Maximum Rising Strength Is a Strong Predictor of Femoral Neck Bone Mineral Density in Healthy Women. H. Blain*[1], I. Jaussent*[2], E. Thomas[3], M. Picot*[2], J. Micallef*[4], C. Jeandel*[1]. [1]Department of Internal Medicine and Gériatrics, Centre Antonin Balmes, Montpellier, France, [2]Department of Medical Informatics, University Hospital, Montpellier, France, [3]Department of Rheumatology, University Hospital, Montpellier, France, [4]Movement Analysis Laboratory, Propara Center, Montpellier, France.

Maximum knee extension strength (KES) is a strong predictor of femoral neck bone mineral density (FN BMD), but its measurement does not take into account other muscle forces of the lower limbs that are possibly involved in hip BMD maintenance. We recently developed an instrument for measuring maximum rising strength (MRS) by dynamometry and showed in 97 healthy subjects aged 23 to 90 years that the coefficient of variation of the mean of three peak values at 60° and 70° knee flexion of MRS measured in triplicate at three different occasions was 13.7%, close to that of KES (9.6%). The aim of the present study conducted in 249 other healthy women aged 18 to 76 years was to investigate whether MRS could be a better determinant of FN BMD (measured by DEXA) than KES. Using the Mann-Whitney U test, FN BMD was found to be correlated with age, height, weight, lean mass, MRS ($p<0.001$), and KES ($p<0.01$), and with physical activity performed during the last five years (measured using QUANTAP software) (p=0.05) but not with fat mass nor calcium intake. In multiple regression models, FN BMD was associated with age (OR=2.8 [CI,1.59-4.92]; $p<0.001$), weight (OR=0.37 [0.17-0.79]; p=0.001) and with MRS (OR=0.57 [0.35-0.93]; $p<0.05$) but not with KES. The present study shows that MRS is a stronger determinant of FN BMD than KES in healthy women, independent of their age, anthropometric features, and physical activity habits. These results suggest the interest of including assessment of MRS in screening programs for women who are at high risk of low FN BMD and suggest the possible interest of this instrument for lower limb strengthening and for increasing FN BMD in women at risk of fracture of the femoral neck bone.

Comparison of BMD, Percent Body Fat and Bone Turnover in Ultra-distance Runners and Sedentary Controls. B. Cassim*[1], A. MacGregor*[2], M. Mars*[3]. [1]Department of Medicine, University of KwaZulu-Natal, Durban, South Africa, [2]Department of Biomedical Science, Mangosuthu Techikon, Durban, South Africa, [3]Department of Telehealth, University of KwaZulu-Natal, Durban, South Africa.

Women athletes who participate in vigorous physical activity are at risk to develop osteoporosis. This study was undertaken to compare the BMD, % body fat and biochemical markers of bone turnover in 55 premenopausal runners and 47 premenopausal sedentary healthy women and to determine the relationship between % body fat and BMD. BMD and % body fat were measured using the Hologic QDR 4500 densitometer. Commercial kits were used to measure urinary deoxypyridinoline crosslinks (DpD) and cross-linked N-telopeptides of type 1 collagen (NTx) and bone specific alkaline phosphatase (BALP) in the 55 runners and 18 controls and osteocalcin (OC) in 26 runners and 18 controls. The unpaired students t test and Pearson's correlation were used for statistical analysis. The runners were older than the control subjects (38.8 ± 4.7 yrs v 33.8 ± 6.3 yrs; $p < 0.0001$). Significant BMD and bone marker results are presented in the table. Runners had a significantly lower % body fat compared to controls (21.6 ± 5.7% v 38.2 ± 7%; $p < 0.0001$). In the controls, there was a significant correlation between % body fat and BMD at the total trunk ($r = 0.61$; $p < 0.05$), total hip ($r = 0.81$; $p< 0.0001$), femoral neck ($r = 0.64$; $p< 0.05$), trochanter ($r = 0.71$; $p < 0.001$) and intertrochanter region ($r = 0.76$; $p< 0.001$). In the runners there was a negative correlation between % body fat and BMD at the total legs ($r = -0.38$; $p < 0.05$). This study confirms the site specific positive effects of exercise on BMD in eumenorrhoeic ultradistance runners and suggests that this is due to a decreased bone turnover. The low % body fat was not a risk factor for a low BMD in this cohort.

Comparison of BMD and Markers of Bone Turnover in Ultra-distance Runners and Sedentary Controls

BMD g/cm²	Runners(n = 55)	Controls(n = 47)	p Value
Total hip	0.935 ± 0.132	0.881 ± 0.125	<0.05
Neck	0.831 ± 0.127	0.785 ± 0.106	<0.05
Inter- trochanter	1.111 ± 0.172	1.036 ± 0.153	<0.05
Total arms	0.722 ± 0.050	0.923 ± 0.154	<0.0001
Total legs	1.126 ± 0.119	1.014 ± 0.080	<0.001
DpD (nM DpD/mM creatinine)	4.9 ± 1.9	6.3 ± 3.5	<0.05
Osteocalcin (nmol/L)	1.1 ± 0.5(n = 26)	2.0 ± 1.9	<0.05

Improved Bone Strength in Women Following a 24-Week Total Body Periodized Resistance Training Program. H. M. Isome*[1], B. C. Nindl*[1], R. Evans[1], M. Lester*[1], D. Catrambone*[1], L. Gotshalk*[2], W. J. Kraemer*[3]. [1]Military Performance Divsion, US Army Research Institute for Environmental Medicine, Natick, MA, USA, [2]Health and Physical Education, University of Hawaii, Hilo, HI, USA, [3]Kinesiology, University of Connecticut, Storrs, CT, USA.

This study evaluated the effects of 4 periodized resistance training programs on parameters of bone strength as measured by MRI. Seventy-nine untrained women (23.1±3.5y) were randomly assigned to: total body low repetition (TL) (3-8 RM, n=18), total body high repetition (TH) (8-12 RM, n=21), upper body low repetition (UL) (3-8 RM, n=21) and upper body high repetition (UH) (8-12 RM, n=19). All training was performed three times weekly for 24 weeks, with at least 24 hours of rest between sessions. Cross-sectional MRI images of the femur were taken before training (T1), at 12 weeks (T2), and after 24 weeks (T3) of training. Fifteen 10mm thick transaxial T1-weighted images were obtained at equal distances between the base of the femoral head and the distal end of the femur. Slice eight (mid-femur) was then analyzed using Scion Image v4.02 for Windows. Measures of bone strength included maximum second moment of area (I_{max}), minimum second moment of area (I_{min}), and polar second moment of area (J). Significant increases in femur strength were only observed in groups TH and TL. Increases were not evident at 12 weeks (T1-T2), but increased significantly from T2-T3 for I_{max} (1.5 and 1.5%), I_{min} (3.0 and 2.7%) and J (2.2 and 2.0%) in groups TH and TL, respectively ($p<0.001$). An overall increase in I_{max} (1.7 and 1.6%), I_{min} (3.2 and 3.0%) and J (2.3 and 2.2%) was observed in groups TH and TL, respectively, over the study period ($p<0.001$). No changes were observed in the UH or UL groups at any time point for any variable. We did not find significant differences between the TH and TL training groups. This study demonstrates that total body periodized resistance training significantly improves strength parameters of the femur, but may not be evident until after 12 weeks. Furthermore, adaptation in bone strength is localized to site specific areas that undergo repetitive loading associated with resistance training.

Skeletal Biomechanics of the Florida Manatee. K. B. Clifton[1], J. Yan*[2], J. J. Mecholsky*[2], R. L. Reep*[1]. [1]Physiological Sciences, University of Florida, Gainesville, FL, USA, [2]Materials Science and Engineering, University of Florida, Gainesville, FL, USA.

Watercraft-related mortality of the Florida manatee, caused by propeller wounds or impact, accounts for 25% of all deaths from 1974-2004, and comprises 85% of human-related deaths. Reducing watercraft-related mortality is identified as a high priority in the manatee recovery plan. In order to establish safe boat speeds for manatee protection, an estimate of the forces required to fracture their bone is needed. A first step to improve the understanding of biological effects of boat strikes is to understand the material properties of manatee bone. This study investigated the material properties of manatee rib bone. Flexural strength, fracture toughness, Young's modulus, and work of fracture were measured for two size classes (subadults, adults) by sex. Parallelpipeds were machined from ribs in the cranial, middle, and caudal body regions, and fractured in three-point bending. Fractographic analysis of fracture surfaces was used to calculate fracture toughness, and ultrasound was used to validate elastic modulus measurements. Mean flexural strength by animal ranged from 73-159 MPa, mean fracture toughness from 1.4-2.9 $MPa{\cdot}m^{1/2}$, mean elastic modulus from 4-18 GPa, and mean work of fracture 3-6 $MJ{\cdot}m^{-3}$. In comparison, typical flexural strengths for human and bovine bone tested in 3-point bending are 209 MPa and 224 MPa, respectively. Toughness of human and bovine bone ranges from 2.2-6.3 $MPa{\cdot}m^{1/2}$. Most variables were significantly different between sexes and age classes ($p<0.05$). Material properties increased with body size up to 265 cm total length, then leveled off or declined with increasing body size in the adults. Data indicate that manatee bone may be on average less strong and tough than other mammalian bone, which is consistent with their aquatic, shallow water habitat. Material properties are likely correlated to mineral content (67-70%), plexiform organization, and low remodeling rate.

IGF-I Enhances Bone Recovery after 2 Weeks of Unloading. B. Boudignon*, P. Kurimoto*, S. Nishida, Y. Wang, H. Elalieh*, J. Cao, D. D. Bikle, B. P. Halloran. Endocrine unit, VAMC, San Francisco, CA, USA.

One of the most abundant growth factors in the bone, IGF-I is produced by bone cells, and stimulates osteoblast proliferation and bone formation. Studies show that IGF-I increases bone volume in normally loaded animals. However, during skeletal unloading induced by hindlimb elevation bone is resistant to the anabolic effects of IGF-I. In this context we wanted to know whether IGF-I could promote bone recovery during 2 weeks of reloading after a 2 week period hindlimb unloading, and if so whether the effects of IGF-I would be amplified by the reapplied load. Thirty six, 12 week old rats were divided into six groups; loaded (4 weeks), unloaded (4 weeks) and unloaded/reloaded (2/2 weeks), and treated with IGF-1 infusion (2.5 mg/kg/d) or vehicle during the final two weeks. Cortical bone volume (tibia) was assessed at the time of reloading and before sacrifice. Tibial fat free weight, cortical BFR, and bone histomorphometry of the tibial metaphysis were assessed at the end of the experiment. Cortical bone volume did not change significantly during the four week experiment, a finding not surprising in such a short amount of time. However, tibial fat free weight was less in unloaded vehicle treated animals than in the loaded animals. Periosteal BFR decreased during unloading. During the 2 week recovery period in which skeletal loading was restored to normal, BFR in both the vehicle and IGF-I treated animals increased but the effect was greatly exaggerated in the animals treated with IGF-I. In IGF-I treated animals bone mass was restored more rapidly than in vehicle treated animals. These data show that unloading induces resistance to IGF-I, but that reloading after a period of skeletal unloading increases bone sensitivity to IGF-I. Thus IGF-I administration may be of benefit in treating patients following a period of immobilization when such patients are remobilized.

Mechanical Intervention Enhances Bone and Muscle in Young Women with Low Bone Density. V. Gilsanz[1], T. A. L. Wren[1], M. Sanchez*[1], C. Rubin[2]. [1]Radiology & Orthopaedics, Childrens Hospital Los Angeles, Los Angeles, CA, USA, [2]Biomedical Engineering, State University of New York, Stony Brook, NY, USA.

The purpose of this study was to determine whether high frequency, low magnitude mechanical stimulation can enhance bone and muscle in young women with low bone density. Cancellous density of the lumbar spine was measured by computed tomography (CT) in 150 healthy, sexually mature (Tanner 5) young women (age 16-21 yr) who had sustained a fracture. Those with the lowest density were divided into Intervention and Control groups (24 subjects per group). Those in the Intervention group were asked to stand on a vibrating platform (30 Hz vertical sinusoidal motion with 0.3g peak-to-peak acceleration) for 10 min every day for a year. CT images were obtained at the lumbar spine (L1-L3) and midshaft of the femur at baseline and 1-year. Cancellous bone density and area of the paraspinous musculature were measured from the vertebral images; cortical bone area and thigh muscle area were measured from the femoral images. The Intervention group showed greater increases in vertebral cancellous bone density and femur cortical bone area (Table). The Intervention group also showed greater increases in muscle area although statistical significance was obtained for the paraspinous musculature only (Table). These results demonstrate that a simple, non-pharmacalogical intervention can enhance bone properties in both the axial and appendicular skeleton of young women at risk for developing low peak bone mass and osteoporosis later in life. In addition, this is the first study to observe changes in muscle following low magnitude mechanical stimulation, suggesting that muscle activity may play an important role in mediating the bone response to the intervention. Low level mechanical stimulation appears to be a promising option for early intervention in those most likely to develop osteoporosis.

Percentage change from baseline to 1-year, mean (SD)

	Control % change	Intervention % change	p-value from t-test
Vertebral cancellous bone density	0.09 (4.54)	2.14 (4.93)	.065
Femur cortical bone area	1.09 (3.67)	3.35 (3.71)	.039
Paraspinous muscle area	0.51 (4.98)	5.38 (6.88)	.002
Thigh muscle area	2.17 (2.69)	3.63 (3.63)	.363

Playing Golf Is Associated with Increased Vertebral Bone Size and Mass in Post Menopausal Women. S. L. Bass[1], J. Cook*[2], K. Singleton*[1], J. Black*[1], R. Daly[1]. [1]Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia, [2]School of Physiotherapy, La Trob University, Bundoora, Australia.

A golf swing results in lateral bending that imparts shear, compressive and torsional strains on the spine. These forces, together with the rapid changes in the direction of their application and the intermittent nature of the game, create an ideal loading environment for an optimal osteogenic response. Thus we hypothesized that women who play regular golf would have greater lumbar spine bone traits than active controls. Forty-nine postmenopausal women aged 62.2 (95% CI: 60.3, 64.2) years who had been playing golf for 16.8 (12.8, 18.8) years were compared to 34 active controls aged 60.2 (58.0, 62.5) years matched for age, height, weight, age of menopause, years post menopause and prior use of HRT. No subjects were currently using HRT. BMD, BMC and bone area were assessed by DXA. The degree of arthritis at the lumbar spine was quantified by an experienced radiologist from QCT scout scans.Lumbar spine BMD, BMC and bone area were 10%, 15% and 5% greater respectively in the golfers (table). The greater bone area was due to a 4% greater vertebral body width (not height). No differences in BMD were detected at total body or hip. There was no difference in the severity of arthritis between the golfers and controls; the lumbar spine of the majority of subjects was either normal or mildly arthritic.

Lumbar Spine (L1-L4)	Golfers (n=49)	Controls (n=34)
BMD (g/cm^2)	1.138 (1.099, 1.177)*	1.035 (0.977, 1.093)
BMC (g)	63.1 (60.0, 66.2)*	55.0 (50.8, 59.2)
Area (cm)	55.52 (53.98, 57.06) *	53.11 (51.39, 54.84)
Width (cm)	4.10 (4.02, 4.19) *	3.97 (3.88, 4.06)

[mean (95% CI)] *p<0.05

In summary, playing golf was associated with increased lumbar spine BMC, BMD and bone width. There was no evidence that playing golf was associated with increased incidence or severity of osteoarthritis. Thus the greater bone size and mass observed in the golfers is likely to be due to the load imparted by the swing. In conclusion, regular golf may be an ideal exercise for reducing the risk of low vertebral bone strength in postmenopausal women.

Disclosures: ***S.L. Bass****, None.*

High Frequency Accelerations Attenuate Disuse-Induced Trabecular Bone Loss. R. A. Garman[1], L. R. Donahue[2], C. T. Rubin[1], S. Judex[1]. [1]Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

High frequency low-level mechanical stimuli applied through whole-body vibrations to the weight bearing skeleton are anabolic. Administered by standing on a vibrating plate, these signals, while clinically promising, are limited by their reliance on weight bearing (standing on the plate may be difficult for the elderly, spinal cord injuries, etc.) and the skeletal sites responsive to the stimulus (only weight bearing bones of the lower and axial skeleton can be targeted). Recently, we demonstrated that high frequency accelerations, in the absence of weight bearing, are also anabolic in bone. This stimulus is based on subtle acceleratory motions that can be applied to specific segments of the skeleton and does not require external (e.g., weight bearing) or internal (e.g., muscle) forces. Here we hypothesized that high frequency accelerations can attenuate bone loss induced by mechanical unloading. The hindlimbs of ten adult female BALB/cByJ mice were unloaded for 3wk. Once a day for 20min, the left hindlimb was subjected to acceleratory motions (45Hz, 0.6g), while the right hindlimb served as a contralateral control. *In vivo* micro-computed tomography was used to describe the longitudinal changes in trabecular and cortical bone morphology for the metaphysis and epiphysis. Comparing the amount of bone loss between accelerated and contralateral (disuse-only) tibia within each mouse revealed that low-magnitude accelerations ameliorated metaphyseal trabecular bone loss, as the decrease in bone volume fraction was 29% greater in disuse-only tibiae than in accelerated tibiae ($p<0.03$). Trabecular bone micro-architecture responded similarly, as changes in trabecular number and trabecular separation were greater in disuse-only bones (Tb.N: -200%; Tb.Sp: +60%). However, accelerated tibiae experienced 73% greater bone loss in the metaphyseal cortex than disuse-only tibiae ($p<0.02$). In the epiphysis, there was no difference in the adaptive response of trabecular bone between tibiae, although accelerated tibiae displayed a greater increase in both periosteal (+120%, $p<0.01$) and endocortical areas (+250%, $p<0.01$) of the epiphyseal cortex, as compared to disuse-only tibiae. The results demonstrate that the application of accelerations can significantly alter the changes in bone morphology associated with unloading. These signals, unlike most loading regimes, are not based on deforming the skeleton and can be applied in the absence of weight bearing to specific sites of bone loss. Exploration of cellular activities responsible for the morphology changes will enable us to further elucidate bone's responsiveness to acceleratory motions.

Low-Level Mechanical Vibrations Enhance Bone Formation without Loss of Bone Quality in the Growing Skeleton. L. Xie*[1], B. Busa*[1], L. Donahue[2], C. Rubin[1], L. Miller[3], S. Judex[1]. [1]Biomedical engineering, Stony Brook University, Stony brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, MN, USA, [3]Brookhaven National Laboratory, Upton, NY, USA.

Extremely small magnitude, high-frequency, mechanical stimuli are capable of enhancing bone quantity and micro-architecture in the growing skeleton. Preliminary data indicate that these changes in bone morphology can be accounted for, at least in part, by a decrease in bone's *catabolic* activity. The hypothesis of this study was that, in addition to reduced osteoclastic activity, whole body vibrations (WBV) can concomitantly increase bone's *anabolic* activity in the growing mouse skeleton and that the chemical quality of mechanically stimulated bone is similar to that of normal bone. Eight-week old female BALB/cByJ mice were divided into three groups, baseline control (n=8), age-matched control (n=10), and WBV at 45Hz (0.3g) for 15min/d (n=10). Experimental mice were injected with calcein on day 15 and 20. After the 3-wk experimental protocol, 5-µm undecalcified frontal sections were analyzed for indices of bone formation and *in situ* chemical composition. Five spectra (12x12 µm) enclosed by double calcein labels on either side of endocortical surface of the metaphysis were analyzed by synchrotron infrared microspectroscopy (Brookhaven National Laboratory). *In vivo* strain gaging of two additional mice indicated that WBV induced strain oscillations of approximately ten microstrain on the periosteal surface of the proximal tibia. Comparisons between age-matched controls and vibrated mice indicated that superimposing the extremely low-level

mechanical signal on habitual activities for 15min/d increased bone's anabolic activity (BFR/BS) on the endocortical surface of the metaphysis by 30% ($p<0.05$). Chemical analyses revealed the newly formed bone (2-7d old) stimulated by WBV had similar bone properties as newly formed bone without WBV. There were no significant differences in bone mineral crystallinity, phosphate content, carbonate content, acid phosphate-to-total phosphate content, and mineral-to-matrix ratios. WBV, however, significantly decreased the collagen cross-linking ratios (1660/1690) in bone on endocortical surface ($p<0.05$), likely related to the increase in reducible cross-links of dihydroxylysinonorleucine (DHLNL-1690). These data indicate that short durations of extremely low-levels of vibrations can enhance bone formation without loss of bone quality during skeletal growth. Considering their anabolic and anti-catabolic efficacy, these signal may be able to provide a non-pharmacological and safe means for increasing peak bone mass and decreasing the incidence of osteoporotic or stress fractures later in life.

Monitoring Load-Driven Fluid Flow Using Microparticles. M. Su*, P. Zhang*, Y. Huang*, H. Yokota. Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Bone is a mechanosensitive tissue, and load-induced fluid flow in a porous bone matrix is considered a critical determinant in bone remodeling. The long-term objective is to characterize load-induced fluid flow in trabecular and cortical bones and evaluate the role of fluid flow in osteogenic potentials. The specific aim of the current study was to develop a novel method of monitoring load-induced fluid flow in a three-dimensional collagen matrix and bone samples *ex vivo* using microparticles. Two engineering goals were to develop a custom-made piezoelectric mechanical loader mountable to a fluorescence microscope (Nikon E600) and to image in real time a motion of microparticles on a surface of porous materials in response to well-controlled mechanical loading. The piezoelectric loader was constructed using a bimorph-type actuator (Megacera, Inc.). The actuator was driven by a piezoelectric driver (PZD700 M/S, TREK) and controlled by a BNC-2110 interface (National Instruments) with a custom-made MatLab program. Load-induced fluid flow was visualized through the motion of polystyrene microspheres and fluorescence nanoparticles (Polysciences, Inc.), ~ 0.5 to 3 μm in diameter. Time elapsed images were taken at varying intervals with a 10X objective lens, and the captured images were analyzed using MetaMorph software (Universal Imaging Co.). In order to examine the effects of matrix porosity, we deposited a varying amount of hydroxyapatite to type I collagen matrix (CollaCote, Sulzer Dental, Inc.). The matrix was soaked in a 500-mM $CaCl_2$ solution followed by a 500-mM Na_2HPO_4 solution for 15 min each. The matrix was then thoroughly rinsed in sterile water between immersions, and alternate immersion in $CaCl_2$ and Na_2HPO_4 solutions was repeated. In response to sinusoidal loads at 1-5 Hz, the motion of fluid flow inside the matrix was correlated to the distance from the neutral plane of the matrix (matrix center). Compared to fluid flow in the matrix with coarse pores (~ 100 μm in diameter), the flow amplitude and velocity were elevated in the matrix with fine pores (~ 20 μm in diameter) as well as in the matrix deposited with hydroxyapatite. On the surface of matrices as well as mouse femurs *ex vivo*, the microparticles moved vertical to the loading axis synchronous to the applied loads. No motion of the microspheres was observed in the matrix covered with collagen gel. In summary, the described microparticle-based visualization method is useful to investigate fluid flow in three-dimensional porous materials in response to mechanical loading.

Loss of Half Runx2 Gene Dosage Specifically Exacerbates Reduction in Bone Formation Parameters Due to Unloading. R. Salingcarnboriboon[1], K. Tsuji[1], T. Komori[2], M. Noda[1]. [1]Dept. of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Dept. of Developmental and Reconstructive Medicine, Division of Oral Cytology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Molecular mechanisms underlying reduction of bone formation in mechanical unloaded condition have not yet been fully understood. Runx2 has been suggested to be involved in mechanical signal in vitro. However, the roles of Runx2 in mechanical stimuli *in vivo* have not yet been known. The purpose of this paper is to examine the roles of Runx2 in unloading-induced bone loss *in vivo*. Tail-suspension induced significant loss of trabecular bone in wild type mice, whereas loss of half Runx2 gene dosage in Runx2 heterozygous knockout mice (Runx2+/-) exacerbated trabecular bone loss. Furthermore, reduction of femoral cortical bone thickness and BMD were observed in Runx2+/- mice after TS but not apparent in Wt mice. Heterozygous loss of Runx2 gene significantly suppressed the endosteal and periosteal mineral apposition rate (MAR) and bone formation rate (BFR) in the cortical bone to nearly undetectable levels after subjected to TS. Similarly, Runx2+/- also exacerbated the suppression of MAR and BFR by TS in trabecular bone compartment. Runx2 and Osterix mRNA expression in cortical bone envelope was reduced significantly by TS in Wt mice. In contrast, Runx2 and Osterix gene in Runx2+/- mice were not altered even after TS suggesting the presence of mechanism downstream to these molecules. Surprisingly, in Runx2+/- mice Runx2 protein was down-regulated to nearly null level after TS. We further demonstrated that Cbl-b, the E3 ubiquitin ligage gene that has been reported to be up regulated after TS, bound directly to Runx2 and repressed transcriptional activity on 1.3 osteocalcin promoter suggesting the possible involvement of Cbl-b in degradation of Runx2 protein. These data indicated that Runx2 is a critical target of unloading stimuli to alter osteoblastic activity and bone formation.

Differential Effect of Indomethacin on Cell Number and Alkaline Phosphatase Production during Osteogenesis *In Vitro*. W. J. Peterson[1], D. T. Yamaguchi[2]. [1]Grecc 691/11g, VA Greater Los Angeles Healthcare System and UCLA School of Medicine, Los Angeles, CA, USA, [2]Research Service 691/151, VA Greater Los Angeles Healthcare System and UCLA School of Medicine, Los Angeles, CA, USA.

Prostaglandins regulate bone formation. While it is known that osteoblasts go through distinct stages of proliferation and differentiation before mineralization, the intricate role that prostaglandins may play in this process under long term osteogenic conditions has not been established. Controversial results have been reported on prostaglandin activity, however, this may be due to differences in cell types and methods of assay used for study. Another source of controversy may be the phenotypic changes that occur during the developmental sequence of osteogenesis. Thus, osteoproge nitor cells undergo extensive proliferation before becoming differentiated osteoblasts. Once confluent, these cells continue their maturation, producing extracellular matrix proteins. It is possible that prostaglandins may affect either proliferation and/or differentiation at various intervals during the developmental process of bone formation. To test this hypothesis, we selected the MC3T3-E1 cell line because it is a well-known in vitro model that undergoes a developmental sequence of proliferation and differentiation similar to osteoblasts in primary cultures. Our approach to this study was to treat cultures with indomethacin to inactivate cyclooxygenase at various times after culture initiation. The effect of reduced prostaglandin synthesis and secretion on proliferation and differentiation was determined by assessing cell number and alkaline phosphatase production. Data are expressed as the mean ± SE. The results show: (1) no effect of indomethacin concentration (4-64uM) on cell number in cultures treated for 7 days; (2) maximal enhancement of alkaline phosphatase production (255% of control) per cell was observed using 64 uM of indomethacin in cultures treated for 7 days; (3) decreased cell number was first observed on day 10 in cultures treated with indomethacin for 12 days (61%, 55%, 33% of control on days 10, 11, and 12, respectively); (4) effects of indomethacin on cell number and alkaline phosphatase production are independent of exposure time; (5) indomethacin treatment enhanced the rate of alkaline phosphatase production per cell in cultures treated for 12 days (300% and 412% of control on days 11 and 12, respectively). These results suggest that prostaglandins may contribute to bone formation by regulating (1) the total number of osteoblasts per culture; (2) the proportion of osteoblasts undergoing differentiation and (3) the rate of alkaline phosphatase production per differentiated osteoblast.

Inflammatory Kinins Synergistically Potentiate IL-1β Induced Bone Resorption by a Mechanism Involving Increased Expressions of COX-2, mPGES-1, cPLA$_2$ and Prostaglandin Dependent Increased RANKL mRNA. A. B. Brechter, U. H. Lerner. Oral Cell Biology, Odontology, UMEÅ, Sweden.

The effects of a variety of kinins and kinin analogues on unstimulated and cytokine stimulated prostaglandin biosynthesis and on the expression of enzymes involved in arachidonic acid metabolism were studied in a human osteoblastic cell line, MG-63. In addition, the effects of kinins on cytokine induced prostaglandin biosynthesis and expression of molecules crucial for osteoclast differentiation was assessed in mouse calvarial bones. Co-treatment of MG-63 cells with BK and either interleukin-1α (IL-1α), IL-1β or tumour necrosis factor-α (TNF-α) resulted in synergistic stimulation of prostaglandin E_2 (PGE_2) formation. The interactions were dependent on the concentrations of IL-1β and TNF-α, as well as that of bradykinin (BK). IL-1β induced PGE_2 formation was synergistically potentiated by several kinins and kinin analogues with affinity for BK B1 and B2 receptors and these interactions were specifically inhibited by B1 and B2 receptor antagonists. IL-1β, TNF-α, BK B1 and B2 receptor agonists enhanced the expression of cyclooxygenase-2 (COX-2) mRNA. Co-stimulation resulted in synergistic potentiation of cytokine induced COX-2 mRNA and protein expression by BK B1 and B2 receptor activation. Membrane-associated PGE synthase-1 (mPGES-1) mRNA expression was upregulated by IL-1α, a response that was synergistically potentiated by both BK and DALBK. Co-treatment with IL-1α and either BK or DALBK resulted in a small enhancement of cPLA$_2$ mRNA, whereas COX-1 mRNA was unaffected. No synergistic interactions were observed in cells co-stimulated with kinins and either IL-6, IL-11, IL-17, OSM, LIF or TGF-β. In mouse calvariae, BK and DALBK synergistically potentiated IL-1β induced PGE_2 formation, COX-2 mRNA, as well as receptor activator of NF-κB ligand (RANKL) mRNA. The synergistic effect on PGE_2 formation, was abolished by indomethacin, and the synergistic effect on RANKL was substancially inhibited by indomethacin. These results show that BK B1 and B2 receptors synergistically potentiate IL-1β and TNF-α induced stimulation of prostaglandin biosynthesis in osteoblasts by a mechanism involving increased COX-2, mPGES-1 and cPLA$_2$ expression. The interactions also result in PGE_2-dependent enhanced expression of the osteoclast differentiation cytokine RANKL. These data explain the mechanism why kinins synergistically potentiate IL-1β induced bone resorption in mouse calvariae.

Effects of 1,25-Dihydroxyvitamin D_3 and 25-Hydroxyvitamin D_3 on Osteoblast Differentiation in Human Marrow Stromal Cell Cultures. J. Glowacki[1], S. M. Mueller*[2], J. S. Greenberger[3], I. Bleiberg*[4], M. S. LeBoff[5]. [1]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, [2]University Hospital, Zurich, Switzerland, [3]Radiation Oncology, University of Pittsburgh, Pittsburgh, PA, USA, [4]Sackler School of Medicine, Tel Aviv, Israel, [5]Medicine, Brigham and Women's Hospital, Boston, MA, USA.

In vivo and *in vitro* studies indicate that a sub-population of bone marrow stromal cells has the potential to differentiate into osteoblasts. With alkaline phosphatase (AlkP) as an early indicator of osteoblastogenesis, we reported that there was a significant age-related decrease in osteoblast differentiation in marrow from men aged 38 to 80 years of age [J Cell Biochem 82:583, 2001]. We tested the hypothesis that that both $1,25(OH)_2D_3$ and 25-hydroxyvitamin D_3 ($25OHD_3$) stimulate osteoblastogenesis in marrow from elderly men and women. Bone marrow was obtained as discarded material from men and women undergoing total hip replacement for osteoarthritis. Low-density mononuclear cells were isolated and selected for adherence. Four thousand cells were cultured in each well of a 96-well plate with osteogenic supplements (10 nM dexamethasone, 5 mM ß-glycerophosphate, 170 µM ascorbic phosphate). AlkP activity was measured after 6 days with the p-nitrophenol method with an ELISA plate reader. First, in a series of samples from 13 men (age range 27-79 years), 10 nM $1,25(OH)_2D_3$ stimulated AlkP significantly in all samples (mean 164%), but with a significant decrease with age ($r=-0.803$, $p=0.0009$). Second, dose-response effects and comparison of $1,25(OH)_2D_3$ and $25OHD_3$ were studied with marrow stromal cells from elderly men and women (N= 17, 64-83 years). The $1,25(OH)_2D_3$ stimulated 16 (94%), with peak stimulation between 1 and 10 nM $1,25(OH)_2D_3$. Of the 9 samples with which comparisons were made, 7 (78%) were stimulated by $1,25(OH)_2D_3$ and by $25OHD_3$. There was equivalent stimulation by $1,25(OH)_2D_3$ and $25OHD_3$ in cells from 2 men and 1 woman. Thus, although there are differences in magnitude of stimulation, in peak dose, and in relative effects of vitamin D metabolites, normal marrow from elders shows osteoanabolic response to $1,25(OH)_2D_3$ and by $25OHD_3$. We speculate that vitamin D status of the subject may account for differences in *in vitro* behavior of marrow stromal cells. The vitamin D status of the subjects whose marrow was used in these studies was not determined, but in other work we reported that there was vitamin D-deficiency (serum 25OHD < 37.5 nmol/L) in 22% of 68 women admitted for total hip replacement for osteoarthritis from the same pool as those whose discarded marrow was used in this work. In addition, 4% had elevated serum parathyroid hormone (>6.8 pmol/L)[J Bone Joint Surg 85A: 2371, 2003].

Venous Ligation-Mediated Bone Adaptation Requires COX-2. H. Y. Stevens*, D. R. Meays*, J. Yeh*, L. M. Bjursten*, J. A. Frangos. La Jolla Bioengineering Institute, La Jolla, CA, USA.

Prostaglandins are local mediators of bone resorption and formation, known to be involved in bone's adaptive response to fluid shear stress (FSS). We have previously described a model of trabecular bone loss in hindlimb suspended mice and rats and demonstrated partial protection from osteopenia by ligation of the femoral vein. The increased FSS resulting from this ligation drove bone adaptation in the absence of mechanical loading. In this study we investigated the role of COX-2 in this adaptive response to FSS by use of *COX-2* knockout mice. Heterozygotic breeders (*COX-2* +/-) were generated from *COX-2* -/- males (B6; 129-Ptgs2^{tm1Jed}) and *COX-2* +/+ females (B6; 129SF2/J). Female offspring were genotyped as *COX-2* knockout (KO); *COX-2* heterozygote (HET) and *COX-2* wild type (WT) at 4 weeks and recruited at 7 weeks. The proximal metaphysis of each femur was scanned *in vivo* by peripheral quantitative computed tomography (pQCT) and calcein administered. Six slices were recorded for the trochanteric region to assess initial volumetric bone mineral density (vBMD). On Day 2 the animals underwent venous ligation of a randomly-assigned femoral vein, with sham-operation of the contralateral limb and after 2 days' recovery, the mice were tail suspended for 10 days. On Day 14 femora were scanned *in vivo* by pQCT, xylenol orange administered and the mice left to ambulate normally for 3 days before euthanasia (Day 17). Average percentage loss in trabecular vBMD was calculated for each bone. At the conclusion of the study, femora were embedded in glycol methacrylate for histomorphometric analysis. All animals lost comparable amounts of trabecular bone from sham limbs as a result of suspension. In WT mice, loss of trabecular BMD in the venous-ligated limb was significantly less than that of the sham-operated limb (ligated -33.9 ± 2.1 (% ± SEM); sham -38.9 ± 2.4, $n = 9$, $p < 0.05$); this effect, however, was not seen in KO (ligated -35.9 ± 2.9; sham -34.0 ± 3.1) or HET mice. Percentage gain in femoral periosteal circumference was greater in the ligated limb than in the sham limb for WT mice. KO and HET mice already possess femora of larger periosteal circumference than their WT littermates and ligation in these bones did not result in an increase in perimeter relative to sham. Histomorphometry on embedded KO femora revealed thinner cortices compared to WT and HET and less mineralizing perimeter compared to WT (total label). Therefore we propose that *COX-2* deficiency affects recruitment of osteoblasts along the endocortical surface. This is the first *in vivo* study to show that fluid-flow mediated bone adaptation, independent of mechanical strain, is *COX-2* dependent.

Dissolution of the Inorganic Phase of Bone Leads to Release of Calcium, which Has an Important Auto-Regulatory Role in Osteoclast Survival, and Affects the Coupling of Bone Formation to Bone Resorption. K. Henriksen[1], R. H. Nielsen*[1], M. G. Sørensen*[1], J. Gram*[2], S. Schaller*[1], J. Bollerslev[3], M. A. Karsdal[1], T. J. Martin[4]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Ribe County Hospital, Esbjerg, Denmark, [3]National University Hospital, Oslo, Norway, [4]SVIMR, Melbourne, Australia.

Osteoclasts dissolute the inorganic phase of bone via acidification of the osteoclastic resorption lacunae by hydrochloric acid through the V-ATPase and the chloride channel ClC-7. Attenuated function of these results in osteopetrosis, characterized by increased osteoclast numbers, low or absent bone resorption and normal bone formation, suggesting that the coupling principle has been challenged. We investigated if the release of calcium during dissolution of the inorganic phase by the V-ATPase and ClC-7 is important for controlling osteoclast survival, bone resorption and for the coupling of bone formation to bone resorption *in vivo*. We used synthetic inhibitors of ClC-7 (NS5818/PB1), V-ATPase (bafilomycin A1), addition of calcium and the calcium channel antagonist Ryanodine in cultures of human osteoclasts on calcified and decalcified cortical bone slices, and the rat OVX model. NS5818 and bafilomycin dose-dependently inhibited bone resorption by mature osteoclasts, which inversely correlated to increases in the survival of calcitonin receptor positive multinuclear osteoclasts up to 300% at full inhibition. By comparison of osteoclast survival on normal bone slices to that of decalcified bone slices, inhibition of acidification led to increased survival only on normal bone, but not on decalcified bone. To specifically study the role of calcium in osteoclast survival, we used the calcium channel antagonist ryanodine and addition of calcium. We found that inhibition of calcium channels by ryanodine dose-dependently increased osteoclast survival up to 100% at 90µM, and that calcium dose-dependently increased osteoclast apoptosis, with maximum effect at 40mM. We used a potent ClC-7 inhibitor (PB1) *in vivo* in the OVX model (oral dosing 100mg/kg/rat). Resorption was restored to sham levels, whereas bone formation was unchanged compared to OVX levels, as investigated by CTX-I and osteocalcin in serum. In conclusion, the release of calcium during acidification of the resorption lacuna, induces apoptosis of the osteoclasts, which controls the resorptive activity, thus forming a regulatory loop. Inhibition of osteoclastic bone resorption *in vivo* by blocking acidification does not lead to reduced bone formation in contrast to other anti-resorptive treatments. Thus, acidification attenuated osteoclasts that are non-resorbing may still be able to generate signals that are essential for bone formation.

Generation of Cell-Based Models for Studying Classical and Non-Classical ER Action in Osteoblastic Cells. A. Sanyal, V. Rudnik*, F. A. Syed, S. Khosla. Endocrinology Research, Mayo Clinic, Rochester, MN, USA.

Studies with female mice lacking classical ERE signaling of the Estrogen Receptor alpha (ER-α) have shown that these mice (ERα$^-$/NERKI) gained cortical bone following ovariectomy, and estradiol dose-dependently suppressed this increase; these changes were the opposite of those seen in wild type (WT) mice [JBMR vol. 19, suppl. 1 p S339, 2004]. These paradoxical effects of ovariectomy and estrogen on cortical bone in ERα$^-$/NERKI mice could be due to an alteration of the balance between classical (through EREs) and non-classical (through response elements other than EREs) signaling of ER-α in osteoblastic cells. To evaluate the effects of classical and non-classical signaling pathways in osteoblastic cells, we have sought to develop cell-based models using a human osteosarcoma cell line, U2OS, that is devoid of endogenous ERs. WT and NERKI mouse ER-α, cloned into the pcDNA3.1 vector, were used independently to transfect the U2OS cells. Neomycin-resistant colonies were isolated by ring cloning. The colonies were tested at the mRNA and also at the protein levels for the expression of the WT and the NERKI ER-α. One colony from each group that showed the expression of the respective proteins was tested in a functional assay with reporter plasmids containing either EREs or AP1 response elements. Our results showed that the clone containing the WT ER-α significantly upregulated luciferase activity from the ERE-luciferase reporter in response to estradiol treatment. ICI, when used alone, could not activate transcription of the luciferase reporter and abrogated the effects of estradiol. The clone containing the NERKI ER-α, on the other hand, failed to upregulate luciferase activity driven by an ERE in response to either estradiol or ICI alone or in conjunction with estradiol treatment, showing its inability to function through EREs, and hence, the classical pathway. Both NERKI and WT mER-α clones, however, activated the AP1-luciferase reporter in response to estradiol, indicating their abilities to act through the nonclassical pathway. Thus, we have generated cell-based model systems that can be used for dissecting the classical vs nonclassical ER pathways in osteoblastic cells at the molecular level.

Hypoxia Induces PGE_2 and OPG Release from MC3T3-E1 Osteoblastic Cells. C. M. Lee, C. E. Yellowley. VM: APC, University of California, Davis, Davis, CA, USA.

It has been suggested that changes in regional oxygen tension may stimulate local bone cell activity and ultimately regulate bone maintenance and repair. Prostaglandin E_2 (PGE_2) is a potent regulator of bone remodeling exerting its affects on both osteoblast and osteoclast differentiation and activity. Osteoblasts regulate bone remodeling activity by expressing receptor activator of NF-κB ligand (RANKL) to induce, and osteoprotegerin

(OPG) to suppress osteoclastogenesis. In this study we examined the effect of lowering oxygen tension on levels of PGE_2, RANKL and OPG. Osteoblastic MC3T3-E1 cells were cultured in 2%, 5% or 21% oxygen. Conditioned media and whole cell lysates were collected at time points between 0 and 72 hours. RANKL protein levels were quantified by Western blot analysis. Media PGE_2 and OPG levels were quantified by ELISA. PGE_2 levels in media were markedly higher in cells cultured at 2% oxygen for 6 and 24 hours compared to cells cultured at 5 and 21% oxygen. OPG levels in cells grown in 2% oxygen were significantly increased at 24h compared to 5 and 21%. RANKL protein expression was not detectable by western blot analysis. Our data suggest that reduced oxygen tension significantly elevates PGE_2 and OPG release from MC3T3-E1 osteoblastic cells. Conditions inducing hypoxia in bone may include regional hypoxia at fracture sites and mechanical disuse. Since PGE_2, OPG and RANKL are involved in bone turnover, their modulation under hypoxic conditions may play a role in bone repair and remodeling under these conditions.

RUNX2 Potentiates, but Is not Required for, RANKL Expression in Mesenchymal Cells. Q. Fu[1], W. Wang*[2], B. R. Olsen*[2], S. C. Manolagas[1], C. A. O'Brien[1]. [1]Endo/Metab, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. Arkansas for Med. Sciences, Little Rock, AR, USA, [2]Department of Cell Biology, Harvard Medical School, Boston, MA, USA.

RANKL gene expression is limited primarily to bone and lymphocyte-containing tissues and stimulation of RANKL by osteoclastogenic hormones and cytokines is limited to cells of the mesenchymal lineage. However, the molecular basis of this cell type-specificity remains unknown. We have shown previously that cAMP-responsiveness of the murine RANKL gene is mediated in part by a distal enhancer, located 74 kb upstream from the transcription start site, which contains 2 cAMP response elements that are conserved among mammalian species. We now show that this enhancer also contains a potential RUNX2 binding site that is present in the RANKL gene of mammals and birds. Mutation of this binding site in the context of a luciferase reporter construct containing 120 kb of the murine RANKL 5-flanking region reduced basal and cAMP-stimulated RANKL transcriptional activity, suggesting that RUNX2 contributes to RANKL gene expression. RUNX2 binding to this sequence element was confirmed by gel shift assays using an anti-RUNX2 antibody. In addition, over-expression of RUNX2 in a stromal/osteoblastic cell line elevated the maximal cAMP-stimulation of the endogenous RANKL gene by 3-fold. However, expression of a dominant-negative version of RUNX2, consisting of the RUNX2 DNA-binding domain, did not suppress basal or cAMP-stimulated RANKL expression, but did suppress osteocalcin and bone sialoprotein expression. Conversely, expression of full-length RUNX2 in a hepatocyte cell line activated the endogenous osteocalcin and bone sialoprotein genes but did not activate either the endogenous RANKL gene or a stably integrated RANKL transgene. Moreover, dibutyryl-cAMP stimulated RANKL mRNA to the same extent in both wildtype and RUNX2-deficient mouse embryonic fibroblasts (MEFs). To determine whether other members of the RUNX family might participate in the control of RANKL in the absence of RUNX2, we quantified RUNX1 and RUNX3 mRNA in primary bone marrow stromal cells, a stromal/osteoblastic cell line, and MEFs. RUNX1 and RUNX3, as well as the non-DNA binding subunit Cbfb, were present in all three cell types. We conclude from these results that RUNX2, and perhaps RUNX1 or RUNX3, potentiate, but are not required for, RANKL expression in mesenchymal cells. Moreover, RUNX2 is not sufficient to confer RANKL expression in non-mesenchymal derived cells. Finally, these results suggest that although RUNX family members play a role in the cell type-specific expression of RANKL, additional factors are likely to be involved.

Prostaglandin E_2 Receptor (EP4) Agonist Stimulates Osteoblasts and Increases Bone Volume. T. Ninomiya*[1], H. Nakamura[2], A. Hosoya*[2], Y. Arai*[1], N. Sahara*[1], K. Yamaguchi*[3], H. Oida*[3], H. Ozawa[1]. [1]Institute for Oral Science, Matsumoto Dental University, Nagano, Japan, [2]Department of Oral Histology, Matsumoto Dental University, Nagano, Japan, [3]Fukui Research Institute, ONO Pharmaceutical CO., LTD., Fukui, Japan.

Prostaglandin (PG) E_2 promotes bone resorption and bone formation. PGE_2 has four receptor subtypes which have been identified and cloned, designated as EP1, EP2, EP3, and EP4. EP4 receptor mediates PGE_2 induced osteoclasts differentiation in bone organ culture. On the other hand, it had reported that EP4 activation induced de novo bone formation within immobilized rats. However, the mechanism of bone formation induced by EP4 activation is not clarified. In this study, we investigated the mechanism of increased bone volume by EP4 activation using EP4 agonist treated rats. The effects of EP4 activation on bone structure and bone cell were evaluated by bone morphometric and histological analysis. Moreover, the measurement using in vivo μCT was performed for investigating the effects of EP4 activation against a rat. Eighty male Sprague-Dawley rats aged 6 weeks were used in this experiment. EP4 agonist (ONO-4819, 10 μg/kg BW) was subcutaneously injected into back two times a day at 8-h intervals for 5 weeks. The rats of control group received saline in the same way. Rats were fixed by 4% paraformaldehyde at 1, 3, 5, 7, 14, 21, 28, and 35th day after starting an injection of EP4 agonist. The left and right tibiae from each group obtained at each time point were used on the experiment of bone morphometric and histological analysis, respectively. Four rats (n=2) chosen from control and EP4 agonist group were subjected to analysis with in vivo μCT (R_mCT, Rigaku, Tokyo) at each time point. On 1, 3, and 5th day, parameters of morphometric analysis were did not show any difference between control and EP4 agonist group. However, bone volume and trabecular number of EP4 agonist group on 14th day increased approximately 1.16-fold compared with these of control group. In the experiments using in vivo μCT, volume of bone formation on 21th day was higher than that of bone resorption. Moreover, histological data revealed that EP4 agonist induces activation of osteoblasts. These findings were associated with increase of bone volume morphometric findings. It was clearly that EP4 activation by EP4 agonist increased bone volume. Then, it was revealed that the methods using in vivo μCT is available for evaluate a substantial effect to bone resorption or formation. This study suggests that EP4 agonist acts to osteoblasts and accelerates bone formation by activation of osteoblasts.

Transforming Growth Factor Beta (TGFb) Stimulates CCL5/RANTES mRNA Expression and Secretion from Osteoblasts. S. Yano[1], D. Kanuparthi*[2], S. Huang*[2], E. M. Brown[2], N. Chattopadhyay*[2]. [1]Endocrinology and Metabolism, Hematology/Oncology, Shimane University Faculty of Medicine, Shimane, Japan, [2]Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA.

TGFb is a cytokine released from bone matrix, which stimulates osteoblast (OB) proliferation and growth. CCL5/RANTES is a chemokine secreted from both OBs and osteoclasts; it regulates several functions of these cells by autocrine/paracrine modes of action. We show here that 1 to 10 ng/ml TGFb in a concentration-dependent manner induces RANTES secretion from mouse primary calvarial OBs and from the MC3T3-E1 OB cell line. Induction of RANTES secretion by 5 ng/ml TGFb is observed as early as 4 h, and is not suppressed by 5 mM actinomycin D, thereby suggesting that the effect of TGFb is exerted at a post-transcriptional level at this early time point. TGFb, however, increases the level of RANTES mRNA in an 18 h incubation with calvarial OBs and MC3T3-E1 cells, indicating that longer treatment increases RANTES mRNA expression. TGFb induces RANTES secretion from osteoblasts via the p38 MAP kinase pathway but not via the Src kinase pathway, as 10 mM SB203580 (a p38 MAPK inhibitor) abolished TGFb-induced RANTES secretion, while 300 nM PP-2 (Src kinase inhibitor) did not. Finally, 5 ng/ml TGFb produced rapid phosphorylation of p38 MAPK in MC3T3-E1 cells. Therefore, we conclude that TGFb induces RANTES mRNA and stimulates RANTES secretion from OBs, acting at least in part at a post-transcriptional level with the participation of the p38 MAPK pathway. Given that RANTES promotes the survival of OBs and enhances their chemotaxis (Yano, et al., Endocrinology 2005;146:2324-2335), it could participate in the mechanism through which osteoclastic bone resorption is coupled to subsequent osteoblastic renewal of bone.

Intraarticular Osteochondral Fracture-Induced Hemarthrosis Contains Osteoprogenitor Cells and Can Be a Useful Cell Source for Bone Regeneration. T. Niikura, M. Miwa*, Y. Sakai*, S. Lee, R. Kuroda*, T. Fujishiro*, S. Kubo*, M. Doita*, M. Kurosaka*. Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan.

Bone marrow stromal cells from the iliac bone are commonly used as a cell source at a clinical stage of bone regeneration therapy. However, there are drawbacks in their use, due to the invasiveness of bone marrow aspiration from a patient. Moreover, available cells from a single procedure are limited. Therefore, obtaining cells less invasively and investigating possible new cell sources are important goals. We hypothesized that an intraarticular osteochondral fracture-induced hemarthrosis is a potentially useful cell source, because it is likely it will contain osteoprogenitor cells from bone marrow that can be obtained in the absence of unnecessary invasion to the patient. Moreover, we can utilize a material which has been previously discarded as medical waste. Therefore we investigated whether the hemarthrosis-derived cells have the potential to differentiate into osteoblasts. We enrolled six patients suffering from osteochondral fractures of knee joints in this study. Patients were routinely treated with aspiration of the hemarthrosis, and then isolation and culture of the hemarthrosis-derived cells was conducted. Informed consent for participation in the study was obtained from all patients and the project was approved by the Ethics of Human Experiments of the Faculty of Medicine, Kobe University prior to start of the study. Mononuclear cells were harvested by density gradient centrifugations. After the expansion in the primary culture, we cultured these cells in a medium supplemented with dexamethasone, β-glycerophosphate, and ascorbic acid, or without them as control. The culture of these cells showed the formation of colonies of fibroblast-like spindle shape cells in the primary culture. The morphology of the treated cells appeared osteoblastic, cuboidal shape differing from the fibroblastic, spindle-like shape observed in the control. Matrix mineralization was observed only in the treated culture using alizarin red S staining. Moreover, alkaline phosphatase activity determined by the release of p-nitrophenol from p-nitrophenyl phosphate, and gene expressions of alkaline phosphatase, parathyroid hormone receptor, and osteopontin which were analyzed by RT-PCR were up-regulated in the treated culture compared with the control. Flowcytometry analysis of these cells showed positive for CD 29, 44, 105, 166, and negative for CD 14, 34, 45. Our results demonstrate that these cells contain osteoprogenitor cells, and are highly possibly derived from bone marrow, and are a useful cell source for bone regeneration.

The Effect of Oxygen Diffusion Time on the Colony Formation and Proliferation of Human Connective Tissue Progenitor Cells in Primary Tissue Culture. S. M. Villarruel, R. Sinha*, C. A. Boehm*, J. Tao*, K. A. Powell*, G. F. Muschler. Biomedical Engineering, Cleveland Clinic Foundation, Cleveland, OH, USA.

Bone marrow (BM) contains a heterogeneous mixture connective tissue progenitors cells (CTPs), capable of forming one or more connective tissues. Understanding the effect pO_2 on CTP performance has important implications on in vitro assay and cell transplantation strategies. Oxygen can be toxic to cells through the generation of reactive oxygen species. Previously we showed that colony formation by CTPs increased at pO_2 of 7.6, 38, and 76 to mm Hg compared to pO_2 of 152 mmHg conventionally used for in vitro assays. This work investigates the effect of transient exposure to supraphysiological (152 mmHg) conditions during CTP culture. Conventional media preparation is supersaturated with atmospheric oxygen. To estimate the time necessary for atmospheric medium to reach steady state with lower pO_2 conditions following medium exchange a mathematical model of oxygen diffusion in tissue culture was developed using Ficks 2nd Law in 1D. This model predicted that 5 hours was necessary to achieve steady state with the lowest oxygen tension condition, P_{O2}= 7.6 mmHg. Pre-equilibration of medium to low pO_2 conditions prior to media exchange is a potentially important variable in assay of CTP performance. Iliac crest BM was harvested from 12 patients. Samples were cultured under osteoblastic conditions for six days. Cells were cultured in eight groups at one of four pO_2 levels (152, 76, 38, or 7.6 mmHg) using media that was either equilibrated at 152 mm Hg (control) or equilibrated at the appropriate lower pO_2. CTP cultures were assayed using imaging methods. A Quantix camera and motorized microscope controlled by Metamorph was used. Three-hundred individual 10x images were collected and montaged to create one full field of view image of each culture well. Quantitative characterization of individual CTP-derived colonies was performed. A total of 9,310 colonies containing 843,876 cells were assayed. Colony formation was 35% higher in lower oxygen levels when compared to 152 mmHg control. Treatment with pre-equilibrated media demonstrated greater colony forming efficiency at both 76 and 38 mmHg, suggesting that intermittent hyperoxia compromises CTP colony formation. Pre-equilibration did not have an effect on colony formation at 7.6 mmHg, suggesting a balance between hypoxia and transient hyperoxia. Proliferation rate among the colonies that were formed under each condition was not changed by pre-equilibration. Median cell density decreased with decreasing pO_2 in both groups. This work demonstrates that even short term exposure to hyperoxia using atmospheric pO_2 media reduces CTP colony forming efficiency.

Over-Potentiation of the Anabolic Actions of Specific Prostaglandin E EP4 Signaling by Osteopontin-Deficiency in Ovariectomized Mice. N. Kato[1], K. Kitahara*[1], S. R. Rittling*[2], D. T. Denhardt*[2], H. Kurosawa*[3], M. Noda[1]. [1]Molecular Pharmacology, 21st COE Program, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Cell Biology and Neuroscience, Rutgers University, Piscataway, NJ, USA, [3]Orthopedics, Juntendo University, Tokyo, Japan.

In order to resume bone mass in severely osteopenic patients, anabolic actions of the agents have been sought. One of the possible agents is prostaglandin E EP4 receptor agonist (EP4A). However, such anabolic actions of EP4A should be further potentiated to obtain full recovery of bone mass. Osteopontin (OPN) was shown to modulate bone formation in vivo. Therefore, we examined at the molecular levels the effects of OPN-deficiency on the EP4 induced gene expression in osteoblasts and on bone formation in ovariectomized mice model. EP4A (ONO-AE1-329) was injected 3 times per day for 5 days a week for 4 weeks subcutaneously into the back of wild type (WT) or OPN deficient (OPN-KO) mice. Total RNA was extracted from the bone of each animals. The mRNA expression levels of the genes encoding proteins related to osteoblastic phenotypes were examined. EP4A treatment increased the expression levels of the OPN but not type 1 collagen (COL), ALP as well as upstream transcription factor gene, osterix, in WT. In contrast, expression levels of COL and ALP, and osterix were enhanced in OPN-KO mice after EP4A treatment. Thus, OPN is a specific target of the EP4 and is involved in supprresion of EP4 activation. In order to examine the effects of OPN-deficiency on EP4 dependent activation of bone formation in osteopenic model, ovariectomy was conducted in WT and OPN-KO mice which were treated with either vehicle or EP4A. Ovariectomy suppressed the levels of bone volume in WT. EP4A enhanced bone mass in sham operated WT by about 20%, and resumed bone mass to reduce the suppression of bone mass levels by ovariectomy to reach up to 80% of the levels in sham operated group. OPN-deficiency did not alter the basal levels of bone volume and ovariectomy-induced bone loss was less than the levels observed in WT as reported previously. Strikingly, in OPN-KO mice, EP4A enhanced bone mass significantly up to 40% more than the bone mass level in OPN-KO mice treated with vehicle. In the presence of such over-enhanced bone mass, ovariectomy no longer alter the levels of bone volume. Thus, OPN-deficiency potentiated anabolic action of EP4 even in ovariectomized mice. Simultaneous suppression of bone resorption due to ovariectomy by OPN-KO could result in superinduction of bone volume compared to sham operated OPN-KO or sham operated WT. These data indicated the advantageous regimen of the cotreatment with EP4A and the antagonist against OPN of the bone loss due to ovariectomy.

Accelerating Fracture Healing by Manipulating Arachidonic Acid Metabolism. J. P. O'Connor, M. B. Manigrasso*. Orthopaedics, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

Cyclooxygenases and lipoxygenases catalyze the conversion of arachidonic acid into prostaglandins and leukotrienes, respectively. These bioactive lipids participate in cell signaling events and are critical mediators of inflammation. We have previously shown that genetic or pharmacological ablation of cyclooxygenase-2 activity severely impairs fracture healing in rodents, indicating that inflammation or prostaglandin-mediated signaling events are essential for normal bone regeneration. Since arachidonic acid also is a lipoxygenase substrate, we hypothesized that loss of cyclooxygenase-2 activity would lead to increased levels of leukotrienes or a higher leukotriene to prostaglandin ratio during the inflammatory phase of fracture healing and that this altered level of leukotrienes could contribute to inhibition of bone regeneration. To test our hypothesis, fracture healing was assessed in mice genetically deficient for 5-lipoxygenase. Radiographs and histology indicated that fracture bridging occurred 2 weeks after fracture in mice lacking 5-lipoxygenase activity as compared to 3 weeks after fracture in wild-type control mice of identical genetic background and age. Torsional mechanical testing showed that after 4 weeks of healing, the material strength of the healing femurs from the 5-lipoxygenase deficient mice was approximately twice as strong as the controls ($P < 0.001$). The data support our hypothesis that excess leukotrienes impair fracture healing when cyclooxygenase activity is impaired. The data also indicate that pharmacological manipulation of arachidonic acid metabolism can be used to accelerate bone regeneration.

