wild-type (WT) littermates aged 1, 2, 4, 6, and 12 months of age. At this sampling site, the 1-month-old KO animals had a bone mineral density (BMD) that was not different from that of WT (500 ± 4.2 vs. 507 ± 31.3 mg/ccm for KO vs. WT, mean ± SE, N=3/group); however, by 2 months of age, KO BMD was significantly less ($p<0.05$) than WT (594 ± 15.7 vs. 642 ± 22.4 mg/ccm for KO vs. WT, N=4-6/group). This difference appeared to be maintained at 4, 6, and 12 months of age, suggesting that PAPP-A exerts its greatest influence on bone development during the transition into puberty. Histomorphometric data from 2-month-old mice indicate that the KO animals had significantly ($p<0.05$) suppressed bone formation rates at both endocortical (5.24 ± 0.53 vs. 7.82 ± 0.76 $\mu m^2/d$ for KO vs. WT, N=4-5/group) and cancellous (0.80 ± 0.08 vs. 1.06 ± 0.04 $\mu m^{2/}$ $\mu m^2/d$ for KO vs. WT, N=4-5/group) surfaces relative to WT controls. Taken together, these preliminary data indicate an early role for PAPP-A in the acquisition of peak bone mass in the murine skeleton. Our ongoing analyses will provide a more complete picture of the IGF-I signaling system, and PAPP-A in particular, in bone development and maintenance.

Jab1 regulates $SCF^{\beta\text{-}TrCP1}$ mediated Smad4 Protein Degradation in TGF-β/BMP Signaling. M. Wan, J. Huang*, Y. Tang*, C. Lu*, N. Wang*, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

TGF-β superfamily of cytokines exerts a wide variety of biological activities, in particular, the regulation of skeletal development and bone development and remodeling. Smad4 is the common mediator shared in the TGF-β/BMP signaling pathways. Thus, the regulation of Smad4 protein steady state level is an important means of modulating TGF-β/BMP function. Previously, we identified that $SCF^{\beta\text{-}TrCP1}$, an E3 ubiquitin ligase complex containing F-box protein β-TrCP1, as a critical determinant for the protein degradation of Smad4. Jun Activation Binding protein (Jab1), another Smad4 protein degradation regulator, regulates $SCF^{\beta\text{-}TrCP1}$-mediated Smad4 protein degradation. However, the detailed mechanism of this event is not clear. Here we found that β-TrCP1 interacts with Smad4 protein at its MH1 plus Linker region. Sequence analysis of the Smad4 MH1 region revealed a motif: DL**S**GLTLQ**S,** which is similar to the consensus sequence D**S**GβX**S** (S-S motif) within common β-TrCP1 substrates. To determine whether β-TrCP1-Smad4 interaction is mediated by this motif, we generated two Smad4 mutation constructs by either replacing two serine residues with alanine (S-S mutation) or deletion of this motif (S-S deletion). The β-TrCP1-Smad4 binding was significantly decreased with either S-S mutation or S-S deletion. We then investigated how Jab1 regulates β-TrCP1-Smad4 binding. Jab1 overexpression significantly enhanced the interaction between β-TrCP1 and Smad4, whereas Jab1 siRNA reduced the interaction. It has been shown that Jab1-associated protein kinase(s) phosphorylates protein substrates for their degradation such as p53. We therefore examined whether Jab1 regulates β-TrCP1-Smad4 interaction through phosphorylation. Both Curcumin and Emolin, two inhibitors of Jab1-associated protein kinase(s), significantly reduced the interaction between β-TrCP1 and Smad4, indicating that Jab1-mediated phosphorylation of Smad4 is required for Smad4 recognition by β-TrCP1. Finally, we examined whether Jab1 and $SCF^{\beta\text{-}TrCP1}$ down-regulate TGF-β-mediated gene transcription. TGF-β response reporter plasmids, (SBE) 4-luc, and ARE-luc were cotransfected with SCF components and/or Jab1 plasmids in Mv1Lu cells. Expression of either SCF or Jab1 inhibits TGF-β-induced transcriptional activity, and expression of both enhanced the inhibition. In summary, we find that $SCF^{\text{-}TrCP1}$ is the E3 ligase of Smad4, and Jab1 regulates the interaction between β-TrCP1 and Smad4 by phosphorylation of Smad4 S-S motif for $SCF^{\beta\text{-}TrCP1}$-mediated Smad4 protein degradation. These findings revealed a novel mechanism that Jab1 controls the TGF-β/BMP activity by regulating Smad4 protein degradation.

Regulation of Matrix Metalloproteinases by TGF-Beta in Renal Cell Carcinoma Bone Metastasis. S. L. Kominsky, M. Doucet*, D. Nell*, K. Weber. Department of Orthopaedic Surgery, Johns Hopkins Medical Institute, Baltimore, MD, USA.

Matrix metalloproteinases (MMPs) are best known for their role in facilitating the invasion and migration of cancer cells through the ECM; however, MMPs also play a role in regulating cell growth and angiogenesis. While the role of MMPs in primary tumors has been extensively studied, their role in the colonization and growth of tumor cells at secondary sites has not been well defined. It is believed that degradation of the unmineralized bone matrix is necessary for the initiation of bone resorption, providing osteoclasts access to the mineralized bone surface. Due to their ability to degrade type I collagen, the major collagen constituent of unmineralized bone matrix, MMPs -1, -2, -8, -13, and -14 may play a role in bone resorption. Renal cell carcinoma (RCC)-derived bone metastases are predominantly osteolytic and exhibit extensive vascularization. Surprisingly, the specific mechanisms of RCC interaction with bone have been scarcely studied despite the inability to prevent or eliminate bone metastasis. We have shown that TGF-β, an abundant growth factor in the bone microenvironment, is essential for human bone-derived RCC cell growth following intratibial injection in nude mice. Interestingly, we have found that TGF-β increases the expression and activation of MMPs in human bone-derived RCC cell lines that cause lytic lesions in the nude mouse tibia (RBM1-IT4, RBM23), versus cell lines incapable of growing in the murine bone environment (RBM21A, RBM17C), despite equivalent activation of TGF-β signaling. Treatment with TGF-β resulted in the increased mRNA expression of MMPs -1, -2, -13, -14 by RT-PCR beginning as early as 3 hours following treatment. Correspondingly, protein expression of both the latent and active forms of MMPs -1, -2, and -13 was increased following treatment with TGF-β for a period of 72 hours, as determined by Western analysis of conditioned media. TGF-β-induced increases in MMP -1, -2, and -13 activity was confirmed by gelatin zymography analysis. Although TGF-β had no detectable effect on MMP-9 mRNA expression, gelatin zymography analysis showed an increase in the active form of MMP-9. Concordant with *in vitro* studies, IHC analysis revealed that MMPs -2, -9, and -13 were expressed *in vivo* following injection of RBM1-IT4 cells into the nude mouse tibia. Further, MMP-2 and -13 were expressed in 8/10 and 12/13 human RCC bone metastasis tissues, respectively, by IHC analysis. These data show that TGF-β can increase the expression and activation of MMPs involved in the degradation of type I collagen and angiogenesis, and suggest their potential involvement in RCC tumor growth and bone destruction.

Conditional Deletion of the TGF-β Type II Receptor (TβRII) in Prx-1 Expressing Cells Results in Defects in the Appendicular Skeleton and Calvaria. K. S. Shimer*[1], L. O'Rear*[1], R. Chandler*[2], S. Aakula*[2], L. Longobardi*[1], D. Mortlock*[2], A. Chytil*[2], H. Moses*[2], A. Spagnoli[1]. [1]Pediatrics, Vanderbilt University Medical Center, Nashville, TN, USA, [2]Vanderbilt University Medical Center, Nashville, TN, USA.

Studying the role of TGF-β signaling in developing cartilage is difficult secondary to the early embryonic lethality associated with TβRII knock-out. To address the role of TGF-β signaling in limb bud, joint and calvaria development we conditionally inactivated the TβRII in Prx-1 expressing cells by using a cre-loxP system. Prx-1 is a paired-related homeobox gene that plays a central role in regulating the growth of skeletal primordia. *Prx1-Cre* mice carry a cre-reporter gene under a PRX-1 enhancer that drives Cre expression in the limb buds and a subset of calvaria mesenchymal cells starting around embryonic day (E) 9.5. To generate $Tgfbr2^{Prx1KO}$ we mated *Prx1-Cre* mice with homozygous $Tgfbr2^{flox/flox}$ mice in which the TGF-β binding site of TβRII is floxed. On $Tgfbr2^{Prx1KO}$ and heterozygous $Tgfbr2^{flox+/-}$ Cre negative (control) mice at P0, histomorphometric staining was performed using Hematoxylin & Eosin, Alcian Blue and Alizarin Red staining. We have generated homozygous $Tgfbr2^{Prx1KO}$ mice that are deficient in TβRII in limb bud primordia and a subset of calvaria mesenchymal cells. $Tgfbr2^{Prx1KO}$ are smaller than controls. The $Tgfbr2^{Prx1KO}$ birth weight is 1.03±0.06 grams and 1.96±0.13 grams for controls p=0.0003. Length at birth for $Tgfbr2^{Prx1KO}$ is 2.60±0.14 cm vs 3.58±0.15 cm in controls p=0.0005. They display a lack of small joint formation with minimal ossification centers of the phalanges, brachydactyly, bent metatarse, carpal/tarsal synostosis with rudimentary bones and rhizomelic limbs with dysplastic metaphyses. Furthermore, $Tgfbr2^{Prx1KO}$ mice showed minimal parietal and occipital bone formation, intracranial bleeding and died within hours of birth. Our data provides critical information regarding mechanisms of skeletal development and indicates that TGF-β signaling plays an essential role in skeletogenesis. In particular, we found that TGF-β is critical for small joint formation, calvaria formation and endochondrial growth as indicated by rhizomelic limbs with dysplastic metaphyses. Understanding the role of TGF-β in osteochondrogenesis will shed further light in the pathophysiologic mechanisms underlying osteochondrodysplasias and degenerative cartilage diseases.

Mechanical Inhibition of RANKL Expression Is Regulated by H-Ras-GTPase in a Lipid Raft Dependent Manner. J. Rubin[1], T. C. Murphy*[1], J. Rahnert*[1], M. S. Nanes[1], E. M. Greenfield[2], H. Jo*[3], X. Fan[1]. [1]Medicine, Emory University and VAMC, Decatur, GA, USA, [2]Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, [3]Biomedical Engineering, Emory University, Atlanta, GA, USA.

Mechanical input is well known to regulate bone remodeling yet the molecular events involved in mechanical signal transduction are poorly understood. We here investigate proximal events leading to the ERK1/2 activation that is required for mechanical repression of RANKL expression, the factor that controls local recruitment of osteoclasts. Primary murine bone stromal cells were subjected to a regimen of dynamic mechanical strain via substrate deformation (1-2%, 10 cpm). Mechanical strain was shown to activate Ras-GTPase within 2 minutes, in particular the H-Ras isoform. Pharmacological inhibition of H-Ras function using a farneysl transferase I inhibitor added 24 hour prior to application of the strain regimen prevented mechanical activation of H-Ras as well as the downstream mechanorepression of RANKL analyzed the next day by semi-quantitative RT-PCR. To further confirm the role of H-Ras in mechanorepression of RANKL, we generated Ras-isoform specific siRNA. Silencing of H-Ras, but not K-Ras, abrogated strain effects on RANKL expression. H-Ras specific inhibition of mechanorepression of RANKL was also demonstrated in a murine pre-osteoblast cell line which was generated from a T-Ag expressing mouse (CIMC-4 cell line); K-Ras silencing has no effect. H-Ras is known to be targeted to lipid raft microdomains by virtue of its post-transcriptional modifications. We asked whether H-Ras activation required its presence in the lipid raft: cholesterol depletion of rafts using cyclodextrin prevented mechanical activation of H-Ras. Using a non-detergent method to separate lipid raft microdomains from other membrane and cytosolic components, we found that after activation by mechanical strain, H-Ras was displaced out of the lipid raft domain. That the mechanical repression of RANKL requires activation of H-Ras, a specific isoform of Ras-GTP residing in the lipid raft microdomain, suggests that spatial arrangements are critical for generation of specific downstream events in response to mechanical signals. By partitioning signals this way, cells may be able to generate different downstream responses through seemingly similar signaling cascades.

Mechanically Induced DMP1 and MEPE Expression in Osteocytes: Correlation to Mechanical Strain, Osteogenic Response and Gene Expression Threshold. J. Gluhak-Heinrich*[1], W. Yang*[2], L. F. Bonewald[3], A. G. Robling*[4], C. H. Turner*[4], S. E. Harris[2]. [1]Orthodontics, UTHSCSA, San Antonio, TX, USA, [2]Periodontics, UTHSCSA, San Antonio, TX, USA, [3]Oral Biology, UMKC, Kansas City, MO, USA, [4]Orthopedics, Indiana University Medical School, Indianopolis, IN, USA.

Dentin matrix protein (DMP) and matrix extracellular phosphoglycoprotein (MEPE) are selectively expressed in osteocytes and may modulate mineralization within the osteocyte canalicular system. By altering the osteocyte microenvironment, they may change how the osteocyte responds to mechanical loading. We have previously shown increased gene expression of DMP1 and MEPE after mechanically loading of bone. We now present the spatial and temporal correlation between DMP1 and MEPE expression, mechanical strain, and new bone formation in the mouse ulna subject to axial loading. Ulnae from 4-month-old C57BL/6 mice were loaded with a single 30-second bout of dynamic loading (2.4N peak load, and 2Hz). DMP1 and MEPE mRNA expression was analyzed with quantitative *in situ* hybridization 1, 2 and 24 hours after loading . Each data set consisted of expression patterns at 7 locations along the proximal-distal axis of the ulna. 1 and 2 hours after loading we find 2-3 fold increases in DMP1 expression in osteocytes. At these early times there was no significant change in MEPE expression either by Northern analysis or *in situ* hybridization. 24 hours after loading, we found a significant 3-10 fold increase in DMP1 and MEPE expression in osteocytes. The regions of maximum expression of both genes were on the medial and lateral sides of the ulna and correlated to the estimated mechanical strains. Along the longitudinal axis, expression of both DMP1 and MEPE mRNA was highest 2 mm distal to the mid-shaft (the location of greatest mechanical strain) and highest in osteocytes closer to periosteal and endosteal surfaces (locations of new bone formation). We developed in 3D model for DMP1 and MEPE expression along the mouse ulna. From these data, we determined the Gene Expression Threshold (GEt), or minimum level of strain required to activate either MEPE or DMP1. The DMP1 gene had a lower GEt and was activated earlier (1 hr) than MEPE gene (24 hr). Thus, gene expression in osteocytes correlated with predicted local strains that in turn were correlated to new bone formation measured using histomorphometry. Both DMP1 and MEPE proteins are found concentrated in the canalicular and lacunar walls surrounding the osteocyte cell body and cell process. These proteins most likely play key roles in local mineralization within the canalicular, lacunar system, and throughout the bone matrix. Mechanical loading appears to regulate expression of these genes and may modulate local mineralization.

Parathyroid Hormone Receptor Signaling Abrogates or Reverses Mechanical Unloading-Induced Signaling in Transgenic Mice Expressing Osteoblast-Specific Constitutively Active PTH/PTHrP Receptor. N. Ono[1], L. Calvi[2], E. Schipani[2], H. M. Kronenberg[2], K. Soma*[3], M. Noda[1]. [1]Molecular Pharmacology, 21st COE Program, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Endocrine Unit, MGH, Harvard Medical School, Boston, MA, USA, [3]Orthodontic Science, Tokyo Medical and Dental University, Tokyo, Japan.

Although unloading causes severe bone loss, the mechanisms underlying such events have not yet been fully understood. Unloading could be modulated by extracellular matrix proteins such as osteopontin and intracellular signaling molecules such as MAPK, and these modulators may be shared in hormonal signaling. The intermittent treatment of parathyroid hormone (PTH), a major regulator of calcium homeostasis, could result in the increase in bone mass, phenomenologically resembling what bone could respond to mechanical stimuli. In order to understand the signaling events in unloading-induced bone loss, we subjected the transgenic mice expressing osteoblast-specific constitutively active PTH/PTHrP receptor to tail suspension. In the primary trabeculae, unloading reduced trabecular BV/TV of wild-type (WT) by 50%, whereas NO REDUCTION was observed in transgenic mice (TG). In the secondary trabeculae, BV/TV was 2.5-fold higher in TG compared to WT as reported previously. BV/TV was reduced in WT by about 50%, whereas BARELY ALTERED in TG due to unloading. In terms of BMD of the whole bone, WT yielded statistically significant reduction after tail suspension. Though there was moderate suppression of BMD due to unloading in TG, the difference was not statistically significant, suggesting that the whole bone structure would be quite insensitive to unloading under constitutively active PTH signaling. Deoxypyridinoline (Dpyd) excretion into urine in TG was about 3 times higher than WT among loaded mice. Interestingly, unloading enhanced Dpyd excretion in WT, but suppressed it in TG. Thus these data indicated that unloading induced-signaling could be interfered by the presence of constitutively active PTH receptor signaling. Further reversal phenomena were observed in TRAP positive cell development in culture in the presence of vitaminD and dexamethasone to induce osteoclast-like cell formation. Unloading suppressed the levels of TRAP positive cell development in TG, contrasting with unaltered levels in WT. These data indicated that PTH receptor signaling crosses with the signals induced by unloading, either abrogating or reversing the effects of unloading induced-events.

The Climbing Exercise Prevents Trabecular Bone Loss with Highly Expressed mRNA of Estrogen Receptor alpha in Bone Cells after Ovariectomy in Mice. N. Nakura*, T. Mori, N. Okimoto, A. Sakai, T. Nakamura. Orthopaedics, University of occupational environmental health Japan, Fukuoka, Japan.

To investigate the effect of climbing exercise on trabecular bone turnover, bone marrow cell development and gene expression for bone cells in ovariectomized mice, 100 C57BL/6J mice, 8 weeks of age, were assigned to baseline control and 3 groups: ground control group (sham), ovariectomized ground control group (OVX) and ovariectomized climbing exercise group (OVX+Ex). The mice of each group were sacrificed at 2, 4 and 8 weeks after the treatment. OVX+Ex mice were housed in a 100-cm tower cage and had to climb up to drink water toward a bottle placed at the top. We obtained bilateral femurs and tibias to evaluate bone mineral density (BMD) by DXA, trabecular bone turnover by histomorphometry, and mRNA expression in bone cells by real-time RT-PCR. At 8 weeks, BMD of the left femur in OVX significantly decreased compared with that in sham. BMD in OVX+Ex was maintained to the same level of that in sham throughout the experimental period. The trabecular bone volume (BV/TV) of the proximal tibia in OVX decreased compared with that in sham, but that in OVX+Ex was significantly increased compared with that in OVX and maintained to the same level of that in sham at 4 and 8 weeks. At 4 weeks, the osteoclasts surface (Oc.S/BS) and osteoclast number(Oc.N/BS) in OVX increased compared with those in sham, but those in OVX+Ex were restored to the same levels of those in sham. At 8 weeks, bone formation rate (BFR/BS) of periosteal surface and the mineralizing surface (MS/BS) in OVX+Ex increased compared with those in OVX. At 8 weeks, climbing exercise showed the significant increases in parameters of bone formation including BFR/BS and MS/BS compared with those in OVX. Quantitative RT-PCR using whole bone of femur revealed that at 8 weeks, estrogen recepter alpha (ERalpha) mRNA expression in OVX+Ex significantly increased compared with that in OVX. In conclusion, our results indicate that the climbing exercise prevents trabecular bone loss in ovariectomized mice. The climbing exercise reduced bone resorption in ovariectomized mice initially, and increased in bone formation finally. This subsequent increase in bone formation parameter after climbing exercise seems to be associated with highly expressed mRNA of ERalpha in bone cells.

Nucleocytoplasmic Cas Interacting Zinc Finger Protein (CIZ) Acts as a Conversion Sensor for both Mechanical and Estrogenic Signaling in the Process of Disuse and Ovariectomy Induced Bone Loss. K. Hino[1], T. Nakamoto*[2], M. Morinobu*[3], H. Yamamoto*[3], H. Hirai*[2], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Dept of Hematology and Oncology, University of Tokyo, Tokyo, Japan, [3]Orthopedics, Ehime University, Ehime, Japan.

Postmenopausal osteoporosis and disuse-induced osteopenia are two major causes to increase risk of fractures in most of the aged population. The mechanisms underlying sensing of mechanical stress in bone is largely unknown. CIZ binds to p130 Cas which localizes at cell adhesion complex and translocates into nuclei to modulate transcription via acting through (G/C)AAAAA located in the promoter regions of MMP genes and antagonizes against BMP(MCB2000, JEM2005). We tested our hypothesis that mechanical stress signaling would be mediated by such nucleocytoplasmic shuttling proteins which would link signals from the cell adhesion site to nuclear events, and that such mechanosensitive signaling could be converged with estrogenic signaling. Unloading (tail suspension ;TS) reduced cancellous bone volume in WT mice by about 40%. In contrast CIZ deficient mice did not exhibit such reduction in cancellous bone mass due to TS. This was not limited to cancellous bone since bone loss due to TS in cortical midshaft and epiphyseal area was also blocked by CIZ deficiency. Mineralized nodule formation in the culture of bone marrow cells taken out from the bone of mice subjected to TS was suppressed by about 40% in WT mice. CIZ deficiency almost totally blocked such reduction in nodule formation induced by TS. Histomorphmetric analysis revealed that tail suspension suppresed the levels of MAR and such suppression by TS of MAR was reduced by CIZ deficiency. Similarly, in WT mice TS reduction in BFR was suppressed in CIZ deficient mice. Marginal increase in Oc.S and Oc.N was observed at end point of TS in WT mice, but neither WT nor CIZ deficient mice indicated difference in the levels of Oc.S and Oc.N by unloading. Similarly, systemic bone resorption parameters such as deoxypyridinoline exceartion were similar between WT and CIZ deficient mice regardless of loading or unloading condition suggesting that CIZ mediates mechanical signaling specifically in osteoblastic but not osteoclastic side in the animals subjected to unloading. To test whether estrogenic signaling is also mediated by the presence of CIZ, the animals were subjected to ovariectomy(OVX). OVX reduced cancellous bone mass in WT mice. In contrast, OVX failed to reduce bone mass in the absence of CIZ. These data indicated that nucleocytoplasmic shuttling protein, CIZ, acts as a mechanosensor as well as a sensing molecule for estrogenic signaling, and plays a pivotal role in the maintenance of bone mass.

Beta-Blockade Mitigates Bone Loss with Hindlimb Unloading. K. Baek*, S. A. Bloomfield. Health and kinesiology, Texas A&M, College station, TX, USA.

Leptin may be a candidate responsible for linking energy metabolism to bone mass and also may play a role in bone loss during hundlimb unloading(HU). In previous work, we have observed that serum leptin decreases more in rats exposed to HU than to food restriction; this may be due to SNS activation of β-adrenoreceptors inhibiting release of leptin from adipose. Our objective was to test whether β-blockade or administration of a leptin analog would attenuate bone loss with HU. Male, 6-mo-old Sprague-Dawley rats were randomized into six groups (n=10 each): 3 groups of HU rats treated with vehicle (HU-V), leptin analog (HU-L;Ly355101, Lilly), or β-blocker(HU-β;DL-propanolol ,Sigma) via osmotic pump during 28d HU, and 3 groups of cage activity controls treated with the same 3 agents and pair-fed to HU rats (CC-V, CC-L and CC-β, respectively). On day 0 and 28, peripheral computed tomography (Stratec XCT Research M) assessed bone mineral density (BMD). Proximal tibiae metaphyses were analyzed by standard histomorphometry for mineral apposition rate (MAR), bone formation rate (BFR), and forming and resorbing surfaces. All animal procedures were approved by Texas A&M University Laboratory Animal Care Committee. Although all groups lost their body weight (BW) at first week, by day 28 all groups except HU-β gained BW compared to initial BW ($p<0.05$). The 11% decline in total BMD observed in HU-V was attenuated in HU-β rats (7%) and HU-L rats (5%) ($p<0.05$). The 20% decline in trabecular BMD observed in HU-V group was attenuated in HU-β rats (11 %) and HU-L rats (10%) ($p<0.05$). MAR in HU-L & HU-β was significantly greater than in HU-V (2.04 & 1.96 vs 1.27, respectively; $p<0.05$). Percent forming surface in HU-L & HU-β tended to be greater than in HU-V (7.90 & 6.54 vs 4.39, respectively; $p< 0.09$). Percent resorbing surface in HU-L & HU-β was significantly lower than in HU-V (4.31 & 3.03 vs 12.70, respectively; $p<0.0001$). No significant differences in histomorphometric values were observed among CC-L, CC-β and CC-V. The decrease in serum leptin (by ELISA, Crystal Chem) was significantly less in HU-β (-25%) and in HU-L (-31%) than in HU-V (-62%)($p<0.05$) and did not correlate well with changes in body weight. We conclude that β-blockade is as effective as leptin analog administration in mitigating bone loss with HU through both stimulation of osteoblastic activity and suppression of osteoclastic activity, perhaps by disinhibition of leptin release from adipose.

Relative to Body Weight, Obesity Reduces Femoral Neck Structural Strength in Women among the Women's Health Initiative Observational Study. T. J. Beck[1], J. Cauley[2], C. E. Lewis[3], A. LaCroix[4], T. Bassford*[5], D. A. Nelson[6], S. Going*[5], D. Sherrill*[5], T. Lohman[5], R. D. Jackson[7], M. LeBoff[8], E. Outwater*[5], Z. Wang*[9], G. Wu*[5], N. Wright*[5], S. Nicholas*[5], Z. Chen[5]. [1]Johns Hopkins U., Baltimore, MD, USA, [2]U. of Pittsburgh, Pittsburgh, PA, USA, [3]U. of AL, Birmingham, AL, USA, [4]Fred Huch. Canc. Res. Ctr., Seattle, WA, USA, [5]U. of AZ, Tuscon, AZ, USA, [6]Wayne St. U., Detroit, MI, USA, [7]OH State U., Columbus, OH, USA, [8]Harvard U., Boston, MA, USA, [9]Columbia U., New York, NY, USA.

The obese have higher BMD so most assume that their bones are relatively stronger. However data in children indicate that femur structure scales with lean mass not body weight, suggesting that muscle forces stimulate bone adaptation. To determine the relationship between body weight and hip structural strength in postmenopausal women, we used the Hip Structure Analysis (HSA) program to examine femoral neck BMD and cross-sectional geometry in a substudy of 1410 women in the Women's Health Initiative Observational Study. Women (50-79 yr at baseline) were partitioned into categories of body mass index (BMI in kg/m^2): underweight (<18.5, n=15), normal (18.5-24.9 n=483), overweight (25-29.9, n=497), obese I (30-34.9, n=248) obese II (35-39.9 N = 94) and extremely obese III (>=40, n=73). Femur neck BMD, bone cross-sectional area (CSA), outer diameter and section modulus (Z, an index of bending strength) were compared between BMI categories before and after normalizing to individual body weight. Although outer diameter did not, BMD, CSA, and Z were higher with higher BMI; each category differed from all others ($p<0.05$). After scaling to body weight, the trend with BMI reversed so that BMD, CSA outer diameter and section modulus were lower with higher BMI category, ($p<0.05$ vs. any group). The Figure plots mean Z values (95%CI) by category scaled to those with normal BMI, with and without normalization to body weight. Bending strength increases with BMI but less than the increase in weight. The same pattern is evident in CSA (axial strength) and BMD. We conclude that as a proportion of body weight, femur strength is reduced with greater obesity. It is unknown whether obesity makes fractures more likely; fat padding reduces impacts in certain fractures. Nevertheless traumatic forces that cause fractures are a function of body weight and femurs of the obese are disproportionately weaker in relation to those forces.

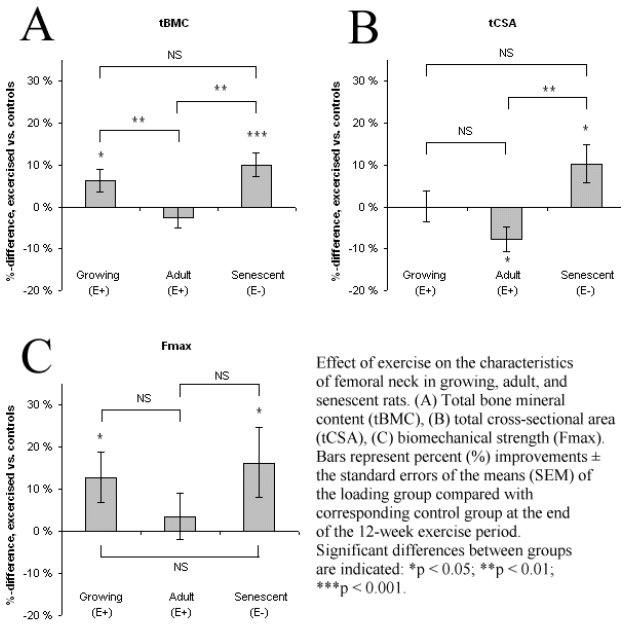
Estrogen-Withdrawal Increases the Mechanosensitivity of Bones to Loading. I. Pajamäki[1], O. Leppänen[1], J. Jokihaara[1], H. Sievänen[2], P. Kannus[2], T. L. N. Järvinen[1]. [1]Department of Orthopaedics and Traumatology, University of Tampere, Tampere, Finland, [2]UKK Institute, Tampere, Finland.

Estrogen, the primary non-mechanical regulator of female bones, has been suggested to enhance the mechanosensitivity of bones to loading. In this virtually life-long experiment, we evaluated whether the estrogen-status of the rats modulates the skeletal responsiveness to loading. A total of 105 growing [5-17-week-old, normal estrous cycle (E+)], adult [47-59-week-old, normal estrous cycle (E+)] and senescent [90-102-week-old, menopausal (E-)] female Sprague-Dawley rats were used. At entry, rats were randomly assigned into 6 groups; 3 control groups (n=15/group) and 3 exercise groups (n=20/group). In the exercise groups, rats were subjected to an identical, 12-week period of progressive treadmill training. At each time point, a comprehensive structural analysis of the femoral neck was performed (peripheral quantitative computed tomography and mechanical testing). The menopausal status of the senescent rats was confirmed by microscopic examination of the ovaries and uterus (the absence of functional follicles in the ovaries and uterine atrophy denoting the menopausal status) in age-matched control rats prior to the execution of the exercise period. In comparison to their age-matched controls, twelve weeks of treadmill training resulted in significant increases in femoral neck total bone mineral content (tBMC) in growing (E+) and senescent (E-) rats (A in figure below). In addition, a significant exercise-induced increase in the total cross-sectional area of the femoral neck (tCSA) was observed in senescent (E-) rats (B in fig.). These changes resulted in significantly increased breaking load of the femoral neck (F_{max}) in growing (E+) and senescent (E-) rats (C in fig.). In contrast, no exercise-induced benefits were observed in femoral neck parameters in the adult (E+) rats. In conclusion, these findings are in perfect agreement with both experimental and clinical studies, as we observed an estrogen-induced packing of mechanically excess mineral into fertile (adult) female skeleton, and consequent damping of the mechanosensitivity of these bones. At menopause, this extra

"bone stock" was shed, and consequently, the mechanosensitivity of bones to loading was regained.



Effect of exercise on the characteristics of femoral neck in growing, adult, and senescent rats. (A) Total bone mineral content (tBMC), (B) total cross-sectional area (tCSA), (C) biomechanical strength (Fmax). Bars represent percent (%) improvements ± the standard errors of the means (SEM) of the loading group compared with corresponding control group at the end of the 12-week exercise period. Significant differences between groups are indicated: *$p < 0.05$; **$p < 0.01$; ***$p < 0.001$.

Novel Mechanoresponsive BMD and Bone Size QTL Identified in a Genome Wide Linkage Study Involving C57BL/6J-C3H/HeJ Intercross. C. Kesavan, S. Mohan, H. Yu*, S. Oberholtzer*, J. E. Wergedal, D. J. Baylink. JLP VAMC and LLU, Loma Linda, CA, USA.

Previously, we demonstrated that 2 wks of 4-point bending caused a dramatic 15% increase in volumetric BMD (vBMD) in the tibia of C57BL/6J (B6) but not C3H/HeJ (C3H) mice. To identify the genetic loci that contribute to variation in BMD response to mechanical loading (ML), we performed a genome wide linkage study in the B6-C3H mice intercross. The left tibiae of 329 B6-C3H F2 female mice at 10 wk age were subjected to 9 N cyclic load at 2Hz for 36 cycles daily for 2 wks while right tibia was used as unloaded control. Two days after the last loading, vBMD and bone size (periosteal circ.) were measured by pQCT. ML- induced changes ([loaded-unloaded/unloaded] X 100) in vBMD (-5 to +15%) and bone size (-5 to +20%) in the B6-C3H F2 mice showed normal distributions consistent with the complex traits controlled by several genes. % change in BMD or bone size in the F2 mice of loaded bones did not correlate with body wt, suggesting that variation in bone anabolic response to ML is independent of body size. Genome-wide search using 110 microsatellite markers with 15 cM intervals in the F2 mice revealed the following ML QTLs for BMD and bone size phenotypes (% change in loaded vs unloaded bone) using MAPQTL program (a=P<0.01; b=P<0.05):

Phenotype	Locus	LOD Score	% Variation
vBMD	D1Mit113	3.4[a]	4.7
vBMD	D8Mit88	4.2[a]	5.8
vBMD	D9Mit336	2.5[b]	3.5
Bone Size	D8Mit49	3.0[b]	4.1
Bone Size	D9Mit97	2.8[b]	3.9
Bone Size	D11Mit333	2.6[b]	3.6
Bone Size	D18Mit64	2.8[b]	3.5

We found that ML BMD QTL for chr. 8 and 9 and bone size QTL for chr. 8 and 18 could not be detected using phenotype data from unloaded bones, suggesting that these QTLs are unique to ML phenotypes. Furthermore, chromosome 8 BMD QTL has not been reported for BMD in any other inbred strain crosses. Conclusions: 1) Our study provides the first demonstration of chromosomal location of genetic loci affecting variation in skeletal anabolic response to ML in the B6-C3H intercross. 2) Only 15 % of the genetic variation was accounted for by the identified ML QTL suggesting additional QTL or interactions exist. 3) Future identification of the genes responsible for the ML QTL should lead to improved understanding of molecular pathways for ML-induced skeletal anabolic response.

Bone Fluid Flow Induced By Skeletal Muscle Dynamics and its Role in Bone Adaptation. Y. Qin, H. Lam*, L. Orzechowski*, Y. Xia. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

Skeletal muscle dynamics appears to retard disuse osteopenia. Exercise increase blood flow to the skeletal tissues, i.e., bone and muscle. To further elucidate the mechanism of muscle dynamics initiated bone remodeling, we propose that muscle dynamics generated by physiologic contraction can induce fluid flow and enhance perfusion in bone, which may act as a mediator in initiating and regulating osteonal adaptation. While we have previous shown that applying dynamic intramedullary pressure (ImP) stimulated new bone formation and inhibit disuse resorption, the objectives for this work were to evaluate (a) the role of muscle dynamics induced ImP, (b) the response of cortical perfusion enhanced by muscle contraction, and (c) its role for in vivo bone adaptation. Total of twelve 9-month old rats were used in the perfusion and in vivo study (n=4 for perfusion, n=4 for in vivo experimental and n=4 for sham control). In the pressure and perfusion measurement, an electronic muscle stimulator was used to the skeletal muscle adjacent to the right femur and excited with frequencies of 1, 2.5, 3.5, 20, 25, 35, 45 and 60 Hz. Convective filtration in the intracortical capillary was evaluated using fluorescent microspheres. Under in vivo study, a hind limb suspension (HLS) rat model was developed to generate interstitial fluid flow in femur via dynamic muscle contraction. Daily fluid flow loading was administrated via a low magnitude muscle stimulator at frequency of 10 Hz, 5 min/day, for 3 weeks. Dynamic muscle contraction significantly generated fluid ImP, in which ImP increased on the order of 8+/-1.4 mmHg at 1 Hz, 8.7+/-0.5 mmHg at 2.5 Hz, 9.3+/-4.7 mmHg at 25 Hz, and 1.8+/-0.1 at 45 Hz, with baseline of 2 mmHg generated by heart beats. Fluorescent tracer indicated that the perfusion in experimental bone was 3x greater than in the control. In the in vivo results, histomorphometry analysis indicated significant trabecular bone remodeling, in which the ratio of labeled vs. bone surface (LS/BS) has more than 50% increase in the experimental distal femur compared to contralateral control. Double labels have shown in the experimental group, but not in the sham control, in which mineral deposition rate (MAR) was at 1.5 micron/day. These results suggest that dynamic contraction of muscle may generate hyper-tension in the skeletal nutrient vessel and induce ImP, and may substantially influence the fluid flow in bone. Physiologic and dynamic muscle contraction may serve as a non-invasive source for generating fluid flow in bone, which can trigger modeling and remodeling in bone. This may help to devise a biomechanical based intervention for treating osteoporosis, muscle atrophy, and accelerating fracture healing.

A School Curriculum Based Exercise Program Increase Bone Mineral Accrual in Boys and Girls during Early Adolescence-Four Years Data from the POP-Study (Pediatric Osteoporosis Prevention Study) - a Prospective Controlled Intervention Study in 221 Children. C. Linden, P. Gardsell*, H. Ahlborg, M. Karlsson. Orthopaedics, University Hospital Malmö, Malmö, Sweden.

The longest reported prospective controlled intervention study with exercise in growing children which evaluate the accrual of bone mineral span 20 months. The purpose of this study was to evaluate the effect of an exercise intervention program within the school curriculum during the first school years, to catch also children not specifically interested in exercise, and to present the so far longest controlled follow-up data of exercise during growth. A population based cohort including 73 healthy Caucasian boys (aged 7.8 ± 0.6 at baseline) and 48 girls (aged 7.7 ± 0.6) in the only school in the Bunkeflo society outside Malmö, Sweden, were included in a school curriculum with 40 minutes physical activity every school day. One hundred healthy age and gender matched children (52 boys and 48 girls) in three nearby schools served as controls. These children were assigned to the general Swedish curriculum of physical activity in these grades (60-90 min/w). Bone mineral content (BMC; g) were measured with dual X-ray absorbtiometry (DXA) at the lumbar spine (LS) and femoral neck (FN) before initiation of the intervention and then yearly for four years. The slope for each individual was estimated from the repeated measurements, and the annual changes calculated. Data is presented as mean ± SD. There were no differences in age, height, weight or BMC at baseline. In boys, the annual gain in BMC in the LS was greater in the intervention group in comparison with the controls during the 4 year follow-up, 7.0 ± 2.3 versus (vs.) 6.2 ± 1.5, $p<0.05$. In girls, a similar effect was seen in the LS 9.1 ± 4.1 vs. 7.1 ± 3.3 and in the FN 0.39 ± 0.20 vs. 0.29 ± 0.17, $p < 0.01$ respectively. The annual increase of the FN width (mm) was also greater in the intervention group, 1.23 ± 0.42 vs. 1.07 ± 0.49 in boys and 1.45 ± 0.91 vs. 1.03 ± 0.76 in girls, $p < 0.05$. The discrepancies remained after adjusting for differences in weight gain, height gain and pubertal development during the study, except for FN width in girls ($p=0.08$). A school based exercise program within the general curriculum during the first four school years seems to increase the accrual of bone mass and bone size. This is the first published intervention study that is population based and include the intervention within the school curriculum. Furthermore, it is so far the only intervention study that exceeds 20 months. Based on the data in this study it seems that increased time spent in physical education classes may increase peak bone mass and subsequently can be used as a prevention strategy for osteoporosis.

Cbl-Mediated Ubiquitination of alpha 5 Integrin Subunit Mediates Fibronectin-Dependent Osteoblast Detachment and Apoptosis Induced by FGFR-2 Activation. K. Kaabeche*[1], H. Guenou*[1], D. Bouvard*[2], N. Didelot*[1], A. Listrat*[1], P. J. Marie[1]. [1]Laboratory of Osteoblast Biology and Pathology, Inserm U606, Paris, France, [2]LEDAC, UMR CNRS/UJF 5538, La Tronche, France.

Fibroblast growth factor receptor (FGFR) signaling is an important mechanism regulating osteoblast function and osteogenesis. To gain further insight into the regulatory role of FGFR-2 signaling in osteoblasts, we investigated integrin-mediated attachment and cell survival in osteoblasts expressing activated FGFR-2. Human calvarial osteoblasts obtained from a patient with Apert syndrome (craniosynostosis) exhibiting a S252W FGFR-2 mutation showed reduced cell attachment on fibronectin in culture compared to control cells. This was associated with reduced expression of the alpha 5 integrin subunit which we found by immunohistochemistry to be expressed in human calvarial osteoblasts in vivo. Treatment with lactacystin, a potent inhibitor of proteasome, restored alpha 5 integrin levels in FGFR-2 mutant osteoblasts. Immunoprecipitation analysis showed that alpha 5 integrin interacts with both the E3 ubiquitin ligase Cbl and ubiquitin. Immunocytochemistry revealed that alpha 5 integrin colocalizes with FGFR-2 and Cbl at the leading edge in membrane ruffle regions in normal and mutant FGFR-2 osteoblasts. Transfection with the 70Z-Cbl mutant lacking the RING domain required for Cbl ubiquitin interaction, or with the G306E Cbl mutant that abolishes the binding ability of Cbl phosphotyrosine binding domain, restored alpha 5 integrin levels in FGFR-2 mutant osteoblasts. This suggests that Cbl-mediated ubiquitination plays an essential role in alpha 5 integrin proteasome degradation induced by FGFR-2 activation. Reduced alpha 5 integrin expression was associated with increased Bax/Bcl-2 ratio and increased caspase-9 and caspase-3 activities in FGFR-2 mutant osteoblasts. Forced expression of alpha 5 integrin rescued cell attachment and corrected both the Bax/Bcl-2 ratio and caspase-3 and caspase-9 activities in FGFR-2 mutant osteoblasts. We conclude that Cbl recruitment induced by FGFR-2 activation triggers alpha 5 integrin degradation by the proteasome, which results in reduced osteoblast attachment on fibronectin and caspase-dependent apoptosis. This identifies a functional role of the alpha 5 integrin subunit in the induction of apoptosis triggered by FGFR-2 activation in osteoblasts, and reveals a novel Cbl-dependent mechanism involved in the coordinated regulation of cell apoptosis induced by alpha 5 integrin degradation.

The Evidence that *Bcl-2* Is Dispensable for the Anabolic Action of PTH in Bone. J. Yamashita*, Y. P. Chun*, N. S. Data, L. K. McCauley. School of Dentistrey, University of Michigan, Ann Arbor, MI, USA.

It is well recognized that intermittent administration of PTH has anabolic actions in bone. The proposed mechanism of this action has focused on two theories. First, anabolic PTH may increase the proliferation of pre-osteoblasts and stimulate their maturation. Second, PTH may extend the life span of mineral-forming osteoblasts by suppressing apoptosis. Despite suggestive evidence, the exact mechanisms of PTH anabolic actions are unclear. *Bcl-2*, which plays a pivotal role in preventing apoptosis, has drawn special attention. It has been hypothesized that PTH stimulates *bcl-2* so that mature osteoblasts can survive longer, resulting in increased bone formation. In this study, we tested the hypothesis that the activation of *bcl-2* is essential for the anabolic action of PTH in bone. Calvarial osteoblasts and splenocytes were isolated from *bcl-2*$^{+/+}$, *bcl-2*$^{+/-}$, and *bcl-2*$^{-/-}$ mice and their *bcl-2* expression verified. Proliferation and mineralization assays revealed that *bcl-2*$^{-/-}$ osteoblasts were not significantly different from *bcl-2*$^{+/+}$ and *bcl-2*$^{+/-}$ osteoblasts. There was also no significant difference found between the genotypes in survival rate with etoposide-induced apoptosis in osteoblasts although primary *bcl-2*$^{+/+}$ splenocytes displayed greater protection than *bcl-2*$^{-/-}$. To determine the role of *bcl-2* in bone formation, two *in vivo* approaches were utilized. The first approach involved a novel implant system where vertebrae (vossicles) from neonatal *bcl-2*$^{+/+}$, *bcl-2*$^{+/-}$, or *bcl-2*$^{-/-}$ mice were implanted to immunodeficient mice and PTH (80μg/kg/day) was administered daily for 3 weeks. The second approach was daily administration of PTH (50μg/kg/day) to *bcl-2*$^{+/+}$, *bcl-2*$^{+/-}$, and *bcl-2*$^{-/-}$ mice from day-4 to day-13 of age. Histomorphometric and statistical analyses indicated that regardless of the genotype the vossicles responded similarly to PTH with substantially increased bone area when compared to vehicle-control groups ($p < 0.001$). Similarly, in the intact mice of PTH-administered groups there was increased metaphyseal trabecular bone area in the tibiae regardless of the genotype. In summary, there were no major differences detected in the osteoblast activity between *bcl-2*$^{+/+}$ and *bcl-2*$^{-/-}$ *in vivo* or *in vitro*. Our results indicate that, contrary to previous suggestions, *bcl-2* is dispensable in osteoblasts for the anabolic action of PTH.

Transgenic Expression of Human Bcl-2 in Osteoblasts Promotes Differentiation but Inhibits Bone Formation in Ex Vivo Calvarial Osteoblast Cultures. W. Zhang, A. G. Pantschenko*, M. McCarthy*, G. Gronowicz. Orthopedic Surgery, Uconn Health Center, Farmington, CT, USA.

Apoptosis is important in regulating bone homeostasis and turnover, and Bcl-2 is a key regulator of apoptosis in osteoblasts. In this study, we examined the role of Bcl-2 on the proliferation, differentiation, mineralization and apoptosis of murine transgenic osteoblasts. A Col2.3Bcl-2 transgenic mouse line was generated with 1.8 kb human Bcl-2 (hBcl-2) cDNA driven by the 2.3 kb rat Col1a1 promoter, so that hBcl-2 was expressed in mature osteoblasts. Animal use was approved by the Center for Laboratory Animal Care at UCHC. Calvarial osteoblasts were isolated from neonatal wild-type (+/+) and transgenic (tg/+) littermates by sequential digestion and cultured in DMEM with 10% FBS. For differentiation, the media was changed to α-MEM and supplemented with 50μg/ml ascorbic acid and 4mM β-glycerophosphate. HBcl-2 transcript and protein expression were detected by real-time PCR and Western blot. Culture doubling time was determined over 9 days for cells grown in DMEM by fluorometric DNA analysis. Acridine orange/ ethidium bromide staining and TUNEL were used to study apoptosis. The transcripts of type I collagen (Col1a1), bone sialoprotein (BSP) and osteocalcin (OC) were measured by Northern blot at days 14, 21, 28 and 35. Mineralization was determined by measuring calcium content and alizarin red staining. All assays were repeated at least 3 times. HBcl-2 expression increased during differentiation to over 100-fold more than endogenous mouse Bcl-2 without an effect on mouse Bcl-2 expression. There was no significant difference in the population doubling time between +/+ and tg/+ osteoblasts. The transgene was functional as indicated by the inhibition of apoptosis in tg/+ but not +/+ osteoblasts in response to 1 to1000 nM corticosterone. Col2.3Bcl-2 promoted differentiation as indicated by the stronger expression of bone matrix markers in the tg/+ cells, especially BSP and OC. Tg/+ osteoblasts produced significantly less mineralization than +/+ on days 14, 21, and 28 with 47% less calcification on day 28. Alizarin red staining was also decreased in tg/+ cells. Apoptosis was found primarily in the mineralized nodules as shown by TUNEL, and it was decreased in tg/+ cultures on days 14, 21, 28 with 34% less apoptosis on day 28 than the +/+. In conclusion, overexpression of hBcl-2 protected osteoblasts from glucocorticoid-induced apoptosis and promoted their differentiation, but had no effect on endogenous mouse Bcl-2 or the proliferation of osteoblasts. Importantly, overexpression of hBcl-2 impaired mineral deposition and decreased apoptosis, suggesting that apoptosis is essential for osteoblast mineralization *in vitro*.

Parathyroid Hormone Increases Osteoblastic Jagged1 through Protein Kinase A (PKA) Activation. J. M. Weber*, S. R. Forsythe*, C. A. Christianson*, L. M. Calvi. Medicine, Endocrine Division, University of Rochester School of Medicine, Rochester, NY, USA.

In the bone marrow, osteoblastic cells have been shown to be an important component of the hematopoietic stem cell (HSC) niche. We demonstrated that activation of the PTH Receptor (PTHR1) in osteoblastic cells expands HSCs. Activation of the Notch signaling pathway was necessary to mediate the PTH-induced expansion of HSC. This pathway, through cell-cell interactions plays a fundamental role in HSC self-renewal. In particular, stromal cell expression of the Notch ligand Jagged1 has been shown to be sufficient for HSC expansion in vitro. To explore PTH regulation of Jagged1, we studied mice treated with intermittent PTH (1-34). In untreated adult mice, immunohistochemical analysis of the long bones showed low levels of Jagged1 protein in endosteal osteoblasts at both the metaphysis and diaphysis. In contrast, no Jagged1 was found in periosteal osteoblasts. As early as 5 days after PTH treatment, endosteal osteoblastic Jagged1 levels were increased compared to vehicle-treated animals. To study the molecular mechanisms involved in PTH regulation of osteoblastic Jagged1, we utilized rat osteosarcoma UMR106 cells, known to express the PTH1R. Jagged1 expression was increased in a time and dose-dependent fashion when measured by realtime PCR in RNA from UMR106 cells treated with PTH compared with vehicle. Western blot analysis with two distinct anti-Jagged1 antibodies confirmed the PTH-dependent increase in Jagged1 protein. In osteoblasts, PTH(1-34) is known to activate both the adenylate cyclase (AC) and the protein kinase C (PKC) signaling cascades downstream of the PTH1R. We independently determined the effect of activating either pathway on Jagged1. Forskolin, an AC activator, dramatically increased Jagged1 expression and protein. In addition, we could reproduce the Jagged1 increase in mRNA using PTH(1-31), which predominantly activates PKA downstream of AC. Moreover, PKA stimulation with cell-permeable cAMP analogues dibutiryl-cAMP and 8-bromo-cAMP stimulated Jagged1. Treatment with PTH (1-34) in the presence of the PKA inhibitor H89 inhibited the PTH-dependent Jagged1 increase. In contrast, Jagged1 levels were not increased by treatment with PTH(13-34), which predominantly activates PKC, or PMA, a PKC activator. In summary, osteoblastic cell treatment with PTH increases expression of the Notch ligand Jagged1 through activation of the AC/PKA signaling pathway downstream of the PTH1R. Further definition of the molecular mechanisms underlying osteoblastic PTH-dependent modulation of Jagged1and its role in the PTH-induced enhanced osteoblastic support of HSC is likely to provide targets for manipulation of the HSC niche.

HB954, an Orphan 7 Transmembrane Receptor, Is Expressed at High Levels in Bone. J. R. Connor[1], C. A. Watson*[2], C. Hanning*[1], S. Hoffman*[1], P. Liang*[1], D. Rickard*[1], P. Hegde*[3], E. Docherty*[3], A. Morrison*[3], G. Hagger*[2], J. Minnion*[2], S. Kumar[1]. [1]Musculoskeletal Diseases, GlaxoSmithKline, Collegeville, PA, USA, [2]Discovery Research, GlaxoSmithKline, Collegeville, PA, USA, [3]Genetics Research, GlaxoSmithKline, Collegeville, PA, USA.

HB954 was identified as an orphan 7 transmembrane receptor expressed at high levels in bone. The purpose of this study was to investigate the role of HB954 in bone formation and remodeling. Expression of HB954 mRNA was analyzed by TaqMan using standard techniques against a variety of human tissues and by in situ hybridization using 35S labeled riboprobes on cryostat sections of human osteoclastoma. Serial sections were stained for alkaline phosphatase. Human mesenchymal stem cells were differentiated to osteoblasts, adipocytes or chondrocytes by the supplier (Clonetics, Walkersville, MD) and

the RNA, harvested at time points up to 21 days, was analyzed for differential gene expression by transcriptome analysis using Affymetrix Chip technology. Human tissues were obtained with informed consent and with the approval of the institutional review board. Finally, 9 week old HB954 knockout (129ola/C57Bl/6) mice were examined for bone phenotype by histomorphometry following double calcein labeling and by microCT analysis. All procedures were performed in accordance with protocols approved by the GSK Institutional Animal Care and Use Committee. HB954 mRNA was expressed at high levels (15,000 copies of HB954 mRNA per ng mRNA pool) in bone compared to a variety of other tissues including liver, brain, adipose, cartilage and bone marrow by TaqMan analysis. In human osteoclastoma, HB954 mRNA was detected at high levels by in situ hybridization in osteoblasts on bone surfaces and in alkaline phosphatase positive areas of bone formation. During the time course of differentiation of human mesenchymal stem cells to osteoblasts, adipocytes or chondrocytes, HB954 was significantly and specifically upregulated at early time points in osteoblasts but downregulated in adipocytes and chondrocytes. In HB954 knockout mice, histomorphometric analysis demonstrated increased bone volume in knockout versus wild types due to increased and thickened trabeculae, increased modeling and decreased resorption. MicroCT analysis of the proximal tibia demonstrated trends toward increased bone volume per total volume, increased trabecular number and thickness, and increased connectivity density. In summary, the unique and high expression of HB954 in osteoblasts suggests a role in bone formation or remodeling. The observation of strong trends toward increased bone mass in the HB954 knockouts provides additional support for a role for this receptor in bone formation.

Modulation of Runx2 Expression Effects Bone Parameters *In Vitro* and *In Vivo*. C. A. Frolik[1], A. G. Geiser*[1], G. Krishnan[1], C. D. Jones*[1], K. A. Houck*[1], E. C. Black*[1], L. M. Helvering*[1], T. L. Moore*[1], H. A. Bullock*[1], R. J. S. Galvin[1], L. Ma[1], M. Sato[1], R. C. Smith*[1], P. Ducy[2], G. Karsenty[3]. [1]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, USA, [2]Cell Biology, Baylor College of Medicine, Houston, TX, USA, [3]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

Runx2, an osteoblast-specific transcription factor, is essential for osteoblast differentiation. Compounds that modulate Runx2 expression or activity could have important effects on bone. LSN509010 was identified as a compound that increased Runx2 mRNA expression in C3H10T1/2 cells and also enhanced the transcription of a luciferase reporter plasmid containing the Runx2 binding element (OSE). In C2C12 and C3H10T1/2 cells, LSN509010 increased alkaline phosphatase activity, an effect that was dependent on BMP in C2C12 cells and amplified by BMP in C3H10T1/2 cells. The compound increased mineralization of cartilage rudiments maintained in organ culture and this increase was diminished by an antisense oligonucleotide to Runx2. LSN509010 also decreased osteoclast differentiation as determined in both osteoblast supported and osteoblast independent models. Since analogs of retinoic acid also increased alkaline phosphatase activity in C3H10T1/2 cells, LSN509010 was examined for retinoid-like activity. LSN509010 activated the DR5 retinoic acid response element in a transient transfection assay and a retinoic acid receptor (RAR) pan-antagonist blocked the response to retinoic acid analogs and LSN509010 in C3H10T1/2 and C2C12 cells. However, in the metatarsal assay, 13-cis-retinoic acid had a detrimental effect, not observed with LY509010, which was reversed by the RAR pan-antagonist. Finally, in vivo, LSN509010 increased bone volume in an intraosseous infusion model and increased femoral midshaft bone mineral density in a delayed dosing ovariectomized rat model. These findings suggest that modulation of Runx2 expression may lead to positive bone effects in vivo.

Multiple Histone Deacetylases and Histone Deacetylase Inhibitors Influence Runx2 Activities and Osteoblast Maturation. E. D. Jensen*[1], T. M. Schroeder*[1], X. Li*[1], J. J. Westendorf[2]. [1]University of Minnesota, Minneapolis, MN, USA, [2]Orthopaedic Surgery, University of Minnesota, Minneapolis, MN, USA.

Runx2 (Cbfa-1/ AML-3) is a key transcriptional regulator of bone and chondrocyte development, and influences cancer-associated bone disease. Runx2 acts as both a context-dependent activator and repressor of transcription. These opposing activities are mediated by interactions between Runx2 and a variety of co-activators and co-repressors, including p300/ CBP, YAP, Groucho/TLE, and histone deacetylases, notably HDAC3, HDAC4 and HDAC6. Histone deacetylases are recruited to promoters by transcription factors and repress gene expression by catalyzing the removal of acetyl groups from histones and other proteins, therein altering chromatin structure. HDAC Inhibitors (HDIs) are currently in phase I and II clinical cancer trials, but their effects on bone formation are not well characterized. In the current study, we show that Runx2 colocalizes and/or co-precipitates with the class II histone deacetylases, HDAC7, HDAC9-related protein (HDRP), and HDAC10. Multiple domains of Runx2 are required for these interactions. HDAC7, but not HDRP or HDAC10, attenuated the ability of Runx2 to activate the osteocalcin promoter. As we previously demonstrated with HDAC3 and HDAC6, HDAC7 and HDRP are expressed with Runx2 in a number of mesenchymal and osteoid tissue culture cell lines. General inhibition of HDAC activity by multiple small molecule HDIs accelerated mineralization of osteoblast cultures and increased alkaline phosphatase production by calvarial organ cultures without affecting osteoblast viability. Together our data suggest that general HDAC activity regulates osteoblast maturation and bone formation, but each HDAC may regulate Runx2 target genes in specific ways.

C/EBP Homologous Protein (CHOP, Ddit3) Overexpression Inhibits Osteoblastic Function and Causes Severe Osteopenia. R. C. Pereira*, L. Stadmeyer*, D. Smith*, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

CCAAT/enhancer binding proteins (C/EBPs) are transcription factors with important roles in cell differentiation and function. C/EBP homologous protein (CHOP) is a nuclear protein that forms heterodimers with C/EBPs and with membes of the cyclic AMP response element binding protein/activator of transcription factor family. Studies in *chop* null mice revealed that CHOP is necessary to maintain normal bone mass, and CHOP overexpression *in vitro* accelerates osteoblastogenesis by enhancing BMP/Smad signaling. However, the effects of CHOP overexpression on osteoblastic cell fate and function *in vivo* are not known. To evaluate the role of CHOP expression in skeletal cell function, we created transgenic mice overexpressing CHOP under the control of a 3.6 kilobase (kb) fragment of the rat type I collagen promoter or of a 3.9 kb fragment of the human osteocalcin promoter. One month old homozygous CHOP overexpressing mice were compared to wild type littermates and their skeletal phenotypes defined by radiological and histomorphometric analyses. The skeletal phenotype of type I collagen and osteocalcin CHOP transgenics was similar, but type I collagen CHOP transgenics displayed lower body weight. Contact radiography did not reveal radiological abnormalities in CHOP transgenics, except for cortical thinning. Bone mineral density (BMD) was reduced, particularly in type I collagen CHOP transgenics, which exhibited a 10 to 20% reduction in femoral BMD. Bone histomorphometry confirmed that CHOP transgenics had severe osteopenia and trabecular bone volume/total volume was reduced by 30 to 50% in both lines. The decrease was secondary to a reduction in trabecular number. CHOP transgenics exhibited normal number of osteoblasts and osteclasts/perimeter, and normal osteoblast and osteoclast surfaces. Bone eroded surface was not affected, indicating normal bone resorption. Dynamic histomorphometry revealed a marked decrease in bone mineral apposition rate of 35 to 60% in both transgenic lines, indicating that the trabecular bone loss was secondary to impaired osteoblastic function. Since type I collagen is expressed in undifferentiated cells, the normal osteoblast number suggests that osteoblast differentiation was not affected. In conclusion, although CHOP is necessary to maintain bone mass *in vivo*, its overexpression inhibits bone formation, causing severe osteopenia. The mechanism may involve CHOP dimerization with transcription factors required for the maintenance of osteoblastic function.

Dominant-Negative Odd-Skipped Related 2 Impaired Parietal Bone Formation. S. Kawai*[1], T. Yoneda[2], A. Amano*[1]. [1]Department of Oral Frontier Biology, Osaka University Graduate School of Dentistry, Suita-Osaka, Japan, [2]Department of Biochemistry, Osaka University Graduate School of Dentistry, Suita-Osaka, Japan.

The drosophila pair-rule gene Odd-skipped encodes a zinc finger transcription factor required for accurate segment formation in the embryonic development. Mammalian homologues, odd-skipped related 1 (Osr1) and odd-skipped related 2 (Osr2), were subsequently cloned from both mice and humans. Mouse Osr1 has been shown to share a 65% homology with Osr2 and 100% homology in zinc finger domain. Osr1 is expressed in the intermediate mesoderm, limb, lung, and branchial arch of fetuses, as well as adult colon, small intestine, prostate, and testis tissues. While, Osr2 is preferentially expressed in the mesonephric vesicles, mandibular mesenchyme, and limb mesenchyme of fetuses. The function of Osr2 in the bone is not fully understood though Osr2 is expressed during limb development. To analyze the function of Osr2 in bone development, transgenic mice were generated using dominant negative Osr2 driven by a 5kb mouse Osr2 gene promoter (Osr2ΔN Tg). The genotype was confirmed by PCR of tail genome using transgene-specific primers. The growth was significantly retarded in Osr2ΔN Tg compared with wild type mice. At 2 weeks after birth, soft X-ray analysis of transgenic mice revealed markedly increased radiolucency compared with the wild type. Judged by skeletons of newborn mice stained with alcian blue and alizarin red those intensities of skull and skeletal elements of Osr2ΔN Tg were apparently reduced. Morphologically, calvaria of Osr2ΔN Tg composed of markedly thinner parietal bones and less number of osteoblastic cells on parietal bone surfaces, which indicates delayed intramembranous ossification. RT-PCR analysis revealed that expressions of osteoblast marker genes were significantly reduced or scarcely detected in primary osteoblastic cells of Osr2ΔN Tg, those included alkaline phosphatase, osteocalcin, Runx2, and osterix. These findings indicate that Osr2 play an important role during the process of parietal bone formation.

Mandibular Phenotype of p20C/EBPß Transgenic Mice: Reduced Alveolar Bone Mass and Site-Specific Dentin Dysplasia. T. Savage*[1], D. J. Adams*[2], M. Mina*[3], J. R. Harrison*[1]. [1]Orthodontics, University of Connecticut Health Center, Farmington, CT, USA, [2]Orthopaedics, University of Connecticut Health Center, Farmington, CT, USA, [3]Pediatric Dentistry, University of Connecticut Health Center, Farmington, CT, USA.

CCAAT enhancer binding proteins (C/EBP) comprise a family of basic-leucine zipper transcription factors that regulate cellular differentiation and function. To determine the role of C/EBP transcription factors in osteoblasts and odontoblasts, we generated a transgenic (TG) mouse model with Co1a1 (Col3.6) promoter-targeted expression of a FLAG-tagged dominant negative C/EBP isoform, p20C/EBPß (formerly LIP). Two of the four transgenic lines presented with a gross tooth phenotype manifested by incisor breakage, overgrowth and malocclusion. Histological examination revealed that the amount of alveolar bone was greatly reduced in TG compared to wild type (WT) mice. By microCT, the bone volume fraction of the mandible was reduced at the level of the first (WT 86 ± 1%, TG 62 ± 4%) and third (WT 79 ± 1%, TG 57 ± 4%) molars, demonstrating a severe mandibular osteopenia. The lingual dentin morphology of TG incisors differed dramatically. Labial dentin (enamel side) showed normal thickness and tubular structure, whereas the lingual dentin was thinner (25-30% of WT at the alveolar crest) with an amorphous globular structure characteristic of dentin dysplasia. FLAG immunostaining was seen in both lingual and labial odontoblasts, indicating that the site-specific defect was not due to a lack of labial transgene expression. Northern blot analysis demonstrated reduced osteocalcin expression in TG mandibles, while bone sialoprotein was increased, consistent with prior results in calvariae and long bones. Dental sialophosphoprotein (DSPP), a marker of the odontoblast lineage whose absence causes dentin dysplasia, was reduced in TG mice. By fluorescence microscopy, Col2.3-GFP, a marker of the odontoblast lineage, was expressed in both labial and lingual odontoblasts, although GFP-marked lingual odontoblasts appeared to be more flattened than WT cells. Moreover, GFP-positive processes in the lingual dentin tubules were truncated and less organized than those in WT dentin. By *in situ* hybridization, DSPP was expressed in TG lingual odontoblasts, but the signal appeared to be less intense than that seen in WT odontoblasts. These data suggest that C/EBP transcription factors may be involved in the regulation of both osteogenesis and odontogenesis. The differential effect of the p20C/EBPß transgene on distinct odontoblast populations suggests cellular heterogeneity within the lineage reflecting cell autonomous differences or the effects of local signals.

Runx2 Association with Microtubules: A Potential Role in Nucleo-Cytoplasmic Shuttling. S. M. Pockwinse*[1], A. Rajgopal*[1], D. W. Young[1], K. A. Mujeeb*[1], A. Javed[1], J. B. Lian[1], A. J. van Wijnen[1], J. L. Stein*[1], S. J. Doxsey*[2], G. S. Stein[1]. [1]Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, [2]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, USA.

Transcriptional activity of Runx2, a key factor in bone formation, is modulated by co-regulatory factors, including SMAD 2,3,4 and HDAC 6 that have been shown to associate with microtubules. We pursued biochemical and in situ studies to investigate whether Runx2 interacts with microtubules. We find that soluble α tubulin co-immunoprecipitates with Runx2 while a control IgG does not precipitate tubulin. We next performed microtubule co-sedimentation assays with or without taxol (Paclitaxel), a chemotherapeutic agent that stabilizes microtubules. Lysates from Runx2 expressing cells were incubated with taxol stabilized microtubules and centrifuged through a sucrose cushion. The pellet (microtubules) and supernatant fractions were examined for the presence of Runx2 by western blot analysis. We observed that the amount of pelleted Runx2 increases with increasing amounts of polymerized microtubules. Furthermore, if microtubules were depolymerized with nocodazole, Runx2 was not found in the pelleted fraction. These results indicate that Runx2 associates with microtubules. We identified a specific domain of Runx2 that interacts with microtubules. Using the co-sedimentation assay, we show that full-length and N-terminus (1-361) Runx2, but not the C-terminus (323-528), bind to and are pelleted with taxol-stabilized microtubules. Thus, there is a specific interaction between the Runx2 N-terminus and microtubules. Morphological analysis using immunofluorescence shows that Runx2 redistributes from the nucleus to the cytoplasm when microtubules are stabilized with taxol. Quantitation using the linescan function of the Metamorph software program confirms that nuclear Runx2 decreases in taxol treated cells with a concomitant increase in cytoplasmic levels. By confocal microscopy the taxol induced cytoplasmic Runx2 appears to be linearly arranged and associated with microtubules. To understand the potential significance of the Runx2-microtubule interactions, we blocked nuclear export using leptomycin B prior to taxol treatment. Under these conditions, Runx2 did not redistribute from nucleus to cytoplasm. Taken together, these data show that Runx2 associates with microtubules and shuttles between the nucleus and cytoplasm. We propose that nuclear-cytoplasmic shuttling may represent a mechanism for regulation of Runx2 transcriptional activity.

Functional Study of a Unique Polyglutamine Stretch in RUNX2. P. M. Fonseca*[1], G. Zhou[1], Y. Chen*[1], B. Lee[2]. [1]Molecular Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]Howard Hughes Medical Institute, Chevy Chase, MD, USA.

RUNX2 is a non-redundant transcriptional activator involved in osteoblast differentiation and chondrocyte maturation. It contains a unique N-terminal polyglutamine-alanine (QA) domain consisting of a stretch of 23 residues of glutamine and 17 residues of alanine. Mutations in RUNX2 cause an inherited skeletal malformation syndrome, cleidocranial dysplasia (CCD). Until now, only one expansion in the alanine tract has been reported in an individual with CCD, while shortenings of the tract are benign polymorphic variants. Polyglutamine expansions are known to cause several neurodegenerative diseases, but the function of the QA tract in RUNX2 is still unclear. In this study, we generated a series of mutant forms of RUNX2 with a deleted (7QE2A-RUNX2) or expanded (72QE23A-RUNX2) QA domain. *In vitro* studies show that 7QE2A-RUNX2 results in reduced transactivation capacity of a reporter gene, while expansions only reduce transactivation when they exceed 70 repeats. Mice over expressing 7QE2A-RUNX2 under the osteoblast-specific action of promoter Col1a1 present short stature at birth. Skeletal preparations revealed delayed closure of fontanel while clavicles appeared normal. Preliminary radiographic analysis of a transgenic mouse suggests lower bone mass. Transgenic mice also show absence of upper teeth and overgrown lower teeth with malocclusion. Interestingly, a fragment containing only the QA domain exhibited a dominant-negative effect on full-length RUNX2 in RUNX2 transactivation assay in ROS17 cells. To test this *in vivo*, we also generated transgenic mice over expressing only the QA domain in osteoblasts. One of the founders was about half the size of the non-transgenic littermates and died prematurely, also showing lower bone density. We are in progress of analyzing the transgenic mice by histology, RNA *in situ* hybridization and real-time RT-PCR. The analysis of these different transgenic mice will lead to a better understanding of the function of the QA tract in RUNX2.

Activation of Small G-Protein Rap1 Increases Bone Mass. A. Ueda*, T. Hiraga, T. Yoneda. Biochem, Osaka Univ Grad Sch of Dent, Osaka, Japan.

Small G-Proteins such as Ras, Rho and Rab have been shown to play a variety of roles in bone metabolism. Ras stimulates osteoblast differentiation and prolongs osteoclast survival. Rho and Rab are reported to promote the formation of actin ring and ruffled border, respectively. The small G-protein Rap1, which is a family member of Ras and originally identified as a natural antagonist of Ras, has been implicated in cell attachment and proliferation. However, the role of Rap1 in bone metabolism has not been explored. To approach this, we firstly studied bones of mice deficient in SPA-1 gene, which specifically inactivates Rap1. Histomorphometrical examination demonstrated significant increase in trabecular bone volume and decrease in osteoclast number in SPA-1-deficient (SPA-1-/-) mice compared with wild-type (WT) mice. Furthermore, calcein double-labeling experiments revealed that bone formation rate was significantly increased in SPA-1-/- mice. Western blot analyses showed that Rap1 was expressed in both osteoblasts and osteoclasts obtained from WT and SPA-1-/- mice at equivalent levels. Ral-GDS pull-down assay showed that Rap1 was markedly activated in osteoclasts and osteoblasts of SPA-1-/- mice compared with those of WT mice. These results collectively suggest that Rap1 activation is involved in the regulation of bone mass. To further understand the role of Rap1 in bone, we examined the effects of Rap1 on osteoblast differentiation in vitro using the multipotent mesenchymal cell line C3H10T1/2. BMP2 increased Rap1 activity along with osteoblastic differentiation of C3H10T1/2 cells. SPA-1 overexpression in C3H10T1/2 cells by retrovirus system suppressed BMP2-induced osteoblast differentiation. In contrast, overexpression of Epac, which specifically activates Rap1, enhanced osteoblastogenic effects of BMP2. In addition, Epac significantly increased the proliferation of C3H10T1/2 cells, whereas SPA-1 decreased it. We next examined whether Rap1 plays a role in osteoclast differentiation. TRAP-positive multinucleated osteoclast-like cell formation induced by soluble RANKL and M-CSF was significantly reduced in SPA-1-/- mice-derived spleen cell cultures. RT-PCR analysis showed that OPG expression was elevated in SPA-1-/- marrow stromal cells, suggesting that Rap1 activation negatively regulates osteoclast differentiation. On the other hand, actin ring formation, which is critical to osteoclastic bone resorption, was not affected in SPA-1-/- osteoclast-like cells. In conclusion, our results suggest that Rap1 activation increases bone mass by promoting osteoblast differentiation and inhibiting osteoclast formation. Rap1 may be an important small G-protein in the regulation of bone metabolism.

The Blunting of the Bone Anabolic Response to PTH Observed after Frequently Dosed Bisphosphonates in Rats May Be Explained by Inhibition of Farnesyl Diphosphate Synthase in Osteoblasts. J. A. Gasser, P. Ingold*, A. Rebmann*, M. Susa. Musculoskeletal Diseases, Novartis Institutes for Biomedical Research, Basel, Switzerland.

Chronic exposure to the bisphosphonate (BP) alendronate (ALN) has been shown to blunt the bone anabolic response to parathyroid hormone (PTH) in rats (Gasser, J Musculoskel Neuron Interact, 1:53, 2000) and human (Finkelstein, NEJM, 349:1216, 2003). We aimed to investigate the potential mechanism behind the BP-PTH interaction and determine whether a single BP injection exerted a different effect than chronic ALN.

Skeletally mature 16-month-old Wistar rats were treated with ALN (28μg/kg s.c. twice per week) or vehicle for 16 weeks before starting daily s.c.-injections of 100μg/kg hPTH(1-38) 5 times per week. The anabolic response was monitored by serial quantitative computed tomography (pQCT) and mechanical properties. The response to PTH was significantly blunted in the femur and tibia of ALN-pretreated rats; pQCT measurements indicated a 2-week delay. In addition, ALN-pretreated rats did not develop the full anabolic response observed in vehicle-pretreated rats over time. In pursuit of a potential mechanism, equipotent therapeutic doses of the BPs ALN (200μg/kg) and zoledronic acid (ZOL; 32μg/kg) were administered as single i.v. injections. A 10 times higher dose of ZOL (322μg/kg) was also administered. Daily s.c. PTH(1-34) treatment (40μg/kg, 5x/week) was initiated 24h later and continued for 6 weeks. Serial measurements of BMD, cortical and trabecular architecture in the proximal tibia metaphysis by pQCT (XCT Research) and *in vivo* microCT (vivaCT40) indicated a normal bone anabolic response in all cortical and cancellous structural parameters in ALN and ZOL treated animals, including those given the supra-pharmacological dose of ZOL. PTH is able to activate flat bone lining cells into cuboid, collagen-synthesizing osteoblasts (Obs) within 6 hours of administration. Our data suggest that chronic BP exposure may reduce the ability of PTH to activate bone lining cells into matrix-secreting Obs, a crucial step in the early bone anabolic response to PTH. In contrast, single i.v. injection of BP (even 10 times therapeutic dose) did not impair the response to PTH in rats. Single i.v. and chronic BP dosing result in a very different exposure pattern of bone cells to BP. Although Obs are not generally considered to be a target for BP inhibition, chronic dosing may be sufficient to exert a cumulative, direct inhibitory effect on the anabolic response of Obs to PTH. As in osteoclasts, inhibition of FPP-synthase by BP may reduce protein prenylation in Obs and thus disrupt cytoskeletal function, thereby preventing the shape change required for the activation of bone lining cells.

TGF-β Regulates CNC Proliferation and Differentiation during Frontal Bone Development. T. Sasaki, Y. Ito*, S. Chou*, P. Bringas, Jr*, K. Oka*, M. M. Urata*, H. C. Slavkin*, Y. Chai*. Center for Craniofacial Molecular Biology, School of Dentistry University of Southern California, Los Angeles, CA, USA.

The murine frontal bone derives entirely from the cranial neural crest during calvarial morphogenesis. TGF-β signaling can induce premature suture obliteration in cultured fetal rat calvaria and plays an important regulatory role in postnatal calvarial development. It is not known, however, what the functional significance of TGF-β signaling is in regulating the fate of cranial neural crest (CNC) cells during frontal bone development. We show that mice with *Tgfbr2* conditional gene ablation in the neural crest have severe frontal bone defect with complete phenotype penetrance. Importantly, loss of *Tgfbr2* does not affect the migration of CNC cells during frontal bone development. TGF-β IIR is specifically required for proliferation and terminal differentiation of the osteoprogenitor cells in the CNC-derived frontal bone anlagen on the side of the developing skull while the orbital surface portion of the frontal bone forms despite the cell proliferation defect, inferring a differential requirement for TGF-β signaling during the development of different regions of the frontal bone. At the molecular level, TGF-β signaling regulates the expression of *Twist*, which may then differentially regulate the expression of *Fgfr* and *Dlx5* to control osteoprogenitor proliferation and differentiation, respectively. This study reveals the TGF-β signaling cascade that regulates the development of the CNC-derived frontal bone and provides a model for investigating abnormal CNC development.

Enhanced Bone Mass in Mice Lacking G Protein-Coupled Receptor Kinases. L. Wang*, R. F. Spurney. Medicine, Duke University Medical Center, Durham, NC, USA.

G-protein coupled receptor (GPCR) systems are important regulators of bone remodeling. Studies from this laboratory suggest that the osseous effects of GPCR systems in bone are modulated by the rate of receptor desensitization. This desensitization is largely mediated by phosphorylation of GPCR proteins by a family of enzymes termed GRKs. In this regard, we previously found that: 1. Targeted overexpression of GRK2 in osteoblasts promotes bone loss (Am J Physiol 288:E826-834, 2005), and 2. Expression of a peptide GRK inhibitor in osteoblasts enhances bone mass (J Clin Invest 109:1361-1371, 2002). To further investigate the role of GRKs in regulating bone formation in vivo, we measured bone mineral content (BMC) and bone mineral density (BMD) in mice in which individual GRK genes had been disrupted by homologous recombination. Because homozygous disruption of GRK2 is lethal, studies using these animals were restricted to heterozygous mice (GRK2+/-). As shown in the table below, whole body BMC and BMD at 6 weeks of age was not altered by disruption of individual GRK genes. Because both GRK2 and GRK3 are likely to play important roles in regulating GPCR responsiveness in bone (J Clin Invest 109:1361-1371, 2002), we bred GRK2+/- and GRK3-/- mice to create mice lacking GRK3 and heterozygous for disruption of the GRK2 gene (GRK2+/-GRK3-/-). In GRK2+/-GRK3-/- mutant (MT) mice, both BMC (316 ± 6.8mg [WT] vs 361 ± 1.2mg [MT]; P=0.0018) and BMD (38.5 ± 4.8 mg/cm2 [WT] vs 41.8 ± 0.4 mg/cm2 (MT); P=0.0055) were significantly increased compared to WT animals. Taken together, these data suggest that GRK2 and GRK3 have overlapping effects in osseous tissues and that both GRK2 and GRK3 play key roles in modulating GPCR responsiveness in bone.

	GRK knockout mice	
	BMC (mg)	BMD(mg/cm2)
Wild type (WT)	308 Â± 7.9	39.1 Â± 0.6
GRK2+/-	327 Â± 19	38.9 Â± 0.9
GRK3-/-	315 Â± 6.3	39.2 Â± 0.4

Phosphatidylinositol 3 Kinase (PI 3 K)-Dependent Erk1/2 Activation Represents A Novel Mechanism of Statin-Induced BMP-2 Expression and Osteoblast Differentiation. N. Ghosh-Choudhury. Pathology, University of Texas Health Science Center at San Antonio and South Texas Veterans Health Care System;, San Antonio, TX, USA.

Statins, inhibitors of HMG CoA reductase, stimulate expression of BMP-2 resulting in new bone formation. We have previously reported requirement of Erk1/2 and PI 3 K for BMP-2-induced growth and differentiation of osteoblasts. We investigated the signaling mechanism involving these two central pathways in BMP-2 expression in response to statins in 2T3 mouse osteoblasts. Simvastatin and lovastatin (referred as "statins" hereafter), but not pravastatin, increased BMP-2 promoter activity. Statins activated Erk1/2 MAPK in a time-dependent manner with optimal activation at 5 minutes as judged by activation-specific phospho-Erk1/2 immunoblotting and immunecomplex kinase assays, respectively. In contrast, statins had no effect on two other MAP kinases, JNK and p38. To examine the functional consequences of Erk1/2, its phosphorylation-dependent transactivation of Elk-1 transcription factor was examined. Statins stimulated transactivation of Elk-1 as determined by a reporter transfection assay in 2T3 cells. U0126, an inhibitor of MEK, blocked stain-induced Erk1/2 activation, resulting in significant attenuation of Elk-1-transactivation. Presence of GTP-bound Ras is essential for increase in Erk1/2 activity. Therefore, the effect of statin on Ras-GTP formation was determined using a pull down assay with Ras binding domain of Raf fused to glutathione S-transferase (GST-RBD). In this assay, only activated GTP-bound Ras interacts with GST-RBD. Statins increased formation of Ras-GTP in a time-dependent manner with optimal activation at 5 minutes similar to the activation pattern of Erk1/2 described above. These data for the first time indicate activation of Ras-Erk1/2 signaling in statin-induced BMP-2 expression. We have previously shown involvement of PI 3 K and its target Akt in BMP-2 expression and osteoblast differentiation. Ly294002, an inhibitor of PI 3 K, blocked statin-induced lipid kinase activity, resulting in attenuation of Erk1/2 activity. Adenovirus-mediated expression of dominant negative Akt prevented Erk1/2 activity in response to statins. Expression of both dominant negative PI 3 K and Akt kinase prevented statin-induced BMP-2 transcription. Also, the tumor suppressor protein PTEN, which inactivates PI 3 K signaling, inhibited expression of BMP-2 in response to statins. Furthermore, dominant negative Erk2 blocked BMP-2 expression. Together, these data provide the first evidence for a novel mechanism involving a cross-talk between PI 3 K and MAPK signal relay for statin-induced BMP-2 expression necessary for osteoblast differentiation.

Haploinsufficiency of Beta-Catenin Results in Reduced Bone Mass. P. Maye*[1], A. C. Lichtler[1], B. Kream[2], D. Rowe[1]. [1]Genetics & Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Endocrinology, University of Connecticut Health Center, Farmington, CT, USA.

Biochemical studies have shown that signaling through either LRP5 or LRP6 can activate the Wnt/beta-catenin signaling pathway, suggesting a functional redundancy exists between these two co-receptors. Surprisingly, recent genetic studies have shown that both LRP5 and LRP6 are required for proper bone formation and LRP5/6 compound mutants have an even greater deficiency in bone formation. This strongly suggests that in order to maintain normal levels of bone, extremely high levels of Wnt/beta-catenin signaling are required. Therefore, we hypothesized that mice deficient for one copy of the beta-catenin gene should result in lower bone mass and might serve as a model to study the effects of reduced levels of canonical Wnt signaling on bone formation, which may be analogous to complete loss of LRP5. We report that bone from both beta-catenin germline heterozygous mice and beta catenin heterozygous mice, that were conditionally inactivated by a 3.6KB Collagen Type I promoter driving Cre recombinase, have reduced bone mass compared to their wild-type littermate controls. Additionally, bone marrow stromal cell cultures derived from beta-catenin heterozygous animals exhibit limited growth and mineralization. In addition, heterozygous stromal cell cultures can be rescued by treatment with lithium chloride, a GSK3-Beta inhibitor. Thus, mice haploinsufficient for beta catenin or tissue restricted deficient via conditional inactivation, reveal a significant bone deficiency, demonstrating that beta catenin gene dosage is crucial for normal levels of bone formation. We speculate that mice haploinsufficient for beta-catenin will be a useful animal model to study osteoporosis.

Treatment of Young Male Monkeys for 12 Months With a Highly Potent Inhibitor of Cathepsin K Inhibits Bone Resorption, and Increases Bone Mineral Density and Strength. S. Kumar[1], S. Rehm[1], R. Boyce[1], J. Birmingham[1], G. Stroup[1], C. Jerome[2], P. Weir[1]. [1]GlaxoSmithKline, King of Prussia, PA, USA, [2]SkeleTech, Bothell, WA, USA.

Cathepsin K is a cysteine protease that is highly and selectively expressed in osteoclasts, and likely plays a key role in osteoclast-mediated bone resorption. SB-462795 is a potent inhibitor of human cathepsin K, L and V (Ki = 41, 68 and 53 pM, respectively), with 39-300 fold selectivity over other cathepsins. This study evaluated the pharmacological and toxicological effects of SB-462795 in monkeys, in which the enzyme is identical to the human form. Four groups of eight, 3-5 year-old, male, cynomolgus monkeys received vehicle or SB-462795 at 3, 30, or 1000 mg/kg/day by daily gavage for 52 weeks. Bone biomarkers and bone density (BMD, by DEXA and pQCT) were measured periodically; bone biomechanical testing, bone histomorphometry, gross and histopathologic evaluations were performed terminally. The compound was well tolerated at all doses, with no evidence of significant toxicity. Systemic drug exposure was only approximately 4-fold higher at 1000 mg/kg/day than at 30 mg/kg/day. Compared with pre-treatment values, treatment at 30 or 1000 mg/kg/day had significant and comparable effects to reduce cartilage and bone resorption biomarkers. At Week 52 at 30 or 1000 mg/kg/day, respectively, urinary Type II Collagen /Creatinine (UCRT) ratios were 79% and 74% lower and N-Telopeptide /UCRT ratios were 65% and 73% lower. There was also a decrease in one bone formation marker (Bone-specific Alkaline Phosphatase, activity 35% and 43% lower, respectively, at 30 or 1000 mg/kg/day in Week 52) but not another (Osteocalcin). BMD was significantly increased in lumbar spine, femur neck, and distal radius (predominantly trabecular bone), and in mid-femur and proximal radius (predominantly cortical bone). Of special interest was that mid-femur exhibited a dose-dependent decrease in medullary cavity area, consistent with positive bone balance on endocortical surfaces, and increased total area, consistent with stimulation of bone formation on the periosteal surface. Upon biomechanical testing, maximum load was significantly increased by 42% and 49%, respectively, at 30 and 1000 mg/kg/day in lumbar vertebrae. Histomorphometric data (LV2 and mid-femur) showed significantly decreased activation on all endosteal surfaces, consistent with a reduction in bone turnover in animals treated at 30 and 1000 mg/kg/day. Overall, SB-462795 appears to increase bone strength in young male monkeys by decreasing bone turnover and improving the balance between bone resorption and formation. The drug did not exhibit any toxicity nor compromise bone quality even at the highest dose tested (1000 mg/kg/day).

Cathepsin K Knockout Mice Lose Bone Following Ovariectomy. S. J. Hoffman, P. Liang, C. A. Capriotti, J. A. Vasko-Moser, S. Kumar, G. Stroup. GlaxoSmithKline, King of Prussia, PA, USA.

Cathepsin K is a cysteine protease that plays an essential role in osteoclast-mediated degradation of the organic matrix of bone. Knockout of the enzyme in mice as well as lack of functional enzyme in the human condition, pycnodysostosis, results in osteopetrosis. In the current study, changes in bone mass were evaluated in cathepsin K knockout mice following ovariectomy (Ovx). Wild-type (WT) and cathepsin K knockout (KO) mice underwent Ovx or sham-surgery at 4 months of age and groups of animals were sacrificed at 4 and 8 weeks post-surgery. In vivo analysis by peripheral Quantitative Computed Tomography (pQCT) was performed at the proximal metaphysis of the tibia. Dynamic histomorphometry and micro-computed tomography (micro-CT) of the trabecular bone of the tibial proximal metaphysis were also performed. Histological assessment at baseline showed that KO mice had 4.6-fold greater trabecular bone volume than their WT counterparts. This finding was corroborated by pQCT evaluation which showed a 53% increase in total BMC in the KO animals. Eight weeks after Ovx, KO animals had lost 0.24 mm^2 (51%) of trabecular bone compared to 0.1 mm^2 (67%) in the WT animals. Ovx KO animals had significantly lower Tb.Th (33%) and Tb.N (22%) and higher Tb.Sp (52%) than KO sham animals. WT Ovx animals showed relatively no change in Tb.Th but a small non-significant decrease in Tb.N (39%) and an increase in Tb.Sp (15%). Analysis by pQCT showed a significant decrease in vBMD in Ovx KO and WT animals compared to sham controls. Levels of plasma osteocalcin were similar in WT and KO mice at 4 months of age and increased significantly with ovariectomy. However, plasma levels of C-telopeptide of collagen I (CTX), a resorption biomarker, were significantly higher in KO mice (33.4 ng/mL) than WT mice (7.5 ng/mL) at baseline. Following ovariectomy, CTX levels were significantly higher in KO Ovx animals relative to sham controls at weeks 4 and 8. However, there was no significant change in this marker following ovariectomy in WT animals. Collectively, the histology and BMD data show clearly that bone loss occurs in cathepsin K-deficient mice. This suggests that proteinases other than cathepsin K can compensate and play a role in estrogen-deficient bone loss in aged mice, and that cathepsin K plays more of a developmental role in bone turnover in mice. These data are contrary to the pronounced anti-resorptive effects of cathepsin K inhibitors in estrogen deficient monkeys.

Histomorphometric and Biochemical Evidence for a Cortical Bone-Forming Effect of a Cathepsin K Inhibitor in Ovariectomized Cynomolgus Monkeys. G. Stroup[1], C. Jerome[2], D. S. Yamashita[1], S. Kumar[1]. [1]GlaxoSmithKline, King of Prussia, PA, USA, [2]SkeleTech, Bothell, WA, USA.

Cathepsin K has been shown to play an important role in bone matrix degradation during osteoclastic bone resorption. We studied the effects of SB-462795, a novel, potent inhibitor of cathepsins K, L and V, on biochemical markers and histomorphometric measures of bone turnover at several sites in aged ovariectomized female monkeys following oral delivery. After collection of baseline data, adult female cynomolgus monkeys were randomized to 6 groups of 20 each, of which one was sham-ovariectomized (Sham) and the remainder ovariectomized (Ovx). Ovx animals were treated with vehicle, SB-462795 at 1, 3, or 10 mg/kg/d by gavage, or oral vehicle plus alendronate at 0.05 mg/kg by IV injection once every 2 weeks for 9 months. SB-462795 dose-dependently decreased urinary excretion of collagen-N-telopeptide. Significant reductions were observed between 1 week and 2 months at doses of 1 and 3 mg/kg/d, and for the entire duration of the study starting at week 1 at 10 mg/kg/d. Significant reduction of this biomarker by alendronate treatment was not observed until week 3 and continued to month 9. SB-462795 at 10 mg/kg/d decreased bone formation markers to a lesser extent than the bone resorption markers, and significantly increased serum osteocalcin from 3 to 9 months (1mg/kg/d) and at month 9 (3 mg/kg/d). In contrast, robust decreases in bone formation markers occurred with alendronate treatment. This suggests that SB-462795 may inhibit bone turnover while providing a more favorable balance of resorption and formation compared to a bisphosphonate. Histomorphometry data revealed a dose-dependent reduction in both bone resorption and formation parameters at cancellous sites (lumbar vertebra and femoral neck) with SB-462795 treatment and a similar reduction due to alendronate treatment. However, a stimulatory effect on femur periosteal bone was observed with SB-462795 treatment. This effect was significant ($P<0.1$) at the low dose only but was of similar magnitude at all three doses (Ps.BFR/BV increased 150%, 217% and 167% at 1, 3 and 10 mg/kg/d respectively, relative to Ovx). In contrast the impact of alendronate was an increase of only 17%. Furthermore, a significant increase in endosteal turnover, which was inversely related to dose level, was observed with SB-462795. Endosteal porosity and BFR were significantly higher at 1mg/kg/d than Ovx. At 10 mg/kg/d there was generally no difference relative to Ovx. These findings suggest that SB-462795 significantly differs from alendronate in that it may have classic anti-resorptive effects in cancellous bone, and a novel, beneficial, stimulatory effect on cortical bone.

Osteopetrosis in Oxidized LDL Receptor (SR-A) Knockout Mice. W. J. S. de Villier*[1], B. Garvy*[2], T. R. Nagy*[3], F. F. Safadi[4], H. H. Malluche[1], M. C. Faugere*[1], J. P. Williams[1]. [1]Internal Medicine, University of Kentucky, Lexington, KY, USA, [2]Microbiology and Immunology, University of Kentucky, Lexington, KY, USA, [3]Nutrition Sciences, University of Alabama at Birmingham, Birmingham, AL, USA, [4]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA.

The Class A Scavenger Receptor (SR-A), or oxidized low density lipoprotein (LDL) receptor, is predominantly expressed by macrophages and is primarily involved in uptake of oxidized LDL. SR-A is also important in macrophage attachment which is mediated via a G protein coupled mechanism. Osteoclasts are monocyte/macrophage derived and disruption of cell attachment inhibits osteoclast development, therefore we evaluated the effect of SR-A deletion on bone remodeling. All comparisons reported are for animals at 4 weeks of age. SR-AI/II was eliminated by homologous recombination on a 129SvJ background. Knockout (KO) animals are larger than wildtype (WT). WT females average 11.2 +/- 0.9 g, while the KOs weigh 20.8 +/- 0.4 g. Body composition analyses were performed with a GE-Lunar PIXImus densitometer. Total lean and fat body mass were greater in KO animals for both sexes, but there was no significant difference in the percentage of lean and fat body mass between WT and KO, indicating that the KO animals are proportionally larger. However, bone mineral density (BMD) and content (BMC) are both significantly greater in the KO compared to WT animals ($p< .0002$ and $p< .002$, respectively). MicroCT analysis (Scanco) confirmed that total volume, bone volume as well as trabecular number and thickness were all significantly greater in KO mice. Furthermore, as expected with the increased bone volume, trabecular separation was greater in WT mice. Histomorphometric analysis of cellular and dynamic parameters of bone from KO and WT mice were measured at standardized sites under the growth plate in the femoral metaphysis using the semi-automatic method (Osteoplan II, Kontron, Munich). Analysis indicates a complex phenotype with a hypertrophied growth plate and a trend toward increased adiposity in the bone marrow of KO animals ($p< .07$). Significantly, there was also an approximate 50% reduction in osteoclast number compared to the WT mice that was independent of sex. Furthermore, there were no differences in osteoblast number or surface area between male and female WT and KO animals. In vitro osteoclast differentiation experiments with marrow macrophages from WT and KOs were problematic due to poor cell attachment of the KO derived macrophages. The phenotype observed upon deletion of the macrophage oxidized LDL receptor (SR-A) suggests novel roles for this receptor protein in animal growth/development and bone remodeling.

Syk, Src and avb3 Integrin Form a Complex Which Regulates the Osteoclast Cytoskeleton. W. Zou, H. Kitaura, Y. Liu*, F. P. Ross, S. L. Teitelbaum. Department of Pathology, Washington University School of Medicine, St. Louis, MO, USA.

$\alpha_v\beta_3$ integrin engagement in the osteoclast leads to cytoskeletal reorganization and activates a signaling cascade critical for bone resorption. c-Src transduces $\alpha_v\beta_3$ signaling and is essential for actin-ring formation and bone resorption, but the potential role of another non-receptor tyrosine kinase, Syk, has not been elucidated. We find that Syk deficiency does not affect osteoclast differentiation but disrupts the cytoskeleton, as formation of actin rings and bone resorption are completely arrested when the cells are maintained on dentin. These defects are normalized by retroviral-mediated Syk expression in Syk-/- osteoclasts. We next asked if Syk modulation of the osteoclast cytoskeleton involves c-Src and/or the $\alpha_v\beta_3$ integrin. In co-immunoprecipitation experiments, Syk and c-Src associate with each other and both bind the cytoplasmic tail of the β3 integrin subunit in a matrix adhesion-dependent manner. Consistent with integrin modulation of the complex, association between Syk and c-Src in β3 integrin-/- osteoclasts is dramatically reduced as compared to wild type, although expression of these tyrosine kinases is unaltered. Further confirming the central role of the integrin, its reconstitution in β3-/- osteoclasts rescues Syk and c-Src association. Binding of c-Src to $\alpha_v\beta_3$ does not occur in Syk-/- osteoclasts but conversely, Syk continues to associate with the integrin in c-Src-/- osteoclasts. On the other hand, Src family inhibitors or the absence of c-Src in osteoclasts arrests $\alpha_v\beta_3$-induced Syk phosphorylation and c-Src/Syk association. Finally, Syk activates Vav3, an event essential for integrin-mediated organization of the osteoclast cytoskeleton. These findings establish a model in which $\alpha_v\beta_3$-mediated organization of osteoclast cytoskeleton involves recruitment of Syk to the activated integrin, leading to a tri-molecular complex involving $\alpha_v\beta_3$ and the two kinases. Activated c-Src phosphorylates Syk which, in turn, activates Vav3, the Rho-family guanine nucleotide exchange factor. Thus, Syk is critical for $\alpha_v\beta_3$ mediated signals which prompt cytoskeletal organization in the osteoclast.

Marrow Stromal Cells Modulate the Contributions of Macrophages and T-cells to TNF-alpha Induced Osteoclastogenesis *In Vivo*. H. Kitaura, S. Wei*, P. Zhou, S. Takeshita, H. Kim, D. V. Novack, F. P. Ross, S. L. Teitelbaum. Department of Pathology, Washington University School of Medicine, St. Louis, MO, USA.

Bone marrow macrophages (BMMs), stromal cells and T-cells participate in TNF-induced osteoclastogenesis and therefore, the periarticular osteolysis attending inflammatory arthritis. Hence, our purpose was to determine the in vivo contribution of each cell type, as a direct or indirect TNF target, in the osteoclastogenic process. To this end we first generated chimeric mice using wild type (WT) or TNF receptor deficient (TNFR-/-) marrow, both immunodepleted of T-cells and stromal cells. Following lethal irradiation of WT or TNFR-/- mice to eliminate native marrow while retaining native stromal cells, the animals were reciprocally transplanted with the BMM-containing samples (i.e. WT > TNFR-/-; TNFR-/- > WT). As controls, similarly-treated WT marrow was transplanted into WT mice (WT > WT) and TNFR-/- marrow into TNFR-/- mice (TNFR-/- > TNFR-/-). Each group was administered increasing doses of TNF. The number of osteoclast was increased in a dose dependent manner. The number of osteoclasts in TNFR-/- > WT is less than WT > WT chimeras confirming that TNF directly induces BMMs to undergo osteoclast differentiation. However, the reduction of osteoclast number in TNFR-/- > WT is less than in WT > TNFR-/- indicating that while both BMMs and stromal cells participate as direct cytokine targets in TNF-induced osteoclastogenesis, stromal cells are dominant. TNF increases the number of BMMs in TNFR-/- > WT and WT > WT but not WT > TNFR-/- mice. This suggests that the mechanism by which stromal cells mediate inflammatory osteoclastogenesis involves M-CSF, Confirming this hypothesis, administration of a mAb to the M-CSF receptor, c-fms, completely blocks osteoclastogenesis and bone erosion induced by TNF administration or inflammatory arthritis. Documenting that T-cells participate in TNF-simulated bone resorption, injection of the cytokine into mice immunodepleted of these lymphocytes, blunts TNF's osteoclastogenic effect ($p<.01$). On the other hand, reconstituting naïve TNFR-/- mice with purified WT T-cells does not increase osteoclast number in response to TNF. Thus while T-cells participate in TNF-induced osteoclastogenesis they are not direct targets of the cytokine. We conclude that marrow stromal cells are central to TNF-mediated osteoclast recruitment by modulating the contributions of osteoclast precursors and T-cells. Our data also establish M-CSF or its receptor as potential therapeutic targets in inflammatory osteolysis.

MCP-1 Induces Super Abundant NFATc1 Expression and Results in TRAP+ Multinuclear Cells with Calcitonin Receptor Expression, but these Fail to Resorb Bone and Are Not Osteoclasts. M. S. Kim*, C. J. Day*, C. L. Magno*, S. R. J. Stephens*, N. A. Morrison. School of Medical Science, Griffith University, Gold Coast, Australia.

Monocyte chemotactic protein 1 (MCP-1) is a CC chemokine that is induced by RANKL in human osteoclasts. MCP-1 enhances osteoclast formation in the presence of RANKL. In the absence of RANKL, treatment of human monocytes with MCP-1 and M-CSF results in TRAP+ multinucleated cells that are positive for calcitonin receptor and a number of other osteoclast markers. These cells look like osteoclasts and express a large range of osteoclast marker genes including a much greater abundance of NFATc1 compared to authentic osteoclasts induced by RANKL. The purpose of this study was to investigate the pathways of action of MCP-1 in osteoclast formation using osteoclasts derived in vitro from human peripheral blood mononuclear cells (PBMC). Human osteoclasts differentiate from PBMC in the presence of RANKL and M-CSF. Osteoclast formation mediated by RANKL was inhibited by both p38MAPK and ERK1/2 antagonists (SB203580 and U0126, respectively). PBMC treated with RANKL and SB203580 were small with a 2-3 nuclei, whereas U0126 treatment resulted in mononuclear cells. In marked contrast, MCP-1 mediated formation of TRAP+ multinucleated cells was only suppressed by the ERK1/2 antagonist (U0126), while SB203580 had no effect. In the presence of RANKL, MCP-1 rescued osteoclast formation from suppression by SB203580 (the p38MAPK antagonist), but could not rescue the effects of U0126 (the ERK1/2 antagonist). These data show that the formation of authentic osteoclasts requires both the p38MAPK and ERK1/2 pathways, and that blockade of p38MAPK can be circumvented by MCP-1. Furthermore, the formation of TRAP+ multinuclear cells induced by MCP-1 requires only the ERK1/2 pathway. Excess NFATc1 (noted in MCP-1 treated cells), is not sufficient for the formation of bone resorbing osteoclasts, although it is associated with cells that have the appearance of osteoclasts and express many genes in common. Despite high NFATc1 mRNA and nuclear NFATc1, the MCP-1 induced TRAP+ multinucleated cells are negative for bone resorption and cannot be called osteoclasts. Therefore, high NFATc1 expression does not automatically make an osteoclast, but is associated with multinucleation and TRAP positive status but not bone resorption. We propose that the MCP-1 induced TRAP+ multinuclear cells represent an ERK1/2 dependent stage in osteoclast differentiation, after NFATc1 induction and cellular fusion, but prior to the development of bone resorption activity.

Interleukin (IL)-12 Mediates the Anti-Osteoclastogenic Effect of CpG-oligodexynucleotides. A. Amcheslavsky*, Z. Bar-Shavit. Experimental Medicine and Cancer Research, Hebrew University Faculty of Medicine, Jerusalem, Israel.

Bacterial DNA activates the innate immune system via interactions with Toll-like receptor 9 (TLR9). This receptor recognizes CpG-oligodeoxynucleotides (CpG-ODNs) mimicking the CpG dinucleotides in certain sequence contexts characterizing bacterial DNA. Pathogen-derived molecules which activate different TLRs on bone cells are considered responsible for bacteria-induced pathological bone loss. Most studies show increased osteoclast differentiation by TLR ligands. In recent years, however, it was found that activation of TLRs in early osteoclast precursors (OCPs) results in inhibition of RANKL-induced osteoclast differentiation. The objective of the present study is to identify the mechanism leading to this inhibitory effect of a TLR ligand. Since both RANKL-RANK and CpG-ODN-TLR9 interactions result in the synthesis of the pro-osteoclastogenic cytokine TNF-α, we hypothesized that CpG-ODN (but not RANKL) in addition induces the synthesis of an anti-osteoclastogenic factor. Control OCPs and cells treated with RANKL, CpG-ODN or their combination were studied using DNA arrays (GEArray Q Series Mouse NF-κB Signaling Pathway Gene Array, MM-016, SuperArray). We found marked increase in the established osteoclastogenesis inhibitor IL-12 mRNA levels in OCPs treated with CpG-ODN and CpG-ODN+RANKL, but not in OCPs treated with RANKL alone. Detailed northern and western analyses confirmed that addition of CpG-ODN to OCPs induces an increase in IL-12 mRNA and protein levels. No such effect was observed with RANKL. Moreover, using ELISA we showed that IL-12 is released from OCPs in response to CpG-ODN (but not in response to RANKL). In correlation with these findings, IL-12 inhibited RANKL-induced osteoclast differentiation and specific anti-IL-12-antibodies inhibited the anti-osteoclastogenic effect of CpG-ODN. In conclusion, activation of TLR9 by its ligand, CpG-ODN, results in synthesis and release of IL-12 opposing RANKL-induced osteoclast differentiation.

Placental Growth Factor Is a Positive Regulator of Bone Remodeling. L. Coenegrachts*[1], S. Torrekens*[1], R. Van Looveren*[1], P. Carmeliet*[2], R. Bouillon[1], G. Carmeliet[1]. [1]Laboratory of Experimental Medicine and Endocrinology, KULeuven, Leuven, Belgium, [2]The Center for Transgene Technology and Gene Therapy, Flanders Interuniversity Institute for Biotechnology, K.U.Leuven, Leuven, Belgium.

Vascular endothelial growth factor (VEGF) is critical for bone development and fracture repair. Placental growth factor (PlGF), a VEGF homologue, was shown to be involved in bone loss associated with arthritis, suggesting a role in pathological bone

metabolism. Therefore, we investigated the role of PlGF in different models of remodeling comparing wild type (WT) and PlGF deficient (PlGF$^{-/-}$) mice. PlGF$^{-/-}$ mice are viable, fertile and do not display any developmental abnormalities. However, with older age, bone turnover is decreased compared to WT mice, as evidenced by a significant decrease of the mineral apposition rate (MAR; -49%) and bone formation rate (BFR; -62%) in 20-week old mice, without manifest effect on bone mass. This is reflected by reduced serum osteocalcin levels (-40%) and urinary excretion of collagen cross-links (-15%). In addition, differentiation of osteoclasts and formation of osteoblast colony-forming units in vitro was significantly decreased in PlGF$^{-/-}$ cultures. Secondly, four weeks of skeletal unloading by tail suspension -a model of low turnover rate- induced severe bone loss (-51% of trabecular bone volume (TBV); $p<0.05$) in 16-week old WT mice with manifest decrease in MAR (-56%) and BFR (-65%) ($p<0.01$). In contrast, PlGF$^{-/-}$ mice showed a non-significant loss in TBV (-25%) without any changes in MAR and BFR. Thirdly, in the model of glucocorticoid induced osteoporosis, administration of prednisolone (2.1 mg/kg/d) during four weeks to 16-week old WT mice decreased TBV by 41% and trabecular density by 35% (pQCT analysis) ($p<0.05$). In PlGF$^{-/-}$ mice only a 25% decrease of TBV and a 21% decrease in trabecular density was found. Furthermore, pregnancy followed by a lactation period of three weeks decreased trabecular density more in WT mice (-68%; $p<0.001$) than in PlGF$^{-/-}$ mice (-47%; $p<0.01$). In addition, cortical thickness decreased only in WT mice (-10%; $p<0.01$), suggesting cortical resorption in WT but not in PlGF$^{-/-}$ mice. Finally, when a high turnover rate was induced by ovariectomy, 10-week old WT and PlGF$^{-/-}$ mice showed a similar decrease in trabecular density after two and four weeks. In conclusion, deficiency of PlGF results in low bone turnover due to decreased osteoclast formation and differentiation of osteoprogenitors. Consequently, decreased bone loss is observed in PlGF deficient mice in osteoporosis models with a low turnover rate.

DC-STAMP Is Essential for Cell-Cell Fusion of Macrophage Lineage Cells and Is Regulated by Ap-1 and NFAT. M. Yagi*[1], T. Miyamoto[1], N. Hosogane*[1], N. Fujita*[1], K. Morita*[1], K. Ninomiya*[1], T. Suzuki*[1], K. Matsuo[2], Y. Toyama*[1], T. Suda*[3]. [1]Orthopaedics, Keio University School of Medicine, Tokyo, Japan, [2]Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan, [3]Cell Differentiation, Keio University School of Medicine, Tokyo, Japan.

DC-STAMP (Dendritic Cell Specific Transmembrane Protein) is a seven transmembrane protein, which is highly expressed in osteoclasts in the presence of M-CSF and RANKL. As we described last ASBMR meeting, multinucleated osteoclasts do not formed in DC-STAMP deficient mice, indicating that DC-STAMP is essential for osteoclast fusion. Here, we analyzed the function of DC-STAMP in macrophage fusion and how DC-STAMP is transcriptionally regulated in the macrophage and osteoclast lineages. Foreign body giant cells (FBGCs) are known to form via fusion of mononuclear precursors. In DC-SATMP deficient mice, formation of FBGCs in response to implants was abrogated. Furthermore, FBGC formation by macrophages was abrogated in cells derived from DC-STAMP deficient mice under all culture conditions tested, namely in the presence of IL-3 plus IL-4, GM-CSF plus IL-4, as well as GM-CSF plus RANKL. Therefore, DC-STAMP is essential for macrophage fusion as well. In order to analyze the regulation of DC-STAMP gene expression by transcriptional factors, we cloned 4-kb and 0.2-kb fragments of the 5'flanking region of DC-STAMP. RANKL, IL-3 plus IL-4 activated both of the DC-STAMP reporter constructs 10-fold higher than promoter-less control. Thus, the 0.2-kb promoter is sufficient for inducing DC-STAMP expression. The 0.2-kb promoter region of the mouse DC-STAMP gene contains two potential AP-1 sites and three putative NFAT binding sites. The promoter was activated by RANKL, IL-3 plus IL-4, or overexpression of c-Fos or NFAT. Consistently the construct containing mutated AP-1 or NFAT consensus binding sites were not activated in osteoclastogenesis and FBGC formation. Moreover, DC-STAMP was not induced in cells derived from c-Fos deficient mice even in the presence of M-CSF and RANKL. However, in contrast to the complete inhibition of osteoclastogenesis, FBGCs were formed in cells derived from c-Fos deficient mice. Thus, while c-Fos and NFAT are essential transcriptional factors for DC-STAMP expression during osteoclast formation, these transcriptional factors are not essential for FBGC formation, suggesting that other AP-1 family members might substitute for c-Fos in macrophages. These data demonstrate that DC-STAMP is essential for cell-cell fusion not only in osteoclastogenesis, but also in macrophage fusion. However, macrophage fusion appears less dependent on c-Fos and NFATc1 than osteoclast fusion.

Highly Potent Analogs of 1α,25-Dihydroxy Vitamin D_3 Induce Osteoclastogenesis and Hypercalcemia in Osteopetrotic op/op Mice, but not in Oosteoclast-Absent c-fos Deficient Mice. M. Sato*[1], Y. Nakamichi[2], N. Sato*[3], M. Nakamura[4], T. Ninomiya*[2], H. Nakamura[5], M. Shimizu*[6], H. Ozawa*[2], N. Takahashi[2], N. Udagawa[4]. [1]Graduate School of Oral Medicine, Matsumoto Dental Univ., Shiojiri, Japan, [2]Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, [3]Department of Periodontology, Aichi Gakuin Univ., Nagoya, Japan, [4]Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan, [5]Department of Oral Histology, Matsumoto Dental Univ., Shiojiri, Japan, [6]Laboratory of Medical Chemistry, Tokyo Medical and Dental Univ., Tokyo, Japan.

2-methylene-19-nor-(20S)-1α,25-dihydroxyvitamin D_3 (2MD), an analog of 1α,25-dihydroxyvitamin D_3 ($1,25D_3$), has been shown to strongly induce bone formation both *in vitro* and *in vivo*. We have synthesized five new substituents at C-2 position of 2MD (2MD analogs) and five new 22-oxa compounds of these 2MD analogs (2MD 22-oxa analogs), and examined their activities in stimulation of osteoclastogenesis and induction of hypercalcemia. 2MD analogs were 100 times as potent as those of $1,25D_3$ in stimulation of osteoclast formation *in vitro* and in induction of receptor acvtivator of NF kB ligand (RANKL), 25-hydroxyvitamin D_3-24 hydroxylase and osteopontin mRNA expression in osteoblasts in culture. The osteoclast inducing activities of 2MD 22-oxa analogs were much lower than those of 2MD analogs. Osteoprotegerin knockout (OPG$^{-/-}$) mice exhibited extremely high concentrations of serum RANKL. To evaluate the effects of 2MD analogs on serum RANKL levels, the same amounts of 2MD analogs and $1,25D_3$ were daily administered into OPG$^{-/-}$ mice for 2 days. Elevation of serum concentrations of RANKL and calcium was much greater in 2MD analog-treated mice than in $1,25D_3$-treated mice. RANKL mRNA expression was increased in bone but not in thymus or spleen in both 2MD analog-treated and $1,25D_3$-treated mice. Surprisingly, when 2 MD analogs were administered into macrophage colony-stimulating factor (M-CSF) deficient op/op mice, many osteoclasts appeared in bone tissues and hypercalcemia was induced in the mice with 2 days. In contrast, administration of 2MD analogs into c-fos deficient mice failed to induce osteoclastogenesis and hypercalcemia. These results suggest (1) that osteoclastic bone resorption is indispensable for hypercalcemic action of vitamin D_3, and (2) that 2MD analogs induce osteoclastogenesis even in the absence of M-CSF in vivo.

Genetic Variability in Osteoclast Activity and 3-Dimensional Spatial Distribution Within 14 Day Post Birth Femurs. S. Stapleton[1], D. Malouf*[1], D. Hindson*[1], K. J. Jepsen[2], C. Price[2], L. C. Gerstenfeld[1]. [1]Orthopaedic Surgery, Boston University School of Medicine, Boston, MA, USA, [2]Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Numerous studies have shown that variation in bone morphology in different inbred strains of mice is genetically determined. The genetic variation is reflected in different rates of formation and resorption on endosteal vs. periosteal surfaces; the relative amount and location of cellular activities thus determining the relationship between bone size and the mechanical demands imposed by weight bearing during growth. A quantitative measure of osteoclast numbers and their 3-dimensional spatial distribution were assessed in A/J, C57BL/6J (B6), and C3H/HeJ (C3H) strains of mice. Transverse serial sections were taken at 100 micron increments along the length of femurs from 14 day mice and stained for osteoclast activity. Serial sections were arranged in stacks and the 3-D spatial distribution of osteoclasts within the femurs was reconstructed (AJ and C3H are presented). Renderings of the bone in differing longitudinal planes, or for TRAP activity alone, were examined. Moving distally along the femur revealed an approximate 50/50 distribution of TRAP staining on both endosteal and periosteal surfaces within AJ and B6 femurs, but no discernable pattern for C3H. The AJ strain, which has the smallest bone mass, had the highest level of TRAP activity with the majority of the enzyme activity seen either on the periosteal or opposing endosteal surfaces (compare the distribution of the pattern of dark grey coloring that denotes areas of TRAP activity). For the B6 strain, which had the next highest level, a pattern similar to AJ resulted, but with less staining visualized on the bone surfaces. Interestingly, this strain has the thinnest cortices and largest meduallary space. TRAP staining in the C3H animals was almost unobservable when viewed in the reconstructions and this strain has both the thickest cortices and highest bone mass. These data demonstrate profound differences, in both the quantity and spatial characteristics of osteoclastic activities, in different strains of inbred mice. This suggested that both these features of cellular activity are relatable to spatial geometry and overall mass of a bone and are genetically regulated.

NF-κB p65 Subunit Is Critical for the Osteoclastogenic Effect of RANKL. C. Menaa, A. Abdouelaziz*, J. Lebovitz*, C. Froelich*, S. Sprague. Medicine, Evanston Northwestern Healthcare, Evanston, IL, USA.

NF-κB is a key transcription factor in osteoclast (OC) biology and mediates the effect and the expression of major osteoclastogenic factors such as RANKL, IL-1, and TNF-α However, the critical subunits involved in differentiation are not yet well defined. In mammals, NF-κB exists as homodimers and heterodimers composed of combinations of different subunits, NF-κB1 (p50/p105), NF-κB2 (p52/p100), p65, cRel, and RelB. The role of p50 and p52 in OC formation has been demonstrated *in vivo*. However, since these subunits are deficient in transcription activity, p65 or other subunits (RelB, c-Rel) should provide such a function and therefore, the p50 or p52 are necessary to form the complex resulting in nuclear DNA binding capacity. Last year, we presented studies which demonstrated that IκB mutant, that prevents nuclear translocation of p65 subunits, blocks OC formation. Therefore, the role of p65 in mediating the effect of RANKL in OC differentiation was now examined. Since p65 deletion gene is embryonic lethal, we developed OC precursors (RAW 264.7 cells) expressing a dominant negative c-terminal truncation of p65 (p65RHD) where amino acids (332-550) have been deleted. This mutant lacks the transactivation domain but retains the capacity of dimerization with other subunits and DNA binding as shown by gel shift assay and reporter gene using luciferase in response to RANKL and TNF-α. Furthermore, OC precursor stable cell line over-expressing the p65RHD is resistant to the development of mature OCs following RANKL stimulation compared to WT cells. Moreover, the addition of TAT-p65RHD to bone marrow cells stimulated with RANKL and M-CSF blocks OC formation in a dose dependent manner. This effect was not due to a blockade at the fusion step of OC precursors but rather to a deviation into OC differentiation as assessed by analyzing the expression of the OC markers, calcitonin receptor and β-integrin. Further analysis also demonstrated that the absence of p65 activity does not alter the OC precursor proliferation, RANK receptor expression or the capacity to respond to RANKL as measured by IκB degradation. In summary, these data demonstrate, for the first time, that p65 subunit is essential for OC differentiation. Thus, NF-κB activity requires either p65/p50 or p65/p52 as complex for successful osteoclastogenesis in response to RANKL. In conclusion, these results highlight the importance role of p65 as a key factor in NF-κB activity during bone resorption.

Col3.6 Promoter Drives the Expression of GFP in the Osteoclastic Lineage. I. Boban*[1], K. Prior*[2], C. Jacquin*[2], T. Barisic-Dujmovic*[1], S. H. Clark[1], H. L. Aguila[2]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Center for Immunotherapy, University of Connecticut Health Center, Farmington, CT, USA.

The type I collagen promoter has been used to develop transgene constructs that are useful to mark different stages of osteoblastic differentiation. The Col3.6 promoter has been shown to be active in preosteoblasts and osteoblasts. However, it is not specific for bone and can drive expression in other collagen producing cells. In contrast, expression from the Col2.3 promoter is restricted to osteoblasts and osteocytes. To evaluate the existence of circulating skeletal progenitor cells, a parabiosis model was developed in which Col3.6GFP transgenic mice were surgically joined with mice bearing a Col2.3 ΔTK transgene. After common circulation was established, parabiotic pairs were treated with ganciclovir (GCV). In single Col2.3 ΔTK mice this treatment induces ablation of osteoblasts and destruction of bone marrow (BM). However, in the Col2.3 ΔTK parabiont BM destruction was not observed suggesting a transfer of cells between parabionts. To evaluate the engraftment, stromal cell cultures were initiated with BM isolated from both parabionts. Cultures from Col2.3ΔTK parabionts did not display mineralized colonies co-expressing GFP suggesting that in this model, osteoblast progenitor cells did not circulate and engraft in the Col2.3 ΔTK parabiont. In contrast, scattered GFP positive clusters were observed that included large cells with morphology similar to osteoclast like cells (OCL). These OCL were also TRAP positive. As osteoclasts are of hematopoietic origin, purified hematopoietic stem cells were isolated from Col 3.6GFP mice. These purified cells (Lineage$^-$ Sca-1$^+$ c-kit$^+$) were transplanted into GCV treated Col2.3ΔTK mice. Thirty days after transplantation, bone histology from these mice showed GFP positive cells around trabecular bone and on the endosteum and periosteum surfaces. Cultures of BM cells under osteoclast differentiation conditions showed OCL expressing GFP. To exclude the possibility that OCL were generated by fusion between GFP cells in the donor with osteoclast progenitors from the host, osteoclast progenitor cells [(B220, CD3, Mac-1)$^-$ c-fms$^+$] were purified from Col3.6GFP, Col2.3GFP and C57BL/6 mice and cultured under osteoclast differentiation conditions. OCL were generated in all the cultures, but only the OCL from Col3.6GFP mice were positive for GFP. Further RT-PCR showed that OCL did not express collagen, indicating that the Col3.6 promoter contains elements that are active during osteoclastogenesis. Thus caution should be used when utilizing this promoter in the study of mesenchymal progenitor cells.

Rac-2 Knockout Mice Have Increased Bone Mass and Osteoclasts with Reduced Resorptive Activity. T. Itokawa*, M. Zhu*, N. Troiano*, K. Insogna. Internal Medicine /Endocrinology, Yale University School of Medicine, New Haven, CT, USA.

Work from several laboratories has underscored the importance of the Rho family of small GTPases in regulating osteoclast motility and resorption. Recent work in macrophages has suggested a role for Rac-2 in targeting activated ß-3 integrins in macrophages. To explore the potential role of Rac-2 in osteoclast biology we examined the bone phenotype of Rac-2 knockout mice. These mice, were of normal size and had normal tooth structure. However histomorphometric analysis (Table) demonstrated increased bone mass with normal to high-normal numbers of osteoclasts. Osteoblast number and function was normal. Increased bone density in the setting of high-normal osteoclast number and normal osteoblast function suggests defective osteoclast resorptive capacity as the basis for this skeletal abnormality. We examined the phenotypic appearance of isolated mature osteoclasts from Rac-2 wild-type mice and were unable to detect any differences in actin cytoskeletal architecture. Survival of mature osteoclasts prepared from wild-type and Rac-2 k/o mice was no different when cells were cultured in alpha MEM supplemented with10% FCS. To quantify resorptive activity, mature osteoclasts were prepared by co-culturing osteoblasts and bone marrow from Rac-2 k/o mice on collagen gels and replating mature osteoclasts onto Osteologic® discs. Resorptive surface was quantified using Image J software. Basal resorptive activity was significantly attenuated in cells prepared from Rac-2 knockout mice. Specifically, the resorptive activity of Rac-2 k/o osteoclasts was reduced by 59% when compared to the resorptive activity of wild-type osteoclasts. We conclude that osteoclast function is defective in Rac-2 knockout mice resulting in an increased bone mass in these animals. Defective integrin targeting may be one mechanism for reduced resorptive activity of these cells.

F275

Cloning and Characterization of the Annexin II Receptor. G. Lu[1], H. Maeda*[2], S. V. Reddy[3], N. Kurihara[1], G. D. Roodman[4]. [1]Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, [2]Oral Rehabilitation, Kyushu University Hospital, Kyushu, Japan, [3]Dept. of Pediatrics, Medical University of South Carolina, Charleston, SC, USA, [4]Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Annexin II (AX2) is a heterotetramer, consisting of two p11 and two p36 kDa subunits that is produced by osteoclasts (OCL) and increases OCL formation. AX2 indirectly stimulates OCL formation by inducing production of granulocyte-macrophage colony-stimulating factor (GM-CSF) and RANK ligand (RANKL). We have shown that biotinylated AX2 binds to normal primary human marrow stromal cells and the Paget's marrow-derived PSV10 stromal cell line. ^{125}I-labeled AX2 binding assays with PSV10 cells demonstrated that there was a single class of receptors with a K_d of 5.79 nM and B_{max} and 2.13 x 10^5 receptors per cell. AX3 or AX5 did not bind the receptor. We then screened a human marrow cDNA expression library for a putative AX2 receptor since no annexin receptor had been previously identified. We identified a cDNA clone that encoded a 26-kDa protein that when expressed in HEK 293 cells, bound the p11 subunit to the cell surface. Further, chemical cross-linking (DTME) of biotinylated AX2 with intact PSV10 cells identified a 50 kDa band on Western blot analysis that reacted with both an anti-p11 antibody and streptavidin, but not an anti-p36 antibody. Western blot analysis of lysates from PSV 10 cells that had bound AX2 and been immunoprecipitated with an anti-p11 antibody detected a 26-kDa (without DTME) or a 50-kDa (with DTME) band respectively. When the putative AX2 receptor was over-expressed in HEK 293 cells and cell lysates immunoprecipitated with an anti-p11 antibody, similar results were observed. In addition, a rabbit polyclonal antibody raised against the putative AX2 receptor also recognized the 26-kDa protein band detected in PSV10 cells, as well as in HEK 293 cells transiently expressing the AX2 receptor cDNA clone. Further, treatment of human primary marrow stromal cells and marrow-derived PSV10 cells with the AX2 receptor antibody in the absence of AX2 modestly increased expression of GM-CSF and RANKL mRNA by RT-PCR in a dose-dependent manner. Importantly, the AX2 receptor antibody blocked the stimulatory effects of AX2 but not 1,25-$(OH)_2D_3$ on the OCL formation in human marrow culture in a dose-dependent manner. Thus we have identified the first surface receptor for an annexin and showed that it mediates the effects of AX2 on OCL formation. Identification of the AX2 receptor should permit further characterization of the role AX2 plays in normal and pathologic OCL formation and to identify small molecules that induce or block signaling by this receptor.