Gene Array Analysis of Connexin43 Null Osteoblasts. M. Watkins*, J. Screen*, B. Guillotin*, R. Civitelli. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

Connexin43 (Cx43) is the major gap junction protein expressed by osteoblasts and osteocytes, and it is critically involved in bone formation. Mice genetically deficient of *Cx43* exhibit developmental abnormalities of the skeleton and impaired osteoblast function, attended by decreased expression of osteoblast genes, such as *osteocalcin* and α_1*(I) collagen*, and delayed mineralization in vitro. To further understand how Cx43 regulates osteoblast function, we performed a systematic analysis of gene expression profile of *Cx43* null osteoblasts compared to wild type cells using a gene array approach. Cells were isolated from the calvaria of newborn *Cx43* null and wild type littermates, and grown to confluence before RNA extraction. Cell extracts from 3 separate cell isolates from animals of 3 different litters were used individually. Total RNAs were dye labeled and hybridized to a 27kb mouse genomic cDNA array (Affimetrix Murine U74A chip). Genes whose expression was >4-fold different between *Cx43* null and wild type, consistently in all 3 experiments, were considered differentially expressed. Expression levels of 17% of the 12,326 genes were significantly down regulated in the Cx43 null samples compared to wild type; among these, *IGFBP-5*, *MMP12* and *Cxcl5*. Conversely, expression of only 2% of the assayed genes was significantly upregulated in Cx43 null osteoblasts compared to wild type osteoblasts, including *forkhead box-1* and *jun-b*. Differential gene expression was confirmed in a subset of these genes by real-time quantitative PCR. Osteoblast specific genes, including *Cbfa1/ Runx2*, *alkaline phosphatase*, α_1*(I) collagen* and *osteocalcin* were analyzed by real-time quantitative PCR, and their expression profile was consistent with an immature osteoblastic phenotype in *Cx43* null calvarial cells, results entirely in agreement with the notion that lack of *Cx43* reduces the differentiation potential of osteoblastic cells. Data from this systematic analysis should be helpful in assessing the molecular mechanisms by which Cx43 modulates osteoblast differentiation and bone formation.

Strong and Rapid Induction of Osteoblast Differentiation by Cbfa1/Til-1 Overexpression for Bone Tissue Engineering Applications. H. Kojima*, T. Uemura. Nanotechnology Research Institute, National Institute of Advanced Industrial Science and Technology(AIST), Tsukuba, Ibaraki, Japan.

Core binding factor alpha-1 (Cbfa1), known as an essential transcription factor for osteogenic lineage, has two major N-terminal isoforms: Pebp2alphaA and Til-1. To study the roles of these isoforms in bone regeneration, we applied an adenoviral vector carrying their genes to transduce primary osteoprogenitor cells in vitro and in vivo. Overexpression of the two isoforms induced rapid and marked osteoblast differentiation, with Til-1 being more effective in vitro, by examination of the alkaline phosphatase activity, calcium content, and Alizarin red staining. Til-1 overexpressing cells/porous biodegradable ceramic composites were transplanted into subcutaneous and bone defect sites in Fischer rats (cultured bone transplantation model) and markedly affected in vivo bone formation and osteoblast markers. The results demonstrated that the reconstitution of bone tissues, such as cortical bone and trabecular bone was accelerated by implantation of Til-1 overexpressing cells/porous biodegradable ceramic composites. Moreover, the new bone formation by Til-1 overexpression appeared to reflect replacement of new bone within the implant boundaries. To ascertain whether implanted Cbfa1 overexpressing cells could differentiate into osteogenic cells to create bone or whether it stimulated the surrounding recipient tissue to regenerate bone, implanted male donor cells were visualized by fluorescent in situ hybridization analysis. The proportion of implanted cells in the presumptive bone forming region was over 80% and did not change throughout from 3 days to 8 weeks after implantation. These findings suggested that the newly formed bone in the porous area of the scaffold is mostly produced by the implanted donor cells or their

derived cells, effectively by Til-1 overexpression. These in vitro and in vivo results suggested that the adenoviral vector encoding the Cbfa1 gene (Til-1) induced a rapid differentiation of osteoblasts in vitro and in vivo and could provide practical and instantaneous applications of bone tissue engineering to patients with skeletal defects.

***In Vitro* Study of the Collagen and Osteocalcin Gene Expression in Osteoblasts of Patients with Postmenopausal Osteoporosis.** S. Ruiz*[1], X. Nogués[2], A. Enjuanes*[1], J. C. Monllau*[3], E. Cáceres*[3], L. Mellibovsky*[2], J. Blanch[4], I. Aymar*[5], A. Díez-Pérez[2]. [1]URFOA, IMIM, Barcelona, Spain, [2]Internal Medicine Department.URFOA, Hospital del Mar,IMIM,UAB, Barcelona, Spain, [3]Orthopedic Department, Hospital del Mar,IMIM,UAB, Barcelona, Spain, [4]Rheumatology department, Hospital del Mar,IMIM,UAB, Barcelona, Spain, [5]URFOA, Hospital del Mar,IMIM,UAB, Barcelona, Spain.

In osteoporosis there is a negative balance between bone formation and resorption. This could be explained either by an intrinsic osteoblastic dysfunction or by abnormalities in their extrinsic regulatory elements. To further differentiate between both hypothesis *in vitro* studies of osteoblastic function at a cellular level are needed. *In vitro* measurements of Cbfa1 and BMP-2, implicated in the osteoblastic differentiation, and COL1A1 and osteocalcin gene expression, involved in the bone matrix deposition, were performed in a group of postmenopausal women with osteoporosis and in non osteoporotic controls. Twenty-one cases were included. Nine (age 74±6.3) were osteoporotic by BMD values (WHO criteria) and 12 were non-osteoporotic controls (age 69.7±5.8). Osteoblasts were cultured from trabecular bone of specimens obtained during total knee replacement surgery following the method described by Nacher et al (1). Cell lines were characterized by alkaline phosphatase activity and gene expression of osteocalcin. Cells were cultured in DMEM with 10% FCS for measurement of gene expression levels of Cbfa1, BMP-2, COL1A1 and osteocalcin. In the first subculture, and after synchronization, cells were incubated for 24 hours in basal conditions (0.1% BSA). Extraction of mRNA and reverse-transcriptase reaction (RT) were performed to obtain complementary DNA. Finally, gene expression was measured by real-time PCR. The different results are summarized in the table

	Cases (N=9)	Controls (N=12)	p (ANOVA)
Age	74 (6.3)	69.7 (5.8)	0.367
Lumbar spine BMD(g/cm^2)	0.917±0.130	1.066±0.240	0.004*
Femoral neck BMD(g/cm^2)	0.591±0.073	0.782±0.068	0.000*
Cbfa1 (AU)	2.13 (0.35)	2.24 (0.30)	0.810
BMP-2 (AU)	1.64 (0.32)	1.20 (0.20)	0.232
COL1A1 (AU)	1.29 (0.28)	2.29 (0.28)	0.049*
Osteocalcin (AU)	1.38 (0.15)	0.88 (0.17)	0.053

(*Significant effect, p<0.05. AU:Arbitrary Units)

Conclusions: In women with postmenopausal osteoporosis there is a significant decrease in the gene expression levels of type 1 collagen. This suggest an intrinsic osteoblastic defect that might result in a reduced bone matrix deposition and bone loss.

Runx2-Mediated Transcriptional Regulation of Osterix in Chondrocytes. Y. Nishio*, Y. Wang*, M. Paris*, E. M. Schwarz, R. J. O'keefe, H. Drissi. Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

Osterix (Osx) and Runx2 are required mediators of skeletal development. Null mice for both proteins present abrogation of bone formation while their cartilage anlagen are fully formed. However, differences in cartilage terminal maturation between Osx and Runx2 knockout mice were reported. Using mouse limb bud-derived cells; we investigated the regulation of Osx in comparison to Runx2 in these progenitors undergoing chondrocyte hypertrophy between 2 and 16 days in culture. Both Osx and Runx2 mRNA are up-regulated throughout chondrocyte differentiation. Furthermore, BMP-2 induction of chondrocyte maturation is accompanied with up-regulation of both Osx and Runx2 transcripts between 4 and 16 days in culture. However, while TGF-beta which delays chondrocyte maturation has a very potent inhibitory effect on Runx2 mRNA at all time points, it only significantly inhibits Osx levels after 12 and 16 days in culture. Together these results suggest a possible temporal cooperative effect between these two factors during chondrocyte maturation. To further determine the transcriptional mechanisms underlying Osx expression, we isolated 2 kb 5' upstream region of the mouse Osx gene. Our 5'-RACE experiments determined a cap site for Osx mRNA at approximately -99 nucleotides upstream of the ATG. Sequence analysis of this TATA-less promoter shows several putative response elements for a variety of bone and cartilage related transcription factors including homedomain proteins, Sox9, VDRE, SMAD binding elements, as well as zinc finger proteins including Runx and Sp motifs. Transfection of the osterix promoter driving the luciferase reporter gene into C3H10T1/2, ATDC-5 and MC3T3 cells shows a strong basal promoter activity between 0.5 and 2 kb. Further deletion mutant analyses show that the most proximal 0.8 kb of Osx promoter contains the highest activating domains while strong repressive domains were identified between 1.8 and 2kb. However, no significant tissue specificity between chondrocytes, osteblasts and embryonic fibroblasts was observed using these deletion constructs. Two putative Runx sites are overlapping between nt-713 and nt-698. Over-expression experiments indicate that Runx2 significantly transactivates the Osx promoter by at least 2 fold indicating that Osx is downstream of Runx2 in mesenchymal cells. Similarly, over-expression of Osx also induces its promoter indicating a positive auto-regulation in these cells. Site directed mutagenesis is currently underway to further verify the regulation of Osx by itself and Runx2. Thus our results show for the first time a Runx-mediated pathway by which Osx is regulated in chondrocytes.

Development of an Osteoblast-Specific DNA Nuclear Targeting Sequence from the Human Type I Alpha 2 Procollagen Promoter for Development of Efficient Plasmid Expression Vectors. D. D. Strong[1], D. A. Dean*[2], T. A. Linkhart[1]. [1]Research, Loma Linda VA Medical Center, Loma Linda, CA, USA, [2]Medicine, Northwestern University, Chicago, IL, USA.

Translocation of plasmid DNA into the nucleus is an important rate-limiting step affecting transgene expression levels in non-dividing cells. Inclusion of a viral (SV40) DNA nuclear targeting sequence (DTS) in plasmid vectors enhances nuclear import efficiency and increases transgene delivery and expression *in vitro* and *in vivo*. Plasmid nuclear import involves cellular transcription factors that bind in the cytoplasm to the viral DTS and translocate the DNA by a nuclear localization signal (NLS) and α/β importin dependent process. To determine if osteoblast specific gene promoters contained transcription factor binding sequences that could enhance osteoblast specific plasmid nuclear targeting by a similar mechanism, a series of promoters from genes specifically and robustly expressed in osteoblasts (osteocalcin, collagen, BSP and Runx2) were cloned into the pGL3-reporter vector and microinjected into the cytoplasm of non-dividing cells. Nuclear import was monitored by *in situ* hybridization with a fluorescein-dUTP-labeled pGL3 vector probe. The plasmids were transfected into dividing osteoblasts, fibroblasts, and chondrocytes to determine promoter activity levels. Osteoblast specific promoter (luciferase) activity was normalized to β-gal activity expressed from the co-transfected pCMVβ-gal vector. Each promoter tested demonstrated robust transcriptional activity in osteoblasts (ROS17/2.8) compared to the mouse osteocalcin (mOC) promoter (bp -1393 to +18), set at 100%: rat (r) Col1a1 (bp -2050 to +119) 300% > human (h) Runx2 (bp-345 to +8) 260%> hCol1a2 (bp -267 to +45) 247% hRunx2 (bp -2060 to +8) 240%> hCol1a1 (bp -290 to +172) 120% >hBSP (bp -1917 to +44) 120% >hOC (bp -345 to +28) 104%. By contrast, very low levels of activity were detected after transfection of chondrocytes, fibroblasts and marrow stromal cells. When tested for DNA nuclear import activity, only the hCol1a2 construct, the shortest of the promoters tested, showed nuclear import activity. Further, this DTS activity was osteoblast-specific and only occurred in human and rodent osteoblasts. Site-directed mutagenesis of putative transcription factor binding sites indicated that multiple response elements were required for osteoblast specific nuclear targeting. In conclusion, the hCol1a2 promoter contains a novel osteoblast-specific DTS that can be used for nonviral expression vector construction to increase transgene expression and increase the safety profile by specifically targeting osteoblasts in skeletal tissue with gene therapeutics.

Regulation of Gene Expression in U2OS Human Osteoblast-Like Cells by TGFβ Inducible Early Gene-1. M. Subramaniam[1], J. R. Hawse[1], D. G. Monroe[1], K. Rasmussen*[1], M. Oursler[2], T. C. Spelsberg[1]. [1]Biochemisty and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

TGFβ inducible early gene-1 (TIEG) was originally identified in human osteoblasts as a primary response gene induced by TGFβ. The TIEG gene encodes a 480 amino acid protein that contains three zinc fingers and belongs to the Krüppel-like family of transcription factors. TIEG is known to play a role in the regulation of gene expression, including Smad 2 and 7, and in the repression of cell proliferation. In order to understand the mechanisms by which TIEG mediates such cellular effects as TGFβ signaling, cell proliferation and regulation of gene expression, it is essential to first identify those genes that are directly regulated by TIEG. We have created a doxycycline inducible TIEG human osteosarcoma cell line (U2OS) and have utilized microarray analysis to identify specific genes whose expression is altered in the presence of TIEG. U2OS-TIEG cells were treated with doxycycline for 24 hours and total RNA was isolated from control and doxycycline treated cells. Microarray analysis using human focus arrays (Affymetrix) identified 46 genes whose expression was either increased or decreased by 2-fold or greater levels in the presence of TIEG. Of these, 34 genes exhibited increased expression including the leptin receptor, a CCAAT-box-binding transcription factor, cell division cycle 2 and cyclin E2. Another 12 genes exhibited decreased expression in the presence of TIEG including chemokine ligand 1, an actin binding protein, L1 cell adhesion molecule and interestingly, TIEG itself. Confirmation of detected gene expression differences was carried out by semi-quantitative RT-PCR. Since a number of genes involved in the regulation of cell cycle exhibited altered expression levels and, since TIEG is known to play an important role in the regulation of cell proliferation, we sought to determine the effect of TIEG expression on osteoblast proliferation. TIEG expression resulted in a suppression of U2OS cell proliferation with a maximal decrease of 50% at 72 hours. Taken together, these data indicate that TIEG regulates the induction and repression of a number of genes involved in a wide variety of cellular processes and that TIEG expression also results in decreased U2OS cell proliferation.

Activation of LEF/TCF- and Runx2- Dependent Transcription by MINT, the Msx2 Interacting Nuclear Matrix Target: Structure-Function Analysis. O. L. Sierra, S. Cheng, A. P. Loewy*, D. A. Towler. Dept of Medicine, Bone & Mineral Diseases, Washington University, St Louis, MO, USA.

MINT augments transcription from the osteocalcin FGF responsive element (OCFRE) via Runx2 activation domain 3. MINT co-localizes with the active form of PolII in the osteoblast nucleus, indicating that MINT functions as a nuclear scaffold for organizing osteoblast transcription. Spen - the Drosophilan ortholog of MINT - is required for embryonic responses to Wingless- the Drosophilan ortholog of Wnt1 and Wnt3a. Since canonical Wnt/catenin/LEF signaling is critical for osteoblast development, we assessed effects of MINT on LEF/TCF-dependent transcription. We studied signaling in 10T1/2 cells, an osteoprogenitor line that expresses endogenous MINT and responds to Wnt3a. Transient expression of full length MINT(1-3576) augments basal (5- to 12-fold) and Wnt3-stimulated (5-fold) transcription from a LEF/TCF responsive promoter - luciferase reporter, LEFLUC. By contrast, MINT(1-3576) has no effect on Smad-dependent transcription. MINT has 4 major domains: (1) the N-terminal RRM domain; (2) the Msx2 interacting MSXB /MID domain; (3) the Notch- inhibitory / RBP-J binding domain RAM7; and (4) the C-terminal SPOC domain (binds histone deacetylases / HDACs and mediates MINT homodimeric interactions). To better understand structural features of MINT that contribute to transactivation, we generated a series of MINT variants and assessed activity in transient co-transfection assays (nuclear localization signal in all variants). Like MINT(1-3576) and MINT(1-3237), MINT(1-2640) enhanced FGF2 activation of the OCFRE. However, MINT(1-2066) - lacking the MSXB/MID domain - could not augment OCFRE activity. LEFLUC activation was dependent upon MINT residues 2640-3237 (domain containing RAM7); although activating the OCFRE, MINT(1-2640) did not upregulate LEFLUC (suppressed activity). The spen C-terminal domain has been shown to function as dominant negative. Therefore, we generated EYFP-MINT(3101-3576), and studied actions of this nuclear putative dominant negative on OCFRE-LUC and LEF-LUC. EYFP-MINT(3101-3576) abrogated MINT(1-3576) activation of LEF-LUC and OCRE-LUC. In summary, MINT enhances FGF2- and Wnt3a-dependent transcription, but has little if any direct effect on Smad-dependent transcription. The MINT MSXB/MID domain plays an important role in transcriptional activation of the OCFRE, while the MINT domain 2640 to 3237 containing RAM7 is required for LEFLUC activation. The MINT C-terminus regulates both activities. This suggests that overlapping yet distinct domains of MINT function to integrate nuclear responses to osteogenic transcription factors.

The Activated Phospho-CREB Transcription Factor Stimulates BMP-2 Expression in Murine Osteoblast Cells; A Novel Mediator of PTH Action. J. R. Edwards*, M. Zhao, M. Qiao*, S. E. Harris*, G. R. Mundy. Cellular and Structural Biology, UTHSCSA, San Antonio, TX, USA.

Bone morphogenetic protein-2 (BMP-2) and parathyroid hormone (PTH) are known to be important anabolic factors in skeletal tissues. BMP-2 is a bone-derived growth regulatory factor capable of stimulating osteoblast differentiation from mesenchymal precursors and enhancing the activity of mature cells. Intermittent doses of PTH stimulate an increase in bone formation, but the mechanism of action by which this occurs remains largely unknown. PTH is known to activate protein kinase A (PKA) by stimulating cAMP. PKA can phosphorylate the cAMP response element binding protein (CREB), leading to nuclear translocation and gene transcription. Three putative CREB binding sites have been identified within the human BMP-2 promoter region, and in nerve cells, phospho-CREB has been shown to bind the BMP-2 gene. As PTH has been demonstrated to increase phospho-CREB, we investigated the possibility that the anabolic effects of PTH treatment are due to increased BMP-2 transcription and expression through CREB. To test this hypothesis, we used a reporter assay employing a luciferase tagged BMP-2 promoter sequence to assess the activity of the BMP-2 promoter within C2C12 and UMR106 cells. Transfected cells were treated with PTH (10, 50, 100nM), compounds reported to either prevent cAMP degradation (IBMX, 100μM) or inhibit PKA activity (KT-5720, 5μM), or transfected along with either active CREB cDNA or a vector control. RT- and Realtime-PCR was used to accurately assess expression of BMP-2 following treatments. Alkaline phosphatase levels were also determined in CREB transfected and PTH treated cells. CREB transfected UMR106 or C2C12 cells demonstrated up to x40 increase in BMP-2 promoter activity compared to vector controls. This effect was increased in CREB-transfected cultures treated with IBMX. Interestingly, a decrease in BMP-2 promoter activity was observed in samples treated with PKA inhibitor, KT-5720, following CREB transfection. PTH and IBMX treatment of serum-starved C2C12 cells also resulted in an increase in BMP-2 promoter activity compared to vehicle control, in the absence of active CREB cDNA. BMP-2 mRNA expression of CREB transfected cells was initially determined by RT-PCR. Realtime-PCR demonstrated increased BMP-2 expression in cells transfected with CREB. A small increase in alkaline phosphatase activity was also observed in CREB transfected cells compared to vector controls. Our study suggests that PTH stimulates BMP-2 expression in osteoblastic cell lines and this effect is mediated by PKA and CREB. This may be one of the mechanisms by which PTH induces osteoblast differentiation and causes an anabolic effect on bone.

Runx2 Regulates Gene Expression of Aromatase a Terminal Enzyme Responsible for Estrogen Biosynthesis. J. Jeong*[1], H. Kim*[1], S. Kang*[1], S. Lee*[1], H. Kim*[1], E. Park[1], S. Kim[1], A. J. van Wijnen[2], J. L. Stein[2], J. B. Lian[2], G. S. Stein[2], J. Choi[1]. [1]Biochemistry, Kyungpook National University, School of Medicine, Skeletal Diseases Genome Research Center, Daegu, Republic of Korea, [2]Cell Biology, UMASS Medical School, Worcester, MA, USA.

Runx2 transcription factor is a critical regulator of osteoblast differentiation. Estrogen is another key regulator for bone growth, development and maintenance of adult bone health. Although both Runx2 and estrogen pathways are important in bone homeostasis, the relationship between Runx2 and genes responsible to the production of estrogen in bone has not been clearly understood. Here we show the evidence that aromatase, a terminal enzyme responsible for estrogen biosynthesis in mammals, is one of Runx2 downstream target genes. Aromatase has many tissue specific promoters. To see whether which promoters are active in bone cell lines, we performed RT-PCR using extracted RNA from human chondrosarcoma cell line A4 and osteosarcoma cell line HOS cells. Both cells revealed the activity of bone related promoters; promoter I.6 and promoter I.4. Next, to determine whether Runx2 regulates aromatase gene expression, we cloned promoter I.4 from human genomic DNA and the 0.8 kb Exon I.4 promoter sequence showed three Runx binding sites. In promoter luciferase assay, Runx2 increased aromatase gene promoter activity. In chromatin immunoprecipitation and gel mobility shift assay, endogenous Runx2 binds aromatase promoter. HeLa cells stably transfected with Runx2 expression vector showed higher expression of aromatase protein than that of empty vector stable cells, which was confirmed by western blot analysis. HeLa cells expressing Runx2 also produced estrogen much higher than that of control cells. However, progesterone production was not changed by Runx2 expression. Collectively, these results indicate that aromatase, a key peripheral estrogen production regulator, is one of Runx2 downstream target genes in bone cells.

Myeloid Elf-1 like Factor (MEF) Acts as a Repressor in Osteoblast Differentiation. Y. Kim*, B. Kim*, S. Lee*, W. Lee*, H. Ryoo, J. Cho. Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea.

Runx and Ets family proteins control the expression of genes that are critical for biological processes such as proliferation, differentiation and cell death. Previous studies indicated that there are interactions between Runx and Ets family proteins and some of those interactions are important gene expressions and the cell differentiation. Myeloid elf-1 like factor (MEF) is a member of the Ets transcription factor family. In this study, we investigated the role of MEF in osteoblast differentiation. We observed that the expression of MEF suppresses the alkaline phosphatase activity induced by Runx2 and BMP-2 stimulation. We found that the MEF-mediated suppression of osteoblast differentiation is critically related with Runx2 regulation. First, MEF overexpression suppressed the positive effect of Runx2 on osteoblast differentiation probably through the downregulation of positive regulator, Dlx5, and the upregulation of negative regulator, Msx2 and Mab21. The notion is supported by our observations that MEF stimulated the transcription of Msx2 and Mab21 which have repressive function in BMP signaling pathway and suppressed the transcription of Dlx5. Second, we also found that Runx2 and MEF protein physically interact and make a complex, and the interaction is closely related with Runx2 binding to the cis-acting element, OSE2, in osteocalcin promoter. In addition, co-transfection of MEF almost completely diminished the induction of 6xOSE2-luciferase reporter activity by Runx2 transfection. Together our findings suggest that MEF functions as a negative regulator of osteoblast differentiation through functional regulation of Runx2 transcription factor by protein to protein interaction as well as transcriptional regulation on both activators and repressors for osteoblast differentiation.

Expression of Dlx Genes During Osteoblast Differentiation. H. Li*[1], I. Kalajzic[1], S. Suriyapperuma*[1], D. Velonis*[2], M. S. Islam*[1], M. Mina*[2], A. C. Lichtler[1]. [1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Pediatric Dentistry, University of Connecticut Health Center, Farmington, CT, USA.

We and others have shown that Dlx genes are important for osteoblast differentiation. Although Dlx5 single knock out mice display minimal long bone defects, and the Dlx5/6 double mutant embryos have a retarded ossification in both long bones and craniofacial bones, these mice still have significant bone formation. If Dlx genes are necessary for bone formation, then there must be redundant functions of Dlx genes. We believe a comprehensive study of the expression patterns and levels of all the Dlx genes is necessary. We did Q-PCR analysis by using Taqman probes to quantify the relative Dlx gene expression levels at day 2, 5, 7, 14, and 20 of primary mouse calvarial osteoblast cultures from day 5 neonatal pups. Since the amplification efficiencies of all the primers were close to 100%, a comparison of the ddCT value between Dlx genes will give the relative amount of gene expression at a particular time point. Our results show that Dlx4 is not significantly expressed at all the time points; Dlx1 and Dlx6 are slightly higher than Dlx4; Dlx2 is expressed at moderate levels, with highest level at day 2. Dlx5 and Dlx3 are the most highly expressed at all time points and both genes increased dramatically at later culture times. The Dlx3 message levels at day 20 were about 50 times higher than at day 5. Micro-

array and Q-PCR analysis were applied to study the Dlx3 message level using RNA derived from FACS sorted calvarial cells at different stages from DMP-1-GFP, pOBCol3.6GFP or pOBCol2.3GFP transgenic mice. The Dlx3 expression levels are about 800 to 2000 fold higher in DMP-1-GFP or 2.3 GFP positive cells from day 17 cultures, which correspond to highly differentiated cells, than Col3.6 GFP positive cells from day 7 cultures, which represent pre-osteoblasts. *In situ* hybridization of Dlx3 in sections from developing chick calvaria and mandible, detected the Dlx3 message in the condensing preosteogenic mesenchyme, the osteogenic cells in the periosteum covering the newly formed bone as well as in the osteogenic cells lining the bone marrow spaces in the more advanced stages of bone formation. These results are consistent with our previous studies as well as those of other laboratories that suggest that Dlx3 may play an important role in regulating bone development. Because the knockout of the Dlx3 gene is an embryonic lethal, its role in regulating osteoblast differentiation must be studied by creating an osteoblast specific knock out. Revealing the role of the Dlx family of genes in osteoblast differentiation will probably require creating combined knockouts of multiple genes.

Titanium Particles Induce COX-2 through a NFkB Dependent Pathway in Fibroblast-Like Synoviocytes. X. Wei*, H. Drissi, X. Zhang, M. J. Zuscik, E. M. Schwarz, R. J. O'Keefe. Orthopaedics, University of Rochester, rochester, NY, USA.

Osteolysis is a major complication of joint replacement surgery and is related to wear debris particle mediated stimulation of biological pathways and effectors that result in bone resorption. An in vivo calvarial bone resorption model has shown that particles fail to stimulate osteolysis in a COX-2 -/- mice, but cause abundant bone resorption in wild type mice. Recent in vitro studies showed that titanium particles induce RANKL in fibroblast-like synoviocytes (FLS) through a COX2/PGE2 mediated mechanism, and that FLS expressed RANKL supports osteoclastogenesis. In this study, experiments were performed to examine the molecular mechanism involved in COX-2 gene induction. Titanium particles induced both COX-2 mRNA and protein levels in FLS. Luciferase reporter assays showed induction of the COX-2 promoter activity following stimulation with titanium particles. However, activation of the promoter was abolished when NFkB binding sites were mutated. Both Western blot, which demonstrated IkB degradation, and EMSA, which showed gel retardation of an NFkB consensus oligonucleotide, confirmed activation of NFkB in FLS following titanium stimulation. Chromatin IP analysis was used to demonstrate association of NFkB to the native COX-2 promoter and demonstrated in vivo binding of NFkB (p65) to the endogenous COX-2 promoter region following treatment with titanium particles. The role of NFkB in the responsiveness of FLS cells to particles was further investigated in FLS cells stably expressing dominant negative IkB (mIkB). Both induction of COX-2 by particles and interaction of p65 and COX-2 promoter were abolished in FLS cells expressing mIkB. Altogether the data support the hypothesis that COX2 gene activation by titanium particles in FLS is NFkB dependent. Since COX-2/PGE2 leads to RANKL induction in FLS cells, particle activation of NFkB is a critical target to prevent wear mediated osteolysis.

Cooperative Interactions between ATF4 and Runx2/Cbfa1 Stimulate Osteoblast-Specific Osteocalcin Gene Expression. G. Xiao[1], D. Jiang*[1], C. Ge*[1], Z. Zhao*[1], H. Bouls*[1], M. Phimphilai*[1], X. Yang*[2], G. Karsenty[2]. [1]Periodontics/Prevention/Geriatrics, The University of Michigan, Ann Arbor, MI, USA, [2]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

The role of ATF4 in osteoblast differentiation and bone formation was recently described using ATF4-deficient mice (Yang et al., Cell 117, 387-398, 2004). However, the mechanisms of ATF4 in bone cells are still not clear. In this study, we determined the molecular mechanisms through which ATF4 activates mouse osteocalcin (Ocn) gene 2 (mOG2) expression and mOG2 promoter activity. ATF4 increased levels of Ocn mRNA and mOG2 promoter activity in Runx2-containing osteoblasts but not in non-osteoblastic cells that lack detectable Runx2 protein. However, ATF4 increased Ocn mRNA and mOG2 promoter activity in non-osteoblastic cells when Runx2 was co-expressed. Mutational analysis of the OSE1 (ATF4-binding site) and the two OSE2s (Runx2-binding sites) in the 657-bp mOG2 promoter demonstrated that ATF4 and Runx2 activate Ocn via cooperative interactions with these sites. Pull-down assays showed that ATF4 and Runx2 physically interact in osteoblasts or when both factors were co-transfected in COS-7 cells. Regions within Runx2 responsible for ATF4 binding and activation were identified. This study is the first demonstration that cooperative interactions between ATF4 and Runx2/Cbfa1 stimulate osteoblast-specific Ocn expression and suggests that this regulation may represent a novel intramolecular mechanism regulating Runx2 activity and, thereby, osteoblast differentiation and bone formation.

Mechanoinduction of FosB in Human Bone Marrow Stromal Cells. E. Hesse[1], M. Jagodzinski*[1], M. Wehmeier*[2], W. C. Horne[3], R. Baron[3]. [1]Trauma Surgery, Hannover Medical School, Hannover, Germany, [2]Clinical Chemistry, Hannover Medical School, Hannover, Germany, [3]Orthopaedics & Rehabilitation, Yale University School of Medicine, New Haven, CT, USA.

Alternative splicing of the AP-1 family transcription factor FosB generates two truncated isoforms (ΔFosB and Δ2ΔFosB) that promote osteoblast differentiation and bone formation when over-expressed in mice. It was recently shown in a mouse model that FosB gene transcription is rapidly induced by mechanical stress applied both *in vivo* and *in vitro*. The aim of this study was to determine the effect of different mechanical strain patterns on FosB expression in human bone marrow stromal cells (hBMSC). hBMSCs were isolated from bone marrow aspirates obtained from seven healthy donors according standard protocols. The cell population was cultured in the presence of ascorbic acid, β-glycerophosphate and dexamethasone to induce osteoblast differentiation. At passage four, cells were plated on silicone dishes and subjected to cyclic mechanical strain (either 2% or 8% deformation, 1 Hz) for one, two or three periods of two hr on day one or for three 2 hr periods on day 4 or day 7, using a computer controlled uni-axial stretching device. Samples were treated independently. RNA was then extracted and FosB mRNA expression was measured by quantitative real-time RT-PCR and normalized to unstrained controls. Statistical analysis was done by ANOVA with pairwise comparison and Mann-Whitney test. FosB expression in samples subjected to mechanostimulation at the 8% strain level was significantly ($p<0.05$) higher than the levels in matched 2% strain samples under all conditions. In day 1 samples, FosB expression increased progressively with the number of periods of 8% strain. Samples subjected to three periods of 8% strain on day 1, day 4 or day 7 had similar high expression levels. In the day 1 samples subjected to the 2% strain level, one and two periods of strain induced similar small increases in FosB expression, while the third period of strain induced a significant further increase. In contrast to the responses to 8% strain, the response to three periods of 2% strain increased with time in culture to day 4, then decreased to near-basal levels at day 7. Thus, we conclude that axial mechanostimulation induces FosB transcription in human mesenchymal osteoblast precursor cells in a cell-autonomous manner. The response varies with the absolute amount of strain, the number of strain events and, for low strain conditions, the number of days in culture. These data confirm the connection between mechanical strain and FosB expression, suggesting a role of FosB isoforms in mediating the effect of strain on bone formation in humans.

ATP6i, a Subunit of the Vacuolar Proton Pump, Is Expressed in Osteoblasts, but not Required for their Mineralization. A. F. Schilling, T. Linn*, M. Gebauer*, M. Priemel, J. M. Rueger*, T. Schinke, M. Amling. Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany.

Approximately 50 % of the cases with autosomal recessive osteopetrosis are caused by mutations of the human ATP6i gene that encodes one subunit of the vaculoar proton pump (V-ATPase) necessary for osteoclastic bone resorption. In osteosclerotic oc/oc-mice a deletion within the murine ATP6i gene results in severe osteopetrosis associated with rickets. To analyze whether the mineralization defect observed in the oc/oc-mice is specific for impaired osteoclastic function, we first compared their phenotype with another mouse model of osteopetrosis, the c-src-deficient mice. Whereas the trabecular bone volume at the age of 2 weeks was strongly increased compared to wildtype littermates in both osteopetrotic models (BV/TV: 61.1 ± 4.2 % in oc/oc vs. 75.6 ± 5.1 % in c-src-/- vs. 15 ± 1.2 % in wildtype mice), the severe mineralization defects were specifically found in the oc/oc-mice (osteoid volume (OV/BV): 8.8 ± 0.8 % vs. 0.2 ± 0.1 % vs. 0.7 ± 0.2 %). So the osteomalacia is specific to ATP6i deficiency and independent of osteoclast dysfunction. Studying osteoblastic gene expression in the course of differentiation using an Affymetrix gene array we found that ATP6i was one of the genes that was strongly induced by mineralization of the cultures, thereby suggesting that ATP6i is required for bone mineralization in a cell-autonomous manner. To analyze this possibility we next assayed ATP6i expression by Northern Blotting. Although, we did find expression of ATP6i in mineralizing osteoblasts, we observed that the expression level was markedly lower compared to osteoclasts. This finding was confirmed by in-situ hybridization where ATP6i expression was readily detectable in osteoclasts, but virtually absent in osteoblasts as well as in growth plate chondrocytes. Most importantly however, when we analyzed primary osteoblasts derived from oc/oc-mice ex vivo, we found that they mineralized equally well as wildtype cultures. Taken together, these results suggest that the severe defects of bone mineralization in the absence of ATP6i are not caused by cell-autonomous defects of osteoclasts or osteoblasts. In contrast, it is most likely, that they are a solely a consequence of an impaired calcium homeostasis, since oc/oc-mice are hypocalcemic, unlike the c-src-deficient mice (6.5 ± 0.4 mg/dl vs. 9.3 ± 0.5 mg/dl vs. 9.2 ± 0.6 mg/dl).

Jun B as a Key Mediator of PTHrP Actions on Cementoblasts. J. E. Berry*[1], E. L. Ealba*[1], N. S. Datta[1], G. J. Pettway*[1], E. Swanson*[2], M. J. Somerman[2], L. K. McCauley[1]. [1]University of Michigan, Ann Arbor, MI, USA, [2]University of Washington, Seattle, WA, USA.

The process of remodeling requires a balance of osteoclast and osteoblast function, and is mediated through OPG and RANKL. In the periodontium, this balance is also important for tooth eruption and protection from root resorption. The focus of this study was to determine the role of PTHrP in mediating cementoblast effects on this process. Assays revealed that immortalized murine cementoblasts express OPG and RANKL, and expression is altered by PTHrP in a similar manner as osteoblasts. PTHrP (0.1 μM) treatment caused a 5-fold reduction in OPG and a 9-fold increase in RANKL, by ELISA. In parallel experiments, cementoblasts treated with PTHrP were evaluated by ELISA (nuclear isolates) and Northern blot for AP-1 transcription factors. The mRNA and protein of all Fos family members and JunB, but not c-Jun or JunD, were elevated. To further investigate the specific effects of JunB, cementoblasts were stably transfected with an expression plasmid containing full-length junB or a vector control plasmid. Untransfected cementoblasts and cells transfected with vector or junB were treated with vehicle or PTHrP. Cell lysates from untransfected and vector transfected cells showed a 4-fold decrease in OPG levels with PTHrP treatment, while junB transfectants had control levels of OPG less than the lowest level seen in treated control cells. OPG expression in the junB transfectants was not altered by addition of PTHrP, suggesting junB overexpression was mimicking a PTHrP down-regulated OPG state. Additionally, co-cultures with RAW cells indicated that junB transfectants were better able to support osteoclastogenesis than control cells, as evaluated by TRAP staining and enumeration. Investigation of downstream effects of JunB overexpression showed levels of BSP and osterix mRNA were dramatically reduced as compared to controls, and in vitro mineralization as measured by von Kossa staining was abolished, suggesting JunB restricts cementoblast differentiation. Western blot assay of cell cycle proteins showed an increase of cyclins D1 and A, indicating a shift in proliferation capacity of overexpressing cells. Control and JunB overexpressing cells implanted subcutaneously in nude mice also exhibited distinct differences, with JunB showing less mineralization and greater cell numbers. These data suggest that JunB plays a role in modulating osteoclastogenesis via OPG and restricting cementoblast maturation. Importantly, the fact that cementoblasts are very sensitive to PTHrP and JunB indicates that they may normally be responsible for limiting cementum remodeling, but can be induced to support odontoclastogenesis under certain circumstances.

T-box 3, a Transcription Factor, Is an Important Regulator of Osteoblast Proliferation. K. Govoni, J. Rung-Aroon*, D. J. Baylink, S. Mohan. JLP VAMC and LLU, Loma Linda, CA, USA.

T-box (Tbx) genes are a family of transcription factors known to be involved in regulating several key developmental processes in various tissues. We identified Tbx3 as an acute growth hormone (GH) responsive gene using whole genome microarray analysis of RNA extracted from bones of GH-deficient (*lit/lit*) mice after a single injection of GH. Little is known about Tbx3, except that a mutation of Tbx3 results in human ulnar-mammary syndrome. In addition to the microarray data, we have found that Tbx3 expression is increased by GH, bone morphogenic protein-7, and Wnt3a in mouse osteoblast cells. Based on these data, we proposed the hypothesis that Tbx3 is an important regulator of osteoblast cell proliferation. To test this hypothesis, we used small interfering (si) RNA, to knock-down the expression of Tbx3 and evaluated the consequence on proliferation of MG63 human osteosarcoma cells. Using non-silencing Alexa Fluor 488-labeled control siRNA and transfection reagent (RNAiFect), we determined that with 300nM siRNA, our transfection efficiency was 60 to 70%. Using an alamarBlue assay, we determined that Tbx3 siRNA reduced osteoblast cell number 20 to 30% ($P < 0.01$). In addition, Tbx3 siRNA reduced serum-induced cell number by 30 to 40% ($P < 0.01$). No reduction in cell number was observed with transfection reagent alone or siRNA in the absence of transfection reagent. To determine if the effect of siRNA on cell number was due to decreased cell proliferation and not due to increased apoptosis, we measured DNA synthesis by determining [^{3}H]thymidine incorporation into the cell, as well as, caspase activity, a measure of apoptosis. DNA synthesis decreased by 25 to 45% ($P < 0.01$) by Tbx3 siRNA in the presence of serum and no effect of siRNA was observed on caspase activity ($P > 0.1$). These data suggest that the decreased cell number, was due to inhibition of cell proliferation rather than induction of cell death. In conclusion, blocking Tbx3 expression inhibits both basal and serum-induced osteoblast cell proliferation, but does not induce cell death. Therefore, we predict that Tbx3 may be an important intracellular mediator of growth factor action on osteoblast proliferation.

Twist Dimer Selection Regulates Cranial Suture Patterning and Fusion. J. Connerney*, V. Andreeva*, Y. Leshem*, C. Muentener*, M. Mercado*, D. B. Spicer. Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, ME, USA.

Haploinsufficiency of the basic-Helix-Loop-Helix (bHLH) transcription factor TWIST results in premature closure of the cranial sutures, termed craniosynostosis, however the mechanism underlying this defect is unclear. Here we have tested the hypothesis that the activity of Twist is dependent on its dimer partner and Twist dimer formation is dynamically regulated in the cranial sutures. The cranial sutures are the growth centers separating the bones of the skull and are composed of two opposing osteogenic fronts and an intervening mesenchyme. Based upon the expression patterns of Twist and other HLH genes within the cranial sutures we hypothesized that Twist forms homodimers in the osteogenic fronts and Twist/E protein heterodimers in the mid-sutures. We have tested this hypothesis by determining if genes that are differentially regulated by these dimers are expressed in the predicted domains within the sutures. Our results support this hypothesis and importantly we have found that the Twist dimers differentially regulate the expression of mediators of the signaling pathways that regulate suture patency. Furthermore, Twist haploinsufficiency alters the ratio between these dimers, favoring an increase in homodimers, which results in an expansion of the osteogenic fronts and suture fusion. Finally, we are able to inhibit suture fusion in Twist +/- mice by promoting the formation of Twist/E protein heterodimers by either increasing E protein levels or decreasing the levels of the HLH inhibitor Id. Therefore, we have begun to provide a mechanistic understanding of craniosynostosis and have identified dimer partner selection as an important mediator of Twist function.

Lef1 Overexpression Prevents Late Osteoblast Differentiation. R. A. Kahler[1], J. J. Westendorf[2]. [1]Graduate Program in Microbiology, Immunology and Cancer Biology, University of Minnesota, Minneapolis, MN, USA, [2]Department of Orthopaedic Surgery, University of Minnesota, Minneapolis, MN, USA.

Recent studies have shown that the Wnt signaling pathway is important for normal bone development and osteoblast function. Lef1 is a nuclear effector of the Wnt signaling pathway. Lef1 binds to and represses Runx2-mediated activity of the osteocalcin promoter. As osteoblast differentiation proceeds, Lef1 expression declines. These observations led to the hypothesis that Lef1 may repress the expression of late osteoblast differentiation genes and that the decline in Lef1 expression during differentiation is necessary to facilitate the upregulation of osteocalcin and other late differentiation genes. In order to study the biological role of Lef1 in osteoblast differentiation, we employed RNAi to reduce Lef1 expression in MC3T3 preosteoblasts. Stably Lef1-suppressed MC3T3 cells did not have any significant changes in proliferation or cell cycle. Differentiating Lef1-suppressed osteoblasts express differentiation markers, including alkaline phosphatase, osteocalcin and mineralization three to four days earlier than control cells. In order to determine what effect Lef1 overexpression would have on osteoblast differentiation, we have produced an MC3T3 cell line overexpressing Lef1. GFP expression via an internal ribosomal entry site was used to select Lef1 overexpressing cells as well as the empty vector control cells. Lef1 overexpression was confirmed using electrophoretic mobility shift assay as well as quantitative RT-PCR. Lef1 overexpression did not significantly alter cell proliferation. When induced to differentiate, Lef1 overexpressing cells have lower expression of the early differentiation marker alkaline phosphatase compared to control GFP cells and do not mineralize. Quantitative RT-PCR confirmed that expression of the late osteoblast differentiation genes, osteocalcin and bone sialoprotein, are delayed and decreased in Lef1 overexpressing cells compared to control cells. Runx2 levels, however, were not changed. These results suggest that Lef1 expression is regulated during osteoblast differentiation and that Lef1 expression must decrease in order to allow osteoblast differentiation to proceed.

Large-Scale Proteomic and Microarray Analysis of Inorganic Phosphate Treated MC3T3-E1 Cells Reveals Ddynamic Changes in Protein Regulation and Gene Expression. G. R. Beck[1], C. E. Camalier*[1], K. A. Conrads*[1], K. A. Simpson*[1], D. A. Lucas*[2], T. D. Veenstra*[2], T. P. Conrads*[2]. [1]Center for Cancer Research, National Cancer Institute, Frederick, MD, USA, [2]Laboratory of Proteomics and Analytical Technologies, SAIC-NCI, Frederick, MD, USA.

We have recently identified inorganic phosphate that is generated during osteoblast differentiation as an important signaling molecule necessary for pre-osteoblasts to reach a mineralization competent state. We have taken a systems approach to understanding the influences of inorganic phosphate on the process of differentiation and mineralization. To this end we have conducted microarray, proteomics, inhibitor and promoter studies on MC3T3-E1 cells treated with 10 mM inorganic phosphate for times ranging from 15 minutes to 24 hours. Our results reveal dynamic changes in signal transduction pathways, gene expression and protein levels starting within the first 15 minutes of exposure to elevated inorganic phosphate and extending through 24 hours. The products of the early phosphate responsive genes range in function from transcriptional activators to effectors of signaling pathways and include, among others members of the AP-1 transcription factor family. The increased expression of the majority of these immediate early genes, do not require protein synthesis and are ERK1/2 dependent. Ultimately changes in the cell phenotype are regulated by changes in both protein level and function. To evaluate downstream changes in the proteome in response to elevated phosphate we have used cleavable isotope-coded affinity tag (cICAT) labeling. This technique allows for the identification and determination of changes in relative abundance of thousands of proteins from cell lysate. A cICAT study of MC3T3-E1 cells treated with inorganic phosphate for 24 hours identified over 2500 proteins, 16% of which were altered by greater than 1.75 fold. A number of the identified phosphate-regulated proteins are involved in extracellular matrix function and cell metabolism. Taken together with the microarray studies the results suggest a role for inorganic phosphate as a signaling molecule capable of dynamically regulating gene expression and protein levels through discrete signaling networks. One

important effect on cell function and differentiation appears to be the regulation of the transition of the extracellular matrix from formation to maturation to mineralization. These studies not only begin to shed light on the mechanisms by which inorganic phosphate functions as a signaling molecule in osteoblast differentiation and mineralization but also demonstrate the power of large-scale systems analysis as an approach to understanding changes in cell function.

The Bone Phenotype of ICER Transgenic Mice Is not due to Alterations in ATF4 Expression. T. K. Chandhoke, B. E. Kream. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Inducible cAMP early repressor (ICER) is a member of the CREM transcription factor family and serves as a dominant negative regulator of cAMP-mediated transcription. ICER contains a basic leucine zipper (bZIP) region for DNA binding and dimerization. PTH has been shown to induce ICER expression potently and transiently in cultured osteoblasts and in calvariae *in vivo*. To establish the role of ICER in bone, we previously developed transgenic mice to overexpress ICER *in vivo* by cloning ICER cDNA with an N-terminal FLAG epitope downstream of a 3.6 kb fragment of the rat Col1a1 promoter (pOBCol3.6-ICER), targeting ICER overexpression broadly to cells of the osteoblast lineage. ICER transgenic mice showed reduced body size and weight, a dramatic reduction in trabecular bone parameters and disruption of cortical bone integrity. Femurs showed a marked reduction in osteocalcin (OC) expression while Col1a1 and bone sialoprotein (BSP) expression was less affected. *Ex vivo* analysis of osteogenic bone marrow stromal cell cultures showed reduced expression of Col1a1, BSP and OC as well as reduced mineralization. The aim of the present study was to determine whether the bone phenotype of ICER mice is due to alterations in ATF4 expression and/or function. *Atf4*-deficient mice display a distinct skeletal phenotype that resembles ICER transgenic mice in their reduction of trabecular bone volume, impaired osteoblast function and loss of OC expression *in vivo*. To examine whether ATF4 is in the ICER regulatory pathway, we examined ATF4 protein expression at days 14 and 21 in primary mouse calvarial osteoblasts (mCOB) cultured to confluence and then treated with ascorbate and β-glycerophosphate. Western blot analysis did not show a significant change in ATF4 protein expression, suggesting it may not be regulated by ICER. ATF4 has also been shown to post-translationally modify type I collagen synthesis. To determine if type I collagen protein synthesis was disrupted in ICER transgenic mice, reflecting an ATF4-like action, we examined collagen protein synthesis assessed by ^{3}H-proline incorporation into cultured neonatal mouse calvariae. There was no significant difference in percent collagen synthesis in ICER calvariae compared to WT. While these results suggest ATF4 expression is not affected by ICER, it is possible that ICER binds ATF4, a bZIP protein, and inhibits some of its osteoblast functions. Currently, co-immunoprecipitation experiments of ICER and ATF4 in mCOB cultures are being utilized to better understand the potential interaction of these two transcription factors. In addition, it is possible ICER binds to a variety of other bZIP transcription factors, disrupting their function.

Transcription of the RUNX2/CBFA1 Gene Involves a SWI/SNF-Independent and BMP2-Enhanced Chromatin Remodeling at the P1 Promoter. F. Cruzat*[1], A. Villagra*[1], J. Olate*[1], A. van Wijnen[2], J. Lian[2], G. Stein[2], J. Stein*[2], A. Imbalzano*[2], M. A. Montecino[1]. [1]Departamento de Bioqumica y Biologia Molecular, Universidad de Concepcion, Concepcion, Chile, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

The Runx2 transcription factor is essential for skeletal development as it up-regulates the expression of several bone-related genes. It has been indicated that the promoter P1 controls the expression of the Runx2-II isoform in osteoblastic cells. However, the specific molecular mechanisms involved in this tissue-specific regulation have not been definitively established. Changes in chromatin organization accompany transcriptional activity of eukaryotic genes. These chromatin-remodeling events can be mediated by the SWI/SNF complex, which alters chromatin structure in an ATP-dependent manner. Here, we have generated osteoblastic cell lines that inducibly express an ATPase-defective Brg1 catalytic subunit which forms inactive SWI/SNF complexes. The presence of these complexes result in inhibition of both expression and chromatin remodeling of bone-phenotypic markers expressed at late stages of osteoblast differentiation. In contrast, these inactive complexes neither affect RUNX2 transcription nor reduce chromatin remodeling at the P1 promoter, indicating that both processes are independent of SWI/SNF activity. Additionally, we find that the BMP2-dependent induction of Runx2 transcription in C2C12 myoblastic cells is accompanied by a significant enhancement in nuclease hypersensitivity at a highly specific region of the proximal P1 promoter, also in an SWI/SNF-independent manner. Together with previous results, our findings indicate that RUNX2 transcription requires a SWI/SNF-independent chromatin-remodeling event that sets the gene for transcription during early stages of development.

Ror2: A Novel Regulator of Osteoblast Differentiation. J. Billiard, Y. Liu*, R. A. Bhat, A. Mangine*, R. A. Moran*, L. M. Seestaller-Wehr*, P. V. N. Bodine. Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA.

Ror2 is an orphan receptor tyrosine kinase with no signaling pathway identified. Mutations in the Ror2 gene cause severe skeletal defects in humans and mice. We have previously shown that Ror2 is expressed in human osteoblasts and is strongly regulated during differentiation being almost undetectable in pluripotent mesenchimal stem cells (hMSC) and increasing >30-fold after 21 days in osteogenic medium. We also showed that in late stages of differentiation, modeled by our collection of human conditionally immortalized osteoblastic (HOB) cell lines, Ror2 is highly expressed in committed proliferating pre-osteoblasts, but disappears in osteocytes. Thus Ror2 peaks in mid-stages of osteoblastic differentiation. Here we over-expressed Ror2 in cells that have the lowest endogenous levels of the receptor, undifferentiated hMSC and pre-osteocytes, and assessed its effects on markers of osteoblastic differentiation. We used adenoviral constructs to over-express Ror2, kinase-dead mutant Ror2KD, or β-galactosidase (β-gal) in hMSC and monitored matrix mineralization over 21 days in presence of ascorbic acid and β-glycerophosphate. Alizarin red histochemistry revealed that by day 9, Ror2-infected cells formed ~4 times more mineralized matrix than did the β-gal-infected controls. This effect was independent of the receptor kinase activity, since it was also observed in Ror2KD-infected cells. Infection with Ror2 or Ror2KD viruses also strongly promoted matrix mineralization in MC3T3-E1 murine osteoblast-like cells. Thus Ror2 expression increased formation of an extracellular matrix that undergoes mineralization, the ultimate phenotypic expression of an osteogenic tissue. Next, we stably transfected the HOB pre-osteocytic cell line with Ror2, Ror2KD, or empty vector and assessed alkaline phosphatase (AP) activity, osteocalcin secretion and apoptosis. In 3 independent clones, Ror2 over-expression inhibited AP activity by 80%, potentiated osteocalcin secretion by 3-fold and increased apoptosis by 1.6-fold. All these changes, including the fall in AP activity, are consistent with Ror2 promoting differentiation in late stages of human osteoblast formation. These changes were also observed in the Ror2KD line, but Ror2KD appeared less efficacious than the wild-type kinase in causing these effects. In summary, our studies identify Ror2 as a new regulator of osteoblast survival and differentiation, suggesting a novel role for this orphan receptor in bone formation.

C/EBPα Isoforms Regulate Differentiation of Mesenchymal Stem Cells into Osteoblasts and Adipocytes. M. Ueda*, K. Hata*, F. Ikeda*, T. Matsubara, R. Nishimura, T. Yoneda. Dept Biochem, Osaka Univ Grad Sch Dent, suita, Japan.

Osteoblasts and adipocytes share the common precursors of undifferentiated mesenchymal stem cells. The molecular mechanism that controls the commitment of the mesenchymal stem cells to osteoblasts and adipocytes are yet to be elucidated. Recent studies have shown that the transcription factor CCAAT/enhancer-binding protein (C/EBP) β and C/EBPδ promote not only adipogenesis but also osteoblastogenesis, suggesting the importance of C/EBP family proteins in the regulation of osteoblastogenesis as well as adipogenesis. Of note, C/EBPα, which is involved in the regulation of the late stages of adipocytic differentiation, is also shown to stimulate osteoblast differentiation. C/EBPα has two isoforms, namely p20 and p30, which completely or partially devoid of the transcription activation domain, respectively. Role of these two isoforms in mesenchymal cell differentiation is unknown. In the present study, we examined this using the C3H10T1/2 pluripotent mesenchymal cells. Western blot analyses showed that p20 and p30 are expressed in cells of osteoblast lineage. To examine whether p20 and p30 affect the differentiation of mesenchymal cells, cDNA of these molecules were overexpressed in C3H10T1/2 cells using an adenovirus system. P20 and p30 enhanced BMP2-induced osteoblastic differentiation of C3H10T1/2 cells, despite the fact that both isoforms have no transcription activation domain. To understand the molecular mechanism underlying this, interactions of p20 or p30 with Runx2 were examined. Overexpression of p20 or p30 dramatically enhanced Runx2-induced osteoblast differentiation. In contrast, p20 or p30 did not influence osterix-induced osteoblast differentiation. Consistent with these results, we found that p20 or p30 co-immunoprecipitated with Runx2. These results suggest that p20 and p30 control osteoblastogenesis in physical cooperation with Runx2. We next investigated the role of p20 and p30 in adipogenesis. Overexpression of C/EBPα induced adipocyte differentiation of C3H10T1/2 cells, whereas p20 or p30 showed no effects on adipogenesis. Of interest, overexpression of p20 or p30 inhibited adipogenesis induced by C/EBPα or C/EBPβ/δ. In contrast, p20 or p30 did not affect the adipogenesis induced by PPARγ, a critical transcription factor that regulates the late stages of adipogenesis. The results suggest that p20 or p30 specifically inhibits the C/EBP-induced adipogenesis in a dominant-negative fashion. In conclusion, our results suggest that C/EBPα isoform p20 and p30 are important transcription factors that control the direction of mesenchymal stem cell differentiation toward osteoblasts and adipocytes.

Effects of IL-23 and IL-27, Newly Identified IL-12-Related Cytokines, on Osteoblasts and Osteoclasts. S. Kamiya*[1], K. Ono*[1], T. Ohwaki*[2], N. Morishima*[2], M. Asakawa*[2], T. Yoshimoto*[2], S. Wada*[1]. [1]Clinical Sciences, Josai International University, Chiba, Japan, [2]Intractable Immune System Disease Research Center, Tokyo Medical University, Tokyo, Japan.

Objective : Interleukin (IL)-23 and IL-27 is a novel IL-12 family member that plays a role in the regulation of T helper 1 differentiation. IL-27 induces proliferation and synergizes with IL-12 in interferon (IFN)-gamma production from naive CD4+ T cells, whereas IL-23 stimulates IFN-gamma production and proliferation in memory CD4+ T cells. Cytokines, such as IL-12 and IFN-gamma, are shown to be involved in bone metabolism, however the effects of IL-23 and 27 have not been fully clarified. In the present study, we have examined the effects of IL-23 and 27 on bone metabolism. Methods: Using primary calvarial osteoblasts (OB), derived from neonatal (0- to 2-day-old) ddY mice, the analysis of tyrosine phosphorylation of signal transducer and activator of transcription (STAT) 3 (Western blot), cell proliferation (WST-8 assay), alkaline phosphatase (ALP) activity (p-nitrophenylphosphate degradation assay), mineralization (von Kossa staining), and mRNA (ALP, type I procollagen, osteocalcin, and Runx2) expression (RT-PCR) in the presence or absence of Il-23 and 27 was investigated. We furthermore examined the effects of IL-23 and 27 on RANKL expression (flow cytometry) on OB and osteoclastogenesis (tartrate-resistant acid phosphatase staining) in the co-cultures of OB and bone marrow cells. We also compared the effects of IL-23 and 27 with those of IL-6/soluble IL-6R. Results: When OB were treated with Il-23 and 27 for 1h, tyrosine phosphorylation of STAT3 was clearly identified. However, neither IL-23 nor 27 affected OB proliferation, ALP activity, mineralization and OB specific mRNA expression as compared with those of control. These interleukins did not stimulate RANKL expression and osteoclastogenesis in co-cultures. Osteoclastogenesis induced by 1,25(OH)2D3 was neither affected by IL-23 nor 27. In contrast, IL-6 induced tyrosine phosphorylation of STAT3 in OB as well as IL23 and 27, but also increased ALP activity and its mRNA expression. IL-6 also inhibited mineralization at day 12-15 and induced RANKL expression. Osteoclastogenesis was also found to increase in co-culture system. There was a good correlation between osteoclastogenesis and RANKL expression on OB. Conclusions: IL-23 and 27 induced tyrosine phosphorylation of STAT3 in OB, but significant roles of the signaling have not been identified. We are now further investigating whether the modulation of intracellular signaling by IL-23 and 27 affects other cellular functions of OB, and the contribution of T cells to osteoclastogenesis in the presence of IL-23 and 27 as well.

DKK-1 Inhibits Differentiation of Primary Human Osteoblastic and MC3T3.E1 Cells in Culture. V. Shalhoub, J. Li*, W. Qui*, D. Martin*, S. Simonet, D. Lacey, W. Richards. Metabolic Disorders, Amgen Inc, Thousand Oaks, CA, USA.

Mutations in LRP5, a component of the canonical Wnt signaling pathway, result in high and low bone phenotypes. Dkk-1 inhibits LRP signaling by bridging LRP and Kremen. Dkk/LRP is then endocytosed along with Kremen, thus interfering with the Wnt-induced interaction of frizzled with LRP. Recently, Dkk-1 over-expressing transgenic mice were shown to have decreased bone mass, supporting a role for DKK-1 as an inhibitor of LRP5 signaling in bone. Thus, the purpose of this study was to examine the direct effects of Dkk-1 on osteoblastic differentiation in culture. MC3T3.E1 cells are pre-determined osteoblastic cells. Over a period of 4 weeks in the presence of differentiation medium (50 ug/ml ascorbic acid and 10 mM beta-glycerol-phosphate), MC3T3.E1 cells up-regulate alkaline phosphatase (AP) and deposit mineral into their extra-cellular matrix. MC3T3.E1 cells were treated with murine Dkk-1 (0, 0.1, 1.0, 10, 100, 1000 ng/ml), initiated one day after plating, and every 48 hrs for three weeks. On days 2, 7, 15, 21, cells were stained for AP and mineral (von Kossa). In addition, AP activity, and calcium and protein accumulation were measured. In the presence of Dkk-1, AP and mineral were decreased in a time and dose dependent manner. For example, at 21 days, 54% and 72% decreases in calcium accumulation were observed with Dkk-1 treatment (1 and 100 ng/ml doses, respectively). Total cellular protein levels showed no differences with dose at any time. Primary adult human osteoblastic cells from femoral bone (41 year old donor), treated with Dkk-1 for 4 weeks similarly showed decreased mineral accumulation. Dkk-1 transcripts were found in the primary adult human osteoblastic cells, as well as adult human bone (39 year old donor). In conclusion, this study supports a role for Dkk-1 as a negative regulator of bone mass in osteoblastic cells in culture and in human bone.

Increasing BMP Responsiveness in Human Mesenchymal Stem Cells *In Vitro* by Addition of the Osteoinductive LMP-1 Gene. M. Viggeswarapu, M. Bargouti*, M. Teklemariam*, N. Baker*, C. Rogers*, L. Zhu*, L. Titus, S. D. Boden. Orthopedics, Emory University, Decatur, GA, USA.

BMPs promote the differentiation of osteoprogenitor cells, and also induce osteogenesis in bone marrow stromal cells (MSCs) from rats and mice. However, compared to results with animal models, BMPs are relatively inefficient in inducing human MSCs to undergo osteogenesis, and are much less effective in promoting bone formation in human clinical trials. Previous studies indicated that, while human MSCs respond to Dex with elevated levels of the osteoblast marker alkaline phosphatase, most isolates of human MSCs fail to show alkaline phosphatase induction in response to BMP-2,-4 and -7. LIM Mineralization Protein-1 (LMP-1) is an intracellular regulatory protein that can induce the expression of multiple BMPs and promote osteoblast differentiation in vitro and in vivo. The purpose of this study was: 1) To determine if LMP-1 can increase the responsiveness of human MSCs to BMP-2 as evidenced by increasing osteoblastic markers, and 2) To determine if LMP-1 can potentiate BMP-2 induction of mineralization by human MSC cultures. Human MSCs were expanded to passage 4 in the absence of Dex, seeded at $3x10^4$ cells/well in a six well plate in MSCBM media from Cambrex, and grown overnight. Some cells were infected for 30 min with Ad5/F35LMP-1 (5-10 pfu/cell) and grown for 72hrs with and without 100 ng/ml rhBMP-2. We used the chimeric adenoviral vector, Ad5/F35, which has been shown to transduce human hematopoetic stem cells and bone marrow hMSCs more effectively than Ad5 vectors. Treatment of cells with Ad5/F35LMP-1 (5-10 pfu/cell) plus 100 ng/ml rhBMP-2 dramatically induced mineralization observed by Alizarin red staining but neither rhBMP-2 nor LMP-1 alone induced mineralization in hMSCs on day 21. Similarly, neither BMP-2 nor LMP-1 alone increased alkaline phosphatase mRNA levels, but the alkaline phosphatase mRNA was increased 13 to 15-fold in cells treated simultaneously with both agents. BMP-2 alone increased the expression of the bone specific gene, osterix, 88 fold, but addition of BMP-2 to human MSCs overexpressing LMP-1 resulted in a synergistic 444 fold increase. Thus, concurrent exposure of human MSCs to LMP-1 enabled an ineffective dose of BMP-2 to facilitate bone formation. These data show that a non-responsive dose of BMP-2 co-administered with a non-osteoinductive dose of Ad5\F35LMP-1 resulted in a significant amount of mineralized bone formation in hMSC cultures. This key observation suggests that lower doses of rhBMP-2 can still have significant effects in the presence of genetically engineered cells.

Adherent Endotoxin Inhibits Spreading and Proliferation of Osteoblasts. J. L. Nalepka*, E. M. Greenfield. Orthopaedics, CWRU, Cleveland, OH, USA.

We have previously shown that adherent endotoxin exists on the surfaces of orthopaedic implants sterilized, processed and packaged by a major implant manufacturer. In addition, early failure of certain lots of implant components has been associated with adherent endotoxin. The current study was designed to examine the effects of adherent endotoxin on attachment, spreading, proliferation and differentiation of osteoblasts. For this purpose, MC3T3-E1 preosteoblastic cells were cultured on titanium alloy (Ti) discs with high and low levels of adherent endotoxin. Adherent endotoxin did not affect cellular attachment assessed by measuring the DNA content of attached cells 15-60 minutes after plating. However, fluorescence microscopy of cells stained with phalloidin or CMdiI showed that adherent endotoxin inhibited spreading. Thus, fewer cells spread on high endotoxin discs than on low endotoxin discs (6.2-fold and 4.3-fold less at 30 minutes and 24 hours respectively, $p < 0.02$). At 24 hours, large three dimensional aggregates containing 5-20 cells formed on high endotoxin discs. High endotoxin also completely blocked the 10-fold increase in cell number that occurs on low endotoxin discs between days 2 and 6. This is partially due to differences in proliferation since BrdU incorporation was 3.0-fold less on high endotoxin discs ($p < 0.0001$). In contrast, cell death assessed by measuring LDH release was not increased on high endotoxin discs. High endotoxin also significantly reduced total alkaline phosphatase activity on days 8-30 ($p < 0.05$). This is due to a decreased number of mature osteoblasts since alkaline phosphatase activity normalized to cell number was not affected. In conclusion, this study showed that adherent endotoxin inhibits spreading and proliferation of osteoblasts and thereby reduces the number of mature osteoblasts. These findings are consistent with the concept that adherent endotoxin impairs osseointegration in vivo and demonstrate that inhibition of cell spreading is the initial effect of adherent endotoxin.

Functional Responses of Osteoblastic Cells to Stimulation by Strontium. T. C. Brennan*[1], M. M. Muir*[1], A. D. Conigrave*[2], R. S. Mason[1]. [1]School of Medical Sciences and Institute for Biomedical Research, University of Sydney, Sydney, Australia, [2]School of Molecular and Microbial Sciences, University of Sydney, Sydney, Australia.

The divalent cation, strontium (Sr^{2+}) has been shown to increase bone formation, decrease bone resorption and reduce the risk of fracture in postmenopausal women. The mechanisms underlying these actions of Sr^{2+} have not yet been elucidated. This study was aimed at evaluating some of the functional responses of the human osteoblast-like cell line, MG63, to stimulation by Sr^{2+}. MG63 cells were cultured in DMEM supplemented with 10% FBS then adapted to serum-free medium for 24 hours before experimental treatments were added. The tested concentrations of Sr^{2+} were 0.01 to 1 mM in the presence of 1 mM Ca^{2+}. Tritiated thymidine incorporation was used to measure the proliferative responses of the cells to Sr^{2+}. Cell proliferation increased 2- to 3-fold as a function of increasing concentrations of Sr^{2+} ($p<0.001$). The EC_{50} was < 0.1 mM, well within the therapeutic range. Alkaline phosphatase activity also increased approximately 2-fold, but only at 1mM Sr^{2+} ($p<0.001$). The differential expression of Receptor Activator of NFKβ-ligand (RANKL) and osteoprotegerin (OPG), which regulate osteoclast generation, was also observed using real-time PCR (RT-PCR). The RANKL:OPG mRNA expression ratio was more than halved by 0.1 and 1 mM Sr^{2+} ($p<0.01$). The EC_{50} for Sr^{2+} was < 0.1 mM. OPG protein concentrations, determined using ELISA, were significantly increased in the presence of Sr^{2+} ($p<0.05$). Soluble RANKL protein (sRANKL) in culture supernatants was not detected. The effects of Sr^{2+} in this bone model were similar to those seen with 0.05mM of the calcium sensor agonist, gadolinium, in the presence of 1mM Ca^{2+}. These data indicate that Sr^{2+}, at pharmacologically relevant concentrations, is a potent regulator of bone cell function *in vitro* as well as *in vivo*. The molecular target for Sr^{2+} is not yet determined.

Androgen Receptor Coordinates both Osteoblast Proliferation and Differentiation. H. Kang[1], M. Tsai*[2], C. Chang*[3], K. Huang*[2]. [1]Graduate Institute of Clinical Medical Sciences, Chang Gung University/Chang Gung Memorial Hospital, Kaohsiung, Taiwan Republic of China, [2]Center for Menopause and Reproductive Medicine Research, Chang Gung Memorial Hospital, Kaohsiung, Taiwan Republic of China, [3]George Whipple Lab for Cancer Research, University of Rochester, Rochester, NY, USA.

Androgens have important effects on the human skeleton in both males and females. Hypogonadism in men is associated with increased bone turnover and bone loss, which is reversed after treatment with androgens. Clinical studies suggested that combined therapy of estrogens plus androgens might enhance bone mineral density and bone mass to a more significant degree than estrogen therapy alone in postmenopausal women. Our previous studies demonstrated that cancellous bone volumes are lower in the 8-week-old androgen receptor knockout (ARKO) mice than in both female and male wt littermates. These data indicate that AR is required for bone formation and osteoblast differentiation. To determine whether AR play a role in control of osteoblast proliferation, we compared proliferation rates of primary calvarial cells isolated from wild-type and ARKO embryos in the presence or absence of DHT treatment by MTT, BrdU incorporation and cell number counting assays. We also generated MC3T3-E1 cells in which over-expression of a stably integrated AR and knockdown expression of a stably AR siRNA to study the role of AR in osteoblastic cell growth. Our data showed that DHT accelerates cell growth of osteoblast cells in a time and dose dependent manner. AR-siRNA prevented DHT-induced Akt phosphorylation and ARKO osteoblast cell growth was slower than wild type osteoblasts. Fluorescence microscopy showed a distinct increase in immunostaining intensity in the nuclear interior after androgen treatment but no change in the subcellular distribution of Akt when the cells were pretreated with anti-androgen, hydroxyflutamide. In addition, androgen promotes mineralization of primary calvarial cells isolated from wild-type mice but not from ARKO mice. To further study the roles of AR on various differentiation stages of osteoblastic cells, the mRNA expression of AR, different stage bone marker genes and AR targeted genes from long-term wild-type and ARKO osteoblastic cell cultures with or without androgens, were quantified using real time PCR. Our data indicates that the role of AR on mineralization is dependent on the differentiation stage of the osteoblasts and the duration of androgen treatment. Together, these findings strongly suggest that the AR signaling is required for androgenic effects on bone metabolism, osteoblast proliferation and mineralization.

Functional Characterization of Wnt3-Fzd1 Chimera and its Role in the Differentiation of C3H10T1/2 Cells into Osteoblasts. R. A. Bhat, B. Stauffer*, P. V. N. Bodine. Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA.

Signaling through the canonical Wnt pathway has a dramatic effect on bone mass. It has been shown that the loss of function of the Wnt co-receptor, LRP5, in both humans and mice leads to decreased bone formation and bone mass, and gain of function mutations in this gene result in high bone mass, indicating the crucial role of Wnt/LRP signaling in bone formation. Wnts are secreted glyco/lipoproteins that interact with a membrane receptor complex composed of a Frizzled (Fzd) receptor and an LRP. Although 19 Wnt genes and 10 Fzd receptors have been identified so far, the specificity of the Wnt-frizzled interaction and the pathway that is stimulated by a specific ligand-receptor pair has not been fully addressed. The present study is focused on the development and validation of a Wnt3-Fzd1 chimera and its utility in the study of Wnt signaling in osteoblast differentiation. In U2OS osteosarcoma cells, the Wnt3-Fzd1 chimera activated a TCF-Luciferase reporter, and the fold induction was much higher than that obtained by Wnt3 cDNA alone. The deletion of the cytoplasmic tail of the Wnt3-Fzd1 chimera resulted in the loss of activation of canonical Wnt signaling. Point mutations in the PDZ domain in the cytoplasmic portion also resulted in the loss of Wnt signaling suggesting a critical role for the cytoplasmic region in Wnt signaling. Recombinant adenoviruses expressing the Wnt3-Fzd1 chimera and cytoplasmic tail deletion mutant were developed. The expression of the Wnt3-Fzd1 chimera up-regulated the TCF-Luciferase reporter, which was totally blocked by Dkk1 protein, suggesting the involvement of LRP in Wnt3-Fzd1 chimera signaling. To identify the role of Wnt signaling in osteoblast differentiation and maturation, murine C3H10T1/2 stromal cells were infected with adenovirus expressing the Wnt3-Fzd1 chimera or β-galactosidase (as a control for virus infection), and the cells were placed in osteogenic media. No increase in the alkaline phosphatase activity was observed between the uninfected and β-gal virus infected cells, suggesting that the virus infection per se had no effect on the differentiation of C3H10T1/2 cells. In Wnt3-Fzd1 chimera infected cells, the alkaline phophatase activity increased as early as day 1, reached a peak on day 2, and decreased thereafter. The results indicate that canonical Wnt signaling driven by the Wnt3-Fzd1 chimera leads to the differentiation of C3H10T1/2 cells into the osteogenic pathway. TheWnt-Fzd chimera model has the potential to dissect the molecular mechanisms involved in the pluripotent stem cell commitment and differentiation into a cell type specific lineage.

Gene Regulation in Adipogenic Transdifferentiation of Committed Osteoblasts. T. Schilling*[1], U. Nöth*[2], F. Jakob*[1], N. Schütze[1]. [1]Molecular Orthopaedics, Orthopaedic Institute, Wuerzburg, Germany, [2]Tissue Engineering, Orthopaedic Institute, Wuerzburg, Germany.

Diseases such as osteoporosis and osteonecrosis, may partly trace back to the age-related expansion of adipose tissue at the expense of osteogenic differentiation in human bone marrow. The molecular events of this adipogenic degeneration process are largely unknown. Recently, we established a cell culture system of human bone marrow-derived mesenchymal stem cells, in which the cells can be reprogrammed (transdifferentiated) during their differentiation from osteoblasts into adipocytes. After adipogenic transdifferentiation of committed osteoblasts (cells differentiated in osteogenic medium for 2 weeks), RT-PCR analysis displayed only adipogenic markers, but no osteogenic markers. To discover the fundamental molecular pathways of this reprogramming process at the level of global gene expression patterns, we performed an Affymetrix gene array analysis by comparing transdifferentiated adipocytes with committed osteoblasts. RNA was isolated 3 and 24 hours after the initiation of transdifferentiation (i. e. addition of adipogenic medium to committed osteoblasts) and compared with RNA from committed osteoblasts to identify potential control factors initiating the transdifferentiation process. The gene array analysis detected 248 regulated genes (signal log ratio at least 1.32, i. e. fold change at least 2.5, at one or both time points examined). Regulated gene products mainly belonged to the gene ontology classes of cell metabolism, cell signaling, transcription, development, and transport. The regulation pattern of 18 out of 22 selected genes (based on at least 4-fold regulation and functional potential; e. g. core promoter element binding protein, cysteine rich angiogenic inducer 61, kruppel like factor 4, and fatty acid binding protein 4) could be confirmed by semi-quantitative RT-PCR. Most of these gene products were also regulated in independent experiments. Our results show reproducible molecular changes associated with the transdifferentiation of mesenchymal stem cell-derived osteoblasts into adipocytes. Further investigation of selected gene products regarding their functions could reveal novel signaling processes initiating transdifferentiation or even acting as “molecular switches”. Thus, novel targets could be detected for therapeutic applications in order to prevent adipogenic degeneration and to stimulate osteogenic differentiation.

Interactive Network Construction and Pathway Analysis of Differentially Expressed Proteins at the Critical Cellular Events of Fracture Repair. H. Wang[1], J. T. Ryaby[1], R. Quigg*[2], X. Li*[2]. [1]Research and Development, OrthoLogic Corp, Tempe, AZ, USA, [2]Functional Genomics Facility, University of Chicago, Chicago, IL, USA.

Bone repair consists of inflammation, intramembranous ossification, chondrogenesis, endochondral ossification and remodeling. To better understand the translational regulation of these distinct but interrelated cellular events, we used the second generation of the BD Clontech™ Antibody Microarray to dissect and functionally characterize the differentially expressed proteins at each cellular event between intact and fractured rat femur. Genetic network analysis showed that proteins differentially expressed at a given cellular event tend to be physically or functionally correlated. Seventeen such interacting networks were established over five cellular events that were most frequently associated with cell cycle, cell death, cell-to-cell signaling and interaction, and cell growth and proliferation. Pathway analysis identified 18 molecular pathways that were significantly enriched during the bone repair process. Of those, ERK/MAPK, NF-kB, PDGF and T cell receptor signaling pathways were significant during three or more cellular events. The analysis revealed dynamic temporal expression patterns and cellular event-specific functions. The inflammation event at day 1 was characteristic of the molecular preparation initiating fracture repair. During this event, up-regulation of mitogenesis- and S phase-related proteins and down-regulation of meiosis-related proteins were prominently featured. Intramembranous ossification at day 4 was highlighted by down-regulation of the cell death-related proteins. Chondrogenesis at day 7 was molecularly most active; twelve molecular pathways were potentially active at this stage, including PDGF, VEGF, PPAR and P13K/AKT pathways. Endochondral ossification at day 14 was morphologically a key stage of generating permanent bone while molecularly exhibited a clear transition from the molecular/cellular function to the physiological system development/function. Osteoclast-mediated remodeling at day 28 was dominated by the integrin signaling pathway. The differential expression of representative proteins was confirmed by immunoblotting. The distinct changes in protein expression during these cellular events provide a molecular basis for developing cellular event-targeted therapeutic strategy to accelerate bone healing.

Anterior Cruciate Ligament Injury-Induced Hemarthrosis of the Knee as an Alternative Cell Source for Bone Regeneration. S. Lee, M. Miwa*, Y. Sakai*, R. Kuroda*, T. Matsumoto, T. Niikura*, M. Kurosaka*. Department of Orthopadeic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan.

The use of mesenchymal progenitor cells is promising for regenerative medicine. The most common source of such cells has been the bone marrow, although bone marrow procurement is an invasive procedure. In an attempt to searching for alternative sources of osteoprogenitor cells that could be obtained with minimal discomfort, we looked into

hemarthrosis caused by acute injuries of the anterior cruciate ligament (ACL) of the knee. The purpose of this study was to determine if cells derived from ACL injury-induced hemarthrosis could differentiate into osteoblast-lineage *in vitro*. Hemarthrosis was aspirated from the knee joint of 14 patients, 15-50 years of age, suffering from acute ACL injuries without intra-articular fractures. Mononuclear cells were isolated from the aspirated bloody joint fluids, which would otherwise be discarded, by density gradient separation, and cultured in α-MEM containing 10% FBS. The plastic adhering cells gave rise to colonies which first became visible around day 7 of culture as cells exhibited a fibroblast-like spindle shape, and the colonies eventually (by days 28) merged to form a uniform multicellular layer. At subconfluence, the adherent fibroblast-like cells were evaluated for cell surface marker expression using flow cytometry. The cells were consistently positive for CD29, CD44, CD105, and CD166, and were negative for CD14, CD34, and CD45, indicating these cells are not hematopoietic origin. Following treatment with osteogenic supplement, β-glycerophosphate, ascorbic acid, and dexamethasone or $1,25(OH)_2D_3$, the morphological transformation of the cells from spindle-like into cuboidal shapes was observed. Treatment of osteogenic supplement for 28 days resulted in a significant increase in activity of osteoblast-associated protein alkaline phosphatase (ALP) with maximum values attained on day 21 ($p < 0.001$, compared with that in the untreated cultures). Matrix mineralization was demonstrated on day 28 by Alizarin Red staining. RT-PCR analysis revealed that mRNA levels of osteoblast-related genes, ALP, osteocalcin, bone sialoprotein and osteopontin were up-regulated in the treated cultures. These results were similar to those observed in human bone marrow stromal cells from healthy volunteers. Taken together, our findings show that cells derived from ACL injury-induced hemarthrosis contain osteoprogenitor cells. 'Waste' ACL injury-induced hemarthrosis, which is easy to harvest with minimal invasion and discomfort, will be an alternative source for cell-based therapy such as augmentation of the tendon graft healing to bone in ACL reconstruction.

Suppressive Role of Regucalcin on Cell Differentiation and Mineralization in Osteoblastic MC3T3-E1 Cells. M. Yamaguchi, M. Kobayashi*, S. Uchiyama*. Laboratory of Endocrinology and Molecular Metabolism, Graduate School of Nutritional Sciences, University of Shizuoka, Shizuoka, Japan.

Regucalcin was discovered by Yamaguchi in 1978 years. This protein plays the multifunctional role as regurator in cell signaling system in many cells. Bone loss has been induced in regucalcin transgenic rats. Regucalcin has been shown to stimulate osteoclastic resorption in vitro. Furthermore, the role of regucalcin in the regulation of osteoblastic cell function was investigated. Osteoblastic MC3T3-E1 cells with subconfluent monolayers were cultured in a medium containing regucalcin (10-10 to 10-8 M) without fetal bovine serum (FBS). Regucalcin had no effect on osteoblastic cell proliferation. The results of RT-PCR analysis with specific primers showed that the expression of Runx2 and IGF-I mRNAs in osteoblastic cells was significantly suppressed in the presence of regucalcin (10-10 or 10-9 M). TGF-beta1 mRNA levels were significantly enhanced by the 24 h-culture with regucalcin. Alpha 1(I) collagen and G3PDH mRNA levels were not significantly changed by culture with regucalcin. Alkaline phosphatase activity was significantly decreased in the lysate of cells cultured for 24 or 48 h with regucalcin (10-10 or 10-8 M). The expression of regucalcin in osteoblastic cells was demonstrated by RT-PCR and Western blot analysis. When regucalcin (10-7 M) was added into the enzyme reaction mixture containing the lysate of osteoblastic cells cultured in the absence of regucalcin, alkaline phosphatase activity was significantly decreased. Also, Ca2+/calmodulin-dependent nitric oxide (NO) synthase activity in the cell lysate was significantly decreased by addition of regucalcin (10-10 or 10-8 M) into the reaction mixture. The presence of anti-regucalcin monoclonal antibody (5 or 10 ng/ml) in the enzyme reaction mixture caused a significant increase in NO synthase activity in the cell lysate in the presence or absence of Ca2+/calmodulin, suggesting a role of endogenous regucalcin. When osteoblastic cells with subconfluency were cultured in the presence of regucalcin (10-10 or 10-9 M) for 18 days, the results with Alizarin red staining showed that the mineralization was markedly suppressed by culture with regucalcin. This study demonstrates that regucalcin regulates the function of osteoblastic cells, and that the protein suppresses cell differenciation and mineralization. This finding was a first time.

Dlk1/Pref-1 Maintains Self-Renewing Undifferentiated State of Human Mesenchymal Stem Cells by Upregulating Cytokine and Chemokine Gene Expression. B. M. Abdallah*[1], Q. Tan*[2], J. Dahlgaard*[2], M. Kassem[1]. [1]Endocrinology Dept., Odense University Hospital, Odense, Denmark, [2]Department of Clinical Biochemistry and Genetics, Odense University Hospital, Odense, Denmark.

Dlk1/Pref-1 (delta like 1/pre-adipocyte factor 1) is a transmembrane protein belongs to the EGF-like homeotic proteins including Notch receptor and its ligands. We have previously shown that Dlk1 is a novel molecule that maintains the self-renewing undifferentiated state of human mesenchymal stem cells (hMSC) through inhibition of osteoblast and adipocyte differentiation (Abdallah BM, et. al., JBMR, 19:841-852, 2004). To investigate the molecular mechanisms underlying these effects, we identified the Dlk1-regulated genes in hMSC line over-expressing Dlk1 gene (hMSC-Dlk1) using DNA Microarray technology. Highly purified RNA from both control hMSC line (negative for Dlk1 expression) and hMSC-Dlk1 cells was subjected to gene chip analysis using the Affymetrix HG-U133A and this was followed by quantitative real-time PCR analysis. Sixty nine genes were found to be significantly up-regulated (with > 3 folds) in hMSC-Dlk1 compared to control cell line. Interestingly, around 40% of these genes were annotated as pro-inflammatory cytokines including interleukins (IL) (e.g. IL-1α, IL-1β, IL-6); chemokines (e.g. IL8, CXCL-2,-3,-6, -11 and CCL20) and several other immune response factors (e.g. complement components 1 and 3). Real-time PCR analysis confirmed more than 90% of the DNA chip data. We have also found that the conditioned medium from hMSC-Dlk1 cell line (containing the secreted soluble active form of Dlk1) induced the same pattern of up-regulated cytokines and chemokines in either control hMSC line or normal hMSC lines obtained from several healthy donors. In addition, Dlk1 exerted synergistic effects on cytokine production e.g. IL-1, IL-6, IL-8, CCL20 and RANTES in presence of lipopolysaccharid [LPS (dose 1 and 100 ng/ml)] and upregulated their gene expression by 3, 6, 4.5, 7 and 3.8 folds respectively. In conclusion, the stimulatory effect of Dlk1 on cytokines expression by hMSC provides a novel mechanism by which Dlk1 exerts its inhibitory effect on hMSC osteoblast and adipocyte differentiation and consequently the maintenance of its self renewal capacity. Moreover, our findings suggest a new role for Dlk1 in the inflammatory and immune regulatory responses that need further investigations.

Oxysterols Enhance Osteoblast Differentiation *In Vitro* and Bone Healing *In Vivo*. T. Aghaloo[1], C. Amantea*[2], C. Cowan*[3], J. Richardson*[2], B. Wu[3], F. Parhami[2], S. Tetradis[1]. [1]School of Dentistry, Los Angeles, CA, USA, [2]Geffen School of Medicine, Los Angeles, CA, USA, [3]Bioengineering, UCLA, Los Angeles, CA, USA.

Anabolic agents that enhance bone formation are important for prevention and management of bone diseases. Oxysterols, naturally-occurring cholesterol oxidation products with multiple biologic activities, are made in part by cellular cytochrome P450 enzymes and autooxidation. We previously reported that continuous treatment of M2-10B4 (M2) mouse marrow stromal cells with specific oxysterol combinations induced osteogenic differentiation assessed by Runx2 protein expression and DNA binding activity, alkaline phosphatase (ALP) activity, osteocalcin (OCN) mRNA expression, and mineralization. Here, we investigated the ability of short term treatment of M2 cells with osteogenic oxysterols 22(S)-hydroxycholesterol + 20(S)-hydroxycholesterol (SS) to induce osteoblastic differentiation. We also explored the ability of these oxysterols to promote bone healing *in vivo*. M2 cells were treated with vehicle or 5 μM SS for 0.5, 1, 2, 4, and 8 h. Oxysterols were removed, and cells allowed to differentiate in osteogenic medium (RPMI+5% FBS+50 μg/ml asc +3 mM β-glycerophos). Osteogenic differentiation was assessed by ALP activity at 4 days, OCN mRNA expression at 8 days, and mineralization at 14 days. As little as 0.5 h SS treatment caused a 22-fold increase in ALP activity (Control: 5 ± 2; SS: 110 ± 3 units/mg protein ± SD; $p<0.001$). OCN mRNA expression and mineralization were significantly induced with only 4 h SS treatment by Northern and ^{45}Ca assays, respectively. Next, to explore the effects of osteogenic oxysterols *in vivo*, we utilized the established critical sized 5 mm rat calvarial defect model. Poly(lactic-co-glycolic acid) (PLGA) scaffolds alone or coated with 140 ng (low dose) and 1400 ng (high dose) oxysterol cocktail were implanted into the defects. Rats were sacrificed at 6 weeks and examined by μCT (μCT40, Scanco, PA). After scanning at medium resolution utilizing 55 kVp and 72 mA, 3D reconstructions were made, and the bone volume (BV; mm^3), total volume (TV; mm^3), and BV/TV ratio in the volume of interest (VOI; 5 mm defect) were measured. The PLGA scaffold alone showed slight bone healing (BV/TV = 0.17425). Low dose (BV/TV = 0.256933; $p<0.05$) and high dose oxysterols (BV/TV = 0.259478; $p<0.05$) significantly enhanced bone formation. Our results suggest that brief exposure to osteogenic oxysterols was sufficient to trigger events leading to osteoblastic cell formation. Oxysterols also induced 1.4-fold greater bone regeneration than control in a calvarial defect model. These *in vitro* and *in vivo* results identify oxysterols as anabolic agents with potential applications in bone healing.

Regulation of the Differentiation of Mesenchymal Stem Cells by Retinoic Acid. K. Hisada*[1], K. Hata*[1], H. Ikeda*[1], T. Matsubara*[1], F. Ichida*[1], H. Yamamoto*[1], H. Yatani*[1], A. Yamaguchi*[2], R. Nishimura*[1], T. Yoneda*[1]. [1]Biochem, Osaka Univ Grad Sch Dent, Suita, Japan, [2]Pathol, Tokyo Medic and Dent Univ Grad Sch, Suita, Japan.

Previous studies have shown that retinoic acid (RA), a physiologically potent metabolite of vitamin A, stimulates osteoblastogenesis and inhibits adipogenesis. RA has been also shown to enhance BMP2-induced osteoblast differentiation, suggesting the interactions of RA with BMP2 are critical to the differentiation of mesenchymal stem cells. In the present study, we attempted to investigate the molecular mechanism by which RA promotes osteoblastogenesis and inhibits adipogenesis with a focus on the cross-talk between RA and BMP signaling. To approach this, we first determined the effects of RA on osteoblastogenesis using the pluripotent mesenchymal cell line C3H10T1/2 that differentiates to osteoblasts and adipocytes by BMP2 treatment. RA alone induced osteoblast differentiation by elevating alkaline phosphatase (ALP) activity. This action of RA was enhanced in the presence of BMP2. On the other hand, RA markedly inhibited BMP2-indcued adipogenesis. To explore the relationship between RA and BMP2 signaling during osteoblast differentiation, we determined the interactions of RA receptor (RAR) propagation with BMP2 signaling molecule Smad1 and Smad4. RA increased Smad1- and Smad4-induced ALP activity in C3H10T1/2 cells. Treatment with RA also increased transcriptional activity of Smad1 and Smad4. Furthermore, immunoprecipitation experiments showed that RAR physically associated with Smad1 and Smad4. These results suggest that RA signaling functionally and physically interact with Smad, thereby up-

regulating the osteoblastogenic action of BMP2. To our surprise, RA did not influence the expression and function of Runx2. In addition, RA induced ALP activity in mesenchymal cells isolated from Runx2-deficient mice. Furthermore, RA had little effects on osteoblastogenic activity of osterix. We next studied the molecular mechanism by which RA inhibits adipocyte differentiation. Since transcription factors, C/EBP family and PPARγ, play important roles in the regulation of adipogenesis, we examined the interactions of RA with these transcription factors. RA markedly inhibited the adipogenic action of C/EBPβ and C/EBPβ-induced PPARγ expression. Furthermore, RA suppressed the adipogenesis induced by PPARγ. In conclusion, our data suggest that RA stimulates osteoblastogenesis in cooperation with Smad but independent of Runx2 and osterix. RA inhibits adipogenesis through suppression of C/EBPβ and PPARγ. Thus, RA regulates the commitment of mesenchymal stem cell to osteoblasts and adipocytes at transcriptional levels.

Regulation of Osteoblastic Differentiation by Recombinant Mouse Amelogenin. M. Matsuzawa*[1], T. Sheu*[2], C. Huang*[2], R. Mroczek*[2], S. Kimoto*[1], H. Shinji*[1], S. Sato*[1], T. Kawase*[1], J. Puzas[2]. [1]Kanagawa Dental College, Yokosuka, Japan, [2]Orthopaedics, University of Rochester, Rochester, NY, USA.

Objectives: Amelogenins have been found to be abundant in enamel and have been reported to induce differentiation and mineralization in a variety of cells. However, the mechanism for regulation of this differentiation is not clear. The aim of this study was to characterize the effect of amelogenin on osteoblasts and periodontal ligament cells (PDL) and to identify possible proteins with which amelogenin can interact. Methods: To examine protein interactions of amelogenin, a phage display biopanning technique was used. In this experiment an osteoblast cDNA phage library, expressed in T7 phage, was used to bind a "bait" protein of interest. The bait protein was purified full-length mouse recombinant amelogenin (rM179). The recombinant amelogenin was immobilized on the bottom of a 96-well culture dish. The osteoblast cDNA phage library was exposed to amelogenin to test protein-protein interaction and specifically bound phage were then eluted. For the differentiation experiments purified rM179 protein was added to cultured PDL and ROS17/2.8 osteoblasts for 7 days. The mRNA expression of Runx2, type I collagen (COL1), bone sialoprotein, osteopontin, osteocalcin (OCN), osteonectin (ON), alkaline phosphatase (ALP), RANK ligand (RANKL), and osteoprotegerin (OPG) were quantitatively analyzed by RT-PCR. We also measured activation of the TGFbeta signaling pathway. Results: The DNA sequence that demonstrated one of the highest affinities for rM179 in the biopanning experiment was tissue inhibitor of metalloproteinase-2 (TIMP2). The physiological function of this association has been tested in a MMP functional assay. Exposure of amelogenin to osteoblasts increased mRNA for Runx2, COL1, ALP, and OCN. In the PDL cells, amelogenin increased RANKL mRNA levels whereas ON and OPG remained unchanged. Amelogenin was also found to activate TGFbeta signaling with a 4-fold increase. Conclusion: Amelogenin binds TIMP2 with very high affinity. This association may explain, in part, the mechanism by which degradation of the surrounding matrix by MMP's is a stimulus for osteoblast differentiation and nodule formation. Moreover, it appears that amelogenin can activate the TGFbeta signaling pathway without interaction with the TGFbeta receptor. Both effects would play a role in the regeneration of bone and periodontal ligament structures during development and/or during disease states.

Overexpression of Wnt10b from the FABP4 Promoter in Mice Results in Increased Trabecular Bone Mass by Increasing Bone Formation and Mineralization. Y. L. Ma[1], Q. Q. Zeng*[1], C. N. Bennett[2], K. A. Longo*[2], W. S. Wright*[2], K. D. Hankenson[3], O. A. MacDougald[2], G. Krishnan[1]. [1]Endocrine Research, Eli Lilly and Company, Indianapolis, IN, USA, [2]Molecular and Integrative Physiology, University of Michigan Medical School, Ann Arbor, MI, USA, [3]Orthopedic Surgery, University of Michigan Medical School, Ann Arbor, MI, USA.

Activation of Wnt signaling by Wnt10b inhibits differentiation of preadipocytes and promotes osteogenesis in vivo (Bennett etc. *PNAS*; 102:9, 3324-29, 2005). To explore mechanisms whereby Wnt signaling increases osteogenesis, we used a metatarsal organ culture model to establish direct osteogenic action of Wnt10b. Treatment of metatarsals with conditioned media from Wnt10b overexpressing cells did not result in an increase in mineralization as visualized by light microscopy. In contrast, metatarsal organ co-culture with Wnt10b overexpressing cells yielded an increase in mineralization as visualized by light microscopy. Further, to establish the cellular mechanism of osteogenesis, we conducted histomorphometric analyses in 3 months old male FABP4-Wnt10b transgenic mice. At the distal femur, FABP4-Wnt10b mice showed increased trabecular area when compared to wild type littermate. Increased bone mass was the result of an increase in trabecular width and trabecular number, with a corresponding decrease in trabecular separation. Though there was no statistically significant difference in percent osteoblast surface, dynamic histomorphometric analyses revealed a significant increase in mineralizing surface (23%), mineral appositional rate (21%) and bone formation rate (50%) in the secondary spongiosa. Osteoclast number tended to decrease but the change did not reach statistical significance. Although no substantial changes were found in cortical bone of mid-femur at this age mice, a significant amount of marrow trabecular bone was seen in all the FABP4-Wnt10b mice, which was not seen in wild type mice. Our data confirm that Wnt signaling increases osteogenesis to promote bone formation and mineralization.

From Human Marrow Mesenchymal Stem Cells to Bone, Fat, Neural Cells and Cartilage: An *In Vitro* Study. C. Shih, J. Shyu. Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan Republic of China.

Mesenchymal stem cells (MSCs) are essential during development and its potential role in regenerative medicine is promising in the new future. In addition, current evidences suggested that the decrease in bone formation with age is associated with an imbalance between osteoblast and adipocyte differentiation from marrow MSCs. However, knowledge of phenotype characteristics of these MSCs and the controlling factors is relatively unknown. Thus, the aim of this study was to isolate, culture, and investigate the multiple potential of human bone marrow MSCs by density gradient separation method, CD marker selection, differentiation marker expression, bone colony formation, von Kossa stain, H& E stain , Safranin O stain , and light, phase contrast and fluorescent microscopy. MSCs ,from human bone marrow, were isolated ,purified, and expanded in DMEM medium. Appearance of cuboid-shaped osteoblastic cells, unmineralized, and mineralized colonies were noted 5, 10 and 14 days, respectively, after osteogenic induction. Histological sections showed mineralized matrix with lining osteoblasts and entrapped osteocytes. With adipogenic induction, small size lipid droplets began to appear within cytoplasm 4 days later. More and larger lipid droplets accumulation was noted 10 days after induction. After adding retinoid acid (RA) for 5 days, MAP2 positive cells were detected by immunocytochemical staining. GFAP positive cells were detected 12 days after neurogenic induction. Moreover, MSCs formed cartilage-like tissue using PLGA scaffold in a bioreactor about 2 weeks after chondrogenic induction. Much more cartilage matrix formation was noted 8 and 12 weeks in culture. The results of this study indicated human bone marrow CD 34^- MSCs could be isolated, cultured, and induced to undergo osteogenesis, adipogenesis, neurogenesis and chondrogenesis ***in vitro***.

Dimethyl Sulfoxide Enhances Osteoblastic Differentiation of Murine Pre-Osteoblast Cells. W. M. W. Cheung, W. W. Ng*, A. W. C. Kung. Department of Medicine and Research Centre of Heart, Brain, Hormone and Healthy Aging, The University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Dimethyl sulfoxide (DMSO) is the most effective solvent that mixes readily with most water-insoluble and water-soluble substances. Similar to retinoic acid, DMSO demonstrates diverse differentiation-inducing effects on many cell types, including leukemia cells, myoblasts and embryonic stem cells. Recently, it is demonstrated that the DMSO-induced differentiation of leukemia cells is mediated via the upregulation of the tumor suppressor PTEN, which leads to the decrease of Akt phosphorylation. Although DMSO serves as solvent for most ligand-receptor studies of bone formation, the effect of DMSO on bone formation remains obscure. In this study, the effect of DMSO on osteoblast differentiation and phenotype-specific gene expression was examined using murine preosteoblast MC3T3E1 clone 4 (MC) cells as model systems. At concentrations of 0.5-1%, DMSO enhanced the osteoblast differentiation of MC cells as demonstrated by Von Kossa staining. Using real-time RT-PCR, DMSO was shown to upregulate the expression of alkaline phosphatase and collagen type Iα. To examine if DMSO acted on specific stage, osteogenic medium was supplemented with 1% DMSO transiently during osteoblast differentiation of MC cells. It was observed that maximum bone nodule formation was resulted when DMSO was supplemented at day 0-5 when compared with control. Expression of osteoblast-specific transcription factors, Runx2 and osterix, was upregulated during the differentiation process. DMSO treatment at day 5-10 or 10-15 resulted in no significant increase in bone nodule formation, suggesting that DMSO affects mainly the differentiation process but not the maturation, nor matrix mineralization process of osteoblast differentiation. While the expression of activated p42/p44 MAP kinases (MAPK) was downregulated, blockage of activated MAPK further enhanced the DMSO-mediated osteoblast differentiation. These data demonstrate that DMSO enhances osteoblast differentiation of MC cells by affecting the differentiation process via the inhibition of MAPK pathway.

Fulvic Acid of Mumie Promotes Osteoblastic Differentiation in MC3T3-E1 Cells. E. Kim[1], J. Choi*[2], H. Jung*[2], I. Nam-Goong*[3], Y. Kim*[1]. [1]Internal Medicine, Ulsan University Hospital, University of Ulsan, Ulsan, Republic of Korea, [2]Biomedical Research Center, Ulsan University Hospital, Ulsan, Republic of Korea, [3]Internal Medicine, Ulsan University Hospital, Ulsan, Republic of Korea.

Mumie is a semihard black resin formed by long-term humification and fulvic acid (MFA) from fractionated from crude Mumie is believed to have therapeutic properties and regeneration of bone tissue. **Purpose:** The purpose of this study was to investigate the effects of MFA on the osteoblastic differentiation in MC3T3-E1 cells. **Methods:** MC3T3-E1 cells were treated with different concentrations (100-1000 μg/mL) of MFA in α-MEM medium for 1, 3, 6, 9, 12, 15, and 18 days. Cells incubated with simvastatin served as positive control or without MFA served as negative control. At the end of each incubation period, cells were harvested and alkaline phosphatase (ALP) activity was determined compared with control groups. Total mRNA was also extracted from MFA-treated cells and RT-PCR was performed to determine the mRNA levels of ALP and osteoprotegerin (OPG). **Results:** MFA enhanced ALP activity in a dose- and time-dependent pattern in

MC3T3-E1 cells. ALP activity was showed at relatively low doses (100 μg/mL) of MFA. ALP activity was highly elevated after culturing for 15 days in MFA-treated cells compared with positive control. It also significantly increased by MFA treatment from 9 to day 18 culture ($P < 0.01$) compared with negative control. RT-PCR analysis showed that MFA increased in the expression of ALP and OPG in MC3T3-E1 cells. **Conclusions:** This result indicates that MFA promotes osteoblastic differentiation, suggesting that it could be used for the treatment of bone metabolic disease such as osteoporosis.

The Stimulatory Effect of the Polyphenols in the Extract of Greens+™ Herbal Preparation on the Mineralized Bone Nodule Formation (MBNF) of SaOS-2 Cells Is Mediated via its Inhibitory Effect on the Intracellular Reactive Oxygen Species (iROS). L. G. Rao[1], B. Balachandran*[1], A. V. Rao*[2]. [1]Medicine/Div Endocrinology & Metab, University of Toronto, St. Michael's Hospital, Toronto, ON, Canada, [2]Department of Nutritional Sciences, University of Toronto, Toronto, ON, Canada.

Oxidative stress has been implicated in the pathophysiology of osteoporosis. Epidemiological studies associate polyphenol intake with increased bone mineral density. Polyphenols from plants have potent antioxidant properties. A commercially available herbal preparation, greens+™, is a good source of polyphenols. We studied the effects of the polyphenol extract of greens+™ on alkaline phosphatase activity (ALP) and MBNF in cultures of the human osteoblast cell line SaOS-2 and explored whether these effects involved iROS. The SaOS-2 cells were cultured in supplemented Ham's F-12 medium in the absence or presence of greens+™ extracts containing various concentrations of total polyphenol. Control cultures received the vehicle used to prepare Greens+™ extracts. Greens+™ extracts were added at day eight and at every medium change thereafter. At various time points, ALP was analyzed using the Lowry method and MBNF was analyzed by the von Kossa technique. To determine whether the polyphenol extracts inhibited iROS, the cells were incubated with varying concentrations of Greens+™ polyphenolic extracts at day 8 for 48 hours and the concentration of iROS analyzed by the 2',7'-dichlorofluorescein diacetate (2,7-DCFH-DA) fluorescent assay. To mimic oxidative stress condition, experiments were also carried out in the presence of hydrogen peroxide (H_2O_2). Our data showed that treatment of SaOS-2 cells with polyphenolic extracts of greens+™ resulted initially in a stimulation followed by inhibition of ALP and stimulation of mineralized bone nodule numbers and area ($p<0.05$) in a time and dose-dependent manner. The polyphenolic extracts of Greens+™ significantly inhibited the endogenous production of iROS. Addition of H_2O_2 increased iROS in a time and dose-dependent manner ($p<0.05$) that was inhibited dose-dependently by the polyphenolic greens+™ extract ($p<0.05$). Similarly, varying concentrations of the polyphenol epicatechin, a major polyphenolic component of green tea, also inhibited the endogenous and H_2O_2-stimulated production of iROS, but to a lesser extent than the polyphenolic extract of Greens+™. In conclusion, our results showed that greens+™ extract influenced human osteoblasts differentiation and stimulated mineralization mediated by inhibition of iROS production. Our data suggests that greens+™ maybe an agent for the prevention of osteoporosis.

Notch1 RAM Domain and Ankyrin Repeats Are Required for Notch Signaling and Action in Osteoblasts. V. Deregowski, E. Gazzerro, L. Priest*, S. Rydziel, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Notch receptors play a critical role in cell fate decisions and suppress osteoblast differentiation. The Notch receptor is a single pass transmembrane receptor activated by contact with membrane bound ligands Delta and Serrate/Jagged, which result in the proteolytic cleavage of the Notch receptor and the release of its intracellular domain (NICD). Notch interacts with members of the CBF1, Suppressor of Hairless, Lag-1/RBP-Jk (CSL) family of transcription factors, an interaction presumably mediated by the RBP-Jk associated module (RAM domain), that results in the activation of transcription. Deletion of the RAM domain results in loss of CSL induction in C2C12 cells, but the contribution of the ankyrin repeats, the second major component of the Notch gene, to this pathway is less clear. The purpose of this work was to determine the pathways responsible for inhibitory effects of Notch on osteoblastogenesis, and the contributions of the RAM domain and ankyrin repeats to this process. ST-2 stromal cells were transduced with retroviral vectors overexpressing NICD, or deletion mutants, lacking the RAM domain or the ankyrin repeats, under the control of the cytomegalovirus promoter. In an initial experiment, the expression of target and partner genes utilized for Notch signaling was examined by Northern blot analysis. Notch overexpression caused an increase in the RBP-Jk/CSL pathway-dependent hairy and E (spl) (HES)-1 transcripts, but did not change the expression of Deltex 1, 2 and 3, which are associated with activation of CSL-independent pathways. Confirming that Notch acts in osteoblastic cells by using the RBP-Jk/CSL pathway, acute co-transfection experiments revealed that NICD enhanced the transactivation of transiently transfected 12xCSL constructs containing 12 repeats of an RBP-Jk/CSL binding site directing luciferase expression. Removal of the RAM domain resulted in a partial loss, whereas removal of the ankyrin repeats resulted in total loss of 12xCSL activity, indicating that ankyrin repeats are at least as important in the induction of the CSL pathway as the RAM domain. Accordingly, deletion of ankyrin repeats resulted in loss of HES-1 transcript induction. NICD overexpression inhibited the effect of BMP-2 and of Wnt3a on alkaline phosphatase activity (APA), and deletion of the RAM domain or ankyrin repeats resulted in loss of the inhibitory effect on APA and on Wnt signaling, as evidenced by changes in Wnt induced secreted protein 1 transcript levels. In conclusion, both the RAM domain and ankyrin repeats are required for Notch signaling through the RBP-Jk/CSL pathway, which appears responsible for the inhibitory effect of Notch on osteoblastogenesis.

Integrin Beta-1 Silencing Alters Osteoblast Response to Substrate Microtopography and 1,25(OH)2D3. L. Wang[1], R. Olivares-Navarrete*[1], B. F. Bell*[1], G. Zhao*[1], M. Wieland*[2], D. L. Cochran*[3], B. D. Boyan[1], Z. Schwartz[1]. [1]Georgia Institute of Technology, Atlanta, GA, USA, [2]Institut Straumann, Waldenburg, Switzerland, [3]University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Surface microroughness increases osteoblast differentiation and enhances responses of osteoblasts to $1,25(OH)_2D_3$. Beta-1 integrin expression is increased in osteoblasts grown on Ti substrates with rough microarchitecture, and is regulated by $1,25(OH)_2D_3$ in a surface-dependent manner, suggesting that beta-1 plays a role in mediating osteoblast response. Here, we silenced beta-1 expression in MG63 human osteoblast-like cells using small interfering RNA (siRNA) and examined response to surface microtopography and $1,25(OH)_2D_3$. MG63 cells were transfected with plasmids containing beta-1 siRNA template as well as with control plasmids containing scrambled beta-1 sequences. Stably transfected cells were selected: MG63-B and MG63-BS, respectively. Beta-1 mRNA was reduced 65% in MG63-B cells but was unaffected in MG63-BS cells based on real time PCR analysis. Normal and transfected cells were grown on tissue culture plastic or Ti disks of different surface microtopographies: Ra < 0.6μm, Ra = 4-5μm, and Ra > 5μm. At harvest, alkaline phosphatase activity was measured in cell lysates and levels of osteocalcin, TGF-b1, PGE_2, and osteoprotegerin (OPG) in the conditioned media were measured by immunoassay. We compared beta-1 silencing in cells cultured on plastic with blocking integrin signaling using two different anti-beta-1 monoclonal antibodies. After initial attachment, antibodies were present throughout the 7-day culture. Beta-1 silenced MG63 cells cultured on plastic had reduced alkaline phosphatase activity and levels of osteocalcin, TGF-b1, PGE_2, and OPG in comparison with wild type or MG63-BS cells. Moreover, beta-1 silencing, but not the scrambled template, inhibited surface roughness effects on these parameters. $1,25(OH)_2D_3$ increased alkaline phosphatase activity, and levels of osteocalcin, PGE_2, and OPG in wild type and MG63-BS cells and its effects were synergistic with those of the surface. However, effects of $1,25(OH)_2D_3$ were partially inhibited by beta-1 silencing. Effects of beta-1 silencing differed from those of anti-beta-1 antibodies, which in turn, depended on the antibody used. These findings indicate that beta-1 functions in osteoblastic differentiation modulated by either surface microarchitecture or $1,25(OH)_2D_3$, that beta-1 mediates, in part, the synergistic effects of surface roughness and $1,25(OH)_2D_3$, and global reduction in beta-1 differs from selective inhibition of ligand binding.

Beta-Cryptoxanthin Stimulates Cell Differentiation and Mineralization in Osteoblastic MC3T3-E1 Cells. S. Uchiyama*, M. Yamaguchi. Laboratory of Endocrinology and Molecular Metabolism, University of Shizuoka, University of Shizuoka, Shizuoka, Japan.

Beta-cryptoxanthin (CRP), a kind of carotenoid, has been shown to stimulate bone formation and inhibit bone resorption in vitro. CRP can inhibit osteoclastogenesis in bone marrow culture system. Furthermore, the effect of CRP on cell differentiation and mineralization in osteoblastic MC3T3-E1 cells was investigated. Cells were cultured for 72 hours in a alpha-MEM containing 10% FBS, and the cells with subconfluency were changed to a medium containing either vehicle or CRP (10-8 to 10-6 M) without FBS. Cells were also cultured for 3 to 21 days. Gene expression in osteoblastic cells was determined using RT-PCR. Culture with CRP (10-7 or 10-6 M) for 3 days caused a significant increase in Runx2 type 1, Runx2 type 2, alpha 1 (I) collagen and alkaline phosphatase mRNA levels in osteoblastic cells. These increases were completely blocked in the presence of cycloheximide, an inhibitor of protein synthesis, or 5,6-dichloro-1-beta-D-ribofuranosylbenzimidazole, an inhibitor of transcriptional activity. Vitamin A (10-6 M) did not have a significant effect on Runx2 type 1 mRNA expression in the cells. The effect of CRP(10-6 M) in stimulating Runx2 type 1 and a1 (I) collagen mRNA levels, protein content and alkaline phosphatase activity in the cells was also seen in the presence of vitamin A (10-6 M), suggesting that the mode of CRP action differs from that of vitamin A. Prolonged culture with CRP (10-6 M) for 3-21 days caused a significant increase in cell number, DNA content, protein content and alkaline phosphatase activity in osteoblastic cells, suggesting that CRP stimulates cell proliferation and differentiation. Moreover, culture with CRP (10-7 or 10-6 M) for 5 to 21 days caused a remarkable increase in mineralition. This study demonstrates that beta-cryptoxanthin has a stimulatory effect on cell differentiation and mineralization due to enhancing gene expression of proteins which involve in bone formation, indicating that the carotenoid is an activator in osteoblastic bone formation.

Particulate Wear Debris Alter Osteoclast Maturation through a COX-2 Dependent Mechanism. S. E. Prosser*, J. A. Struve, A. Palisch*, J. T. Ninomiya. Dept of Orthopaedics, Medical College of Wisconsin, Milwaukee, WI, USA.

Osteolysis and implant loosening remain the primary cause of implant failure following total joint arthroplasty. Although it is clear particulate debris play an important role in the process, the mechanisms involved in loosening remain complex. While the proteins RANKL and OPG are central in the maintenance of normal bone homeostasis, less is known about their function in osteolysis generated by particulate debris. More importantly, the intracellular signal transduction pathways involved in the activation of these proteins in response to particulate debris have not been fully characterized. We therefore hypothesized that regulation of the RANKL/OPG ration in response to particulate debris occurred through alterations in the gene expression and synthesis of cyclooxygenase-2(COX-2), a protein critical in the inflammatory response. We also hypothesized that inhibition of COX-2 activity would decrease the effects of particulate debris on the RANKL/OPG ratio, and subsequently result in a decrease in the maturation of osteoclast precursors. Titanium particles were added to osteoblasts in culture. Effects on COX-2 protein level were assessed by Western blots and prostaglandin secretion was determined by ELISA. Alterations in the gene expression of RANKL and OPG were determined by real-time PCR while OPG secretion was quantitated by ELISA. A specific inhibitor of COX-2, NS-398, was added 1 hour prior to addition of titanium and effects were determined as above. Cell lysates were collected and used to determine the effects on osteoclast maturation using a murine marrow cell assay. Addition of titanium particles to cells caused an increase in COX-2 protein levels at 2 and 6 hours and this corresponded to a 10-15 fold increase in secreted PGE_2 at 6 to 12 hours. COX-2 activity was blocked using the specific inhibitor NS-398 and this blocked PGE_2 secretion. The secretion and gene expression of OPG was increased in response to titanium but this increase was unaffected by the inhibition of COX-2. However, wear debris increased RANKL gene expression and this increase was reduced by the inhibition of COX-2. Whole cell lysates from osteoblasts incubated with wear debris increased osteoclast maturation and this effect was blocked by inhibition of COX-2. Taken together these findings demonstrate that titanium wear debris alter osteoclast maturation through a COX-2 dependent mechanism. In part, COX-2 altered the RANKL/OPG ratio by increasing RANKL gene expression rather than decreasing OPG secretion. This would also suggest that the COX-2 inhibitors which are widely used in the treatment of arthritis may also play a role in the prevention and regulation of osteolysis and implant loosening.

Wear Debris Induces MCP-1 through COX-2 Dependent Pathway in Fibroblasts. J. T. Ninomiya, J. A. Struve. Dept of Orthopaedics, Medical College of Wisconsin, Milwaukee, WI, USA.

Aseptic loosening remains the primary cause of implant failure following total joint replacement. Wear debris from the loosening of orthopedic implants induces macrophage activation, pro-inflammatory cytokine release and osteoclast differentiation leading to osteolysis. Osteolytic membranes around failed total joint arthroplasties are infiltrated with macrophages, fibroblasts and giant cells as well as orthopaedic wear debris. Fibroblasts are known to secrete proinflammatory cytokines and degradative enzymes in response to wear debris. Recent studies show that fibroblasts also release monocyte chemoattractant protein-1 (MCP-1) in response to titanium and PMMA. MCP-1 is a chemokine that attracts monocytes and macrophages to sites of inflammation and has been found in membranes retrieved from failed total joint arthoplasties. Although we know fibroblasts produce MCP-1, the signaling mechanism by which MCP-1 is induced in fibroblasts is not clearly understood. Therefore we chose to investigate the particle induced signal transduction pathways that lead to increased MCP-1 production. Titanium particles were added to human foreskin fibroblasts in culture. Effects on COX-2 protein levels were assessed by Western blot and prostaglandin secretion was determined by ELISA. MCP-1 gene expression was determined by semiquantitive RT-PCR while protein was measured by ELISA. A specific inhibitor of COX-2 (NS-398) was added 1 hour prior to addition of titanium and effects were determined as above. Fibroblasts stimulated with titanium showed a dose dependent release of MCP-1 at 24 hours. At doses of 0.25 vol% and 0.5 vol%, titanium showed significant increases of MCP-1 over non-stimulated fibroblasts. Using a time course, a 0.5 vol% dose of titanium significantly increased MCP-1 protein at 12, 24 and 48 hours. With addition of a COX-2 inhibitor(NS-398), the MCP-1 level was reduced to control level at 24 hour and significantly reduced at 48 hours. MCP-1 gene expression is induced at 24 hours and the expression is reduced with the addition of the COX-2 inhibitor. PGE_2 protein was significantly induced by titanium and when the COX-2 inhibitor was added the protein levels were reduced to control amounts. Western blots show that titanium increases COX-2 protein levels and the addition of NS-398 blocks that induction. These findings suggest that MCP-1 induced by fibroblasts is modulated through the COX-2 pathway. Therefore, COX-2 inhibitors currently available may be useful in treating implant loosening due to wear debris induced ostelysis

RNA Interference with Gq and G11 Proteins Suppresses Messenger RNA Expression of Osteoblast Functional Genes and Induces Changes in Cellular Morphology in Mouse Osteoblasts. A. Iida-Klein[1], D. S. Bischoff*[2], J. Zhu*[2], D. W. Dempster[1], T. J. Hahn[2], D. T. Yamaguchi[2]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA.

During bone remodeling, resting osteoblasts become activated upon receipt of external stimuli for bone formation and transform from a flat to a more cuboidal shape. In cardiac myocytes and platelets, guanine-nucleotide regulatory protein alpha q subunit (Gq) has been shown to play a role in cellular hypertrophy and cytoskeletal reorganization. We therefore hypothesized that Gq may play a role in regulation of cellular morphology and function in osteoblasts. Highly differentiated mouse calvarial MC4 osteoblasts were transfected with Gq and G11 siRNA at a 1:6 ratio of siRNA to liposome, and the temporal patterns of mRNA expression of Gq and G11 were examined by quantitative real time RT-PCR. Maximal Gq silencing at 90% ($p<0.0001$) was achieved by 24 hr, gradually decreasing to 67% ($p<0.001$) at 48 hr, and 42% ($p<0.01$) at 72 hr. Similarly, maximal G11 silencing at 95% ($p<0.001$) was achieved by 24 hr, but the silencing effect continued until 72 hrs. Gq silencing at the protein level was confirmed at 24 hr by significant suppression of Gq protein band density using western blot. Messenger RNA expression levels of three osteoblast-specific functional genes (core-binding factor alpha 1 [cbfa1], bone sialoprotein [BSP], and alkaline phosphatase [ALP]) were also measured by quantitative real time RT-PCR. Upon maximal Gq silencing at 24 hr, mRNA expression of cbfa1, BSP and ALP was suppressed by 70%, 92% and 52 % (all, $p<0.01$), respectively. Similar suppression of these osteoblast-specific genes was observed by maximal G11 silencing. In addition, osteoblast morphology was altered by Gq and G11 silencing, and the cells became flattened at 24 and 48 hr. The more cuboidal morphological phenotype was recovered over time. Thus, these results support our hypothesis that the Gq family of G proteins may play an important role in osteoblast function and cellular morphology.