Delineation of TRAF2, 5, and 6 in RANKL Signaling and Osteoclastogenesis by the Use of Decoy Peptides. A. T. Poblenz*[1], S. Singh*[2], B. G. Darnay*[1]. [1]Experimental Therapeutics, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA, [2]Imgenex Corporation, San Diego, CA, USA.

Osteoclastogenesis plays a central role in the development and maintenance of normal bone tissue, which requires osteoblastic matrix deposition and osteoclastic resorption to be closely coordinated. Interference with the process of osteoclastogenesis alters the kinetics of bone remodeling resulting in abnormal bone development. The osteoclast is the pivotal cell in the degradation of the bone matrix and stimulation of osteoclastic bone resorption is associated with a wide variety of human diseases. RANK and its ligand (RANKL) are essential mediators of osteoclastogenesis. RANK signals through TRAF molecules and activates the NF-kB and MAP kinase pathways. We have previously identified a unique TRAF6-binding motif in RANK, which is distinct from other TRAFs. Furthermore, a peptide from RANK (residues 342-349) has been co-crystallized with the TRAF-C domain of TRAF6 and its structure indicates distinct molecular interactions. As TRAF6 is a critical adaptor molecule in RANK signal transduction, we previously developed cell-permeable TRAF6 decoy peptides (T6DP), which specifically target the interaction of TRAF6 with RANK and demonstrated that T6DPs inhibit RANKL-mediated signaling and osteoclast differentiation of RAW264.7 cells and primary mouse bone marrow derived monocytes (BMM). We earlier utilized a long leader peptide for the internalization of T6DP, since then we have employed the use of a palmitic acid linkage at the N-terminus of the peptides to allow for internalization. Through N- and C-terminal deletions, we have defined the sequence RKIPTEDEY as a minimal scaffold for TRAF6 binding and inhibition of RANKL-mediated osteoclastogenesis. Furthermore, T6DPs effectively blocked activation of NF-κB and JNK by RANKL. Additionally, we also demonstrated that TRAF6 is required in the first 24 hours of RANKL treatment for proper osteoclastogenesis. In an effort to identify the role of TRAF2 and TRAF5 in osteoclastogenesis, we utilized the same strategy as above and generated TRAF2/5 decoy peptides. Preliminary results indicate that blocking the interaction of TRAF2/5 with RANK had no effect on RANKL-mediated osteoclastogenesis. Thus, disruption of at least the TRAF6-RANK interaction may prove useful as a novel target for the development of therapeutic agents for osteolytic diseases.

Cbl Downregulates Osteoclast Activity through Tyrosine Kinase-Binding Domain-Dependent Interactions. C. Itzstein[1], A. Sanjay[2], L. Neff*[1], W. Horne[1], R. Baron[1]. [1]Yale University, New Haven, CT, USA, [2]Temple University, Philadelphia, PA, USA.

Cbl is a major target of Src kinase in osteoclasts (OCs). $Cbl^{-/-}$ OCs exhibit reduced *in vitro* and *in vivo* motility, and Cbl forms a tri-molecular complex with Pyk2 and Src downstream of integrins that is necessary for normal OC activity. Structurally, the N-terminal half of Cbl includes a phosphotyrosine-binding domain (designated TKB) and a RING domain required for the ubiquitin ligase activity of Cbl, while the C-terminal half contains several proline-rich motifs and regulatory tyrosines that interact with SH3 and SH2 protein-binding domains, respectively. Cbl downregulates non-receptor and receptor tyrosine kinases (N/RTKs), including Src and the EGF receptor (EGFR), interacting with them via its TKB domain and/or motifs in the C-terminal half. The contributions of these two interactions were analyzed by examining the effects of disabling or deleting Cbl binding domains on the association of Cbl with Src and the EGFR and also on *in vitro* bone resorption. HEK293 cells were co-transfected with constitutively active Src and myc-tagged 1/ wild-type (WT) Cbl, 2/ full-length Cbl with a disabled TKB domain (CblG306E), 3/ v-Cbl, which consists of only the TKB domain, 4/ v-CblG306E, 5/ 70Z-Cbl, which lacks ubiquitin ligase activity due to a deletion in the linker and RING domain, or 6/ the C-terminal half of Cbl (Cbl-CT), which lacks the TKB and RING domains. WT Cbl, v-Cbl, 70Z-Cbl and Cbl-CT all bound active Src, showing that both the TKB domain and C-terminal half motifs of Cbl independently mediate the Cbl-Src interaction. Despite the TKB-null mutation, CblG306E also bound Src, confirming that the Cbl-CT motifs are sufficient for binding. In contrast, v-CblG306E failed to bind Src, showing that phosphotyrosine-binding activity is required for the TKB domain-Src interaction. Similar results were obtained for Cbl binding to activated EGFR, confirming that N/RTKs interact with both regions of Cbl. To compare the roles of Cbl's binding domains in OC activity, the Cbl constructs were expressed in murine OCLs using the adenovirus system, and their effects on *in vitro* bone resorption was analyzed. WT Cbl, CblG306E, v-CblG306E and Cbl-CT had no effect on pit formation. In contrast, v-Cbl and 70Z-Cbl increased pit formation by 110% ($p<0.05$) and by 35% ($p<0.05$), respectively. Interestingly, v-Cbl, 70Z-Cbl and Cbl-CT all lack a functional RING domain, while only v-Cbl and 70Z-Cbl, which have functional TKB domains, stimulated bone resorption. Thus, the TKB-dependent targeting of the RING domain-dependent ubiquitin ligase activity of Cbl appears to be essential for a negative-feedback mechanism that decreases OC activity through down regulation of tyrosine kinases.

NEMO Integrates Cytokine-Induced Osteoclastogenesis. Y. Abu-Amer, S. Dai*. Orthopaedics and Cell Biology & Physiology, Washington University School of Medicine, Saint Louis, MO, USA.

The transcription factor NF-κB is considered central component mediating osteoclastogenesis and inflammatory responses that lead to bone erosion transmitted by RANKL and inflammatory cytokines, respectively. This notion is supported by the requirement of p50/p52 NF-κB subunits for osteoclast formation. Initial RANKL binding to its cognate receptor triggers ample signaling events, notably recruitment of the adaptor protein TRAF6 and several tyrosine and serine/threonine kinase to RANK cytoplasmic domain. These steps are followed by series of constructive ubiquitination events culminating with poly-ubiquitination of IκB Kinase-γ (also known as NEMO). NEMO is assumed to undergo polymerization and acts as a scaffold platform to recruit dimers of IKKα and IKKβ to the kinase complex. This conformational proximity permits IKK cross-autophosphorylation leading to activation of the kinase complex, phosphorylation of the NF-κB-inhibitory protein and activation of this transcription factor. We hypothesized that attenuation of NEMO oligomerization following cytokine stimulation of osteoclast precursors may disrupt formation of the IKK complex and thus inhibit basal (RANKL) and TNF-induced osteoclastogenesis. This hypothesis is supported by previous findings indicating that small decoy peptides targeting domain interaction between NEMO and IKKα/β successfully block osteoclastogenesis in vitro and focal bone erosion in vivo. In this study we utilized peptide sequences derived from the NEMO coiled-coil (CC2) and leucine zipper (LZ) domains, documented as the sequences required for NEMO oligomerization. These peptides were fused to PTD of HIV1-tat domain to enable cellular transduction. Using co-immunoprecipitation studies, we show that PTD-CC2 and PTD-LZ bind to NEMO. This interaction appears to destabilize NEMO as it degrades rapidly within one hour. Furthermore, we show that these NEMO-derived peptides attenuate activation of IKKβ in a manner similar to that accomplished with NEMO-binding peptide. Most importantly, we provide evidence that PTD-CC2 and PTD-LZ are potent inhibitors of RANKL and TNF-induced osteoclastogenesis. In summary, it appears that NEMO-derived peptides designed to interfere with NEMO oligomerization, destabilize NEMO expression, attenuate cytokine-induced IKKβ activation, and arrest osteoclastogenesis. Thus, NEMO-derived CC2 and LZ peptides provide a promising tool to inhibit osteoclastogenesis.

Cx43-/floxOCN^{Cre} Mice Lacking Cx43 in Osteoblasts and Osteocytes Exhibit Normal Bone Accrual and Adult Peak Bone Mass. L. Plotkin, J. Aguirre, K. Vyas*, S. Stewart*, R. Weinstein, S. Manolagas, T. Bellido. Endocrinology, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Connexin (Cx) 43 is the major gap junction protein expressed in osteoblasts and osteocytes. Reduced Cx43 function in osteoblastic cells *in vitro* or its deletion in mice results in osteoblast dysfunction and delayed ossification. Furthermore, Cx43 expression and channels or hemichannels formed by Cx43 are required for at least some of the effects of bisphosphonates, PTH and mechanical stimulation on osteoblasts and osteocytes. Cx43 deletion in mice results in perinatal lethality precluding their study beyond birth. To determine the relevance of Cx43 function in osteoblastic cells in the adult skeleton, we generated mice deficient in Cx43 specifically in osteoblasts and osteocytes using the Cre/LoxP technology. Mice heterozygous for Cx43 (Cx43+/-) were mated with mice expressing Cre recombinase driven by the human osteocalcin promoter (OCN^{Cre}). The resulting Cx43+/-;OCN^{Cre} were bred with mice expressing "floxed" Cx43 (fl). Calvaria cells derived from Cx43-/fl^{Cre} and Cx43-/fl expressed about 50% less Cx43 mRNA than Cx43+/fl^{Cre} or Cx43+/fl cells. In addition, 21 days of culture under differentiating conditions reduced Cx43 expression in Cx43-/fl^{Cre} calvaria cells to 20% of that of Cx43-/fl, whereas osteocalcin mRNA increased by 1,000 fold in both cell types. These results confirm the deletion of Cx43 by the Cre recombinase only in osteocalcin expressing cells. No differences were found in the weight of the animals or in the bone phenotype. Thus, global, spinal and hindlimb BMD measured by DEXA were similar in all four genotypes. This contrasts with previous evidence showing that Cx43-/fl^{Cre} mice in which Cre was driven by the murine osteocalcin promoter have lower global BMD compared to Cx43-/fl mice. In addition, we found no differences in vertebral bone geometry among animals of all genotypes. However, the femurs of Cx43-/fl^{Cre} mice had higher bone and bone marrow diameters at the midshaft and increased moment of inertia, but the cortical area was not different from Cx43-/fl mice. Thus, deletion of Cx43 in cells of the osteoblastic lineage does not affect bone accrual, suggesting that activation of Cx43 by endogenous ligands is not required to reach adult peak bone mass. However, these results do not exclude the possibility that Cx43 could be required for the maintenance of bone mass and strength under certain challenges, such as lack of mechanical stimulation or bisphosphonate administration.

Transgenic Expression of the Diphtheria Toxin Receptor, Otherwise Known as Heparin-Binding EGF-Like Growth Factor, in Osteoblasts and Osteocytes Reduces Bone Mass and Strength. C. A. O'Brien, Q. Fu, L. I. Plotkin, T. Bellido, J. J. Goellner*, R. L. Jilka, R. S. Weinstein, S. C. Manolagas. Endo/Metab, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas for Med. Sciences, Little Rock, AR, USA.

The goal of these studies was to determine the role of apoptosis of mature osteoblasts and osteocytes in the control of bone mass and strength. To accomplish this, we sought to create a transgenic mouse in which these non-dividing cells can be specifically and conditionally ablated in vivo by administration of diphtheria toxin (DT). Wildtype mice are resistant to DT since the murine homologue of the primate diphtheria toxin receptor (DTR), also known as heparin-binding EGF-like growth factor (HB-EGF), does not effectively bind DT. Transgenic mice were created with a construct consisting of the monkey DTR inserted downstream from the human osteocalcin promoter (OCN). Nine transgenic founders were obtained and 7 of these were smaller than wildtype littermates and displayed abnormal or waddling gait. Three of these mice died after weaning. Three of the remaining mice were not fertile and had low BMD and shortened limbs. Two of the remaining lines were fertile and indistinguishable from wildtype littermates. Adherent bone marrow cells from these 2 lines were not sensitive to DT in vitro indicating that DTR expression in these mice was extremely low. The remaining affected founder was fertile and transgene mRNA was highly expressed and detected only in bone. Limbs in these mice were shorter than wildtype littermates and spinal and hindlimb BMD were reduced. Consistent with the low BMD, vertebral compression strength was reduced in transgenic mice compared to wildtype littermates. DT eliminated transgene mRNA expression in primary bone marrow cells from these mice indicating that DTR levels were sufficient to confer DT-induced cell death in this line of mice. Overexpression of the monkey DTR in the osteocyte cell line MLO-Y4 conferred sensitivity to DT, but also elevated apoptosis even in the absence of DT. The latter result suggests the possibility that the bone phenotype of the OCN-DTR mice involves an increase in apoptosis of osteoblasts and/or osteocytes. The presence of a bone phenotype in OCN-DTR mice in the absence of DT indicates that this approach is not suitable for studies requiring conditional ablation of mature osteoblasts and osteocytes. Use of inducible caspase 3 activation rather than DTR to induce cell death may circumvent the problems associated with OCN promoter-driven DTR expression. Nonetheless, these results demonstrate that HB-EGF is a negative regulator of bone mass and strength possibly via control of osteoblast and/or osteocyte survival.

Fracture Risk Assessment, Is T-Score Misleading? A. Hoiseth. Sentrum Røntgeninstitutt, Oslo, Norway.

T-scores give discordance in patient classification. Given a linear rate of bone loss and normally distributed parameters at all age groups, the proportion of cases below a given T-score is given by the ratio "rate of loss"/"range of dispersion at baseline". This ratio for total spine BMD is, compared to the same ratio for total hip BMD, as 2.7 to 1. Thus, a substantially larger number of cases will be defined as having osteoporosis by spine BMD than by hip BMD. However, while the loss seems linear for hip BMD, spine BMD is curvilinear. Furthermore, the original Holgic reference values show an increased range of dispersion by age, indicating a between individuals non-linear rate of loss. Using total hip and -spine BMD measured in 38.840 females (mean age 61.6 years; range 10-95; SD 11.5), the actual age dependent variation in BMD was determined and the frequency of osteoporosis classification assessed. From the age of 47 years the rate of reduced total hip BMD was linear (~0.004g/cm^2/year). In the spine it was linear between age 40 and 65 (~0.008 g/cm^2/year). After age 65 there was an insignificant further loss. The SD of the dispersion was fairly constant in all age groups, but with a significant positive skewness for spine BMD after age 65 (skewness~0.8). At age 62 18% were classified as having osteoporosis by hip BMD and 32% by the spine; at age 67 the corresponding values were 22% and 43%; the difference between hip and spine was smaller at higher age, thus at age 77 the same values were 43% and 48% respectively. At age 67 years 41% were classified as having osteoporosis, 10% by both hip and spine BMD, 3% by hip BMD and 28% by spine BMD only. The same vales were 45%, 18%, 5% and 22% at age 77. In a subgroup of 8.307 patients with fracture history, risk ratios (RR) for having had more than 2 fractures was 2.8 for osteoporosis defined both by combined hip and spine and by hip only. RR was 2 for spine only. The RR for a hip fracture was 6.7 for hip BMD and 2.9 for spine BMD. RR for a spine fracture was 1.5 for hip BMD and 2 for spine BMD. In comparison, with a cut-off at Z-score -1 approximately 20% of patients were defined as having osteoporosis with a RR of at least 8 for hip fractures. Based on T-scores a substantial discordance between classification of osteoporosis was seen. Due to nonlinear age dependent reduction and a positive skewness of spine BMD, this discordance became less by age. However, as many as 50% of all may by time be defined as having osteoporosis and at age 70 spine BMD alone will account for more than 50% of the cases. Furthermore, a comparatively large number of low fracture risk patients seem to be defined as having osteoporosis by this approach. The T-score definition for osteoporosis may not give cost effective medical fracture intervention. It is suggested that the T-score should be replaced by the age adjusted Z-score.

Bone Mineral Density (BMD) Predicts Incident Vertebral Fractures: Fifteen Years of Follow-Up. J. A. Cauley[1], L. Lui[2], L. Palermo[2], M. C. Hochberg[3], K. E. Ensrud[4], T. Hillier*[5], S. R. Cummings[6]. [1]U of Pittsburgh, Pittsburgh, PA, USA, [2]U of California, San Francisco, CA, USA, [3]U of Maryland, Balitmore, MD, USA, [4]VA Medical Center & U of Minnesota, Minneapolis, MN, USA, [5]Kaiser Center for Health Research, Portland, OR, USA, [6]UCSF & SFCC, CPMC Research Institute, San Francisco, CA, USA.

Low BMD predicts incident vertebral fractures over 4-5 years but the long term prediction of fractures is unknown. To test the hypothesis that low BMD predicts incident vertebral fractures over 15 years, we studied 2,680 Caucasian women age 65 years or older when they enrolled in the Study of Osteoporotic Fractures. All women had lateral lumbar and thoracic vertebral x-rays at baseline and an average of 15 years later. Using vertebral morphometry, anterior (Ha), posterior (Hp) and mid-vertebral height (Hm) were measured and 3 ratios formed (Ha/Hp; Hm/Hp, ($Hp_{(i)}/Hp_{(i-1)}$ and $Ha_{(i)}/Ha_{(i-1)}$), or ($Hp_{(i)}/Hp_{(I+1)}$ and $Ha_{(i)}/Ha_{(I+1)}$)) > 3 SDs. Prevalent vertebral fractures were considered present at baseline if any ratio was > 3 SDs below the expected mean. Incident vertebral fractures were defined as ≥ 20% and at least 4mm decrease in vertebral height at any level. BMD was measured in the distal and proximal radius and calcaneus at baseline using single photon absorptiometry (Osteoanalyzer). BMD of the proximal femur and lumbar spine was measured by DXA at the first follow-up visit 2 years later (Hologic, Inc). Logistic regression analysis was used to calculate the odds ratio (95% confidence intervals) of vertebral fracture per 1 standard deviation (SD) decrease in BMD after adjustment for baseline age and clinic. 492 (18.4%) of these women experienced an incident vertebral fracture during the 15-year follow-up. The odds ratios ranged from 1.46 to 2.16 for each SD decrease in BMD in prediction of incident vertebral fractures 15 years later (Table). There were no significant differences among BMD sites in the prediction of fracture. The association of low BMD and incident vertebral fracture was similar in women with and without a prevalent vertebral fracture at baseline (Table) and in women < age 70 vs. ≥ age 70 at baseline (data not shown). We conclude that a single measurement of BMD predicts vertebral fracture risk even after 15 years. Repeat BMD testing for the purpose of predicting vertebral fracture among women age 65 or older may not be indicated.

Table: Odds Ratio (95% CI) of vertebral fracture per 1 SD Decrease in BMD.

BMD Site	All Women (n=2,680)	Prevalent Vertebral Yes (n=394)	Fracture at Baseline No (N=2,286)
Calcaneus	1.74 (1.54, 1.96)	1.61 (1.26, 2.07)	1.58 (1.38, 1.82)
Distal Radius	1.58 (1.41, 1.77)	1.33 (1.07, 1.66)	1.52 (1.33, 1.74)
Proximal Radius	1.46 (1.31, .63)	1.41 (1.13, 1.76)	1.36 (1.20, 1.54)
Total Hip	1.83 (1.62, 2.07)	1.88 (1.45, 2.45)	1.60 (1.39, 1.84)
Femoral Neck	1.78 (1.57, 2.02)	1.51 (1.18, 1.92)	1.66 (1.44, 1.93)
Lumbar Spine	2.16 (1.89, 2.46)	1.96 (1.50, 2.55)	1.99 (1.71, 2.32)

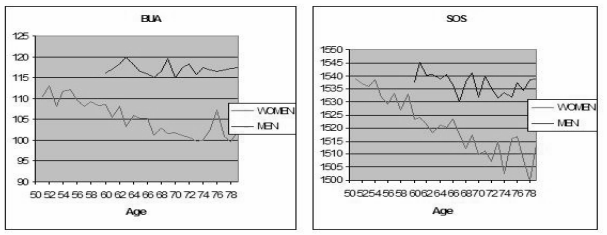
Normative Data for Ultrasound Measurement of the Calcaneous within Italian Males and Females: The ESOPO Study. S. Maggi*[1], M. Noale*[1], S. Adami[2], O. Di Munno*[3], P. Filipponi[4], S. Giannini[5], G. Isaia[6], L. Sinigaglia*[7], D. de Feo[8], G. Crepaldi[1]. [1]CNR Aging Center, Padova, Italy, [2]Rheumatology, Valeggio Hospital, Verona, Italy, [3]Rheumatology, Pisa University, Pisa, Italy, [4]Internal Medicine, Umbertide Hospital, Perugia, Italy, [5]Internal Medicine, Padova University, Padova, Italy, [6]Internal Medicine, Torino University, Torino, Italy, [7]Rheumatology, Gaetano Pini, Milano, Italy, [8]Procter & Gamble, Rome, Italy.

The purpose of this study was to generate normative data for Italian females aged 40-79 and males aged 60-79 years participating in the Epidemiologic Study On the Prevalence of Osteoporosis (ESOPO), using the Lunar Achilles Express (Lunar Co, Madison, USA). The ESOPO is a cross-sectional study aiming at assessing risk of osteoporosis and fracture in a cohort of Italians, representative of the general population. The overall study population is represented by a random sample of 11,011 women and 4,981 men. All participants were administered a questionnaire on the most relevant risk factors for osteoporosis, that allowed us to apply the following exclusion criteria: corticosteroids use, menopause before the age of 45 years, ovariectomy, breast-feeding in the previous year, use of hormone replacement therapy, a previous osteoporotic fracture. Other information available included smoking status, BMI, wine and coffee consumption, physical exercise, daily calcium intake, weight at 25 years, family history of fracture, bed-ridden status for 2+ months, milk consumption up to 25 years, age at menarche, amenorrhea for 6+ months, drugs consumption, hysterectomy, estrogens use, abortions, pregnancy. Average decreases of 8 % in BUA (111 at 50 years of age vs 102 at 79 years) and 2% in SOS (1539 vs 1512) for females, while no significant changes with age in males have been detected. These data show lower values for women and a decline at a greater rate than in men.



Disclosures: ***S. Maggi****, None.*

The Net Acid-Producing American Diet Adversely Affects Whole Body and Hip Bone Density Assessed Cross-Sectionally in Older Individuals. S. Perry*[1], F. A. Tylavsky[1], K. A. Ryder*[2], J. Cauley[3], J. Lee*[4], S. Pope*[5], T. Harris*[6], A. Sebastian*[7], D. E. Sellmeyer[7]. [1]Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN, USA, [2]Medicine, University of Tennessee Health Science Center, Memphis, TN, USA, [3]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [4]Epidemiology, University of North Carolina Chapel Hill, Chapel Hill, NC, USA, [5]Epidemiolgy, University of Arkansas, Little Rock, AR, USA, [6]Natioal Institute on Aging, Bethesda, MD, USA, [7]University of California San Francisco, San Francisco, CA, USA.

Net dietary acid loads purportedly adversely affect skeletal health in older individuals. This study used nutrient data from a food frequency questionnaire (FFQ) to estimate renal net acid excretion (RNAE)_an index of diet net acid load_and related it to systemic acid-base status and bone mineral density (BMD). We obtained values for dietary intake of kilocalories, protein, phosphorus, calcium, magnesium and potassium using an interviewer administered FFQ to participants in the Health Aging and Body Composition study. The community-based sample of 1520 comprised a majority of white (63.6%) and male (53.6%) participants, with a mean age of 73.5 years at baseline. We estimated RNAE dietary mineral and protein-sulfur intake and the net organic acid production (calculated from anthropometric data as urinary excretion of organic anions proportional to body surface area). We measured BMD of the whole body and hip by dual-energy X-ray absorptiometry (4500A, Hologic, Inc.) In multivariate regression analysis, BMD of both whole body and hip was associated negatively with RNAE/ kg of body weight, ($p<0.0001$). BMD declined with increasing values of RNAE; i.e, the greater the diet net acid load, the lower the BMD. By quartile of RNAE/kg of body weight:

	1 (Lowest)	2	3	4 (Highest)
†Whole Body BMD	1.112*	1.107*	1.097	1.082
†Total Hip BMD	0.910*	0.921*	0.900*	0.858
RNAE, meq/day	24.1	37.7	45.0	54.9

†Adjusted for race, gender, clinical site, tobacco use, hypertension, diabetes, urine creatinine, estrogen use and kilocalorie intake. * $p<0.0001$ compared to highest quartile

We conclude that estimates of diet net acid load from anthropometric data plus FFQ-derived diet nutrient composition data predict the degree of diet-dependent metabolic acidosis and bone mineral density in a large scale epidemiological study of older Americans. The findings reveal that, in older Americans, greater diet net acid loads associate with greater degrees of metabolic acidosis and lower bone densities of whole body and hip. It remains undetermined whether losses of BMD in relation to the size of diet net acid load occur progressively over time.

Low Plasma Vitamin B12 Is Associated with Increased Hip Fracture Risk in Elderly Men and Women: The Framingham Study. R. R. McLean[1], P. F. Jacques*[2], J. Selhub*[2], L. Fredman*[3], E. J. Samelson[4], D. P. Kiel[4], L. A. Cupples*[3], M. T. Hannan[4]. [1]Hebrew SeniorLife, Boston, MA, USA, [2]USDA HNRC, Tufts Univ, Boston, MA, USA, [3]BU Sch of Public Health, Boston, MA, USA, [4]Hebrew SeniorLife & Harv Med Sch, Boston, MA, USA.

Recent studies suggest plasma homocysteine concentration (tHcy) is associated with hip fracture (HFx) risk among elders. There is, however, little evidence that homocysteine directly affects bone and it has been hypothesized that tHcy may instead be a marker for the true causal factor. This factor may be low vitamin B12 which contributes to elevations in tHcy and is associated with bone density. We examined the association between plasma vitamin B12 concentration and HFx risk in men and women in the Framingham Study original cohort. Non-fasting blood samples were drawn from 375 men and 529 women (mean age 76 yr, range 67-96) in 1988-89 and plasma vitamin B12 (pmol/L) was measured by radioimmunoassay (RIA). Using the cutoff at which individuals are at a risk of vitamin B12 deficiency participants were classified as having normal (≥258 pmol/L) or low (<258 pmol/L) B12. Incident HFxs were ascertained from time of blood draw through December 2001. Sex- and age-adjusted incidence rates of HFx were calculated for B12 groups. Cox proportional hazards regression was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) estimating the relative risk of HFx for low versus normal B12, adjusting for baseline measures: gender, age (yr), height (in), weight (lbs), smoking (cig/d), alcohol consumption (oz/wk), caffeine intake (>2 cup/d: y/n) and physical activity index. To determine any residual effect of B12 after accounting for any tHcy effect an additional regression was performed adjusting for tHcy status as defined by a common cut point for hyperhomocysteinemia (>14 μmol/L: y/n). The prevalence of low B12 was 41%. Mean follow-up time was 9.9 yr for the normal B12 group and 9.4 yr for the low B12 group, with 51 and 40 HFxs occurring for each group, respectively. Sex- and age-adjusted HFx incidence rates (95% CI) for the normal and low B12 groups were 9.1 (6.6, 11.6) and 12.5 (8.6, 16.4) per 1000 person-yrs, respectively. Participants with low B12 had a 39% multivariable adjusted increased risk of HFx compared to those with normal B12 (HR=1.39; 95% CI: 0.91, 2.13). After accounting for tHcy there remained a residual association between B12 and HFx (HR=1.29; 95% CI: 0.83, 1.99). Although neither effect measure was statistically significant, these findings suggest plasma vitamin B12 may be an independent and potentially modifiable risk factor for HFx among older persons. Further work is needed to evaluate how interrelations among components of homocysteine metabolism (including folate, vitamin B6) impact HFx.

Indications for VFA in Densitometry Patients. T. J. Vokes[1], D. Gillen*[2], J. Lovett*[1]. [1]Medicine/Endocrinology, University of Chicago, Chicago, IL, USA, [2]Department of Statistics, University of California, Irvine, Irvine, CA, USA.

Vertebral Fracture Assessment (VFA) is a new method for detecting vertebral fractures on the densitometer, usually performed with BMD measurement. It is presently unclear which patients should have VFA examination at the time of their densitometry visit. We evaluated the association of vertebral fractures seen on VFA with several factors (see table) associated with risk of vertebral fractures in population studies. 423 women aged 19-94 years (mean 64+13) who were referred for routine densitometry at the University of Chicago and agreed to participate in the study had VFA imaging and BMD measurement at the lumbar spine and the femoral neck using Prodigy (GE medical systems), and filled out an osteoporosis risk factors questionnaire. Presence of fractures was ascertained using Genant's semiquantitative method with the percent deformation confirmed using built in morphometry software. Fractures were present in 103 subjects (24%). The association of a given risk factor with probability of having a fracture was described using the relative risk of fracture as a summary measure. Confidence intervals and p-values for the relative risk were calculated based upon the normal approximation to the binomial distribution. Significant correlates of the risk of vertebral fracture in the sample included age greater than 65, self reported height loss > 4cm, history of peripheral osteoporotic fractures as an adult, and osteoporosis at hip or spine. History of steroid use was not found to be significantly associated with the risk of vertebral fracture. All of the factors noted above maintained a significant independent effect after adjustment for age. When 12 subjects with mild (grade 1) fractures or 49 women younger than 50 were excluded from the analysis the relative risk was numerically higher for all risk factors (data not shown). We conclude that the above risk factors, alone or in combination, may be reasonable indications to perform VFA in densitometry patients.

Risk factor	**RR (95% CI)**	**p value**	Frequ. in F (**sensitivity**)	Frequ. in N (**specificity**)
Age>65	**2.99 (1.99-4.50)**	**<0.001**	78/103 (76%)	138/320 (57%)
Height loss >4cm	**2.86(1.66-4.93)**	**<0.001**	34/73 (47%)	60/257 (77%)
Peripheral Fx	**1.7 (1.20-2.40)**	**0.003**	41/96 (43%)	84/314 (73%)
T-score<-2.5 at hip	**2.0 (1.40-2.87)**	**<0.001**	63/99 (64%)	131/317 (59%)
T-score<-2.5 at spine	**1.44 (1.03-2.01)**	**0.035**	46/102 (45%)	107/319 (66%)
Steroid use	1.36 (0.87-2.13)	0.192	16/101(16%)	41/319 (87%)
Any risk factor	**6.16 (2-18.85)**	**<0.001**	100/103 (97%)	257/320 (20%)

Do Prevalent Radiographic Vertebral Fractures and prior Non-Spine Fractures Continue to Confer an Increased Risk of Incident Hip Fracture after 10 Years of Follow-Up? J. T. Schousboe[1], H. A. Fink[2], L. Lui*[3], B. C. Taylor[2], M. C. Nevitt[3], K. E. Ensrud[2]. [1]Park Nicollet Clinic & University of Minnesota, Minneapolis, MN, USA, [2]VAMC & University of Minnesota, Minneapolis, MN, USA, [3]SOF Coordinating Center, UCSF, San Francisco, CA, USA.

While a history of prior fractures is an independent predictor of incident hip fracture (HF), it is unclear whether this is so for prior fractures that occurred in the distant past. We used data from the Study of Osteoporotic Fractures (SOF), a large prospective cohort study of women age ≥ 65, to examine the associations of prevalent radiographic vertebral fractures (RVF) and self-reported prior non-spine fracture (NSF) ascertained at SOF exam 1 with incident HF occurring during three approximate follow-up time periods; 0-4 years after exam 1, 4-10 years after exam 1, and >10 years after exam 1. Cox regression was used to assess age-adjusted, age and hip BMD-adjusted, and multivariable-adjusted hazard ratios for incident HF in those with the predictor fracture (RVF or NSF) at baseline versus those without the predictor fracture at baseline. For each analysis, those with incident HF between exam 1 and the start of the follow-up period were excluded.

Table: Hazard Ratios (95% CI) for Incident HF Associated With Predictor Fracture[a] by Follow-up Period

Predictor Fracture	Follow-up Period After Exam 1 (Number of Incident HF)		
	4 yrs[b] (102)	4 to 10 yrs[c] (328)	>10 yrs (317)
RVF at Exam 1	1.74 (1.13 - 2.69)	1.69 (1.33 - 2.15)	1.16 (0.88 - 1.53)
NSF Before Exam 1	1.46 (0.97 - 2.20)	1.28 (1.02 - 1.60)	1.20 (0.96 - 1.51)

[a]Adjusted for age, hip BMD, body mass index, falls in the prior 12 months, walking speed; models with RVF as predictor also adjusted for history of HF prior to exam 1
[b]Mean follow-up time 3.7 years after exam 1
[c]Follow-up period from mean 3.7 years after exam 1 to mean 10.2 years after exam 1

Prior self-reported NSF and prevalent RVF are associated with an increased risk of hip fracture for up to 10 years after ascertainment of NSF and RVF status, but these associations appear to wane with additional follow-up time beyond 10 years.

Disclosures: ***J.T. Schousboe****, Hologic, Inc. 2.*

Osteoporosis Fractures and Costs by Race/Ethnicity and Gender in the USA. R. Burge*[1], A. King*[1], D. Solomon*[2], A. Tosteson*[3], J. Wong*[4], B. Dawson-Hughes[5]. [1]Proctor & Gamble, Cincinnati, OH, USA, [2]Brigham & Women's Hospital, Boston, MA, USA, [3]Darthmouth College, Lebanon, NH, USA, [4]Tufts Univ-NEMC, Boston, MA, USA, [5]Tufts University, Boston, MA, USA.

Osteoporosis leads to increased fracture risk throughout the skeleton.The disease has been thoroughly studied in white women but not across race/ethnicity groups and for men.The aim was to estimate osteoporosis fracture incidence and costs by race/ethnicity and gender in the USA.A Markov model of the natural history of osteoporosis was used to estimate fractures & costs in 2005 for men and women aged 50-99 years, by race/ethnicity (U.S. Census Bureau categories:White, Black, Hispanic, Other [Asian/Pacific Islander, Native American, other]).Hip fracture incidence rates were calculated from national hospital discharge data; clinical incidence rates for all other fracture types were obtained from published data.Mean costs per fracture were based on hospital discharge data analyses & estimates from the literature.Annual fractures & costs by race/ethnicity and gender were projected to 2025, & were based on population estimates. Predicted total incident fractures in 2005 were over 2.05 mil., and costs were $16.9 bil. Whites accounted for 86% of fractures and 88% of costs.Fracture incidence per 10,000 (age 50-99), by race/ethnicity, was 260, 127, 160, and 165 for White, Black, Hispanic, and Other populations, respectively.Women incurred 71% of total fractures, with an incidence of 342 per 10,000; men had an incidence rate of 170 per 10,000.

	2005		2025	
Race	Fx (000s) (%)	$ Costs M (%)	Fx (000s) (%)	$ Costs M (%)
White	1,768 (86)	14,951 (88)	2,399 (79)	20,547 (81)
Non-White	283 (14)	1,964 (12)	637 (21)	4,721 (19)
Black	107 (5)	709 (4)	185 (6)	1,268 (5)
Hisp	103 (5)	754 (4)	268 (9)	2,071 (8)
Other	72 (4)	502 (3)	185 (6)	1,381 (5)
Gender				
Female	1,456 (71)	12,797 (76)	2,110 (70)	18,571 (73)
Male	595 (29)	4,119 (24)	925 (30)	6,698 (27)
Total	2,050	16,915	3,036	25,268

Assuming constant treatment patterns, total incident fractures are predicted to increase by 48% to over 3 million by 2025.Shares of annual fractures & costs for Black, Hispanic and Other grow to 21% and 19%, respectively.Hispanics have the highest fracture & costs in 2025 among these groups.The most rapid growth in fractures & costs (2005-2025) is projected for Hispanics (175%) and the Other race/ethnicity group (175%).The proportion of fractures & costs in 2025 for men rises slightly to 30% & 27%, respectively.Over 2 million clinical fractures with costs over $16.9 B are predicted for 2005.By 2025, fracture incidence is expected to rise dramatically among Black, Hispanic and Other populations, especially for Hispanic and Other.Diagnosis and treatment need to increase greatly to offset projected societal burden of osteoporosis in all segments of the aging population.

The Association of High Sensitivity C-Reactive Protein Levels with Fracture Risk in Postmenopausal Women: Geelong Osteoporosis Study. J. A. Pasco[1], M. A. Kotowicz[1], M. J. Henry*[1], H. Spilsbury*[2], G. C. Nicholson[1], J. Box*[2], H. G. Schneider[2]. [1]Clinical & Biomedical Sciences: Barwon Health, The University of Melbourne, Geelong, Australia, [2]Alfred Pathology Service, Prahran, Australia.

Reduced bone mass and increased risk of fracture are common among patients with inflammatory diseases. Furthermore, mediators of inflammation like IL-6 or TNFa have been shown to stimulate bone resorption. Systemic inflammation may be implicated in the pathophysiology of osteoporosis. We therefore tested the association between serum high sensitivity C-reactive protein (hsCRP) levels and risk of fracture in 744 postmenopausal women randomly-selected from the community and enrolled in the Geelong Osteoporosis Study, 1994-7. Baseline hsCRP levels were measured using a high-sensitivity immunoturbimetrical assay; BMD was also measured at baseline. Fractures were identified from radiological reports. Subjects were followed longitudinally until the end of 2002, or until sustaining a fracture, death, or migration from the study region. Multivariable Cox proportional hazards regression was used to determine the association between hsCRP and fracture. 126 fractures were sustained during 4013 person-years of follow-up. Median hsCRP concentration was 2.5 mg/L (IQR 1.3-4.9). After adjusting for potential confounders, women with hsCRP in the highest quartile (≥4.9 mg/L) had a 1.6-fold (95%CI 1.1-2.4) greater risk of fracture than the lower quartiles pooled, independent of BMD. Both increased hsCRP and increased bone deficits contributed to increased fracture risk. Using hsCRP quartiles 1-3 and normal hip BMD (T-score>-1.0) as the referent group, women in the highest hsCRP quartile and with low BMD (T-score<-2.5) had the highest adjusted fracture risk (RR=9.1; 95%CI 3.6-23). Elevating hsCRP from quartiles 1-3 into the highest quartile was equivalent to increasing the fracture risk normally associated with osteopenia to that of osteoporosis. A similar pattern was observed for BMD measured at the spine. Circulating hsCRP is an independent predictor of fracture risk in postmenopausal women. These results may implicate systemic inflammation as a factor in the pathophysiology of osteoporosis. hsCRP may be a useful assay to predict fracture risk in conjunction with BMD.

Initial Experience with a New Computerized Method for Clinical Assessment of Vertebral Deformations. M. T. Lund*[1], L. B. Tankó[2], M. de Bruijne*[1], M. Nielsen*[1], C. Christiansen[2]. [1]Technical University of Copenhagen, Copenhagen S, Denmark, [2]Center for Clinical and Basic Research, Ballerup, Denmark.

Currently, the diagnosis of a vertebral fracture in clinical trials relies on a 20% decrease in body height of a vertebra as measured on digitized lateral X-rays. Due to the categorical nature of this study parameter, clinical trials continue to demand a large number of participants and long follow-up time. The aim of the present study was to obtain initial experience with a novel computerized technique taking into account morphometric alterations over the full shape of the vertebra. The proposed method incorporates two key features: 1) A measure of fracture is based on changes in the shape of the vertebral body 2) The changes are quantified with reference to a predicted normal shape of the respective vertebra, incorporating data on the biological variation of intact vertebrae. The present analysis was based on 91 randomly chosen radiographs of the lumbar spine (L1-L4). Radiographs were digitalized and subsequently annotated with pre-defined landmarks. The statistical models of the normal vertebral shape were derived from a dataset of unfractured vertebrae to predict the normal shape of one vertebra from the shape of adjacent vertebrae (regularized multiple linear regression/ridge regression). The regression model accurately predicts the shape of the intact vertebra. In 95 % of the cases was the prediction error <5% of the mean vertebral height with an average prediction error of 2.7% (<0.8mm). The obtained prediction accuracy is close to the maximum that can be expected with the current model. The prediction error gives the deviation from the expected intact shape and can therefore be directly used to assess the degree of abnormality for each vertebra. Presence of fracture had a mean prediction error of 11.7%. An expample of fracture with reference to predicted normal shape is shown in Figure 1. In conclusion, this novel computerized technique carries notable potentials for the quantitative monitoring of vertebral deformations. Accurate measures of the changes in vertebral shape might provide us with continuous measures of vertebral deformation, which in turn could decrease number of patients and/or follow-up time in clinical trials assessing the efficacy of drug candidates.

Large Scale Analysis of the VDR Translation Start Site Polymorphism and Fracture in Older Women. S. P. Moffett[1], J. M. Zmuda[1], J. A. Cauley[1], K. L. Stone[2], L. Lui[2], K. E. Ensrud[3], T. A. Hillier[4], M. C. Hochberg*[5], G. Peltz*[6], S. R. Cummings[7]. [1]Epidemiology, Univ of Pittsburgh, Pittsburgh, PA, USA, [2]Univ of California, San Francisco, CA, USA, [3]Veterans Affairs Med Center, Minneapolis, MN, USA, [4]Kaiser Permanente Center for Health Research Northwest/Hawaii, Portland, OR, USA, [5]Univ of Maryland School of Med, Baltimore, MD, USA, [6]Roche Molecular Systems, Palo Alto, CA, USA, [7]Epidemiology, California Pacific Med Center, Pittsburgh, PA, USA.

The Vitamin D Receptor (VDR) is a nuclear receptor that regulates bone formation and resorption. A common C to T polymorphism in exon 2 of the VDR gene introduces a translation start site and a protein that differs in length by 3 amino acids (T=427aa, C=424aa; rs10735810). We conducted genetic association analyses of this polymorphism, bone mineral density (BMD) and fracture in 6680 women aged ≥65 years. BMD was measured using single-photon (wrist) or dual-energy X-ray (hip, spine) absorptiometry. Incident fractures were confirmed by physician adjudication of radiology reports. There were 2,532 incident fractures (excluding vertebral and traumatic fractures) during 13.6 years of follow-up including 509 wrist and 703 hip fractures. While no association was found between the VDR start codon polymorphism and either hip or spine BMD, women with the C/C genotype had significantly lower distal radius BMD compared to those with the T/T genotype (CC=0.358, CT=0.361, TT=0.369, p-value=0.003), an association not altered by adjusting for potential confounders. The C/C genotype was also associated with increased risk of non-spine, non-traumatic fracture (RR: 1.18; 95% C.I.: 1.04, 1.33; p=0.009) and wrist fracture (RR: 1.33; 95% C.I.: 1.01, 1.75; p=0.04) compared to the T/T genotype in age-adjusted models. Further adjustments for potential confounding factors had little effect on these associations while adjustments for distal radius BMD only slightly attenuated the associations. The VDR start codon polymorphism was not associated with hip fracture (RR: 0.94; 95% C.I.: 0.76, 1.19; p=0.64). The population attributable risk (PAR) of the C/C genotype for incident fractures was 6.1%. The PAR for established risk factors for fracture were: low hip BMD (PAR=16.3%), maternal history of fracture (PAR=5.1%), low body weight (PAR=5.3%), corticosteroid use (PAR=1.3%), and smoking (PAR=1.6%). The common and potentially functional translation start site polymorphism in the VDR gene confers a modestly increased relative risk of fracture among older Caucasian American women. However, the high frequency of this variant translates to a population attributable risk that is similar to or greater than several established risk factors for fracture.

Differences in Site-Specific Fracture Risk among Older Women with Discordant Results for Osteoporosis at Hip and Spine. H. Fink[1], S. Litwack-Harrison*[2], B. Taylor[1], K. Ensrud[1], J. Schousboe[3], K. Stone[2], D. Black[2], S. Cummings[2]. [1]VA Medical Center, Minneapolis, MN, USA, [2]SF Coordinating Center, CPMC Research Institute and UCSF, SF, CA, USA, [3]Park Nicollet Clinic, Minneapolis, MN, USA.

T-score values for BMD of the hip and spine often disagree. Specifically, some women have a T-score ≤-2.5 at one site but not the other. The value of this pattern for future risk of fractures (fx) is not known. To describe the patterns of fx when hip and spine BMD T-scores differ, we analyzed data from the Study of Osteoporotic Fractures (SOF), a prospective cohort study of women aged ≥65 years. At the 2nd SOF exam, women underwent BMD measurement at both hip and spine by DEXA (QDR 1000, Hologic, Inc.). "Osteoporosis" was defined separately at the femoral neck (FN) and lumbar spine (LS) as T-score ≤-2.5. For the present analyses, the 7761 women (>99%) who also provided prospective fracture follow-up data were categorized as osteoporotic at FN only (n=702), at LS only (n=1341), at both FN and LS (n=1225), or at neither site (n=4493). Incident hip fx occurring after the 2nd SOF exam were validated by x-ray reports. Incident radiographic spine fx were defined morphometrically by ≥20% and at least 4 mm decrease in vertebral height at any level in women who completed spine films at the 3rd and 8th SOF exams (mean interval 11.3 yrs). After adjusting for age and weight, for each of these categories of osteoporosis we calculated hazard ratios (HR) for prediction of hip fractures, and odds ratios (OR) for prediction of incident spine fractures. Of 7761 women followed for hip fx, 832 (10.7%) experienced an incident hip fx during 11.2 years of follow-up. Of 2364 women with repeat spine films, 375 (15.9%) experienced an incident radiographic spine fx. Women with T-scores ≤-2.5 at the FN, but not the LS, had a substantially increased risk of hip, but not vertebral fx. Conversely, those with T-scores ≤-2.5 at the LS but not the hip had a substantially increased risk of vertebral, but not hip fx. Women who have T-scores ≤-2.5 at both sites have a substantially increased risk of both types of fx.

Table 1. Risk of hip and vertebral fracture by pattern of BMD T-score

	BMD, mean g/ cm2 (SD)		*Incident fx rate, n/ 1000 person-yr*	*Cumulative fx rate, n/ 1000 person-yr*	*Incident fx risk**	
Osteoporosis (T<-2.5) at:	*FN*	*Spine*	*Hip*	*Spine*	*Hip, HR (95%CI)*	*Spine, OR (95%CI)*
FN only	.53 (.04)	.87 (.09)	23.7	14.4	3.0 (2.4-3.7)	1.5 (0.9-2.5)
LS only	.64 (.06)	.70 (.06)	7.6	21.5	1.2 (0.95-1.5)	2.8 (2.1-3.8)
FN and LS	.51 (.04)	.66 (.07)	21.3	27.9	2.8 (2.3-3.3)	4.0 (2.9-5.6)
Neither	.71 (.09)	.95 (.13)	6.1	9.2	1.0 (referent)	1.0 (referent)

*Adjusted for age and weight

We conclude, that with respect to hip and spine, BMD T-score ≤-2.5 at one site but not the other increases risk of fracture at that site, but does not significantly increase risk of fracture at the other site.

Disclosures: ***H. Fink****, None.*

Hip Fractures in Women - Secular Trends Over 30 Years. H. G. Ahlborg, O. Johnell, M. K. Karlsson. Department of Orthopaedics, Malmo, Sweden.

Osteoporosis and its consequence of hip fracture represent a major public health problem among elderly women. Although the incidence of hip fractures has been reported to dramatically increase worldwide during the last decades, its not clear whether these findings are the result of an increasing prevalence of osteoporosis and/or an increasing proportion of elderly women in the population. This study was designed to characterize secular trends in the incidence of hip fractures within a female population with a stable prevalence of osteoporosis during the last three decades (1). All hip fractures, which occurred in the female population of Malmo aged 50 years or older, in the time between 1967-68, 1974-75, 1980-85, 1987-95 and 1999-2001, were identified at the Department of Diagnostic Radiology and Department of Orthopaedics. Demographic data were drawn from the yearbook of Local Statistics, which includes the annually number of inhabitants in Malmo by gender and one-year age groups between 1967 and 2001. The incidence of hip fracture was calculated and expressed as the number of hip fractures per 10,000 women per year. In the calculation of the age-adjusted fracture incidence, age adjustment was done by direct standardisation with the mean population between 1967 and 2001 as the standard population. Time-trend analysis was done by linear regression analysis. During the 23-year observation period from 1967 to 2001, altogether 1,136,435 person-years were generated and 8,059 hip fractures were registered in the target population. The annual number of hip fractures increased by 132% from 189 in 1967 to 439 in 2001. As the number of women aged 50 years or more in the population only slightly increased during the observation period, the crude incidence of hip fractures increased by 110% from 40 in 1967 to 84 in 2001. The overall trend in crude incidence between 1967 and 2001 was increasing (1.58 per 10,000 women per year; 95 percent confidence interval, 1.17 to 1.99), whereas the age-adjusted incidence was found to be stable over the same period (0.22 per 10,000 women per year; 95 percent confidence interval, -0.16 to 0.60). When the trend in the age-adjusted incidence was compared to the trend in the crude incidence, it was estimated that the proportion of variance of the trend in the crude incidence explained by demographic changes in the population was 69 percent. These data suggests that the increased crude incidence of hip fractures in elderly women is more likely to be attributable to demographic changes in the population, than to secular deterioration in bone mineral density.

5yr Outcomes of a Program Offering Routine Assessment and Treatment of Osteoporosis after Fracture in Patients Over 50yr: Refracture Rates and Mortality. A. R. McLellan[1], M. Fraser*[1], A. Reece*[2]. [1]Division of Cardiovascular Sciences & Medicine, Western Infirmary, Glasgow, United Kingdom, [2]Department of Orthopaedic Surgery, Western Infirmary, Glasgow, United Kingdom.

Although secondary prevention of fractures (fx) using treatments for osteoporosis is endorsed by national guidelines, this is seldom achieved. The Fracture Liaison Service (FLS) offers routine assessment & treatment, where necessary, for fx secondary prevention (FxSP) to all women & men ≥50yr presenting to our orthopaedic and A&E services with a new fx at any site. We describe mortality after fx and the characteristics of those who refractured (refx) during the first 5yr of the FLS. Our aim is to inform progress in developing services to achieve optimal FxSP. In the first 5yr of the FLS, 6137 patients with 6755 fx (97% were non-vertebral fx) were offered assessment &/or treatment for FxSP; 79% accepted & 21% declined. 15.9% of 6137 patients died. Mortality increased with age, was higher in men (O.R.(95%C.I.)2.11(1.83to2.44) and was higher after fx of hip(2.7(1.81to2.60)) & humerus(1.30(1.03to1.64)) compared to fx of radius/ulna, ankle & hand/foot. Depending on the patients' health status and willingness to be assessed, the FLS triaged fx cases into 6 groups among which mortality ranged from 6.7% (in patients who were fully assessed incl.DXA) to 38.2% (in those who had been assessed previously, and were usually on treatment). The refx rate in the first 5yr, among the 6137 patients was 8.8%. Refx were commoner in women (9.5% v 6.1%) but were more rapid in men: by 1 month after fx, 12% of male refx v 6% of female refx had occurred(p=0.02). Those with refx were older (74.6 v 72yr) and had lower BMD (LS T-score(mean(SD),-2.34(1.34)v-1.95(1.39),p=0.0001). Refx rates varied from 6% after fx of ankle or hand/foot, to 14% after vertebral fx. 10% of those with hip fx sustained a refx. Refx risk increased with higher cumulative past fx history; for each past fx ≥50yrs, risk of refx increased by 1.62(1.43to1.82) (p=0.0001). 31% of refx in the first 5yr of the FLS occurred within 6 months of the original fx; it is doubtful if treatments for osteoporosis will have impacted on these early, non-vertebral refx. Routine delivery of interventions for FxSP can be achieved in patients with new fx through services such as the FLS: intervention requires participation of the patients but can be tailored to their health status. While deployment of treatments with proven efficacy in reducing the incidence of osteoporotic fx is an essential component of the interventions offered by the FLS, this in itself may not be sufficient; if early refx are to be prevented, it may also be necessary to address non-skeletal risk factors for fracture such as those that determine risk of falling.

F334

Rates of Fracture after Stroke in International Population-Based Cohorts. C. W. Shinoff*[1], S. Sidney*[2], O. Johnell*[3], S. C. Johnston*[4], T. P. van Staa*[5], C. Cooper*[5], H. E. Whitson*[6], K. W. Lyles*[6], S. R. Cummings[1]. [1]San Francisco Coordinating Center, San Francisco, CA, USA, [2]Kaiser Division of Research, Oakland, CA, USA, [3]Department of Orthopaedics, Malmö University Hospital, Malmö, Sweden, [4]University of California San Francisco, San Francisco, CA, USA, [5]University of Southampton School of Medicine, Southampton, United Kingdom, [6]Duke University and VA Medical Centers, Durham, NC, USA.

About 700,000 people have a first or recurrent stroke every year in the United States. There may be increased risk for hospitalized hip fracture after stroke, but the risk of other types of fracture is not known. The objective of this study was to estimate rates of non-spine fracture after stroke in population-based cohorts, stratified by age and gender. We analyzed data from four large populations: Northern California Kaiser-Permanente patients; Study of Osteoporotic Fractures (SOF) participants; Swedish National Registry; General Practice Research Database (GPRD) from the U.K. Complete data were available for fractures treated in ambulatory care. Each cohort was analyzed separately, for rates of hip and non-spine fracture, within 1 and 2 years of stroke. The number of stroke patients were: Kaiser, 11,286; SOF, 1,554; Sweden, 15,858; GPRD, 5,114. The fracture rates were highest among those aged 70 and over. In the Kaiser cohort, non-spine fracture incidence in the first year after stroke was: 5.1 per 100 person-years for women <70 years compared to 8.2 for women over 70 years. In those aged 70 and over, the fracture rates were higher in women than men.(TABLE) In the Kaiser cohort, the rate of post-stroke fracture among Caucasians was higher than in other race/ethnic groups. Among women, fractures occurred at higher rate during the first year after stroke. Risk of hip fracture in the first year after stroke in women was higher in the Swedish cohort (6.2 per 100 person-years) than in the other cohorts (Kaiser, 2.5; SOF, 1.7; GPRD, 1.4). The risk of fracture in the first year after stroke is very high, with rates of hip fracture greater than in any other defined clinical population. The rates of non-spine fracture among those age 70 and over were about 6 to 7 times higher than the annual rate in the general U.S. population over the age of 70 (1% women and .5% men). Strategies to reduce this risk should be developed.

Differences in Hip Bone Mineral Density and Body Composition in a Multi-Ethnic Cohort of Older Men. Y. Sheu*[1], J. M. Zmuda[1], J. A. Cauley*[1], C. H. Bunker*[1], A. L. Patrick*[2], V. W. Wheeler*[2], E. Barrett-Connor*[3], M. L. Stefanick*[4], H. A. Fink*[5], C. E. Lewis*[6], L. M. Marshall*[7], E. S. Orwoll*[7]. [1]Department of Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA, [2]The Tobago Health Studies Office, Scarborough, Trinidad and Tobago, [3]University of California, San Diego, CA, USA, [4]Stanford Center for Research and Disease Control, Palo Alto, CA, USA, [5]VA Medical Center & University of Minnesota,, Minneapolis, MN, USA, [6]University of Alabama at Birmingham, Birmingham, AL, USA, [7]Oregon Health & Sciences University, Portland, OR, USA.

Compared with women, little is known about osteoporosis in men, particularly among non-white men. Thus, we have begun to characterize ethnic differences in bone mineral density (BMD) and bone mineral apparent density (BMAD) in a multi-ethnic cohort of older men. We hypothesized that there are major ethnic differences in BMD and BMAD that are independent of ethnic differences in body size and composition. The sample consisted of 5,475 men aged 65 to 80 years (mean=71.5) from the Osteoporotic Fractures in Men (MrOS) and Tobago Bone Health Studies (4,584 Caucasians; 230 African Americans; 180 Asian Americans; and 481 Afro-Caribbeans). Femoral neck BMD and BMAD, total body fat mass, total body fat percentage and appendicular lean body mass were measured by dual-energy X-ray absorptiometry (Hologic QDR 4500). Body size, body composition, BMD and BMAD were significantly different across the ethnic groups (Table; all p<0.001). Height was greatest in Caucasians and lowest in Asians. Men of African origin had greater appendicular lean mass, BMD and BMAD compared with other ethnic groups. BMD and BMAD were 1 standard deviation (SD) greater in Afro-Caribbeans compared with Caucasians and Asians and 1/3 SD higher than in African Americans. BMD and BMAD differences were independent of differences in body size and body composition. Caucasian and Asian American men have considerably lower hip BMD and BMAD than men of African ancestry. These differences are not explained by ethnic differences in body size or body composition. Further studies are needed to identify the factors contributing to the ethnic differences in bone health among older men.

	Afro-Carribean	African American	Caucasian	Asian
Height (cm)[a]	171.6 (6.3)	174.0 (7.2)	175.0 (6.5)	167.0 (5.9)
Body Fat (%)[b]	20.9 (6.1)	25.1 (5.5)	26.3 (5.4)	24.2 (4.8)
Appendicular Lean Mass (kg)[b]	28.8 (4.2)	26.7 (4.5)	24.6 (3.3)	23.0 (2.6)
BMD (g/cm^2)[c]	.92 (.14)	.87 (.15)	.79 (.13)	.80 (.11)
BMAD (g/cm^3)[c]	.17 (.03)	.16(.03)	.14 (.03)	.14 (.02)

Values are mean (SD). [a]Adjusted for age; [b]Adjusted for age, height; [c]Adjusted for age, height, total body lean and fat mass.

Characterization of Genomic Variation at the Wnt10b Locus: Novel Association of Wnt10b Genotypes with Bone Density in a Multi-Ethnic Sample of Older Men. J. I. Oakley[1], S. P. Moffett[1], L. M. Yerges*[1], C. S. Nestlerode*[1], V. W. Wheeler*[2], A. L. Patrick*[2], C. H. Bunker*[1], J. M. Zmuda[1]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Tobago Health Studies Office, Scarborough, Trinidad and Tobago.

Wnts comprise a family of secreted growth factors that regulate developmental processes. Recently, activation of the Wnt signaling pathway by Wnt10b was shown to stimulate osteoblastogenesis and bone formation in transgenic mice. To further evaluate the role of Wnt10b in bone mass regulation in humans, we resequenced about 8 kb of the *Wnt10b* gene region including 2.5 kb upstream of the transcriptional start site, the 5' and 3' untranslated regions (UTRs), the entire coding sequence, most of the introns including a highly conserved region in intron 3, and ~1 kb downstream of the 3'UTR in 192 individuals (96 African, 96 Caucasian). We identified 26 single nucleotide polymorphisms (SNPs) in the Caucasian and 20 SNPs in the African samples for a total of 38 unique SNPs with minor allele frequency ≥0.01. The majority of the 38 SNPs (79%) were not present in NCBI dbSNP database (build 124) whereas 11 of the 19 SNPs reported in dbSNP (58%) were not confirmed by our analysis. We genotyped 7 of the 8 common SNPs across the *Wnt10b* gene region in 260 Caucasian and 1001 Afro-Caribbean men aged 40 years and older using the TaqMan genotyping platform. We analyzed the relationship between genotypes at these 7 polymorphic sites and whole body and proximal femur bone mineral density (BMD) measured by DXA. Among Caucasians, a T to G polymorphism in a predicted exon splice enhancer site in the 3' UTR was significantly associated with whole body BMD (GG=1.13±0.13; GT + TT=1.18±0.11; P=0.01). Hip BMD was also significantly associated with this polymorphism in Caucasians (GG=0.91±0.19; GT + TT=0.96±0.14; P=0.04). The GG genotype was less common among Afro-Caribbeans than Caucasians (2% vs. 16%), but also tended to be associated with lower whole body BMD in this population (GG=1.22 ±0.12; GT + TT=1.26±0.12; P=0.09). A synonymous G to A variant in a predicted exon splice enhancer site in exon 5 was also associated with whole body BMD among Caucasians (AA=1.14±0.13; GA + GG=1.18±0.11; P=0.01) but not among the Afro-Caribbeans (AA=1.25 ±0.12; GA + GG=1.26 ±0.12; P=0.40). The variant in the 3' UTR and the variant in exon 5 were in high linkage disequilibrium in both the Afro-Caribbean (D'=1.00) and Caucasian men (D'=0.992). The present analysis suggests that Wnt10b may be a novel genetic element in the regulation of BMD variation within and between ethnic groups.

Beta Blockers Reduce the Prevalence of Fracture: Influence on Bone Mineral Density, Bone Geometry and Microarchitecture. N. Bonnet*[1], C. Gadois*[1], G. Lemineur*[2], E. Lespessailles[1], D. Courteix[1], L. Benhamou[1]. [1]U658Inserm & ATOSEP, Université d'Orléans, ORLEANS, France, [2]Medical imaging, D3A medical system, ORLEANS, France.

Animal data suggest that bone remodeling is under β-adrenergic control via the sympathetic nervous system. The purpose of this cross-sectional study was to assess the prevalence of non traumatic fractures in post-menopausal women under β blockers treatment, versus controls and to evaluate the BMD, bone geometry and trabecular bone microarchitecture. We evaluated the association between β blockers use and bone status in a post menopausal women population from the age of 41 to 96 (mean 65.2 ± 9.3). We have investigated a group of 944 women - 131 were taking β blockers. From the controls, we have extracted 252 age-matched women. Proximal femur DXA scans were analyzed using a hip analysis program (Hologic) to calculate the subperiosteal width, cortical thickness, bone cross-sectional area (CSA), bone cross-sectional moment of inertia, buckling ratio and section modulus (Z) at the neck and femoral shaft. Trabecular porosity was assessed by the technique described by Beck T.J. et al. (2000) at the neck region. Bone microarchitecture was investigated by fractal analysis of texture on calcaneus radiographs in a subgroup of 43 subjects. Vertebral fractures were diagnosed by vertebral deformity on radiographs. Fracture odds ratio under β blockers was 0.58 (95% CI, 0.12-0.70). β blockers use was associated with a higher BMD at the total hip (+3.7%, $p < 0.05$), neck (+5%, $p < 0.05$) and trochanter (+4.6%, $p < 0.05$). No significant difference was observed on L1-L4 BMD. Proximal femur scans revealed significantly higher CSA (+5.4%, $p < 0.05$), cortical thickness (+5.2%, $p < 0.05$) and lower trabecular porosity (-1.0%, $p < 0.05$), buckling ratio (-4.3%, $p < 0.05$) at the neck under β blockers. It was noticed that femoral shaft geometry did not significantly differ under β blockers. Medication use and lifestyle factors indicated no association between β blockers and smoking, alcohol use, physical activity, calcium supplementation, antidepressants, statins, corticosteroids and estrogen therapies. The Hmean parameter, was significantly higher in the β blockers group (0.625 versus 0.610 in controls, p<0.05), reflecting a better trabecular microarchitectural organization. Our data suggest that current use of β blockers is associated with a reduction of osteoporotic fractures, higher BMD, better femoral neck geometry. Furthermore, preliminary results suggest benefic effects of βblockers on trabecular micrarchitecture. β blockers are widely used for the management of cardiovascular diseases and may have the dual benefit of also reducing bone fragility.

Risk Factors for Falls in Older Adults with Diabetes. A. V. Schwartz[1], E. Vittinghoff*[1], D. E. Sellmeyer[1], N. De Rekeneire*[2], K. R. Feingold*[1], M. C. Nevitt[1], E. S. Strotmeyer[3], H. E. Resnick*[4], R. I. Shorr*[5], J. A. Cauley[3], K. A. Faulkner[3], S. R. Cummings[6], T. B. Harris*[2]. [1]Epidemiology and Biostatistics, UCSF, San Francisco, CA, USA, [2]National Institute on Aging, Bethesda, MD, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA, [4]Medstar Research Institute, Hyattsville, MD, USA, [5]University of Tennessee, Memphis, TN, USA, [6]California Pacific Medical Center, San Francisco, CA, USA.

Older adults with type 2 diabetes mellitus (DM) are more likely to fall but little is known about risk factors for falls in this population. We examined glycemic control and other risk factors for falls in older DM adults who participated in the Health, Aging, and Body Composition Study of 3,075 white and black, well-functioning men and women age 70-79 years. Of 2,940 participants with baseline data on DM, 719 (24%) participants had DM, defined by self-report, use of hypoglycemic medication, or an elevated fasting glucose (≥ 126 mg/dl) or 2-hour glucose (≥ 200 mg/dl). Hemoglobin A_{1c} (A1C) was measured at baseline (Y1) and Y4, vision (visual acuity, contrast sensitivity, stereopsis) at Y3, and peripheral nerve function (light touch discrimination, vibration threshold, peroneal nerve conduction velocity and amplitude) at Y4. Weight was measured annually. At baseline, mean weight was 80.7 kg (SD 14.9), mean A1C was 7.6% (SD 1.6), and 16% reported insulin use. Participants reported the number of falls in the previous year at each annual clinic visit. Falling was evaluated over five years of follow-up using ordinal logistic models. In unadjusted models, older age, weight loss, insulin use, reduced light touch discrimination, poor nerve conduction amplitude, poor visual acuity, and poor contrast sensitivity were associated with an increased fall risk. In models adjusted for age, gender, race, and variables in the table, the odds ratio (OR) for more frequent falls in those with poor glycemic control (A1C ≥ 9%) compared with A1C<9% was 1.36 (95% CI: 0.94, 1.99); older age, weight loss and poor nerve conduction amplitude were associated with increased fall risk (Table).

Adjusted OR for more frequent falls in older DM adults

	OR	(95% CI)
A1C (≥9% vs <9%)	1.36	(0.94, 1.99)
Peroneal nerve stimulation amplitude (worst quartile vs all others)	1.50	(1.06, 2.11)
Contrast sensitivity (worst quartile vs all others)	1.38	(0.96, 1.99)
Insulin use (yes)	1.42	(0.99, 2.04)
Weight change: Stable weight (<2 kg/yr)	1.00	Reference
Weight loss (≥2 kg/yr)	1.44	(1.15, 1.81)
Weight gain (≥2 kg/yr)	1.17	(0.93, 1.47)

Our results suggest that poor glycemic control and its long-term complications (poor peripheral nerve function and vision) are associated with increased fall risk. Weight loss, a marker of frailty in the elderly, was a risk factor for falls even in this overweight population.

What Is the Optimal Level of Serum 25-Hydroxyvitamin D for Bone Health in Older People? Results from the Longitudinal Aging Study Amsterdam. P. Lips[1], S. M. F. Pluijm*[2], J. H. Smit*[3], N. M. van Schoor*[3]. [1]Endocrinology, VU University Medical Center, Amsterdam, The Netherlands, [2]Public Health, Erasmus University Medical Center, Rotterdam, The Netherlands, [3]EMGO Institute, VU University Medical Center, Amsterdam, The Netherlands.

Vitamin D deficiency is common in the elderly. It causes secondary hyperparathyroidism, increased bone turnover and bone loss. Serum 25-hydroxyvitamin D (25(OH)D) may influence these variables up to a threshold concentration, which may be between 50 and 80 nmol/l. The aim of this study was to assess the threshold serum 25(OH)D with regard to serum parathyroid hormone (PTH) concentration, bone ultrasound parameters and bone turnover markers in the healthy elderly Dutch population. The study was done in the framework of the Longitudinal Aging Study Amsterdam (LASA), a longitudinal study in a representative sample of the older Dutch population. Blood and urine samples were obtained, and ultrasound measurements were performed in 1319 community-dwelling men (643) and women (676), aged 65 years and older on January 1, 1996. Serum 25(OH)D was measured by competitive protein binding assay. Serum PTH, serum osteocalcin and urinary deoxypyridinolin (DPD) were measured by radioimmunological methods. Ultrasound variables were measured in the heel with the CUBA Clinical instrument.Serum 25(OH)D was < 12.5 nmol in 1.6 %, < 25 nmol/l in 11.5 %, < 50 nmol/l in 48.4 %, < 75 nmol/l in 82.4 % and > 75 nmol/l in 17.6 % of the respondents. Mean serum PTH decreased gradually from 4.8 pmol/l when serum 25(OH)D < 12.5 nmol/l to 2.7 pmol/l when serum 25(OH)D>75 nmol/l. This decrease was very significant up to the last step (50-75 vs > 75 nmol/l) after correction for age and sex. Serum osteocalcin decreased from 2.6 nmol/l when serum 25(OH)D < 12.5 nmol/l to 2.1 nmol/l when serum 25(OH)D> 75 nmol/l, but this decrease was not significant after correction for age and sex. Urinary deoxypyridinolin/creatinine decreased from 7.3 nmol/mmol when serum 25(OH)D<12.5 nmol/l to 5.0 nmol/mmol when serum 25(OH)D>75 nmol/l, being significant up till 25 nmol/l after correction for age and sex. Broadband ultrasound attenuation increased from 61.9 dB/MHz when serum 25(OH)D<12.5 nmol/l to 74.8 dB/MHz when serum 25(OH)D>75 nmol/l, but this was not significant after correction for age and sex. Speed of sound increased from1603 m/s when serum 25(OH)D<12.5 nmol/l to 1638 m/s when serum 25(OH)D>75 nmol/l. This increase was significant up till 50 nmol/l after correction for age and sex. Results were similar in men and women. In conclusion, bone health in older men and women may improve when serum 25(OH)D is raised over 50 nmol /l, and probably even over 75 nmol/l.

F351

Low Vitamin D Level as a Risk Factor for Fractures in Community-Dwelling Older People. N. M. Van Schoor*[1], S. M. F. Pluijm*[2], J. H. Smit*[3], N. Kuchuk*[4], P. Lips[4]. [1]EMGO Institute, VU University Medical Center, Amsterdam, The Netherlands, [2]Department of Public Health, Erasmus University Medical Center, Rotterdam, The Netherlands, [3]Department of Sociology and Social Gerontology, Vrije Universiteit, Amsterdam, The Netherlands, [4]Department of Endocrinology, VU University Medical Center, Amsterdam, The Netherlands.

Vitamin D deficiency and insufficiency are very common in elderly people. The objective of this study is to examine whether a low vitamin D level is independently related to fractures. The study was conducted among 1320 community-dwelling older people (65 years or older on January 1, 1996) of the Longitudinal Aging Study Amsterdam (LASA). Serum 25(OH)D was measured by competitive protein binding assay in 1995/96. Fractures were prospectively assessed by a fall calendar between 1995/96 and 1998/99, and retrospectively between 1998/99 and 2001/02. Fractures were verified by the general practitioner or hospital. Of our population, 11.3% had a serum 25(OH)D below 25 nmol/l, and 48.4% had a value below 50 nmol/l. Furthermore, 132 persons (9.8%) had one or more fractures, of which 115 persons (8.5%) had one or more osteoporotic fractures (excluding head, foot, toe, hand and finger fractures, and fractures caused by traffic accidents). Different thresholds of serum 25(OH)D were examined with a threshold of 30 nmol/l giving the largest effects. Persons with a serum 25(OH)D equal to or below 30 nmol/l had a 1.69 times higher risk for osteoporotic fractures than persons with a value larger than 30 nmol/l (95% CI: 1.08-2.65). An interaction effect with age was found (p=0.02). Therefore, further results were presented separately for persons aged 65-75 years at baseline (n=656) and for persons aged 75-89 years at baseline (n=664). In the youngest age group, 8.2% had a serum 25(OH)D below 30 nmol/l (35.2% below 50 nmol/l) and 7.2% had one or more osteoporotic fractures. In the oldest age group, 27.0% had a serum 25(OH)D below 30 nmol/l (61.4% below 50 nmol/l) and 10.2% had one or more osteoporotic fractures. In the univariate analyses, a serum 25(OH)D equal to or below 30 nmol/l was significantly related to osteoporotic fractures (OR= 3.45; 95% CI: 1.61-7.40) in the youngest age group, and not in the oldest age group (OR=1.09; 95% CI: 0.62-1.92). After adjustment for sex, body mass index and seven major chronic diseases, a serum 25(OH)D equal to or below 30 nmol/l was significantly related to osteoporotic fractures (OR=3.28; 95% BI: 1.41-7.62) in the youngest age group. In conclusion, in our study, a serum 25(OH)D below 30 nmol/l is a risk factor for osteoporotic fractures during six year of follow-up in persons aged 65-75 years at baseline, independent of sex, body mass index and chronic disease.

Influence of Oral Contraceptive Use on Parameters of Bone Mass and Geometry in Young Women. M. Hartard[1], C. Kleinmond*[1], M. Wiseman*[2], E. R. Weissenbacher*[3], R. Erben[4]. [1]Faculty of Sport Science, AG-MSI, Technische Universitaet Muenchen, Munich, Germany, [2]Leibniz Data Processing Center, Bavarian Academy of Sciences, Munich, Germany, [3]Department of Gynecology and Obstetrics, Ludwig Maximilians Universitaet, Munich, Germany, [4]Institute of Animal Physiology, Ludwig Maximilians Universitaet, Munich, Germany.

It was the aim of this retrospective analyze to examine the influences of low dosed oral contraceptives (OC) on parameters of bone mass and geometry in 261 young women aged 18 to 24 years. Hip (Fig.1) and lumbar spine bone mineral density (BMD) were evaluated by DXA (Norland XR 26 Mark II). Parameters of tibial bone mineral content (BMC), bone geometry and volumetric BMD were assessed by pQCT (XCT-2000 of STRATEC) at shank levels of 4% and 38%. The women were allocated into "Ever" (> 0.5 years OCuse) or "Never" OC users (</=0.5 years OCuse) and based on the results of multiple regression analysis we classified subjects into 4 groups: 1) subjects with 3 years after menarche (OC Risk1) 3) subjects with total OC use of > 2 years and start of OC use > 3 years after menarche, or total use of less than 2 years but start of OC use within 3 years after menarche, respectively (OC Risk2) and 4) women with total OC use for more than 2 years and OC initiation within 3 years after menarche (OC Risk 3). Statistical differences between 4 groups were evaluated by one-way analysis of variance (ANOVA), followed by Dunnett's multiple comparison test. An unpaired t-test was used between "Ever" and "Never" users. Women in the OC Risk 3 group were characterized by 9% lower hip areal BMD, 5% lower spine areal BMD, 5 - 6% lower distal tibial total and trabecular volumetric BMD, and 6% lower total BMC at the tibial shaft relative to control subjects (</= 6 months of OC use). In addition, women who had ever used OCs for more than 6 months had lower bone mass at the hip, distal tibia, and tibial shaft, despite similar height, weight, BMI, hours of exercise, and calcium intake compared with never users (</= 6 months of OC use). At the tibial shaft, OC use was associated with reduced periosteal apposition and medullary expansion. We conclude that OC use was associated with a decreased bone mass at all regions observed and obviously with influences on bone geometry of distal tibia in this group of young women.

Prevalent Fractures, Low Bone Mineral Density and Ageing Are Associated with Greater Histomorphometric Indicators of Microdamage Accumulation in Postmenopausal Women. J. J. Stepan[1], D. B. Burr[2], I. Pavo[3], A. Sipos[3], D. Michalska*[1], J. Li[2], H. Petto*[3], M. Westmore[3], D. Michalsky*[1], M. Sato[3], H. Dobnig[4]. [1]Department of Internal Medicine 3, Charles University, Faculty of Medicine, Prague, Czech Republic, [2]Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, [3]Lilly Research Laboratories, Indianapolis, IN, USA, [4]Department of Internal Medicine, Medical University Graz, Graz, Austria.

This is the first exploratory investigation of the relationship between risk factors for fracture and microdamage accumulation in a clinical trial. We report baseline data from an ongoing open-label, uncontrolled two-center clinical trial. Sixty-six postmenopausal women with osteoporosis (mean age of 68.0 years, BMD T-score of -1.7 at total hip and -2.8 at lumbar spine; 62% with prevalent fractures) were recruited. Thirty-eight had been treated previously with alendronate (ALN) 10 mg/day-70 mg/week (mean duration 63.6 months) while twenty-eight were treatment naïve (TN). BMD, biochemical markers of bone turnover and transiliac bone biopsies (N=55) were analyzed at baseline. No overall differences in crack density (Cr.Dn; ALN: 1.46 #/mm^2, 95%CI 0.8-2.1; TN: 0.95 #/mm^2, 95% CI 0.3-1.6, P=0.26) and crack surface density (Cr.S.Dn; ALN: 70.5 µm/mm^2, 95% CI 37-104; TN: 43.5 µm/mm^2, 95% CI 18-69, P=0.2) were detected between ALN and TN patients. The presence of prevalent fractures was significantly correlated with greater Cr.Dn (r=0.30, P=0.025) and Cr.S.Dn (r=0.33, P=0.013). Among ALN patients, lower total hip BMD was associated with higher Cr.Dn (r=-0.45, P=0.017) and Cr.S.Dn (r=-0.49, P=0.008) and increased age was also associated with higher Cr.Dn (r=0.52, P=0.005) and Cr.S.Dn (r=0.52, P=0.005). These associations were not evident in TN subjects. We found no significant associations between biochemical and histomorphometric markers of bone

turnover and microdamage accumulation. Although patient demographics were similar, Cr.Dn and Cr.S.Dn were different between the two centers (P<0.01), apparently due to different techniques applied for bone biopsy sampling. At Center I (N=41) with lower values and variability, ALN patients had significantly more total microdamage (Cr.S.Dn of 44 μm/mm^2, 95%CI 28-60) than TN patients (25 μm/mm^2, 95%CI 16-35, P=0.046). This difference remained significant after adjustment for age, prevalent fractures and total hip BMD (P=0.031). We conclude that increased microdamage accumulation occurs in older patients, those with low BMD and those with prevalent fractures. These associations appear more pronounced in ALN-treated patients. Microdamage characteristics may also depend on biopsy sampling technique.

Trans-Menopausal Changes in the Trabecular Bone Structure. M. P. Akhter, B. L. McGuckin*, T. D. Howard*, S. P. Bare*, K. M. Davies*, J. M. Lappe, R. R. Recker. Medicine, Creighton University, Omaha, NE, USA.

Post-menopausal osteoporosis is a disease of elderly women, that is characterized by atraumatic fractures of various skeletal sites. The overall hypothesis for this analysis is that the variables describing trabecular bone micro-architecture will be affected by change in hormonal status of women just prior to, and early after, last menses, and that volumetric bone mass, density, and trabecular structure will decline significantly. The study was designed to capture true longitudinal transmenopausal changes in three-dimensional (3D) trabecular bone architecture. Currently, minimal data exist regarding trabecular bone volumetric structure, mass, and density in human transilial bone biopsies that are obtained before and after menopause. Fifty-one transilial biopsies specimens were obtained on entry (pre-menopausal and >age 46), and at 12 months past the last menstrual period. Bone architecture was quantified using standard histomorphometric (histo) and micro-computed tomography (m-CT-40, Scanco) techniques. Embedded bone biopsies were scanned at 30-micron resolution such that the volume of interest was similar as in the two dimensional (2D) histomorphometric analyses. Simple regression analyses were done to determine the relationship between variables measured by 2D histo and 3D micro-CT. In addition, paired t-tests were used to compare pre- and post-menopausal bone structure data from each technique. There was good correlation between the structural variables measured by 2D histo and the 3D micro-CT. The correlation (r) ranged from 0.5 to 0.69 between the standard histo and the micro-CT measured variables (BV/TV, trabecular thickness and spacing). BV/TV showed highest correlation (r=0.69) between 2D histo and the 3D micro-CT. Most of the variables (from both histo and micro-CT) either showed the declining trends (P =0.065) (BV/TV histo) or were significantly decreased (BV/TV 3D micro-CT, trabecular number) in bone structure in post-menopausal women (Table). In addition, both trabecular spacing and the structure model index increased in the post-menopausal women suggesting the thinning of trabeculae (Table). These data suggest that 3D micro-CT measurements are comparable to standard histo measurements, and that most of the structural measurements are sensitive to hormonal status (pre- and post-menopausal) in women.

Trabecular Bone Structure		
Mean ± SD	Pre	Post
BV/TV % (2D Histo)	23.2 ± 5.5	21.6 ± 4.6 [b]
BV/TV % (3D micro-CT)	28.3 ± 7.1	24.9 ± 7.4 [a]

Non Invasive Measurement of Trabecular Architecture by 3D-pQCT Discriminates Osteopenic Women With and Without Fractures. S. Boutroy*[1], M. L. Bouxsein[2], F. Munoz*[1], P. D. Delmas[1]. [1]INSERM Research Unit 403 and Claude Bernard University of Lyon, Lyon, France, [2]Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical, Boston, MA, USA.

Assessment of trabecular (Tb) architecture may enhance the prediction of fracture risk and improve monitoring of treatment response. A new high-resolution 3D-pQCT system permits *in vivo* assessment of Tb architecture and volumetric BMD (vBMD) at the distal radius and tibia with a voxel size of 82μm^3. Our aim was to evaluate the clinical performance of this 3D-pQCT system. We determined the short-term reproducibility (CV) of density and architecture parameters by measuring 8 healthy volunteers 3 times each. We also compared 3D-pQCT measurements in 108 healthy premenopausal (preM) and 148 postmenopausal (postM) women (w), classified by femoral neck or spine BMD as osteopenic (n=113) or osteoporotic (n=35). Furthermore, we compared DXA and 3D-pQCT values in postM osteopenic w with (n=42) and without prior fracture history (n=71). The precision of 3D-pQCT measurements was similar at both sites, with a CV of 0.5 to 1.3% for total, Tb and cortical vBMD, and 2.3 to 3.1% for Tb architecture. Bone density and architecture differed significantly between preM and postM w, and between postM osteopenic and osteoporotic w at both sites. For example, postM w had lower vBMD (11 to 37%), Tb number (12 to 23%) and cortical thickness (28 to 41%) and more heterogenous Tb distribution (53 to 83%) than preM w. Osteoporotic w had lower vBMD (5 to 18%), cortical thickness (15 to 18%) and Tb number (8.5 to 10%) than osteopenic w. Furthermore, although their spine and hip BMD did not differ, osteopenic w with a prior fracture history had lower total density, Tb density, number, separation and more heterogeneous Tb distribution at the radius compared to osteopenic w with no fracture history. There was no difference at the tibia between the two groups. In summary, 3D-pQCT is promising to assess Tb architecture at peripheral sites, with its excellent reproducibility and ability to detect age- and disease-related changes. 3D-pQCT of the radius - but not hip and spine DXA - could differentiate osteopenic w with and without fracture history, suggesting that it might detect early architectural damage and therefore might be useful for assessing fracture risk in postM w. These preliminary and cross-sectional data should be validated prospectively.

Mean values at the distal radius of postmenopausal osteopenic women with and without history of fracture (mean ± SD)

	Osteopenic women without fracture (n = 66)	Osteopenic women with fracture (n = 40)	p-value
Total density (mg HA/cm^3)	263 ± 61	238 ± 60	0.037
Cortical density (mg HA/cm^3)	813 ± 80	789 ± 81	ns
Trabecular density (mg HA/cm^3)	129 ± 35	114 ± 35	0.031
Trabecular number (mm^{-1})	1.49 ± 0.28	1.37 ± 0.29	0.046
Trabecular thickness (μm)	72 ± 10	68 ± 13	ns
Trabecular separation (μm)	630 ± 174	700 ± 200	0.034
Distribution of trabeculae (mm)	0.32 ± 0.18	0.38 ± 0.22	0.023
Cortical thickness (μm)	592 ± 171	537 ± 172	ns

In Vivo **Analysis of Vertebral Microstructure for Evaluation of Fracture Risk.** M. Ito[1], K. Ikeda[2], M. Uetani*[3], H. Orimo*[4]. [1]Radiology, Nagasaki University, Nagasaki, Japan, [2]Bone and Joint Disease, National Center for Geriatrics and Gerontology, Aichi, Japan, [3]Radiology, Nagasaki University, nagasaki, Japan, [4]Health Science University, Tokyo, Japan.

Bone mineral density (BMD) measurement by dual X-ray absorptiometry (DXA) alone has limitations in predicting fracture, and methods for clinical assessment of bone quality, including microstructure, are awaited. The present study was undertaken to examine the applicability of multidetector row computed tomography (MDCT) for clinical assessment of fracture risk. We first evaluated the relationship of microstructure parameters (obtained by MDCT) with ultimate load (as determined by compression test), using 4 femoral head specimens obtained during surgery. A significant correlation with ultimate load was obtained for apparent bone volume fraction (app BV/TV) (p<0.05), structure model index (SMI) (p<0.05) and app Tb.N (p<0.05). We then analyzed vertebral microstructure in 82 postmenopausal women (55-76 years old), including 39 women with and 43 without a recent vertebral fracture. Microstructure indices obtained by MDCT scanning revealed much higher relative risk for prevalent vertebral fracture (odds ratio: 16.0 for SMI, 13.6 for app BV/TV, and 13.1 for Euler's number) than did spinal BMD obtained by DXA (odds ratio: 4.8). MDCT can provide volumetric BMD values, which also revealed high association with fracture (odds ratio: 12.7). Microstructure parameters (especially SMI), when combined with BMD, gave even higher odds ratio than did those of single microstructure alone. This is the first in vivo imaging and analysis of vertebral micro-architecture by MDCT, and microstructure parameters, together with volumetric BMD obtained at the same time, may be useful for clinical assessment of fracture risk.

Synergistic Induction of Osteoblastic 11β-Hydroxysteroid Dehydrogenase Type 1 by Inflammatory Cytokines and Glucocorticoids: A Novel Mechanism for Glucocorticoid-Induced Bone Disease. M. S. Cooper, K. Kaur*, R. Hardy*, C. D. Buckley*, P. M. Stewart*, M. Hewison. Division of Medical Sciences, University of Birmingham, Birmingham, United Kingdom.

When used to treat inflammatory disease therapeutic glucocorticoids cause rapid bone loss. However clinical studies suggest that in patients without inflammation glucocorticoids have little impact on the skeleton. The mechanism by which inflammation magnifies the effects of glucocorticoids is unknown. We have proposed that intracellular glucocorticoid generation (inactive cortisone/prednisone to active cortisol/prednisolone conversion) via the 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) enzyme determines the clinical effects of glucocorticoids on bone. In healthy subjects the effect of prednisolone on bone formation markers is predicted by measures of 11β-HSD1 activity. We have now examined the hypothesis that the modifying effect of inflammation is due to increased local glucocorticoid generation in human osteoblasts. In MG63 osteosarcoma cells and primary osteoblasts IL-1β and TNFα potently induced 11β-HSD1 expression and activity (100 to 200-fold) whereas DEX treatment only mildly increased expression (10 to 50-fold). However, when combined with IL-1β or TNFα, DEX synergistically induced 11β-HSD1 expression and activity (1500-fold). Similar induction was also seen in primary cultures of human fibroblasts from bone marrow and synovium. This effect was specific for 11β-HSD1 with DEX inhibiting the cytokine induction of other genes such as OPG and COX-2. Glucocorticoid receptor α and β, and H6PDH (11β-HSD1 cofactor generating enzyme) expression were unchanged. Time course and actinomycin D studies showed that the synergistic effect of cytokines and glucocorticoids on 11β-HSD1 expression is transcriptional. However subsequent promoter-reporter analyses indicated that DEX and cortisol act to suppress IL-1/TNFα-induced luciferase activity, suggesting a novel mechanism for synergistic induction of 11β-HSD1 gene promoter activity. In response to

inflammation 11β-HSD1 activity increases in osteoblasts. This effect is magnified by glucocorticoid treatment. Inflammatory cytokine/glucocorticoid synergism of 11β-HSD1 induction is a potential mechanism to explain the modifying effect of inflammation on glucocorticoid-induced bone loss.

Glucocorticoids Act Directly on Osteoclasts to Increase Their Lifespan and Reduce Bone Density. D. Jia, C. A. O'Brien, A. M. Parfitt, S. C. Manolagas, R. S. Weinstein. Div of Endo/Metab, Center for Osteoporosis, Central Arkansas Veterans Healthcare System, Univ of Arkansas for Med Sci, Little Rock, AR, USA.

Whether the negative impact of excess glucocorticoids on the skeleton is due to direct effects on bone cells, indirect effects on extraskeletal tissues, or both is unknown. To determine the contribution of direct effects of glucocorticoids on osteoclasts in vivo, we blocked glucocorticoid action on these cells via transgenic expression of 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2), an enzyme that inactivates glucocorticoids. Osteoclast-specific expression was achieved by insertion of the 11β-HSD2 cDNA downstream from the tartrate-resistant acid phosphatase (TRAP) promoter. The transgene did not affect normal bone development or turnover as demonstrated by identical bone density, strength, and histomorphometry in adult transgenic and wildtype animals. Osteoclast precursor-enriched bone marrow cells from either genotype formed TRAP-positive multinucleated osteoclasts in vitro following 5 days of treatment with the receptor activator of NF-κB ligand (RANKL) and macrophage-colony stimulating factor (M-CSF). Baseline apoptosis, assayed by caspase-3 activity, was reduced by glucocorticoids in cultures of wildtype osteoclasts but this effect was greatly attenuated in osteoclasts from the transgenic animals. Furthermore, the ability of glucocorticoids to prevent alendronate-induced osteoclast apoptosis in wildtype cells was abrogated in osteoclasts taken from the TRAP-11β-HSD2 mice. In wild type mice, administration of excess glucocorticoids for 7 days induced more than a four-fold loss of spinal BMD when compared with placebo. Strikingly, the glucocorticoid-induced loss of BMD was completely abrogated in the TRAP-11β-HSD2 mice. These results provide the first in vivo evidence that the glucocorticoid-induced prolongation of osteoclast lifespan is indeed the result of direct actions of glucocorticoids on these cells. Furthermore, these results confirm that the early, rapid loss of bone characteristic of glucocorticoid-induced osteoporosis results from direct glucocorticoid action on osteoclasts, rather than through secondary hypogonadism or hyperparathyroidism.

CD40 Ligand Prevents Gluococorticoid-Induced Bone Loss by Increasing Bone Formation, Decreasing Bone Resorption and Inhibiting Osteocyte Apoptosis. W. Yao[1], G. Balooch[2], R. Nalla*[3], M. Guive*[2], J. Kinney[3], L. Bonewald[4], N. Lane[1]. [1]Medicine, UCDMC, Sacramento, CA, USA, [2]UCSF, San Francisco, CA, USA, [3]Lawrence Berkeley National Labaratory, Berkeley, CA, USA, [4]University of Missouri at Kansas City School of Dentistry, Kansas City, MO, USA.

Glucocorticoid (GC) excess has been proposed to occur through GC inhibition of bone formation, elevation of bone resorption and apoptosis of osteoblasts and osteocytes. CD40L is a known survival ligand for osteoblast and osteocytes (Ahuja et al, JBMR, 2003). We conducted this study to assess the effects of CD40L on an *in vivo* model of GC bone loss in which 4 mo. old Swiss-Webster mice were treated for 21 days with placebo (PL), GC (1.4mg slow release prednisolone pellet) or GC + CD40L (50μg/mouse, sc, 2X/wk (Amgen, Thousand Oaks, CA). Urine and serum samples were collected to measure bone turnover markers. At sacrifice, the 5th LVB were used for uCT scans and then processed for bone histomorphometry. Compression tests were performed on the 4rd lumbar vertebrae and 3-point bending tests were performed on the right tibiae. Results: Compared to the placebo treated mice, BV/TV, Tb.N and Tb.Th were lowered by 54%, 42%, 9% ($p<0.05$), respectively, in the GC treated animals. These changes were accompanied by increased bone resorption (DPD/Cr, sRANKL, Oc.S), decreased bone formation (osteocalcin, MAR, BFR) and increased apoptotic osteocytes ($p<0.05$). CD40L treatment not only prevented GC-induced bone loss, but appeared to increase Tb.Th by preventing GC induced bone resorption and apoptotic osteocytes. Lumbar compression and 3-point bending tests revealed significant decreases in compression modulus, stiffness and energy to failure in GC-treated animals compared to PL group ($p<0.05$) while GC + CD40L group had significant increased energy to failure compared to PL. Conclusions: Our results indicate that CD40L treatment can prevent GCs induced deterioration of both bone structure and mechanical properties most likely by sustaining osteoblast activity and osteocyte survival while simultaneously preventing elevated osteoclast activity. Therefore, CD40L appears to be an attractive agent for the treatment of bone loss due to glucocorticoid excess. The mechanism for CD40L's ability to resist GC induced changes in osteoblast activity and osteocyte survival is currently under investigation.

Estradiol Therapy Inhibits *In Vitro* Osteoclastogenesis and RANKL Expression in the Bone Marrow of Postmenopausal Women. H. Kaneko*[1], P. Taxel[2], K. Lee[2], Y. Toyama*[1], H. L. Aguila*[2], L. G. Raisz[2], J. A. Lorenzo[2]. [1]Orthopedics, Keio University School of Medicine, Tokyo, Japan, [2]Medicine, University of CT Health Center, Farmington, CT, USA.

Estrogen deficiency at menopause increases osteoclast (OCL) formation and bone resorption, predisposing women to osteoporosis. We examined in vitro OCL formation in cultured bone marrow cells from 3 premenopausal and 8 postmenopausal women before (B) and after (A) 3 weeks of estrogen (E) therapy (1 mg/day of micronized 17 beta estradiol). Subjects were postmenopausal and had not received E for at least 1 year. Bone marrow mononuclear (BMM) cells were prepared from bone marrow aspirates by ficoll-hypaque density gradient separation. OCL formation was stimulated with MCSF (30 ng/ml) and varying concentrations of RANKL for 14 days in 48 well plates. OCL were identified as TRAP positive multinucleated cells. We also examined the effects of E on the percentage of B-lymphocytes (CD-19+ cells) and cells expressing RANKL protein in uncultured bone marrow using flow cytometry and an anti-CD-19 or two anti-RANKL monoclonal antibodies (Ab) in 5 of the postmenopausal women and 3 premenopausal controls. Initial characterization of the bone marrow used forward/side light scatter to identify the granulocyte-enriched (R1) and the lymphocyte/monocyte-enriched (R2) subpopulations. Baseline bone mineral density in subjects, measured by DEXA, ranged from a T score of 1.6 to -3.1 in the lumbar spine and 0.3 to -1.8 in the femur. RANKL (3-100 ng/ml) produced a dose-dependent increase in OC formation and E therapy significantly ($p<0.01$) inhibited OCL formation by 33 to 50% (OCL/well for RANKL 3 ng/ml B= 102 ± 25, A= 51 ± 20; for RANKL 30 ng/ml B= 338 ± 29, A= 216 ± 19; for RANKL 100 ng/ml B= 442 ± 53, A= 283 ± 21, values are mean ± SEM). Treatment with E did not affect the percentage of CD-19+ B-lymphocytes in the total marrow but did increase CD-19+ cells in R2 and decrease CD-19+ cells in R1. Anti- RANKL Ab binding was generally low (typically 0.2-3.5% of cells in R1 and 0.7-4.3 % of cells in R2 prior to E). There was no effect of E on the percentage of cells binding the anti-RANKL Ab in the R1 fraction. However, in the R2 fraction E treatment decreased the percentage of cells binding anti-RANKL Ab by 68 ± 9% ($p<0.01$). These results demonstrate that 3 weeks of in vivo E treatment decreases the ability of human bone marrow cells to form OCL in vitro. Changes in the osteoclastic potential of bone marrow cells are likely involved in the ability of estrogen to regulate bone mass and influence the development of osteoporosis.

FSH as a Direct Regulator of Bone Degradation in the Human. B. B. Yaroslavskiy*[1], A. C. Sharrow*[1], D. J. Papachristou*[1], M. Virji*[1], L. Sun*[2], Z. Zhang*[2], Y. Peng*[2], J. Iqbal*[2], S. Zaidi*[2], H. Zhou*[2], L. L. Zhu*[2], B. S. Moonga*[2], M. Zaidi[2], H. C. Blair[1]. [1]Pathology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Mount Sinai Bone Program and Orthopedics Research Laboratories, Mount Sinai School of Medicine, New York, NY, USA.

It has long been an issue how estrogen can function as a sole regulator for sex-related effects on bone turnover. Complex schemes are required to explain how estrogen, mainly via ERα, can accomplish a wide variety of regulatory activities in hypogonadal men and women. We found a direct relationship of FSH to organic anions, phosphate or lactate, in early menopausal women. This is consistent with bone loss on estrogen withdrawal. However, these data were also compatible with a new hypothesis, that the glycoprotein hormone FSH may directly regulate bone turnover. A precedent, direct skeletal effects of the related glycoprotein hormone TSH, traditionally thought to affect only thyroxin production, was recently reported [Cell 115: 151, 2003]. Affymetrix screening of human CD14+ cells and osteoclasts produced using RANKL and CSF-1 revealed that osteoclasts but not CD14+ cells expressed the FSH receptor (FSHR). PCR confirmed FSHR mRNA in osteoclasts. Western blots showed FSHR protein in human osteoclasts, matching a granulosa cell line positive control. Based on rapid bone loss in early menopausal women with very high FSH (> 100 IU/l) and very low estrogen, we posited further that the osteoclast, and possibly some types of macrophages, are activated directly by FSH, augmenting estrogen effects which predominately reduces osteoclast formation via a nongenomic mechanism, while ERα is downregulated in the mature osteoclast [J Biol Chem 280: 13720, 2005]. We tested whether FSH promoted osteoclastic survival or activity. FSH gave a concentration-dependent increase in osteoclast number and pit formation at 14-21 d, with peak response at 30 ng/ml (equivalent to FSH at ~100 IU/l), and no resorption over control in GnRH or LH controls. In addition, with FSH treatment at short to intermediate times (2-18 h), osteoclasts on nonresorbable substrate showed reduced spread area, while attachment structures including podosomes and the actin ring appeared to be enhanced, in keeping with effects of FSH on motility and activity. Attached cell area was increased by addition of pertussis toxin (PTX), suggesting that effects of FSH are primarily mediated by a Gi pathway, although multiple regulatory pathways may be involved. Downstream, phosphorylation of the survival factor Akt, often modified by motility and adhesion factors, was increased by FSH with prolonged activity (to 18 h), which was reduced to ~control levels by PTX. We conclude that FSH directly stimulates human osteoclast activity and survival.

Alendronate Prevents Bone Loss in Men on Androgen Deprivation Therapy for Prostate Cancer. S. L. Greenspan[1], J. M. Wagner[1], J. B. Nelson*[2], N. M. Resnick*[1], R. A. Parker*[3]. [1]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [2]Urology, University of Pittsburgh, Pittsburgh, PA, USA, [3]Center for Biostatistics in AIDS Research, Harvard School of Public Health, Pittsburgh, PA, USA.

Prostate cancer is the most common visceral malignancy and the second leading cause of cancer death in men. Androgen deprivation therapy (ADT) is the cornerstone of treatment for more advanced disease and is utilized as preventive therapy for recurrence of prostate cancer. Because chronic ADT often results in bone loss, we postulated that this loss could be reversed with a once weekly oral bisphosphonate. To address these hypotheses, we enrolled 112 men with nonmetastatic prostate cancer (mean age 71.5±8.4 years) who were on ADT for at least 6 months in an NIH-funded, 2-year, double-blind, placebo-controlled, randomized, partial cross-over clinical trial. Participants were randomized to alendronate 70 mg once weekly or placebo, and received appropriate calcium and vitamin D supplementation. This abstract reports the analysis of the primary endpoint results after one year of therapy. Only 9% of men had normal bone mass by World Health Organization criteria at the hip and spine (39% had osteoporosis; 52% had osteopenia). In men on alendronate therapy, bone mass increased significantly at the spine and hip (see Table). In contrast, men on placebo had significant decreases of bone mass at the spine, hip, and forearm. There were significant differences between the two treatment groups at all skeletal sites. Therapy was well-tolerated with no between-group differences in adverse events. In summary, less than 10% of men with nonmetastatic prostate cancer on ADT had a normal BMD. After 12 months on ADT, the placebo-treated men had significant additional bone loss; men treated with once weekly oral alendronate had significant gains. Since most men remain on ADT indefinitely, it is important to assess bone mass and consider measures to prevent bone loss.

	Percent Change in BMD at 12 Months

Direct Inhibitory, and T Cell Mediated Stimulatory Effects on Osteoclastogenesis Determine the Net Activity of IFNγ on Bone *In Vivo*. Y. Gao, M. Robbie-Ryan, K. Page*, W. Qian*, X. Yang*, M. N. Weitzmann, R. Pacifici. Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA.

IFNγ has been implicated in the bone loss induced by ovariectomy (ovx) and inflammation, but its role remains controversial as IFNγ was shown both to inhibit and stimulate osteoclast (OC) formation and bone loss. rIFNγ blocked OC formation in monocyte cultures, confirming that it posses a direct anti-osteoclastogenic activity. Next, antigen presenting cells (APC) were pretreated with rIFNγ and cocultured with T cells to induce antigen presentation (AP) driven T cell activation. Pretreatment of APC with rIFNγ markedly increased TNF, RANKL and IFNγ levels in APC/T cell culture media (CM), demonstrating that IFNγ activates T cells via AP. When added to cultures of IFNγR-/- monocytes, rIFNγ pretreated APC/T cell CM increased osteoclastogenesis 2 fold more than control CM. In contrast, rIFNγ pretreated APC/T CM and control CM caused equal OC formation in cultures of WT monocytes. Thus, IFNγ represses OC by targeting monocytes, but stimulates OC by indirectly activating T cells via APC. To determine the effects of IFNγ in vivo, WT, nude, and nude mice reconstituted with WT T cells were injected IP with rIFNγ (10^6 IU/kg, twice a week, for 3 weeks). rIFNγ induced significant bone loss in WT mice (-7.2 %) and nude mice transferred with WT T cells (-9.3 %), but not in nude mice (+1.1 %). rIFNγ also caused a 2-3 fold increase in bone resorption, AP and TNF and RANKL production in T cell replete, but not T cell deficient mice. Thus, in healthy T cell replete mice the net effect of IFNγ is that of increasing bone loss. Next, we examined the role of IFNγ in 3 models of bone loss: ovx, which causes mild T cell activation through AP, LPS treatment, which causes maximal T cell activation through TLR-4, and blunted TGFβ signaling in T cells, which activates T cells both directly and through AP. We found that ovx caused significant T cell activation and bone loss in WT but not in IFNγR-/- mice. In contrast, LPS induced more severe bone loss in IFNγR -/- mice than in WT mice. To investigate the role of IFNγ in conditions of blunted TGFβ signaling in T cells, we adoptively transferred into nude mice T cells insensitive to TGFβ (CD4dnTGFβIIR), T cells lacking both TGFβ signaling and IFNγ (CD4dnTGFβIIR/IFNγ-/-), and WT T cells. Recipients of CD4dnTGFbIIR T cells sustained a bone loss 2 fold greater than hosts of CD4dnTGFβIIR/IFNγ-/- T cells, while recipients of WT T cells had no bone loss. We conclude that IFNγ directly blocks OC formation but indirectly stimulates osteoclastogenesis through AP induced T cell activation. The net effect of IFNγ on bone resorption in vivo depends on the pattern of T cell activation induced by specific disease states.

Mast Cell Deficient Mice Delay the Development of Osteopenia after Ovariectomy. S. Lotinun[1], G. L. Evans*[2], R. T. Turner[1]. [1]Department of Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, [2]Department of Orthopedics, Mayo Clinic, Rochester, MN, USA.

Mast cells produce and secrete proinflammatory cytokines implicated in post-menopausal bone loss and might provide a critical cellular link between estrogen deficiency and increased bone turnover. Mice carrying mutations at the dominant white spotting (*W*) locus coding for the c-*Kit* tyrosine kinase receptor have greatly reduced numbers of tissue mast cells. We utilized mast cell deficient mice, WBB6F1/J-$Kit^{W}Kit^{W-v}$ (W/W^v) to examine the functional role of mast cell as a mediator of ovariectomy (OVX) associated bone loss. Four-week-old female W/W^v mice and wild type (WT) littermates were ovariectomized. Bone mineral density (BMD) and bone mineral content (BMC) of whole body, tibia, femur and lumbar vertebrae were measured at 2, 4, 6, 8 and 10 weeks after OVX using PIXImus small animal densitometer and bone histomorphometry was analyzed at 15 weeks of age. Compared to WT, W/W^v mice had significant decreases in BMD in whole body, tibia, femur and lumbar vertebrae, largely due to a reduction in BMC. Histomorphometry indicated that the cross-sectional, cortical and marrow area of cortical bone were smaller in W/W^v mice. There was no change in double-labeled surface, mineral apposition rate and bone formation rate in cortical bone. Cancellous bone formation rate was suppressed in W/W^v mice compared with WT controls. Four weeks after OVX, a significant reduction in BMD and BMC was observed in all bones of WT. However, mice deficient in mast cells reduced response to OVX, so that by six weeks following OVX, there was no significant difference in BMD and BMC between OVX WT and OVX W/W^v mice. Histomorphometric analysis of cortical and cancellous bone of tibiae indicated less bone mass in OVX WT but not OVX W/W^v mice when compared to corresponding controls. Cancellous bone volume was reduced by 56% in OVX WT compared with WT controls whereas a slight decrease was observed in OVX W/W^v mice. In addition, OVX increased osteoblast surface by 6 fold and osteoclast surface by 2.4 fold in cancellous bone of WT controls but no differences were observed in W/W^v mice. Compared to WT, mast cell deficient mice have a lower peak bone mass and are resistant to OVX induced bone loss. These findings suggest that mast cells or c-*Kit* signaling contributes to normal bone growth and turnover and bone loss after OVX.

Association between Oxidative Stress and Bone and Mineral Metabolism. K. Baek*, M. Kang, S. Shim*, H. Tae*, J. Han, H. Kim*, K. Lee*. St.Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea.

Reactive oxygen species (ROS), such as superoxide and hydrogen peroxide, can cause damage to DNA, protein abd lipids. Oxidative stress has been implicated in a wide variety of disease processes, including atherosclerosis, diabetes, neurodegerative disorders and process of aging. Recently, it has been also suggested that oxidtive stress is causally associated with pathogenesis of osteoporosis. In this study, we investigated the association between the marker of oxidative stress and either the bone turnover markers and bone mineral density (BMD). We also examined the effects of hydrogen peroxide(H_2O_2) on the formation of osteoclasts in human bone marrow cell culture. Oxidative stress was evaluated in serum by measurement of 8-hydroxy-2-deoxyguanosine (8-OHdG) in 135 postmenopausal subjects (68.2 ± 4.9 years, BMI 24.4 ± 2.8). Women who had taken drugs which affect bone metabolism and who had pas history of smoking were excluded. The biochemical markers of bone formation (osteocalcin) and resorption (ICTP) were measured from the same specimen. BMD of lumbar spine, and hip were measured by dual energy X-ray absorptiometry. In multivariate linear regression analyses, the 8-OHdG levels were negatively associated with BMD of lumbar spine, total proximal femur, femoral neck, and trochanter and positively associated with the ICTP levels. Odds ratio(OR) of the 8-OHdG for osteoporosis in lumbar spine and osteoporosis and/or osteopenia in total proximal femur were 1.70 (1.20-2.39, p=0.003) and 1.36 (0.97-1.91, p=0.043), respectively. OR for increased bone resorption was 4.22 (1.44-7.72, p=0.009) in the highest 8-OHdG quantile. In vitro bone marrow cell cultures, H_2O_2 caused a concentration-dependent activation of TRAP positive multinucleated giant cells. H_2O_2 also increased area of pits per dentin slice. RT-PCR measurments of RANKL, OPG, and M-CSF mRNA expression in primary human osteoblasts culture showed that H_2O_2 stimulted the expression of M-CSF and also increased the RANKL/OPG ratio. These findings suggest that oxidative stress is associated with increased bone resorption and low bone mass in healthy women.

Central Nervous Control of Bone Loss in Response to Unloading Is Mediated via Ventromedial Hypothalamus (VMH). K. Hino*[1], A. Nifuji[1], K. Nakashima[1], H. Yamamoto*[2], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Orthopedics, Ehime University, Matsuyama, Japan.

Disuse osteoporosis has been major causes for the fracture risk. However, the mechanisms underlying such unloading induced bone loss have not been fully understood. We hypothesize that ventromedial hypothalamus (VMH) would be the center for the central nervous control of bone loss due to unloading. To test this hypothesis, mice were treated with gold thioglucose (GTG), a compound that destroys neurons in ventromedial hypothalamus (VMH) and were subjected to tail suspension (TS). In GTG-treated mice, GTG treatment was conducted by injection of GTG at 4weeks old. This mice were used at age of 10weeks. Unloading for two weeks reduced trabecular bone volume in saline-treated mice. GTG-treated mice revealed 31% reduction in the basal trabecular bone volume. In contrast to saline-treated mice, TS no longer suppressed the levels of bone volume in GTG-treated mice. Such GTG inhibition of bone loss was not limited to femur as it was observed in vertebral cancellous bone. In terms of cortical bone, bone mass was reduced by TS in saline-treated mice and GTG treatment alone preserved most of the bone mass (6% reduction). In GTG mice, TS failed to suppress cortical bone volume. TS suppressed mineral apposition rate (MAR) by 24% in saline-treated mice. GTG treatment alone reduced MAR by 23%. However, TS again failed to suppress MAR in GTG mice. Similarly, mineralizing surface as well as bone formation rate was all suppressed by TS in saline-treated mice but not in GTG-treated mice. No difference was observed in terms of TS effect on osteoclast surface as well as ostoclast number in either saline or GTG-treated mice. Mineralized nodule formation was suppressed in saline-treated mice by TS but not in GTG treated mice, indicating that the effect of destruction in VMH would be observed at least at cellular levels. Regarding the GTG prevention of TS-induced bone loss, one of the possibility was that bone volume was a at the far bottom level where further suppression may be no longer observed. To test such possibility, we conducted orchidectomy (ORX). In saline-treated mice, ORX suppressed bone mass by 62%. GTG-treatment alone reduced trabecullar bone volume by 31%. However, ORX reduced bone volume further by 51% in GTG-treated mice. This is in contrast to the GTG blockage of the bone loss due to TS. Even in the presence of ORX-induced bone loss, additional TS further reduced bone mass in the absence of GTG treatment, but not in the presence of GTG treatment. Thus, VMH neuron plays the central role in specifically mediating the bone loss due to TS. These data indicate that VMH neuron plays a pivotal role in mediating unloading-induced bone loss.

Ovariectomy Increase the Formation of T Cell Niches at the Resorption Surfaces. F. Grassi, K. Page*, W. Qian*, M. N. Weitzmann, R. Pacifici. Dep of Medicine, Division of Endocrinology, Metabolism and Lipids, Emory University, Atlanta, GA, USA.

It has been reported that T cell produced cytokines are pivotal for stimulating osteoclast (OC) formation and inducing bone loss after ovariectomy (ovx). The mechanism by which ovx augments remodeling is unknown, but it could be that T cell regulate the spatial distribution of remodeling units by secreting factors in discrete niches of the bone marrow (BM). We thus asked whether T cells localize in the proximity of bone surfaces in order to induce OC formation, and whether estrogen regulates the spatial distribution of T cells. Mice were sacrificed 4 weeks after ovx or sham operation and longitudinal sections of femurs and tibiae were immunostained for TRAP (an OC marker) and CD3 (a T cell marker). Video imaging was utilized to delineate the BM area localized within 60 μm from the endosteal surface, which was arbitrarily defined as endosteal BM area. The rest of the BM was defined as central BM. We then analyzed the number of OC and T cells in the total, central and endosteal BM areas. We determined the endosteal BM areas to be 23.6 % of the total BM area. If T cells were randomly distributed then ~ 23.6 % of the T cells should fall within the endosteal BM. We found that the spatial distribution of T cells was not random ($p < 0.05$) and under estrogenic control. In fact, sham mice had 44 ± 2.6 % of their T cells in the endosteal region while ovx mice had 56.4 ± 3.8 % ($p < 0.05$). Attesting to specificity, analysis of total BM cells revealed that the observed BM area occupied by BM cells was identical to the predicted values in both sham and ovx mice. Thus, contrary to T cells, total BM cells are randomly distributed. Next, we asked whether the T cells colocalize with OC. To this aim, we divided cortical endosteal surfaces in segments of 0.3 mm and sorted it according to the surface size covered by OC. In OC poor endosteal areas (OC surface ≤10% of total bone surface) T cells occupied 1.8 ± 0.2 % of the area. In OC intermediate area (OC surface equal to 10 - 30 % of total bone surface) T cells occupied 2.85 ± 0.39 % of the area, while OC rich areas (OC surface ≥30 % of total bone surface) T cells occupied 5.62 ± 0.85 % of the area. Furthermore, the T cell/OC ratio was equal in sham and ovx mice. These findings demonstrate that T cells are found in greater abundance in close proximity to OC. In summary, we show that T cells forms niches in the proximity of remodeling bone surfaces and that ovx increase the localization of T cell nearby areas of active resorption. These data support the hypothesis that T cells activate the resorption of specific bone areas through their accumulation in specially defined endosteal areas.

Arrestins Selectively Regulate the Inhibitory Effects of Adrenergic Agonists on Bone and Fat. D. Pierroz[1], E. Bianchi*[1], D. Manen*[1], R. Rizzoli[1], M. L. Bouxsein[2], S. L. Ferrari[1]. [1]Div. of Bone Diseases, Geneva University Hospital, Geneva, Switzerland, [2]Orthopedic Biomechanics Lab., Beth Israel Deaconess Med. Center and Harvard Med. School, Boston, MA, USA.

Stimulation of ß2 adrenergic receptors (ß2AR) expressed in osteoblasts has been reported to decrease trabecular bone volume. Cytoplasmic arrestins (ßarr) play a central role in the desensitization of ß2AR-mediated signaling in vitro, and we previously found that ßarr2 KO mice have low bone mass and micro-architecture. We hypothesized that these skeletal alterations could reflect poor regulation of adrenergic activity in bone in absence of ßarr2. For this purpose, 6-wk-old male wild-type (WT) and ßarr2 KO mice were treated with isoproterenol (ISO, 10mg/kg/d), a non-specific ßAR agonist, or vehicle (VEH) (n=4-6/group). Total body (TB), spine (Sp.) and femur (Fem.) BMD, and % fat were evaluated by pDXA after 0, 4 and 8 wks, whereas trabecular (Tb) and cortical (Cort.) micro-architecture at the distal and mid-femur was evaluated after 8 wks by mCT. TB, Sp. and Fem. BMD were significantly lower in KO than WT mice ($p=0.002$-0.014 by repeated measures ANOVA), although these differences were observed only in the VEH group. Indeed, ISO significantly decreased TB and Fem. BMD after 4 and 8 wks in WT ($p<0.05$) but not in KO ($Pinteraction<0.05$), and decreased Sp. BMD more prominently in WT (-24%) than KO (-12%) after 8 wks ($Pinter.=0.05$). Hence, after ISO treatment, BMD became as low in WT as in KO mice. In contrast, percentage fat mass did not differ between KO and WT mice and was significantly decreased by ISO ($p=0.02$) in both KO and WT ($Pinter=ns$). In the femur, Tb. BV/TV and Tb. Number, cort. cross-sectional area, bone area, marrow area and cort. thickness were significantly lower in KO than WT ($p=0.003$-0.029 by 2F-ANOVA), but again these differences were observed only in VEH groups. Indeed, ISO-induced inhibition of bone architecture was more prominent and/or significant in WT than KO ($Pinter=0.008$-0.10). Quantitative RT-PCR showed that arrestins were similarly expressed in bone and fat. However, only ß2AR was expressed in bone, whereas in fat, ß3AR was more prominently expressed than ß2AR and ß1AR. These results indicate that inhibition of bone mass and architecture by adrenergic agonists is blunted in absence of ßarrestin2 and suggest that skeletal alterations in ßarr2 KO mice may reflect improper regulation of adrenergic activity in bone. In contrast, adrenergic effects on fat are independent of ßarr2, consistent with the fact that they are primarily mediated by the ß3AR which does not interact with arrestins. Hence, interactions between ßAR and arrestins selectively regulate the inhibitory effects of adrenergic stimulation on bone and fat.

PPAR Antagonist Prevents Type I Diabetic Bone Adiposity and Bone Loss. S. Botolin*, L. R. McCabe. Physiology, Michigan State University, East Lansing, MI, USA.

Diabetes type I is associated with an increased risk for osteoporosis. Correspondingly, we demonstrated that streptozotocin induced type I diabetes in mice is associated with significant bone loss marked by suppressed osteoblast maturation (reduced osteocalcin mRNA levels and mineralization). A second component of the skeletal response to type I diabetes involves an induction of marrow adiposity marked by increased tibial PPARgamma2 (PPARg2) and aP2 mRNA levels. The purpose of this study is to test if prevention of cellular progression toward an adipocyte-like phenotype will ameliorate diabetic bone loss. Methods: Streptozotocin-induced adult diabetic mice were treated with vehicle or a PPARg antagonist. At 5, 14, 21, and 28 days post-induction of diabetes, tibias, serum, femoral fat pads and livers were harvested from control, control plus PPARg antagonist, diabetic and diabetic plus PPARg antagonist treated mice. Tibias were analyzed for bone mineral density (by uCT), histomorphometry (adiposity) and mRNA levels of osteoblast and adipose markers. Serum glucose, triglycerides and osmolality were also determined. Results: While untreated diabetic tibias showed a dramatic loss in bone mineral density and an increase in adiposity compared to controls, treatment with a PPARg antagonist prevented the diabetes-induced changes. These findings were supported by gene expression and morphometric analyses. Specifically, diabetic mice receiving PPARg antagonist treatment exhibited tibial PPARg2, aP2 and resistin mRNA levels that were no longer significantly different from controls. Treated mice also exhibited diminished bone loss. Interestingly, serum triglyceride levels were decreased in diabetic mice treated with the PPARg antagonist when compared with untreated diabetic mice. Conclusions: PPARg antagonist treatment rescues the osteoporotic phenotype and osteogenic gene expression, while inhibiting the adipogenic phenotype and gene expression in diabetic mouse tibias. These findings demonstrate a relationship between adiposity and bone loss, and suggest that bone adiposity plays an active role in the regulation of bone mineral density.

Decreased Defense against Reactive Oxygen Species: A Common Pathogenetic Mechanism of the Effects of Aging and Estrogen Deficiency on Bone. S. C. Manolagas, M. Almeida, L. Han, R. Weinstein, R. Jilka, T. Bellido, C. O'Brien, S. Kousteni. Div. Endocrinol., Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas Med. Sci., Little Rock, AR, USA.

The molecular and cellular mechanisms of the adverse effects of aging on bone and the extent to which estrogen deficiency contributes to the age-related bone loss are unknown. Nonetheless, recent evidence indicates that the pro-apoptotic effects of estrogens on

osteoclasts and their ability to suppress osteoclastogenesis as well as their anti-apoptotic effect on osteoblasts are mediated via cytoplasmic kinases and require non-protein thiols, such as glutathione. Based on this and mounting evidence that increased levels of reactive oxygen species (ROS) represent a major mechanism of aging and age-related diseases, we have searched for a mechanistic link among aging, ROS, estrogens, cytoplasmic kinases, and the birth and death of bone cells. We report that female C57BL/6 mice lose bone strength and mass progressively between the ages of 8 and 31 months. Importantly, the loss of strength is detectable 9 months before the loss of BMD, and is correlated with aging independently of BMD. These changes are temporally associated with increased osteoblast apoptosis; decreased glutathione reductase (GSR) activity; increased levels of ROS in the bone marrow; and a corresponding increase (in lysates from vertebrae) in the phosphorylation of Ser36 of the $p66^{shc}$ adapter protein, which is part of a signal transduction pathway that is activated by increased intracellular ROS and leads to apoptosis. In line with these findings, H_2O_2 stimulated the phosphorylation of $p66^{shc}$ in OB-6 osteoblastic cells, and this effect was suppressed by 10^{-8} M of E_2 or estren. In addition both compounds rapidly inhibited H_2O_2-induced expression of ATF4 - a substrate of Rsk2 and an integral component of a negative feedback pathway controlling amino acid import leading to synthesis of glutathione. Importantly, $p66^{shc}$ phosphorylation increased 5 d following ovx in wild type controls as well as $ER\alpha^{NERKI/-}$ mice in which the ERα is incapable of DNA binding strongly suggesting that $p66^{shc}$ phosphorylation is negatively regulated by estrogens *in vivo*, and that this effect is mediated via a nongenotropic mechanism of ERα action. Based on these results we hypothesize that increased ROS levels with advancing age is a fundamental mechanism of the age-dependent decline of bone strength and mass, and loss of estrogens exaggerates the adverse effects of aging on bone by decreasing defense against ROS, thereby, contributing perpetually to the loss of bone mass and strength that persists for decades after menopause, and is associated with old age.

Relating Increases in Bone Mineral Density and Fracture Risk Reduction with Early Suppression in Biomarkers of Bone Turnover: A Literature-Based Meta-Analysis of Bisphosphonate Treatments. M. Crane*[1], T. Davis*[2], R. Kaldate*[3], C. Black*[1], R. Davies*[1], V. Devas*[1], W. Williams*[1]. [1]GlaxoSmithKline, Collegeville, PA, USA, [2]ClinForce, RTP, NC, USA, [3]Smith Hanley, New York, NY, USA.

The relationship between bisphosphonate-related suppression of bone turnover markers and corresponding increases in bone mineral density (BMD) and fracture risk reduction is unclear. This meta-analysis further explores the nature of these relationships. Data on vertebral fracture rates, spine BMD and five biomarkers were obtained from 85 studies identified by a literature search. Spearman's correlations were computed to assess the strength of the associations. Linear regression on log-transformed values was used to model the changes from baseline in BMD at 6 and 12 months as functions of change from baseline in biomarkers at 1, 3 and 6 months, respectively. A nonlinear cumulative risk model was used to relate vertebral fracture rates over 24 to 36 month time periods with biomarker changes as factors. For each biomarker, the correlation with BMD showed a moderate to strong association (r: 0.63 to 0.90). In particular the association was strong for changes at 3 and 6 months in bone specific alkaline phosphotase (BSAP), osteocalcin (OC) and uNTX, and at 1, 3, and 6 months for uCTX and sCTX. Of particular interest is that correlation was highest (r=0.90) for the month 1 assessment of sCTX (**Figure**). Linear regression in all cases showed a positive association between BMD gains and biomarker suppression. The analysis for modeling the fracture risk rate, although based on fewer studies than the BMD analysis reported above, indicated that lower fracture rates were significantly ($p<0.05$) associated with greater decreases from baseline for OC, uCTX and uNTX. However, the confidence intervals for odds ratios were too wide for quantitative prediction in most cases. In summary, a strong relationship is present between BMD gains and early suppression in each biomarker, especially at month 1 for markers of bone resorption. This result suggests that studies of duration as short as one month may be sufficient for estimating the effect of a bisphosphonate on resorption. Lower vertebral fracture rates are also significantly associated with early suppression in most biomarkers. However, our results are not sufficient to suggest the use of biomarkers as surrogate markers for fracture rate.

Increased Turnover after Discontinuing Alendronate Predicts Bone Loss over 5 Years: The FLEX Study. D. C. Bauer[1], A. Schwartz[1], M. C. Hochberg[2], A. C. Santora[3], L. Palermo*[1], D. M. Black[1]. [1]Epidemiology and Biostatistics, UCSF, San Francisco, CA, USA, [2]Medicine, University of Maryland, Baltimore, MD, USA, [3]Merck Research Laboratory, Rahway, NJ, USA.