Kremen 2 Is Required for Dkk1 Mediated Iinhibition of LRP5/6-Wnt3a-TCF Signals in U2OS Osteoblast-Like Cells. B. M. Bhat[1], H. Lam*[1], V. E. Coleburn*[1], P. Yaworsky*[2], F. J. Bex[1]. [1]Women's Health & Bone, Osteoporosis Group, Wyeth Research, Collegeville, PA, USA, [2]Biological Technologies, Wyeth Research, Cambridge, MA, USA.

Recent analyses of LRP5 mutations in humans and mice have revealed the pivotal role LRP5 and Wnt-signaling play in bone metabolism. LRP5/6 and the secreted antagonist Dkk1 interact with recently identified single pass, transmembrane receptors Kremen1 (Krm1) and Kremen2 (Krm2) and synergistically inhibit the LRP5/6-Wnt-β Catenin signal. In addition, Kremens facilitate rapid endocytosis of LRP5/6 from the cell membrane and block LRP5/6-Wnt signaling. To investigate the functional role of Kremens we cloned Krm2 from U2OS cells and identified four splice variants. Analysis of these variants by Wnt-TCF assays in U2OS cells indicated that the variant lacking 44 C-terminal amino acids (aa) can enhance Dkk1 mediated inhibition, although the maximum effect was seen with the full length clone. Reports indicate that Krm2 activity is mediated by its interaction with the second cysteine-rich domain of Dkk1 and also that Krm2 can convert the LRP6-Wnt signal activator Dkk2 into an inhibitor in 293 cells. Recently, we have identified downstream deletion to the second cysteine-rich domain of Dkk1 that removes 21 C-terminal aa containing a putative N-glycosylation site, results in loss of its inhibitory function. To study whether Krm2 can alleviate the functional defect of Dkk1 deletion, co-transfection experiments were performed. They revealed that Krm2 could not reverse the lack of inhibitory function in the truncated Dkk1 and hence suggested that Krm2 requires this 21 aa region of Dkk1 to block LRP5-Wnt-TCF-signaling. To evaluate the functional importance of Krm2 in U2OS bone cells, we carried out Krm2 siRNA co-transfections with TCF reporters. In the absence of Wnt3a, a 2-3-fold increase in TCF activity as compared to the control siRNAs was observed. Thus, by inhibiting Krm2, a TCF signal is generated in bone cells presumably by releasing the Krm2-Dkk1 mediated suppression of the endogenous signal. In addition, when Krm2 siRNA was co-transfected with Wnt3a, there was a synergistic activation of the TCF signal. Moreover, Krm2 siRNA co-transfection with Dkk1 and Wnt3a abolished Dkk1 mediated inhibition (~95%) of Wnt-TCF signal in U2OS cells. These studies indicate the presence of functional endogenous Krm2 in U2OS bone cells as well as support the requirement of Krm2 for Dkk1 inhibitory function.

Essential Roles of MAP Kinases p38 and ERK in the Activation of Osteoblastic Cells by Parathyroid Hormone. A. Rey*, D. Manen*, R. Rizzoli, S. Ferrari, J. Caverzasio. Service of Bone Diseases, Department of Rehabilitation and Geriatrics, University of Geneva, Switzerland.

Increased bone formation by PTH is mainly due to activation of osteoblastic cell differentiation (OBD), an effect largely mediated by the cAMP-Protein Kinase A (PKA) signaling pathway. The molecular mechanism by which PKA and/or the possible implication of other pathways in PTH-induced OBD are largely unknown. MAP kinases (MAPKs) have recently been shown to play a significant role in OBD. We thus investigated the role of MAPKs in the activation of osteoblastic cells by PTH. In early differentiated MC3T3-E1 cells, 10^{-7} M human PTH(1-34) (hPTH) enhanced alkaline

phosphatase (ALP) activity (8-10 fold) and doubled the production of osteocalcin (OC) after 24 h incubation. These effects were fully mimicked by 10 μM forskolin (FSK). They were blunted by H89 (25 μM) but not by Go6983 (10 μM), which are specific inhibitors of PKA and PKC, respectively, confirming a major role of PKA in PTH-induced OBD. Activation of MAPKs by PTH in MC3T3-E1 cells was investigated using Western blot analysis. In confluent cells, hPTH enhanced p38 MAP kinase by 2.5±0.3 fold ($p<0.01$) at 2 h. This effect started after 1 h incubation, lasted about 2 hrs and was mimicked by 10 μM FSK (3.5±0.2 fold, $p<0.001$). The stimulation of p38 by hPTH was completely blocked by 10 and 25 μM H89 suggesting a PKA-dependent mechanism of activation. Associated with this effect, the stimulation of ALP induced by hPTH was dose-dependently (5-25 μM) and completely inhibited by SB202190, a specific p38 inhibitor. This compound, however, did not influence PTH-induced cellular cAMP or OC production. As previously shown, PTH also enhanced ERK activity. However, preincubation of cells with 10 μM of U0126, a selective inhibitor of ERK activation, significantly reduced OC production, but did not influence PTH stimulation of cAMP and ALP. Finally, a 5 week PTH(1-34) exposure significantly enhanced by 5-fold MC3T3-E1 matrix mineralization assessed as by alizarine red staining. This effect was markedly decreased (> 80%) by the p38 (10 μM) but not by the ERK inhibitor (10 μM). In conclusion, these results describe for the first time that PTH can activate p38 in addition to ERK in osteoblastic cells and that this effect is mediated by a PKA-dependent mechanism. MAP kinases p38 and ERK are essential signaling pathways for PTH-induced osteoblastic differentiation. The p38 pathway plays a major role in enhanced ALP and matrix mineralization induced by PTH whereas ERK is rather implicated in changes of OC, strongly suggesting distinct signaling pathways downstream PKA in PTH-induced osteoblastic differentiation.

Wnt 3a and a GSK3β Inhibitor Differentially Regulate Wnt Pathway and Bone Formation Associated Genes in Primary Human Osteoblasts. L. V. Hale*, D. L. Halladay*, C. A. Frolik, B. A. Diseroad*, C. M. Kelepouris*, Y. G. Yue*, J. Shou*, T. Wei*, T. Stewart*, A. Kumar*, L. Gelbert*, J. Onyia, P. Chen*, S. Huang*, R. J. S. Galvin. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, USA.

Wnt glycoproteins comprise a highly conserved family of secreted lipid modified signaling molecules. These proteins regulate cell-to-cell interactions and are powerful regulators of cell proliferation and differentiation. The conventional (canonical) Wnt pathway involves proteins that directly participate in gene transcription and cell adhesion and has recently been implicated in bone formation. To further investigate the role of this pathway in bone formation, the effects of Wnt 3a and the GSK-3β inhibitor, 603281-31-8, on human pre-osteoblasts (hOBs, L. X. Bi, Univ Texas Medical Branch) were evaluated in primary cell culture. The hOBs mineralize in the presence of β-glycercolphosphate, ascorbate, and dexamethasone producing a mineral identified by X-ray diffraction to be consistent with hydroxyapatite (HA). Both Wnt 3a conditioned medium (CM) and the GSK-3β inhibitor enhance this mineralization to approximately the same magnitude in a dose-dependent manner. However, in contrast to inhibitor treated cells, at higher concentrations the Wnt 3a CM causes cell detachment. Microarray analysis of the treated hOBs followed by Taqman gene expression validation indicate that Wnt 3a CM and the GSK-3β inhibitor similarly regulate expression of Axin2, DKK2, BMP4, osteomodulin (OMD), FZD8, ADAM19, as well as, a number of other genes not currently associated with bone. Fold-changes in gene expression seen with the inhibitor are much greater and often sustained longer than the fold-changes induced by Wnt 3a CM even though the genes are regulated in the same direction. Our data indicate that both Wnt 3a CM and the GSK-3β inhibitor, 603281-31-8, are able to up-regulate HA accumulation in hOB cell culture. Likewise, they are both able to regulate specific genes linked to bone, as well as, a number of genes not currently thought to be connected to bone formation. However, the magnitude and timing of this regulation is different between the two treatments. Therefore, it is proposed that the GSK-3β inhibitor bypasses some of the pathway regulatory steps that normally control the bone response to Wnt 3a.

Further Indications for an Aantagonistic Role in LRP5-Mediated Wnt Signaling for Dickkopf1, Dickkopf3, Kremen1, and also Sclerostin. W. Balemans*, L. Van Wesenbeeck*, W. Van Hul. Dept. Medical Genetics, University of Antwerp, 2610 Antwerp, Belgium.

Wnt signaling plays an important role in many developmental processes and is regulated at multiple levels. Low density lipoprotein receptor-related protein 5 (LRP5), a co-receptor for Wnt proteins, activates canonical Wnt signaling, and is found to be associated with osteoporosis pseudoglioma syndrome (OPPG) and high bone density disorders. Extracellulary, Wnt signaling is modulated by a number of antagonists, including members of the Dickkopf (Dkk) and Kremen (Krm) families. Dkk1, Dkk2 and Dkk4 have been shown to bind LRP5/6. Whereas Dkk1, Dkk3 and Dkk4 inhibit Wnt signaling, Dkk2 can act as an activator or an inhibitor depending on the cellular context. The single transmembrane proteins Krm1 and Krm2 strongly cooperate with Dkk1, Dkk2 and Dkk4 to potentiate Dkk-mediated inhibition of Wnt signaling. Recently, sclerostin has been put forward as an additional candidate to modulate Wnt signaling. Loss of function of this protein causes sclerosteosis and van Buchem disease, two sclerosing bone dysplasias. Thus far, two studies suggested a modulatory effect of sclerostin on Wnt signaling. Although results from the first report postulated an indirect effect, a more recent study showed a direct inhibition of the Wnt pathway by binding of sclerostin to LRP5. In this study, the ability of Dkk1, Dkk3, Krm1 and sclerostin to modulate LRP5-mediated Wnt signaling was investigated using a TCF reporter based assay in HEK293T cells. Transient transfection of a mouse Wnt1 expression construct slightly increased TCF-dependent transcriptional activation, which was further potentiated by co-expressing human LRP5. Co-transfection of increasing amounts of human Dkk1 and Dkk3 resulted in a dose-dependent decrease in LRP5-mediated Wnt signaling. Mouse Krm1 did not show a significant modulation of TCF transcriptional activity, however, when co-transfected with human Dkk1, a strong potentiation of Dkk1-mediated inhibition could be observed. Finally, a dose-dependent inhibition of LRP5-mediated Wnt signaling was also observed when transfecting mouse sclerostin. To conclude, our data confirmed antagonistic roles for Dkk1, Dkk3, Krm1, and also sclerostin on LRP5-mediated Wnt signaling. However, additional studies are necessarry to find out whether sclerostin acts directly or indirectly on this pathway. In the past, molecular genetic and cell biology studies have already demonstrated important roles for LRP5, sclerostin and Dkk1 in bone tissue. Whereas no such functional roles have been found for Dkk3 and Krm1, molecular and cell biological experiments are currently ongoing in our lab to investigate this.

Bisphosphonates Regulate Mediators of Cell Transduction in Osteoblasts. Q. Sun[1], R. W. Katz[2], J. P. Bilezikian[1]. [1]Division of Endocrinology, College of Physicians and Surgeons, Columbia University, New York, NY, USA, [2]Oral Medicine, College of Dentistry, New York University, New York, NY, USA.

Although bisphosphonates (BPs) have long been regarded to affect osteoclast actions primarily, recent studies have suggested that the osteoblast is also an important target. We previously reported that BPs suppress prenylation of small GTPases and stimulate total GTPase activity in osteoblasts (the UMR-106 cell line). In this study, we further describe the effects of BPs on Rho A, a member of the Rho family of GTPases in UMR-106 cells. Rho A prenylation was measured by immunoprecipitation after labeling with C14-mevalonate. Overnight exposure of cells to 0.1 mM risedronate (RIS) reduced Rho A prenylation by 61% below control levels. Under the same experimental conditions, exposure to alendronate (ALN) had a much smaller, 15% inhibitory effect (ALN vs RIS, $p < 0.001$). RIS stimulated GTPase activity to a greater extent than ALN: 156% vs 119% ($p <0.05$). RIS also inhibited GTP binding to UMR 106 cells to a greater extent than ALN: 21% vs 10%. Under our experimental conditions, there was no translocation of Rho A from the cell membrane into cytosol. We conclude that in UMR 106 cells, BPs inhibit prenylation, stimulate GTPase activity, and inhibit GTP binding of Rho A, with RIS having a greater effect on these 3 processes than ALN. The results define further specific biochemical targets of BPs on osteoblasts and should help to elucidate molecular mechanisms of BP action in this newly recognized target cell.

Metabolic Acidosis-Induced Calcium Signals in Primary Osteoblasts. K. K. Frick, K. Nehrke*, N. S. Krieger, D. A. Bushinsky. Medicine/Nephrology Unit, University of Rochester, Rochester, NY, USA.

Compared to incubation in neutral pH medium, incubation of neonatal mouse calvariae in medium simulating physiologic metabolic acidosis (Met, reduced pH due to decreased $[HCO_3^-]$) induces a marked increase in net Ca efflux. In contrast, incubation in isohydric medium simulating respiratory acidosis (Resp, reduced pH due to increased Pco_2) has little effect on Ca flux. The Met-induced increase in net Ca efflux results from stimulation of osteoclastic resorption mediated through changes in osteoblastic activity. Met induces osteoblasts to increase COX-2 activity and expression of RANKL while simultaneously decreasing expression of type 1 collagen and alkaline phosphatase; again Resp has little effect on these parameters. The recent identification of G-protein-coupled proton sensing receptors (PSRs) provides a potential mechanism for transduction of an acidic extracellular pH into cellular responses. We have identified transcripts for the 4 known PSRs, OGR1, GPR4, TDAG8, and G2A, in total RNA isolated from cultured calvariae. To determine if one or more PSRs modulate Met-stimulated bone Ca efflux, we utilized the PSR inhibitor $CuCl_2$ (100μM) and found that it significantly inhibited Met-induced Ca efflux. Activation of PSRs appears to be coupled to increased inositol phosphate (OGR1) or cAMP (GPR4, TDAG8, possibly G2A) production. Using changes in intracellular Ca (Ca_i) as a surrogate for changes in inositol phosphate, we performed fluorescent imaging of fura-loaded primary osteoblasts grown on glass coverslips. The cells were analyzed in a closed chamber with entry and exit ports to facilitate rapid medium change at a fixed pH, Pco_2 and $[HCO_3^-]$. Infusion of physiologic Met medium (pH = 7.11, Pco_2 = 45 mmHg, $[HCO_3^-]$ = 14 mM) induced a marked, rapid, flow-independent, transient increase in Ca_i in individual cells. In contrast, infusion of Resp medium (pH = 7.14, Pco_2 = 82 mmHg, $[HCO_3^-]$ = 26 mM) had no effect on Ca_i, even though the reduction in pH_i with Resp (as measured with BCECF) was at least as great as the reduction in pH_i with Met. These results indicate that a reduction in pH caused by a decrease in $[HCO_3^-]$ (Met) acts through a cell surface receptor, such as a PSR, to elicit Ca_i transients which may then modulate osteoblastic activity, implementing the subsequent increase in osteoclastic bone resorption. In contrast an equivalent reduction in pH caused by an increase in Pco_2 (Resp) did not elicit a Ca_i transient, indicating that the sensitivity of the PSR is modulated by $[HCO_3^-]$.

Notch1 Overexpression Inhibits Osteoblastogenesis by Suppressing Wnt/B-catenin but not BMP Signaling. V. Deregowski, E. Gazzerro, L. Priest*, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Notch are transmembrane receptors that control cell fate decisions. Upon Delta or Jagged/Serrate ligand binding, Notch receptors undergo proteolytic cleavages leading to the release and nuclear translocation of the Notch intracellular domain (NICD), where it regulates transcription. ST-2 cells transduced with a retroviral vector overexpressing Notch 1 (NICD) under the control of a cytomegalovirus promoter exhibit impaired osteblastogenesis. NICD overexpression inhibits the effect of bone morphpogenetic protein (BMP)-2 and Wnt3a on markers of osteoblastogenesis, such as mineralized nodule formation and alkaline phosphatase activity (APA). To explore the mechanisms involved, we examined whether NICD overexpression modified BMP or Wnt signaling. BMP-2 induced the phosphorylation of Smad 1/5/8 and enhanced the transactivation of a transiently transfected BMP-responsive 12xSBE-Oc-pGL3 construct, containing 12 repeats of a Smad binding site directing luciferase expression, but NICD overexpression did not modify the level of phosphorylated Smad 1/5/8 or the transactiviation of the 12xSBE construct in control or BMP-2 treated cells. BMP-2 had no significant effect on the phosphorylation of the mitogen activated protein (MAP) kinases ERK, p38 or JNK, and this was not changed by Notch. Since NICD overexpression prevented BMP-2 and Wnt induced osteoblastogenesis without altering BMP signaling, we examined whether Notch altered Wnt signaling. NICD overexpression decreased the activity of a Wnt/β-catenin responsive construct, pTOPFLASH, containing multiple Tcf4/Lef1 binding sequences upstream of the luciferase gene. NICD overexpression also decreased the levels of ß-catenin and transcripts of Wnt1 Induced Secreted Protein 1, a Wnt target gene involved in osteoblastogenesis. Transfection of a stable mutant β-catenin expression construct or the use of a Glycogen-Synthase Kinase 3β (GSK 3β) inhibitor (CHIR 99021), known to stabilize β-catenin by preventing its ubiquitination, partially rescued the inhibitory effect of Notch on Wnt signaling as determined by the transactivation of pTOPFLASH, despite a normalization of β-catenin levels by the GSK 3β inhibitor. Accordingly, GSK 3ß inhibition only partially rescued the suppression of APA caused by Notch, indicating that restoration of β-catenin levels is not sufficient to rescue Wnt signaling and activity. In conclusion, Notch1 overexpression prevents BMP-2 and Wnt biological effects, without altering BMP signaling, indicating that Wnt signaling is required for osteoblastogenesis. Notch1 acts by reducing β-catenin levels and by alternate signals to suppress the Wnt/β-catenin pathway.

Expression of Phosphodiesterase 4 Variants in Osteoblastic Cells. C. Nomura-Furuwatari*, Y. Ohta*, Y. Imai, K. Nakagawa*, K. Takaoka. Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

Bone formation is promoted with the treatments of BMPs and/or chemical compounds. Rolipram, a selective inhibitor of phosphodiesterase 4 (PDE4), is one of the chemical compounds promoting ossification in vivo. Four genes encoding PDE4 isoforms (PDE4A, PDE4B, PDE4C and PDE4D) are found in mammalian. Alternative splicing of PDE4 genes generates approximate 15 kinds of PDE4 variants. In order to identify active PDE4 variants in bone formation system, we investigated the expression of PDE4 variants in respond to BMP treatment in osteoblastic cells. Expression of four PDE4 isoforms in osteoblastic cells was detected by RT-PCR. PDE4A and 4D were detectable in ST2, MC3T3-E1, C3H10T1/2 and primary-cultured calvarial osteoblast (PCO). PDE4A and PDE4D splicing variants in ST2 and PCO were identified by 5'-RACE method. PDE4A1, PDE4A10 and a novel variant of PDE4D were detected in ST2 cells. PDE4A10, PDE4D1, and the novel variant were detected in PCO. Previous reports indicated the induction of several variants with the increase of intracellular cAMP concentration. To examine the changes in the expression level of these variants with the treatment of BMP or cAMP, PCO was treated BMP4 and/or rolipram for 24 hours. Expression of PDE4A and 4D were quantified by real-time RT-PCR. PDE4D expression was increased 3 fold by the treatmnent of BMP4, 4 fold by rolipram, and 10 fold by both of BMP4 and rolipram respectively in compared to untreated cells. However, expression level of PDE4A showed no change with the treatment of BMP and/or rolipram. Real-time RT-PCR analysis showed that 4D1 was increased, but not in the novel variant. Induction of PDE4D1 by the elevation of intracellular cAMP concentration was also recognized in ST2, C2C12, MC3T3-E1 and C3H10T1/2. These results suggest that PDE4D1 is most important to control intracellular cAMP concentration in osteoblastic cells. Therapeutic potential of PDE4 inhibitors has been reported to cause some side-effects e.g. nausea and vomiting. Identification of PDE4 splicing variants expressing in bone formation is required for the development of compounds of lesser side-effects.

Roles for c-Abl in BMP Signaling, Id1 Expression, and Osteoblast Senescence. H. Kua*[1], Y. Hu*[1], X. Wang*[1], S. Boast*[2], S. Goff*[2], B. Li[1]. [1]Institute of Molecular and Cell Biology, Singapore, Singapore, [2]Columbia University, New York, NY, USA.

Mice lacking c-Abl exhibit a variety of complex phenotypes including retarded growth, premature death, lymphopenia and aging associated osteoporosis. Yet little is known on how c-Abl deficiency led to these abnormalities. We thus used the bone phenotypes to dissect the physiological function of c-Abl. Here we report that *c-Abl*$^{-/-}$ osteoblasts showed reduced proliferation potential and they underwent premature senescence, manifested by increased expression of senescence associated β galactosidase and $p16^{INKa}$, without affecting the expression of p19/p53/p21. The elevated p16 expression in *c-Abl*$^{-/-}$ osteoblasts was likely achieved by enhanced activation of ERKs (positive regulator) and down-regulation of Id1 (a negative regulator). c-Abl was found to positively regulate expression of Id1, a target gene of BMPs that are synthesized and secreted by osteoblasts, by modulating Smad1/5/8 phosphorylation, indicating a positive role for c-Abl in BMP signaling. In accordance, blockade of BMP actions by noggin/chordin resulted in a reduction of Id1, up-regulation of p16, and retarded growth in osteoblasts. This premature senescence of *c-Abl*$^{-/-}$ osteoblasts could be rescued by c-Abl reconstitution or retroviral expression of Id1, and could be abrogated by p53 deficiency, but appeared to utilize a distinct mechanism from oxidative stress induced senescence. Our findings revealed novel roles for c-Abl in the BMP signaling pathway, Id1 induction, and osteoblast senescence. *c-Abl*$^{-/-}$ mice present an animal model that links premature senescence of osteoblasts to aging associated osteoporosis.

Characteristics of Circulating Mesenchymal Stem Cells in Fracture Non-Union Patients. C. Wan, Q. He*, M. McCaigue*, D. Marsh*, G. Li. Department of Trauma and Orthopaedic Surgery, Queen's University of Belfast, Belfast, United Kingdom.

The existence of peripheral blood derived mesenchymal stem cells (PB-MSCs) have been documented in adult human with low numbers. We have demonstrated previously that the number of PB-MSCs increased in the patients with fracture non-union. The present study was to compare the biological characteristics of the PB-MSCs from fracture non-union patients, with human bone marrow derived MSCs (BM-MSCs). 200 ml PB was collected from fracture non-union patients (n=9) and normal donors (n=8). Bone marrow from patients undergone hip replacement were used as controls. The mononuclear cells (MNCs) were isolated and cultured in α-MEM containing 15% FBS. The colony forming efficiency (CFE) of the PB-MNCs and BM-MNCs was calculated, and the phenotypes of PB-MSCs and BM-MSCs were compared using immunocytochemistry and flow cytometry methods. Their multipotent differentiation potentials into osteoblasts, chondrocytes, adipocytes, neurogenic and angiogenic cells were examined under specific inductive culture media. The in vivo osteogenic potential of PB-MSCs was examined by implanting the HA-TCP blocks seeded with PB-MSCs into the SCID mice for 12 weeks. After 28 days in culture, fibroblastic colonies were formed in the PB-MNCs cultures in 5 of 9 fracture non-union patients, with CFE ranging from 2.08-2.86 per 10^8 MNCs. No fibroblastic colony was seen in PB-MNCs cultures of the 8 normal donors. Under flow cytometry examination, PB-MSCs and BM-MSCs were CD34 (low) and CD105+, but PB-MSCs were CD29-, CD44-, and ALP (low), whereas BM-MSCs were CD29+, CD44+, and ALP (high). Under specific differentiation inductions, the PB-MSCs differentiated into osteoblastic cells (ALP+, type I collagen+, osteocalcin+); chondrocytes (type II collagen+ and Alcian Blue nodules+); adipocytes (Oil red-O positive lipid accumulation). Neurogenic and endothelial differentiation of the PB-MSCs were also confirmed. For implantation study, newly formed woven bones were found in the biomaterials seeded with PB-MSCs, and they were positive for human osteocalcin immunostaining. This study indicated that there were more PB-MSCs in the peripheral circulation of the fracture non-union patients than that in the normal subjects. The PB-MSCs were clearly multi-potential cells, which had shared some common phenotypic markers with BM-MSCs, as well as many distinguishable makers from the BM-MSCs. The recruitment of the PB-MSCs through circulation might be a general phenomenon of systemic responses in many pathological conditions, such as fracture or wound healing and other systemic diseases. Further understanding the roles of PB-MSCs in diseases and repair may lead to novel therapeutic strategies.

Immunity of Allogeneic Mesenchymal Stem Cells. X. Chen*[1], M. Armstrong*[2], G. Li[1]. [1]Department of Trauma and Orthopaedic Surgery, Queen's University of Belfast, Belfast, United Kingdom, [2]Department of Immunology, Queen's University of Belfast, Belfast, United Kingdom.

Interactions between T cells and mesenchyaml stem cells (MSCs) demonstrated that MSCs possessed immuno-suppressive properties and were able to escape the host immune surveillance. The aim of this study was to examine the xenogeneic properties of rat mesenchymal stem cells (rMSCs) and their terminally differentiated cells upon contact with human lymphocytes and dendrtic cells (DCs). Rat mononuclear cells (rMNCs) were harvested from adult GFP rat femur and cultured in DMEM at a concentration of 3×10^5cells/cm^2 for 2-3 weeks. The attached primary rMSCs were passaged and subjected to adipogenic, chondrogenic and osteogenic media for further 13-28 days. The growth

kinetics of the rMSCs was assessed by BrdU incorporation and ELISA methods. Histology and immunocytochemistry (ICC) staining were used to confirm the phenotypes of differentiated rMSCs. The undifferentiated and differentiated rMSCs were seeded onto 96-well plates serving as target cells and human peripheral blood lympocytes (hPBLs) as effecter cells. The released lactate dehydrogenase (LDH) upon cell lysis was measured. A Dunn chamber chemotaxis analysis system was used to investigate the chemotatic potentials of rMSCs to human peripheral blood monocyte-derived DCs (hDCs). The migration of differentiated and undifferentiated rMSCs in the Dun chamber system was tracked over a 10-hour period from the time-lapse images and statistically analysed. ICC and histology examinations confirmed the differentiation of rMSCs into osteoblasts, chondrocytes and adipocytes under induction media culture. The rate of cell proliferation was significantly reduced in rMSCs under chondrogenic induction. The chondrogenic MSCs had shown significant higher cyto-toxicity upon co-culture with hPBLs ($p=0.737$ VS positive control), while the other three test groups had low level of cyto-toxicity when compared with positive controls (pMSCs=0.000, pAdi=0.000, pOsteo=0.001). For Dunn chamber chemotaxis test, only chondrogenic rMSCs migrated towards to hDCs during 10h period (speed = 18.30 ± 1.86 μm/ hr, $p< 0.0001$), while cell in the other groups showed random movements. The data indicated that among the three differentiated lineages, only chondrogenically differentiated MSCs were capable of interacting with DCs, and eliciting T cell-mediated cytotoxic immune responses in vitro. The adiogenic and osteogenic MSCs retain their immuno-suppressive properties as undifferentiated MSCs. Thus, allogeneic MSCs may be used to repair bone and soft tissue damages, but chondrogenically differentiated allogeneic MSCs may induce immune responses leading to their destruction.

The Effect of Osteoactivin (OA) in Mesenchymal Stem Cell Differentiation. M. C. Rico, S. Salihoglu*, M. P. Hurley*, A. I. Nwaneshiudu*, S. N. Popoff, F. F. Safadi. Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA.

Bone development is a complex process involving the expression of multiple genes coding for proteins that specifically induce the differentiation and activation of osteogenic cells. In particular, the differentiation of osteoblasts is a critical component requiring the expression of specific growth factors and regulatory proteins that control cell proliferation, differentiation and maturation. Among these proteins, osteoactivin (OA) has been implicated in osteoblast differentiation and function. Our laboratory previously showed that over-expression of OA in osteoblasts leads to an increase in their differentiation and function. In this study, we examined the effects of OA in mesenchymal stem cell (MSC) differentiation using the C2C12 and C3H10T1/2 MSC lines. OA was over-expressed in MSCs using a retroviral system. Osteoactivin protein expression was increased two-fold in over-expressing cells compared to Lac Z control cells for both C2C12 and C3H10T1/2. In addition, OA infection was compared to BMP-2 stimulation in the differentiation of MSCs. As expected, BMP-2 treatment alone of MSCs showed a moderate increase in the number of alkaline phosphatase (ALP) positive cells, increased in ALP cytoplasmic granule size and color intensity, indicating that BMP-2 was contributing to osteoblast differentiation. Furthermore, when MSCs were infected with an OA retrovirus, it showed an increase in the number of ALP positive cells in OA infected compared with uninfected cells. Moreover, OA infection showed even greater ALP staining when compared to BMP-2 stimulation. The most dramatic increase in the number of ALP positive cells were observed when MSCs were sequentially infected with OA retrovirus followed by BMP-2 stimulation. Interestingly, the C2C12 cells over-expressing OA showed a decrease in myocyte differentiation when compared to control cells. This was determined by visualization of contracting myocytes and staining for MF20, a marker for differentiating myoblasts. Using immunofluorescence staining, C3H10T1/2 OA over-expressing cells showed a dramatic increase in cell size and the formation of focal adhesion complexes. Overall, this data suggest that OA may play an important role in osteoblast differentiation from MSCs, possibly independently from BMP-2 stimulation. Future studies are required to determine the mechanism/s of action of OA in inducing MSCs commitment into osteoblasts.

Calcium Receptor Expression and the Effects of Different Extracellular Calcium Concentrations on VCAM+ Murine Bone Marrow Cells. T. Chen, L. Rodrigues*, W. Chang, D. Shoback. Endocrine Research Unit, VA Medical Center, San Francisco, CA, USA.

Previous studies have shown that cell populations derived from bone and bone marrow respond to exposure to different extracellular calcium concentrations ([Ca]e). Changes in [Ca]e have been implicated in the regulation of osteoblast proliferation and DNA synthesis, macrophage migration, osteoclast-mediated bone resorption, gene expression, and signal transduction. We previously showed that high [Ca]e stimulated the formation of tartrate resistant alkaline phosphatase (TRAP)+ cells, TRAP activity, and the expression of TRAP-5b and calcitonin receptor mRNA in cultured murine bone marrow cells indicating enhanced development of osteoclasts in these marrow cultures. To determine whether high [Ca]e were affecting gene expression globally and whether CaRs might mediate these effects, we isolated marrow from 6-week old male Black Swiss mice and sorted out bone marrow stromal cells (BMSCs) positive for CD106 or vascular cell adhesion molecule 1 (VCAM-1) by magnetic-activated cell sorting (MACS) using monoclonal antibodies to VCAM-1. We assessed the expression of the Ca receptor (CaR), VCAM-1 and the cell surface marker CD44 by confocal immunocytochemistry and changes in gene expression (osteopontin, OP; receptor activator of nuclear factor kappa B ligand, RANK-L; osteoprotegerin, OPG; type 1 collagen, coll 1) by real time quantitative PCR (qPCR). In >80% of freshly isolated VCAM-1+ BMSCs, we observed strong cell-surface expression of CaRs that co-localized with the surface markers VCAM-1 and CD44. CaR immunoreactivity was also present in submembrane compartments. CaR expression persisted with culturing VCAM+ cells for 3 days at 1.8 mM Ca and co-localized with the surface marker CD44. qPCR was performed on RNA isolated from VCAM-1+ cells grown at different [Ca]e for 7 days, and results were normalized to the mouse L19 gene (N=2 experiments in triplicate). OP mRNA increased at [Ca]e of 1.7-, 5.0-, and 7.8-fold at 1.0, 3.0 and 6.0 mM Ca vs control cultures at 0.5 mM Ca. RANK-L RNA rose by 1.7-, 7.3- and 19-fold at 1.0, 3.0 and 6.0 mM Ca vs cultures grown at 0.5 mM Ca. There were no significant changes in OPG and coll 1 mRNA over the range of [Ca]e tested. These studies indicate that CaR protein is exressed in VCAM-1+ BMSCs and that high [Ca]e selectively regulate gene expression and in particular the expression of RANK-L mRNA, a surface molecule essential in the development and maintenance of function of bone-resorbing osteoclasts. These studies support a role for Ca generated locally in the bone microenvironment in the control of bone resorption. Studies are in progress to assess the role of CaRs in Ca-sensing by BMSCs.

Quantitative Analysis of Bone Marrow, Fat, and Muscle as Sources of Human Connective Tissue Progenitors. C. Nakamoto*, C. Boehm*, D. Zamborsky*, H. Tao*, K. Powell*, G. F. Muschler. Biomedical Engineering, The Cleveland Clinic Foundation, Cleveland, OH, USA.

Adult musculoskeletal tissues contain heterogeneous populations of stem cells and progenitor cells (connective tissue progenitors, CTPs). The design of optimal methods for CTP targeting, harvest or processing for autogenous cell therapy requires characterization of the demographics of the CTP populations in normal tissues and their biological potential, which was the aim of this study. Bone marrow aspirates (BM), fat, and muscle tissue samples were obtained from 6 human subjects (age, 68~70). Fat and muscle tissue samples were minced and treated with collagenase type I and dyspase. Cells from BM, fat, and muscle were counted and assayed for prevalence of CTPs using an established CTP colony formation assay. At day 6 cells were fixed and stained with DAPI. Fluorescent images of CTP cultures were acquired with a CCD camera. Quantitative characterization was performed on 3890 colonies (cell number, colony area) using a custom software. Fat and muscle samples (mean volume 3.1±1.0 ml and 1.3±0.6 ml, respectively) provided 10.6±11.3x10^6 cells/ml and 12.2±11.3x10^6 cells/ml, respectively, and a prevalence of 698±1137 and 150±152 CTPs/10^6 cells, respectively. In contrast, an average bone marrow aspirates provided 25±13x10^6 cells/ml with a prevalence of 45±36 CTPs/10^6 cells. The concentration of nucleated cells in a BM aspirate sample was roughly a 2 fold higher than fat or muscle. However, the prevalence of CTPs among nucleated tissue-derived cells was the highest in fat (4 fold higher than muscle and 15 fold higher than BM). Furthermore, the overall concentration of CTPs was highest in fat (7400 CTPs/ml) compared to 1830 CTPs/ml in muscle and 1120 CTPs/ml in marrow aspirate). Colony size varied widely in all tissues, implying mean cycle times ranging from 17.9 to 32.8 hours. Fat-derived CTPs demonstrated lower mean proliferation rate, lower cell density in a colony than both muscle- and BM-derived cells. These data support the demographics of CTPs in marrow, fat, and muscle differs significantly. The biological potential of CTPs populations resident in these tissues also differs significantly, as manifest by differences in colony size and morphology (proliferation, migration and differentiation) under standardized conditions. Colony level analysis of CTPs is required to characterize the heterogeneity of tissue resident and tissue derived CTPs. Using morphometry and additional differentiation markers in vitro, to quantify subsets of tissue resident CTPs, this analysis can be a powerful tool for CTP population-based analysis.

The Effects of the Angiogenic Inducer hCyr61 (CCN) on Human Bone Marrow-Derived Mesenchymal Stem Cells and the Endothelial Cell Line EAhy 926 - a Gene Expression Study. R. Wagemanns*, S. Jatzke*, F. Welzel*, U. Noeth*, F. Jakob*, N. Schuetze. Molecular Orthopaedics, Orthopaedic Institute, Wuerzburg, Germany.

The human cystein rich protein 61 (hCYR61/CCN1) belongs to the CCN family of proteins which plays a role in fundamental cellular processes such as proliferation, differentiation and angiogenesis. Aim of the present study was to identify additional target cells for hCYR61 action in the bone microenvironment and to define the hCYR61 function at the level of gene expression profiling. Mesenchymal stem cells (MSCs) from human bone marrow were isolated from the femoral head obtained from patients undergoing total hip arthroplasty. Recombinant hCYR61 protein (rhCYR61) was purified from supernatants of baculovirus infected SF21 insect cells by affinity chromatography with protein G sepharose. Expanded MSCs and the endothelial cell line EAhy 926 were treated with rhCYR61 for various time points and concentrations. The proliferation of MSCs and EAhy 926 was determined photometrically using the WST-1 test. Total RNA was isolated and amplified according to standard procedures. The global gene expression pattern was performed with RNA from MSCs treated with rhCYR61 for 4 and 24 hours and with the EAhy 926 treated for 4 hours using the Affymetrix Chip HG-U133. Array analysis data were reevaluated by RT-PCR. MSCs and the endothelial cell line EAhy926 responded to the rhCYR61 treatment with an increase in proliferation rate of 30-100% in the concentration range of rhCYR61 between 0,5 and 1,5 µg/ml cell culture medium. Array analysis of the MSCs identified rhCYR61-dependent gene products which represented transcription factors, growth factors and chemokines (25 candidates, 6 up, 9 down, cut off 2,5-fold regulation). Results indicate that human bone marrow-derived MSCs and endothelial cell line EAhy 926 are target cells for rhCYR61 function. The regulation

pattern of rhCYR61-dependent gene products strengthens the view that hCYR61 represents an integrator for signal transduction processes in cells within the human bone microenvironment. The extracellular signaling protein hCYR61 could represent an important control factor to enhance the stem cell pool. Together with its function in human osteoblasts and the role as an angiogenesis promoter the protein represents a candidate to coordinate tissue regeneration.

Calcium Phosphate Surfaces Promote Osteogenic Differentiation of Mesenchymal Stem Cells. P. Muller*[1], U. Bulnheim*[1], A. Diener*[1], F. Luthen*[1], B. Nebe*[1], K. Klinkenberg*[2], H. Neumann*[2], A. Liebold*[3], C. Stamm*[3], J. Rychly[4]. [1]Department of Internal Medicine, University of Rostock, Rostock, Germany, [2]DOT GmbH, Rostock, Germany, [3]Department of Cardiac Surgery, University of Rostock, Rostock, Germany, [4]Experimental Research Center, University of Rostock, Rostock, Germany.

Expansion and differentiation of mesenchymal stem cells on a scaffold in vitro which then can be implanted into bone represents a promising approach to regenerate bone after defects. We tested the effect of material surfaces on the differentiation of human mesenchymal stem cells. Mesenchymal stem cells were isolated from human bone marrow by cell adhesion to a purity of 95 % as tested by cell surface markers. After 14 days in expansion medium cells were seeded on a degradable xerogel composite (BONIT®matrix) composed of hydroxyapatite and β-tricalcium phosphate (XC), on hydroxyapatite coated titanium (HA) and on tissue culture plastics (TC) and cultured for further 14 days in osteoblastic differentiation medium containing glycerophosphate, ascorbic acid and dexamethasone. By staining of alkaline phosphatase (ALP) as a marker for differentiated osteoblasts we found that cells on XC and HA revealed a higher expression of ALP compared with cells on TC. We then further tested whether expansion medium is sufficient to differentiate stem cells to osteoblasts on the material surfaces. After 7 and 14 days in this medium we found a significant number of differentiated osteoblasts on XC and HA, whereas cells on TC remained negative for ALP. This result indicates that the material surfaces which contained calcium phosphate stimulate the differentiation of mesenchymal stem cells and suggests that characteristics of the material surfaces may replace the effects of components in the differentiation medium. Concerning cell characteristics that are related to cell adhesion we found a more compact cell morphology and a higher mobility of focal adhesions on calcium phosphate surfaces compared with tissue culture plastics. As a general mechanism that is probably involved in the switch from proliferation of mesenchymal stem cells to osteoblast differentiation we observed a translocation of the cell cycle inhibitor $p21^{Cip/WAF1}$ from the nucleus on day 7 of the cell culture to the cytoplasm on day 21. Together, the results indicate that calcium phosphate surfaces promote osteogenic cell differentiation which is controlled by cell adhesion mechanisms. As a general mechanism of the switch from proliferation to osteoblast differentiation we propose an intracellular translocation of the protein $p21^{Cip/WAF1}$.

Central Control of Bone Marrow Adipocyte Populations by Leptin. M. Hamrick[1], M. Della-Fera*[2], D. Hartzell*[2], Y. Choi*[2], C. Baile[2]. [1]Medical College of Georgia, Augusta, GA, USA, [2]University of Georgia, Athens, GA, USA.

Bone marrow adipogenesis is known to increase with age, and bone formation rate is inversely correlated with adipocyte number in bone biopsies of adult men and women. The negative impact of marrow adipogenesis on bone health is further indicated by the fact that women with osteoporosis have higher numbers of marrow adipocytes than those women with healthy bone. We have shown that leptin-deficient mice have low bone mass in the limb skeleton, and their limb bones also show increased bone marrow adipogenesis. We have also found that peripheral leptin treatment in leptin-deficient ob/ob mice reduces bone marrow adipocyte size and number, and that intracerebroventricular (icv) administration of leptin in rats causes adipose tissue in peripheral fat depots to undergo apoptosis in addition to activating lipolysis. We tested the hypothesis that leptin-induced reduction of bone marrow adipocyte number is mediated through a central, hypothalamic signaling pathway. Direct hypothalamic (ventromedial hypothalamus) injections of either vehicle (aCSF, 0.5 µl/injection) or 0.5 µg/day leptin (0.25µg/injection) were administered to male Sprague-Dawley rats (n=10 per group) twice daily for five days. The right tibia was cut across the proximal third of the shaft, decalcified in EDTA, embedded in paraffin, and sectioned at 5µm. Adipocytes were counted over a 0.10 mm^2 area and adipocyte density (N.At/Ma.Ar) expressed as the number of adipocytes per tissue area. Bone marrow was flushed from the right femur and a Beadlyte suspension array used to analyze adipocyte apoptosis in marrow samples using caspase-3 concentration as an apoptotic marker. Analysis of the proximal tibias from treated rats reveal that central (VMH) leptin administration significantly ($P<.001$) decreased adipocyte number by more than 50% in bone marrow. Analysis of caspase-3 concentration in bone marrow taken from the hindlimbs of control and treated rats reveals that leptin treatment significantly ($P<.001$) increased caspase-3 levels in bone marrow. Together, these data suggest that leptin regulates adipocyte apoptosis in bone marrow through a central, hypothalamic signaling pathway.

Osteoporosis and Impairment of Osteoblast Differentiation in Mouse Models of Accelerated Aging. R. J. Pignolo[1], Y. Choi*[2], F. B. Johnson*[2]. [1]Department of Medicine, University of Pennsylvania, Philadelphia, PA, USA, [2]Department of Pathology, University of Pennsylvania, Philadelphia, PA, USA.

Telomeres shorten with age in most human tissues, including bone, and because telomere shortening is a cause of cellular replicative senescence in cultured cells, including osteoblasts and mesenchymal stem cells (MSCs), we hypothesized that telomere shortening contributes to the aging of bone. Since laboratory strains of mice have telomeres that are 5-10 times longer than human telomeres, mice must lack telomerase for several generations (3-6, depending on genetic background) before telomeres become critically short and phenotypic defects can be easily detected. Osteoporosis is common in individuals with the Werner (WRN) premature aging syndrome. One of the targets of the WRN helicase is telomeric DNA and, given that mice have much longer telomeres than humans, murine telomeres never become short enough to elicit the "aging" phenotypes (in the absence of WRN) that occur in human cells. By combining the WRN mutation with the shortened telomeres of telomerase (TERC) knockout mice, synthetic defects in proliferative tissues have been observed. Here we demonstrate for the first time that deficiencies in genome maintenance molecules such as TERC and WRN, alone or in combination, cause a low bone mass phenotype (as measured by small animal DXA) and are the result of impairment in osteoblast differentiation and function. Markers of bone formation are reduced or absent in bone marrow-derived MSCs from WRN and TERC mutant mice while osteoclast differentiation is unchanged. We also show that bone marrow-derived MSCs from mutant mice have a reduced in vitro life span and display impaired osteogenic potential concomitant with characteristics of premature senescence. These data provide strong evidence that replicative aging of osteoblast precursors is an important mechanism of senile osteoporosis.

The Importance of Extracellular Matrix Components in the Culture and Differentiation of Adult Human Mesenchymal Stem Cells. T. Helledie*, C. Dombrowski*, Z. Zhou*, V. Nurcombe*, S. Cool. Stem and Tissue Repair, Institute of Molecular and Cell Biology, Singapore, Singapore.

In all tissues of the body there is a sub-population of adult stem cells. These multi-potential cells are recruited and activated to take part in tissue regeneration. Adult stem cells are a promising resource for therapy, but their numbers are low and they need propagation in vitro to be of therapeutic use. When these cells are cultured ex vivo it has proven difficult to recreate their natural microenvironment - “the niche”. The niche is a sum of signals from interactions with the extracellular matrix (ECM) and neighboring cells, and the hormonal status in the microenvironment. In addition to the direct interaction with the stem cells, specific components of the ECM play key roles in the regulation and presentation of growth and adhesion factors, thus controlling intracellular signaling. By adding proteoglycan together with growth factors to the culture of bone marrow-derived adult human mesenchymal stem cells (hMSC), we have optimized the culture conditions for growth and differentiation of these cells. We have analyzed the effect of the proteoglycans on proliferation and differentiation of hMSC by using FACS analysis, CFU-F assays and differentiative staining. Knowledge of the interactions between proteoglycans, tissue-specific mitogens and other elements of the stem cell niche will ultimately lead to key discoveries in the use of ECM components for tissue engineering.

The Role of Stromal Derived Factor-1 Alpha in Bone Remodelling. A. Zannettino*, A. Kortesidis*, A. Farrugia*, S. Gronthos. Division of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia.

The balance between bone formation and resorption is regulated by different cellular components within the bone marrow microenvironment. We surveyed a stromal cell cDNA library constructed from purified bone marrow stromal stem cells (BMSSC) in order to identify putative regulatory factors of bone turnover. Stromal derived factor-1 alpha (SDF-1) was one highly expressed gene found to be prevalent in uncommitted BMSSC. The chemokine, SDF-1 and its receptor, CXCR4 are involved with various functions such as mediating trafficking of cells between the bone marrow and peripheral blood. In the bone marrow, SDF-1 is expressed by endothelial cells, perivascular cells, some stromal elements in the marrow spaces and at the endosteal surfaces. We found that immature pre-osteogenic cells expressed greater levels of SDF-1 when compared with differentiated bone cells including osteoblasts, bone lining cells and osteocytes. Correspondingly, SDF-1 gene expression was rapidly down-regulated when BMSSC were cultured under osteoinductive conditions. Retrovirally transduced BMSSC, secreting high SDF-1 levels, displayed an enhanced ability to form ectopic bone in vivo and an increased capacity for cellular growth and survival in vitro. To examine the effect of SDF-1 on bone resorption, peripheral blood-derived osteoclast precursor cells were cultured under osteoclast-inductive conditions in the presence of recombinant human SDF-1. Our studies showed that SDF-1 mediated a measurable increase in both the number and the size of the resorption lacunae formed. The SDF-1 induced osteoclast activation correlated to an increase in the expression of a number of osteoclast associated genes including, RANKL, RANK, TRAP, matrix metalloprotease-9, Carbonic Anhydrase II, and Cathepsin K. In summary, our data suggest that SDF-1 plays a role in the maintenance and survival of immature BMSSC, and the recruitment and activation of osteoclast precursor cells.

Heparin Promotes Adipogenic Differentiation of Mesenchymal Precursors by Altering Cell-Eextracellular Matrix Interactions. W. Luo*[1], M. S. Friedman*[1], C. N. Bennett*[1], O. A. MacDougald*[2], J. D. Miller*[1], K. D. Hankenson[1]. [1]Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA, [2]Molecular and Integrative Physiology, University of Michigan, Ann Arbor, MI, USA.

A variety of growth factors have reciprocal effects on the osteoblast and adipocyte differentiation of marrow-derived mesenchymal progenitors. Recent work suggests that heparin has a positive affect on adipocyte differentiation, while, heparin negatively affects bone formation in vivo and osteoblast cell differentiation and function in vitro. In this study we have further explored the role of heparin in adipogenic induction of mesenchymal precursors. We have found that heparin is not sufficient to induce adipogenic induction of three different mesenchymal progenitors (immortalized murine marrow stromal cells, ST2 cells, or 3T3L1 preadipocytes), but heparin can potentiate adipogenic induction of these cells. Indeed, heparin is not sufficient to induce expression of the adipocyte transcription factors, PPAR-gamma and C/EBP-alpha, nor the later stage adipocyte markers, LPL and FABP4, but heparin treatment in combination with standard adipogenic induction results in enhanced expression of these genes. This effect is dose and time dependent; heparin promotes adipogenic differentiation at concentrations greater than 0.1 microgram/ml when applied before day 3 of induction. The effect of heparin is independent of cell proliferation and cell density, and experiments with two different lipid-free conditions, serum-free and delipidated serum, indicate that heparin promotes adipogenesis independent of extracellular lipid or lipoprotein lipase activity. The effect of heparin is not due to its strong anionic charge because another anionic glycosaminoglycan, dextran, does not promote differentiation. Remarkably, short-term heparin treatment alters the morphology and adhesion characteristics of progenitor cells and longer treatment, in association with adipogenic induction, results in cell rounding and aggregation. In addition, heparin is able to counteract the negative effects of strong adhesive substrates, such as fibronectin, collagen and poly-L-lysine, on adipogenesis. We hypothesize that heparin promotes adipogenesis by disrupting cell-extracellular matrix interactions. This is consistent with recently published studies which suggest that cell rounding and subsequent inhibition of Rho signaling is required for adipogenesis, while Rho activation leads to osteoblasts formation.

Comparing Osteoprogenitor Source and Transplantation Protocols. L. Wang*, Y. Liu*, X. Jiang*, D. W. Rowe. Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA.

As interest in the therapeutic use of adult stem stems increases, it will become increasing difficult to judge which source of progenitor cells or transplantation protocol is optimal for engraftment and integration into host bone. Because the number of combinations that need to be evaluated will be large, a rapid and sensitive method will be required to identify promising strategies. We are utilizing bone restricted promoter-GFP constructs to distinguish between host and donor contribution to bone formation when progenitor cells are injected into the host marrow space. A comparison of transplantation of syngeneic C57Bl/6 donor -> recipient protocol with or without concomitant total body irradiation (TBI) and bone marrow transplantation (BMT) clearly showed greater engraftment when the endogenous bone is forced to recover from TBI. Thus the TBI/BMT protocol makes allogenic transplantation a feasible method for engraftment evaluation and experience to date shows persistence of donor derived osteoblasts for at least 6 months. Comparison of various sources of progenitor cells indicate that freshly isolated calvarial digest cell exceed culture expanded calvarial cells, marrow stromal fibroblasts cultures grown either at low density or in the presence of FGF2 in their ability to engraft and make new bone matrix. Extended passaging or time in culture further reduced osteogenic differentiation. Freshly obtained calvarial cells also exceeded the ability of other progenitor cells to distribute widely throughout the marrow space. Adipose derived stromal cells and dermal fibroblast failed to show osteogenic activity. The possibility of inducing immune tolerance by systemic transplantation of new born mice was examined. While wide tissue distribution including bone and persistence of injected cells was observed, the engrafting cells were not osteogenic. Dermal fibroblasts exceeded osteoprogenitor cells derived from calvaria or marrow stromal in their ability to home to bone. To make these transplantation experiments more quantitative, protocols are being developed that use three colors of GFP to identify the host, reference donor and test donor cells. Similar to the competitive engraftment protocol used in the hematopoietic field, this approach not only relates the relative engraftments of the test versus a reference progenitor cell but can be used to assess intramarrow distribution and longevity. Developing standardized and quantitative methods for evaluating transplantation protocols and progenitor cell populations will be a requirement of federal licensing authorities and the reagent mice discussed here provide one avenue to meet this demand.

***In Vivo* Expansion and *In Vitro* Characterization of Pluripotent Adherent Stromal Cells in Mouse Adipose Tissue.** Z. Huang[1], J. Bryan*[1], H. Yu*[1], W. Horton[2], L. Sandell[1]. [1]Orthopaedic Surgery, Washington University, St Louis, MO, USA, [2]Oregon Health Sciences University, Portland, OR, USA.

Pluripotent adherent stromal cells (ASC) are a rare stem cell population that exists in the "niche" environment of many adult tissues. Scarcity of ASCs, immature in vitro culture condition and lack of unique cell surface markers hinder in vitro rapid expansion and purification of ASCs from transgenic and knockout mice. To address this, we investigated whether it was feasible to in vivo expand pluripotent adipose ASCs. 4 weeks old (4 wks) and 8 weeks old (8 wks) C57/B6 male mice were divided into 2 groups each and fed on normal diet (ND) and high fat diet (HFD) for approximately 2 and half months. Body weights were increased by 57%, 148%, 28% and 68% for mice on ND (4 wks), HFD (4 wks), ND (8 wks) and HFD (8 wks), respectively. Total fat weights (visceral and inguinal fat pats) were 0.88, 4.11, 0.60 and 3.60 grams for mice on ND (4 wks), HFD (4 wks), ND (8 wks) and HFD (8 wks), respectively. HFD increased total fat accumulation by 3.7 fold and 5.0 fold for mice (4 wks) and (8 wks), respectively. Adipose ASCs were isolated by collagenase digestion and attachment selection. They were fibroblast-like with no adipocyte present. Total cell numbers were 2.4×10^4, 5.5×10^5, 3.4×10^4 and 7.2×10^5 for mice on ND (4 wks), HFD (4 wks), ND (8 wks) and HFD (8 wks), respectively. HFD increased total ASCs by 22.5 fold and 20.0 fold for mice (4 wks) and (8 wks), respectively. Interestingly, ASCs per gram of fat were also increased by HFD, with 4.5 fold and 3.1 fold for mice (4 wks) and (8 wks), respectively. Pluripotency of adipose ASCs was tested for their ability to differentiate into three cell lineages, adipocytes, osteoblasts, and chondrocytes. Adipogenic differentiation was evident by intense Oil Red staining and increased RNA levels of CEBPα, Adipsin, and PPARγ 1 and 2. Osteogenic differentiation was confirmed by increased nodule formation, Alizarin Red staining and increased RNA levels of alkaline phosphatase, osteopontin, and Runx2. Chondrogenic differentiation was confirmed by appearance of fluorescence in micromass culture using ASCs isolated from mice expressing EGFP under the type II-collagen promoter, and increased RNA levels of type II collagen, aggrecan, alkaline phosphatase and bone sialoprotein. Taken together, we have confirmed for the first time that mesenchymal ASC in adipose tissue can be expanded in vivo and have successfully established new methods to verify pluripotency of ASCs in vitro. Successful expansion and isolation of pluripotent ASCs in large quantity will facilitate further study of molecular mechanisms of mesenchymal cell differentiation in vitro using transgenic and knockout mice.

Critical Requirement of JNK Activity for the Maintenance of Commitment to Osteoclasts. E. Chang*, J. Ha*, H. Huang*, H. Kim*, J. Ko. Cell and Developmental Biology, Seoul National Univ. College of Dentistry, Seoul, Republic of Korea.

Monocyte/macrophage lineage of hematopoietic cells serves as osteoclast precursors, which can further differentiate to mature osteoclast in microenvironment of bone. This precursor cells can differentiate to TRAP positive mononuclear pre fusion osteoclasts, which give rise to multinucleated osteoclasts in response to receptor aactivator of nuclear factor kB (NF-kB) ligand (RANKL). In this study, we found the mechanism by which JNK inhibition reverses the phenotype of mononuclear pre fusion osteoclasts into osteoclast precursors during RANKL-induced osteoclast differentiaion. We show that JNK inhibition by SP600125 treatment specifically inhibits early stage of osteoclast differentiation but not late stage of it. The inhibitory effect of SP600125 down-regulated mRNA of various markers of osteoclasts and TNF receptor 1 (TNFR1), TNFR2, and RANK. Furthermore, pre fusion osteoclast cells treated with SP600125 for 24 h showed low expression of TNFR1, TNFR2, and RANK and high expression of macrophage antigen CD11b. Interestingly, cells in the presence of SP600125 showed higher phagocytic activity than pre fusion osteoclasts. Consistent with this, JNK inhibition repressed human peripheral monocyte derived osteoclast differentiation at the stage of pre-osteoclasts. We propose that JNK activity is required at the stage of pre fusion osteoclast differentiation into mature osteoclasts by maintaining their phenotype of osteoclast lineage.

Osteoclasts Prefer Old Bone. D. J. Leeming*[1], R. H. Nielsen*[1], I. Byrjalsen*[1], M. G. Sorensen*[1], C. Christiansen[2], T. J. Martin[3], K. Henriksen[1], P. Qvist[1], M. A. Karsdal[1]. [1]Nordic Bioscience, Herlev, Denmark, [2]Center for Clinical and Basic Research, Ballerup, Denmark, [3]SVIMR, Melbourne, Australia.

Osteoclasts resorb bone in order to repair micro cracks to maintain the quality of bone. How osteoclasts target old bone in order to sustain the quality of the skeleton by constant remodelling is currently not known. We investigated the hypothesis that old bones accumulate signals, which target the bone for remodelling by osteoclasts. Human osteoclasts were assessed for their ability to resorb bone, survive and differentiate on old versus young bone. Bovine cortical bone slices from 9-month-old calves and 8-year-old cows were used. The bones were assessed by measuring the amount of native form (α-CTX) and the age-modified from (β-CTX) of collagen type I. Monocytes were isolated from human peripheral blood using a CD14+ bead sorting system, seeded on young and old bone and cultured in the presence of 25ng/ml of M-CSF and RANKL in 10% serum for 21 days. Mature human osteoclasts were seeded on young and old bone and cultured for 5 days in 10% serum with 25ng/ml M-CSF and RANKL, followed by 48 hours in 0.1%

BSA. Subsequently, osteoclast numbers were investigated by counting of TRAP positive multinuclear cells and measurement of TRAP activity. Osteoclastic resorption was investigated by measurement of the β-CTX in the conditioned medium. Cortical bones slices from old cows contained 3 times lower alpha/beta ratios than that of young bones ($p<0.01$). The formation of osteoclasts from osteoclast precursors cultured on young bone was more than 50% ($p<0.001$) reduced compared to those formed on old bone, and osteoclastic resorption measured by β-CTX was 80% ($p<0.001$) reduced on young bon compared to old bone. Mature osteoclasts were investigated by seeding already mature osteoclasts on young and old bone. Mature osteoclastic resorption was reduced 75% ($p<0.001$) on young bone compared to that of old bone. By counting of cells on the bones, it was found that old bones had two times ($p<0.01$) the number of multinuclear osteoclasts, whereas the number of mononuclear cells was two times higher on the young bone ($p<0.01$). To ensure that the differences observed between young and old bone were not caused by individual differences in the bones and animals, we investigated bones from 14 different old cows and 4 young calves and found similar results. In summary, these data clearly show that old bones are more susceptible to bone resorption by osteoclasts than young bones, and that old bone support osteoclastogenesis better than that of young bone. Thus, the age of the bones might play an important role in controlling the amount of resorption, and thus play important roles in targeting osteoclasts to old bone in the remodelling process.

Overexpression of ADAM8 in Osteoclast Precursors Increases Osteoclast Formation and Decreases Trabecular Bone Volume *In Vivo*. V. Garcia Palacios[1], M. A. Subler*[2], H. Y. Chung[1], S. J. Choi[1], K. Patrene*[1], H. C. Blair[3], J. J. Windle[2], G. D. Roodman[4]. [1]Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, [3]Pathology, University of Pittsburgh, Pittsburgh, PA, USA, [4]Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

Members of the ADAM (A Disintegrin And Metalloprotease) family of proteins are Type I transmembrane proteins involved in cell proliferation, differentiation, migration, adhesion, fusion, and cell morphogenesis. They are composed of several homologous structural domains including metalloprotease, disintegrin, cysteine-rich, EGF-like, transmembrane and cytoplasmic domains. We reported that ADAM8 is the ADAM family member most highly expressed in OCL precursors and that blocking ADAM8 expression inhibits OCL formation. ADAM 8 also appears to have a role in immune function through its capacity to induce leukocyte migration and cell adhesion. ADAM8 is upregulated in particle-induced arthritis, suggesting that overexpression of ADAM8 plays a role in the bone destruction associated with this process. It is our hypothesis that ADAM8 may be associated with a variety of inflammatory arthritides, and it may mediate the bone destruction in these conditions. To test this hypothesis, we targeted ADAM8 to cells in the OCL lineage in vivo using the TRAP promoter to measure the effects of increased ADAM8 expression on OCL activity in vivo. Transgenic mice overexpressing ADAM8 formed twofold more multinucleated TRAP (+) cells in marrow cultures than control mouse cultures. Importantly, as these mice increased in age, their OCL formation capacity increased up to threefold as compared with the wild type littermates. Micro-computed tomography analysis of the fifth vertebrae from TRAP-ADAM8 mice showed that the trabecular bone fraction (bone area/total area; BAr/TAr) was 40 ± 7%, vs. 59 ± 3.5% for wild type mice. These data demonstrating that increased expression of ADAM8 targeted to OCLs results in enhanced OCL formation, increased OCL precursors in vivo, and decreased trabecular bone, support an important role for ADAM8 in OCL formation and are consistent with ADAM8 mediating bone destruction in inflammatory bone disease.

The Expression of Novel Human RANKL mRNAs in Cell Types Associated with Inflammatory Bone Loss. N. C. Walsh[1], A. R. Pettit[2], C. A. Manning*[1], J. Wang[1], K. P. McHugh[1], E. M. Gravallese*[1]. [1]Beth Israel Deaconess Medical Center, New England Baptist Bone and Joint Institute, Harvard Medical School, Boston, MA, USA, [2]Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia.

RANKL expression is requisite for osteoclastogenesis in physiologic bone remodeling and in inflammation-induced bone loss. This study characterizes the expression of RANKL mRNA splice variants in cell types known to be sources of RANKL in inflammation-induced bone loss. RANKL was described as a membrane-bound protein that can be cleaved to produce a functional soluble protein. Splice variants of the human RANKL (hRANKL) mRNA have also been described including one encoding a putative secreted form (AB037599, Fig 1). We have identified two EST sequences (BC040889, BM564083) in the hRANKL UniGene Cluster Hs.333791, that have additional sequence 5' of the original secreted RANKL mRNA. Genomic mapping shows that this additional sequence represents a 5' extension of the first exon of AB037599 (designated E1C) and includes 2 novel exons, designated E1A and E1B upstream of E1C (Fig 1). Expression of the BC040889 transcript was verified by RT-PCR from the human osteosarcoma cell line, Saos-2, the Jurkat T cell line and from primary T cells. We have also identified a novel splice variant of this sequence that lacks E1C. Importantly, the expression of both of these novel hRANKL mRNAs is upregulated by TNF-α or PTHrP in Saos-2, and by activation in Jurkat and primary T cells (CD3/CD28 or PMA/ionomycin). The longest open reading frame for both transcripts begins at E2, the start of the extracellular domain of the RANKL protein, indicating that these transcripts encode a putative secreted form of this protein. Comparative genome analysis demonstrates the conservation of 1.8kB of sequence proximal to E1A, containing conserved binding sites for transcription factors implicated in inflammatory signaling. Preliminary studies indicate that this 1.8kb sequence acts as a basal promoter in transient transfection of Jurkat T cells and is inducible by PMA/ionomycin. This study is the first to identify the expression of mRNAs encoding a putative secreted form of hRANKL in cells known to express RANKL in inflammatory bone loss and highlights a novel regulatory region that may direct the expression of secreted hRANKL mRNAs in this setting.

Cell Cycle Progression and Arrest in the Presence of RANKL Are Necessary for Osteoclastogenesis. T. Mizoguchi*[1], Y. Yamamoto*[2], T. Yamashita[3], Y. Kobayashi[1], N. Udagawa[3], M. Ito*[1], N. Takahashi[4]. [1]Institute for Oral Science, Matsumoto Dental Univ., Nagano, Japan, [2]Aichi Gakuin Univ., Nagoya, Japan, [3]Biochemistry, Matsumoto Dental Univ., Nagano, Japan, [4]Graduate School of Oral Medicine, Matsumoto Dental Univ., Nagano, Japan.

Osteoclasts are terminally differentiated cells. We examined the role of cell cycle regulatory molecules in osteoclastogenesis. Mouse bone marrow macrophages (BMMϕ) differentiated into osteoclasts in the presence of M-CSF and RANKL within 3 days. When hydroxyurea was added to BMMϕ cultures at the beginning of the culture, both cell proliferation and osteoclast formation were inhibited. However, osteoclast formation was markedly enhanced, when hydroxyurea was added after culture for 1 day. These results suggest that cell cycle progression of BMMϕ in the presence of RANKL is required for their differentiation into osteoclasts, and that the cell cycle arrest immediately after the proliferation enhances osteoclastic differentiation. These results were confirmed by the experiment of bromodeoxyuridine labeling. When the labeling was performed at the beginning of the culture in the presence of RANKL, all nuclei of osteoclasts were labeled. In contrast, when the labeling was performed after culture for 1 day and for 2 days in the presence of RANKL, 80% and 20% nuclei of osteoclasts, respectively, were labeled. This suggests that cell proliferation and cell cycle arrest occurs during osteoclast formation after stimulation of RANKL. A complex of cyclin and cyclin-dependent kinase (Cdk) drives the cell cycle. BMMϕ expressed cyclins D1, D2, D3 and E1, and Cdks 2, 4 and 6. Expression of those proteins in BMMϕ was decreased by the treatment with RANKL. The expression of cip/kip family proteins, $p21^{cip1}$ and $p27^{kip1}$, both of which inhibit Cdk activity and induce cell cycle arrest, was examined in BMMϕ. Expression of $p27^{kip1}$ was up-regulated but that of $p21^{cip1}$ was down-regulated in BMMϕ treated with RANKL. This suggests that $p27^{kip1}$ is involved in cell cycle arrest of RANKL-treated BMMϕ. When BMMϕ were co-transfected with cyclin D1 and Cdk 4 cDNAs, BMMϕ proliferated and failed to differentiate into osteoclasts even in the presence of RANKL. In contrast, osteoclastic differentiation was accelerated in BMMϕ transfected with $p27^{kip1}$ cDNA. To elucidate whether RANKL-regulated cell cycle is specific for BMMϕ or not, osteoblasts were transfected with RANK cDNA. RANKL activated p38, JNK and NF-B in osteoblasts expressing RANK, but failed to induce the cell cycle arrest. These results suggest that cell proliferation and cell cycle arrest immediately after the proliferation in osteoclast precursors in the presence of RANKL are required for their differentiation into osteoclasts.

Effects of Trichostatin A on Apoptosis and Differentiation of Osteoclasts. T. Yi*[1], J. Seo*[1], H. Kim*[1], S. Ko[2], J. Baek[1], G. Kim*[1], K. Woo*[1]. [1]Dept. of Cell and Developmental Biology, Seoul National University, School of Dentistry, Seoul, Republic of Korea, [2]Dept. of Pharmacology, Kangnung National University, School of Dentistry, Kangnung, Republic of Korea.

Histone deacetylase inhibitors (HDIs) are a new promising class of anticancer agents since they selectively inhibit the proliferation of tumor cells in culture and in vivo by inducing cell-cycle arrest, terminal differentiation, and/or apoptosis. Recently, some types of normal cells have been reported to be susceptible to HDIs. In this study, the effects of

Trichostatin A (TSA), one of HDIs, on osteoclasts were examined. TSA was continuously or transiently treated to mouse bone marrow macrophage/monocyte lineage cells during the differentiation into osteoclasts induced by M-CSF and RANKL. TSA (100 nM) increased the apoptosis of both preosteoclasts and mature osteoclasts, and activated the procaspases. TSA tended to affect to differentiation of osteoclast in a stage-specific manner. We also observed that TSA enhanced expressions of cyclin-dependent kinase inhibitors (p21waf1 and p15ink4b) and TRAIL/TRAIL R2, which are known to regulate the osteoclast differentiation. These findings indicate that osteoclast is one of susceptible cells to HDIs and imply that the precisely regulated acetylation might be involved in the osteoclastic differentiation.

Urokinase Receptor Is Involved in Bone Remodeling by Influencing Osteoclasts Resorbtion. F. Furlan[1], N. Jorgensen[2], J. Jemsen*[2], A. Rubinacci*[3], E. Mrak*[3], M. Marenzana*[3], F. Blasi*[1]. [1]Molecular Gentics, University Vita-Salute, HSR, Milano, Italy, [2]Endocrinology, Copenhagen University, Copenhagen, Denmark, [3]Bone Metabolic Unit, HSR, Milano, Italy.

Urokinase receptor (uPAR) is actively involved in the regulation of important cell functions like adhesion and migration and it has been shown to interact with integrins. It has been previously shown that the major players of bone remodeling, osteoblasts (obs) and osteoclasts (ocs), produce urokinase (uPA) and express its receptor (uPAR). Moreover, The purpose of this study was to investigate the role of uPAR in bone remodeling. We analyzed the bone phenotype in uPAR-null female mice. The size of mutant mice was reduced as compared to normal animals, and in more details, there was a significant decrease in tibia length in mutant mice as compared to Wt. Bone mass analysis of uPAR Ko by peripheral quantitative computed tomography (pQCT), revealed an increase in bone mass with respect to wild type ($p<0.02$). The histomorphometric analysis of the tibia in uPAR Ko showed a reduction in the bone volume compared to wild type (more bone density but less bone volume) with a significant reduction in cortical thickness in Ko mice, and a reduction of resorbing surface in Ko bones compare to Wt. Moreover, mechanical tests showed a reduction in the capability to sustain a given load in uPAR Ko tibias as compared to tibias from wild type female animals ($p<0.02$). To explore the cellular basis of the bone defect in uPAR Ko mice, we cultured osteoblasts and osteoclasts in vitro. The results showed a proliferative advantage with no difference in apoptosis, and a higher susceptibility to matrix mineralization in uPAR Ko as compared to Wt obs. The production of proteins involved in the mineralization process, like alkaline phosphatase (ALP), was increased only during the first weeks of obs maturation. After 4 weeks, ALP was similar in both genotypes. RANKL expression on obs surface did not change between two different genotypes at different stages of differentiation. On the contrary the number of ocs formed in vitro using uPAR Ko monocytes was decreased compared to Wt. Moreover, we have found that uPAR co-localized with integrin b3 on ocs podosoms by confocal microscopy. Therefore, we would like to better understand the role of uPAR in ocs function by crossing uPAR Ko mice with integrin b3 ko mice. Experiments in order to investigate the downstream pathways in obs and ocs (AP1 family) are under current investigation. Together our preliminary data indicate that uPAR may play an important role in bone physiology by influencing osteoclasts function.

MCP-1 Expression Correlates with Multinucleation of Human Osteoclasts. C. J. Day*, S. R. J. Stephens*, M. S. Kim*, N. A. Morrison. School of Medical Science, Griffith University, Gold Coast, Australia.

Osteoclasts are characterized as multinuclear cells positive for TRAP, calcitonin receptor (CTR), cathepsin K (CTSK) and NFATc1. MCP-1 is a CC chemokine that is induced by RANKL and suppressed by GM-CSF. In the absence of RANKL, treatment with MCP-1 and M-CSF results in multinucleated cells that are TRAP+ and express a range of osteoclast markers, including NFATc1, but do not resorb bone. In this study we examine the correlation between MCP-1 expression and multinucleation, using real time quantitative PCR to measure gene expression relative to RNA content rather than cell number. The role of different signalling pathways in human osteoclast differentiation were tested using antagonists: SB203580 (p38MAPK), U0126 (ERK1/2), rapamycin (mTOR), intracellular calcium regulators (IC-IBMECA) and NFATc1 inhibitors (cyclosporin A, CSA). In the mouse, SB203580 and CSA blocked osteoclast formation, while U0126 and rapamycin excited osteoclast formation. In contrast, in the human osteoclast system, only rapamycin permits multinuclear cell formation, while SB203580, U0126 and CSA block the formation of multinuclear cells. We sought another inhibitor of osteoclast formation based on our observation that the adenosine A3 receptor is induced by RANKL. Treatment with IC-IBMECA (an adenosine A3 agonist) inhibited the formation of multinuclear cells and also suppressed MCP-1 induction. RANKL induction of MCP-1 was abolished by those agents that blocked multinuclear cell formation (SB203580, U0126, CSA and IC-IBMECA) but MCP-1 induction was not affected by rapamycin. In stark contrast, the RANKL induction of TRAP and NFATc1 were not altered by any of these agents compared to the M-CSF and RANKL treated control, illustrating that TRAP and NFATc1 expression is not correlated with multinucleation. Although RANKL induction of TRAP and NFATc1 was not affected, the expression of CTR and CTSK showed differential effects when treated with osteoclast inhibitors. Treatment with SB203580 and IC-IBMECA resulted in down-regulation of CTSK. CTR expression in the presence of inhibitors was reduced with the exception of IC-IBMECA. Treatment with IC-IBMECA resulted in higher CTR expression than in control osteoclasts, suggesting an adenosine effect on CTR expression. The consistent outcome of the inhibitor experiments is that MCP-1 expression is highly correlated with multinucleation. Cells can be positive for TRAP and NFATc1 but are not multinuclear unless MCP-1 expression is also present. This correlation is consistent with the observation that adding exogenous MCP-1 results in multinuclear polykaryons that are TRAP+, CTR+ and have high levels of NFATc1 but do not degrade bone.

Truncation Mutants of RANKL within the TNF-Like Core Domain Inhibit RANKL-Induced Osteoclast Differentiation and Activation. C. Wang*[1], J. W. Tan*[1], N. J. Pavlos*[1], J. M. Li*[2], J. Cornish[2], M. H. Zheng[1], J. Xu[1]. [1]Dept. of Orthopaedic Surgery, The University of Western Australia, Nedlands, Australia, [2]Dept. of Medicine, University of Auckland, **Auckland, New Zealand.**

Receptor activator of NF-kB ligand (RANKL) is a crucial factor necessary for osteoclast differentiation and activation. In this study we have examined the role of the TNF-like core domain of RANKL in osteoclast differentiation and activation. To this end, a series of truncation mutants of the TNF-like core domain of RANKL were expressed as GST-fusion proteins, and their biological activities assessed using a number of pro-osteoclastogenic systems. Osteoclastogenesis assays revealed that while GST-rRANKL (aa160-318) containing the full TNF-like core region strongly induced osteoclast formation, RANKL truncation mutants GST-rRANKL (aa239-318), (aa160-268), (aa160-291), (aa246-318) display significantly decreased osteoclastogenic activity. Consistently, the decrease in osteoclast number correlates with decreased TRACP activity and reduced calcitonin receptor and cathapsin K gene expression. Furthermore, competition studies revealed that all RANKL truncation mutants were capable of inhibiting RANKL (aa160-318)-induced osteoclast formation but with different efficacy, RANKL mutant (aa246-318) being the most potent. RANKL mutant (aa246-318) was also found to competitively decrease RANKL (aa160-318)-induced osteoclastic bone resorption *in vitro*. Interestingly, GST pull down studies reveal that all RANKL mutants have reduced binding affinity to RANK. In addition, all RANKL mutants display significant reduction in the activation of crucial osteoclastic signalling pathways including NF-kB, ERK, JNKs and have decreased IKBα degradation as compared to the full-length protein. Together, our data indicate that RANKL mutants within the TNF-like core domain may act as competitive inhibitors of RANKL-induced osteoclast differentiation and activation and thus may offer potential therapeutic approaches to combat bone lytic disorders.

Characterization of the Osteoclast Precursors Committed by TRANCE. A. Mochizuki*[1], M. Takami[1], T. Kawawa*[2], Y. Miyamoto[1], T. Suzawa[1], A. Yamada*[1], R. Suzumoto*[3], T. Sasaki[3], A. Shiba*[4], R. Kamijo[1]. [1]Department of Biochemistry, School of Dentistry, Showa University, Tokyo, Japan, [2]Department of Prosthodontics, School of Dentistry, Showa University, Tokyo, Japan, [3]Department of Oral Historogy, School of Dentistry, Showa University, Tokyo, Japan, [4]Yomonkai Research Center, Tokyo, Japan.

Macrophages are capable to differentiate into osteoclasts in response to TRANCE (RANKL), indicating that TRANCE commits macrophages to be osteoclasts. To elucidate the mechanisms of this commitment, we determined when the macrophages are committed to be osteoclasts after TRANCE stimulation, and characterized the committed cells. Addition of TRANCE into the macrophage cultures induced osteoclast formation within 72h. When GM-CSF was added simultaneously with TRANCE, osteoclast formation was inhibited and dendritic cells were formed. However, GM-CSF could not inhibit osteoclast formation from macrophages pretreated with TRANCE for more than 24 h, suggesting that macrophages stimulated with TRANCE for 24 h are already committed to osteoclasts. TRAP activity of the committed cells was still as weak as fresh macrophages. Other inhibitory factors such as IL-4 and IFN-gamma also failed to inhibit osteoclast differentiation from the committed cells. On the other hand, addition of OPG induced the cell death of the committed cells but not macrophages, suggesting that TRANCE is an essential factor for survival of committed cells. Interestingly, LPS and GM-CSF substituted for TRANCE and M-CSF, respectively to induce osteoclast formation from the committed cells. When zymosan particles were added to macrophage cultures, the macrophages incorporated the particles but never differentiated into osteoclasts by the stimulation with TRANCE. However, the committed cells incorporated zymosans and differentiated into osteoclasts by TRANCE stimulation. The zymosan particles were observed in the cytoplasm of bone resorbing osteoclasts by electron microscopic examination. Analysis of mRNA expression in the committed cells by RT-PCR revealed that committed cells express mRNAs typically expressed in macrophages as well as in osteoclasts. When macrophages were stimulated with LPS, intracellular signals were activated and TNF-alpha mRNA expression was strongly induced. In the committed cells, although the intracellular signals were activated, TNF-alpha mRNA expression level was significantly lower than macrophages. In conclusion, committed cells possess very unique characteristics that were different from macrophages and osteoclasts.

Osteoclast Precursors Inhibit Osteoprotegerin Production by Osteoblasts during Mineralization. M. van Driel*, H. Jahr*, B. C. J. van der Eerden, C. J. Buurman*, M. Koedam*, A. G. Uitterlinden, H. A. P. Pols, J. P. T. van Leeuwen. Internal Medicine, Erasmus MC, Rotterdam, The Netherlands.

Osteoblasts play a pivotal role in bone metabolism as they are the bone forming cell while they also control bone resorption via regulation of osteoclast formation. Osteoblasts express the stimulator of osteoclast formation, RANKL, and its decoy receptor osteoprotegerin (OPG) and several factors have been shown to regulate RANKL and OPG production by osteoblasts of various origins. However, yet it is unknown whether there is a relation between the functional status (mineralization) of osteoblasts and their osteoclast supporting function, nor is it known whether in return osteoclasts can modify this osteoblast supporting function. To answer these questions we used a human osteoblast cell line (SV-HFO) that shows ongoing matrix production, has highest alkaline phosphatase activity around day 14 of culture and subsequently starts to mineralize the formed matrix. Osteoblasts were co-cultured with the osteoclast precursor cell line RAW264.7 in the presence of RANKL starting at day 9 (no mineralization; NM), day 16 (onset of mineralization; OM) or day 23 (fully mineralizing; FM) of osteoblast culture. Osteoclast formation was assessed at days 3, 5, 7 and 10 after start of co-culture. When RAW264.7 cells were seeded at the NM or OM stage within 5 days TRAP+ cells were formed which were shown to be functional by demineralization of calcified matrix formed. In contrast, when RAW264.7 cells were seeded at the FM stage up to 7 days no TRAP+ cells were detected and only a few TRAP+ cells appeared at day 10. Significance of osteoblast activity at the FM stage for inhibition of osteoclast formation was shown by using osteoblasts that were killed at day 23 by freeze thaw cycles. In this situation within 5 days after seeding RAW264.7 cells TRAP+ cells were formed. OPG measurement supported the observed inhibition of osteoclast formation as OPG production at the FM stage is about 10 fold higher than in the NM and OM stages, 519±77 and 51±10 pg/ml, respectively. This matched qPCR analyses that also demonstrated a progressive decrease in OPG/RANKL ratio during mineralization. Interestingly, co-culture with RAW264.7 cells resulted in a strong inhibition (80-85%) of OPG production by osteoblasts in the FM stage. In conclusion, the current study demonstrates that support of osteoclast formation is dependent on the osteoblasts functional status with osteoblast in the mineralizing stage being inhibitory for osteoclast formation. Moreover, the experiments show a novel feedback between osteoclasts and osteoblasts in which preosteoclasts down-regulate OPG production by osteoblasts thereby facilitating osteoclast formation.

The Effect of AZD0530, a Highly Selective Src Inhibitor, on Bone Turnover in Healthy Males. R. A. Hannon[1], G. Clack[2], A. Swaisland*[2], C. Churchman*[2], R. D. Finkelman[3], R. Eastell[1]. [1]Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, [2]AstraZeneca, Macclesfield, United Kingdom, [3]AstraZeneca Pharmaceuticals, Wilmington, DE, USA.

AZD0530 is a highly selective, dual-specific, orally available small molecule inhibitor of Src and Abl kinases. Src kinase plays an essential role in RANK-mediated osteoclast activation but may inhibit osteoblast activity. Abl may be required for normal osteoblast function. To examine the effect of AZD0530 on osteoclast and osteoblast activity we investigated changes in markers of bone turnover in response to AZD0530 treatment in a multiple ascending dose study in healthy male volunteers (ages 18-55 years). The study comprised placebo and 4 dose levels given to cohorts each of 12 volunteers. Volunteers in each cohort received a single dose of 60-250mg AZ0530 (n = 9) or placebo (n= 3) repeated, 7 or 10 days later, as multiple daily doses for 10 or 14 days. Serum and second morning urine were collected after an overnight fast prior to and 24 and 48 hours after the single dose and prior to and 24 and 48 hours after the final dose. Samples were collected at a follow-up visit 10-14 days after the last dose in the cohorts receiving the two highest doses. Markers of bone resorption measured were serum cross-linked C telopeptide of type I collagen (sCTX), urinary cross-linked N telopeptide (NTX), expressed as a ratio to urinary creatinine, and serum tartrate resistant acid phosphatase 5b (TRAP 5b). Markers of bone formation measured were procollagen serum type I N terminal propeptide (PINP) and bone specific alkaline phosphatase (Bone ALP).

Mean (95% CI) percentage changes from baseline in bone turnover markers 24 hours

Dose ADZ0503	sCTX	uNTX/Cr	TRAP 5b	PINP	Bone ALP
Placebo	+17% (-7%,+49%)	+5% (-23%, +44%)	+9% (0%, +17%)	+17% (-1%,+38%)	+3% (-5%,+11%)
60mg	-24% (-41%, -1%)	-3% (-32%, +37%)	+2% (-7%, +11%)	+3% (-14%,+24%)	+5% (-4%, +15%)
125mg	-55% (-65%,-43%)	-39% (-56%, -15%)	-13% (-19%,-5%)	+23% (+3%,+46%)	+10% (+1%,+19%)
185mg	-71% (-77%,-63%)	-69% (-78%, -56%)	-14% (-21%,-6%)	+33% (+11%, +58%)	-3% (-11%,+5%)
250mg	-88% (-91%,-84%)	-67% (-77%, -53%)	-11% (-18%,-3%)	+13% (-6%,+35%)	+9% (0%, +19%)

Provisional PK-PD modeling suggests the relationship between AZD0530 plasma concentrations and CTX suppression is well described by an inhibitory sigmoid E-max model. Levels of sCTX and uNTX/Cr but not TRAP 5b appear to rise back rapidly towards baseline following cessation of dosing with the two highest doses. PINP tended to decrease after cessation of treatment, possibly reflecting the temporal difference in resorption and formation during bone remodelling. We conclude that suppression of Src kinase activity inhibits osteoclast-mediated bone resorption. The potential effect of Src inhibition on markers of bone formation warrants further investigation. AZD0530 may have therapeutic benefit in treating osteoclast-driven metastatic bone disease and osteoporosis.

c-Jun Suppresses and JunB Enhances the Stimulation of Cathepsin K Promoter Activity by NFAT2 in RAW 264.7 Cells. B. R. Troen, A. F. Martinez*, M. Pang*, I. Fernandez*, W. Balkan*. Miami VAMC, Miller School of Medicine, University of Miami, Miami, FL, USA.

Receptor activator of NFkB ligand (RANKL) is a critical mediator of osteoclastogenesis and stimulates cathepsin K (CTSK) expression. However the regulation of CTSK expression is incompletely understood. Because RANKL treatment differentiates and activates osteoclasts via AP-1 and NFAT2, we have chosen to study the regulation of CTSK expression via AP-1 and NFAT2 in RAW 264.7 osteoclast precursor cells. Transfection analysis with CTSK promoter-luciferase plasmids unexpectedly demonstrated that c-jun inhibited CTSK promoter activity, whereas junB and a dominant negative c-jun (DN-c-jun) stimulated activity. Concurrent c-fos over-expression markedly enhanced the stimulation by junB. Surprisingly, both c-fos and a dominant negative c-fos (DN-c-fos) alone markedly suppressed CTSK promoter activity. Transfections with a minimal promoter-luciferase vector containing three tandem consensus AP-1 binding sites (3xAP-1-luc) exhibited the expected stimulation by c-fos and suppression of promoter activity by DN-c-jun and DN-c-fos. Interestingly, c-jun inhibited 3xAP-1 promoter activity. Over-expression of NFAT2 dramatically enhanced CTSK promoter activity. Deletion mutation analysis revealed that as few as 238 bp of the CTSK promoter exhibited a marked response to NFAT2. Mutation of a putative NFAT binding site 85 bp upstream of the transcription initiation site significantly reduced the response of the CTSK promoter to NFAT2. Since components of AP-1 have been shown to interact with NFAT2, we examined whether there are co-regulatory effects upon the CTSK promoter. Both junB and DN-c-jun acted synergistically with NFAT2 to dramatically stimulate CTSK promoter activity. In contrast, c-fos, c-jun, and DN-c-fos all suppressed the stimulation of CTSK promoter activity by NFAT2. Western blot analysis demonstrated that RANKL stimulated junB expression in a dose and time dependent manner. Therefore RANKL stimulates CTSK expression, at least in part, via junB in RAW cells, and both junB and DN-c-jun appear to stimulate CTSK promoter activity by facilitating the action of NFAT2. The apparent antagonism between c-jun and junB and the paradoxical effects of c-fos and DN-c-jun demonstrate that the regulation of CTSK transcription in RAW cells depends upon a critical balance between the components of AP-1 and NFAT2, which appear to act in a complex and, in some cases, unexpected manner. Direct binding assays will help to elucidate the essential protein-protein interactions that regulate transcription of the CTSK gene in response to RANKL.

KR62776, a Novel PPAR-γ Agonist, Suppresses RANKL-Induced Osteoclast Differentiation through Inhibition of MAP Kinase Activation. J. Park*[1], J. Hong*[1], T. Kim*[1], J. Choi[2], M. Bae*[3], H. Cheon*[3], S. Kim[4], E. Park[5]. [1]Skeletal Diseases Genome Research Center, Biomedical Institute, Kyungpook National University Hospital, Daegu, Republic of Korea, [2]Department of Biochemistry, Kyungpook National University, Daegu, Republic of Korea, [3]Medicinal Science Division, Korea Research Institute of Chemical Technology, Daejeon, Republic of Korea, [4]Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, [5]Cell and Developmental Biology, Biomedical Institute, Kyungpook National University Hospital, Daegu, Republic of Korea.

Peroxisome proliferator-activated receptor-γ (PPAR-γ) regulates the adipogenic differentiation at the expense of osteoblast differentiation, and inflammatory response pathways through inhibition of the mitogen-activated protein kinase (MAPK) pathways or the activation of the nuclear factor kappa B (NF-kB). Recently, thiazolidinedione class of anti-diabetic agents including troglitazone, pioglitazone, and rogiglitazone that activate PPAR-γ has also been implicated in regulation of osteoclast differentiation/function. We screened chemical library and identified KR62776 as a novel PPAR-γ agonist which has potential for treatment of Type 2 diabetes and obesity. In this study, we investigated the effects of KR62776 on osteoclast differentiation and function, and its influence on receptor activator of nuclear factor-kB ligand (RANKL)-induced early intracellular signaling pathways. KR62776 markedly decreased the differentiation of murine and human bone marrow mononuclear (BMM) cells and RAW264.7 cells into osteoclasts, as revealed by the reduced number of tartrate resistant acid phosphatase (TRAP)-positive multinucleated cells and decreased TRAP activity. KR62776 appears to have no cytotoxic effect on osteoclast precursors. Analysis of the mechanisms showed that KR62776 inhibited the RANKL-induced activation of p38 mitogen-activated protein kinase (p38MAPK) and c-Jun N-terminal kinase (JNK). Taken together, these results demonstrate that KR62776 has inhibitory activities on osteoclast differentiation through mechanisms involving inhibition of the RANKL-induced p38MAPK and JNK activation.

c-Src Recruits SHIP to Podosomes in Osteoclasts, Leading to an Attenuation of Bone Resorption. K. Yogo[1], M. Mizutamari*[1], K. Mishima*[1], N. Ishida*[1], T. Sasaki*[2], T. Takeya*[1]. [1]Graduate school of Bilogical Sciences, Nara Institue of Science and Technology, Ikoma, Japan, [2]Department of Pathology and Immunology, Akita University School of Medicine, Akita, Japan.

c-Src plays an essential role in bone resorption by regulating cytoskeletal organization. Phosphatidylinositol 3'-kinase (PI3K) is one of the major downstream targets of c-Src and it has been reported that the Src/PI3K pathway is required for podosome assembly, motility and bone resorption in osteoclasts. Although SH2-containing 5'-inositol phosphatase (SHIP) has been known to antagonize PI3K pathway and act as a negative regulator in bone resorption, little is known about how SHIP activity is regulated or what molecule regulates the localization of SHIP in osteoclasts. In this study, we investigated the functional relationship between c-Src and SHIP in osteoclasts. First, we found that Src enhanced bone resorbing activity and was most effective in *ship*$^{-/-}$ osteoclasts when assayed *in vitro*. Immunohistochemical analysis showed that SHIP appeared to localize to podosomes in osteoclasts and Src family kinase inhibitor PP1 or expressing dominant negative c-Src (K295M) impaired the localization. In addition, SHIP localized to focal adhesions in the presence of constitutively active form of c-Src (Y527F) in HeLa cells. These results suggest that the activity of c-Src is essential for the localization of SHIP to podosomes in osteoclast. Next, we examined the effect of direct association with c-Src on the localization of SHIP. We found that SHIP could bind to Src-SH3 domain through the P126-P129 region in the N-terminus, but the interaction was dispensable for the Src induced localization of SHIP in HeLa cells. Meanwhile, we identified p130^{Cas} and c-Cbl as novel SHIP-binding proteins in osteoclasts using co-immunoprecipitation with anti-SHIP antibody. The interactions appeared to be dependent on Src kinase activity and we found that Cas and c-Cbl associated with the SH2 domain of SHIP. Further, we investigated the role of the SHIP SH2 domain in bone resorption *in vitro* and found that SHIP lacking a functional SH2 domain could not rescue the hyper-bone resorbing activity of *ship*$^{-/-}$ osteoclasts whereas wild-type SHIP could. Taken together, these results demonstrated that c-Src recruits SHIP to podosomes in a kinase activity-dependent manner in osteoclasts, and SHIP consequently functions in podosomes as a negative regulator of bone resorbing reactions activated by c-Src.

Role of Protein Kinases C Signaling Pathway in the Effects of Strontium Ranelate on Osteoclasts. A. S. Lemaire-Hurtel*, R. Mentaverri*, A. Wattel*, S. Kamel*, M. Brazier. UMRO, Université de Picardie Jules Vernes, Amiens, France.

Strontium ranelate is a new anti-osteoporotic agent which has demonstrated its efficacy in reducing significantly the risk of vertebral and hip fracture in postmenopausal women. Strontium ranelate simultaneously stimulates bone formation and decreases bone resorption, which results in a rebalance of bone turnover in favor of bone formation. The intracellular signaling pathways involved in strontium ranelate effects are still under investigation. We and others have demonstrated that extracellular strontium (Sr) is a full agonist of the extracellular G-protein-coupled calcium-sensing receptor (CaR)[1] and that Sr inhibits bone resorption decreasing OCs recrutement, OCs activities and by increasing OCs apoptosis[2]. We investigated intracellular signaling pathways which could be modulated by the CaR[3] on both calcium (Ca)- and strontium ranelate-induced OCs apoptosis. Whereas phospholipase C was involved in the Sr- and Ca-induced OCs apoptosis, specific inhibitors of the IP_3-dependent signaling reduced by 50% the Ca-induced effects and failed to modulate the Sr-induced OCs apoptosis. These results suggested that strontium ranelate acts through different intracellular signaling pathways which might be diacylglycerol (DAG) and protein kinase C (PKC)-dependent. In the present study, purified mature OCs were cultured with PKC activators (OAG: analogous of DAG and phorbol esters: PMA, PDBu) in order to demonstrate the role of the DAG-PKC pathway in the OCs apoptosis. OCs apoptosis displayed a dose dependent increase in presence of these PKC activators: OAG (100µM), PMA (10µM) and PDBu (1mM). In a second time, OCs were cultured with strontium ranelate (24mM) or Ca in presence of non selective PKC inhibitors (calphostin C, staurosporine), or selective inhibitors of PKC isoforms (Gö-6976: inhibitor of conventional isoforms, and Ro-320432: inhibitor of α, β 1 and ε isoforms) versus strontium ranelate (24mM) or Ca alone. The presence of PKC inhibitors significantly reduced the strontium ranelate-induced OC apoptosis: $p<0.01$ with calphostin C (1nM), $p<0.001$ with staurosporin (1nM) and $p<0.0001$ with both Gö-6976 (0.1nM) and Ro-320432 (1nM). Interestingly, such PKC inhibitors had no effect on the Ca-induced OCs apoptosis, confirming that intracellular pathways involved in strontium ranelate or Ca-induced OCs apoptosis were different. All together, our data indicate that strontium ranelate acts on OCs apoptosis through PKCs isoforms α and/or β 1, while Ca effects are IP_3 dependent.

Endotoxin Adherent to Orthopaedic Wear Particles Activates Toll-Like Receptor-4 (TLR-4)-Dependent Signaling Pathways without Inducing TLR Association with Lipid Rafts. M. A. Beidelschies*, A. S. Islam*, M. V. Smith*, V. M. Goldberg*, E. M. Greenfield. Orthopaedics, Case Western Reserve University and University Hospitals of Cleveland, Cleveland, OH, USA.

Aseptic loosening of orthopaedic implants is due to a cascade of events, including production of wear particles, and pro-inflammatory cytokines which stimulate osteoclast differentiation. We have shown that adherent endotoxin substantially increases the effects of the wear particles both in cell culture models and in the murine calvarial model. Moreover, these effects are dependent on TLR-4, the primary receptor for soluble LPS (the classical endotoxin produced by Gram-negative bacteria). We hypothesized that adherent endotoxin activates TLRs by mechanisms that differ from those used by soluble LPS. In support of this, wear particles did not induce TLR-4 or TLR-2 to associate with lipid rafts. In contrast, TLR-4 and TLR-2 associated with lipid rafts in response, respectively, to soluble LPS and soluble LTA (a major immunostimulatory molecule produced by Gram-positive bacteria). We further hypothesized that the intracellular signaling pathways induced by adherent endotoxin are similar to those induced by soluble LPS. We found that particles with adherent endotoxin rapidly induced NF-kB p65 translocation to the nucleus, and stimulated phosphorylation of Akt and all three MAPK pathways (p38, ERK1/2, and JNK), while "endotoxin-free" particles induced substantially slower and weaker effects. Moreover, specific pathway inhibitors of ERK1/2 and PI3K/Akt blocked TNF production induced by particles with adherent endotoxin. Stimulation with wear particles increased Egr-1 expression, a transcription factor downstream of ERK1/2. Adherent endotoxin potentiated this expression and ERK1/2 pathway inhibitors blocked Egr-1 expression. p38 and JNK inhibitors did not block particle-induced TNF production. Specificity of the various inhibitors was demonstrated by showing that relatively inactive analogues did not mimic their effects and that their effects occurred at concentrations that were similar to those needed to block activation of their target pathways. The inhibitors did not block activation of related pathways and did not induce cytotoxicity. Overall, these results show that wear particles induce a signaling platform that is independent of lipid rafts. Furthermore, these results, taken together with those of other workers on NF-kB, show that the NF-kB, ERK1/2, and PI3K/Akt pathways act together to mediate production of TNF by endotoxin adherent to wear particles.

The MEK/ERK Pathway Regulates Osteoclast Survival Through Regulation of Immediate Early Genes Egr1 and Egr2. E. W. Bradley[1], M. J. Oursler[2]. [1]Graduate School, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Reducing osteoclast numbers through targeting osteoclast survival pathways may provide future therapeutic targets to slow pathological bone loss and it is a goal of our research to define the signaling pathways regulating osteoclast survival. We have shown that chemical inhibition of MEK or protein synthesis inhibition leads to increased osteoclast apoptosis and we are focusing on discovering the mechanisms by which MEK promotes osteoclast survival. We therefore are seeking to identify downstream targets of MEK that support osteoclast survival. Using gene array technology coupled with Real Time PCR confirmation, we have identified two immediate early genes, Egr1 and Egr2, which function downstream of MEK in osteoclasts. Egr1 and Egr2 expression was inhibited by chemical inhibition of MEK1/2. Further, over-expression of constitutively active MEK1 leads to increased expression of Egr1 and Egr2. These data confirmed that Egr1 and Egr2 are downstream targets of the MEK/ERK pathway and studies were undertaken to explore the role of these early response genes in osteoclast survival. Over-expression of Nab2, the nuclear co-repressor for Egr1 and Egr2, led to an increase in osteoclast apoptosis. Since Nab2 blocks both Egr1 and Egr2, we wanted to determine the respective roles of these early response genes in osteoclast survival. Overexpression of Egr1 did not repress osteoclast apoptosis, leading to the conclusion that Egr2 is the downstream effector of MEK/ERK promotion of osteoclast survival. In order to determine whether Egr1 could replace Egr2 in supporting osteoclast survival, we chemically blocked MEK signaling and looked at the effect of Egr1 over-expression. Over-expression of Egr1 bypassed the effects of chemical inhibition of MEK 1/2 and led to decreased osteoclast apoptosis. In this study, Egr1 was capable of replacing Egr2 and promoting osteoclast survival. We conclude from these data that, although Egr1 is not the downstream effector of osteoclast survival, it can substitute for Egr2 when Egr2 expression is blocked by inhibiting MEK signaling. To determine whether additional targets were important in MEK-mediated support of osteoclast survival, we compared the impacts of MEK inhibition, Nab2 over-expression to inhibit Egr family members, and combined MEK and Nab2 over-expression on osteoclast survival. When compared to chemical inhibition of MEK1/2 alone, over-expression of Nab2 in combination with chemical inhibition of MEK1/2 did not further increase osteoclast apoptosis. These data support that MEK-mediated support of osteoclast survival is through increased expression of Egr family members.

Overexpression of Leupaxin in Osteoclasts and Effects on Osteoclast Function. S. N. Sahu*, M. A. Khadeer*, G. Bai*, B. W. Robertson*, A. Gupta. Biomedical Sciences, University of Maryland, Baltimore, MD, USA.

Within the actin-rich podosomal complex in osteoclasts, several signaling molecules have been identified and characterized, which include structural proteins, protein tyrosine kinases, and regulators of the actin cytoskeleton. Leupaxin (LPXN), which belongs to the paxillin superfamily of adaptor proteins, has previously been identified as a component of the sealing zone in osteoclasts. LPXN bears ~37% identity to paxillin, and possesses multiple protein-protein interaction motifs such as repeated N-terminal leucine (L)- and aspartate (D)-rich sequences known as LD motifs, and C-terminal LIM (for Lin-11 Isl-1 Mec-3) domains. In osteoclasts, LPXN associates with a variety of proteins found in the sealing zone that include the protein tyrosine kinase Pyk2, the protein-tyrosine phosphatase-PEST (PTP-PEST), and regulators of the actin cytoskeleton. It was previously demonstrated that inhibition of LPXN expression resulted in reduced osteoclast resorptive activity. LPXN was previously cloned from a rabbit osteoclast cDNA library, and was found to be approximately 85% identical to the murine ortholog. A comparison of the amino acid sequences for the rabbit, human and murine orthologs of LPXN revealed that the second LD motif (LD2) was completely absent in the murine ortholog of LPXN, but which was highly conserved in both the human and rabbit orthologs. In the current study, we have examined the consequences of adenovirus-mediated overexpression of LPXN orthologs on murine osteoclast function. First, overexpression of the "endogenous" LPXN in murine osteoclasts (mLPXN) resulted in enhanced resorptive activity that was paralleled by an enhanced localization of key podosomal proteins at or near the sealing zone. However, when the rabbit ortholog of LPXN (rLPXN) was "ectopically" overexpressed in (murine) osteoclasts, an apparent "loss-of-function" resulted, which was paralleled by mis-localization of a similar repertoire of podosomal proteins. In order to determine a biochemical basis for our observations, a comparison of the amino acid sequences for both species orthologs was performed, which revealed the presence of a second leucine-aspartate (LD2)-rich protein-protein interaction domain, present only in rLPXN. Using GST-affinity precipitation, the LD2 motif present in rLPXN was found to bind Src. The ectopic overexpression of either the rLPXN or the LD2 domain resident in the rLPXN sequence, disrupted the normal localization of endogenous Src at the sealing zone in murine osteoclasts. In conclusion, we hypothesize that overexpression of rLPXN disrupts murine osteoclast function by causing a mis-localization of Src away from its normal distribution at the sealing zone.

SHIP1 Regulates Osteoclastogenesis by Blockage of Proliferation of Osteoclast Precursors. P. Zhou[1], H. Kitaura[1], S. L. Teitelbaum[1], N. Namba*[2], C. D. Helgason*[3], R. K. Humphries*[3], G. Krystal*[3], F. P. Ross[1], S. Takeshita[1]. [1]Pathology, Washington University, St Louis, MO, USA, [2]Pediatrics, Okayama University, Okayama, Japan, [3]Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada.

SHIP1 is an SH2-containing inositol-5-phosphatase which negatively regulates phosphatidylinositol-3-kinase (PI3-K)-initiated signaling by dephosphorylating phosphatidylinositol-3, 4, 5-triphosphate. SHIP1 is essential for normal bone homeostasis, as knock out mice contain increased numbers of hyper-resorptive osteoclasts leading to osteoporosis. Here we characterize the mechanism by which SHIP1 negatively regulates osteoclast differentiation. We find that inhibition of M-CSF dependent osteoclast precursor proliferation by SHIP1 contributes to the ability of the lipid phosphatase to suppress osteoclastogenesis. SHIP1$^{-/-}$ osteoclast precursors in the form of bone marrow macrophages are hyperproliferative, but not longer-lived, in response to M-CSF. This accelerated proliferation correlates with elevated accumulation of cyclins D1, D2 and D3, hyperphosphorylation of the tumor suppressor retinoblastoma protein (Rb) and accelerated down-regulation of p27, an inhibitor of cyclin-dependent kinases (CDKs). Our observation that M-CSF up-regulates cyclin D3 provides the first documentation of this fact. In the absence of SHIP1, M-CSF induced activation of Akt but not ERK is enhanced. Similarly, inhibition of PI3-K activity by the specific inhibitor, LY294002, abrogates M-CSF induced Akt activation, D-type cyclin expression and Rb phosphorylation. The PI3-K inhibitor also down-regulates p27 and dose dependently blocks osteoclast precursor proliferation, while not affecting cell viability. Reconstitution of SHIP1 expression in SHIP1$^{-/-}$ osteoclast precursors via retrovirus corrects their enhanced Akt activation, proliferation and osteoclastogenesis. Retroviral expression of SHIP1 mutants lacking phosphatase activity, or the N-terminal SH2 domain or the C-terminal 163 amino acids in SHIP1$^{-/-}$ osteoclast precursors fails to rescue enhanced osteoclastogenesis, documenting the requirement of these domains in SHIP1-regulated osteoclast precursor proliferation and osteoclastogenesis. Finally, osteoclastogenesis and peri-articular bone erosions are markedly increased in SHIP1$^{-/-}$ mice with inflammatory arthritis, a condition characterized by increased M-CSF expression. The SHIP1-Akt pathway therefore suppresses bone loss in pathological states associated with excessive M-CSF.

Gain and Loss Function Study Reveals that RGS10 Expressed Predominately in Osteoclast Is a Critical Mediator in [Ca^{2+}]i Ocillations and Osteoclast Differentiation. S. Yang*, W. Chen*, Y. Li. Cytokine Biology, The Forsyth Institute, Harvard School of Dental Medicine, Boston, MA, USA.

It was reported that RANKL selectively evokes the [Ca^{2+}]i oscillations that led to calcineurin-mediated activation of NFATc1, osteoclast specific gene expression and osteoclast terminal differentiation. However, the mechanism underlying how RANKL evokes [Ca^{2+}]i oscillations is unknown. We hypothesized that related signaling proteins may be induced by RANKL and are involved in the RANKL-regulated [Ca^{2+}]i oscillation-NFAT2 pathway. Using genome-wide Microarray screening to identify RANKL- inducible genes, we found that the mouse Regulator of G-protein Signaling 10 (RGS10) gene was predominately expressed in RANKL-induced osteoclast-like cells (OLCs). To characterize whether RGS10 is expressed in human osteoclast, Northern blotting and *in situ* hybridization were performed. The results proved that RGS10 is predominately expressed in human osteoclast. Previous reports indicate that "Regulators of G-protein signaling," or RGS proteins, play an important role in the regulation of [Ca^{2+}]i oscillations in the immune, neural and cardiovascular systems. We hypothesize RGS10 may specifically regulate [Ca^{2+}]i oscillations and lead to transcription and expression of osteoclast specific genes. To test the hypothesis, we used a gain and loss-function approach. Silencing of RGS10 expression using RNA interference (RNAi) blocked osteoclast terminal differentiation induced by RANKL. Our data further demonstrated that the failure of osteoclast terminal differentiation resulted from the absence of [Ca^{2+}]i oscillations and lack of NFAT2 expression. Over-expression of RGS10 caused about 5% precursor cells to differentiate to TRAP+ mononuclear cells in absence of RANKL induction and largely increased the sensitivity to RANKL signaling in osteoclast differentiation. However, over-expression of RGS10 was unable to evoke [Ca^{2+}]i oscillations without RANKL signaling, indicating RGS10 may cooperate with other factor(s) induced by RANKL to regulate [Ca^{2+}]i oscillations and terminal differentiation of osteoclasts. These results thus reveal that RGS10 is involved in the RANKL evoking signaling pathway as a critical regulator of [Ca^{2+}]i oscillations and is an essential factor for the terminal differentiation of osteoclasts induced by RANKL.

Stimulation of TREM2, A DAP12-associated Receptor, Leads to SHIP-1 Association with DAP12. J. A. Torchia*[1], S. C. Spusta*[1], W. E. Seaman*[2], W. G. Kerr*[3], M. C. Nakamura[1], M. B. Humphrey[2]. [1]Dept. of Medicine, VA Medical Center and University of California, San Francisco, CA, USA, [2]Dept. of Medicine and Microbiology/Immunology, VA Medical Center and University of California, San Francisco, CA, USA, [3]Dept. of Interdisciplinary Oncology, University of South Florida and Moffitt Comprehensive Cancer Center, Tampa, FL, USA.

TREM2 (Triggering Receptor Expressed on Myeloid cells-2) and its signaling chain DAP12 are present in myeloid lineage cells including osteoclasts (OC). Deficiency of TREM2 and DAP12 are associated with abnormal OC development and function in humans and mouse. We have previously shown that TREM2-DAP12 stimulation leads to enhanced *in vitro* osteoclastogenesis and that *in vitro* mouse OC differentiation is dependent on DAP12 signals mediated through the ITAM motif in DAP12. To further define the signals stimulated by TREM2-DAP12, we transfected the preosteoclast cell line RAW264.7 with FLAG-tagged TREM2, FLAG-DAP12, or ITAM mutants of FLAG-DAP12, and determined proteins associated with DAP12 following FLAG-antibody ligation. Our studies reveal that FLAG crosslinking of FLAG-DAP12 or FLAG-TREM2 on RAW264.7 cells leads to enhanced association of SHIP-1 with the DAP12 adapter protein (at 20 and 40 min), which was not seen after ligation with isotype control Ab. The SHIP-1 association with DAP12 appeared to require an intact DAP12 cytoplasmic ITAM motif, as mutation of the both tyrosines within the ITAM decreased the SHIP-1 association observed with FLAG ligation in RAW264.7 cells expressing the Y65F/Y76F-FLAG-DAP12 mutant. SHIP-1 also co-precipitated with DAP12 in OC generated from C57BL6 BMM and from OC generated with RAW264.7 cells treated with RANKL and MCSF. In RAW264.7 cells transduced with shRNAi for SHIP-1, we observed decreased SHIP-1 association with DAP12 using immunoprecipitation with DAP12 antibodies. We also evaluated TREM2 stimulation of SHIP-1 deficient OC precursors during osteoclastogenesis. Crosslinking with anti-TREM2 monoclonal Ab but not control Ab lead to a 4 fold increase in OC generated from SHIP-1$^{-/-}$ BMM compared to wild type BMM. These results show a novel association of the DAP12 signaling adapter protein with SHIP-1 in both macrophages and OC. Association of SHIP-1 with ITAM motifs of other adapter proteins (CD3 chains) has been observed in other cell types. Stimulation of the DAP12-associated receptor TREM2 or DAP12 directly enhanced the association of SHIP-1 with DAP12, dependent on an intact ITAM motif. SHIP-1 has previously been shown to regulate osteoclastogenesis. Our study showing that in the absence of SHIP-1, TREM2-DAP12 crosslinking enhanced osteoclastogenesis suggests that SHIP-1 serves a role as an inhibitor of DAP12 signaling in OC.

IL-11 and IL-6 Stimulation of Osteoclast Formation Depends on STAT- but not ERK-mediated Pathways in Osteoblasts. J. M. W. Quinn[1], A. Nakamura*[1], B. J. Jenkins*[2], N. A. Sims[3], M. Ernst*[2], T. J. Martin*[1], M. T. Gillespie[1]. [1]Bone, Joint and Cancer Group, St. Vincent's Institute, Fitzroy, Australia, [2]The Ludwig Institute for Cancer Research, Melbourne, Australia, [3]Dept. of Medicine, The University of Melbourne, Fitzroy, Australia.

Cytokines acting through gp130, notably IL-11 and IL-6, play important roles in osteolysis. Both IL-11 and IL-6 stimulate RANKL production in osteoblasts (OB) and thereby trigger osteoclast formation in OB-haemopoietic cell co-cultures. Several osteolytic factors induce IL-11 in OB, which acts as an autocrine stimulus. The role of IL-6 is less clear but it is implicated in ovariectomy-induced bone loss. Two signaling pathways downstream of gp130 are known, involving STAT1/3 and SHP2/ras/ERK. Although dominant negative block of STAT3 in transfected UAMS-32 stromal cells reduces osteoclast formation in co-cultures, the roles of these pathways in OB has not been clarified. We employed cells from two knock-in mouse strains: $gp130^{deltaSTAT/deltaSTAT}$ (d-STAT), which express truncated gp130 incapable of signalling via STAT1/3, and $gp130^{Y757F/Y757F}$ (Y757F), which cannot signal via SHP2/ras/ERK. When bone marrow cells from these mice were stimulated by recombinant RANKL and M-CSF, d-STAT bone marrow formed similar numbers of osteoclasts to wild type (WT), while Y757F bone marrow yielded approximately two-fold more. IL-6 and IL-11 powerfully inhibited RANKL-stimulated osteoclast formation in Y757F bone marrow. In contrast, IL-11 had no effect on d-STAT and WT osteoclast formation, and IL-6 caused only a small reduction (<40%). Coculture of WT bone marrow cells with OB from WT, Y757F or heterozygous $gp130^{deltaSTAT/+}$ mice resulted in formation of large numbers of osteoclasts in response to 1,25 dihydroxyvitamin-D3, IL-11 and IL-6, although for IL-6 the addition of IL-6 soluble receptor (IL-6sR) was required for maximal effects, as previously reported. In contrast, in cocultures using d-STAT OB, IL-11 and IL-6+IL-6sR caused no osteoclast differentiation, and the stimulus provided by 1,25 dihydroxyvitamin-D3 was greatly diminished, consistent with ablation of autocrine IL-11 action. Although gp130 ERK and STAT signals frequently oppose each other, ERK pathway blockade by PD98059 did not rescue osteoclast formation supported by d-STAT OB. We conclude that gp130 STAT1/3 signals in osteoclast progenitors can reduce osteoclast differentiation, but gp130 STAT1/3 signals in OB are essential for IL-6 and IL-11 dependent osteoclast formation in co-cultures.

Rab3D Regulates a Novel Vesicular Trafficking Pathway that Is Required for Osteoclastic Bone Resorption. N. J. Pavlos*[1], J. Xu*[2], D. Riedel*[3], J. S. Yeoh*[1], S. L. Teitelbaum,[4], J. M. Papadimitriou*[5], R. Jahn*[3], F. P. Ross[4], M. H. Zheng[1]. [1]Dept. of Orthopaedic Surgery, The University of Western Australia, Nedlands, Australia, [2]Dept. of Orthopaedic surgery, The University of Western Australia, Nedlands, Australia, [3]Department of Neurobiology, Max Planck Institute for Biophysical Chemistry, Göttingen, Germany, [4]Department of Pathology, Washington University School of Medicine, St Louis, MO, USA, [5]Dept. of Pathology, The University of Western Australia, Nedlands, Australia.

Rab3 proteins are a subfamily of GTPases, known to mediate membrane transport in eukaryotic cells and play a role in exocytosis. Our data indicate that Rab3D is the major Rab3 species expressed in osteoclasts. To investigate the role of Rab3D in osteoclast physiology we examined the skeletal architecture of Rab3D-deficient mice and found an osteosclerotic phenotype. Although basal osteoclast number in null animals is normal the total eroded surface is significantly reduced, suggesting that the resorptive defect is due to attenuated osteoclast activity. Consistent with this hypothesis, ultra-structural analysis reveals that $Rab3D^{-/-}$ osteoclasts exhibit irregular ruffled borders. Furthermore, while over-expression of wild-type, constitutively active or prenylation-deficient Rab3D has no significant effects, over-expression of GTP-binding deficient Rab3D impairs bone resorption *in vitro*. Finally, sub-cellular localisation studies reveal that, unlike wild-type or constitutively active Rab3D, which associate with a non-endosomal/lysosomal subset of post-*trans*-Golgi network (TGN) vesicles, inactive Rab3D localizes to the TGN and inhibits biogenesis of Rab3D-bearing vesicles. Collectively, our data suggest that Rab3D modulates a post-TGN trafficking step that is required for osteoclastic bone resorption.

RAB3D-Dependent Vesicular Trafficking Is Mediated through its Interaction with TCTEX-1, a Light Chain of the Cytoplasmic DYnEIN Microtubule Motor Comples. J. Xu*[1], N. J. Pavlos*[1], A. Carrello*[1], K. Kroeger*[2], K. Ednet*[2], M. H. Zheng[1]. [1]Dept. of Orthopaedic Surgery, The University of Western Australia, Nedlands, Australia, [2]Western Australia Institute for Medical Research, The University of Western Australia, Nedlands, Australia.

Rab3D belongs to the family of small GTPases involved in the regulation of exocytosis. We have recently shown that Rab3D-deficient mice exhibit an osteosclerotic phenotype and that Rab3D is required for the maintenance of the osteoclastic resorptive organelle, namely the ruffled border membrane. Here, to further delineate the mechanism(s) underlying this phenomenon, we have employed a yeast two-hybrid system to identify potential Rab3D interacting proteins. Screening a mouse embryonic cDNA library, 5 clones (T18, -30, -37, -39 and -40) were positively identified which specifically interacted with the N-terminus of Rab3D. Database searches identified these clones as mouse Tctex-1, a 14 kDa light chain of the multimeric cytoplasmic dynein motor complex. A specific interaction between Rab3D and Tctex-1 was confirmed by GST-pull down and co-localisation studies. Truncation analyses mapped the Tctex-1 binding site to the switch II/GTP-binding motif of Rab3D (amino acids 74-95). Consistently, bioluminescence resonance energy transfer (BRET) analysis demonstrated that Tctex-1 preferentially associated with the GTP-bound conformation form of Rab3D in live cells. When overexpressed, Flag-Tctex-1, GFP-dynamitin, or antisense-Tctex-1 disrupted the spatial distribution of Rab3D *in vivo*. Additionally, Rab3D-secretory granules localise to microtubules and are redistributed by nocodazole treatment into -COPI-positive Golgi mini-stacks in transfected COS-1 cells. These data lend support to the notion that Rab GTPases and molecular motor proteins act in concert to regulate directional membrane transport and furthermore suggest that Rab3D may functions to recruit and regulate the activity of cytoplasmic dynein Tctex-1, controlling the sorting and microtubule-dependent targeting of post-Golgi secretory granules to the ruffled border membrane during osteoclastic bone resorption.

The Role of Pyk2/Src in Calcitonin-induced Podosome Reassembly and Sealing Zone Detachment in Osteoclasts. J. Shyu, C. Shih, W. Lin*, H. Liu*. Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan Republic of China.