Bone turnover increases after discontinuation of alendronate therapy, but the relationship between short-term changes in turnover and long-term skeletal outcomes is unknown. The effects of discontinuation of alendronate on bone turnover markers, bone loss, and fracture were investigated in the FIT Long-Term Extension (FLEX) Trial among women who had previously used alendronate for an average of 5 years but received placebo in FLEX. Among the 1099 FLEX subjects who had previously received alendronate (ALN) during the Fracture Intervention Trial (FIT), 437 (40%) were randomized to receive placebo for an additional 5 years. Hip BMD was measured at FLEX baseline and at yearly visits. Clinical fractures were centrally adjudicated by review of x-ray reports or radiographs, and morphometric vertebral fractures were detected on paired radiographs obtained at baseline and after 5 years. Serum Bone ALP (Ostase, Hybritech) and urine NTX/Cr (Ostex) were measured at the FLEX baseline visit and after 1 year. Among placebo-treated women in FLEX, the mean (SD) age at baseline was 73.7 (5.9), mean (SD) total hip BMD was 0.72 (0.09), and geometric mean (SD) levels of Bone ALP and NTX were 9.1 (3.4) ng/ml, 19.6 (12.9) nmol/mmol Cr, respectively. After 1 year of placebo, Bone ALP and NTX increased by 17.1% (95% CI: 14.2, 20.1) and 23.3% (95% CI: 17.3,29.6), respectively. Greater 1-year absolute increases in Bone ALP were associated with greater hip bone loss over 5 years (Figure); results were similar for NTX (p trend = 0.03). Relationships between change in turnover and incident non-spine fracture (n=82) were inconsistent, perhaps due to small numbers, but there was a trend towards a larger increase in NTX among those with non-spine fracture compared to those without fracture (35.2% vs. 20.7%, p=0.075). In summary, among postmenopausal women that discontinue long-term alendronate therapy, short-term increases in bone turnover are associated with higher rates of bone loss over 5 years. Additional studies are needed to determine if increased turnover after discontinuing alendronate is associated with increased fracture risk.

Human Farnesyl Diphosphate Synthase (FDPS): Crystal Structure and Molecular Interactions with Nnitrogen-Containing Bisphosphonates. K. Kavanagh*[1], K. Guo*[1], X. Wu*[1], S. Knapp*[1], F. H. Ebetino[2], J. E. Dunford[3], M. J. Rogers[3], R. G. G. Russell[4], U. Oppermann*[1]. [1]Structural Genomics Consortium, Botnar Research Centre, University of Oxford, OXFORD, United Kingdom, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [3]Bone Research Group, Institute of Medical Sciences,University of Aberdeen, Aberdeen, United Kingdom, [4]Nuffield Dept Orthopaedic Surgery, Botnar Research Centre, University of Oxford, OXFORD, United Kingdom.

Farnesyl diphosphate synthase (FDPS) is a key regulatory enzyme in the mevalonate pathway that produces sterols and isoprenoid lipids. FDPS is now known to be the major molecular target of nitrogen-containing bisphosphonates (N-BPs), and the consequent inhibition of prenylation of several GTPases by N-BPs in osteoclasts leads to disruption of their resorptive activity and survival. The active site of FDPS contains two substrate-binding sites (for GPP/DMAPP, geranyl pyrophosphate/dimethyl allyl pyrophosphate, and for IPP, isopentenyl pyrophosphate), but the precise way in which BPs act on FDPS remains unresolved. Previous modeling and kinetic studies have indicated that N-BPs might inhibit the binding of both substrates. We report here for the first time the crystal structure of human FDPS. In order to define the molecular interactions, human FDPS was co-crystallized with the potent N-BP, risedronate. The 2.0Å structure of human FDPS in complex with Mg^{2+} and the tight-binding inhibitor, risedronate (Kd: 160 nM), shows the binding mode for this important class of inhibitors. Risedronate occupies the chain-elongation site as predicted, but not the IPP site. Two aspartate clusters chelate the Mg^{2+} ions that mediate ligand binding and are involved in catalysis. However, contrary to predictions suggesting two inhibitor-binding sites on FDPS, current studies using isothermal titration calorimetry (ITC), revised kinetic analysis, as well as the crystal structure itself, indicate a one-to-one stoichiometry, with risedronate being a strong inhibitor of the binding of the GPP substrate (IC_{50}: 10.3±0.07nM). The ITC experiments reveal that bisphosphonate binding to FDPS is predominantly entropy driven. These results

will further the understanding of structure-activity relationships among N-BPs and FDPS, and will enable optimization of their pharmacological potential.

Human FDPS in complex with risedronate

Efficacy of Intravenous Ibandronate Injections in Postmenopausal Osteoporosis: 1-Year Findings from DIVA. M. Bolognese[1], D. M. Reid[2], B. Langdahl[3], C. Hughes*[4], P. Ward*[4], D. Masanauskaite*[4], W. P. Olszynski[5]. [1]Bethesda Health Research, Bethesda, MD, USA, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]Århus Amtssygehus, Århus, Denmark, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]Midtown Medical Center, Saskatoon, SK, Canada.

Intravenous (i.v.) bisphosphonate injections may provide a useful alternative for women with postmenopausal osteoporosis (PMO) who are unable to use or tolerate oral bisphosphonates. Ibandronate (Boniva), a potent, nitrogen-containing bisphosphonate, can be administered with extended dosing intervals, either orally or by rapid (15-30 seconds) i.v. injection. DIVA, a double-blind, double-dummy, phase III study involving 1,395 women (aged 55-80 years; ≥5 years postmenopause) with PMO (lumbar spine [L2-L4] BMD T-score <-2.5 and ≥-5), is ongoing to establish the optimal i.v. ibandronate dose regimen. In this study, participants are receiving either 2mg every 2 months (q2mo) or 3mg every 3 months (q3mo) i.v. ibandronate injections or an active comparator regimen of proven efficacy (2.5mg daily oral ibandronate; 3-year vertebral fracture risk reduction: 52%). Daily calcium (500mg) and vitamin D (400IU) supplements are also provided. One-year results demonstrated lumbar spine BMD increases (primary study endpoint) of 5.1%, 4.8% and 3.8% in the q2mo, q3mo and daily groups, respectively. Versus the established daily regimen, both i.v. regimens were proven statistically non-inferior (1% margin) and superior ($p<0.001$). Increases in total hip, femoral neck and trochanter BMD were also larger in both i.v. arms than the oral arm. At 1 year, residual levels of the biochemical marker of bone resorption serum CTX were decreased substantially in all treatment arms: -64.6% in the q2mo group, -58.6% in the q3mo group and -62.6% in the daily group. In conclusion, i.v. ibandronate injections are at least as effective in increasing BMD as a daily oral regimen with proven antifracture efficacy in women with PMO. A pre-planned 2-year analysis will further explore the efficacy and safety of these regimens. I.v. ibandronate injections are likely to be of significant utility for women in whom oral bisphosphonates cannot be used.

Alendronate Has an Anabolic Effect on Bone through the Differentiation of Mesenchymal Stem Cells. G. Duque[1], D. Rivas*[2]. [1]Medicine/Geriatrics, McGill University, Montreal, PQ, Canada, [2]Center Bloomfield for Research in Aging, McGill University, Montreal, PQ, Canada.

Introduction: Alendronate has demonstrated its effectiveness in preventing bone loss in post-menopausal patients through the regulation of osteoclastic activity. However, it has also proven to be effective in elderly populations where instead of high osteoclastic activity the predominant mechanism of bone loss is the ineffective differentiation of mesenchymal stem cells (MSC) with a subsequent deficit in osteoblastogenesis. The aim of this study is to determine the effect of alendronate on bone MSC differentiation which may suggest a potential anabolic effect of Alendronate in bone. **Hypothesis:** The effect seen in the Alendronate treatment of senile osteoporosis is explained by its anabolic effect either by the inhibition of the adipogenic or the stimulation of osteogenic differentiation of MSCs. **Methodology**: Human MSCs (BioWhittaker) were plated at a density of 5 x 10^5 cells per well in 150 cm^2 dishes containing mesenchymal stem cell growth medium. After the cells reached 60% confluence, medium was replaced with MSC growth medium, adipogenic or osteogenic medium with and without vitamin D (10^{-8} M) and supplemented with Alendronate at increasing concentrations (10^{-10}M to 10^{-7}M).Untreated differentiating MSCs were used as control. The drugs were present in the cultures for 21 days of both osteogenic and adipogenic stimulation. Alkaline phosphatase (ALP), oil red O and Alizarin red staining were performed at timed intervals (week 1, 2 and 3). Additionally, the expression of Cbfa1 and PPARγ2 was also measured in protein extracts. **Results:** We found that Alendronate has a significant effect on ALP activity ($p<0.01$), on MSC proliferation ($p<0.001$), and on cell-mediated mineralization ($p<0.01$). This effect was highly significant at 10^{-8M} of Alendronate and was potentiated by the presence of vitamin D in the medium ($p<0.001$). Additionally, the expression of Cbfa1 quantified by densitometry was significantly increased in MSC treated with both Alendronate alone ($p<0.01$) and Alendronate+vitamin D ($p<0.001$) as compared to vitamin D alone or non-treated cells. Finally, PPARγ2 expression was only reduced in MSC in adipogenic medium containing both Alendronate and vitamin D. This effect was associated with a lower number of lipid droplets. **Conclusion:** This study shows a potential anabolic effect of alendronate on bone through the stimulation of osteogenic differentiation of MSC. Additionally, this effect is also potentiated by the addition of vitamin D to the Alendronate-treated cells. Finally, a potential inhibitory effect of Alendronate in bone marrow adipogenesis was also seen when combined with vitamin D

Influence of Alendronate on Periosteal and Endocortical Bone formation in the Ilium of Osteoporotic Women. S. Bare*[1], S. Recker[1], R. Recker[1], D. Kimmel[2]. [1]Creighton University, Omaha, NE, USA, [2]Molecular Endocrinology, Merck & Co., West Point, PA, USA.

Alendronate (ALN) increases bone mineral density (BMD), reduces bone resorption markers, and reduces hip and vertebral fracture risk in post-menopausal osteoporotic women. Our purpose is to document the bone envelope-specific effects of ALN in humans using transilial biopsy specimens (TIBx). Post-menopausal osteoporotic women with T-scores <-2 were treated for 1-2yrs with Placebo (PBO), 1, 2.5, or 5mg/d ALN orally. TIBx were obtained from 137 subjects at the end of treatment following double fluorochrome (Fl) labeling. The specimens were examined for total surface (BS), single (1XL), and double (2XL)-Fl labeled surface, and mineral apposition rate (MAR) in periosteal (Ps) and endocortical (Ec) envelopes. 2XL/BS was calculated omitted those individuals without 2XL. Kruskal-Wallis ANOVA with Student-Neuman Keuls post-hoc testing (P<.05, *; P<.001, **) was applied to all endpoints for each envelope.

Osteoporotic Women treated with Alendronate					
Envelope (Group)	Surface (mm)	% with 2XL	% with Any Label	2XL/BS (%)	MAR (μm/d) (N)
Ps(PBO)	30±9	39	77	1.35±0.99	0.80±0.34 (15)
Ps(1mg/d)	31±8	34	81	0.96±0.78	0.77±0.46 (11)
Ps(2.5mg/d)	28±8	31	83	1.27±1.26	0.79±0.39 (11)
Ps(5mg/d)	29±8	31	62	2.06±1.53	0.71±0.16 (9)
Ec(PBO)	33±9	92	97	6.11±4.74	0.73±0.21 (36)
Ec(1mg/d)	34±9	78	91	3.40±3.12*	0.82±0.38 (25)
Ec(2.5mg/d)	31±9	63*	77*	2.50±1.91*	0.78±0.34 (22)
Ec(5mg/d)	32±8	28**	59*	3.24±3.20*	0.70±0.08 (8)

The percentage of PBO subjects with Ps 2XL was ~40%, vs. ~90% with Ec 2XL. 2.5 and 5mg/d ALN reduced the percentage of subjects with Ec 2XL by 32-70%. Ec 2XL/BS was decreased by all ALN doses. In contrast, ALN had no significant effect on either Ps envelope population labeling percentage or 2XL/BS. The Ec results were similar to those for the trabecular envelope (data not shown). **Conclusion:** Quantitative analysis of the TIBx can reveal differences in the way various bone envelopes behave during treatment with bone active agents. The Ps envelope has a much lower, perhaps 10-fold, rate of bone formation than the Ec envelope. The Ec, but not the Ps, envelope responds to ALN by decreasing its rate of bone formation. The Ps envelope of osteoporotic women has a low, but measurable level of bone formation that is not affected by ALN. These data suggest that ALN positively affects cortical bone by permitting customary periosteal expansion, while slowing the rate of Ec bone remodeling, an action that slows bone loss, from the Ec surface.

Calcium and Vitamin D_3 Fortified Milk Reduces Bone Loss at Clinically Relevant Skeletal Sites in Older Men: A 2-year Randomised Controlled Trial. R. M. Daly, M. Brown*, S. Bass, S. Kukuljan*, C. Nowson*. School of Exercise and Nutrition Sciences, Deakin University, Melbourne, Australia.

Osteoporosis and its related problems are now recognised as an increasing public health problem in men. This highlights the importance of identifying lifestyle interventions that are effective at maintaining bone mass and bone strength in men. The aim of this study was to examine the effect of milk fortified with additional calcium (milk minerals, 1000 mg/d of Ca) and vitamin D_3 (800 IU/d) on BMD, geometry and strength in men aged over 50 yrs. This was a 2 yr RCT in which 167 men were randomly assigned to receive either 400 mls of low fat (<1%) UHT fortified milk per day or to a control group receiving no additional milk. aBMD was assessed every 6 mths by DXA; L1-L3 trabecular vBMD and mid-femur total, cortical and medullary area, and cortical vBMD were assessed at baseline and 24 mths by QCT (n=110). Data were analysed using pooled time series regression analysis for longitudinal data with random effect models. Baseline characteristics between the groups were no different. Mean (±SD) dietary Ca intake at baseline was 941 ± 387 mg/d and mean serum 25(OH)D was 77 ± 23 nmol/L. A total of 149 men completed the study, and compliance with the fortified milk averaged 88%. At the FN, total hip and UD radius, the loss in aBMD was 0.9% to 1.6% less in the milk compared to control group (Figure). No differences were detected for L2-L4 aBMD after 24 mths. Both groups experienced a similar and significant reduction in L1-L3 trabecular vBMD [milk 2.5%; control 2.4%, both $p<0.05$]. In contrast, the reduction in mid-femur cortical vBMD was less in the milk compared to control group [1.5% vs 2.5%, interaction $p=0.06$]. Mid femur medullary area remained unchanged in the milk group [-0.04 ± 2.6%] but increased by 0.85 ± 2.9% [$p=0.06$] in controls [interaction, $p=0.12$]. Serum 25(OH)D levels increased and PTH

decreased in the milk relative to control group after 12 mths [net difference 25(OH)D 29.0%; PTH -17.4%, both p<0.001]. These differences remained after 24 mths. Body weight remained unchanged in both groups. In conclusion, supplementing the diet of men aged over 50 with 400 mls of low fat milk fortified with calcium and vitamin D_3 may represent a simple, inexpensive and effective strategy to increase dietary calcium and vitamin D levels to stop or slow age-related bone loss at clinically important skeletal sites.

Effects of Raloxifene or Alendronate on Fracture Risk Reduction: Results from the EVA (Evista®/Alendronate Comparison) Trial. R. Recker[1], D. Kendler[2], C. Recknor[3], T. Rooney[4], E. M. Lewiecki[5], W. H. Utian*[6], J. Cauley[7], J. Lorraine*[8], Y. Qu*[8], P. M. Kulkarni*[8], L. Plouffe*[8], J. L. Stock[8]. [1]Creighton Univ., Omaha, NE, USA, [2]Osteoporosis Research Centre, Vancouver, BC, Canada, [3]United Osteoporosis Center, Gainesville, GA, USA, [4]Mercy Arthritis & Osteoporosis Center, Des Moines, IA, USA, [5]New Mexico Clinical Reseach & Osteoporosis Center, Albuquerque, NM, USA, [6]Rapid Medical Research, Cleveland, OH, USA, [7]University of Pittsburgh, Pittsburgh, PA, USA, [8]Eli Lilly, Indianapolis, IN, USA.

EVA is the first head-to-head, double-blind, randomized trial designed to compare 2 osteoporosis therapies for fracture risk reduction efficacy. The original protocol planned to treat 3000 postmenopausal women [50-80 yr old, femoral neck BMD NHANES T-score ≥-4.0 to ≤-2.5, no prevalent vertebral fractures (VF), no prior bone-active agent use] with raloxifene 60 mg/d (RLX) or alendronate 10 mg/d (ALN) for 5 yr. The primary endpoint was the number of women with ≥1 new osteoporotic VF or nonvertebral fracture (NVF), assessed by a central reader. EVA was stopped early, due to difficulty in finding treatment-naïve women to meet enrollment goals within the planned timeline, resulting in insufficient power to show noninferiority of RLX to ALN. Analyses of fractures (Table), except VF, were based upon 1412 of the 1423 women randomized (mean age 66 yr). After 312 ± 254 (mean ± SD) days, fracture risks were not different between groups (Table), except for moderate/severe VF, a pre-specified endpoint, which occurred in fewer women in the RLX group. BMD increases at 2 yr differed from baseline and between groups (P<0.05), at the lumbar spine (ALN 5.4%, RLX 2.5%), femoral neck (ALN 3.9%, RLX 2.3%), and total hip (ALN 3.9%, RLX 1.8%). Similar numbers of women in each group had ≥1 adverse event (AE) and discontinued due to an AE. The only AEs that differed between groups were colonoscopy, diarrhea, and nausea (each P<0.05); each was more common with ALN. In the RLX group, 1 woman had a pulmonary embolism, 1 in the ALN group had a deep venous thrombosis, and 1 in each group developed breast cancer. In summary, these limited data show no between-group differences in overall fracture risk. There are significant BMD changes between groups. Safety profiles are as expected from trial and post-marketing reports.

Type of Fracture	Women with ≥ 1 New Fracture, n(%)		
	ALN (N=713)	RLX (N=699)	ALN vs. RLX RR (95% CI) or P-Value [a]
Vertebral or Nonvertebral	22 (3.1)	20 (2.9)	1.08 (0.60, 1.95)
Vertebral [b]	8 (3.1)	5 (1.9)	1.63 (0.57, 5.70)
-Moderate/ Severe Vertebral [b]	4 (1.6)	0	P=0.04
-Clinical Vertebral	3 (0.4)	0	P=0.10
Nonvertebral	14 (2.0)	15 (2.2)	0.92 (0.45, 1.86)
-Nonvertebral-Six [c]	11 (1.5)	10 (1.4)	1.08 (0.47, 2.46)
-Hip	1 (0.1)	2 (0.3)	0.49 (0.04, 3.77)
-Wrist	6 (0.8)	8 (1.1)	0.74 (0.27, 2.02)

[a] Exact unconditional test
[b] ALN n=255; RLX n=259
[c] Clavicle, humerus, wrist, pelvis, hip, leg

Lasofoxifene Increased BMD of the Spine and Hip and Decreased Bone Turnover Markers in Postmenopausal Women With Low or Normal BMD. M. McClung[1], E. Siris*[2], S. Cummings[3], H. Bone[4], R. Recker[5], P. Delmas[6], J. Zanchetta*[7], M. Lewiecki[8], C. Zerbini*[9], S. Miller*[10], K. Wolter[11], J. Proulx[11], R. Brunell*[11], D. Radecki[11]. [1]Oregon Osteoporosis Center, Portland, OR, USA, [2]NY Presbyterian Hosp-Columbia Univ, New York, NY, USA, [3]San Francisco Coordinating Ctr, San Francisco, CA, USA, [4]Michigan Bone and Mineral Clinic, Detroit, MI, USA, [5]Creighton Univ, Omaha, NE, USA, [6]Univ Claude Bernard, Lyon, France, [7]Instituto de Investigaciones Metabolicas, Buenos Aires, Argentina, [8]New Mexico Clinical Research & Osteoporosis Ctr, Albuquerque, NM, USA, [9]Hospital Helopolis, Sao Paulo, Brazil, [10]SAM Clinical Research Center, San Antonio, TX, USA, [11]Pfizer Global Research and Development, New London, CT, USA.

Increased bone mineral density (BMD) and reduced bone turnover markers have been reported in Phase 2 trials with lasofoxifene, a new SERM. We report the pooled results from two identical Phase 3, double-blind trials. 1907 postmenopausal women (lumbar spine T-score 0 to -2.5) were randomized to lasofoxifene 0.025 mg/d, 0.25 mg/d, or 0.5 mg/d or placebo (PBO) daily for 2 years. They also received daily calcium and vitamin D. The primary endpoint, change in L1-L4 lumbar spine BMD at 2 years, was evaluated using an *a priori* fixed sequence multiple comparisons procedure on data pooled from both studies. At 2 years, patients treated with 0.025 mg/d, 0.25 mg/d, or 0.5 mg/d lasofoxifene had a significant increase in lumbar spine BMD from baseline: 1.5%, 2.3%, and 2.3%, respectively ($p \leq 0.001$) compared with a decrease of 0.7% with placebo. All 3 lasofoxifene doses significantly increased BMD of the total hip and its subcomponents ($p \leq 0.001$ vs. PBO). Lasofoxifene significantly increased BMD of the lumbar spine and total hip for all 3 doses at 6 and 12 months. At 6 and 24 months, lasofoxifene groups exhibited significant decreases in bone turnover markers vs. PBO. Median percent changes from baseline at 6 m for 0.025 mg/d, 0.25 mg/d and 0.5 mg/d lasofoxifene (underlined) and PBO respectively were osteocalcin: -9.40%, -22.5%, -20.8%, 5.71%; CTX: -37.5, -49.9%, -50.9%, -0.43; and P1NP: -30.0%, -40.5%, -40.5%, -4.6% ($p \leq 0.001$). Bone biopsies in lasofoxifene-treated subjects showed bone of normal quality. Overall, lasofoxifene was generally safe and well-tolerated. Adverse events often reported included hot flushes, leg cramps, and increased vaginal moisture. In postmenopausal women with low or normal BMD, lasofoxifene treatment significantly increased lumbar spine and hip BMD and decreased bone turnover markers, with beneficial changes observed as early as 6 months. Lasofoxifene may be an appropriate therapy for the prevention of bone loss in postmenopausal women.

Intermittent Administration of Human Parathyroid Hormone Enhances Bone Formation and Bone Union at the Site of Cancellous Bone Osteotomy in Normal and Ovariectomized Rats. K. Nozaka, N. Miyakoshi, Y. Kasukawa, S. Maekawa, H. Noguchi, E. Itoi. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Intermittent administration of human parathyroid hormone (hPTH) has been reported to promote bone formation acting on osteoblasts and their precursor cells. The hPTH treatment also has been shown to enhance fracture healing and callus formation on cortical bone in animals. However, little is known about the effects of hPTH on cancellous bone healing. Therefore, the purposes of this study were: 1) to evaluate whether intermittent administration of hPTH enhances bone formation and bone union at the site of cancellous bone osteotomy; and 2) to elucidate the mechanisms of hPTH effects on bone marrow cells at and around the site of osteotomy. Following a cancellous bone osteotomy performed at the left proximal tibia in seven-month-old Wistar rats with ovariectomy (OVX) or sham-operation, hPTH (1-34) (100μg/kg) or its vehicle was administered subcutaneously once a week for 4 weeks. One week after the final administration, bilateral tibiae were harvested for decalcified histologic sections. The right tibiae were used as a non-operated control. In addition to the conventional bone histomorphometry, the adipocyte volume (AV/MV; %) and the number of adipocyte per marrow volume (N.A/MV; /mm^2) were measured to evaluate the amount of fat tissue in bone marrow. The percentages of proliferating cell nuclear antigen (PCNA) positive cells in bone marrow cells were also evaluated. hPTH treatment decreased AV/MV and N.A/MV in the OVX group, and increased 1) bone formation and volume both in the sham-operated and OVX groups, 2) the percentage of PCNA positive cells both in the sham-operated and OVX groups, 3) PCNA positive cells at the osteotomy site more than non-osteotomy site in the OVX group, and 4) bone union rate both in the sham-operated and OVX groups. These results suggested that: 1) the hPTH treatment increased osteoblastogenesis and decreased adipocytogenesis at the site of cancellous bone osteotomy; and 2) hPTH might have a selective action in promoting bone union at the site of cancellous bone osteotomy. We conclude that intermittent administration of hPTH enhances bone formation and bone union at the site of cancellous bone osteotomy by, at least in part, a local regulation of bone formation in normal and OVX rats.

Treatment of Postmenopausal Osteoporotic Women with Parathyroid Hormone 1-84 for 18 Months Improves Trabecular Bone Architecture: A Study of Iliac Crest Biopsies Using Micro-Computed Tomography. D. W. Dempster*[1], I. A. Moreau*[2], A. Varela*[2], S. Y. Smith*[2], L. G. Ste-Marie*[3], J. Fox*[4], M. K. Newman*[4], R. R. Recker*[5]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]CTBR, Senneville, PQ, Canada, [3]Centre de Recherche du CHUM - Hospital Saint-Luc, Montreal, PQ, Canada, [4]NPS Pharmaceuticals, Salt Lake City, UT, USA, [5]Creighton University, Omaha, NE, USA.

Iliac crest biopsies were obtained from postmenopausal osteoporotic women enrolled in the TOP Study after 18 months of daily sc injections of placebo or 100 μg parathyroid hormone 1-84 (PTH). All subjects received daily treatment with calcium (700 mg) and vitamin D (400 IU). There were no significant differences between groups in age, weight, bone turnover markers, or spine and hip bone mineral density at baseline. Recently we reported (ASBMR, 2004) results of quantitative histomorphometry in these biopsies. Relative to placebo-treated subjects, cancellous bone volume (Cn.BV/TV), was 48% higher in subjects treated with PTH. This increase could be accounted for by increases in trabecular number (Tb.N) (24%) and thickness (Tb.Th) (17%) which resulted in a 21% decrease in trabecular separation (Tb.Sp). Prior to sectioning for histomorphometry, the biopsies (n = 8 / group) were subjected to micro-computed tomography (Micro-CT 20, Scanco Medical, AG). The values for trabecular structure obtained by μCT were very similar to those obtained by histomorphometry. Compared to placebo-treated subjects, mean Cn.BV/TV was 45% higher in PTH-treated subjects (PTH = 23.3% ± 2.0 vs placebo = 16.1% ± 1.4; $P = 0.036$). The higher Cn.BV/TV was the result of 12% and 17% increases, in mean Tb.N (PTH = 1.40/mm ± 0.06, placebo = 1.25/mm ± 0.04; $P = 0.093$) and mean Tb.Th (PTH = 186 μm ± 12, placebo = 159 μm ± 11; $P = 0.128$), respectively, with a 10% lower mean Tb.Sp (PTH = 696 μm ± 27, placebo = 771 μm ± 23; $P = 0.036$). Importantly, mean connectivity density (Conn.D) was 22% higher (PTH = 4.81/mm^3 ± 0.34, placebo = 3.93/mm^3 ± 0.52; $P = 0.074$). The mean structure model index (SMI) was also significantly lower (55%) in PTH-treated subjects relative to placebo-treated subjects (0.49 ± 0.25 vs 1.09 ± 0.16, respectively; $P = 0.046$), indicating a better connected trabecular architecture with a more plate-like structure, both indicative of a stronger bone. In conclusion, relative to placebo, treatment of osteoporotic women for 18 months with PTH resulted in marked increases in Cn.BV/TV, improved trabecular connectivity and a more plate-like structure. Structural variables obtained by μCT and bone histomorphometry were remarkably similar. All of these results are consistent with an increase in bone strength and the marked reduction in vertebral fracture incidence observed in the TOP Study.

Changes in Osteoblast, Chondrocyte, and Adipocyte Lineages Mediate the Bone Anabolic Actions of PTH and Small Molecule GSK3 Inhibitor. N. H. Kulkarni*[1], T. Wei*[1], A. Kumar*[1], E. Dow*[1], T. Stewart*[1], J. Shou*[1], M. N'Cho*[1], D. L. Halladay*[1], T. Engler*[1], T. J. Martin[2], H. U. Bryant[1], Y. L. Ma[1], M. Liu*[1], J. E. onyia[1]. [1]Lilly Research Labs, Greenfield, IN, USA, [2]SVMRI, Fitzroy, Victoria, Australia.

Parathyroid hormone (PTH) and an orally bioavailable small molecule glycogen synthase kinase3 (GSK3) α/β dual inhibitor 603281-31-8, administered once daily increase bone formation *in vivo*. The cellular basis for the anabolic effects has been shown largely to impact cells of osteoblast lineage. The present study was designed to decipher molecular mechanisms behind the anabolic phenotype of PTH and 603281-31-8 in an osteopenic rat model using whole genome array profiling and pathway mapping. Female 6-month old rats were ovariectomized (Ovx) and permitted to lose bone for one month, followed by treatment with PTH (1-38) at 10 μg/kg/d sc or 603281-31-8 at 3 mg/kg/d po for 60 days. Twenty-four hr after the last treatment, RNA was isolated from distal femur metaphysis and subjected to gene expression analysis. Differentially expressed genes ($p<0.05$) were subjected to pathway analysis to delineate relevant functional processes involved in skeletal biology. Genes involved in biological pathways such as morphogenesis, cell growth, differentiation, apoptosis, and extracellular matrix were significantly altered by Ovx and the treatments. Analysis of morphogenesis genes showed an overrepresentation of genes involved in osteogenesis/bone remodeling, chondrogenesis/cartilage condensation and adipogenesis. A striking finding (confirmed by Real-Time PCR) was that Ovx substantially decreased the markers of osteogenesis (Collagen α_1 (I), α_1(V), osteocalcin, BSP, osteonectin, osteopontin, matrix gla protein) and of chondrogenesis (Collagenα_1 (II), Collagen (X), aggrecan1, COMP, Cdrap) and increased markers of adipogenesis (PPARγ, LPL, leptin, CEBPA, Adipsin, FABP4, SREBF1, ADFP, caveolin 1, PEPCK). PTH and the GSK3 inhibitor reversed these effects, albeit at different levels. Overall, PTH was more efficacious at regulating these markers, with normalization to control or below control levels. Additionally, in intact animals, the inhibitory effects of PTH on the adipogenic markers tested so far were evident after 1-to-5 days of treatment. These results suggest that the anabolic actions of PTH and 603281-31-8 *in vivo* involve effects on other mesenchymal lineages (chondrocytes & adipocytes). The changes in cartilage markers in bone suggest an ongoing biosynthetic turnover of cartilage, but may also reflect progressive bone formation as a result of endochondral ossification. The decrease in adipogenesis markers by these anabolic agents might be a requirement for their stimulation of bone formation.

Pamidronate Treatment Affects Metaphyseal Modeling in Children with Osteogenesis Imperfecta. C. Land, F. Rauch, F. Glorieux. Shriners Hospital for Children, McGill University, Montreal, PQ, Canada.

Cyclical intravenous therapy with pamidronate is of clinical benefit in children and adolescents with moderate to severe osteogenesis imperfecta (OI). However, recent case reports show that this medication has the potential to interfere with femoral metaphyseal modeling (shaping). In this study we elucidated the effects of pamidronate on the shape of the growing distal femur. We compared radiographs from 55 children with moderate to severe OI (mean age 6.5 years, range 2.2 -15.3 years; 29 girls) who had received between 2 and 4 years of pamidronate therapy (annual dose 9 mg/kg) and 55 untreated OI patients who were matched for age, sex and OI type. Distal femoral metaphyseal width (MW) was measured at a site whose distance to the growth plate corresponded to half of growth plate width (GPW). Metaphyseal index (MI) was calculated as the ratio between MW and GPW (Ward et al., Bone, in press). Even though the treatment and control groups had similar GPW, the two groups differed significantly with regard to MW (Table). Consequently MI was higher in treated patients, indicating a significant effect of pamidronate on metaphyseal modeling. This shows that pamidronate interferes with the process of periosteal resorption that is normally responsible for shaping the distal femoral metaphysis. However, at present, there is no evidence that this radiological adverse event is of clinical significance.

Variable	n	Pamidronate	n	Untreated	P value
GPW type I	8	5.91±0.92	8	6.02±0.92	0.81
GPW type III	18	3.93±1.00	18	3.66±1.64	0.54
GPW type IV	29	5.16±1.24	29	5.10±1.61	0.88
MW type I	8	4.26±0.53	8	3.19±0.55	<0.001
MW type III	18	2.82±0.69	18	1.94±0.42	<0.001
MW type IV	29	3.65±0.75	29	2.88±0.62	<0.001
MI type I	8	0.73±0.07	8	0.53±0.07	<0.001
MI type III	18	0.72±0.10	18	0.60±0.18	<0.02
MI type IV	29	0.72±0.08	29	0.58±0.08	<0.001

Values are mean±SD. GPW and MW are given in cm.

FGF23 Mutants Causing Familial Ttumoral Calcinosis Are Differentially Processed. T. E. M. Larsson[1], S. S. Davis*[1], H. J. Garringer*[1], S. D. Mooney*[1], M. S. Draman*[2], M. J. Cullen*[2], K. E. White[1]. [1]Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Endocrinology, Trinity College, Dublin Medical School, Dublin, Ireland.

Familial tumoral calcinosis (TC) is a heritable disorder characterized by high serum Pi, normal or elevated serum $1,25(OH)_2D_3$, and ectopic periarticular and/or vascular calcifications. We, and others, have previously identified two recessive mutations in *Fibroblast growth factor-23 (FGF23)*, serine 71/glycine (S71G) and serine 129/ phenylalanine (S129F), as causative for TC. Our reported S71G TC patients had markedly elevated C-terminal serum FGF23 levels (>3000 RU/mL, (ref: 50±55 RU/mL)), however low-normal intact FGF23 levels. Therefore, the goal of our study was to understand the pathophysiology of these FGF23 TC mutations. Studies of the entire FGF23 S71G kindred revealed that heterozygous carriers (S/G, n=5) had elevated serum FGF23 C-terminal fragments compared to wt (S/S, n=6) family members (74.1±5.5 vs. 54.6±4.7 RU/mL**,** $P<0.025$), whereas intact FGF23 levels were not different. Carriers also presented with normal serum Pi and $1,25(OH)_2D_3$, and displayed no evident disease phenotype. To understand the differential processing of FGF23 in TC patients, we transiently expressed the S71G and S129F mutants in HEK293 cells. FGF23 ELISA and Western analyses of conditioned media and cell lysates revealed increased proteolytic cleavage of FGF23, and a limited secretion of intact FGF23, parallel observations with the serum FGF23 profiles of our TC patients. Furthermore, expressing S71G and S129F FGF23s, in tandem with the known ADHR mutations that disrupt the furin-like protease RXXR motif, rescued FGF23 secretion by stabilizing the intact polypeptides. This finding was supported by similar sensitivity of these mutants to trypsin digests. Finally, S71G, but not the S129F mutant FGF23, is secreted by cells when incubated at low temperature (29°C), indicating that S71G mutant FGF23 protein structure may be in part corrected by cellular chaperones under these conditions. In summary, carriers for the S71G mutation have normal phenotypes, and FGF23 mutations causing TC lead to increased intracellular proteolysis of FGF23. Moreover, furin-like proteases play an important role in TC and may act as intracellular "quality control monitors", thus more efficiently processing FGF23s with improper folding or post-translational modification. Our findings provide new insights into the role of FGF23 in TC, as well as in Pi and vitamin D metabolism.

A Homozygous S129P Missense Mutation in FGF-23 Causes Tumoral Calcinosis with Hhyperphosphatemia. C. Bergwitz[1], S. Banerjee*[1], H. Abu-Zahra*[1], H. Kaji[2], T. Sugimoto[3], K. Chihara[2], A. Miyauchi[4], H. Jüppner[1]. [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Department of Endocrinology/Metabolism, Kobe University, Kobe, Japan, [3]Department of Endocrinology/Metabolism, Shimane University Medical School, Shimane, Japan, [4]Department of Medicine, National Hyogo-Chuo Hospital, Sanda-shi, Japan.

Familial tumoral calcinosis with hyperphosphatemia (FTC) is an autosomal recessive disorder that can be caused by homozygous mutations in either *GALNT3* or *FGF23*. We analyzed the three exons encoding FGF23 and all intron/exon borders in genomic DNA of a previously reported individual affected by FTC [Yamaguchi 1995, Bone 16(4):247S]; serum phosphate 7.0 mg/dl (2.5-4.5), $1,25(OH)_2$-D 44 pg/ml (15-60), %TRP 98.8% (85-96), TmP/GFR 2.7 (0.8-1.35) and C-terminal FGF23 20233 RU/ml (50±51), intact FGF23 38 pg/ml (15-60). PTH and serum calcium were normal. We identified a homozygous nucleotide change c.385T->C in *FGF23* exon 2 that changes codon 129 from serine to proline (S129P). A different mutation in this codon (S129F) was previously reported in another case of FTC [Araya et al. 2004, JBMR 19:S41]. The patient's unaffected mother and normal controls are currently being analyzed. For functional analysis the S129P mutation, as well as two previously reported *FGF23* mutations, S71G and S129F, were introduced into an expression plasmid encoding human (h) FGF23 to yield [P129]hFGF23, [F129]hFGF23, and [G71]hFGF23; these plasmids were expressed in COS-7 and HEK293 cells. Medium and cell lysate were subjected to Western blot analysis using affinity purified anti-hFGF23(59-68) and anti-hFGF23(206-222) antibodies generated in goats (Immutopics). Lysates of HEK293 cells expressing wild-type FGF23 (WT-FGF23) revealed a 27 kDa band representing the intact and a 32 kDa band that presumably represents an intact, possibly modified form of FGF23. The 32 kDa peptide was efficiently secreted into the medium, along with N- and C-terminal fragments. Lysates from cells expressing [P129]hFGF23 revealed the 27 kDa intact molecule, but lacked the modified 32 kDa form. Only small amounts of N- and C-terminal fragments appeared in the medium, while intact FGF23 was undetectable. This suggests that P129 may prevent modification of [P129]hFGF23, thereby limiting the secretion of the intact protein into the medium. To determine whether the apparent lack of modification of [P129]hFGF23 is due to a lack of O-linked glycosylation, we currently determine whether WT-FGF23 undergoes such a modification at one or several of the conserved serine residues.

Determination of Carrier Status in ADO2: An *In Vitro* Study of Clinically Unaffected Gene Carriers. K. Chu*, R. Snyder*, M. J. Econs. Medicine, Indiana University School of Medicine, Indianapolis, IN, USA.

Autosomal dominant osteopetrosis type II (ADO2) is a heritable osteosclerotic disorder that results from heterozygous mutations in the ClCN7 gene. However, of those individuals with a ClCN7 mutation, 1/3 are asymptomatic carriers. Disease severity in the remaining 2/3 is highly variable. The most severely affected manifest multiple fractures, osteomyelitis, visual loss and, occassionally, bone marrow failure. There is no genotype/ phenotype correlation and families frequently have both carriers and severely affected individuals. To determine whether the carrier status results from the bone micro environment (i.e. secretion of cytokines, hormonal environment, and condition of the other bone cells) or is intrinsic to the osteoclasts, we performed in vitro osteoclast cell culture in affected patients, carriers and normal controls (n=5 in each group). Subjects were matched for age, sex and ethnicity. Human peripheral blood mononuclear cells were isolated by magnetic beads and differentiated into osteoclasts by stimulation with hRANK-L and hM-CSF. Cell fusion, F-actin ring formation, TRAP activity, cell acidic microenvironment analysis were investigated and no significant difference was found between the three groups. However, osteoclasts from the carrier and normal groups generated more extensive and continuous resorption pits compared to the affected groups, which had rare and restricted pits (figure 1). Moreover, the pits from the carrier and the normal groups formed much earlier and extended much more rapidly than the pits from the affected groups (figure 2). There were no significant differents between the carrier and normal groups at any time point. In conclusion, osteoclasts from the carriers, in contrast to those from the affected individuals (who had the same ClCN7 mutations) function normally in cell culture. This finding supports the hypothesis that intrinsic osteoclast factors determine whether an individual with a ClCN7 mutation becomes an affected patient or an asymptomatic carrier. Further understanding of this mechanism is likely to lead to the development of new approaches for the treatment of affected patients.

Caveolin-1 Deficient Mice Exhibit Sexually Dimorphic Changes in Bone Phenotype: Micro-CT and Biomechanical and Biomechanical Analysis. H. Yao*[1], Z. Schwartz[1], H. Jo*[2], J. Rubin[2], R. E. Guldberg*[1], K. Wong*[1], L. Wang[1], B. D. Boyan[1]. [1]Georgia Institute of Technology, Atlanta, GA, USA, [2]Emory University Medical School, Atlanta, GA, USA.

Caveolae are plasma membrane invaginations that play an important role in numerous cellular processes including transport and signaling. Mice lacking caveolin-1 (Cav-1), the major scaffolding protein in caveolae, exhibit vascular dysfunction and pulmonary defects, and endothelial cells from these Cav-$1^{-/-}$ mice have altered response to mechanical strain. Recent studies have shown that estrogen receptors traffic into and out of caveolae via Cav-1 in response to estrogen, suggesting that mechanically-sensitive bone might also exhibit a Cav-$1^{-/-}$ phenotype and that it might be sex-specific. To test this, we evaluated the phenotypic consequences of knocking out the Cav-1 gene in bone. Cav-$1^{-/-}$ and C57BL/6 wild-type male and female 8-week-old mice were used for these studies. A total of 32 femora (8 mice per genotype per sex) were scanned using micro-CT to obtain high-resolution images of the trabecular bone in the distal femur, as well as cortical bone in the mid-diaphysis. After scanning, the femora were tested to destruction in four-point bending at the mid-diaphysis. Morphologic parameters for trabecular and cortical bone as well as structural and material properties of cortical bone were determined. The Cav-$1^{-/-}$ mice displayed enlarged growth plates for both male (18% increase in height) and female (93.1% increase in height) groups. The bone volume fraction, as well as trabecular thickness, in the metaphysis were significantly increased in the Cav-$1^{-/-}$ mice, especially in the female group. In contrast, trabecular bone mineral densities in the metaphysis for knockout mice were slightly lower than the wild-type in both male and female groups. While the Cav-$1^{-/-}$ mice had thicker cortical bone and higher maximum load in the mid-diaphysis, the value of the elastic modulus in the male Cav-$1^{-/-}$ mice was lower than the wild-type counterpart. Interestingly, the values of elastic modulus in Cav-$1^{-/-}$ female mice and both wild type groups were similar. Overall, the absence of Cav-1 increased bone tissue formation. Knocking out Cav-1 reduced bone quality in male animals based on elastic modulus, but not in female animals. Our results confirmed that Cav-1 is needed for normal bone physiology, and suggest that the absence of Cav-1 causes sexually dimorphic changes. The increase size of the growth plate in the Cav-$1^{-/-}$ mice, particularly in female bones, may be related to the altered microarchitecture observed in the metaphysis.

Reduced 25-Hydroxyvitamin D_3-1alpha-Hydroxylase Activity Impacts Negatively on the Secondary Hyperparathyroidism Arising from FGF23 Overexpression. H. Fu*, X. Bai*, D. Miao, J. Gao*, D. Goltzman, A. C. Karaplis. McGill University, Montreal, PQ, Canada.

Fibroblast growth factor 23 (FGF23) is a recently characterized protein likely involved in the regulation of serum phosphate homeostasis. We have previously generated transgenic mice expressing and secreting from the liver human FGF23(R176Q), a mutant form that fails to be degraded by furin proteases (Tg). High circulating levels of FGF23 were associated with disturbances in the regulation of phosphate and vitamin D metabolism as well as calcium homeostasis and elevated PTH levels due to secondary hyperparathyroidism may have also contributed to renal phosphate wasting. We and others have also previously reported a mouse model deficient in $1,25(OH)_2D_3$ by targeted ablation of the 25-hydroxyvitamin D_3-1alpha-hydroxylase gene (K.O.). After weaning, mice that were fed a regular mouse chow, developed secondary hyperparathyroidism, retarded growth, and the skeletal abnormalities characteristic of rickets. To further investigate the role of secondary hyperparathyroidism and the 1-alpha hydroxylase enzyme in the biochemical alterations associated with FGF23 overexpression, the FGF23(R176Q) transgene was crossed into the K.O. background (Tg/K.O.). Post weaning these mice, relative to Tg mice, when fed a regular diet (1% Ca, 0.67% P), exhibited profound growth retardation and early demise by 2 months of age. In the Tg/K.O. mice relative to the Tg animals, serum levels of calcium decreased slightly while PTH levels increased dramatically and serum phosphorus and renal phosphate threshold diminished significantly from the already low levels seen in the Tg mice. Alkaline phosphatase activity was dramatically increased and bone volume and osteoid volume rose markedly above the high levels already seen in the Tg mice. When these animals were fed a rescue diet (2% Ca, 1.25% P, 20% lactose) post weaning, near-normal growth and survival were observed in both Tg and Tg/K.O. models, and much less pronounced changes in serum calcium, phosphorus, PTH, and alkaline phosphatase activity were seen compared to mice on a regular diet. Although serum phosphorus remained low, bone volume decreased and mineralization was markedly improved in both Tg and Tg/K.O. mice. In summary, our findings show that 1-alpha hydroxylase activity can play a pivotal role in modifying the biochemical and skeletal changes arising from FGF23 overexpression. Our findings also add further support to the premise that secondary hyperparathyroidism is an integral component of this disturbed state and that elevated PTH levels contribute to the renal phosphate wasting and to increased bone formation thereby potentiating the osteomalacia associated with this deranged state.

Adult Hypophosphatasia Treated with Teriparatide. C. L. Deal[1], M. P. Whyte[2]. [1]Cleveland Clinic, Cleveland, OH, USA, [2]Research Center, Shriners Hospitals for Children, St. Louis, MO, USA.

We report the first case of hypophosphatasia (HPP) treated with teriparatide (rhPTH 1-34, TPTD). HPP features low circulating alkaline phosphatase (ALP) activity from deactivating mutation of the gene encoding the "tissue nonspecific" isoenzyme of ALP (TNSALP). Extracellular accumulation of inorganic pyrophosphate (PPi) impairs skeletal mineralization causing rickets in children and osteomalacia in adults. There is no established medical therapy. Adult HPP typically presents with poorly-healing metatarsal stress fractures (MTSF) and unhealing femoral pseudofractures (FPF). At age 54, our patient had a painful MTSF with delayed healing over 7 months. Two MTSFs occurred 2 years later and did not heal. A FPF ensued. Pain occurred at fracture sites. Serum ALP ranged from 10-24 IU/L (40-150 nl) and bone-specific ALP was 6 IU/L (12-31 nl). Other biochemical studies were unremarkable except for two further features of HPP: elevated serum inorganic phosphate (Pi) level of 5.1 mg/dl and vitamin B6 concentration of 603 ug/L. DXA of the lumbar spine and total hip showed Z-scores of +2.9 and +1.5, respectively. Treatment was begun at age 56 with 20 mcg TPTD. After 2 mo, pain improved 50% and 90% in thigh and foot. After 4 mo, no fracture site was painful. Therapy was discontinued briefly when NTX rose and OC fell. X-rays of the feet showed significant healing after 4 mo in 2 MTSFs and delayed healing with exuberant callus in 1 MTSF (no callus was present 9 mo after MTSF prior to TPTD treatment). The FPF appeared completely healed after 9 mo. A marked reduction in chondrocalcinosis in the symphysis pubis was seen after 9 mo of TPTD. Sequential biochemical studies, including improved serum ALP activity, are below. Ours is the first report of HPP treated with TPTD. Complete pain relief at fracture sites occurred after 2 mo; MTSP and FPF healed. Biochemical studies documented increased ALP, NTX, and OC suggesting restoration of bone remodeling, but without hypercalcemia. Little change in circulating vitamin B6 levels suggested a focal (skeletal) effect from TPTD treatment. TPTD may engender clinical improvement and fracture healing in adult HHP due to enhanced osteoblast production of TNSALP and/or phosphaturia lowering (at mineralization sites) extracellular Pi levels which act as a competitive inhibitor of TNSALP.

	4/04 (start Rx)	6/04	8/04 (stop Rx)	11/04 (resume Rx)	2/05	Normal Range

Phosphate Depletion and Hypophosphatemia Directly Regulate FGF-23 Expression. M. Takaiwa[1], B. Yuan[1], H. Tanaka[2], R. Kumar[3], M. K. Drezner[1]. [1]University of Wisconsin, Madison, WI, USA, [2]Okayama University, Okayama, Japan, [3]Mayo Clinic, Rochester, MN, USA.

Regulation of phosphate homeostasis is a complex process, likely involving both conventional hormones, such as parathyroid hormone and 1,25-dihydroxyvitamin D, as well as recently discovered novel factors, FGF-23 and sFRP-4. The integrated counter-regulatory effects of oral phosphate intake and serum phosphorus levels on these hormonal/metabolic factors remain incompletely defined. Thus, in the present study we sought to elucidate the effects of oral phosphate depletion and consequent hypophosphatemia on renal expression of sFRP-4 and 25-hydroxyvitamin D-1α-hydroxylase and bone expression of FGF-23. We fed C57BL/6J mice, 8-12 weeks of age, a standard (Pi 1.0%, Ca 0.95%, Vitamin D 4.5 IU/g) or Pi depleted diet (Pi 0.02%, Ca 0.95%, Vitamin D 4.5 IU/g) for 3 days and quantified expression of the respective genes by real-time PCR using ABI 7000 (Applied Biosystems). We extended these observations by evaluating the protein abundance (Westerns) of renal 25-hydroxyvitamin D-1α-hydroxylase and sFRP and the circulating levels of FGF-23 (ELISA). After 3 days of phosphate depletion, the serum phosphorus level in the treated mice decreased significantly ($p<0.001$) from 6.6±0.3 to 4.2±0.1 mg/dl. In concert, FGF-23 gene expression significantly ($p< 0.05$) decreased (30%), resulting in a concordant 70% decrement in the circulating levels of this protein. In contrast, renal expression of sFRP-4 and protein abundance did not change in response to the hypophosphatemic challenge. However, not unexpectedly, in response to the hypophosphatemia, renal 25-hydroxyvitamin D-1α-hydroxylase gene expression increased (1.0±0.05 vs. 2.4±0.3 fold), as did the protein content (1.0±0.07 vs 1.49±0.15 fold). Since previous observations (J Biol Chem 2005; 280:2543-9) indicate $1,25(OH)_2D$ dose dependently increases serum FGF-23 levels, our data suggest that phosphate depletion and hypophosphatemia attenuate these effects and independently regulate FGF-23 production. To confirm that the phosphate effects were independent and direct, we examined *in vitro* the effects of phosphate on FGF-23 gene expression in the mouse mesenchymal cell line ST-2. We found that phosphate significantly increased FGF-23 gene expression in a dose dependent manner, consistent with the diminished FGF-23 observed in response to hypophosphatemia. These results indicate that phosphate depletion and hypophosphatemia directly counter-regulate FGF-23 production and consequently circulating levels, suggesting that FGF-23 and the osteoblasts producing this factor may directly participate in a feedback loop regulating phosphate homeostasis.

AC-100, a Fragment of MEPE, Promotes New Dentin Formation in both Direct and Indirect Pulp Capping Models in Beagle Dogs. M. Lazarov[1], C. Middleton-Hardie[1], M. Shih*[2], A. Negron*[2], V. Kiklevich*[3], M. Powers*[3], D. Rosen[1]. [1]Research and Development, Acologix, Inc, Hayward, CA, USA, [2]Skeletech, Bothell, WA, USA, [3]Department of Veterinary Clinical Sciences, Washington State University, Pullman, WA, USA.

MEPE, a protein originally cloned from tumors associated with hypophosphatemic osteomalacia, is expressed primarily in normal human bone and odontoblast cells. AC-100 (Dentonin), a central 23-amino acid fragment of MEPE, contains motifs that are important in regulating cellular activities in the bone and dentin microenvironment. In vivo studies indicate that AC-100 is able to stimulate new dentin and bone formation in teeth and bone respectively. Unlike BMPs, no bone or dentin formation has been observed locally following subcutaneous administration of AC-100. Here we report that AC-100 stimulates new dentin formation in both direct and indirect pulp capping models in dogs. **Methods:** Deep class V preparations were made with or without penetrating the pulp cavity of the maxillary teeth in Beagle dogs. Each tooth was treated with AC-100 or with negative control (saline) or positive control (Dycal). Animals were sacrificed and teeth were analyzed histologically. **Results:** In the indirect pulp capping portion of the study at 3 days post surgery the saline or Dycal treated teeth showed an inflammatory response in the pulp tissue. Application of AC-100 completely abolished the pulp inflammation and dose-dependently decreased the number of apoptotic cells in the pulp. At 28 days post surgery the saline-treated teeth showed little new dentin formation while application of AC-100 induced a dose-dependent stimulation of dentin growth comparable to and better than Dycal. Considerably better results were obtained employing a multiple-dose application schedule. In the direct pulp capping portion of the study at 56 days the teeth that were sealed using saline showed no dentin bridge formation in 4 out of 5 dogs, while application of 200 μg of AC-100 stimulated complete bridging of the defects in 3 out of 5 dogs. **Conclusion:** AC-100 stimulates new dentin growth and dentin bridge formation in both direct and indirect pulp capping studies in dogs in a dose and application method dependent manner. Importantly, the mechanism of action of AC-100 is notably different from the mechanism of the dentin stimulating agents available for clinical use at present. The currently approved agents stimulate dentin growth through non-physiologic irritation of the pulp tissue. In contrast, AC-100 achieves its activity by producing new dentin, while exhibiting reduced inflammatory and apoptotic activities locally.

Measles Virus Nucleocapsid Protein Increases TNF-α Induced Osteoclast Differentiation. T. Honjo[1], N. Kurihara[1], J. J. Windle[2], G. D. Roodman[3]. [1]Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, Virginia Commonwealth Univ., Richmond, VA, USA, [3]Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Osteoclasts (OCL) from Paget's patients (PD) are abnormal and contain Measles Virus Nucleocapsid Protein (MVNP) transcripts. Furthermore, human OCL precursors transfected with MVNP demonstrate many features of pagetic OCL. We previously reported that OCL precursors from patients with Paget's disease or normal OCL precursors transfected with MVNP are hyperresponsive to RANKL and $1,25\text{-}(OH)_2D_3$. We determined if MVNP could also increase TNF-α responsivity of OCL precursors. To test this hypothesis, we used normal human bone marrow transfected with MVNP and OCL precursors from transgenic mice with MVNP targeted to the OCL lineage using the TRAP promoter (TRAP/MVNP). NIH3T3 cells transfected with MVNP or empty vector (EV) were also used as surrogate for OCL precursors and to further examine the NF-κB pathway. Marrow cultures from TRAP-MVNP mice formed markedly increased numbers of OCL that were hyper-nucleated compared to wild type OCL. OCL precursors from TRAP/MVNP mice formed OCL at lower concentrations of $1,25\text{-}(OH)_2D_3$ and TNF-α than those required for normal marrow cultures. Western blot analysis and real time PCR showed treatment of MVNP-transfected human CFU-GM cells or TRAP/MVNP OCL precursors with TNF-α increased both p62 and TRAF2 expression levels approximately 200%, and increased IKK-γ 1.3-fold compared to results with EV-transfected cells. IKK-γ is an important regulator of NF-κB signaling induced by TNF-α, and is absolutely required for IKK activation by TNF-α. We then determined if these effects resulted in enhanced NF-κB signaling. Basal NF-κB in MVNP-transfected human CFU-GM and TRAP/MVNP mouse OCL precursors was increased 2-fold compared to EV-transfected cells and wild type OCL precursors, and was increased 2.7-fold when MVNP-transfected cells and TRAP/MVNP OCL precursors were treated with TNF-α. Furthermore, a 7-fold increase in basal NF-κB reporter gene activity was seen in MVNP-transfected NIH3T3 cells compared to EV-transfected cells. TNF-α also increased (by 350%) the phosphorylation of IKK-γ within 15 minutes after addition of TNF-α in MVNP-transfected NIH3T3 cells compared with EV-transfected cells. These results demonstrate that MVNP increases TNF-α induced OCL differentiation and activation by increasing NF-κB signaling through increased expression of p62, TRAF2 and IKK-γ. These results suggest that MVNP's effects on TNF-α signaling may contribute to the increased OCL formation in PD.

Stunted Growth and Altered Bone Phenotype in IL-6 Transgenic Mice. N. Rucci[1], E. Spica[1], C. Di Giacinto[1], A. Del Fattore*[1], R. Paro*[1], S. Berni*[2], P. Ballanti*[2], M. Vivarelli*[3], F. Muratori*[3], F. De Benedetti*[3], A. Teti[1]. [1]Department of Experimental Medicine, University of L'Aquila, L'Aquila, Italy, [2]Department of Experimental Medicine and Pathology, University of Rome "La Sapienza", Rome, Italy, [3]Ospedale Bambino Gesù, Rome, Italy.

Osteoporosis and stunted growth are common complications of chronic inflammation in children. IL-6 is a pro-inflammatory cytokine which increases in inflammatory diseases. We observed that the skeleton of NSE/hIL6-transgenic mice (TG) expressing high circulating levels of hIL-6 from birth was smaller than wild type (WT), with decreased longitudinal growth and mineralization. In these mice, trabecular bone was reduced, with increased osteoclast- and decreased osteoblast-number and -surface. Cortical bone was thinner, with increased endosteal osteoclast number, and showed halved periosteal and abrogated endosteal apposition. Calvarial and endochondral developments were delayed and growth plate thickness was reduced. In vivo, increment of urinary DPD excretion and low serum levels of osteocalcin demonstrated increased bone resorption, and decreased osteoblast activity, respectively, which correlated with body weight in TG but not in WT mice. A 4-fold higher number of TRAcP positive mononuclear precursors was observed in TG bone marrow that originated a 1.6-fold higher number of mature multinucleated osteoclasts, with an average 4.14±0.29 nuclei/cell. Calvarial osteoblasts from TG mice showed decreased proliferation, ALP activity and mineralized nodules, which were also reduced in WT osteoblasts treated with rhIL-6. TG osteoblasts demonstrated no changes in Runx-2 and ALP transcripts versus WT cells, with no modulation of these genes in rhIL-6-treated WT osteoblasts. In contrast, the osteocalcin and collagen-1a2 mRNAs were down-regulated in TG osteoblasts and in WT osteoblasts treated with rhIL-6 compared to untreated WT cells, indicating that osteoblast function rather than differentiation was impaired by IL-6. Mouse IL-6 transcript was increased in TG osteoblasts, and treatment with exogenous rhIL-6 induced the expression of endogenous mouse IL-6 in the WT osteoblasts. These results underscore the effects of IL-6 on skeletal tissues and provide a novel standpoint to explain the uncoupling of osteoclast/osteoblast activity and the growth defect in juvenile chronic inflammatory diseases.

Prevalence of Orthopedic Complications in Overweight Children and Adolescents: A Multi-Dimensional Cross-Sectional Analysis. E. D. Taylor*, M. Tanofsky-Kraff*, D. Adler-Wailes*, K. Calis*, S. Ghorbani*, M. Mirch*, K. Theim*, S. Brady*, J. A. Yanovski*. National Institute of Child Health and Human Development - Unit on Growth and Obesity, National Institutes of Health, Bethesda, MD, USA.

Overweight in children 6-17 y has increased 3-fold in the United States since the 1970's, with the Centers for Disease Control now finding more than 15% of US children and adolescents are overweight (BMI $\geq 95^{th}$ percentile for age and sex). Previous studies have described debilitating orthopedic complications of excess weight in overweight adult populations. However, few prospective data are available that quantify the prevalence of weight-related orthopedic conditions in a sample of otherwise healthy overweight children. This study compared the prevalence of orthopedic diagnoses and musculoskeletal conditions in overweight (OW) and non-overweight (NOW) children. Subjects were 227 OW (mean age 12.6 ± 2.7y) and 128 NOW (mean age 11.8 ± 2.9y) children and adolescents enrolled in pediatric clinical studies at the National Institutes of Health in Bethesda, Maryland between 1996 and 2004. A *medical chart review* documented pertinent orthopedic past medical history and general physical exam findings related to musculoskeletal complaints. *Questionnaire data* from 183 subjects who completed "The Impact of Weight on Quality of Life - adolescent version" (IWQOL-A) questionnaire were also reviewed to study the effects of excess adiposity on the "Mobility" subscale score. To examine systematically the effects of overweight on *lower extremity alignment,* bilateral metaphyseal-diaphyseal angle (MDA) measurements were obtained from 260 subjects who underwent whole body dual-energy x-ray absorptiometry (DEXA) scanning. The prevalence of reported fractures was significantly greater in OW than NOW children (13.1 vs. 3.9%, $p = 0.0053$). The prevalence of any reported musculoskeletal discomfort was also greater in OW than NOW children (12.6 vs. 3.9%, $p = 0.0073$). In the OW group, the most common musculoskeletal joint complaint was knee pain (6.3 vs. 2.3%, $p = 0.10$). OW children and adolescents reported greater impairment in mobility than their NOW counterparts (mobility score 17.0 vs. 11.6, $p < 0.001$). Bilateral MDA measurements showed greater degree of valgus alignment in the OW group compared to the NOW group for both the right (6.5 vs. 5.2°, $p<0.05$) and left (7.2 vs. 4.8°, $p< 0.05$) lower extremities. In conclusion, reported fractures, musculoskeletal discomfort, impaired mobility, and valgus lower extremity alignment are more prevalent in OW than NOW children and adolescents. Future studies should explore role of overweight on bone quality and the severity of joint abnormalities in the pediatric population.

Homozygosity for TNSALP Mutation C1348T (Arg433Cys) Causes Infantile Hypophosphatasia Manifesting Transient Disease Correction and Variably Lethal Outcome in a Black Kindred. M. P. Whyte[1], K. Essmyer*[1], M. Geimer*[2], S. Mumm[2]. [1]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA, [2]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Hypophosphatasia (HPP) features low circulating alkaline phosphatase (ALP) activity (hypophosphat*asemia*) from deactivating mutation of the gene encoding the "tissue nonspecific" isoenzyme of ALP (TNSALP) and is associated with a remarkable range of disease severity. Extracellular accumulation of inorganic pyrophosphate (PPi), one of several TNSALP substrates and an inhibitor of hydroxyapatite crystal nucleation, impairs skeletal mineralization causing rickets or osteomalacia. There is no established medical therapy. Here, we characterize HPP prevalence in blacks and determine the molecular basis for variably lethal and transiently reversible infantile HPP in a black kindred. A report in 1986 details temporary correction of severe HPP in this black family where "infantile" HPP was fatal in two of three patients representing two sibships. At this time, the improvement in one patient followed efforts to increase TNSALP activity endogenously and suggested upregulation of the *TNSALP* gene. Here, we assessed 29 years' experience to document HPP's prevalence in blacks and identified this kindred's *TNSALP* defect. Ethnicity was known for 119 HPP families studied directly and race was ascertained for an additional 159 of 235 consultand HPP families worldwide. Only this family was black. Homozygosity for *TNSALP* missense mutation C1384T(Arg433Cys) accounted for their infantile HPP. The *TNSALP* promoter was intact. Modeling of TNSALP(433Cys) indicated compromise of the enzyme's catalytic site. We find that HPP is especially rare in blacks. Homozygous *TNSALP(C1348T)* causes variably lethal and transiently reversible HPP in this black kindred. The mutation has been reported to cause severe HPP in whites. Although not fully understood, HPP manifestations from homozygous TNSALP(433Cys) can correct, perhaps with clues for HPP's phenotypic variation and treatment.

Retention, Distribution, and Effects of Intra-Osseously Administered Ibandronate in the Infarcted Femoral Head. S. Athavale*[1], J. Aya-Ay*[1], F. Bauss[2], H. Kim[1]. [1]Shriners Hospital for Children, Tampa, FL, USA, [2]Roche Diagnostic GmbH, Penzberg, Germany.

Legg-Calve-Perthes disease (LCPD) is a juvenile form of osteonecrosis of the femoral head (FH), which can lead to FH deformity and premature osteoarthritis. Ibandronate (IB), a new potent bisphosphonate, has been shown to prevent FH deformity in a large animal model of LCPD when administered parenterally. However, since LCPD is a localized hip disorder, there is a need to explore the therapeutic potential of local, intra-osseous injection of IB to prevent FH deformity. This route has the advantage of avoiding systemic distribution of the drug in the immature skeleton for a localized condition. The purpose of this study was to determine the retention, distribution, and effects of intra-osseous injection of IB in the infarcted head. Ischemic necrosis was induced in 12 piglets by placing a ligature tightly around the femoral neck. A repeat arthrotomy was performed 1 wk later to inject 1ml of ^{14}C-IB (56ug/ml) directly into the head. The heads were retrieved at 48h, 3 and 7wks after the injection. The amount of ^{14}C-IB retained in the infarcted head was determined using liquid scintillation analysis. The distribution of ^{14}C-IB within the head was determined using autoradiography. Liquid scintillation analysis showed 660 folds higher radioactivity level in the infarcted heads compared to the control heads with 29.5% retention of the radioactivity at 7wks. Autoradiographic assessment revealed diffuse distribution of ^{14}C-IB in 2/4 heads and with anterior only distribution in the other 2/4 heads at 48h. Histological assessment showed extensive revascularization of the infarcted heads at 7wks with preservation of trabecular bone in some areas. During the study period, the femora grew 4.7cm (51% increase) and the animals gained 12.1kg (175% increase), indicating a rapid growth and bone turnover. To our knowledge, this is the first study that has investigated the therapeutic potential of local intra-osseous injection of bisphosphonate in the context of ischemic osteonecrosis. In addition to limiting the delivery of the drug to the target tissue, local injection has the advantage of bypassing the need for having restored blood flow to the infarcted head for the delivery of the drug. Our study shows that a single intra-osseous injection of IB can be retained within the infarcted head for at least 7wks in this rapidly growing animal model. This route of administration did not hinder revascularization of the infarcted head and preserved some portions of the head. Further improvements in the injection technique may allow more even distribution of IB within the femoral head and enhance the protective effect of IB on preserving the trabecular framework.

Role of Ezrin in the Parathyroid Hormone-Mediated Downregulation of Sodium-Dependent Phosphate Transporter (NaPi-IIa) in Opossum Kidney Cells. Y. Taketani, K. Nashiki*, A. Nakamura*, N. Sawada*, H. Yamamoto, H. Arai, E. Takeda. Department of Clinical Nutrition, University of Tokushima Graduate School, Tokushima, Japan.

Type IIa sodium-dependent phosphate (Pi) transporter (NaPi-IIa) carries out rate-limiting step of renal Pi reabsorption. Parathyroid hormone (PTH), a potent inhibitor for the Pi reabsorption, is rapidly involved in endocytosis of NaPi-IIa from apical membrane

to inhibit Pi transport immediately. We have reported that PTH mediated-phosphorylation of common substrates for both PKA and PKC in the membrane microdomains would be important for the downregulation of NaPi-IIa. We also found that ezrin, a member of ERM (ezrin-radixin-moesin) protein family, was a specific substrate for PKA and PKC in response to PTH. To understand the role of ezrin in the downregulation of NaPi-IIa, we investigated the phosphorylation of ezrin in response to PTH and the effect of dominant-negative ezrin on the downregulation of NaPi-IIa by PTH using OK-N2 cells (opossum kidney cells stably expressing NaPi-IIa). Go6978 (PKC-inhibitor) and H-89 (PKA-inhibitor) inhibited both PTH-mediated phosphorylation of ezrin and downregulation of NaPi-IIa. However, PTH did not affect the phosphorylation of ezrin at Thr567. Other phosphorylation site(s) must be important for the downregulation of NaPi-IIa. Since it has been known that ezrin can bind to NaPi-IIa via NHERF-1/EBP50 at N-terminal part, and also bind to cytoskeletal actin at C-terminal part, we expressed the dominant-negative ezrin (N-terminal half of ezrin) in OK-N2 cells. Overexpression of dominant-negative ezrin not only decreased apical targeting of NaPi-IIa, but also inhibited the PTH-mediated NaPi-IIa downregulation. Therefore, phosphorylation of ezrin by PTH may modulate the supermolecular complex of NaPi-IIa/NHERF-1/ezrin/actin targeted to the apical membrane, and may be trigger for NaPi-IIa endocytosis. Ezrin may be a key molecule for the hormonal regulation and apical targeting of NaPi-IIa in renal proximal tubular cells.

Signaling Selective PTH (1-34) Analogs Accelerate Bone Formation. D. Yang[1], M. Bouxsein[2], R. Chiusaroli*[1], E. Schipani[1], P. Pajevic[1], J. Guo[1], R. Singh*[1], F. R. Bringhurst[1]. [1]Endocrine Unit, Massachusetts General Hospital & Harvard Medical School, Boston, MA, USA, [2]Orthopedic Biomechanics, Beth Israel Deaconess Medical Center, Boston, MA, USA.

PTH regulates osteoblastic function by activating PTH/PTHrP receptors (PTH1Rs), which trigger several signaling pathways in parallel, including adenylyl cyclase (AC)/PKA and PKCs via both PLC-dependent and PLC-independent mechanisms. These signaling functions have been mapped to distinct domains within PTH(1-34). To study PTH1R signaling pathways that mediate regulation of bone formation, two analogs with restricted patterns of PTH1R signaling were synthesized. [G1,R19]hPTH(1-28), which lacks the 29-34 domain of hPTH(1-34) required for PLC-independent PKC activation and incorporates a Ser1 to Gly1 mutation that blocks PLC activation ((the Arg19 change restores binding affinity otherwise lost by the C-terminal truncation), stimulates only cAMP/PKA signaling. [G1,R19]hPTH(1-34), with the 29-34 domain, was shown to activate cAMP/PKA and PLC-independent PKC. Doses of these peptides equipotent to 40 mg/kg hPTH(1-34) in acutely elevating blood cAMP 10 min after s.c. injection were administered to female C57BL mice 5 days/week for 4 weeks. Retesting of the blood cAMP responses after 4 weeks showed that acute AC activation was not altered by the preceding PTH treatment. Human PTH(1-34) increased total body BMD (PIXImus) and total femur BMD (4 weeks), which was mimicked by [G1,R19]hPTH(1-34) (a similar trend seen with [G1,R19]hPTH(1-28) was not significant). Micro-CT showed that all three analogs increased bone volume of the distal femur, T5 vertebra, and femur mid-shaft thickness, whereas [G1,R19]hPTH(1-34) was more potent in enhancing the microstructure of trabecular bone (as shown by ConnD and SMI). We conclude that the PLC signaling pathway is not required for PTH(1-34) to exert an anabolic effect on bone metabolism and that stimulation of cAMP/PKA alone, as demonstrated by the selective analog [G1,R19]hPTH(1-28), can increase bone formation with intermittent treatment. The PLC-independent PKC signaling pathway could play a role in the anabolic response by augmenting trabecular bone microstructure.

PTH Mediates Early Stem Cell Recruitment during Fracture Repair. G. L. Barnes, S. Kakar*, L. C. Gerstenfeld, T. A. Einhorn. Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

Parathyroid hormone (PTH) is the first FDA approved systemic anabolic factor that has been shown to increase bone mass in osteoporotic patients. There is an increasing awareness that the anabolic activity of PTH may have additional applications in Orthopaedics. Several studies have recently reported on the enhanced healing of fractures treated with systemically administered PTH. However, the molecular mechanisms by which either enhanced healing or regain of bone mass in osteoporotic conditions is achieved remain elusive. The majority of research to date has focused on the role of PTH in modulating osteoblast function in the context of coupled remodeling. While this may be an important component of PTH mediated enhanced bone formation, alternate mechanisms may exist in fracture repair that occurs through an endochondral process dependent on early chondrogenic events. In order to define the stages of fracture repair enhanced by PTH treatment we analyzed the tissue, cellular, and molecular effects of PTH treatment (40 µg/Kg, PTH 1-34) during bone healing in a murine femoral fracture model. Radiographically, we observe that PTH treatment lead to increased mineralization of the fracture callus by day 10 and an earlier bridging of the fracture site. Histological analysis demonstrated that PTH increased the rate of cartilage recruitment, the total quantity of cartilage and its rate of hypertrophic maturation. Molecular analysis confirmed these observations showing that PTH treated fractures expressed Col2A1 and Col10A1 on average two days earlier than in vehicle treated animals. The earlier induction of cartilage hypertrophy was accompanied by an earlier induction of matrix metalloproteinases, specifically MMP9, associated with cartilage turnover and callus vascularization, critical steps in the endochondral repair process. Analysis of regulatory molecules associated with these early chondrogenic events demonstrated that PTH treatment lead to enhanced and earlier expression of Wnts-4 and -5b both shown in previous studies to be important regulators of chondroprogenitor proliferation and maturation. Together these results support the conclusion that PTH treatment enhanced fracture healing in part by inducing nascent mesenchymal cell recruitment into the chondrogenic lineage and by enhancing the subsequent maturation and expansion of these cells through a Wnt mediated mechanism. Finally these results suggest that PTH may have efficacy as a therapeutic to enhance fracture healing over a very short time course of systemic treatment.

Calcium Transport into Milk Is Impaired in Deafwaddler Mice. J. N. VanHouten*[1], M. C. Neville*[2], J. J. Wysolmerski[1]. [1]Endocrinology, Yale University, New Haven, CT, USA, [2]Physiology, University of Colorado, Denver, CO, USA.

Milk production requires the transport of large amounts of calcium across the mammary epithelium. Prior work had suggested that, within mammary epithelial cells, calcium is transported into the Golgi apparatus where it becomes associated with casein micelles and enters milk via the secretory pathway. In order to define the molecules involved in transepithelial calcium transport in breast tissue, we performed a microarray analysis examining the transition between pregnancy and lactation in normal mice. This analysis demonstrated that plasma membrane calcium ATPase 2 (PMCA2) is the most abundant calcium transporter expressed in the mammary gland during lactation. Quantitative real-time RT-PCR demonstrated a 30-fold induction of PMCA2 mRNA levels in the mammary gland during the transition from pregnancy to lactation. Immunofluorescence and immunoelectron microscopy demonstrated that PMCA2 is located exclusively on the apical plasma membrane of mammary epithelial cells during lactation. Deafwaddler mice have neurological and inner ear defects due to loss-of-function mutations in the PMCA2 gene (Atp2b2). The dfw mutation is a single bp substitution resulting in reduced activity of the transporter, while the dfw-2J mutation is a 2 bp deletion that is functionally null. We analyzed milk calcium concentrations and maternal calcium metabolism in heterozygous and homozygous dfw and dfw-2J mice and wild type controls. Dfw-2J homozygotes showed a 75% reduction in milk calcium, while the heterozygous dfw-2J and homozygous dfw mice displayed lesser reductions in milk calcium concentrations. These results confirm that PMCA2 is necessary for the normal transport of calcium into milk. Furthermore, our data suggest that, in contrast to the generally accepted paradigm, a significant portion of the calcium in milk is transported from the cytoplasm directly across the apical membrane of mammary epithelial cells. We have previously found that the calcium-sensing receptor (CaR) regulates calcium transport into milk. Since the CaR has been shown to regulate PMCA activity in MDCK cells, we are currently examining the possibility that CaR signaling regulates PMCA2 activity in lactating mammary cells.

Phenylalanine-34 of Parathyroid Hormone Modulates Regulation of PTH(7-34)-Induced Type I PTH Receptor (PTH1R) Internalization by the Sodium/Proton Exchanger Regulatory Factor Type I (NHERF1/EBP50). W. B. Sneddon. Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Internalization of the Parathyroid Hormone Type I Receptor (PTH1R) is regulated in a cell- and ligand-specific manner. We previously demonstrated that the presence or absence of the sodium/proton exchanger regulatory factor type 1 (NHERF1; EBP50) is pivotal in determining the range of peptides that internalize the PTH1R. PTH(7-34) and PTHrP(7-34), which bind to, but do not activate the PTH1R, internalize the PTH1R 80% after 15 min in kidney distal tubule (DT) cells, where NHERF1 is not expressed. Introduction of NHERF1 into distal tubule cells blocks PTH(7-34)-, but not PTHrP(7-34)-induced PTH1R internalization. To delineate the sequences within PTH that confer NHERF1-sensitivity to PTH1R internalization, a series of chimeric PTH/PTHrP fragments were synthesized and tested for their ability to induce PTH1R internalization. PTH1R internalization was measured by real time confocal fluorescence microscopy of mouse DT cells stably expressing 10^6 EGFP-tagged PTH1R/cell. PTHrP sequences in the C terminal of PTH(7-34) abolished NHERF1 sensitivity for PTH1R internalization. PTH(7-21)/PTHrP(22-34), PTH(7-32)/PTHrP(33-34) and PTH(7-33)/PTHrP(34) at 1 µM each internalized the PTH1R 50-70% in a NHERF1-independent manner. When the C terminus of PTHrP was replaced with homologous amino acids from PTH, NHERF1 inhibited PTH1R internalization. These experiments implicated position 34 (F in PTH, A in PTHrP) as being critical in determining the role of NHERF1 in PTH1R internalization. None of the chimeric peptides tested above activated the PTH1R but effectively competed for 1 nM PTH(1-34) in cyclic AMP assays. In the absence of NHERF1, PTHrP(7-21)/PTH(22-34) competed with an EC_{50} of 0.1 nM, as compared with 100 nM for PTH(7-21)/PTHrP(22-34). In the presence of NHERF1, however, both PTHrP(7-21)/PTH(22-34) and PTH(7-21)/PTHrP(22-34) had comparable EC_{50} s (200 nM and 800 nM, respectively). Chimeric peptides substituted in the 32-34 positions competed for PTH(1-34) with EC_{50} s in the 100-1000 nM range and these values were not affected by the presence of NHERF1. Therefore, the sequences responsible for the NHERF1 sensitivity of PTH1R binding, in contrast to internalization, lie in the region of PTH(22-31). We conclude, therefore, that position 34 in PTH dictates NHERF1-dependent PTH1R internalization by non-activating PTH peptides and could provide a target for developing agents that can nonselectively downregulate the PTH1R.

Human XLαs (hXLαs) Functions as a Powerful α Stimulatory G Protein Subunit. A. Linglart*[1], M. J. Mahon[1], T. Dean*[1], T. J. Gardella[1], G. N. Hendy[2], H. Jüppner[1], M. Bastepe[1]. [1]Endocrine Unit, Mass. Gen. Hosp. and Harvard Medical School, Boston, MA, USA, [2]Depts. of Medicine, Physiology, and Human Genetics, McGill University and Royal Victoria Hosp., Montreal, PQ, Canada.

XLα_s and the G protein α stimulatory subunit (Gα_s) differ by their N-termini but share their C-terminal domains encoded by exons 2-13 of *GNAS*. Gα_s is, in most tissues, biallelically expressed, whereas XLα_s expression occurs only from the paternal allele. We have previously shown that hXLα_s can mediate cAMP formation after agonist stimulation of G protein coupled receptors in cells that endogenously lack Gα_s and XLα_s (Gnas$^{E2-/-}$ cells). Moreover, loss of function mutations of *GNAS* alter receptor mediated cAMP generation through Gα_s and hXLα_s, suggesting that hXLα_s might be involved in phenotypes of diseases caused by paternally inherited mutations of *GNAS*, such as Albright's osteodystrophy and progressive osseous heteroplasia. To confirm that hXLα_s functions as a component of the G protein, we characterized hXLα_s signaling function in Gnas$^{E2-/-}$ and COS-7 cells. Transduction of Gnas$^{E2-/-}$ cells with an adenoviral vector encoding hXLα_s, followed by confocal immunofluorescence microscopy with a hXLα_s-specific antibody, determined that hXLα_s localizes to both the cell membrane and the transGolgi network. In membrane binding assays, cotransduction of Gnas$^{E2-/-}$ cells with the human PTH receptor (PTHR1) and Gα_s or hXLα_s fully recovered receptor binding of PTH(1-15) analog, which, in contrast to PTH(1-34), completely failed to bind PTHR1 expressed alone in Gnas$^{E2-/-}$ cells. Through the use of metal affinity chromatography, hXLα_s could be co-purified and co-precipitated with the G$\beta_1\gamma_2$ subunits from membranes of COS-7 cells triply transduced with hXL$_s$, His_6-tagged Gβ_1 and Gγ_2. These data indicate that hXLα_s localizes to the cell membrane and interacts with PTHR1 and the G$\beta_1\gamma_2$ subunits. In addition, transduction of increasing amounts of Gα_s or hXLα_s in Gnas$^{E2-/-}$ cells showed a 2-fold greater cAMP generation in hXLα_s transduced cells, both during the basal state and following endogenous β adrenergic receptor stimulation. Northern blot, quantitative RT-PCR and Western-blot analysis confirmed the greater efficiency of hXLα_s in stimulating adenylyl cyclase, showing a 3 to 5-fold lower expression of hXLα_s mRNA and protein compared to Gα_s in transduced Gnas$^{E2-/-}$ cells. Interestingly, PTH(1-34) treatment induced similar levels of Gα_s and hXLα_s dependent cAMP formation. In conclusion, we showed that hXLα_s can mediate signaling as a stimulatory G protein, and that it might be more efficient than Gα_s in a receptor selective manner. Further studies are required to elucidate the function of hXLα_s and its involvement in disease pathogenesis.

Adipogenesis Is Enhanced in Bone Marrow Stromal Cells Lacking the Vitamin D Receptor. L. Cianferotti, M. B. Demay. Endocrine Unit, Massachusetts General Hospital Harvard Medical School, Boston, MA, USA.

The bone marrow contains multipotential mesenchymal stem cells (BMSCs) that are able to differentiate into multiple cell lineages including myocytes, chondrocytes, osteoblasts, and adipocytes. It has been demonstrated in a variety of bone marrow stromal cell models, either cell lines or primary cultures, that the differentiation into these lineages can be influenced by hormones and local growth factors. Factors that promote osteoblastic differentiation are generally considered to be inhibitory for adipocyte differentiation and vice versa. BMSCs are known to be target cells for the biologically active metabolite of vitamin D, 1,25-dihydroxyvitamin D (1,25D). The effects of 1,25D on osteoblastic and adipocytic cell differentiation are conflicting and they depend upon the species of origin as well as on the type and maturational stage of the cells. In primary cultures of murine BMSCs, 1,25D has been shown to inhibit adipocyte differentiation. To determine whether the ablation of the vitamin D receptor (VDR) results in an increased adipocytic commitment, the pattern of adipocytic differentiation in BMSC, isolated from VDR-null mice, was evaluated. BMSCs were harvested by flushing femora and tibiae from 17 day old wild-type and VDR knockout mice according to a standard protocol and seeded at a cell density of $4x10^5$ cells/cm^2. After 2h incubation at 37°C in 7% CO_2, humified air the nonhaderent cells were removed and fresh supplemented DMEM was added. Then cells were cultured until 80% confluent and then exposed to adipogenic agonists (0.5 mM methylisobutyl-xanthine, 0.5 μM hydrocortisone and 60 μM indomethacin, MHI) and/or 10^{-8} M 1,25D for 3 days. Cells treated with DMEM were used as controls. Cultures were harvested 10 days after the addition of the adipogenic agonists. Differentiation was assessed on fixed cultures with Oil Red O and alkaline phosphatase staining. The absence of the VDR did not alter the number of osteogenic or adipogenic foci under basal conditions. However, MHI induction resulted in an increased number of adipogenic foci in the VDR-null cultures relative to the MHI-treated wild-type cultures. While MHI treatment alone did not alter the number of osteogenic foci in the wild-type or VDR-null cultures, co-treatment with 1,25D and MHI blocked the effects of MHI on adipogenic differentiation in the wild-type cultures. Treatment with 1,25D alone did not alter the number of adipogenic foci, however, dramatically decreased the number of osteogenic foci in the wild-type cultures. These findings demonstrate that the absence of the VDR enhances adipogenesis and support a direct effect of 1,25D on differentiation of BMSCs.

Phosphorylation of the Human Retinoid X Receptor Prevents Vitamin D-Dependent Nucleocytoplasmic Trafficking. L. Nguyen-Yamamoto[1], S. Laporte*[1], S. Mader*[2], M. Marcoritto*[1], D. C. Huang[1], R. Kremer[1]. [1]Medicine, McGill University Health Center, Montreal, PQ, Canada, [2]Biochemistry, University of Montreal, Montreal, PQ, Canada.

In previous studies we demonstrated that resistance to the action of 1,25 dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) occurs in *ras*-transformed human keratinocytes (HPK1A-*Ras*) cells due to phosphorylation of the heterodimeric partner of the vitamin D receptor (VDR), the retinoid X receptor (RXRα), at serine 260, through the mitogen-activated protein kinase (MAP kinase) cascade (Solomom C *et al*. 1999). In the present study, we further explored the mechanism responsible for this resistance by examining the consequences of human (h) RXRα phosphorylation on nuclear/cytoplasmic distribution of the receptor following its induction by $1,25(OH)_2D_3$ in the presence or absence of the MAP kinase inhibitor, U0126 (Promega). Nucleocytoplasmic trafficking of hRXRα was visualized using green fluorescent protein labeled hRXRα (GFP-hRXRα), generated using pGFP-CMV topaz into which the hRXRα cDNA was inserted . This plasmid was then transiently transfected into immortalized human keratinocytes (HPK1A) or *ras*-transformed human keratinocytes (HPK1A-*ras*) in the presence or absence of 10uM of U0126. Cells were treated with or without 10^{-7}M of $1,25(OH)_2D_3$ for 1; 1,5; 2 ; 24 and 48 hr and GFP-hRXRα distribution was assessed by confocal microscopy. In the absence of $1,25(OH)_2D_3$ GFP-hRXRα distribution was predominantly cytoplasmic in both HPK1A and HPK1A-*Ras* cells. In HPK1A cells GFP-hRXRα reorganization occured rapidly in a time dependent manner after $1,25(OH)_2D_3$ treatment. Two hours after addition of $1,25(OH)_2D_3$, GFP-hRXRα moved from the cytoplasm to the perinuclear region forming a visible ring around the nucleus and then rapidly penetrating the nuclear compartment. In contrast cytoplasmic transport towards the nucleus was delayed for at least 24 h in *ras*-transformed keratinocytes. Addition of 10 uM U0126 restored GFP-hRXRα movements in response to $1,25(OH)_2D_3$ in *ras*-transformed cells but did not alter nucleocytoplasmic trafficking in HPK1A cells. Similar results were observed using a non-phosphorylable hRXRα mutant (Ala 260hRXRα). These results therefore demonstrate that RXR phosphorylation delays its nuclear translocation and may explain the attenuated VDR-mediated transactivation and resistance to the growth inhibitory action of $1,25(OH)_2D_3$ observed in *ras*-transformed keratinocytes.

Nongenomic Estrogen Signalling Regulates Osteoclast Formation via An Adaptor Protein, BCAR1, that also Modifies Breast Cancer Progression. L. J. Robinson*, A. C. Sharrow*, V. García Palacios, J. Xue*, H. C. Blair. Pathology, University of Pittsburgh and Veteran's Affairs Medical Center, Pittsburgh, PA, USA.

It was discovered in trials of synthetic estrogen receptor modulators (SERMs) for osteoporosis that these compounds also modify breast cancer progression. Effects vary with agent. Some SERMs such as daidzein closely mimic estrogen effects and may increase risk, while others such as raloxifene or tamoxifen dramatically lower cancer risk. Despite their importance to osteoporosis and neoplasia, the mechanisms of estrogen and SERM activity remain poorly understood. We recently reported that estrogen and SERMs regulate osteoclast differentiation via non-genomic rapid effects (~15 min) on NF-κB [J Biol Chem 280:13720, 2005]. Estrogen effects include interference with Map-kinase activation, but time course data show that the earliest effects are on NF-κB activation. Here we show that a gene identified in breast cancer antiestrogen resistance, BCAR1, is a key element in nongenomic estrogen signaling in osteoclast differentiation. BCAR1 is an adaptor protein, the human homolog of murine p130Cas. Immunoprecipitation of ERα from murine Raw264.7 cells or human CD14 monocytes co-precipitated BCAR1. This occurred even after 18h in 10 nM estradiol. Thus, even at high estrogen activity a significant portion of the estrogen-bound ERα is cytoplasmic and capable of nongenomic interactions. The association of BCAR1 with ERα was greatly enhanced by short exposures to estrogen (5-15 minutes), and formation of the ERα-BCAR1 complex was further enhanced by concurrent RANKL stimulation. The antiestrogen ICI182780 abolished BCAR pulldown; tamxoifen had intermediate effects, with less marked stimulation of BCAR1 coprecipitation and no enhancement by RANKL. The estrogen-ER-BCAR1 complex might interfere with NF-κB signaling through effects on Src or other tyrosine kinases, direct interactions with upstream signaling proteins such as trafs, or by the inhibition of IκB degradation, which was observed following estrogen stimulation. The effects of RANKL on ERα-BCAR association, however, suggest that structural stabilization of the intermediate adaptor protein complex is also involved. Probing these complexes for traf6 showed variable association, with precipitation of traf 6 increasing by about 70% at 5 min in estradiol + RANKL, with ~half this effect in estradiol, relative to control, and with differences decreasing to undetectable levels by 15 min. We conclude that estrogen and SERMs, via BCAR1, regulate RANKL signalling. A similar nongenomic mechanism may thus regulate growth and survival in breast epithelium, and probably contributes to the effects of SERMs on breast cancer incidence.

Inhibition of Glucocorticoid Signaling by Overexpression of 11beta HSD2 in Mature Osteoblasts Inhibits Nodule Formation and Increases Adipogenesis *In Vitro*. H. Zhou, K. Brennan*, Y. Zheng*, C. R. Dunstan, M. J. Seibel. Bone Research Program, ANZAC Research Institue, Sydney, Australia.

Transgenic (tg) expression of 11beta-hydroxysteroid dehydrogenase type 2 (HSD2), a glucocorticoid (GC) inactivating enzyme, under the control of a 2.3Kb collagen type I promotor (Col2.3-HSD2) abrogates intracellular GC signalling in mature osteoblasts, as demonstrated by Sher et al. (1). To characterise the phenotypic and functional properties of osteoblasts overexpressing Col2.3-HSD2, primary osteoblast cultures were generated from the calvaria of 1-day-old tg mice and wildtype (WT) littermates. Col2.3-HSD2 tg cultures developed 50% fewer nodules compared to WT after 2 weeks culture in the presence of 10 nM corticosterone, ascorbate and beta-glycerophosphate. Alkaline phosphatase (ALP) activity was decreased from day 3 in Col2.3-HSD2 tg cultures. At the same time, a significant increase in adipocyte numbers was observed in the cultures from Col2.3-HSD2 tg mice, suggesting a shift in lineage commitment from osteoblast to adipocyte. RNA was isolated at days 1, 3 and 7 of cultures. Quantitative RT-PCR revealed that mRNA for HSD2 was only detected in Col2.3-HSD2 tg mice with increased expression levels observed from day 3 to day 7, indicating that the number of mature osteoblasts was increasing during culture. At day 1, mRNA for Runx2, ALP, and osteocalcin were expressed at low but similar levels in cells from both Col2.3-HSD2 tg and WT. These mRNA levels remained low after 3 days in cells cultured from Col2.3-HSD2 tg mice, while they increased concurrently with osteoblast differentiation in the WT culture. Conversely, mRNA expression of the adipogenic transcription factors C/EBP alpha and PPAR gamma was increased at day 3 in Col2.3-HSD2 tg cultures but not in WT cultures. These results indicate that disruption of GC signalling in mature osteoblasts impairs early osteoblast differentiation and promotes adipogenic differentiation. This suggests the existence of a GC regulated paracrine signal between mature osteoblasts and their mesenchymal precursors that influences lineage commitment.

Genetic Evidence of Androgen Receptor Function in Osteoclasts. T. Nakamura[1], T. Watanabe*[1], Y. Nakamichi[1], Y. Azuma[2], K. Yoshimura*[1], T. Matsumoto*[1], T. Fukuda*[1], E. Ochiai*[1], D. Metzger*[3], P. Chambon*[3], T. Sato*[1], S. Kato[1]. [1]Institute of Molecular and Cellular Biosciences, The University of Tokyo/ ERATO, JST, Tokyo, Japan, [2]Pharmaceutical Discovery Research Laboratories, Teijin Pharma Limited, Tokyo, Japan, [3]Institut de Geneique et de Biologie Moleculaire et Cellulaire, CNRS/ INSERM/ ULP, College de France, Strasbourg, France.

Anabolic action of androgens in bone has been well described to increase BMD and bone mass. Such androgen action is believed to mediate nuclear androgen receptor (AR), and in fact, ablation of AR in male mice resulted in loss of BMD with high bone turnover. Androgen appears to suppress bone resorption (Kawano. H et al., PNAS, 100, 9416-9421, 2003). However, primary target cells of such androgen actions in bones have not yet been defined, though AR expression is detectable in osteoblasts, but not in osteoclasts. To directly examine physiological impact of AR in osteoclasts, we used a Cre/loxP system to disrupt AR gene in osteoclasts. First, we established Cathepsin K-Cre knock-in mice as an osteoclast-specific Cre expression Tg mice line. To generate osteoclast-specific ARKO (Oc-ARKO) mice, we then crossed the Cathepsin K-Cre mice with floxed AR mice. The Oc-ARKO mice had normal appearance, with no difference from the WT mice in the growth rate, gonad development and circulating hormone levels. However, 3D-micro CT analysis of distal femora from Oc-ARKO mice showed marked decrease of trabecular bone volume. Furthermore, histomorphometric analysis of the lumber spine showed significantly increased number of osteoclasts with enhancement of the other bone resorption parameters compared with control mice. Reflecting increased bone resorption, the levels of urinary deoxypyridinoline was increased. Importantly, the bone formation parameters were also increased in Oc-ARKO mice. Thus, from the present findings all together, it is likely that anabolic action of androgens is exerted by suppression of bone resorption through AR at least in part in osteoclasts.

Loss of ERα Signaling via EREs Is Associated with Differential Effects on Total Body vs. Marrow Fat. F. A. Syed, U. I. L. Moedder, D. G. Fraser*, S. Khosla. Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA.

Estrogen receptor α (ERα) is known to play an important role in both bone and adipose tissue. We have previously demonstrated that mice with a deleted ERα allele on one chromosome and a knock-in of a mutant ERα that cannot bind EREs on the other chromosome (ERα-/NERKI) have a paradoxical response to ovariectomy (ovx) and E replacement in cortical bone (JBMR vol.19 :S339, 2004). In the present study, we examined consequences of loss of classical ERα signaling (via EREs) on total body and marrow fat in female mice. As assessed by DXA, ERα-/NERKI mice had lower total body bone mineral density (BMD) (by 16%) but higher total body percent fat (by 56%) as compared to their wild type (WT) littermates ($P < 0.01$ for all comparisons), despite having similar body weights. By contrast, while trabecular bone volume/total volume (BV/TV) in the tibial metaphysis was similar in female ERα-/NERKI and WT mice, ERα-/NERKI mice had a marked (~10-fold) reduction in bone marrow adipocyte number and volume per tissue area ($P < 0.001$). Moreover, whereas WT female mice had an increase in percent total body fat following ovx (of +257%), ERα-/NERKI showed the opposite trend (decrease of 68%, $P < 0.01$ for a treatment x genotype interaction by ANOVA), reminiscent of the paradoxical responses to ovx in cortical bone we previously observed in ERα-/NERKI mice. Again, in contrast to this paradoxical response to ovx in ERα-/NERKI mice for total body fat, the bone marrow adipocyte parameters increased comparably following ovx in the ERα-/NERKI and WT mice ($P = 0.575$ and $P = 0.394$ for a treatment x genotype interaction by ANOVA for adipocyte number and volume respectively). Collectively, these findings demonstrate that loss of classical ERE signaling has very different consequences for total body vs. marrow fat. The preservation of trabecular BV/TV and marked deficit in bone marrow adipocyte number and volume in the ERα-/NERKI suggests a fundamental defect either in the mesenchymal precursors to these cells and/or in bone marrow adipocyte differentiation that is not evident in non-marrow adipocytes. Defining further the mechanism(s) of these site-specific differences in estrogen regulation of bone marrow vs. non-marrow adipocytes should provide novel insights into estrogen regulation of adipocytes at different sites as well as into estrogen effects on mesenchymal precursor cells and on adipocyte/osteoblast differentiation.

Gain Bones by Cutting off Fat. X. Shi[1], X. Cao[2], X. Shen*[2]. [1]Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, [2]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Bone marrow mesenchymal stem/progenitor cells (MSCs) can differentiate into multiple cell lineages. Accumulating evidence has shown that the osteoblast and adipocyte are two dominant lineages and that the commitment of MSCs toward these two pathways is reciprocal, i.e, when adipocyte pathway is blocked, the MSCs enter osteoblast pathway. CCAAT/enhancer-binding protein-alpha (C/EBPa), an important adipogenic factor, is also a potent inhibitor of cell proliferation. C/EBPa arrests cell proliferation by interacting with cyclin-dependent kinases (Cdk2/4) and disrupting their association with cyclins. We have found that glucocorticoid-induced leucine zipper (GILZ), a recently identified transcription factor whose expression is induced by glucocorticoid (GC), blocks adipocyte differentiation. To investigate the molecular mechanisms by which GILZ inhibits adipocyte differentiation, we examined the effects of GILZ on C/EBPa expression and the possible involvement of GILZ in C/EBP-alpha-mediated cell cycle arrest. We found, in co-immunoprecipitation assays, that GILZ physically interacts with C/EBPa but not Cdk2, however, GILZ disrupts the interaction between C/EBPa and Cdk2, suggesting that the disruption of C/EBPa and Cdk2 interaction by GILZ is responsible for GILZ-mediated inhibition of adipocyte differentiation. The mRNA level and the promoter activity of C/EBPa were also inhibited by GILZ as shown by real-time RT-PCR and promoter-luciferase analyses, respectively. Because C/EBPa can bind to its own promoter and autoregulate its expression, we also examined whether GILZ affects the binding of C/EBPa to its own promoter region. Chromatin immunoprecipitation (ChIP) assay showed that C/EBPa binds to its own promoter in the region between nucleotides -109 to -245 covering a well-characterized C/EBP binding site (-176 to -203). Treatment of the cells with dexamethasone, which induces GILZ expression, inhibited the DNA-binding activity of C/EBPa. Interestingly, the expression of C/EBP-beta and -delta, which also bind to this C/EBP binding site, was not affected as demonstrated by real-time RT-PCR and immunohistological staining experiments. These studies reveal a novel mechanism of transcriptional regulation of adipocyte differentiation and suggest a possibility of increasing new bone formation by inhibiting fat formation.

Androgen Action on Cortical Bone Surfaces Requires a Functional Androgen Receptor: Evidence from the Androgen Receptor Knock-out Mouse Model. K. Venken*, K. De Gendt*, S. Boonen, R. Bouillon, J. Swinnen*, G. Verhoeven*, D. Vanderschueren. K.U.Leuven, Leuven, Belgium.

Males develop wider bones than females during puberty. It remains uncertain to what extent this extra periosteal expansion in males is mediated by the androgen receptor (AR). The aim of the present study was to determine whether androgen action on male cortical bone modeling depends on activation of the AR or, alternatively, on aromatisation of androgens into estrogens. To this end, 3-week-old AR knock-out mice (ARKO) and corresponding male WTs were either sham-operated (sham) or orchidectomized (orx). Orx mice were treated with either vehicle, testosterone (T) (1.5 µg/day via subcutaneous implants) or T plus aromatase inhibitor (AI) (anastrazole, 10 mg/kg/day p.o.). At 8 weeks of age, endocortical and periosteal growth of the mid-femoral shaft was assessed by dynamic histomorphometry. Periosteal osteoblast number and activity were decreased in sham ARKO mice compared to sham WT, as reflected by a significantly reduced periosteal mineralizing perimeter (Min. Pm.) (-56%, $P<0.001$) and mineral apposition rate (MAR) (-32%, $P<0.05$). As a result, the periosteal bone formation rate (BFR) ($P<0.05$) was reduced to more than 50% in ARKO mice ($P<0.05$), associated with a decreased periosteal perimeter (-14%, $P<0.0005$) and cross-sectional area (-13%, $P=0.0001$). Moreover, the endocortical MAR and BFR were significantly increased in sham ARKO mice (+72% and +110% vs sham WT, respectively, $P<0.05$), concomitant with a decreased endocortical perimeter (-5%, $P=0.01$) and medullary area (-9%, $P<0.005$). Furthermore, administration of T to orx WT mice significantly increased the periosteal Min. Pm. (+141% vs orx WT, $P<0.0001$) and BFR (+163%, $P<0.005$), resulting in an increased periosteal perimeter (+10%, $P<0.0001$) and cortical thickness (+47%, $P<0.0001$). Interestingly, administration

of T plus AI partly reduced the effects of T on the periosteal Min. Pm. (-25%, $P<0.0001$ vs WT orx + T) and BFR (-34%, $P<0.005$), resulting in a thinner cortex (-7%, $P<0.0001$) and smaller periosteal perimeter (-9%, $P<0.0001$). In contrast, the periosteal and endocortical bone surface of ARKO mice remained completely unresponsive to either T or T plus AI. Therefore, AR-mediated androgen action is clearly important for cortical bone growth in male mice; however, part of the androgen effect on the periosteal bone surface is also explained by aromatisation of androgens to estrogens. Moreover, this effect of aromatisation is only observed in the presence of a functional AR. We conclude that the AR is critically involved in cortical bone modeling and differentially regulates endocortical and periosteal growth, with suppressive versus stimulatory effects, respectively.

Recruitment of Vitamin D and Estrogen Hormone-Specific Modifiers to Chromatin. H. Chen, M. Hewison, L. Nguyen*, J. S. Adams. Endocrinology/ Medicine, Burns and Allen Research Institute and Division of Endocrinology, Cedars-Sinai Medical Center, David Geffen School of Medicine at UC, Los Angeles, CA, USA.

Heterogeneous nuclear ribonucleoproteins (hnRNPs) are naturally-occurring nucleic acid binding proteins. Generally recognized for their ability to regulate mRNA processing and splicing, hnRNPs can also compete *in trans* with sterol/steroid hormone receptor dimers for their cognate *cis* response elements in the promoters of hormone-regulated genes. In this mode the hnRNPs act predominantly as dominant-negative inhibitors of transactivation. When relatively over-expressed in either subhuman or human primate cells, these hnRNPs can cause hormone resistance *in vivo*. Here we employed chromatin immunoprecipitation (ChIP) studies to visualize the temporal recruitment and assembly of two such endogenous, dominant-negative-acting hnRNPs, one a human vitamin D response element binding protein (VDRE-BP) and another a primate estrogen response element binding protein (ERE-BP), as well as competitive vitamin D receptor (VDR) and estrogen receptor *alpha* (ER) on native VDR-VDRE- and ER-ERE-responsive promoters. The time course of interaction of ligand-activated VDR and ER with the VDRE in the 24-hydroxlase promoter and ERE in the cathepsin D promoter, respectively, was monitored in control (wild-type) cells as well as in those naturally over-expressing the VDRE-BP and ERE-BP cell lines. Cells were treated without or with 10 nM 17ß-estradiol (E2) or 1,25-dihydroxyvitamin D_3 (1,25-D) for 15, 30, 45, 60, 75, 90, 120 and 165 min before disruption and ChIP with anti-VDR, -ER, -hnRNP antibody or with nonspecific IgG followed by VDRE and ERE amplification by PCR. In control cells, lacking substantial amounts of the VDRE-BP and ERE-BP, the VDRE and ERE were relatively unoccupied by the VDR and ER in the absence of added hormone. Hormone exposure led to maximum recruitment of VDR and ER to the promoter as early as 15 min and an "on-off" cycling interval of 60 min for both the VDR-VDRE and ER-ERE. The VDR-VDRE and ER-ERE interaction in hnRNP over-expressing cells was characteristically altered from the wild-type, control situation: 1] before ligand exposure the response elements were already occupied by the VDRE-BP and ERE-BP; and 2] after hormone exposure there was a quantitative decrease and temporal delay in VDR and ER recruitment to the promoter as well as prolongation of the receptor-response element "on-off" cycle. Taken together, these data indicate that hnRNPs can legislate vitamin D- and estrogen-resistance by virtue of their persistent presence on the VDRE and ERE, respectively, blocking 1,25-D-VDR and E2-ER-driven transactivation.

Antiresorptive Effects of Calcitriol Are Independent of Parathyroid Hormone Secretion in Rats. R. G. Erben[1], M. Herber*[2], K. Weber*[2]. [1]University of Veterinary Medicine, Institute of Pathophysiology, Vienna, Austria, [2]University of Munich, Institute of Animal Physiology, Munich, Germany.

It is unclear at present whether the antiresorptive effects of vitamin D analogs in vivo are mediated through a suppression of parathyroid hormone (PTH) secretion or through a direct antiresorptive action on bone. In the current experiment, we examined the skeletal effects of calcitriol administration in sham-operated (SHAM) rats, parathyroidectomized (PTX) rats, and PTX rats supplemented with physiological doses of rPTH(1-34). Seventy-two female 6-month-old Fischer 344 rats were either PTX or sham-operated. The success of PTX was confirmed by measurement of ionized blood calcium 2 days after surgery. Subsequently, half of the PTX rats received subcutaneously implanted osmotic minipumps delivering 8 µg rPTH(1-34) per kg body weight per day. This dose of rPTH(1-34) was found to normalize hypocalcemia and serum PTH in PTX rats in preliminary experiments. All other rats received minipumps delivering vehicle. Beginning the day after implantation of the minipumps, groups of SHAM, PTX, and PTH-supplemented PTX rats (n = 8 each) received vehicle, 0.05, or 0.1 µg calcitriol/kg/day orally via the diet. Preliminary experiments had shown that the antiresorptive and bone anabolic effect of calcitriol is most pronounced when the drug is administered orally via the diet. All animals were killed 2 weeks after the start of the experiment. PTX resulted in hypocalcemia, and very low, but detectable immunoreactive serum PTH levels, 17 days postsurgery. Supplementation of PTX rats with rPTH(1-34) resulted in complete normalization of circulating PTH and serum calcium levels. Calcitriol administration increased serum calcium in PTX and rPTH(1-34)-supplemented PTX rats, but not in SHAM rats. However, all calcitriol-treated rats were hypercalciuric, independent of circulating PTH levels. Vertebral bone formation rate increased dose-dependently in calcitriol-treated rats, especially in PTX rats. Interestingly, the most pronounced decrease in urinary collagen cross-link excretion induced by calcitriol was found in rPTH(1-34)-supplemented PTX rats, showing that the antiresorptive effects of calcitriol occurs in the presence of constant, physiological levels of PTH. Thus, the antiresorptive effects of calcitriol in vivo are not solely mediated through suppression of PTH secretion.

Clinical Relevance of Determing Vit-D by Fractionating 25-hydroxy-Vit-D into 25-hydroxy-Vit-D2 and 25-hydroxy-Vit-D3. R. J. Singh. Dept. of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA.

Introduction: Measurement of 25 OH vitamin D provides the single best assessment of vitamin D nutritional status. Vitamin D is an essential component in the regulation of calcium and bone metabolism. Vitamin D (calciferol) is a term used to include both cholecalciferol D3 and ergocalciferol D2. Both of these compounds are transported to the liver where they are hydroxylated to produce 25-hydroxyvitamin D. D2 and D3 are both used to supplement vitamin D deficient patients. Decreased levels may be due to dietary deficiency, mal-absorption, liver disease and in patients receiving medications that accelerate vitamin D metabolism. In addition Vitamin D levels vary widely with age and geographic region. Materials and Methods: LC-MS/MS method: Deuterated stable isotope (d3-25-hydroxyvitamin D) is added to a 0.2-mL plasma sample as internal standard. 25-Hydroxyvitamin D2, D3, and the internal standard are extracted using acetonitrile precipitation. The extracts are then further purified online and analyzed by LC-MS/MS using multiple reaction monitoring. 25-OH-VitD2 and 25-OH-VitD3 are quantified individually and a sum was used for correaltion studies. Interassay CVs were less than 15% at various D2 and D3 levels. Sensitivity is set at 2 ng/mL for D3 based on interassay CV of 12.9% at 1.7 ng/mL. Sensitivity was 4 ng/mL for D2 based on interassay CV of 14.0% at 4.2 ng/mL. 100 patient samples submitted for 25 OH Vit-D analysis were used for the method comparison studies with the Diasorin RIA, LIAISON® (DiaSorin, Inc, Stillwater, MN) and the Nichols Advantage. Results and Conclusions: Quantification of 25 OH vitamin D with 100 patient samples by liquid chromatography-tandem mass spectrometry resulted in individual values for D2 and D3. The combined total values of 25 OH vitamin D were then compared to the values from immunoassays. Comparison of the LC-MS/MS method to the RIA (LC-MS-MC = 0.91(RIA) + 5.4 ng/mL (r=0.93)) and the LIA (LC-MS/MS method = 1.02(LIA) + 2.0 ng/mL (r=0.90)) yielded acceptable correlations in the range from 7-150 ng/mL, but poor correlation to another immunoassay due to under detection of 25-OH D2. In Conclusion the LC-MS/MS method which is considered to be a gold standard method for the measurement of 25 OH vitamin D is now widely available for clinical use and has several advantages over the immunoassays.

Determinants of Bone Mineral Density in Female Adolescents. Z. Harel*[1], M. Gold*[2], B. Cromer[3], A. Bruner*[4], M. Stager*[3], L. Bachrach[5], P. Hertweck*[6], A. Nelson*[7], D. Nelson[8], S. Coupey*[9]. [1]Hasbro Children's Hospital and Brown University, Providence, RI, USA, [2]Children's Hospital of Pittsburgh, Pittsburgh, PA, USA, [3]Metro-Health Medical Center, Cleveland, OH, USA, [4]Johns Hopkins University School of Medicine, Baltimore, MD, USA, [5]Stanford University School of Medicine, Stanford, CA, USA, [6]University of Louisville, Louisville, KY, USA, [7]David Geffen School of Medicine at UCLA, Torrance, CA, USA, [8]Wayne State University School of Medicine, Detroit, MI, USA, [9]Children's Hospital at Montefiore, New York, NY, USA.

During adolescence, bone formation prevails over resorption, resulting in accumulation of 40% of peak bone mass. We examined several factors that may affect bone mass accrual during this critical period. The population comprised 389 healthy postmenarchal adolescent girls aged 11-18 years, who were recruited into a prospective, IRB-approved, ongoing study of the effect of depot medroxyprogesterone acetate (Depo-Provera® 150 mg) on bone health in adolescents. Healthcare providers collected demographic, reproductive health, and lifestyle data, and performed a complete physical examination. Body mass index (BMI) was calculated. Prior to study initiation, bone mineral density (BMD) at the lumbar spine, total hip, and femoral neck was measured by dual-energy X-ray absorptiometry (DXA), and markers of bone metabolism (serum osteocalcin, bone-specific alkaline phosphatase [AP], and urinary N-telopeptide [uNTX]) were measured. Potential associations between baseline BMD values and other parameters were assessed by analysis of variance and Pearson's correlation coefficients (PCC). Subjects enrolled in the study had mean [±SD (range)] chronological age 14.9 ±1.7 (11-18) years, gynecologic age 39.9 ±23.0 (0.5-119) months post menarche, and BMI 23.5 ±4.6 (16.0-42.2) kg/m^2. Ethnic distribution was African American 46%, Caucasian 35%, and other races 19%; 9.3% had previously been pregnant. Positive correlations were observed between lumbar spine BMD and chronological age, gynecologic age, and BMI (PCC 0.301, 0.349, 0.371, respectively). Average total hip and femoral neck BMDs were significantly higher (p=0.0028 and p=0.0060, respectively) in African Americans than in other participants. Smoking and alcohol use were not associated with significant differences in BMD. Negative correlations were observed between lumbar spine BMD and both uNTX (PCC -0.406) and AP (PCC -0.363) levels. Our data indicate that chronological age, gynecologic age, BMI, and race are independent determinants of BMD in adolescents. Serum AP and uNTX levels are inversely associated with BMD values in this age group.

Octacalcium Phosphate(OCP) and Other Transient Mineral Species Are Observed in Mouse Sutures during Normal Development and Craniosynostosis. V. Popescu*[1], N. J. Crane*[1], M. D. Morris*[1], M. A. Ignelzi Jr.[2], P. Steenhuis*[2]. [1]Chemistry Department, University of Michigan, Ann Arbor, MI, USA, [2]Department of Orthodontics and Pediatric Dentistry, University of Michigan, Ann Arbor, MI, USA.

We have studied early mineralization of calvarial tissue from fetal day 18.5 B6CBA F1/J wild-type mice bone cultured in serum free media for up to 3 days. Specimens were treated with FGF2-soaked heparin acrylic beads to mimic craniosynostosis. Control specimens received beads containing only the culture medium. Tissue specimens were analyzed using Raman microspectroscopy at intervals of several hours. At each time point multiple spectra were obtained and multivariate curve resolution was used to obtain the spectra of mineral species and to estimate the relative amounts of minerals. During the first 24 h of both normal and accelerated mineralization we observed a transient intermediate similar to OCP, and a highly disorder calcium phosphate, similar to amorphous calcium phosphate (ACP), postulated precursors of bone mineral. We also observed normal bone mineral. For the OCP-like material, the P-O stretch was found at 955 cm 1 and there was an additional HPO4-2 P-O stretch at 1010-1014 cm 1, as expected for OCP. Additionally a broad band was found at 945 cm 1, characteristic of disordered calcium phosphate or ACP. Bone mineral, P-O stretch 957-962 cm 1, was found at all time points. This is the first observation of non-apatitic early mineral in bone tissue. ACP and OCP have been detected as carbonated apatite precursors in inorganic model systems, but not in bone tissue itself. Detection of the same intermediates in normal and accelerated mineralization is further confirmation that craniosynostotic mineralization follows the same chemistry as normal mineralization, but at a more rapid rate.

Assignments for the Raman Bands of the Tissue Components

Raman shift (cm-1)	Band Assignment	Component
945 cm-1	phosphate, P-O	ACP, disordered mineral
955 cm-1	phosphate, P-O	OCP
1010-1014 cm-1	monohydrogen phosphate, P-O	OCP
957-962 cm-1	phosphate, P-O bone mineral	carbonated apatite

Determinants of Total Body and Forearm Bone Mass in Chinese Postmenarcheal Girls. K. Zhu*[1], H. Greenfield*[1], Q. Zhang*[1], L. H. Foo*[1], G. S. Ma*[2], C. T. Cowell[3], D. R. Fraser*[1]. [1]Faculty of Veterinary Science, University of Sydney, Sydney, Australia, [2]Institute for Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China, [3]Institute of Endocrinology and Diabetes, Children's Hospital at Westmead, Westmead, Australia.

The aim of this study was to evaluate the relationship between bone mass and weight, height, bone age, pubertal development, dietary intakes, physical activity and vitamin D status in Chinese postmenarcheal girls. The study subjects were 175 girls aged 15 ± 0.4 years from 17 schools in Beijing, who were in the control group of a milk intervention trial. Bone mineral content (BMC) and density (BMD) and bone area (BA) of total body and distal and proximal forearm were assessed by dual-energy X-ray absorptiometry (Norland XR-36). Dietary intakes were evaluated by two 3-day food records and physical activity by a questionnaire of past-year activity. Serum 25(OH)D concentrations were determined by radioimmunoassay (DiaSorin) in fasting blood samples obtained in late winter. This study was carried out with the approval of the ethics committees of the University of Sydney, Australia and the Institute for Nutrition and Food Safety, China. BMC and BMD of both total body and forearm were positively correlated with weight, height, bone age, Tanner stage of breast and pubic hair development, physical activity level, milk intake, total months of menstruation, and serum 25(OH)D concentration ($P<0.05$) . The relationships between these variables and bone mass were further evaluated in multiple regression models. Corresponding BA was the most important predictor of total body and forearm BMC and accounted for 39.0-60.4% of the variation. Body weight entered all the regression models as the most important predictor of BMD (explaining 17.2 - 41.7% of the variation) and the second most important predictor of BMC (explaining 7.8-13.8% of the variation). The only other variable entering the regression models for total body BMC and BMD was milk intake, which accounted for 2.8-6.0% of the variation. Other significant predictors of proximal and distal forearm BMC and BMD were bone age (explaining 3-10.9% of the variation), serum 25(OH)D concentration (explaining 1.0-2.3% of the variation), and milk intake (for proximal forearm only, explaining 3.2-6.1% of the variation). The study results indicated that milk intake and vitamin D status were important determinants of bone mass in Chinese postmenarcheal girls. Increasing milk intake and improving vitamin D status may have beneficial effects on peak bone mass attainment in this population.

Age at Pubertal Growth Spurt Is a Predictor of Final Height as a Result of Affected Appendicular but not Axial Skeletal Growth - *The GOOD Study*. S. H. Windahl[1], J. M. Kindblom[1], M. Lorentzon[1], E. Norjavaara*[2], Å. Hellqvist*[3], S. Nilsson*[3], D. Mellström[1], C. Ohlsson[1]. [1]Center for Bone Research at the Sahlgrenska Academy, Departments of Internal Medicine and Geriatrics, Gothenburg University, Gothenburg, Sweden, [2]Institute for the Health of Women and Children, Gothenburg University, Gothenburg, Sweden, [3]Swegene Bioinformatics, Gothenburg University, Gothenburg, Sweden.

The control of linear growth is complex and depends on a number of factors including nutrition and hormones. Pharmacological manipulation of pubertal onset has been used to modulate final height in girls. However, the role of age at pubertal onset for final height in boys is unclear. A problem with assessments of growth is that most sets of height growth reference values are based on cross sectional studies. The aim with the current study was to investigate the importance of age at pubertal growth spurt for final height and body

proportions in a large well characterized cohort of young men. Detailed growth charts from birth up to 18-20 years of age were available for 549 men participating in the *G*othenburg *O*steoporosis and *O*besity *D*eterminants (*GOOD*) study. These growth charts were analysed using the infancy-childhood-pubertal growth model and used for the calculation of peak height velocity (PHV), occurring two years after the initiation of puberty. The time of PHV was then correlated with measurements of final height as well as upper (axial skeleton, sitting height) and lower (appendicular skeleton, height-sitting height) segments. Measurements of height, upper and lower segment at young adult age revealed that age at pubertal growth spurt was a strong positive predictor for final height (β= 0.128, p=0.003) and a strong negative predictor for the ratio between upper and lower segment (β= -0.213, p<0.001). We next compared the subjects with early puberty (EP, the 15% with earliest PHV, 12.0 ± 0.4 years of age) with those with late puberty (LP, the 15 % with latest PHV, 15.2 ± 0.5 years of age). The positive association of age at PHV with final height was reflected by increased length of the lower segment (+2.5±0.6 cm over EP, p=0.002) but unaltered sitting height (-0.4±0.4 cm over EP, NS) in subjects with LP compared with EP. Consequently, the ratio between the upper and lower segment was reduced (-3.31 ± 0.81%, p<0.001). We have determined PHV for 549 young Swedish men using longitudinal growth curves. Our results demonstrate that age at the pubertal growth spurt is a strong positive predictor of final height, reflecting increased appendicular but not axial skeletal growth in subjects with LP.

A Randomised Controlled Trial (RCT) of Calcium Supplementation in School-Children and Gymnasts. K. A. Ward[1], S. A. Roberts*[1], S. A. New*[2], J. E. Adams[1], M. Z. Mughal[3]. [1]University of Manchester, Manchester, United Kingdom, [2]University of Surrey, Guildford, United Kingdom, [3]Central Manchester and Manchester Children's University Hospitals NHS Trust, Manchester, United Kingdom.

The adaptation of bone to exercise has been shown to be modified by calcium. The aim of this double-blind RCT was to investigate whether there was a differential response to calcium supplementation in elite gymnasts (G, 15 hours exercise/ week) and school children (controls; C 7 hours exercise/ week). The primary hypothesis was that G who took calcium supplements would have greater increases in cortical and trabecular bone mineral density (CtBMD, TrBMD) at the radius (R) and tibia (T). Secondary outcomes were changes in bone geometry at the R, T and lumbar spine and total body measurements. Children were randomised to 12 months daily supplementation of 500g calcium carbonate (Calcichew™, Shire Pharmaceuticals) or placebo. Outcome measures were taken using peripheral quantitative computed tomography (pQCT) (distal and diaphyseal R and T) and dual energy X-ray absorptiometry (DXA) (lumbar spine and whole body). Eighty-six subjects (49 females) participated in the RCT (44G: 42C) and 75 subjects completed the trial (45 females, 39G: 36C). Data were analysed by analysis of covariance adjusting for baseline value, age, height, gender and puberty, and delay between baseline measurement and start of intervention. The primary analysis was for a calcium-exercise interaction; a pooled calcium effect with no interaction was also tested. The primary outcome measures are given in the table and expressed as a ratio of calcium: placebo.

Variable	Controls	Gymnasts	Pooled effect P	Interaction P
T CtBMD	1.00 *(0.99, 1.01)*	1.01 *(1.00, 1.02)*	0.357	0.207
T TrBMD	1.05 *(1.00, 1.09)*	0.98 *(0.94, 1.02)*	0.370	0.035
R CtBMD	1.01 *(0.98, 1.01)*	0.99 *(0.98, 1.01)*	0.250	0.675
R TrBMD	1.07 *(0.99, 1.15)*	0.96 *(0.89, 1.03)*	0.663	0.053

Results are presented as ratios (*95% CI*) For all other secondary outcomes at R, T, spine and whole body no significant interactions were found. In conclusion, there was no beneficial effect of calcium in gymnasts who already consume their recommended nutrient intake (800mg/day) for calcium. The interaction between calcium and exercise may only occur in children who do not participate in regular sports at the beginning of the intervention. We speculate that G have already adapted their bones (geometry and density) to the demands imposed upon them by the loading they are subjected to during gymnastics and do not require extra calcium supplementation.

A Novel Strategy to Study Healthy Elementary School Communities in Mexico City Focused in Osteoporosis Prevention at Different Socio Economical Levels; Invest in your Bones Program. A. F. Goribar*, L. De Villafranca*, A. Cabra*, J. A. Tamayo*. International Osteoporosis Foundation, Comite Mexicano para Prevención de la Osteoporosis, Mexico, Mexico.

The purpose of this study was to develop a strategy to obtain the participation of the whole school community, named: school master, teachers, parents and students in our long term program, and to define if there is a difference in bone development between two socio economical environments (SE) public; lower C, (Pu) and private; middle B+ to high A, (Pi). The first phase objectives are: education, sensitization, teachers and students measuring their bone status, parents knowing the results of their own kids. Three motivational conferences: to the teachers coupled by SOS attenuation at the forearm and tibia: their own bones, parents and students given by their teachers coupled to a school activity. We got an informed consent to measure SOS in the kids Sunlight omnisense 8000S, height, weight & BMI were recorded. 3 Pu and 3 Pi schools participated. We included a total of 1459 students, 828 from Pi, 631 from Pu centers, over 95% of total population. Aged 6 to 12 years, 748 male, 711 female. As seen in the graphs 52.1% of the total population is bellow the 25th percentile of SOS, irrespectively of BMI, age & sex. A significant difference was also found between Pu vs Pr; 41.3% of Pu vs. 28.8% of Pi students were bellow the 25th percentile. This novel approach demonstrates that school community is quite sensitive to this strategy, irrespectively of their SE. Almost the total of the teachers and student population participated in the program. A key factor is the combination of a well designed conference to the teachers and parents, coupled with a direct measurement of the teachers own bones. The students interest was boosted by the educational activity and they knowing their own bone status. SOS measurements showed a significant deficiency in the development status of the bones in 52.1% of these healthy student populations. A significant influence of SE was also demonstrated.