Osteoclasts (OCs) are multinucleated, terminally differentiated cells which play an essential role in bone resorption. To resorb bone, OCs attach to extracellular matrix or the bone surface via specialized attachment structures called podosomes, which form a prominent F-actin-rich ring that is thought to correspond to the sealing zone of resorbing OCs. It had been showed that Pyk2/Src/Cbl complex is critical to the $\alpha_v\beta_3$ integrin-mediated signaling in podosome. The concept of outside-in and inside-out of integrin-mediated signaling has been elucidated in depth through the study of Pyk2/Src/Cbl complex. Calcitonin (CT) is a 32-amino acid polypeptide which inhibits OC motility, induces OC retraction, and disrupts the actin-ring structure of OCs. Thus it is reasonable to assume that the Pyk2/Src/Cbl complex in podosome could be the potential target for the CT-induced signaling. In isolated authentic rabbit OCs cultured on extracellular matrix-coated Petri dish, we previously showed that CT induced dephosphorylation and redistribution of Pyk2. The dephosphorylation of Pyk2 would be expected to prevent the formation of Pyk2/Src/Cbl complex and therefore inhibit OC motility and attachment. However, the effects of CT on Pyk2/Src/Cbl complex function and their distribution in OCs are not clear. We therefore investigated whether CT affects Pyk2/Src association and Src phosphorylation in OCs by using the immunoprecipitation and Western blot methods. The result showed that CT induced an increase of Src tyrosine phosphorylation and Pyk2/Src association. Using immunofluorescent confocal analysis, we showed that CT induces dephosphorylation of Pyk2 in the sealing zone and increase Src tyrosine phosphorylation and Pyk2/Src association in the central region of OCs. Further examination using specific Y416 and Y527 phosphorylation antibodies of Src showed that CT induced increase of Y416 but not Y527 phosphorylation. The increase of Y416 and decrease of Y527 phosphorylation were found in the central region of OCs after CT stimulation. In conclusions, CT may induce podosome reassembly and sealing zone detachment by decrease Pyk2 phosphorylation in the sealing zone and increase Y416 phosphorylation of Src and Pyk2/Src association in the central region of OCs.

Regulation of Human Osteoclast Function by Redox and sRANKL-induced Intracellular ROS Production. J. M. Hodge*, N. Zimmerman*, L. A. Hodgson*, C. J. Aitken*, M. A. Chacksfield*, M. A. Kirkland*, G. C. Nicholson. Clinical and Biomedical Sciences, The University of Melbourne, Geelong, Victoria, Australia.

In animal models, reactive oxygen species (ROS) have been shown to activate osteoclasts and have been implicated as second messengers in RANKL-mediated osteoclastogenesis. The aim of this study was to investigate the role of ROS in the function of mature human osteoclasts. Osteoclasts were generated by culture of CFU-GM with human M-CSF and RANKL for 14 days. Modulation of resorbing capacity and survival were assessed in mature osteoclasts dissociated from the plastic substrate and re-cultured on dentine slices. Treatment with RANKL enhanced the survival of mature osteoclasts on dentine and was absolutely required for resorption. Resorption was further enhanced by the presence of both M-CSF and RANKL. Co-treatment with hydrogen peroxide (50μM) for 24 hours resulted in a 130% increase in osteoclast size and a 34% increase in resorption. In contrast, co-treatment with the thiol antioxidant *N*-acetylcysteine (NAC; 10 mM) reduced osteoclast size by 22% and number by 50%, and resorption was completely inhibited. When mature osteoclasts were RANKL- and serum-starved for 3 hours and then stimulated with RANKL (150 ng/mL) for 30 minutes, increased intracellular ROS-production was detected using fluorescence microscopy and the ROS-sensitive dye CM-H_2DCFDA. Pre-treatment with NAC blocked RANKL-induced intracellular ROS. Treatment with RANKL also stimulated a time-dependent increase in intracellular hydrogen peroxide, as measured using Amplex Red reagent, with peak accumulation at 10 minutes. Electrophoretic mobility shift assay demonstrated that pre-treatment of osteoclast precursors with hydrogen peroxide (10μM) for 16 hours resulted in increased RANKL-induced NF-κB activity, whereas pre-treatment with NAC (10mM) blocked this activity. Human osteoclast function is stimulated by ROS and inhibited by antioxidant quenching of ROS. Stimulation of osteoclast survival and resorbing activity by RANKL may be mediated by ligand-mediated intracellular ROS production.

Impact of Increasing Overweight Prevalence on the Prevalence of Osteoporosis in Older US Women. A. Looker[1], K. Flegal*[1], L. J. Melton[2]. [1]National Center for Health Statistics/CDC, Hyattsville, MD, USA, [2]Mayo Clinic, Rochester, MN, USA.

The prevalence of overweight among older women in the United States has increased from 62 to 68% since the third National Health and Nutrition Examination Survey (NHANES III 1988-94) was conducted. Higher body mass index (BMI) is associated with higher bone mineral density (BMD), but the impact of the overweight increase on the prevalence of femur neck osteoporosis (FN OP) is not known. In the present study, we used osteoporosis data from NHANES III and overweight prevalence data from NHANES 1999-2002 to address this question in older women. The probability of FN OP for overweight (BMI>=25) vs normal weight women (BMI<25) was calculated using data for 3299 women ages 50+ years from NHANES III. FN OP was defined using T-scores based on 20-29 year old non-Hispanic white women; femoral bone density data were obtained using dual energy x-ray absorptiometry (Hologic QDR 1000). BMI was based on measured height and weight. In NHANES III, BMI was significantly related to femur neck BMD overall (r=0.47), and the prevalence of FN OP was significantly lower in overweight women than in normal weight women (10% vs 32%, respectively). The expected prevalence of FN OP given the higher current prevalence of overweight was then estimated by applying osteoporosis probabilities from NHANES III to the prevalence of overweight and normal weight for women ages 50+ years (n=2111) from NHANES 99-02. Given the current prevalence of overweight, the expected prevalence of FN OP in older women from NHANES 99-02 was only 1% lower than the prevalence observed in NHANES III (17% vs 18%, respectively). These results indicate that FN OP prevalence would be expected to decline by 0.22 units for every 1 unit increase in overweight prevalence. The estimated impact of overweight is likely small in part because the effect of increasing overweight is confined to a small proportion (e.g., 6%) of the total population of older women. Our results suggest overweight prevalence would need to increase to 91% (+23 units) among older women in order to lower FN OP prevalence by 5 units (-5%). In conclusion, although overweight is significantly related to bone density, the increasing prevalence of overweight among older US women appears unlikely to be accompanied by a significant reduction in osteoporosis prevalence.

Seasonal Importance on Vitamin D Deficiency in French Submariners. L. Bégot*[1], F. Labarthe*[2], N. Granger-Veyron*[2], E. Zérath*[1], X. Holy[1]. [1]Integrated Physiology, IMASSA, Brétigny sur Orge, France, [2]Health service, ESNLE, Brest, France.

The effects of total sunlight deprivation on vitamin D metabolism were studied in two 2-month French ballistic missile submarine patrols. One was with summer and the other with winter departure. Blood and urine samples were collected four times per patrol on 20 healthy male subjects: pre-patrol control and after 20, 41, and 58 days in the submarine at sea. Samples were frozen until analyses. No subject received sunlight or vitamin D supplementation during the 60-day patrols. Pre-patrol 25(OH)D values were normal for 75 % of submariners when departure was in summer and decreased thereafter during patrol (-41% at the end of patrol). 20%, 4% and 0% of subjects had 25(OH)D levels above what is considered as normal value (32 ng/ml) after 20, 41 and 58 days respectively. Pre-patrol values of 25(OH)D were low (17.18 ± 1.11 ng/ml) at the occasion of winter departure and continued to decrease with patrol duration. 35% of submariners had values below 13 ng/ml considered as a deficiency level. 1,25(OH)2D was also significantly decreased during both patrols and the lowest values were observed at the end of the mission in the members of the winter patrol. A rapid decline in bone formation (total or bone ALP) and increase in bone resorption (ICTP and DPD) markers were observed at 20 days for both missions. Meanwhile serum pCO2 was found increased and blood pH decreased due to high ambient CO2 in the submarines atmosphere (0.7%) compared to 0.03% in normal air. Significant decrease in urinary excretion of calcium and slight increase in serum calcium were found from the 20th day. PTH was found decreased for both patrols. At the same time, change in urinary calcium levels associated with the increase in bone resorption could be consistent with a risk of nephrolithiasis development. The deficiency in vitamin D in subjects submitted to sunlight deprivation during submarine mission, and particularly for winter departure, could be consistent with a dietary supplementation. However, this kind of treatment should be discussed considering the risk for renal stone formation mainly due to the rise in intestinal absorption.

Use of Vitamin D and Calcium Supplements in Women with Osteoporosis. P. Miller[1], Y. Chen[2], E. Barrett-Connor[3], S. Brenneman*[2], E. Siris[4]. [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Outcomes Research and Management, Merck & Co., Inc, West Point, PA, USA, [3]Department of Family and Preventive Medicine, University of California, San Diego, La Jolla, CA, USA, [4]Metabolic Bone Disease Program, Columbia University Medical Center, New York, NY, USA.

Vitamin D and calcium are essential for the management of osteoporosis. We evaluated the utilization of vitamin D and calcium supplements and factors related to their use in women with osteoporosis or fracture in the National Osteoporosis Risk Assessment (NORA). NORA participants were postmenopausal women age >= 50 who had no prior diagnosis of osteoporosis and no osteoporosis-specific treatment. Of 100,697 participants who responded to a follow-up survey around 3 years post baseline, 69,390 provided complete information on fractures, use of calcium, vitamin D, multivitamins and osteoporosis-specific medication. Descriptive analyses were stratified by multivitamin (MV) use (overall 65%) because MV generally provides some supplementation of calcium and vitamin D. MV usage was not affected by osteoporosis status, fracture or medication use. Logistic regression determined factors related to calcium and vitamin D use. Percent of women who reported calcium and vitamin D use stratified by MV use is shown in Table below for women who were on osteoporosis treatment, had a T-score <= -2.5, or had an incident fracture. Factors independently related to calcium use included younger age, higher education, good to excellent health, non-smoking, T-score <-1.0, osteoporosis medication use, MV use and ethnicity. Factors related to vitamin D were fracture since baseline, T-score <-1.0, osteoporosis medication use and MV use. We concluded that, in NORA, a smaller proportion of women reported taking vitamin D supplement compared to calcium supplement, even those being actively treated for osteoporosis. Vitamin D supplementation was less frequent in non-users of multivitamins compared to users of multivitamins. Efforts should be made to ensure adequate vitamin D supplementation in osteoporosis management

	Osteoporosis Treatment	Baseline T-score <= -2.5	Incident Fracture
MV users			
Calcium	86%	79%	78%
Vitamin D	47%	41%	39%
No MV users			
Calcium	64%	53%	44%
Vitamin D	27%	23%	19%

Antioxidant Defense System in Postmenopausal Women Residing in Endemic Flurotic and Non Flurotic Areas. S. Ravula*[1], C. V. Harinarayan[2], U. V Prasad[3], T. Ramalakshmi*[3], M. Vijayabhaskar*[4], E. G. T. V. Kumar*[3], R. Arunakumari*[4]. [1]Biochemistry, University of Health sciences, Tirupati, India, [2]Endocrinology & Metabolism, Sri Venkateswara Institute of Medical Sciences, Tirupati, India, [3]Endocrinology & Metabolism, Sri Venkateswara Institute of Medical Sciences, Tirupati, India, [4]Biochemistry, University of Health sciences, Tirupati, India.

To study the antioxidant defense system in postmenopausal women residing in flurotic and non flurotic areas. Twenty five post menopausal women (>10years menopause) (with mean age 57 years) residing in endemic flurotic and non flurotic villages (water fluoride >2ppm and <0.35ppm respectively) were studied for their dietary calcium (DC), phytates (DPH), urinary fluoride (UF), serum fluoride (SF), calcium (SCA), phosphorus (SPH), alkaline phosphatase (SAP), ntact parathormone (PTH), 25(OH)D (VIT D) levels, lipid per oxidation (MDA), glutathione - S- transferase (GST) and catalase (CAT) . The mean and standard deviation of these parameters are shown below:

	units	NON FLUROTICS		FLUROTICS	
		Mean	SD	MEAN	SD
UF	ppm	0.62	0.13	2.24	0.9*
SF	ppm	0.07	0.01	0.19	0.03*
DC	mg/day	288	36	255	19*
DPH	mg/day	152	15	169	15*
SCA	mg/dl	9.46	0.71	9.15	1.25
SPH	mg/dl	3.27	0.28	4.22	0.47*
SAP	KAU	5.61	1.11	8.64	1.82*
PTH	pg/ml	8.04	2.96	10.08	7.77
VITD	ng/ml	19.18	7.23	22.54	10.23
MDA	nmol/ml	2.79	0.35	3.82	0.35*
CATALASE	KU/gm Hb	54.37	23.37	42.99	19.22
GST	IU/L	65.5	26.89	40	18.22*

*p<0.0001 compared to controls

The dietary calcium was far below the RDA of the country. The vitamin D and PTH levels were comparable in both the villages. The antioxidant levels were significantly lower in women residing in fluorotic village. Women in non flurotic village showed a strong positive correlation between catalase and PTH (r0.54;p<0.01) and negative correlation with SAP (r-0.52;p<0.008). In flurotic villages MDA showed a negative correlation with SF (r-0.6;p<0.001) and positive correlation with DC (r 0.43; p<0.03). GST showed a negative correlation with PTH (r -0,42; p<0.04).For comparable age group, duration of menopause and vitamin D status, women residing in flurotic area showed less antioxidant defense system and higher lipid per oxidation compared to the women residing in non flurotic area. The poor antioxidant system could be attributed to high serum fluoride levels in these patients. The poor anti oxidant defense system could have a detrimental effect on bone mineral metabolism and mineralization

Air Pollution and Bone Mineral Density. K. Alver*[1], A. J. Søgaard*[1], J. A. Falch*[2], P. Nafstad*[3], H. E. Meyer[3]. [1]Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway, [2]Center of Endocrionology, Aker University Hospital, Oslo, Norway, [3]Institute of General Practice and Community Medicine, University of Oslo, Oslo, Norway.

Higher fracture rates and more osteoporosis have been reported in urban compared to rural populations. Whether pollution can explain part of these differences is not known. Heavy metals, such as aluminium, cadmium and lead have been proposed as risk factors for osteoporosis because of the ability to be deposited in the skeleton, and an inhaled poisonous substance like tobacco smoking is established as a risk factor for osteoporosis and osteoporotic fractures. There is also indication that inflammatory processes, which might be affected by air pollution, might harm the skeleton. Pursuing this, the aim of this exploratory study was to investigate the association between indicators of air pollution and bone mineral density (BMD) in elderly Norwegian men. As part of the Oslo Health Study 2000-01, bone densitometry was performed in a sub-sample of 697 men aged 75/76 years with Dual Energy X-ray Absorptiometry (DXA). Air pollution was estimated by AIRQUIS, a model developed by The Norwegian Institute of Air Research. The model is based on information on emission, traffic counts, weather conditions, topography and measurements, and estimates daily levels of exposure for nitrogen dioxide (NO_2) and particles (PM_{10} and $PM_{2.5}$). NO_2 and $PM_{2.5}$ can be considered as indicators of traffic related air pollution. For PM_{10} also other sources of emission like heating of dwellings and buildings will contribute to the exposure levels. Linking information from this model with information about each participant by the unique personal id-number produced estimates for air pollution exposure at the participants' home addresses. Regression analyses were used to study the association between indicators of air pollution (annual mean 1999) and BMD. Preliminary analysis showed a weak, but statistically significant, negative association between $PM_{2.5}$ and total body BMD (b=-0.004, p=0.042). After adjusting for smoking status, education and body mass index, the association became significant with all three air pollution indicators ($PM_{2.5}$: b=-0.005, p=0.008; PM_{10}: b=-0.003, p=0.006; NO_2: b=-0.0007, p=0.028). The same pattern was also found for the association between total femur BMD and air pollution, although none of those associations were significant. In sum, we found a weak, but significant inverse association between indicators of air pollution and BMD. These initial findings warrant further investigation.

Intake of Vitamin D and Milk Was Associated with Increase in Muscle Mass and Decrease in Body Fat during Dieting in Young Women. T. Hirota[1], I. Kawasaki[1], H. Ikeda[1], T. Aoe[1], K. Hirota[2]. [1]Research Laboratory, Tsuji Academy of Nutrition, Osaka-city, Japan, [2]Obstetrics & Gynecology, Nissay Hospital, Osaka-city, Japan.

A diet-induced weight loss reduces bone mass and increases fracture risk later in life. However, unnecessary dieting is quite common among young slender women because of their slim images. Limited epidemiological and experimental data support the possibility that dietary calcium intake plays a role in body weight regulation. The objective was to assess the effect of dieting with or without milk supplementation on not only bone mineral density (BMD) but also fat and lean mass in normal weight young women. Furthermore the effect of vitamin D intake on change in lean and fat mass was also examined. Fifty one normal weight (body weight; 53.3±5.6 kg, body mass index; 21.05±1.63, 17.9~24.8) female students (aged 23.1±4.7 y) were engaged in dieting by decreasing in energy intake and increasing in physical exercise for 4 months. They were divided into 2 groups during dieting; one (n=28, milk group) was supplemented with milk (more than 200 ml/day) and the other (n=23, control group) was no supplement. We also observed subgroup of different intakes of vitamin D below or above average (4.7±3.4 μg/day). Vitamin D is not allowed to add to milk in our country. BMD (L2-4 and femoral neck), total body fat, and lean (muscle) mass were measured by DXA (GE Lunar, DPX) before and after dieting for 4 months. Nutritional intakes such as vitamin D and calcium were calculated from 3-day dietary record. Changes of body weight in all subjects during dieting were -0.71±2.05 kg (-6.7~4 kg; $p<0.05$) and those of BMD in L2-4 and femoral neck were -0.002 ±0.030 g/cm^2 (-0.055~0.135 g/cm^2) and -0.003±0.027 g/cm^2 (-0.068~0.067 g/cm^2), respectively. The changes of body fat and lean mass were -0.3±3.0 kg (-6.7~5.7 kg) and -0.4±2.4 kg (-5.2~5.8 kg), respectively. Any significant changes in BMD were not observed in all groups after moderate weight loss. However, higher reduction of body fat during dieting was observed in milk group (-0.8±2.8 kg), and further higher reduction was found in subgroup of milk with higher vitamin D (-2.7±2.2 kg; $p<0.01$) in comparison with control group (0.3±3.2 kg). Lean mass was found to be increased much more in milk with higher vitamin D subgroup (1.7±1.2 kg; $p<0.01$ versus -1.0±2.5 kg as control) during dieting. Intake of vitamin D was associated with the decrease in fat mass and increase in lean mass.Thus we suggest the decrease in lean mass as well as BMD by a diet-induced weight loss could be compensated by the increase intake of vitamin D and dairy product or calcium. It should be more important for elderly people who easily lose weight in order to prevent bone fracture.

Underutilization of Calcium in an Osteoporotic Population. W. Y. Chow*[1], R. P. Heaney[2]. [1]Health Outcomes, sanofi-aventis, Bridgewater, NJ, USA, [2]Creighton University, Omaha, NE, USA.

The adequate intake of calcium is crucial for reducing bone loss, supporting osteoporosis treatments, and lowering risk of fractures in osteoporotic patients. Despite recommendations set forth by the National Osteoporosis Foundation and the Surgeon General's Report on Bone Health, consumption of dietary calcium remains low in patients with osteoporosis. According to the latest NHANES data, the median calcium intake in postmenopausal women is about 563 mg per day. The present study was undertaken to evaluate the utilization of calcium supplements in patients who are receiving anti-resorptive therapy. A cross-sectional study using the self-administered National Health and Wellness Survey was conducted by a healthcare consumer research company, Consumer Health Sciences (Princeton, NJ), in 2003 and 2004. Data on healthcare attitudes, behaviors, and over-the-counter (OTC) and prescriptive medication use were collected from a nationally representative sample of the US population. A total of 3420 osteoporotic patients were sampled from an internet panel and were stratified by education, gender, age and race. The patients included in the study (350 men and 3070 women) had a mean age of 61.5 years (range 18-65 years) and reported osteoporosis (physician-diagnosed) between 2003 and 2004. 997 patients (59.4%) and 947 patients (54.4%) indicated current use of a pharmacologic therapy for osteoporosis in 2003 and 2004, respectively. Of those treated with a bisphosphonate, 186 (36%) patients reported using an OTC calcium supplement in 2003; a similar proportion (33%; n=216) reported concomitant calcium supplement use in 2004. In the concomitant use cohort, the length of time over which patients reported using OTC calcium did not differ between 2003 and 2004 (85 months vs 92 months, $P>0.05$). Compliance with OTC calcium, measured by the number of days that patients used the supplement in the past month, decreased in 2004 compared with 2003 (-1.7 days; $P<0.001$).Calcium supplementation is underutilized in this osteoporotic population. Neither the proportion of calcium users nor compliance with calcium supplementation improved from 2003 to 2004. Efforts need to be made to ensure that every patient with osteoporosis receive at least the recommended daily intake of calcium.

Patient Characteristics

	2003	2004	2003-2004

Deficiency of Vitamin D and K Is Highly Prevalent in Patients with Hip Fracture. T. Nakano*[1], K. Tanaka[2], M. Yoshizawa*[3], M. Kamao*[4], N. Tsugawa*[4], T. Okano[4]. [1]Orthopedics, Tamana Central Hospital, Tamana, Kumamoto, Japan, [2]Food and Nutrition, Kyoto Women's University, Kyoto, Japan, [3]Life and Environmental Sciences, Osaka Prefecture University, Osaka, Japan, [4]Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

The deficiency of vitamin D and K has been reported to be the risk factor for non-vertebral fracture. In this paper, we have measured plasma concentrations of vitamin D and K shortly after hip fracture to gain insight into the nutritional status of these patients at the time of the fracture. Seventy patients with hip fracture (17 males, 53 females; aged 84.2 +/- 7.3) were evaluated for their vitamin D and K status. In most patients, their blood samples were obtained within 24 hours after the fracture. Their plasma 25(OH)D and intact PTH levels were 13.3 +/- 8.2 (median; 12.2) ng/ml and 62.8 +/- 32.1 (median; 54.0) pg/ml, respectively. The plasma concentrations for phylloquinone, menaquinone-4 (MK4), and menaquinone-7 (MK-7) were 0.39 +/- 0.34 ng/ml (median 0.27), 0.06 +/- 0.11 (median; 0.05) ng/ml , and 1.67 +/- 2.34 (median; 0.82) ng/ml, respectively. Circulating level of undercarboxylated osteocalcin (ucOC), which represents vitamin K deficiency in the skeleton, was 4.85 +/- 4.03 (median; 3.29) ng/ml. Blood samples were also obtained from 22 age-matched nursing home residents adjacent to the hospital (5 males, 17 females; aged 85.4 +/- 6.9). Extremely low 25(OH)D concentration and high intact PTH levels suggest severe vitamin D deficiency. Low levels of PK and MK-7 together with high ucOC concentration indicate vitamin K deficiency in the skeleton. Since blood samples were obtained shortly after the fracture, above results are likely to represent the patients' nutritional status before fracture. Thus, most patients with hip fracture is in vitamin D- and K-deficient state, and these deficiencies are likely to predispose elderly people to fracture.

High Prevalence of Vitamin D Inadequacy among Community Dwelling Post-Menopausal Women with Osteoporosis . P. Lips[1], J. Chandler[2], K. Lippuner*[3], E. Ragi*[4], J. Norquist*[2], P. Delmas*[5], D. Hosking[6]. [1]Vrije Universiteit Medical Center, Amsterdam, Netherlands Antilles, [2]Merck Research Laboratories, Blue Bell, PA, USA, [3]Osteoporosis Policlinic University Hospital, Berne, Switzerland, [4]Centro de Diag. e Pesq da Osteoporose do Espirito Santo Vitoria, -, Brazil, [5]Hopital Edouard Herriot, Centre Prevention Osteoporose, Lyon, France, [6]Nottingham City Hospital, David Evans Medical Research Centre, Nottingham, United Kingdom.

This study describes the distribution of serum 25-hydroxyvitamin D [25(OH)D] and the relationship with parathyroid hormone (PTH) levels among postmenopausal women with osteoporosis in various regions and across two seasons. A cohort of 2102 community-dwelling, postmenopausal women with osteoporosis from 18 countries [North, Central and Southern Europe, Middle East, Latin America, Asia and Pacific Rim] were recruited between May 2004 and April 2005. Serum 25(OH)D (Nichols Advantage competitive binding chemiluminescence immunoassay) and PTH were measured. Information on factors that could influence vitamin D status was obtained by patient questionnaire. Descriptive statistics were used to evaluate mean serum 25(OH)D and PTH levels by season and region and to estimate the frequency of vitamin D inadequacy defined as < 30 ng/ml. Mean age was 67.2 years, range 41 to 92, with 33% >70 years. 39% reported taking a vitamin D supplement >= 400 IU daily; 79% reported taking prescription medication for osteoporosis. Overall mean 25(OH)D was 27.2 ng/ml (SD=13.0, range 7-120). Overall prevalence of vitamin D inadequacy was 62%. Among women recruited during summer, prevalence of inadequacy was 61% and among those recruited during winter, prevalence was 65%. PTH values began to rise at 25(OH)D levels ≤ 30 ng/ml, supporting 30 ng/ml as the appropriate cutoff to define vitamin D inadequacy. Seasonal and regional distribution of vitamin D inadequacy is shown below:

Region	25(OH)D < 30 ng/ml (%) Overall	Summer	Winter
Europe (n = 794)	54	52	58
Middle East (n = 314)	81	81	83
Asia* (n = 512)	70	63	81
Latin America* (n = 351)	53	57	51
Pacific Rim (n = 131)	62	71**	59
OVERALL (n=2102)	62	61	66

(*includes at least one equatorial country) (**complete data not yet available)
Results suggest that vitamin D inadequacy is widespread among women with osteoporosis across all continents. In this cross-sectional sample, the prevalence of vitamin D inadequacy is high regardless of latitude or season. Results underscore a need to improve physician and patient awareness of the importance of adequate vitamin D supplementation in postmenopausal women with osteoporosis.

Prevalence of Low Calcium Intake in Postmenopausal Osteoporotic Women: The Need for Supplementation. R. P. Heaney[1], S. Magowan[2], X. Zhou*[2], S. Boonen[3]. [1]Creighton University, Omaha, NE, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [3]Leuven University, Leuven, Belgium.

Guidelines recommend that women over age 50 consume > 1200 mg/day of calcium. Calcium supplementation has been an integral part of all registration trials for osteoporosis since the Study of Osteoporotic Fractures (SOF), 1986-1988. The 1994 -1996 Continuing Survey of Food Intakes by Individuals (CSFII) reports over 90% of women, 50 years and older, consume less than the recommended level of 1200 mg/day of calcium in their diet. The objective of this analysis is to investigate the mean calcium daily intake and the prevalence of insufficient calcium intake among postmenopausal women based on 6 major osteoporosis Phase III trials conducted in the last 10 years. The percentage of women with daily baseline intakes below the minimum 1200 mg/day was calculated based on the reported mean and standard deviation of the average daily intakes from each trial. The aggregate baseline mean calcium intake was calculated from mean calcium daily and weighted for the number of patients enrolled in each trial. This analysis included 11,474 postmenopausal women with mean ages ranging from 53-71 years. The weighted mean calcium intake (all sources) for all 6 trials was 727 mg/day, which was slightly higher than the recently obtained 2004 NHANES data of 660 mg/day. The percent of postmenopausal women with insufficient calcium intake (below 1200 mg/day) was estimated to be 85.0% (Table 1).

Table 1

YEAR	STUDY	GROUP	NUMBER (patients)	MEAN AGE (years)	INTAKE MG (SD)	PERCENT < 1200 mg*
1995	Liberman et al.	All	994	63.0	738 (539)	80.4%
1996	FIT I	Treatment	1002	70.7	652 (417)	90.6%
		Placebo	1005	71	619 (397)	92.8%
1998	EPIC	Treatment	452	53	910 (506)	71.7%
		Treatment	445	54	971 (565)	65.7%
		Treatment	102	53	935 (594)	67.2%
		Placebo	461	53	889 (445)	75.8%
1998	FIT II	Treatment	2214	67.6	634 (405)	91.9%
		Placebo	2218	67.7	638 (395)	92.3%
2000	PROOF	Treatment	316	68.2	907 (563)	69.9%
		Treatment	316	69	911 (452)	73.9%
		Treatment	312	67.9	874 (480)	75.1%
		Placebo	311	68.2	979 (592)	64.6%
2001	Neer et al.	Treatment	444	69	786 (443)	82.5%
		Treatment	434	70	757 (449)	83.8%
		Placebo	448	69	762 (433)	84.4%
REVIEW	All STUDIES	All	11,474	66.3 yr	727 mg/d	85.0%

* calculation assumed a normal distribution with parameters
These data derived from the baseline assessments of major osteoporosis trials suggest that, despite increased public awareness, little has changed in the average daily calcium intake since SOF 1988 (714mg/day). Baseline calcium intake of patients is still approximately 500mg/day below the recommended daily amount. Postmenopausal osteoporotic women would benefit from a treatment regimen that includes calcium supplementation with their prescription medicine in order to maximize the fracture risk reduction benefits of osteoporosis therapy.

The Influence of Lifestyle Factors on Bone Mineral Density at the Mid Radius Assessed Using pQCT. S. R. Pye*[1], K. A. Ward*[2], D. K. Roy*[1], C. M. Swarbrick*[1], J. E. Adams*[2], A. J. Silman*[1], T. W. O'Neill[1]. [1]ARC Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Department of Imaging Science and Biomedical Engineering, The University of Manchester, Manchester, United Kingdom.

There are few data concerning the influence of lifestyle factors on bone mass and geometry assessed using peripheral quantitative computed tomography (pQCT). The aim of this analysis was to determine the influence of lifestyle factors on volumetric bone mineral density (vBMD) and total area (TA) at the mid radius in premenopausal women. 94 Caucasian women aged 26 to 36 years were recruited from population registers in Manchester (UK), and invited to attend for a lifestyle questionnaire which included questions concerning smoking, levels of regular physical activity (light, moderate, heavy, very heavy [scored 1-4]) and also duration of sports and physical exercise sufficient to produce sweating (per week: never, occasionally, < 1 hour, 1-2 hours, > 2 hours [scored 1-5]) during three age periods (11-17 years, 18-25 years and 26-35 years). For each of the physical activity variables, scores from each of the three age-periods were summed to provide an overall score, increasing values representing increasing activity. In addition, 69 (73%) subjects completed a 4-day food diary from which daily calcium intake was calculated. Height and weight were recorded. Volumetric BMD (vBMD) and total area (TA) were measured at the mid-shaft radius using pQCT (Stratec XCT 2000). Linear regression was used to explore the relationship between the pQCT parameters and putative risk factors with adjustments made for age, height and weight. The mean age of subjects was 31.4 years. Mean value for height was 1.6m, weight 72.8Kg and dietary calcium intake 787mg. 42% of subjects were current smokers. Mean vBMD was 1300.8mg/cm^3 (SD=19.1) and TA 104.2mm^2 (SD=16.4). Compared to those in the lowest tertile of duration of physical exercise, those in the upper tertile (score > 11) had an increased vBMD (β coefficient 11.9; 95% CI 2.6, 21.2). There was, however, no association with TA (β coefficient -0.6; 95% CI -1.9, 0.7). Levels of regular physical activity, smoking and dietary calcium intake were not associated with either vBMD or TA. Increased duration of physical exercise is associated with an increase in vBMD though not TA at the mid radius in premenopausal women.

Risk Factors for Vitamin D Inadequacy among Women with Osteoporosis: An International Study. R. Rizzoli*[1], J. Eisman*[2], O. Ljunggren*[3], J. Chandler[4], J. Norquist*[4], G. Krishnarajah*[4], S. Lim*[5]. [1]Hopital Cantonal Universitaire de Geneve, Geneve, Switzerland, [2]Garvan Institute of Medical Research, Sydney, Australia, [3]Department of Medical Sciences, University Hospital, Uppsala, Sweden, [4]Merck Research Laboratories, Blue Bell, PA, USA, [5]Severance Hospital Department of Internal Medicine, Seoul, Republic of Korea.

This study determined risk factors for vitamin D inadequacy (25(OH)D <30 ng/ml) among postmenopausal women with osteoporosis in various regions of the world. A cohort of 2102 community-dwelling, postmenopausal women with osteoporosis from 18 countries [including Europe, Middle East, Latin America, Asia and Pacific Rim] were recruited. 1285 were recruited from May-October 2004 and 912 from December 2004 through April 2005. General health, education, sun exposure, skin reactivity, diet, recent travel to sunny climates, and vitamin D supplement use were collected by questionnaire. Other factors assessed included Body Mass Index (BMI), season, and latitude. Serum 25(OH)D (Nichols

Advantage) and PTH were measured at a single office visit. Multivariate logistic regression models estimated the odds ratios for vitamin D inadequacy for significant predictors. Mean age was 67.2 years, range 41 to 92. Overall mean 25(OH)D was 27.2 ng/ml (SD=13.0, range 7-120, median=25). PTH began to rise with total 25(OH)D < 30 ng/ml despite concerns of potential underestimation of 25(OH)D_2. Approximately 62% of women had vitamin D inadequacy. BMI >=30 kg/m^2, inadequate vitamin D supplementation, poor or fair health, and low sun exposure were significant predictors of vitamin D inadequacy. (Table) Countries with marked seasons had somewhat higher prevalence of vitamin D inadequacy than equatorial countries, but prevalence of inadequacy did not differ between summer and winter. Prevalence of vitamin D inadequacy ranged from 30% to 70% in equatorial countries and from 30% to nearly 100% in non-equatorial countries. These findings suggest a high prevalence of vitamin D inadequacy worldwide with modifiable factors of high body mass index, inadequate vitamin D supplementation, and low sun exposure. These results underscore a need to improve physician and patient awareness of the importance of adequate vitamin D supplementation in postmenopausal women with osteoporosis.

Risk Factor	Odds Ratios (95% CI) for Vitamin D inadequacy
BMI	
<=30 kg/m^2	**Ref**
>30 kg/m^2	**2.1 (1.5,2.9)**
Season	
Equatorial climate	**Ref**

Population-Based Evidence that Serum 25(OH)D Levels below 80 nmol/L Reflect Vitamin D Deficiency. J. M. Lappe, D. Travers-Gustafson*, M. J. Barger-Lux*, K. M. Davies*, R. P. Heaney, R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Optimal vitamin D nutrition is essential for skeletal health. Low levels of serum 25(OH)D and the concomitant decrease in serum calcium lead to an increase in serum parathyroid hormone (PTH). PTH increases mobilization of calcium from the skeleton that can cause and exacerbate osteoporosis. However, uncertainty exists regarding the optimum level of serum 25OHD, i.e. the level at which PTH stabilizes. Numerous studies suggest that 25(OH)D levels below 80 nmol/L are deficient. The purpose of this analysis is to evaluate the relationship between serum PTH and 25(OH)D in a randomly selected population-based sample of postmenopausal women. The analysis was conducted on data from 1179 white women randomly selected from the population of healthy postmenopausal women over 55 years of age in a nine-county farming area of Nebraska. Participants were enrolled into an intervention study of calcium and vitamin D. This report includes only data collected at baseline. Blood was drawn after a three-hour fast, and PTH and 25(OH)D were analyzed by RIA (Nichols Laboratories). Data were analyzed with SPSS Version 12.0 (SPSS Inc. Chicago). Persons with serum PTH above the 95th percentile of this population and those with serum calcium values in the highest quintile were excluded from the analysis since they most likely had primary and secondary hyperparathyroidism. Among the remaining subjects, the best fit for values of PTH and 25(OH)D was bilinear, and the point at which the curve flattened was approximately 80 nmol/L. Below this value, PTH dropped by 0.29 pg/ml per nmol/L of 25(OH)D increase. Above the cut-off, PTH was insensitive to 25(OH)D. Thus, findings from this population-based sample further support the existing evidence that values of 25(OH)D below 80 nmol/L are deficient.

Increased Skin Pigmentation in β-Thalassemia Patients Does not Reduce UV-Mediated Vitamin D Synthesis. R. Dresner-Pollak[1], C. D. Enk*[2], A. W. Goldfarb*[3]. [1]Endocrinology, Hadassah - Hebrew University Medical Center, Jerusalem, Israel, [2]Dermatology, Hadassah - Hebrew University Medical Center, Jerusalem, Israel, [3]Hematology, Hadassah - Hebrew University Medical Center, Jerusalem, Israel.

Decreased serum 25-hydroxyvitamin D3 (25-OH-D) level has been reported in β-Thalassemia patients and may contribute to their bone disease (Dresner Pollak R, Br J Haematol 2000). Vitamin D3 is made by photoconversion of 7-dehydrocholesterol (7-DHC) in the skin to previtamin D3. Increased skin pigmentation has been shown to limit vitamin D3 synthesis because melanin competes with 7-DHC for the ultraviolet radiation (UVR). Increased skin pigmentation is a major clinical feature of severe β-Thalassemia, caused by both melanin and iron deposition. To study the effect of increased skin pigmentation on the production of vitamin D3 in β-Thalassemia we measured circulating 25-OH-D concentrations after exposure to a single standard dose of UVR. Minimal erythemal dose (MED mJ/cm2), defined as the lowest UVR sufficient to produce perceptible erythema at 24 hours, was determined in 10 Thalassemia major patients and 10 healthy skin type-matched controls, using a xenon arc solar stimulator. In 4 Thelassemia patients and 4 healthy controls, serial blood samples were obtained for 8 days to determine the change in circulating 25-OH-D level by radioimmunoassy (Incstar) in response to a single total body exposure to 1 MED. Mean MED was significantly lower in Thalassmia patients (91.4 ±22.8 mJ/cm2) compared to controls (132.8±31.7 mJ/cm2, $p<0.01$), indicating the increased skin photosensitivity in Thalassemia patients possibly because of excess iron (Morliere P, Biochim Biophys Acta, 1997). Basal 25-OH-D concentration was significantly lower in Thalassemia patients compared to controls (10.5±6.0 ng/ml vs. 32±7.5 ng/ml, $p<0.05$). However, the increase in serum 25-OH-D over basal level in response to UVR was not significantly different between Thalassemia patients (44-80%) and controls (42-50%). Our findings suggest that vitamin D deficiency in β-Thalassemia patients cannot be attributed to increased skin pigmentation associated with decreased vitamin D production. Other explanations such as increased oxidation of vitamin D should be explored.

Characteristics of Men with Normal BMD and VFA-Detected Fractures. N. Vallarta-Ast, S. Agrawal*, D. Krueger, N. Binkley. University of Wisconsin Osteoporosis Clinical Research Program, Madison, WI, USA.

Densitometric vertebral fracture assessment (VFA) is a useful technology to identify fracture in men. However, some men with VFA-identified fractures have normal BMD. Whether these men have "osteoporosis" is not clear. To begin characterizing such men, DXA studies, including VFA, of 827 male veterans referred for clinical bone mass measurement at the Middleton VAMC were reviewed. Of these men, 33 (4.0%) were identified who had grade 2 or 3 vertebral compression fractures using the Genant semiquantitative (SQ) system, but normal BMD at all three routinely imaged sites (L1-4 spine, proximal femur and one-third radius). Based upon history (including prior fracture, falls, medication and/or toxin use) obtained by the DXA technologist, these men were divided into three groups by inferring future fracture risk: high (prior low-trauma fracture, 17), low (prior high-trauma fracture, 7) and unknown (no prior known fracture, 9). Of those men with high or unknown presumed fracture risk, 77% (20/26) had historical risk factors contributing to skeletal fragility or a history of fracture with falling. The most common single fracture risk factor was chronic corticosteroid use (6/20), followed by other medications or toxins associated with bone loss (e.g., heparin, chemotherapeutics, alcohol abuse or anti-epileptics) in 11/20. An additional 6/20 related a history of frequent falls. Other noteworthy historical conditions included ulcerative colitis, hyperparathyroidism, chronic renal insufficiency and hypovitaminosis D. In only 6/26 were no fracture risk factors identified by history. Additionally, the spinal deformity index (SDI) was calculated for these men. SDI is the sum of the SQ grade for visualized vertebral bodies from T4-L4. By combining fracture number and severity, the SDI has recently been identified as predictor of future fracture risk in postmenopausal women. Mean SDI calculated for the fracture risk groups described above was 3.3, 2.0 and 2.7 in the high, low and unknown risk groups respectively. As such, a trend ($p = 0.08$) toward higher SDI was observed in men with prior low trauma fracture. In conclusion, medical history obtained by the DXA technologist identifies traumatic events and/or detects risk factors for fracture in the vast majority of men with normal BMD and VFA-identified fractures. Obviously, not all VFA-identified fractures are due to osteoporosis; however, medical history combined with SDI may help identify men at higher risk for future fracture. Finally, the high prevalence of secondary causes of bone loss suggests that a metabolic bone disease evaluation may be prudent in men with VFA-identified fractures in the presence of normal BMD

The Spinal Curvature Irregularity Index Predicts Vertebral Fractures: A Comparison with Spine and Femur BMD. G. Maalouf[1], N. Schaaf*[2], R. Zebaze*[3], N. Maalouf*[4], J. Wehbe*[1], E. Seeman*[3]. [1]St. George Hosp., Beirut, Lebanon, [2]K.U., Leuven, Belgium, [3]Departm. Endocrinology, Austin and Repatriation Med. Centre, Melbourne, Australia, [4]Southwestern Med. Center, Dallas, TX, USA.

Vertebral fractures (VFs) are the most common consequence of osteoporosis. Diagnosing VFs from radiographs or DXA vertebral fracture assessment (VFA) images of thoracolumbar spine is an important tool in evaluation of osteoporosis. However, accurate diagnosis of VFs using these methods can be difficult. There is often no clear distinction between a structural failure and normal anatomic variation in anterior, middle and posterior height of the vertebrae. In this study we determined the capability of the Spinal Curvature Irregularity Index (SCII) to identify vertebral deformities. The SCII is the integrated average of the vertebral heights (VHs) over the thoracolumbar spine to give a quantitative estimate of the regularity of the spinal curvature (Zebaze,2004,JBMR). A large SCII is presumed to correlate with presence of vertebral deformities. We compared the capability of SCII in identifying vertebral deformities with that of spine and femur mineral density (BMD). VHs and spine and femur BMD values were obtained from VFA, AP-spine and femur DXA scans (Lunar Prodigy GE Healthcare) in 463 Lebanese women aged 20-89 yrs. ROC analysis and logistic regression was performed using Analyse-it and Minitab. SCII was cube root transformed for normality. T-test was used to compare average transformed SCII. The average SCII was significantly higher for subjects with one or more deformities ($p<0.0001$). SCII increases significantly with increasing numbers of vertebral deformities. The probability of having a deformity increases 2.1 times for every SD increase in SCII. ROC analysis shows that SCII is a better diagnostic tool for VFs than femur or spine BMD.

We conclude that the SCII clearly distinguishes between subjects with and without vertebral deformities. SCII is a superior predictor of vertebral deformity than is spine or femur BMD.

ROC Analysis: Area under the curve for identification of the presence of vertebral deformities

Variable	Area	95% CI	p*
SCII	0.721	0.674, 0.768	<0.0001
Total Femur BMD	0.589	0.537, 0.640	0.0004
Femur Neck BMD	0.586	0.534, 0.637	0.0006
Femur Troch BMD	0.564	0.512, 0.617	0.0083
L1-L4 Spine BMD	0.542	0.489, 0.595	0.0612
L2-L4 Spine BMD	0.543	0.490, 0.596	0.0563

*Probablity that there is no distinction between subjects with and without deformities

Combined Deterioration of Cancellous and Cortical Bone Structure and the Risk of Vertebral Fragility Fracture. S. Qiu, S. Palnitkar*, D. Rao. Bone & Mineral Research Lab, Henry Ford Health System, Detroit, MI, USA.

The effects of bone architectural deterioration on the risk of vertebral fracture have usually been studied by cancellous and cortical bone respectively. There is little information about the risk of vertebral fracture in subjects with both cancellous and cortical bone compromised. Iliac bone biopsies were performed in 144 postmenopausal white women, aged 50 to 73 years. Of them, 66 were non-fracture subjects and 78 suffered from non-traumatic vertebral fracture not just deformity. Conventional bone histomorphometry was conducted for all the subjects. In cancellous bone, the measurements included cancellous bone volume (BV/TV-Cn), trabecular thickness (Tb.Th), trabecular number (Tb.N) and trabecular separation (Tb.Sp), and in cortical bone, the cortical bone volume (BV/TV-Ct) and thickness (Ct.Th). The same measurements were also performed in 38 premenopausal women aged 20-49 years and a value of 1SD below the mean was used as the cutoff for determining the vertebral fracture risk. Logistic regression analysis demonstrated that Tb.N and Ct.Th were the most positive variables to affect the risk of vertebral fracture. The non-fracture postmenopausal women and fracture patients were separately divided into 4 groups depending on the level of Tb.N and Ct.Th: 1) normal Tb.N and Ct.Th; 2) low Tb.N but normal Ct.Th; 2) low Ct.Th but normal Tb.N and 4) low Tb.N and Ct.Th. Compared to the group with normal Tb.N and Ct.Th, the increase in the risk of vertebral fracture was similar in the groups with only low Tb.N (Odds ratio 3.29, 95% CI 1.14-9.45) and only low Ct.Th (Odds ratio 3.43, 95% CI 1.14-13.6). However, this risk increased to 27 fold (95% CI 7.63-95.2) in the group with low Tb.N and low Ct.Th. In non-fracture postmenopausal women, the prevalence of low Tb.N and Ct.Th was only 7.6% but in fracture patients the prevalence was 50%. Our study suggests that the combination of compromised cortical and cancellous bone structure confers a greater risk to vertebral fragility fracture, an observation that has hitherto been overlooked.

Hip Fracture Incidence over a 10-Year Period: Reversal of a Secular Trend Related to a Specific Decrease of the Age-Adjusted Incidence in Institutional-Dwelling Elderly Women. T. Chevalley[1], E. Guilley*[2], F. Herrmann*[1], P. Hoffmeyer*[3], C. H. Rapin*[2], R. Rizzoli[1]. [1]Service of Bone Diseases, Rehabilitation and Geriatrics, University Hospitals Geneva, Switzerland, [2]Centre for Interdisciplinary Gerontology, University Hospitals Geneva, Switzerland, [3]Service of Orthopaedic Surgery, University Hospitals Geneva, Switzerland.

Hip fracture in the elderly is the main burden of osteoporosis in terms of mortality, disability, impairment of quality of life and costs. On the other hand, there is an increase of age-adjusted hip fracture incidence (secular trend) in many studies. Long-term data on secular changes in women and men within a defined community are still scarce. We specifically examined from 1991 to 2000 the age distribution of patients with hip fracture, the secular changes in the incidence rates of hip fracture in women and men in a well defined community, and the influence of the residential status (institutional-dwelling or home-dwelling). All patients 60 years of age and older discharged with a diagnosis of a hip fracture (ICD-10 code: S72.0 and S72.1) were retrospectively identified from the computer records of the Geneva university hospital, which is receiving 95% of hip fracture occurring in a well defined area. From 1991 to 2000, 3951 hip fractures were recorded. This concerned 1409 institutional-dwelling women and 215 men and 1776 home-dwelling women and 551 men. Mean age (± SD) of women and men with hip fracture was 86.4±6.5 and 84.5±7.9 years in institutional-dwelling elderly, and 81.6.±8.5 and 79.7±8.9 years in home-dwelling elderly ($p<0.001$). Over a 10-year period, mean age increased by +0.13 year per year ($p=0.032$) and by +0.14 year per year ($p=0.038$), in institutional-dwelling and home-dwelling elderly women, respectively. In men of the corresponding groups, mean age changes were +0.28 year ($p=0.129$) and -0.06 year (NS), respectively. The age-adjusted incidence rate of hip fractures, standardized to the 2000 Geneva population, decreased significantly by 1.3% per year in women ($p=0.039$) and remained unchanged in men (+0.5% per year, $p=0.686$). Among institutional-dwelling elderly women, hip fracture incidence decreased by 1.9% per year ($p=0.044$) whereas it remained stable (+0.0% per year, $p=0.978$) among home-dwelling women. In men, no significant change in hip fracture incidence occurred among institutional-dwelling (+1.0%, $p=0.666$) nor home-dwelling (+0.8% per year, $p=0.565$). In conclusion, despite an increase in the mean age of hip fractured women, the decrease in the age-adjusted incidence of hip fracture in institutional-dwelling elderly women was responsible for the significant decrease in age-adjusted incidence of hip fracture observed in women but not in men.

Renal Function and Risk of Hip and Vertebral Fractures among Older Women. K. Ensrud[1], L. Lui[2], A. Ishani*[1], M. Shlipak*[2], B. Taylor[1], D. Antoniucci*[2], K. Stone[2], S. Jamal[3], M. Homan[1], S. Cummings[2]. [1]VAMC & U of MN, Minneapolis, MN, USA, [2]UCSF & CPMC, San Francisco, CA, USA, [3]U Toronto, Toronto, ON, Canada.

An increased rate of fractures has been observed in patients with end-stage renal disease, but the effect of less severe renal dysfunction on fracture risk is uncertain. To test the hypothesis that community-dwelling older women with impaired renal function are at increased risk of hip and vertebral fractures (fxs), we conducted a case-cohort study within the Study of Osteoporotic Fractures, a prospective cohort study of 9,704 women ≥65 yrs. Baseline renal function in random samples of women who had fxs of 2 types since the baseline exam (149 with incident hip fx, 150 with incident vertebral fx) was compared with that in control women without incident fx of the specified type (376 & 293 controls for cases of hip and vertebral fx, respectively). Controls were drawn from a pool of 400 women randomly selected from the cohort regardless of fx status. We estimated the creatinine clearance (CrCl) in ml/min for each participant using the Cockcroft-Gault formula incorporating baseline age, gender, weight and serum creatinine; CrCl was classified by modified National Kidney Foundation criteria for chronic kidney disease. For the hip fx (vertebral fx) analyses, 46% (51%) had a CrCl ≥ 60, 29% (29%) had a CrCl 45-59 and 25% (20%) had a CrCl <45. Fx cases were validated by x-ray reports (hip fx) and spine films taken at baseline & 3rd exam an average of 3.7 yrs later (vertebral fx). There was an independent, graded association between reduced renal function and the risk of hip fx; compared with women with normal renal function, those with moderate renal impairment had a 2.3-fold increase in risk. The relationship between renal function and vertebral fx was weaker in magnitude and did not reach significance. Further adjustment for health status, smoking, diabetes, prior fx and physical activity or substituting femoral neck or spine BMD for calcaneal BMD did not alter our results.

Renal Function	Relative Risk of Fx*	
	Hip Fx RH (95%CI)	Vertebral Fx OR (95% CI)
CrCl ≥ 60 ml/min	1.0 (referent)	1.0 (referent)
CrCl 45-59 ml/min	1.6 (0.9-2.8)	1.1 (0.6-1.9)
CrCl < 45 ml/min	2.3 (1.2-4.7)	1.3 (0.6-2.8)

*adjusted for age, weight and calcaneal BMD

Older community-dwelling women with moderate renal dysfunction are at increased risk of hip fx. Our results in context of several studies reporting associations between chronic kidney disease and cardiovascular disease highlight the potential public health impact of chronic renal insufficiency.

Gender Specific BMD Profile in Norwegian Patients with Forearm Fractures. H. C. Gulseth*[1], C. G. Gjesdal[2], G. Haugeberg*[3]. [1]Dept of Rheumatology, Betanien Hospital, Skien, Norway, [2]Dept of Rheumatology, Haukeland University Hospital, Bergen, Norway, [3]Dept of Rheumatology, Sorlandet Hospital, Kristiansand, Norway.

Osteoporotic fractures of the hip and spine are highly frequent in the Norwegian population. Several international studies have shown a relationship between osteoporosis and low impact forearm fractures in patients > 50 years. The main purpose of this study was to assess the prevalence of osteoporosis in Norwegian patients with low impact forearm fractures. Furthermore, we wanted to examine whether patient bone mineral density (BMD) for patients with low impact forearm fractures differed from the expected BMD for age. 640 patients aged > 50 years with low impact forearm fractures were included from three Norwegian Hospitals (Bergen n=272, Skien n=240 and Kristiansand n=128). The patients had hip and spine BMD measured according to the standard procedures with Lunar™ DXA equipment. Gender specific T and Z scores were extrapolated from the Lunar™ reference data. These reference data have previously been validated in a large scale Norwegian population study. A significant proportion of men and women with low impact wrist fractures had osteoporosis. The proportion was expectedly higher among female patients. Osteoporosis was defined as a T score below 2.5 SD in either hip or spine. 41% (n=554) of females had osteoporosis, of which 23% was in the hip and 31% in the spine. In the male patients, 28% (n= 84) had osteoporosis, 16% in the hip and 19% in the spine. In female patients the prevalence of osteoporosis increased with increasing age, but the same relationship was not observed in the male patients. Both men and women with low impact forearm fracture had a significantly lower BMD than expected from the Lunar™ reference data. Despite standardising for gender, age and weight, the mean Z score was significantly lower for men than for women. In the female patients the mean Z score (95% CI) in the hip was -0.43 (-0.50 to -0.35) and in the spine -0.19 (-0.31 to -0.07). In the male patients mean Z score (95% CI) in the hip was -0.73 (-0.98 to -0.48) and in the spine -0.64 (-0.10 to -0.29). The reason for this gender specific BMD profile in forearm fracture patients is unknown.

Age related prevalence of osteoporosis

Age (Years)	**50-59**	**60-69**	**70-79**	**80+**
Women (n)	126	165	151	112

The Prevalence of Vertebral Fractures in Mexican Men over 50 Years. A Population-Based Study. P. Clark[1], M. Deleze[2], F. Cons-Molina[3], J. Salmeron*[4], S. Ragi[5], L. Palermo*[6], S. R. Cummings[7]. [1]Clinical Epidemiology Unit-Faculty of Medicine UNAM, IMSS, Mexico City, Mexico, [2]Clinica de Osteoporosis, Puebla, Mexico, [3]Unidad de Diagnostico de Osteoporosis, Mexicali, Mexico, [4]Epidemiology & Health System Unit, IMSS, Morelos, Mexico, [5]CEDOES, Vitoria, Brazil, [6]Coordinating Center, University of California, San Francisco, CA, USA, [7]SF Coordinating Center, CPMC Research Institute and UC San Francisco, San Francisco, CA, USA.

Osteoporosis in men has become a focus of research in the last decade in response to the increasing awareness of the heath impact of this condition in males due to high mortality and economical impact. We reported recently that Mexican women have a high rate of vertebral fractures, similar to the results reported in the United States and some European countries. To date, no studies on the prevalence of vertebral fractures have been reported in Mexican men. Therefore, the aim of this study was to determine the prevalence of vertebral fractures in men 50 years and over in the City of Puebla, Mexico, following the same protocol used from our previous study in women. A stratified sample of 413 randomly selected men from Puebla, Mexico was surveyed in a face to face interview. A questionnaire was used to get information on demographics, osteoporosis risk factors and some life styles. BMD in two regions and lateral dorsal/lumbar X-rays were obtained in all cases in accordance with international protocols to be able to make cross-national comparisons. Digital morphometry was used to determine vertebral deformities by a modified Eastell criterion. The overall prevalence of vertebral fractures was 9.7 %. The prevalence increased with age having the highest prevalence in the older group as seen in the table. The prevalence of vertebral fractures in men is half of the prevalence estimated for women (19.5%). The higher prevalence in women starts at age 70 (18.6 % CI 10.7-26.6) while in men the higher prevalence starts a decade later. This pattern is similar with the patterns in other European countries and the USA. We conclude that vertebral fractures are more frequent in older age Mexican men, and these figures have to be taken into consideration by Mexican health authorities to plan future programs oriented to prevent and treat fragility fractures in men.

Age	Total N	Num of Fx	Prevalence and 95% CI
50-59	101	2	2.0 (-0.74-4.70)
60-69	103	8	7.8 (2.60-12.94)
70-79	106	8	7.5 (2.52-12.58)
> 80	103	22	21.4 (13.45-29.27)
Total	413	40	9.7 (6.83-12.54)

***In Vivo* 3 D Reconstruction of Human Vertebrae Using 3 Dimensional X-Ray Absorptiometry (3D-XA).** S. Kolta[1], D. Mitton*[2], S. Quiligotti*[2], C. Ambrosi*[2], C. Roux[1], W. Skalli*[2]. [1]Rheumatology, Cochin hospital, Paris, France, [2]LBM, ENSAM, CNRS, Paris, France.

Lumbar spine BMD measured by DXA is an important risk factor for vertebral fracture. However, it is highly dependent on patient positioning and inter individual variations. Other parameters such as vertebral body size and shape independently affect its strength. Recent advances in stereoradiographic reconstruction techniques allow obtaining 3D bone geometry from landmarks identified on 2 radiographs and an a priori knowledge. The aim of our study was to evaluate the accuracy and precision of 3D reconstruction of human vertebrae using 2 perpendicular DXA scans both ex-vivo and in vivo. Sixteen human dried lumbar vertebrae were used to calculate the accuracy. They were scanned using a helical CT-scanner. The 3D reconstruction containing up to approximately 2000 points, were obtained using the SliceOmatic® software (accuracy ± 1 mm). DXA acquisitions of the vertebrae were performed using a standard Hologic QDR 4500 A device. The DXA scans were acquired in AP and lateral incidences. From both DXA images, anatomical landmarks were identified and 3D detailed models were reconstructed. The accuracy of 3D-XA reconstructions was evaluated in comparison with the CT-scan ones by superimposing the two models using geometrical transformations and a least square matching method. Results were expressed as point to surface distances. The AP and lateral views of the thoraco-lumbar spines (from T4 to L4) of 20 female patients, aged 61 ± 8 y, acquired by the imaging software on the same DXA device were used to calculate the precision. Their 3D reconstruction using the 3D-XA method was performed twice by 2 different observers. A set of geometric parameters including lateral, anterior and posterior vertebral body heights, superior, middle and inferior width and depth were calculated from 3D-XA reconstructions of 3 different observers for L1 - L4 vertebrae. Quantitative comparisons between the CT-scan reference reconstructions and the 3D-XA for the dried vertebrae yielded mean difference for the whole vertebrae of -0.2 ± 1.3 mm. Mean absolute value was 1.0 mm and 95% of errors < 2.6 mm. Maximal error reached 6.4 mm on the transverse process. The precision of the in vivo 3D reconstruction of the human vertebrae using the 3D-XA method showed a mean difference between the 2 observers of 0.4 ± 0.9 mm (2 RMS i.e. 95% of differences < 2.3 mm). Mean errors for geometric parameters calculated from 3D-XA ranged from 0.5 - 1.2 mm according to the parameter, (2 RMS 1.3 - 2.9 mm, < 9%) and maximal errors 1.9 - 4.7 mm (<16%). This pilot study shows that 3D-XA of human vertebrae is feasible in vivo using a standard DXA device allowing direct measurement of geometric parameters of the vertebrae.

Fracture Risk Related to Selected Factors According to Site and External Cause of Injury. The 10-year Follow-Up Data of OSTPRE Study. R. J. Honkanen[1], M. T. Tuppurainen*[2], H. P. Kroger[3]. [1]Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, [2]Gynaecology, Kuopio University Hospital, Kuopio, Finland, [3]Surgery, Kuopio University Hospital, Kuopio, Finland.

The purpose was to find out differences in fracture risks according to site and external cause of fracture. The 10-year follow-up data of The Osteoporosis Risk Factor and Prevention (OSTPRE) Study cohort was used. The cohort was established in 1989 by selecting all women (N=14220) born in 1932-41 and resident in Kuopio Province, Finland. 11074 women responded to postal enquiries in 1989, 1994 and 1999. A total of 1915 women reported a follow-up fracture verified by patient record perusal. The effects of fracture history, smoking and nutritional calcium intake at baseline as well as hormone replacement therapy (HRT) during follow-up were studied as 3-category variables. In addition, a sum risk score (range 0-8) was formed out of these factors and was used as a 3-category (low, medium and high risk) variable in univariate and multivariate logistic regression. Considerable differences between fracture types and external cause categories were found (Table). The results imply that these factors apply better for osteoporotic fracture than other fracture risk estimation.

Table. Fracture risk related to selected factors according to site and external cause of fracture

Physical Activity and Fracture Risk in Older Men: A Prospective Study. K. L. Stone[1], S. R. Cummings[1], S. Harrison*[1], P. M. Cawthon[1], J. A. Cauley[2], K. E. Ensrud[3], D. C. Bauer[4], M. Stefanick*[5], B. Chan*[6], L. Marshall*[6], L. Lambert*[6], E. S. Orwoll[6]. [1]San Francisco Coordinating Center, San Francisco, CA, USA, [2]University of Pittsburgh, Pittsburgh, PA, USA, [3]University of Minnesota, Minneapolis, MN, USA, [4]University of California, San Francisco, San Francisco, CA, USA, [5]Stanford University, Palo Alto, CA, USA, [6]Oregon Health Sciences University, Portland, OR, USA.

Prior studies suggest that increased physical activity in older adults may prevent falls and improve bone mineral density (BMD). Increased activity levels are associated with decreased risk of hip fracture in older women, but there is little data on this topic in men. Therefore we tested the association of physical activity and risk of non-spine and hip fractures in the Osteoporotic Fractures in Men (MrOS) study. During the MrOS baseline examination, 5995 men aged 65 and older were enrolled at six US clinic sites. Physical activity was assessed using the Physical Activity Scale for the Elderly (PASE). Activity levels were categorized as low (lowest quartile), medium (2^{nd} or 3^{rd} quartile) and high (upper quartile). Total hip BMD was assessed by DXA (Hologic QDR 4500W). Participants were contacted every four months by mail or phone to prospectively ascertain the occurrence of fractures. All fractures were confirmed by review of radiology reports. During a mean follow-up of 3.6 years, 256 men suffered non-spine fractures, and 46 had incident hip fractures. After adjustment for age and BMI, those with low activity levels had a 38% increased risk of non-spine fracture (Relative Hazard=1.38; 95% confidence interval 1.03 - 1.84) and 87% increased risk of hip fracture (RH=1.87; 0.98 - 3.57) compared to those with medium activity levels. Those with high activity levels did not differ significantly from those with medium activity levels. Controlling for smoking and alcohol, health status and comorbidities did not substantially alter the results, however increased risk of fracture among those with low activity levels (compared to medium activity) was attenuated after adjustment for hip BMD (RH=1.23; 95% CI 0.92-1.66 for non-spine fracture; RH=1.35; 95% CI 0.69-2.63 for hip fracture). When activity levels were classified according to type of activity (recreational, household chores, occupational), low levels of recreational activity were most strongly associated with risk of hip fracture (RH=2.87; 1.18 - 6.94). There were no apparent differences in non-spine fracture risk according to type of activity. In conclusion, older men with low activity levels are at increased risk of non-spine and hip fracture. This association is at least partly explained by low BMD. Low levels of recreational activity may be a stronger indicator of hip fracture risk.

Vitamin K Circulating Levels and Associations with Bone Metabolism in Healthy Japanese Women. N. Tsugawa*[1], M. Shiraki[2], Y. Suhara*[1], M. Kamao*[1], K. Tanaka[3], T. Okano[1]. [1]Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [2]Research Institute and Practice for Involutional Diseases, Nagano, Japan, [3]Nutrition, Kyoto Women's University, Kyoto, Japan.

It is generally accepted that vitamin K deficiency is associated with low bone mineral density (BMD) and increased risk of bone fracture. Among the vitamin K homologues, phylloquinone (K_1), menaquinone-4 (MK-4) and menaquinone-7 (MK-7) are primarily observed in human plasma, however, the data are limited on their circulating levels and their associations with bone metabolism, or with γ-carboxylation of osteocalcin molecule. Our objectives were to measure circulating concentrations of K_1, MK-4, and MK-7 in Japanese women, and to elucidate whether each form of vitamin K has a significant association with bone metabolism. Healthy Japanese women (n=407), aged 30-88 yr (62.7±10.9 yr) were stratified by their age into three groups, the 30~49 yr (n=52), the 50~60 yr (n=219), and the 70~ yr (n=136) groups. Plasma K_1, MK-4, MK-7, undercarboxylated osteocalcin (ucOC; measured by the novel electro chemiluminessence immunoassay [ECLIA]), intact OC, Ca, P, bone-derived alkaline phosphatase activity (BAP), and urinary creatinine, N-terminal telopeptide (NTx), and deoxypyridinoline (DPD) were measured. As a result, K_1, MK-4, and MK-7 were detected in 100, 56.8, and 97.8 % of all subjects, respectively, and on average, MK-7 was highest and MK-4 was lowest among the three K vitamins in all age groups. K_1 and MK-7 correlated inversely with ucOC, but nutritional basal concentration of MK-4 had no associations with ucOC. Plasma K_1+MK-7 concentration required to minimize the ucOC concentration was less than 1.3 ng/mL in the 30~40 yr group, 4.7 ng/mL in the 50~69 yr group and more than 10.1 ng/mL in the eldest group. Bone metabolic markers did not correlate with vitamin K homologues concentrations except for relationship between K_1 and urinary DPD at 50~69 yr group and 70~ yr groups. As a conclusion, the certain role of ucOC remains unclear, however, if submaximal γ-carboxylation relates the prevention of fracture or bone mineral loss, circulating vitamin K concentrations in elderly people should be maintained higher than young people.

Skeletal Effects of Chronic Obstructive Pulmonary Disease: the EOLO Study. G. Crepaldi[1], S. Maggi*[1], S. Adami[2], D. de Feo[3], S. Giannini[4], S. Gonnelli[5], G. Guglielmi*[6], G. Martini[5], R. Nuti[5]. [1]CNR Aging Center, Padova, Italy, [2]Rheumatology, Valeggio Hospital, Verona, Verona, Italy, [3]Procter & Gamble, Rome, Italy, [4]Internal Medicine, University of Padova, Padova, Italy, [5]Internal Medicine, University of Siena, Siena, Italy, [6]Radiology, Scientific Institute Hospital "CSS", San Giovanni Rotondo, Foggia, Italy.

The musculoskeletal system is frequently weakened by disabling pathologies like chronic obstructive pulmonary disease (COPD) and the factors involved in this association are multiple, as summarized in the following figure.Of particular concern is the fact that COPD patients are at higher risk for severe vertebral fractures, responsible for a lower lung function that leads to a worsening of the condition. A large, epidemiological study has been undertaken in order to assess the prevalence rates of osteoporosis and osteopenia in a random sample of patients referring to the outpatient pulmonary clinics in 100 centers in Italy (Evaluation of Obstructive Lung disease and Osteoporosis, E.O.L.O. Study for the EOLO Study Group). Each center is enrolling 80 patients, aged 50+ years, who are undergoing a routine assessment for COPD. After informed consent, their medical charts are reviewed and a complete evaluation for osteoporosis, including an interview and a bone ultrasound evaluation using the Achilles Express apparatus (Lunar Co, Madison, USA) are conducted. Subjects are excluded from the study for coexisting cancer, renal, hepatic, thyroid diseases, as well as for previous treatment with drugs affecting bone metabolism. The main objectives of the study are to define the prevalence rates of osteopenia and osteoporosis and of vertebral fractures and to compare them with data available in a population based study conducted in Italy in 2001 in the same centers (ESOPO). Secondary objectives are to evaluate the impact of the use of oral versus inhaled corticosteroids and of the duration of the COPD on the number and severity of vertebral fractures. A pilot and a feasibility studies have been conducted in January 2005, while the data collection phase began in February and is expected to last until July. Preliminary results will be available starting from September 2005.

Impact of Early Osteoporosis Treatment on Subsequent Fracture Prevention Among Women With Clinical Vertebral Fracture. R. Lindsay[1], N. N. Borisov*[2], R. L. Sheer*[2], M. Steinbuch*[2]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Procter & Gamble Pharmaceuticals, Inc., Mason, OH, USA.

This study evaluated osteoporosis treatment use and its effect on prevention of subsequent fractures among women with a clinical vertebral fracture, utilizing an integrated administrative, medical and pharmacy claims database. A retrospective cohort study was conducted among women (aged 45+) with a new vertebral fracture verified with a diagnostic code and a record of radiologic exam, between July 1, 2000 and June 30, 2003. The cohort was followed for 12 months after the vertebral fracture to identify a subsequent fracture (vertebral and non-vertebral), osteoporosis treatment, and its subsequent fracture prevention effect. The following exclusion criteria were applied to the data: (1) in the 6 months period prior to the vertebral fracture, women with a record of previous (a) vertebral or non-vertebral fractures, (b) treatment with risedronate, alendronate, nasal calcitonin, or raloxifene, or (c) Paget's disease treatment, and (2) at any point of the study, women with a record of malignant neoplasm and/or trauma "E codes". A total of 7,233 women were identified with a new clinical vertebral fracture. The mean age was 73 years. Majority of the population (80%) did not receive any osteoporosis treatment (bisphosphonates or nasal calcitonin); 1,056 women (15%) received osteoporosis treatment within 90 days of their vertebral fracture (early-treatment cohort), and 358 women (5%) received treatment after 90 days of their vertebral fracture (late-treatment cohort). During the 1-year follow-up, 18% of untreated women experienced a subsequent fracture (vertebral or non-vertebral, n=1,039). Among women in the early-treatment cohort only 85 (8%) had a subsequent fracture (RR=0.51, $p<0.01$ compared to no treatment cohort), and in the late-treatment cohort, 76 (21%) had a subsequent fracture (RR=1.05, $p=0.73$ compared to no treatment cohort). Osteoporosis treatments were effective in their subsequent fracture prevention compared to no treatment as follows: risedronate (RR=0.30, $p<0.01$), alendronate (RR=0.47, $p<0.01$), and nasal calcitonin (RR=0.67, $p=0.03$). Among women aged 45+ years with a clinical vertebral fracture, the majority did not receive any osteoporosis treatment. Among those who received treatment, there was a significantly lower risk of developing a subsequent fracture. The early-treatment cohort trended toward fewer fractures compared to the late-treatment cohort. This suggests that a

fragility fracture demands immediate attention and rapid, effective treatment. Risedronate was observed to have a 70% reduction in the occurrence of subsequent fractures within 1 year of vertebral fracture.

Adherence with Drug Therapy and Risk of Fracture among Women with Postmenopausal Osteoporosis. D. Weycker*[1], D. Macarios*[2], G. Oster*[1]. [1]Policy Analysis Inc., Brookline, MA, USA, [2]Amgen Inc., Thousand Oaks, CA, USA.

Osteoporosis drug therapy has been reported to prevent fracture in clinical trials. Little is known, however, about the relationship between adherence with such therapy and risk of fracture in clinical practice. A retrospective nested case-control design was employed. Data were obtained from a medical claims database containing information from over 30 US health plans on 15 million lives annually. Study subjects consisted of all women aged ≥45 years with postmenopausal osteoporosis (PMO) who initiated osteoporosis drug therapy (bisphosphonates, calcitonin, or raloxifene) between July 1998 and December 2003; those with secondary causes of osteoporosis were excluded. "Cases" consisted of all subjects who experienced an osteoporotic-related fracture between date of therapy initiation and end of observation period. "Controls" consisted of subjects who did not experience such a fracture during this period; they were matched to cases (1:1) based on age, drug therapy, therapy initiation date, and duration of follow-up (date of therapy initiation to date of fracture for cases). Adherence was measured based on number of therapy-days through end of follow-up. Conditional logistic regression was employed to examine relationship between adherence with osteoporosis drug therapy and odds of fracture, controlling for potential confounders. A total of 16,031 women with PMO initiated osteoporosis drug therapy; 724 (5%) experienced fracture following therapy initiation (mean duration of follow-up, 220 days). In multivariate logistic regression, odds of fracture were significantly lower for those with ≥180 (vs. <30) days of therapy; odds did not differ for those with 30-179 (vs. <30) days of therapy (Table). Among women with postmenopausal osteoporosis, poor adherence with osteoporosis drug therapy is associated with increased risk of fracture.

Odds of fracture, by level of drug adherence

	Unadjusted		Adjusted*

Degree of Vertebral Deformities Is Associated with Topology of Trabecular Network Measured Noninvasively at Radius and Tibia Surrogate Sites. G. A. Ladinsky*, B. Vasilic*, A. Popescu*, M. Wald*, B. Zemel*, P. J. Snyder, L. Loh*, H. K. Song*, P. K. Saha*, A. Wright*, F. W. Wehrli. University of Pennsylvania, Philadelphia, PA, USA.

Bone loss after menopause is accompanied by architectural changes of trabecular bone (TB) that contribute independently to the bone's reduced mechanical competence. Until recently, however, there was no modality capable of assessing TB architecture noninvasively. In order to examine the hypothesis that TB network topology determines fracture resistance independent of BMD, we examined patients with varying degrees of vertebral deformity by means of the MRI-based virtual bone biopsy (VBB) conducted in the distal radius and distal tibia in women with age>60 years and BMD T scores -2.5±1.0. Images were acquired at 1.5T and processed to yield bone volume fraction (BV/TV) maps with a final voxel size of 62x62x103μm^3. Vertebral deformities were assessed from mid-line sagittal MRIs (wedge, biconcavity and compression deformity) and a spinal deformity index (SDI) determined as the weighted sum of the three types of deformity. Digital topological analysis (DTA) was conducted on the skeletonized TB images (in which plates and rods are converted to surfaces and curves) and the voxel type (curve, surface, junction between fundamental types) determined. DTA voxel densities and TB thickness were determined as described previously and associations examined between these structural measures and SDI using single and multi-parameter regression models. Erosion index (EI, ratio of parameters expected to increase with osteoclastic resorption divided by those expected to decrease), density of voxels for curve-type trabeculae (C), and profile-edges (PE, essentially free ends) correlated positively with SDI while BV/TV, Tb.Th correlated negatively. Interestingly, there was no association between vertebral BMD by DEXA and SDI. Finally, the DTA parameters from both anatomic sites were found to be equally associated with vertebral deformity status as shown by a plot of the correlation coefficients for each parameter examined. The findings are in agreement with a less connected, more strut-like TB network paralleling increased susceptibility for vertebral deformity. (Sponsors: NIH RO1AR49553, T32DK07006)

Bone Turnover by Osteocalcin and Risks of Breast Cancer and Fracture: A Prospective Study. S. R. Cummings, T. Blackwell*. S.F. Coordinating Center, CPMC Research Institute and UC San Francisco, San Francisco, CA, USA.

Women with little or no estradiol (E2) tend to have high rates of bone remodeling and increased levels of osteocalcin (OC). Women with little or no E2 also have a substantially decreased risk of breast cancer. E2 is also synthesized by aromatase in both osteoblasts and breast tissue. We used the placebo group of the Multiple Outcomes of Raloxifene (MORE) trial to test the hypothesis that women with high OC levels have a decreased risk of breast cancer. We compared this association to the relationship of OC to risk of fracture. OC was measured at baseline (CIS Biointernational) in 913 postmenopausal women (mean age 67.5 years) with low BMD or osteoporosis. Serum E2 was measured by a double-antibody method (Covance). Incident breast cancer was confirmed by histopathology reports. Incident non-spine fractures were confirmed by radiographs and incident vertebral fractures by semiquantitative grading and morphometry of baseline and follow-up spine radiographs. After adjustment for age, OC level had no relationship to risk of non-spine (RH=1.10; 95%CI 0.88-1.38) or vertebral fracture (RR=1.13; 95%CI 0.86-1.47). Twelve incident breast cancer cases were confirmed during the 4-year trial. After adjustment for age, women with high OC (>28 μg/L) had a lower risk (no cases) of breast cancer than did women with lower OC levels (P for trend =0.027; Figure). Adjustment for baseline E2 did not attenuate this relationship. If confirmed by larger studies, OC may be a better marker of breast cancer than fracture risk.

Factors Associated with the Ppresence of a Vertebral Fracture in a Population of Hip Fracture Patients. C. O Dwyer*[1], M. C. Casey*[1], M. Healy*[1], N. Maher*[1], C. Walsh*[2], J. B. Walsh[1]. [1]Medicine for the Elderly, St James Hospital, Dublin, Ireland, [2]Medical Statistics, Trinity College Dublin, Dublin, Ireland.

Introduction: All Hip fracture patients require a DXA scan to outrule Osteopenia or Osteoporosis and more recently lateral vertebral morphometric examination has been performed in conjunction with this investigation. We studied a group of hip fracture patients using both densitometry and bone biochemistry to identify any possible associations of vertebral fractures (VFx) when they are present in hip fracture patients. Methods: 69 patients who presented with hip fracture had DEXA and lateral vertebral morphometry carried out. Osteoporosis was defined as T Score of <-2.5 at the hip or spine. All patients had serum bone markers performed within 48 hours of admission including

Osteocalcin (OC), C- telopeptide (CTx), Parathyroid Hormone(PTH) and 25(OH)vitamin D. Results: 19/69 (28%) had evidence of vertebral fracture on DEXA. Mean age was 77yrs in those without fracture and 81yrs in those with VFx. Those who had vertebral fracture had a mean weight of 50kg as apposed to those without 58kg ($p<0.04$). As expected the mean Femoral T score of those with vertebral fracture was -3.5 as apposed to -2.4 in those without ($p<0.004$).Likewise the mean Total Hip BMD mean was also lower in the VFx group ($p<0.003$). No significant differences were noted between the PTH levels in either group. There was a non significant trend towards mean osteocalcin and CTx values being lower in the vertebral fracture group. Conclusion: In those presenting with a hip fracture the presenceof a Vertebral fracture on DEXA scanning is associated with a significantly lower Hip BMD. However on assessment of bone markers ,although there was a trend to reduced bone turnover in this VFx group, this did not reach statistical significance and a larger study is required to assess these trends further.

Falls, Fractures and Health Status in Elderly Women Following Second Eye Cataract Surgery: A Randomised Controlled Trial. T. Masud[1], R. Harwood*[1], F. Osborne*[2], R. Gregson*[1], A. Zaman*[1], A. Foss*[1]. [1]Medicine, Nottingham City Hospital, Nottingham, United Kingdom, [2]Opthalmology, Queens Medical centre, Nottingham, United Kingdom.

We have previously shown that expedited first eye cataract surgery can significantly reduce fall rates and fractures (Harwood et al, BJ Opthalmol 2005;89:53-9). Most cataracts in elderly people are bilateral. Some binocular functions, such as stereopsis, are associated with risk of falling. The aim of this follow up study was to determine if second eye cataract surgery can further reduce the risk of falling, and to measure associated health gains. 239 women aged over 70 years, with one un-operated cataract, were randomised to expedited (approximately 4 weeks) or routine (12 months wait) surgery. Falls were ascertained by diary, with follow up every 3 months. Health status including confidence (Tinetti Falls Efficacy Scale) and handicap (London Handicap Scale) was measured after 6 months. Visual function (especially stereopsis) improved in the operated group. Over 12 months follow-up, the rate of falling was reduced by 32% in the operated group (rate ratio 0.68, 95%CI 0.39-1.19; p=0.18). Confidence (mean diff 3.6 95%CI 0.9-6.2; p=0.008), and handicap (mean diff 4.4 95%CI=2.2-6.5; p<0.001) improved in the operated group compared with the control group. Five participants in the operated group had fractures (4%) compared to 2 (2%) in the control group (p=0.45). Second eye catarct surgery improves visual disability and general health and tended to reduce the rate of falling. The power of the study was not sufficient however to show any effect on fractures.

Bone Mineral Density in Myocardial Infarction Survivors. J. H. Magnus, D. Broussard*. Tulane University Health Sciences Center, New Orleans, LA, USA.

Cardiovascular disease and osteoporosis have several common risk factors, and quite a few studies suggest a relationship. The objective of this study was to study cardiovascular disease risk factors and bone mineral density in subjects self-reporting previous myocardial infarction. This cross-sectional study used data from 1,393 white women and 1,309 white men aged 50-79 years who participated in the Third National Health and Nutrition Examination Survey (NHANES III) excluded those self reporting treated osteoporosis. Gender-specific mean BMD values for young adults were used to define osteoporosis and low BMD. The prevalences of osteoporosis and low BMD among those reporting a previous myocardial infarction were not significant when adjusting for age. Multiple logistic regression analysis revealed that self-reporting a previous myocardial infarction was significantly associated with low bone mineral density in men (odds ratio 1.68, [95% CI 1.14-2.47] P=0.009) , but not in women, (odds ratio 1.63, [95% CI, 0.89 to 2.99] P=0.12). Age, cigarette smoking, physical inactivity and low body mass index were significantly associated with low BMD in both women and men and fasting glucose and HDL showed a slight protective effect. Previous fracture was strongly associated with low BMD in women (odds ratio 2.11, [95% CI, 1.13 to 3.93] P=0.02) as well as in men but the confidence intervals were very wide in men. We did however, not confirm earlier reports that stroke are associated with low BMD. These findings demonstrate that male survivors of myocardial infarction have low bone mineral density. Men surviving a heart attack should have their bone mineral density measured and osteoporosis prophylaxis if needed.

Characteristics of Males Who Fracture: Comparison with Post-Menopausal Women. A. Stewart*, J. Shotton*, D. M. Reid. Osteoporosis Research Unit, University of Aberdeen, Aberdeen, United Kingdom.

Approximately 1 in 12 men and 1 in 3 women in the UK sustain a low trauma fracture over the age of 50 years. A low trauma fracture is often seen as an indicator of osteoporosis (OP). A local Fracture Liaison Service (FLS) has been in operation since 2003 and is offered to all men and women over the age of 60 years who sustain a low-trauma fracture. Patients are referred for bone mineral density (BMD) assessment by dual energy x-ray absorptiometry (DXA). A clinician reports all scans and suggests treatment, if required, to their primary care physician. To date 555 males have been referred to the FLS, of whom 369 (66.5%) were invited for a DXA scan (the remaining 186 were excluded by protocol), and 275 (74.5% of those invited) have attended. The DXA scans were categorised according to WHO criteria. Of the men 41.6% had normal BMD at both sites, 37.1% had osteopenia at one or both sites, while only 21.3% had OP of at least one site. The DXA reports recorded the following options: invited to attend a Bone Clinic for further investigations; exclude secondary causes then treat with bisphosphonates if appropriate; bisphosphonate therapy; general lifestyle advice and other therapy, including calcium and vitamin D therapy. To compare we analysed the 871 females who attended for DXA scans. Only 5.1% of the males were referred for the Bone Clinic, 7.3% should have secondary causes excluded then treated with bisphosphonates, 9.5% should start bisphosphonates and 78.1% received general lifestyle advice. This compares to 7.2%, 9.2%, 20.6% and 63.0% respectively for females. The most common fracture site was the wrist for both males (25.4%) and females (43.4%). With regard risk factors 70% of the males had smoked (current and past), the mean units of alcohol consumed per week was 11.1 (SD 13.1), mean hours of exercise per week was 9.8 (SD 9.8), 63% indicated a previous fracture, 77.3% had had a fall in the last year, only 12% indicated a family history of OP, 16.3% had taken steroids and only 9.9% indicated taking some form of OP treatment. Significant differences (all p <0.01) were found between genders only for smoking (females: 49.1%), mean alcohol units (females: 2.9 (SD 4.8)), mean hours of exercise (females: 6.3 (SD 8.7)), falls (females: 89.4%) and OP treatment (females: 46.7%). In conclusion, in comparison to women, the majority of men who fracture do not require OP treatment. Hence DXA scans could be targeted in a more efficient manner by eliminating those who may have had a high trauma fracture. Therefore this indicates that in a Fracture Liaison Service environment males may need to be dealt with in different ways to women to target services/treatment in the most effective way.

Implications of a T-Score of -2.5 in Men Ages 50-65. R. A. Adler, C. S. Ryan*, V. I. Petkov. Endocrinology, McGuire VAMC, Richmond, VA, USA.

DXA testing is best established for white postmenopausal women, but the meaning of a T-score of -2.5 in a man aged 50-65 is unclear. To help determine the clinical relevance of such a test, we retrospectively reviewed a convenience sample of 50 men ages 50-65 referred to a Metabolic Bone Clinic for osteoporosis. All the men had a T-score of the spine, hip, or distal 1/3 radius of -2.5 or worse. We determined why they had a bone mineral density test, final diagnoses, and risk factors for osteoporosis. Of the 50, 15 (30%) had a fracture (mostly minimal trauma) that led to a DXA test. Nine men were tested because of extensive exposure to oral glucocorticoids, and 2 had x-ray evidence of low bone mass. In addition, 4 had hypogonadism, 3 had multiple sclerosis, and 11 had chronic lung disease or asthma with use of oral or inhaled steroids. Our medical center has done screening studies in men, and 18 of 50 (36%) were identified by these studies, mostly using the OST screening tool. Thus, we reviewed risk factors and diagnoses uncovered in men found by screening projects. In 13 men who had DXA tests because of OST, 10 had low vitamin D levels. Hypogonadism was found in 2 and alcohol abuse in 2 others. Half of the men were smokers. Therefore, the meaning of a T-score of -2.5 in a man aged 50-65 should be viewed in the context of reasons for DXA testing. If there are good reasons for DXA testing, it is likely that the man is at risk for fracture. Indeed, of those men not found by screening tests, almost half (15/32) had a clinical fracture. The others had diagnoses or risk factors that made them susceptible to fracture. Those men whose osteoporosis was identified by screening tools also had demonstrable risk factors. We conclude that if a man aged 50-65 has a reason for DXA testing and has a T-score of -2.5 or worse, he should be considered at risk for fracture and should be treated. Until we have large studies determining 10 year fracture rates for men, evaluation and treatment are appropriate.

Men with Osteoporosis Discovered by the Osteoporosis Self-Assessment Tool (OST): Are They Different from other Men with Osteoporosis? V. I. Petkov, M. I. Williams*, C. S. Ryan*, R. A. Adler. Endocrinology, McGuire VAMC, Richmond, VA, USA.

The Osteoporosis Self-assessment Tool (OST) was developed as a screening instrument to determine the likelihood of low bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA). The OST formula utilizes only two risk factors (age and weight) and stratifies the risk of osteoporosis into high, moderate and low. The purpose of this study is to determine the prevalence of risk factors, secondary causes, and laboratory abnormalities of bone and mineral metabolism in men diagnosed with osteoporosis (OP) as a result of OST screening (OST men) compared with other men with OP. We analyzed 160 consecutive men referred to a Metabolic Bone Clinic at a Veterans Affairs Medical Center (VAMC) between 7/02 and 7/04. OST was implemented as an electronic clinical reminder in the year 10/02 - 9/03. We reported previously that this intervention uncovered many men with OP. OP risk factors, conditions associated with secondary OP, and laboratory results were determined through retrospective chart review. OST men (N = 65) were older and tended to be shorter, with lower weight and bmi, and less exposure to drugs negatively affecting bone metabolism as compared to osteoporotic men (N= 95) who had BMD testing not related to screening studies. No difference in mean laboratory parameters was found (serum calcium and phosphorus, spot urine calcium to creatinine ratio, 25 OH vitamin D, PTH, sex hormones, thyroid function tests, serum creatinine, liver function tests, and alkaline phosphatase). In both groups, more than 2/3 were Caucasians, 80% used tobacco, 30% reported more than 2 drinks/day, more than half had sedentary lifestyle, 83% consumed < 1000 mg of calcium/day, and 43% < 400 IU of vitamin D. In both groups, about half reported a previous fracture, most due to minimal trauma. OST men had significantly lower prevalence of conditions associated with secondary OP (45% vs. 65%). At least one lab abnormality (most frequently vitamin D deficiency/insufficiency) was

present in 94% of OST men vs. 85% of the other men. The prevalence of OP risk factors was high in men diagnosed with OP due to OST screening and was similar to findings in other osteoporotic men.

Bone Loss Associated with Post Gastrectomy in Japan. Y. Onoda*[1], K. Shiota*[1], K. Takaguchi*[2], T. Inaba*[2], K. Kita*[2], Y. Takei*[3], A. Satou*[4], M. Ando*[5], K. Kawamura*[6]. [1]Department of Surgery, Kagawa Prefectural Central Hospital, Takamatsu, Japan, [2]Department of Internal Medicine, Kagawa Prefectural Central Hospital, Takamatsu, Japan, [3]Department of Orthopaedics, Ritsurin Hospital, Takamatsu, Japan, [4]Department of Internal Medicine, Kagawa Prefectural Saiseikai Hospital, Takamatsu, Japan, [5]Department of Internal Medicine, Mitoyo General Hospital, Toyohama, Japan, [6]Department of Health, Kibi International University, Takahashi, Japan.

Partial or total gastorectomy due to peptic ulcer or stomach cancer has been an effective common operation but bone disorders sometimes occurs depending on the extent of the resection, and this will become our major concern after the gastorectomy. The objective of this study was to investigate the pathogenesis of bone disorders associated with postgastorectomy in elderly Japanese men. Fifty male patients (ranged from 48 to 82 years old) who received gastrectomy (PGX) at the *Kagawa Prefectural Central Hospital* were investigated. The PGX patients were examined their bone mineral density (BMD) with dual X-ray absorptiometry (QDR2000 or QDR4000, Toyo-Medic Inc.) at the lumber spine. Osteoporosis or osteopenia were diagnosed according to their T-scores. The biological markers for bone metabolism and gastric endocrinal function, and existence of helicobacter pilori (HP) as a status of the remnant stomach were evaluated. Numbers of patients diagnosed as osteopenia and osteoporosis in PGX group were 9 (10.3%) and 5 (5.8%), respectively. BMD was significantly associated with the BMI and body weight in PGX group ($p<0.005$). BMD's were negatively associated with urinary NTX ($r=-0.4321$, $p<0.005$) and serum HDL levels ($r=-0.4314$, $p<0.005$). HP was positively correlated with BMD levels ($r=0.373$, $p=0.011$). On the other hand, urinary NTX levels were negatively associated with HP($r=-0.3990$, $p=0.007$). Relatively high levels of i-PTH and $1,25(OH)_2D_3$ were observed in several PGX patients, but this was not corresponded to the low serum Ca and the low BMD. No significant correlation was found between BMD and other biological markers for bone metabolism or gastric functions. No reduced serum level of vitamin D was observed in PGX group, and no apparent relationship was confirmed between BMD and impaired absorption of vitamin D due to gastrectomy.This study suggests that only low BMI will be a risk factor for low bone in PGX patients and that that the bone loss in PGX patients who were diagnosed as osteopenia or osteoporosis was not attributed to the stimulated bone resorption. The further investigation or the longitudinal observation of these PGX patients should be carried in order to reveal the pathogenesis of bone loss in patients with lowered gastric function such as PGX.

Diabetes Status may Rule Out Bone Mineral Density Testing in Men but not in Women. D. L. Broussard*, J. H. Magnus. Tulane University Health Sciences Center, New Orleans, LA, USA.

One of the greatest challenges for clinicians is to distinguish patients who should have BMD testing from those who are not likely to have low BMD. The purpose of this study was to explore whether diabetes status in older persons could be used to identify patients who do not require BMD testing. The relationship between diabetes and BMD was evaluated among the 4,915 African American, Mexican American, and white women and men aged 50-79 years who participated in the Third National Health and Nutrition Examination Survey (NHANES III) and did not self-report prior treatment for osteoporosis. Low BMD was classified as a total hip BMD of 1 SD or more below the young adult men BMD value. Race/ethnic and gender-specific mean BMD values for young adults were used to define low BMD. The prevalences of low BMD in subjects with and without diabetes were statistically significantly different when adjusted for age and race/ethnicity, but not when adjusting for body mass index. Multiple logistic regression analysis that controlled for several cardiovascular disease risk factors as well as osteoporosis risk factors revealed that diabetes was significantly associated with low BMD in men (odds ratio 0.72, [95% CI 0.54-0.94] P=0.02), but not in women, (odds ratio 0.80, [95% CI, 0.61 to 1.04] P=0.09). As expected, age, cigarette smoking, body mass index, and physical inactivity were independently associated with low BMD in both women and men. An interaction between diabetes and body mass index in this sample could not be established. The findings from this study suggest that bone density testing is probably not necessary for older diabetic men. However, the presence of diabetes should not exclude bone density testing in women. Even though it appears as though at least part of the relationship between diabetes and BMD acts through body mass index further research is needed to partition the individual influences of BMI and diabetes.

The Risk of Non-Vertebral and Hip Fracture and Prevalent Falls in Older Men: The MrOS Study. B. K. S. Chan[1], L. M. Marshall[1], L. C. Lambert[1], J. A. Cauley[2], K. E. Ensrud[3], E. S. Orwoll[1], S. R. Cummings[4]. [1]Endocrinology, Oregon Health & Science University, Portland, OR, USA, [2]University of Pittsburgh, Pittsburgh, PA, USA, [3]University of Minnesota, Minneapolis, MN, USA, [4]CPMC Research Institute, San Francisco, CA, USA.

Falling is an important risk factor of non-vertebral fracture, particularly hip fracture. However, most previous reports of this association are from studies of older women or institutionalized adults. Therefore, we estimated the association of fall history on the incidence of non-vertebral and hip fractures in the MrOS cohort of community dwelling US men ages 65 years and older. 5,995 men completed baseline questionnaires. 96% of the men completed mid-study questionnaires (mean 2.0 years after baseline). Both questionnaires asked participants if they had fallen during the past 12 months, whether their fall resulted in an injury (including fracture, head injury, sprain or strain, bruising or bleeding, and other injury), and the number of times they had fallen. Fractures were reported on tri-annual questionnaires and confirmed from radiographs. Fracture follow-up was complete for 99% of the cohort. Mean follow-up was 3.7 years. Cox proportional hazards regression models were used to estimate hazard ratios (HR) for non-vertebral fracture and for hip fracture. Fall information was modeled as a time-dependent variable. Baseline information was updated by mid-study information, if available. We confirmed 256 non-vertebral fractures (11 per 1,000 person-years), including 46 hip fractures (2 per 1,000 person-years). 1,267 men (21%) reported a fall history at baseline (mean 1.8 falls per participant). 56% of these falls resulted in an injury. Similarly, 1,614 men (28%) reported a fall history at mid-study (mean 2.0 falls per participant). 55% of these falls resulted in an injury.

Outcome	Risk factor	HR	95% CI
Non-vertebral fracture*	Any prevalent fall	2.1	1.6, 2.7
	Injury from fall	2.3	1.7, 3.1
	No injury from fall	1.9	1.4, 2.7
	Per increase in number of falls	1.3	1.2, 1.4
Hip fracture*	Any prevalent fall	1.8	1.0, 3.3
	Injury from fall	2.2	1.1, 4.3
	No injury from fall	1.4	0.6, 3.2
	Per increase in number of falls	1.2	1.0, 1.5

* Adjusted for clinical site, age, and leg power measured by the Nottingham power rig

Older men who have fallen have twice the risk of non-vertebral and hip fractures as those who have not fallen. The risk from falls resulting in injury were greater, but not statistically greater, than the risk from falls with no injury. The increase of one fall was associated with a 30% non-vertebral fracture risk increase and a 20% hip fracture risk increase. These data are consistent with previous studies. Fall prevention may be important in preventing fractures in older men.

Risk Factors Associated with Osteoporosis in African-American U.S. Men Veterans. J. J. Shin*[1], E. Wininger*[2], C. Engelhart*[1], M. B. Zimering*[1]. [1]Endocrinology, Dept of Veterans Affairs, Lyons, NJ, USA, [2]Endocrinology, University of Medicine and Dentistry of New Jersey- New Jersey Medical School, Newark, NJ, USA.

Osteoporosis is a frequently missed diagnosis in the African-American population even in some men who have suffered fragility fractures. In a prior study in older white men veterans (n~ 600, mean age 69 yrs) five risk factors (age, body weight, emphysema, gastrectomy, two or more prior fractures) were each independently associated with femoral neck bone mineral density (FN-BMD). The aim of the current study was to test whether these or two additional risk factors (physical activity, stooped posture) correlated with BMD in ambulatory outpatient African- American men veterans (n =134, mean age 61 yrs) from New Jersey. African-American men had significantly ($p<.0001$) higher FN-BMD ($0.875 \pm .162$) compared to white men ($0.767 \pm .131$) g/cm ^{2}. However, using NHANES III gender/ethnicity specific male normative data, the FN mean T-scores for African-American men were similar (-1.27 ± 1.04 *vs* $-1.20 \pm .96$) to those in white men. The prevalence for FN osteoporosis ($T \leq -2.5$) was 7.6% and 10.5 % for whites and African-Americans, respectively. Lumbar spine (L1-L4) osteoporosis was apparent in a substantially higher proportion of younger African-American patients (15.7%) compared to older white men (6.3%). The overall prevalence of osteoporosis (lumbar spine or FN) among African-American patients was 19%. In univariate correlation analysis, body weight and occupational-related physical activity correlated significantly with both FN- and L1-L4 BMD. In multiple regression analyses, age (coeff -.0324; $p <.0001$) and body weight (coeff .0087; $p<.001$) correlated with FN-BMD; body weight (coeff .0154; $p< .0001$), and physical activity (coeff 0.514; $p=.013$) were independent predictors of L1-L4 BMD. Similar proportions of white (9.8%) and black (9%) men veterans reporting having suffered two or more prior fractures after the age of 40 yrs. Still there was no association between two or more prior fractures and osteoporosis in black men veterans. These results imply that aside from age and body weight, the same, self-reported risk factors associated with osteoporosis in white men did not predict osteoporosis in black men veterans. Body weight and (self-reported) physical activity were useful in devising a risk index [93% sensitivity and 50% specificity] for predicting spinal osteoporosis in black men veterans. The substantial prevalence of osteoporosis in African-American male veterans suggests that a risk index may be useful for identifying patients likely to benefit from BMD testing.

The Effects of Thiazide, NSAIDS, and Steroid Use on Bone Mineral Density in Men. B. Heaton*, E. A. Krall. Health Policy & Health Services Research, Boston University School of Dental Medicine, Boston, MA, USA.

Various medications have been shown to affect bone mineral density in men and women, particularly common medications used to treat ailments associated with aging such as hypertension, and inflammation. We examined associations between changes in bone mineral density and use of non-steroidal anti-inflammatory drugs (NSAIDS), thiazides, and corticosteroids in a cohort of men. Subjects were 361 men who have participated in the Normative Aging Study (NAS) since 1961 and enrolled in a bone density study from 1998 to 2003. Their ages ranged from 56 to 89 at baseline. Bone mineral density (BMD) was measured three times over a two-year period. Information on medication use, smoking status and dietary calcium intake was available from NAS study records. BMD measurement sites included total body (N=292), total forearm (N=294), femoral neck (N=273), and total femur (N=273). Data analysis was completed using ANOVA for repeated measures and proportional hazards regression. Potential confounders (cigarette use, calcium intake, age and body mass index) were included in the models. Seventy-two men used thiazides, 17 used steroids, and 40 used NSAIDS. Average durations of use for thiazides, steroids, and NSAIDS were 15, 8.9, and 8.9 years, respectively. Results showed a significant association of thiazide with increased BMD at the total forearm (p=0.02), and marginal significance at the total body (p=0.06), but no associations at the femoral neck and total femur. NSAIDS seemed to have a negative effect, with marginal significance, at the total body (p=.07), total forearm (p=.18) and total femur (p=.10). Femoral neck BMD was 3% lower among NSAIDS users compared to non-users but the difference was not statistically significant. However, for each year of use, NSAIDS users with normal femoral neck BMD at baseline were 1.3 times more likely to develop osteopenia or osteoporosis during follow-up (Hazards ratio=1.3, 95% confidence interval=1.1 to 1.4). Findings for steroids were not significant at any site, possibly due to the small number of steroid users. Much of the literature to date reporting on medication use and the effect on bone mineral density has been conducted in women or in populations with unique diseases of or injuries to the bone. These results provide insight on the effects of three medications on bone mineral density in a population of men representative of the general population having controlled for potential confounding factors.

Ethnic Differences in Bone Mineral Density And Vitamin D Status among Hispanic Men: Results From BACH/BONE. A. B. Araujo[1], M. F. Holick[2], T. C. Chen[2], J. Mathieu*[2], A. K. Turner[2], C. Link*[1], T. G. Travison*[1], J. B. McKinlay*[1]. [1]New England Research Institutes, Watertown, MA, USA, [2]School of Medicine, Boston University, Boston, MA, USA.

Data on race/ethnic differences in bone mineral density (BMD) and vitamin D status among men are relatively rare. A few studies have presented these data in Hispanic men. Despite the ethnic diversity of Hispanic populations, no study has provided estimates of BMD or vitamin D levels by ethnic background among Hispanic men. Our objective was to estimate ethnic differences in femoral neck areal BMD and 25-hydroxyvitamin D (25OHD) among 234 Hispanic men participating in the Boston Area Community Health/ Bone (BACH/BONE) Survey, a population-based cross-sectional study of skeletal health in a racially/ethnically diverse sample of Boston men aged 30-79 y. Ethnicity was determined by self-report, classified as Puerto Rican (n=84, 36%), South American (n=44, 19%), Dominican (n=42, 18%), Central American (n=37, 16%), and Other (n=27, 12%). BMD (g/cm^2) was measured with a Hologic QDR 4500W. Serum 25OHD was measured by competitive protein binding without prior chromatography. Mean age was 46.7±11.1 y. Mean femoral neck BMD was 0.870±0.935 g/cm^2. Mean 25OHD was 33.6±15.9 ng/ml. Age-adjusted mean femoral neck BMD was lowest among South American men (0.839 g/ cm^2). Relative to South American men, Dominican men had 7.1% higher BMD, followed by Puerto Rican (+5.4%), Central American (+3.1%), and Other (+1.7%) Hispanic men. Moreover, there was significant variation in the age-related decline in femoral neck BMD among the ethnic groups. South American men had the greatest decline (-0.76%/y), followed by Puerto Rican (-0.58%/y), Central American (-0.50%/y), Other (-0.28%/y), and Dominican (-0.03%/y) men. Differences persisted with adjustment for body composition and number of years since immigration. Age-adjusted mean 25OHD was lowest among Puerto Rican men (31.1 ng/ml). Relative to Puerto Rican men, South American men had 21.0% higher 25OHD, followed by Central American (+16.0%), Dominican (+12.2%), and Other (+4.1%) Hispanic men. There were no ethnic differences in the age-related change in 25OHD. In the first study to present estimates of BMD and 25OHD levels in Hispanic men by ethnic background, we show modest and relatively large differences in BMD and 25OHD, respectively. This suggests the possibility of differences in fracture risk and vitamin D insufficiency among Hispanic men, and highlights the importance of considering ethnic background in evaluations of skeletal health.

Higher Serum 1,25-dihydroxy Vitamin D and 25-hydroxy Vitamin D Levels Are Associated with Better Physical Performance in Elderly Postmenopausal Women. P. B. Rapuri[1], J. C. Gallagher[1], L. Smith*[2]. [1]Bone Metabolism, Creighton University, Omaha, NE, USA, [2]Department of Preventive and Societal Medicine, University of Nebraska Medical Center, Omaha, NE, USA.

Vitamin D metabolites have been suggested to have a role in muscle strength, thereby affect the rate of falls in elderly women. An association between serum 25 hydroxy vitamin D (25OHD) and lower extremity function has been reported. There is no information on whether the active form of vitamin D, 1,25-dihydroxy vitamin D ($1,25(OH)_2D_3$) is associated with the measures of physical performance. In 489 elderly women, age range 65-77 years, we examined the association between serum 25OHD, $1,25(OH)_2D_3$ or parathyroid hormone (PTH) and measures of physical performance of muscle strength at baseline. Timed rise (time to rise from a chair 3 times as quickly as possible), timed walk at normal speed a distance of 5 meters, grip strength (Hand Dynamometer in 90^0 of shoulder flexion) and exercise/activity score (PASE) were compared between quartiles of serum 25OHD, $1,25(OH)_2D_3$ and PTH. The data were analyzed by analysis of covariance adjusting for age, BMI, calcium intake, caffeine intake and season was added to the 25OHD model. For serum 25OHD, women in the lowest quartile compared to higher quartiles were slower for the timed rise test, PASE score, timed walk normal and grip strength. Women with serum 25OHD levels < 31 ng/ml demonstrated worse physical performance. When the data was examined according to quartiles of serum $1,25(OH)_2D_3$, similar results were found. Women in the lowest quartile compared to higher quartiles of $1,25(OH)_2D_3$ were slower on timed rising, timed walk, grip strength and PASE scores, though statistical significance was observed only for grip strength. There was no significant association between serum PTH and physical performance measures. In conclusion, higher concentrations of serum 25OHD and $1,25(OH)_2D_3$ are associated with better musculoskeletal function in the upper and lower extremities. $1,25(OH)_2D_3$ which is the active form of vitamin D, rather than 25OHD, is probably playing the major role in muscle strength.

Physical Performance Measures Compared by Quartiles of 25OHD and 1,25(OH)2D3

	Timed rise (sec)	Timed walk normal (sec)	Grip Strength (kg)
25OHD ng/ml			
Q1 5.7-24.5 (n=119)	9.6±0.40	5.1±0.10	24.6±0.40

Family Physicians' Awareness of Key Osteoporosis Risk Factors and the Utilization of Bone Mineral Density (BMD) Testing Following a Multifaceted Osteoporosis Educational Intervention: Canadian Quality Circle (CQC) Pilot Project. A. Papaioannou[1], G. Ioannidis[1], B. Kvern*[2], A. Hodsman[3], D. Johnstone*[4], C. Crowley[4], J. D. Adachi[1]. [1]McMaster University, Hamilton, ON, Canada, [2]University of Manitoba, Winnipeg, MB, Canada, [3]University of Western Ontario, London, ON, Canada, [4]Procter and Gamble Pharmaceuticals, Toronto, ON, Canada.

The CQC project was developed to facilitate knowledge transfer and dissemination of the Canadian Osteoporosis Guidelines to family physicians. 52 family physicians (FPs) were recruited as members of 7 Quality Circles (QC). Members collected data on two separate occasions (wave 1, wave 2) for different patients via chart reviews and the completion of the data capture form on OP risk factors, diagnosis, and treatment. A total of 1505 and 1359 patient records were selected at random in waves 1 and 2, respectively. All patients were women 55 years of age and older. From wave 1, individual and QC data were collated in profiles and provided to the members. The QC's then met to discuss the profiles, identify and analyze barriers, recommend solutions, and participate in an OP problem based workshop. The primary focus of the workshop was to assess postmenopausal OP and risk factor identification. Wave 2 chart audit occurred after the intervention and was used to provide feedback on practice patterns. The current analyses examined physicians' percieved awareness of key risk factors (as described in the guidelines) including age (>65 yr), a prior fracture (hip, spine, or wrist), and family history of fracture, and the use of BMD testing in patients with key risk factors. The guidelines recommend that BMD testing should be conducted for all patients with key risk factors. Based on percentage and respective to wave 1 and wave 2, most FPs indicated that they were aware of their patients' key risk factors status for age (100%, 100%), hip fracture (98%, 100%), vertebral fracture (96%, 98%), and wrist fracture (96%, 100%). Fewer were aware of the status of their patients' family history of fracture (46%, 68%). A large proportion of these patients with key risk factors did not have a BMD test: age (36%, 28%), hip fracture (29%, 21%), vertebral fracture (24%, 18%), wrist fracture (19%, 15%), and family history of fracture (15%, 24%). In conclusion, most FPs were aware of their patients' key risk factors status other than family history of fracture. There was a disconnect between identification of high risk patients and requesting a BMD test for these patients. Future QC interventions should focus on bridging the gap between risk factor identification and further diagnostic work up (e.g., BMD) and if appropriate treatment initiation.

Relationships between Falls, Spinal Mobility, and Muscle Strength in Patients with Osteoporosis. Y. Kasukawa, N. Miyakoshi, Y. Ishikawa*, M. Hongo, Y. Shimada*, E. Itoi. Department of Orthopedic Surgery, Akita University, Akita, Japan.

Falls and fall-related fractures are one of the important health problems in the elderly especially among those with osteoporosis. Multiple factors such as physical activity, body balance, and muscle strength of lower extremity have been considered as determinants of falls. We have recently demonstrated that decreased spinal mobility impairs the quality of life in patients with osteoporosis. According to these backgrounds, we hypothesized that the spinal mobility also could be a determinant of falls in these patients. To test this hypothesis, relationships between falls and spinal mobility, body balance, and muscle strength were evaluated in a total of 62 patients with osteoporosis (mean age, 71 years). All the participants had no neurological or other metabolic disorders except osteoporosis. They were divided into the fall group (n=26; 5 males and 21 females) that had histories of falls and/or fear of falling, or the non-fall group (n=36; 14 males and 22 females) that had no such episodes. The thoracic and lumbar kyphosis angles and range of motion (ROM) of the spine were measured in the upright position and at maximum flexion/extension with a computer-assisted device (Spinal Mouse®). The swaying and postural instability were evaluated using a computerized stabilometer (JK-101®). Grip strengths of bilateral hands were measured with a hand grip dynamometer. There were no significant differences in age, gender, height, body weight, and body mass index between the groups. The average grip strength of bilateral hands was 23% less in the fall group compared to the non-fall group ($p<0.05$). Lumbar spinal ROM was 29% less in the fall group than the non-fall group ($p<0.05$). However, no significant differences were observed between the groups in thoracic spinal ROM, total spinal ROM, and thoracic and lumbar kyphosis angles. The parameters reflecting the distance of body sway (the total and timed track length of the center of gravity, and the rectangular and total area covered by the track of the center of gravity) showed no significant differences between the groups. The results of the present study suggested that the decreased muscle strength and lumbar spinal mobility could be risk factors for falls in patients with osteoporosis.

An Age Related Decrease in Creatinine Clearance Is Associated with an Increase in Number of Falls in Untreated Women but not in Women Receiving Calcitriol. J. C. Gallagher[1], P. B. Rapuri[1], L. M. Smith*[2]. [1]Bone Metabolism, Creighton University, Omaha, NE, USA, [2]Department of Preventive and Societal Medicine, University of Nebraska Medical Center, Omaha, NE, USA.

An increase in the incidence of falls in the elderly is an important risk factor for fractures. An age related decrease in creatinine clearance (CrCl) and, a decrease in serum 1,25-dihydroxy vitamin D_3 ($1,25(OH)_2D_3$) with age may be risk factors which lead to falls in the elderly. In a double blind placebo controlled 3 year study designed to test the efficacy of calcitriol and estrogen in reversing bone loss in elderly women, we also collected prospectively data on falls. In the present study, we examined the effect of age related decline in renal function on fall incidence by comparing groups with a GFR < or >65 ml/min in untreated and treated women. The study population comprised of 489 normal elderly women aged 65-77 years randomized to 4 treatment groups, placebo (n=112), calcitriol (n=101) 0.25 mcg bid, conjugated equine estrogens (n=100) 0.625mg/d and calcitriol + estrogen (n=102). Data were analyzed using SAS statistical package. The cumulative number of falls were compared between groups in an intent to treat analysis for women with CrCl <65 ml/min and >65 ml/min. Using a Poisson regression model, CrCl was a statistically significant predictor of falls in the placebo group ($p=0.05$) but not in the estrogen or calcitriol groups. The mean cumulative number of falls per subject on placebo was 1.60 for CrCl <65 ml/min and 1.16 for CrCl >65 ml/min ($p=0.05$). In the calcitriol group the mean cumulative number of falls per subject was 0.89 for CrCl <65 ml/min and 0.88 for CrCl>65 ml/min (p=ns). In the estrogen group, the mean cumulative number of falls per subject was 1.14 for CrCl <65 ml/min and 1.26 for CrCl >65 ml/min(p=ns). For calcitriol + estrogen group, the mean cumulative number of falls per subject was 0.91 for CrCl <65 ml/min and 1.26 for CrCl>65 ml/min (p=ns). Comparing the groups with CrCl <65 ml/min, the odds of a fall were 1.8 (95% CI 1.2-2.8) times greater on placebo than on calcitriol, 1.79 (95% CI 1.2-2.6) greater compared to on calcitriol + estrogen and 1.4 (95% CI 0.9-2.1) greater compared to on estrogen only. There was a significant correlation ($r=0.15$, $p<0.001$) between serum $1,25(OH)_2D_3$ and CrCl. The group with CrCl<65ml/min had significantly lower ($p<0.001$) serum $1,25(OH)_2D_3$ levels (33.4 ±0.69 vs 35.5 ±0.47 pg/ml) than women with CrCl >65 ml/min. In summary, untreated elderly women with a CrCl <65ml/min had a highly significant increase in the number of falls whereas women treated with calcitriol had a significant reduction in the number of falls probably by increasing serum $1,25(OH)_2D_3$ and improving muscle strength.
ns=not significant

Postural Deformity and Postural Balance in Patients with Osteoporosis. Y. Ishikawa*, N. Miyakoshi, M. Hongo, Y. Kasukawa, S. Maekawa, H. Noguchi, Y. Shimada*, E. Itoi*. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Postural instability has been considered as a risk factor for falls and osteoporotic fractures. Previous studies demonstrated that several factors, such as neurological disorders, visual impairment, and muscle weakness had significant relationships with postural instability. In addition to these factors, postural deformity might also be a possible risk factor for postural instability and falls. The aim of this study, therefore, was to evaluate the influence of the postural deformity on postural balance in patients with osteoporosis. Sixty-one patients with osteoporosis (19 males and 42 females) with an average age of 74 years (range, 54-96 years) were included in this study. Their thoracic and lumbar kyphosis angles and the spinal inclination that reflected a forward bending posture were evaluated with a computer-assisted device (SpinalMouse®). The swaying and postural instability were evaluated using a computerized stabilometer (JK-101®) showing the following parameters: 1) timed track length; 2) enveloped area; 3) rectangular area; 4) deviation of lateral sway origin; 5) timed track length in lateral direction; 6) deviation of anteroposterior sway origin; and 7) timed track length in anteroposterior direction. The relationships between the parameters of postural deformity and postural balance were then analyzed using Pearson's correlation coefficients. No significant correlations were observed between all the parameters of postural balance and the thoracic kyphosis angle. However, all the parameters except two parameters indicating anteroposterior sways (deviation of anteroposterior sway origin and timed track length in anteroposterior direction) showed significant positive correlations with the lumbar kyphosis angle ($p<0.05$, $r=0.263$-0.456). Furthermore, all the parameters of postural balance showed significant positive correlations with the spinal inclination ($p<0.05$, $r=0.395$-0.664). These findings suggest that the lumbar kyphosis (but not thoracic kyphosis) which affects the spinal inclination and postural balance may be a risk factor for falls.

Repeated Measurements Analysis of Bone Fragility Risk Factors: First Results. G. Livshits*[1], I. Malkin*[1], G. Bigman*[1], E. Kobyliansky*[1], M. J. H. Seibel[2]. [1]Sackler Faculty of Medicine, Tel Aviv University, Israel, [2]ANZAC Research Institute, Univ of Sydney, Sydney, Australia.

The contribution of genetic factors to inter-individual differences in the main components of bone strength, such as bone mineral density (BMD), bone size (BS) and bone geometry (BG) are presently well established. However, very little is known about the genetic effects on the rate and pattern of age related changes in these variables. The objective of the present study was to examine the contribution of putative genetic influences and life style factors (alcohol consumption, smoking and obesity) on the rate of change in BMD, BS, and BG in an ethnically homogeneous sample of Chuvasha families (Caucasians). The study was conducted on some 800 healthy individuals, of which 290 were measured twice after an interval of eight years. Computerized digital images of hand bones radiographs were examined for BMD, BS, and BG in all participating individuals. The studied phenotypes were not modified by HRT or any other continuous medical treatment. The family data were subjected to model fitting statistical-genetic analysis in order to find the most parsimonious and best fitting description of the above traits variation. The results showed that alcohol consumption and smoking did not significantly affect any of the studied bone traits. Age, sex and obesity significantly affected variation of the baseline levels of each of the traits, but did not contribute to the rate of their change after the effect on the baseline level was taken into account. Genetic effects were highly significant and prominent for baseline levels of all bone variables (but not their change) as expected. The rate of change in BS and BG depended very little on genetic factors (3 - 7% of the variation, $p<0.06$). However, the latter were highly significant ($p<0.001$) and strong, explaining 44% to 51% of the variation for changes of all examined BMD characteristics. The present analysis suggests that baseline variations in BMD and the rate of age related changes are likely influenced by different genetic sources.

What Are the Most Common Risk Factors for Osteoporsis in Postmenopausal Spanish Women between 50-65 Years? C. Carbonel*[1], M. L. Rentero*[2], M. Romera[3], S. FARO Group*[4]. [1]ABS Via Roma, Barcelona, Spain, [2]Medical Department Lilly, Madrid, Spain, [3]Hospitalet, U. Reumatology, Barcelona, Spain, [4]Primary Care, Centers, Spain.

To describe the prevalence of osteoporosis risk factors in a sample of postmenopausal women from 50 to 65 years old attended in Primary Care Centers in Spain. This is an observational, descriptive, cross-section study. 5000 women have participated in the study. They have been distributed in three age groups: 1906 women 50-55 years, 1378 women 56-59 years and 1615 women 60-65 years distributed between 96 centers of Primary Care Demographic, anthropometrical, osteoporosis and fracture risk factors were collected. Quantitative bone ultrasound scan was made to both the right and the left foot calcareous using Sahara equipment. Quantitative variables are described by the mean, median values and typical deviation, first and third quartile, and range (maximum and minimum values) are analyzed using ANOVA model. Qualitative variables are described by frequency and percentage and analyzed by Chi square test or, if non- applicable, by Fisher exact test. Confidence intervals of 95% are used. Baseline data: Menarche age: 12,87, menopausal

age: 48,49, number of children: 2,4, weight 69,7 +/- 11,8 Kg, Height 157cm, mean BMI is 28.3. Among the analyzed risk-factors 15.1% of women have had surgical menopause, 10.0% (490) are unable to stand up from a chair, 78.1% (3825) have never smoked, 10.3 % (505) have a history of fractures; forearm is the most frequent one. Decrease of height is 30.4% (1490). Intake of Calcium below 600 mg/day is 43.1% (2111).Drugs related with risk of osteoporosis and falls 35.1% (1718). Benzodiazepines are the most commonly used drugs in 22.7%. History of familiar fractures is 22.3% (1094). Kyphosis 8,7% (916). Problems in her sensory perception that affect her ability to walk 7% (341). Other diseases affect the bone 11,9% (585). Number of hours per week the patients perform intentional physical activity 3,9 hours/per week, number of falls the patient sustained in the last year 22,8% (1119), observed loss weight greater than 10 % in the last ten years 8,1% (398). Risk factors of osteoporosis with more prevalence in Primary Care are modificable factors, especially intake of calcium less than 600 mg/day. Drugs as benzodiazepine could be important. Decrease of height and history familiar fractures are risk factors very frequently in the attention medical. It could be of great value to the physician the assessment of risk factors. It could mean a good way to approach osteoporosis diagnosis, to detect high-risk women and to evaluate the need of a DEXA measure.