Molecular Dissection of BMP Signaling Pathways in Control and Fibrodysplasia Ossificans Progressiva Lymphoblastoid Cells. J. L. Fiori*, P. C. Billings*, F. S. Kaplan, E. M. Shore. Orthopaedic Surgery, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP) is a rare genetic disease characterized by progressive heterotopic ossification and congenital malformation of the great toes. Perivascular accumulation of lymphocytes with subsequent infiltration and death of skeletal muscle are the earliest histopathological findings. Although the molecular mechanisms giving rise to this condition have not been fully elucidated, we have hypothesized that defects in the bone morphogenetic protein (BMP) signaling pathway play an important role in FOP pathophysiology. Previously, we demonstrated that BMP4 is overexpressed and BMP4 antagonists are underexpressed in FOP lymphoblastoid cells (LCLs). Also, the BMP receptor type IA (BMPRIA) is elevated 6-fold on the surface of FOP cells compared with controls. BMP receptors activate at least two downstream pathways; the canonical Smad pathway and the p38 MAPK pathway. In this study, we investigated the BMP signaling pathways and transcriptional targets in control and FOP LCLs. Basal mRNA levels of the early BMP response genes ID1 and ID3 were similar in control and FOP LCLs. However, in the presence of BMP4, levels of ID1 and ID3 in FOP cells were at least 2-fold higher than control cells. Although the Smad pathway has been described as the major transducer of BMP signaling in most reported cell types, we detected very low levels of Smad1 mRNA and protein in cultured LCLs as well as in primary B cells and found no upregulation of MSX2, a BMP-Smad specific target gene, following BMP4 treatment of control and FOP cells. When control LCLs were transfected with a Smad1 expression construct, treatment with BMP4 resulted in the induction of ID1, ID3, and MSX2. In contrast, MSX2 expression was not observed in cells transfected with Smad6 (inhibitory Smad) and treated with BMP4. Therefore, LCLs do not normally activate the Smad pathway in response to BMP4, but have the ability to utilize this pathway if the necessary components are provided. BMP induction of ID1 and ID3 is reported to be mediated through both Smad and p38 MAPK pathways. We determined that expression of ID1 and ID3 was specifically blocked by SB203580, a p38 MAPK inhibitor, in control and FOP cells, suggesting that these genes are downstream targets of the BMP-p38 MAPK pathway. We conclude that Smad mediated signaling is not a significant pathway in human lymphoblasts and that p38 MAPK may be a key mediator of BMP in these cells. Differences in the BMP-p38 MAPK signaling pathway between control and FOP LCLs may provide an opportunity to identify therapeutic targets for this disabling disease.

Expression of Bone Morphogenetic Proteins and their Receptors in the Bone Marrow Megakaryocytes of Mice Genetically Impaired for GATA-1 Expression (GATA-1^{low} Mice): a Possible Role in Osteosclerosis. R. Garimella[1], M. A. Kacena[2], S. Tague*[1], M. C. Horowitz[2], H. Clarke Anderson[1]. [1]University of Kansas Medical Center, Kansas City, KS, USA, [2]Yale University School of Medicine, New Haven, CT, USA.

Bone marrow megakaryocytes contain various growth factors implicated in the process of bone remodeling and repair, such as bone morphogenetic proteins (BMPs), transforming growth factor-β (TGF-)β, platelet derived growth factor (PDGF), osteocalcin (OC), osteopontin (OPN), osteoprotegrin (OPG), and vascular endothelial growth factor (VEGF). To date, only BMPs have been shown to induce new bone formation, in vivo. GATA-1 is a zinc finger transcription factor that plays an important role in erythroid and megakaryocyte differentiation. Low level expression of GATA-1 in mice results in excessive accumulation of immature megakaryocytes in the spleen and bone marrow, a reduction in blood platelets, and a striking increase in bone (osteosclerosis). The bone marrow in GATA-1^{low} mice contains elevated levels of TGF-β1, PDGF, VEGF and osteocalcin compared to normal mice. The hypotheses of our current study are (1) that the megakaryocytes in the bone marrow of GATA-1^{low} mice contribute to the osteosclerosis by stimulating bone formation via the expression of BMPs, which can upregulate osteoblast proliferation and differentiation and (2) that the osteosclerosis, seen in GATA-1^{low} mice, is not due to reduced osteoclast activity. Immunohistochemistry was performed to localize the expression of BMPs and their receptors in 5 μm paraffin embedded, decalcified, and paraformaldehyde (4 %) fixed tibia and spleen sections from twelve month-old GATA-1 wild-type and GATA-1^{low} mice, using polyclonal goat-anti-human BMP-2, 4, 6, 7, BMPR-IA, and BMPR-II antibodies. Marrow megakaryocytes of GATA-1 wild-type and GATA-1^{low} mice showed moderate to intense staining for BMP-2, BMP-4, BMP-6, BMP-7, BMPR-IA and BMPR-II, while splenic megakaryocytes showed no BMP-immunostaining. Overall, BMP expression in the bone marrow of GATA-1^{low} mice was more than that seen in controls, owing to an increased number of megakaryocytes and osteoblasts. To ascertain that the osteosclerosis seen in GATA-1^{low} mice is not due to reduced osteoclast activity, we performed TRAP staining and morphometry, and found that the number of TRAP^{+} osteoclasts was more in GATA-1^{low} mice than in controls. These findings demonstrate the presence of significant amounts of BMP-2, BMP-4, BMP-6, BMP-7, along with their receptors, in bone marrow megakaryocytes, which may, in part, be responsible for the stimulation of osteoblastic activity and resulting osteosclerosis seen in GATA-1^{low} mice.

Ectopic Bone Formation in Response to BMP2 as Compared to DBM Shows Both Similar and Unique Profiles of Transcriptional Expression. J. L. Fitch[1], K. T. S. Palomares*[2], K. Behnam*[3], D. Knaack*[3], T. A. Einhorn[1], L. C. Gerstenfeld[1]. [1]Orthopaedic Surgery, Boston University School of Medicine, Boston, MA, USA, [2]Biomedical Engineering, Boston University College of Engineering, Boston, MA, USA, [3]Osteotech, Inc., Eatontown, NJ, USA.

Demineralized bone matrix (DBM) is capable of inducing *de novo* cartilage and bone at extraskeletal sites. Bone morphogenetic proteins (BMPs) have been ascribed to primarily be responsible for the bioactivity of DBM. However, the bone matrix contains other morphogens, cytokines and mitogens that play a role in skeletal cell differentiation. This study compared the bioactivities associated with DBM and BMP2 by using active DBM, heat inactivated DBM and heat inactivated DBM conjugated to rhBMP2 that were implanted intramuscularly in nude rats over a 28 day time course. Transcriptional profiling of ~600 known skeletal tissue-associated genes was performed using a custom made 50nt oligo-nucleotide microarray. The mean expression values obtained for individual genes within the entire data set were used as the reference for that gene's expression and the transcriptional activity of a given gene was only considered if it was 1.5 fold greater or lesser than the reference. Using hierarchical clustering, separate groups of genes were identified as being uniquely induced by BMP2 or active DBM. While the expression data indicated that active DBM and BMP2 both induce osteogenesis via endochondral differentiation, conjugating BMP2 to DBM's osteoconductive matrix resulted in more rapid and robust differentiation. Selective genes that showed increased expression by both DBM and BMP-2 included osteocalcin (*oc*), bone sialoprotein (*bsp*), ras homolog gene family member b (*arhb*) and matrix metalloproteinases (*mmp*) 9 and 13. In addition to genes that were upregulated due to either treatment, we identified subset of genes that were uniquely upregulated as a result of DBM treatment alone. These included *bmp3*, nuclear hormone receptor co-activator interacting factor 1 (*nif1*), cartilage-derived retinoic acid-sensitive protein (*cd-rap*) and chloride intracellular channel 4 (*clic4*). Our results indicate that the bioactivity of DBM is more complex than that a single BMP (BMP-2). Because other BMPs are known to be found in DBM the current data does not discriminate if this more complex inductive activity is due to these activities or other morphogenetic factors.

Adenosine 3', 5'-Cyclic Monophosphate (cAMP) Enhances Bone Morphogenetic Protein (BMP) Activities through the Suppression of Smad6 Expression in Osteoprogenitor Cells. R. Sugama*, T. Koike, Y. Imai*, C. Nomura*, K. Takaoka. Department of Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan.

Bone morphogenetic proteins (BMPs) present potent osteogenic activities. In considering efficacious use of the BMPs, a basic important problem is low responsiveness of human mesenchymal cells to the BMP. In order to overcome the problem, additional agents or methods that intensify the BMP activity would be desired. Phosphodiesterase inhibitor, Pentoxifyline (PeTx), facilitates BMP activities but the precise mechanisms are currently unknown. We have hypothesized that elevation of intracellular cAMP level might intensify BMP signaling with interference to negative feed back mechanism. The purpose of this study is to elucidate the changes in mRNA expression of inhibitory Smad (Smad6) and in phosphorylated receptor-regulated Smads levels by cAMP and BMP-4 in osteogenic ST2 cells. PeTx alone had no effect on ALP activity in ST2 cells. In contrast, PeTx enhanced BMP-4-induced ALP activities in a dose-dependent manner. Intracellular level of cAMP increased about 7 times in 15 minutes after the addition of PeTx (0.9 mM). There was no additive effect on the level of cAMP by simultaneous addition of BMP-4 and PeTx. The effect of PeTx to enhance BMP action was mimicked by dbcAMP. In ST2 cells, Smad6 mRNA expression was increased by BMP-4 treatment. Quantitative real-time RT-PCR of the Smad6 mRNA expression treated with or without BMP-4 (300 ng/ml) and various doses of dbcAMP (100 to 2000 μM) revealed that dbcAMP reduced the BMP-4 induced Smad6 expression in a dose-dependent manner. Same result was obtained by Northern blotting. Phosphorylation of Smad1/5/8 after BMP-4 stimulation started from 1 hour later and became undetectable after day 3. Addition of dbcAMP did not exhibit significant effects on phosphorylation of Smad1/5/8 at 1 hour or 24 hour time points after treatments but maintained the phosphorylated Smad1/5/8 until day 5. These results indicate that elevated intracellular cAMP might enhance BMP signaling by suppressing Smad6 induction and prolonging intracellular BMP signaling. We concluded that the suppression of BMP-4 induced Smad6 expression would be one of the mechanisms for enhanced BMP action by PeTx and dbcAMP treatments. Manipulation of the BMP signaling loop may also provide a new insight to enhance efficacy of BMP-mediated local new bone formation for the treatment of damaged bone.

rhBMP-2 Enhances Bone Formation in a Biodegradable Scaffold. T. E. Hefferan, E. Jabbari*, A. Florschutz*, R. M. Mardones*, L. Lu*, B. L. Currier*, M. J. Yaszemski*. Dept of Orthopedics, Mayo Clinic College of Medicine, Rochester, MN, USA.

In the United States approximately 1 million patients per year require bone grafting procedures to repair skeletal defects. Current grafting options include the use of either autologous or allograph bone, metals, ceramics or bone cements, each of which have drawbacks. Synthetic biodegradable polymers have characteristics which could facilitate the repair of these defects. Therefore we investigated skeletal repair using a poly(propylene fumarate) (PPF) scaffold in conjunction with an osteogenic agent, rhBMP-2 (kindly provided by Wyeth), to induce bone formation in a critical size defect animal model. A 5 mm defect was generated in the femur of male Sprague-Dawley rats. Twelve animals were assigned to a treatment group and the defect was filled with either: PPF scaffold, PPF scaffold coated with rhBMP-2 (20 ug/ml), PPF scaffold with rhBMP-2 (25 ug/200mg) loaded microspheres or PPF scaffold with vehicle loaded microspheres. Poly(DL-lactic-co-glycolic acid) microspheres were embedded in the scaffold in order to examine the effect of encapsulation on the bone-forming activity of rhBMP-2. Scaffolds were harvested at 3, 6 and 12 weeks and bone mineral density (BMD) was measured using PIXImus DEXA (GE Healthcare). After determining the BMD, the scaffolds were processed for histology and stained with Goldners-Trichrome to evaluate mineralized tissue formation. At 3 weeks all scaffolds had similar BMD. At 6 weeks the scaffolds coated with rhBMP-2 had a significantly higher BMD (0.236 $\pm$ 0.014 g/cm2) compared to the PPF control scaffold (0.155 $\pm$ 0.018 g/cm2) ($p<0.05$). Also at 12 weeks the BMD of the rhBMP-2 coated scaffolds was significantly greater than the PPF control scaffold (0.294 $\pm$ 0.01 vs. 0.194 $\pm$ 0.03 g/cm2) $p<0.01$. Two-way ANOVA showed borderline significance ($p=0.055$) for the effect of the scaffold, while the effect of time was highly significant ($p=0.0001$). In fact, the BMD was greater at 12 weeks compared to 3 weeks for the PPF scaffold with vehicle microspheres ($p<0.01$), PPF scaffold with rhBMP-2 microspheres ($p<0.01$) and PPF scaffold coated with rhBMP-2 ($p<0.01$). In addition, Goldners staining showed adding rhBMP-2 to the scaffold resulted in better integration between the scaffold and the surrounding bone. The scaffolds without rhBMP-2 had less mineralization and more fibrous tissue. In conclusion, rhBMP-2 enhances bone formation in PPF scaffolds as shown by increased BMD and mineralization. Therefore, combining rhBMP-2 with a synthetic biodegradable polymer holds promise for the treatment of skeletal defects.

Proteomic Analysis of Bone Biomineralization Foci Isolated by Laser Capture Microscopy from Osteoblast Cultures. J. P. Gorski, N. T. Huffman*, H. Wright*. Oral Biology, Univ. of Missouri-Kansas City, Kansas City, MO, USA.

Biomineralization foci (BMF) are recently identified extracellular sites of mineral crystal nucleation in common osteoblastic culture models and in developing bone. Supramolecular complexes of 10-100 microns in diameter, BMF contain matrix vesicles and other membrane limited vesicles up to 900 nm in diameter. BMF are also enriched in bone acidic glycoprotein-75 (BAG-75), a phosphoprotein restricted to developing embryonic and primary bone, and, in bone sialoprotein. The goal of our study was to develop a method to isolate BMF and to begin to characterize their proteome in order to understand the underlying mineralization mechanism. UMR-106-01 osteoblastic cells were seeded at 4.8 x 10^5 cells/ml and grown on glass slides. Using a standardized protocol, cultures reach confluency by 64 h after plating. BGP (7 mM beta-glycerolphosphate) was added at 64 h and the location of mineral deposits scored 24 h later after fixation and staining with Alizarin red S dye (ARS). On culture slides, all specific ARS staining was associated with BMF. ARS-positive BMF were then isolated by laser capture microscopy (LCM) using an Arcturus Pix IIe microscope. BMF from several culture slides and different "caps" were pooled (2500-3000 BMF/preparation), extracted, and decalcified in 4 M guanidine HCl containing 0.5 M EDTA and protease inhibitors. Entire culture slides containing cells and BMF were also processed similarly and used as a total cell layer control. Extracts were subjected to one-dimensional SDS PAGE and either stained with Sypro Ruby or immunoblotted onto membranes and subjected to chemiluminescent detection. Also, stained bands were cut out, trypsinized, and subjected to mass spectrometric peptide mapping. Compared with the total cell layer, BMF were preferentially enriched in BAG-75 and bone sialoprotein, however, BMF exclusively contain a 50 kDa fragment rather than the 75 kDa BAG-75 precursor form. In contrast, fetuin and albumin from serum, and mitochondrial marker aspartate amino transferase were preferentially enriched in the total cell layer. Mass fingerprinting studies identified synaptotagmin VII (27% coverage) and immunoblotting studies confirmed its assignment as a 58,000 molecular weight component of BMF. The latter is thought to function in vesicular transport/secretion and may play a role in BMF assembly. Our study indicates that LCM can be used to isolate sufficient quantities of mineral containing BMF for proteomic and functional studies. The absence of fetuin from laser microscope captured BMF suggests the latter structures act as a barrier to mineralization inhibitors and provide a protected environment within which active mineral nucleation can occur.

Calcification versus Ossification - Histologic Features of Calcific Deposits of the Shoulder. C. Bartl*[1], P. Magosch*[2], S. Lichtenberg*[2], P. Habermeyer*[2], R. Bartl*[3]. [1]Dep. of Sportorthopaedics, Technical University, Munich, Germany, [2]Shoulder and Elbow Surgery, ATOS Clinic, Heidelberg, Germany, [3]Bavarian Osteoporosis Center, LMU, Munich, Germany.

The pathogenesis of Calcifying Tendinitis (CT) is still not well established. A high percentage of patients describe persistent complaints after conservative or shock wave therapy of deposits around the shoulder. Prognostic factors for outcome could not yet be identified. The purpose of this study was to evaluate the histologic nature of the calcific deposits and their correlation with radiologic findings. 83 shoulders (79 patients) with a radiologically confirmed deposit were prospectively scheduled for arthroscopic shoulder surgery. Preoperatively the deposits were graded as fluffy (1) or sharply demarcated (2) on standard radiographs. After arthroscopic removal of the deposits biopsies were embedded in methylmethacrylate. Sections were stained (Giemsa-, Gomori- and Ladewig-stain) and also immunohistology (Monoclonal anti-human macrophage antibodies -CD 68- and monoclonal endothel antibodies -CD 34-, DAKO) as well as analysis of collagen types (Polyclonal antibodies to collagen type I, II, III, Acris) was performed. Three distinct histologic stages (HS) of the deposits could be identified
Stage I: Calcification n=24(29%)
Stage II: Fibrotic Organisation n=7(8%)
Stage III: Ossification n=52(63%)
No significant correlation between the preoperative radiologic appearance and the histologic stage of the deposits could be identified >Basic histology and immunohistology revealed the presence of bone specific cells in all stage III deposits: Osteoclasts (CD 68, Giemsa), Osteocytes (Giemsa, Ladewig) and woven bone (Gomori). Also collagen type I proof was positive in over 90% of the cases. Stage I deposits consist only of a calcific mass divided by fibrous strands with no cells between. Stage II deposits show high vascularisation and a positive collagen III proof. In this study three definite histologic stages of deposits were identified that have not been described previously in Calcifying Tendinitis of the shoulder. The stage of ossification and not the classical calcific deposit (I) represents the major part of the cases. We underline the hypothesis that CT is an active cell-mediated tissue process which leads to fibrotic organisation and finally to production of primitive bone (`fibro-osseous metaplasia`) in a high number of cases. The significance of histologic stages of the deposits for pathogenesis and treatment of Calcifying Tendinitis of the shoulder must be evaluated in further studies.

An Unexpected Phenotype in Cathepsin K Deficiency. A. L. Boskey[1], L. Spevak*[1], E. Pourmand*[1], B. D. Gelb*[2], M. B. Schlaffler[2]. [1]Research Division, Hospital for Special Surgery, New York, NY, USA, [2]Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Cathepsin K (catK) is a cysteine protease with collagenolytic and proteoglycan degradative activities that is involved in osteoclast action, and is thought to be modify growth plate (GP) proteoglycans. Patients lacking catK activity show osteosclerosis and dwarfism, suggesting a role for CatK in endochondral ossification (EO). To define the role of catK in EO we asked if catK plays a direct or indirect (osteoclast-mediated) role in modulating GP matrix structure. CatK knockout (KO) mice have thicker bones and more numerous trabeculae but increased numbers of osteoclasts relative to age-matched wild type (WT) controls. The calcified cartilage and trabecular bone (just below GP) was characterized using infrared imaging (FTIRI) in 10 wk old KO and age, background, and sex-matched WT mice. Since proteoglycan aggregates (PGA) inhibit GP calcification we predicted that the KO in which PGA degradation would be limited would have decreased mineral content, mineral crystal size, carbonate/phosphate ratio, and collagen maturity as determined by FTIRI. Contrary to expectation, the KO GP had significantly increased mineral/matrix ratio (figure), increased collagen cross-link ratio, and no significant changes in mineral properties. The GP findings either indicate the failure of osteoclasts (whose functions depend on catK) to remodel the cartilage as it calcifies, an upregulation of another degradative enzyme in the absence of cathepsin K, an alteration in vascular invasion (facilitating calcification), or the possibility that the in vivo function of the enzyme does not match that observed in vitro. Parallel to these studies we added a broad spectrum cathepsin inhibitor (inhibitor III, Calbiochem) at 0-0.05 uM to calcifying chick limb-bud chondrocyte micro-mass cultures after the initiation of calcification. In this system there was a similar unexpected increase in calcification when the activity of the cathepsins was blocked. Since there is no osteoclast remodeling in this culture system, clearly there are effects on mineralization associated with matrix formation or endochondral ossification when cathepsin activity is limited. Thus, in the growth plate, catK may act as a mineralization inhibitor via matrix modification in ways we do not yet understand.

Integrin Alpha Is Indispensable for Ligaments to Resist Mechanical Stress-Induced Mineralization. F. Takizawa*[1], T. Yoshizawa[1], S. Maruyama*[2], F. Iizawa*[1], A. Matsuda*[1], O. Ishibashi[1], T. Saku*[2], H. Yoshie*[3], U. Mayer*[4], H. Kawashima[1]. [1]Cell Biology and Molecular Pharmacology, Niigata University, Niigata, Japan, [2]Oral Pathology, Niigata University, Niigata, Japan, [3]Periodontology, Niigata University, Niigata, Japan, [4]Wellcome Trust Center for Cell-Matrix Research, University of Manchester, Manchster, United Kingdom.

Mechanical stress (MS) promotes differentiation and maturation of osteoblasts and increases bone density and strength. In contrast, ligaments never mineralize in vivo despite constant exposure to intermittent MS. This led us to hypothesize that ligaments have a mechanism by which mineralization is prevented against MS. However, studies dealing with the response of ligament cells to MS are scarce and controversial, because there has been no established cell line available. To circumvent this problem, we have recently established a cell line, designated PDL-L2, from mouse periodontal ligament (PDL). This cell line has an early differentiation stage osteogenic character, but does not mineralize in vitro in medium favoring osteogenic mineralization despite expression of a significant amount of alkaline phosphatase and Runx2. Using this cell line, we examined how ligament cells respond to MS. MS induced sequential activation of FAK, ERK1/2, Runx and osteocalcin (OCN) production, and eventual mineralization in MC3T3E1 cells, but failed to induce any of these effects in PDL-L2 cells. Although details of mechanotransduction signaling pathways are not elucidated yet, accumulating evidence indicates that cells sense MS through integrins. cDNA microarray and RT-PCR demonstrated that integrin a7 was abundantly expressed in PDL-L2 but not in MC3T3-E1 cells. This was also confirmed at protein level by western blot and immunoprecipitation

analysis. In addition, in situ hybridization analysis demonstrated that integrin a7 was abundantly expressed in PDL cells but not in adjacent osteoblasts. Since both cell lines similarly express integrins a5, a2 and b1, we reasoned that the presence of integrin a7 might alter the mechanotransduction signal pathway. Indeed, when expression of integrin a7 in PDL-L2 was reduced by means of RNAi, MS induced sequencial activation of FAK, ERK1/2, Runx2 and OCN production, leading to mineralization in a similar manner observed in MC3T3-E1 cells. Moreover, integrin a7 KO mice developed ectopic mineralization in the PDL. These data clearly demonstrate that ligaments have a mechanism to resist MS-induced mineralization, in which integrin a7 is indispensable. Failure of this mechanism may be involved in the development of ossification of the posterior longitudinal ligaments of the spine.

HtrA1 Regulates the Deposition of a Mineralized Matrix by Osteoblasts. K. D. Hadfield*[1], C. Farrington Rock*[2], S. L. Dallas[3], L. Sudre*[1], G. A. Wallis*[1], R. P. Boot-Handford*[1], A. E. Canfield*[1]. [1]Wellcome Trust Centre for Cell-Matrix Research, The University of Manchester, Manchester, United Kingdom, [2]Cedars-Sinai Medical Center, Los Angeles, CA, USA, [3]University of Missouri, Kansas City, MO, USA.

HtrA1 is a secreted multi-domain protein with proven serine protease activity. There is increasing evidence to suggest that this protein plays a role in regulating skeletal development and pathology. First, HtrA1 is expressed in developing skeletal elements. Second, HtrA1 inhibits signalling mediated by TGFβ-family members. Third, HtrA1 is elevated in human osteoarthritic cartilage compared to controls. Finally, we have shown that HtrA1 is up-regulated as pericytes undergo osteogenic differentiation and mineralization. The purpose of this study was to investigate the role of HtrA1 in regulating matrix calcification and to identify which domains are essential for its activity. HtrA1 was markedly up-regulated in post-confluent cultures of the 2T3 murine osteoblast cell line and the growth plate chondrocyte ATDC5 cell line, just prior to calcification and was then down-regulated as matrix calcification occurred. The functional role of HtrA1 in osteoblast differentiation and matrix calcification was investigated using two complimentary approaches. First, a full-length HtrA1 expression plasmid was generated and transfected into 2T3 cells to generate stable over-expressing clones. These clones showed delayed mineralization relative to controls as determined by Alizarin red staining and ^{45}Ca incorporation. Furthermore, preliminary results have shown that high expression of HtrA1 negates BMP-2-induced mineralization of these cells. Second, recombinant full-length HtrA1 (rhHtrA1) and a series of domain-specific deletion constructs have been produced using a mammalian expression system. The protease activity of these proteins was confirmed by their ability to degrade β-casein. These proteins were added back to 2T3 cells and their effects on matrix mineralization determined. We report that rhHtrA1 decreases the extent of mineralization in 2T3 cells compared to controls. Finally, we tested the hypothesis that HtrA1 degrades specific matrix proteins, the loss of which is associated with matrix calcification. Accordingly, rhHtrA1 was found to degrade both recombinant decorin and matrix Gla protein (MGP). Furthermore, we demonstrated that both the protease domain and the PDZ domain were necessary for the degradation of MGP, whereas the PDZ domain was not essential for the degradation of decorin. Taken together, these results suggest that HtrA1 may regulate matrix calcification either via the inhibition of BMP-2 signalling and/or via the degradation of specific matrix proteins.

The Elastic Lamellae of Devitalized Rat Aortas Calcify Rapidly When Incubated in Serum: Implications for the Pathogenesis of Vascular Calcification. P. A. Price, W. S. Chan*, M. K. Williamson. Biology, University of California, San Diego, La Jolla, CA, USA.

The present studies show for the first time that EDTA-extracted, devitalized rat aortas calcify rapidly when incubated at 37°C in rat serum or plasma. This serum-induced artery calcification begins with numerous calcification foci in the elastic lamellae of the artery media, the same location seen for calcification in the arteries of patients with uremia and diabetes, and in the matrix Gla protein (MGP)-deficient rodent. The elastic lamellae of devitalized aortas also calcify when incubated in human serum for 6 days at 37°C, but only if serum phosphate is first raised from the normal 1mM level in human serum to 2mM or greater (the level normally found in rats). It is of interest to note that elevated serum phosphate is a strong predictor of medial artery calcification in uremic patients. Devitalized aortas also calcify when incubated in DMEM containing as little as 1.5% rat serum, but not when incubated in DMEM alone. Since the addition of 1.5% serum has a trivial impact on the ionic composition of DMEM, the probable explanation for this effect is that serum contains an agent that induces artery calcification. Living aortas do not calcify when incubated in DMEM containing serum, which suggests that vascular cells normally prevent the serum-induced calcification of the artery media *in vivo*. This hypothesis is supported by the observation that the living rat aortas secrete the calcification inhibitor MGP into culture medium at a rate of 3μg/aorta/day over the course of these experiments. The serum factor that initiates calcification of elastic lamellae in devitalized arteries has the same potency, size, and protease sensitivity as the serum factor recently shown to initiate the re-calcification of the type 1 collagen matrix of demineralized bone (J. Biol. Chem. (2004) 279:19169-80). If one serum calcification factor is indeed responsible for initiating calcification of collagen and elastin matrices, it could help to explain how agents that act specifically on bone, such as alendronate, ibandronate, and osteoprotegerin, are able to potently inhibit artery calcification in the rat (J. Biol. Chem. (2004) 279: 1594-1600).

Histone Deacetylase Inhibitors: New Strategy for the Management of Rheumatoid Arthritis. H. S. Lin*, C. Y. Hu*, H. Y. Chan*, Y. Y. Liew*, H. P. Huang*, L. Lepescheux*, E. Bastianelli*, R. Baron, P. Clement-Lacroix, G. Rawadi. ProStrakan, Romainville, France.

Bone destruction is a characteristic feature of rheumatoid arthritis (RA) and constitutes a major cause of progressive disability. Bone loss involves osteoclasts, which are responsible for periarticular joint destruction, and are induced by a first step inflammatory process. Osteoclastogenesis secondary to the inflammatory process is evident in animal models of RA such as collagen-induced arthritis (CIA). It has been shown that synovial cells in CIA and RA release several inflammatory cytokines and treatment of CIA with anti-inflammatory agent blocks osteoclastogenesis, thereby preventing focal bone destruction. MS-275 and suberoylanilide hydroxamic acid (SAHA) are two histone deacetylase inhibitors (HDACi), a class of compounds known to have anti-inflammatory properties. In the present study, the anti-rheumatoid arthritis effects of MS-275 and SAHA were tested in two rodent collagen induced arthritis models. Animals were treated with SAHA or MS-275 and monitored 2-3 times per week for paw swelling. On day 36 after induction, the arthritis bearing mice had maximal clinical score. The clinical score of SAHA (50 or 5 mg/kg) and low dose of MS-275 (3 mg/kg) treated mice was about 30% and 60%, respectively lower than the clinical score in the vehicle group; while high dose MS-275 (10 mg/kg) treated mice had no significant clinical symptom of arthritis. Similar results were also observed in rats and MS-275 (3 mg/kg) could even completely prevent the onset of swelling of both paws in rats. At two weeks after onset of arthritis, the hind paws were evaluated using radiography and histology; while left tibia was analyzed with tomograph micro-CT. Radiological observation indicated HDACi treated animal had less or even no bone destruction; while the control animals suffered from serious bone erosion. Histopathologic analyses indicated the preventive effect of HDACi in structural joint damage. The protective effects of HDACi in bone loss associated with CIA were also documented. The anti-RA effects of the tested HDACi appeared to be dose dependent. These findings demonstrate that HADCi have powerful anti-inflammatory effects leading to bone protection in arthritis. In conclusion, HDACi could be a new strategy for the management of RA.

PGE2 Signal through EP2 Promotes the Growth of Articular Chondrocytes. T. Aoyama[1], B. Liang*[2], T. Matsusaki*[2], T. Nakayama*[2], T. Nakamura[2], J. Toguchida[1]. [1]Department of Tissue Regeneration, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan, [2]Department of Orthopedic Surgery, Kyoto University, Kyoto, Japan.

Prostaglandin E2 (PGE2) exhibits pleiotropic effects in various types of tissue through four types of receptor, EP1-4. The role of PGE2 in the metabolism of articular cartilage is still a matter of debate. We examined the expression of EPs and effect of agonists for each EP on articular chondrocytes. Immunohistochemical and RT-PCR analyses revealed that chondrocytes in human articular cartilage expressed EP2 and EP3 with less intensity, whereas EP1 and EP4 were not detected in any cells. A chondrocyte cell line, MMA2, was established from articular cartilage of p53-/- mice and used to analyze the effects of agonists for each EP, which were provided by Ono Pharmaceutical Co. MMA2 expressed EP2 as well as primary cultured chondrocytes, and the treatment with EP2 agonist increased the level of intracellular cAMP in a concentration-dependent manner, suggesting a functional role for EP2 in MMA2. Molecules downstream of the PGE2 signal through EP2 in MMA2 were investigated by gene-expression profiling before and after the treatment with EP2 agonist (1μM) using a cDNA microarray. 22 genes were isolated as up-regulated by the treatment of EP2 agonist, including several growth-promoting and apoptosis-protecting genes such as the cyclinD1, fibronectin, integrin alpha 5, AP2 alpha, and 14-3-3 gamma genes. The up-regulation of these genes by the EP2 agonist was confirmed in human articular chondrocytes by quantitative mRNA analysis, suggesting a growth-promoting effect of the EP2 agonist on normal articular chondrocytes. The cellular incorporation of BrdU by primary human articular chondrocytes was decreased by the treatment with indomethacin (5μM) and increased by EP2 agonist (1μM). Growth promoting effect of EP2 agonist for articular chondrocytes was further analyzed in organ culture of rat femora, and the proportion of PCNA-positive cells was significantly increased after a 14-day incubation with EP2 agonist (Fig.1). These results suggested that the EP2 agonist was able to exert growth-promoting effects on cells surrounded by cartilage matrix, and combined with suitable drug-delivery systems, EP2 agonist is a promising therapeutic compound for the treatment of degenerative cartilage diseases.

Wnt Signaling in Human and Bovine Articular Chondrocytes. K. E. Yates, S. Shortkroff*. Orthopedic Research, Brigham and Women's Hospital, Boston, MA, USA.

The Wnt signaling network is one of the major regulators of embryonic skeletal development. After birth, Wnts continue to function in osteoblast differentiation and bone density. Whether Wnts are similarly active in cartilage, however, is less clear. In this study, we hypothesized that Wnt signals regulate chondrocyte function. Human articular chondrocytes were isolated from cartilage discarded during total knee replacement surgeries for treatment of osteoarthritis. Bovine articular chondrocytes were isolated from shoulders of young calves. Gene expression of Wnt pathway components was measured by cDNA array (Superarray, Inc.) and by RT-PCR. Proteoglycan content was evaluated by Alcian blue staining of monolayer cultures. Conditioned media were prepared from L and LWnt3a cells (American Type Culture Collection). Whole cell lysates and nuclear extracts were prepared using a commercially available kit (ActiveMotif, Inc). Western blots were probed with anti-β-catenin (Santa Cruz Biologicals) and anti-histone H4 antibodies (Upstate Biotechnology). Human articular chondrocytes (n=3) were found to express high levels of b-*CATENIN*, *AXIN2*, and *FRZB* mRNAs. The AXIN2 protein is induced in response to Wnt signals and acts as a negative feedback inhibitor; FRZB competes with Wnt proteins for receptors. The presence of those components in hACs, therefore, was indicative of active Wnt/b-catenin signaling in those cells. RT-PCR confirmed expression of several Wnt mRNAs in hACs that are known to transduce signals via the canonical b-catenin pathway (*WNT7a*, *WNT10b*, *WNT14*). Moreover, treatment of bACs with Wnt3a induced stabilization of b-catenin in a similar time-frame as in control L cells (maximal response within 3h). *In vitro* aging/de-differentiation of bACs by cell passaging also stabilized b-catenin in bACs, prior to the expected decrease in matrix proteoglycan. B-catenin levels were not altered in primary cultures that achieved confluence. Those results suggested that the loss of chondrocyte phenotype in passaged bACs was associated with an increase in Wnt signaling via the canonical b-catenin pathway. It was surprising, therefore, that addition of the Wnt antagonist lithium chloride (LiCl) did not mimic the effect of *in vitro* aging on proteoglycan synthesis by bACs. Immunoblot analyses showed that b-catenin was not stabilized in bACs by short term (up to 6 h) or extended exposure (48 h) to 5 mM LiCl. Moreover, b-catenin was not stabilized after 48 h exposure to increasing amounts of LiCl (5, 10, and 20 mM). The mechanism underlying this resistance to LiCl in bACs is not known. Nevertheless, our data indicate that the Wnt/b-catenin signaling pathway is active, and actively modulated, in articular chondrocytes

***In Vivo* Delivery of Fluoresceinated Dextrans to the Murine Growth Plate: Imaging of Three Vascular Routes by Multiphoton Microscopy.** C. Farnum*[1], M. Lenox*[1], W. Zipfel*[2], W. Horton*[3], R. Williams*[2]. [1]Biomedical Sciences, Cornell University, Ithaca, NY, USA, [2]Applied and Engineering Physics, Cornell University, Ithaca, NY, USA, [3]Shriner's Hospital for Children, Portland, OR, USA.

Bone elongation by endochondral ossification occurs through the differentiation cascade of chondrocytes of cartilaginous growth plates. Molecules from the systemic vasculature reach the growth plate from three different directions: epiphyseal, metaphyseal and via a ring vessel and plexus associated with the perichondrium. This study is an analysis of the real-time dynamics of entrance of fluoresceinated tracers of different molecular weights into the growth plate from the systemic vasculature, and tests the hypothesis that molecular weight is a key variable in the determination of both the directionality and the extent of tracer movement into the growth plate. Multiphoton microscopy was used for direct in vivo imaging of the murine proximal tibial growth plate in anesthetized 4-5 week old transgenic mice with green fluorescent protein linked to the collagen II promoter. Mice were given an intracardiac injection of either fluorescein (332.3 Da) or fluoresceinated dextrans of 3, 10, 40, 70 kDa, singly or sequentially. For each tracer, directionality and rate of arrival, together with extent of movement within the growth plate, were imaged in real time. For each image series, fluorescence data were summed transversely across the growth plate. Arrival time was defined as the first time at which the position-specific fluorescence reach one half of its 5-minute value. The amount of tracer entering compared with that available in the vasculature varied with molecular weight, falling off significantly from fluorescein to dextrans of 3 kDa and 10 kDa, while 40 kDa and 70 kDa dextrans did not enter. Rate of entrance and potential directionality of entrance from the systemic injection did not appear to differ for fluorescein and the 3 kDa and 10 kDa dextrans. The potential for movement within the growth plate was equally permissive from either the metaphyseal or the epiphyseal side. These results have implications for understanding paracrine and systemic regulation of growth plate chondrocyte differentiation, as well as variables associated with effective drug delivery to the growth plate.

Thyroid Hormone (T3) Realizes Ideal Redifferentiation of Dedifferentiated Chondrocytes in Cooperation with BMP-2 and Insulin. K. Hoshi, G. Liu*, T. Ogasawara, Y. Asawa*, U. Chung, T. Takato*, K. Nakamura, H. Kawaguchi. The Univsersity of Tokyo, Graduate School of Medicine, Tokyo, Japan.

Chondrocytes isolated from donor cartilage should be made to proliferate in vitro, for the application in cartilage tissue engineering. However, decrease in the matrix synthesis of collagen type II (col2) and increase in collagen type I (col1) inevitably occur during the proliferation culture, termed dedifferentiation. 3D culture or hydrostatic pressure had been reported to induce redifferentiation of the dedifferentiated chondrocytes. For a more effective induction, we attempted to optimize combinations of soluble factors that are certificated for medical use, in the present study. We used human dedifferentiated chondrocytes originating from ears, ribs and joints. The combinational effects of 12 soluble factors (FGF-2, BMP-2, IGF-I, insulin, etc,) on the PG accumulation were examined using the analysis of variance in fractional factorial design. As a result, the combination of BMP-2 and insulin (BI) most significantly enhanced the PG accumulation. BI also promoted the expression of col2 and decreased that of col1 compared with the control containing no factors. However, BI also increased the expression of collagen type X (col10) that may induce endochondral ossification, suggesting a disadvantage to regenerate permanent cartilage. When we examined the third factor, the addition of thyroid hormone (T3) to BI (BIT) increased the expression col2 more effectively and unpredictably decreased col10 to the level of the control, because T3 had been known to enhance the hypertrophy of chondrocytes and their expression of col10. These effects of BI or BIT were reproducibly seen in chondrocytes of both hyaline and elastic cartilage. Histological and biochemical findings from the in vitro and in vivo regenerated cartilage stimulated by BIT confirmed the abundant PG and col2 content, compared with that in the control, while the compression strength was superior in BIT, being almost equivalent to that of the native cartilage. Regarding the molecular mechanisms, BI stimulated the phosphorylation of both Smad 1/5/8 and Akt, while it also enhanced the expression of Runx2. On the other hand, T3 added to BI induced the partial inhibition of both the Akt phosphorylation and Runx2 upregulation. When the Akt inhibitor was used instead of T3, the expression of col2 was promoted, compared with that in BI, while those of Runx2 and col10 decreased, corresponding to those seen in BIT. In conclusion, the addition of T3 to BI produces the ideal effects on the regeneration of permanent cartilage through the partial inhibition of the Akt activation, proposing a novel and practical technique for cartilage tissue engineering.

Prospective Study of Indian Hedgehog and Parathyroid Related-Peptide Expressions in the Rat Growth Plate during Recovery of Growth Retardation. V. Pelletier*, V. Lascau-Coman*, N. Dion, G. Mailhot*, J. L. Petit*, C. Deschênes*, M. Gascon-Barré, L. G. Ste-Marie. Saint-Luc Hospital, CHUM Research Centre, Montréal, PQ, Canada.

Previously, we demonstrated that rats fed with D and Ca depleted diet (D-Ca-) present growth retardation. When D-Ca- rats were repleted with a high Ca content diet ($Ca+_3$) during 14 days (d), there was a partial reversion of growth retardation with a rate of weight gain equal to 50% of normal rats. In addition, when D-Ca- were repleted with a low Ca repletion diet ($Ca+_{0,5}$) growth rate was improved reaching 80% of normal rats. To characterize the dynamic changes occurring at the tibial growth plate (GP) during the 14d of repletion with the high or low Ca diets, we performed undecalcified bone morphometry on proximal tibia taken from rats sacrificed at 0, 3, 7 and 14d after the repletion diets. No significant differences for the GP thickness was observed between D-Ca-, $Ca+_3$ and $Ca+_{0,5}$ at 0, 3 and 7d. However at 14d, the $Ca+_3$ rats showed a markedly enlarged GP compared to D-Ca- (1210 ±440µm and 449 ±55µm, respectively; p=0,002) while $Ca+_{0,5}$ had intermediary GP thickness (680 ±186µm) which was not significantly different from D-Ca-and $Ca+_3$. To further study the endochondral ossification occurring in these animals, we performed immunohistochemistry of Indian Hedgehog (Ihh) and parathyroid hormone related-peptide **(**PTHrP), 2 proteins involved in proliferation and maturation of GP chondrocytes. In $Ca+_3$ rats as early as 3d of repletion, levels of Ihh and PTHrP were increased higher than in D-Ca- and $Ca+_{0,5}$ and continued to increase up to 14d. In the $Ca+_{0,5}$ rats at 3d, the expression level of both proteins were found to be similar to D-Ca- and then increased by 7d and 14d but at a lower intensity than $Ca+_3$ rats. During the study period, serum phosphorus did not significantly change in D-Ca- and $Ca+_{0,5}$ (3,45 ±0,2mM and 3,03 ±0,4mM, respectively) whereas in $Ca+_3$, it fell significantly to 1,19 ±0,36mM ($p<0,001$) after 3d and remained at these low levels at 14d (0,63 ±0,22mM). The $Ca+_{0,5}$ rats which had the best growth recovery, showed an increased expression of Ihh and PTHrP without an enlarged GP. Although $Ca+_3$ rats presented a markedly increased expressions of Ihh and PTHrP, they had a lesser growth recovery as they developed a rachitic GP. It is interesting to note that in this group the over-expression of Ihh and PTHrP as the hypophosphatemia preceded the onset of GP widening. Taken together, these results show that the mechanism of catch up growth is related to the increase of Ihh and PTHrP expressions however, the early development of hypophosphatemia in $Ca+_3$ rats induces rickets which impedes the growth recovery.

IL-1-Induced Chondrocyte Death Mediated by iNOS and NADPH Oxidase. R. Yasuhara*[1], Y. Miyamoto*[1], A. Yamada*[1], M. Takami[1], T. Suzawa[1], T. Akaike*[2], T. Akuta*[2], R. Kamijo[1]. [1]Biochemistry, Showa University, Tokyo, Japan, [2]Microbiology, Kumamoto University, Kumamoto, Japan.

IL-1 (interleukin-1) acts as a key mediator of the degeneration of articular cartilage in RA (rheumatoid arthritis) and OA (osteoarthritis), where chondrocyte death is observed. It is still controversial, however, whether IL-1 induces chondrocyte death. In the present study, the viability of mouse chondrocyte-like ATDC5 cells was reduced by the treatment with IL-1β for 48 h or longer. IL-1β augmented the expression of the catalytic subunit of NADPH oxidase, $gp91^{phox}$, as well as inducible NO synthase in ATDC5 cells. Generation of nitrated guanosine and tyrosine suggested the formation of reactive nitrogen species including $ONOO^-$ (peroxynitrite), a reaction product of NO and O_2^- in ATDC5 cells and rat primary chondrocytes treated with IL-1β. Death of ATDC5 cells after IL-β1 treatment was prevented by an NADPH oxidase inhibitor, AEBSF, an NO synthase inhibitor L-NAME, and a $ONOO^-$ scavenger uric acid. The viability of ATDC5 cells was reduced by a $ONOO^-$ generator SIN-1, but not by NO or S-nitrosoglutatione. Disruption of mitochondrial membrane potential and ATP deprivation were observed in IL-1β-treated ATDC5 cells. Both of which were restored by L-NAME, AEBSF or uric acid. On the other hand, any morphological or biochemical sign indicating apoptosis was not observed in these cells. There results suggest that the death of chondrocyte-like ATDC5 cells was mediated at least in part by mitochondrial dysfunction and energy depletion through $ONOO^-$ formation after IL-1β treatment.

Regulation of Thrombospondin-2 Expression during Marrow Stromal Cell Differentiation. H. Shitaye*, M. Frohm*, J. Miller, K. D. Hankenson. Orthopaedic Surgery, University of Michgian, Ann Arbor, MI, USA.

Marrow stromal cells (MSC) are precursors that give rise to osteoblasts, adipocytes and chondrocytes. Various growth factors regulate differentiation of MSC; however, the role of the extracellular matrix (ECM) in regulating differentiation is relatively unexplored. Thrombospondin-2 (TSP2) is an ECM protein that is highly expressed in bone, cartilage, and the developing skeleton. Studies using knock out mice and TSP2-null primary cells have revealed that TSP2 plays an important role in MSC function. For this study, we determined whether TSP2 expression is altered during MSC differentiation and elucidated molecular mechanisms that regulate TSP2 expression. ST2 cells (murine MSC line) were induced to undergo either osteogenic (BMP2, β-glycerol phosphate, ascorbate) or adipogenic (either methyl-isobutyl-xanthine, dexamethasone, and insulin (MDI) or troglitazone (TZD)) differentiation and TSP2 mRNA and protein levels were measured 1, 3, 6, 9 and 12 days post-induction. In osteo-induced cells, TSP2 mRNA and protein levels increased by ~ 6 fold relative to un-induced controls. In cells induced to undergo adipogenic differentiation with MDI, TSP2 mRNA level decreased to ~20% of un-induced controls by day 3 of the induction protocol and returned to control levels when switched to insulin alone. TZD induced cells showed no decrease in TSP2 expression despite accumulating similar levels of lipid as MDI induced cells suggesting that TSP2 down-regulation occurs prior to PPARγ induction. We next investigated mechanisms that may be involved in TSP2 down-regulation by MDI induction. We first determined which component of the MDI is responsible for TSP2 down regulation by treating cells with different combinations of IBMX, dexamethasone, and insulin and found that IBMX caused the greatest decrease in TSP2 expression. IBMX is a phosphodiesterase inhibitor that increases cAMP levels which in turn activates cAMP dependent Protein Kinase A (PKA). In order to determine whether this pathway is involved in regulating TSP2 expression, we treated cells with 8-Br cAMP (a cAMP analog), forskolin (a PKA activator), and H89 (a PKA inhibitor) alone and in combination with IBMX. Treatment with any of these compounds alone had little effect on TSP2 expression but both 8-Br-cAMP and forskolin acted synergistically with IBMX to inhibit TSP2 expression. Furthermore, inhibition of PKA with H89 abolished the negative effect of IBMX indicating that down-regulation of TSP2 expression is PKA dependent. Further work will be directed toward identifying cis-acting factors involved in regulating TSP2 expression, as well as characterizing mechanisms involved in TSP2 up-regulation during osteoblast differentiation.

Absence of Skeletal Abnormalities in Mice Lacking the Osteoblast-Specific Phosphatase OST-PTP. J. Ahn*[1], R. Dacquin*[1], E. Olmsted-Davis*[2], G. Karsenty[1]. [1]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]Pediatrics, Baylor College of Medicine, Houston, TX, USA.

OST-PTP (osteotesticular protein tyrosine phosphatase) is a receptor-like tyrosine phosphatase expressed in sertoli cells and in osteoblasts during development and after birth. In bone OST-PTP is more abundant tin periosteal osteoblasts. In an effort to identify a function for this molecule during skeletal development and/or bone remodeling we generated mice lacking OST-PTP only in differentiated osteoblasts through homologous recombination in embryonic stem (ES) cells. To that end we generated a floxed allele of *Ost-ptp* and crossed these mice with transgenic mice expressing Cre recombinase under the control of the osteoblast-specific fragment of the *α1(I) collagen* promoter. The efficiency and cell-specificity of recombination at the *Ost-ptp* locus in osteoblasts was approximately 70% and no recombination was observed in other cell types. Mice lacking OST-PTP only in osteoblasts mutant were born at the expected mendelian ratio had normal life expectancy and did not display any overt phenotypic abnormality. Alizarin red/ alcian blue staining of skeletal preparations of wild type and $OST\text{-}PTP_{ob}$-/- embryos did not show any abnormalities in skeletal development. Likewise, histological and histomorphometric analyses performed in 3 month-old mice failed to detect any bone mass abnormality in $OST\text{-}PTP_{ob}$-/- mice. Experiments are in progress to determine whether OST-PTP is required for mechano-transduction in the entire animal. In summary the inactivation of OST-PTP failed to identify a function for this protein in the skeleton.

Identification and Characterization of the Mustang Gene Promoter. C. Liu*, M. Hadjiargyrou. Biomedical Engineering, SUNY at Stony Brook, Stony Brook, NY, USA.

We previously identified Mustang, a novel gene that is exclusively expressed in cells of the musculoskeletal system. While Mustang expression is almost undetectable in intact bone (except in periosteum osteoprogenitor cells and articular cartilage), it is robustly upregulated during bone regeneration in osteoblasts and proliferating chondrocytes. In contrast, its expression in adult skeletal muscle is abundant. In vitro experiments also revealed that Mustang expression coincides with osteoblast and chondrocyte proliferation and myocyte differentiation. As such, Mustang represents a unique “marker” for these cells and thus identifying its tissue specific transcriptional regulation would enable us to characterize its functional significance in the musculoskeletal system. To accomplish this, we isolated and characterized a 1512bp mouse genomic clone corresponding to the 5’-flanking region of the gene. Bioinformatic analysis of this putative promoter identified a transcription start site (TSS), a TATA box, and transcription factor binding sites, including four AP-1 (activator protein-1) and two AP-2 sites. The overall Mustang promoter activity, as monitored by luciferase assays in myogenic (C2C12), chondrogenic (RCJ3.15) and osteogenic (MC3T3) cells, was found to be significantly higher than in non-Mustang expressing cells (COS-7 and HeLa), even reaching levels above those of the control SV40 promoter. Further, the contribution of each of the AP-1 and AP-2 sites was determined with serially deleted promoter constructs in transfected C2C12 cells. Our data indicate that only two of the four AP-1 sites (those closest to the TSS) are required for transcriptional

activation, as their deletion dramatically decreases luciferase activity (~75%) as compared to the full length fragment. In contrast deletion of both AP-2 sites, results in a very small decrease (~12.5%) in luciferase activity, thus indicating that these sites contribute weakly to the transcriptional activation of Mustang. We further characterized the binding subunits of the AP-1 site by electrophoretic mobility shift assay (EMSA) and identified that in both proliferating and differentiating C2C12 cells, c-Fos, Fra-2 and JunD were the only AP-1 members responsible for transcriptional activation. Therefore, given its unique cell specificity and transcriptional strength, the Mustang promoter appears to be a suitable candidate for utilization in cell lineage studies via the use of transgenic mice and could unveil cellular mechanisms responsible for musculoskeletal development and regeneration.

Gene Expression of Passaged Human Articular Chondrocytes. Z. Lin*[1], J. Xu[1], J. Fitzgerald*[2], D. Wood*[1], M. H. Zheng[1]. [1]Department of Orthopaedic Surgery, Univerisity of Western Australia, Nedlands, WA, Australia, [2]Biological Engineering Division, Massachusetts Institute of Technology, Cambridge, MA, USA.

Autologous chondrocyte implantation (ACI) relies on the use of cultured cell in vitro, and the biosynthetic profile of cultured chondrocytes has been shown to be altered during the in vitro expansion. This study investigated the gene expression profile of chondrocyte associated genes during serially passaged human articular chondrocytes. Several clusters of genes were selected for these studies. These include extracellular matrix proteins (aggrecan, type I collagen, type II collagen, Type X collagen, fibromodulin, fibronectin, and link protein), matrix proteinases (MMP-1, MMP-3, MMP-9, MMP-13, ADAMTS-4 and ADAMTS-5), proteinase inhibitors (TIMP-1, TIMP-2 and TIMP-3), cytokines (IL-1β, TGFβ, TNFα, and IGF-1), transcription factors (Sox-9, c-fos and c-jun), and intercellular signaling (COX-2, MAPk1, and NOS2). Quantitative Real-time PCR was employed measure mRNA levels. A clustering analysis using Euclidean distance was done to further classify the gene expression pattern. Our results showed that with increasing passage numbers, matrix protein aggrecan, type II collagen and fibromodulin decreased their gene expression, whereas fibronectin and link protein increased expression. Matrix proteinases, MMP3, 9, 13 and ADAMTS-4, 5, showed a decreased expression pattern during subculture especially when cultured to sixth passages, whilst the expression of proteinase inhibitors (TIMP1, 2, 3) remained constant. Cytokine IL-1 has an increasing expression trend in serial cultured chondrocytes. No significant alternation was found on the expression levels of TNF-α, TGF-β, IGF-1 and transcription factors, Sox-9, c-fos and c-jun. These results suggest that with the increase of passage numbers, the chondrocyte gene expression profile is altered at various degrees, though the gene expression level of transcription factors which contribute to the hyaline cartilage regeneration are unchanged. This information might be useful for the future development of efficient approaches for the cultivation of human articular chondrocytes for ACI.

Effect of Weigh Reduction on the Quality of Life of Patients with Osteoarthritis and Obesity . C. Lee*[1], H. Lee*[1], S. Bae*[2], W. Choi*[2]. [1]Department of Internal Medicine, Hanyang University Guri Hospital, Guri,, Republic of Korea, [2]Department of Internal Medicine, Hanyang University Hospital, Seoul, Republic of Korea.

This study was to exam the effect of weigh reduction on the quality of life of patients with osteoarthritis and obesity. The participants of this study were 15 women with osteoarthritis and obesity who visitied the Hanyang University Hospital Rhematology Department. Data were collected for 2 years from 2003 to 2004. Weight, height, abdominal circumference, and BMI were measured before and after obesity therapy program which consisted of medical and behavior therapy. And also KWOMAC(Korean Western Ontario and McMaster Universities) and KSF-36 (Korean Medical Outcomes Study 36-Item Short Form) were used as a Health-related quality of life instrument. In use of KWOMAC, total KWOMAC score before and after treatment showed no significant change (34.00 ± 16.52 (10~60) vs 27.13 ± 24.71(10~49)) but pain showed significant change (6.50±3.38(1~11) vs 5.13 ± 3.27(1~10), P <0.05). In use of KSF-36, Global score before and after treatment showed no significant change (49.43 ± 5.25(38.8~56.4) vs 57.62 ± 8.10(50.3~65.8)) but bodily pain (36.25 ± 21.34(30~70) vs 33.75 ± 13.03(20~50), P <0.05) and mental health(47.50 ± 20.33 (16~84) vs 62.00 ± 10.69 (48~80), P <0.05) showed significant changes. In conclusion, according to the result of this study, in treatment of patients with osteoarthritis and obesity, weigh reduction improved the quality of life. .

Table 1. Korean Western Ontario and McMaster Universities (KWOMAC) scores before and after treatment

	Before	After	P value
Pain	6.50±3.38	5.13 ± 3.27	<0.05
Stiffness	3.50 ± 2.20	2.13 ±1.81	NS
Function	24.00 ± 13.01	19.88 ±8.77	NS
Total KWOMAC score	34.00 ± 16.52	27.13 ± 24.71	NS

Markers for Early Implant Performance Correlating with Bonding Strength between Titanium Implants and Bone. M. Monjo*, S. Lamolle*, J. E. Ellingsen*, H. J. Rønold*, S. P. Lyngstadaas*. Oral Research Laboratory. Institute for Clinical Dentistry., University of Oslo, Oslo, Norway.

Previous in vivo studies have shown that tensile testing using coin shaped titanium implants is a suitable method for direct in situ measurement of the attachment strength between implant and cortical bone. Using this model, we investigated the correlation between bone bonding strength and several bone markers to evaluate the progress of bone healing and implant performance. Titanium coins with a diameter of 6.25 mm and a height of 1.95 mm were blasted with titanium dioxide (TiO_2) particles with a size between 106 and 180 μm, and placed into the cortical bone of the proximal tibia of 46 New Zealand White rabbits, 4 implants in each animal. After a healing time period of 4 weeks, animals were sacrificed, and the tibial bone with implants exposed placed in a pull-out test machine. During the pull-out test, implants were stressed with an increasing force perpendicular to the test surface, at constant speed, until detaching from the bone. A load versus time plot was recorded. After implant detachment, bone fluid from the implant site was collected for ALP activity analysis. Total protein and RNA was isolated from tissue attached to the extracted implants. Gene expression of bone marker genes (osteocalcin, collagen type I, runx2, IGF-I) and housekeeping genes (18S rRNA, GAPDH and β-actin) was analyzed using real-time RT-PCR. To obtain further data on the quality of the new bone formed at the implant interface, x-ray analyses were performed to measure the relative content of calcium, phosphor and carbon. Correlations between pull-out force and ALP activity, relative mineral content, total protein, and expression of bone marker genes, were assessed by Pearson's correlation coefficient. After 4 weeks of healing time, the pull-out force needed to detach the implants from the tibial cortical bone was found to be positively correlated to the relative mineral content (p=0.013) and negatively correlated to the total protein (p=0.003), indicating that at this stage, the increase in mineral content associated with bone bonding strength was accompanied by a decrease in the organic constituents. Also ALP activity in the bone fluid was negatively correlated to the pull-out force (p=0.019), pointing to a delayed healing in implants with low pull-out values and primary mineralization still ongoing. Finally, a positive correlation was observed between the pull-out force and the expression of osteocalcin (p=0.005), IGF-I (p=0.015), runx2 (p=0.043) and collagen I (p=0.064). These results suggest that the evaluation of these markers might be important in the assessment of new implant surfaces for rapid bone healing and improved implant performance.

Anti-Depressants, Depressing Effects on Bone? B. I. Gustafsson*[1], E. Waarsing*[2], K. Stunes*[1], L. Thommesen*[1], H. Waldum*[1], H. van Leeuwen*[2], U. Syversen[1], H. Weinans*[2], I. Westbroek*[2]. [1]NTNU, Trondheim, Norway, [2]Erasmus MC, Rotterdam, The Netherlands.

Recently more evidence became available about the effects of serotonin on bone metabolism. Earlier we demonstrated functional serotonin receptors in osteoblasts and osteocytes. Furthermore, the serotonin transporter (5-HTT) has also been shown in bone cells, and disruption of 5-HTT results in decreased bone quality. Recently, the use of Selective Serotonin Reuptake Inhibitors (SSRIs) and their effects on bone metabolism, has been under debate. In the current study, we have studied the effects of the SSRI, fluoxetine, on mouse osteoblasts (OB) and human osteoclasts (OC) *in vitro* as well as investigated the effect of long-term fluoxetine use on bone metabolism in rats. Our *in vitro* data show that OC activity was increased by 30 ± 8% when adding fluoxetine concentrations up to 1 μM, higher concentrations resulted in an inhibition of OC activity, but was not toxic. Proliferation of OB was not affected in the lower concentration range (≤0.1μM), however it was inhibited at higher concentrations (>1 μM), and RANKL release was increased, while OPG release was decreased at all concentrations (≤10 μM), again indicating a possible stimulation of OC activity. Three month-old female Sprague-Dawley rats were treated orally with fluoxetine for 6 months (5 mg/kg/day). BMD was determined by means of DXA, and bone architecture was investigated in detail using μCT scanning of right femurs. Left femurs were used for mechanical experiments. Total body BMD was significantly decreased in growing rats treated with doses of fluoxetine that are within therapeutical range. μCT analysis showed that bone architecture of the metaphysis of the femur was significantly changed by fluoxetine treatment. Cortical bone volume was decreased, marrow cavity was increased, and trabecular thickness was decreased when treated with fluoxetine. These results imply that endosteal resorption was increased in fluoxetine treated animals, which is consistent with our *in vitro* data. Furthermore, three-point bending experiments showed that mechanical properties of the bone tissue were altered by fluoxetine. Stress and Youngs modulus were decreased in the fluoxetine group, indicating changes in quality of the bone tissue. Geometry (cross-sectional moment of inertia) however was non-significantly increased, resulting in similar bone strength. In conclusion, we demonstrate that, fluoxetine stimulates osteoclastic activity *in vitro* and most probably *in vivo* as well. Furthermore, we also show decreased quality of bone tissue in fluoxetine treated rats.

Mineralization and Bone Turnover at the Human Femoral Mid-Shaft. H. M. Goldman[1], B. P. George*[2], C. D. L. Thomas*[3], J. G. Clement*[3]. [1]Neurobiology & Anatomy, Drexel University College of Medicine, Philadelphia, PA, USA, [2]Drexel University College of Medicine, Philadelphia, PA, USA, [3]Oral Anatomy and Surgery Unit, School of Dental Science, University of Melbourne, Melbourne, Australia.

Previous research has demonstrated distinct regional variability in the degree of bone mineralization at the Human mid-shaft femur (Goldman et al., J Anat 2003). As bone formed by secondary remodeling was not examined separately from primary bone in that study, it was not possible to determine whether this variability was due to regional differences in the amount of remodeling (number of poorly mineralized Haversian Systems) or in the amount of bone modeling (periosteal or endosteal apposition). Further study of such variation in mineralization density and bone turnover is important for enhancing our understanding of the bone aging process, and resultant bone quality. Entire cross-sections (N=37 adults, divided into three age groups with roughly equal sex distribution) were imaged using backscattered electron microscopy. The percentage area of low mineralization bone (gray levels < 96 within a 0-255 range) was calculated for each of 16 sectors located radially around the bone cortex. This measure of 'new bone formation' included regions of secondarily remodeled bone and any bone of periosteal apposition. Within a sub-sample of young (N= 5) and old (N =6) individuals, osteons with low mineralization were counted within postero-medial and antero-lateral cortices. Regions of primary circumferential bone (regardless of degree of mineralization) were then manually traced (utilizing polarized light microscopy images of same field of view areas) to determine a percentage area of non-remodeled bone cortex. In the younger age group, the antero-lateral cortex had a significantly higher percentage of newly formed bone relative to the postero-medial cortex ($p < 0.01$). Similar results were found in the older age group ($p < 0.05$). Middle and older age groups had significantly higher proportions of newly formed bone than the younger age group ($p < 0.001$). Within younger individuals of the sub-sample, an average of 89% fewer new remodeling events were observed on the postero-medial cortex relative to the antero-lateral cortex. The former also contained a significantly higher proportion of primary bone, most of which was highly mineralized. The older group was more heterogenous, but the postero-medial cortex still contained an average of 15% fewer new remodeling events. These data suggest that regional differences in bone turnover rates lead to long lasting effects on the distribution and quantity of primary versus secondary tissue types that is reflected in bone's mineralization density distribution.

Impact of Glucose-dependent Insulinotropic Receptor Knockout on Mouse Behavior. K. H. Ding[1], Q. Zhong[1], D. Xie[1], J. Duan*[2], C. Baile*[3], H. Chen*[4], M. Della-Fera*[2], A. Mulloy[1], W. Bollag*[1], R. Gujral*[1], W. Curl*[5], C. M. Isales[6]. [1]Medicine, Medical College of Georgia, Augusta, GA, USA, [2]Agricultural Biotechnology, University of Georgia, Athens, GA, USA, [3]Agricultural Biotechnology, University of Georgia, Augusta, GA, USA, [4]Neurological Surgery, University of Florida, Gainesville, FL, USA, [5]Orthopedic Surgery, Medical College of Georgia, Augusta, GA, USA, [6]Medicine and Orthopedic Surgery, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

We have previously reported that a rise in glucose-dependent insulinotropic peptide (GIP), an enteric hormone released from endocrine cells in the proximal small intestine in response to nutrient intake, increases osteoblastic activity and subsequently bone mass. We have also reported that GIP receptor knockout mice have lower bone mass than controls. However, as these GIPR KO mice age they develop compensatory mechanisms involving increased secretion of hormones (particularly leptin) that ameliorate the impact of GIP receptor loss on bone mass. Since both leptin and GIP may have central nervous system effects on feeding behavior we examined the impact of GIP receptor knockout on mouse behavior. At four months of age standardized mouse behavior testing revealed that GIP receptor knockout mice had significantly increased open field locomotor activity (Distance traveled (cm): 784.6+67.3 vs. 996.2+52.3, Control vs. GIPR KO, Means+SEM, $p<0.02$), decreased tail flick latency (7.0+0.04 vs. 5.6+0.3 seconds, Control vs. GIPR KO, Means+SEM, $p<0.01$) and increased open arm entries in the Elevated Plus-Maze (10.6+1.3 vs. 16.9+1.9 % open arm entries, Means+SEM control vs. GIPR KO $p<0.01$). These data were consistent with GIPR KO mice having an increased activity level compared to control mice. In an effort to define the underlying mechanisms, hypothalamic mRNA from GIPR KO and control mice was analyzed by microfluidic analysis. Compared to Control mice, GIPR KO mice were found to have a significant (greater than two-fold, $p<0.01$) increase in mRNA expression of CART (cocaine and amphetamine regulated transcript) a neuropeptide involved in feeding behavior and recently shown to play a role in mediating CNS leptin effects on bone mass. Taken together, these data demonstrate that GIP has significant central nervous system effects and that compensatory changes in bone mass observed in aging GIPR KO mice may be in part mediated by leptin-induced changed in CART.

The C-Terminal of Matrix Gla Protein Binds Vitronectin. S. K. Nishimoto, M. Nishimoto*. Molecular Sciences, University of Tennessee, Health Science Center, Memphis, TN, USA.

Matrix Gla Protein (MGP) is an essential inhibitor of calcification. Loss of MGP results in Keutel Syndrome with patients suffering from cartilage calcification and arterial stenosis. Mice lacking MGP have extensive cartilage and vascular calcification that leads to perinatal death. The molecular basis for its calcification inhibitory activity is not yet determined. Mechanisms suggested include binding to calcified deposits, regulation of BMPs/TGF-β, and interaction with fetuin/calcium complexes. Additional activities and functions may exist for MGP. This is supported by high MGP synthesis during organ development and high MGP synthesis by many types of cancer. It is possible that MGP acts as to modulate cell-matrix interactions of migrating cells. A matricellular role for MGP predicts that it binds to selected matrix proteins in order to alter cellular interactions with matrix. The purpose is to prove that vitronectin interacts with MGP, to determine the MGP region involved in binding, and suggest a role for MGP-vitronectin interactions in embryonic development. Methods: Protein interactions are assayed by gel overlays with labeled vitronectin or MGP, and elution peak shifts on gel filtration. The binding of vitronectin to MGP or MGP peptides is determined by nitrocellulose filter binding assay. MGP and vitronectin are localized using polyclonal anti-MGP and monoclonal anti-vitronectin antibodies in paraffin embedded embryonic kidney. Results: Vitronectin binding is saturable and consistent with a single class of binding sites. MGP binds to vitronectin but not collagen, fibromodulin, heparin, osteocalcin, chondroitin sulfate, laminin, ovalbumin or albumin. MGP binds vitronectin by a naturally occurring MGP C-terminus, peptide 61-77. MGP and the 61-77 MGP peptide also bind fibronectin. MGP and vitronectin focally co-localize in embryonic kidney. Co-localization *in vivo* suggests that MGP-vitronectin binding may modify cell interactions with vitronectin. Thus MGP is proposed to cause cells to migrate or adhere differently. MGP may augment the capacity of cells to migrate during processes such as embryonic development, wound repair, or tumor cell metastasis. Conclusions: The current study demonstrates MGP binds vitronectin via a C-terminal region that is highly conserved. Co-localization of MGP and vitronectin suggests that the binding is physiologically relevant during elevated MGP synthesis in the embryonic kidney.

A Tendon Specific Angiogenesis Inhibitor, Soluble ChM1L Regulates Hypovascularity of Tendon. K. Yamana*, Y. Nakayama*, Y. Takahashi*, H. Wada*, Y. Yamanaka*, Y. Kasahara*, H. Mitsuhashi*, S. Kondo*, T. Kamimura*, Y. Azuma. Teijin Institute for Bio-medical Research, Hino, Tokyo, Japan.

Tendon is typically characterized as hypovascular dense connective tissue that attach muscle to bone. In contrast to cartilage, a hypovascular tissue as well as tendon, little is known about the mechanisms of tendon tissue generation and maintenance of hypovascularity in tendon. Cartilage includes several endogenous angiogenesis inhibitors such as Chondromodulin-I (ChM-I), a secreted glycoprotein specifically expressed in cartilage. However, no existence of tendon-specific angiogenesis inhibitor has been reported. We have recently discovered ChM1L, a type II transmembrane glycoprotein, which is expressed in tendon and has high homology to ChM-I. We hypothesized that ChM1L is a key regulatory molecule that is involved in hypovascularity of tendon. To evaluate this hypothesis, we examined, (1) specificity of ChM1L mRNA expression by real-time PCR, (2) processing of ChM1L protein, and (3) anti-angiogenic activity of ChM1L protein *in vitro* and *in vivo*. ChM1L mRNA was preferentially expressed in mouse Achilles tendon and tenocytes by real-time PCR, compared to other 9 tissues and 5 cell lines. Immunoblot analysis revealed that soluble form of ChM1L protein (sChM1L) was detected in mouse Achilles tendon, and culture medium of COS7 and 293T cells transfected with transmembrane form of ChM1L expression vector. N-terminal sequencing and deglycosylation analysis revealed that sChM1L was secreted as non-glycosylated protein following cleavage at potential processing site, R-H-A-R. Processing of ChM1L was abrogated by furin inhibitor, golgi-disturbing agent (Brefeldin A), and deletion or mutation of R-H-A-R. Purified recombinant furin cleaved the transmembrane form of ChM1L protein. Recombinant sChM1L protein produced in E. coli inhibited DNA synthesis of endothelial cells *in vitro* induced by FGF-2, VEGF, HGF, or FBS, whereas sChM1L didn't inhibit DNA synthesis of fibroblasts. Moreover, sChM1L inhibited migration and tube formation of endothelial cells. Furthermore, sChM1L inhibited angiogenesis *in vivo* by the directed *in vivo* angiogenesis assay. In mouse tumor models using B16-F10 melanoma or Lewis lung carcinoma cells, sChM1L inhibited tumor growth, and this effect correlated with a low density of blood vessels in the tumors of sChM1L-treated mice. Taken together, these results indicate that sChM1L is a tendon specific angiogenesis inhibitor, which is secreted by furin-mediated processing in the trans-golgi network and may play an important role in the maintenance of vascularity in tendon.

Ca2+/Calmodulin-Dependent Protein Kinase II (CaM kinase II) Phosphorylation of Ets2 in a Mechanotransduction Pathway of Cranial Morphogenesis. J. L. Borke[1], J. R. Chen*[2], C. S. Chew*[3], J. C. Yu*[4], T. T. Wu*[5], N. N. Do*[1], X. W. Hou*[6]. [1]Oral Biology and Maxillofacial Pathology, Medical College of Georgia, Augusta, GA, USA, [2]I-Shou University, Kaohsiung, Taiwan Republic of China, [3]Cell Biology and Anatomy, Medical College of Georgia, Augusta, GA, USA, [4]Surgery, Medical College of Georgia, Augusta, GA, USA, [5]Savannah River National Laboratory, Aiken, SC, USA, [6]Stomatology, Third Hospital of Hebei Medical University, ShiJiaZhuang, China.

Our studies introduce a novel mechanism of mechanotransduction with an Ets family member as the key intermediate linking stretch-induced changes in cell membrane permeability to changes in cranial morphogenesis. Our data suggests that as intracellular Ca++ increases, CaM kinase II phosphorylates Ets2 changing its affinity for binding sites in the promoter regions of target genes important for cranial morphogenesis. This pathway is significant for mechanotransduction because Ca++-dependent phosphorylation of Ets2 could be initiated by Ca++ influx after cell stretching. We performed immunohistochemistry on 1 day old rat calvaria with anti-Ets2 antibodies and showed localization of Ets2 in the nuclei of cells of the forming cranial sutures and bone. We isolated mRNA and protein from bone-suture-bone explants of rat coronal sutures in organ culture with and without stretching. We prepared Western blots using Ets2 antibody in the presence and absence of a phosphorylation inhibitor. This study shows that the MW of Ets2 is increased by loading in the absence but not the presence of phosphorylation inhibitor. Bacterially expressed 1 -70 Ets2 protein was phosphorylated by CaM kinase II in the presence of γ-32P ATP. The identity of phosphorylated Ets2 was confirmed by subsequent Western blot analysis using anti-Ets2 antibody. Examination of the promoter region of several important target genes in bone development including BMP2&6, osteocalcin, osteonectin, osteopontin, and Tbx2, reveals putative binding sites for Ets2. Competition between the promoter of one of these target genes (Tbx2) and antibody to Ets2 promotes up-regulation of this gene. Electrophoretic mobility shift assay (EMSA) results show antibody competition with two nuclear extracts for binding to labeled probes representing Ets2 binding sequence in the Tbx2 promoter. Taken together, these findings suggest that the influx of Ca++ promotes Ca++-dependent phosphorylation of Ets2 and release of Ets2 from binding to the promoter region of genes important for bone development and cranial morphogenesis.

Mapping the Mechanical Environment Surrounding Loaded Titanium Implants Using a Novel FEA/Histology Technique. X. W. Hou*[1], N. N. Do*[2], J. L. Borke[3]. [1]Stomatology, Third Hospital of Hebei Medical University, ShiJiaZhuang, China, [2]Oral Biology and Maxillofacial Pathology, Medical College of Georgia, Augusta, GA, USA, [3]Oral Biology and Maxillofacial Pathology, Medical College of Georgia, Augusta, GA, USA.

Finite element analysis (FEA) is a well established computer based analysis method used to predict the stress and strain characteristics of objects under applied mechanical loading. We present a novel use of the FEA technique to map the load environment in histological sections of bone surrounding mechanically loaded titanium implants. For this study we used paraffin embedded tissue sections of bone surrounding 1mm x 3mm titanium micro-screws (implants) installed in retired breeder rat maxilla following extraction of the maxillary first molar. Radiographs of implant sites were prepared after installation and again prior to sacrifice. Tissues were decalcified and sections of the maxilla containing the implants were processed for immunohistochemistry using antibodies to bone marker proteins. Stained sections were imported into the WinTopo program (SoftSoft.net, Biggleswade, Bedfordshire, UK), which transforms and saves the images in the "dxf" file format. In this format, FEA can be performed on the images using the J.L Analyzer 9.0 FEA program (AutoFEA Engineering Software Technology Inc., Norwalk, California, USA). For our studies we created 2D models containing between 2000 and 4000 nodes incorporating published values for the modulus of elasticity and Poisson's ratio of composite bone and titanium with an applied load of 5N corresponding to a physiological bite force in rats. Comparisons were made to archived tissues surrounding human implants. The resulting stress maps created for each section were combined with the immunohistochemistry by image overlay to characterize the load environment, tissue characteristics, and protein expression in each tissue. Results show that sites of high compressive load correlate with sites of osteoclastic bone resorption, and sites of high shear stress correlate with the expression of bone formation markers. This novel technique offers a useful method for correlating the mechanical environment to the localization of cellular changes and sites of altered gene and protein expression in histological sections.

Contribution of the Advanced Glycation End Product Pentosidine to Compressive Biomechanical Properties of Human Lumbar Vertebrae. S. Viguet-Carrin*[1], J. P. Roux*[1], M. E. Arlot[1], E. Gineyts*[1], F. Duboeuf*[1], Z. Merabet*[1], M. L. Bouxsein[2], P. D. Delmas[1]. [1]INSERM Unit 403, C. Bernard University, Lyon, France, [2]Orthopaedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA.

Collagen structure is believed to play an important role in bone strength. Yet, few studies have analyzed the contribution to bone strength of posttranslational modifications of type I collagen independent of bone density. Thus, the aim of this study was to analyze the relative contributions of bone density, and both enzymatic and non-enzymatic crosslinks (advanced glycation end products) of type I collagen to the biomechanical properties of human vertebrae. Nineteen L3 vertebrae (age 26-93; 10 males, 9 females) were collected after necropsy. Bone mineral density (BMD) of the vertebral body was measured by lateral DXA. Compressive stiffness, failure load and work to fracture (energy absorbed) were directly measured and the apparent elastic modulus, ultimate strength and toughness were estimated by correcting the load-displacement data by the minimal cross-sectional area of the vertebral body. After mechanical testing, the concentration of both enzymatic pyridinoline (PYD), deoxypyridinoline (DPD) and the non-enzymatic crosslinks pentosidine (PEN) were analyzed by reversed-phase HPLC on trabecular and cortical bone separately and normalized to the hydroxyproline content. BMD was significantly positively correlated with stiffness ($r^2 = 0.74$; $p<0.0001$), failure load ($r^2 = 0.69$; $p<0.0001$) and work to fracture ($r^2 = 0.44$; $p=0.003$). The trabecular concentrations of PEN -but not of PYD nor DPD- contributed to the failure load and work to fracture over and above BMD (multiple $R^2 = 0.82$ and 0.67 respectively, $p<0.0001$ for both), but not to the prediction of stiffness. Similarly, ultimate stress and estimated toughness were better explained by BMD + PEN (multiple $R^2 = 0.66$ $p = 0.0002$ and $r^2 = 0.55$ $p = 0.002$ respectively) than by BMD alone ($r^2 = 0.52$ and $r^2 = 0.31$ respectively). In summary: 1) the concentration of collagen crosslinks did not contribute to bone stiffness and estimated elastic modulus, properties that are reported to depend mainly on bone mineral content; 2) the concentration of PEN in trabecular bone contributed independently of BMD to failure load and work to fracture of human lumbar vertebrae. We conclude that the impact of PEN on skeletal fragility deserves more attention.

Chronic Monitoring of Telemetered Bone Marrow Pressure in the Rodent. D. R. Meays*, H. Y. Stevens, J. A. Frangos. La Jolla Bioengineering Institute, La Jolla, CA, USA.

It has been previously observed that venous ligation of the canine hindlimb increased venous pressure immediately but that the pressure decreased after several weeks due to deployment of collateral blood vessels[1]. We previously showed, however, that venous ligation leads to prolonged increases in intramedullary pressure (IMP) in the rat. In this study we investigated the continuous measurement of IMP in the alert and unanesthetized rat using telemetry. This unique application of telemetry allowed us to measure IMP in both unsuspended and hindlimb suspended rats over the course of 21 days. Pressure transducers were implanted into the bone marrow cavity by inserting a 0.4 mm ∅ catheter tip through a hole drilled distal to the femoral head, the hole sealed with bone cement and the transmitter secured onto the peritoneal wall. With the receiver placed under the animal's cage, telemetered pressure data was collected. Pressure readings were recorded in the early morning when the animal was awake and grooming. Intramedullary pressures, in limbs of animals subjected to femoral vein ligation or sham-operation, were recorded for the period of hindlimb suspension. This pressure was maintained throughout the suspension period of 21 days. The amplitude of the cardiac-induced pulsations was 0.8 mm Hg with a frequency of 1 Hz. We optimized the implantation of a vascular occluder cuff around the iliac vein in the hindlimb-suspended rat model to test the effects of increases in intra-osseous pressure of an intermittent nature and varying duration as opposed to a permanent ligation. In previous studies an intermittent occlusion of 30 min per day for 3 weeks was shown to increase tibial weight relative to controls. The contra-lateral vein had the same size cuff placed around it but was not occluded during the study. Preocclusion ImP was recorded as 10.5 mm Hg and this consistently rose to 15 mm Hg upon each occlusion on the same animal. Blood flow resulting from the iliac vein occlusion was monitored using an ultrasonic micro-flow probe, with flow in the artery reaching zero upon occlusion and climbing to normal levels of 1.2 ml/min after occlusion. The permanent occlusion of the femoral vein in rats caused an elevated and persistent intra-osseous pressure. Similarly, the transient occlusion of the iliac vein of the rat via an occluder cuff caused a consistent increase in ImP and a decreased blood flow in the femoral vein, both of which reverted back to normal once the occlusion was released.

Elevated Serum FGF23 Concentrations in Plasma Cell Dyscrasias. I. J. Stewart*[1], C. Roddie*[2], A. Gill*[2], A. Clarkson*[2], M. Miramms*[1], A. E. Nelson*[1], L. Coyle*[2], C. Ward*[2], P. Clifton-Bligh*[2], B. G. Robinson*[1], R. S. Mason[3], R. J. Clifton-Bligh*[1]. [1]Kolling Institute of Medical Research, Sydney, Australia, [2]Royal North Shore Hospital, Sydney, Australia, [3]The University of Sydney, Sydney, Australia.

Fibroblast growth factor 23 (FGF23) is now recognized as a key regulator of phosphate metabolism. The syndrome of tumour-induced osteomalacia (TIO) is typically associated with mesenchymal tumours and elevated serum FGF23 concentrations. TIO is less commonly associated with non-mesenchymal tumours and serum FGF23 has not yet been studied in these cases. We identified an elevated serum FGF23 concentration (161 RU/mL) in one patient with small B-cell lymphoma and hypophosphatemia, prompting us to examine serum FGF23 in other patients with B-cell neoplasms. Serum FGF23 concentrations measured using the FGF23 C-terminal ELISA (Immunotopics, CA) in 26 normal controls was 23 ± 11 RU/mL (mean ± SD). Serum FGF23 levels were elevated in 5/16 patients with myeloma (57, 83, 83, 89, 1111 RU/mL), 3/18 patients with monoclonal gammopathy of uncertain significance (MGUS)(81, 123, 177 RU/mL), and 1/12 patients with chronic lymphocytic leukaemia (249 RU/mL). In myeloma and MGUS patients, serum FGF23 concentrations were significantly and positively associated with serum paraprotein and beta-2 microglobulin concentrations (p = 0.0006). Hypophosphatemia was not observed even in those patients with elevated FGF23, and a weak positive correlation was noted between serum FGF23 and phosphate concentrations (p = 0.03). Dysplastic plasma cells in bone marrow biopsy samples showed intense FGF23 expression in a perinuclear distribution, a pattern also typical for FGF23 localisation in mesenchymal tumours. Our findings contribute to an expanding literature regarding abnormal FGF/FGF receptor-signalling in myeloma. The absence of hypophosphatemia in these cases suggests either that FGF23 produced by dysplastic B-cells lacks systemic bioactivity or that other factors contribute to maintain serum phosphate.

Are Bone Marrow Dendritic Cells a Major Key in the Understanding of Monoclonal Gammopathies (MGUS)? N. Josselin*[1], M. Rousselet*[1], N. Ifrah*[1], M. F. Basle*[1], R. Bataille*[2], M. Audran[1], D. Chappard[1]. [1]Faculté de Médecine, INSERM, EMI0335-LHEA, Angers, France, [2]INSERM, U601, Nantes, France.

MGUS represents the common manifestation of multiple disorders and normal variants; it can represent an early stage of malignant disorders like B lymphoma or myeloma. Dendritic cells (DC) are specialized cells having a leading part in different development stages of B lymphocytes. DC originate from the same stem cell than osteoclasts and under particular culture conditions (M-CSF, IL-6), immature DC can differentiate into osteoclasts. Plasma cells induce an overexpression of RANKL in stromal cells in myeloma patients leading to osteoclastogenesis. It was hypothesized that DC genesis might also be increased in MGUS. Only few studies have been interested in the link existing between DC and MGUS. Bone and bone marrow biopsies were performed in 94 patients. Four normal control cases were similarly processed. Biopsy specimens were embedded in methacrylates. Stainings for histomorphometry were done with Goldner trichrome and TRAcP identification of osteoclasts. Bone marrow dendritic cells were detected using an antibody directed against the S-100 protein. For each patient, the number of bone marrow dendritic cells (20 consecutive fields) was compared to histomorphometric results and diagnosis. According to histopathological criteria, patients were classified into MGUS (44 cases), myeloma (44 cases), B lymphomas (6 cases). The average number of bone marrow DC was significantly higher in B lymphomas than in myeloma (p=0.0003; 24.4 ± 11.4 vs 5.1 ± 0.9), MGUS (p=0.003; 8.5 ± 1.2) and control cases (0.75 ± 0.25). The osteoclastic surfaces were higher in myeloma compared to B lymphoma (p=0.002; 23.3 ± 2.3 vs 10.1 ± 2.3) and MGUS (p<0.0001; 12.4 ± 1.3). DC were often mixed with B lymphoma cells (66.7 % of B lymphomas). Moreover, B lymphomas were frequently associated with mononucleated osteoclasts. There was no significant correlation between the number of dendritic cells and osteoclast parameters. DC appeared significantly increased in MGUS and especially in B lymphomas. It is likely that different cytokine networks are involved in myeloma and B lymphomas. This can favor the genesis of DC and mononucleated osteoclasts which are not observed in myelomas.

Interaction of Metastatic Melanoma Cells and Osteoblasts Induces Collagenase 3 (Mmp13), a Potent Regulator of Bone Resorption. M. Inada[1], M. Takita*[1], S. M. Krane[2], C. Miyaura[1]. [1]Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, [2]Center for Immunology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Mmp13 is a key molecule produced by osteoblasts in inflammatory bone resorption. Recently we reported that Mmp13 deficient mice (Mmp13-/-) exhibit an abnormal phenotype in cartilage and bone suggesting that Mmp13 is important for cartilage development and bone remodeling. It has also been suggested that Mmp13 invasion and metastases in a variety of malignant tumors. Here we examine whether Mmp13 is produced by cancer cells or osteoblasts/stromal cells in bone metastases. Malignant melanoma cells (B16) were suspended in PBS and injected into the left ventricle of C57Bl6 mice with a 27-gauge needle under anaesthesia. B16-injected mice were sacrificed at 12 days after injection and left femur was prepared for paraffin sectioning for tartrate-resistant acid phosphatase (TRAP) staining. The right femur was removed for measurement of bone mineral density (BMD) by DEXA to evaluate B16 induced bone resorption. Metastatic colonization in distal femurs was assessed by the black color of the melanoma. Histomorphometry showed suppressed BV/TV and Tb.th and increased Tb.sp in B16-injected mice indicating that cancer metastasis clearly increased bone resorption. DEXA confirmed B16-induced bone resorption in distal femurs. TRAP staining showed increased numbers of osteoclasts located close to cancer cells. When bone marrow cells and osteoblasts were co-cultured on fixed B16 cells, TRAP+ multinucleated osteoclasts were formed. When osteoblasts were cultured on fixed B16 cells, levels of Mmp13 and receptor activator of NF-kb ligand (Rankl) were increased. Mmp13 production was suppressed by treatment with a p38 MAP kinase inhibitor in a dose-dependent manner, suggesting that induction of Mmp13 in osteoblasts is regulated by cell-cell contact with B16 cells, mediated through the MAP kinase pathway. Thus, induction of Rankl and Mmp13 by contact of B16 cells with osteoblasts can promote osteoclastic bone resorption and soft tissue collagenolysis generating space in bone for cancer cell proliferation at sites of melanoma metastasis.

Cells of the Bone Marrow Microenvironment Protect Myeloma Cells from Apoptosis Induced by TRAIL but not by Agonists of TRAIL Death Receptors. R. M. Locklin*[1], P. I. Croucher[2], R. G. G. Russell[1], C. M. Shipman*[3]. [1]Institute of Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [2]Division of Clinical Sciences, University of Sheffield Medical School, Sheffield, United Kingdom, [3]University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Myeloma cells grow preferentially in the bone marrow where their interactions with bone marrow stromal cells (BMSCs), osteoblasts (Obs) and osteoclasts are crucial for myeloma growth and the development of osteolytic bone disease. Osteoprotegerin (OPG) is secreted by BMSCs and Obs and functions as a soluble decoy receptor for both RANKL, thus inhibiting bone resorption, and TNF-related apoptosis-inducing ligand (TRAIL). TRAIL is produced by activated T-cells and is thought to mediate immune system anti-tumour activity by inducing tumour cell apoptosis. It binds to four membrane-bound receptors; death-inducing receptors DR4 and DR5 and decoy receptors DcR1 and DcR2. OPG also binds to TRAIL and we have previously shown that OPG released from MG63 osteoblast-like cells can inhibit TRAIL-induced apoptosis of myeloma cells. We hypothesise that OPG produced by cells of the bone marrow microenvironment may protect myeloma cells against TRAIL-induced apoptosis. This study aimed to determine whether BMSCs and Obs can protect myeloma cells against apoptosis induced by TRAIL or TRAIL receptor agonists using co-cultures of myeloma cells with primary human BMSCs, MG63 osteoblast-like cells or the normal osteoblast-like hPOB-tert cell line. The TRAIL-sensitive human myeloma cell lines NCI H929 and RPMI 8226 expressed both DR4 and DR5 on the cell surface. TRAIL or agonist antibodies to DR4 or DR5 induced apoptosis of myeloma cells in a dose- and time-dependent manner. In contrast to TRAIL, apoptosis induced by these agonists was not blocked by rhOPG or by media conditioned by osteoblast-like cells. Using dual colour flow cytometry, we demonstrated that myeloma cells are protected from TRAIL-induced apoptosis by co-culture with MG63 cells, hPOB-tert cells, or primary normal human BMSCs. In contrast, the induction of myeloma cell apoptosis by the agonist to DR5 was not blocked by these co-cultures. Cell surface TRAIL receptor expression was not regulated by TRAIL, rhOPG, osteoblast-like cell conditioned media or co-culture with osteoblastic cells. Our study demonstrates that cells of the bone marrow microenvironment protect myeloma cells against TRAIL-induced apoptosis. Specific agonist antibodies to active apoptosis-inducing TRAIL receptors are not inhibited by BMSCs or Obs and thus offer an alternative possibility for specific anti-myeloma therapy.

Antitumor Efficacy of the RANK Ligand Inhibitor OPG-Fc in the MDA-231 Breast Cancer and PC3 Prostate Cancer Experimental Osteolytic Metastases Models. R. Miller*, J. Jones*, M. Tometsko*, A. Armstrong*, N. Zhang*, J. Leal*, E. Trueblood*, W. Dougall. Amgen Inc., Seattle, WA, USA.

Bone metastases are a frequent complication of cancer and are commonly observed in patients with advanced breast and prostate cancer. In lytic bone metastases, tumor cells interact with the bone microenvironment to induce osteoclastogenesis, leading to bone destruction. RANK ligand (RANKL) is essential for osteoclast differentiation, function, and survival. Tumor cell-mediated osteolysis is thought to occur ultimately via induction of RANKL within the bone stroma, and inhibition of RANKL in animal models of breast cancer metastases blocks tumor-induced osteolysis and prevents the increase in bony tumor burden (Morony et al., 2001). The aims of this study were to define the mechanisms of the antitumor effect of RANKL inhibition on skeletal metastases and to test if similar effects are observed in both breast and prostate cancer-induced osteolysis. We first examined the effects of the RANK ligand inhibitor OPG-Fc on tumor-induced osteolysis and tumor burden in mice inoculated with MDA-MB-231 breast cancer cells. At 14 days post-inoculation, tumor-bearing mice received OPG-Fc subcutaneuously (3 mg/kg, 3x/week). Radiographic analysis on day 28 indicated that OPG-Fc treatment prevented the progression of tumor-induced osteolysis. Serological, histological, and histomorphometric analyses also revealed that OPG-Fc treatment eliminated mature and immature osteoclasts, reduced tumor-induced bone resorption, and reduced osseous tumor burden. Comparable results were obtained after OPG-Fc treatment of mice with established skeletal PC3 prostate tumors and osteolytic lesions. To examine the potential mechanisms underlying the reduction in tumor burden, levels of proliferation and apoptosis markers in established breast tumors, taken from mice treated with OPG-Fc over 5 days, were analyzed by immunostaining. Short-term OPG-Fc treatment substantially reduced tumor cell histone H3 phosphorylation and increased activated caspase-3. Increased activated caspase-3 and decreased phospho-histone H3 levels were also observed in MDA-MB-231 skeletal tumors after combined treatment with OPG-Fc and the cytotoxic agent cytoxan. These data suggest that RANKL inhibition effectively blocks pathologic osteolysis induced by either breast cancer or prostate cancer cells in osteolytic metastases models. The significant reduction in skeletal tumor burden observed after OPG-Fc treatment appears to be due to a reduction in the growth rate and survival of tumor cells, indicating that RANKL inhibition may reduce tumor proliferation and increase tumor cell apoptosis within bone.

Receptor Activator of NF-kappaB Ligand Influences Malignant Activities of Metastatic Breast Cancer Cells. M. R. Ray*[1], A. L. Allan*[1], A. B. Tuck*[2], A. F. Chambers*[2]. [1]Department of Oncology, London Regional Cancer Program, London, ON, Canada, [2]Departments of Pathology & Oncology, University of Western Ontario, London, ON, Canada.

Development of metastatic breast cancer can have devastating consequences that result in decreased quality of living and loss of life. Bone is amongst the most common sites for breast cancer metastasis, and factors in the bone microenvironment are thought to have a role in the metastatic process. Receptor activator of NF-kappaB (RANK) and its ligand, RANKL, are abundant in the bone microenvironment and have a crucial role in normal bone homeostasis. Activation of RANK by RANKL initiates differentiation of osteoclast precursors, through activation of NF-kappaB and AP-1 transcription factors, and gives rise to mature, multi-nucleated osteoclasts that are responsible for bone resorption. However, an emerging role for the RANK/RANKL signaling pathway has recently been described for normal development of the mammary epithelium in lactating mice. Therefore, to evaluate the role of RANK activity in breast cancer progression, *in vitro* responses to RANKL have been assessed for three breast epithelial carcinoma cell lines that have varying degrees of metastatic abilities: MDA-MB-435, -231 and -468. All three cell lines are tumourigenic in mice. However, MDA-MB-435 and -231 cells are highly metastatic, while MDA-MB-468 cells are non-metastatic. Initial Western blot experiments were carried out to determine RANK expression, and all three cell lines were found to express the RANK receptor. Therefore, cellular activities including adhesion to matrix proteins, proliferation, adhesion to bone marrow endothelial cells (BMECs) and motility were determined in the presence or absence of RANKL. Presence of RANKL significantly enhanced growth rates of the metastatic MDA-MB-435 and -231 cells, but did not alter the growth rate of non-metastatic MDA-MB-468 cells. RANKL also significantly enhanced adhesion of MDA-MB-231 cells to extracellular matrix proteins, but did not alter adhesion to BMECs for any of the three cell lines. Finally, RANKL may act as a chemoattractant to draw the metastatic breast cancer cells into the bone. The results described here suggest that RANKL influences behaviour of metastatic breast cancer cells, possibly by differential regulation of NF-kappaB and AP-1 transcription factors, and may encourage development of breast cancer metastases in bone.

In Vivo **Imaging of Metastatic Osteolytic Prostate Cancer Lesions: Inhibition of BMPs and RANKL Decreases Tumor Formation.** B. T. Feeley[1], A. H. Conduah*[1], K. Roth*[1], N. Liu*[1], J. Huard*[2], J. R. Lieberman[1]. [1]Orthopaedic Surgery, University of California, Los Angeles, Los Angeles, CA, USA, [2]Department of Molecular Genetics & Biochemisty; Department of Orthopaedic Surgery, University of Pittsburgh, Pittsburgh, PA, USA.

Introduction: Most prostate cancer metastases to bone are osteoblastic, but some lesions are mixed or purely lytic. In addition, it is hypothesized that osteolytic activity, governed by the RANK-RANKL pathway, is necessary for the development of osteoblastic lesions. We have previously shown that overexpression of noggin with a retroviral vector (RN) inhibits the growth of osteolytic and osteoblastic metastatic prostate cancer lesions, and that treatment with RANK:Fc, a soluble inhibitor of the RANK-RANKL pathway, also inhibits the development of osteolytic lesions. In this study, we sought to determine the effects of inhibiting both osteolytic and osteoblastic pathways on the formation of metastatic osteolytic lesions.We used *in vivo* charged coupled device (CCD) imaging to follow tumor burden following implantation of osteolytic cells. **Methods**: SCID mice were treated with $1x10^5$ PC-3 cells in an intratibial injection model of metastasis. Group I: PC-3 cells transduced with a lentivirus encoding the luciferase (Lenti-Luc) reporter gene; Group II: PC-3 cells transduced with Lenti-Luc+RN; Group III: PC-3 cells+Lenti-Luc and treated twice weekly with RANK:Fc; and Group IV: PC-3 cells+Lenti-Luc+RN, treated with RANK:Fc. Radiographs and CCD images were obtained every 10 days for 50 days.**Results**: Tumor size was significantly smaller at 50 days in all treatment groups vs. PC-3 cells (Table I). Radiographic and histologic analysis confirmed smaller tumor size at each timepoint. CCD imaging demonstrated that animals treated with PC-3 cells (Group I) had an exponentially increasing signal at each timepoint. Groups II, III, and IV all had decreased signal intensity compared to Group I at 20, 30, 40, and 50 days ($p<0.05$ at these timepoints vs. Group I), although no significant difference between the groups was noted (Table I). **Discussion**: Our data confirms that treatment with RANK:Fc and RetroNog inhibit two key pathways in the formation of osteolytic metastatic prostate cancer lesions. *In vivo* CCD imaging is a successful technique to follow the progression of metastatic lesions in bone, and can also be used to follow treatment of these lesions *in vivo.*

	Summary of Data			
	PC-3	PC-3+RN	PC-3+RANK:Fc	PC-3+RN+RANK:Fc
Tumor Size at 50 days	18.1 ± 4.2 mm	12.4 ± 3.3mm*	9.3 ± 1.9mm*	8.1 ± 2.1mm*
CCD signal intensity (photons/sec) at 50 days	$9.3x10^{10}$	$6.5x10^7$	$6.7x10^5$	$4.5x10^5$

Bone-Residing Breast Cancers Show Differential Gene Expression of Metastasis-Related Genes Compared to Orthotopic Tumors in a Mouse Model of Human Breast Cancer Metastasis to Human Bone. K. Anderson*[1], C. Kuperwasser*[2], M. Rosenblatt[1]. [1]Physiology, Tufts University School of Medicine and Molecular Oncology Research Institute, Boston, MA, USA, [2]Anatomy, Tufts University School of Medicine and Molecular Oncology Research Institute, Boston, MA, USA.

Over half of all patients with advanced breast cancer develop bone metastasis, a virtually incurable condition. Metastasis to bone results in increased morbidity, producing pain, pathological fractures, nerve compression, and hypercalcemia. There are few agents specific for treating bone metastasis; advancement in this area requires a better understanding of the process by which breast cancer metastasizes. We aim to understand the mechanisms of breast cancer osteotropism, and determine how specific stromal environments influence gene expression in order to favor the establishment of secondary colonies of breast cancer cells. To mimic all of the steps in the natural progression of human breast cancer, we implanted human bone grafts (freshly obtained from total hip surgery) subcutaneously into immunodeficient mice. Two subclones of human breast cancer cell lines SUM-159 and SUM-1315 were generated by serial passaging in human bone. These cells exhibit increased growth in bone compared to the parental cell lines, producing osteolytic lesions. These “bone-specific” subclones show increased migration toward bone stromal cells *in vitro*, and increased propensity to form bone metastasis *in vivo.* The stable expression of a luciferase/GFP fusion gene in both the parental and bone-passaged subclones enables us to to image and monitor xenografted tumor cells *in vivo*. Using this model, we show that, after intracardiac injection, human breast cancer cells preferentially colonize and proliferate in the implanted human bone grafts compared to the mouse skeleton. In order to identify genes associated with tumors growing in bone, we performed transcriptional profiling using cDNA microarrays highlighting genes differentially expressed in bone-residing versus mammary fat pad-residing (orthotopic) tumors. We found expression of genes associated with different aspects of metastasis, such as regulation of extracellular matrix remodeling, migration, angiogenesis, and apoptosis in and different stromal environments. Among the genes observed to be up and down-regulated, several have been implicated in the development of metastasis and decreased survival in women with breast cancer.

Similar Reductions in Bone Turnover Markers with Oral Ibandronate and Intravenous (I.V.) Zoledronic Acid for Bone Metastases from Breast Cancer: Phase III Trial Results. J. Body[1], M. Lichinitser*[2], S. Tjulandin*[2], P. Garnero*[3], B. Bergström*[4]. [1]Université Libre de Bruxelles, Institut Jules Bordet, Belgium, Belgium, [2]Centre of RAMS, NN Blokhin Russian Cancer Research, Moscow, Russian Federation, [3]Synarc, Lyon, France, [4]Hoffmann-La Roche Inc., Nutley, NJ, USA.

Bone markers are useful surrogates of clinical response to antiresorptive therapy in metastatic bone disease. Suppression of these markers correlates with a reduction in skeletal-related events and metastatic bone pain. This head-to-head trial examined the effect of oral ibandronate and i.v. zoledronic acid on markers of bone resorption and formation. In this multicenter, randomized, open-label, parallel group study, advanced breast cancer patients with at least one confirmed osteolytic or mixed bone lesion received oral ibandronate 50mg/day (n=114) or a 15-minute infusion of i.v. zoledronic acid 4mg (n=110) every 4 weeks for 12 weeks. Eligibility criteria included: ≥18 years of age; life expectancy ≥6 months, WHO Performance Status of 0, 1 or 2; serum creatinine ≤3.0 mg/dL. The primary endpoint was the mean percentage change in cross-linked C-terminal telopeptide of type I collagen in serum (S-CTX) at Week 12. Bone specific alkaline phosphatase (BAP), the amino-terminal procollagen propeptides of type I collagen (P1NP), and osteocalcin (OC) were also measured. Mean percentage changes from baseline at Week 12 are shown in Table 1. These results show that once-daily oral ibandronate suppresses tumor-induced bone resorption as effectively as i.v. zoledronic acid infused every 4 weeks. Oral ibandronate was non-inferior to zoledronic acid for the primary endpoint S-CTX, with similar effects on serum levels of BAP, P1NP and OC.

Table 1. Mean % change from baseline at Week 12 (95% CI).

	Oral ibandronate 50mg	I.v. zoledronic acid 4mg
S-CTX	-77% (-82% to -73%)	-75% (-82% to -67%)
BAP	-35% (-43% to -28%)	-32% (-47% to -17%)
P1NP	-48% (-56% to -40%)	-42% (-55% to -29%)
OC	-35% (-40% to -30%)	-34% (-45% to -22%)

Sequence- and Dose-Dependent Synergistic Effects of Acute and Long Term Ibandronate Exposure in Combination with Single and Fractionated Ionizing Radiation Doses on Human Breast Cancer Cell Growth Inhibition. F. Journe[1], N. Magne*[2], C. Chaboteaux*[1], E. Kinnaert*[3], P. Van Houtte*[2], J. Body[1]. [1]Laboratory of Endocrinology and Bone Diseases, Institut Jules Bordet, Bruxelles, Belgium, [2]Department of Radiotherapy, Institut Jules Bordet, Bruxelles, Belgium, [3]LOCE, Institut Jules Bordet, Bruxelles, Belgium.

Breast cancer cells commonly colonize the skeleton and stimulate osteoclast-mediated bone resorption. Bisphosphonates have therefore emerged as a rational approach for the management of bone metastases. *In vitro* studies have shown that they inhibit proliferation and induce apoptosis of cancer cells. Radiotherapy is also a highly effective treatment for bone metastases. Experimental studies reveal that ionizing radiation (RX) may alter cancer cell functions and induce apoptosis. The objectives of our study were to examine the cytotoxic effects resulting from various combinations of ibandronate (Iban) and RX on MCF-7 and MDA-MB-231 breast cancer cell lines. In an acute bisphosphonate exposure scheme (48h), single radiation doses (1, 4, 8 and 12 Gy) were given before, at halftime of, or after Iban incubation (30 to 200 µM for MCF-7 cells, 100 to 200 µM for MDA-MB-231 cells). In a chronic Iban exposure scheme (5 weeks), the single RX doses were applied at the end of Iban exposure (1 to 30 µM for both cell lines); the highest single radiation doses (8 and 12 Gy) were also compared with fractionated RX doses (4x2 and 4x3 Gy). The combination of acute Iban with RX led to synergistic effects for the ER-negative cell line (MDA-MB-231), whatever the doses and the sequences used. In contrast, for the ER-positive cell line (MCF-7), synergistic effects were only observed with low doses of Iban (30 µM), whatever the RX doses and the sequences used; synergy was more marked when Iban followed RX. Only additive effects were observed with higher Iban concentrations (100 and 200 µM). After long term Iban exposure, high single RX doses (8 and 12 Gy), and even more the corresponding fractionated RX doses (4x2 and 4x3 Gy), induced synergistic effects with Iban on MDA-MB-231 cells, while low single RX doses (1 and 4 Gy) showed additive effects, whatever the Iban concentrations used. By contrast, synergy was only detected for MCF-7 cells with low Iban concentrations (1 and 3 µM), whatever the RX doses used. In conclusion, these *in vitro* data reveal that the combination of Iban with ionizing radiation could exert synergistic effects on the inhibition of breast cancer cells growth, and indicate that sequencing is of importance, especially on ER-positive cells. Our data might provide a rationale for an optimal design of clinical protocols associating bisphosphonate administration and radiotherapy.

Single vs Dual Femur Monitoring with DXA. C. Simonelli, M. Schoeller*. Osteoporosis Care Services, HealthEast Clinics, Woodbury, MN, USA.

Dual energy x-ray absorptiometry (DXA) is a widely accepted method to monitor patients under treatment for osteoporosis to determine whether therapy has prevented further bone loss and reduced future fracture risk. Evaluation of treatment efficacy is related directly to measurement precision error; the smaller the precision error, the smaller the biological change that can be detected. Monitoring the effects of antiresorptive drugs is generally done at the spine and proximal femur, with larger changes seen at the spine due to the higher proportion of cancellous bone. In older patients, the spine measurement may be compromised due to osteophytes and other degenerative changes. We compared measurements of single femur, dual femur, and spine for evaluation of treatment efficacy. We measured bone mineral density (BMD) with DXA (Lunar Prodigy, GE Healthcare) at the spine (L1-L4) and bilateral proximal femur in 96 postmenopausal women (mean age 62.1 ± 9.2 years) on antiresorptive therapy. Changes in BMD were evaluated after an average of 1.2 years of therapy. Femur results were reported for left total femur (TF), right TF, and dual TF (average of left and right). There was no significant difference in average BMD change (1.3% increase) between left TF and dual TF (p=0.80), or between right TF and dual TF (p=0.70). There was a slightly larger gain at the spine (1.6%). Using 95% confidence level and this center's measured precision error, the least significant change was determined to be 2.8% for single TF, 2.1% for dual TF, and 3.4% for spine. Significant BMD changes were seen in 24% of women for single TF, 33% for dual TF, and 31% for spine. There was a biologically significant decrease in BMD in 5% of women for single TF, 6% for dual TF, and 10% for spine. About 40% of the women who had a positive or negative significant change at dual TF did not have a significant change, positive or negative respectively, at the spine. We conclude that a) the average change in BMD for single total femur and dual total femur was equivalent in this treatment group, b) the number of patients with a positive biologically significant change was somewhat higher (albeit not significantly) for dual femur than single femur or spine, and c) about 40% of patients with a significant change at the dual total femur did not have a corresponding significant change at the spine.

	Left Total Femur	Right Total Femur	Dual Total Femur	Spine
CV	1.0%	1.0%	0.8%	1.2%
Least Significant Change	2.8%	2.8%	2.1%	3.4%
Average Change	1.3%	1.3%	1.3%	1.6%
% with Significant + Change	24%*	22%*	33%*	31%*
% with Significant - Change	5%	5%	6%	10%
% Significant + Change Femur Only	39%	57%	47%	
% Significant - Change Femur Only	40%	20%	33%	

* p=0.08 single vs. dual femur; p=0.14 single femur vs. spine; p=0.76 dual femur vs. spine

Prediction of Vertebral Fracture Risk by Radiographic Absorptiometry and Quantitative Ultrasound in Japanese Women. Y. Abe, K. Aoyagi. Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

The purpose of this study was to explore the ability of radiographic absorptiometry (RA) and quantitative ultrasound (QUS) to predict fracture risk prospectively among 367 Japanese women ages 42 to 91 years (mean age = 67.6, SD = 9.2 years); average follow-up was 3.4 years. Bone measurements were performed at baseline using RA for metacarpal bone and QUS for calcaneus (stiffness index). Lateral spine radiographs were obtained at baseline and at follow-up. Radiographic vertebral deformities at baseline were assessed by quantitative morphometry, defined as vertebral heights more than 3 SD below the normal mean. An incident vertebral fracture was defined as a decrease of more than 20 % in vertebral heights on subsequent films. The prospective associations of vertebral fractures with vertebral deformities and bone measurements at baseline were examined using logistic regression, adjusting for age. Presence of one or more vertebral deformities was strongly associated with subsequent vertebral fracture risk. The age-adjusted odds ratio was 3.19 (95% confidence interval [CI]: 1.70 to 5.99). Metacarpal bone mineral density (BMD) measured using RA had a significant prospective association with incident vertebral fractures. The age-adjusted odds ratio (corresponding to 1 SD decrease in bone mass) was 1.88 (95% CI: 1.35 to 2.61). Stiffness index of calcaneus also significantly predicted future vertebral fracture risk, with age-adjusted odds radio of 1.44 (95%CI: 1.05 to 1.98). When adjusting for the presence of vertebral deformities as well as age, metacarpal BMD had a significant association with future vertebral fracture risk, but stiffness index did not. The age-adjusted odds ratios were 1.78 (95%CI; 1.27 to 2.48) for metacarpal BMD and 1.28 (95%CI; 0.92 to 1.77) for stiffness index. Our results suggest that the presence of previous vertebral deformities was a strong predictor for subsequent fractures. In addition, both metacarpal RA and calcaneal QUS are significant predictors of vertebral fractures. We reported earlier that metacarpal RA and calcaneal QUS had significant associations with the presence of vertebral deformities. Although dual X-ray absorptiometry at axial sites is currently considered necessary for diagnosing osteoporosis, these convenient techniques, with relatively low cost and portability, could be promising alternatives for assessing fracture risk.

Peripheral Quantitative Computed Tomography at the Tibia in Individuals with SCI: Reproducibility and Methodological Considerations. L. M. Giangregorio[1], C. Gordon[2], J. Bugaresti*[3]. [1]Spinal Cord Rehab Program, Toronto Rehabilitation Institute, Toronto, ON, Canada, [2]Department of Radiology, McMaster University, Hamilton, ON, Canada, [3]Department of Medicine, McMaster University, Hamilton, ON, Canada.

The present study investigated the reproducibility and utility of BMD and bone geometry measurements at the tibia in individuals with spinal cord injury (SCI) using peripheral quantitative computed tomography (pQCT). It was hypothesized that issues such as spasticity, contractures, and low BMD might influence the utility and precision of this technique in the SCI population. Nine individuals with SCI were recruited to participate in the study. Spasticity prevented positioning and scanning of one participant. Of the remaining 8 participants, the average age was 41 years and the average years post injury was 13. Six individuals had cervical lesions and two had lesions at T10. pQCT scans were performed twice at the ultra-distal tibia (4% site) and two-thirds tibia (66% of tibia length, measuring proximally from distal end), with repositioning between sets of scans. Trabecular BMD (mg/cm^3) was evaluated at the 4% site. The analysis threshold for trabecular bone was set at 200mg/cm^3 due to low BMD values in some patients. At the 66% site, total and cortical BMD, bone area (cm^2), and strength-strain indices (SSI - polar, x, and y) were evaluated. For each outcome, the root mean squared coefficient of variation (RMSCV) was calculated. The average (±SD) trabecular BMD at the 4% site was 100.6±47.9 mg/cm^3, and the RMSCV for trabecular BMD at this site was 2.6%. At the 66% site, the RMSCVs for total BMD, cortical BMD and bone area were 1.59%, 1.55% and 1.73% respectively. The RMSCV for polar SSI was 1.89%, and for SSIx and SSIy the RMSCVs were 3.97% and 3.06%, respectively. For individuals with limited mobility (i.e. complete cervical lesions), two technicians were required for positioning of the limb in the scanner. pQCT is a valuable tool for assessing volumetric BMD and bone geometry at the tibia in SCI as it does not require the patient to transfer out of a wheelchair. However, methodological issues such as spasticity and low BMD can influence proper positioning and analysis. Further, the RMSCV for trabecular BMD was high relative to the average BMD value in this group, and may limit the ability to detect change in this variable. Further study of the reproducibility and utility of this technique a larger number of individuals with SCI is warranted.

A New Method of Measurement of Mandibular Bone Mineral Density and Correlations with Dental Clinical Findings. Y. Takaishi*[1], T. Ikeo*[2], H. Morii[3], M. Takeda*[4], K. Hide*[5], T. Arai*[4], K. Nonaka*[6]. [1]Takaishi Dental Clinic, Himeji, Japan, [2]Osaka Dental University, Osaka, Japan, [3]Emeritus Professor, Osaka City University, Osaka, Japan, [4]Furuno Electric Co.,Ltd., Nishinomiya, Japan, [5]Furuno Electric Co.,Ltd, Nishinomiya, Japan, [6]Elk Corporation, Tokyo, Japan.

While alveolar bones have been supposed to be affected by the process of osteoporosis as a systemic disease, it is important to evaluate how is bone mineral density (BMD) of alveolar bones from standpoint of both dental and medical practice. Forty post-menopausal Japanese women with the mean age 59.4±5.6(SD) years were studied with the written consent for the study. Twenty women were in their fifties and the rest in their sixties. Many methods of measurement of BMD of alveolar bones have been proposed, but the root area of mandibular first premolar was selected for measurement of BMD in the present study. A definite area of the root of the mandibular first premolar was divided into squares for measurement of brightness of each square from the soft ware developed by us. The distribution curve of brightness of each square was obtained and the mean value was calculated for each patient. Lumbar spine BMD was measured by Hologic QDR 4500W and the speed of sound (SOS) of calcaneous by quantitative ultrasound (QUS) by CM-100 (Furuno Electric, Co, Nihinomiya). Age-related significant decrease of alveolar BMD was demonstrated. There were significant correlations between alveolar BMD and lumbar spine BMD and between alveolar BMD and calcaneous SOS. Dentist made dental clinical observations including the depth of pockets, mobility of teeth and alveolar bone resorption by the method of Schei. Biochemical parameters of bone turnover were measured including bone alkaline phosphatase (BAP) and urinary deoxypyridinoline (DPD). Lumbar spine BMD showed significant negative correlation with BAP but the coefficient correlations between alveolar BMD and calcaneous BMD and BAP did not reach significant level. Multivariate analysis of factors in relation to dental clinical findings (attachment level) showed significant contributions of age, BAP, urinary DPD, urinary calcium/creatinine and calcaneous SOS. In conclusion, analysis of bone density at the root of mandibular first premolar could be an indicator of bone loss in patients with osteoporosis and periodontal diseases. There was an age-related bone loss from this method of measurement of alveolar BMD. However, it seemed that many factors may contribute to the bone loss in alveolar bones in addition to risk factors which may contribute to the pathogenesis of systemic osteoporosis .

Use of MRI of the Distal Radius to Assess Qualitative and Quantitative Aspects of Cortical Bone In Postmenopausal Women. D. C. Newitt[1], B. Hyun*[1], D. M. Black[1], C. J. Rosen[2], S. Majumdar[1]. [1]UCSF, San Francisco, CA, USA, [2]St Joseph Hospital, Bangor, ME, USA.

The purpose of this study was to use high resolution (HR) MRI to evaluate cortical shell geometry of the distal radius in post-menopausal women. We evaluated baseline wrist MRI scans from 41 post-menopausal women (age = 59 +/- 6, range 46 to 69 yrs) enrolled in the POWR (PTR Once Weekly Research) study. Subjects were non-osteoporotic (spine BMD T-score> -2.5), with femoral neck DXA BMD T-score between -1 and -2. A Siemens 1.5T Symphony scanner with a dedicated wrist coil was used to acquire high resolution (.16 x .16 x 2 mm^3) axial images of the distal radius using a 3D gradient echo sequence. The images were evaluated for focal signal areas within the cortex. A semi-automated program was used to segment the cortex from soft tissues, and cortical volume and mean cortical thickness were evaluated from 2 to 3cm proximal to the distal radius endplate. Figure 1 shows mean cortical thickness v. age, indicating a small trend to decreasing thickness with increasing age (.009mm/yr, r=0.31). Ultra-distal BMD (by DXA) was weakly correlated with cortical thickness (r=0.52) and volume (r=0.49). In 34 of 41 subjects there was no visible MR signal from the cortex, indicating little or no soft tissue in this region, while 7 subjects showed varying degrees of apparently fatty signal inclusions. Figure 2 shows a representative image from a subject with significant fat inclusions (white arrow) within the cortex. These results demonstrate that geometry of the distal radius cortex, and by extension other extremity bones, can be measured with HR MRI. In addition, focal areas of cortical porosity can be evaluated. In combination with previously demonstrated trabecular structure evaluation, HR MRI provides a tool for non-invasive evaluation of bone geometry and structure in vivo, which is unique in not requiring ionizing radiation.

Assessment of Trabecular Bone Structure with Magnetic Resonance T_2 Relaxation Time. Y. Akyol*[1], F. Canturk*[1], G. Alayli*[1], D. Durmus*[1], B. Diren*[2]. [1]Physical Medicine and Rehabilitation, Medical Faculty, Samsun, Turkey, [2]Radiology, Medical Faculty, Samsun, Turkey.

This study was planned to investigate the utility of magnetic resonance imaging (MR), dual energy x-ray absorptiometry (DEXA) and ultrasound measurements in the assessment of osteoporosis quantitatively. The study group consisted of 31 osteoporotic postmenopausal women (age range 45-72 years) and control group consisted of 31 healthy postmenopausal women (age range 48-70 years). DEXA measurements were performed at lumbar vertebrae (L_2, L_3, L_4) and at femur (femoral neck, intertrochanteric region, wards triangle). The ultrasound parameters broadband ultrasound attenuation (BUA), speed of sound (SOS) and stiffness were measured in the calcaneus. The MR T_2 relaxation time (T_2 RT) measurements were performed at L_3 vertebrae and calcaneus. The results of MR imaging, DEXA and US measurements of the study and control groups were compared with each other. T_2 RT of osteoporotic patients were significantly higher than healthy controls ($p<0.001$). Although there was no correlation between T_2 RT and age, there was a moderate negative correlation between T_2 RT and weight, body mass index, menopause age. As postmenopausal period got longer T_2 RT values increased. A strong negative correlation was determined between bone mineral density (BMD) measured by DEXA and T_2 RT. There was a moderate negative correlation between T_2 RT and US measurements (BUA, SOS, and Stiffness). US measurement of study group were significantly higher than the control group ($p<0.001$). A moderate correlation was determined between US measurements and DEXA measurements. Since, prolonged T_2 RT in the osteoporotic patients indicates low bone quality; it seems to be possible to discriminate postmenopausal osteoporotic and healthy women with MR T_2 RT which assess trabecular bone structure.

Changes in the Geometry of the Proximal Femur throughout Life. L. Del Rio, S. Di Gregorio, J. Rosales*, M. Garcia*, M. Ramiro*, L. Castro*. CETIR Centre Medic, Barcelona, Spain.

Bone strength is related to bone mineral density (BMD), distribution of density, and macro and micro-structural factors. It is known that both bone geometry and BMD change in the growing skeleton, and that BMD decreases in the aging population. However, it is not clear how bone geometry changes with aging. Geometry of the proximal femur is of particular interest due to the clinical importance of hip fracture. We measured proximal femur geometry in a 1611 healthy subjects (1273 females and 338 males) between the ages of 10 and 78 years. Dual-energy x-ray absorptiometry (DXA) scans of the femur scans were performed with the Lunar Prodigy (GE Healthcare). Hip axis length (HAL), femur neck length (D2), cross-sectional area (CSA), cross-sectional moment of inertia (CSMI), neck-shaft angle (Θ), and other parameters were measured using the Hip Strength Analysis program. During the period of skeletal growth, females had significantly longer D2 and larger Θ compared to males. At young adulthood, HAL, CSA, CSMI, and D2 were higher in men than women. No significant difference in Θ was observed with age (grouped by decade) from young adulthood until age 50 years, although femur neck width and Θ decreased in both sexes with age. Neck-shaft angle decreased significantly, $p<0.0001$, in men (6.0 degrees) and women (3.4 degrees) between the ages of 10 and 78 years. A small but significant increase in CSA with age was observed in both sexes after young adulthood. Femur neck width and length were larger in adult men than women. HAL increased from childhood to adulthood, reaching the maximum value at ages 30-40 years, after which HAL remained constant.We conclude that significant changes in femur geometry, that may impact the risk of hip fracture, occur throughout life.

Dental X-Rays Identify Women with Low Hip and Spine BMD. S. Liew[1], D. Steines*[1], M. Jeffcoat*[2], G. Adams*[1], P. Lang*[1], C. Arnaud[1]. [1]Imaging Therapeutics, Foster City, CA, USA, [2]University of Alabama, Birmingham, AL, USA.

It is estimated that less than 30% of postmenopausal women in the US with osteoporosis have been diagnosed. While numerous diagnostic technologies exist, the cost effectiveness in utilizing these techniques for mass screening is still debatable. We have developed an automated computer based technique to estimate the bone mineral density of hip and spine using digitized, calibrated, periapical dental x-rays. In a prospective optimization trial to develop this technology, hip and spine DXA BMD were measured in 48 postmenopausal women, and each had 2 periapical x-rays of the anterior mandible taken. The group had a mean spine BMD T-score of -1.4 (sd=1.5), mean hip BMD T-score of -1.8 (sd=1.3), mean age of 60.5 (sd=14.5), and a mean BMI of 23.9 (sd=5.1). Dental x-rays were taken with a phantom embedded in the film holder. They were digitized using a desktop scanner and analyzed using an algorithm that measures the bone density as well as a number of parameters that characterize the mandibular trabecular pattern. A composite parameter, the mandibular index (MI), was developed from these measurements. MI correlates with spine DXA BMD ($r=0.66, p<0.001$). This correlation coincides with the correlation of spine BMD with hip BMD ($r=0.66, p<0.001$) in this study. MI also correlated with hip BMD ($r=0.57, p<0.001$). We applied a leave-one-out cross validation process to identify patients with T-score <= -2.5 of hip or/and spine BMD. ROC curves showed that the MI can provide sensitivity of 81% (95% CI 59-94%, AUC=0.88) with 80% specificity. Age and BMI given the same specificity provided a sensitivity of 39% (95% CI 14.5-69.2%, AUC=0.70). T-score cutoffs of less than or equal to -2, -1.5 and -1 achieved sensitivity levels of 74%, 64%, and 57% respectively using MI. These results suggest that MI measurements correlate with hip and spine BMD to a similar degree as spine with hip BMD and can be more accurate than age and BMI in identifying women with osteoporosis. MI measurements do not require expensive capital equipment and can be employed during patient's routine dental exams to screen for osteoporosis. A prospective study is in progress to establish the population reference values and to further validate the technique.

Anabolic Changes in Vertebral Trabecular Microstructure in Osteoporotic Postmenopausal Women Treated for 2 years with Human Parathyroid Hormone Fragment (hPTH 1-34) as Determined by a New, Automated Noninvasive Imaging Technology that Uses Ordinary Lateral Spine Radiographs. C. Arnaud[1], S. Liew[1], D. Steines*[1], R. Vargas-Voracek[1], S. Sanchez*[2], P. Hess[1]. [1]Imaging Therapeutics, Foster City, CA, USA, [2]University of California San Francisco, San Francisco, CA, USA.

Until recently, quantitative assessment of trabecular structure required either bone biopsy followed by microscopy or 3-dimensional micro computed tomography (3D μCT). Non-invasive options include the use of expensive capital equipment such as magnetic resonance imaging (MRI) of peripheral bones. We developed a new, noninvasive, 2D automated image analysis technology that uses ordinary radiographs that can measure surrogate trabecular parameters comparable to those measured by 3D μCT. In general, it involves x-ray digitization, identification of regions of interest, background subtraction, and trabecular pattern extraction. Parameters of trabecular structures are measured using computer algorithms. In previous work, we applied this novel technology to ordinary radiographs of cores of proximal cadaveric femora showing that 2D measurements of trabecular structure correlate well with 3D μCT measurements. Those 2D measurements also correlate with biomechanical failure loads applied to those cores as well to whole proximal femora (JBMR; Abst # 1218, Abst # 107; 18 Suppl 2; 2003). We applied the same technology to in-vivo lateral vertebral radiographs obtained in a previously performed study of the effect of hPTH (1-34) on the bone density of estrogen treated postmenopausal osteoporotic women (JBMR; Abst #1019; 14 suppl 1; 1999). The results are summarized below.

Structural Parameter	PTH (n=24) % Change Between Baseline and 2 Yrs	t-test p value	Placebo (n=27) % Change Between Baseline and 2 Yrs	t-test p value
L5 # Trabecular Fragments	- 14%	0.00005	+5.8%	0.30371
L5 Area ratio (bone/total)	+ 1.7%	0.00087	+0.6%	0.39795
L5 Inter-connectivity Index	+ 35%	0.00074	+3.4%	0.75119
L5 Network Length	+23.1%	0.00004	-0.9%	0.88123

The 2D trabecular parameters shown above demonstrated highly significant changes from baseline in the PTH group whereas none of the corresponding parameters changed significantly in the placebo group. The results indicate that hPTH (1-34) dramatically reduces trabecular fragmentation, while increasing the trabecular bone/area ratio, the interconnectivity index and the trabecular network length. These changes are consistent with those shown in PTH treated subjects reported previously by others using 3D μCT and provides strong evidence that noninvasive vertebral x-ray 2D image analysis can play a major role in the future, noninvasive, clinical evaluation of bone structure.

Relationship between Quantitative Ultrasound of the Calcaneus and Mortality in Postmenopausal Women: A 3-Year Prospective Study. J. González-Macías[1], J. Vilà*[2], S. Tojeiro*[3], M. Turégano*[4], J. A. Castro*[5], M. R. González*[6], E. de la Figuera*[7], M. Borge*[8], B. García-López*[9], M. B. Brun*[10], F. Marín[11]. [1]Dept. Internal Medicine, H.U. Valdecilla, Santander, Spain, [2]IMIM, Barcelona, Spain, [3]C.S. San Fernando, Madrid, Spain, [4]C.S. Zona Centro, Cáceres, Spain, [5]C.S. Cartuja-Almanjayar, Granada, Spain, [6]C.S. Salvador Pau, Valencia, Spain, [7]C.S. Delicias Sur, Zaragoza, Spain, [8]C.S. Arturo Eyres Sur, Valladolid, Spain, [9]C.S. San Andrés, Murcia, Spain, [10]C.A.P. Moncada i Reixac, Barcelona, Spain, [11]Medical Research, Eli Lilly, Madrid, Spain.

Several studies have reported the association of low bone mineral density measured with dual-energy absorption densitometry (DXA), with an increased mortality risk. A recent study has also demonstrated that low quantitative bone ultrasound (QUS) values are associated with an increased mortality (Bauer et al. Osteoporos Int 2002). ECOSAP is a 3-year prospective cohort study to test the ability of calcaneus QUS and several clinical risk factors of osteoporosis and fractures, to predict the non-vertebral fracture risk in 5201 women aged $\geq$ 65 years . The aim of the present analysis was to test the relationship of QUS with mortality in the ECOSAP cohort. Women were selected using non-probabilistic sampling of consecutive cases regardless of the reason for consultation in 58 Primary Care Centers (PCC) in Spain. All women [aged 72.3$\pm$5.3 years (mean$\pm$SD)] were assessed with a Sahara® equipment, and completed a health questionnaire. They were followed for up to 3 years with regular visits to the PCCs every 6 months. The physician recorded if the patient died and the cause of death. Cox proportional hazard regression model was designed to estimate the Hazard Rate (HR) of all-cause mortality per one standard deviation reduction in QUS parameters. One hundred (1.9%) women died during a median of 36.1 months of follow-up, for a total of 15,281 patient-years. Women who died were on average older and more likely to report a history of hearing or sight problems, chronic pulmonary obstructive disease (CPOD), diabetes mellitus (DM), and treatment with thyroxine or antiarrythmics. After adjustment for age, none of the QUS variables showed statistically significant differences between the patients who died and the survivors. Final multivariate model for the best-fitted QUS variable (SOS) included age (HR: 1.11; 1.07-1.15), sight/hearing problems (HR: 2.70; 1.58-4.64), thyroxine therapy (HR: 3.60; IC: 1.65-7.83), DM (HR: 2.24; 1.31-3.82); CPOD (HR: 3.30; 1.60-6.84). SOS was marginally non-significant: (HR:1.19; 0.97-1.45)($p=0.094$). In conclusion, we did not observe a relationship between QUS and mortality in postmenopausal women in the ECOSAP study.

Do Axial Transmission Ultrasound Measurements of Bone Differ According to Ambient Temperature? A. S. Khan*, K. Brooke-Wavell, G. Havenith*. Human Sciences, Loughborough University, Leicestershire, United Kingdom.

The study examined whether axial transmission ultrasound measurements of bone vary according to ambient temperature and concomitant changes in tissue temperature. Ten healthy volunteers (5 men, 5 women) spent 20 minutes acclimatising in an environmentally controlled chamber at each of three ambient temperatures: 10, 20 and 30 °C, whilst wearing standard light clothing. Speed of sound (SOS) was then measured at the radius, tibia, proximal phalanx of digit III and metatarsal V using a Sunlight Omnisense device. Skin temperature was measured at the dorsal surface of the hand. Participants gave written informed consent for all procedures, which have been approved by the University Ethical Advisory Committee. Skin temperature varied significantly according to environmental temperature (table). Radial and tibial SOS did not differ in the different conditions. Phalangeal SOS decreased with increasing temperature, being 3% lower at 30 than 10 °C. Metatarsal SOS also differed significantly according to temperature by ≤2%.

Table: Skin temperature and SOS according to ambient temperature: mean (standard error)

Ambient temperature (°C)	10	20	30	
Skin temperature (°C)	24.1 (0.2)	30.3 (0.2)	33.7 (0.6)	*
Radius SOS (m/s)	4161 (48)	4172 (24)	4147 (30)	
Tibia SOS (m/s)	3942 (23)	4002 (32)	3931 (20)	
Phalanx SOS (m/s)	4037 (54)	3989 (56)	3907 (63)	*
Metatarsal SOS (m/s)	3503 (81)	3574 (82)	3525 (103)	*

*Differ according to ambient temperature: $p<0.05$

Speed of sound at the radius and tibia did not differ according to ambient temperatures covering the range that might be encountered in most laboratory or field situations. At the extremity sites (phalanx and metatarsal) some small but statistically significant variation according to ambient temperature was observed, possibly related to alterations in tissue temperature. Extremes of ambient temperature may influence axial transmission ultrasound measurements of bone at the extremities although not at radius and tibia.

Evaluation of a New Multi-Site Quantitative Ultrasound Device in Childhood and Puberty - Precision and Normative Data for Caucasian Girls. A. Oldenburg*, O. Bock, D. Felsenberg. Centre for Muscle and Bone Research, Charite - Campus Benjamin Franklin, Berlin, Germany.

Quantitative Ultrasound (QUS) is a promising tool for bone health assessment in children, although there is uncertainty about the exact bone-entity measured by this technique. The aim of this study was to evaluate in-vitro- and in-vivo-precision and to acquire normative data for the Sunlight Omnisense™ in girls between 7 and 18 yrs of age. The study was conducted in 335 healthy Caucasian girls, mean age 12.6 years (range 7-18 yrs) - after institutional review board approval and in accordance with the Declaration of Helsinki. Anthropometric data, menarche and Tanner stages of breast and pubes were recorded. Ultrasound measurements, obtaining maximum speed of sound (SOS), have been performed at distal radius, mid-shaft tibia and proximal phalanx of the 3rd finger using Sunlight Omnisense™, a new multi-site QUS device. In-vitro-precision (phantom) of 0.25% and 0.28% was determined by daily measurements. The in-vivo-short-term precision was 0.41% (radius), 0.36% (tibia) and 0.45% (phalanx). In-vivo-long-term precision was 0.85% (radius), 1.47% (tibia) und 0.67% (phalanx). Reference values of SOS have been calculated for radius, tibia, and phalanges for girls in the age from 7 to 18 yrs. Age group related SOS values - mean (standard deviation/SD) - range at the distal radius from 3719.63 m/s (90.73) to 4001.40 m/s (69.87) with an annual increase of 26.50 m/s (3.14), at the tibia from 3517.38 m/s (144.00) to 3819.17 m/s (99.62) with an annual increase of 32.68 m/s (4.19) and at the phalanx from 3823.21 m/s (214.82) to 4028.60 m/s (126.43) m/s with an annual increase of 16.12 m/s (5.40). During puberty, mostly between the age of 13 and 14 yrs, SOS is increasing significantly ($p < 0.001$), but at radius and tibia only. SOS values at tibia and radius differ significantly ($p < 0.001$) between the grouped Tanner stages 1-3 and 4-5. SOS correlates positively and significantly with age and pubertal stages. With this study normative data for the Sunlight Omnisense™ device were established for Caucasian girls aged 7-18 yrs, as a prerequisite for evidence based use of the technique in a female paediatric population.

Multisite Ultrasound and Vertebral Deformity: Findings from the Canadian Multicentre Osteoporosis Study (CaMOS). W. P. Olszynski[1], G. Ioannidis[2], J. P. Brown[3], D. A. Hanley[4], J. D. Adachi[2], K. S. Davison[3]. [1]Medicine, University of Saskatchewan, Saskatoon, SK, Canada, [2]Medicine, McMaster University, Hamilton, ON, Canada, [3]Medicine, University of Laval, Ste. Foy, PQ, Canada, [4]Medicine, University of Calgary, Calgary, AB, Canada.

The use of multisite ultrasound to assess fracture risk is an attractive technology due to its simplicity of use, lack of ionizing radiation, low capital cost, and portability. It has been hypothesized that the qualitative ultrasound assesses the architectural properties of bone, such as stiffness, trabecular connectivity, and cortical porosity, rather than density. This investigation used a subset of the Canadian Multicentre Osteoporosis Study (CaMOS) dataset to cross-sectionally assess the association between ultrasound (speed of sound) at the distal radius, phalanx or tibia and vertebral deformity (>3 SD lower than population mean in anterior, middle, or posterior vertebral height) in women aged 50 years or greater. Data from Saskatoon, Quebec, St. John's, Calgary and Hamilton were used in this analysis. A Sunlight OmniSense Multisite Ultrasound (Israel) was used for all ultrasound assessments and all ultrasound data was collected at year 5 of CaMOS. A general linear model analysis was used to assess the association between ultrasound measures at all sites and vertebral deformity risk with correction for height, weight, age, and CaMOS centre. Following a radiograph of the spine at year 5 of CaMOS, 744 women (74.4%) were found to have no vertebral deformity, whereas 256 women had a vertebral deformity (25.6%). Women without a vertebral deformity had higher ultrasound measurements at the distal radius by 30.2 m/s (95% CI: 5.5, 55.1), at the tibia by 32.3 m/s (95% CI: 9.6, 55.0), and at the phalanx by 10.6 m/s (95% CI: -20.8, 42.0; NS). This analysis has shown that the Sunlight OmniSense Multisite Ultrasound has the ability to discriminate between women with or without vertebral deformity whether used at the distal radius or tibia, but not the phalanx, site. Since the data analysis for vertebral deformities and non-vertebral fractures in CaMOS is ongoing and soon to be completed, updated analyses investigating the use of Sunlight OmniSense Multisite Ultrasound for discriminating between those with a risk for both vertebral deformity and non-vertebral fracture will be reported at the meeting.

Map of the Heel BUA May Provide Additional Information on Longitudinal Changes in Skeletal Integrity. R. K. Bhattacharya[1], J. Goll*[2], K. T. Vujevich*[1], D. L. Medich*[1], S. M. Sereika*[1], S. L. Greenspan[1]. [1]Endocrinology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Quidel, Mountainview, CA, CA, USA.

Although bone mass accounts for 50-70% of the variance of fracture risk, other factors such as bone geometry, bone turnover, and biochemical indices also contribute. Traditionally, calcaneal ultrasound measures bone mass by broadband ultrasound attenuation (BUA). The QUS-2 Ultrasonometer (Quidel Corp., Mountainview, CA) reports BUA, averaged over a cross-sectional area of the calcaneus of about 1 cm^2. In addition, it measures "maps" of BUA values at discrete locations in a 2-dimentional grid on the heel, at a resolution of a few millimeters. These maps show substantial heterogeneity and biological diversity. We have previously described four ultrasound-derived topographical maps of the heel and found that the maps were associated with hip and spine bone mineral density as well as weight and body mass index. To determine whether longitudinal changes in BUA, bone mass, or biochemical markers were associated with the three-dimensional maps of the heel, we examined these variables in 88 early postmenopausal women previously naive to treatments that affect bone mineral metabolism. The age range was 40-60 (mean age 50). The maps were blindly assigned groups A-D based on certain topological features or shapes that were observed. Subjects were followed for 6 month. Percent changes in subgroup D's BUA measurements were significantly correlated with the 6-month percent decrease in osteocalcin. There was a borderline trend for significance for subgroup D's BUA percent changes and increase in PA spine and trochanteric bone mineral density (Table). We conclude that these maps may help identify a subgroup of patients who have early changes in spine and trochanteric bone density - areas rich in trabecular bone. Further studies are needed to determine the clinical utility of these findings.

Table below describes the Spearman correlations between percent change in BUA QUS-2 and measures of BMD over a 6 month period.

Correlations of 6 Month Changes in BUA with Change in Bone Mineral Density or Bone Markers				
6-Month Change	BUA Group A	BUA Group B	BUA Group C	BUA Group D
PA spine	.084	.343	-.018	.397**
Trochanter	.246	-.206	-.066	.430*
Total hip	-.242	-.071	.088	.168
Femoral neck	.094	.038	-.093	-.084
Osteocalcin	.061	-.170	-.223	-.519***
NTx	-.084	.056	.151	.131

*P=0.058, **P=0.083, ***P=0.019

LRP5 Impacts not only Bone Mass but also Bone Modelling and Shaft Thickness. A. Saarinen*[1], W. G. Cole*[2], E. B. Sochett[3], E. Marttinen*[4], A. E. Lehesjoki*[1], O. Makitie[4]. [1]Department of Medical Genetics, Folkhalsanin Institute of Genetics, University of Helsinki, Helsinki, Finland, [2]Orthopaedic Surgery, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [3]Pediatric Endocrinology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [4]Metabolic Bone Clinic, The Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland.

Osteoporosis-pseudoglioma syndrome (OPPG) is an autosomal recessive condition characterized by blindness and osteoporosis. OPPG is caused by homozygous mutations in the *LRP5* gene encoding the LDL Receptor-Related Protein 5. Heterozygous *LRP5* mutations have been associated with childhood onset primary osteoporosis characterized by recurrent fractures, even in the absence of low bone density. In order to gain more understanding on the impact of *LRP5* mutations on human skeletal development we have assessed characteristics of bone health, including fracture history, bone mineral density (BMD, Hologic Discovery A) and radiographs, in two patients with OPPG and in three related carriers of the same *LRP5* mutation. The R570W mutation, previously reported by Gong et al. (2001), was identified by direct sequencing of PCR amplified exon 8 of the *LRP5* gene. Two adult siblings (Patients 1 and 2) with OPPG were homozygous, and two healthy daughters (Patients 3 and 4) and an aunt (Patient 5) of Patient 2 were heterozygous for the mutation. The patients with OPPG had severe osteoporosis and multiple compression fractures. The adolescent carriers of the mutation were healthy and had had no fractures. In contrast, the 85 year old aunt had a history of several peripheral fractures at adult age. The radiographs of the homozygotes showed in addition to multiple compression fractures, severe generalized osteopenia with very thin and bowed long bones and abnormally wide metaphyseal ends of the tubular bones. The carriers had no compression fractures but abnormally thin tubular bones with overtubulation of the metaphyseal ends.

Parameter	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5
LRP5 mutation	Homozygous	Homozygous	Heterozygous	Heterozygous	Heterozygous
Age / Sex	58 / F	52 / M	19 / F	15 / F	85 / F
Vision	Blind	Blind	Normal	Normal	Normal
Peripheral fractures	++	++	-	-	+++
Lumbar spine BMD Z-score	-4.1	-3.3	-0.7	-0.3	NA
Femoral neck BMD Z-score	-4.8	-1.3	-0.3	-0.8	NA

These observations suggest that in addition to its impact on bone mass accrual *LRP5* has a role in bone modelling. Findings in the heterozygotes suggest that despite normal bone density these individuals may be more prone to fracture at adult age because of the abnormally thin bone shafts and lack of normal modelling of the tubular bones.

Genetic Diversity of Skeletal Ontogeny Is Recapitulated during Fracture Healing. K. J. Jepsen[1], C. Price[1], P. Nasser*[1], M. Alapatt*[2], S. N. Stapleton[2], L. Silkman*[2], S. Kakar[2], T. A. Einhorn[2], L. C. Gerstenfeld[2]. [1]Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, [2]Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

Microarchitecture (microCT) and mechanical properties (torque to failure) were examined over 35 days of fracture healing in A/J, C57BL/6J (B6), and C3H/HeJ (C3H) inbred strains of mice. These studies demonstrated that the major architectural characteristics of bone quality (moment of inertia, cortical area, trabecular volume), which varied significantly among the strains, were recapitulated during fracture healing. The strain having the highest pre-fracture strength (C3H) however regained this property the slowest. Both micro-CT analysis and the temporal expression patterns of cartilage versus bone mRNAs demonstrated very slow (≥ 2 wk delay) cartilage resorption for C3H compared to B6. This was due to the slower transit of C3H bones through the endochondral phase. Furthermore, this slower transit time could be related to genetic variablity in the rate of endochondral maturation based on the 5-7 day difference in times of peak chondrocyte hypertophy based on Col10A1 expression. Quantitative analysis of the expression of both cartilage and bone extracellular matrix mRNAs showed a direct correlation between the total anabolic activity of a given strain of mouse and the overall volume of bone tissue formed such that (C3H>B6>AJ). Examination of 14 day post birth growth plates demonstrated similar temporal patterns of endochondral progression with the AJ and B6 mouse strains showing substantially advanced stages of maturation as comapred to C3H that lagged behind. These data suggested that the genetic elements, which control the primary structural attributes of bone quality are recapitulated during fracture healing and can be easily assessed in the temporal window of fracture healing. These data indicate that the basic temporal and quantitative attributes of endochondral bone formation during fracture healing are genetically regulated. Finally, we show that the rate of bone healing is not simply related to variability in bone quality but is also controled by other factors associated with genetic variablity intrinsic to endochondral bone formation.

The Effects of Ovariectomy on Bone Quality of *Hrk*-Deficient Mice. L. M. Wise[1], B. Sukhu*[1], A. Benito*[2], G. Nunez*[2], A. Jurisicova*[1], M. D. Grynpas[1]. [1]Samuel Lunenfeld Research Institute, University of Toronto, Toronto, ON, Canada, [2]Department of Pathology & Comprehensive Cancer Center, University of Michigan Medical School, Ann Arbor, MI, USA.

Hrk and *Bax* are pro-apoptotic members of the *Bcl-2* gene family. Aged *Bax*-deficient mice exhibit a phenotype in ovarian reserve, which subsequently impacts on bone quality. We have previously shown that young *Hrk*-knockout (KO) mice also display alteration of bone quality, likely caused by increased osteoblast survival. Given the known relationship between *Hrk* and *Bax*, and the observed ovarian reserve phenotype in *Bax*-KO mice, the effect of ovariectomy on *Hrk*-KO is the focus of this work. Groups of KO (n=9) and WT (n=13) mice were ovariectomized (OVX) at 3 months of age, aged further for 3 extra months, and compared to intact age-matched control KO (n=10) and WT (n=12) females. Dual energy x-ray absorptiometry was performed on all mice to determine bone mineral density (BMD). Structural and turnover parameters were evaluated using histomorphometry on sections of undecalcified distal femora. To evaluate mechanical properties, 3-point bending, torsion testing and femoral neck fracture were performed on the femora, while unilateral compression was performed on the 5th lumbar vertebrae. The expected reduction in overall BMD due to OVX was observed in both WT (-6%) and KO (-8%) mice. However, bone mineral content in KO mice was unaffected due to OVX whereas the WT showed a 10% decrease. Structural and turnover parameters were also largely unaffected by OVX in KO mice, while WT mice experienced a significant reduction in both trabecular bone volume (-29%) and trabecular number (-27%). Mechanical tests on femora indicate that although the OVX reduced some mechanical properties in both WT and KO mice, KO cortical bone was significantly more affected by the OVX (for example, bending toughness; -58% versus -33% in WT). Vertebral compression showed similarly reduced mechanical properties in trabecular bone due to OVX in both WT and KO mice. Although both WT and KO mice experienced a similar reduction in BMD, the OVX did not cause a reduction in absolute mineral content in KO mice. Further, the OVX did not cause the expected structural effects on KO trabecular bone. By contrast, the mechanical properties of KO cortical bone were significantly more affected by OVX. Thus, the decreased mechanical integrity is likely due to the inherent material properties of bone; while more mineral may be present, it perhaps may not be properly packed within the organic matrix. As such, bone material properties will be further evaluated using back-scattered electron imaging and x-ray diffraction techniques.

Detecting BMD and Bone Size QTL Using a Cross of MRL and CAST Inbred Strains of Mice Both of Which Exhibit High BMD. H. Yu[1], S. Mohan[1], B. Edderkaoui[1], G. Masinde*[1], J. E. Wergedal[1], W. Beamer[2], D. J. Baylink[1]. [1]JLP VAMC and LLU, Loma Linda, CA, USA, [2]Jackson Labs, Bar Harbor, ME, USA.

Previous studies to identify genetic loci involved in BMD regulation involved the use of inbred strains of mice with high BMD and low BMD for generating F_2 mice. We have used a similar strategy and identified several BMD QTL using crosses involving high BMD CAST/EiJ (CAST) and low BMD C57BL/6J (B6) as well as high BMD MRL/MpJ (MRL) and low BMD SJL/J (SJL) mice. The identified QTL were contributed not only by alleles from a high BMD parent strain but also by alleles from a low BMD parent strain. In this study, we tested the hypothesis that novel QTL can be identified using a cross of two inbred strains of mouse (MRL and CAST), both of which exhibit high BMD. To this end, we generated 328 MRL X CAST F_2 (171 female and 157 male) mice and measured femur BMD and periosteal perimeter (P.Pm, a measure of bone size) using pQCT. Whole genome genotyping was performed using 86 microsatellite markers at 10 - 15 cM intervals. QTL analysis was carried out using the interval mapping and permutation test options of MapQTL.

Phenotype	Marker	Position (cM)	LOD Score (P)	Source
BMD	D10Mit31	36	3.44 (< 0.05)	CAST
BMD	D15Mit115	24	2.66 (< 0.05)	MRL
P.Pm	D2Mit411	77.6	2.97 (< 0.05)	MRL
P.Pm	D9Mit336	35	3.46 (< 0.01)	MRL
P.Pm	D19Mit17	43	2.18 (< 0.05)	MRL

Comparison of identified QTL in this cross with those obtained in earlier B6 X CAST and MRL X SJL crosses revealed the following: 1) The major BMD QTL on chromosome (chr) 1 detected using B6 X CAST or MRL X SJL crosses could not be found using an intercross between MRL X CAST, suggesting that this locus may be present in the both high BMD strains. 2) A new BMD QTL on chr 10 was identified in the MRL X CAST cross that was not present in either MRL X SJL or B6 X CAST crosses, indicating that novel QTL could be identified under different genetic backgrounds. 3) The Chr 2 and 9 QTL for bone size were similar to those detected in MRL X SJL cross, but Chr 19 bone size QTL was new. In conclusion: 1) our data demonstrate the utility of crosses involving two inbred strains of mice both of which exhibit similar phenotype in identification of novel QTL for a phenotype of

interest; and 2) the QTL data generated from various inbred strain crosses should be used in the future identification of candidate gene using SNP haplotype analysis or other techniques once the genomes of various inbred strains of mice are fully sequenced.

Verification and Fine Mapping of a Chromosome X QTL that Influences Femoral Cross-sectional Geometry and Bending Strength in Mice. R. F. Klein, D. C. Dinulescu*, E. A. Larson*, T. G. Munsey*, J. N. Kansagor*, C. Vanek, D. A. Olson*, J. K. Belknap*, E. S. Orwoll. Bone and Mineral Unit, Oregon Health & Science University, Portland, OR, USA.

Size and shape are critical determinants of the mechanical properties of skeletal elements and are highly heritable. In previous studies, using an F_2 intercross between C57BL/6J (B6) and DBA/2J (D2) mouse strains, we have described 4 quantitative trait loci (QTL) that contribute to natural variation in femoral cross-sectional moment of inertia (CSMI) - a composite biomechanical measure of the size, shape and distribution of bone mass around the longitudinal axis of the femur. One of these QTL resides within chromosome X (Chr X) and contributes a substantial proportion of the geometric and biomechanical variation between B6 and D2 femora. Selective breeding was used to transfer the chromosomal fragment containing the Chr X QTL interval from a B6 onto a D2 genetic background. Comparison of the resulting congenic mouse strain with the background D2 strain established that a 150 megabase (Mb) B6 genomic interval of Chr X in isolation confers increased mid-shaft femoral CSMI (0.085 ± 0.002 mm^2 *vs.* 0.075 ± 0.002 mm^2, $p < 0.0001$). In order to confirm and narrow the location of CSMI QTL gene(s), we developed 4 subcongenic lines that contain different regions that provided overlapping coverage of the Chr X QTL region. Phenotypic analyses indicated that 20-week-old congenic mice bearing a 60 Mb region of B6 genomic material between *DXMit144* and *DXMit117* exhibited 16% greater ($p < 0.0001$) CSMI compared to control D2 mice. There were no differences in the QTL effect or position between males and females. Consistent with the increased CSMI, these Chr X congenic mice also showed a 5% increase ($p < 0.005$) in femoral cortical area, 17% increase ($p < 0.005$) in femoral marrow area and 6% increase ($p < 0.005$) in femoral ultimate failure load compared to control mice. The improved femoral cross-sectional geometry and resistance to bending of the congenic mice was not accompanied by changes in body weight, whole body BMD, femoral length or cortical thickness. Our data, using interval-specific congenic mice bred by introgressing a chromosomal region from the B6 donor strain into the D2 strain of contrasting phenotype, offer potentially much more precise QTL localization by establishing definitive limits for the Chr X region containing a femoral CSMI QTL. Ultimately, these congenic strains will provide an invaluable resource for further defining specific aspects of genetic architecture (e.g., mode of inheritance, gene order, gene-gene and gene-environment interactions, etc.) and for in depth studies of the mechanisms by which the Chr X QTL gene (or genes) affect skeletal development.

Analysis of Global Expression of *MEN1* Gene Expression by Ribozymes and siRNAs in Cultured Cells. A. Falchetti, E. Luzi*, I. Tognarini*, F. Marini*, G. Galli*, A. Carossino*, L. Masi, M. Brandi. Internal Medicine, University of Florence, Florence, Italy.

Multiple endocrine neoplasia type 1 (MEN1) is characterized by the occurrence of tumors of the parathyroids, endocrine pancreas, and the anterior pituitary, including more than 20 other endocrine and nonendocrine tumor combinations. *MEN1* gene, a tumor suppressor gene encodes a protein, menin, with a molecular mass of 67 kDa. Loss of heterozygosity (LOH) at 11q13 has been found in MEN1 tumors, but also in sporadic pituitary tumors and in 30-70% of sporadic parathyroids and endocrine pancreas tumors, a subset of those with LOH at 11q13 exhibiting mutations in the *MEN1* gene. MEN1 mRNA and protein are expressed in all normal studied tissues, leaving the basis for endocrine predominance of neoplasia unexplained. Mutations in the *MEN1* gene frequently predict protein truncation possibly leading to inactivated function consistent with the idea of a tumor suppressor gene as mouse models furtherly support. It has been shown that menin interacts with AP-1 transcription factor JunD, Smad3 and inhibits NFκB-mediated transactivation. Moreover, it has been shown that menin also interacts with pem, nm23, GFAP, the 32-kDa subunit of REPA, and nonmuscle myosin II-A heavy chain. Menin uncouples Elk-1, JunD, and c-Jun phosphorylation from MAPK activation. Furthermore, overexpression of menin suppresses insulin-induced AP-1 activity in CHO-IR cells, expressing high levels of insulin receptor, and c-Fos induction at the transcriptional level. However, the effects of *MEN1* in human neuroendocrine cells and its role in gene regulation remain elusive. We begun to study the role of *MEN1* gene, its mRNA and menin protein in the global gene expression network in fibroblasts from MEN1 patients both with heterozygote truncating mutation of gene and from healthy individuals. Preliminary data show that no differences exist in protein expression in both affected and unaffected subjects, suggesting that the wild-type allele could compensate for a similar level of menin expression. Currently, we have designed specific ribozymes and siRNAs against different target along MEN1 mRNA in order to downregulate the wild-type allele and to obtain informations on the MEN1 mRNA gene transcription regulation levels.

High-Throughput Functional and Morphological Phenotyping of 2,000 Murine Femora. G. H. van Lenthe[1], T. Kohler*[1], R. Voide*[1], L. R. Donahue[2], R. Müller[1]. [1]Institute for Biomedical Engineering, ETH and University Zurich, Zurich, Switzerland, [2]The Jackson Laboratories, Bar Harbor, ME, USA.

The gold standard to determine bone strength is experimental biomechanics. However, it has its limitations, as it is a destructive test, laborious, and prone to errors, especially when testing small bones. Therefore, we recently used microstructural finite element analysis to determine bone strength directly from bone structure. We have applied this technique to femora of two murine growth-hormone (GH) deficient inbred strains (B6-*lit/lit* and C3.B6-*lit/lit*), and to their wild-type counterparts (B6-*lit/+* and C3H-*lit/+*). We found that GH had a sex-specific action on bone strength (Fig. 1), increasing strength more in males than in females. To further investigate the genetics causing the non-GH related differences in bone strength, an F2 population of 2,000 mice was produced based on the two GH-deficient parental strains.

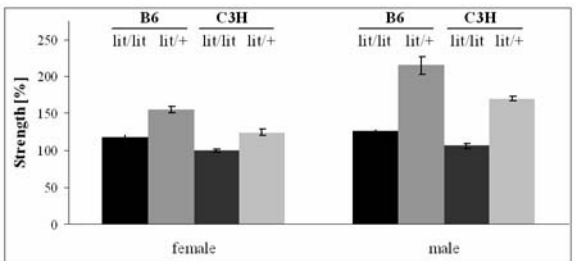

Figure 1: Femoral neck strength for two growth-hormone deficient inbred strains of mice, and of their wild-type counterparts

At four months of age, all 2,000 femora were μCT scanned using a 20 μm resolution. After automated alignment, microstructural finite element models were automatically created from which strength was calculated. In addition, morphometric parameters were calculated for different volumes of interest: whole bone, distal metaphysis, and femoral neck. As expected, we found large variations between femora and most parameters had a Gaussian distribution. On average, males had stronger femora than females. Interestingly, bone strength was not highly correlated to bone mass, but to femoral neck volume. We showed that high-throughput characterization of murine femora is now possible, allowing scanning, morphometric and functional analysis of 70 femora per day. The functional and morphological data obtained in this study, in combination with data on genomic markers that has been acquired for all 2,000 mice, will allow us to locate genetic loci for bone volume and other architectural parameters. Even more so, it will allow us to locate genetic loci for bone strength directly, rather than the fore-mentioned surrogate markers of bone strength.

Test of Linkage and Association of 14 Genetic Loci with Bone Size. H. Lau*[1], M. Ng*[1], L. Jin[1], A. Paterson*[2], P. Sham*[3], K. Luk*[4], V. Chan*[1], A. Kung[1]. [1]Medicine, The University of Hong Kong, Hong Kong, China, [2]Program in Genetics and Genomic Biology, University of Toronto, Toroto, ON, Canada, [3]Genome Research Centre, The University of Hong Kong, Hong Kong, China, [4]Department of Orthopaedic Surgery & Traumatology, The University of Hong Kong, Hong Kong, China.

Bone size is an important independent contributor to bone strength, a determinant of osteoporotic fracture. To evaluate the genetic determinants of bone size, linkage and/or association of 14 polymorphic loci of 8 candidate genes were studied in 177 southern Chinese pedigrees of 674 subjects (567 females and 107 males). Four skeletal sites were studied, including the L1-4 lumbar spine, trochanter, femoral neck and total hip region. Age, sex, height and weight were included as covariates in the analysis. The candidate genes studied include estrogen receptor alpha (ERα) and beta (ERβ), calcium sensing receptor (CASR), vitamin D receptor (VDR), collagen type Iα1 (COLIA1), LDL receptor-related protein 5 (LRP5), transforming growth factor β1 (TGF β), and parathyroid hormone receptor 1 (PTHR1). Multi-point variance component linkage analysis was performed using the MERLIN program. Linkage was observed between D14S1026 genotypes of ERβ with total hip area; CASR genotypes with femoral neck bone area; 266A/G, 2220C/T and 3989C/T genotypes of LRP5 with total hip bone area. Association of bone size was determined using the quantitative transmission disequilibrium test (QTDT). After covariates adjustment, total family association revealed significant association of D14S1026 genotypes of ERβ with spine, trochanter and total hip bone area; D3S1289 genotypes with femoral neck, trochanter and hip region bone area; and CASR genotype with femoral neck and total hip bone area. These results were also seen when only the females were studied. In addition, 2T/C of VDR was associated with spine bone area in all subjects while 266A/G of LRP5 was associated with total hip bone area when the females were analysed separately. When all subjects were analysed, significant within-family association was detected between D14S1026 genotypes of ERβ with spine bone area. Overall, these data suggested ERβ, CASR and LRP5 are important candidate genes for determining bone size variation. In addition, VDR gene and D3S1289 may also contribute to bone size variation.

Genetic Effects on Bone Loss in Peri- and Post-Menopausal Women: A Longitudinal Twin Study. J. MAKOVEY*[1], V. Naganathan[2], T. V. Nguyen[3], P. Sambrook[1]. [1]Department of Rheumatology, Institute of Bone and Joint Research, Royal North Shore Hospital, University of Sydney, Sydney, Australia, [2]Centre for Education and Research on Ageing, Concord Hospital, University of Sydney, Sydney, Australia, [3]Bone and Mineral Research Program,, Garvan Institute of Medical Research, Sydney, Australia.

Cross-sectional twin and family studies have shown that bone density variance is mainly under genetic influences. The relative magnitude of genetic and environmental components on bone loss variance however is not clear. The aim of this study was to assess the heritability of bone loss in peri- and post-menopausal women. A sample of 176 pairs of twins (88 MZ and 88 DZ), (mean age 57 years (range: 45 - 57)) were seen. Each individual had base line BMD measurements at lumbar spine and the femoral neck measured by a HOLOGIC QDR-4500W bone densitometer and a repeat measure, on average 3.9 years (range: 1 - 7.5 years) later. Change in BMD (dBMD) was expressed as percent gain or loss per year. Intraclass correlation coefficients in dBMD were calculated for MZ and DZ pairs. Genetic model-fitting analysis was used to partition the total variance of dBMD into three components: genetic component (G), common environmental component shared by the twins (C), and specific environmental component, including measurement error (E). The index of heritability was estimated as the ratio of genetic variance over total variance. The mean (± SD) of annual change in BMD was -0.42±1.4 at the lumbar spine and -0.31±1.28 at the femoral neck. There was no significant difference in rate of bone loss between MZ and DZ twins. At the lumbar spine the intraclass correlation in MZ twins (0.39) was significantly higher than in DZ twins (0.19). However, at the femoral neck the intraclass correlation was low in both MZ twins (0.09) and DZ twins (0.00). Results of genetic model-fitting analysis indicated that the index of heritability for dBMD at the lumbar spine was 0.4. There was, however, no significant genetic effect on dBMD at the femoral neck. These data suggest that although genetic effects on bone loss with ageing are less pronounced than those on peak bone mass, they still account for approximately 40% of the between-individuals variation in bone loss at the lumbar spine in pre- and post-menopausal women.

Lean Mass Plays a Significant and Sex-Specific Role in Resemblance for Femoral Neck Bone Mineral Density in Parent-Offspring Pairs. H. Blain*[1], A. Vuillemin*[2], E. Le Bihan*[3], F. Guillemin*[2], P. Jouanny*[4], F. Blotman[5], C. Jeandel*[1]. [1]Department of Internal Medicine and Gériatrics, Centre Antonin Balmes, Montpellier, France, [2]Department of Clinical Epidemiology, Henri Poincaré University, Nancy, France, [3]Department of Clinical Epidemiology,, Henri Poincaré University, Nancy, France, [4]Department of Internal Medicine and Gériatrics, University Hospital, Rennes, France, [5]Department of Rheumatology, University Hospital, Montpellier, France.

The aim of the present study was to examine the respective influence of heritable anthropometric factors on familial association in femoral neck bone mineral density (FN BMD) in a healthy community-dwelling sample constituted of 173 parent-child pairs, including 86 mother-daughter, 32 mother-son, 32 father-daughter, and 23 father-son pairs from 128 families. Pearson's correlations were used to examine parent-offspring associations in FN BMD and other factors. Multivariate regressions were performed in a Bayesian frame. Heritability (h^2) is defined as the regression coefficient of the mean of the parent's BMD. After adjustment for parents and children's age, smoking habits, calcium and alcohol intake, physical activity, as well as menopause and hormonal replacement therapy, if relevant, heritability estimates for FN BMD were found to be significant in father-daughter (h^2 = 0.68), mother-daughter (h^2 = 0.40), and in mother-son pairs (h^2 = 0.23), but not significant in father-son pairs. The lean mass of mothers and sons was not intercorrelated, but adjustment for the lean mass of the sons dramatically enhanced FN BMD h^2 in mother-son pairs (from 0.23 to 0.61). The lean mass of mothers and daughters was strongly intercorrelated, and adjustment for the lean mass of the daughters strongly reduced the FN BMD h^2 (from 0.40 to 0.23). Adjustment for fat mass and height of children did not affect the heritability estimates. In conclusion, anthropometric parameters are not involved in the heritability of FN BMD in father-daughter pairs or in the lack of heritability of FN BMD in father-son pairs. Lean mass resemblance between mothers and daughters plays a important role in the significant FN BMD heritability in mother-daughter pairs. Lean mass, which is not significantly correlated in mother-son pairs, plays a significant role in the heritability of FN BMD in mother-son pairs, suggesting that a low FN BMD has to be sought in sons of women with low FN BMD, particularly if the lean mass of sons and mothers is low.

Relationships between Quantitative Ultrasound and Vitamin D Receptor Gene in a Geographical Isolated Population From Lampedusa Island. C. Cepollaro[1], A. Falchetti[1], C. Sferrazza[2], A. Gozzini*[1], L. Masi[1], N. Napoli[2], G. Di Fede*[2], V. Cannone*[2], G. Cusumano*[2], M. C. Pandolfo*[2], G. B. Rini[2], A. Tanini[1], M. L. Brandi[1]. [1]Department of Internal Medicine, University of Florence, Florence, Italy, [2]Department of Internal Medicine, University of Palermo, Palermo, Italy.

Quantitative ultrasound (QUS) has been proposed as an alternative method for non invasive assessment of bone status, as it reflects both bone mass and qualitative aspects of bone. QUS may predict the risk of fracture independent of bone density. It has been suggested that heritability estimates of the QUS parameters are comparable with those of bone mineral density (BMD). However, in contrast to the many reports using BMD, genetic studies using QUS measurements are extremely rare. Several candidate genes have been proposed to be involved in the pathogenesis of osteoporosis, such as vitamin D receptor (*VDR*) gene. Genetic dissection of a multifactorial disease, such as osteoporosis, has taken advantage by several analytical models; one of the most promising genetic approach in complex diseases is represented by isolated population studies. The aim of our study was to investigate the association between QUS and polymorphism of VDR in a geographical isolated population from Lampedusa Island. Total population of Lampedusa consists of 5908 individuals with 2867 women. We analyzed 424 women (14,8% of total female population), 277 postmenopausal and 147 non-menopausal, for *VDR-FokI* genotypes. Allelic frequencies determined by *VDR-FokI* polymorphism were equal to 49% for the F allele and 51% for the f allele. Thus, *FF*, *Ff* and *ff* genotypes frequencies were 33,17 %, 32,69%, 33,89%, respectively. QUS at calcaneus were obtained in the study population by DTU-one (Osteometer Meditech, Hawthorn, CA, USA). Measurements were made at the right calcaneus, unless foot deformity or oedema precluded measurement in which cases the left heel was used. In order to assess the precision, two consecutive measurements were made in 30 healthy women, repositioning the foot between each measurement. The precision error was 0.4% and 1.2% for SOS and BUA, respectively. ANCOVA analysis was performed to evaluate the association of genotypes with ultrasound parameters (SOS and BUA). After adjustment for potential confounders (age, height, weight, YSM, calcium intake), SOS and BUA showed a significant relationship with *FOKI* genotypes ($p<0.001$). In particular, women with *ff* genotype exhibited a significant lower SOS and BUA, when compared to *Ff* and *FF* genotypes. The strong association that we have found between *FOKI VDR* polymorphism and QUS parameters may suggest that such polymorphism could be associated not only with bone mineral content, but also with bone quality.

Disclosures: ***C. Cepollaro****, None.*

Identification of Gain Function Mutation in the Calcium-Sensing Receptor in an Italian Family with Autosomal Dominant Hypocalcemia. L. Masi[1], G. Leoncini*[1], E. Procopio*[2], A. Amedei*[1], A. Falchetti[1], R. Imbriaco*[1], R. Livi*[1], A. Tanini[1], M. L. Brandi[1]. [1]Department of Internal Medicine, University of Florence, Florence, Italy, [2]Department of Pediatric, University of Florence, Florence, Italy.

The calcium sensing receptor (CaR) was first identified in the parathyroid cells and was later found to be expressed in the kidney and other tissues. The human CaR gene encodes a polypeptide of 1078 amino acids. Inactivating mutations in the CaR gene are responsible of an elevation in extracellular calcium, leading to mild moderate hypercalcemia and relative hypocalciuria called Familial Hypocalciuric Hypocalcemic (FHH). Conversely, activating mutations in the CaR gene are associated with reverse phenotype, autosomal dominant hypocalcemic (ADH) and a sporadic hypoparathyroidism. So far, about 20 activating mutations in the CaR gene have been identified. Recently a $Ser^{820}Phe$ mutation in the CaR has been described in Japanese family. In the present study we described an Italian family affected by ADH in whom a CaR mutation was identified. The proband was a girl 13 year old affected by a mild hypocalcemia and hypercalciuria with normal range value of PTH. She underwent a computed tomographic examination of the brain because of headache which showed the presence of calcificatin of the basal ganglia. In addition a juvanile hypertension was present in the proband. Baseline biochemical data of the family members showed a mild hypocalcemia and hypertension in the mather and two of four uncles. Genomic DNA of all subjects was extracted from white blood cells with standard procedure. In the proband, all protein-coding exons (exons 2-7) of the CaR gene were amplified by PCR with standard procedures using primer pairs as described in the literature. Nucleotide sequences of both strands of the PCR products were determined by direct sequencing with a DNA kit and an automated DNA sequencer (ABI PRISM 3100, Perkiln-Elmer Corp). A $Ser^{820}Phe$ activating mutation of the CaR was found. In summary, we have idenfied the $Ser^{820}Phe$ activating mutation in a Italian familiy affected by Hypertension and ADH.

Polymorphisms of the Growth Hormone Receptor, Growth Hormone Secretagogue Receptor and Growth Hormone Releasing Hormone Genes Are Associated with Bone Mass: The Hertfordshire Cohort Study. E. M. Dennison*[1], H. E. Syddall*[1], I. N. M. Day*[2], T. R. Gaunt*[2], S. Rodriguez*[2], C. Cooper[1]. [1]MRC Epidemiology Resource Centre, University of Southampton, Southampton, United Kingdom, [2]Human Genetics Division, University of Southampton, Southampton, United Kingdom.

We have previously demonstrated relationships between single nucleotide polymorphisms in the growth hormone gene and adult bone mass in a UK population. Here we report associations between polymorphisms of the growth hormone receptor, growth hormone secretagogue receptor and growth hormone releasing hormone genes with bone mass in an extension to the original study. Four hundred and ninety eight men and 468 women aged 59-71 years living in Hertfordshire, UK were recruited. A lifestyle questionnaire was administered and bone mass at the lumbar spine and femoral neck measured using a Hologic QDR 4500 instrument. DNA was obtained from whole blood samples using standard extraction techniques. Single nucleotide variants in the growth hormone receptor gene (coded GGHRV12), the growth hormone secretagogue receptor gene (coded GGHSRV02), and the growth hormone releasing hormone gene (coded GGHRHV10) were analysed. Ethical approval was obtained, and the study conducted in accordance with the Declaration of Helsinki. Among men, GGHRHV10 12 heterozygotes had higher bone mineral content (BMC) and bone mineral density (BMD) at the total femur than GGHRHV10 11 homozygotes (test for trend BMC p=0.02, BMD p=0.12, fully adjusted for age, social class, body mass index, physical activity, calcium intake, cigarette and alcohol consumption). Similar relationships were observed in women at the lumbar spine (mean BMC lumbar spine GGHRHV10 11 genotype = 56.9g, GGHRHV10 12 genotype = 68.4g, p<0.001, fully adjusted; mean BMD lumbar spine GGHRHV10 11 genotype = 0.96g/cm^2, GGHRHV10 12 genotype = 1.10 g/cm^2, p<0.001 fully adjusted). Among men, individuals of genotype GGHRV12 22 had higher BMC and BMD at the lumbar spine than those of GGHRV12 11 or GGHRV12 12 genotype (test for trend BMC p=0.05; BMD p=0.03, fully adjusted). No such relationships were observed among women. Finally, among men, individuals of genotype GGHSRV02 22 had lower BMC and BMD at the lumbar spine than those of GGHSRV02 11 or GGHSRV02 12 genotype (test for trend BMC p=0.09, BMD p=0.12, fully adjusted). Again, no such relationships were observed among women. We have demonstrated relationships between polymorphisms of the growth hormone receptor, growth hormone secretagogue receptor and growth hormone releasing hormone genes with bone mass in a UK cohort that varied according to sex; we hypothesize that this sexual dimorphism may reflect a greater effect of genotype on peak bone mass that bone loss.

Intron 1 Polymorphism (A/C) of *FDPS* Gene: A New Genetic Marker for N-BPs Therapy Response? S. Carbonell Sala*, A. Falchetti, V. Martineti*, F. Marini*, F. Del Monte*, L. Masi, N. Fossi*, A. Amedei*, F. Franceschelli*, A. Tanini, M. Brandi. Internal Medicine, University of Florence, Florence, Italy.

Bisphosphonates (BPs) are potent inhibitors of the bone osteoclast-mediated resorption. They are usually divided in two main pharmacological classes: those who inhibit protein prenylation (amino-bisphosphonates, N-BPs) and those who are metabolized to ATP analogues (not N-BPs). Recent studies have found that N-BPs can specifically inhibit some enzymes of the intracellular mevalonate pathway required for prenylation, post-translation lipid modification of different signaling proteins (small GTPases). Their inactivation could therefore explain at least in part the cellular effects of BPs. However, the existence of not responders to N-BPs therapy, the variability on therapy response and the tendency to develop adverse events remain to be determined. The aim of this project is the polymorphism analysis of farnesyl pyrophosphate-synthase (*FDPS*) gene to assess genetic aspects of N-BPs response. We evaluated the genotype distribution for A/C polymorphism, located on intron 1 of *FDPS* gene, in Italian population. Our findings show that *A* allele frequency is 0.82, while C allele frequency is 0.18, with an heterozygosity index of 0.2981 (^{2} Test p=0,29). As it was already showed for other genes involved in bone metabolism, also these *FDPS* genotypes distribution data are opposed to the ones described in Japanese population. The polymorphism information content of this marker is informative (PIC=0,29). Our future goal is to perform a case-control study with patients involved on clinic trials with N-BPs, searching the eventual correlation between polymorphism and therapy response, in order to early identify the subjects that could benefit BPs therapy, and patients genetically susceptible to develop adverse events.

The aim of this study was to verify if polymorphisms of VDR, COLIA1 and ESR1 genes are accompanied by variation in BMD at different measurement sites in a large Polish cohort of men. The study group comprised 532, adult males (age range 20-80 years), randomly selected in 7 centres from the Polish population. DNA was isolated from peripheral blood with using Gentra Isolation Kits. Polymorphisms were evaluated with RFLP technique, and determined by restrictive enzymes: BsmI (VDR), Van91I (COLIA1, Sp1 binding site polymorphism), and PvuII and XbaI simultaneously (ESR1). BMD of the Femoral Neck, Trochanter, Total Hip and Lumbar Spine L2-L4 were evaluated by DXA (Lunar DPX-L). Subjects with systemic disorders were excluded for the statistical examination (ANOVA). The frequency of VDR genotypes was [bb] 37%, [Bb] 40,6%, [BB] 22,4% with allele (b) 57,2%, allele (B) 42,8%. The frequency of COLIA1 genotypes was [GG] 65,9%, [GT] 30,7%, [TT] 3,4% with allele (G) 81,2%, allele (T) 18,8%. The frequency of ESR1 genotypes was [px,px] 23,6%, [px,PX] 37,5%, [PX,PX] 16,3%, [PX,Px] 9,6%, [Px,px] 12,1%, [Px,Px] 0,9%, with haplotypes px (1) =48,4%, PX (2)=39,8%, Px (3)=11,8%, pX (4) haplotype was not found. There was no observed association between the VDR BsmI variation and BMD values for any site. For COLIA1 gene an association between Sp1 binding site polymorphism and BMD in femoral neck was found. Carriers of the G allele had 8,4% higher BMD values (p<0,03, normalized for age,) compared to [TT] non-carriers. Analysis of ESR1 gene polymorphisms showed that carriers of the PX (2) haplotype have 3,6% higher BMD values for Total Hip (p<0,04) and 4,6% for Trochanter (p<0,01), both normalized for age. None of investigated polymorphisms was associated with BMD at the Lumbar Spine. We conclude that the COLIA1 Sp1 G allele and the ESR1 haplotype 2 (PX) allele are associated with higher BMD in men from the Polish population, at several hip locations, but not at the lumbar spine.

Lysophosphatidic Acid Stimulates the Motility of MC3T3-E1 Osteoblastic Cells. J. S. Fotos*[1], D. S. Galileo*[1], N. J. Karin[2]. [1]Biological Sciences, University of Delaware, Newark, DE, USA, [2]Biological Sciences Division, Pacific Northwest National Laboratory, Richland, WA, USA.

Lysophosphatidic acid (LPA), a bioactive lipid generated by degranulating platelets during blood clot formation, is postulated to regulate angiogenesis and wound healing. LPA has growth factor-like actions on a variety of cell types but little is known about its potential role as a regulator of bone cell function. We previously reported that LPA is a potent Ca^{2+} signaling agonist in MC3T3-E1 cells, and that this signaling was blocked by pertussis toxin, consistent with a requirement for G protein-coupled receptors (GPCR) in LPA function. LPA has been shown to enhance the migration of endothelial and cancer cells but it is not known if this lipid can alter osteoblast motility. We used quantitative time-lapse video micrography to analyze the migration of MC3T3-E1 cells after linear wounds were introduced into cell monolayers. LPA-treated cells refilled the wounds to a much greater extent than control osteoblasts, exhibiting a two-fold increase in the average migration distance per cell. Lipid treatment also elicited substantial changes in cell shape and actin cytoskeletal structure. LPA-treated cells contained fewer stress fibers and possessed long membrane processes that were enriched in F-actin. RT-PCR analysis showed that MC3T3-E1 cells express all four known LPA-specific GPCR (LPA_1-LPA_4) with a relative mRNA abundance of $LPA_1 > LPA_2 > LPA_4 >> LPA_3$. LPA-induced increases in osteoblast motility were antagonized by both pertussis toxin and Ki16425, a subtype-specific blocker of LPA_1 and LPA_3. In parallel with its effect on osteoblast migration, Ki16425 also inhibited LPA-induced Ca^{2+} signaling in a dose-dependent manner. Alendronate, which inhibited the LPA-induced migration of ovarian cancer cells, had no effect on the ability of LPA to stimulate osteoblast motility. Our data show that LPA stimulates osteoblast motility via a mechanism that is linked to GPCR, particularly LPA_1, and possibly Ca^{2+} signaling. We postulate that LPA is among the platelet-derived factors that promote osteoblast migration during bone fracture healing.

Expression and Regulation of CCN Genes in Murine Osteoblasts. M. S. Parisi*, E. Gazzerro, S. Rydziel, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Members of the CCN family of genes include cysteine-rich 61 (CYR61), connective tissue growth factor (CTGF), nephroblastoma overexpressed (NOV), and Wnt-induced secreted proteins (WISP) 1, 2 and 3. CCN proteins are related to the insulin-like growth factor binding proteins (IGFBP), and to antagonists of Wnt and bone morphogenetic proteins (BMP), but their function in skeletal tissue is unknown. In an initial effort to assess the role of CCN proteins in the skeleton, we examined the expression and regulation of CCN genes in primary cultures of murine osteoblasts treated with transforming growth factor ß (TGF ß), BMP-2 and cortisol. Northern blot analysis revealed the presence of CYR61, CTGF, NOV and WISP 1 and 2 transcripts in murine osteoblasts. WISP 3 transcripts were not detected. Continuous treatment of osteoblasts with TGF ß at 2 nM and BMP-2 at 3.3 nM caused a time-dependent increase in CYR61, CTGF and WISP 1 and 2 mRNA levels. TGF ß treatment decreased NOV transcripts. The stimulatory effect was observed after 2 to 6 h of exposure to TGF ß or BMP-2, whereas the decrease in NOV mRNA caused by TGF ß occurred after 24 h. Treatment with cortisol at 1 µM for 2 to 6 h increased CYR61 and CTGF after 2 to 6 h, WISP 2 mRNA levels after 24 h, and decreased WISP-1 mRNA levels after 24 to 48 h, but had no effect on NOV expression. In accordance with the results obtained by Northern blot analysis, Western blot analysis of conditioned medium from osteoblast cultures showed that TGF ß/BMP-2 increased the protein levels of CYR61, CTGF and WISP 1 and TGF ß decreases NOV protein levels. Cortisol increased CYR61 and CTGF. Nuclear run-on assays performed on nuclei from osteoblasts treated for 2 to 6 h revealed that BMP-2 and TGF ß enhanced CYR61, CTGF, and WISP 1 and 2 transcription. Suppression of NOV transcription could not be detected due to low control levels. Cortisol increased CYR61 and CTGF and decreased WISP 1 gene transcription. In conclusion, five of the six known CCN genes are expressed by osteoblasts and their expression is regulated by transcriptional mechanisms by TGF ß, BMP-2 and cortisol. Consequently, CCN genes could mediate selected actions of TGF ß, BMP-2 and cortisol on osteoblastic differentiation and function.

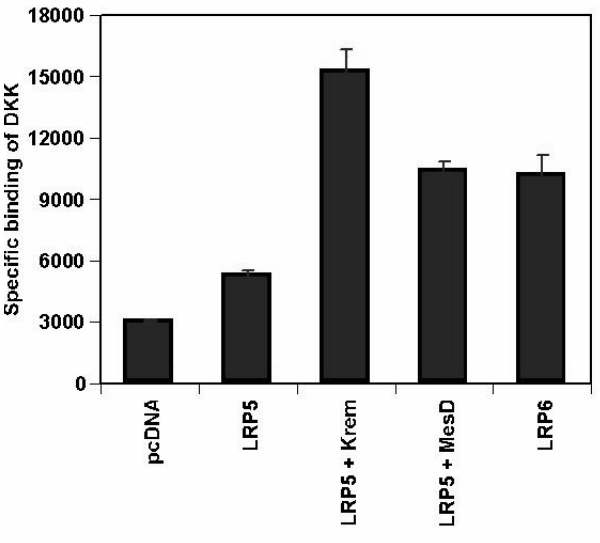
Kremen-2 and MesD Each Enhance Binding of DKK1 to Cells Over-Expressing LRP5 in a Radioactive Binding Assay. R. J. Murrills[1], J. J. Matteo*[1], P. J. Yaworsky[2], B. M. Bhat[1], F. J. Bex[1]. [1]Women's Health & Bone, Wyeth Research, Collegeville, PA, USA, [2]Biological Technologies, Wyeth Research, Cambridge, MA, USA.

Wnt signaling plays a critical role in the proliferation and differentiation of osteoblasts, and involves the interaction of numerous proteins in a complex and sometimes poorly understood manner. DKK1 antagonizes Wnt signaling by binding to LRP5/6, a co-receptor for frizzled, in addition to other proteins such as Kremen. Kremen reportedly forms a ternary complex with LRP5/6 and DKK leading to internalization and depletion of surface receptors, enhancing the negative effect of DKK upon Wnt signaling. MesD is thought to function as a chaperone protein, guiding LRP5/6 proteins to the cell surface. We have investigated the effects of co-transfecting Kremen-2 or MesD on the binding of DKK1 to LRP5 and LRP6 using a whole cell binding assay. 293 cells were seeded in 48-well plates and transfected with pcDNA, LRP5 or LRP6, with or without Kremen-2 or the chaperone protein MesD. Transfected cells were rinsed and exposed to 0.4nM ^{125}I-labeled purified DKK1 for 3h at room temperature; non-specific binding was determined using an excess of cold DKK1. Cells transfected with pcDNA alone showed moderate binding of DKK1, consistent with the known expression of LRP5/LRP6 in 293 cells. When LRP5 was transfected alone, there was at best a modest increase in the total counts, relative to pcDNA, which contrasted with a robust increase in binding when LRP6 was transfected alone. Co-transfection of Kremen-2 and LRP5 resulted in a marked, apparently synergistic increase in the total amount of radioligand bound, which could be blocked dose-dependently by co-incubation with cold DKK1. Similarly, co-transfection of the chaperone protein MesD with LRP5 also resulted in an apparently synergistic increase in binding.



Our data suggest that (1) LRP6 binds DKK1 more strongly than LRP5 (2) Binding of DKK1 to cells expressing LRP5 can be increased either by co-transfecting kremen-2 or MesD. Further studies to control for LRP5/6 internalization or cellular redistribution will provide additional support.

Temporal Expression of Lrp5/6, Dkk1 and Other Wnt-Signaling Components in Embryonic, Growing, and Adult Mouse Bone. W. G. Richards*[1], J. Pretorius*[2], J. Li[3], D. L. Lacey[1], W. S. Simonet[1], C. Paszty[1]. [1]Metabolic Disorders, Amgen, Thousand Oaks, CA, USA, [2]Pathology, Amgen, Thousand Oaks, CA, USA, [3]Licensing, Amgen, Thousand Oaks, CA, USA.

Gain-of-function and loss-of-function mutations in the Wnt co-receptor Lrp5 result in high and low bone mass respectively in primates and rodents. In addition, alterations in other components of the canonical Wnt signaling pathway result in increased or decreased bone mass depending upon whether Wnt signaling is activated or repressed. To strengthen our understanding of how members of the canonical Wnt signaling pathway contribute to bone mass, we used *in situ* hybridization to study the expression of the Wnt co-receptors Lrp5, Lrp6 and other modulators of Wnt signaling, Dkk1, Dkk2, Dkk3, Wif-1 and Sfrp4, during embryogenesis and in bone isolated from adolescent and adult mice. Expression of both Lrp5 and Lrp6 were detected as early as e12.5 in cartilage primordium from areas of developing bone. Lrp6, Wif-1 and Sfrp4 were observed in several tissues in the developing embryo, including bone. Dkk1 was also expressed in several regions from e11.5 to e15.5, with expression in bone first noted at e15.5. However, unlike the other molecules studied, Dkk1 expression became more restricted to bone as the embryo developed. Postnatally, in growing and adult mice Dkk1 expression was detected primarily in bone, whereas the other modulators of Wnt signaling, with the exception of Dkk2, were detected in various tissues, including bone. In the adult mouse Lrp6 expression was confined primarily to cells of epithelial origin and only limited expression was detected in adult bone. Lrp5 was more widely expressed than Lrp6 or Dkk1 in growing and adult bone. Both Lrp5 and Dkk1 expression co-localized to osteoblasts underlying the growth plate. Dkk1 expression was also detected in osteocytes within adult bone. Periosteal expression of Sfrp4 and Dkk3 were observed, whereas no expression of Dkk2 was seen in bone. Wif-1 was detected in osteoblasts and endosteal lining cells in marrow spaces throughout adult bone. Overall, the expression of these Wnt signaling components supports their role in regulating development and growth of mouse bone. For instance, the progressively restricted expression of Dkk1 to bone implies that it plays a prominent role in regulating Wnt signaling during bone development and growth. In addition, the more pronounced expression of Lrp5 compared to Lrp6 in adult bone, suggests that Lrp5 plays a more prominent role as a mediator of canonical Wnt signaling in adult mouse bone.

Reduced Bone Loss by Docosahexaenoic Acid (DHA) than Eicosapentaenoic Acid (EPA) in Ovariectomized Mice. M. M. Rahman*, A. Bhattacharya*, J. Banu, G. Fernandes*. Med/Clinical Immunology & Rheumatology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Estrogen deficiency predisposes women to develop postmenopausal osteoporosis which is characterized by progressive loss of bone leading to increased risk of fractures. Recently, omega-3 fatty acids have been found to decrease bone loss in ovariectomized (OVX) mice. However, a comparative study between DHA and EPA enriched fatty acids on postmenopausal bone loss has not yet been investigated. In this study, 2 months old OVX and sham operated mice (5 mice per group) were fed 10% corn oil (CO) or 10% fish oil with either 50% EPA and 5% DHA (50/5) or 5% EPA and 50% DHA (5/50). After 12 weeks on diet, bone mineral density (BMD) was analyzed by DEXA. The data revealed that ovariectomy induced bone loss in the femur, tibia and lumber vertebrae was significantly less in mice on 5/50 diet when compared to those on 50/5 and CO diets. To elucidate the mechanism by which DHA protects bone loss in OVX mice when compared to EPA, we carried out in vitro studies using RAW 264.7 cells. Two different concentrations (50 μM and 100μM) of DHA or EPA were used. We found that DHA significantly inhibited the receptor activator of NF-κB ligand (RANKL) stimulated multinucleated TRAP-positive cells formation in a dose dependent manner when compared to EPA or linoleic acid (LA). RANKL stimulated TNF-α production in RAW cells was also significantly decreased with DHA when compared to EPA and LA. By reverse transcription-polymerase chain reaction (RT-PCR) analysis, osteoclast-specific mRNA expression of cathepsin K, calcitonin receptor (CTR) and MMP-9 was also found to be significantly reduced with DHA when compared to EPA and LA. Moreover, bone resorption assay using calcium phosphate coated plate showed dramatic inhibition of RANKL stimulated pit formation of RAW cells treated with DHA when compared to EPA and LA. Thus DHA appears to be the most beneficial ω-3 fatty acid in preventing osteoclast activation and bone resorption. In summary, this study suggests that concentrated DHA ω-3 fatty acid is more efficient in reducing ovariectomy-induced bone loss than EPA.

Enamel Matrix Derivative Induces Osteoprotegerin Production by Human Osteoblasts. C. Galli*[1], G. M. Macaluso*[1], M. Pedrazzoni[2], R. Vescovini*[2], P. Sansoni*[2], R. Delsignore*[1], G. Passeri[2]. [1]Chair of Periodontology, Univ. of Parma, Parma, Italy, [2]Dep. Internal Medicine, Univ. of Parma, Parma, Italy.

Skeletal regeneration techniques increasingly rely on the use of exogenous molecules able to enhance bone tissue formation in pathological or traumatic defects. Enamel Matrix Derivative (EMD) from porcine tooth germs has been largely used to promote tooth ligament regeneration within periodontal pockets. Recent evidence suggests that EMD may contribute to induce osteoblasts' growth and differentiation. The present study aims to investigate EMD effects on growth, differentiation and bone balance markers in osteoblastic cells, in particular focusing on local factors relevant for bone remodeling, such as OPG and RANK-L. Cells were derived from bone specimen harvested from a healthy donor operated for mandibular reduction. These osteoblasts were producing osteocalcin and ALP, and were CD44 positive. Cells were cultured in the absence or in the presence of EMD at concentration of 20 and 50 μg/ml. Cell growth was measured by MTT assay at day 3, 6 and 9 of culture, ALP activity, osteocalcin, OPG, and RANK-L production were assayed at week 1, 2 and 3. Bone nodules formation was detected by alizarin red staining in parallel cultures after 3 weeks. Our results show that cell growth was significantly increased by EMD as compared to control at all 3 time points ($p<0.05$ at days 3 and 6, $p<0.001$ at day 9) and differentiation markers were enhanced in 50 μg/ml EMD treated cultures at week 2 and 3 (ALP $p<0.01$ and osteocalcin $p<0.05$). Supernatants from 50 μg/ml EMD treated cultures showed a significantly higher amount of OPG at week 1, 2 and 3 ($p<0.01$), while RANK-L was significantly decreased at week 3 ($p<0.001$). Mineralized nodules number and dimension were higher in the 50 μg/ml EMD treated cultures ($p<0.01$) as compared to control. Our findings suggest that EMD is able to enhance osteoblastic cell growth and expression of differentiation markers. Moreover, EMD is able to create a favorable osteogenic microenvironment by enhancing OPG production, decreasing RANK-L release and promoting bone mineralized nodule formation. EMD can therefore be considered a promising tool for alveolar bone regeneration.

Effects of Aging on Angiogenic Response Following Ischemic Necrosis of the Femoral Head. H. Bian[1], L. Gerstenfeld*[2], T. A. Einhorn*[2], H. Kim[1]. [1]Shriners Hospital For Children, Tampa, FL, USA, [2]Boston University Medical Center, Boston, MA, USA.

Clinical studies show that the healing time and the extent of repair following ischemic necrosis of the femoral head (INFH) vary considerably depending on the age of onset. In patients near skeletal maturity and adults, the healing time is prolonged and the extent of repair is decreased compared to children with INFH. We hypothesize that revascularization of the femoral head following ischemic necrosis is impaired as a function of age, and that impaired revascularization is associated with an age-dependent reduction in the expression of a key angiogenic factor, VEGF and its transcription factor, HIF-1α. The purpose of this study was to determine the effects of aging on VEGF and HIF-1α expression using a large animal model of INFH and a cartilage explant model of hypoxia. For the animal study, 4 young pigs (4 wks old) and 4 "adolescent" pigs (6 months old) were surgically induced with INFH by placing a ligature tightly around the right femoral neck. The epiphyseal cartilage from the infarcted and normal femoral heads was assessed at 24h and 1 wk after the operation for VEGF and HIF-1α expression using RNAse protection assay (RPA). For the in vitro study, cartilage explants (5 x 5 x 1mm thick) were incubated in DMEM without serum and placed into a hypoxia chamber containing 1% O_2, 5% CO_2 and 94% N_2. The explants were assessed at 2 to 24h using RPA and western blot analysis. In the in vivo study, VEGF expression was reduced in the older animals at 24 h and 1 wk after the induction of ischemia, compared to the younger animals. In addition, the relative response rate was decreased in the older animals. The baseline HIF-1α expression was lower in the older animals compared to the younger animals. However, HIF-1α level did not change with ischemia in both age groups. Explant studies showed similar results with decreased VEGF expression in the explants from the older animals at 2 to 24h after hypoxia. HIF-1α mRNA and protein levels were also decreased in the explants from the older animals. These findings support the hypothesis that there is an age-dependent reduction in VEGF and HIF-1α expression following ischemia, which may explain impaired revascularization and repair seen in the adolescent and adult patients with INFH.

Prior Intra-Arterial Injection of Mesenchymal Stem Cells Does not Enhance the Osteogenic Effects of Basic Fibroblast Growth Factor in Aged Ovariectomized Rats. U. T. Iwaniec[1], K. Moore*[2], M. F. Rivera*[1], S. M. Vanegas*[1], N. N. Teoh*[1], T. J. Wronski[1]. [1]Physiological Sciences, University of Florida, Gainesville, FL, USA, [2]Animal Sciences, University of Florida, Gainesville, FL, USA.

Previous studies have shown that the efficacy of PTH is limited in aged ovariectomized (OVX) rats with severe cancellous osteopenia due to lack of adequate numbers of bone spicules to serve as templates for new bone formation. Basic fibroblast growth factor (bFGF) may be useful in overcoming this limitation by its ability to induce formation of osteoid spicules within bone marrow. However, bFGF also has a diminished osteogenic effect in aged OVX rats, presumably due to an age-related decline in the population of mesenchymal stem cells (MSCs) that serve as targets for the growth factor. Therefore, the goal of this study was to determine whether prior treatment of aged OVX rats with MSCs would enhance the bone anabolic effects of bFGF. MSCs were harvested from the femoral bone marrow of relatively young OVX rats, expanded in culture, and cryogenically preserved for future use. Baseline (BSL) OVX and sham-operated rats were sacrificed at one year post-surgery (15 months old). Other groups of aged OVX rats were injected in their right femoral arteries with MSCs ($2x10^6$ cells/kg body weight) or culture medium alone. These animals were then injected SC with bFGF (1 mg/kg) at 4 hours after intra-arterial injection of MSCs. The bFGF treatments were continued daily for a period of 3 weeks. The right proximal tibiae were then collected and processed for quantitative bone histomorphometry. Data are expressed as mean ± SD and analyzed using the Kruskal-Wallis test followed by a non-parametric post-hoc test. In aged OVX rats injected intra-arterially with culture medium alone, treatment with bFGF induced an 11-fold increase in osteoid surface and a 7.5-fold increase in osteoblast surface compared to BSL OVX rats (69.3 ± 24.5% vs. 6.1 ± 3.9% and 49.2 ± 20.0% vs. 6.5 ± 4.0%, respectively). Osteoid volume was also markedly increased by bFGF treatment (7.9 ± 5.7% vs. 0.1 ± 0.1%). In aged OVX rats injected intra-arterially with MSCs, bFGF treatment induced a 14-fold increase in osteoid surface (88.0 ± 9.0%), a 9.5-fold increase in osteoblast surface (61.6 ± 14.8%), and a marked increase in osteoid volume (10.4 ± 6.6%) compared to BSL OVX rats. However, the mean values for this group were not significantly different from those of bFGF-treated OVX rats previously injected with culture medium alone. Osteoclast surface was markedly decreased in both bFGF-treated groups compared to BSL OVX rats. In summary, our results indicate that prior intra-arterial injection of MSCs does not enhance the bone anabolic effects of bFGF in the proximal tibia of aged OVX rats.

Adenovirus-Mediated Overexpression of FGF23 Suppresses Osteoblast Development and Matrix Mineralization in Fetal Rat Calvaria Cell Cultures. H. Wang*[1], R. Yamamoto*[2], K. Tanne*[2], J. E. Aubin[3], N. Maeda*[1], Y. Yoshiko[1]. [1]Oral Growth and Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [2]Orthodontics and Craniofacial Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [3]Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada.

FGF23 has been identified as a mediator of such hypophosphatemic diseases as autosomal dominant hypophosphatemic rickets, tumor-induced osteomalacia and possibly X-linked hypophosphatemic rickets. In skeletal tissue, mineralization defects are seen in FGF23-deficient hyperphosphatemic mice as well as in genetically-engineered hypophosphatemic mice overexpressing FGF23. Recent and growing evidence strongly suggests that FGF23 plays a central role in phosphate (Pi) homeostasis, predominantly through its effects on renal vitamin D metabolism and phosphate reabsorption. However, the FGF23 gene is widely expressed in multiple tissues including bone and cartilage, suggesting that the polypeptide may elicit at least some of its effects via other cell/tissue-specific effects. Taken together with our data that FGF23 mRNA is differentially expressed during osteoblast development and downregulated when osteoid nodules are induced to mineralize with β-glycerophosphate (βGP) in the fetal rat calvaria (RC) cell culture model, we speculated that FGF23 may act as a local factor on bone formation. To further address this possibility, we constructed recombinant adenovirus-human FGF23 (AV-FGF23) by using the Adeno-X^{TM} expression system and assessed the effects of FGF23 overexpression during osteoblast development and matrix mineralization in the RC model. Infection of proliferating cells with AV-FGF23 did not affect cell growth as compared to cells infected with control AV (AV-c). However, we found that cells overexpressing FGF23 made fewer and smaller nodules than control cultures with a parallel decrease in levels of osteoblast differentiation marker mRNAs. Furthermore, FGF23 overexpression inhibited osteoid nodule mineralization in the presence of β-glycerophosphate. Concomitant with these phenotypic changes in AV-FGF23- vs. AV-c-infected RC cells, overexpression of FGF23 decreased NaPi uptake in RC cells. Thus, we conclude that FGF23 may act as a negative regulator of osteoblast development and matrix mineralization independently of its systemic effects on Pi homeostasis.

A Novel Recessive Mutation in Fibroblast Growth Factor-23 (FGF-23) Causes a Tumoral Calcinosis. L. Masi[1], A. Gozzini*[1], S. Carbonell*[1], A. Amedei*[1], A. Falchetti[1], R. Capanna*[2], A. Tanini[1], M. L. Brandi[1]. [1]Department of Internal Medicine, University of Florence, Florence, Italy, [2]Department of Orthopaedic, University of Florence, Florence, Italy.

Tumoral calcinosis (TC) is a rare genetic disorder characterized by periarticular cystic and solid tumorals calcifications. Biochemical markers of disorder include hyperphospatemia and an elevated serum of calcitriol concentration in every patients. The hyperphosphatemia results form an increase in capacity of renal tubular phosphate reabsorption. The identification of phosphotonin family hormones suggest that mutations of these molecules could be involved in the pathogenesis of TC. One of these molecules is represented by FGF-23. The TC phenotype is similar to that described in the FGF-23 knockout mice. In the present study we described a new FGF-23 mutation in a subject affected by TC. A Caucasian women (years 67) was examined for a history of ectopic calcification. Biochemical exams showed and hyperphosphathemia and hyperphosphaturia with normal value of PTH and 1-25 (OH)2 D3. The patient presented a big shoulder calcification and also a calcification of femoral artery. We expanded the family tree through detailed family histories, which importantly revealed that parents were consanguineous. Hystologically the mass was characterized by calcium deposition and granulomatous reaction around the mass. Genomic DNA was extracted from blood collected from the patient, her daughter and her grandchild by standard procedure. DNA was not available from her parents. All three FGF-23 coding exons, as well as conserved splice sites, were amplified by standard PCR procedure. Nucleotide sequences were determined by direct sequencing with a DNA kit and an automated DNA sequencer (ABI PRISM 3100 - Perkiln-Elmer Corp). We discovered a new homozygous codon 41, His/Gln (CAC-CAA) substitution in exon 1 of FGF-23 gene in the affected patient. A heterozygous substitution was present in the daughter . No mutation were found in the two children. FGF-23 gene mutation was not found in the SNP database (www.ncbi.nih.gov/snp). In summary, a recessive mutation in FGF 23 causes TC. Understanding the functional significance and molecular physiology of this novel mutation will reveal critical information regarding the role of FGF-23 in states of normal and of disorder of phosphate homeostasis.

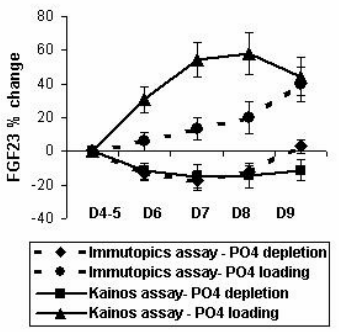
1st vs. 2nd Generation Assays in Detecting Changes in Blood FGF-23 with Dietary Phosphate. S. M. Burnett, S. Gunawardene*, F. R. Bringhurst, H. Jueppner, J. S. Finkelstein. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Fibroblast growth factor 23 (FGF23) is elevated in phosphate (PO_4) wasting disorders. Serum $P0_4$ levels are elevated in the FGF23 KO mouse suggesting that FGF23 plays a physiologic role in $P0_4$ regulation. To examine the effects of dietary $P0_4$ on FGF23 in humans, we randomly assigned 66 healthy subjects, age 18-45, to either a low or high PO_4 diet for 4 days, after a 4 day control diet. During deprivation, dietary PO_4 was 0.5g daily and subjects consumed PO_4 binders QID. During PO_4 loading, subjects consumed 2.5g PO_4 daily from diet and supplements. Blood FGF23 was measured using both a 1st generation immunometric assay detecting intact and C-terminal FGF23 (*Immutopics*), and a 2nd generation immunometric assay detecting only intact FGF23 (*Kainos*). Data are presented as mean ± SD. PO_4 loading increased 24 hour urine PO_4 excretion and $FePO_4$ ($p<0.01$). PO_4 deprivation decreased 24 hour urine PO_4 excretion and $FePO_4$ ($p<0.01$). Changes in FGF23 differed markedly in the 2 assays.



With PO_4 loading, the 2nd generation assay detected earlier and greater increases in FGF23 from 35±9 to 50±16 pg/mL ($p< 0.01$), an overall increase of ~ 60%; while the 1st generation assay detected a smaller increase in FGF23 from 57±31 to 74±52 RU/mL ($p<0.01$), an overall increase of ~ 30%. With PO_4 deprivation, the 2nd generation assay detected a ~ 20% sustained decrease in FGF23 from 37±13 to 31±10 pg/mL ($p<0.01$); while the 1st generation assay detected a transient fall in FGF23, the levels then returned to baseline, 58±31 vs. 56±32 RU/mL ($p=0.13$). There was weak correlation between the assays ($r=0.26$). The 2nd generation assay better detected correlations between FGF23 and PO_4 indices. These preliminary data suggest that physiologic changes in FGF23 are better detected using a 2nd generation assay that only measures intact FGF23, than using an assay which detects both intact FGF23 and C-terminal fragments.

Correlation Analysis of FGF23 vs. PO4 indices				
R coefficients	Blood PO_4	24 hour urine PO_4	$FePO_4$	1,25 $(OH)_2$ vitamin D
2nd generation FGF23 assay	0.37	0.45	0.28	-0.26

Vitamin D_3 but not PTH Regulates Fgf23 Gene Transcription in Osteoblasts. S. Liu, W. Tang*, J. Zhou*, L. D. Quarles. Internal Medicine/The Kidney Institute, University of Kansas Medical Center, Kansas City, KS, USA.

FGF23 is a hormone that inhibits sodium-dependent phosphate re-absorption and 1α-hydroxylase activity in the kidney resulting in phosphaturia and diminished 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) production. Recently, we have demonstrated that FGF23 is expressed in osteoblasts and may act as a counter-regulatory hormone for $1,25(OH)_2D_3$ -mediated increases in gastrointestinal phosphate absorption. In the current study, we further explored the mechanisms of $1,25(OH)_2D_3$ regulation of Fgf23 gene transcription and evaluated the effects of PTH on FGF23 production. Serum Fgf23 concentrations were measured in adult mice 4, 8, 24 hours after IP injections of $1,25(OH)_2D_3$ at a dosage of 100 ng/kg body weight or PTH1-34 at a dosage of 80 μg/kg body weight. PTH administration had no significant effect on serum Fgf23 levels over 24 hours. In contrast, $1,25(OH)_2D_3$ increased serum Fgf23 levels (mean ± SEM) from a baseline value of 90.6 ± 8.1 pg/ml to 141.0 ± 6.9 pg/ml ($p<0.01$) at 4 hours, reaching a peak concentration of 213.8 ± 14.6 pg/ml at 8 hours ($p<0.01$). $1,25(OH)_2D_3$ treatment resulted in a decrease in serum PTH levels from 37.6 ± 7.6 to 19.1 ± 1.8 pg/ml (mean ± SEM; $p<0.05$) at 8 hours and no changes in serum calcium or phosphate levels. We also observed a 4-fold increase of Fgf23 transcripts by real-time RT-PCR in calvaria isolated from mice 8 hours after injection of 1,25 $(OH)_2D_3$. In addition, we demonstrated that $1,25(OH)_2D_3$ added to the culture medium increases Fgf23 mRNA levels in ROS17/2.8 osteoblasts. Promoter/reporter construct analysis of the murine *Fgf23* 5'-flanking region in ROS17/2.8 osteoblasts demonstrated the ability of $1,25(OH)_2D_3$ to stimulate promoter activity in a dose dependent manner. The stimulatory effect was localized to a region between -1300 and -1260 bp upstream of Fgf23 translation start site. Sequence analysis of this region did not show a typical vitamin D response element (VDRE). Our data suggest that $1,25(OH)_2D_3$ stimulates the production of FGF23 by osteoblasts through non-classical mechanisms. This novel regulation of FGF23 production in osteoblasts by $1,25(OH)_2D_3$ provides further evidence for a bone-kidney axis regulating systemic phosphate homeostasis.

Effects of R-FB, a Unique Nonsteroidal Anti-Inflammatory Drug (NSAID), on COX2-Mediated Inhibition of Insulin-like Growth Factor Binding Protein-6 (BP6) Transcription. S. L. Hall, J. C. Felt*, T. A. Linkhart, D. D. Strong. Musculoskeletal Disease Center, LLVAHCS, LLU, Loma Linda, CA, USA.

NSAIDs reduce prostaglandin (PG) synthesis by inhibiting cyclooxygenase-1 and -2 (COX2) enzymes. NSAIDs have anti-inflammatory and anti-nociceptive effects and may decrease Alzheimer's dementia and cancer risk, but side effects such as gastrointestinal (GI) damage and cardiac risk, limit their use. NSAIDs also produce detrimental bone effects such as ↓ fracture healing, ↓ osteogenesis, and ↑ bone resorption. These skeletal effects may be due to inhibition of COX2 which has been proposed to mediate increased bone formation in response to mechanical loading and fracture repair. PGs promote osteoblast (ob) differentiation and survival, and stimulate bone formation, *in vivo*. Consistent with these data, we previously showed that overexpression of COX2 decreased transcription of BP6 (a potent, constitutively expressed inhibitor of ob differentiation), suggesting that some COX2 skeletal effects may be mediated via BP6 expression. In this study, we used BP6 transcriptional regulation by COX2 as an endpoint to compare if different NSAIDs act by similar or different mechanisms. Flurbiprofen (FB), a nonselective NSAID, exists as a racemic mixture of R- and S-enantiomers (R-FB and S-FB) with minimal stereo-inversion in humans. R-FB efficacy is similar to other NSAIDs but data suggests it acts by modulating transcription factors rather than by COX inhibition, and it is not GI-toxic. The effects of R-FB and other NSAIDs on BP6 promoter activity were assessed in the presence and absence of COX2 overexpression. We cotransfected human ob-like osteosarcoma cells with a Luciferase reporter construct containing 158 bps of BP6 proximal promoter and a COX2 expression vector incubated with and without IC50 doses of several NSAIDs. Luciferase and protein content were determined 24 hrs after transfection. In the absence of NSAIDs, COX2 overexpression reduced BP6 promoter activity by 55% ($p< 0.0002$). At low (anti-inflammatory) and intermediate (neuroprotective) doses, the COX2 effect was attenuated or abolished by several NSAIDs (ibuprofen, diclofenac, celecoxib, Dup697) but not by R-FB($p< 0.0004$). Reversal of the COX2 effect by R-FB was observed only at high (anti-tumor) doses. In summary, at low and intermediate doses COX2 inhibition of BP6 promoter activity was reversed by treatment with NSAIDs that inhibit PG synthesis, but not by R-FB. These data are consistent with reports that R-FB acts by alternative mechanism(s) and that COX2 transcriptional effects are mediated by PG production. Furthermore, in light of its lack of effect on COX2 activity, further study into the potential of R-FB as a "bone safe" NSAID is warranted.

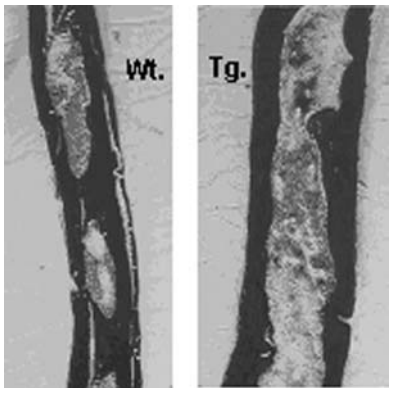
Transgenic Mice Overexpressing Pregnancy-Associated Plasma Protein (PAPP)-A, an IGFBP Protease, in Ssteoblasts Exhibit a Dramatic Increase in Bone Accretion. X. Qin[1], J. E. Wergedal[1], M. Rehage*[2], K. Tran*[2], J. Newton*[2], D. J. Baylink[1], S. Mohan[1]. [1]JLP VAMC and LLU, Loma Linda, CA, USA, [2]JLP VAMC, Loma Linda, CA, USA.

IGFs play an important role in the regulation of peak bone mass. The actions of IGF in bone are modulated by IGFBPs which are in turn regulated by IGFBP proteases. Based on *in vitro* studies that osteoblasts (OBs) produce an IGFBP specific protease, PAPP-A, which degrades inhibitory IGFBPs and thereby releases IGFs for biological action, we hypothesized that transgenic overexpression of PAPP-A in OBs should exert anabolic effects on bone *in vivo*. To test this hypothesis, we generated human PAPP-A construct driven by rat type I collagen promoter and tested the efficacy of this construct in MG63 and HEPG2 cells *in vitro*. We found that active recombinant PAPP-A (FLAG tagged) with the expected molecular mass was detected in the conditioned medium of MG63 but not HepG2 liver cells. We next generated transgenic founders and confirmed expression of PAPP-A transgene by RT-PCR analysis. Femurs of female mice from 3 liters of F1 generation (10 transgenic and 5 wild type) at 3 months were analyzed by pQCT (Table).

Parameter	% of wild type (Mean±SEM)
Length	106±0.8*
BMC	127±9.4*
Bone area	125±7.1**
Peri. Circ.	128±4.5**
Endo. Circ	112±1.5*

*=P<0.05; **=P<0.01



Consistent with the increased bone accretion in femurs, calvaria thickness and skull BMD measured by DXA at 6 months were increased by 43±7.7% (n=3, P<0.01) and 20±5.8% (n=3, P<0.05), respectively. Histological analysis of calvaria suggests that the increase in cortical thickness is caused by increased amount of osteoid indicating new bone formation (Figure). *In vivo* DXA analysis of a second founder also revealed an increase in skull BMD. Conclusions: 1) Transgenic mice overepressing PAPP-A exhibit a dramatic increase in BMC and bone size phenotypes at multiple sites; 2) Modulation of local IGF actions by upregulating PAPP-A expression and/or activity could provide a therapeutic opportunity to treat bone disorders.

The Role of IGF-I Signaling in Regulating Osteoclastogenesis. Y. Wang, S. Nishida, H. Z. ElAlieh*, E. C. Buxton*, R. K. Long*, B. P. Halloran, D. D. Bikle. Endocrine Unit, University of California, San Francisco, VA Medical Center, San Francisco, CA, USA.

Although insulin-like growth factor-I (IGF-I) has been clearly identified as an important growth factor in regulating osteoblast proliferation and function, information regarding its role in osteoclastogenesis is limited and conflicting. Our study was designed to analyze the role of IGF-I in modulating osteoclastogenesis using mice homozygous for targeted ablation of the IGF-I gene (IGF-I$^{-/-}$). To determine the effects of IGF-I on osteoclasts, wild-type (IGF-I$^{+/+}$) mice were treated with IGF-I or vehicle. The number of osteoclasts in IGF-I treated mice increased 1.5 fold compared to vehicle treated mice. In contrast, the number of osteoclasts in the IGF-I$^{-/-}$ mice were 76% of that observed in the IGF-I$^{+/+}$ mice. To clarify the mechanism by which IGF-I regulates osteoclastogenesis, we cultured osteoclast precursors from IGF-I$^{+/+}$ mice and IGF-I$^{-/-}$ mice for six days in the presence of RANKL and M-CSF. The number of osteoclasts (3 or more nuclei) observed in the culture from IGF-I$^{-/-}$ mice was significantly less (55%) than that from the IGF-I$^{+/+}$ mice. When IGF-I$^{-/-}$ osteoblasts and IGF-I$^{+/+}$ osteoclasts were co-cultured, the number of osteoclasts formed was only 11% of that from co-cultures of IGF-I$^{+/+}$ osteoblasts and osteoclasts. When IGF-I$^{+/+}$ osteoblasts and IGF-I$^{-/-}$ osteoclasts were co-cultured, the number of osteoclasts formed was 48 % of that observed in co-cultures of IGF-I$^{+/+}$ osteoblasts and osteoclasts. To investigate if the RANKL/RANK signaling pathway was involved in this process, mRNA levels of RANKL and RANK were measured in bone tissue (marrow removed) using real-time PCR. In IGF-I$^{-/-}$ mice, mRNA levels of RANKL and RANK were 55% and 33% of that in IGF-I$^{+/+}$ mice, respectively. To evaluate if IGF-I could rescue the abnormal osteoclastogenesis in IGF-I$^{-/-}$ mice, 10 ng/ml of IGF-I was added to the osteoclast precursor cultures. IGF-I increased the size (735 nuclei/ 100 osteoclasts), number (2.6 fold) and function (2.7 fold increase in resorption area in dentine) of osteoclasts in cultures from IGF-I$^{+/+}$ mice, with lesser effects in cultures from IGF-I$^{-/-}$ mice (400 nuclei/ 100 osteoclasts, and 2.0 fold increase in osteoclast number). In summary, our results indicate that IGF-I increases the size, number and function of osteoclasts. IGF-I is required for the normal interaction between the osteoblast and osteoclast via its regulation of RANKL and RANK expression.The role of osteoblasts in stimulating osteoclastogenesis is more impacted by lack of IGF-I than the ability of osteoclast precursors to respond to osteoblastic stimulation, although both osteoblasts and osteoclast precursors appear to function subnormally in the absence of IGF-I.

Non-canonical Wnt 11 Transcriptionally Suppresses Expression of Insulin-like Growth Factor Binding Protein-6, an Inhibitor of Osteoblast Differentiation. C. Strohbach*[1], T. A. Linkhart[1], S. Mohan[1], Y. Shi*[2], C. Glackin[3], D. D. Strong[1]. [1]Research 151, VA Loma Linda Healthcare System, Loma Linda, CA, USA, [2]Neurosciences, City of Hope, Beckman Research Institute, Duarte, CA, USA, [3]Molecular Medicine, City of Hope, Beckman Research Institute, Duarte, CA, USA.

IGFBP-6 (BP-6) overexpression decreases osteoblast (Ob) marker gene expression and binds to LMP-1, a nuclear protein that increases Ob differentiation. Based on these findings, we propose the hypothesis that osteoregulatory agents may mediate their effects on Ob differentiation in part by regulating BP-6 expression. As a means to test this hypothesis, we first measured BP-6 expression changes during Ob differentiation in a mineralizing MC3T3-E1 mouse Ob model system. Differentiation was induced with media containing β-glycerophosphate and ascorbic acid for 21 days. RNA was isolated at days 0, 3, 7, 14, and 21. Differentiation was confirmed by Von Kossa and Alizarin Red staining and mRNA measurement of osteocalcin. Using real-time PCR, we found that BP-6 mRNA levels progressively decreased (2-4 fold) as differentiation proceeded. We next tested the effects of Wnt 1 and Wnt 11 on BP-6 expression based on findings that 1) Wnt1 and Wnt 11 are expressed by osteoblasts, 2) non-canonical Wnt11 inhibits Twist expression and stimulates Ob differentiation, 3) functional LEF/TCF elements responsive to β-catenin reside in the BP-6 promoter and 4) conanical Wnt 1 and non-canonical Wnt 11 interact to regulate proliferation and differentiation in other mesenchymal tissues. Accordingly, we found that Wnt1 mRNA was constitutively expressed at low levels throughout MC3T3 cell differentiation, while Wnt11 mRNA expression was markedly upregulated early in differentiating cultures (4-fold increase at day 3). We next tested the ability of Wnt1 and Wnt11 to regulate BP-6 promoter activity. MC3T3 cells were co-transfected with a reporter vector containing 1.7 kb of the BP-6 promoter linked to luciferase, together with either Wnt1, Wnt11, or constitutively active β-catenin expression vectors in the presence or absence of LEF expression vector. Active β-catenin expression dose-dependently stimulated BP-6 promoter activity up to 2.4-fold in the presence of LEF and Wnt1 dose-dependently stimulated BP-6 promoter activity up to 20-fold in the presence of LEF. By

contrast, Wnt11 dose-dependently reduced basal BP-6 promoter activity up to 8.5-fold and this inhibition was reversed by addition of LEF. In conclusion, differential effects of Wnt1 and Wnt11 on BP-6 transcription may be mediated via β-catenin dependent and independent pathways. Wnt 11 may stimulate osteoblast differentiation in part by suppression of BP-6 at the transcriptional level.

Effects of 24-Months of Gymnastics Training on Insulin-Like Growth Factors in Prepubertal Females. R. A. Gildea*[1], E. M. Laing[1], D. B. Hall*[2], C. M. Modlesky[3], T. J. Beck[4], A. R. Wilson*[1], C. A. Baile*[1], R. D. Lewis[1]. [1]Department of Foods & Nutrition, The University of Georgia, Athens, GA, USA, [2]Department of Statistics, The University of Georgia, Athens, GA, USA, [3]Department of Health, Nutrition and Exercise Science, University of Delaware, Newark, DE, USA, [4]Department of Radiology, Johns Hopkins Medical Institute, Baltimore, MD, USA.

The positive bone response to high impact loading exercise, such as gymnastics, in children may be partially mediated by insulin-like growth factors (IGFs). The present study was conducted to investigate the effects of 24-months of recreational artistic gymnastics participation on bone and plasma growth factors in 142 prepubertal females, 4-8 years of age. Gymnasts (GYM; n = 64) and controls (CON; n = 78) were not participating in organized activities prior to enrolling in the study. Bone area (BA), BMC and areal BMD (aBMD) of the total body, lumbar spine (LS), total proximal femur (TPF), and the forearm were determined using DXA (Hologic, QDR 1000-W), and structural properties of bone including BMD, cross sectional area (CSA) and section modulus (Z) of the intertrochanteric (IT) and shaft regions of the TPF using the hip structural analysis (HSA) program. Insulin-like growth factor-I (IGF-I), and IGF binding protein-3 (IGFBP-3) were determined using a chemiluminescent assay (IMMULITE®, DPC). Using ANCOVA, log values of IGF-I, IGFBP-3 and IGF-I/IGFBP-3 increased in GYM ($p < 0.02$ for all measures) and CON ($p < 0.0001$ for all measures) by 24-months, and the increases were similar between groups. In GYM, changes in log IGFs were not correlated with bone measures. In CON, the 24-month change in log IGF-I was positively correlated with TPF BMC and aBMD (partial r = 0.28 and 0.28 respectively, $p < 0.03$) and LS BA, BMC and aBMD (partial r = 0.25, 0.33 and 0.31 respectively, $p < 0.05$) when controlling for baseline age and height. When GYM and CON were combined, there were positive correlations between the 24-month change in log IGF-I and IT CSA and Z (partial r = 0.20 and 0.24 respectively, $p < 0.04$) and shaft Z (partial r = 0.24, $p < 0.01$) when controlling for baseline age and height. Significant negative correlations were observed between hours of gymnastics participation and the 24-month change in log values for IGF-I, IGFBP-3 and IGF-I/IFGBP-3 (r = -0.46, -0.38 and -0.38 respectively, $p < 0.01$). The discrepancy between GYM and CON with respect to the IGFs and bone correlations is not fully understood, however, may be related to the degree of variability in gymnastics participation.

Effect of IGF-I on Chondrogenic Differentiation of Mouse Bone Marrow Derived Mesenchymal Stem Cells. S. Aakula*[1], L. Longobardi*[2], L. O'Rear*[2], K. Shimer*[2], W. A. Horton*[3], A. Spagnoli[2]. [1]General Surgery, Vanderbilt University, Nashville, TN, USA, [2]Pediatrics, Vanderbilt University, Nashville, TN, USA, [3]Research Center, Shriners Hospital for Children, Portland, OR, USA.

Chondrogenesis is initiated by the migration of chondroprogenitors to the future bone sites, where they undergo condensation, proliferation and differentiation. Bone marrow (BM) contains mesenchymal stem cells (MSC) that express a chondrogenic potential when cultured in high density pellets with TGFβ. The role of IGF-I in the chondrogenic potential of MSC is poorly understood. In our study we evaluated the effect of IGF-I on chondrogenic pellet differentiation, alone or in combination with TGFβ, analyzing the expression of different chondrocyte markers. MSC were isolated from long bones of 4-week old transgenic mice in which the expression of GFP is controlled by the murine type II collagen promoter/enhancer (Col2-GFP) to produce a fluorescent reporter for chondrogenic differentiation. MSC were immunodepleted of CD34, CD45 and CD11b positive hematopoietic cells and induced to form high density chondrogenic pellets by culturing them in serum- and insulin-free defined medium. To assess chondrocyte differentiation, pellets from Col2-GFP and WT-FVB mice were cultured for 7 days with or without des-IGF-I (100ng/ml) and/or TGFβ (10 ng/ml). GFP expression was visualized by confocal microscopy. Total RNA, isolated from 20 pellets for each condition, was reversed transcripted and cDNAs were analyzed by quantitative real time PCR for the expression of type II collagen and Sox-9. IGF-I, similarly to TGFβ, was able to drive the expression of collagen II in viable Col2-GFP chondrogenic pellets, as determined by the increase in GFP expression. To confirm this result, we analyzed the expression of chondrocyte markers in WT-MSC pellets by quantitative real time PCR. After normalization for the housekeeping gene GAPDH, we found that IGF-I, as well as TGFβ, determined an increase in the expression of collagen II (119 ± 23 fold for IGF-I and 40 ± 0.9 fold for TGFβ) compared to untreated control (1 ± 0.59; n=3; $p<0.05$). We also found that IGF-I, similarly to TGFβ, induced expression of Sox-9 (5.7 ± 1.5 fold for IGF-I and 4 ± 1.7 fold for TGFβ) compared to untreated control (1 ± 0.35; $p<0.05$). IGF-I effect on the expression of collagen II and Sox-9 was additive to the TGFβ action (326 ± 16 fold for collagen II and 18.7 ± 4.7 fold for Sox-9 vs respective untreated controls; n=3; $p<0.05$). Our data indicate that IGF-I plays a major chondroinductive role in BM derived MSC. IGF-I effect is comparable and additive to TGFβ action. Understanding the role of IGF-I in MSC chondrogenesis provides critical information to optimize the use of MSC in cartilage diseases.

IGF Signaling in the Growth Plate Early Regeneration after Irradiation. Y. Wang*[1], J. A. Horton*[1], J. A. Strauss*[1], C. E. Farnum*[2], T. A. Damron*[1]. [1]Orthopedic surgery, SUNY upstate medical university, Syracuse, NY, USA, [2]Department of Biomedocal Sciences, Cornell University, Ithaca, NY, USA.

Radiotherapy plays an important role in the treatment of specific childhood malignant neoplasms. However, radiation-induced growth arrest is a major adverse consequence of radiotherapy in children. Potential treatments to minimize this complication require a better understanding the effect of radiation on growth factors involved in growth plate regeneration after radiotherapy. The insulin like growth factor (IGF) pathway has been widely investigated in musculoskeletal studies. IGF-I stimulates proliferation of chondrocytes in the growth plate proliferative zone. IGF-I has also been shown to stimulate osteoblast proliferation, matrix protein synthesis, and bone formation. In addition, skeletal expression of IGF-I is critical for bone cell differentiation. IGF-II is highly expressed in growth plate reserve and proliferative zones, where it serves an anti-apoptosis function. Our initial work examining histomorphometry, and immunohistochemistry after a single fraction model in the five week old rat has shown initiation of growth plate regeneration by 2 weeks. We combined cDNA microarray and laser capture microdissection to study the effect of radiation on growth factors in growth plate. In situ hybridization was used to confirm the microarray findings. Microarray data show that IGFII expression increased 8.3 fold in the PZ and 2.3 fold HZ and IGF1R increased 2.4 fold in the HZ at one week after irradiation. In addition, growth hormone receptor (GhR) increased in both zones at one week after irradiation Both of these changes precede increases in parathyroid like hormone related protein (PTHrP), fibroblastic growth factor (FGF), bone morphogenetic protein (BMP), and transforming growth factor β (TGFβ) at a transcriptional level. In this study, we focused on early recovery response at one week and late radio-recovery at two weeks. At the early time point, IGF1R, IGFII, and GhR were increased in IGF pathways after irradiation while showing an injury response at two weeks which indicated that IGF pathway play an significant role in the early radio-recovery response. Our studies suggested that the potential for recovery following growth plate injury is driven by IGF primarily and by PTHrP, BMP, FGF, and TGFβ secondarily, resulting initially in accumulation of matrix followed closely by appearance of regenerative proliferative clones, the restoration of which is directly related to reduction of limb length discrepancy.

Demineralized Bone Activates Wnt Signaling in Human Dermal Fibroblasts: The Role of TGFbeta/Smad Signaling. S. Zhou, J. Glowacki. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Demineralized bone powder (DBP) induces chondro/osteogenic differentiation of human dermal fibroblasts (hDFs) in three-dimensional culture, but the initiating mechanisms have not been identified. Our previous data showed that, although BMP-2 was originally isolated as a putative active factor in DBP, rhBMP-2 alone and DBP do not affect all the same genes or in the same ways in hDFs [JBMR, 19(10):1732-41, 2004] and that TGF-β, in cooperation with Wnt signal, promotes chondrocyte differentiation in human marrow stromal cells [JBMR 19(3):463-470, 2004]. In this study, we tested the hypotheses that DBP would affect expression of Wnt signaling genes and that DBP's effects would require TGFβ/Smad pathway. An induction model was used in which hDFs were cultured with and without DBP in a porous collagen sponge. Effects of DBP and TGF-β1 (10 ng/ml) were compared by microarray, RT-PCR, and Western blot analysis of selected genes in the TGFβ/Smad and Wnt signaling pathways. At day 3, DBP and TGF-β1 have similar effects on TGF/βSmad target gene *TGFBI, PAI-1*, and *IGFBP3* expression in hDFs in 3D collagen sponges. A specific inhibitor (SB431542, 10 μM) of TGFβ type I receptor (ALK-5) antagonized the stimulation by DBP and TGF-β1 on *TGFBI*, *IGFBP3*, *ID3* gene expression. This is evidence that DBP activates TGFβ/Smad signaling in hDFs. To compare the effects of DBP and TGF-β1 on Wnt signaling, we used RT-PCR and Wnt signal pathway microarray analysis. The results showed that DBP and TGF-β1 have similar effects on Wnt signals; both stabilized intracellular Wnt signal molecule β-catenin proteins (Western blot), upregulated Wnt4, 5a, 7b, 10b, 11, 14,16b and downregulated 2b, 5b gene expression (RT-PCR) in hDFs. Other Wnts were either not modulated by DBP or TGF-β1, or were undetectable in hDFs. The effects of DBP on Wnt gene expression requires TGFβ signaling because SB431542 inhibited the stimulation of DBP on Wnt7b. In conclusion, this study verified that Demineralized Bone modulates expression of Wnt signaling genes and that DBP's effects require TGFβ/Smad pathway in hDFs. These and previous data indicate that multiple signaling pathways are involved in DBPchondro/osteoinduced target human dermal fibroblasts (hDFs) *in vitro*. One of the pathways involves the modulation of Wnt signals through TGFβ/Smad.

A Novel Large Latent Complex of TGFb Is Produced by Hypertrophic Chondrocytes. A. Selim[1], P. M. Mattioli*[2], V. L. Scheinfeld*[2], M. D'Angelo[2]. [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Department of Anatomy and Center for the Study of Chronic Diseases of Aging, Philadelphia College of Osteopathic Medicine, Philadelphia, PA, USA.

Chondrocytes produce transforming growth factor beta (TGFb) and store it in their matrix in a large latent complex (LLC) that includes latent TGFb binding protein (LTBP). Large quantities of activated TGFb are produced as a result of hypertrophy in chondrocytes and collagenase 3 (MMP-13) is involved in the activation of TGFb from its latent complexes. In this study, tibial hypertrophic chondrocytes were isolated from day 19 chicks, immunoprecipitated with antiserum to LTBP1 and MMP-13 and immunoblotted with antiserum to TGFb. Immunoblots contained bands of immunoreactivity corresponding to a novel 250 kDa LLC, the 60kDa bLAP N-terminus fragment of TGFb and the 25kDa homodimer of TGFb. Thus, the novel LLC for TGFb produced by hypertrophic chondrocytes includes MMP-13. An alternatively spliced, short form of LTBP 1 has been identified whose N-terminus plays a role in tissue transglutaminase-dependent TGFb activation mechanism. To determine the involvement of our novel LLC in more efficient activation of TGFb, we designed primers to differentiate the long form of LTBP from the short form. Reverse-transcription PCR of total RNA isolated from serum-free alginate cultures revealed that early hypertrophic chondrocytes produce both the long and short forms of LTBP, but the late hypertrophic chondrocytes only produce LTBP short. Therefore, as a chondrocyte nears terminal differentiation, LTBPshort is preferentially produced suggesting that chondrocytes shift to a more easily activated form of the LLC. Since the protease sensitive hinge region on LTBPshort is the target for LLC release by enzymes studied to date, it is plausible that association of MMP-13 to LTBPshort places the metalloproteinase in a position for more efficient activation of the chondrocyte-unique TGFb LLC. Through our own bioinformatics assessment based on previously published models of the TGFb LLC, we are suggesting that the hemopexin domain of MMP-13 interacts with EGF-CA domains of LBTPshort in such an orientation that the peptidase domain of MMP-13 lies in close proximity to the linker region of LBTPshort. This orientation is supported by existence of candidate amino acids in the linker region of LTBPshort, Gly-Ile bonds at positions 807/808 and 819/820, that are known to interact with the peptidase domain of MMP-13. The association of MMP-13 with LLC points to a novel storage and activation process for chondrocyte-produced TGFb that would allow for local and rapid control of release and activation of TGFb from matrix storage.

TGF-Beta Signaling in Early Limb Chondrogenesis. H. Seo*, S. Dong*, R. Serra. Cell Biololgy, University of Alabama at Birmingham, Birmingham, AL, USA.

Chondrogenesis is the first step for endochondral bone formation. It begins with the condensation of mesenchymal cells. During this process, condensing cells begin to form and deposit an extracellular matrix (ECM) that is a characteristic for cartilage. Type II collagen (Col2a) is one of the ECM molecules known as a specific marker of chondrogenesis. Previously, many studies have implicated TGF-b as an essential regulator of chondrogenic differentiation and Col2a expression in mensenchymal cells through unknown mechanisms. Another essential factor for chondrogenesis is Sox9, a transcription factor that regulates Col2a1 expression. Studies in mice showed that Sox9 haploinsufficiency results in lethal skeletal malformations including campomelic dysplasia. To determine the role of TGF-b signaling in chondrogenesis and Sox9 function, we generated an adenovirus vector that expresses a truncated, dominant-negative form of the TGF-b type II receptor (DNIIR). When DNIIR was expressed in C3H10T1/2 cells or mouse embryonic limb bud cell before condensation, Sox9 protein and mRNA levels were remarkably down-regulated and cartilage nodule formation was inhibited. In contrast, exogenous addition of TGF-b to limb bud cells resulted in an increase in the level of phophorylated Sox9 without alterations in total protein or mRNA levels. These results suggest a model in which TGF-b signaling is required for chondrogenesis via regulation of Sox9 activation. To further understand the role of TGF-b signaling on chondrogenesis, mice that express the cre recombinase under the control of the Prx1-promoter were crossed with mice in which both alleles of the TGF-b type II receptor were surround with LoxP sites. We propose this conditional knockout of TGF-b type II receptor will explain the overall role of TGF-b signaling on early chondrogenesis in the limb.

Yeast-2-Hybrid Analysis Identifies Novel Protein Interactions with TGFβ Inducible Early Gene-1. J. R. Hawse[1], M. Subramaniam[1], M. Oursler[2], B. A. Davies*[1], B. J. Bellin*[1], B. F. Horazdovsky*[1], T. C. Spelsberg[1]. [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

TGFβ inducible early gene-1 (TIEG) is a member of the Krüppel-like transcription factor family that was originally identified and characterized in human osteoblasts. TIEG is known to regulate the expression of a number of genes and plays an important role in mediating TGFβ effects in cells by enhancing the Smad signaling pathway. In order to elucidate the manner by which TIEG functions, we have utilized yeast-2-hybrid assays to identify specific proteins with which TIEG interacts. A Matchmaker System 3 yeast-2-hybrid kit (Clontech) was used to identify potential protein-protein interactions with TIEG. Screening of clones was conducted using high stringency selection plates to decrease the potential for identifying false-positives. Sequencing analysis of yeast colonies identified 28 unique genes that potentially interact with the human TIEG protein including the previously identified seven in absentia homologue 1 gene as well as the co-repressor, mSin3a, interferon regulatory factor 2 binding protein, actin binding double zinc-finger protein, apolipoprotein D, and the mithochondrial inner membrane preprotein translocase TIM17a, to name a few. GST pull-downs and co-immunoprecipitation assays are ongoing to further confirm the interactions between TIEG and the identified proteins of interest. Previous studies have shown that the TIEG family of proteins is capable of interacting with mSin3a through an alpha-helical repression motif. Our laboratory has also demonstrated that TIEG down-regulates Smad-7 expression by binding to a GC rich sequence upstream of the promoter. Since mSin3a was identified as a TIEG-1 interacting protein, we are currently performing chromatin immunoprecipitation assays on the Smad-7 promoter to determine if the mSin3a-histone deacetylase complex is recruited by TIEG to repress Smad-7 gene expression. Experiments are also currently underway to purify the human TIEG protein for subsequent use in protein array studies which will allow us to determine if TIEG is capable of interacting with over 1800 known human proteins. Identification of specific proteins via the above mentioned methods is an essential first step in the determination of how TIEG functions as a transcription factor and the mechanisms by which it elicits its effects on cell signaling, growth and function.

Effect of Recombinant Human Transforming Growth Factor-beta2 Dose on Bone Formation in Rat Femur Titanium Implant Model. K. Sena*, A. S. Virdi, D. R. Sumner. Anatomy & Cell Biology, Rush University Medical Center, Chicago, IL, USA.

Growth factors such as transforming growth factor-beta (TGF-β) and bone morphogenetic proteins (BMP) have been shown to enhance bone repair and implant fixation in a number of animal models. Recently, we reported that application of recombinant human transforming growth factor-beta2 (rhTGF-β2) enhances peri-implant bone volume and bone-implant contact in a rat model where treatment with 10 μg TGF-β2 showed the greatest effect and lower doses (0.1 and 1 μg) were not effective. To further investigate this effect and to establish an optimal dose for future studies, present experiment evaluated the effect of three concentrations of rhTGF-β2 spanning across 10 μg dose on bone regeneration and mechanical fixation in the same model. The study was approved by the local Institutional Animal Care and Use Committee. Four groups (13 animals per group, 52 animals total) received unilateral femoral implantation of hydroxyapatite/tricalcium phosphate coated titanium (Ti/HATCP) implants. Three groups consisted of rats implanted with 1 of 3 doses of rhTGF-β2 (5, 10, 20 μg) loaded on to the implants. Implants in the control groups were treated with buffer only. Four weeks post-surgery, all implanted femurs were analyzed by micro computed tomography (μCT). Ten samples from each group were subjected to mechanical pull-out test to measure the strength of fixation of the implant. The remaining 3 specimens were embedded in plastic resin and sectioned for routine histology. From the μCT data, five comparable regions were selected along the length of the implant. The scanned sections were contoured to exclude the implant and bone volume per total volume (BV/TV) was calculated for region between the endocortical perimeter and the implant (diaphyseal sites). Compared to control, all rhTGF-β2-treated groups had significantly higher BV/TV than the control group ($p < 0.001$). These findings are consistent with our previous studies which demonstrated enhanced peri-implant bone volume with 10 μg of rhTGF-β2. Bone-implant contact didn't show difference between control and 5, 10 μg treated groups, however 20 μg group had less contact than the control. The mechanical pull-out tests showed decrease in strength in the rhTGF-β2 treated groups and this difference was significant between all rhTGF-β2-treated groups and the control group. Thus, while rhTGF-β2 was able to enhance bone formation (BV/TV), the relative lack of bone-implant contact depressed the strength of fixation, suggesting that the location as well as the amount of bone regeneration is important.

Isolation and Identification of Serum Factor(s) as BMP-4, which Inhibits Myogenesis and Induces Osteoblast Differentiation. K. Kodaira*[1], T. Katagiri[2], M. Goto*[1], A. Tomoyasu*[1], M. Namiki*[3], R. Kamijo[3], K. Higashio*[1], T. Suda[4]. [1]Fuji Gotemba Research Labs, Chugai Pharmaceutical co., Ltd., Shizuoka, Japan, [2]Division of Pathophisiology, Saitama Medical School, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan, [3]Department of Biochemistry School of Dentistry, Showa University, Tokyo, Japan, [4]Saitama Medical School, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan.

Unknown serum factor(s) regulates proliferation, differentiation and function of various types of cells. Fetal bovine serum (FBS) stimulates osteoblast differentiation and inhibits myogenic differentiation in vitro. We found that treatment of myogenic cells with FBS for 1 h induced expression of Id1, one of the early responsive genes for BMP signaling, via a 29 bp BMP-responsive element. FBS induced phosphorylation of Smad1/5/8 and their DNA-binding to the BMP-responsive element in the Id1 gene. Furthermore, inhibition of BMP signaling by expressing either dominant-negative BMP receptor (dnBMPR), noggin, or I-Smad similarly induced marked enhancement of myogenic differentiation even in the presence of a high concentration of FBS. Addition of recombinant dnBMPR or noggin to the osteoblast cultures suppressed dose-dependently osteoblast maturation in the presence of FBS, suggesting that the responsible factor(s) in FBS for inducing Id1 expression and regulating myogenic and osteoblast differentiation is a common BMP-like activity. We attempted to isolate the ALP-inducing activity of FBS by a series of column chromatography from 5 L of FBS. Finally, we obtained an active band with an apparent molecular weight of about 33kDa on SDS-PAGE under non-reducing conditions, and its activity was abolished under reducing conditions. After in gel-digestion of the band with trypsin, a fragment of the BMP-4 protein identical to both human and mouse sequences was detected by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Furthermore, we found that the ALP-inducing activity of serum was high, but its specific activity was gradually decreased on the purification process. Interestingly, the ALP-inducing activity in serum was always eluted in a fraction larger than 100kDa by molecular sieving chromatography. To our knowledge, this is the first report to isolate and to unequivocally identify a serum factor(s) as BMP-4. The present study also suggests that the formation of a large complex comprised BMP-4 and other molecules potentiates its biological activity in serum.

Osteoblastic Expression of Transforming Growth Factor (TGF)-β1 Is Increased in Osteoarthritic Patients and Reduced in the Elderly. C. G. Eriksen*[1], H. J. Olsen*[1], L. B. Husted[1], K. Søballe*[2], B. L. Langdahl[1]. [1]Endocrinology, Aarhus University Hospital, Aarhus Sygehus, Aarhus C, Denmark, [2]Orthopedics, Aarhus University Hospital, Aarhus Sygehus, Aarhus C, Denmark.

Osteoporosis and osteoarthritis are both very common diseases. Osteoporosis is defined as reduced BMD whereas osteoarthritis is associated with increased BMD. Likewise it is known, that BMD declines after peak bone mass is reached. We hypothesised, that these different phenotypes are caused by differences in osteoblastic expression of Transforming Growth factor (TGF-β1), Receptor activator of NF-kappaB (RANKL), Osteoprotegerin (OPG) and Interleukin (IL)-6. The four genes were chosen because they are expressed by osteoblasts and are involved in control of osteoblast and osteoclast activity; Standardized bone biopsies have been obtained from the femoral neck from 22 osteoporotic and 21 osteoarthritic patients during surgery for hemi- or total hip replacement. From 18 patients, 15 healthy age matched controls and 15 young individuals bone marrow aspirations from crista iliaca posterior were obtained. Osteoblasts and osteoblast precursor cells from bone biopsies and bone marrow aspirations were cultured until confluency. The quantitative gene expression analyses were carried out on the basis of Trizol/phenol isolated mRNA by using SYBR Green real-time PCR technique. The relative expression of the genes of interest (TGF-β1, RANKL, OPG, and IL-6) is calculated in relation to three carefully selected housekeeping genes for each comparison. Osteoblasts from osteoarthritic bone marrow expressed more TGF-β1 than osteoblasts from healthy age matched controls ($p<0.05$). There were no significant differences in the relative expression of RANKL, OPG, IL-6 and the ratio RANKL/OPG between the two groups. The more mature osteoblasts from osteoarthritic bone biopsies expressed more TGF-β1 ($p<0.01$) and RANKL ($p<0.001$) than the more immature osteoblasts obtained from bone marrow. OPG expression was not different and the ratio RANKL/OPG was higher in the more mature osteoblasts ($p<0.01$). There was no difference in the relative expression IL-6. Osteoblasts obtained from bone marrow from healthy young individuals expressed more TGF-β1 and OPG ($p<0.05$) and less IL-6 ($p<0.05$) than healthy elderly individuals. There was no difference in expression of RANKL between the two groups, however, the ratio RANKL/OPG tended to be reduced ($p=0.08$). In conclusion, we have demonstrated that osteoblasts from young individuals express more TGF-β1 and OPG and less IL-6, favouring bone formation over bone resorption. Furthermore, osteoblasts from osteoarthritic bone express higher levels of TGF-β1 compared to age-matched controls.

TGF-Beta Signaling Regulates the Mechanical Properties and Composition of Bone Matrix. G. Balooch*[1], G. W. Marshall*[1], M. Balooch*[1], S. J. Marshall*[1], R. O. Ritchie*[2], R. K. Nalla*[2], R. Derynck*[1], T. Alliston[1]. [1]University of California, San Francisco, San Francisco, CA, USA, [2]Lawrence Berkeley National Laboratory, Berkeley, CA, USA.

The ability of bone to resist fracture is determined by the bone mass and architecture, and the mechanical properties and composition of the bone matrix. Several signaling pathways, including estrogen, parathyroid hormone, and TGF-β, have been implicated in the control of bone mass and architecture. Presumably bone matrix mechanical properties are highly regulated; however, the regulators themselves remain unknown. TGF-β inhibits terminal osteoblast differentiation by binding its cell-surface receptor and activating Smad3 to regulate transcription of genes required for osteoblast differentiation. We hypothesized that TGF-β regulates mechanical properties and composition of bone matrix - including elastic modulus, fracture toughness, and bone mineral concentration (BMC). Existing transgenic mouse models show altered TGF-β signaling, from 16-fold (D4 mice) and 2.5-fold (D5 mice) over-expression of TGF-β in bone, to decreased TGF-β signaling due to osteoblast expression of a dominant negative TGF-β receptor (E1 mice) and targeted deletion of the Smad3 gene (Smad3+/- and -/- mice). Bones from these mice were evaluated using atomic force microscopy and elastic modulus mapping to measure elastic modulus (E), three-point bending to measure fracture toughness, and synchrotron x-ray tomography (XTM) to measure BMC. Mice with elevated TGF-β signaling (D4, D5) had up to 23% reduced E ($p<.001$) while mice in which TGF-β signaling was impaired (E1, Smad3+/-, and Smad3-/-) had up to 54% increased E ($p<.001$) compared to WT littermates. Histomorphometric, x-ray, XTM, and 3-D XTM reconstruction analyses showed that Smad3+/- bone, like E1 bone, possessed increased BV/TV, 48% increased cortical thickness ($p<.001$), and 53% increased BMC ($p<.01$) relative to WT. Osteopenic Smad3-/- mice had reduced BMC, likely secondary to systemic effects of Smad3 loss. In addition to elevated E and BMC, Smad3+/- mice also had elevated fracture toughness, similar to E1 mice that also had partially reduced TGF-β signaling, albeit through a different mechanism. Therefore, partial reduction of TGF-β signaling in bone is sufficient to produce bone with increased cortical thickness, structural bone parameters, mineral content and local mechanical properties, enabling these bones to better resist fracture. Our results suggest that a reduction of TGF-β signaling may be considered as a therapeutic target to treat bone disorders. We will investigate the effect on bone matrix properties of TGF-βRI kinase inhibitors, currently being considered for treatment of cancer metastases.

TGF-Beta1 Regulation of ATF-3 and its Target Genes in Bone Metastasizing Breast Cancer Cells. N. Selvamurugan[1], S. Kwok*[1], S. R. Rittling*[2], M. Reiss*[3], N. C. Partridge[1]. [1]Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, [2]Rutgers University, Piscataway, NJ, USA, [3]The Cancer Institute of New Jersey, New Brunswick, NJ, USA.

Transforming growth factor-β1 (TGF-β1) is the most potent known growth inhibitor for normal epithelial cells. In breast tissue, loss of this TGF-β1 anti-proliferative response favors tumor formation. Moreover, in breast cancer cells, TGF-β1 is a crucial molecule for stimulation of invasion and formation of bone metastases. The molecular mechanisms of how TGF-β1 mediates these effects have yet to be completely determined. We have found that the transcription factor, activating transcription factor-3 (ATF-3) is strongly stimulated and its level is sustained by TGF-β1 in highly invasive and metastatic human breast cancer (MDA-MB231) and mouse mammary pad tumor cells (r3T), in contrast to the transient stimulation and repression of ATF-3 by TGF-β1 in non-cancerous cells. ATF-3 is also expressed in human primary breast tumors. Overexpression of ATF-3 increased normal human mammary epithelial cell (MCF-10A) number and DNA synthesis. Since TGF-β1 stimulates and sustains expression of ATF-3 in breast cancer cells and ATF-3 increases cell proliferation in normal human mammary epithelial cells, we next determined whether knockdown of ATF-3 expression in breast cancer cells has any effect on expression of cell cycle genes. TGF-β1 stimulated expression of cyclin A1, -B1, -D1, and -E in these cells while knockdown of ATF-3 with siRNA resulted in a decreased expression of only cyclin A1 in both control and TGF-β1-stimulated MDA-MB231 cells. Since MDA-MB231 cells are highly invasive and metastatic in nature and TGF-β1 stimulates matrix metalloproteinase-13 (MMP-13; collagenase-3; an invasive and metastatic gene), we next determined whether MMP-13 is a target gene for ATF-3. Transient transfection of ATF-3 siRNA reduced both the control and TGF-β1-stimulated MMP-13 promoter activity in MDA-MB231 cells. To determine whether ATF-3 associates with the MMP-13 promoter, chromatin immunoprecipitation was carried out using an ATF-3 antibody and PCR amplification of DNA fragments corresponding to the TGF-β-responsive region of the MMP-13 promoter. The results identified *in vivo* the presence of ATF-3 protein on the MMP-13 promoter, and a shift and an increased binding of this protein from the AP-1 site to the RD/Runx binding site by TGF-β1 in MDA-MB231 cells. Thus, we are the first to identify the TGF-β1-regulation of ATF-3 and its target genes, cyclin A1 and MMP-13 in bone metastasizing breast cancer cells. The dysregulation of ATF-3 by TGF-β1 in breast cancer cells may be key to the subsequent metastasis of these cells to bone.

Baseline Bone Morphology and Cell Activity May Predict the Degree of Disuse Osteopenia. M. E. Squire[1], A. Brazin*[1], L. R. Donahue[2], C. Rubin[1], S. Judex[1]. [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

The removal of functional loading rapidly decreases trabecular bone quantity within weight-bearing bones. Using male and female F1 crossbreds (BALB/cByJ x C3H/HeJ), we previously demonstrated that the deleterious effects of unloading (3 wk) on trabecular bone quantity were gender-dependent and that the magnitude of the effect varied across anatomic sites within a bone (metaphysis vs. epiphysis) and across distinct bones (femur vs. tibia). Here we tested the hypothesis that the gender- and site-specific mechanosensitivity demonstrated in the F1 skeleton can be predicted by differences in baseline indices of bone morphology and/or variations in bone's formative and resorptive activities. Micro-computed tomography (12μm) determined the ratio of bone surface to bone volume (BS/BV) and bone volume fraction (BV/TV) in the trabecular metaphyseal and epiphyseal regions of the distal femur and proximal tibia harvested from adult (4 mo) male and female (n=10 each) F1 mice. In these same regions of bones from a second set of F1 mice (n=10 per gender), histomorphometry was used to assess indices of bone formation (MS/BS, MAR) while resorptive activity (Oc.S/BS) was determined by staining for tartrate resistant acid phosphatase (TRAP). Across the four regions, linear regressions tested the relation between baseline BS/BV, BV/TV, MS/BS, MAR, Oc.S/BS and the relative loss in BV/TV after 3 wk of disuse . The results revealed a correlation between baseline BS/BV and percent bone loss across the four regions in both females (r^2= 0.99, $p<0.01$) and males (r^2= 0.86, $p<0.07$), suggesting that a greater ratio of BS/BV may result in greater bone loss. Baseline BV/TV and percent bone loss were inverse correlated in both females and males (r^2= 0.97, $p<0.02$ and r^2= 0.86, $p=0.07$), suggesting that less bone is lost from regions that have greater baseline bone quantity. This inverse relation between bone quantity and bone loss has been previously demonstrated within the skeleton of female BALB/cByJ and across skeletons from second generation BALB/cByJ x C3H/HeJ mice. Results from the current study also revealed that, in females, disuse-induced bone loss was correlated to MAR (r^2= 0.78, $p=0.11$), whereas in males this loss was correlated to MS/BS (r^2= 0.70, $p=0.16$), suggesting gender differences in baseline predictors of skeletal mechanosensitivity. Oc.S/BS was not correlated to relative bone loss in either females (r^2= 0.15) or males (r^2= 0.36). Taken together, the results suggest that, in the absence of genetic factors, baseline bone morphology and indices of bone formation may explain, in part, the gender- and site-specific sensitivity of the skeleton to unloading.

Mechanical Loading Alters RANKL and OPG Expression in MC3T3-E1 Cells. H. Lee[1], D. KIM[1], J. A. Karmin*[1], S. Lee*[1], J. Yang*[2], F. Y. LEE[1]. [1]Center for Orthopaedic Research, Columbia University, New York, NY, USA, [2]Anesthesiology, Columbia University, New York, NY, USA.

Bone adapts to mechanical loading to maintain its structural and functional integrity. However, the underlying molecular mechanisms by which bone cells respond to various mechanical environments are not fully understood. Osteoblasts play a pivotal role in bone formation and the regulation of osteoclastogenesis by generating RANKL (receptor activator of nuclear factor kappa B ligand) and OPG (osteoprotegerin). The balanced action of RANKL and OPG may be one of the key factors in the regulation of bone remodeling. However, the biochemical responses of these molecules to mechanical loading have yet to be studied in depth. In the present study, therefore, we used following two experimental paradigms to verify the aforementioned issue. Murine RANKL cDNA with HA and V5His tags at its N and C-terminal regions, respectively, were transfected into MC3T3-E1 pre-osteoblast cells cultured in 6-well bioflex culture plates. Then the cells were bi-equiaxially stretched (0, 0.5, 1, 2.5, and 5% strains) at a frequency of 1 Hz for 15 minutes once a day for 7 consecutive days using a Flexcell 4000 with a Tension Plus Control Unit. To detect secreted soluble RANKL-V5 in the conditioned medium, a Talon pull down assay was performed in conjunction with immunoblotting. Meanwhile, *in vitro* mechanical loading to bone cells in a direct manner do not truly represent *in vivo* condition. Furthermore, fluid shear stress generated by enforced fluid flow in lacunae-canaliculi porosities in response to mechanical loading may govern osteoclastogenesis via regulation of the expressions of RANKL and OPG from osteoblast. Thus 0, 1, 5, and 10 dynes/cm^2 at 0.5 Hz of shear stresses were applied to MC3T3-E1 cells which were grown in a monolayer on the cover slide for 15 min using a STREAMER^{TM} system. We found that membrane-bound RANKL protein increased while the level of secreted RANKL-V5His protein decreased as mechanical strain increases. We also found that RANKL and OPG protein expressions increased in a fluid shear stress-dependent manner, and the RANKL/OPG ratio decreased as the intensity of fluid shear stress increased. RANKL/OPG ratio also found to be decreased as duration of shear stress increased. Taken together, mechanical loading may be a key initiator of bone remodeling by modulating the balance of RANKL and OPG expression.

Fluid Flow Regulation of the 3'-Untranslated Region of Cyclooxygenase-2 in MC3T3-E1 Cells. M. Mehrotra, O. Voznesensky*, M. Saegusa*, C. Pilbeam. Dept. of Medicine, University of Connecticut Heath Center, Farmington, CT, USA.

Mechanical strains may be transduced into biochemical signals by generating interstitial fluid flow (FF) within the mineralized bone matrix. FF induces expression of cyclooxygenase-2 (COX-2), the major enzyme involved in prostaglandin production, in osteoblasts. The COX-2 3'-untranslated region (3'-UTR) contains multiple copies of the adenosine and uridine (AU)-rich elements known to influence mRNA stability by interacting with specific RNA binding proteins. It is likely that, in addition to regulating transcription of COX-2 mRNA, FF also regulates stability of COX-2 mRNA via the 3'-UTR. We stably transfected MC3T3-E1 cells with the entire mouse COX-2 3'-UTR (1-2232 bp), cloned into pGL3 firefly luciferase vector, or with the vector only to examine effects of the COX-2 3'-UTR on luciferase protein and mRNA stability. In static culture, luciferase activity and mRNA (measured by real time qPCR) were >3-fold higher in cells carrying the full 3'-UTR than in vector only cells, suggesting mRNA stabilization by the full 3'-UTR in the absence of FF. In cells subjected to 30 min of pulsatile FF and then returned to static culture (post FF culture), the induction of COX-2 mRNA peaked at 2 h post FF and remained elevated for more than 4 h. The luciferase mRNA level in cells with the full COX-2 3'-UTR was decreased relative to vector only cells at 1 h post FF but subsequently increased 2-fold at 4 h post FF, suggesting that the 3'-UTR destabilized mRNA initially after FF but subsequently increased stabilization in post FF static culture. When cells were subjected to 30 min of FF and then treated with the transcription inhibitor actinomycin (ACT) as they were placed into static culture, luciferase mRNA levels in cells with the full COX-2 3'-UTR decreased more slowly (30% over 4 h) than levels in vector only cells (70% over 4 h) and were always higher than levels in vector only cells, suggesting that ACT might prevent transcription of a destabilizing factor interacting with the COX-2 3'-UTR. Destabilization of COX-2 mRNA may be associated with tristetraprolin, a zinc finger protein that can bind to AU-rich elements in the 3'-UTR of COX-2. Tristetraprolin was highly expressed in MC3T3-E1 cells under no flow conditions, and FF for 30 min increased mRNA expression 3.5-fold. However, in post-FF cultures, tristetraprolin mRNA expression decreased, falling to 1/5 of the level in no flow cells by 4 h of post-FF culture. These studies suggest that the full COX-2 3'-UTR enhances mRNA stability in static culture following briefly applied FF. We speculate that regulation of tristetraprolin expression by FF is one of the factors involved in this effect.

Model Microgravity Decreases Osteoblastogenesis of Human Mesenchymal Stem Cells by Upregulation of Nitric Oxide Synthase 2 and Hypoxia Inducible Factor 1 alpha. K. Fulzele*, V. E. Meyers*, J. M. McDonald, M. Zayzafoon. The Department of Pathology, The University of Alabama at Birmingham, Birmingham, AL, USA.

The lack of gravitational stimulus during space travel or lack of mechanical environment during disuse and aging negatively affects osteoblastogenesis resulting in skeletal abnormalities such as osteopenia, decreased bone formation, decreased mineralization and reduced bone strength. We have previously demonstrate that modeled microgravity (MMG) inhibits osteoblastogenesis and induces adipogenesis of human mesenchymal stem cells (hMSC) by disrupting the actin cytoskeleton and inhibiting the small GTPase, RhoA. Increasing expression of inducible nitric oxide synthase (NOS2) and hypoxia inducible factor-1α (HIF-1α) are known to be associated with early adipocytic commitment and differentiation. The purpose of this study is to examine the effects of MMG on the expression of NOS2 and HIF-1α to elucidate the mechanism by which MMG suppresses osteoblastogenesis. Mesenchymal stem cells cultured in MMG acutely induce NOS2 protein expression within 1 hour and reaches plateau within 6 hours. Intracellular nitric oxide, measured by fluorescence staining with 4, 5-diaminofluorescein (DAF-2), increases to a maximal concentration after 6 hours of culture in MMG. Furthermore HIF-1α protein expression is rapidly induced after 30 minutes of MMG and returns to basal levels by 6 hours. In addition, electromotility shift assay demonstrates that MMG increases the DNA-binding activity of the hypoxia response element. These results were not due to hypoxia as MMG does not alter the pH, pO2 and pCO2 compared to gravity cultured cells, measured using a Radiometer ABL 715 blood gas analyzer. Selective inhibition of NOS2 activity by 1400W partially restored actin cytoskeletal stress fibers and reduced intracellular lipid accumulation in hMSC after 7 days of culture in MMG. Taken together, these results suggest a novel mechanism whereby MMG results in cytoskeletal disruption, reduced osteoblastogenesis and enhanced adipogenesis of hMSC by normoxic upregulation of HIF-1α and NOS2. Our work suggests that the inhibition of NOS2 activity may prove to be a novel countermeasure to rescue osteoblastogenesis in spaceflight-induced bone loss.

The Role of PKC-induced Cytoskeleton Rearrangement in Parathyoid Hormone Enhanced $[Ca^{2+}]_i$ Response to Mechanical Stimulation in Osteoblasts. J. Zhang*, V. P. Formin, R. L. Duncan. Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

A rapid increase in intracellular free Ca^{2+} ($[Ca^{2+}]_i$) is the earliest measured response to mechanical stimulation in osteoblasts. We have shown that parathyroid hormone (PTH) significantly enhances this mechanical-induced response by altering ion channel kinetics. While the PTH-induced changes in channel kinetics appear to be the result of protein kinase A (PKA) activation, we have found that PTH produces rearrangement of the actin cytoskeleton that, in turn, sensitizes the mechanosensitive cation-selective channel (MSCC) to respond to mechanical stimulation. Although previous data do not implicate PKC activation in the PTH augmentation of the $[Ca^{2+}]_i$ response to fluid shear, we have recently found that PKC activation can enhance the $[Ca^{2+}]_i$ response to mechanical load in a time dependent manner. Here we postulate that activation of PKC by PTH can increase the $[Ca^{2+}]_i$ response to mechanical loading by changing the actin organization. Using MC3T3-E1 preosteoblastic cells loaded with fura-2, we found that pre-incubation with 50nM PTH for 10min produced a 4.5 fold increase in the peak $[Ca^{2+}]_i$. Further, addition of 1 μM GF109203X (a general PKC inhibitor) for 10 min prior to PTH treatment significantly reduced the peak $[Ca^{2+}]_i$ response to hypotonic challenge. Addition of 4β-phorbol 12-myristate 13-acetate (PMA; 1μM) did not increase the $[Ca^{2+}]_i$ above that of PTH treatment alone. These data suggested that the PTH enhanced $[Ca^{2+}]_i$ response to mechanical stimulation at least partially involved the activation of PKC pathway. We found that only PKCα exhibited translocation from cytoplasm to plasma membrane region during hypotonic challange. Inhibition of PKCα activation with the PKCα-specific inhibitor, Go6976, attenuated the hypotonic-induced $[Ca^{2+}]_i$ response, while specific inhibition of PKC with LY379196 did not. Treatment of MC3T3-E1 cells with 50nM PTH for 30min significantly disrupted the actin cytoskeleton and decreased the amount of stress fibers. Similar effects were observed with 1μM PMA. Pretreatment with either the general PKC inhibitor, GFX, or Go6976 ablated the PTH effect on the actin cytoskeleton while PKCβ inhibitor LY379196 failed to do so. These data indicate that PTH alters the actin cytoskeleton through PKCα activation, thereby enhancing the $[Ca^{2+}]_i$ response to mechanical stimulation by altering the kinetics of the MSCC.

Ski Inhibits TGF-β Signaling and Accelerates Hypertrophic Differentiation in Chondrocytes. K. Kim*, M. Pirri*, Q. Wu, R. N. Rosier, M. J. Zuscik. Orthopaedics, University of Rochester, Rochester, NY, USA.

It is well established that TGF-β signaling, which potently inhibits chondrocyte maturation, is required for maintenance of articular cartilage and regulation of the hypertrophic program during endochondral ossification. The seminal *in vivo* findings that support this idea derive from mouse models that display loss of TGF-β signaling, which display accelerated chondrocyte maturation in both articular and growth plate cartilages. Thus, endogenous negative regulation of the TGF-β signaling cascade likely plays a central role in the modulation of chondrocyte differentiation during skeletal development and repair processes. One such inhibitor of this cascade is Ski, a transcriptional co-repressor that links Smads to histone deacetylase, leading to blockade of target gene expression that would normally be induced by Smad-containing transcriptional complexes. Regarding specificity, Ski is known to inhibit TGF-β signaling via a strong interaction with Smads 2, 3 and 4 while BMP signaling is unaffected due to Ski's weak interaction with Smads 1 and 5. We hypothesize that due to the central regulatory role of TGF-β/Smad signaling in chondrocytes, inhibition of signaling by Ski is an important regulatory event in chondrocyte differentiation. As such, we predict that Ski-induced loss of signaling on this axis will lead to accelerated maturation of chondrocytes. We tested this hypothesis in the chick upper sternal chondrocyte (USC) model by assessing Ski expression and signaling function and by examining the phenotypic impact of Ski gain-of-function. Establishing that Ski is up-regulated as chondrocytes progress toward terminal maturity, the Ski mRNA expression pattern mirrors that of type X collagen during a six day time course. Suggesting that this up-regulation leads to reduced TGF-β signaling, over-expression of Ski in USCs completely abolishes both basal and TGF-β-stimulated signaling on the P3TP-luciferase reporter. The mechanism of this inhibition in USCs was determined via immunoprecipitation/western blot experiments which indicated that following TGF-β treatment, Ski specifically associates with phospho-Smad2 and to a lesser extent with phospho-Smad3 and Smad4. Finally, demonstrating a regulatory role, Ski over-expression leads to accelerated maturation in USCs, evidenced by increased type X collagen mRNA expression and enhanced alkaline phosphatase activity. Taken together, these results suggest that Ski participates in regulation of chondrocyte maturation through its inhibition of TGF-β signaling. Dis-regulation of the expression/function of Ski may therefore have ramifications in developmental and repair processes in the skeleton.

Quantitatively Profiling the Expression of P2Y Purinergic Receptors in Human Bone Related Cells and Their Intracellular Calcium Responses to Oscillatory Fluid Flow. Y. Gu*, C. M. Davis*, H. J. Donahue, J. You. Orthopaedics & Rehabilitation, The Pennsylvania State University College of Medicine, Hershey, PA, USA.

Substantial evidence has indicated that extracellular nucleotides signaling through P2Y purinergic receptors play an important role in the regulation of bone metabolism. To date, five major human P2Y purinergic receptors (P2Y1, P2Y2, P2Y4, P2Y6, and P2Y11) have been cloned. We hypothesize that different expression patterns/levels of P2Y purinergic receptors in bone cells may affect the ability of the cells to perceive and respond to changes in their extracellular milieu, both physical and chemical (hormonal). The aims of this study were to quantitatively profile the mRNA levels of five subtypes of P2Y receptors expressed in different human bone related cells, and to examine intracellular calcium (Ca^{2+}_i) mobilization responses to oscillatory fluid flow induced by mechanical loading. We first employed real time RT-PCR to profile the mRNA expression levels of five subtypes of P2Y receptors in different human bone related cells, including hFOB and MG-63 cell lines, human mesenchymal stem cells, and primary human osteoblastic cells from osteoporotic patients and non-osteoporotic patients. Our results demonstrated that bone cells expressed different P2Y receptor mRNA levels at different stages or in different bone cell lines. However, the profile of P2Y receptor mRNA expression levels for osteoblastic cells from osteoporotic patients was consistent with the profile in osteoblastic cells from non-osteoporotic patients. Secondly, we utilized fluorescent imaging techniques to quantify Ca^{2+}_i mobilization in response to oscillatory fluid flow. Similar to our P2Y profile results, there was no statistically significant difference in oscillatory fluid flow-induced Ca^{2+}_i mobilization between osteoblastic cells from osteoporotic patients and those from non-osteoporotic patients. However, the percentage of hFOB cells responding with an increase in $[Ca^{2+}]_i$ to oscillatory fluid flow was significantly ($p<0.05$) less than that in MG-63 cells, human mesenchymal stem cells or primary human osteoblastic cells. After examining the sum of mRNA copy numbers of all subtypes of P2Y receptors, we found that the sum of all P2Y mRNA copy number was positively correlated with the percentage of cells responding to fluid flow with an increase in $[Ca^{2+}]_i$, suggesting that P2Y receptors play an important role in bone cell responses to fluid flow.

Influence of Different Loading Modalities on Non-Weight Bearing and Weight Bearing Bone Structure. R. Nikander*[1], H. Sievänen*[1], A. Heinonen[2], P. Kannus*[1]. [1]UKK Institute, Tampere, Finland, [2]Health, University of Jyväskylä, Jyväskylä, Finland.

Bone structure is known to adapt to the specific loading environment it regularly experiences. In this cross-sectional study of 113 young adult female athletes, representing volleyball, hurdling, racket-playing, soccer, and swimming, and their 30 non-athletic counterparts, we measured with pQCT the total bone mineral content, total area, cortical wall thickness, trabecular and cortical density, and polar section modulus at weight bearing tibia and at non-weight bearing radius and humerus. Our goal was to deepen the present, mostly DXA-based information (e.g. Nikander et al. JBMR 2005;20:520-528) on the influence of external loading modalities and internal joint moments on bone structure. In the tibia, substantial sport-specific skeletal benefits, swimming excluded, were observed (e.g. from racket players' 27% to hurdlers' 44% higher distal tibia section moduli). Estimated joint moment and loading modality explained ($p<0.05$) from 29% to 50%, and from 8% to 25% of the variation in most bone variables, respectively. In the upper extremities, sports activity, the swimming included, was associated with clear benefits in bone variables (e.g. from swimmers' 19% to volleyballers' 27% higher humeral shaft section modulus). In contrast to tibia, only the estimated joint moment was clearly associated ($p<0.05$) with structural characteristics, accounting for 6% to 26% of the variation in bone variables at shaft sites, but not at the distal site. Regardless of site, impact loading was clearly associated with strong bone structures, but the role of dynamic muscle activity and concequent joint moments became quite distinct in the upper extremities. It is thus obvious that different loading components dominate the specific skeletal adaptation in weight bearing and non-weight bearing bones.

Loading Frequency-Dependent Enhancement of Bone Formation in Mouse Tibia with Knee-Loading Modality. P. Zhang*[1], S. M. Tanaka*[2], H. Jiang*[3], M. Su*[1], H. Yokota[3]. [1]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Natural Science and Technology, Kanazawa University, Ishikawa, Japan, [3]Biomedical Engineering, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA.

The aim of the current study was to examine the role of mechanical loads applied to the tibial epiphysis underneath the knee. The specific question was whether this knee loading would present frequency-dependent enhancement of bone formation in the diaphysis without inducing *in situ* deformation of cortical bone. Twenty-four female C57/BL/6 mice

(~ 14 weeks old) were divided into three groups for three loading frequencies (5, 10 or 15 Hz, N = 8), and the loads with a peak-to-peak force of 0.5 N were applied to the left knee in the lateral-medial direction using a custom-made piezoelectric loader. Loads were given for 3 min per day for 3 consecutive days, and the right tibia was used as non-loading control. Mice were given an intraperitoneal injection of calcein at 30 μg/g body mass on days 2 and 6 after the last loading, and they were sacrificed 13 days after the last loading. The histomorphometric data such as mineralizing surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS) were determined at two cross-sections, 25% (~ 4 mm) and 50% (~ 8 mm) distal to the knee. The results clearly showed frequency-dependent loading effects. First, the tibial cross-sectional area at 25% was significantly increased by the loading at 5 and 10 Hz ($p < 0.05$). Second, bone formation was enhanced on the periosteal surface, and the loading at 5 Hz resulted in a significant increase in the morphometric parameters ($p < 0.01$ for MS/BS; and $p < 0.001$ for MAR and BFR/BS). These parameters were elevated similarly at 10 Hz ($p < 0.05$ for MS/BS; and $p < 0.01$ for MAR and BFR/BS). Third, among the periosteal surfaces, bone formation was most effective in the medial surface with the loading at 5 and 10 Hz. In the section at 50%, the tibial cross-sectional area was significantly increased by the loading at 5 Hz ($p < 0.01$). On the periosteal surface, the loading at 5 Hz resulted in a significant increase in the morphometric parameters ($p < 0.05$ for MAR; $p < 0.01$ for MS/BS; and $p < 0.001$ for BFR/BS). In all measurements, no statistical difference was observed by the loading at 15 Hz. The strain in the tibia *ex vivo* ~ 4 mm and ~ 8 mm distant from the loading site (N = 4) was < 50 μstrains with the described knee-loading modality. Therefore, our results support that bone formation can be enhanced without *in situ* deformation. In summary, we demonstrate that the knee loading modality is an effective means to enhance bone formation in the tibial periosteum and the enhancement is maximized with the loading frequency at 5 Hz.

Augmentation of Bone Gains during the Anabolic Post-Lactation Recovery Period Utilizing a Rat Bipedal Stance Model. J. E. Shea[1], S. L. Doody*[1], P. A. Eisenman*[2], S. C. Miller[1]. [1]Radiobiology, University of Utah, Salt Lake City, UT, USA, [2]Exercise and Sport Science, University of Utah, Salt Lake City, UT, USA.

There are profound changes in maternal metabolism and mineral homeostasis to meet the requirements of milk production during lactation, with bone loss occuring during lactation in all species studied. This catabolism during lactation is compensated by a marked anabolic phase that rebuilds skeletal structure and mineral stores after lactation. We sought to determine the influence of skeletal loading on cancellous bone during the post-lactation recovery period, utilizing a rat bipedal stance model. Established breeder rats were divided into three groups. The first, a baseline group (Base; n =8) was taken at parturition. The second group of rats (n = 8) was maintained through lactation and a 6-week recovery period after weaning in normal cages (Rec). While, the third group (n = 8) was maintained in a raised cage through lactation and a 6-week recovery period after weaning (Rec-RC). The raised cage set-up requires the rats to stand on their hind legs to obtain food and water. The animals were given flourochrome markers 2 and 10 days prior to necropsy. Bone mineral content (BMC), bone mineral density (BMD), percent cancellous bone and cancellous bone formation indices were measured. The data are presented as the mean ± standard deviation. The femoral BMD of animals housed in raised cages (0.179 ± 0.008) was 9% higher than Base (0.163 ± 0.01) and 6% higher than Rec (0.169 ± 0.007). While, the femoral BMC of Rec-RC (0.467 ± 0.034) was statistically higher than Base (0.417 ± 0.034) but not Rec (0.438 ± 0.028). There were no differences between the Base and Rec groups in terms of BMD or BMC. However, the percent bone (BV/TV) in the proximal tibia, as determined by morphometry, was 20% higher in Rec-RC (24 ± 4) than Base (19 ± 7) and 17% higher than Rec (20 ± 3). There were no differences between the three groups in terms of the following bone formation indices: percent double labeled surface, mineral apposition rate, and bone formation rate. The data show that a relatively modest skeletal loading regimen significantly augmented increases in cancellous bone mass and density during the post-lactation anabolic period. An increase in skeletal loading (e.g. a reasonable exercise program) during this period may represent a unique opportunity to actually increase skeletal mass and strength in the adult female skeleton. This differs from other, non-pharmacological interventions that, at best, act to minimize loss of mass and strength with age. A greater bone mass in the adult female skeleton may provide an increased margin of protection against the development of osteoporosis and fractures later in life.

Three-Point Bending of Rat Femoral Midshaft in the Primary Loading Direction, the Mediolateral Plane - Introduction and Validation of a Novel Biomechanical Testing Protocol. O. Leppänen[1], H. Sievänen*[2], T. L. N. Järvinen[3]. [1]Medical School, University of Tampere, Tampere, Finland, [2]Bone Research Group, UKK-institute, Tampere, Finland, [3]Department of Orthopaedics and Traumatology, University of Tampere, Tampere, Finland.

Bones adapt their strength according to the incident loading. In the rat femoral midshaft, the principal direction of loading is in the medial and lateral plane. For obvious anatomical and subsequent practical reasons, three-point bending of rat femoral diaphysis has always been carried out in the anteroposterior direction. Therefore, to determine the mechanical properties of the femoral shaft in the apparent primary loading direction, we developed a test protocol that allows biomechanical testing of rat femoral midshaft in the mediolateral plane. This protocol was then validated by determining the repeatabilities (root-mean-square coefficient of variation, CV_{rms}) of bone strength, stiffness, and energy absorption (toughness). Thirty-eight pairs of Sprague-Dawley rat femora with a large variance in size were excised and subjected to a comprehensive structural analysis. All bones underwent peripheral quantitative computed tomography (pQCT) scanning of femoral midshaft, followed by the mediolateral three-point bending of the diaphysis. The repeatabilities (CV_{rms}) of the densitometric and mechanical parameters were determined by comparing the data from the ipsilateral and contralateral femora. On 37 pairs of femora, the testing was successful with a very constant failure mechanism; the failure taking place in the exact midshaft and the fracture line being perpendicular to the long axis of the bone without signs of torsion. The protocol showed excellent repeatability as the CV_{rms} of the structural strength, stiffness, and energy absorption were 3.8%, 6.6%, and 14.5%, respectively. The CV_{rms} for structural strength and stiffness in the mediolateral three-point bending were almost identical to the repeatabilities of the pQCT variables, indicating that the error of the method was minimal. However, the test showed considerably poorer repeatabilities for the energy absorption. In conclusion, we have introduced a new testing method for the determination of the structural strength of the rat femoral midshaft in mediolateral direction, the apparent principal loading direction of the bone site. This protocol was shown to be highly repeatable in terms of structural strength and stiffness.

Effects of Long-Term Tennis Playing on Bone Gross Geometry at the Distal Radius: A Quantitative Magnetic Resonance Imaging Study. G. Ducher*[1], S. Même*[2], C. Magni*[3], J. Viala*[3], C. Chappard[1], D. Courteix[1], C. Benhamou[1]. [1]Faculty of Sport Sciences & Inserm, EA 3895 & U658, Orleans, France, [2]CNRS, Centre de Biophysique Moléculaire - UPR 4301, Orleans, France, [3]Hopital of Orleans, Orleans, France.

The purpose of this study was to characterize the geometric changes of the dominant radius in response to long-term tennis playing using magnetic resonance imaging (MRI). Twenty competitive tennis players (10 men and 10 women, age: 23.1 ± 4.7 years, with 14.3 ± 3.4 years of practice), were recruited. Axial slices were obtained on both distal radii with a spin-echo sequence (TR: 645 ms, TE: 20 ms, pixel size: 195×195 μm, slice thickness: 2 mm) using a 1.5 T MR device. Six contiguous slices were analysed, covering 1.2 cm of the distal radius, starting 1.8 cm far from the articular surface between the radius and the lunatum. The total bone area, cortical area, endocortical area and muscle area were manually defined on each slice. Volumetric measurements were calculated as the summed products of measured areas and slice thickness over the region of interest. Bone mineral content (BMC) was derived from the DXA scan of the distal radius in order to match the region of interest scanned by MRI. Volumetric bone mineral density (BMD) was calculated as the quotient of DXA-derived BMC on the MRI-derived total bone volume. The comparison between the dominant and nondominant radius was performed by a parametric paired t-test. Significant relative side-to-side differences ($p<0.0001$) were found in muscle volume (+9.7%), BMC (+13.5%), total bone volume (+10.3%) and endocortical volume (+20.6%) but not in cortical volume (+2.6%, ns). The asymmetry in total bone volume explained 75% of the variance of the BMC asymmetry ($p<0.0001$). Volumetric BMD was slightly higher on the dominant side (+3.3%, $p<0.05$). On both sides, muscle volume was related to all bone parameters, except volumetric BMD ($r=0.48$-0.83, $p<0.05$-0.0001). The asymmetry in muscle volume did not correlate with any of the asymmetries in bone parameters. BMC was still greater on the dominant side after adjusting for muscle volume, whereas the side-to-side differences in bone geometric parameters disappeared. This study indicates that the greater BMC induced by long-term tennis playing at the dominant distal radius is mainly due to increased bone size, improving mechanical strength. Cortical volume is not significantly increased, except in the one-handed backhand players. The muscular volume and strength appeared to play a role in the bone response to loading. However, muscle and bone asymmetries were not correlated, suggesting that other stimuli, directly applied to the radius, may also stimulate bone mineral accrual.

Diffuse Damage Causes a Greater Loss of Local Material Properties of Cortical Bone than Linear Microcracks. T. Diab*, D. Vashishth*.
Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, USA.

Historically, only bone mass has been considered to predict fracture risk but several recent studies have shown that other factors, including accumulation of microdamage may affect bone quality and contribute to bone fragility [Burr *et al*., J Biomech 1998]. *In vivo*, microdamage occurs in the form of linear microcracks and diffuse damage. Evidence is beginning to emerge that different damage morphologies may affect bone quality differently [Diab and Vashishth, Bone In press], however, limited information exists on the effects of damage morphologies on local bone tissue properties. In this study, seven rectangular beams were wet machined from the anterior quadrant of bovine tibiae, and subjected to a four-point bending fatigue loading [Physiological conditions, 5000µstrain]. Following fatigue loading, mechanical assessment of damage was done by microindentation based measurements of the local tissue hardness. Target areas of interest included a) diffuse damage region, b) 50 to 100 µm zone surrounding diffuse damage, c) 0 to 50 µm zone surrounding linear microcracks, and d) 50 to 100 µm zone surrounding linear microcracks. For statistical analyses, data were examined using an ANOVA test. The results demonstrate that compared to controls, diffuse damage (Region a) and 0 to 50 µm zone surrounding linear microcracks (Region c) show a significant drop in hardness ($p < 0.05$). The percentage of hardness loss was, however, distinct. Region (a) lost 83% more hardness than region (c). Based on these results we conclude that linear microcracks and diffuse damage affect the local bone properties differently. Linear microcracks are associated with 50 µm zone that is softer than the surrounding bone tissue. The magnitude of local hardness loss due to a linear microcrack is, however, limited and is 83% less than the local hardness loss caused by the formation of diffuse damage. Based on evidence from engineering materials it is argued that greater softening of the local tissue properties will cause a greater dissipation of external applied energy and prevent a catastrophic fracture. Age-related modifications in bone quality, that alter the propensity of human bone to form diffuse damage over linear microcracks [Diab and Vashishth, Trans. ORS 2005], would therefore increase its propensity to fracture.

The Role of Caspase3 in Bone Metabolism. H. Amano[1], K. Takahashi*[2], S. Niida[3], S. Yamada*[1]. [1]Pharamacology, School of Dentistry, Showa University, Tokyo, Japan, [2]Physiological Chemistry, School of Pharmaceutical Science, Showa University, Tokyo, Japan, [3]Dept of Bone and Joint Disease, National Center for Geriatrics and Gerontology, Obu, Japan.

Apoptosis is defined as programmed cell death, which is characterized by cell contraction and fragmentation, and nuclear aggregation and fragmentation. Various types of molecular signaling control Apoptosis. Caspase3, a type of cysteine protease, can be activated by stimulus, leading to degradation of a broad range of intracellular substances such as PARP and to induction of apoptosis. Approximately one-half of osteoblasts involved in bone formation undergo apoptosis during the process of transformation into osteocytes when embedded within the bone. In addition, osteoclasts are known to enter apoptosis away from the bone surface after bone resorption. Apoptosis in bone-related cells is considered an essential metabolic system in bone structure; moreover, Caspase3 may play a significant role in this process. We investigated the role of Caspase3 via utility of mice carrying a Caspase3 gene deficiency. Following completion of visual observation and x-ray photography of mouse skulls (8 weeks of age), skullcaps from mice with the gene deficiency exhibited quaquaversal (dome-like) formation characterized by an obtuse angle between the eye-ear plane and the anteroposterior diameter of the occipital skull-base in comparison with the wild type; consequently, growth suppression of the skull was apparent. Moreover, in mice with the gene deficiency, increased membranous ossification and mandibular prognathism were detected with increasing age. Newborn tibias, following fixation as tissue sections by conventional fixation, were decalcified, embedded in paraffin and observed under the microscope after TRAP staining for osteoclast counting; decreased osteoclast number was evident in mice with the gene deficiency. To investigate whether this decrease was a consequence of reduction of osteoblast support, osteoblasts were adjusted from calvaria and OPG mRNA expression was evaluated. Mice with the gene deficiency displayed elevated osteoblast OPG mRNA expression in comparison to the wild type. Increased calcification in osteoblasts carrying the gene deficiency was also demonstrated *in vitro*. This study confirmed abnormal skull formation with increased bone formation and resorption in mice lacking the Caspase3 gene, which controls apoptosis. Caspase3 gene maintains a delicate balance between bone formation and bone resorption; moreover, it adjusts normal skull development via control of apoptosis in osteoblasts and osteoclasts.

Actions of PTH on Cell Proliferation and Apoptosis in Osteoprogenitor Cells From Mouse Calvarial Cultures Expressing a GFP Reporter. Y. Wang, Y. Liu*, D. W. Rowe. University of Connecticut Health Center, Farmington, CT, USA.

Previously we have shown that early transient parathyroid hormone (PTH) treatment increases subsequent bone nodule formation in primary calvarial osteoblast cultures and this anabolic effect is not associated with an increase in total DNA content. To understand how this transient PTH treatment contributes to an anabolic outcome, we investigated the actions of PTH during and immediately after treatment of osteoblast cultures expressing stage-specific green fluorescent protein (GFP). Calvarial osteoblasts isolated from mice transgenic for pOBCol3.6GFP, which is activated in the preosteoblast stage, were cultured with 25 nM PTH for 7 days. Flow cytometry was then used to examine the effects of PTH on cell proliferation and apoptosis between GFP(+) and GFP(-) populations in the pre- and post-confluent cultures. Proliferating cells were labeled with BrdU and detected by fluorescent APC-conjugated anti-BrdU. Cell cycle was analyzed with flow cytometry using fluorescence of GFP, APC (for BrdU), and 7-AAD (for total DNA content). Results showed that in pre-confluent cultures, PTH caused a significant decrease in the percentage of cells in S phase, with a corresponding increase of cells in G0/G1 and G2+M phases in both GFP(+) and GFP(-) populations. However, there was no significant difference in the percentage of cells in S phase between GFP(+) and GFP(-) populations in the PTH-treated cultures. In contrast to its inhibitory effect in the pre-confluent cultures, PTH did not affect the percentage of cells in S phase once the cultures reached confluence. To measure apoptosis, apoptotic cells were detected by the binding of APC-conjugated annexin V. PTH significantly reduced the incidence of apoptosis in pre-confluent cultures. This reduction resulted solely from the decrease of apoptosis in the GFP(-) population, indicating PTH treatment increases the survival of GFP(-) cells in pre-confluent cultures. However, PTH treatment did not significantly alter the occurrence of apoptosis in post-confluent cultures. In conclusion, PTH reduced the percentage of cells in the S phase of the cell cycle in pre-confluent cultures, but this effect was lost once confluence was reached. In addition, PTH inhibited apoptosis in pre-confluent but not post-confluent cultures, and this effect was restricted to the GFP(-) population. We interpret this data to reflect one manifestation of PTH action on multipotential osteoprogenitor cells. PTH appears to enhance the progenitor population to commit to an osteogenic fate and this action results in a higher proportion of cells that achieve full osteoblast differentiation.

The Experiment Study of Osteocalcin Promoter A20 Fusion Gene Inhibiting Osteoblast Apoptosis. Y. Qin*, Z. Zhang, J. He*. Center for Osteoporosis, Shanghai sixth hospital, Shanghai Jiaotong Universty, Shanghai, China.

To investigate that A20 protects mice osteoblast against apoptosis in vitro. At first the osteocalcin-A20 chimeric gene (OC-A20) was constructed by fusing a segment of the mouse osteocalcin promoter with a human A20 complementary DNA. MC3T3-E1 cells was transferred stablly with vector OC-A20,and A20 mRNA and A20 protein expression were detected by RT-PCR and Western blotting. MC3T3-E1 cells, mouse embryo fibroblast NIH3T3 cells and human embryo kidney epithelial 293 cells were transiently transferred with OC-A20 gene,We didn't found that A20 mRNA expression in NIH3T3 and 293 cells. When OC-A20 or pcDNA3 transfer MC3T3-E1 cells were cultured in the presence of TNF-α for 8 h, cell apoptosis increased in pcDNA3 transfer cells compared with OC-A20-transfer cells by FACS. When the percentage of apoptosis were detected by TUNEL, we also found that the apoptosis increased in pcDNA3 group than OC-A20 group ($P<0.001$). Simultaneously, cell apoptosis was determined by DNA gel electrophoresis. The results showed that DNA ladder was detected in pcDNA3-transferred group, OC-A20-transfer MC3T3-E1 cells had only one trace. In the study, osteocalcin promoter and A20 fusion gene was constructed successfully at first. Through MC3T3-E1 , NIH3T3 and 293 cells transferred with OC-A20 gene, we confirmed that OC promoter A20 fusion gene was specific expression in MC3T3-E1cells. It is the first time that efficacy of A20 protects MC3T3-E1 cells against TNF-α induced apoptosis was verified by FACS, TUNEL and DNA Ladder . Then OC-A20 transgenic mice were generated.

Transcriptional Activation of Cyclin D1 Promoter by PTHrP Contributes to Cell Cycle Progression in Proliferating Osteoblasts. N. S. Datta, C. Chen*, L. K. McCauley. Perio/Prev/Geriatrics, University of Michigan, Ann Aror, MI, USA.

PTHrP has been implicated in the control of bone cell turnover but the mechanisms underlying its effect on osteoblast proliferation and differentiation have not been clearly defined. Cyclin D1 is a key regulator of G1 progression of the cell cycle. Our previous studies demonstrated that PTHrP signaling through cyclin D1 plays a role in the regulation of cell cycle progression in differentiating osteoblasts, which correlated with changes in the expressions of cyclin D1, CDK1 and JunB. In this report to define the mechanism by which PTHrP regulates osteoblast proliferation, we first investigated the expression of cyclin D1 by western blot analysis. Mouse calvarial MC3T3 cells were synchronized by serum starvation and induced with 0.1 μM PTHrP for 2-24h. Results showed sustained expression of cyclin D1 protein in these cells with PTHrP treatment. Performing cyclin D1 promoter/ luciferase assays PTHrP significantly up-regulated cyclin D1 expression at the transcriptional level. Using a series of cyclin D1 promoter mutants (provided by RG Pestell and F Beier), luciferase assays revealed that regulation of PTHrP involved both AP-1 and CRE sites which were necessary but not sufficient alone for PTHrP mediated cyclin D1 activity. However, using both AP-1 and CRE mutants completely abolished the PTHrP effect of cyclin D1. Our studies also suggested that regulation of cyclin D1 protein accumulation is likely at the level of post-transcriptional or post-translational control(s). Finally, a moderate increase of CDK1 and sustained expressions of cyclins E and A proteins following PTHrP induction in proliferating cells was observed. Interestingly, PTHrP regulation did not seem to involve Jun B in proliferating MC3T3 osteoblasts. Together, these studies suggested a differential regulation of PTHrP in the cell cycle machinery of osteoblasts indicating that the action of PTHrP is developmental stage specific. While inhibition of cyclin D1 induced osteoblastic cell growth arrest in differentiated stage, the induction of cyclin D1 expression by PTHrP may be critical for continuous cell cycle progression in proliferating osteoblasts contributing to bone cell turnover.

Interaction of the PGE_2 and JNK/p38 MAPK Signaling Pathways in Osteoblast-Adipocyte Fate Choices of Bipotential Progenitor Cells in Rat Calvaria Cell Cultures. T. Minamizaki*[1], Y. Yoshiko[2], K. Kozai*[1], J. E. Aubin[3], N. Meada*[2]. [1]Department of Pediatric Dentistry, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [2]Department of Oral Growth and Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, [3]Department of Molecular and Medical Genetics, Faculty of Medicine, University of Toronto, Toronto, ON, Canada.

Prostaglandin E_2 (PGE_2) is a well-known effective modulator of bone metabolism, with evidence from both hormone injections and recent experimental animal models that PGE_2 is, in particular, a powerful systemic and local anabolic agent. The anabolic effects of PGE_2 may be mediated, at least in part, by recruitment of new osteoblasts from their precursor cells via an EP2 and EP4 receptor-mediated cAMP-PKC signaling pathway. To address this further, we injected PGE_2, EP2 (EP2A) or EP4 (EP4A) agonists over the sagittal suture of the calvariae of newborn rats; in each case, the number of BrdU-labeled cells close to the newly formed bone was increased. Using the fetal rat calvaria (RC) cell culture model and pulse treatment protocols, we established that PGE_2 elicits its osteogenic stimulatory effects by acting on alkaline phosphatase-negative and/or positive precursor cells (osteoprogenitor cells) rather than pre-osteoblasts or mature osteoblasts. Given evidence for bipotential progenitors in RC cultures, we next asked whether the progenitor cell targets of PGE_2 may be bipotential osteo-adipocyte precursors. PGE_2 significantly increased the number of mineralized nodules, while concomitantly stimulating formation of a few adipocyte colonies. Similarly, Jun N-terminal kinase (JNK) (Dicumarol) and p38 map kinase (SB203580) inhibitors slightly but significantly increased adipocyte number in the RC model; both Dicumarol and SB203580 also increased levels of $PPAR\gamma_2$ and adipocyte marker mRNAs. Notably, combined treatment of RC cells with EP agonists and MAPK inhibitors robustly increased these adipogenic parameters. SB203580 but not Dicumarol also inhibited both basal and EP agonist-induced osteoblast differentiation. ERK inhibitors (U0126) were ineffective in these experiments. Thus, we conclude that the JNK/p38 MAPK signaling pathway may interact with the EP2/EP4-mediated PGE_2 pathway to regulate osteoblast-adipocyte fate choices of bipotential precursors.

Vitamin K-Dependent Gamma-Glutamyl Carboxylase Activity of Vitamin K Compounds in Liver and Bone. T. Okano, K. Nakagawa*. Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

Vitamin K is a cofactor for gamma-glutamyl carboxylase (GGCX), an enzyme catalyzing the post-translational modification of glutamyl residues (Glu) to gamma-carboxyglutamyl (Gla) residues in some proteins. In bone, osteocalcin, which has three Gla residues, is thought to be involved in the regulation of mineralization. Vitamin K compounds share a common chemical structure consisting of a naphthoquinone nucleus capable of redox cycling. Vitamin K1 (phylloquinone: PK) has a long phytol side-chain, whereas vitamin K2 has an unsaturated side-chain composed 1-13 isoprene unit. Menaquinone-4 (MK-4), a vitamin K2, possesses a significant pharmacological activity on bone formation and is used as a medication for osteoporosis in Japan. MK-4 enhanced the accumulation of Gla osteocalcin and the osteocalcin synthesis in cultured osteoblasts. The vitamin K-dependent gamma-carboxylation system consists of integral membrane proteins located in the endoplasmic reticulum membrane and includes the GGCX and warfarin-sensitive enzyme vitamin K 2,3-epoxide reductase (VKOR), which provides GGCX with reduced vitamin K cofactor. The endoplasmic reticulum chaperone protein calumenin is associated with GGCX and inhibits its activity. In the present study, we have examined the effects of PK and MK-4 on GGCX, VKOR, calumenin and osteocalcin mRNA expression and GGCX activity in hepatocyte and osteoblast cells. We used the cell lines derived from hepatocellular carcinoma (HepG2) and osteoblast (MG-63) cells. MK-4 was found to induce growth arrest in these cells tested. We also examined the co-factor activity of PK and MK-4 for the GGCX of microsomes from mouse liver, HepG2 or MG-63 cells. Co-factor activity of PK for GGCX was significantly weaker than that of MK-4. Moreover, GGCX, VKOR, calumenin mRNA expression in HepG2 and MG-63 cells were altered by the treatment with MK-4. However, PK and MK-4 did not affect the osteocalcin mRNA expression and vitamin D-dependent transcriptional activity on a human osteocalcin gene promoter in transfected MG-63 cells. In conclusion, these results indicate that molecular targets of PK and MK-4 in liver and bone may be side-chain structure-specific for the vitamin K molecule.

Smoke Exposure Alters the Bone Response to Estrogen Deficiency. D. M. Cullen, R. Kumar*, G. Alvarez*, M. P. Akhter. Osteoporosis Research, Creighton University, Omaha, NE, USA.

Smoking is associated with decreased bone mass and greater fracture risk in human epidemiology studies. The purpose of this study was to examine the interaction of ovariectomy and smoke exposure on bone remodeling in rats. We know that estrogen deficiency results in increased osteoclast and osteoblast activation and have seen the same pattern with smoke exposure. However, smoke exposure may suppress osteoblast formation rates. Adult (4 mo old, 266 (22) g) female Sprague-Dawley rats were randomized to four groups of 12 rats (sham or ovariectomized, and control or smoke exposed). Rats were exposure to a mixture of mainstream and sidestream cigarette smoke for 12 weeks at 2 hrs/d weekdays and 1 hr weekends at a concentration of 100 total suspended particles /mm^3. The ovariectomized rats were pair fed to match body weight in sham rats. There was no smoke effect on body weight. Calcein was injected to label mineralization, the proximal tibia was processed undecalcified, and sections measured for bone volume (BV/TV, %), osteoclast surface (Oc.S/BV, um^2/ um^3), mineralizing surface (MS/BS, %), mineral apposition rate (MAR, um^2/d), and bone formation rate (BFR/BV, %/day). A two factor General Linear Model was used to test for effects due to Ovariectomy (Ovx) or Smoke and the interaction of these factors. Planned comparisons were used to test differences between individual groups (Table). We found that Ovariectomy decreased cancellous BV/TV ($P<0.001$) consistent with the activation of osteoclasts ($P=0.006$). Smoke did not alter BV/TV, but tended to increase osteoclasts ($P=0.065$). Compared to Nonsmoking-Sham rats both Ovariectomy and Smoke exposure treatments independently resulted in greater MS/BS, MAR, and BFR. However, there was an interaction between Smoke and Ovariectomy such that smoke exposure partially suppressed these formation measures in the ovariectomized rats. We conclude that smoke exposure stimulates cancellous bone remodeling as measured by osteoclast surface, but suppresses the formation phase of remodeling as measured by osteoblast activation (MS/BS) and osteoblast work (MAR, BFR). In women the effects of estrogen deficiency or menopause on bone loss, due to increased remodeling may be magnified in smokers in osteoblast function is suppressed.

	Control		Smoke		
Variable	Sham	Ovx	Sham	Ovx	Interact

Involvement of p300/CBP in Regulation of Id1 Promoter Activity by Wnt3a and Bone Morphogenetic Protein 2 in Osteoblastic Differentiation. A. Nakashima*[1], T. Katagiri[2], H. Takaku*[3], A. Minagawa*[3], M. Nashimoto*[3], M. Tamura[1]. [1]Department of Biochemitry and Molecular Biology, Graduate School of Dental Medicine, Hokkaido University, Sapporo, Japan, [2]Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical School, Hidaka, Japan, [3]Department of Applied Life Sciences, Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan.

It has been shown that loss of function of the Wnt co-recepter, LRP5, in both humans and mice leads to decreased bone formation and bone mass, and a point mutation in this gene results in high bone mass, indicating the crucial role that Wnt/LRP5 signaling plays in bone formation. However, the exact signaling mechanisms by which Wnt members regulate bone formation remain to be elucidated. Previously, we showed that the Id1 mRNA level induced by bone morphogenetic protein (BMP)2 was decreased by Wnt3a in C2C12 cells. This suppression is mediated by a 29-bp GC rich region of the BMP2-responsive element (BRE) of the human Id1 gene promoter and an interaction between Smad1/4 and β-catenin was identified and found to be crucial for Wnt-mediated suppression of the BMP2 response. In this study, we investigated whether a transcriptional co-activator is involved in regulation of transcription by Smad and β-catenin in osteoblast differentiation and functional cross-talk of Wnt and BMP2 signaling. p300, originally described as a protein which co-precipitated with adenovirus E1A, enhanced the BMP2-induced transactivation of IdWT4F-luc, a BMP2 responsive reporter. A dominant-negative form of p300 did not alter this promoter activity. Moreover, overexpression of p300 diminished Wnt-mediated suppression of the BMP2 response in Id1 gene promoter activity. These results identify the involvement of p300 in Id1 expression mediated by Wnt/β-catenin signaling, and is the first study to demonstrate the presence of a coactivator by which Wnt/LRP5 regulates the BMP2-response in osteoblastic differentiation.

Mouse RANKL Gene Transcription Is Reversibly Suppressed by CpG Methylation of its Promoter Region. R. Kitazawa, K. Mori*, T. Kondo, S. Kitazawa. Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

The mouse RANKL gene promoter contains Runx2-binding sites, a vitamin D responsive element (VDRE) shared by CRE, and two CpG clustering regions: one around the transcription and translation start sites (-65/+350) and the other downstream of the VDRE (-920/-800). To clarify the epigenetic regulation of the RANKL gene, we analyzed the genomic DNA of the two subpopulations of ST2 cells: P9 which express RANKL and support osteoclastogenesis in response to vitamin D and P16 which do not, and found a higher frequency of CpG methylation of the -65/+350 region in P16 than in P9. Since VDR expression assessed by Western blotting and the specific binding to VDRE oligonucleotide assessed by EMSA were detected to an equal extent in P9 and P16, deterioration of the VDR signal was negated. By ChIP assay using anti-H3, -H4 antibodies and pairs of primers designed to amplify -950/-680 (containing VDRE) and -250/+10 (containing the transcription start site), histone acetylation in response to vitamin D occurred in P9 but not in P16, suggesting that CpG methylation in -65/+350 affects DNA acetylation. The effect of in vitro methylation on RANKL gene promoter was then analyzed. Promoter construct pGL3-1005 containing VDRE was methylated with SssI methylase (as pGL3-m1005) and transfected into P9 and P16. In both P9 and P16 the steady-state activity of pGL3-m1005 was 20% of that of pGL3-1005; pGL3-m1005 did not respond to vitamin D, whereas pGL3-1005 did. The effects of demethylating agent 5-Aza-dC on RANKL expression and osteoclastogenesis in the coculture were also analyzed. Assessed by quantitative RT-PCR and Western blotting, the expression of RANKL mRNA and protein in response to vitamin D was significantly restored in P16 by 5-Aza-dC treatment; by immunohistochemistry, RANKL protein expression was heterogeneously restored in P16. Furthermore, 5-Aza-dC treatment partially restored osteoclastogenesis in P16 cells. Our data suggest that CpG methylation of the promoter may reversibly suppress RANKL gene activation by vitamin D. The epigenetic mechanism may cause the heterogeneity and diversity of stromal/osteoblastic cells in response to bone-resorbing stimuli.

Histone Deacetylase (HDAC) Inhibitors Induce the TCF/LEF-Driven Luciferase and Have Similar Effects on HDAC Activity in Nuclear Extracts from Bone and HeLa Cells. A. Regmi*, D. L. Halladay*, L. V. Hale*, C. A. Frolik, E. C. Black*, R. J. S. Galvin. Musculoskeletal Researc h, Eli Lilly and Company, Indianapolis, IN, USA.

Previous studies have provided evidence that HDACs repress TCF mediated gene transcriptional activity (Brantjes et al. Nucleic Acids Res 2001 29:1410-9; Levanon et al. PNAS USA 1998 95:11590-5). The present study was conducted to profile HDACs 1-11 mRNA expression in human bone and osteoblast-like cells and to evaluate the effects of HDAC inhibitors in bone cells. HDAC mRNA from human bone (53 and 85 years old donor), human osteosarcoma (SaOS-2) cells and human primary osteoblasts (hOB, L. X. Bi, Univ Texas Medical Branch) was profiled using Taqman analysis. HDACs 1-11 mRNA was present in both SaOS-2 cells and hOB at similar levels. HDACs 1-11 mRNA was expressed in human bone with the exceptions of the 85-year old donor, which did not have detectable HDAC4 mRNA and HDAC5 mRNA, which was present in low abundance in both donors. The effects of various HDAC inhibitors (Triochostatin A, MS-275, M-344, Scriptaid, Oxamflatin, Valproic Acid) on HDAC activity in nuclear extracts from mouse pluripotential cells (C3H10T1/2), SaOS-2 cells and human epithelial (HeLa) cells were evaluated. Splitomycin, a sirtulin inhibitor was used as a negative control. The compounds were also tested in a rat osteoblast cell line (UMR-106) stably transfected with the TCF/LEF-driven luciferase. There was no difference in the HDAC inhibitory activity when comparing nuclear extracts from the three cells types. Triochostatin A, Oxamflatin and M-344 had IC_{50} in the range of 10-100 nM and MS-275, Scriptaid and Valproic Acid had IC_{50} in the range of 0.13 - 250 µM. All HDAC inhibitors also up regulated the TCF/LEF-driven luciferase in a concentration dependent manner. One HDAC inhibitor (M-344) was tested in a C3H10T1/2 cell differentiation assay and it increased alkaline phosphatase activity in a concentration dependent manner. In summary, bone cells contain mRNA for HDACs 1-11. A comparison of nuclear extracts between bone and epithelial cells did not show differences between HDAC activities in the presence of inhibitors. HDAC inhibitors up regulated TCF/LEF-driven luciferase in bone cells and an HDAC inhibitor induced osteoblast differentiation in C3H10T1/2 cells. Although further studies are necessary to clarify the role of HDAC inhibitors in the Wnt-induced signaling pathway, these studies do further support a role for HDACs in TCF-induced effects.

Compounds that Activate Runx2-Dependent Reporter Gene, Induce Osteocalcin and Enhance Osteoblast Differentiation Cause Bone Loss *In Vivo*. M. Susa, C. Halleux, D. Rohner*, D. Packert Jensen*, R. Vuille*, F. Natt*, T. Buhl*, R. Lattmann*, J. A. Gasser. Novartis Institutes for BioMedical Research, Basel, Switzerland.

Runx2, a master gene regulator of osteogenesis, is necessary for bone formation during development. Runx2 type II isoform (Osf2) expression was claimed to be sufficient for osteoblastic differentiation. However, data from cell culture do not support sufficiency of mere Runx2 expression for osteoblast differentiation. We sought to identify compounds that stimulate Runx2 activity in osteoblasts in order to study Runx2 role in vitro and in adult rodents in vivo. Pre-osteoblastic MC3T3-E1 cells were stably transfected with OSE2-Luciferase reporter gene, containing multimeric OSE2 response element for Runx2, derived from the osteocalcin promoter. High throughput compound screen with selected MC3T3-1b cell line resulted in one major class of activating compounds: amino thiazoles, which were inactive in several other reporter gene cell lines, but stimulated Runx2-dependent OSE2 activity in transient co-transfections. Compounds induced stably transfected OSE2-Luciferase up to 7-fold and Runx2 target gene osteocalcin up to 60-fold. In the presence of low doses of osteogenic stimulus, they could also enhance mineralization of MC3T3-1b cells up to 6-fold. However, compound concentration causing stable osteocalcin induction only transiently stimulated other osteoblast marker genes and was associated with osteoblast-selective apoptosis. Down-regulation of Runx2 type II isoform by anti-sense oligonucleotides did not reduce OSE2 activity, suggesting a role for other Runx2 isoforms, in agreement with Runx2 type II-specific knockout data (1). Structure-activity relationship studies of about 1,000 compounds indicated that osteoblast stimulation can be dissociated from OSE2 activation. One compound with acceptable bioavailability was tested in vivo in a 4-week intact rat model. The compound apparently induced an osteoclast-mediated loss of cancellous bone. It inhibited osteoclasts in vitro, but induced several osteoclastogenic cytokines in osteoblasts, most prominently TGF-b and IL-11. We conclude that Runx2 type II can be dissociated from OSE2 activation and that OSE2 activation can be dissociated from osteoblast stimulation. Runx2-activating amino thiazole compounds cause uncoordinated osteoblast gene activation, associated with osteoblast apoptosis and production of osteoclastogenic cytokines. In agreement with these data, a dominant effect in vivo was a loss of bone. Compounds from amino thiazole class could be of further use in vitro in osteoblast and osteoclast research and in vivo as inducers of bone loss.

Runx2 Modulates RANKL Expression by Repressing Its Steady-state Level in Mouse Osteoblastic/ Stromal Cells. K. Mori*[1], R. Kitazawa[1], T. Kondo[1], A. Yamaguchi[2], S. Kitazawa[1]. [1]Division of Molecular Pathology, Kobe university Graduate School of Medicne, Kobe, Japan, [2]Department of Oral Pathology, Tokyo Medical and Dental University, Tokyo, Japan.

Runx2, an essential transcription factor for bone formation, is also known to modulate osteoclastogenesis. In mouse RANKL gene, besides two putative Runx2 binding sites (-210, -195) in the basic promoter region, the Runx2 binding site located as far as 74 kb upstream from the transcription starting site plays critical roles in regulating the gene (Q. Fu et al. ASBMR 2004). We investigated the role of Runx2 in RANKL gene expression in mouse stromal cell line ST2 and in Runx2 -/- mouse-derived mesenchymal cell line C6. C6 and ST2 cells were cultured with or without 1α,25(OH)2D3 (VitD) and Dexamethasone (Dex) for 24 hours, then the expression of RANKL, OPG and Runx2 was quantified by realtime RT-PCR. Steady-state RANKL mRNA expression was higher in C6 cells than in ST2 cells. Conversely, with the Tet-On system, when the expression of Runx2 mRNA was restored in C6 cells, RANKL mRNA expression decreased to 70% of its steady-state expression level, suggesting that Runx2 has a repressive effect on the steady-state expression of the RANKL gene. In C6 cells, RANKL mRNA expression increased 2-fold by VitD treatment, but decreased to 32% by Dex treatment. Moreover, in contrast to the 38-fold increase of RANKL expression in ST2 cells by VitD and Dex treatment, C6 cells did not demonstrate such superinduction. On the other hand, administration of Folskolin (FK) resulted in a 14-fold increase of RANKL mRNA expression in C6 cells, suggesting that the induction of RANKL gene expression by protein kinase A signaling is mostly independent of Runx2. Reflecting the modest increase of RANKL expression by steroids, in the coculture system using C6 cells and normal mouse bone marrow macrophages, TRAP-positive multinucleated giant cells were induced with VitD treatment alone, and their number increased further by treatment with both VitD and Dex. We therefore speculate that Runx2 expression is crucial in repressing the steady-state expression of RANKL gene and thereby playing an important role in modulating RANKL gene expression.

Prenatal Onset of Osteosclerosis in Fra1 Transgenic Mice. T. Yamaguchi*[1], T. Nishiwaki*[1], Y. Toyama*[1], K. Matsuo[2]. [1]Department of Orthopedic Surgery, Keio University School of Medicine, Tokyo, Japan, [2]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan.

Fra1 is a component of the dimeric transcription factor AP-1. Fra1 transgenic (Tg) mice develop osteosclerosis, which is due to cell-autonomous enhancement of osteoblastic bone formation. Osteosclerosis in Fra1 Tg mice is reported to begin by four weeks of age, and progress over several months until the bone marrow cavity is occluded. However, the age of onset and pathogenesis of the osteosclerosis is unknown. To reveal the age of onset, we used an *in vivo* computed tomography scanner (LaTheta; Aloka, Japan). Tibial bone mineral density (BMD) of Fra1 Tg mice and wild-type littermates at various ages (n=15, each genotype) was measured twice a week over the course of three weeks under anesthesia. In addition, 16.5 d.p.c. embryos were isolated and tibial BMD was measured by the CT scanner, and mineralized areas were quantified on histological sections after von Kossa stain. *In vivo* analysis revealed higher BMD in Fra1 Tg mice as early as three days after birth. Consistently, von Kossa stain showed a larger proportion of mineralized area in three day-old Fra1 Tg tibiae than wild-type controls (n=8, each genotype), suggesting that osteosclerosis has an earlier onset. Prenatal analysis using tibiae isolated at 16.5 d.p.c. demonstrated increased BMD in Fra1 Tg embryos (wild-type n=12, Fra1 Tg n=8). Furthermore, von Kossa stain showed a larger proportion of mineralized area in 16.5 d.p.c. Fra1 Tg tibiae (n=7) than wild-type controls (n=11). Finally, Alizarin red- and Alcian blue-stained skeletal preparations of 15.5 d.p.c. embryos showed that development of bone and cartilage in Fra1 Tg mice and wild-type was indistinguishable. Therefore, while the ossification in Fra1 Tg mice starts at approximately the same time as in wild-type mice, once ossification has begun, elevated bone formation results in osteosclerosis in Fra1 Tg mice. We conclude that osteosclerosis in Fra1 Tg mice starts before birth. This rationalizes comparative biochemical analysis of pre- or neonatal bones prior to osteosclerotic structural alterations to reveal the pathogenesis of enhanced bone formation in Fra1 Tg mice.

Human Endothelial Cells Inhibit MSC Differentiation into Mature Osteoblasts *In Vitro* by Interfering with Osterix Expression. T. R. Meury*, M. Alini*. Cell Biology & Biochemistry, AO-Research Institute, Davos-Platz, Switzerland.

Several cell types have the capacity to influence the differentiation/commitment of mesenchymal stem cells (MSC) into a certain lineage. In this study, we were interested in the influence of endothelial cells (EC) on dexamethasone-induced differentiation of MSC into mature osteoblasts. We therefore performed co-cultures (indirect contact, conditioned medium) of human umbilical vein endothelial cells and mesenchymal stem cells (isolated from human bone marrow aspirates) for up to 28 days in osteogenic medium (OM), containing dexamethasone, beta-glycerophospate and ascorbic acid. Typical osteoblastic markers were analyzed, including calcium-incorporation, ALP activity and gene expression using real-time RT-PCR. As expected, osteogenic medium induced an osteoblastic phenotype in MSC, as shown by high calcium-incorporation and ALP activity as well as elevated expression of osteoblastic marker genes encoding for extracellular matrix components like type 1 collagen, bone sialoprotein, osteonectin or MMP-13. The osteoblastic transcription factors Runx2 and Osterix (Osx) were also up regulated by OM. Co-cultures of MSC with EC in OM clearly down regulated calcium incorporation, ALP activity and gene expression of extracellular matrix proteins. Interestingly, the transcription factor Runx2 was not affected by EC, but Osx was significantly down regulated. There was no influence of EC on the expression of other mesenchymal transcription factors like the chondrocytic marker Sox9 or the adipocytic marker PPAR-gamma. This suggests, that EC are able to arrest final osteoblastic differentiation of MSC at a pre-osteoblastic stage by interfering with Osx expression. The fact that Runx2 as well as Sox9 and PPAR-gamma were not affected hints, that the inhibition takes place at a later stage than the Runx2-driven osteo-chondro-bipotential precursor stage, and that by this inhibition, the MSC are not driven to a chondrogenic or adipogenic phenotype. Fibroblast- or chondrocyte-conditioned medium did not have this effect on MSC differentiation, indicating that the inhibitory effect we observed was EC-specific. In conclusion, we have shown that EC specifically have an inhibitory effect on dexamethasone-induced MSC differentiation *in vitro* by suppressing Osx expression.

Molecular Phenotyping of Cell Lines from Osteoblastic Lineage Using Real-Time PCR TaqMan Low Density Arrays. C. Halleux, T. Grabenstaetter*, N. Luong-Nguyen*, D. Rohner*, M. Susa. Musculoskeletal Diseases, Novartis Institutes for BioMedical Research, Basel, Switzerland.

Several mouse osteoblastic cell lines at various stages of osteoblastic differentiation are available for in vitro studies. Comparative molecular characterization of these cell lines, which would better define their phenotype and enable a more informed decision on their use, has not yet been done. Here we used a novel, advanced application of real-time PCR, the TaqMan Low Density Arrays, to simultaneously and quantitatively measure mRNA levels for 24 osteoblast markers in three murine cell lines: pluripotent C3H10T1/2 cells, stromal, osteoclast-supporting ST2 cells, pre-osteoblastic MC3T3-E1 cells, and in the most mature primary mouse calvarial osteoblasts. Cells were treated with osteogenic stimulus (ascorbic acid, beta-glycerophosphate and 1000 ng/ml BMP-2) or with 25 ng/ml TGF-beta1 for 1 and 3 days. We focused on upregulated genes. All four cell cultures displayed high levels of collagen type I alpha 1 and alpha 2 chain (Ct values of 15-19), whose expression are characteristic for osteoblastic cell lines. In all four cultures, BMP-2 or TGF-b1 stimulated expression of Dlx5 and TCF7, suggesting that initial events in BMP and Wnt signaling are not dependent on stage of osteoblastic differentiation. Primary osteoblasts, MC3T3-E1 and, to a lesser degree, ST2 cells, but not C3H10T1/2 cells showed a strong response of classical osteoblast markers alkaline phosphatase, bone sialoprotein and osteocalcin to BMP-2 stimulation. MC3T3-E1, ST2 and C3H10T1/2, but not primary cells responded well to BMP-2 or TGF-b1 with induction of Notch target gene hey1, osteogenic AP-1 component fra-1, fibromodulin and TGF-b1, suggesting that more mature cells lose responsiveness to these factors. MC3T3-E1 and ST2 cells, but not primary osteoblasts nor C3H10T1/2 induced well transcription factors Msx2, Osx, Smad6, c-fos and Id2. In MC3T3-E1, ST2 and C3H10T1/2 cells integrin alpha 2 chain was induced, pointing to the importance of collagen signaling in pre-osteoblastic, stromal and pluripotent cells. In MC3T3 cells, BMP-2 induced well PTH receptor and moderately osteomodulin and in ST2 cells, TGF-b1 increased OPG. We conclude that molecular phenotyping confirms the place of these cellular models in osteoblast lineage and reveals more details than previously known. This fast, reliable and quantitative method enables quick profiling of cells with respect to osteoblast-related genes and may find application in assessing effects of compounds on osteoblasts in vitro, as well as in profiling of osteoblast status in mouse bone ex vivo.

Expression of Periostin in Human Normal Tissue and Fibrous Dysplasia. T. Kashima[1], K. Shimazu*[2], T. Nishiyama*[2], M. Shimazaki*[2], I. Kii*[2], M. Fukayama*[1], A. E. Grigoriadis[3], A. Kudo[2]. [1]Pathology, University of Tokyo, Tokyo, Japan, [2]Biological Information, Tokyo Institute of Technology, Yokohama, Japan, [3]Craniofacial development, King's College London, Guy's hospital, London, United Kingdom.

Periostin is a 90 kDa secreted protein which was originally cloned from murine osteoblast-like MC3T3-E1 cells. It is specifically expressed in the periodontal ligament and the periosteum in adult mice and is thought to function as a mechanosensor in the remodeling of the periodontal ligament. To examine further the tissue distribution and cellular pattern of periostin expression in human, a polyclonal anti-serum against human periostin was raised and used for immunohistochemistry (IHC). Initial screening of various normal and pathological samples was examined using a tissue microarray. Periostin was strongly localized not only to the periodontal ligament, the periosteum and surface of the articular cartilage, but also to the endocardium, the valves, the wall of the arteries and arterioles, where mechanical stress is normally occurring. Veins were negative for immunoreactivity, further supporting the hypothesis that periostin acts as a mechanosensor. As a marker of osteoblastic differentiation, periostin is also highly expressed at sites of intramembranous ossification in fetal calvaria but not in mature osteoblasts lining surfaces of trabecular bone. We therefore also examined fibrous dysplasia (FD) since the histology of FD is thought to resemble intramembranous ossification and collagen fibers in the periodontal ligament known as “Sharpey’s fibers”. We examined 40 cases of monoostotic FD, aged from 3 to 60 years old. In all FD cases, periostin was strongly positive in fibroblastic cells which were attached perpendicularly to woven bone, but bone matrix itself was negative. Finally, since it has been well documented that the c-Fos protooncogene is upregulated by mutation of the Gs alpha unit in FD patients, we speculated that periostin expression might be controlled by c-Fos. To investigate this, the expression of periostin in murine osteosarcomas arising in c-*fos* transgenic mice were also examined by in situ hybridization and IHC. Interestingly, periostin was expressed in immature lining osteoblastic tumor cells but not in fibroblastic tumor cells. Further, expression analyses employing previously established MC3T3-E1 cells which conditionally overexpress c-*fos* in are now in progress. Taken together, these data suggest that periostin is expressed in mesenchymal tissues subjected to mechanical stress, and may have a role in skeletal pathologies.

TRAIL and TNFα Regulate Human Osteocyte-Osteon Structure by Removal of Gap-Junctions via Proteasomal Degradation with a Probable β-Catenin Downstream Mechanism. A. C. Sharrow*, Y. Li, A. Micsenyi*, C. W. Borysenko*, T. Lehmann*, A. Wells*, S. E. Kalla*, V. García Palacios, S. P. Monga*, H. C. Blair. Pathology, University of Pittsburgh and Pittsburgh VA Medical Center, Pittsburgh, PA, USA.

Osteoblasts express Death Receptor-5 (TRAIL-R2) and TNFR1 (P55) but resist apoptosis when exposed to their ligands. Osteoblasts function in multicellular units, osteons, organized by connexin43 (CX43) connexons, elaborate protein complexes that have intricate interactions with adaptor and regulatory proteins including β-catenin, a key component of the Wnt pathway. TRAIL or TNFα decreased intracellular connections in serum starved human MG63 cells and in nontransformed osteoblasts; RANKL and IL-1 controls were unaffected. Microinjection of lucifer yellow showed that serum starvation promoted connected cell groups, but TRAIL eliminated these almost entirely in MG63 and mature osteoblasts; immature osteoblasts responded similarly but only to TNFα. Western blots and immune localization of CX43 showed dramatic reduction by TRAIL or TNFα depending on cell differentiation state. Doublet-discrimination flow cytometry of MG63 showed cell shape changes and was consistent with decreased connectivity in response to TRAIL. If CX43 is separated from the connexon, β-Catenin, in other organ systems, undergoes nuclear localization and initiates events including CX43 mRNA synthesis and G2M cell cycle arrest. Real-time PCR showed that CX43 transcription in MG63 increased after TRAIL treatment that reduced CX43 protein, and TRAIL decreased MG63 S phase by 80% with a parallel increase in G2. After removal of TRAIL, cells re-established connections and expressed alkaline phosphatase, but cell number did not increase as in controls, suggesting that TRAIL can terminate proliferation. In MG63 the proteasomal inhibitor lactacystin eliminated CX43 reduction after TRAIL or TNFα, although 24 h serum starved cells had reduced CX43 and β-catenin. A decline in β-catenin occurred with or without lactacystin. This suggests that non-proteasomal mechanisms degrade β-catenin and that dissociation of CX43-β-catenin complexes does not require CX43 degradation. We conclude that TRAIL or TNFα, via DR5 or TNFR1, regulate osteoblast CX43 redistribution and degradation. Downstream events can arrest cell division and alter protein expression, and are probably mediated by β-catenin redistribution and activation. Thus TRAIL and TNFα receptors are late regulators of multicellular structure, with secondary effects on cell cycle and expression of proteins. Early β-catenin activation and nuclear localization after TRAIL or TNFα activation may be crucial thus defining a novel mechanism that regulates osteon structure.

Culture of Marrow Derived Mesenchymal Stem Cells in 3-Dimensional Matrices Made by Marrow Stromal Cells Promotes Retention of the Stem Cell Phenotype. X. Chen, S. C. Manolagas, R. L. Jilka. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Mesenchymal stem cells (MSCs) both replicate to produce identical daughter stem cells and differentiate into diverse cell types including osteoblasts. However, MSCs lose their unique properties and exhibit senescence-associated growth arrest when grown in standard 2-dimensional (2D) culture systems, thereby impairing investigation of their behavior and limiting their therapeutic potential. In other tissues, the extracellular matrix (ECM) forms part of the specialized niche that controls stem cell behavior. Therefore, we hypothesized that an appropriate ECM is required for studying MSCs in vitro. To test this hypothesis, we quantified the adhesion, differentiation, and BMP-2 responsiveness of murine MSCs cultured on cell-free 3D matrices made by cultured murine marrow stromal cells, as compared to uncoated plastic, or plastic coated with type I collagen or fibronectin. These matrices were ~100 μm thick as determined by confocal and electron microscopy, and contained collagen as well as osteonectin, biglycan, and decorin. The distribution and content of these proteins was unaffected by removal of cells with 0.5% Triton-100 and 20 mM NH_4OH. 3D matrices promoted attachment and proliferation of MSCs as reflected by a >2-fold increase in the number and size of fibroblastic colonies arising from these progenitors (CFU-F). Compared to 2D systems, cells cultured in 3D matrices under basal conditions secreted 5-fold less osteocalcin. Addition of ascorbcate-2-phosphate increased osteocalcin secretion in all cultures at day 15 and 25, but absolute levels remain 2-3-fold lower in 3D cultures. Previous studies of ours showed that osteoblastogenesis in 2D cultures depends on endogenous production of BMP-2/4; and that BMP-4 binds to the ECM. Therefore, we suspected that the retardation of osteoblastogenesis in 3D cultures reflected retention of the undifferentiated phenotype of MSCs due to sequestration of endogenous BMP-2/4, rather than loss of osteogenic capacity. Consistent with this, addition of BMP-2 (10 -100 ng/ml) at day 10 to cells cultured in 3D matrices dose-dependently stimulated expression of alkaline phosphatase activity (2-fold) and osteocalcin secretion (5-fold). In contrast, MSCs cultured on 2D systems failed to respond to exogenous BMP-2. Indeed, this is the first report of a response of murine marrow-derived MSCs to low concentrations of BMP-2. These findings indicate that, as in other stem cell niches, the ECM plays an essential role in the control of MSC behavior, perhaps by regulating exposure of cells to pro-differentiating growth factors such as BMPs.

1α,25-Dihydroxyvitamin D_3 and Wnt Pathway Effects on Proliferation and Differentiation of Osteoblastic Cells. Y. Shi*[1], J. A. Eisman[1], E. M. Gardiner[2]. [1]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, [2]School of Medicine, University of Queensland, Brisbane, Australia.

Active hormonal vitamin D, 1α,25-dihydroxyvitamin D_3 [1,25D_3], induces osteoblastic cell cycle arrest and matrix mineralization. The Wnt pathway regulates cell proliferation and differentiation in development and disease, with many reports linking the Wnt pathway to osteoblast differentiation and bone mass. Lithium chloride (LiCl) mimics activation of the canonical Wnt pathway by stabilizing ß-catenin, which complexes with other transcription factors to regulate gene expression. Here, the effects of continuous treatment with 1,25D_3 and/or LiCl initiated at various stages of proliferation and differentiation were investigated in pre-osteoblastic MC3T3-E1 cultures. Cell proliferation was measured by BrdU incorporation, mineralized nodules were detected by Von Kossa staining, and gene expression was evaluated by quantitative RT-PCR. Initiating 1,25D_3 or LiCl treatment in subconfluent cultures (Day 1) inhibited cell proliferation in a dose-response manner and combining 1,25D_3 plus LiCl treatment had an additive effect, markedly reducing proliferation and mineralized nodule number and size. Treatment of matrix-forming cultures (Day 6) with 1,25D_3 or LiCl also reduced mineralized nodule number and size, but treatment with either agent after mineralization onset (Day 13) reduced nodule size but not number. Runx2 expression was not altered 24 hours after either LiCl or 1,25D_3 at any time point. 1,25D_3, but not LiCl, treatment at Day 1 was associated with decreased twist 1 expression. In contrast, LiCl treatment at Day 6 was associated with decreased osterix expression level, whereas 1,25D_3 had no effect on this gene. Thus, the Wnt pathway appeared to regulate osteoblastogenesis in pre- and post-confluent MC3T3-E1 cultures but was less active after onset of mineralization. In contrast, 1,25D_3 had effects at all culture stages, and the Wnt and vitamin D regulatory pathways were additive in pre-mineralizing cultures. Thus, although 1,25D_3 and LiCl had similar effects on differentiation of these osteogenic cultures, their underlying molecular mechanisms are distinct and additive, providing a basis for physiological interactions between these two bone anabolic pathways.

N-Acetylcysteine Stimulates Mineralized Nodule Formation in Mouse Calvarial Osteoblasts. J. H. Jun*, M. Song*, S. Lee*, K. M. Woo*, G. S. Kim*, J. H. Baek. Department of Pharmacology and Dental Therapeutics, School of Dentistry, Seoul National University, Seoul, Republic of Korea.

N-acetylcysteine (NAC) is a precursor of glutathione and has oxygen radical-scavenging properties. The effectiveness of NAC administration in the prevention of several diseases induced by reactive oxygen species has been reported. Recent report showed that NAC prevented bone resorption in ovariectomized mice, suggesting the possibility of NAC as a therapeutic agent for osteoporosis. Thus we examined the effect of NAC on bone formation, the other side of bone remodeling. Long-term treatment of NAC increased the mineralized nodule formation in primary cultured mouse calvarial osteoblasts. In accordance with this stimulatory effect, NAC significantly enhanced the mRNA expression of osteoblast differentiation associated genes such as alkaline phosphatase, osteocalcin, bone sialoprotein, and osterix. NAC increased the expression of bone morphogenetic protein-2, -4, -7 and transforming growth factor-beta. While glutathione showed similar stimulatory effects, caffeic acid phenethyl ester, a strong phenolic antioxidant, did not stimulate osteoblast differentiation, suggesting that the osteogenic effect of NAC needs thiol group. Taken together, these results suggest that NAC might exert potent anti-osteoporotic effect by stimulating bone formation as well as by inhibiting bone resorption.

Omega-3 Fatty Acids Inhibit *In Vitro* Vascular Calcification via the p38-MAPK Pathway. M. Abedin*, J. Lim*, D. Park*, T. Tang*, L. L. Demer, Y. Tintut. Medicine, UCLA, Los Angeles, CA, USA.

Fish oil supplementation improves outcome in coronary artery disease and evidence suggests a reduction of vascular calcification in an animal model. However, the mechanism of their action on vascular calcification is not fully understood. In this report, we identify the intracellular signaling pathways, through which omega-3 fatty acids, active ingredients of fish oil, inhibit vascular calcification. Eicosapentanoic acid (EPA) or docosahexanoic acid (DHA) inhibited alkaline phosphatase (ALP) activity and mineralization of calcifying vascular cells, a subpopulation of bovine aortic medial cells that undergo osteoblastic differentiation and form calcified matrix in vitro. Western blot analysis showed that DHA activated p38-MAPK but not ERK or Akt. Co-treatment of DHA with an inhibitor of p38-MAPK, reversed the DHA inhibitory effects on ALP activity. Pretreatment with DHA also inhibited the ALP activity and mineralization induced by the inflammatory cytokine, IL-6. DHA and anisomycin, a p38-MAPK activator, partially attenuated STAT-3 activation induced by IL-6. These results suggest that omega-3 fatty acids inhibit vascular calcification by stimulating the p38-MAPK pathway.

BMP-2 Activates β-Catenin Signaling in Osteoblasts. Y. Yan, Y. Lim*, M. Chen*, R. J. O'Keefe, D. Chen. Orthopaedics, University of Rochester, Rochester, NY, USA.

Recent studies demonstrate that BMP-2 has a synergistic effect with β-catenin to promote osteoblast differentiation. To determine the molecular mechanism of the interaction between BMP-2 and β-catenin, experiments were performed to assess the effect of BMP-2 on β-catenin signaling in 2T3 and MC3T3 osteoblasts. BMP-2 increased protein levels of the non-phosphorylated active form of β-catenin in a dose-dependent (10-200 ng/ml) and time-specific (24 h treatment) manner on Western blots. Consistent with this finding, BMP-2 induced β-catenin nuclear translocation (immunostaining) and enhanced protein levels of nuclear β-catenin (Western blot) in osteoblasts. BMP-2 activated β-catenin signaling by regulating the expression and activity of three critical molecules in the β-catenin signaling pathway: 1) BMP-2 inhibited Kremen-1 mRNA expression in a dose-dependent manner in 2T3 cells; 2) BMP-2 stimulated Lrp5 mRNA expression (over 2-fold, Northern blot) in 2T3 cells; and 3) BMP-2 inhibited β-TrCP protein expression (Western blot) in a dose-dependent manner. Maximal concentrations of BMP-2 nearly abolished β-TrCP expression in osteoblasts. β-TrCP is an E3 ubiquitin ligase in the $SCF^{\beta\text{-}TrCP}$ protein complex and induces β-catenin degradation in a dose-dependent manner in osteoblasts. Thus, the effects of BMP-2 on each of these genes would tend to enhance β-catenin signaling. β-catenin-deficient osteoblasts were used to further assess the importance of β-catenin signaling downstream of BMP-2. Primary osteoblasts isolated from β-catenin-loxP mice and infected with Cre recombinase-expressing adenovirus (AdCMV-Cre) had deletion of the β-catenin gene. In these cells, osteoblast proliferation (BrdU labeling, ~40% reduction) and expression of cyclin D1 protein were decreased and ALP activity and expression of osteoblast marker genes such as type I collagen, osteopontin and osteocalcin were inhibited 45-70% compared with control osteoblasts isolated from β-catenin-loxP mice and infected with AdCMV-GFP. BMP-2-induced osteoblast marker gene expression (type I collagen and osteopontin) and mineralized bone nodule formation were significantly inhibited in β-catenin-deficient osteoblasts. Altogether the findings show that BMP-2 regulates the expression of genes controlling β-catenin signaling and that enhanced β-catenin signaling plays a critical role in BMP-2-induced osteoblast differentiation.

Beta-Catenin Regulates NFAT Signaling Pathway in Osteoblasts. H. Yeo*, J. M. McDonald, M. Zayzafoon. The Department of Pathology, The University of Alabama at Birmingham, Birmingham, AL, USA.

The Nuclear Factor of Activated T cells (NFAT) is a family of transcription factors that regulates gene expression and differentiation of several cells, including osteoclasts. We have previously shown that NFAT, specifically NFATc1, negatively regulates osteoblast differentiation by inhibiting Fra-2 expression. Wnt/β-catenin signaling is another important regulator of bone formation and osteoblast differentiation. Crosstalk between NFAT and Wnt/β-catenin signaling has been previously reported but never examined in osteoblasts. The purpose of this study is to examine the relationship between NFATc1 and β-catenin during osteoblast differentiation. These studies were peformed using a murine clonal osteogenic cell line, MC3T3-E1, and a mouse pluripotent mesenchymal stem cell line, C3h10T1/2. Here we show by Western blot analysis that the protein expression of both NFATc1 and β-catenin increases during osteoblast proliferation and early differentiation and decreases during mineralization, while the gene expression of both NFATc1 and β-catenin, as determined by RT-PCR remains unchanged, suggesting a post-transcriptional regulatory mechanism. Inhibition of proteasomic degradation in osteoblasts by MG132, a proteasome inhibitor, increases, dose- and time- dependently, the levels of NFATc1 and β-catenin. To elucidate the direct role of β-catenin in NFATc1 activity, we silenced β-catenin in osteoblasts using siRNA. Here we demonstrate by Western blotting and luciferase assay that the silencing of β-catenin decreases NFATc1 protein expression and NFAT transactivation. Furthermore, β-catenin siRNA decreases NFAT DNA-binding activity, as demonstrated by electrophoretic mobility shift assay. Treatment with MG132, while silencing β-catenin, rescues the decrease in NFATc1 protein expression and transactivation suggesting that NFATc1 is protected from proteasomic degradation by β-catenin. Finally, we show by immunoprecipitation and by three-dimensional computer based binding models that NFATc1 physically interacts with β-catenin. Taken together, our results suggest that during early osteoblast differentiation β-catenin and NFATc1 bind resulting in protection of NFATc1 from proteasomic degradation.

Intercellular Junctions, Phosphatidylinositol Signaling and Osteoblast Differentiation. A. R. Guntur*[1], M. C. Naski[2]. [1]Biochemistry, University of Texas Health Science Center at San Antonio, San antonio, TX, USA, [2]Pathology and Biochemistry, University of Texas Health Science Center at San A ntonio, San antonio, TX, USA.

Bone synthesis requires synchronous osteoblast differentiation and vectoral secretion of bone matrix. At sites of rapid bone synthesis osteoblasts form a tightly opposed layer of cells that secrete matrix toward the bone surface. We hypothesize that these cells synchronize their differentiation through activation of signaling cascades that are regulated by intercellular contact. To test this hypothesis we studied the assembly of intercellular junctions in MC3T3E1 osteoblasts. Immunoflourescence localization showed that intercellular contact leads to calcium dependent assembly of adherens junctions containing N-cadherin, β-catenin and p120. Interestingly, the tight junction protein zonula occludens-1 was also targeted to intercellular contacts. Significantly, the assembly of those junctions coincided with the activation of the phosphatidylinositol 3- kinase signaling pathway. This was demonstrated by increased phosphorylation of PTEN at Ser380 and a concomitant activation AKT through phosphorylation at Ser 473 and inactivation of glycogen synthase kinase3β via phosphorylation at Ser9. The assembly of intercellular junctions and activation of phosphatidylinositol 3-kinase signaling also coincided with osteoblast differentiation as evidenced by 1) the induction of osterix, an essential osteoblast transcription factor and 2) increased expression of the osteoblast matrix genes osteoglycin and osteomodulin. We conclude that osteoblast differentiation is coupled to adherens junction assembly and activation of phosphatidylinositol 3-kinase signaling.

A Highly Potent Inhibitor of Cathepsin K Inhibits Bone Resorption both *In Vitro* and in Acute Model of Bone Resorption *In Vivo* in Monkeys. S. Kumar, L. Dare, J. A. Vasko-Moser, S. M. Hwang, T. Tomaszek, D. S. Yamashita, R. W. Marquis, H. Oh, J. U. Jeong, D. F. Veber, M. Gowen, G. Stroup. GlaxoSmithKline, King of Prussia, PA, USA.

Cathepsin K (catK) is a cysteine protease that is highly and selectively expressed in osteoclasts. Substantial evidence indicates that catK plays a key role in osteoclast-mediated bone resorption and that its pharmacological inhibition should result in inhibition of bone resorption *in vivo*. We have identified SB-462795, a potent inhibitor of human cathepsins K, L and V (Ki = 41, 68 and 53 pM, respectively) that exhibits 39-300 fold selectivity over other cathepsins. SB-462795 inhibited catK activity in sections of human osteoclastoma with an IC_{50} ~ 45 nM and inhibited human osteoclast-mediated bone resorption with an IC_{50} ~ 20 nM. The anti-resorptive potential of SB-462795 was evaluated in normal and Ovx female monkeys. Serum levels of the C- and N-terminal telopeptides of Type I collagen (CTx and NTx respectively) and urinary levels of NTx were monitored as biomarkers of bone resorption and serum osteocalcin was measured as a marker of bone formation. Subcutaneous (12 mg/kg) and oral (3, 10, 30 mg/kg) administration of SB-462795 to medically OVX (treatment with GnRHa) female monkeys clearly inhibited bone resorption as measured by inhibition of bone resorption markers in serum and urine. A single subcutaneous dose of 12 mg/kg resulted in a ~70 and ~78% inhibition of serum CTx at 1.5 and 72 hours, respectively. Similarly, oral dosing at 10 and 30 mg/kg also resulted in approximately 50% reduction in urinary NTx in the first 24 hours. The maximal effect in normal female monkeys was achieved after a single oral dose of 10 mg/kg where ~38% reduction in urinary NTx was observed for 48 hours. In these studies SB-462795 did not have a substantial impact on osteocalcin, a bone formation marker. Repeat oral administration of SB-462795 at 3 mg/kg to normal female monkeys for 5 days resulted in a progressive inhibition of resorption that was maximal on Day 5 (57%). After termination of dosing, both serum and urinary NTx returned to near control levels within 48 hours. In summary, both *in vitro* and *in vivo* data indicate that SB-462795 potently inhibits human catK in osteoclasts, resulting in bone resorption inhibition both *in vitro* and in the monkey *in vivo*. I*n vivo* bone resorption inhibition was measurable very rapidly after compound administration using validated markers of bone resorption, suggesting that SB-462795 will be effective at inhibiting the elevated bone resorption seen in post-menopausal osteoporosis. Furthermore, activity can be rapidly monitored by biochemical markers of bone resorption, suggesting that measurement of these markers should prove beneficial in monitoring clinical efficacy.

Bone Loss Following Ovariectomy in Cathepsin K Knockout Mice Is Attenuated by a Broad-Spectrum Matrix Metalloproteinase Inhibitor. S. J. Hoffman, P. Liang, C. A. Capriotti, J. A. Vasko-Moser, S. Kumar, G. B. Stroup. GlaxoSmithKline, King of Prussia, PA, USA.

Cathepsin K (catK), a cysteine protease, plays an essential role in osteoclast mediated degradation of bone organic matrix. Knockout of the enzyme in mice and lack of functional enzyme in the human condition pycnodysostosis result in osteopetrosis. Recent evidence suggests that proteinases other than catK play a role in bone loss following ovariectomy in aged mice and that catK may play more of a developmental role in bone turnover in this species. Prinomastat (AG3340) is a broad-spectrum, synthetic, nonpeptide, matrix metalloproteinase (MMP) inhibitor with selective inhibitory activity against MMPs 2, 9, 3, and membrane type-MMP1. In this study, effects of Prinomastat on bone were evaluated in catK deficient mice following ovariectomy (Ovx). Four month old catK deficient mice were randomized based on body weight into the following groups: baseline; sham + vehicle (acidified water, pH2.5) bid po; Ovx + vehicle bid po; Ovx + Prinomastat at 10 mg/kg bid po; and Ovx + Prinomastat at 30 mg/kg bid po. Baseline groups received no treatment or surgery and were euthanized on day 0. Dosing was initiated on day 1 post-surgery and continued for 8 weeks. Primary measures were histomorphometry of the proximal tibia and mid-femur and micro-computed tomography (micro-CT) of the 3rd lumbar vertebrae. Following Ovx, %Tb.Ar in the proximal tibia was significantly reduced relative to sham control animals. Prinomastat treatment resulted in 19% (ns) and 52% ($p=0.05$) protection of this loss at 10 and 30 mg/kg, respectively, and dose-dependent trends toward greater trabecular thickness and number, although these changes were not significant compared to Ovx controls. No significant effects due to Ovx or treatment were observed on bone formation or resorption rates (% eroded perimeter). MicroCT analysis of trabecular bone in the 3rd lumbar vertebrae showed lower BV/TV in Ovx (0.30) versus sham (0.34) mice (ns). Prinomastat treatment resulted in a higher BV/TV, 0.32 (ns) and 0.38 ($p<0.05$) at 10 and 30 mg/kg, respectively, than in Ovx control animals. Gains in BV/TV were due to increased Tb.Th and TB.N. The high dose of Prinomastat also significantly reduced the Structure Model Index (-0.26 vs. -1.49 for the Ovx and Prinomastat 30 mg/kg groups, respectively, $p < 0.01$) suggesting that Prinomastat treatment results in a more mechanically stable structure. In conclusion, Prinomastat prevented Ovx-induced trabecular bone loss. Contrary to the pronounced anti-resorptive effects of catK inhibitors in estrogen deficient monkeys, these data suggest that MMPs compensate and play a major role in trabecular bone turnover following ovariectomy in catK deficient mice.

SB-462795, a Cathepsin Inhibitor, Prevents the Loss of Bone Mass at Several Sites in Ovariectomized Cynomolgus Monkeys. G. Stroup[1], C. Jerome[2], D. S. Yamashita[1], S. Kumar[1]. [1]GlaxoSmithKline, King of Prussia, PA, USA, [2]SkeleTech, Bothell, WA, USA.

Cathepsin K has been shown to play an important role in bone matrix degradation during osteoclastic bone resorption. We tested the ability of SB-462795, a novel, potent inhibitor of cathepsins K, L and V, to prevent loss of bone mass at several sites in aged ovariectomized (Ovx) female monkeys following oral delivery, and compared SB-462795 to IV alendronate. After collection of baseline data, adult female cynomolgus monkeys were randomized to 6 groups of 20 each, of which one was sham-ovariectomized (Sham) and the remainder Ovx. Ovx animals were treated with vehicle, SB-462795 at 1, 3, or 10 mg/kg/d by gavage, or oral vehicle plus alendronate at 0.05 mg/kg by IV injection once every 2 weeks for 9 months. All statistical comparisons are with Ovx, vehicle-treated animals. DXA analysis showed a significant ($p<0.001$) difference in aBMD between Sham and Ovx groups at the lumbar spine and proximal and distal femur after 9 months. Animals treated with SB-462795 had dose-dependent improvement in aBMD at the lumbar spine and proximal and distal femur. Protection from the relative loss of aBMD was observed with the high dose of SB-462795 at all three sites. At the distal femur SB-462795 prevented 73% of the loss in aBMD ($p<0.01$) while alendronate showed a non-significant 23% protection ($p>0.1$). At the proximal femur the level of protection by the two agents was 35% and 34%, respectively ($p < 0.1$). At the lumbar spine, SB-462795 protected 42% ($p<0.1$) while alendronate protected 100% ($p<0.001$) of the loss in aBMD. Femoral neck analysis using pQCT showed a similar level of protection of total vBMD by SB-462795 (58%, $p<0.05$) and alendronate (51%), but the latter was not statistically significant ($p>0.1$). Total BMC was significantly improved by SB-462795 (40%, $p<0.05$) but not by alendronate (24%, $p>0.1$). Both agents had a similar, positive effect on trabecular vBMD and BMC. Ovariectomy caused a 0.9% decrease in cortical area at the femoral neck. Treatment with SB-462795 at the high dose increased cortical area by 6.7% ($p<0.1$). A non-significant 2% increase in cortical area was observed with alendronate treatment. SB-462795 significantly improved cortical BMC (56% protection, $p<0.05$) but alendronate did not (25% protection, $p>0.1$). In conclusion, SB-462795 significantly prevented bone loss at several sites in Ovx monkeys. Femoral neck pQCT analysis indicated that, compared to alendronate, SB-462795 had a similar effect on trabecular bone but a more positive effect on cortical bone at this site. These data suggest site-specific differences in activity between bisphosphonates and cathepsin inhibitors that could potentially translate into differential efficacy.

Matrix Metalloproteases from Cells of the Osteoclastic Lineage Resorb Demineralized Collagen in the Absence of Cathepsin K Activity. K. Henriksen[1], M. G. Sørensen*[1], R. H. Nielsen*[1], M. H. Dziegiel*[2], S. Schaller*[1], M. A. Karsdal[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]HS Blodbank, National University Hospital, Copenhagen, Denmark.

Loss of activity of the cystein proteinase cathepsin K leads to the disease pycnodysostosis, a disease characterized by defective osteoclastic degradation of type I collagen without impairment of dissolution of the inorganic phase of bone. Recent evidence suggest that degradation of the organic matrix takes place in the cathepsin K deficient individuals, however the molecular rational for this remains to be investigated. To investigate the osteoclastic proteolytic ”machinery”, we isolated CD14 positive monocytes from peripheral blood from humans, and cultured them in the presence of 25ng/ml RANKL and M-CSF to induce osteoclastogenesis. Mature osteoclasts were seeded on normal cortical calcified bone slices or bone slices decalcified with EDTA and cultured in the presence or absence of either the cystein protease inhibitor E64 or the Matrix Metalloproteinase (MMP) inhibitor GM6001 alone or in combination. We found that E64 completely blocked the release of the C-terminal crosslinked telopeptide of type I collagen (CTX) on calcified bone, as expected. In alignment GM6001 only inhibited the CTX release by 10-15%, confirming that the main protease involved in bone degradation under normal circumstances is Cathepsin K. In sharp contrast, when decalcified bone was used, MMP activity was responsible for 70-80% of the CTX fragments in face of 20-30% arising from Cathepsin K activity. To further investigate the release of extracellular matrix protease generated collagen fragments, we tested the release of the carboxyterminal telopeptide of type I collagen (ICTP), on both normal and decalcified bone in the presence and absence of protease inhibitors. On calcified bone, the release of ICTP was detected only when cathepsin K was inhibited. In addition, the release of ICTP in the presence of E64 was dose-dependently inhibited by GM6001, confirming that MMPs from cells of the osteoclastic lineage can release this fragment. On the decalcified bones, the ICTP fragment was released by the osteoclasts in the absence of inhibitors, and the release could be completely abrogated by the addition of GM6001, further confirming that MMPs are

important for the degradation of the decalcified bones. In conclusion, we have shown that MMPs are likely to play a role in the compensation for the loss of cathepsin K activity in the function of human osteoclasts.

Tropomyosin Isoforms Localize to Distinct Microfilament Populations in Osteoclasts. B. McMichael*[1], P. Kotadiya*[1], L. S. Holliday[2], B. S. Lee[1]. [1]Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA, [2]Orthodontics, University of Florida, Gainesville, FL, USA.

Osteoclasts are highly motile cells that transiently adopt a polarized phenotype during bone resorption. Because of the fluidity in cell shape associated with these processes, osteoclasts possess a dynamic cytoskeleton that contains specialized actin structures involved in motility (podosomes) and attachment during bone resorption (an F-actin ring surrounding the ruffled membrane). Here we have examined osteoclasts for the expression and distribution of tropomyosins, which are actin-binding proteins that regulate the stability of microfilaments and regulate their access to other proteins such as gelsolin, cofilin, Arp2/3, and myosins. Through Western analysis, immunocytochemistry, and RT-PCR, we assayed for the presence of 16 nonmuscle, nonbrain tropomyosin isoforms, and detected 6 that were expressed at moderate to high levels. Several of these were up-regulated during osteoclast differentiation. Immunocytochemical analysis showed that the isoforms were localized to distinct F-actin pools. One of these, Tm-4, co-localized with the actin core of podosomes, in addition to the peripheral and dorsal microfilaments of actin rings. Two similar tropomyosins, Tm-5a and -5b, were up-regulated during osteoclast differentiation, and associated with peripheral structures of podosomes instead of the actin core, but had a distribution similar to Tm-4 in actin rings. Tms -2 and -3, which are not expressed in macrophages, were expressed at moderate levels in osteoclasts. These were more generally distributed through the cells than other isoforms, but showed some enrichment near regions of podosomes. They also were intercalated loosely into the dorsal microfilaments of actin rings. These results demonstrate that tropomyosin isoforms are involved in the attachment structures of osteoclasts, and are likely to play specific roles in regulation of critical microfilament pools.

Suppression of Nonmuscle Myosin IIA in Differentiating Osteoclast Cultures Affects Cell Adherence and Multinucleation. B. McMichael*[1], P. Kotadiya*[1], R. B. Wysolmerski*[2], B. S. Lee[1]. [1]Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA, [2]Pathology, St. Louis University, St. Louis, MO, USA.

We previously demonstrated that the nonmuscle myosin isoform IIA is associated with attachment structures of osteoclasts. This motor protein co-localizes with the actin core of podosomes and with the actin ring surrounding the ruffled border of polarized osteoclasts (the sealing zone). To define potential roles of myosin IIA in cell adhesion, we suppressed its expression via RNA interference technology. RAW 264.7 macrophages were induced to differentiate into osteoclasts by addition of RANKL, and were transfected with siRNAs when osteoclast formation first became evident (about day 4 of culture). Both inhibition of the corresponding mRNA and an altered cellular phenotype were demonstrable by two days following introduction of siRNAs. siRNA-treated cells that were lifted from their surface and re-plated demonstrated a diminished capacity to attach to either glass or bone substrates. Further, siRNA-treated cells were much larger in diameter and contained significantly greater numbers of nuclei than mock-treated cells. Finally, siRNA-treated cells generated dramatically more F-actin rings than mock-treated cells on bone. These results suggest that myosin IIA is required for appropriate attachment of osteoclasts, and may exert a suppressive effect on motility (affecting the extent of cell fusion) and sealing zone formation.

Osteoclasts and Mother Of Pearl Resorption: *In Vivo* and *In Vitro* Studies. D. Duplat*[1], A. Chabadel*[2], M. Gallet*[3], O. Delattre*[4], S. Berland*[1], L. Bédouet*[1], C. Milet*[1], M. Brazier[3], S. Kamel*[3], P. Jurdic[2], E. Lopez*[1]. [1]DMPA, Muséum National d'Histoire Naturelle, Paris, France, [2]LBMC, ENS-Lyon, Lyon, France, [3]UMRO, Faculté de Pharmacie, Amiens, France, [4]Service Orthopédie, CHRU, Fort de France, France.

The nacre, mother-of-pearl, from the shell of the oyster *Pinctada margaritifera* is composed of calcium carbonate crystallized in aragonite tablets forming a lamellar structure. Our previous studies have demonstrated that the nacre exhibited biological activity on bone stem cells and osteoblasts and induced bone formation. Since bone remodelling is a balance between resorption by osteoclasts and new bone formation by osteoblasts, we wonder what happens when osteoclasts meets nacre? *In vitro* and *in vivo* studies were performed to consider mammalian osteoclasts in the nacre resorbing process. *In vivo* studies were performed on 14 sheep femurs implanted with raw nacre for 3 to 9 months. The femurs containing the implants were dissected out and subjected to histological study and morphometry to assess the changes that had occurred at the bone and nacre interface. Raw nacre implants persist even after 9 months of implantation into bone tissue in sheep. However the nacre surface undergoes a limited biodegradation process, smooth-surfaced nacre implants were seen to become microporous after implantation. The nacre surface resorption process was investigated using *in vitro* studies. CD14 cells (osteoclast precursors) were experimentally differentiated and osteoclasts isolated from 10 days old rabbit long bones were both seeded on nacre slices. Osteoclasts on nacre were observed for adhesion and resorption by Scanning Electron Microscopy. The osteoclast cytoskeleton organization was analysed on osteoclast precursors isolated from 6 weeks old mouse spleen seeded on nacre slices. The *in situ* cell localization of F-actin and vinculine was investigated using confocal microscopy to point out adhesion and resorption activities. Osteoclasts from human, rabbit and mouse can adhere and resorb nacre. However the setting of the sealing zone and consequently the osteoclast activity depend on the orientation of the aragonite tablets facing the osteoclasts as shown by *in vitro* studies. It arises that nacre *in vivo* can also be subjected to resorption by osteoclast activity. In that case, the size and shape of the nacre are key factors in determining the nacre implant biodegradation rate and kinetics by osteoclasts.

Guanylyl Cyclase and cGMP-Dependent Protein Kinase I Induce Calcium and Calpain-Dependent Cytoskeletal Rearrangement in Osteoclasts, but Calcium Signals Are not Sufficient to Initiate Motility. B. B. Yaroslavskiy*, S. E. Kalla*, A. C. Sharrow*, H. C. Blair. Pathology and of Cell Biology and Physiology, University of Pittsburgh, and Veteran's Affairs Medical Center, Pittsburgh, PA, USA.

Osteoclasts are highly regulated motile cells. Motility and survival respond to signals including the CSF-1, via fms, and nitric oxide (NO). Osteoclast survival is regulated by NO-generated free radicals, but at moderate NO activity, cGMP generation by the NO-dependent guanylyl cyclase is the predominant osteoclast NO regulatory mechanism. Downstream, the cGMP-dependent protein kinase I (PKG I) induces motility via phosphorylation of the adaptor protein VASP. VASP directs the NO signal to the podosomal complex that is also regulated by other motility signals, and regulates detachment. However, VASP phosphorylation by PKG I is insufficient for motility. We observed by Ca^{2+} imaging of human osteoclasts that, after NO/cGMP activation, Ca^{2+} currents occur at the detachment (trailing edge). This suggested Ca^{2+}-activated proteinase activity. Gene screening showed that osteoclasts express the Ca^{2+}-activated proteinases, M- and μ-calpain, the latter commonly active in cytoskeletal rearrangement for motility after Y-kinase receptor stimulation. Zymography and fluorescent calpain substrates in situ showed that μ-calpain was consumed after PKG I activation, and motility was blocked by calpain inhibitors. In contrast, Ca^{2+}-induced contraction was caused by ionomycin at sublethal concentrations or by 20 mM supernatant Ca^{2+}, but Ca^{2+} was insufficient to initiate detachment, indicating that upstream signals with direct effects on attachment structures are also required. Sequential fluo3 imaging to showed that Ca^{2+} increases and cell contraction were concurrent. NO increased src tyrosine phosphorylation, but surprisingly the PI-3-kinase/p-Akt pathway did not appear to be activated, in contrast to expectations based on post-Y-kinase receptor mechanisms. In ionomycin plus NO, osteoclasts detached, while after NO synthase inhibitors or PKG I inhibitors, cells shrank ~20% in ionomycin but did not detach. In no case was motility induced by artificial Ca^{2+} fluxes, which caused cells to retract symmetrically, while calcium fluxes by dual wavelength ratio imaging in NO treated osteoclasts were asymmetrical and occurred at attachments. We conclude that NO-induced motility requires Ca^{2+} fluxes related to detachment, that p-src is probably an intermediate, and that downstream Ca^{2+} signals function in cytoskeletal rearrangement whether motility is initiated by NO or other mechanisms such as integrin or Y-kinase receptors. On the other hand, Ca^{2+} currents alone are insufficient to initiate motility.

$\alpha_9\beta_1$ Integrin Signaling Is Required for Normal Osteoclast Activity. H. Rao[1], V. Garcia Palacios[1], D. Sheppard*[2], J. Anderson*[1], K. Patrene*[1], S. J. Choi[3], H. C. Blair[4], G. D. Roodman[1]. [1]Medicine-Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Medicine, University of California at San Francisco, San Francisco, CA, USA, [3]National Institute of Dental and Craniofacial Research, Bethesda, MD, USA, [4]Pathology, University of Pittsburgh, Pittsburgh, PA, USA.

Recently, we found that $\alpha_9\beta_1$, a previously unknown integrin expressed on osteoclasts (OCL) and OCL precursors, is a receptor for a disintegrin and metalloproteinase (ADAM) 8. ADAM8 is a novel stimulator of OCL differentiation whose disintegrin domain mediates its effects on OCL formation. ADAM8 does not bind $\alpha_v\beta_3$ integrin. To access $\alpha_9\beta_1$ integrin regulates osteoclastogenesis and bone resorption, we measured OCL formation in bone marrow cultures and performed bone histomorphometry on vertebrae from 7 day old α_9 knockout (-/-) and wild type (WT) mice. α_9-/- mice die of chylothorax at about 10 days of age. Normal numbers of OCLs formed in α_9-/- marrow cultures, but the OCLs were smaller and more contracted compared to WT. Analysis of the bone resorption capacity and cytoskeleton of α_9-/- OCLs formed in vitro showed they formed fewer resorption pits and failed to form normal actin rings compared to WT. Importantly, treatment of bone marrow cultures from β_3 integrin -/- mice with ADAM8, partially rescued the abnormal OCL cytoskeletal of the β_3-/- OCL. ADAM8 treatment of α_9-/- bone marrow cultures failed to rescue the abnormal α_9-/- OCL cytoskeleton. Histologic analysis of α_9-/- vertebrae showed thickened trabecular regions and retained cartilage within vertebral bodies of α_9-/- mice. Three dimensional μqCT analysis of α_9-/- vertebrae also

showed a significant increase in trabecular bone volume/ total tissue volume (WT=16%±1.6; -/-= 20%±4.1; p=0.04), and a tendency of decreased trabecular separation (p=0.06) compared to WT mice. These results suggested that $\alpha_9\beta_1$ is required for normal OCL activity. We then determined how $\alpha_9\beta_1$ might signal in OCL. Previous reports showed that the α_9 integrin cytoplasmic domain binds to paxillin in Chinese Hamster Ovary cells. OCLs express paxillin which is phosphorylated on multiple tyrosine and serine residues in response to cell adhesion, and /or exposure to various soluble growth factors and cytokines. Therefore, we determine if α_9 integrin transduced signals through paxillin. Serum starved OCL precursors from WT and α_9-/- were exposed to ADAM8 or vehicle for 10 to 30 minutes. Immunoblot analysis showed transient tyrosine phosphorylation (pY118) of paxillin after 10 min of ADAM8 stimulation of WT, but not α_9-/- OCL. These results support an important role for $\alpha_9\beta_1$ integrin in OCL formation and function that is independent of $\alpha_v\beta_3$ activity.

Actin Assembly Induced by Cortactin Is Essential for Osteoclast to Resorb Bone. R. Faccio[1], S. Tehrani*[2], J. A. Cooper*[2]. [1]Department of Orthopaedic Surgery, Washington University, St. Louis, MO, USA, [2]Department of Cell Biology, Washington University, St. Louis, MO, USA.

Osteoclasts are essential for bone dynamics and calcium homeostasis in vertebrates. Osteoclasts form a tight seal on the bone surface, onto which they secrete acid and resorb bone. The sealing zone contains actin filaments and is presumed to assemble from podosomes, which also contain actin. Cortactin, a c-Src substrate, promotes Arp2/3-mediated actin assembly, is expressed in osteoclasts, and localizes to podosomes. We found that cortactin expression went from undetectable to substantial levels during osteoclast differentiation. To address the role of cortactin and actin assembly in osteoclasts, we depleted cortactin in osteoclasts by RNA interference. Cortactin-depleted osteoclasts had no podosomes, failed to make sealing zones, and did not resorb bone. The cells were normal in other respects, such as size, shape, motility and differentiation markers. We found that cortactin localizes to the nascent podosome, followed by actin assembly. Thus, cortactin has a critical role in osteoclast function related to regulation of podosomes and sealing zones formation, via Arp2/3-mediated actin assembly at the sealing zone.

Thyrotropin (TSH) Differentially Regulates TNFα Expression in Osteoclast and Osteoblast Progenitors. H. Hase*[1], L. Liu*[1], A. Brebene*[1], Y. Peng*[1], H. Amano[2], E. Abe[1]. [1]Medicine, Mt. Sinai School of Medicine, New York, NY, USA, [2]Pharmacology, Showa University School of Dentistry, Tokyo, Japan.

We have provided evidence that thyrotropin (TSH) inhibits bone remodeling and TSH receptor (TSHR) null mice exhibit an osteoporotic phenotype resulting from enhanced osteoclastogenesis and osteoblastogenesis. Our preliminary studies indicated that the enhanced osteoclastogeneisis in the TSHR null mice is due to upregulated expression of TNFα and TNF receptor (TNFR) type I and II. TNFα is known to enhance osteoclast but suppress osteoblast differentiation. We therefore examined the mechanisms by which RANK-L and inflammatory cytokines upregulate TNFα and TNFR, and whether the overexpression of TSHR or caTSHR (constitutively active form of TSHR) in osteoclast and osteoblast progenitors affects TNFα expression and cell differentiation. TSHR expression is temporally upregulated during osteoclast and osteoblast differentiation. RANK-L and certain inflammatory cytokines such as IL-1α/TNFα, lipopolysaccharide (LPS) and phorbol 12-myristate 13-acetate (PMA) enhanced TNFα expression in bone marrow macrophages ($CD11b^+$) and RAW-C3 cell cultures, and these enhanced expression levels were suppressed by treatment with TSH. Overexpression of TSHR and caTSHR in bone marrow macrophages and RAW-C3 cells suppressed TNαF expression under basal and also RANK-L-stimulated conditions. As expected, the effective dose of TSH in osteoclast inhibition was lowered in cells overexpressing TSHR. Interestingly, RANK-L-induced osteoclast formation was completely abolished in cells overexpressing caTSHR. We next examined the effects of cytokines and TSH on TNFα expression and cell differentiation in osteoblasts. TSH itself significantly enhanced TNFα expression in bone marrow stromal cells ($CD106^+$) and calvarial osteoblasts. Overexpression of TSHR and caTSHR in OB6 cells and calvarial osteoblasts also exhibited enhanced TNFα expression without the addition of TSH. In addition, the cells overexpressing caTSHR exhibited inhibition of BMP4-dependent osteoblast differentiation. These results suggest that TNFα plays a critical role in the inhibition of osteoclast and osteoblast differentiation induced by TSH and that the TNFα regulatory mechanisms are likely to be distinct in osteoclast and osteoblast progenitors.

Treatment of Bone Cancer in Mice Transgenic for Cytosine Deaminase Regulated by the TRAP Promoter. M. Ramnaraine, W. Pan*, J. M. Donohue*, C. M. Lynch*, D. Clohisy. Orthopaedic Surgery, University of Minnesota, Minneapolis, MN, USA.

In this investigation we describe an osteoclast-mediated, tumor-targeted gene therapy which affects osteoclasts and cancer cells. Using the cytosine deaminase (CD)/5 fluorocytosine (5FC) prodrug system, we demonstrate effectiveness in vitro and in vivo. Osteoclast-specific delivery was achieved using a transgenic mouse containing the CD gene regulated by the tartrate-resistant acid phosphatase promoter (Tg/TRAP-CD). In this system, 5FC treatment of CD-expressing osteoclasts caused direct killing of osteoclasts and bystander killing of cancer cells. In vitro, osteoclasts from BM of Tg/TRAP-CT or WT mice were exposed to 5FC, resulting in a dose-dependent decrease in osteoclast number in all Tg/TRAP/CD ($p < 0.001$) compared to WT osteoclast cultures. Co-culture of Tg/TRAP-CD or WT osteoclasts with tumor cell lines showed reduction in sarcoma and breast cancer cells in Tg/TRAP-CD co-culture systems ($p < 0.001$) but not systems of tumor cells co-cultured with WT BM. In vivo, Tg/TRAP-CD mice received osteolytic bone sarcoma that after 5FC treatment resulted in elimination of tumor ($p < 0.001$) and reduction in osteoclast number. These studies provide the basis for developing a treatment for primary or metastatic bone cancers which would simultaneously kill tumor cells and eliminate osteoclast-mediated bone destruction.

IL-12 and IL-18 Require IFN-γ and GM-CSF Signaling, and Are Essential for Normal Bone Remodeling and Bone Mass. N. A. Sims[1], D. Mirosa*[2], J. M. W. Quinn[2], N. J. Horwood*[2], M. J. Smyth*[3], M. T. Gillespie*[2]. [1]Dept of Medicine, The University of Melbourne, Fitzroy, Australia, [2]Bone, Joint and Cancer Group, St Vincent's Institute, Fitzroy, Australia, [3]Peter MacCallum Cancer Research Institute, Melbourne, Australia.

Interleukin-18 (IL-18) is a pleiotropic factor that shares structural features with IL-1 and functional activities with IL-12. IL-18 is expressed by osteoblasts and has been reported to inhibit *in vitro* osteoclast formation by acting upon T cells to promote GM-CSF production. In addition to its ability to enhance GM-CSF production, it also increases IFN-γ, another osteoclast inhibitor. Like IL-18, IL-12 is also an inhibitor of osteoclast formation as a result of its actions on T lymphocytes. When combined, IL-12 and IL-18 are powerful synergistic inhibitors of osteoclast formation. As IL-12 and IL-18 both increase IFN-γ and GM-CSF production we examined the contribution of IFN-γ and GM-CSF in the IL-12 and IL-18 responses. In *in vitro* osteoclast formation assays, a neutralising antibody to GM-CSF demonstrated that IL-18 acted through GM-CSF alone, but this antibody only partially rescued IL-12-induced osteoclast formation. Similarly, a neutralising IFN-γ antibody partially rescued IL-12-induced osteoclast formation, and combination of both GM-CSF and IFN-γ neutralising antibodies provided 50% rescue of the IL-12-induced osteoclast formation. However, the combination of GM-CSF and IFN-γ neutralising antibodies completely rescued osteoclast formation from inhibitory synergistic doses of IL-12- and IL-18, demonstrating a requirement for both GM-CSF and IFN-γ for the action of these two interleukins at synergistic doses, but implicating another inhibitor in response to IL-12 alone. Since both IL-12 and IL-18 are expressed in bone, we investigated their involvement in normal bone development, growth, and remodeling, by performing histomorphometric analyses of mice deficient in IL-12, in IL-18, and in both IL-12 and IL-18. No gross skeletal abnormalities were evident in these mice. Histomorphometry revealed an ageing-related osteopenia in each of these knockout mice. While only the IL-18 null mice demonstrated a significant reduction in trabecular bone volume at 10 weeks of age, by 6 months of age, in all three knockouts, both trabecular bone volume and trabecular number were approximately half that of wild type controls. Notably, the phenotype was not more severe in mice deficient in both IL-12 and IL-18 compared to the single IL-12 or IL-18 null mice. These results underscore a central role of IL-12 and IL-18, as well as T lymphocytes, in normal skeletal development.

Expression and Regulation of Resistin in Osteoblasts and Osteoclasts Indicate a Role in Bone Metabolism. K. Stunes*[1], L. Thommesen*[2], M. Monjo*[3], K. Grøsvik*[1], M. Tamburstuen*[3], E. Kjøbli*[2], S. Lyngstadaas*[3], J. Reseland*[3], U. Syversen[1]. [1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [2]Sør-Trøndelag University College, Faculty of Medical Technology and Food Science, Trondheim, Norway, [3]Oral Research Laboratory, Institute for Clinical Dentistry, University of Oslo, Oslo, Norway.

Recent studies have indicated that hormones from adipose tissue possess several biological functions. Leptin and adiponectin have previously been shown to be expressed and regulated in bone cells. In the present study we explore the role of resistin in bone metabolism, using murine preosteoblasts and osteoclasts (MC3T3-E1, RAW 264.7) and primary human bone marrow stem cells, osteoblasts and osteoclasts as model systems. We find that resistin is expressed in the murine osteoclast RAW 264.7 and preosteoblast MC3T3-E1 cell lines, in primary human bone marrow stem cells and in differentiated human osteoblasts. The expression of resistin mRNA in RAW 264.7 is regulated through PKC and PKA-dependent mechanisms. Recombinant resistin enhanced the proliferation of preosteoblasts, and the alkaline phosphatase activity in the medium, as well as the expression of collagen mRNA in osteoblasts. Resistin also enhances the number of differentiated osteoclasts. In RAW 264.7 cells transfected with NFκB reporter plasmid, resistin increased the promoter activity. In addition to the direct effect on osteoclasts, resistin increased the OPG to RANKL ratio and the secretion of IL-6 from osteoblasts, indicating an indirect effect on osteoclast differentiation and activity. Taken together our results indicate that resistin is involved in bone remodelling via paracrine and/or autocrine mechanisms.

TNF Induces Oscillatory and Combinatorial Transcription Factor-DNA Binding: A Requirement for Sustained Gene Expression. J. Iqbal*, M. Zaidi. Medicine, Mt. Sinai School of Medicine and the Bronx VA GRECC, New York, NY, USA.

It has been shown recently that the activation and nuclear translocation of the NF-κB subunit p65 occurs in cycles.[1,2] Nonetheless, it is thought that NF-κB must persistently bind to DNA to induce gene expression. Here, we show for the first time that TNF induces oscillations in NF-κB binding to DNA; that this oscillatory binding is combinatorial; and that the persistence of such oscillations results in sustained gene expression. We analyzed the binding of both NF-κB and c-jun transcription factors to the promoters of target genes, CD38 (an ADP-ribosyl cyclase) and IκBα (an NF-κB inhibitor). Using a combination of chromatin immunoprecipitation (ChIP) assays and real-time PCR, we quantified transcription factor-DNA binding at 15 minute intervals for 7 hours. TNF application to primary bone marrow macrophages resulted in NF-κB recruitment to target promoters with a periodicity of ~3 hours and sustained binding amplitudes. Mathematical modeling suggested that both periodicity and sustained amplitudes arise from the large cytoplasmic-to-nuclear volume of primary macrophages. We also found that c-jun binding to the CD38 promoter was oscillatory with a temporal sequence that overlapped substantially with p65 and p50. To confirm this overlap, we re-ChIPed the CD38 promoter at 0 and 3 hrs post-TNF. TNF induced several combinatorial patterns of binding; for example, p65, p50 and c-jun bound simultaneously with the co-activator Brg-1. In contrast to the CD38 promoter, p65 was the only major oscillatory protein for the IκBα promoter; this substantiates previous findings indicating that p65 is necessary and sufficient for IκBα up-regulation.[3] We next explored transcription factor-DNA binding in response to RANK-L, a member of the TNF superfamily that induces similar signaling pathways to TNF, but with distinct effects on gene transcription. Notably, we found that both CD38 and IκBα mRNA levels were persistently elevated with TNF, but only transiently with RANK-L. This difference was consistent with a single wave of p65, p50 and c-jun binding to target promoters post RANK-L, but with a failure of this binding to oscillate. The results show that oscillatory transcription factor-DNA binding is critical for assembling combinatorial complexes required for cytokine-induced gene expression. Furthermore, differences in the expression of genes induced by closely related cytokines could be explained by their ability to sustain these oscillations.[1]Hoffman, A. (2002) Science 298: 1241-5; [2]Nelson, D.E. (2004) Science 306: 704-8; [3]Hoffman, A. (2003) EMBO J. 22: 5530-9.

c-Fos/NFAT1- or 2-Mediated Osteoclastogenesis Requires NF-κB p50/p52 Expression. Z. Yao[1], K. Matsuo[2], R. Nishimura[3], L. Xing[1], B. Boyce[1]. [1]University of Rochester Medical Center, Rochester, NY, USA, [2]Keio University, Tokyo, Japan, [3]Osaka University, Osaka, Japan.

Expression of the transcription factors, NF-κB, c-Fos, and NFAT, in cells in the osteoclast (ocl) lineage is essential for differentiation of ocl precursors to mature ocls. However, the relationship among NF-κB, c-Fos and NFAT during ocl precursor differentiation is unknown. To study this issue, we used NF-κB p50/p52 double knockout (dKO) and wild-type (wt) splenocytes and a retrovirus gene transfer approach. First, we examined the temporal expression pattern of c-Fos and NFATs1-4, using real time PCR during RANKL-mediated osteoclastogenesis from wt splenocytes. RANKL increased c-Fos mRNA expression in M-CSF-dependent splenic ocl precursors at 8 hrs. This peaked at 24 hrs, prior to multi-nucleated ocl formation, and declined when mature ocls began to form at 48 hrs. In contrast, expression of NFAT1 and 2 mRNA paralleled ocl formation, being up-regulated at 48 hrs, peaking at 72 hrs when mature ocl numbers were highest and decreasing at 96 hrs when ocls were dying off. NFAT3 expression did not change and NFAT4 levels were very low. Next, we examined the effect of RANKL on c-Fos and NFAT expression in NF-κB dKO cells: RANKL failed to induce c-Fos or NFAT up-regulation. c-Fos over-expression rescued RANKL-mediated osteoclast formation and NFAT2 protein expression in NF-κB dKO cells, but did not induce ocls by itself. In contrast, NFAT1 or NFAT2 retrovirus infection alone, unlike c-Fos or NF-κB p50 and p52 over-expression, induced small numbers of TRAP+ ocls from dKO cells. Addition of RANKL or IL-1 induced more ocls (61±5 and 124±15 /well, respectively, for NFAT1; and 149±31 and 145±34 for NFAT2, vs 0±0 for GFP-infected cells). Furthermore, NFAT1 or NFAT2 over-expression alone induced numerous mononucleated TRAP+ cells. Finally, over-expression of NFAT1 or NFAT2 plus IL-1 induced ocl formation from wt splenocytes in the absence of RANKL (21±3 in NFAT1-, 97±18 in NFAT2-, vs 0±0 in GFP-infected cells). In summary, 1) NF-κB p50 and p52 expression is required in ocl precursors for RANKL-induced c-Fos and NFAT1 or 2 expression, and c-Fos precedes NFAT expression; 2) NFAT1 or 2 can substitute for NF-κB, inducing ocl formation from NF-κB dKO splenocytes alone or along with IL-1, independent of RANKL; and 3) cytokines, including RANKL and IL-1, are indispensable for ocl formation induced by c-Fos, but not by NFATs from NF-κB dKO splenocytes. We propose a "temporal" model in which NF-κB increases c-Fos expression in ocl precursors, which results in induction of NFATs1 and 2 and differentiation of TRAP+ cells. Cytokines promote the translocation of these over-expressed transcription factors to ocl nuclei and subsequent ocl maturation.

RANK Deficiency in the Hematopoietic Compartment Alters the Development of Osteoclasts but not Other Hematopoietic Lineages. C. Jacquin[1], S. K. Lee[2], J. A. Lorenzo[2], H. L. Aguila*[1]. [1]Department of Immunology, UConn Health Center, Farmington, CT, USA, [2]Department of Medicine, UConn Health Center, Farmington, CT, USA.

Interactions of RANKL and RANK play a crucial role in the development of both normal bone and hematopoietic tissues. RANK and RANKL deficient mice display a severe osteopetrotic phenotype due to the lack of mature osteoclasts. In addition, these mice demonstrate alterations in the organization of peripheral lymphoid organs and in the development of T and B lymphocytes. To determine whether the hematopoietic abnormalities observed in RANK deficient (RANK -/-) mice are cell autonomous or due to a defective bone microenvironment, we generated bone marrow (BM) chimeric mice by transplanting unfractionated splenocytes from 3-4 week old RANK-/- neonates in a C57BL/6 background (or unfractionated BM cells from wild-type (WT) littermates as control) into lethally irradiated 9-10 week old WT C57BL/6 mice, which were congenic for the CD45 allelic marker. Animals were allowed to recover for at least 11 weeks. Completeness of engraftment, as assessed by flow cytometry, was typically >90%. Flow cytometric analysis of multiple hematopoietic organs showed no significant differences in the development of T, B, dendritic or natural killer cells between RANK-/-→WT and WT→WT chimeras. We also assessed the bone mineral density of tibias and femurs of individual mice from RANK-/-→WT and WT→WT chimeras using DEXA and micro-CT at weeks 11, 17 and 26 post transplantation and found that both groups maintain a similar bone marrow volume at all three time points. Finally, we determined the ability of total BM preparations from both groups (11 weeks post-transplant) to form osteoclast-like cells (OCLs) *in vitro* in the presence of M-CSF and RANKL. Total BM preparations (5,000 or 75,000 cells per well) from individual mice of both groups were plated for 4 or 8 days with 30ng/ml of M-CSF and RANKL. In the WT→WT chimeras, OCLs formed readily (427 ± 46 OCLs per 5,000 plated cells in 4-day cultures), in contrast, BM preparations from RANK-/-→WT were very inefficient at forming OCLs *in vitro* (7 ± 4 OCLs per 75,000 plated cells in 8-day cultures). In conclusion, we find that the hematopoietic abnormalities observed in RANK -/- mice were not present in the RANK-/-→WT chimeras, which unlike RANK -/- mice have a bone marrow cavity. This data suggests that the defects in immune cells in RANK -/- mice are due to their lack of a BM microenvironment. The only deficiency that we observed in RANK-/-→WT chimeras was a defect in osteoclast development. RANK-/-→WT chimeras likely maintain their bone marrow cavity because of decreased turnover in this model.

NFATc1 Mediates RANKL Induction of the β3 Integrin in Osteoclasts. T. N. Crotti, M. R. Flannery*, J. D. Fleming*, S. R. Goldring, K. P. McHugh. Rheumatology and Orthopaedics, BIDMC and Harvard Medical School, Boston, MA, USA.

NFATc1 is a RANKL-induced transcriptional mediator of osteoclast (OC) differentiation, however, the specific molecular targets of NFATc1 have not been identified. The present study was undertaken to determine the role of NFATc1 in RANKL-induced transcription of the β3 integrin gene. Alignment of the human (h) and mouse (m) β3 integrin promoters identifies a region (m promoter -1260 to -1350) displaying 89% sequence homology, with several conserved transcription factor binding sites, including the only conserved NFAT/AP1 site. To define the role of NFATc1 in RANKL-induction of the β3 gene, truncated promoter/reporter constructs were transfected into RAW264 cells.

The full-length (1350 bp) promoter was induced > 10 fold by RANKL treatment. Deletion of the 5' putative NFATc1 binding site (to -1084) reduced RANKL induction to < 2.5 fold. Further evidence implicating NFATc1 in β3 gene regulation was provided by the observation that transduction with a TAT dominant-negative NFATc1 (TAT-dnNFATc1) blocked RANKL induction of the full-length hβ3 promoter. We have shown that transduction with this construct dose-dependently blocked expression of the β3 integrin (as measured by QPCR) and the formation of TRAP positive multinuclear cells in RANKL-treated mouse macrophages. In addition, transactivation of the β3 promoter by cotransfection with NFATc1 resulted in induction of >100 fold. Additionally, transactivation by NFATc1 was dose-dependent. Transactivation by NFATc1 was abolished by deletion of the mβ3 promoter to -1084. Direct binding of NFAT to the mβ3 promoter was demonstrated using EMSA. A 21 bp probe (-1164 to -1185 from the TSS) of the mβ3 gene, bound to NFATc1 in nuclear extracts from Jurkat cells, mouse OCs, and RAW264 cells. Specificity of the shifted bands was determined by competition with consensus NFAT probes. Oligos containing a mutant NFAT site failed to compete. Supershift with anti-NFATc1 identified the shifted complex as NFATc1. Consensus AP-1 sites are not present in this oligo and therefore NFAT binding to the promoter is independent of AP-1. PU.1 was also found to bind to this oligo, as demonstrated by competition with consensus oligos and by supershift with anti-PU.1. Interestingly, PU.1 binding was lost upon mutation of the NFAT binding site indicating requisite NFATc1 binding for PU.1 binding. Furthermore, mutation of the NFAT sites in the hβ3 promoter blocked both RANKL induction and NFATc1 transactivation.Our results provide direct evidence that the β3 intrgrin gene is a specific target of NFATc1 during RANKL-induced OC differentiation and that these effects are mediated through direct binding of NFATc1 to specific sites in the β3 integrin gene promoter.

RANK Expression in Normal and Malignant Haemopoietic Cells: A Monoclonal Antibody Study. G. J. Atkins[1], P. Kostakis*[2], C. Vincent*[1], A. N. Farrugia*[2], D. M. Findlay[1], A. Evdokiou*[1], A. C. W. Zannettino*[2]. [1]Orthopaedics, University of Adelaide, Adelaide, Australia, [2]Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia.

The expression of RANK has been shown to be a prerequisite in order for osteoclast precursors (preOC) to differentiate into functional osteoclasts (OC). Although attributed to the monocytoid lineage, the true nature of the preOC in vivo has remained enigmatic. Also, although it is widely accepted that preOC are bone marrow derived cells and that they circulate in the peripheral blood, the stage at which these cells express RANK has not been adequately studied in the human. We tested a panel of murine monoclonal antibodies (MAbs; kindly supplied by J.P. Houchins, R&D Systems, MN) raised against full length recombinant human RANK, for reactivity by flow cytometry with normal human peripheral blood and bone marrow mononuclear cells (PBMC and BMMC, respectively), Giant Cell Tumour cells (GCT), as a confirmed source of preOC and mature OC, and various cell lines. RANK immunoreactivity in BMMC was observed with subpopulations of CD19+ B-cells, CD56+CD3+ NK cells and CD14+ monocytes. Similar reactivity was observed in PBMC, suggesting that RANK-expressing preOC circulate in the periphery. Positive selection of the RANK+ cells by magnet activated cell sorting (MACS) yielded a distinctive population of viable cells, some of which had large cytoplasmic to nuclear ratios. However, exposure of these cells to recombinant RANKL/M-CSF did not yield functional OC. In contrast, positive selection using a CD14 MAb yielded a population of monocytes that readily differentiated into OC. A possible explanation for the failure of RANK+CD14+ cells to differentiate into OC may be antagonism between the RANK MAb used and recombinant RANKL, for RANK receptors on these cells. Consistent with this, we observed differential effects of RANK MAbs when added to OC-forming assays from CD14+ PBMC precursors; one MAb, designated R24, profoundly inhibited the formation of functional OC, whereas others either did not influence OC formation or appeared to enhance RANKL-mediated OC formation. Furthermore, R24, but not other RANK MAbs, inhibited the resorbing activity of GCT cells in a dose-dependent manner. The specificity of the MAbs used was confirmed by western blot and immunoprecipitation. Our results indicate that RANK+ preOC are represented in the marrow and circulate in the periphery, potentially forming a pool of cells able to respond rapidly to RANKL. However, positive selection of preOC using RANK MAbs may developmentally and functionally inhibit these cells.

Strength of TRAF6 Signaling Determines Osteoclastogenesis. Y. Kadono[1], F. Okada*[2], Y. Choi[3]. [1]Orthopaedic Surgery, University of Tokyo, Faculty of Medicine, Tokyo, Japan, [2]Pahtology and Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, [3]Pathology and Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Only the RANK has been shown to induce osteoclastogenesis in vivo, even though other immune receptors, including CD40 and IL-1R/Toll-like receptor, utilizing TRAF6 to activate overlapping signaling cascades. To clarify whether qualitative or quantitative differences exist between the TRAF6-mediated signals induced by TRANCE and by other ligand-receptor pairs, we first transduced RANK mutants that have mutations in TRAF6 binding sites not to bind TRAF6 into bone marrow macrophages (BMMs), and tested for their capacity to induce osteoclastogenesis. RANK with a single mutation, E342A, E375A or E449A (mutation in 1st, 2nd, or 3rd binding site, respectively), as well as wild type (WT), could successfully induce osteoclastogenesis. RANK mutants bearing two mutations, E342/449A or E375/449A, also induced osteoclastogenesis, but both E342/375A and the triple mutant failed to induce osteoclastogenesis. These results demonstrate that either the 1st or 2nd TRAF6 binding site has a greater capability of inducing osteoclastogenesis than the 3rd site and that at least one of the two membrane-proximal TRAF6 binding sites is required for optimal osteoclastogenesis. We hypothesize that when stronger stimuli are given by overexpression, CD40 can initiate osteoclast differentiation. When we overexpressed WT CD40 and stimulated with anti-CD40, TRAP(+) cells were formed, although most were mononuclear. To enhance the differentiation of TRAP(+) cells by CD40, WT CD40-overexpressing BMMs were treated with TGF-beta, a known costimulatory molecule for osteoclastogenesis. In the presence of TGF-beta, CD40-induced p38 kinase activation was enhanced, and bone-resorbing osteoclasts were formed. This CD40-induced osteoclastogenesis was not inhibited by a soluble form of RANK, which completely inhibited TRANCE-induced osteoclastogenesis. When CD40 mutants containing increased numbers of TRAF6-binding sites in the cytoplasmic tails were transduced, stimulation through these modified CD40 showed a dose-dependent increase in the recruitment of TRAF6, the activation of p38 kinase, and more pronounced osteoclastogenesis. Moreover, precursors overexpressing TRAF6 differentiate into osteoclasts in the absence of additional signals from any stimuli. Our results suggest that differences in the osteoclastogenesis-inducing capacity of TRANCE-R versus other TRAF6-associated receptors may in part stem from a quantitative difference in the TRAF6-mediated signals.

The Role of Calpain in RANKL-Supported Osteoclastogenesis. F. Y. Lee, D. Kim, J. A. Karmin*, S. Chang*, M. Fujisawa*, L. U. Bigliani*, T. A. Blaine*, H. Lee. Center for Orthopaedic Research, Columbia University, New York, NY, USA.

To clarify the role of calpain in RANKL (receptor activator of NF-κB ligand)-supported osteoclastogenesis, RANKL-induced calpain activation was examined using murine RAW 264.7 cells and bone marrow-derived monocytes/macrophages (BMMs) α-spectrinolysis and *in vitro* osteoclastogenesis in conjunction with calpain inhibitors were performed to determine whether calpain is involved in RANKL-supported osteoclastogenesis in these cell types. We then verified those calpain species that play a key role in RANKL-supported osteoclastogenesis using immunoblotting. Finally, changes in calpain activity in response to RANKL were assessed using a calpain activity assay kit. We found that calpain activity increases in a RANKL-dependent manner and that μ-calpain, rather than m-calpain, is activated during RANKL-supported osteoclastogenesis in RAW 264.7 cells and BMMs. Cell permeable calpain inhibitors, such as calpastatin and calpeptin, were sufficient to suppress RANKL-supported osteoclastogenesis based on decreased expression of osteoclastogenic markers, including cathepsin K, MMP9 (matrix metalloproteinase 9), and the generation of TRAP (tartrate resistant acid phosphatase) positive-multinucleated cells in both cell types. Calpain inhibitors also suppressed NF-κB (Nuclear Factor-Kappa B) activation via inhibition of the cleavage of IκBα (inhibitor of NF-κB) in RAW 264.7 cells. Lastly, μ-calpain overexpression in RAW 264.7 cells clearly augmented RANKL-supported osteoclastogenesis, thereby implicating its critical role in this process. Taken together, our findings suggest that calpain is essential to the regulation of RANKL-supported osteoclastogenesis.

Chemotactic Recruitment of Osteoclast Precursors by SDF-1 Is Enhanced by TGFβ Elevation of CXCR4 or Suppressed by IFN-α Inhibition of CXCR4. X. Yu, P. A. Collin-Osdoby, P. A. Osdoby. Department of Biology, Washington University, St Louis, MO, USA.

Directed cell migration is essential for osteoclast precursors (pre-OC) in the circulation or bone marrow to navigate to sites for their expansion, differentiation, and bone resorption in skeletal development, bone remodeling, or pathological conditions exhibiting bone loss. SDF-1 and its unique chemokine receptor, CXCR4, critically regulate many important processes including hematopoietic cell homing to bone marrow and chemoattraction of metastatic, inflammatory, or other cells to particular tissues. SDF-1 is produced by stromal and endothelial cells in normal bone, and by inflamed synoviocytes in arthritic joints. Previously, we showed that SDF-1 induces murine pre-OC chemotaxis, MMP-9 expression and activity, and MMP-9 dependent transcollagen migration. Here, we investigated mechanisms mediating and regulating these key processes using RAW 264.7 or bone marrow cells. MMP-9 mRNA and activity were raised by SDF-1 in a dose- and time-dependent manner, and this occurred via signaling pathways involving NF-κB, PI3K, and p38 MAPK, but not ERK ½ or JNK. Because TGFβ1 is highly expressed in bone, increased in pathological conditions associated with bone loss, and it elevates CXCR4 in some cell types, we investigated if TGFβ1 affected CXCR4 expression and SDF-1 responses in pre-OCs. Both CXCR4 mRNA and protein were dose- and time-dependently increased in RAW and marrow cells by TGFβ1, with maximal effects at 10^{-9} M and 24-48 h, and via a SMAD3 pathway. Moreover, pre-treatment (20 h) of pre-OCs with TGFβ1 to increase CXCR4 led to enhanced chemotactic and intracellular signaling responses to SDF-1, as reflected in a greater sensitivity to low SDF-1 levels, higher peak chemotactic response, and stronger P-Akt and P-Src signals by SDF-1. In contrast, IFN-γ reduced both basal and TGFβ1 stimulated CXCR4 levels and corresponding basal (50%) and TGFβ1 stimulated (100%) chemotaxis to SDF-1. TGFβ, CXCR4 and SDF-1 are all increased in rheumatoid arthritis, and a selective CXCR4 antagonist inhibits OC-mediated bone loss in murine arthritis. Thus, SDF-1 promotion of pre-OC chemotaxis, MMP-9 production, and transmatrix migration may contribute to OC formation and bone resorption in both normal and inflammatory states. Moreover, TGFβ stimulated CXCR4 and SDF-1 responses in pre-OCs could amplify these processes and significantly enhance the abnormal influx and localized development of bone-resorbing OCs at inflamed arthritic sites. Conversely, IFN-γ downregulation of CXCR4 and SDF-1 responses may extend the routes by which IFN-γ interferes with OC formation and bone resorption, by inhibiting recruitment and localized accumulation of pre-OCs.

RANKL Activates NFATc1, Induces Autoregulation and Promotes Accumulation of this Transcription Factor on Osteoclast Target Genes. J. A. Fretz*, N. K. Shevde, J. W. Pike. Biochemistry, University of Wisconsin-Madison, Madison, WI, USA.

Osteoclasts are large multinucleated, bone resorbing cells that are formed from hematopoietic precursors in response to M-CSF and RANKL. While RANKL activates a number of signal transduction pathways and stimulates numerous transcription factors, recent studies have highlighted the requirement for NFATc1 in the processes of differentiation and activation as well as survival. In view of the critical nature of NFATc1 in osteoclastogenesis, we explored the process by which NFATc1 is induced in response to RANKL, the role of this factor in the activation of key osteoclast target genes and its essentiality in osteoclast formation using mouse bone marrow monocytes (BMMs) and the RAW264.7 cell line. Although NFATc1 is present in osteoclast precursors, it is rapidly upregulated in response to RANKL treatment at both the mRNA levels and protein level. Actinomycin D studies in both BMMs and RAW264.7 cells support a predominantly transcriptional upregulation of NFATc1, although the half-life of induced NAFTc1 mRNA is slightly increased. RANKL induction of NFATc1 mRNA is facilitated by the ability of NFATc1 to autoregulate its own expression. Accordingly, ChIP analysis has revealed a selective and time-dependent increase in the binding of NFATc1 to NFATc1 P1, the promoter responsible for production of the NFATc1A isoform. Additional factors activated by RANKL and which bind to the NFATc1promoter include c-fos, junB, p300 and RNA pol II. Regardless of mechanism, NFATc1 upregulation is essential to osteoclast formation as siRNA knockdown of NFATc1 results in a substantial diminution in osteoclast formation. The central role of NFATc1 in osteoclast function also suggests that this factor is likely to induce key osteoclastogenic genes including TRAP, MMP-9, cathepsin K and the calcitonin receptor (CTR). Indeed, ChIP analysis revealed an accumulation of NFATc1 on these genes as well. NFATc1 binding was also accompanied on these genes by additional transcription factors including components of AP-1 and C/EBPb as well as the coactivator p300. Interestingly, while the binding of NFATc1 to TRAP occurred early (12 hours) following induction, association of NFATc1 to the CTR gene occurred much later (48 hours). This observation suggests that an additional factor produced by mature osteoclasts may be essential for CTR regulation. In conclusion, our studies highlight details of the mechanisms by which RANKL induces NFATc1 in osteoclasts as well as mechanisms integral to NFATc1-induced expression of genes responsible for the osteoclast phenotype.

Interleukin-3 Inhibits Osteoclastogenesis By Irreversible Down-Regulation of RANK Expression. S. M. Khapli*, S. D. Yogesha*, M. R. Wani. National Center for Cell Science, Pune, India.

Interleukin-3 (IL-3), a cytokine secreted by activated T lymphocytes, stimulates the proliferation, differentiation, and survival of pluripotent hemopoietic stem cells. Recently, it is shown that IL-3 inhibits receptor activator of NF-κB ligand (RANKL) induced osteoclast differentiation by prevention of RANKL-induced NF-κB signaling, and diverts the cells to the macrophage lineage. In this study, we investigated that IL-3 significantly inhibits RANKL-induced c-Jun N-terminal kinase (JNK) activation. In addition, IL-3 down-regulates expression of c-Fos and nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1) transcription factors induced by RANKL. Furthermore, IL-3 dose not alter expression of TNF receptor-associated factor 6 (TRAF6) but significantly down-regulates RANK expression posttrascriptionally. Interestingly, the inhibitory effect of IL-3 on RANK expression was irreversible. Thus, our results reveal that IL-3 inhibits RANKL-induced osteoclastogenesis by irreversible down-regulation RANK expression, and inhibits important signaling molecules involved in RANKL-induced osteoclastogenesis.

Glucose-Dependent Insulinotropic Peptide Receptors Are Present in Osteoclastic Cells and Modulate Osteoclastic Activity. Q. Zhong[1], K. Ding[1], B. Kang[2], W. Bollag*[1], W. Curl*[2], K. Insogna[3], C. M. Isales[4]. [1]Medicine, Medical College of Georgia, Augusta, GA, USA, [2]Orthopedic Surgery, Medical College of Georgia, Augusta, GA, USA, [3]Medicine, Yale University School of Medicine, New Haven, CT, USA, [4]Medicine and Orthopedic Surgery, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

We have previously shown that receptors for glucose-dependent insulinotropic peptide, a hormone secreted from endocrine cells in the small intestine in response to nutrient intake, are present in osteoblastic cells and that activation of these receptors leads to an increase in collagen type I synthesis and alkaline phosphatase activity. However, in vivo experiments with GIP had suggested that GIP also had antiresorptive effects. To further evaluate this possibility primary rat osteoclasts were isolated and examined for GIP receptor expression. GIP receptor mRNA was found to be strongly expressed in isolated osteoclasts by Northern blotting. GIPR protein could also be identified in osteoclasts by Western blotting and in intact rat bone by immunocytochemistry using a polyclonal antibody against the GIP receptor. Using a fetal long bone resorption assay to assess the functional effects of GIP on osteoclastic activity we found that GIP dose dependently and completely inhibited PTH-induced bone resorption. Fetal long bone resorption assay: (PTH 10 nM: 2.3+0.4 vs GIP 10 nM: 1.5+0.2 and GIP 50 nM: 0.5+0.1 45Ca2+ release fold/ control+SEM, $p<0.01$). Taken together, these data demonstrate that functional GIP receptors are present in osteoclasts and support a role for GIP in nutrient-induced inhibition of bone breakdown.

Role of RAGE in Regulating Osteoclast Function and Bone Mass. Z. Zhou[1], A. Bierhaus*[2], P. Nawroth*[2], D. M. Stern*[3], W. Xiong[1]. [1]IMMAG, Medical College of Georgia, Augusta, GA, USA, [2]Department of Medicine I, University of Heidelberg, Heidelberg, Germany, [3]Dean's Office, Medical College of Georgia, Augusta, GA, USA.

The receptor for advanced glycation end products (RAGE) is a receptor for multiple ligands including advanced glycation end products (AGEs), S100/calgranulins, A-beta, and HMGB1. Activation of RAGE is implicated in the pathogenesis of diabetic complications and neural degenerative diseases. However, the exact role of RAGE in bone remodeling is largely unknown. We demonstrate that mice lacking RAGE showed increased bone mass and bone mineral density (BMD) in vivo. This appeared to correlate well with the defects of osteoclast function cultured in vitro. RAGE mutant osteoclasts exhibited disrupted actin cytoskeletal organization and reduced bone resorptive activity. These results suggest that a defect of osteoclastic cell adhesion and function may contribute to the osteopetrosic phenotype in RAGE knockout mice, and demonstrate a requirement of RAGE in osteoclast function.

The Role of Phosphoaminoacids in Osteoclastic Bone Resorption. Z. Unnisa*, C. Janeiro*, R. Bizios*, D. Vashishth*. Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, USA.

Bone resorption by osteoclasts involves the solubilization of mineral and hydrolysis of collagen. Osteopontin (OPN), present on the bone surface, mediates the attachment of osteoclasts to bone via the $\alpha_v\beta_3$ receptor on the cell membrane and interruption of this integrin mediated adhesion results in inhibition of bone resorption *in vivo* [1]. Since these specific phosphoproteins are exposed to TRAP during bone resorption, modifications in their phosphate content could result in altered bone resorption. Previous studies show that altered OPN phosphate moieties modify osteoclastic bone resorption [2]. Here we investigated the role of phosphorylated amino acids present in the cement line in bone resorption. Transverse slices were obtained from 17 human tibiae (34 to 89 yr). The immunoassay of the bone slices were performed by selecting antibodies specific to phosphoamino acid residues. After staining with the primary antibody, the slices were stained with a FITC-conjugate, secondary antibody. Bone slices were divided into seven groups depending on the antibody used (Table 1). Human osteoclast precursor cells (Cambrex Poietics™) were cultured on bone slices (10,000 precursor cells per bone slice) for 14 days. The bones slices were cleaned of osteoclasts, stained with toluidine blue, and quantified for resorption area (mm^2). The results (Fig. 1) demonstrate that TRAP enzyme has the least specificity toward phosphothreonine as indicated by highest amount of resorption. Bone resorption was totally inhibited in groups V and VII. Based on these results we conclude that the phosphotyrosine domains are important in the resorption functions of osteoclasts. Specifically there is a SH2 (src Homology) binding domain in osteoclasts that recognizes the phosphotyrosine residues present at the cement line and initiates the signals required for resorption.

Molecular Aspects of Polyphosphoinositides in Osteoclast Migration. M. A. Chellaiah. Department of Biomedical Sciences, University of Maryland, Dental School, Baltimore, MD, USA.

Introduction: Phosphoinositides interact with several proteins in osteoclasts (OCs) and arbitrate a wide range of functions. We have previously demonstrated that both PI 4, 5 P2 (PIP2) and PI 3, 4, 5 P2 (PIP3) play active roles in actin cytoskeletal organization by their binding to proteins such as, gelsolin and WASP. This binding regulates podosomes assembly/disassembly and actin ring formation. PIP2 also binds to ezrin, radixin, and moesin (ERM) proteins and controls ERM activity in a variety of cell systems. The aim of this work is to gain an understanding of the mechanism by which PIP2 synthesis and its binding to ERM proteins coordinate CD44 surface expression and osteoclast motility. Results: We have recently demonstrated the relationship between the Rho signaling pathway and PIP2 interaction with WASP. Hence, we analyzed whether a similar mechanism exists in the interaction of PIP2 with ERM proteins. Transduction of TAT-fused constitutively active (CA) RhoVal14 into OCs increased phosphatidylinositol 4-phosphate (PI4P) 5-kinase activity and enhanced cellular levels of PIP2. The effects of RhoVal14 transduction simulate the effects of OPN in OCs. Neomycin (a competitor of PIP2 binding), the Rho inhibitor C3 transferase as well as Rho kinase inhibitor Y27632 reversed OPN or RhoVal14 effect. More over, OCs treated as above or expressing CA-Src by adenoviral infection have demonstrated an increase in PIP2 but not PIP3 association with ERM. Dominant negative Src or Rho Asn19 had no effect on PIP2 binding to ERM. An increase in phosphorylation and PIP2 binding of ERM proteins augment ERM/CD44 interaction and surface expression of CD44. PKC inhibitor staurosporin had no effect on OPN-induced phosphorylation or PIP2 binding of ERM proteins whereas Rho and Rho kinase inhibitors diminished the above-mentioned effects. SiRNA to ezrin not only blocked CD44/ERM/actin complex formation but also surface expression of CD44. OPN or RhoVal14-induced migration is blocked in OCs treated with neomycin, C3 transferase, Y27632, or SiRNA to ezrin in migration analyses. Conclusions: The increased levels of PIP2 in OCs subjected to above-mentioned treatments can be attributed to increased activity of PI4P 5 kinase which is located downstream from the Rho/Rho kinase-dependent pathway. ERM protein is dynamically regulated under these conditions and it may take part in CD44 surface expression. Although our understanding of the signaling mechanism of CD44 surface expression and osteoclast motility is limited, we believe our studies outlined above will provide new insights on these cellular processes.

MKK6-p38 MAPK Signaling Augments Osteoclast Survival. T. Yamashita[1], Y. Kobayashi[1], S. Tanaka[2], N. Udagawa[3], N. Takahashi[1]. [1]Institute for Oral Science, Matsumoto Dental University, Nagano, Japan, [2]Dept of Orthpedic Surgery, University of Tokyo, Tokyo, Japan, [3]Dept of Biochemistry, Matsumoto Dental University, Nagano, Japan.

Previously we reported that p38 MAP kinase (p38 MAPK) was essential for osteoclast differentiation. On the other hand, the survival and activation of osteoclasts were not affected by SB203580, a specific inhibitor for p38MAPK. Osteoclastogenic factors like RANKL, TNF and LPS activate MAPK signaling. To clarify the role of p38 MAPK signaling in osteoclast function, we measured activities of protein kinases involved in p38 MAPK signaling pathway using Western blot analysis. We also determined whether phosphorylation of p38 MAPK modulates osteoclast function using adenovirus-mediated gene transfer. Although osteoclasts expressed p38 MAPK protein at the level equivalent to that of bone marrow macrophages (BMM), phosphorylation of p38 MAPK was induced by LPS in BMM but not in osteoclasts. Other signals such as NF-kappaB and JNK were activated in response to LPS in osteoclasts. MKK3 and MKK6 are shown to selectively phosphorylate p38 MAPK. Then, we analyzed MKK3 and MKK6 in osteoclasts. Although MKK3 and MKK6 were expressed in osteoclasts as well as in BMM, the phosphorylation of MKK3/6 in osteoclasts was not increased by the treatment with LPS. Thus, the phosphorylation of MKK3/6 was depressed in osteoclasts, even JNK-MAP kinase signaling was activated in response to LPS. In order to force-induce phosphorylation of p38 MAPK, osteoclasts were adenovirally transduced with a constitutively active form of MKK6 (MKK6CA) or control LacZ. Western blot analysis showed that phosphorylation of p38 MAPK was observed in osteoclasts transduced with MKK6CA. Osteoclasts overexpressing MKK6CA significantly survived at 24 hours after purification when compared with LacZ-expressed osteoclasts (MKK6CA: 301 ± 31 vs. LacZ: 113 ± 25 TRAP(+) multinuclear cells/well). The survival activity of MKK6CA-expressing osteoclasts evaluated at 48 hours was as high as that of IL-1-treated LacZ-control cells (MKK6CA alone: 114 ± 18; LacZ plus IL-1: 87 ± 14; LacZ alone: 8 ± 2 TRAP(+)MNCs/well). The number of MKK6CA-expressing osteoclasts was reduced one third by the treatment with SB203580, so that p38 MAPK activation might contribute to MKK6CA-induced osteoclast survival. Real-time PCR analysis revealed that overexpression of MKK6CA in osteoclasts did not enhance expression of pro-inflammatory cytokines such as IL-1, TNF and IL-6. These results suggest that mature osteoclasts keep own p38 MAPK signaling in an inactive state to abort their survival. Signaling molecules involved in the p38 MAPK pathway would be novel targets to modulate osteoclast differentiation but not osteoclast function.

The Tec Kinases: Bmx and Btk Play Distinct Regulatory Roles in Osteoclast Differentiation. L. Danks*, B. M. Foxwell*, N. J. Horwood. The Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom.

Src is a cytoplasmic non-receptor tyrosine kinase which is essential for the differentiation of functional osteoclasts. Src kinases regulate the activation of a closely related family known as the Tec kinases which include: Bmx, Btk, Itk/Tsk, Txk/Rlk and Tec. Despite the regulation of Tec kinases by Src, the direct involvement of the Tec kinase family members in osteoclast formation has not been previously described. In this study the function of the Tec kinases; Bone marrow tyrosine kinase gene in chromosome X (Bmx) and Bruton's tyrosine kinase (Btk) was examined by assessing adenoviral over-expression of these signalling proteins on human osteoclast differentiation *in vitro*. Human peripheral blood monocytes were treated with 100 ng/ml M-CSF for 72 hours (hrs). These cells were seeded onto either plastic or matrix (dentine or hydroxyapitite) substrates. Adenoviruses were developed encoding green fluorescent protein (GFP) with either wild type Bmx, kinase-deficient Bmx, wild-type Btk or kinase-deficient Btk. Adenoviruses encoding GFP alone or empty adenoviruses were used as additional controls. The cultures were infected +/- adenoviruses for 2 hrs, washed and incubated in RPMI (10% FBS) with M-CSF 25ng/ml and RANKL 20ng/ml for either 7 days or 21 days. Cultures were assessed for evidence of osteoclast differentiation (TRAP) and osteoclast activation (lacunar pit formation). Western blot analysis revealed that Bmx and Btk are constitutively expressed in osteoclasts formed during 21 days of culture. Bmx over-expression significantly inhibited the formation of TRAP multinucleated cells (MNCs) on plastic and also inhibited the formation of lacunar resorption pits on dentine. Btk over-expression had no effect on the formation of TRAP MNCs but significantly inhibited the lacunar resorbing activity of these cells. Btk may be involved in cytoskeletal reorganization, attachment to matrix and cell motility, this was therefore analysed by actin bundle fluorescent staining and time-lapse microscopy. There was no evidence to suggest that over-expression of Btk or Bmx affected cytoskeletal architecture or cell motility during osteoclast differentiation. Quantitative PCR is being carried out in order to characterise further the effect of Btk over-expression in the regulation of genes involved in osteoclast differentiation (i.e. c-fms, RANK) and those involved in resorption activity (cathepsin K e.t.c). These results suggest that Bmx and Btk signalling molecules have distinct regulatory roles in osteoclast differentiation and activation and may provide insight to the development of specific gene therapies for complex diseases involving bone destruction.

FHL2 Inhibits the Activated Osteoclast in a TRAF6 Dependent Manner. S. Bai[1], H. Kitaura[1], H. Zhao[1], J. Chen*[2], J. M. Muller*[3], R. Schule*[4], B. Darnay*[5], D. Novack[1], F. Ross[1], S. L. Teitelbaum[1]. [1]Washington University School of Medicine, St. Louis, MO, USA, [2]Medicine, University of California at San Diego, La Jolla, CA, USA, [3]Universitata-Frauenklinik und Zentrum fur Klinische Forschung, Freiburg, Germany, [4]Universitats-Frauenklinik und Zentrum fur Klinische Forschung, Freiburg, Germany, [5]the University of Texas, Houston, TX, USA.

TRAF6 associates with the cytoplasmic domain of RANK, an event central to normal osteoclastogenesis. We discovered that TRAF6 also interacts with FHL2, a LIM domain only protein which functions as a transcriptional co-activator or co-repressor in a cell type specific manner. FHL2 mRNA and protein are undetectable in marrow macrophages and increase *parri passu* with osteoclast differentiation, in vitro. FHL2 inhibits TRAF6-induced NF-κB activity in wild type osteoclast precursors and, in keeping with its role as a suppressor of TRAF6-mediated RANK signaling, TRAF6/RANK association is enhanced in FHL2 KO pre-osteoclasts. FHL2 overexpression further delays RANKL-induced osteoclast formation, IκB-α phosphorylation and cytoskeletal organization. Interestingly, osteoclast-residing FHL2 is not detectable in naïve wild type mice, in vivo, but is abundant in those treated with RANK ligand (RANKL) and following induction of inflammatory arthritis. Reflecting increased RANKL sensitivity, osteoclasts generated from FHL2-/- mice reach maturation and optimally organize their cytoskeleton earlier than their wild type counterparts. As a consequence, FHL2-/- osteoclasts are hyper-resorptive and mice lacking the protein undergo enhanced RANKL-stimulated bone loss. FHL2 is, therefore, an anti-osteoclastogenic molecule exerting its effect by attenuating TRAF6-mediated RANK signaling.

TGF-Beta Promotes Osteoclast Survival through Activation of Smad Independent Signaling. A. Gingery[1], M. C. Wilkes*[2], E. B. Leof*[2], M. J. Oursler[3]. [1]Biochemistry and Molecular Biology, University of Minnesota, Duluth, MN, USA, [2]Thoracic Disease Research Unit, Mayo Clinic College of Medicine, Rochester, MN, USA, [3]Endocrine Research Unit, Mayo Clinic College of Medicine, Duluth, MN, USA.

Increased osteoclast (OC) numbers are evident in many pathological bone conditions, causing elevated bone degradation. This results in the release of active Transforming Growth Factor beta (TGF-beta), which has diverse effects on bone metabolism. Thus, it is critical to understand the roles of TGF-beta in OCs. Using co-cultures of OC precursors and the ST2 stromal cell line, we have investigated the impacts of differentiation in the presence of TGF-beta on OC survival. Once the ST2 cells are removed from mature cultures, TGF-beta-induced OC apoptose when TGF-beta is withdrawn at a higher rate than OCs with continued TGF-beta treatment. In contrast, OCs that differentiate in the absence of TGF-beta apoptose when TGF-beta is added to mature cells. Thus, OCs that differentiate in the presence of TGF-beta become dependent on TGF-beta for survival. To further investigate the mechanism by which TGF-beta promotes OC survival, we have explored candidate TGF-beta signaling pathways for evidence of survival involvement. TGF-beta signaling involves both Smad-dependent and Smad-independent pathways. Here we report studies of the respective roles of these two signaling pathways in TGF-beta-mediated survival of OCs differentiated in the presence of TGF-beta. Using an adenoviral expression system, we infected mature TGF-beta-induced OCs with a dominant negative Smad3 expression construct or an empty expression vector for 24 hours. Expression of dominant negative Smad3, which interferes with TGF-beta-induced Smad signaling, did not block the ability of TGF-beta to promote OC survival. These data indicate that TGF-beta-mediated survival was independent of the Smad signaling pathway. To assess the role of Smad-independent signaling, we investigated activation of the PAK2/c-Abl and MEK/ERK signaling pathway components as they can be are activated by TGF-beta independently of Smad signaling and their activation can support cell survival. We compared activation levels in both TGF-beta-induced OCs and OCs differentiated without TGF-beta treatment. Interestingly, activation of the PAK2/c-Abl pathway but not the MEK/ERK pathway was higher in TGF-beta-induced OCs. We conclude from these data that TGF-beta-mediated OC survival signaling is Smad independent and may result from signaling through the PAK2/c-Abl pathway.

Interaction between C-TAK1 and MITF during Osteoclast Differentiation. S. Murphy*, K. Mansky. Diagnostic and Surgical Science, University of Minnesota, Minneapolis, MN, USA.

The severe osteopetrotic phenotype in microphthalmia (mi) mutant mice is caused by a defect in the terminal differentiation of osteoclasts. Immature mononuclear osteoclasts are present in the mi/mi mice, but these do not fuse or form ruffled borders. Thus the products of the MITF gene, the basic helix-loop-helix zipper (bHLHzip) factor MITF, and the closely related bHLHzip factor TFE3 have been shown to be critical regulators of osteoclast differentiation. Because MITF appears to be important for differentiation of osteoclasts, we are interested in proteins that interact with MITF. Using a yeast two-hybrid system, we identified several proteins that interact with the amino terminal region of MITF. One of the proteins we identified was Cdc25C-associated kinase 1 (C-TAK1). We have been able to verify by GST pull down assay and by co-immunoprecipitation that MITF and C-TAK1 can interact with each other. C-TAK1 is a member of the EMK/MARK/Par1 kinase family and was first cloned based on its ability to associate with and phosphorylate Cdc25C. For all the known substrates of C-TAK1, the serine residue phosphorylated by C-TAK1 serves as a 14-3-3 binding site. 14-3-3 proteins have been shown to modulate the nuclear/cytoplasmic shuttling of numerous proteins. We are currently mapping the serine residue in Mitf that is phosphorylated by C-TAK1. When osteoclasts are stimulated with M-CSF, we have observed in nuclear extracts and are confiming by immunofluorscence that MITF moves from the cytoplasm to the nucleus. To understand the mechanism of MITF shuttling in osteoclasts, we are currently demonstrating that MITF and 14-3-3 proteins can interact and that the interaction is dependent upon C-TAK1 phosphorylation. It has been shown upon stimulation of osteoclasts with M-CSF that Erk1/2 phosphorylates MITF and TFE3. We hypothesize that C-TAK1 interacts with MITF in the cytoplasm of osteoclasts and upon M-CSF stimulation MITF is phosphorylated by ERK1/2 and is shuttled into the nucleus where MITF activates genes necessary for osteoclast survival such as Bcl-2.

Gap Junction Channels Mediate Signals Necessary for RANKL-Induced Osteoclastogenesis. S. Matemba*[1], A. Johansson*[2], A. Lie*[1], M. Ransjö[1]. [1]Oral Cell Biology, Odontology, Umeå, Sweden, [2]Periodontology, Odontology, Umeå, Sweden.

Many studies have demonstrated that interactions between osteoblasts/stromal cells and osteoclast precursors play a central role in osteoclastogenesis and osteoclast function. Gap junction intercellular channels provides is a direct pathway for cellular crosstalk and allows adjacent cells to exchange second messengers, ions and cellular metabolites. In osteoblasts, gap junction protein connexin 43 (Cx43), is associated with expression of genes critical for bone formation and phenotypic markers of mature osteoblasts. However, the knowledge of gap junction intercellular communication in osteoclast differentiation and function is fragmentary. We have recently published that mouse bone marrow cultures and micro isolated osteoclasts express Cx43 mRNA (Ransjö et al BBRC, 2003). We here report that RAW 264.7 cells express Cx43 mRNA and immunostaining for Cx43 protein. Functional gap junctions in bone marrow cells and in RAW 264.7 cells were demonstrated by scrape loading and flow cytometry dye transfer techniques. Carbenoxolone (CBX), a pharmacological inhibitor of gap junctions, clearly impaired the dye transfer between bone marrow cells and RAW 264.7 cells. CBX caused a dose dependent significant inhibition of dye transfer and TRAP-positive multinucleated cells formed in 7-8 day mouse marrow cultures stimulated by PTH, forskolin, Vit D_3 and PGE_2. Furthermore, RANKL-stimulated osteoclastogenesis in marrow cultures and in RAW 264.7 cells was significantly inhibited by CBX. Quantitative real-time PCR analysis demonstrated that CBX down regulated the expression of osteoclast phenotypic markers but did not have any significant effects on RANK, RANKL or OPG. However, NFAT2 mRNA in RANKL-stimulated marrow cultures was clearly down regulated by CBX. Taken together, our data indicate that gap junction-mediated signals are critical in osteoclastogenesis and furthermore, our results suggest that the interaction is downstream RANKL.

Microstructural Compositional Changes Associated with Osteocyte Lacunae Detected Using Raman Imaging. J. Ling*[1], M. Miller*[1], D. Moravits*[1], J. Lankford*[1], L. Bonewald[2], D. Nicolella[1]. [1]Southwest Research Institute, San Antonio, TX, USA, [2]Oral Biology, School of Dentistry, University of Missouri-Kansas City, Kansas City, MO, USA.

Previous studies have shown that matrix deformation associated with osteocyte lacunae is significantly greater than macroscopic bone deformation suggesting that osteocytes embedded within lacunae experience significantly higher strains than previously assumed. Determining the matrix composition and how the local micro-structural environment around osteocyte lacunae is altered due to stress is essential towards understanding how strains are transmitted from the surrounding bone matrix to osteocytes. Bone is predominantly a composite of type I collagen fibers and carbonated calcium phosphate

mineral particles. Previous studies have shown that bone mineral crystallinity can be inferred from the width of the phosphate vibrational Raman band at 960 cm^{-1}. Also, the peak location of this band shifts towards higher frequencies in bone matrix under compression and lower frequencies under tension. The objective of this study was to apply Raman imaging to investigate the composition of bone matrix in and around osteocyte lacunae and changes to the matrix microstructural composition around and within lacunae in response to mechanical strain. Human femoral cortical bone was milled into a 3x3x30 mm beam specimen and polished using silicon carbide papers followed by refinement with progressive diamond slurries (from 6 micron down to 0.25 micron). The specimen was loaded using three-point bending in a custom microscopy load frame that operates within the Raman imaging microscope (Renishaw 2000). Three direct Raman images at 952, 960, and 968 cm^{-1} bands were recorded for lacunae located at the tension side of the specimen. As the specimen was loaded to approximately 2000 microstrain on the tension side of the beam, the Raman phosphate vibrational band (960 cm^{-1}) shifted to higher frequencies on one side of the lacuna and towards lower frequencies on the opposite side, indicating that the lacuna is subjected to a complex strain field. Furthermore, the 960 cm^{-1} peak bandwidth was higher for the matrix material within the lacunae as compared to bone matrix material surrounding the lacunae. This change in crystallinity became more pronounced as the bone specimen was deformed. This information indicates that the bone mineral within the osteocyte lacuna is less crystalline compared to the surrounding bone matrix and that the degree of crystallinity decreases as the lacunae undergoes increasing deformation.

The Chemokine, MCP-3, Is Produced by Osteocytes and Protects against Glucocorticoid-Induced Apoptosis. Y. Kitase[1], S. Ko[2], J. Gluhak-Heinrich[3], S. E. Harris[3], L. F. Bonewald[1]. [1]Oral Biology, UMKC, Kansas City, MO, USA, [2]Kangnung National University, College of Dentistry, Kangnung, Republic of Korea, [3]Periodontics and Cellular and Structural Biology, U of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

The monocyte chemoattractant proteins, MCPs, were so named for their capacity to induce chemotaxis of monocytes during inflammation. This chemotactic property was thought to be their principal function. We found that MLO-Y4 osteocyte-like cells produce MCP-3 (20ng/ml/10^4 cells or 500X compared to 2T3 osteoblasts) and MCP1 (40X). This osteocyte model also expresses the receptor for this chemokine, CCR2. *In vitro*, MCP3 is regulated by fluid flow shear stress at 16 dynes/cm^2 increasing 3-4 fold and *in vivo*, using *in situ* hybridization, MCP-3 was found to increase in osteocytes near the surface of alveolar bone and to dramatically increase in periodontal ligament cells in response to tooth movement. Conditioned media from MLO-Y4 cells (10%) stimulates osteoclast precursor (Raw264.7 or MOCP-5) chemotaxis, however, chemotaxis could not be abrogated by neutralizing antibody to MCP3 (10ug/ml). Recombinant MCP-3 (1~100ng/ml) only modestly stimulated Raw264.7 chemotaxis compared to MLO-Y4 conditioned media and had no effect on MOCP-5 chemotaxis suggesting another function for MCP-3. Recently, several studies have shown protective effects by members of this family. MCP-1 has been shown to be produced by osteoblasts and indirectly increases osteoblast number (Posner et al, Bone, 1997) and protects neurons and astrocytes from apoptosis (Eugenin et al, J Neurochem, 2003). RANTES, a related chemokine, promotes osteoblast survival (Yano et al, Endocrinol. 2005). We have found that MCP-3 (100 ng/ml) will block apoptosis of MLO-Y4 cells due to dexamethasone (10^{-6} M) and etoposide (50uM) using both the nuclear fragmentation and the trypan blue exclusion assay. These studies suggest that MCP-3 is produced by osteocytes in response to mechanical strain and that a major function may be not only to recruit osteoclast precursors, but to protect osteocytes against cell death. This study also has important implications for the treatment of glucocorticoid induced osteoporosis.

A Proposed Function for E11 in Osteoblast to Osteocyte Differentiation and Mineralization. C. Barragan-Adjemian, D. Guo, J. Rosser*, L. Bonewald. Oral Biology, University Missouri Kansas City, Kansas City, MO, USA.

E11 is the earliest osteocyte-specific antigen expressed as the osteoblast becomes embedded in osteoid and changes shape to a dendritic morphology. This membrane protein is also found in other cell types that express cytoplasmic extensions and form a barrier with fluid such as kidney podocytes or with air as in type II alveolar lung cells. As osteocytes are in contact with bone fluid and express extensive dendritic networks, it was hypothesized that E11 is responsible for one or both of these functions. To determine the function of E11 in bone cells, MLO-A5 cells were used as a model of late osteoblasts/early osteocytes and MLO-Y4 cells as a model of early osteocytes. MLO-A5 cells express low levels of E11 that increase with time in culture coinciding with the generation of dendritic processes at 3-4 days, maximizes by 9 days when sheets of mineral form and begins to decrease after 12 days of culture. This *in vitro* expression recapitulates *in vivo* expression in bone where E11 appears as the late osteoblast embeds in osteoid, is highest in the osteoid-osteocyte and is reduced in expression in the mature osteocyte surrounded by mineral. The MLO-Y4 cells express very high levels of E11 (100 fold) compared to confluent MLO-A5 cells. To inhibit E11 expression in order to determine function, such a dendrite formation, siRNA was designed. Sequences used include 66-87, 165-185 and 397-417. It was found that a combination of all three siRNAs at 25nM would inhibit E11 expression 80% in MLO-A5 cells and 84% in MLO-Y4 cells. Unfortunately, several commercial transfection vehicles [Transit-ko (Mirus), Lipofectamine 2000 (Invitrogen), Silent (Bio-Rad)] were found to dramatically change cell morphology making assessment of changes in dendricity in MLO-Y4 cells impossible. Vehicle effects were also found on mineralization by MLO-A5 cells. The vehicle Lipofectamine plus (Invitrogen) was found to have no effects on either parameter. Preliminary experiments on MLO-A5 cells at five days of culture after two 24 hr exposures to siRNA suggest that siRNA inhibits mineralization. These cells have been shown to produce 20-50nm mineralized spherical structures as they generate dendritic processes, responsible for initiation of mineralization in these cultures. Experiments are underway to determine if blocking dendrite formation will block the generation of these mineralizing structures.

Proteomic Comparison of Osteoblasts and Osteocytes Reveal Unique Protein Expression Patterns. D. Guo[1], J. Guthrie*[2], J. Zhao*[1], L. Barragan*[1], S. Harris[3], L. Bonewald[1]. [1]UMKC, Kansas City, MO, USA, [2]Midwest Res. Inst., Kansas City, MO, USA, [3]UTHSCSA, San Antonio, TX, USA.

Genome-scale molecular profiling is used to examine global patterns of transcription in cell systems. However, mRNA does not always correlate with corresponding protein abundance, nor with post-translational modifications. Our hypothesis for these studies was that osteocyte proteomic expression will reflect osteocyte function. Total cell lysates of MC3T3 and 2T3 osteoblast cells and MLO-Y4 osteocyte-like cells were applied to 2D gels, analyzed by PDQuest, and differentially expressed spots excised for protein identification using mass spectrometry. Comparison of the protein expression profiles between the two osteoblast-like cells, showed only a 1-2% difference while comparison between MC3T3 and MLO-Y4 cells showed a 25% difference in expressed proteins. 80% of 69 spots were identified; 20 only detectable in MLO-Y4, 27 at least two fold greater in MLO-Y4 compared to MC3T3, 15 only expressed in MC3T3 and 7 two fold greater in MC3T3 compared to MLO-Y4. Direction of change in protein expression generally correlated with gene expression except for vimentin and lamin A where different forms were expressed between MLO-Y4 and MC3T3. Tubulin α6 was only present in osteoblasts while tubulin α3 was only present in MLO-Y4 cells. Collagenα 1 and 2 were only observed in the osteoblasts. Three proteins with greater expression in MLO-Y4 osteocytes compared to osteoblasts, were chosen for *in vivo* validation because of a potential role in osteocyte function. These include; Cap G (macrophage capping protein P24452), destrin (Q9ROP5), and Hypoxia up-regulated factor ORP150 (NP_067370), expressed 14, 5, and 62X greater respectively in MLO-Y4 cells compared to the osteoblast cells and 3 and 5X higher in the gene arrays (ORP150 was not on the array). Cap G and destrin are involved in cytoskeletal rearrangement and therefore may play a role in dendrite formation. CapG is a member of the gelsolin family responsible for capping the barbed ends of actin filaments and destrin, also known as actin depolymerizing factor, is essential in regulating actin filament turnover by severing and enhancing depolymerization of actin filaments. ORP150 is important in neuronal survival in glutamate toxicity and oxygen deprivation and therefore could play a role in osteocyte survival. Immunostaining of murine bone showed that destrin is highly expressed in the embedding osteocyte compared to osteoblasts or mature osteocytes. Staining for the other two proteins are in progress. Comparison of differences in the proteome of osteocytes with osteoblasts should provide considerable insight into the various molecules and pathways responsible for osteocyte function.

Surface Area/Volume Relationships of Secondary Osteons in Equine Radii: Implications for Regional Variations in Convective Nutrient Delivery. S. M. Sorenson*, G. Clark*, J. Hoopes*, W. E. Anderson*, K. Taylor*, J. G. Skedros*. Univ. Utah Dept. Orthop. Surg., SLC, UT, USA.

In human ribs, positive correlations have been reported between osteon area (On.Ar) and Haversian canal area (Hc.Ar), perimeter (Hc.Pm), and osteocyte lacunae number/osteon (Lc.N/On). Hc.Ar and Hc.Pm also increase with increasing Lc.N/On [Qiu et al. 2003 Anat. Rec]. These data imply a coordination between the Haversian canal and osteocytes that may be dependent on nutrient delivery. However, it is unclear if these associations broadly apply in other mammals. Additionally, these relationships may not exist in bones where there are large regional variations in strain gradients and trans-cortical fluid flow. For example, these relationships may differ in bones that receive a non-uniform strain distribution [e.g., tension (T), compression (C), and shear (S)]. We examined 2,350 secondary osteons to evaluate relationships between Hc.Ar, Hc.Pm, On.Ar, and Lc.N/On in a bone that habitually experiences non-uniform strains (hence large regional variations in strain gradients and fluid flow). 50X backscattered electron images were obtained from 10 equine radii at mid-diaphysis in cranial “T”, caudal “C”, and medial/lateral “neutral axis; S” cortices. Sections were also examined in circularly polarized light to determine if osteon morphotypes differ in these regions. Results showed that the T, C, and S cortices exhibited similar correlations despite having variations in strain gradients: moderate-to-high positive correlations between On.Ar and Hc.Ar, Hc.Pm, and Lc.N/On; low positive correlations between Lc.N/On and Hc.Ar and Hc.Pm (Table). The largest surface-to-volume ratios (Hc.Pm/B.Ar) occurred in neutral axis (NA) regions where strain gradients are highest ($p<0.001$ vs. T & C). Additonally, the NA regions had significantly lower Lc.N/On than

the other regions ($p<0.05$). These results may reflect more efficient nutrient transport across NA regions. However, a potentially confounding factor in studies that deem lacuno-canalicular geometries as similar among *all* secondary osteons is that osteons with alternating lamellar organization are prevalent in the "C" and "S" cortices while the "T" cortex consists mostly of parallel-fibered osteons. Lacuno-canalicular geometries, hence conduits for convective fluid flow, might differ between these two osteon morphotypes.

	Correlation Coefficients (r values)

Gene Expression Signatures of the Mouse MLO-Y4 Osteocyte Cell Model: Pathway and Gene Set Enrichment Analysis. W. Yang[1], M. A. Harris[1], D. Guo[2], L. F. Bonewald[2], S. E. Harris[1]. [1]Dept. of Periodontics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [2]Dept. of Oral biology, University of Missouri at Kansas City**,** Kansas City, MO, USA.

The MLO-Y4 mouse osteocyte cell model is widely used to study osteocyte biology *in vitro*. Few markers for osteocytes are recognized and the gene expression patterns and signaling pathways of osteocytes are not well defined. Identifying gene expression sets and signaling pathways should provide information concerning osteocyte function. Therefore, we investigated gene expression patterns of MLO-Y4 cells at low and high density for comparison to 2T3 osteoblast cells at subconfluent and confluent stages of osteoblast differentiation. After hybridization using Clontech Mouse 5K Microarray, gene expression intensity was quantified and statistically analyzed using triplicate experiments, classified using standard clustering algorithms and functionally organized using DAVID-EASE, a program that explore biological themes of microarray results. Northern analysis was performed to validate expression of key genes. From a data set of 181 genes highly overexpressed in MLO-Y4 osteocytes compared to osteoblasts, we built pathway maps to model the pathways that reflect the MLO-Y4 osteocyte gene expression signature. This signature was then compared to a variety of public gene sets characteristic of bone cells such as osteoblasts, osteoclasts, and a variety of other cell types such as macrophages using Gene Set Enrichment Analysis (GSEA). From the pathway analysis, MLO-Y4 osteocyte cells have patterns of expression that reflect activation of acute and defense response pathways, the TGFβ pathway, the interferon activated pathway, and other closely related immune response pathways. As the cells are selected for their dendritic morphology, they have a set of genes that are involved in formation of cell processes or dendrites such as E11, SPP1, CD44, LAMA5. Several genes that inhibit apoptosis are also in the 181 MLO-Y4 gene set, such as Myc, Bag3. From the GSEA analysis, the MLO-Y4 181 gene set has high enrichment scores with other osteoblast differentiation models such as Col1α1 promoter-GFP selected osteoprogenitor maturation profiles, but is not enriched in macrophage, osteoclasts, APC dendritic cells, T cells, B cells. The MLO-Y4 selective gene expression signature can now serve as a basis for further comparison with primary isolated osteocytes and for characterizing osteocyte responses to mechanical signaling.

Heel and Hip Bone Densitometry in Postmenopausal Women with Hip Fractures. J. D. McCrea, T. Hewer*. North Cumbria Osteoporosis Service, North Cumbria Acute Hospitals NHS Trust, Whitehaven, Cumbria, CA28 8JG, United Kingdom.

Reduced heel bone mineral density (BMD) is a risk factor for hip fracture yet there is scant information on heel BMD in patients with hip fractures and no consensus on the levels of reduced heel BMD at which treatment might be indicated. The aim of this study was to compare heel BMD results in postmenopausal female patients with recent hip fractures with those from 429 elderly community dwelling ladies studied previously. All postmenopausal women with low trauma hip fractures requiring surgery admitted to the West Cumberland Hospital in 2004 were included (n=120). After discharge, hip and heel BMD scanning was perfomed using Lunar Prodigy and Pixi scanners (GE Medical Systems) following our standard protocol. Thirty patients (25%) died prior to scanning and a further 43 (36%) did not attend leaving 47 patients (39%) who were scanned (9 heel only, 5 hip only, 33 both sites). Mean ± SD results were: total hip BMD = 0.647 ± 0.132 g/cm^2, T -score = - 2.94 ± 1.10; heel BMD = 0.323 ± 0.10 g/cm^2, T -score = - 2.19 ± 1.22. Results for the hip fracture and community dwelling patients are compared below:

Mean ± SD	Community dwelling patients		Hip fracture patients (n = 47)
	Heel T > - 1.6 (n=301)	Heel T ≤ - 1.6 (n=128)	
Age (years)	72.0 ± 5.3	74.7 ± 6.0	79.2 ± 8.2 $^{<0.001}$
Weight (kg)	71.5 ± 14.3	58.4 ± 11.0	54.3 ± 12.0 $^{0.036}$
Osteoporosis Screening Tool [OST]	- 0.12 ± 3.23	-3.21 ± 2.69	- 5.28 ± 2.66 $^{<0.001}$
Heel BMD (g/cm^2)	0.496 ± 0.08	0.312 ± 0.05	0.323 ± 0.10 ^{NS}

Statistical comparisons (independent samples t tests) between hip fracture patients and patients with heel T ≤ -1.6 are as in the table; for all comparisons between hip fracture patients and patients with heel T > - 1.6 p was < 0.001. 89% of patients scanned were advised to start antiresorptive treatment. Of the 33 patients with both hip and heel BMD results, 22 had hip T -scores ≤- 2.5, 19 had heel T -scores ≤- 1.6 and 17 had heel T scores ≤- 2.0. This latter device specific figure (90% sensitivity & specificity for hip/spine osteoporosis) was adopted following the 2005 UK National Osteoporosis Society (NOS) Position Statement on peripheral DXA. These results from a small group of patients indicate no significant difference between heel BMD in hip fracture patients and the subgroup of primary care patients who had T -scores ≤- 1.6 in our previous community study. Adopting the device specific threshold, however, would have excluded 34% of the community dwelling ladies from treatment which may not be appropriate since BMD is a continuously distributed variable. We conclude that in the absence of central dxa, measurement of heel BMD with the Lunar Pixi, may offer a potentially valuable therapeutic intervention level for elderly women at risk for low trauma hip fractures.

Failure to Motivate Orthopedic Surgeons and Neurologists to Refer High Risk Patients for DEXA Exam. D. R. Mandel, P. L. Scott*, J. A. Holmes*. David R. Mandel, MD, Inc., Mayfield Village, OH, USA.

Osteoporosis patients with important clinical risk factors are often not evaluated in a timely way with bone mineral density (BMD) studies for possible medical therapy. Two large groups at risk are those who have had recent fragility fractures and those who have had a hemiplegic stroke. We initiated a study to educate local orthopedic surgeons and neurologists about these high risk patients. They were provided newsletters and medical articles about the benefits of BMD studies. At educational conferences we invited 40 orthopedic surgeons and 20 neurologists to refer at least 6 patients over a 3-month period of time who had a fragility fracture or a hemiplegic stroke in the past year. Each physician was provided with 6 vouchers which would enable their patients to receive a free DEXA BMD study. Results of the study would then be sent to both referring physicians and the patient's primary care physician. Only two patients were referred for BMD during the first 3 months. A follow-up letter informing the referring physicians of the small number of referrals was sent. Additional medical information and articles were also sent to encourage and motivate them. The study was continued for an additional 3 months with no additional patients referred. These results would indicate that physicians who come in contact with patients at risk for fracture do not refer for BMD studies. Additional study is required to understand what factors encourage and impede physicians to refer their patients who are at high risk for fracture.

Fracture Patients Have Low Bone Mineral Density. A Consecutive Study of 239 Patients. J. Åstrand*, M. Tägil*, K. G. Thorngren*. Orthopaedic department, Lund University, Lund, Sweden.

Purpose: We screened fracture patients at our orthopaedic department for osteoporosis during one year to evaluate a relatively simple routine and identify patients with low BMD that might benefit from treatment. **Methods**: We included all patients between 50-75 years of age visiting our department with a distal radius-, proximal humerus-, vertebrae- or hip fracture from 1 November 2002 to 1 November 2003. A nurse identified patients who recieved a questionnaire concerning riskfactors for osteoporosis and were admitted for a DEXA-scan. Results of the scan were then evaluated together with the questionnaire and the diagnosis "normal", "osteopenia" or "osteoporosis" was established. **Results**: A total of 338 patients (84 males) were contacted, 87 hip fractures (38 males), 196 distal radius fractures (36 males), 27 vertebral fractures (5 males) and 28 with proximal humerus fractures (5 males). 99 patients were excluded: 33 were considered to have had high-energy fractures, 8 could not participate due to illnesses (1), dementia (4), poor language skills (2) or living far away (1). 28 did not want to participate or did not respond to the questionnaire. In total, only 13 patients were already examined and under treatment for osteoporosis. 256 patients were referred for a DEXA-scan (54 males). 16 patients never showed up at the DEXA-scan (3 males) and one woman died. Consequently, 239 patients (51 males) underwent DEXA scans. Of these, 13 % had a normal bone mineral density (<- 1 S.D.), 45 % had osteopenia (-1-2.5 S.D.) and 42 % had osteoporosis (<- 2.5 S.D.). **Conclusions**: In this study, fracture patients between 50-75 years of age had low bone mineral density and needed further investigations and treatment. If patients with low BMD are identified already after their first fracture, treatment can prevent or postpone subsequent fragility fractures. These patients appear at the orthopaedic clinic and orthopaedic surgeons have the opportunity not only to treat the fracture but also identify patients most at risk for future fractures. We organized our routine screening in a low resource demanding way using a team with a doctor, nurse and a secretary.

Intake of ACE Inhibitor Is Associated with Greater BMD in Older Chinese. T. Kwok*[1], H. Lynn[2], W. Samuel*[3]. [1]Medicine & Therapeutics, The Chinese University of Hong Kong, New Territories, Hong Kong Special Administrative Region of China, [2]School of Public Health, The Chinese University of Hong Kong, New Territories, Hong Kong Special Administrative Region of China, [3]Community and Family Medicine, The Chinese University of Hong Kong, New Territories, Hong Kong Special Administrative Region of China.

A cross-sectional study of 1,958 Chinese men and 1,929 women was used to explore the association between ACE inhibitor use and bone mineral density (BMD). The participants were aged 65 years and above, and were recruited using a combination of private solicitation and public advertising from community centers, housing estates, and the general community in Hong Kong. Demographic, medical, and lifestyle information were obtained from face to face interviews using standardized questionnaire, and physical examination measurements include anthropometry, tibial and brachial systolic blood pressures, and total hip and lumbar spine (L1 - L4) BMD. In multiple regression analyses, after adjusting for weight and age, ACE inhibitor use was associated with higher femoral neck and lumbar spine BMD ($p < 0.05$) among females, and higher femoral neck, total hip, and lumbar spine BMD ($p < 0.01$) among males. When further adjustments were made for thiazide, beta-blocker, corticosteriod use, height, history of diabetes, heart disease, presence of atherosclerosis, cigarette smoking, physical activity, and calcium supplement, ACE inhibitor use was associated with higher femoral neck BMD (+0.014 g/cm2, $p = 0.035$) in women, and higher femoral neck (+0.015 g/cm2, $p = 0.014$), total hip (+0.016 g/cm2, $p = 0.021$), and lumbar spine (+0.045 g/cm2, $p < 0.001$) BMD in men. This study demonstrates for the first time that ACE inhibitor use is associated with higher BMD among older Chinese, with the relationship seemingly stronger in men compared to women.

The Postmenopausal Women with Consistently Accelerated Bone Turnover Achieve Lower BMD at Years beyond 10 Years Since Menopause. I. Gorai[1], Y. Uchiyama*[2], H. Yamauchi*[2], K. Kurasawa*[2], O. Chaki[2], F. Hirahara*[2], Y. Ii*[3]. [1]Obstetrics and Gynecology, International University of Health and Welfare Atami Hospital, Atami, Japan, [2]Obstetrics and Gynecology, Yokohama City University School of Medicine, Yokohama, Japan, [3]Biostatistics Pfizer Global R&D Tokyo Laboratory, Pfizer Japan, Tokyo, Japan.

We assessed factors influencing bone mineral density (BMD) and bone loss by measuring bone markers and hormone levels in 257 postmenopausal Japanese women (60.0±5.7yr) who had been followed for eight years. Vertebral BMD was measured every year using DXA, and bone markers and sex steroid hormones were determined at the start of the study. Based on WHO diagnostic criteria, 10.1% of the subjects had osteoporosis, 84.4% had osteopenia, and 5.5% were normal. In cross-sectional study BMD decreased markedly within 10 years since menopause (YSM) and slightly thereafter, which makes a multiple linear regression analysis by separate models. In YSM≤10, increases in age and YSM showed inverse associations with BMD (g/cm2) (0.030 and 0.055 decrease/a yr increase, respectively) and effects of YSM on BMD seem to be independent of age. Elevated NTX levels had negative associations with BMD (r=-0.1999, P=0.0158). In YSM>10, an increase in age showed an inverse association with BMD (0.041 decrease/ a yr increase), however, YSM had no independent effect on bone density. Elevated levels of NOC showed an inverse correlation with BMD. The other bone markers showed non-significant inverse associations with BMD. DHEA values correlated with L-BMD (r=0.2062, P=0.0395). In both groups, BMD increased linearly with body weight (Wt) (0.017 and 0.022 increase/1kg increase, respectively). In longitudinal study stratification of YSM showed differences in rate in bone loss with each quartile (Q1:YSM≤5, Q2: 5<YSM≤10, Q3+Q4: YSM>10), making the analysis by three separate models. In YSM≤5, NOC, total DPD and NTX inversely significantly correlated with BMD and significant correlations were lost after adjustment for ages, YSM and Wt. In 5<YSM≤10, there were significant correlations between total DPD, free DPD and NTX, and bone density, and PYR, total DPD and free DPD significantly correlated with BMD after adjustment for ages, YSM and Wt (r=-0.223, P=0.050, r=-0.300, P=0.008 and r=-0.297, P=0.011, respectively). In YSM>10, we could not find any correlations between each bone marker and BMD both before and after adjustment for ages, YSM and Wt. Each sex steroid hormone level did not correlate with BMD in three groups. The results suggest that postmenopausal women with consistently accelerated bone turnover achieve lower BMD at years beyond 10YSM whereas the effects of raised bone marker levels do not take its effects in early postmenopause.

Social Position in Pregnancy Is Related to Bone Mass in Childhood by Opposing Actions on Height and Weight. E. M. Clark*[1], A. R. Ness*[1], J. R. Tobias[2]. [1]Community Based Medicine, University of Bristol, Bristol, United Kingdom, [2]Clinical Science at South Bristol, University of Bristol, Bristol, United Kingdom.

Evidence that social factors influence skeletal growth raises the possibility that bone mass acquisition in childhood is socially determined. To clarify the role of social factors in bone mass acquisition in childhood, we investigated relationships between these variables in the Avon Longitudinal Study of Parents and Children (ALSPAC). Details on the parents' housing tenure, highest achieved educational qualifications, and fathers' occupation were collected during pregnancy. These measures of social position were linked to DXA results obtained at aged 9.9 years in 6702 children. Linear regression analyses were carried out after adjusting for age and gender. As previously found, measures of social position were positively related to height and negatively related to weight of the children at aged 9.9 years (P<0.001). Measures of social position were unrelated to total body BMC in analyses adjusted for age and gender. However, after adjusting for height, a strong negative association was observed between BMC and all measures of parental social position (P<0.001). After adjusting for weight as well as height, an association between social position and BMC and bone area was no longer observed. In further analyses, we found that adjusting for fat mass of the child led to similar results to those obtained with weight. Finally, we examined whether the associations between social position in pregnancy and bone mass in childhood varied between weight bearing and non-weight bearing sites. In analyses that were adjusted for height alone, social position was found to exert an equivalent negative influence on BMC at the upper limbs, lower limbs and trunk (P<0.001). Adjusting for regional fat mass attenuated this negative influence of social position at the trunk (P=0.45) and lower limbs (P=0.23), whereas a modest effect persisted at the upper limbs (P=0.046). In conclusion, social position in childhood appears to be positively related to bone mass acquisition in childhood as a consequence of enhanced longitudinal growth. However, this influence is counteracted by the tendency for increased fat deposition in those from a lower social position to increase bone area, presumably reflecting the stimulation of appositional bone growth. Furthermore, our observation that adjusting for regional fat mass attenuated the association between social position and BMC to a greater extent at the lower compared to upper limb is consistent with the possibility that fat mass influences periosteal apposition through increased mechanical loading.

Disclosures: ***E.M. Clark****, None.*

Self-rated Health, Forearm BMD and Bone Loss in Men and Women, a Longitudinal Study. The Health Study of Nord-Trøndelag (HUNT), Norway. S. Forsmo, S. E. Lilleeng*, A. Langhammer*. Dept. of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim, Norway.

Several studies have shown that self-rated health represents a good predictor of morbidity and mortality. Less is known whether self-reported health status and longitudinal change in self-reported health correlate with bone mineral density (BMD) and bone loss. The aim of this study was to investigate the association between perceived health status, its change and forearm BMD and bone loss in a non-selected sample of adult men and women. In 1995-97 all citizens aged >19 years (about 92,000) in the county of Nord-Trøndelag were invited to a multipurpose health survey (HUNT). Totally 18265 individuals were invited to forearm bone densitometry, and among them a 5% random population sample with 2779 (60%) men and women meeting. In 2001, 4.6 years after the first screening, follow-up densitometry was performed, and 1734 (62%) men and women from the 5%-sample attended. Mean age at baseline and at follow-up was 50.1 (range 20-85) and 54.6 years (range 24-89), respectively. BMD measurements were performed by single X-ray absorptiometry (Osteometer DTX 100) at the distal and ultradistal non-dominant forearm provided no previous fracture. Subjective health status was rated in four categories (1: poor, 2: not so good, 3: good and 4: very good) based on identical questions at baseline and follow-up. At follow-up 30% women and 22% men rated their health as poor or not so good ($p<0.001$). Change in self-rated health status between baseline and follow-up was categorised as deteriorated, unchanged and improved. No statistically significant difference was found between the sexes for change in health status, in about two-third there was no change, deterioration in 18% and improvement 16%. In linear (men) and quadratic (women) regression models, a strong and positive association was found for self-rated health status and BMD (distal and ultradistal radius), adjusted for age and body weight. Statistically significant bone loss was found in both men and women older than 40 years at baseline. Bone loss was more pronounced at ultradistal than distal site until the age of 60 years in women and 65 years in men. The association between change in self-rated health and bone loss was assessed in linear and polynomial regression models in men and women <80 years adjusting for age, body weight and interval of measurements. A statistically significant association was found at ultradistal radius in men ($p<0.05$), somewhat weaker ($p<0.1$) at distal forearm indicating that improvement in self-rated health status is followed by reduced bone loss and vice-versa. No statistically significant association could be found in women.

Valproic Acid Effects on Bone Mineral Density in Juvenile Sprague-Dawley Rats. B. L. Gracious[1], E. Puzas*[2], E. M. Healy*[3], J. Livingston-Carr*[4]. [1]Psychiatry, University of Rochester, Rochester, NY, USA, [2]Orthopedics, University of Rochester, Rochester, NY, USA, [3]Orthopedics, University of Massachusetts, Worcester, MA, USA, [4]Psychiatry, Beth Israel Hospital, New York, NY, USA.

FDA-approved for the treatment of acute mania in adults, valproic acid (VPA) is increasingly used as a first-line mood stabilizer for children and adolescents with bipolar disorder. Several cross-sectional studies have found decreased bone mineral density associated with VPA in children and adults with epilepsy(1-4). As children may be an especially vulnerable population to develop future osteoporosis if bone mineralization is supressed during development, this study was undertaken to explore the usefulness of an animal model in attempts to understand if VPA has a direct effect on bone mineral density (BMD). Ninety-eight Sprague-Dawley rats (49 male and 49 female) were gavaged daily with VPA at 300mg/kg/day versus sham gavage beginning at 7 weeks of age for up to 8 weeks. Cohorts of 7 male and female rats in each group were sacrificed via CO inhalation at four time points: zero, 2, 4, and 8 weeks. Serum samples for valproate levels were obtained and DEXA was performed to determine bone density and bone mineral content (BMC). Utilizing a 'best fit' model including quadratic factors duration and weight as covariates, BMDfemur, BMDspine, BMCfemur, BMCspine were compared for fixed weight. Significant decreases in BMCspine at 2 and 8 weeks were present (respective $p<0.0001$ and $p<0.008$). Significant decreases were also seen in log[BMDfemur]at 4 and 8 weeks duration ($p<0.0000$ and $p<0.02$). Preliminary evidence suggests that VPA reduces BMCspine and logBMDfemur in juvenile Sprague-Dawley rats. Potential mechanisms include direct inhibition of osteoclast and osteoblast activity altering bone resorption and mineralization, resulting in alterations in bone remodeling at a crucial stage of bone development. Replications of this work and additional human studies examining effects of VPA on BMD and BMC in humans across the life cycle are needed.

Erythropoietin Is an Independent Predictor of Bone Mineral Density in Elderly Men - Mr OS Sweden. D. Mellstrom[1], H. Nilsson-Ehle*[2], E. Orwoll[3], O. Ljunggren[4], O. Johnell[5], C. Ohlsson[6]. [1]Center for Bone Research at the Sahlgrenska Academy, Sahlgrenska academy University of Goteborg, Gothenborg, Sweden, [2]Dep of Internal Medicine and Hematology., Sahlgrenska academy. University of Goteborg, Gothenborg, Sweden, [3]Bone and Mineral Unit, Oregon Health and Sciences University Portland, Portland, OR, USA, [4]Dep of Medical Sciences, University of Uppsala, Uppsala, Sweden, [5]Dep of Orthopedics, Malmoe General Hospital, Malmoe, Sweden, [6]Center for Bone Research at the Sahlgrenska Academy and Division of Clinical Pharmacology, Sahlgrenska academy. University of Goteborg., Gothenborg, Sweden.

The osteoclast is known to be derived from the haematopoietic stem cell and transplantation of maternal blood marrow leads to normal bone mineral density (BMD) and Hemoglobulin (Hb) in children with osteopetrosis. Studies indicate that erythropoietin (EPO) might be a growth factor for malignant cells but also for normal prostate cells. It is not investigated if EPO regulates bone mass. The aim of the present study was to investigate if erythropoietin is associated with BMD in a community based population sample of elderly men in Göteborg, Sweden (n = 1000, Men age 75,2) Mr OS. **Methods:** Hemoglobulin and an extended hematological examination was analysed in all 1000 men between 70 - 80 years of age. Blood sample were drawn from the antecubital vein after 10 hours fasting and non-smoking in the morning. EPO was analysed with an ELISA method (Quantikine IVD, R&D systems, Inc, Minneapolis) in a sub sample of 487 men. BMD was measured with a Hologic 4500 A DXA. **Results:** Mean EPO was 11.0 (6,9) IU/L. EPO correlated, as expected, to blood Hb (r = -0,328 P <0.01). Height, weight, age, physical activity, smoking, calcium intake and Hb were included in regression models for BMD. EPO was an independent predictor of Hip total BMD (β=0.092, P= 0.027), trochanter BMD (β=0.113, P<0.01) but not of spine BMD. EPO was not correlated to age but to body composition (lean mass r = 0,12, P = 0.012; fat mass r = 0.14, P = 0.003). In conclusion we found an independent correlation between Hip BMD and EPO, indicating that EPO might be a growth factor regulating bone mass.

Smoking Is an Independent Risk Factor for Decreased Physical Performance in Elderly Women. P. B. Rapuri[1], J. C. Gallagher[1], L. M. Smith*[2]. [1]Bone Metabolism, Creighton University, Omaha, NE, USA, [2]Department of Preventive and Societal Medicine, University of Nebraska Medical Center, Omaha, NE, USA.

Smoking is associated with increased fracture rate and may be a risk factor for declining physical function with age. In elderly women aged 65-77 years who participated in the STOP IT osteoporosis trial, previously we reported that smoking is associated with lower bone mineral density, lower calcium absorption, lower serum 25hydroxy vitamin D (25OHD) levels, secondary hyperparathyroidism and increased bone resorption. In present study in same population, we examined the association of smoking with physical performance measures of muscle function. Timed rise (time to rise from a chair 3 times as quickly as possible), timed walk over 5 meters at normal speed and grip strength (Hand Dynamometer in 90^0 of shoulder flexion) were compared between smokers and non smokers. We also compared physical performance tests between non, past and current smokers and in light (<1 pack/day) and heavy smokers (>1 pack/day). Data were analyzed using SAS. Significant associations were found between smoking status, age and total body fat. ANCOVA was used to compare physical performance variables while adjusting for confounding variables, age, BMI, calcium and caffeine intake and total body fat. Compared to nonsmokers, current smokers were slower on timed rise and timed walk tests and had decreased grip strength. The effect of current smoking on physical performance measures is equivalent to an age related decline in performance tests of 7-11 years. Smokers compared to non-smokers had significantly higher sex hormone binding globulin (SHBG) and lower serum 25OHD levels. Smokers compared to nonsmokers also had lower serum total estradiol, bioavailable estradiol and bioavailable testosterone, though the differences were not statistically significant. The interaction between smoking and 25OHD or SHBG were not significant. Compared to current smokers, past smokers and women who never smoked had better physical performance measures. There was no significant association between quantity of smoking and physical performance measures. The results suggest that current smoking is an independent risk factor for decreased physical performance in elderly women.

Effect of Smoking on Physical Performance Measures

	Non Smokers (n=268)	Past Smokers (n=163)	Current Smokers (n=56)

Vitamin D Insufficiency in South Indian Rural and Urban Population. C. V.Harinarayan[1], U. V.Prasad[1], T. Ramalakshmi*[1], E. G.T.V.Kumar*[1], P. V.L.N.Srinivasarao*[2], P. R.Parthasarathy*[3], C. R.Surendranath*[1], M. M.Suchitra*[2]. [1]Endocrinology and Metabolism, Sri Venkateswara Institute of Medical Sciences, Tirupati, India, [2]Biochemistry, Sri Venkateswara Institute of Medical Sciences, Tirupati, India, [3]Biochemistry, SV University, Tirupati, India.

To study the prevalence of dietary calcium intake and vitamin D status of south Indian rural and urban population. Urban (n=943) and rural (n=205) population were studied for their dietary intake of calcium(DC), phosphorous and phytate/calcium ratio. Serum calcium (SC), phosphorous(SP), alkaline phosphatase (SAP) levels, 25(OH)D and parathormone(PTH) levels were measured. The dietary calcium, phosphorous (mg/day) and phytate/calcium ratio of urban population was 307±51; 653±104; 0.5±0.1 and rural population was 267±30; 488±68; 0.8±0.1 respectively. The SC, SP (mg/dl), SAP (IU/L), 25(OH)D (ng/ml) and parathormone levels (pmol/l) of the urban population are 9.7±0.5; 3.6±0.7; 81±31; 16.7±8.4; 28±17 and that of rural population was 10±0.7; 2.9±0.5; 64±26;21.4±7.1; 29±10 respectively. The rural population had significantly ($p<0.001$) higher 25(OH)D levels, SC and lower SAP, DC than the urban population. The distribution of varying degree of 25(OH)D levels in the population are shown in table:

Parameter	Age yrs	n	Percentage of population with 25(OH)D levels < 10 ng/ml	10.1-20 ng/ml	>20.1 ng/ml
Urban WG	46±13	943	21	52	27
Rural WG	43±14	205	2.5	53.5	44
Males WG	46±16	243	3	51	46
Females WG	46±13	905	21.4	53	25.6
Urban Males	47±17	134	6	56.7	37.3
Urban Females	46±13	809	23.5	51.2	25.3
Rural Males	45±15	109	NIL	44	56
Rural Females	41±14	96	5.2	64.6	30.2

WG - whole group

In urban population, PTH correlated negatively with 25(OH)D levels (r-0.13;p<0.001),SC(r-0.13;p<0.001)and SP (r-0.01;p<0.01). 25(OH)D levels correlated positively with SC(r 0.13;p<0.001). In rural population, PTH correlated negatively with 25(OH)D (r-0.24;p<0.002), DC(r-0.4;p<0.001) and positively with SAP(r0.3;p<0.001). 25(OH)D levels correlated positively with DC(r0.3;p<0.001) and negatively with SAP (r-0.22;p<0.002). The DC intake of the whole group is inadequate compared to the

Recommended Daily allowances of national guidelines. Around 30% of urban population and 50% of rural males have normal 25(OH)D levels. About 50% of the urban and rural population had 25(OH)D insufficiency. 21% of urban women and 5% of rural women had 25(OH)D deficiency. 25(OH)D deficiency and insufficiency is more common in urban female. The dietary calcium and 25(OH)D insufficiency could reflect fallaciously as osteopenia in BMD measurements. There is an urgent need to enrich the diet with calcium and supplement vitamin D with monitored food fortification programs in the country.

Vitamin D Status and Bone Health in Female Army Recruits. J. P. Greeves*[1], C. K. Wickes*[1], W. D. Fraser[2]. [1]Centre for Human Sciences, QinetiQ Ltd, Farnborough, United Kingdom, [2]Department of Clinical Chemistry, University of Liverpool, Liverpool, United Kingdom.

Vitamin D deficiency can lead to secondary hyperparathyroidism and bone loss, and may be associated with stress fracture risk during military training. This study aimed to establish Vitamin D status and its effect on bone health, in UK female Army recruits. Thirty five female Caucasian recruits age [mean(1SD)], 20.4 (2.9) y; body mass, 61.9 (7.2) kg; height, 1.64 (0.06) m, starting Army Phase 1 training between the months of October and February, volunteered to take part. Bone mineral density (BMD) at the lumbar spine, hip, and whole body; ultrasound speed of sound at the calcaneum (cSOS) and tibia (tSOS); and bone markers (plasma β-CTX, P1NP, Bone ALP, urine free PYD and DPD) were measured during week one of training. Serum parathyroid hormone (sPTH); markers of nutritional status; and information on lifestyle factors, were also obtained. Vitamin D status was determined by HPLC measurement of total serum 25-hydroxyvitamin D (25(OH)D) concentration, and categorised as: Normal (>20 $ng{\cdot}ml^{-1}$); Insufficient (<20 $ng{\cdot}ml^{-1}$); Deficient (<15 $ng{\cdot}ml^{-1}$); and Severely Deficient (<10 $ng{\cdot}ml^{-1}$). The data were analysed using a One-Way ANOVA and a Bonferroni test. Total serum 25(OH)D was below the normal range in 17 (51%) subjects on entry to training. 5 (14%) subjects were Insufficient; 7 (20%) Deficient; and 6 (17%) Severely Deficient. Age, body mass, and height did not differ between subjects grouped by Vitamin D status (P>0.05). sPTH negatively correlated with serum 25(OH)D concentration (r = -0.57; P<0.01). Differences in tSOS, markers of bone resorption (βCTX) and bone formation (P1NP, Bone ALP) are shown in Table 1. No differences in BMD, cSOS, or urinary pyridinolines (UfPYD, UfDPD), were found (P>0.05). We found reduced cortical, but not trabecular bone, and increased bone turnover in female Army recruits when 25(OH)D concentration was below 15 $ng{\cdot}ml^{-1}$. These findings suggest that Vitamin D deficiency may increase the risk of stress fracture injury during Phase 1 training, particularly at the tibia. The benefit of Vitamin D supplementation in preventing further bone loss and reducing the risk of stress fracture injury in female recruits should be determined.

Table 1: Mean (1SD) values for tSOS, and markers of bone turnover between groups

	Normal	Insufficient	Deficient	Severly Deficient
tSOS ($m{\cdot}s^{-1}$)	4038 (82)	4028 (66)	3903 (71)[a]	3910 (134)[a]
-CTX ($\mu g{\cdot}l^{-1}$)	0.51 (0.19)	0.61 (0.26)	0.82 (0.27)[a]	0.62 (0.24)
P1NP ($\mu g{\cdot}l^{-1}$)	51.8 (20.1)	70.8 (37.9)	97.1 (30.2)[a]	100.0 (53.0)[a]
Bone ALP($U{\cdot}l^{-1}$)	16.2 (2.8)	16.4 (5.9)	19.3 (2.3)	27.7 (10.4)[b,c,d]

[a, b] different from Normal (P<0.05, P<0.01, respectively)
[c, d] different from Insufficient (P<0.01) and Deficient (P<0.05) groups, respectively

Lycopene Consumption Significantly Reduces Biomarkers of Oxidative Stress and Bone Resorption in Postmenopausal Women. E. S. Collins*[1], A. V. Rao*[2], R. G. Josse[1], T. M. Murray[1], L. G. Rao[1]. [1]Medicine/ Division of Endocrinology & Metabolism, St. Michael's Hospital, Toronto, ON, Canada, [2]Medicine and Nutritional Science, University of Toronto, Toronto, ON, Canada.

Lycopene is an antioxidant known to counteract the damage caused by reactive oxygen species (ROS) in states of oxidative stress. Although demonstrated to be beneficial in reducing age-related chronic diseases, the effect of lycopene in osteoporosis has not yet been investigated. We examined the relationship between lycopene and oxidative stress parameters and bone turnover markers in 33 postmenopausal women aged 50-60 who completed seven-day estimated food records prior to giving fasting blood samples. Serum samples were used to measure serum lycopene, the oxidative stress markers lipid peroxidation and protein thiols, and the turnover markers bone alkaline phosphatase (BAP) and cross-linked N-telopeptides of Type I Collagen (NTx). Average daily intake of lycopene was determined from the dietary records. The serum lycopene per kilogram body weight of the participants was grouped into quartiles and correlated with the above serum parameters using one-way ANOVA and the Newman-Keuls post test. The average serum lycopene for each group was as follows (nM/kg): group 1; 1.1±0.2, group 2; 2.6±0.1, group 3; 4.0±0.2 and group 4; 8.1±0.6. The groups did not differ significantly in age or body mass index (BMI). There was a significant direct correlation between dietary intake and serum lycopene (ANOVA p<0.005). Higher serum lycopene was found to be associated with a lower NTx (ANOVA p<0.005) and protein oxidation (expressed as protein thiols) (ANOVA p<0.05). There was a trend towards a negative correlation between serum lycopene and BAP and lipid peroxidation. A synergistic effect between lycopene and vitamin C on bone resorption was demonstrated with the following observation: participants who consumed more than 500 mg/day of vitamin C demonstrated a significant, inverse correlation between serum lycopene per kilogram body weight and NTx (r = -0.68, p<0.05). This effect was not seen in participants who consumed less than 500 milligrams per day (mg/day) of vitamin C. In conclusion, these results support our hypothesis that in postmenopausal women dietary lycopene is readily absorbed and is effective in reducing oxidative stress and bone turnover markers, an effect that may be enhanced with vitamin C use. Our data suggest that lycopene may be a candidate agent for the prevention of osteoporosis.

Physical Activity and Dietary Calcium Intake in Older Women Improve Geometric Indices of Bone Strength. M. K. Nurzenski*[1], N. K. Briffa[1], R. I. Price[2], B. Khoo*[2], A. Devine[3], T. J. Beck[4], R. L. Prince[3]. [1]School of Physiotherapy, Curtin University of Technology, Perth, Australia, [2]Medical Technology and Physics, Sir Charles Gairdner Hospital, Perth, Australia, [3]School of Medicine and Pharmacology, University of Western Australia, Perth, Australia, [4]Dept Radiology, Johns Hopkins University, Baltimore, MA, USA.

In a population-based study of elderly women it has been shown that those in the highest tertile of physical activity (PA) and the highest two tertiles of dietary calcium intake (CI) had 4.4 to 6.4% higher hip BMD. The effects of these two lifestyle factors on geometric indices of bone strength have now been examined in 1010 women from the same cohort. Baseline PA and CI were assessed by validated questionnaires, and one year DXA scans (Hologic 4500A) were analysed using hip structural analysis software (v3). Section modulus (Z), an index of bending resistance, cross-sectional area (CSA), an index of axial bone strength and subperiosteal width (SPW) were measured at the femoral neck (NN), intertrochanter (IT) and femoral shaft (S) sites. These data were divided into tertiles of PA and CI and the results compared using ANCOVA (SPSS v11.5) with correction for age, BMI and treatment (calcium/placebo). PA showed a significant dose response effect on CSA and Z at all hip sites (p<0.004) and SPW at S (p=0.03). CSA of the two higher tertiles was 4.8, 3.7 and 3% higher than the lowest tertile at the NN, IT and S sites, respectively. Z was 4.9, 4.9 and 3% higher at these sites. SPW was 0.8% higher at the S. For CI, there was a dose response effect for CSA and Z at the IT and S regions (p<0.05). CSA of the highest tertile was 2.7 and 2.6% higher than the lower two tertiles at these sites. Z was 4.1 and 2.2% higher at these sites. These effects were additive such that the women (n=241) with PA levels in the upper two tertiles and CI in the upper tertile had higher CSA (NN 6.5%, IT 6.1%, S 5.3%) and Z (NN 6.6%, IT 3.8%, S 4.9%). These data suggest that lifestyle factors favourably influence bone structure as well as bone density. This supports the use of population-based lifestyle interventions to improve femoral axial strength and bending resistance to those levels already achieved by around one quarter of the population.

Socioeconomic Status Is a Significant Predictor of Hip Fracture Rates in California 1996 to 2000. S. L. Silverman[1], D. Zingmond*[2]. [1]Cedars-Sinai Medical Center, David Geffen School of Medicine UCLA, Beverly Hills, CA, USA, [2]David Geffen School of Medicine UCLA, Los Angeles, CA, USA.

Purpose: Hip fracture is a significant source of morbidity and mortality. Prior research has identified gender and race as significant factors influencing hip fracture incidence. The impact of socioeconomic status (SES) on hip fracture has been little studied in the general population. **Methods:** Using inpatient discharge abstracts from the California Office of Statewide Health Planning and Development (OSHPD)'s inpatient discharge database (PDD), all patients of age 50 years and older hospitalized in California with acute hip fracture and repair were identified by zip code between 1995 and 2000. Population estimates, income estimates, and place of residence (rural vs urban) by zip code tabulation area (ZCTA) were obtained from the U.S. Census. Poisson regression analyses were performed comparing impact of SES (income by decile by zip code) on hip fracture rates accounting for potential confounders - race, gender, age, and rural residence. **Results:** Between 1996 and 2000, a total of 116,919 persons were admitted with hip fracture out of a population of 8,144,469 persons. 74% were female. 61% were in those 80 years and older and 28% in those 70 to 79 years old. 85% were non-Latino whites (NLW). NLW were 87% of persons in those 80 years and older, but 79% in those 50 to 59 years old. Mean per capita income by ZCTA was $25.0K, but was higher for NLW ($25.8K) than blacks ($17.8K), Latinos ($18.0K), Asians ($24.1K), and others ($23.8K). Mean rural residence (by ZCTA) was 4%. In Poisson regression analyses, compared to the lowest income decile higher income decile predicts lower incidence rate ratio (IRR) of fracture (highest income decile - IRR 0.79, 95% Confidence Interval (CI): 0.77 to 0.82) adjusting for other confounders. Adjusted IRR (AIRR) ranges between 0.79 and 0.85 for the 6 highest deciles (all P < 0.01). Rural residence predicted lower rate of hip fracture (AIRR 0.85, 95% CI: 0.82 to 0.87). Being male, non-White, or younger predicted lower fracture rates. Similar findings were found when analyses were stratified within race. **Conclusions:** Risk of hip fracture is the confluence of multiple factors. The impact of higher SES independent of other demographic characteristics may reflect nutritional status as well access to BMD measurement and medications for osteoporosis that might decrease hip fracture incidence.

Further research to identify the factors mediating the impact of SES on fracture is needed.

Effectiveness of Osteoporosis Care Pathways for Hospital Patients with Fragility Fractures. N. Kolatkar[1], M. S. LeBoff[1], M. B. Harris*[2], J. Glowacki[2]. [1]Medicine, Brigham and Women's Hospital, Boston, MA, USA, [2]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Hip fracture survivors have a 2 to 5-fold increased risk for subsequent fragility fractures. Worldwide, however, less than 27% of hip fracture patients receive post-fracture evaluation and therapy. We previously implemented a computer-assisted care pathway comprising discharge recommendations for a multivitamin, calcium/vitamin D supplements, and an outpatient endocrinology appointment for osteoporosis evaluation. In 2004, we added recommendations for the admitting orthopedic surgeon: initiation of daily calcium carbonate with vitamin D (1000 mg elemental calcium, 200 IU cholecalciferol) and a multivitamin (400 IU cholecalciferol), orders for serum calcium, albumin, and 25-hydroxyvitamin D [25(OH)D; Diasorin RIA: normal 20-57 ng/ml], and endocrinology consultation. To evaluate the effectiveness of these guidelines, we reviewed medical records of all patients aged ≥ 50 years with a fragility fracture of the hip or femur admitted to Brigham and Women's Hospital between August 1 and December 31, 2004 (N=57). For this abstract, effectiveness of the surgeon-driven admission guideline was defined by measurement of serum 25(OH)D during the hospital admission; effectiveness of the discharge guideline was defined by a discharge prescription for calcium and/or multivitamin. Age (mean ± SD) at the time of fracture was 77.5 ± 11.1 years; 42/57 (74%) of patients were women. Serum 25(OH)D was measured in 19/57 (33%) patients; this was considered sub-optimal effectiveness of the admission guidelines. Median serum 25(OH)D level was 19.0 ng/ml; 16/19 patients (84%) were vitamin D-insufficient [serum 25(OH)D <32 ng/ml]. Seven primary orthopedic surgeons cared for the patients. Sub-analysis revealed that of the two surgeons who cared for the most patients, one (a co-author of the admission guideline) ordered serum 25(OH)D for 9/20 (46%) patients, while the other (who was not given specific reminders) ordered it for 1/11 (9%) (p=0.055). 38/57 (67%) were discharged on calcium and/or vitamin D. This analysis suggests that the pre-existing computer-assisted discharge guideline was twice as effective as the newly added surgeon-driven admission guideline (p=0.0007). In sum, effectiveness of guidelines was associated with surgeon reinforcement and familiarity. The prevalence of vitamin D-insufficiency stresses the importance of assessing vitamin D status in patients with fragility fractures. This pilot study highlights the use of care pathways in the implementation of practice guidelines for hospital patients with fragility fractures, and suggests that reinforcement of guidelines can improve patient care.

The Association of Height Loss and New Vertebral Deformity over 1-Year: Results from the Horizon Pivotal Fracture Trial with Zoledronic Acid. J. Zhang*[1], J. Caminis[1], P. Mesenbrink*[1], T. Rosario-Jansen[1], M. Flood*[1], K. Tong*[1], S. Farneth*[2], D. M. Black[2]. [1]Novartis Pharmaceutical, East Hanover, NJ, USA, [2]University of California, San Francisco, San Francisco, CA, USA.

Vertebral deformity is often associated with height loss, but the extent to which short-term height loss might be a useful marker of vertebral deformity is unknown. We used data from the HORIZON PFT (Pivotal Fracture Trial) to examine this association in greater depth. The HORIZON PFT is a multi-national, randomized, double-blind, placebo-controlled clinical trial designed to evaluate the potential of zoledronic acid in reducing the risk of both hip and vertebral fracture in postmenopausal women age 65-89 with osteoporosis. Since the study is still in progress and remains blinded, we combined data from both treatment groups to examine the association between measured height loss over 1-year and new vertebral deformity. Approximately 46% patients had height assessed by stadiometer, and only these patients are included in this analysis. Incidence of new vertebral deformity assessment was based on morphometry and defined by at least 20% and 4 mm decrease in any vertebral height with a confirmation by semi-quantitative reading. A total of 2762 osteoporotic postmenopausal women with 1-year information on vertebral deformity and height measured by stadiometer are included in the analysis. The relationship of height loss over 1-year to new vertebral deformity is summarized in Table 1. The association between height loss over 1-year and new vertebral deformity remains statistically significant, even after adjustment for other risk factors including age, height loss from age 25 to baseline, baseline total hip BMD, and baseline prevalent vertebral deformity.

Table 1. The relationship of height loss over-1 year to new vertebral deformity

Height loss (cm)	Percentage with new vertebral deformity % (n / N)	Odds ratio	95% CI
No loss	0.7% (8 / 1220)	1	
0 < loss ≤1	2.3% (30 / 1283)	3.6	1.7, 7.9
1 < loss ≤2	9.1% (15 / 164)	15.3	6.4, 36.6
2 < loss ≤3	16.3% (8 / 49)	29.6	10.6, 82.7
loss > 3	15.2% (7/ 46)	27.2	9.4, 78.7

Overall, our results show that the probability of having a vertebral deformity over 1 year increases significantly with height loss as measured by stadiometer. We conclude that over 1 year there is a strong association of height loss with occurrence of new vertebral deformity. These data suggest that measured height loss, even over a short period, may be useful, particularly in conjunction with other risk factors such as history of vertebral fracture, in predicting morphometric vertebral fracture

Frequency of Vertebral Fractures and Radiological Signs of Osteoarthritis in Postmenopausal Women Admitted to Internal Medicine. J. del Pino[1], A. López-Bernus*[1], M. García-Martín*[2], P. L. Álvarez-Álvarez*[3], V. del Villar*[4], J. Sánchez-Navarro*[5], M. Valiente*[6], A. Fuertes*[1], P. Martínez-Hernández*[7], I. Carpio*[8], C. Garcés*[8]. [1]Clínico, Salamanca, Spain, [2]Barco de Valdeorras, Orense, Spain, [3]NS Reyes, Burgos, Spain, [4]General, Soria, Spain, [5]Rio Carrión, Palencia, Spain, [6]S Pau i S Tecla, Tarragona, Spain, [7]NSa Reyes, Tenerife, Spain, [8]Lilly, Madrid, Spain.

Osteoporosis and osteoarthritis are prevalent diseases that usually go unrecognized. Both entities may be inversely related. The aim of this study was to assess the frequency of vertebral fractures and radiological signs of osteoarthritis in postmenopausal women admitted to Internal Medicine (IM). Women aged 55-80 years admitted to IM in 20 hospitals were consecutively included in 7 months. Inclusion criteria were: not admitted for osteoporosis, and lateral chest radiograph routinely performed. After being trained by a radiologist expert, each investigator evaluated X-ray films. Fracture was a diminution in vertebral height ≥ 25% (Genant's grades 2 and 3), and patients were classified as having or not fracture. Evaluated signs of osteoarthritis were presence of osteophytes (spondylosis), spondylolisthesis, and joint space narrowing (JSN). Mean (SD) age, prevalence of vertebral fracture, and frequency of each radiological sign of osteoarthritis were recorded. Frequency of ostheoarthritis signs was calculated separately in women with and without vertebral fractures. 689 patients were included; age 71.3 (6.6) years. 30.7% [CI 95% 27.3-34.2] (n=212) had any vertebral fracture. Frequency of each radiological osteoarthritis sign in the total cohort and in the groups of patients with and without vertebral fractures is expressed in table 1.

Table 1: Frequency of osteoarthritis signs in total cohort and in patients with and without vertebral fractures

		Total (N=690)	With VF(N=212)	Without VF(N=478)
Osteophytes	NA	46 (6.7%)	24 (11.3%)	22 (4.6%)
	Yes	213 (30.9%)	75 (35.4%)	138 (28.9%)
	No	430 (62.4%)	113 (53.3%)	318 (66.5%)
Spondylolisthesis	NA	53 (7.7%)	22 (10.4%)	31 (6.5%)
	Yes	22 (3.2%)	11 (5.2%)	11 (2.3%)
	No	615 (89.1%)	179 (84.4%)	436 (912%)
JSN	NA	41 (5.9%)	18 (8.5%)	23 (4.8%)
	Yes	212 (30.8%)	98 (46.2%)	114 (23.9%)
	No	437 (63.3%)	96 (45.3%	341 (71.3%)

NA: Data not available, because either radiological technique or other reasons; VF= vertebral fracture

In summary, postmenopausal women admitted to the internal medicine department for reasons not related to osteoporosis have a high frequency of radiological vertebral fractures. In these women there is also a high prevalence of osteoarthritis signs. Women with vertebral fractures have a trend to present a higher frequency of radiological osteoarthritis signs.

Prevalence of Vitamin D Deficiency in Scottish Adults with Non-Vertebral Fragility Fractures. S. J. Gallacher[1], C. McQuillian*[1], M. Harkness*[1], A. P. Gallagher[1], F. Finlay*[2]. [1]Medical Unit, Southern General Hospital, Glasgow, United Kingdom, [2]Department of Biochemistry, Southern General Hospital, Glasgow, United Kingdom.

Fracture risk and vitamin D deficiency increase with age. Recent guidelines emphasise the importance of calcium and vitamin D supplements in fracture prevention. It is however unclear whether vitamin D deficiency is a risk factor in the majority of fracture patients and whether there is a difference in the degree of vitamin D deficiency amongst different fracture types. Results of serum 25-hydroxy vitamin D were reviewed for 661 consecutive patients (median age 82.4; range 56.6 to 100.2 years) presenting with hip fracture to our unit over a four year period. A further 50 patients (median age 66.5; range 50.6 to 83.8 years) presenting to our Fracture Liaison Service with a variety of non-vertebral fracture types who had DXA proven osteoporosis (lowest T-score spine or hip < -2.5; median -2.8; range -2.5 to -5.2) were also assessed (hip = 13, upper limb fractures = 27, lower limb fractures + others = 10). Vitamin D was measured using a chemiluminescence assay with a lower limit of detection of

15nmol/l (Nichols Institute Diagnostics). Results <15nmol/l were assigned a value of 15nmol/l for analysis purposes. No agreed international consensus exists for a diagnostic serum level of vitamin D deficiency. This work reviews a number of different thresholds ranging from 30-70nmol/l. With respect to the hip fracture patients mean (±SD) vitamin D level was 24.6±17.6nmol/l (10.3ng/ml). 97.8% of these patients had a vitamin D level below 70nmol/l (~30ng/ml), 91.7% patients had a level below 50nmol/l (~20ng/ml) and 74.7% patients had a level below 30nmo/l (~10mg/ml). No seasonal or gender differences were noted. For the prospective osteoporotic non-vertebral fracture patients mean (±SD) vitamin D level was 44.1±25.3nmol/l (18.4ng/ml). 82% of these patients had a vitamin D level below 70nmol/l (~30ng/ml), 72% patients had a level below 50nmol/l (~20ng/ml) and 24.0% patients had a level below 30nmo/l. (~10ng/ml). Numbers in the prospective group are not large enough for detailed statistical analysis but mean vitamin D levels were 34.5nmol/l (hip fractures) versus 48.2nmol/l (non-hip fractures). This study confirms the near universal prevalence of vitamin D deficiency in our population with a particularly high prevalence among hip fracture patients regardless of whether a 50 or 70nmo/l cut-off is used. This illustrates that vitamin D deficiency represents a significant correctable risk factor for fragility fracture in our population and is a particular issue for the very elderly. This observed prevalence of deficiency appears higher than that seen in some other parts of the world.

Detection of Prevalent Vertebral Fractures Using Historical Height Loss: Comparison of Tallest Recalled Height and Armspan for Determining Height Loss. K. Siminoski[1], K. Lee*[2], H. Jen*[2], R. Warshawski*[2]. [1]Radiology and Medicine, University of Alberta, Edmonton, AB, Canada, [2]Radiology, University of Alberta, Edmonton, AB, Canada.

Historical height loss (HHL) determined as the difference between the tallest recalled (TRH) height and current measured height (MH) has moderate accuracy in detecting the presence of vertebral fractures. One way to avoid potential error in recall of TRH might be to replace it with armspan (AS) as a marker of tallest stature. In this study, we have compared the clinical accuracy of HHL determined using tallest recalled height (HHLtrh) versus HHL determined using armspan (HHLas). Subjects were women referred for specialist assessment of osteoporosis (n=287; average age 52 yrs; range: 18-92 years). MH was assessed using a wall-mounted stadiometer and AS was determined using a wall-mounted horizontal anthropometer. Vertebral morphometry was performed on all subjects from T4 to L4. Prevalent vertebral fracture was defined as a vertebral height ratio < 0.80. One or more fractures were present in 30.0%; the average number of fractures among those with fractures was 2.3. HHLtrh was correlated with the presence of prevalent vertebral fractures ($r = 0.563$; $p<0.0001$) as was HHLas ($r = 0.224$, $p<0.0001$). The areas under the ROC curves for detection of vertebral fractures were 0.72 (95% CI, 0.65-0.78) for HHLtrh and 0.58 (95% CI, 0.51-0.65) for HHLas. The likelihood ratio for HHLtrh of 6-8 cm was 14.0 while it was 1.4 for HHLas. For height loss >8 cm, the likelihood ratio was 21.0 for HHLtrh but only 1.8 for HHLas. At an HHL threshold of > 6 cm, sensitivity, specificity, positive predictive value and negative predictive values were greater for HHLtrh than for HHLas (see Table). These results show that even with the errors intrinsic to recall of height, HHL determined using tallest recalled height is superior to HHL calculated using armspan for detection of prevalent vertebral fractures in postmenopausal women. The use of armspan should be limited to those cases where tallest recalled height is not available.

Comparison of TRH and AS using HHL > 6 cm

HHL TYPE	Sensitivity	Specificity	PPV	NPV
HHLtrh	24	99	88	75
HHLas	19	96	40	72

HHLtrh = tallest recalled height minus measured height
HHLas = armspan minus measured height
PPV = positive predictive value
NPV = negative predictive value

Can the Spinal Curvature Irregularity Index (SCII) also Predict Vertebral Fractures in Italian Women. D. Diacinti[1], N. Schaaf*[2], E. D'Erasmo*[1], R. Del Fiacco*[1], S. Minisola*[3], G. Mazzuoli*[3]. [1]Departm. of Clinical Sciences, University "La sapienza", Rome, Italy, [2]K.U., Leuven, Belgium, [3]Department of Clinical Sciences, University "La Sapienza" Rome, Rome, Italy.

Detection and diagnosis of vertebral fractures (VFs) are very important in all stages of osteoporosis. Radiographs or DXA vertebral fracture assessment (VFA) images of thoracolumbar spine are therefore an important tool in the clinical evaluation of osteoporosis. However, diagnosing VFs still can be difficult. There is often no clear distinction between a structural failure and the normal anatomic variation in anterior, middle and posterior height of the vertebrae. The aim of this multicentric study is to determine if the SCII can also identify vertebral deformities in Italian women. The SCII is the integrated average of the vertebral heights (VHs) over the thoracolumbar spine to give a quantitative estimate of the regularity of the spinal curvature (Zebaze et. al. (2004): JBMR, 19; 1099-1104). A large SCII is presumed to correlate with the presence of vertebral deformities. The study was performed with 569 Italian women, aged 28-89 yrs. from 4 different Italian centra. VHs were obtained from VFA (Lunar Prodigy, GE Healthcare). ROC analysis and logistic regression was performed using Minitab. SCII was transformed to ln (SCII) for normality. T-test was used to compare average transformed SCII. 40 women out of the 569 studied subjects had a vertebral deformity. The average SCII was significantly higher for subjects with one or more deformities: 13,40% compared to those without deformities 4,34% ($p < 0,001$). SCII increases significantly with increasing numbers of vertebral deformities. We conclude that the Spinal Curvature Irregularity Index clearly distinguishes between subjects with and without vertebral deformities also in an Italian population.

Evaluation of a New Vertebral Fracture Assessment Method (CADfx) versus Conventional Radiography. F. E. Massari*, M. O. Cachizumba*, S. Gonçalves*, R. A. Gallo*, R. G. Agüero*, F. D. Silveira*, O. Gear*, M. V. Freixá*, M. Bruno*, E. A. Stenglein*, A. Kñallesvsky*, A. Arias*, C. Lombas*, M. B. Zanchetta*, J. R. Zanchetta. IDIM, Buenos Aires, Argentina.

Objective: To evaluate the capacity to detect vertebral fractures through an Hologic Densitometer Automatic Computer Aided Detection Program (CADfx) and compare it to Conventional Radiography. Material and Methods: We selected a stratified sample of 362 caucasic women from a database with a previous dorsolumbar radiography who were participating in an osteoporosis detection campaign with DXA. This sample was split into 2 groups, one of 161 women with some vertebral fractures and another one of 201 women without vertebral fractures. Subsequently, for this study we performed new conventional dorsal and lumbar radiographies and an Instant Visual Assessment (IVA) of the dorsolumbar spine (T4 to L4). Due to a lesser subjectivity of the method, we performed a semiquantitative analysis (Genant's Method) of all dorsal and lumbar spine radiographies, in order to detect the presence of vertebral fractures. This analysis was carried out by a specialist in bone radiology and it was considered a gold standard method. All the images obtained by the IVA method were automatically analysed with the CADfx program (Hologic Discovery A Densitometer). For technical reasons 30 patients were excluded (15 of each group). All these analyses were blind to the physicians as regards to the previous diagnosis of vertebral fractures. A comparison between methods was done on a per vertebra basis in a double entry table, defining the sensitivity and specificity of the CADfx program and its predictive values. A statistical analysis of the subgroups was done based on the segments of vertebral spine assessed (T4-T7; T8-T12; L1-L4). Results: The CADfx program showed a sensitivity of 62.5% and a specificity of 92.1%; with a positive predictive value of 33.6% and negative predictive of 97.5%. When we subdivided the spine analysis by regions we observed an increase of the specificity (96.8%) in fracture detection of the lumbar area. Conclusion: Due to the speed of the method (12 seconds), its innocuousness and its acceptable negative predictive value, this method could be considered as a screening tool to discard vertebral fractures.

Incidence of Femoral Neck Fracture in Okinawa, Japan. H. Arakaki, I. Owan, H. Kudo*, H. Horizono*, F. Kanaya*. Orthopedic Surgery, University of the Ryukyus, Okinawa, Japan.

The occurrence of femoral neck fracture is increasing throughout the world. Hip fractures in aged populations are associated with considerable morbidity and high economic cost. We surveyed the rate of femoral neck fracture occurred in Okinawa in the year 2004, and compared with the same survey which was conducted in 1989. The purpose of this study was to investigate whether the occurence rate of femoral neck fracture increases year by year. Okinawa prefecture is located in southest part of Japan with a population of 1.2 million. The number of hip fracture in 1989 was 502 (103 men and 399 women), but which was increased to 977 (183 men and 794 women) in 2004(Table 1). The average age of patients in 2004 was 81.3 years old, and the average hospital stay was 52 days. 86% were treated operatively. The mortality rate at the discharge was only 0.25%. The subtotal of age-specific incidences of hip fracture by the method of Lewinnek is 44.8 in 1989 and 41.0 in 2004. The number of hip fracture was increased year by year, but age-specific incidence rate has not been changed in 15 years.

Table 1. Number of hip fracture by age group

Age Group	Men	Women	Total
50-59	14	21	35
60-69	30	45	75
70-79	48	164	212
80-89	69	352	421

The Association between Homocysteine Levels and Markers of Bone Metabolism, Bone Density and Fractures. P. Gerdhem[1], K. Ivaska*[2], A. Isaksson*[3], K. Pettersson*[2], K. Vaananen[2], K. Akesson[1], K. J. Obrant[1]. [1]Dep of Orthopedics, Malmo University Hospital, Malmo, Sweden, [2]Institute of Biomedicine, Dep of Anatomy and Dep of Biotechnology, University of Turku, Turku, Finland, [3]Clinical Biochemistry, Lund University Hospital, Lund, Sweden.

Recently the association between high serum homocysteine (Hcy) levels and an increased risk of fracture has been described. The causal relationship between Hcy levels and fracture risk is not clear. We examined the association between Hcy levels, bone metabolism and fractures. Hcy levels were measured in 996 women, all 75 years old (range 75.0-75.9). Biochemical markers of bone metabolism (serum tartrate resistant acid phosphatase 5b, serum cross-linking telopeptide of type I collagen (CTX), urine and serum osteocalcin, urine deoxypyridinoline, serum bone-specific alkaline phosphatase), parathyroid hormone, 25-hydroxy vitamin D and bone density were measured at baseline. Fractures and mortality during a mean follow-up of 4.6 years were recorded. High Hcy levels correlated to high serum CTX ($r=0.19$, $p<0.001$), parathyroid hormone ($r=0.16$, $p<0.001$), serum osteocalcin ($r=0.15$, $p<0.001$) and plasma creatinine ($r=0.36$, $p<0.001$). The correlations between Hcy and the other biochemical markers of bone turnover and hormones were low ($r=0.09$ or less). During the follow-up 163 women sustained at least one fracture (including 46 vertebral, 39 hip and 35 wrist fractures). With each unit increase of the natural-log transformed (ln) Hcy levels vertebral fracture risk increased (odds ratio 2.21; 95% CI 1.002-4.86). The inclusion of creatinine in the logistic regression increased the OR to 2.57 (1.13-5.84). When femoral neck DXA, smoking status or walking speed were included in the logistic regression the association between ln Hcy and vertebral fractures decreased and was no longer significant. An increase of ln Hcy was not associated with a risk increase for any type of fracture, hip or wrist fracture. The correlations between Hcy and bone density measurements (DXA and ultrasound) were low or non-significant. During follow-up, women in the highest homocysteine quartile had a 1.9 times higher mortality rate (95% CI 1.13-3.21) than women in the lowest homocysteine quartile. The association between Hcy and vertebral fractures could to some extent be explained by an association to bone metabolism, especially collagen degradation. However, in this study the association between fractures and Hcy levels were weak or non-significant and were affected by other fracture predictors, such as bone density and walking speed. The increased mortality among women with high homocysteine levels indicates that high homocysteine may be a marker of frailty.

Incidence and Risk Factors for Low Trauma Fractures in Men with Prostate Cancer. H. G. Ahlborg[1], N. D. Nguyen[2], J. R. Center[2], J. A. Eisman[2], T. V. Nguyen[2]. [1]Department of Orthopaedics,, Malmö University Hospital, Malmö, Sweden, [2]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Low bone mineral density (BMD) is a well-known risk factor for fracture in men. Moreover, non-skeletal risk factors, such as postural instability, have been identified to be significant predictors of fracture. However, the relative importance of these risk factors among men with prostate cancer has so far not been examined. This study was aimed at determining the risk of low trauma fracture in men with prostate cancer, and to characterize the association between potentially risk factors and fracture risk. From the prospective, population-based Dubbo Osteoporosis Epidemiology Study, 43 men were identified to have been diagnosed with prostate cancer; among whom, 20 received and 23 did not receive androgen deprivation therapy (ADT). Low trauma fractures were ascertained and compared with expected numbers in the study population and expressed as standard incidence ratio (SIR). Bone mineral density at the femoral neck (FNBMD) as well as postural instability was measured, and life-style factors were recorded in 29 of the subjects prior to the diagnosis of prostate cancer. Potential risk factors were assessed with a log-binomial model and expressed as risk ratios. During the 313 person-years of follow-up, 15 (35%) men sustained at least one low trauma fracture after the diagnosis of prostate cancer. Overall, fracture risk was increased (SIR 3.1, 95% CI 1.8-5.2) predominately among men with ADT (SIR 5.8, 95% CI 2.6-11.0). FNBMD in men with prostate cancer were 0.4 SD higher than in the underlying population ($P<0.05$). Additionally, a 1 SD lower FNBMD was associated with a risk ratio of 1.7 (95% CI 1.0-2.8), and a 1 SD higher rate of FNBMD loss with a risk ratio of 1.6 (95% CI 1.0-2.2) for fracture. These results suggest that men with prostate cancer, particularly those treated with ADT have an increased risk of sustaining a low trauma fracture. Although the average BMD in men with prostate cancer prior to treatment seems to be higher than expected, a low BMD prior to treatment or increased rate of bone loss after initiating of treatment is each a significant predictor of fracture.

Disclosures: ***H.G. Ahlborg****, None.*

Clinical Vertebral Fracture Outcomes: Medical Resource Utilization and Costs in the First Year Following the Fracture. J. Simon[1], N. N. Borisov*[2], R. Sheer*[2], M. Steinbuch*[2]. [1]The George Washington University, Washington, DC, USA, [2]Procter & Gamble Pharmaceuticals, Inc, Mason, OH, USA.

This study evaluated medical outcomes of a clinical vertebral fracture in the first year following the fracture, in a managed care setting, utilizing an integrated administrative, medical and pharmacy claims database. A retrospective cohort study was conducted among women (aged 45+) with a new vertebral fracture (non-trauma) that was verified by a diagnostic code and a record of a radiologic exam, between July 1, 2000 and June 30, 2003. The cohort was followed for 12 months after the vertebral fracture to identify medical resource utilization and direct medical cost related only to the vertebral fracture. The cost was defined as the cost of outpatient, inpatient and long-term medical care. Vertebral fracture related prescription drug costs such as the cost of analgesics, NSAIDs, and opiate agonists was also included. Medical cost for hospitalized and non-hospitalized patients was assessed first to reflect the inpatient hospital proportion of clinical cases in the total cost of the vertebral fracture. All costs were adjusted to 2004 dollar terms using Medical Care Services component of Consumer Price Index. A total of 4,634 women were identified with a new clinical vertebral fracture. The mean age was 76 years. Twenty two percent of women (n=1,024) were admitted to a hospital for their vertebral fracture, of which 20% (n=202) were discharged to long-term care. The average hospital length of stay was 7 days. After the discharge, 69% of hospitalized women continued fracture-related outpatient care. Fifty-nine percent of women with a vertebral fracture (n=2,745) were prescribed analgesics, NSAIDs, or opiate agonists within 15 days of their fracture, with an average 5 scripts per patient during the 1 year follow-up. The average cost of a vertebral fracture among hospitalized women during the follow-up was $2,687 per patient, and among non-hospitalized women was $593. The weighted average cost of the vertebral fracture was estimated at $1,056 per patient during the follow-up. Inpatient care cost was 47% ($498 per patient), outpatient cost was 29% ($303 per patient), prescription drugs cost was 14% ($149 per patient), and long-term care cost was 10% ($107 per patient) of the weighted average cost. Nineteen percent of women with a vertebral fracture sustained a subsequent fracture within 1 year (10% vertebral and 9% non-vertebral). Vertebral fractures create a burden to patients and the health care system in terms of both medical resource utilization and direct medical costs. This suggests that therapies with rapid reduction in fracture risk may offer important cost benefit to health care payers, providers and patients.

Risk of Hip Fracture in Elderly Women Is Defined by Physical Fitness First, by Nutrition Second. D. Chabanel*[1], M. Krieg*[1], D. Ruffieux*[1], J. Cornuz*[1], P. Burckhardt[1], T. SEMOF-group*[2]. [1]University, Lausanne, Switzerland, [2]Switzerland.

Low calcium and protein intake, muscular weakness and propensity to fall are risk factors for osteoporotic fractures. The prospective SEMOF study (Swiss Evaluation of the Methods of the Osteoporotic Fracture risk) on 7788 women over 70 yrs (follow-up 3.5 years) compared the incidence of fractures and falls with the intake of calcium and protein as dairy products (4 questions: nb of portions of milk (2 dl), yogurt (180 g), soft cheese (20g), hard cheese (20g); calculations with PRODI 4.5®), with the chair-test and grip-strength (Dynamometer Jamar®), and with questions concerning fitness. They allowed to calculate:

1. Score for risk of fall 0-5 (5 questions: getting up in the night, dizziness and instability, difficulties in raising from chair, use of canes etc, resting on furnitures while walking at home). >1 = high risk.
2. Score of mobility 0-6 (6 questions : level of activity, walking outdoors, use of stairs, getting in and out of cars, crossing a street, use of public transport systems). <5 = unsatisfactory.
3. General score of inactivity 0 -2 (high risk on score 1 + unsatisfactory on score 2).

Statistics with Stata 8.1®.
The functional tests were corrected for age and BMI. T-Test for parametric, Mann-Withney for non-parametric variables. Anova when N>2.

Score for risk of fall : 0 - 1 - 2 - 3 - 4 - 5:
Incidence of falls (%): 26-30-37-42-54-61
Score of mobility: 0 - 1 - 2 - 3 - 4 - 5 - 6:
Incidence of falls (%): 51-42-36-43-40-31-36
For all differencies p < 0.001. Fall incidence increased (> 30 %), when score for risk of fall > 1. Unsatisfactory mobility when score < 5.

General score of inactivity 0---------- 1----------2			
Incidence of falls--------	-28%---	----36% ------46%	
Calcium/dairy products--	494)(276)--	484(275)--489 (288)	
(mg/day) (SD)			
Proteins (g/day)(SD)---	14.5 (8.0)---	14.3 (8.0)	-14.5 (8.3)
Chair test : Number-----5221--------		1663-------	802
Normal----------	98%* ------	87%*------	53%*
Grip strength: Number --2976--------		920--------	476
Result (kg) (SD) --------20.8 (5.2)*-		19.1 (5.4)*-	17.2 (5.3)*
Hip fracture incidence ---**3.0**---------		**4.4**---------	**9.7**
(per 10'000 women)			

All fractures incidence ----27.8------- 34.2------ 46.7**
***) p=0.015 diff. from group 1*
These scores of risk for fall and of mobility correlated with the incidence of falls in the follow-up. Women with a high inactivity score had more falls and more fractures, but had no lower calcium- and protein-intake in form of dairy products. Women with fractures differed from women without fractures in their scores (sign.), but not in their intakes. Only among the women with a high inactivity score, low intake was associated with higher fracture incidence.

Characteristics of Vertebroplasty Patients: An Analysis of Claims Data from A Large Not-For-Profit Healthcare Insurer. A. S. Mudano*[1], J. Bian*[1], M. Elkins*[1], D. Briggs*[2], A. Neal*[2], J. Cope*[3], T. Gross*[3], D. McGunagle*[3], J. Graham*[3], A. Ferriter*[3], K. G. Saag[1]. [1]Center for Education and Research on Therapeutics of Musculoskeletal Disorders, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Health Management, Blue Cross and Blue Shield of Alabama, Birmingham, AL, USA, [3]Office of Surveillance and Biometrics, Center for Devices and Radiological Health, Food and Drug Administration, Rockville, MD, USA.

Background: Vertebroplasty, a medical procedure that typically involves the injection of methymethacrylate directly into a vertebral body, is used to relieve pain associated with vertebral compression fracture (VCF) and other vertebral pathologic states. Despite its approval by the FDA, growing utilization, and coverage by insurers, there has been little evidence of the common reasons for its use as well as characteristics of patients receiving and physicians performing this procedure. **Objectives:** To examine the utilization patterns and patient/provider characteristics of vertebroplasty in a large population-based cohort. **Methods:** Using administrative claims data from a large regional health insurer with over 3 million enrollees, we used CPT-4 codes to identify a cohort of patients receiving at least one vertebroplasty from January 2003 to June 2004. In order to develop a longitudinal profile of this cohort, we retrieved all claims for these patients from January 2001 to December 2004. ICD-9 diagnosis codes were used to determine likely reasons for this procedure. In addition, we also examined other patient and provider characteristics. **Results:** We identified a total of 121 patients who received 135 separate vertebroplasty procedures. Among the patients, 63% were women. Seventeen percent of the patients were under age 50, and 15% were age 65 or older (mean age of 58 $\pm$ 10 years). Thirteen patients (11%) received multiple vertebroplasties. The main indications for a vertebroplasty at the date of a procedure were pathological fracture of vertebrae (56%) and VCF (20%). Of the 121 patients, 58 patients (48%) had a history of VCF, and 44 patients (36%) had a bone cancer diagnosis (just over half of these patients had at least one oncology visit). Radiologists performed half of all procedures, followed by orthopedic surgeons (30%) and neurosurgeons (10%). The average number of vertebroplasty procedures increased by 25% after September 1, 2003, the date the insurer began to reimburse for this procedure for VCF. **Conclusions:** Although vertebroplasty was used infrequently in this large privately-insured population, its utilization has been increasing. Additional research is underway to assess the long-term impact of vertebroplasty on post-vertebroplasty recurrent VCFs.

Recognizing Osteoporosis and its Consequences in Quebec (ROCQ): The Care Gap Following a Fragility Fracture. J. P. Brown*[1], L. Bessette[1], M. Beaulieu*[2], M. Baranci*[3], S. Jean*[1], K. S. Davison[1], L. G. Ste-Marie[4]. [1]Laval University, Sainte-Foy, PQ, Canada, [2]Merck Frosst Canada, Montreal, PQ, Canada, [3]sanofi-aventis Pharma, Montreal, PQ, Canada, [4]University of Montreal, Montreal, PQ, Canada.

The objective of this analysis is to evaluate the diagnostic and treatment rates of osteoporosis 6 months following a fragility fracture in women 50 years and over participating in a patient health-management programme (ROCQ). ROCQ is a prospective cohort study involving 18 centers in three socio-sanitary regions in the province of Quebec (Canada). At phase 1, women with fragility and traumatic fractures are recruited during their visit to a cast or outpatient clinic and contacted by phone to answer a short questionnaire to identify the specific circumstances of their fracture. During the first phone contact, there is no reference about the possible association between the fracture and osteoporosis, and no investigation nor intervention is proposed. Six months after the fracture event, women are contacted for a second time by phone (phase 2) to evaluate the diagnostic and treatment rates of osteoporosis (bisphosphonates, raloxifene, nasal calcitonin or teriparatide). After 18 months, 926 women (mean age: 63.4 years) have completed phase 1. A total of 752 (81%) sustained a fragility fracture and 174 (19%) sustained a traumatic fracture. Eighty-six percent of women recruited with a fragility fracture were 75 years of age or less. The age distribution between fragility and traumatic fractures was similar. To date, 338 participants with a fragility fracture have completed the questionnaire at phase 2 and 50 (15%) out of these 338 women were already on treatment for osteoporosis at the time of their fracture. Of those with no treatment (288) at phase 1, 52 (18%) initiated pharmacological therapy in the 6-month period following their fracture. At phase 2, 79 (27%) of participants either received a diagnosis of osteoporosis or were on treatment. In ROCQ, 81% of fractures were considered related to osteoporosis while the literature estimates that 70% of the fractures in those over age 45 are attributable to osteoporosis (1). Despite the availability of diagnostic modalities and effective treatments for osteoporosis, there is a substantial care gap (73%) in the management of this disease. The proportion of fragility fractures is higher than expected and the management of osteoporosis is not optimal. The information from this programme may improve post-fracture diagnosis and treatment of osteoporosis in Quebec. ***LRP5* Genetic Variants Influence Bone Mineral Density in Men.** M. A. Koay[1], S. Yeung*[2], M. A. Brown[1], P. R. Ebeling[3]. [1]Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [2]Diabetes and Endocrinology, The Royal Melbourne Hospital, Parkville, Australia, [3]Diabetes and Endocrinology and Medicine, The Royal Melbourne Hospital, Parkville, Australia.

Background: Osteoporosis in men is a poorly recognized condition. The NHANES III survey reported the prevalence of hip osteoporosis was 3-6% in men aged > 50 years. One third of all hip fractures and one fifth of vertebral fractures occur in men. There is increasing evidence that genetic factors underlying BMD and osteoporosis risk operate in a sex-specific manner. A leading genetic candidate in BMD regulation is the *LRP5* gene. Hypothesis: We propose that *LRP5* gene polymorphisms modulate BMD and fracture risk in men. Methods: Two cohorts were recruited. The first cohort comprised men with a history of spinal fractures (n = 78, age 22 to 88 years) and healthy, fracture-naïve men (n=65, age 21 to 80 years). The second cohort comprised 56 families of men with osteoporosis and fragility fractures. Lumbar spine, proximal femur and total body BMD and total body bone mineral content (TBBMC) were measured by DXA. Genomic DNA was obtained for determination of *LRP5* genotypes. *LRP5* allele, genotype and haplotype frequencies in control and fracture populations were compared using contingency table analysis. Association of *LRP5* gene polymorphisms and bone mass indices within families were assessed by QTDT (assuming additive interactions between un-measured environmental and polygenic factors). Results: *LRP5* allele, genotype or haplotypes were expressed at similar frequencies in men with and without fragility fractures, indicating that *LRP5* polymorphisms were not associated with fracture risk in our cohort. Instead QTDT analysis of families of osteoporotic men with fractures identified association between the coding C135242T (F549F) polymorphism in exon 8 and FN BMD Z-score (p = 0.026). Restricting analysis to men did not significantly reduce the strength of this association (p = 0.048). Within families, a trend towards association between height and the C165215T (A1330V) *LRP5* polymorphism in exon 18 was noted (p = 0.062 in the entire family cohort, p = 0.092 men-only analysis). No evidence of linkage between *LRP5* polymorphisms and bone mass nor height was observed. Conclusions: Positive association between the F549F *LRP5* polymorphism and femoral neck BMD, and a trend towards association between the A1330V *LRP5* polymorphism and height were noted in families of men with osteoporosis and fragility fractures. No single *LRP5* polymorphism was predictive of fracture risk. This study confirms previous work, which has demonstrated that *LRP5* gene polymorphisms modulate BMD in men.

Disclosures: ***M.A. Koay****, None.*

Calcification of Abdominal Aorta and Osteoporosis. S. Yaturu[1], J. F. Bridges*[2], B. A. Bryant*[3]. [1]Endocrinology, VAMC/LSUHSC, Shreveport, LA, USA, [2]Nutrition, VAMC, Shreveport, LA, USA, [3]Endocrinology, VAMC, Shreveport, LA, USA.

Calcification is a common feature of atherosclerotic plaques. Coronary calcification and aortic calcification positively correlate with each other. Osteoporosis and Atherosclerotic heart disease are common in elderly people. There is accumulating evidence that osteoporosis is associated with both atherosclerosis and vascular calcification. Bone mineral density (BMD) measured at the lumbar spine in those over 70 years of age may be falsely elevated due to aortic calcification and structural changes within the spine such as osteophytes, osteochondrosis and facet sclerosis. BMD at radius is the proposed alternate site when AP spine data is unreliable. Since spine has more trabecular bone and radius has more trabecular bone, we hypothesized that we there is a need for alternate site to measure. We analyzed the bone mineral density results of 50 subjects with abdominal aortic calcification (AAC), with a mean age of 73. Atherosclerosis, either coronary artery and or peripheral vascular disease is prevalent in 80% of the subjects. The BMD at lateral spine correlates with % abdominal fat (r = 0.46). Though 8 subjects had fragile hip fractures, BMD at 33%radius were within normal range.

Site	BMD	Osteoporosis (%)	Osteopenia	Normal
AP spine	1.181	4	29	67
Lateral Spine	0.578	51	31	18
Hip	0.904	16	51	33
Radius	0.727	9	36	55

In conclusion, AAC was associated with increased abdominal fat, abnormal lipid parameters and decreased bone mineral density. BMD at AP spine in subjects with aortic calcification is unreliable and the lateral spine and hip are better alternatives than the 33% radius.

Men with Hip Fractures Are Younger, Sicker and More Likely to Die. S. L. Silverman[1], D. Zingmond*[2]. [1]Medicine and Rheumatology, Cedars-Sinai Medical Center, David Geffen School of Medicine UCLA, Beverly Hills, CA, USA, [2]Medicine, David Geffen School of Medicine UCLA, Los Angeles, CA, USA.

Purpose: To compare demographics, length of stay, and short and long-term mortality in men and women with hip fracture in California 1991-2001. Methods: Using inpatient discharge abstracts from the California Office of Statewide Planning and Development (OSHPD)'s inpatient discharge database (PDD), all patients hospitalized in California with acute hip fracture and repair were identified between 1991 and 2001. Out of hospital death was ascertained by linkage to the state death registry through 2001. Results: There were fewer hip fractures in men than women (67,680 vs 183,311). Men with hip fractures were younger (mean age 74 vs 81, median age 74 vs 81). Men were more likely minority (17% vs 13% non-Caucasian). Men were sicker (mean Charlson index 1.2 vs 1.0) The percent admitted from SNF were similar (9% of men and 10% of women); however, men stayed longer in hospital (7.3 vs 6.5 days; were more likely to be discharged to home (17% vs 9.5%); and less likely to be discharged to SNF (61% vs 72%). Men were more likely to die in hospital (3.4% vs 1.9%) and more likely to have pulmonary embolism or other cardiovascular complication. Mortality was greater in men at 30 d (9.9% vs 5.6%); 60 d (13.6% vs 8.2%); 180 d (21.2% vs 13.7%) and 365d (27.6% vs 19.0%). Conclusions: Men with hip fractures in the last decade in California were younger, sicker and more likely to die in hospital and long-term. Men with hip fracture should be identified as being at high risk for increased morbidity and mortality.

Referral Patterns for Men to an Osteoporosis Scanning Service from Family Practitioners. A. D. Khan*, G. M. Blake, I. Fogelman. Guy's King's and St Thomas' School of Medicine, London, United Kingdom.

The aim of this study was to investigate the reasons why General Practitioners (GPs) refer men for a bone densitometry examination and the relationship between patients' bone mineral density (BMD) and their clinical risk factors for osteoporosis. A total of 253 male patients referred between January 1998 and December 2004 were identified. Referral letters were reviewed and classified according to the indication for performing a BMD examination. Patients completed a questionnaire that was used to identify risk factors for osteoporosis. Spine and hip BMD scans were performed on a Hologic QDR4500A and interpreted using T- and Z-scores calculated from the manufacturer's reference range for the spine and the NHANES range for the hip. The 253 men (mean age 62.2 y; age range 25 to 91 y) comprised 2.8% of all GP referrals during the 7-year period. The percentage of men increased slightly from 2.4% in 1997 to 3.0% in 2004. The most common reasons for referral were: corticosteroid use (33%); radiographic evidence of osteopenia (19%); back pain (19%); follow-up of a previous scan (14%); recent fracture (12%). The most common risk factors identified on the questionnaire were: corticosteroid use (43%); alcohol intake (> 10 units a week) (35%); current smoking habit (27%); family history of osteoporosis (26%); previous fracture (23%). Forty-three men (17%) had a T-score of -2.5 or less at the spine, 29 (12%) at the femoral neck, and 16 (6%) at the total hip. Multi-variant regression analysis was used to examine the relationship between patients' Z-scores and their clinical risk factors for osteoporosis. For spine Z-score the statistically significant risk factors were: current smoking habit (Z -score decrement = -0.96, p <0.001), previous fracture: (Z -score decrement = -0.72, p = 0.008), and low BMI (< 20): (Z -score decrement = -1.13, p = 0.019). A history of osteoarthritis was associated with increased Z-score (Z-score increment = +1.11, p = 0.001). The same three factors (current smoker, previous fracture, low BMI) were also associated with statistically significant reduction in Z-score at the femoral neck and total hip. Former smokers were indistinguishable from men who had never smoked. In conclusion, only 3% of patients referred by GPs to an osteoporosis screening service were men. The indications given for referral were generally similar to those for women. Three clinical risk factors (current smoker, previous fracture and low BMI) were particularly associated with low Z-scores.

Vertebral Fractures in Patients with Chronic Obstructive Pulmonary Disease. Is Bone Mineral Density a Good Predictor? E. Casado*[1], M. Larrosa*[1], M. Gallego*[2], E. Naval*[2], A. Gómez*[1], J. Gratacòs*[1]. [1]Rheumatology, Hospital Sabadell, Sabadell, Spain, [2]Pneumology, Hospital Sabadell, Sabadell, Spain.

The aim of the study was to evaluate the prevalence of vertebral fractures in male patients with chronic obstructive pulmonary disease (COPD) and to assess the usefulness of dual-energy x-ray absorptiometry (DEXA) to predict vertebral fractures in these patients. A transversal study was conducted. All consecutive male patients with COPD who were visited in a 6-month period both in a Pneumology out-patient clinic and primary care were included. Conventional DEXA (lumbar spine and total femur) and thoracic and lumbar x-ray films were performed in all patients. The diagnosis of osteoporosis was established by bone mineral density (BMD) according to the WHO criteria (T-score ≤-2,5 in any of the explored region). A vertebral fracture was considered when the height of vertebral body was decreased at least 20% in any edge. The severity of COPD was established according to the American Thoracic Society (mild FEV_1>50%; moderated FEV_1 35-50%; severe FEV_1<35%). 99 male patients with COPD were included. Mean age was 67±8 years. COPD was moderated to severe in 60% of patients. Using the WHO criteria 27 patients had osteoporosis (prevalence 28%). 32/94 patients (34%) had vertebral fractures. 10/27 patients (38%) had vertebral fractures in the group of osteoporosis by DEXA, and 22/67 (32%) in the group without osteoporosis. Using the thoracic and lumbar spine x-ray as a gold standard, the presence of osteoporosis by DEXA had a sensitivity of 31%, an specificity of 72% and a negative predictive value of 67%. The prevalence of vertebral fractures in patients with COPD was 34% in our series. The BMD by DEXA does not seem to be a useful tool to predict vertebral fractures in these patients, since 32% of patients without osteoporosis had vertebral fractures.

Neuromuscular Function and Risk of Fractures in Older Men. K. Ensrud[1], R. Fullman[2], L. Marshall[3], H. Fink[1], B. Chan[3], J. Cauley[4], S. Cummings[2], E. Orwoll[3]. [1]VAMC & U of MN, Minneapolis, MN, USA, [2]UCSF & CPMC, San Francisco, CA, USA, [3]OHSU, Portland, OR, USA, [4]U of Pittsburgh, Pittsburgh, PA, USA.

Because men have higher peak bone mass than women and are less likely to experience rapid bone loss due to gonadal insufficiency, factors that increase propensity to falls such as impairment in neuromuscular function may be strong determinants of fracture (fx) risk in older men. To test the hypothesis that men with severe impairment in NMF are at increased risk of fx independent of bone mineral density (BMD), we performed measures of dynamic leg strength (ability and time to rise from a chair 5 times without using the arms), leg power (Nottingham Power Rig), dynamic balance (narrow walk speed) and femoral neck BMD at baseline in 5588 older men (mean age 73.6 yrs) enrolled in the MrOS cohort who were then followed prospectively for fxs. Each measure of NMF was first expressed as a categorical variable with 5 levels (first group comprised of those unable to complete measure and the remaining men divided into 4 groups of equal size) and then as a dichotomous variable (unable vs. able to complete measure). During an average follow-up of 3.7 yrs, 240 men (4%) experienced ≥1 non-spine fx, including 40 (0.6%) who suffered a first hip fx. After controlling for multiple potential confounders including BMD and fall history, men with severe impairment in NMF (as defined by inability to complete a given measure of NMF) were at increased risk of non-spine fx, including hip fx (table). When models for non-spine fx and hip fx included all 3 measures of NMF, inability to rise from a chair remained strongly associated with risk of fx, including hip fx. The relationship between each measure of NMF and non-spine fx was not entirely accounted for by an increased of hip fx; this was especially true for narrow walk where men unable to complete the narrow walk had a 1.9-fold (95%CI 1.2-2.8) increased risk of non-spine non-hip fx.

	Relative Risk of Outcome in Those Unable vs. Able*	
Unable to complete given measure of NMF (%)	Non-spine Fx RH (95% CI)	Hip Fx RH (95%CI)
Chair Stand (2.8%)	2.3 (1.3-3.8)	3.2 (1.3-7.6)
Leg Power (3.0%)	1.7 (1.0-3.1)	3.0 (1.1-8.0)
Narrow walk (8.8%)	1.7 (1.1-2.4)	1.2 (0.5-2.6)

*adjusted for age, clinic, health status, smoking status, physical activity, medical conditions, fall history, body weight and femoral neck BMD; models for non-spine fx also adjusted for race

Severe impairment in NMF in older men may be useful in a clinical setting to identify older men at high risk of fxs. Our findings suggest that inability to rise from a chair is most strongly associated with risk of hip fx, while inability to complete narrow walk is most strongly related to risk of other non-spine fxs.

Osteoporosis in Coumadin Clinic. K. E. Greenwald*, A. Wilson*, M. White-Greenwald. Desert Medical Advances, Palm Desert, CA, USA.

Vitamin K is an essential cofactor required for synthesis of bone matrix. We evaluated osteoporosis in 110 consecutive patients in a coumadin clinic, both men and women all over age 55, collecting data for height, weight, and bone mineral density by ultrasound of the calcaneus (Hologic Sahara). The broadband ultrasound attenuation units (BUA) have been shown previously to have 96% correlation with DEXA by using absolute fracture risk

(Arth& Rheum 48:92; 2003). Background information regarding medical history and concomitant medication was collected by interview and questionnaire. Time on coumadin ranged from 6 months to 20 years. Data was collected on a control cohort of patients with similar heart disease not on coumadin (chosen as a comparison group matched by sex, age, weight, use of alcohol or cigarettes, race, and economic background.) Patients with cancer or metabolic bone disease were excluded from this analysis. Less than 5% of patients were on any therapy for osteoporosis and these small numbers did not affect the statistical results. For men (n=62), the average age was 76 (SD 7), weight 185 lbs (SD 26), and we found the average BUA 70.3 (SD 20.5) with coumadin patients, and BUA 82.3 (SD 19.3) for men not on coumadin. There was no difference in baseline characteristics for the two populations. The difference in BMD was statistically significant $p<0.02$, and became more significant with age (evaluating groups in five year increments). For women (n=48), the average age was 76 (SD 7.2), weight 151 lbs (SD 33), and we found the average BUA 68.1 (SD 3.4) with coumadin patients, and BUA 73.6 (SD 3.1) for women not on coumadin. There was no difference in baseline characteristics for the two populations. The difference in BMD was highly significant, $p<0.00001$, and became more dramatic with age (evaluating groups in five year increments). With osteoporosis defined by absolute risk (red zone of high risk) , the relative risk of osteoporosis was 1.6 (CI 0.012,2.86) for patients taking prolonged warfarin therapy. This was significant for men, women, and for the group as a whole.

Bone Density (* significant)	Men	Women
+ Coumadin	N=45	N=31
BUA	70.3*	68.1*
Control	N=17	N=17
BUA	82.3	73.6

Serum Levels of 1,25-Dihydroxy Vitamin D in Persons of Norwegian and Pakistani Origin Living in Oslo, Norway: The Oslo Health Study. K. Holvik[1], H. E. Meyer[1], R. Selmer*[2], A. J. Søgaard*[2], J. A. Falch*[3], E. Haug*[3]. [1]Department of General Practice and Community Medicine, University of Oslo, Oslo, Norway, [2]Norwegian Institute of Public Health, Oslo, Norway, [3]Center of Endocrinology, Aker University Hospital, Oslo, Norway.

Higher or similar serum levels of the active vitamin D hormone (s-1,25$(OH)_2$D) in spite of low serum levels of 25-hydroxy vitamin D (s-25(OH)D) have been observed in African American subjects when compared to Caucasians. Also, one study from the US observed elevated s-1,25$(OH)_2$D levels in vitamin D-deficient Asian Indian immigrants compared to Caucasians, suggesting a compensatory mechanism in the vitamin D endocrine system. We have previously shown that although ethnic Pakistanis living in Oslo had a very high prevalence of secondary hyperparathyroidism (low s-25(OH)D and high serum parathyroid hormone) compared to ethnic Norwegians[1], the two ethnic groups had similar bone turnover[2] and bone mineral density[3]. The objective of the present study was to investigate s-1,25$(OH)_2$D in Norwegians and Pakistanis. We measured s-1,25$(OH)_2$D, s-25(OH)D and s-PTH in a subgroup of Norwegians and Pakistanis participating in the large cross-sectional Oslo Health Study 2000-2001. We here present results for 560 Norwegian men and women aged 45-60 years and 160 Pakistani men and women aged 30-60 years. Mean (95% CI) s-1,25$(OH)_2$D was 123.2 (120.4, 126.0) pmol/l in Norwegians and 93.5 (88.2, 98.7) pmol/l in Pakistanis ($p<0.0005$). Serum levels were similar in men and women within each ethnic group, and they did not vary with age. Adjustment for s-25(OH)D and s-PTH attenuated the ethnic difference although it was still significant with a mean difference of -9.1 (-17.0, -1.2) pmol/l ($p=0.024$). We conclude that Pakistani men and women living in Oslo have lower s-1,25$(OH)_2$D levels compared to ethnic Norwegians. This could partly, but not exclusively, be attributable to vitamin D deficiency.

A Structural Microsimulation Generates Type I and Type II Osteoporosis from Estrogen Deficiency. D. J. Vanness[1], A. N. A. Tosteson[2], S. E. Gabriel*[3], S. Khosla[4], L. J. Melton, III[5]. [1]Department of Population Health Sciences, University of Wisconsin Medical School, Madison, WI, USA, [2]Department of Medicine and Department of Community and Family Medicine, Dartmouth Medical School, Lebanon, NH, USA, [3]Department of Health Sciences Research, Mayo Clinic College of Medicine, Rochester, MN, USA, [4]Division of Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA, [5]Department of Population Health Sciences, Mayo Clinic College of Medicine, Rochester, MN, USA.

Structural microsimulations (i.e., use of mathematical equations to model the biological processes giving rise to osteoporotic fracture at the individual level) hold potential to be a powerful, theory-based tool for integrating evidence, generating testable hypotheses and evaluating the likely impact of osteoporosis interventions. We have developed a first-generation structural microsimulation in which a bone remodeling process serves both to maintain calcium homeostasis and preserve a constant level of sensed strain. A penalized optimization algorithm varies PTH levels, and consequently rates of excess resorption, to equilibrate supply of and demand for the pool of extracellular calcium. In the simulation, reductions in circulating estrogen at menopause reduce levels of sensed strain, triggering an increase in resorption and an excess supply of extracellular calcium, which in turn induces lower PTH and increased calcium excretion. Resulting changes in bone mass, quality and architecture increase both sensed and actual strain, ultimately resolving the first phase of osteoporosis (type I). In the simulation, long-term suppression of estrogen reduces both gastrointestinal calcium absorption and conversion of vitamin D to its metabolically active forms, thus reducing both the supply of extracellular calcium and promoting excess PTH secretion. The resulting secondary hyperparathyroidism induces a second phase of excess bone resorption that does not resolve over time (type II). Further reductions in bone mass, quality and architecture reduce the bone's work-to-failure, resulting in higher rates of fracture from traumatic loads as simulated by draws from an extreme-value distribution. The next steps in simulation development involve "calibration" of model parameters such that simulated data closely matches both cross-sectional and longitudinal empirical observations and "external validation" through replication of clinical trial data not used in the calibration process. Planned future applications of the simulation include both societal level health program evaluation and decision tools meant to improve the clinical care of individuals at risk of osteoporotic fracture.

Heel Bone Ultrasounds and Resorption Markers as Independent Predictors of Non Vertebral Rracture: a Nested Case-Control Study. M. Krieg[1], W. Riesen*[2], M. Kraenzlin[3], P. Burckhardt[1], J. Cornuz*[1]. [1]Outpatient Clinic, University Hospital, Lausanne, Switzerland, [2]State Hospital, St-Gall, Switzerland, [3]Endocrinology, University Hospital, Basel, Switzerland.

It has been shown that heel bone ultrasounds (QUS) and resorption markers (RM) predict osteoporotic fracture independently of hip DXA in elderly women. However, only limited data are available on the combination of QUS and RM as a screening strategy. SEMOF is a multicenter cohort study of risk factors for non vertebral fracture in 7062 Swiss women aged 70 yrs or older, recruited from population-based listings. All the women were assessed by QUS (Sahara, Hologic), and gave a 2nd fasting urine sample for RM. During a mean follow-up of 2.8 years, 349 women reported a hip, forearm, or proximal humerus low trauma fracture. To assess the predictive power of RM, 250 fractured women and 250 controls (matched for age, BMI, center, and follow-up duration) were randomly selected and included in a nested case-control study. Total pyridinolines (PYD) and deoxypyridinoline (DPD) were measured by high performance liquid chromatography, and corrected by creatinine excretion. From the 500 selected women, 406 urine samples were analysable at the end of the study. 38 women were excluded because they were under HRT or antiresorptive therapy. Finally, 368 women (195 cases, 173 controls) were included in this analyse, mean age 76 yrs and BMI 25 kg/m2. Medians of the different variables were used as cutoffs (66 U for Sahara QUI, 73 nmol/mmol Cr for PYD, 13.9 nmol/mmol Cr for DPD). Associations of the variables with incident fractures were expressed as OR (95% CI) by logistic regression. AUC (95% CI) were also calculated in order to compare the power of the different variables. In conclusion, heel bone ultrasound, pyridinolines and deoxypyridinolines predict osteoporotic non vertebral fracture at the same magnitude in elderly women. Combining a resorption marker with a heel QUS measurement improve the prediction of patient at high risk of fracture.

	Low QUI	High PYD	Low QUI +High PYD	Low QUI +High DPD
OR (95% CI)	2.4 (1.6, 3.7)	1.9 (1.3, 2.9)	3.7 (2.1, 6.5)	3.3 (1.8, 5.9)
AUC (95% CI)	0.65 (0.60, 0.71)	0.62 (0.56, 0.68)	0.70 (0.63, 0.77)	0.68 (0.60, 0.76)

Is DXA a Useful Tool for Assessing Skeletal Muscle Mass in Older Women? Z. Chen[1], Z. Wang*[2], E. Outwater*[1], S. Heymsfield*[2], D. Sherrill*[1], T. Lohman*[1], A. LaCroix*[3], S. Nicholas*[1], G. Wu*[1], N. Wright*[1], L. Arendell*[1], C. Moll*[1], G. Caire*[1], D. A. Nelson*[4], M. Punyanitya*[2], J. Cauley[5], C. E. Lewis[6], T. Beck[7], R. Jackson*[8], M. LeBoff*[9], T. Bassford*[1], S. Going*[1]. [1]University of Arizona, Tucson, AZ, USA, [2]Columbia University, New York, NY, USA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [4]Wayne State University, Detroit, MI, USA, [5]University of Pittsburgh, Pittsburgh, PA, USA, [6]University of Alabama at Birmingham, Birmingham, AL, USA, [7]Johns Hopkins University, Baltimore, MD, USA, [8]Ohio State University, Columbus, OH, USA, [9]Harvard Medical School, Boston, MA, USA.

Skeletal muscle mass (SMM), especially leg muscle, may have direct impact on risk of fall and fracture. Dual-energy x-ray absorptiometry (DXA) measures both bone mineral density and soft tissues and it has been widely used in osteoporosis screening, management and research. Although a method for predicting SMM by DXA measurements has been developed in a previous study, whether DXA can be used to estimate total body and regional SMM in the elderly remains to be studied. Using SMM measurements from magnetic resonance imaging (MRI) as the gold standard for SMM, we examined the utility of DXA-derived measurements in predicting SMM. Postmenopausal women (N = 39) who were 71.3± 6.1 years old, from an ancillary study of the Women's Health Initiative, had total body scans on both MRI (5x GE Signa, 10 mm per slice and 40 mm between slices) and DXA (Hologic Inc, QDR 4500w). DXA analyses were conducted on total and regional body composition from the whole body scans. MRI scans were analyzed using image analysis software (TomoVision Inc, Montereal, Canada). Linear regression analysis was used to study the linear association between MRI-derived SMM and DXA-derived body composition. We found that DXA-derived lean soft tissue mass was highly correlated with MRI-derived SMM (R^2 was 0.607, 0.822 and 0.812 for total body, whole leg and upper leg, respectively). Adding age and % body fat from DXA increased R^2 in the regression models (**Table 1**). In conclusion, DXA-derived body composition measurements are highly correlated with MRI-derived SMM in older women. The DXA measurements and age provide a better prediction for SMM of the leg than of the total body.

Table 1. Regression Models for Predicting MRI-derived SMM

Models	Regression coefficient	SE	P-value	R^2
Total Body				
Lean soft tissue mass (kg)	0.407	0.053	0.000	
Age (year)	-0.173	0.053	0.002	0.706

Osteoporosis Treatment in the Home Health Care Setting: A Window of Opportunity? J. R. Curtis[1], T. Bryant*[2], Y. Kim*[3], D. Scott*[2], M. Rousculp*[4], K. G. Saag[1]. [1]Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Alacare, Inc., Birmingham, AL, USA, [3]Division of Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL, USA, [4]Eli Lilly & Co., Indianapolis, IN, USA.

Purpose Hospitalized fracture patients commonly receive structured home health services upon discharge. However, patterns and predictors of osteoporosis treatment in home health care settings are largely unknown. **Methods** Electronic medical records of a statewide home health agency (~7000 pts/yr) identified patients at high risk for new fracture based on prior fracture, osteoporosis dx, stroke, or glucocorticoid use. Linked medication data was used to compare use of osteoporosis Rx between groups. **Results** We identified 1742 unique high risk patients referred for home health services during 1/03 - 12/04. Potentially overlapping comorbidities of interest included prior fracture of any type (n = 364), hip fracture (n = 78), glucocorticoid use (n = 961), osteoporosis dx (n = 351), and stroke (n = 289). Patients were 71% female, 88% white, 11% Black, mean ± SD age 77 ± 12 yrs, and 95% Medicare enrollees. One-fourth of individuals had impaired decision-making capacity when referred. Individuals were taking a mean of 13 ± 7 concurrent medications. Home health services were provided for a mean of 84 ± 118 days per episode. Ninety-one percent of services were provided in a private residence; 48% of recipients received >1 episode of home health care. Sixteen percent (16%) died or were discharged to hospice, and 11% were readmitted to the hospital at the end of the episode of care. Rates of non-estrogen prescription osteoporosis Rx and calcium ± Vitamin D supplements are shown (Table) and were different between groups for non-estrogen osteoporosis prescription Rx ($p < 0.001$), calcium ± Vitamin D ($p < 0.001$), and the combined endpoint ($p < 0.001$). **Conclusions** Similar to results from both community and nursing home osteoporosis prevention studies, rates of both prescription and non-prescription osteoporosis treatment in home health care settings were relatively low, even among high risk patients. In light of potential difficulties in initiating certain osteoporosis treatments in hospitalized patients, home health care may be an appropriate setting to target intervention efforts aimed at improving quality of osteoporosis care for high risk patients.

Comorbidity	N (%)	Non-estrogen Prescription Rx N (%)	Calcium ± Vitamin D N (%)	Prescription Rx or Calcium ± Vitamin D N (%)
Hip Fracture	71 (4)	13 (18)	15 (21)	23 (32)
Non-hip Fracture	252 (14)	46 (18)	62 (25)	85 (34)

Differential Bone Histomorphometric Characters of the Mandible and Femur in Senescence-Accelerated Mice (SAMP6 and SAMP8), Murine Models for Senile Osteoporosis and Temporomandibular Joint Osteoarthritis. T. Matsuura, Y. Daigo*, Y. Goto*, M. Katafuchi*, K. Tokutomi*, T. Tsuzuki*, H. Sato*. Oral Rehabilitation, Fukuoka Dental College, Fukuoka, Japan.

To characterize the potential status of oral bone with senile osteoporosis (OP) and temporomandibular joint osteoarthritis (TMJOA), we performed histomorphometric analysis of the mandible and femur in three strains of senescence-accelerated mice, SAMP6 as a senile OP model, SAMP8 as a TMJOA model, and SAMR1 as a control. A total of 36 male mice at 2 and 4 months of age were used. Six left mandibles and femurs for each strain and age were examined by histomorphometrical analysis. The analysis of the femur was performed in the distal metaphysis for cortical and trabecular bone assessments, while that of the mandible was in the mandibular ramus for cortical bone assessment and in the alveolar bone for trabecular bone assessment. The cortical bone was assessed by cortical thickness index (CTI) and the trabecular bone was assessed by bone area (B.Ar/T.Ar), trabecular width (Tb.Wi), trabecular number (Tb.N), trabecular separation (Tb.Sp), osteoblast perimeter (N.Ob/B.Pm), and osteoclast perimeter (N.Oc/B.Pm). The experimental protocol was approved by the Ethical Committee for Animal Experiments in our institute. Compared with SAMR1, SAMP6 showed smaller values of B.Ar/T.Ar and Tb.Wi in the femur and mandible at 2 months of age. At 4 months of age, this strain kept the smaller values of these indices and furthermore showed smaller value of CTI in the two bones, larger values of Tb.N and Tb.Sp in the femur, and larger value of Tb.Sp in the mandible. On the contrary, SAMP8 showed larger value of CTI in the two bones at 2 months of age and kept them in the mandible but not in the femur at 4 months of age. This strain did not show smaller bone mass in the trabecular bone. Interestingly, SAMP6 exhibited a smaller value of N.Ob/B.Pm in the femur but not in the mandible at 4 months of age, while SAMP8 did show a smaller value of N.Oc/B.Pm in the mandible but not in the femur at 2 and 4 months of age. Collectively, the mandibles of SAMP6 showed osteoporotic features in structure without a decline in osteoblast numbers, while that of SAMP8 did show the thickening of the cortical bone with a decrease in osteoclast numbers. The mandibles in senile OP and before the onset of TMJOA attack appear to show histologic differences from each other, and specific features different from the femur.

Soluble RANKL Has Detrimental Effects on Cortical and Trabecular Bone Volume, Mineralization and Bone Strength in Mice. Y. Y. Yuan[1], A. G. Lau*[1], P. J. Kostenuik[2], S. Morony[2], S. Adamu[2], F. Asuncion[2], T. A. Bateman[1]. [1]Bioengineering Department, Clemson University, Clemson, SC, USA, [2]Metabolic Disorders, Amgen Inc., Thousand Oaks, CA, USA.

RANKL is an essential mediator of osteoclast formation, activation and survival. Preclinical studies have shown that RANKL inhibition significantly improves bone density and strength at both cortical and trabecular sites. RANKL inhibitors have also been shown to improve cortical geometry in rodents and primates. Cortical structural and material properties are important determinants of bone strength. We hypothesized that the direct injection of soluble RANKL will cause detrimental effects on bone geometry and density and therefore degrade strength. Ten-week-old C57BL/6J female mice (n=12) were injected twice daily (SC) with human recombinant RANKL (0.4 or 2 mg/kg/day) or vehicle (VEH) for 10 days. Mice treated with high-dose RANKL exhibited significant weight loss (11% vs. VEH, $p<0.001$) and hypercalcemia. Low dose RANKL did not cause significant hypercalcemia or weight loss. Bone turnover was greatly accelerated by RANKL, as evidenced by 83.8% and 49.2% increases in serum TRAP-5b levels ($p<0.05$ vs. VEH), 3-4-fold increases in alkaline phosphatase in mice treated with low- and high-dose RANKL, respectively ($p<0.001$ vs. VEH). Both doses of RANKL caused substantial catabolism of both cortical and trabecular bone. Dry and ash weights were used to determine the % mineral content (%Min) of the femoral diaphysis (cortical bone) and the proximal femoral metaphysis (mixed cortical and trabecular bone). Both doses of RANKL caused significant reductions in %Min at both sites ($p<0.05$ vs. VEH). MicroCT analysis of the proximal tibial metaphysis revealed a profound loss of trabecular bone in RANKL-treated mice.

Trabecular bone density was reduced by 85% with both doses of RANKL ($p<0.001$ vs. VEH). Cortical bone geometry and strength were also negatively influenced by RANKL. MicroCT analysis of an 8 mm section of the femoral diaphysis showed that both doses of RANKL significantly reduced cortical bone volume (10-13% vs VEH, $p<0.001$). Biomechanical testing confirmed that RANKL directly reduces bone strength. Three-point bending of the femoral diaphysis showed that both doses of RANKL caused significant reductions in maximum bending load (19-25% lower than VEH, $p<0.001$). These data demonstrate for the first time that soluble RANKL administration has direct catabolic effects on both trabecular and cortical bone. These catabolic effects included reductions in bone volume and mineral density, and a significant decrease in bone strength. Inhibition of RANKL is therefore a logical and promising approach for improving cortical and trabecular bone mass and strength.

Longitudinal Assessment of Bone Architecture in Women - Relation to Hormonal Status, Bone Turnover Markers (BTM) and Fracture Risk. The OFELY Study. P. Szulc, F. Duboeuf*, E. Sornay-Rendu*, F. Munoz*, P. D. Delmas. INSERM 403, Hopital E. Herriot, Lyon, France.

Longitudinal data on age-related changes in bone architecture in women and their relation to the fracture risk are scarce. We studied age-related changes of bone architecture at the third distal radius measured annually by QDR Hologic 2000 in 535 women aged 31-89 from the OFELY cohort. In 53 women, 71 incident fragility fractures occurred during the follow-up (7.1±2.5 years). Before the menopause, areal bone mineral density (aBMD) and cortical thickness decreased due to centrifugal displacement of the constant amount of bone mineral assessed by cross-sectional area (CSA). After the menopause, decrement in CSA and cortical thinning resulted in the decrease of estimated bending strength despite continuous periosteal expansion. In 72 women, these changes were significantly reduced by the hormone replacement therapy. In postmenopausal women, elevated serum levels of BTM (osteocalcin, ß-CTX-I) at baseline were associated with accelerated decrease in CSA and cortical thinning but not with periosteal expansion. Low values of external diameter, CSA, cortical thickness and section modulus were associated with increased risk of incident fracture (O.R. = 1.46 - 1.99 per 1 SD decrease, $p<0.01$-0.0001). Bone width and section modulus remained predictive of fractures after adjustment for aBMD (O.R. = 1.63 and 1.74 per 1 SD decrease, respectively, $p<0.0001$). In summary, our longitudinal data show age-related changes of bone architecture and estimated bending strength at the distal radius that vary according to the hormonal status. Elevated BTM are associated with accelerated bone mineral loss and cortical thinning. Low bone width and section modulus were predictive of incident fractures independently of aBMD.

Latent Hypothyroidism Is Related to Lower Heel QUS in Postmenopausal Japanese Women. S. Sekiguchi, M. Nagata*, K. Nishiwaki-Yasuda, Y. Ono*, K. Inagaki*, T. Matsumoto*, S. Imamura*, H. Kakizawa*, N. Hayakawa*, N. Oda*, A. Suzuki, M. Itoh*. Division of Endocrinology, Fujita Health University, Toyoake Aichi, Japan.

In untreated hypothyroidism, histomorphometric studies have disclosed a decreased bone turnover in both trabecular and cortical bones with an increased cortical thickness. Recent findings suggest that thyroid stimulating hormone (TSH) is a negative regulator of skeletal remodeling by reducing both differentiation of osteoblasts and formation of osteoclasts. In addition, increased fracture risk in untreated hypothyroid patients has been reported to begin up to 8 years before diagnosis. The aim of the present study was to investigate the bone quality by using the heel QUS in the patients with latent hypothyroidism. Subjects were outpatients without any past or present history of thyroid disease. Among 210 postmenopausal women, 23 subjects of 33 patients (Hypo), who had elevated serum TSH level (TSH > 4 μU/ml) with normal serum free T4 (FT4) levels, agreed to join to this study. We also randomly selected 24 control subjects (Cont) from 176 postmenopausal patients with normal thyroid status. Calcaneus osteo sono assessment indeces (OSI) of right feet were measured using the ultrasound bone densitometry AOS-100 (Aloka Co., Japan). Serum TSH levels in Hypo patients (5.31 ± 1.3 μU/ml) were higher than those in Cont patients (2.05 ± 1.1 μU/ml), but there was no significant difference of FT4 levels (Cont 1.33 ± 0.15 ng/dl; Hypo 1.19 ± 0.17 ng/dl). OSI in Hypo subjects (Mean ± SD, 2.138 ± 0.152) were significantly lower than those in Cont subjects (Mean ± SD, 2.347 ± 0.243) (Student's *t*-test, $p < 0.001$). Simple regression statistical analysis showed that OSI decreased according to the increase of serum TSH level ($R = 0.415$, $n = 47$, $P<0.037$). In addition, multiple regression analysis showed that serum TSH level more than 4 μU/ml was associated with the decrease of OSI. These results suggest that latent hypothyroidism affects the structure of bone, resulting in the elevation of fracture risk.

Remodeling Cavities and Stress Risers: A Biomechanical Study on Cancellous Bone Strength. C. J. Hernandez, A. Gupta*, T. M. Keaveney. Orthopaedic Biomechanics Laboratory, Department of Mechanical Engineering, University of California, Berkeley, CA, USA.

Bone turnover has been implicated as an aspect of bone quality. One proposed mechanism for this effect is the possibility that remodeling cavities can act as stress risers, substantially altering the strength of cancellous bone with only small changes in bone mass. This mechanism does not require disconnection of trabeculae and thus is independent of connectivity. In this study we tested this theory, namely, that geometric effects associated with remodeling cavities can alter cancellous bone strength more than would be expected from the associated loss of bone mass. Cubes of cancellous bone (5mm in each dimension) were derived from micro-computed tomography based images (22 m resolution) of vertebral bone from 10 female and 7 male donors (aged 54-90 years). Remodeling cavities (88 m in depth) were added at random to the cancellous bone surface using an algorithm that prevented trabeculae from being disconnected. Cavities were added until a total of 6% of the initial bone mass was removed. Each image was then converted into a high-resolution finite element model to compute elastic modulus (stiffness) and strength of the cube in compression. These models included both material and geometric non-linearities, and can be considered surrogates for actual biomechanical testing. Results indicated that addition of cavities reduced compressive elastic modulus in each sample by 18.4 ± 2.6% (mean ± SD) and strength by 22.2 ± 4.4%. After accounting for differences in bone volume fraction, elastic modulus and strength were typically 11% ($p = 0.10$) and 15% ($p=0.08$) lower when cavities were present, but these changes did not reach statistical significance Overall, the changes reported here represent an upper bound on expected effects since the assumed cavity depth was high. These results suggest two possibilities. First, that there is no appreciable stress riser effect - independent of bone mass. Or second, that stress riser effects are manifested either by cavities that occur exclusively in regions of high stress (van der Linden et al. 2001) (as opposed to random placement studied here), or, under more complex apparent loading conditions than studied here. Further study is therefore recommended to elucidate this potentially important aspect of bone quality.

Inhaled Steroids Decrease Bone Mineral Density and Increase the Risk of Fractures: Data from the GIUMO Study Group. M. Sosa, P. Saavedra*, &. the GIUMO Study*. Medicine, University of Las Palmas de GC, Las Palmas de Gran Canaria, Spain.

Background: Although the negative effect of systemic steroids on bone is well documented, there is not clear evidence about the possible adverse effects of inhaled steroids on bone metabolism and fractures. **Design:** Cross-sectional study performed on 105 women suffering from bronchial asthma treated with inhaled steroids and 133 controls. Bone mineral density (BMD) was measured either by quantitative ultrasound (QUS) at the calcaneus or by dual x-ray absorptiometry (DXA) both at the lumbar spine and proximal femur. **Results:** Patients suffering from bronchial asthma showed no statistically significant changes in BMD measured by DXA or QUS compared to controls. However, the age-adjusted mean at the lumbar spine was of borderline significance ($p = 0.098$), being the 96%CI for the difference of means (-0.006 ; 0.067) and the upper bound for the percentage of diminution of 6.8%. A higher prevalence of fractures was found in the group of women with bronchial asthma, with an age-adjusted odds ratio of 2.79 (95% CI = 1.19 ; 6.54). **Conclusions:** Inhaled steroids do not seem to decrease BMD, but they are associated with an increased risk of fracture in women.

The Participation of Endogenous Parathyroid Hormone in Pathogenesis of Glucocorticoid-Induced Osteoporosis. M. Yamauchi[1], T. Yamaguchi[1], S. Yano[1], H. Kaji[2], K. Chihara*[2], T. Sugimoto[1]. [1]Department of Endocrinology, Metabolism and Hematological Oncology, Shimane University School of Medicine, Izumo, Japan, [2]Division of Endocrinology/Metabolism, Neurology and Hematology/Oncology, Kobe University Graduate School of Medicine, Kobe, Japan.

It is the current recognition that the participation of secondary hyperparathyroidism is minor in the pathogenesis of glucocorticoid (GC)-induced osteoporosis (GIO). However, the role of endogenous PTH in the regulation of bone resorption by GC treatment remains unclear. We examined the effect of endogenous PTH on bone in patients with long-term GC therapy, and also investigated the effects of dexamethasone (Dex) on PTH-induced osteoclast differentiation *in vitro*. One hundred and seventy-four female patients with GC-treatment for more than 6 months were participated in this study (mean: age 47yr, daily dose of predonisolone 10mg, treatment duration 84months). Postmenopausal subjects were ninety. The serum levels of intact PTH and osteocalcin (OC), and urinary level of deoxypyridinoline (DPD) were measured (mean: 35pg/ml, 4.2ng/ml, 6.9nM/nMCr, respectively). BMD measurements were performed by DXA at the lumbar spine, femoral neck and distal one third of radius (mean: 0.857g/cm ^{2}[Zscore -0.440], 0.660[-0.387], 0.616[0.662], respectively). We assessed the architectural parameters of cortical bone by pQCT. Forty women had vertebral fractures (VFr). PTH levels exhibited positive correlation with DPD but not OC levels. Endocortical circumference was positively correlated with PTH levels. BMD at any site as well as cortical bone area and cortical thickness had negative correlations with PTH levels. PTH levels were significantly higher in women with VFr than in those without ones. These results suggest some participation of endogenous PTH in GIO. In unfractionated mouse bone cell cultures, Dex increased PTH/PTHrP receptor mRNA expression by Northern blot analysis and PTH-stimulated cAMP accumulation. Moreover, pretreatment with Dex significantly augmented PTH-induced osteoclast differentiation in a concentration-dependent manner. These findings suggest that GC enhances the sensitivity of bone to endogenous PTH, resulting in relatively accelerated bone resorption. In conclusion, our study showed that endogenous PTH was associated with bone resorption marker, BMD values, cortical thinning and the presence of VFr in GC-treated patients, and that GC augmented PTH-stimulated osteoclast differentiation. Our findings suggest that endogenous PTH, although within the normal range, partly participates in the pathogenesis of GIO presumably via acceleration of bone resorption.

Importance of Age in Rate of Incident Fractures in Glucocorticoid-Induced Osteoporosis. I. Tanaka, H. Oshima. Department of Laboratory Medicine, Fujita Health University School of Medicine, Toyoake, Japan.

[Objective] It has been appreciated that glucocorticoid causes osteoporosis, however, the correlation between age and incidence of fractures has not been established. In this study, we tried to clarify the importance of age in glucocorticoid-induced osteoporosis. [Subjects & Methods] 165 patients (143 females and 22 males) with connective tissue diseases under glucocorticoid therapy were enrolled in this study. The means of age, daily glucocorticoid dosage (prednisolone equivalent), and total glucocorticoid dosage were 50 years old, 8.3mg/day, and 22.8g, respectively. Bone mineral density (BMD) at the lumbar spine was measured at the baseline and after two years with dual-energy X-ray absorptiometry. [Results] 1) The rates of incident fractures were 23.5% [45-49 years old], 60% [55-59 years], 71.4% [65-69 years], and 100% [75-79 years]. 2) There was no threshold of age that evoked new fractures. 3) The rate of incident fractures in patients over 65 years old was high (more than 60%). 4) In the group of patients over 65 years old, incident fracture was 33% (with daily doses ≤5mg of prednisolone), 50% (BMD≥80%), and 60% (without prevalent fractures). [Conclusion] 1) These results suggested that age was an important risk factor for incident fracture in patients with glucocorticoid-induced osteoporosis. 2) Fracture risk in patients over 65 years old was high, regardless of the lack of other risk factors. 3) Patients over 65 years old with glucocorticoid-induced osteoporosis should be treated for preventing osteoporotic fracture.

Bone Mass and Turnover Is Normalized after Successful Treatment of Adult Patients with Endogenous Cushing's Syndrome: A 6-Year Prospective Study. C. Kristo*, R. Jemtland*, T. Ueland*, K. Godang*, J. Bollerslev. Medical Dept., Section of Endocrinology, Rikshospitalet University Hospital, Oslo, Norway.

Endogeneous Cushing's syndrome (CS) is associated with bone loss and an increased risk of fractures. However, the long-term outcome of treatment on bone health has not been adequately clarified. We followed 33 patients with active CS prospectively before and two times after treatment (mean follow-up 33 (n=25) and 71 months (n=18), respectively). The patients were compared to age-, sex-, BMI-matched controls, also followed longitudinally. Bone mineral indices (BMD, BMC, bone area) were evaluated at the lumbar spine (LS), femoral neck (FN), and total body (TB) by DXA. Biochemical markers of bone turnover were assessed by measuring serum levels of osteocalcin and CTX-1. At baseline BMD at the LS, FN and TB was reduced by 14.8% (P<0.001), 15.7% (P<0.001), and 9.2% (P<0.001), respectively, in CS *vs.* controls. Serum osteocalcin was markedly reduced (P=0.014) and CTX increased (P=0.012), without correlation between the markers, indicating uncoupling of bone turnover. At the first follow up, BMD was increased in LS (7.9%, P<0.001) and FN (3.5%, P=0.003) compared to baseline and a positive correlation between increased BMD and time was demonstrated (LS (r=0.59; P=0.002) and FN (r=0.52; P=0.007)). This was paralleled by an increase in osteocalcin (275%, P<0.001) and the biochemical markers became correlated (r=0.92, P<0.001) indicating restoration of coupling. TB which predominantly represents cortical bone did not increase significantly before the second follow-up. At this time point, BMD Z-scores were normalized in all three compartments. In conclusions, these observations demonstrate that uncoupling of bone remodeling most likely explains the serious bone loss in active CS, and that treatment is followed by synchronization of bone remodeling and a successive normalization of bone mass, first evident at predominantly trabecular, later at cortical sites (in the order LS>FN>TB).

Serum Osteoprotegerin Levels Are Increased in Patients with Cushing's Syndrome: A Case-Control Study. A. Dovio*, B. Allasino*, M. Ventura*, L. Saba*, M. Terzolo*, A. Angeli. Dept. of Clinical and Biological Sciences, University of Turin, Orbassano-Turin, Italy.

Osteoprotegerin (OPG) plays a key-role in bone, immune and vascular systems. *In vitro*, glucocorticoids inhibit OPG expression in different cell types. *In vivo*, short-term glucocorticoids administration reduces serum OPG concentrations, while long-term glucocorticoid excess is associated with increased levels. Few data are available on serum OPG levels in Cushing's syndrome (CS). The aim of the present study was to assess serum OPG levels in patients with CS and age- and sex-matched controls, and to analyse correlations between serum OPG and clinical and hormonal variables. We studied 38 patients with CS (male/female 17/21, age (median, range) 55, 23-80 years). Twenty-seven of them had an ACTH-dependent syndrome (21 with Cushing's disease, 6 with ectopic ACTH hypersecretion). Eleven had an adrenal-dependent syndrome (9 with adrenal adenoma, 2 with adrenal carcinoma). 38 healthy subjects, mostly blood donors, served as controls (male/female 16/22, age 55, 22-79 years). Serum OPG concentrations were measured by an ELISA developed in our laboratory using commercially available reagents (OPG DuoSet, R&D Systems, Abingdon, UK). Serum OPG levels were higher in CS patients than in controls (1287, 403-4162 vs. 820, 349-2207 pg/ml, $p < 0.001$), and positively correlated with age in controls but not in CS patients. In the overall group of CS patients, OPG levels positively correlated with serum cortisol at 08:00 and 24:00. No significant correlation was found between serum OPG, on the one hand, and disease duration, bone turnover markers and BMD parameters, on the other one. Due to our previous findings that patients with Cushing's disease have BMD values higher than patients with adrenal adenoma, we searched for differences in serum OPG between these groups. Serum OPG levels were higher in Cushing's disease than in adrenal adenoma patients (1387, 827-2479 vs. 1059, 509-1250 pg/ml, $p < 0.02$); notably, the two groups were comparable for age and serum and 24-h urinary cortisol levels, but expectedly differed for ACTH and DHEA-sulphate levels; consistently with previous results, lumbar and femur BMD values were higher in Cushing's disease than in adrenal adenoma patients. In conclusion, OPG levels are increased in CS patients versus age- and sex-matched controls. In CS patients they positively correlate with serum cortisol and are higher in Cushing's disease than in adrenal adenoma patients. Whether this difference is linked to the greater bone loss observed in adrenal adenoma with respect to Cushing's disease patients remains to be elucidated.

Primary- and Secondary Prophylaxis to the Use of Systemic Glucocorticoid in Primary Health Care. B. R. Nielsen*, N. R. Jorgensen, P. Schwarz. Osteoporosis Research Unit, Dep. of Clinical Biochemistry 339, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark.

Our knowledge of glucocorticoid (GC) induced osteoporosis has increased significantly during the last years, but little information has been published regarding how primary care physicians handles prophylaxis of the condition. The question is, do GC patients receive primary- and secondary prophylaxis. Questionnaire was sent to all 3.617 family doctors in Denmark. We received responds from 1,000 family doctors, among these 535 questionnaires were evaluable representing 1,265,797 citizens corresponding to 23.4% of the Danish population. *Patients in actual treatment;* 303 (56,6%) of the responding physicians recommended calcium + vitamin D for their patients already in GC treatment without DXA of hip and spine or X-ray of the spine. Among the 303 9.9% recommend calcium + vitamin D from GC dosage > 7.5 mg, 27.1% from dosage 7.5 mg, 34.7% from dosage 5 mg and 28.1% from dosage 2.5 mg. Furthermore, we asked by which length of treatment the doctors gave there recommendation. 21.5% began after 1 month of treatment, 65.0% began after 3 months of treatment, whereas 6.0% began after 6 months. Further, 7.3% did not use length of treatment as parameter for starting prophylaxis. Among the doctors (232, 43,4%) who did not begin primary prophylaxis without DXA or X-ray

investigation, 65.1% made decision and began prophylaxis after DXA-skanning of hip or spine in case T-score was below -1, 78.4% began prophylaxis after DXA with a T-score below -2,5. Finally, 80.6% initiated prophylaxis after X-ray verifying vertebral fracture alone or with or without low T-score. *New patients, expected to start long term treatment of GC;* 23 of 535 (4.3%) doctors took routinely X-ray of the spine. 256 (47.9%) forwarded the patients for DXA of hip and spine. 18 (3.4%) did both investigations, whereas 274 (51.2%) did not perform any evaluation at all. 52 (9.7%) recommend calcium + vitamin D + bisphosphonate from the first GC prescription without DXA of hip and spine or X-ray of the spine,while 483 (90.3%) asked for DXA or X-ray before treatment. 138 (25.8%) began the treatment at a T-score of -1, whereas 303 (56.6%) began at T-score -2,5. Only 282 (52.7%) began treatment although X-ray showed vertebral fracture. In conclusion, our increased knowledge of GC side effects on bone and the increased risk of osteoporosis has not yet increased the use of calcium + vitamin D for primary prophylaxis in GC-induced osteoporosis in primary health care.

Progesterone Is Rapidly Inactivated in Human Osteoblasts. M. S. Cooper[1], K. Kaur*[1], W. Arlt*[1], P. M. Stewart*[1], M. Hewison[1], M. Quinkler*[2]. [1]Division of Medical Sciences, University of Birmingham, Birmingham, United Kingdom, [2]Department of Clinical Endocrinology, Charite Campus Mitte, Berlin, Germany.

Progestogenic compounds have been proposed as treatments for osteoporosis. Progesterone receptors are expressed in osteoblasts and progestogens have anabolic effects in vitro. Clinical studies however have failed to show bone related effects with most progesterone preparations. The reason for this discrepancy is not known. We hypothesise that pre-receptor progesterone metabolising enzymes have a major impact on progesterone action in bone and have therefore investigated the metabolism of progesterone in primary cultures of human osteoblasts and MG-63 osteosarcoma cells. Primary osteoblasts were generated from trabecular bone obtained from 7 patients undergoing knee replacement surgery. Sub-confluent monolayers were incubated in triplicate for 16h with 4-^{14}C-progesterone tracer and 50 nM unlabeled progesterone (to mimic luteal phase concentrations). After incubation, steroids were extracted with dichloromethane and two-dimensional thin-layer chromatography (TLC) used for identification. Steroid conversion was measured using a BioRad Molecular Imager. In parallel, RNA was extracted and RT-PCR analysis carried out to identify progesterone metabolizing enzymes. Intensive progesterone metabolism was observed in all primary cultures (up to 40%) with the specific activity being 2.3±0.3 pmol/mg protein/h. The two major products were the inactive 20α-dihydro-progesterone and 5α-dihydro-progesterone. Correspondingly, high expression of the enzymes responsible for these reactions, AKR1C1 and 5-reductase type 1, was observed using RT-PCR. The A-ring reduced metabolites, 3α,5α- and 3β,5α-tetrahydro-progesterone and their 20-reduced products were also detected along with mRNA for enzymes catalyzing these reactions; AKR1C2, 3β-HSD type 1 and hydroxysteroid-epimerase. Whereas expression and activity of most enzymes were similar in osteoblasts from all subjects the expression of 5α-reductase type 1 varied considerably. Expression of metabolizing enzymes also differed between primary osteoblasts and MG-63 cells. Total progesterone metabolism and the activity of specific pathways were unaffected by pre-incubation with 100 nM dexamethasone or estradiol for 72h. Human osteoblasts rapidly convert progesterone to inactive metabolites at an intracellular level. This effect may explain the lack of anabolism with progesterones in vivo and suggests that synthetic progesterones that are unable to be inactivated by osteoblasts may be more efficacious.

Ovariectomy Decreases Trabecular Bone Mass in T-Lymphocyte Deficient Mice. S. K. Lee[1], Y. Kadono*[2], B. Koczon-Jaremko*[1], Y. Choi*[2], J. A. Lorenzo[1]. [1]Endocrinology, University of Connecticut Health Center, Farmington, CT, USA, [2]Pathology & Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Previous studies failed to demonstrate decreases in femoral bone mass with ovariectomy (OVX) in nude mice, which lack T-lymphocytes because they have a defect in thymic development. We examined OVX-induced bone loss in two T-lymphocyte deficient (TLD) mouse models, nude mice and alpha-beta T-cell receptor null (αβT null) mice. All mice were 5-6 weeks at the start of the studies, in a pure C57BL/6 background and examined either at 4 weeks (nude) or 8 weeks (αβT null) post- OVX. Bone mass was determined by DEXA, μ-CT and histomorphometry (histo) in sham-operated (SHAM) or OVX mice. Wild type (WT) C57BL/6 mice were controls. In WT and nude mice DEXA demonstrated significant femoral and vertebral OVX-induced bone loss in WT (7-11% $P<0.05$) but not nudes. However, the effects of OVX on bone mass in nude mice were complex. μ-CT demonstrated that OVX induced a similar loss of trabecular bone mass (TBM) in WT and nude mice (41-45% in femurs and 21-28% in vertebrae, $p<0.05$ for all). Unexpectedly, OVX had dissimilar effects on femoral cortical bone mass (CBM) in WT and nudes. In WT mice OVX caused a 7% decrease in femoral CBM ($p=.05$) but had no effect in nudes. Histo confirmed the μ-CT results and demonstrated significant OVX-induced TBM loss in the femurs of both WT and nudes (44-48%, $p<0.05$) but CBM loss was only seen in WT femurs (22%, $P<0.05$). Concordantly, osteoclasts (Oc) activity measured as Oc area in femoral trabecular bone was increased similarly by OVX in both WT and nude femurs (37-57%, $p<0.05$), suggesting the OVX-induced TBM loss resulted from increased resorption. In WT and T null mice OVX decreased both vertebral and tibial bone mass (5-10%, $p<0.05$) as measured by DEXA. However, in femurs DEXA measured decreases in bone mass only in WT ($p<0.05$). By μ-CT, OVX decreased TBM in WT and αβT null mice equally (35-37%) in both femurs and tibia ($p<0.05$ for all). OVX also induced cortical bone loss in the tibias but not femurs of both WT and αβT null mice. In additional studies we failed to find differences in the number of T-lymphocytes or cells expressing the cytokine TNF-α in the bone marrow of WT OVX mice compared to WT SHAM. These results demonstrate that both WT and TLD mice lose TBM after OVX. However, unlike WT mice, CBM changes in TLD mice are bone specific and seem resistant to the effects of OVX. This latter effect likely explains the inability of DEXA to detect OVX induced bone loss in the femurs of TLD mice since this assay predominantly measures cortical bone mass. It appears that T-lymphocyte loss has no effect on OVX-induced TBM loss. The effects of OVX on CBM are variable and dependent on the model examined.

Mechanical Properties of Tibia in High Level Spinal Cord Injured (SCI) Men Are Decreased in Comparison to Low Level SCI. Y. Dionyssiotis*[1], G. Trovas[2], P. Raptou*[2], A. Galanos*[2], G. Kiniklis*[2], K. Petropoulou*[1], G. P. Lyritis[2]. [1]2nd Rehabilitation Department National Rehabilitation Center, Athens, Greece, [2]Laboratory of Research Musculoskeletal System, Athens, Greece.

The effects of Spinal Cord Injury (SCI) on bone in paralyzed areas are well documented but there are few data regarding the importance of the Level of Injury (LoI) in the decrease of mechanical strength in paralyzed legs. Peripheral quantitative computed tomography (pQCT) permits to assess cortical and trabecular bone density separately and evaluates the geometrical properties of long bones non-invasively. Twenty four men were included in this study:16 had complete SCI in chronic stage (>1,5 yrs) separated as follows :Group A [eight men, high paraplegia :T4-T7 level, mean age: 26,8 yrs ,Duration of Paralysis (DoP) : 6,3 yrs] and group B [eight men, low paraplegia: T8-T12 level, mean age: 37 yrs, DoP:4,3 yrs] in comparison with eight healthy men (group C) of similar age, height, and weight. None of the subjects was given bone acting drugs. All subjects underwent pQCT (STRATEC XCT-3000) of the left tibia. Bone parameters were measured at 4%: Bone Mass Density (BMD) trabecular (BMD trb),BMD total (BMD tot), at 14%: Stress Strain Index (SSIPol 2), at 38% : BMD cortical (BMD crt), Cortical Thickness (THI crt) , Stress Strain Index tibia (SSIPol 3) of the distal end of the tibia and the muscle cross-sectional area (Bone/Muscle Area ratio) was measured at the junction of the proximal third with the middle third of the tibia(at 66% site). Stress-strain index (SSI) parameter obtained multiplying the volumetric cortical density by section modulus, which is derived from the moment of inertia and also takes into account the eccentricity of bone material, was calculated at the 14% and at the 38% site. Results were analyzed with ANOVA. Compared to control (group C) SCI patients had significantly decreased BMD (p-value< 0,0005 for control group vs T4≤LoI≤T7 group and vs T8≤LoI≤T12 group) , indicating severe bone loss after injury. Concerning the LoI , SSI difference between 14% and 38% sites ($DSSI_{2-3}$) was significantly increased in group B (321,41 ± 145,3) in comparison to A (122,76±145,2) (p=0,03).These differences between group A and group B in SSI despite the similarity in BMD maybe attributed to differences in loading. Results indicate that the LoI ,possibly through differences in mechanical loading ,adversely affect the bone strength in high risk fracture sites of the paralyzed lower extremities like the distal tibia. These findings give to the clinician additional informations about the risk of fracture in SCI patients.

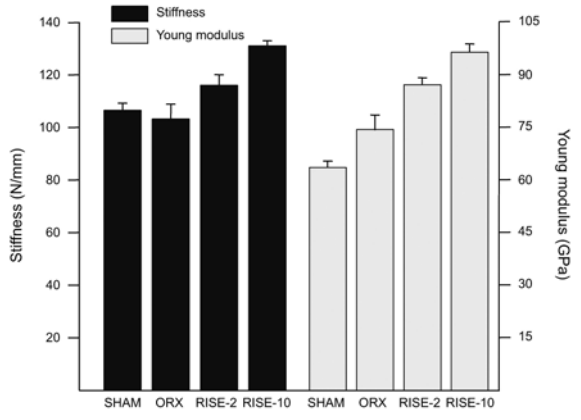
Biomechanical Properties of Bones from Orchidectomized-Rats Treated with Two Doses of Risedronate. G. Mabilleau*, G. Brochier*, H. Libouban*, M. Moreau*, E. Legrand, M. F. Baslé*, D. Chappard. Faculté de Médecine, INSERM, EMI 0335-LHEA, Angers, France.

Orchidectomy (ORX) reduces cortical and cancellous bone mass in adult rats by inducing a high turnover in trabecular bone, an increase in cortical porosity and a decrease in periosteal apposition. Bisphosphonates are useful treatments in high turn-over osteoporosis. Risedronate (RISE) is capable of preserving bone mass in the rat following ovariectomy (OVX) or ORX. 48 adult rats were randomized in 4 groups (6 rats/group): SHAM, ORX and ORX treated with a s.c. injection of RISE (2 or 10 μg/kg/D). Rats were sacrificed at 4 and 16 weeks post-ORX. Radius were dissected and radiographed to measure the outer diameter and the cortical thickness. Biomechanical characteristics were obtained by 3-point bending method. The ulnas of SHAM and RISE-10 rats were reduced in powder to look at the organization of hydroxyapatite crystal networks by electron microscopy. Cortical thickness and radius diameter were strongly influenced by ORX with a decrease of resp. 23.5% and 13.6% at 4w and 26.56% and 6.8% at 16w. RISE-2 or RISE-10 rats had a cortical thickness and radius diameter similar to SHAM rats at 4w. However, at 16w, the 2 μg dose appeared insufficient to preserve radius diameter at the level of SHAM. At 4w post ORX, stiffness was reduced in ORX and RISE-10 vs SHAM rats.

However, when Young modulus (stiffness corrected by the cross-sectional moment of inertia) was considered, a significantly higher value was obtained in ORX than in SHAM or RISE rats. Ultimate stress was significantly higher for ORX than SHAM and RISE rats. At 16w post-ORX, Young modulus of ORX was higher than SHAM but smaller than RISE rats. RISE-10 rats had a significantly higher modulus than RISE-2 rats and a tendency to a less deformation on 3-point bending. No significant difference of ultimate stress was noted among all groups whereas toughness was significantly higher in ORX than in SHAM or RISE-10. RISE did not influence the organization of the hydroxyapatite crystal networks. OVX induces cortical thinning but does not inhibit bone expansion, thus reducing Young modulus. On the contrary, ORX depress periosteal apposition, reduces cortical thickness and bone diameter leading to an increase in Young modulus. It is likely that morphometric characteristics must be used to derive biomechanical parameters. RISE significantly increases Young modulus.



Stiffness and Young modulus at 16w post ORX

Osteocyte Density from Illiac Cancellous Bone Biopsy in Males with Idiopatic Osteoporosis. M. Ciria[1], L. Perez-Edo[1], J. Blanch[1], M. Mariñoso*[2], S. Serrano*[2], X. Garcia-Miguel*[1], A. Diez-Perez[3], J. Carbonell*[1]. [1]Rheumatology, Institut Municipal d'Asisténcia Sanitària, Barcelona, Spain, [2]Pathology, Institut Municipal d'Asisténcia Sanitària, Barcelona, Spain, [3]Internal Medicine, Institut Municipal d'Asisténcia Sanitària, Barcelona, Spain.

In postmenopausal osteoporotic women with vertebral fractures have fewer osteocytes than controls. This fact may contribute to high bone fragility in this type of osteoporosis. There fore, some studies have that idiopathic male osteoporosis (IMO) is characterized by a decrease of bone formation. This fact could be shown a decrease of osteocytes in cancellous bone biopsy. The purpose of the present study is to examine the density of osteocytes in cancellous bone biopsies of male idiopathic osteoporotic subjets and in age-matched healthy controls. We compare 22 men with densitometric osteoporosis (Hologic QDR 1000, Waltham, Mass) defined as T-score values below -2.5 SD in lumbar spine or in femoral neck, with unknown cause of osteoporosis and normocalciuria. Control group included 14 healthy men. Bone illiac biopsy was done after men informed consent was signed. Sections (5 micrometers thick) of bone biopsy were processed with Goldner's trichrome. The number of osteocyte-occupied lacunae (stained) and empty lacunae (unstained) were selected. The number of total lacunae was obtained by additioning both parameters. Results are expressed per bone area (/mm2) and percent osteocyte-occupied lacunae (osteocytes / total lacunae x100). This parameters were examined to < 25 micrometers and > 45 micrometers from the surface to find any difference between the recent and old mineralized bone. Results: Osteocyte density was similar in idiopathic osteoporotic men and in the control group, in new and old mineralized bone. Empty lacunae were higher in osteoporotic cancellous bone biopsy. The difference obtained only marginally significance in the old mineralized bone. Total lacunae density was similar in the two groups. The percent of osteocyte-occupied lacunae was lower in idiopathic male osteoporotic sample. (Table 1). Conclusions: In our sample, idiopathic osteoporotic men showed a increased number of empty lacunae. The osteocyte-occuped lacunae were lower in the older mineralized bone (> 45 micrometers). These facts could be reflecting an accelerated mortality of osteocytes in these patients.

	Osteocytes density		
	Idiopatic masculine osteoporosis	Controls	p
Osteocyte density	132.11 (45.27)	130.95 (39.16)	0.937
Empty lacunae < 25 micras	4.62 (6.16)	2.01 (2.38)	0.14
Empty lacunae > 45 micras	37.7 (23.4)	24.9 (11.3)	0.067
Empty lacunae (total)	42.32 (25.58)	27.3 (11.3)	0.046
Total lacunae density	139.52 (54.89)	128.69 (43.4)	0.54

Osteoporosis in Men: Value of Laboratory Testing. C. S. Ryan*, V. I. Petkov, R. A. Adler. Endocrinology, McGuire VAMC, Richmond, VA, USA.

Osteoporosis is well recognized in women, but a fracture is often the first sign of bone fragility in men. Studies in women with idiopathic osteoporosis suggest that most laboratory evaluation is unhelpful. However, men are more likely to have underlying, possibly correctable causes. The purpose of this study was to compare the prevalence of risk factors, secondary causes and laboratory abnormalities in men with and without previously known causes for osteoporosis. We reviewed the charts of 160 men with osteoporosis diagnosed by bone mineral density (BMD) testing. Group I (n = 69) were referred without a specific diagnosis, and Group II (n = 91) had a known cause of osteoporosis in the consultation request. In addition to screening chemistries, 25 hydroxyvitamin D, testosterone, LH, FSH, TSH, and spot urinary calcium to creatinine ratio were measured. The two groups were similar in age, BMI, calcium and vitamin D intake, and BMD. In Group I, laboratory evaluation revealed a specific diagnosis in 45%, including hypogonadism (23%), vitamin D deficiency (16%), hypercalciuria (11%), subclinical hyperthyroidism (3%), and hyperparathyroidism (3%). In Group II, 38% of pts with steroid-induced osteoporosis had additional diagnoses discovered. Vitamin D deficiency was previously unrecognized in 20% of patients with a known cause for their osteoporosis. In both groups, risk factors for osteoporosis were commonly found including age >65, smoking, vitamin D insufficiency, and prior fracture. Four or more risk factors existed in over 50% of patients in both groups. Evaluation revealed a specific cause in about half of men with "idiopathic" osteoporosis. Among men who already carried a specific diagnosis, additional causes for osteoporosis were identified. Risk factors were common and multifactorial regardless of a specific cause. Some of these (such as smoking, vitamin D insufficiency) are amenable to treatment. In conclusion, contrary to reports about osteoporosis assessment in women, evaluation of men with osteoporosis will often provide useful information and aid in the management of their bone disease.

Bone Mineral Density and Bone Mineral Content in Rats with Testicular Torsion, Detorsion and Orchiectomy: Preliminary Results. B. Tander*[1], F. Canturk*[1], U. Bicakci*[2], T. Basoglu*[3], B. Tander*[2]. [1]Physical Medicine and Rehabilitation, Medical Faculty, Samsun, Turkey, [2]Pediatric Surgery, Medical Faculty, Samsun, Turkey, [3]Nuclear Medicine, Medical Faculty, Samsun, Turkey.

Male osteoporosis is an increasingly considered problem among the current literature, but its etiologic factors are not clear yet. It is believed that, hypogonadism is an important factor related with osteoporosis. Testicular torsion is one of the leading cause of hypogonadism among the children. Its effect on the development of osteoporosis and bone mineral contents in the adulthood has not been investigated yet. We aimed to evaluate the bone mineral densities (BMD) and bone mineral contents (BMC) of adult rats of which testes were torsioned, detorsioned or removed in their childhood. Thirty-two prepubertal (35 days old) male Wistar albino rats were divided into four groups containing each 8 rats. Group 1 was a sham group and these rats underwent scrotal incision only. In group 2 rats (Torsion group), both testes were torsioned 720 degrees, and they were fixed to the scrotum. In group 3 (Torsion and detorsion group), the testes were detorsioned after 4 days of 720 degrees torsion. Group 4 rats (Torsion and Orchiectomy group) underwent orchiectomy at the 4th day subsequent to 720 degrees of bilateral torsion. Three months after surgery, BMD and BMC of all rats were measured by Dual Energy X-ray Absorptiometry (DEXA) the vertebral column, right femoral neck and lomber region (L2-L4), then all of the rats were killed. Table 1 shows the values of the BMD and BMC measurements of the study groups. We found the lowest values of BMD and BMC in all regions in rats with torsion and orchiectomy. However, there were no statistically significant difference between the groups. We can preliminary conclude that testicular torsion in the pediatric rats do not seem to affect the BMD and BMC of the vertebral column and femoral neck in the adulthood. Definitive conclusion of this study could not be reported in this presentation due to the lack of, still continuing, histological and biochemical sample evaluation.

Bone Mineral Density and Bone Markers in Men with Coeliac Disease and Idiopathic Vertebral Fracture. M. W. J. Davie, S. Evans*, D. Powell*, D. Powell*, C. Sharp*, M. Worsfold*. Charles Salt Centre, Robert Jones and Agnes Hunt Hospital, Oswestry, United Kingdom.

Coeliac disease (CD) in men may be associated with osteopenia and secondary hyperparathyroidism, though frequently PTH is within the normal range. Bone turnover has usually been studied in female patients and results have been equivocal. We have studied male patients thus avoiding complications of varying estradiol status. We measured bone markers and bone density (BMD) in 43 men with CD, 43 with untreated idiopathic vertebral osteoporosis (IVF) and 37 healthy men (normals), all matched for age (range 30-79yr). BMD was measured by Hologic QDR4500A at L2-4, femoral neck and whole body (WBBMD) and serum bone-specific alkaline phosphatase (BSAP), iPINP and CrossLaps (CTx), and urine NTx/Cr by commercial assays. Comparisons (paired) and correlations were assessed by nonparametric methods. Studies were passed by the local ethics committee. In men with CD, BSAP (+44%, $p<0.01$) and iPINP (+35%, $p=0.09$) were raised compared with normals, and BSAP was 25% higher than in IVF ($p<0.01$). BSAP in IVF was 15% higher than in normals ($p=0.06$). Compared with normals serum CTx was elevated in patients with IVF ($p<0.05$) but not with CD. NTx/Cr and iPINP were not raised in either IVF or CD. CD patients had lower BMD than normals (WBBMD = -9.2% $p<0.01$) but BMD at all sites was lowest in IVF (WBBMD = -12.8%, $p<0.01$ vs normals; and $p<0.05$ vs CD). In normals NTx/Cr and CTx ($r=0.79$) and iPINP and NTx/Cr ($r=0.47$) were correlated, but iPINP and BSAP were not correlated. In CD and IVF, in contrast, iPINP correlated with BSAP ($r=0.71$and $r=0.64$ respectively). NTx/Cr was not associated with CTx in either disease group. No bone marker correlated with BMD in normals. Correlations between bone markers and BMD were seen only in CD and in IVF. In CD patients BMD L2-4 correlated with iPINP ($r= -0.436$), and IVF subjects showed correlations between CTx and WBBMD ($r=-0.49$) and femoral neck ($r=-0.43$). No association between markers and BMD was seen in normals. BSAP and probably iPINP are raised more in CD than in IVF, despite a smaller loss of bone density. In contrast, in IVF only CTx is raised. This contrasting pattern suggests a different bone disease process in CD, consistent with an osteomalacia-like mechanism related to calcium malabsorption. Measurement of several markers may be valuable in the investigation of low BMD in an individual patient.

Estrogen as a Determinant of Femoral Neck Bone Strength in Elderly Men. S. J. A. G. Goemaere[1], H. Zmierczak*[1], I. Vanpottelbergh*[1], K. Toye*[1], D. Debacquer*[2], T. J. Beck[3], J. Kaufman[1]. [1]Unit for Osteoporosis and Metabolic Bone Disease, Ghent University Hospital, Ghent, Belgium, [2]Department of Public Health, Ghent University Hospital, Ghent, Belgium, [3]Department of Radiology, John Hopkins University, Baltimore, MD, USA.

Bone geometry is a determinant of fracture risk. How changing bone geometry contributes to age-related increase in fracture risk is less well explained. We investigated the role of sex-steroids in elderly men. Elderly men from a population list of a Flemish town were invited to participate in a longitudinal study on aging and bone loss after obtaining informed consent. Subjects with diseases or medications affecting the bone status were excluded. The present analysis pertains to DXA at the hip (Hologic QDR1000+) at start and after 4 years. BMD and geometry at the narrow neck were evaluated by using the hip structural analysis (HSA) software. The following parameters (and their %CV) were obtained: BMD (3.2%), Cross Sectional Area (CSA;3.2%), Width (W;1.9%), Endocortical Diameter (End Cort;2.1%), Average Cortical Thickness (AvgCortex;3.5%), Cross Sectional Moment of Inertia (CSMI; 4.9%), Section Modulus (Sect Mod; 4.3%) and the Buckling Ratio (BR; 5.2%). Fasting serum samples were obtained at baseline for total and bio-available testosteron (T), estradiol (E_2) and SHBG levels. Statistical significant differences are indicated by * $p<0.05$ or ** $p<0.01$ From the 269 participants 147 follow-up data were obtained. Age was 76.0y ± 4.2 and BMI was 26.1 kg/m^2 ± 3.6. In cross-sectional analysis for bioT and (bio)E_2 significant positive correlations were observed with BMD, CSA, Sect Mod and AvgCortex and negative correlations with W, End Cort and BR; no associations with CSMI were observed. Longitudinal data provided significant mean decreases of BMD (-0.6%) and AvgCortex (-0.7%); and significant increases of CSMI (+1.3%), W (+1.0%), End Cort (+1.1%) and BR (1.8%). No significant changes over 4 years were observed for CSA and Sect Mod. The associations between sex-steroids and longitudinal parameters are listed in the table below (age and BMI adjusted pearson correlations). SHBG was not associated with the any of the bone geometry parameters.

	T	BioT	E_2	BioE_2
%Δ BMD	0.13	0.01	0.22**	0.13
%Δ CSA	0.07	-0.04	0.17*	0.10
%Δ W	-0.11	-0.07	-0.10	-0.07
%Δ Sect Mod	-0.01	-0.08	0.21**	0.17*
%Δ End Dia	-0.12	-0.07	-0.12	-0.08
%Δ AvgCortex	0.12	-0.01	0.21**	0.13
%Δ BR	-0.14	-0.03	-0.22**	-0.14

The present longitudinal study provides evidence suggesting a predominant contribution of E_2 compared to T, for the maintenance of the biomechanical competence at the femoral neck in elderly men.

A Novel Relationship between Estrogen and Leptin Levels in Men with Idiopathic Osteoporosis. E. S. Kurland[1], A. Peck*[1], D. J. McMahon[1], J. P. Bilezikian[2]. [1]Department of Medicine, Columbia University, New York, NY, USA, [2]Department of Medicine and Pharmacology, Columbia University, New York, NY, USA.

Idiopathic osteoporosis in men (IO) is a disorder of low bone formation. We have previously reported low E2 and lower BMI in a cohort of 44 men with IO (PT)compared with healthy controls (CO). Evidence linking bone mass, body weight and gonadal steroid regulation to the common pathway of the adipocyte hormone leptin prompted us to measure leptin levels in our PT. Plasma collected after an overnight fast for 30/44 PT and 41/44 CO was analyzed for leptin with values of 6.4 ± 0.9 and 5.4 ± 0.4 ng/mL in PT and CO, respectively (NS). Pearson correlation coefficients between leptin and BMI, T, BioT, E2, BioE2, SHBG, and IGF-I, revealed positive correlation between leptin and BMI in PT and CO respectively ($r= 0.7$ and 0.5; $p <0.0001$ and <0.01). An inverse correlation was noted for leptin and E2 or BioE2 in PT only ($r= -0.4$, $p< 0.05$; r in CO = -0.03, p = NS) with a trend to significance for the difference in r-value between PT and CO ($p =0.08$). To examine the effect of either E2 or BMI on difference in leptin between groups, we created tertiles of each variable,and then compared leptin levels between PT and CO by tertile of the ranked variable. Mean BMI tertiles were: 21.5 (range 16-23.3), 24.7 (23.6-25.6) and 27.8 (25.7-32.2) kg/m^2 for 1rst, 2nd and 3rd tertiles, respectively. E2 tertiles were 16.3 (range 9.1-20.2), 22.8 (20.6-25), and 29.8 (25.3-47.4) pg/mL for 1rst, 2nd and 3rd tertiles, respectively. Leptin values, in ng/mL ranked by E2 tertile were as follows:

	1rst tertile	2nd tertile	3rd tertile
#PT/CO	14/ 9	8/ 15	8/ 17
Leptin ng/mL PT	8.3 ± 1.7	6.2 ± 1.8	4.7 ± 0.9
Letpin ng/mL CO	5.8 ± 0.9	5.5 ± 0.6	5.1 ± 0.8

Leptin values, in ng/mL ranked by BMI tertile were 3.4 ± 0.5, 7.5 ± 1.5 and 10.3 ± 2.0 for PT compared with 3.4 ± 0.5, 5.5 ± 0.5, and 6.4 ± 0.9 for CO. Using ANOVA to test whether leptin differed between groups when ranked for E2 and controlling for BMI revealed a significant difference between groups ($p< 0.01$). In specific, the lowest E2 tertile of patients had a significantly higher leptin level than any of the 3 tertiles of CO ($p <0.05$ for all comparisons). In contrast, when ranked by BMI, groups do not differ significantly for leptin levels with or without controlling for E2 (p= NS). In summary, men with IO have higher leptin levels than controls when ranked by E2 tertiles, with leptin levels decreasing with increasing levels of E2. These data provide new insights into the relationship between leptin and estradiol in IO, a model of low bone formation.

Osteoblastic and Osteocytic Cells Express the Rate-Limiting Enzyme for Serotonin Synthesis and Contain Measurable Serotonin Content. M. M. Bliziotes[1], J. Hashimoto*[2], X. Zhang[2], A. Eshleman*[3], K. Wiren[4]. [1]Medicine, Oregon Health and Science University/Portland VAMC, Portland, OR, USA, [2]Behavioral Neurosciences, Oregon Health and Science University, Portland, OR, USA, [3]Psychiatry, Oregon Health and Science University/Portland VAMC, Portland, OR, USA, [4]Behavioral Neurosciences and Medicine, Oregon Health and Science University/Portland VAMC, Portland, OR, USA.

Neurotransmitter regulation of bone physiology is manifested by the osteopenic phenotype seen in serotonin transporter knockout mice. The serotonin transporter and serotonin receptors have been identified in both osteoblasts and osteocytes. The origin of the serotonin ligand that binds to cognate receptors and transporters in bone cells is unknown. Serotonergic nerves have not been identified in bone. Bone cells could synthesize serotonin, making the ligand effects autocrine/paracrine in nature. We investigated this hypothesis by 1) assessing expression of the initial and rate limiting enzyme in serotonin synthesis, tryptophan hydroxylase (TPH), and 2) measurement of serotonin content in osteoblastic and osteocytic cells. To assess TPH expression in bone cells, we performed semiquantitative RT-PCR using primers for the TPH1 isoenzyme (expressed in non-brain tissues such as gut, spleen and thymus). PCR was carried out for 40 cycles. We analyzed osteoblastic (ROS 17/2.8, MC3T3-E1, UMR 106) and osteocytic (MLO-Y4) cells; B14 rat medullary raphe cells and COS-7 cells were positive and negative controls, respectively. All osteocytic and osteoblastic cells lines analyzed express mRNA for TPH1, and thus have the capability for serotonin synthesis. No amplified products were observed in COS-7 cells, which do not have detectable TPH enzyme activity. TPH protein expression was evaluated with immunoblots using an antibody against recombinant rabbit tryptophan hydroxylase. ROS 17/2.8 and MLO-Y4 cells showed the expected 55 kDa band, while COS-7 cells did not. We next analyzed serotonin content from the same cells with an ELISA assay (Research Diagnostics, Inc.). Analysis was carried out on cell pellets from subconfluent cultures of B14, MLO-Y4, and MC3T3-E1 cells grown in serum free medium for 24 (n=3) or 72 (n=2) hours. The B14 cells contain approximately 50-100 pg serotonin per mg protein. In concert with our findings from the PCR studies of TPH1 expression, the MC3T3 cell line also contained serotonin at levels that exceeded the B14 cells. MLO-Y4 cells showed serotonin content roughly equal to B14 cells, and COS-7 cells had no detectable serotonin. We conclude that osteoblasts and osteocytes are capable of serotonin synthesis, and thus may produce paracrine/autocrine effects through this neurotransmitter on bone cells.

Osteoprotegerin Gene Expression in the Liver of Patients with Primary Biliary Cirrhosis. Lack of Association with Elevated Circulating Levels. A. Enjuanes*[1], N. Guanabens[1], L. Alvarez[1], L. Caballeria*[2], M. Martinez de Osaba*[1], P. Peris[1], A. Monegal*[1], A. Pares*[2]. [1]Metabolic Bone Diseases Unit, Hospital Clinic, IDIBAPS, Barcelona, Spain, [2]Liver Unit, Hospital Clinic, IDIBAPS, Barcelona, Spain.

Osteoprotegerin (OPG), a decoy receptor of the nuclear factor kappa B ligand (RANKL), regulates bone resorption by preventing RANK and RANKL binding. OPG is produced by numerous cell types and a variety of tissues and their expression pattern targets three main biological systems: the osteoarticular, immune and vascular systems. In a previous study we have described high serum OPG levels in patients with primary biliary cirrhosis (PBC), which were associated with the severity of liver damage and unrelated to bone remodeling or osteoporosis. The aim of this study has been to assess if the OPG mRNA gene expression in the liver correlates with serum levels of OPG and with the severity of liver disease. Circulating OPG levels were measured by ELISA in sera from 58 patients with PBC and in a control group of 20 healthy females. Total RNA was prepared from 15 human liver samples (4 normal and 11 PBC), and reverse transcription reaction was performed using 1 μg of total RNA. In a first step, PCR reactions for OPG, tyrosine aminotransferase (TAT) and β-actin was performed in all samples. TAT was used as a hepatocyte phenotype control and β-actin as gene expression control. cDNA obtained from cultured human primary osteoblasts was used as a positive control of OPG expression and osteocalcin gene expression was used to show osteoblast phenotype. In a second step, transcript levels of osteoprotegerin were evaluated by Real-Time PCR. Results were expressed as OPG versus β-actin expression (OPG relative gene expression). Serum OPG levels were significantly higher in PBC (5.5 ± 0.2 pM/l) than in controls (2.9±0.2 pM/l, p<0.0001). Circulating OPG was associated with the severity of liver disease defined by higher bilirubin levels (< 1.2 mg/dl) (6.6 ± 0.6 vs 5.2 ± 0.2 pM/l, p=0.02) and by the Mayo score above 4 (5.9 ± 0.3 vs 4.9 ± 0.2 pM/l, p=0.02). OPG transcripts were observed in all normal and PBC liver samples. No significant differences in the quantitative OPG gene expression was observed between patients (1.9 ± 0.2) and controls (2.3 ± 0.2). In these 11 PBC patients the OPG serum levels were significantly higher (5.4 ± 0.2 pM/l) than in controls (p<0.001). No correlation was found between circulating OPG and their respective transcripts in the liver of PBC patients. In conclusion, the high circulating OPG levels observed in patients with PBC are associated with the severity of liver disease, but not with their gene expression in the liver.

Bone Mineral Density Changes and Bone Turnover in Thyroid Carcinoma Patients Treated with Supraphysiologic Doses of Thyroxine. I. Karner*[1], S. Sijanovic*[2], Z. Hrgovic*[3], D. Bucovic*[4], A. Klobucar*[5], K. Usadel*[6], W. J. Fassbender[7]. [1]Dept. of Gynaecology and Obstetrics, Clinical Hospital Osijek, Osijek, Croatia, [2]Dept. of Nuclear Medicine, Radiation Protection and Pathophysiology, Clinical Hospital Osijek, Osijek, Croatia, [3]Institute for Medical Research and Occupational Health, Zagreb, Croatia, [4]Department of Gynaecology and Obstetrics, Clinical Hospital Osijek, Osijek, Croatia, [5]Dept. of Gynaecology and Obstetrics, General Hospital Sveti Duh, Zagreb, Croatia, [6]Endokrinologikum Frankfurt, Frankfurt am Main, Germany, [7]Dept. of Internal Medicine, Hospital zum Hl. Geist Kempen, Kempen/Ndrh., Germany.

The aim of this one-year prospective study was to determine whether longterm thyroxine treatment is a risk factor for elevated bone turnover, loss of bone mass and subsequent development of osteoporosis. Premenopausal women (N=19), and men (N=9) suffering from differentiated thyroid gland carcinoma in the mean age of 39,0±8,0 years and 41,8±10,0 years were investigated. All of them had undergone a total thyreoidectomy and subsequent thyroxine therapy. The duration of the TSH-suppressive therapy prior to the the beginning of our study was 9,4±6,4 years in the female and 8,1±6,0 years in the male group. The prospective observation was performed by dual X-ray absorptiometry (DXA) at the spine and the femoral neck and by single-photon absorptiometry (SPA) at the distal radius. Laboratory testings included thyroid hormones T3, T4 and TSH, serum calcium, phosphate and PTH, and urinary calcium and phosphate from spontaneous and 24-hour urine samples. Markers of bone formation (osteocalcin, alkaline phosphatase and PICP) and resorption (Ca/Cr and ICTP) were determined. Statistically significant loss of bone mass was observed only on the distal radius in males (p<0,05). At the lumbar spine and femoral neck, only a minor bone loss was registered in a small number of patients. Almost 50 % of the females showed values above the reference range. In more than 30 % of the females, and smaller number of male patients, ICTP values ranged above the reference range, corresponding to elevated bone turnover. These two variables exhibited a slight correlation with bone density at the measured skeletal areas, mostly considering the male group. The results are a proof that accelerated bone turnover and subsequent bone loss occurs during TSH-suppressive thyroxine therapy. In future prospective studies a prolonged time of observation will be necessary, as well as to increase the number of studied patients, in order to better assess the relative risk of osteoporosis in patients undergoing TSH-suppressive treatment more precisely.

Lumbar BMD as the Major Factor Determining Increased Prevalence of Vertebral Fractures in Monoclonal Gammopathy of Undetermined Significance (MGUS). J. Pepe*[1], M. T. Petrucci*[2], I. Nofroni*[3], D. Diacinti*[1], S. Piemonte*[1], E. Romagnoli*[1], E. D'Erasmo*[1], S. Minisola[1]. [1]Dpt of Clinical Sciences, University of Rome, Rome, Italy, [2]Dpt of Haematology, University of Rome, Rome, Italy, [3]Dpt of Experimental Medicine and Clinical Pathology, University of Rome, Rome, Italy.

This study was carried out to investigate the relative contribution of bone mass and turnover to the skeletal fragility reported in MGUS patients. We studied 65 consecutive postmenopausal MGUS patients attending our Institution for routine follow-up; they were divided on the basis of the presence or absence of at least one mild vertebral fracture. Patients with fractures (Fx, n=34) were significantly older (62.8±6.0 yrs), with long-standing disease (8.8±7.1 yrs) in respect to MGUS patients without fractures (NFx, n=31; 59.7±5.0 yrs, p<0.05 and 5.8±4.1 yrs, p<0.05, respectively). Lumbar spine (L = 0.811±0.14 g/cm^2 vs 0.956±0.12), femoral neck (0.660±0.09 vs 0.747±0.10) and total femoral BMD (0.788±0.11 vs 0.884±0.11) were significantly lower (all p<0.001) in Fx-MGUS compared to NFx. Mean serum osteocalcin levels were lower (6.70±2.5 ng/mL vs 7.3±3.0) and mean serum β-CTX levels were higher (0.92±0.32 ng/mL vs 0.76±0.38) in Fx compared to NFx, albeit these differences did not reach statistical significance. However, the RANKL/OPG ratio was significantly higher in Fx compared to NFx (0.092±0.018 vs 0.082± 0.020; p<0.05). ROC curves analysis identified L-BMD as the variable that predicted vertebral fracture (area under the curve 0.817; C.I. 0.713-0.921), better than other parameters (age, years since diagnosis, monoclonal component, biochemical parameters, BMD measurements of the hip). At the value of L-BMD of 0.900 g/cm^2, the sensitivity was 76.5 % and the specificity 63.3%; considering the prevalence (52 %) of vertebral fractures in our patients, the positive predictive value was 70.3% and the negative predictive value was 70.4%. Corresponding figures for a cut off of 0.850 g/cm^2 were: 67.6, 80.0, 79.3, and 68.6%. Our investigation emphasizes the role L-BMD measurement as the most important surrogate for predicting axial strength in MGUS patients. The skeletal fragility might be favored by the uncoupling of the two processes of bone remodeling, as revealed by the high OPG/RANKL ratio of patients with fractures.

Surface Specific Effects of Thiazolidinedione Darglitazone on Bone in Mice. M. Li, Y. Li*, H. A. Simmons, D. R. Healy*, B. Robinson*, L. C. Pan, H. Z. Ke, T. A. Brown. Cardiovascular and Metabolic Diseases, Pfizer Global Research and Development, Groton, CT, USA.

It has been hypothesized that a class of thiazolidinedione drugs (TZD), which are used for treatment of Type 2 diabetics, can increase adipogenesis at the expense of osteogenesis, leading to bone loss. However, the reported skeletal effects of rosiglitazone and troglitazone are varied and their effect on cortical bone is unknown. In this study, we examined the changes in both cancellous and cortical bone of 8-month-old male mice treated with darglitazone (Darg) at 10 mg/kg/d by dosing the compound in a food admixture for 8 weeks. Histomorphometric measurements of lumbar vertebral body, a cancellous bone site, showed a significant decrease in trabecular volume (-25%), number (-13%) and thickness (-13%), and an increase in trabecular separation (+23%) in the mice treated with Darg compared with controls. In addition, mineralizing surface and tissue-volume based bone formation rate were significantly lower, whereas osteoclast surface and number were significantly higher in Darg-treated mice. Furthermore, percent fat area and number of fat cells in bone marrow were significantly increased by 1339% and 457%, respectively, in Darg-treated mice. These data indicated that Darg enhanced adipogenesis and bone resorption and suppressed bone formation in lumbar vertebral cancellous bone in mice. To assess the effects of Darg on cortical bone, pQCT and histomorphometric analyses were performed on the femoral diaphysis. The mice treated with Darg had a significant decrease in total bone content (-10%), total bone density (-10%) and cortical thickness (-8%) and an increase in endocortical circumference (+5%) accompanied with an unchanged periosteal circumference and total bone area. Consistent with pQCT data, histomorphometric measurement showed a decrease in cortical bone area (-11%) and an increase in marrow area (+13%) with unchanged total tissue area. These data indicated that Darg caused bone loss on the endocortical surface that is adjacent to bone marrow. Interestingly, periosteal mineralizing surface, mineral apposition rate and bone formation rate were significantly increased by 32%, 23%, and 55%, respectively, in Darg-treated mice compared with controls. It is unclear whether the increased periosteal bone formation is compensatory or a direct effect of Darg. In summary, Darg, like the TZD rosiglitazone,

caused cancellous bone loss by increasing bone resorption and decreasing bone formation. Our data for the first time showed that Darg induced cortical bone loss on the endocortical surface but increased bone formation on the periosteal surface. These data reveal surface specific effects of the TZD Darg on bone.

Parathyroid Hormone-Related Peptide Is a Candidate Stomach-Derived ECL-Cell Hormone. N. Andersson[1], S. Movérare Skrtic[1], R. Håkanson*[2], C. Ohlsson[1]. [1]Center for Bone Research at the Sahlgrenska Academy, Department of Internal Medicine, Gothenburg University, Gothenburg, Sweden, [2]Department of Experimental Medical Science, Division of Cellular and Molecular Pharmacology, Lund University, Lund, Sweden.

A large part of all endocrine cells in the body are located within the gastrointestinal tract and it is suggested that endocrine signals from the stomach are of importance for the regulation of bone mass, supported by that gastrectomy (Gx) results in bone loss. The mechanism behind the Gx-evoked bone loss is unknown. We and others have demonstrated that the Gx-evoked bone loss reflects the lack of a factor expressed in the fundus part of the stomach. The existence of an osteotropic hormone (referred to as gastrocalcin) in the ECL cells of the gastric mucosa has been suggested. The aim of the study was to obtain a gene expression fingerprint of the gastric ECL cells in order to identify the anticipated ECL-cell hormone. Global gene (45.167 genes/probe sets) expression analysis of mouse stomach was performed in order to identify the ECL-cell peptide/protein. Specific functional activation of the ECL cell population (omeprazole-induced hypergastrinaemia) was used as a tool to generate a specific gene expression fingerprint of the ECL cells. The proposed fingerprint includes 14 genes, among them six known to be expressed by ECL cells (= positive controls), and some novel ones, which are likely to be ECL-cell-related. The known ECL-cell-related genes are those encoding histidine decarboxylase, chromogranin A and B, vesicular monoamine transporter 2, synptophysin and the cholecystokinin-B receptor. In addition, the fingerprint included five genes, which might be peptide hormones or involved in the process of secretion. Interestingly, parathyroid hormone-related peptide (*PTHrP)* was identified as a candidate ECL-cell peptide hormone. *PTHrP* is of particular interest as a candidate ECL-cell hormone as it is (i) induced by gastrin (ii) a recognized peptide hormone, (iii) known to regulate Ca^{2+} homeostasis and bone mass and (iv) expressed by gastric endocrine tumours. The origin and the physiological role of circulating *PTHrP* in healthy adult individuals are unknown. We propose that *PTHrP* is secreted by the ECL cells in the stomach in response to gastrin and that it contributes to the regulation of calcium deposition in bone and the maintenance of normal bone mass (by securing appropriate calcium deposition into bone). However, additional studies are required to determine if *PTHrP* is the osteotropic hormone (gastrocalcin) thought to be produced in the gastric ECL cells.

Radiation Affects the Micro-Architecture of Bone. S. A. Hamilton*[1], M. J. Pecaut*[2], D. S. Gridley*[2], A. Obenaus*[2], T. A. Bateman[1]. [1]Department of Bioengineering, Clemson University, Clemson, SC, USA, [2]Department of Radiation Medicine, Loma Linda University and Medical Center, Loma Linda, CA, USA.

According to the National Institutes of Health about one half of cancer patients receive radiation therapy. Radiation therapy uses ionizing radiation to kill cancer cells and shrink tumors. While precautions are taken to prevent damage to adjacent cells, radiation therapy still damages healthy cells. As advances in treatment increase the length of post-treatment survival, understanding any secondary effects of treatment is progressively more important. For example, presence of two key cytokines for bone metabolism, interleukin-1 beta and tumor necrosis factor alpha, have been shown to be elevated by proton radiation in pediatric patients undergoing radiation for brain tumors. It is hypothesized that expression of these cytokines by therapeutic radiation, gamma and proton, will activate osteoclastic bone resorption and cause a deficit in bone microarchitecture. Female C57BL/6 mice ten weeks of age were irradiated with proton (n=10) and gamma rays (n=10) (2 Gray (Gy)) and sacrificed 110 days post-exposure. The proximal tibia was analyzed using microcomputed tomography (MicroCT- Scanco USA). Results indicated significant losses in trabecular density and connectivity for both proton and gamma sources. The 2 Gy gamma group had a significantly lower trabecular density of 33% ($p = 0.02$) and connectivity density of 65% ($p = 0.03$) than the control group (n=10). The 2 Gy proton group also had a significantly higher trabecular density of 42% ($p = 0.01$) and connectivity density of 70% ($p = 0.02$) than the control group. The loss of trabecular connectivity results in a decrease of loading in the struts. These data demonstrate that bone loss and eventually osteoporosis may be a secondary effect of radiation therapy for cancer treatment, and needs to be considered as survival rates continue to improve. This finding could be particularly critical for younger patients as peak bone mass is achieved by age thirty. If radiation therapy is given during this time period, it is feasible that peak bone mass could be adversely affected which may yield a higher susceptibility to osteoporosis and therefore a greater fracture risk.

Comparison of Lumbar Bone Mineral Density in Korean Women with or without Metabolic Syndrome. S. K. Lee[1], H. W. Baik*[2], K. H. Lee*[2], J. Y. Kim*[2], H. J. Kim*[3], K. J. Ahn*[3], K. S. Park*[3]. [1]Biochemistry/Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea, [2]Biochemistry, Eulji University School of Medicine, Daejeon, Republic of Korea, [3]Internal Medicine, Eulji University School of Medicine, Daejeon, Republic of Korea.

Various studies have shown that higher body mass index (BMI) is a protective factor for bone mineral density (BMD), but there is a race-dependent effect of BMI on BMD. The metabolic syndrome encompasses a set of central obesity, insulin resistance, hypertension, high triglycerides and low HDL-cholesterol and several abnormalities. Little is known about the association between metabolic syndrome and BMD. In this cross-sectional study, we investigated the associations of metabolic syndrome, serum fasting insulin level, homeostasis model assessment-insulin resistance (HOMA-IR), and lumbar BMD in healthy, pre-menopausal (n=50; 43±7 years) and post-menopausal (n=58; 60±6 years) women with normal BMD or osteopenic or osteoporotic but otherwise normal, visiting Eulji University Hospital at Korea. The metabolic syndrome was defined by Adult Treatment Panel III and World Health Organization diagnostic criteria with slight modification of waist circumference. BMD (g/cm^2) was determined at the lumbar spine (L_1-L_4) with dual-energy X-ray absorptiometry scanner. Frequency of osteoporosis was 2% in premenopausal women and 48% in postmenopausal women in this study participants. Frequency of metabolic syndrome was 14% in premenopausal women and 34% in postmenopausal women. Frequency of osteoposis and metabolic syndrome was increased after menopause. Lumbar BMD (0.862±0.156 vs. 0.765±0.162, $p<0.05$), serum fasting insulin level (7.75±4.98 vs. 5.21±4.16 mIU/L, $p<0.05$) and HOMA-IR (1.916±1.286 vs. 1.176±1.016, $p<0.05$) were increased in subjects with metabolic syndrome, compared to those without metabolic syndrome among postmenopausal women, but not among premenopausal women. These results implicated that insulin resistance in metabolic syndrome would not occur in bone and higher insulin levels might play a role in maintaining bone mineral density after menopause. In conclusion, subjects with metablic syndrome have higher lumbar BMD, serum fasting insulin level and HOMA-IR, compared to those without metabolic syndrome in postmenopausal Korean women.

Serum Osteoprotegerin in Patients with Anorexia Nervosa. J. M. Olmos*[1], J. Menéndez-Arango*[2], C. Valero*[1], J. L. Hernández*[1], J. Martínez*[1], C. Lozano-Tonkín[3], J. González-Macías[1]. [1]Medicina Interna, Hospital Universitario M. Valdecilla, Santander, Spain, [2]Psiquiatría, Hospital Universitario M. Valdecilla, Santander, Spain, [3]Medicina Interna, Hospital Clínico San Carlos, Madrid, Spain.

Objectives: To evaluate serum levels of osteoprotegerin (OPG) in patients with anorexia nervosa (AN) and in healthy controls, and to investigate the relationship of OPG levels with bone mineral density (BMD) and several nutritional factors. Patients and methods: We studied 64 Spanish females aged 15-36 yr. (26±7 yr.) with different stages of AN (DSM-IV criteria). Mean body mass index (BMI) was 19±3 kg/m^2. Serum OPG levels were measured by EIA, and leptin concentration by IRMA. Bone mineral density (BMD) and body composition (lean body mass, fat body mass, and % fat mass) were determined by DEXA (Hologic QDR-4500). 39 healthy women (28±8 yr) with a normal BMI (22±3 Kg/m^2) formed the control group. Results: Patients with AN had a lower fat mass, lean body mass, and BMD at lumbar spine (LS), femoral neck (FN) an total hip (TH) than controls. OPG levels were similar in patients and controls. BMD was negatively correlated with leptin, BMI, lean and fat body mass in anorectic patients. No correlation was seen between OPG and BMD. However, patients with poor nutritional status (BMI<18,5 Kg/m^2) had lower BMD and higher OPG values than recovered patients (Table)

	OPG	Z (LS)	Z (FN)	Z (TH)
BMI <18,5 (n:23)	62±24	-1.6±1.1	-1.7±0.9	-1.8±1.0
BMI>18,5 (n:41)	51±16	-0.9±1.0	-0.9±0.9	-0.8±0.8
p	0.05	0.05	0.01	0.01

Conclusions: OPG values were normal in patients with AN. However, anorectic patients with poor nutritional status had higher serum OPG levels and lower BMD than recovered patients.

Simulation Model Suggests Risedronate Surpasses Strontium Ranelate in Clinical Benefits and Cost Savings for Treating Postmenopausal Women with Established Osteoporosis: The Case of Germany. A. A. Kurth*[1], M. K. Pasquale*[2], R. T. Burge*[2], A. Lyssy*[3], R. Saadi*[4]. [1]Orthopaedic Oncology Service and Bone Metabolism, University Hospital Frankfurt, Frankfurt, Germany, [2]Epidemiology & Pharmacoeconomics, P&G Pharmaceuticals, Mason, OH, USA, [3]Customer Business Development, P&G Pharmaceuticals - Germany, Damstadt, Germany, [4]Oncology & Bone/Arthritis, Global Health Outcomes & Market Access, Sanofi-Aventis Pharmaceuticals, Bridgewater, NJ, USA.

Bisphosphonates have demonstrated efficacy in the prevention of osteoporotic fractures and have been considered first-line therapy to date. Strontium ranelate, a new chemical entity in the treatment of osteoporosis, was launched in Germany in October 2004 and is being introduced in most other European markets throughout 2005. This study compares risedronate to strontium ranelate in terms of treatment effect on fracture reduction and overall cost-effectiveness for a population of postmenopausal osteoporotic (PMO) women in Germany. The comparison is based on a previously validated Markov model of the natural history of osteoporosis (Tosteson, 2001). The model simulates treatment scenarios for risedronate and strontium ranelate using as a base case a population of 70-74 year-old PMO women with a prevalent vertebral fracture and BMD T-Score <-2.5. It simulates outcomes for five years of treatment and observation time, as approved by the German Osteoporosis Treatment Guidelines for the prevention of vertebral and hip fractures. Efficacy data for risedronate is taken from Reginster, Minne, Sorensen et. al. (2000) for the reduction in the relative risk of vertebral fractures (49%) and from McClung, Geusens, Miller et. al. (2001) for the reduction in relative risk of hip fractures (60%). For strontium ranelate the efficacy measures used are 41% for vertebral fracture risk reduction (Meunier, Roux, Seeman et. al., 2004) and 36% for hip fracture risk reduction (Reginster, Seeman, Vernejoul et. al., 2005). Other model inputs include fracture incidence rates, relative risk of fracture due to risk factors, health utilities, and costs of fracture treatment and prevention. The analysis is run using German epidemiological and cost data from published sources. In a cohort of 70-74 year-old patients with prevalent vertebral fractures in Germany (EPOS 2002), the model predicts that five years of treatment with risedronate would result in 5491 fewer vertebral and hip fractures and a cost savings of €114 million in comparison to strontium ranelate. These results suggest that treatment with risedronate would have both a clinical and economic benefit.

Treatment-Related Changes in BMD Are not Associated with the Occurrence of a Fragility Fracture While on Risedronate Therapy. R. Lindsay[1], S. Magowan[2], P. Miller[3], J. D. Adachi[4], I. Barton*[5], D. Felsenberg[6], N. B. Watts[7]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]P&G Pharmaceuticals, Mason, OH, USA, [3]Colorado Center for Bone Research, Lakewood, CO, USA, [4]McMaster University, Hamilton, ON, Canada, [5]P&G Pharmaceuticals, Egham, United Kingdom, [6]University Hospital Benjamin Franklin, Berlin, Germany, [7]University of Cincinnati, Cincinnati, OH, USA.

There is a paucity of data addressing the risk determinants for fracture while actually on osteoporosis treatment. This valuable information would be helpful in identifying the higher risk patient. This analysis was designed to determine the effect of different parameters associated with the occurrence of an osteoporotic fracture (vertebral & nonvertebral) while taking risedronate 5 mg/day. The analysis specifically examined 4,324 postmenopausal women randomized to receive risedronate 5 mg/day in the risedronate phase III placebo-controlled fracture endpoint trials over a 3 year period (VERT-MN, VERT-NA and HIP). Women who sustained fragility fractures (F+ group) were compared to women who remained fracture free (F- group). These two groups of women were analyzed to determine the significance of the following parameters to fracture occurrence while on therapy: baseline LS & FN BMD, body mass index (BMI), prevalent vertebral fractures (PVF), and LS & FN BMD percent change from baseline over 3 years. Descriptive statistics were summarized for each fracture group and formally compared using the Wilcoxon Rank Sum test. Over 3 years 523 postmenopausal women sustained a fragility fracture and 3801 women remained fracture-free while on risedronate 5 mg/day therapy. There was a significant difference in baseline BMD scores, prevalent vertebral fracture status and BMI between women who did or did not sustain a fracture during treatment. (Table 1). Changes in lumbar spine or femoral neck BMD during treatment, however, were not different between patients who did or did not suffer from a fragility fracture during treatment.

PARAMETER (Median)	Patients with Fractures (F+) (n=523)	Patients without Fractures (F-) (n=3801)	p-value F(+) v F(-)
Baseline LS T-score	-3.0	-2.6	0.005
Baseline FN T-score	-2.8	-2.6	<0.001
Baseline PVFs	2.0	1.0	<0.001
Baseline BMI (kg/m2)	24.6	25.0	0.020
LS % BMD Change	5.4%	5.1%	0.359
FN % BMD Change	1.6%	1.8%	0.298

Of the investigated parameters, well-established risk factors for fracture such as low BMD, low BMI and prevalent vertebral fracture status allowed a differentiation between patients who did or did not fracture during treatment. Change in BMD with treatment was no different in patients who sustained a fracture compared with those who remained fracture free.

Risedronate Demonstrates Efficacy to Reduce Fragility Fractures Independent of Treatment-Related BMD Changes. N. B. Watts[1], S. Magowan[2], J. P. Brown[3], P. D. Miller[4], I. P. Barton*[5]. [1]University of Cincinnati, Cincinnati, OH, USA, [2]Procter & Gamble Pharmaceuticals, Cincinnati, OH, USA, [3]Laval University, Ste-Foy, PQ, Canada, [4]CCBR, Lakewood, CO, USA, [5]Procter & Gamble Pharmaceuticals, Egham, United Kingdom.

Risedronate 5 mg/day has previously demonstrated fracture efficacy independent of baseline BMD status. There is controversy in the literature if fracture efficacy is also independent of BMD changes experienced over the duration of therapy. This analysis was designed to determine the efficacy of risedronate 5 mg/day in reducing the risk of fragility fractures (vertebral and non-vertebral) in postmenopausal women who either gained or lost BMD over the duration of treatment. The analysis included 2,846 postmenopausal women (placebo N=1418, risedronate N=1428) enrolled in the risedronate phase III 3-year placebo-controlled fracture endpoint trials (VERT-MN & NA, HIP) who had lumbar spine (LS) and/or femoral neck (FN) BMD data available at baseline and post-baseline (3 years or last observation). The efficacy of risedronate in reducing fracture risk was estimated by the Hazard Ratio (HR) within each BMD group using a Cox regression model, stratified by clinical trial. The two groups were similar with regard to clinically important baseline characteristics; age, BMI, prevalent vertebral fracture status, and baseline LS and FN BMD. Antifracture efficacy was statistically significant vs. placebo whether there was gain or loss of BMD at the lumbar spine or the femoral neck (fig 1) and magnitude of antifracture efficacy of risedronate 5 mg/day vs placebo was similar in women whether there was gain or loss of BMD either at the LS or FN (treatment-by-BMD interactions p> 0.6). This study demonstrates that risedronate is efficacious in the reduction of osteoporotic fractures regardless of whether there is a loss or gain in BMD over the duration of treatment as compared to placebo. As pointed out in recent studies, the mechanisms by which agents like risedronate reduce skeletal fragility are complex and only partly reflected in BMD changes.

Bisphosphonates Suppress Periosteal Osteoblast Activity in Rat Femur and Tibia. K. Iwata*. Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Bisphosphonates (BPs) suppress bone resorption by inducing apoptosis of mature osteoclasts and by inhibiting differentiation of osteoclast precursors. In a coupled remodeling system, this will reduce bone formation at the level of the individual remodeling unit. The direct influence of BPs on osteoblasts in vivo is unknown. In vitro they have been shown to inhibit osteoblast apoptosis at low concentrations (potentially leading to increased bone formation), and to induce apoptosis or cell death at high concentrations. In this study we determined the effect of BPs on osteoblast activity on the periosteal surfaces of long bones in rats, where formation is not spatially coupled to resorption at least at the level of the BMU. We administered risedronate (RIS) or alendronate (ALN) to 6-month-old female Sprague-Dawley rats. Control rats (CNT; n=9) were given a daily subcutaneous (sc) injection of saline vehicle. Six groups of rats were injected sc daily for 17 days with RIS at doses of 0.05 μg/kg (RIS-low; n=9), 0.5 μg/kg (RIS-mid; n=9) or 5 μg/kg (RIS-high; n=9); or with ALN at doses of 0.1 μg/kg (ALN-low; n=9), 1.0 μg/kg (ALN-mid; n=8), or 10 μg/kg (ALN-high; n=9). All animals were double labeled with calcein (1-5-1-3), and dynamic histomorphometry was performed on the endosteal and periosteal surfaces of the tibia and femur. Both BPs at all doses significantly

reduced periosteal mineral apposition rate (MAR) in the femur (21-40% vs CNT, p<0.05) and in the tibia (41-52% vs. CNT, p<0.01, Fig1). In the tibia but not in the femur this resulted in a significant (p<0.05) reduction in periosteal bone formation rate (BFR/BS) in all groups. There were no significant differences in MAR on the endosteal surfaces of either femur or tibia, although BFR/BS was significantly reduced in the femur in some dose groups. These results show that in rats, BPs can suppress MAR on periosteal surfaces that are modeling in formation mode. This may indicate a direct effect on osteoblast activity and suppression of bone formation independently of bone resorption, but an indirect effect dependent on suppression of resorption at remote sites (e.g., endosteal surface) cannot be excluded .

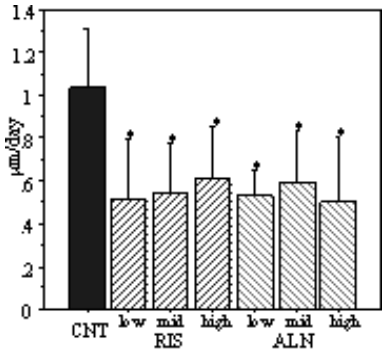

Fig1. MAR of tibial diaphyseal periosteal surface ; p<0.01 : vs CNT

Non-Vertebral Fracture Reduction in Osteoporotic Women Using a Composite Measure of Baseline Fracture Risk. D. E. Black[1], C. E. Barr*[2], S. Papapoulos[3]. [1]Epidemiology and Biostatistics, UCSF, San Francisco, CA, USA, [2]Roche Laboratories, Nutley, NJ, USA, [3]Department of Endocrinology, Leiden University Medical Center, Leiden, Netherlands Antilles.

Recent approaches to identify osteoporotic women at higher risk of fracture have focused on estimating absolute fracture risk using composite algorithms that include clinical risk factors in addition to bone mineral density (BMD) [1]. The observational Study of Osteoporosis Fractures (SOF)[2] developed such a predictive risk index; however, this approach has yet to be applied in a clinical trial setting. The BONE trial[3] demonstrated significant reductions in vertebral fractures with ibandronate across the full study population as well as non-vertebral fracture (NVF) risk reduction in the subgroup of women with femoral neck BMD T-scores below -3.0. Using data from the BONE study, we examined a composite risk measure and its utility in assessing ibandronate efficacy for NVF reduction. The predicted 5-year risk of NVF was estimated using an equation, adapted from the SOF study, incorporating baseline age, lumbar spine BMD, and history of fracture as predictors. Clinical NVFs (clavicle, humerus, wrist, pelvis, hip, and leg) were collected as adverse events, confirmed radiologically, and excluded if due to accident/ trauma. Two alternative categorizations of risk were explored: (a) population tertiles, based on dividing the study population into equal thirds, and (b) absolute risk categories (low/ medium/high) based on the predicted NVF risk. Treatment effects were compared across these risk definitions. The observed number of NVFs across the study population was lower than predicted by this algorithm, especially in low risk groups. We found a significant interaction (p=0.006) between baseline risk of NVF and treatment effect. When defined by population tertiles, there was a 20% risk reduction (p=0.293) among patients in the high risk tertile (predicted 5 year NVF risk>20.4%). When defined by baseline absolute risk, a statistically significant 45% risk reduction was evident in the high risk group (risk>32.9%, p=0.028). Limitations of this analysis include the relatively low overall NVF rate (and consequent small number of fractures) as well as the post-hoc nature of the categories. These results underscore the value of composite measures of fracture risk as a clinical tool. They also provide evidence that ibandronate reduces NVF risk in a select group of high-risk women defined by a broader range of clinically relevant factors.

Alendronate Treatment in Women with Impaired Renal Function: An Analysis of the Fracture Intervention Trial. S. A. Jamal[1], D. C. Bauer[2], K. Ensrud[3], J. A. Cauley[4], M. Hochberg[5], A. Ishani*[3], S. R. Cummings[2]. [1]Medicine, University of Toronto, Toronto, ON, Canada, [2]S.F. Coordinating Center, CPMC Research Institute, and UC San Francisco, San Francisco, CA, USA, [3]University of Minneapolis, Minneapolis, MN, USA, [4]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [5]University of Maryland, Baltimore, MD, USA.

Alendronate is cleared by the kidney and may have sustained effects on bone in subjects with impaired renal function. We hypothesized that as renal function decreased alendronate treatment would result in greater increases in bone mineral density (BMD) and greater decreases in fractures. We studied women participating in the Fracture Intervention Trial (FIT) a randomized controlled trial of alendronate or placebo (n= 6458). Women with serum creatinine above 112 mmol/L, serum parathyroid hormone (PTH) above 85 ng/L in isolation, or serum PTH above 65 ng/L in combination with abnormal serum calcium, alkaline phosphatase or phosphate, were excluded from FIT. We estimated baseline creatinine clearance (CrCl) using the Cockcroft Gault Formula. 581(9%) participants had severely reduced CrCl (<30 ml/min). Alendronate increased BMD regardless of CrCl; women with reduced CrCl had a 5.63% (95% CI: 4.75 to 6.51) increase in total hip BMD compared with 4.80% (95% CI: 4.57 to 5.03) among women with normal to moderate renal dysfunction (interaction p value = 0.04). There was no significant interaction for the increase in spine BMD (interaction p value = 0.75). The absolute changes in hip and spine BMD were similar by CrCl status with no evidence of a treatment effect (interaction p values 0.49 for hip and 0.54 for spine). Treatment with alendronate reduced the risk of clinical fractures to a similar degree in those with (OR: 0.78, 95% CI: 0.51 to 1.21) and without reduced renal function (OR: 0.80, 95% CI; 0.70 to 0.93; P-value for interaction = 0.89). Similarly, treatment with alendronate reduced the risk of morphometric spine fractures to a similar degree in those with (OR: 0.72, 95% CI: 0.31 to 1.7) and without reduced renal function (OR: 0.50, 95% CI: 0.32 to 0.76; P-value for interaction = 0.44). Limiting our fracture analyses to women with osteoporosis (by BMD T scores) did not substantially change our results (interaction p value for clinical fracture: 0.56 and interaction p value for spine fracture 0.54). A limitation of this analysis was that it post hoc analysis and we did not have direct measures of the glomerular filtration rate. Further, there was limited power for fracture analyses.Alendronate has similar effects on hip and spine BMD and reduction in risk of nonspine and spine fractures regardless of renal function as estimated by creatinine clearance.