Lack of Association between Subclinical Menstrual Irregularities and Changes in BMD in Healthy Pre-Menopausal Women. G. A. Hawker, M. French*, E. Waugh*, R. Ridout. University of Toronto, Toronto, ON, Canada.

The aim of this study was to examine the relationship between subclinical menstrual irregularities and changes in BMD among healthy pre-menopausal women. Caucasian women aged 20-40 years with regular menstrual cycles were recruited from the community to participate in a two-year prospective cohort study. We excluded women reporting use of oral contraceptives or other medication or illness known to affect bone metabolism or menstrual function. Physical activity, dietary factors and dietary restraint were assessed at 12-month intervals. BMD at the spine (L2-L4), total body and femoral neck (hip), and body composition were determined by DEXA. A single morning serum sample for estradiol and free testosterone was collected once during days 3-5 of one of the monitored cycles; morning saliva samples were collected daily for up to 12 cycles. Luteal phase length, progesterone levels, and ovulation were determined through urinary ovulation detection, salivary progesterone assays and menstrual diaries. The relationship between BMD change and each of menstrual cycle length, luteal phase length, mean and mid-luteal phase progesterone levels, % monitored cycles that were anovulatory, and serum estradiol and free testosterone were assessed separately for each site, before and after adjusting for age, body composition (% lean mass, weight, BMI), lifestyle factors (physical activity, smoking), dietary factors (calcium, vitamin D, dietary phytoestrogens), and dietary restraint, using linear regression. Of the 332 assessed at baseline, 194 completed the study and are included in this analysis. At baseline, mean age was 32.7 yrs (SD 4.7), mean BMI was 24.3 kg/m^2 (SD 4.7) and % lean mass was 66.25% (SD 9.5). Mean number of cycles monitored was 10.7 (1-14) with a mean cycle length of 28.8 days (23.6 - 55.2 days) and mean luteal phase length of 13.6 days (5.3 - 17.4 days); 22.3% of women experienced at least 1 anovulatory cycle. Mean changes in BMD at the spine, hip and total body were 0.02 gm/cm^2 (-0.11 - 0.12), 0.006 (-0.14 - 0.13), and 0.001 (-0.07 - 0.09), respectively. BMD changes at the spine were positively associated with estradiol and testosterone levels ($p<0.02$). At the hip, BMD changes were positively associated with estradiol levels and negatively with cycle length. These relationships held after adjusting for all other measures. At the total body, changes in BMD were associated with none of the menstrual cycle measures. In this prospective study of healthy pre-menopausal women, we could not confirm prior reports of an association between changes in BMD and sub-clinical menstrual irregularities in pre-menopausal women.

Socioeconomic Variables and Fracture Risk: A Nationwide Register Study from Denmark. P. Vestergaard, L. Rejnmark, L. Mosekilde. The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark.

Purpose: To investigate the effects of income and other socioeconomic variables on fracture risk adjusted for disease related confounders. Methods: Case-control study where all subjects in Denmark with a fracture during the year 2000 (n=124,655) served as cases. From the general population three age- and gender matched subjects were selected as controls (n=373,962). Adjustment were made for income, living with someone vs. living alone, having a job vs. being out of work, education, co-morbidity (Charlson index), number of bed days in hospital, number of contacts to general practitioner, use of corticosteroids, prior fracture, and alcoholism. Results: Income was not associated with fracture risk upon adjustment for the other covariates. Living with someone was associated with a decreased risk of any fracture in all age. A higher education was associated with a decreased fracture risk in the age groups <60 years, but an increased fracture risk among subjects ≥60 years. Being at work was associated with a decreased hip fracture risk among subjects ≥40 years. Alcoholism and a prior fracture were significant predictors of fracture in all age groups. Conclusions: Income does not predict fracture risk in Denmark after adjustment for other social and comorbidity variables. This may signal neutralization of the effect by socio-economic compensation or that income was the product of underlying socio-economic variables.

Disclosures: ***P. Vestergaard****, None.*

Prevalence of Osteoporosis-Associated Skeletal Pain at the Onset of Raloxifene Treatment: A Prospective Multicenter Observational Study in a Naturalistic Setting in Germany. S. Scharla[1], H. Oertel*[2], K. Helsberg*[2], F. Kessler*[2], F. Langer*[2], T. N. Nickelsen[2]. [1]Practice for Internal Medicine and Endocrinology, Bad Reichenhall, Germany, [2]Medical, Lilly Deutschland GmbH, Bad Homburg, Germany.

We assessed the prevalence and characteristics of osteoporosis-associated skeletal pain from the baseline data of a cohort of 3,299 postmenopausal women (mean age 68±9; BMI 25.5±3.9) with osteoporosis who were about to start treatment with the selective estrogen receptor modulator raloxifene in a naturalistic setting. Standardized data were collected by 810 office-based physicians in Germany. The frequency and intensity of pain during the 4 weeks preceding the baseline visit were also self-rated on a patient questionnaire that included a 100 mm VAS scale. The presence of osteoporosis was confirmed by low BMD (89.4%), documented fragility fractures (39.8%), or both. Also, 54.2% of patients had ≥1 clinical osteoporosis risk factor, and 58.1% had received prior drug treatment for osteoporosis. According to the physicians' documentation, 3,080 patients (93.4%) of the cohort experienced skeletal pain at baseline; the median prior duration of pain history was 3 years (>10 months in 75%). Back pain was reported by 85.1% of patients, 41.8% suffered from joint pain, and 32.5% from diffuse bone pain. 78.1% had frequent or permanent pain, and 56.4% required analgesics for skeletal pain. Of the 3,080 patients with pain, 2,864 (93.0%) also reported pain on the patient questionnaire. The mean intensity on the 100 mm VAS was 62.7 +/- 21.6 mm (median 66 mm; n=2,920). Despite the high prevalence of skeletal pain, only 1,313 patients (39.8%) had radiologically confirmed vertebral or clinical non-vertebral fragility fractures in the past (recent vertebral [<6 months] 11.0%, old vertebral 22.9%, non-vertebral 18.9%). However, 83.5% of patients had x-ray findings indicating degenerative changes in the spine, (spondylosis, osteophytes, etc); while 21.7% had concomitant inflammatory or degenerative disease (rheumatoid arthritis, osteoarthritis, etc). Elevated bone markers were reported in 35.2% of patients with data (N=525). In summary, the prevalence of skeletal pain in this osteoporotic cohort was far higher than the prevalence of fragility fractures. Although our cohort may differ in some aspects from the general population of patients with postmenopausal osteoporosis (the imminent start of raloxifene treatment was a baseline characteristic of our cohort by definition), we conclude that skeletal pain is a major problem in osteoporosis patients with and without fractures. Thus, possible beneficial effects of osteoporosis medication on skeletal pain should be evaluated in more detail.

Screening Patients with Fragility Fracture: The Occurrence of Previously Undetected Disease, Particularly Endocrine Disease, Is Significant. G. P. R. Clunie[1], C. Parkinson*[2], S. Stephenson*[1]. [1]Rheumatology, The Ipswich Hospital NHS Trust, Ipswich, United Kingdom, [2]Endocrinology, The Ipswich Hospital NHS Trust, Ipswich, United Kingdom.

In October 2003 we started screening all patients with fragility fracture age 50-75y for osteoporosis, falls risk and underlying bone disease at our institution (National Health Service Hospital serving population of 320,000). In addition to identifying patients with osteoporosis, we prospectively sought to identify patients with previously undisclosed endocrine and other 'bone-relevant' conditions. All patients with a fragility fracture (any site) were initially screened with a DXA scan and biochemistry tests (urea [BUN], serum creatinine, electrolytes, CRP, immunoglobulins, thyroid and liver function tests, Bone Biochemistry, Testosterone and LH [men]) by a Nurse-led team. Abnormalities were discussed (with GPRC) and further blood, imaging and biopsy tests were organised if necessary under specialist medical supervision (GPRC and CP). In 18 months 870 (738 [85%] female) patients were seen, 96 (11%) of whom non-attended one or more visits. Of the 774 patients fully assessed 318 (41%) had distal forearm, 164 (21%) lower leg, 99 (13%) hip, 48 (6%) proximal humerus and 146 (19%) other fractures. Osteoporosis (fracture + any LSp vertebral, total hip or femoral neck BMD T score ≤-2.5) was diagnosed in 227/724 (31%) patients (DXA data was not available for 50). A bisphosphonate, HRT, raloxifene or strontium ranelate was recommended for 405/774 (52%) patients. We made 52 new (major) diagnoses in 45/774 (6%) patients (on average 1 new major diagnosis per 17 patients). Of these, 39 diagnoses were 'osteoporosis/fracture relevant', made in 35/774 (5%) patients (non or 2^c osteoporosis causes of bone fragility). Diagnoses were classed as definite (27) or likely (12) - see table. New diagnoses of less relevance to bone were: hypothyroidism (10 patients), psoriatic arthritis (2 patients) and post-CVA epilepsy.

Condition	*Diagnosis definite*	*Diagnosis likely*
Primary Hyperparathyroid	11	1
Male Hypogonadism	3	5
Osteomalacia	4	4
Hyperthyroid disease	3	
Chronic alcohol excess	3	1
Excessive thyroxine	2	
Other (2)	Hypoparathyroid	Myeloma

This study illustrates the extent of (undisclosed) disease in patients 50-75y old (total 5-6%) presenting with fragility fracture to an orthopaedic service. Institutions implementing a 'fracture liaison' service should consider the likely burden of undiagnosed, particularly endocrine, disease in fracture patients over the age of 50y and should appropriate resources accordingly to support the service.

Correlations between Vitamin D, Parathyroid Hormone, Urinary Calcium Excretion, Markers of Bone Turnover and Bone Density of Patients Referred to an Osteoporosis Center. P. M. Camacho[1], M. Girgis*[2], P. Sapountzi*[1], E. Holmes*[3], J. Sinacore*[4]. [1]Endocrinology and Metabolism, Loyola University of Chicago, Maywood, IL, USA, [2]Loyola University of Chicago, Maywood, IL, USA, [3]Pathology, Loyola University of Chicago, Maywood, IL, USA, [4]Department of Preventive Medicine, Loyola University of Chicago, Maywood, IL, USA.

Vitamin D deficiency is highly prevalent among patients with osteoporosis, leading to secondary hyperparathyroidism, decreased calcium absorption and poor response to therapy. Reports of assay variabilities have led to confusion about interpretation of 25 OHD levels. The primary aim of the study was to characterize the relationships between 25 OHD,1-25 OHD, intact PTH, ionized calcium, phosphorus, 24 urine calcium excretion, bone specific alkaline phosphatase,urinary NTX/creatinine and bone density . We retrospectively analyzed clinical and laboratory data of 163 patients (143 female, 20 male; mean age 62.5 years) evaluated for low bone mass at Loyola University Osteoporosis and Metabolic Bone Disease Center. Patients were excluded if they were on vitamin D therapy or if they had primary hyperparathyroidism. 25-OHD was measured using Nichols chemiluminescent assay and intact PTH with Bayer Centaur assay. The strongest indirect relationship seen was between PTH and UrCa ($r = -0.496$, $p<0.001$). 25OHD showed a significant correlation with UrCa ($r = 0.420$, $p<0.001$), PTH ($r = -0.215$, $p=0.014$), BSAP ($r = -0.288$, $p=0.010$), , and a trend with spine BMD ($r = -0.156$, $p=0.071$). Analysis of the subgroup with 25 OHD <=20 (26% of the group) showed that 25OHD correlated significantly with PTH ($r = -0.354$, $p=0.027$). The strong indirect correlation between PTH and UrCa ($r = -0.540$, $p=0.021$) remained in this group. 1,25OHD showed a trend associated with UrCa ($r = 0.459$, $p=0.064$) and spine BMD ($r = -0.356$, $p=0.069$). Ionized calcium, phosphorus or NTX/creatinine did not show significant correlations with PTH or Vit D levels. In an attempt to "define" vitamin D deficiency, we analyzed the 25 OHD threshold at which patients' PTH levels start to rise and UrCa start to decline. We found the difference between the means of PTH above and below a 25-OHD level of 30ng/ml to be significant. At 35ng/ml the significance was lost. The same 25 OHD level of 30ng/ml showed significant differences in the UrCA of patients with 25OHD above and below this threshold. This relationship was also significant at 35ng/ml and was lost at 40ng/ml. Our study showed that 25OHD weakly correlated with PTH. A level of 30 ng/ml appears to define vitamin D deficiency. This was seen in 48% of the population. Strong correlations seen with UrCa emphasized the importance of this test in the work-up of osteoporosis.

Changes of Mineral/Matrix of Femoral Mid Shaft in Magnesium-Deficient Rats Treated with Vitamin K_2 or Alendronate. M. Kobayashi, K. Hara, Y. Akiyama. Department of Applied Drug Research, Tokyo, Japan.

As the improving effects of agents for osteoporosis on fracture can not be explained by the bone mineral content (BMC) alone, recent studies have reported bone quality as a factor involved in the effects. Previously, we found that rats fed low magnesium (Mg) diet reduced their bone mechanical property, that is, bone quality, without decreasing BMC (Bone 35, 2004). In this study, we compared the effects of a bone formation agent, vitamin K_2 (menatetrenone, K_2), and an anti-resorptive bisphosphonate , alendronate (ALN), using this model, and investigated the mechanism involved in the reduction of bone quality using Fourier transform infrared imaging (FTIRI). We divided 40 four-week-old male Wistar rats into 4 groups; the intact group, the low Mg-control group, the low Mg-K_2 group, and the low Mg-ALN group. Diet containing 90 mg/100 g of Mg was given to rats in the intact group, and diet containing 6 mg/100 g of Mg was given to rats in the three low Mg groups. K_2 was given to rats as a dietary supplement at 60mg/100g diet . ALN was subcutaneously administered at 200 μg/kg twice a week. After 8 weeks, the blood level of Mg and alkaline phosphatase activity in the low Mg-control group were lower than those in the intact group, and urinary deoxypyridinoline level (Dpd/Cr) was increased. The cortical (Ct) BMC and the Ct area for the femoral midshaft in the low Mg-control group were 110% of the values in the intact group. The maximum load and elastic modulus decreased to 81% and 50% of the values in the intact group, respectively. There was no significant difference in the Ct BMC between the low Mg-K_2 group and the low Mg-control group. However, the maximum load and elastic modulus in the low Mg-K_2 group were higher than the values in the low Mg-control group. In the low Mg-ALN group, the Dpd/Cr value was lower than that in the low Mg-control group, and the Ct BMC were higher. However, elastic modulus was similar between the two groups. The mineral/matrix (Min/Mat)ratio by FTIRI at the periosteum portion of inferior region of femoral midshaft increased to 140% of the value in the intact group. K_2 inhibited this change; however, ALN did not inhibit it. The changes in the Min/Mat ratio on FTIRI were correlated with the low Mg diet-related and drug administration-related changes in elastic modulus. Therefore, the Min/Mat ratio contributed to the changes in elastic modulus. These results suggest that K_2 improves the maximum load and elastic modulus by reducing the Min/Mat ratio, and that ALN increases the maximum load by increasing the BMC.

Hip Bone Density Declines Following Gastric Bypass Surgery for Obesity Despite Stable Parathyroid Hormone and Vitamin D Levels. J. Fleischer[1], M. Bessler*[2], M. Johnson*[1], M. Della Badia*[1], N. Restuccia*[2], L. Olivero-Rivera*[2], D. J. McMahon*[1], S. J. Silverberg[1]. [1]Medicine, Columbia University P & S, New York, NY, USA, [2]Surgery, Columbia University P & S, New York, NY, USA.

Although bariatric surgery has become one of the most effective means to treat and prevent the complications of morbid obesity, there is growing concern that these procedures may be associated with adverse effects on skeletal health. Roux-en-Y Gastric Bypass (RYGB) is the most common procedure performed in the United States. Among the mechanisms by which RYGB could impact mineral metabolism are: vitamin D and calcium malabsorption and resultant secondary hyperparathyroidism; weight loss associated increases in bone turnover; and low serum 25-hydroxyvitamin D (25D) levels due to obesity itself. We therefore conducted a prospective observational study to investigate the impact of RYGB on skeletal metabolism. Data are available on the first 15 patients (3 men, 12 women). At baseline (± SEM) mean age was 46.3 yrs; BMI 47.9 ± 1.5 kg/m^2; serum calcium (Ca) 9.1 ± 0.1 mg/dL. Mean 25D was at the low end of normal (21.5 ± 2.0 ng/mL; nl: 9-52) while PTH was at the upper end of normal (49 ± 5 pg/mL; nl: 10-65; 20% high). At 3 months, urinary calcium decreased (143 ± 21 to 73 ± 23 mg/24h; $p<.005$) and PTH trended upward (49 ± 5 to 56 ± 5 pg/mL; $p= 0.1$) despite marked increases in Ca and vitamin D supplements. After one year, patients lost 104 ± 5 lbs. According to surgical protocol, daily supplemental calcium intake increased from 432 ± 139 to 1501 ± 139 mg ($p< .0001$), while daily vitamin D increased from 413 ± 369 to 1694 ± 369 IU ($p=0.01$), with no significant change in serum Ca or 25D levels. Bone turnover markers increased significantly as early as 3 months after surgery, and by 12 months urinary NTx doubled (34 ± 4 to 68 ± 4 BCE/mmol Cr; $p<.0001$), while osteocalcin increased by a more modest 25% (4.1 ± .35 to 5.5 ± .35; $p<.005$). BMD declined at the total hip (-9.1. ± 2.0%, $p<.005$) and femoral neck (-11.5 ± 2.2%, $p<0.0005$), while lumbar spine and forearm BMD were stable. The decline in femoral neck BMD was associated with extent of weight loss ($r=+.97$, $p<.002$) but not with PTH or 25D levels. In summary, following RYGB, bone turnover rose rapidly and hip BMD declined. PTH and 25D remained stable with significant increases in calcium and vitamin D supplementation. In morbidly obese patients undergoing RYGB: 1) careful dosing of supplements may compensate for malabsorption; 2) decreased BMD may be due more to weight loss than to abnormal mineral metabolism. We conclude that pre-operative and ongoing assessment of mineral metabolism is a necessary adjunct to the care of these patients.

Vitamin D Deficiency and Hyperparathyroidism Despite High Caloric Intake in Morbid and Super Obese Patients. N. Sinha*[1], E. Stein*[1], G. Strain*[2], M. Gagner*[2], A. Pomp*[2], G. Dakin*[2], C. P. Sison*[1], R. Bockman[3]. [1]Endocrinology, Cornell University, New York, NY, USA, [2]Surgery, NY Presbyterian Hospital, New York, NY, USA, [3]Endocrinology, Hospital for Special Surgery, New York, NY, USA.

Vitamin D deficiency is extremely prevalent even in subjects with abundant caloric intake. Studies in patients presenting for bariatric surgery have demonstrated vitamin D (Vit D) deficiency and elevated parathyroid hormone (PTH) levels both prior to and following surgery. In our on-going prospective study, alterations in bone metabolism are studied in morbidly and super obese patients being evaluated for Roux-en-Y gastric bypass or biliopancreatic diversion with duodenal switch. At baseline and at various time points over 18 months post-operatively markers of bone turnover, calcitropic hormones and changes in bone density are followed. We specifically obtain anthropomorphic measurements, calcium, vit D and total caloric intake, serum calcium, 25-hydroxy vit D (25-OH VitD), intact PTH and urinary calcium, markers of bone formation, osteocalcin (OC) and bone-specific alkaline phosphatase (BSAP), and bone resorption, urine N-telopeptide (u-NTx) along with bone mineral density assessed by heel ultrasound, since the weight limit for standard densitometry is 300 pounds. To date, baseline data have been reviewed in 8 women and 7 men with mean body mass indices of 44 +/- 5 and 53+/- 10 kg/m2 respectively. Serum calcium, albumin and creatinine were within normal range. Bone relevant data are summarized in the table.

	Males				Females			
	Mean	S.D.	Min	Max	Mean	S.D.	Min	Max
Calcium Intake mg/day	1183	592	540	2077	476	354	36	1028
Caloric Intake kcal/day	3753	772	2793	4618	2549	193	2214	2685
Vit D Intake (IU/day)	361	269	25	777	123	95	10	289
PTH, intact (pg/ml)	102	43	37	151	99	87	24	247
25-OH Vit D (ng/mL)	15	6	8	24	19	6	9	25
u-Ntx (nMBCE/mMCr)	29	14	9	46	30	17	13	62
OC (ng/mL)	8	5	2	12	6	3	1	9
BSAP (mcg/L)	14	11	6	26	19	4	12	23

Severe vitamin D deficiency (<10ng/mL) was found in 23% of patients. Vitamin D levels below 20 ng/mL were found in 69% of patients. All of our subjects had vitamin D levels below 30 ng/mL. We conclude that vitamin D deficiency and insufficiency are common in morbid and super obese patients. Despite extremely high caloric intake, careful dietary analysis revealed inadequate intake of both calcium and vitamin D reflecting poor nutritional choice and content. Women had significantly lower calcium intake when compared to men ($p=0.03$), with a trend toward lower vitamin D intake. The elevated PTH in the setting of prevalent vitamin D deficiency is reflective of secondary hyperparathyroidism in these patients. Despite PTH elevations markers of bone formation and resorption were not elevated and did not reflect a high bone turnover state.

Is Vitamin-D Status More Important than Abundant Calcium Intake for Normal Calcium Homeostasis? G. Sigurdsson[1], L. Steingrimsdottir*[2], O. Gunnarsson*[3], O. S. Indridason*[1], L. Franzson*[4]. [1]Department of Medicine, University Hospital, Reykjavik, Iceland, [2]Public Health Institute of Iceland, Reykjavik, Iceland, [3]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [4]Clinical Chemistry, University Hospital, Reykjavik, Iceland.

The importance of adequate vitamin-D status and sufficient calcium intake is well recognized for optimum bone health. The interrelationship between calcium intake and vitamin-D status has not been addressed adequately in the past. The objective of this study was to evaluate the relative importance of high calcium intake and serum 25-hydroxy-vitamin-D (S-25(OH)D) for calcium homeostasis in healthy adults as determined by serum parathyroid hormone (S-PTH). The study group was a randomly selected population based group of men and women, age 35-85 years (n=2310). The calcium intake was assessed by a food frequency questionnaire and S-25(OH)D (RIA) and S-PTH (ECLIA) measured. The recruitment was evenly distributed through the whole year. Participation rate was 70% but after exclusion of those with diseases or medications affecting calcium metabolism 944 participants comprised the final study group. This was divided into three groups according to calcium intake (<800 mg, 800-1200 mg and >1200 mg/day) and other three groups according to S-25(OH)D values (<25, 25-45 and >45 nmol/l). The association between calcium intake, S-25(OH)D and S-PTH was assessed by ANCOVA and adjustment made for age, sex, smoking and body mass index. The lowest S-PTH values were observed in the groups with S-25(OH)D >45 nmol/l irrespective of calcium intake. When S-25(OH)D was 25-45 nmol/l, there was a significant increase in S-PTH, compared with S-25(OH)D > 45 nmol/l only when calcium intake was under 1200 mg/day. When S-25(OH)D was <25 nmol/l there was a significant increase in S-PTH in all calcium intake groups, compared with S-25(OH)D >45 nmol/l. At these low S-25(OH)D values there was a significant difference between calcium intake groups; those consuming >1200 mg/day had significantly lower S-PTH than those consuming <800 mg/day (p=0.02). These results indicate that adequate vitamin-D status with S-25(OH)D >45 nmol/l is sufficient to keep S-PTH in the ideal range even when calcium intake is below 800 mg/day. When S-25(OH)D is below 25 nmol/l high calcium intake >1200 mg/day does not prevent a significant rise in S-PTH even though it does significantly ameliorate the increase. Adequate vitamin-D status is crucial for calcium homeostasis and may reduce the requirements for calcium.

Dietary Restriction Alters Bone Density and Femoral Biomechanics in Aged Male Rats. J. Mardon*[1], A. Zangarelli*[2], S. Walrand*[2], Y. Boirie*[2], M. Davicco*[1], P. Lebecque*[1], M. Horcajada*[1], V. Coxam[1]. [1]U3M, INRA, Saint Genès Champanelle, France, [2]UMPE, INRA, Clermont-Ferrand, France.

Dietary restriction and more specifically caloric restriction are known to consistently extend lifespan of animals and significantly reduce age-associated disease and lesions. However, despite these beneficial aspects it may adversely affect bone physiology and mechanics. Thus, it could be considered as a factor risk in the development of osteoporosis. We investigated the effect of a five month dietary restriction in aged male rats on bone status and metabolism. Two groups of fifteen month-old Wistar male rats were examined in this study. Ten control animals were fed ad libitum with a standard diet. Another group of ten restricted rats was fed 40% less energy than controls. However, daily intakes of lipids, vitamins and minerals were the same in both groups. After five months of restriction, dietary-restricted animals showed a reduced body weight compared to controls as well as reduced leptin levels in plasma, suggesting a lower body fat mass, as well. Bone biomarkers assessment showed that osteocalcin concentrations did not vary among the two groups. However, urinary deoxypyridinoline levels significantly decreased. So, resorption was reduced with restriction. Femoral diameters and lengths were not affected by the diet. Femoral bone mineral density (BMD) was measured using dual energy X-ray absorptiometry (DEXA). Restricted animals exhibited lower total, metaphysal and diaphysal BMD than rats fed ad libitum. The assessment of biomechanical properties revealed a significant reduction in fracture load associated with restriction. Given that body weight is a major determinant of bone mass, BMD and biomechanical values were adjusted for this parameter. Normalization revealed that body weight reduction accounted for changes in fracture resistance, however it did not for changes in BMD: it was significantly higher for restricted animals. Those data demonstrated that, BMD and fracture load were adversely influenced by the decrease in the level of diet intake. Dietary restriction seemed to alter bone biomechanics proportionnally to the way it affected body weight. This study suggests that dietary restriction is not without potential risk as lower BMD and biomechanic resistance are associated with increased risk of fractures.

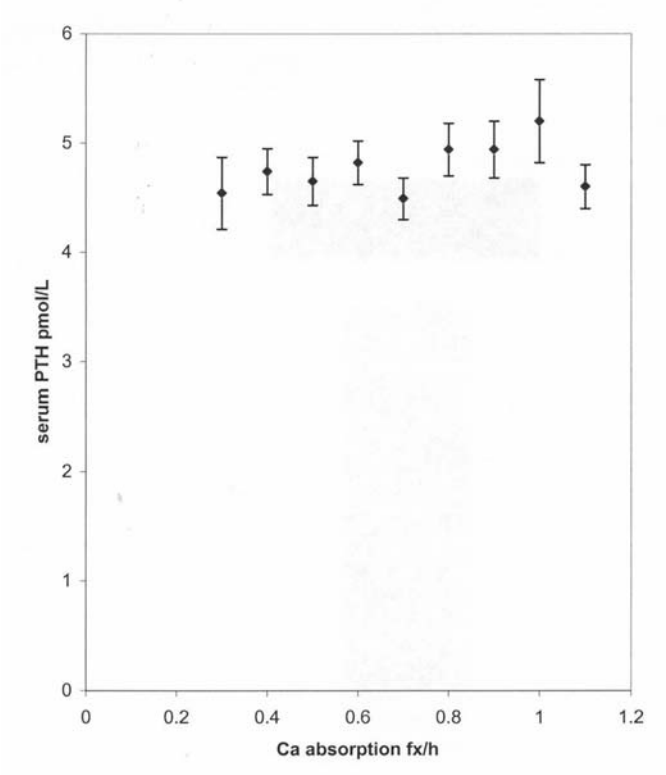
What Is the Cause of Hyperparathyroidism in Vitamin D Deficiency? A. G. Need[1], M. Horowitz*[2], P. D. O'Loughlin*[1], P. S. Coates*[1], C. Nordin[1]. [1]Clinical Biochemistry, Institute of Med and Vet Science, Adelaide, Australia, [2]Medicine, Royal Adelaide Hospital, Adelaide, Australia.

Vitamin D deficiency causes a significant rise in serum parathyroid hormone (PTH), particularly when serum 25-hydroxyvitamin D (25(OH)D) levels fall below 40 nmol/L [1]. It is commonly claimed that this rise in PTH is caused by malabsorption of calcium as 25(OH)D levels fall but this, to our knowledge, has never been demonstrated. To test this hypothesis we have examined serum ionised calcium, calcium absorption, PTH and 25(OH)D, measured by previously described methods [1] in 1017 postmenopausal women attending our osteoporosis clinics. PTH was not related to calcium absorption (figure).



COEFFICIENTS OF CORRELATION

	PTH	Ca2+	Ca absorption	1,25(OH)2D
Ca2+	-0.139***			
Ca absorption	0.035	-0.012		
1,25(OH)2D	0.116***	-0.053	0.338***	
25(OH)D	-0.222***	0.027	0.092**	0.212***

Our data do not support the hypothesis that low calcium absorption due to low 25(OH)D stimulates PTH. There is a trend for a positive relation between 25(OH)D and ionised calcium which, although not statistically significant, suggests that the rise in PTH at low 25(OH)D levels is due to lack of the “calcemic action” of vitamin D as suggested by Carlsson and Lindquist [2].

Influence of Soy Isoflavones Consumption on the Evolution of Bone Mass in Rat. J. Mardon*[1], J. Mathey*[1], C. Puel*[1], S. Kati-Coulibaly*[2], M. Davicco*[1], P. Lebecque*[1], M. Horcajada*[1], V. Coxam[1]. [1]U3M, INRA, Saint Genès Champanelle, France, [2]Laboratoire de Nutrition et Pharmacologie, UFR Biosciences, Abidjan, Cote d'Ivoire.

Research into human nutrition has led to an awareness of the health benefits that diet can offer by providing a complex array of naturally occurring bioactive molecules, such as phytoestrogens. Indeed, the bone-sparing effect of soy isoflavones (IF) has been demonstrated through epidemiological studies carried out in the Asian population. Nevertheless, there is no clear evidence if such a protection would result from a lifelong exposure. It is thus of the greatest interest to investigate the consequences of an early exposure. Sixty females Wistar rats were randomly divided into two groups (n=30). They were either fed a standard diet devoid of any soy proteins or the same food enriched with isoflavones (ADM, containing 348 mg of total IF (0.87 mg IF/g of diet). After an adaptation period of 30 days, they were allowed to mate and stayed on the same regimen during the whole gestation and lactation period. At weaning, female pups were allocated to 4 nutritional groups : within each experimental group, the animals were split into 2 groups fed either the standard (control diet) or the IF rich diet. At 2, 3, 6, 12, 18 and 24 months after birth, respectively, 10 animals in each group were intraperitonally anesthetized with chloral hydrate. 48 h before death, the body composition was estimated by dual energy X-ray absorptiometry. On day -1, the 24 h urines were collected to assess deoxypyridinoline (DPD). Blood samples were collected to assess osteocalcin. Femurs were collected for mechanical testing and bone mineral density (BMD) measurement. Peak bone mass was achieved between 6 and 12 months. At 24 months, BMD was higher in perinatally exposed animals, whether exposure was followed or not after weaning. In the same way, femoral failure load during ageing was higher in the pups born from mothers exposed during pregnancy. In conclusion, the present experiment provides evidences for possible long-term outcomes after early exposure to phytoestrogens. We speculate that changes observed

in our experimental conditions may have occurred as a consequence of programming effects, like it is known for the endocrine and immune systems. Consequently, it must be ruled out that early programming events may be essential for the full protection.

Dietary Onion Quercetin Inhibits Bone Loss in Ovariectomized Mice. M. Tsuji[1], H. Yamamoto[1], T. Sato[1], Y. Taketani[1], S. Kato[2], T. Inakuma*[3], E. Takeda[1]. [1]Department of Clinical Nutrition, Institute of Health Biosciences, University of Tokushima, Tokushima, Japan, [2]Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, [3]Biogenics Research, Kagome Co., LTD., Tochigi, Japan.

Estrogen replacement therapy is indeed effective in preventing bone loss caused by menopause, but it is also accompanied by some adverse effects, such as uterine bleeding and breast cancer. This study was focused on development of nutraceuticals from onion extracts, to prevent and treat osteoporosis after menopause without any side effects. The effects of various onion extractions were tested by osteoclast formation assay using RAW264 mouse macrophage cells or primary bone marrow monocytes. Treatment with the liposoluble fraction extracted from raw onion, not baked or microwaved onion significantly reduced osteoclast numbers. HPLC analysis revealed that quercetin concentrations in each extracts were correlated with their preventive effects on osteoclast formation. Indeed, we elicited that quercetin, not rutin, inhibited the RANKL induced osteoclast formation in dose-dependent manner. Therefore, we investigated the effects of quercetin on bone loss in osteoporosis *in vivo*. Female C57BL/6J mice (9 weeks) were ovariectomized (OVX) or sham-operated (sham) as control. OVX mice were randomly allocated to three groups receiving a control diet (OVX) or diet with 0.25 % and 2.5% quercetin (LQ and HQ). Sham mice were given the same control diet. Following the 4-week experimental period, plasma concentration of total quercetin in LQ and HQ groups were 2.5μM and 7μM, respectively. Bone mineral density (BMD) and stress strain index (SSI) at lumber spines L3 and femur bones were estimated by peripheral quantitative computed tomography (pQCT). Dietary quercetin, especially in HQ group, prevented the reduction of BMD and SSI in OVX mice. On the other hand, dietary quercetin did not induce estrogenic side effects in uterus. Furthermore, real-time PCR analysis revealed that the mRNA expression levels of TRPV6 (intestinal calcium transporter) were decreased by 40% in OVX mice when compared with sham mice, but not changed by dietary quercetin. These results suggest that quercetin is a potent inhibitor of osteoclastgenesis and dietary quercetin protect against bone loss in OVX mice.

Effects of Soluble Silicon Compound and Deep-Sea Water on Biochemical and Mechanical Properties of Bone and the Related Gene Expression in Mice. F. Maehira[1], Y. Iinuma*[1], Y. Eguchi*[2], I. Miyagi*[1]. [1]Biometabolic Chemistry, Faculty of Medicine, University of the Ryukyus, Okinawa, Japan, [2]Research Laboratory Center, Faculty of Medicine, University of the Ryukyus, Okinawa, Japan.

Silicon is an essential element for the formation of collagen and glycosaminoglycans in bone and cartilage. The silicon contents of seawater increases with increases of depth; 64 μM SiO_2 (1.8 ppm Si) in deep-sea water (DW) from 612-m in depth vs. 2.5 μM (0.07 ppm) in surface seawater (SW). The effects of DW on the bone metabolism were studied in comparison with sodium metasilicate (Si) and SW, in the cell culture and in the animal experiment using murine model of senile osteoporosis, SAMP6 and its control SAMR1. The additions of 10% DW from which NaCl was eliminated or 10 ppm Si as sodium metasilicate to the α-MEM medium exhibited the best cellular growth and the highest activities of ALP in MC3T3-E1 osteoblasts and TRAP in osteoclast-like cells compared with the medium control. The $^{45}CaCl_2$ uptake was significantly enhanced in both MC3T3-E1 cells and osteoclast-like cells by the media containing 10% DW or 10ppm Si, as compared with the medium control. The enhancement of Ca uptake is beneficial to bone formation in osteoblasts and activates a transcription factor for terminal differentiation of osteoclasts. The results from the cell culture study indicated that DW and Si stimulates both osteoblastogenesis and osteoclastogenesis, i.e., bone turn-over. To investigate the effects of DW on the bone metabolism, weanling SAMP6 and SAMR1were maintained for 6-months in the semisolid diet containing 39%of DW, SW from which NaCl was eliminated, and 200 ppm Si. Three-point bending tests indicated that DW increased the stiffness and the strength of bone, and the amount of energy absorbed in femurs of both strains R1 and P6 with greater increases in the former compared to the controls. The mRNA was extracted from the bone marrow of SAMR1 after the 6 month-experiment. The expressions of mRNA related to the bone metabolism were determined by RT-PCR, followed by real-time PCR. The mRNA expression of IL-11 and BMP-2, both of which stimulate the osteoblast development, and TGF-β which stimulates the expression of osteoclastogenesis inhibitory factor (OCIF), were significantly increased as well as type I procollagen mRNA. In addition, the expression of both OCIF and osteoclast differentiation factor (ODF) were elevated, resulting in the distinct increases of OCIF/ODF ratio. In conclusion, the results indicated that a soluble silicate and deep-sea water as its natural material stimulated the cell growth in both osteoblasts and osteoclasts in the cell culture, and promoted the bone metabolic turn-over in favor of the bone formation in the animal experiment.

Celiac Disease and Vitamin D Status in Community-Dwelling Subjects with Hip Fractures. N. S. Kolatkar[1], J. Magaziner[2], W. Hawkes*[2], K. H. Mikulec[3], N. A. Glass[1], M. S. LeBoff[1]. [1]Skeletal Health and Osteoporosis Center, Division of Endocrinology, Diabetes, and Hypertension, Brigham and Women's Hospital, Boston, MA, USA, [2]Department of Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD, USA, [3]Division of Endocrinology, St. Luke's Hospital, Chesterfield, MO, USA.

Celiac disease is a reversible cause of low bone mass and vitamin D deficiency. However, the contribution of celiac disease to the high prevalence of vitamin D deficiency in patients with fragility fractures is unknown. Our group previously reported (LeBoff *et. al.* JAMA 1999) that elderly women with hip fractures have a greater prevalence of vitamin D deficiency compared with those admitted for elective joint replacement. To evaluate the contribution of celiac disease to vitamin D deficiency in women with hip fractures, we measured serum 25-hydroxyvitamin D [25(OH)D; DiaSorin RIA: normal 20-57 ng/ml] and tissue transglutaminase IgA (tTG-IgA; ELISA: normal <1 U) in 152 community-dwelling elderly women with hip fractures from Boston (n=30) and Baltimore (n=127), and 62 women admitted for elective joint replacement from Boston. In patients with normal tTG-IgA, serum total IgA (ELISA: normal 70-400 mg/dl) was determined and if low, tTG-IgG (ELISA: normal <20 U) was measured. Celiac disease was defined by tTG-IgA >7 U or tTG-IgG >26 U (sensitivity and specificity ≥ 95% for these methods). For the hip fracture patients, the age (mean ± SD) for the Boston and Baltimore cohorts was 77.9 ± 9.2 and 80.8 ± 7.9 years, and 91% and 96% were Caucasian, respectively. The (mean ± SD) age of patients admitted for elective joint replacement was 65.5 ± 9.2 years and 97% were Caucasian. Our findings follow:

	Hip Fracture Patients			Elective Joint Replacement
	Boston n=30	Baltimore n=127	Total n=157	Boston n=62
Median 25(OH)D (ng/ml)	13.0	14.4	14.1	21.3
Patients with celiac disease	1 (3.33%)	2 (1.57%)	3 (1.91%)	1 (1.61%)

The proportion with celiac disease in the combined hip fracture cohort was not significantly different from the elective joint replacement cohort despite a significantly lower median 25(OH)D level (14.1 v. 21.3 ng/ml, p<0.0001). While our study is limited by lack of biopsy confirmation, the prevalence of celiac disease observed in our hip fracture cohorts was slightly higher than reported in U.S. Caucasians (0.33-1.5%). To definitively determine if celiac disease contributes to the high prevalence of vitamin D deficiency in hip fracture patients, larger studies are warranted, as understanding this relationship may have important implications for fracture prevention and treatment.

Lactose Intolerance and Skeletal Calcium Balance - Decreased Calcium Intake or Impaired Calcium Resorption? B. M. Obermayer-Pietsch*[1], M. Gugatschka*[1], A. Strele*[2], S. Reitter*[1], W. Plank*[1], A. Fahrleitner-Pammer[1], H. Dobnig[1], W. Goessler*[3], W. Renner*[4]. [1]Department of Internal Medicine, Medical University, Graz, Austria, [2]Center for Medical Research, Unit of Biostatistics, Medical University, Graz, Austria, [3]Institute for Analytical Chemistry, Karl-Franzens University, Graz, Austria, [4]Center for Medical Research, Medical University, Graz, Austria.

Lactose intolerance (LI) has been shown to reduce dairy intake in affected individuals due to intestinal lactase deficiency with consecutive lactose malabsorption, a condition affecting more than half of the human population. We recently reported on primary adult LI in postmenopausal women, defined by the LCT polymorphism, describing an association with reduced calcium supply, a decrease in bone mineral density and an increased number of nonvertebral fractures. However, it remains unclear, whether reduced bone mineral density in subjects with LI is a result of reduced calcium intake, impaired calcium absorption, or both. Out of the initial study, 133 women were reinvited according to their LCT genotype TT or CC. Seventy-three of them (genotypes TT n=41, CC n=32) were available for a conventional H2 breath test and a simultaneous non-radioactive strontium absorption test that shows a close correlation to intestinal calcium absorption. Blood samples for glucose and strontium were drawn at baseline and 60 and 150 minutes after ingestion of 2.32 mmol strontium and 50 g lactose. Subjects with LI (LCT genotype CC, H2 test positive) showed a 50% decrease in dairy calcium consumption. Serum strontium levels in CC subjects were comparable at baseline and after 60 minutes, however, differed significantly from TT subjects at 150 minutes following strontium and lactose administration (-45%, p<0.001). LI may thus not only reduce an individual's calcium intake in terms of dairy product consumption but also impair intestinal calcium absorption in the presence of lactose. Since lactose is a widespread ingredient of foods and medications, an additional decrease in calcium absorption could further contribute significantly to the risk of calcium imbalance and skeletal fragility in lactose intolerant subjects.

Bone Plays a Major Role in the Clearance of Triglyceride-Rich Lipoproteins from the Circulation in Mice. A. C. Niemeier*[1], D. Niedzielska*[2], U. Beisiegel*[2], W. Rüther*[3], J. Heeren*[2]. [1]Dpt. of Orthopaedics and IBM II: Molecular Cell Biology, University Hospital Hamburg-Eppendorf, Hamburg, Germany, [2]IBM II: Molecular Cell Biology, University Hospital Hamburg-Eppendorf, Hamburg, Germany, [3]Dpt. of Orthopaedics, University Hospital Hamburg-Eppendorf, Hamburg, Germany.

Dietary lipids and lipophilic substances including lipophilic vitamins have important functions in bone metabolism. Triglyceride-rich lipoproteins (TRL) act as postprandial plasma carriers of dietary lipids and lipophilic vitamins and are responsible for their delivery to target organs. TRL uptake into the liver - as the central organ of lipoprotein metabolism - has been well characterized while the uptake process into peripheral organs is less well understood. No data are available on the uptake of TRL into mouse bone. Here, we investigated the uptake of TRL into murine bone in vivo. TRL were obtained from plasma of a hypertriglyeridemic patient as well as from a healthy normolipidemic proband and hydrolyzed in vitro by lipoprotein lipase (LPL) to obtain TRL-remnants (TRL-R), which represent the physiological ligand for lipoprotein receptors. TRL-R were labeled with Cy3-fluorescent dye and injected intraveneously into C57Bl/6 (wild-type) animals. Immunodeficient SCID mice served as a control to exclude confounding immunological reactions against the human particles. Animals were systemically perfused at 20 and 60 minutes after injection. Organs were taken, processed for immunohistochemistry and confocal laser microscopy was performed. Of all organs analyzed (bone, liver, heart, skeletal muscle, kidney and spleen) highest amounts of fluorescence were detected in liver, bone marrow and kidney. After 20 minutes, uptake was observed into sinusoidal endothelial cells in liver and bone. Immunocounterstaining against the structural TRL-R component apolipoprotein E (apoE) proved that the signal was due to uptake of intact TRL-R particles in liver and bone. In contrast, kidney signals were found to be derived from free Cy3 dye. After 60 minutes, an apoE-associated signal translocation into underlying parenchymal cells was observed in liver and to a much lesser degree in bone, while Cy3 dye concomitantly dissociated from TRL-R and appeared in the urine. In conclusion, via this novel approach, we provide evidence that substantial amounts of TRL-R are cleared by murine bone marrow sinusoidal endothelial cells. This mechanism is likely to contribute to the physiological delivery of lipids and lipophilic vitamins to other bone cells. To better understand the fate of the particles after endothelial attachment, further investigations are currently being performed.

Possible Correlation of Vitamin D- and K-Deficiency and Bone Loss in Patients with Inflammatory Bowel Disease. K. Tanaka[1], Y. Nakanishi*[1], K. Shide*[2], H. Tsuji*[2], H. Nakase*[3], T. Chiba*[3], M. Kamao*[4], N. Tsugawa*[4], M. Yoshizawa*[5], S. Kido*[1], T. Okano[4]. [1]Food and Nutrition, Kyoto Women's University, Kyoto, Japan, [2]Clinical Nutrition, Kyoto University Hospital, Kyoto, Japan, [3]Gastroenterology, Kyoto University Hospital, Kyoto, Japan, [4]Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [5]Life and Environmental Sciences, Osaka Prefecture University, Osaka, Japan.

Patients with inflammatory bowel disease (IBD) were evaluated for their bone mineral density (BMD) at lumbar spine, total hip, and radius using QDR-2000 (Hologic). Their plasma levels of 25-dihidroxy vitamin D; 25(OH)D, vitamin K (phyloquinone;PK, menaquinone 4;MK-4, menaquinone-7;MK-7), intact PTH, and indices of vitamin K deficiency (protein induced by vitamin K;PIVKA and undercarboxylated osteocalcin; ucOC) were measured. Their food intake was also evaluated. The subjects cocnsisted of 26 patients with Crohn's disease (CD) and 25 patients with ulcerative colitis (UC). BMD, as expressed as age-adjusted Z value, was -1 to -2 SD, which was significantly lower in CD than in UC. Plasam concentration of 25(OH)D, PK, MK-4, and MK-7 was far below the reference value in Japanese population. Again they were lower in CD than in UC. Intact PTH level was significantly higher in CD than in UC. Plsama levels of 25(OH)D or PK correlated with BMDs. However, their food intake of vitamin D and K was far above the current requirement in Japan, and did not correlate with corresponding plasma levels. In contrast, their fat intake correlated with plasma concentration of vitamin D and K. Thus, severe malabsorption due to the inflammtion in their intestine and restricted fat intake was strongly suspected. There was no significant difference in BMD between patients who were under glucocorticoid treatment and those who were not. Our results show that bone loss is an important clinical problem in IBD, and that nutritional factors are quite likely to be involved in its pathogenesis.

Vitamin D Status in Chronic Pancreatitis. P. L. Selby[1], A. J. Makin*[2], S. Gilfedder*[2], M. Davies[1], J. L. Berry[1]. [1]Medicine, University of Manchester, Manchester, United Kingdom, [2]Gastroenterology, Manchester Royal Infirmary, Manchester, United Kingdom.

In chronic pancreatitis there is an exocrine deficiency of pancreatic secretion resulting in the malabsorption of protein and fat. Vitamin D is an important fat-soluble vitamin which may be poorly absorbed under these circumstances resulting in potential skeletal problems for patients with chronic pancreatitis. Although some studies have suggested that patients with chronic pancreatitis do have an increased risk of vitamin D deficiency the relationship with the severity of pancreatic exocrine deficiency is less well established. We have therefore sought to establish that relationship in a group of patients with chronic pancreatitis. 86 patients with chronic pancreatitis diagnosed by computed tomography or ERCP were studied. All had blood samples taken for measurement of vitamin D metabolites and parathyroid hormone. In addition, pancreatic exocrine secretion was measured using the PABA test which results in a pancreatic excretion index (PEI: normal value >0.7). The mean age was 49 (SD 14) years. There was exocrine pancreatitic insufficiency with a mean PEI of 0.35 (95% confidence interval 0.30 - 0.41). Vitamin D levels were insufficient with mean 25OHD level of 9.0 ng/ml (following logarithmic transformation: 95% confidence interval 7.5 - 10.9). $1,25(OH)_2D$ was within normal limits with a geometric mean of 28.9pg/ml (95% confidence limit 25.7 - 32.5). 21 patients (24%) had 25OHD levels of <5 ng/ml thereby putting them at risk of osteomalacia. A further 36 (42%) of patients had 25OHD levels of between 5 and 15 ng/ml suggesting that their vitamin D status was inadequate for optimal bone health. Thus only 34% of patients with chronic pancreatitis had adequate vitamin D status. There was a significant correlation between log 25 OHD and PEI ($r = 0.27$, $p = 0.03$) and between log 25 OHD and log PTH ($r = -0.41$, $p = 0.0006$). These results indicate that vitamin D deficiency is an important problem in patients with chronic pancreatitis. It is associated with the presence of secondary hyperparathyroidism and is worsened by the degree of exocrine pancreatic damage. Attention should therefore be paid to vitamin D status and bone health in patients with chronic pancreatitis.

Does Soy Protein Supplementation Modulate Hematological Parameters in Postmenopausal Women? D. Y. Soung*[1], D. A. Khalil[1], A. Patade*[1], E. A. Lucas[1], B. J. Smith[2], L. Devareddy*[1], A. B. Arquitt*[1], B. H. Arjmandi[1]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Department of Surgery, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA.

Despite the reported health benefits of soy isoflavones, there are concerns about their long-term use because ipriflavone, a synthetic isoflavone, has been shown to cause lymphocytopenia in postmenopausal women. Thus, the objective of this study was to investigate whether one year consumption of soy products (containing about 60 mg isoflavones) on a daily basis unfavorably alter hematological parameters in postmenopausal women not on hormone replacement therapy. Eighty-seven eligible postmenopausal women were randomly assigned to consume soy or control foods daily for one year. Following an overnight fast, venous blood was collected at baseline and at the end of the treatment period and analyzed for a complete blood count using an automated combined impedance-light focusing hematology counter (Pentra 120 Retic Hematology Instrument, ABX Diagnostics, Irvine, CA). The results are presented in the table below.

TABLE *Effects of one year supplementation of soy or control foods on hematological parameters*

Measures	Control (n=27)			Soy (n=35)		
	Baseline	Final	*P* values	Baseline	Final	*P* values
WBC($x10^3/mm^3$)	5.91±0.31	5.91±0.32	0.9701	5.56±0.28	5.75±0.28	0.2884
LYM%	32.15±1.56	32.04±1.60	0.9300	33.55±1.41	32.94±1.42	0.9300
MON%	8.59±0.45	8.66±0.47	0.8900	9.78±0.41	8.63±0.42	0.0200*
NEU%	53.84±1.78	52.8±1.84	0.5270	51.06±1.6	52.10±1.62	0.4490
EOS%	3.22±0.32	3.40±0.33	0.5090	3.68±0.29	3.32±0.29	0.1430
BAS%	2.18±0.24	2.97±0.26	0.0017*	1.91±0.22	2.96±0.23	0.0006*
Hb (g/L)	137± 2	137±2	0.7630	132± 2	135± 2	0.0364*
MCHC (g/L)	337± 2	343± 2	0.0212*	336± 2	342± 2	0.0126*
RDW (%)	13.22±0.24	14.00±0.25	0.0054*	13.27±0.22	13.83±0.22	0.0239*

Data represent least square mean ± SE. *Differences were considered significant at *P* value <0.05. WBC = white blood cells, LYM % = percentage of lymphocytes, MON % = percentage of monocytes, NEU % = percentage of neutrophil, EOS % = percentage of eosinophils, BAS % = percentage of basophils, Hb = hemoglobin, MCHC = mean corpuscular hemoglobin concentration, and RDW = red cell distribution width index. Our results indicate that consumption of 25g soy protein with 60 mg isoflavones daily for 1 year does not cause lymphocytopenia in postmenopausal women. However, the extent to which higher doses of isoflavones affect parameters, e.g. monocytes, basophils, and hemoglobin, and the interpretation of these findings needs further investigation.

Varying Presentations of Vitamin D Deficiency Post Bariatric Surgery. M. Charitou*, S. Weinerman, H. L. Katzeff*. Medicine/Endocrinology, North Shore Long Island Jewish Health System, Lake Success, NY, USA.

Vitamin D deficiency as well as decreased BMD have been well described after bariatric surgery. Time to disease presentation is highly variable. We report a series of three cases of varying degrees of Vitamin D deficiency and bone loss. Case 1: D.S is a 53 yo female with a history of a 100 pound weight loss post bariatric surgery who originally presented in 1998 with an elevated PTH and a low-normal Ca found on routine PE. Her Vit D was modestly low at initial evaluation. At follow up 3 years later her Vit D was undetectable despite taking 400 IU/day. Her Vit D levels were difficult to normalize and despite being on Vit D 50,000 TIW and adequate calcium she was still deficient. At this point she was started on calcitriol.

Date	3/3/01	1/14/04	4/30/04	3/19/05
Vit D25/1,25	22/64	<7/	9/54	8/
PTH	90	93.6	83.6	69
Ca	8.5	8.3	8.1	8.6
BMD	7/01		5/04	
Spine	+0.97		+0.64	
Hip	+0.14		-0.3	
forearm	+1.08		+0.1	

Case 2: S.K is a 49 yo man with a history of biliopancreatic diversion 5 years prior who has lost 300 pounds over the first 2 years. Patients weight has been stable over the past 3 years however has had low 25 (OH) Vit D since his surgery. Despite being on daily supplementation of 1200 IU Vit D and twice weekly supplementation of Vit D 50,000 IU his 25 (OH) Vit D was still low. He was started on calcitriol.

Date	2/25/05	4/6/05
Vit D25/1,25	14	22
PTH		115
Ca	8.5	8.6
BMD	4/25/05	
Spine T score	-1.2	
Hip T score	-1.4	

Case 3:M.Z is a 60 year old female with a history of gastric bypass 2 years prior which resulted in a 140 pound weight loss. She was referred for evaluation of worsening BMD on oral bisphosphonate therapy. She was subsequently diagnosed with Vit D deficiency. She is currently taking Vit D 50,000 IU once weekly.

Date	1/31/05	4/13/05
Vit D25/1,25	13/45	23/64
PTH	47.5	97
Ca	8.6	8.5
BMD	5/03	12/04
Spine T score	-2.31	-3.0
Hip T score	+0.03	-0.53

Patients develop malabsorption through a variety of mechanisms after bariatric surgery. This can be so severe that despite high doses of Vit D they can still be deficient. These refractory cases may benefit from treatment with calcitriol or sunlight exposure.

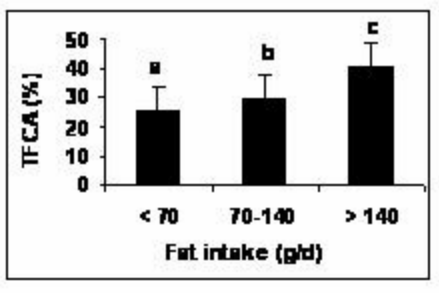
M337

Fat Intake Influences Calcium Absorption and Bone Mass. S. A. Shapses[1], C. S. Riedt*[1], R. E. Brolin*[2], M. P. Field*[3], R. M. Sherrell*[3]. [1]Nutritional Sciences, Rutgers University, New Brunswick, NJ, USA, [2]Surgery, Princeton Medical Center, Princeton, NJ, USA, [3]IMCS, Rutgers University, New Brunswick, NJ, USA.

Calcium (Ca) absorption is influenced by dietary intake, yet to our knowledge no previous report has examined this relationship over a wide range of body weights. Our primary goal was to determine how macronutrients and Ca-regulating hormones influence Ca absorption and bone by examining women with variable nutrient intakes. In this study, 141 women (BMI: 23 - 74 kg/m^2, age: 24 - 75 years) were retrospectively examined for associations between true fractional calcium absorption (TFCA) and macronutrient intake, hormones, and bone mass. TFCA was measured by dual stable Ca isotope method (^{42}Ca and ^{43}Ca). Regional BMD and BMC was measured by DXA. Serum hormones included parathyroid hormone, estradiol, 1,25 dihydroxyvitamin D, 25-hydroxyvitamin D. Food intake was estimated using three day food records. In a stepwise regression model including age, body weight, hormones, dietary Ca and macronutrient intake, the largest independent predictor of TFCA was dietary fat intake (range 10 - 218 g/d) (**Table**). Fat intake together with age and serum PTH explained 31% of the variance in TFCA. TFCA differed in each tertile of fat intake ($p < 0.0001$), averaging 25.5 ± 7.6 %, 29.4 ± 9.0 % and 40.5 ± 8.2 % from lowest to highest tertile, respectively (**Figure**). The calories from fat (%) in each tertile was 30 ± 8 %, 38 ± 6 % and 50 ± 16 %. In addition, women in the middle compared to lowest tertile of fat intake had greater ($p < 0.05$) BMD and BMC at the femoral neck and trochanter, and greater ultradistal and 1/3 radius BMD and total body BMC, independent of body weight. TFCA was an independent predictor of BMD at all sites measured, explaining 2-8 % of the variance. These findings show that dietary fat intake is a primary predictor of TFCA in women, and intake in the lowest tertile (consuming < 70 g/d; ~ 30 % fat calories) results in lower TFCA and bone mass. The relationship between low fat diets and bone health requires further study.

N=141	Partial R^2	p-value
Dietary fat intake	0.2072	< 0.0001
Age	0.0619	0.0009
PTH	0.0354	0.0095



Disclosures: ***S.A. Shapses****, None.*

M338

Dietary Silicon Intake Is Associated with Bone Mineral Density in Premenopausal Women and Postmenopausal Women Taking HRT. H. M. Macdonald[1], A. E. Hardcastle*[1], R. Jugdaohsingh*[2], D. M. Reid[1], J. J. Powell*[3]. [1]Medicine and Therapeutics, University of Aberdeen, Aberdeen, United Kingdom, [2]GI Laboratory, Rayne Institute, St Thomas's Hospital, Lonodn, United Kingdom, [3]MRC Human Nutrition Research, Cambridge, United Kingdom.

The relationship between intake of fruits and vegetables and bone health has been gaining interest recently. They may be beneficial because of their acid-balancing properties or because of other compoments they contain (vitamin C, folate, vitamin K, magnesium and anti-oxidants) that could plausibly affect bone health. Silicon, found in cereals, fruits and vegetables and some alcoholic beverages is an important mineral consituent of bone. Animal and cellular studies have indicated that silicon is involved in bone formation but there are few studies examining its role in humans. In the Framingham offspring cohort association between dietary silicon and hip BMD was found for premenopausal women, less so for men, but not for postmenopausal women, suggesting a hormonal (estrogen) interaction. We examined whether silicon intake is associated with markers of bone health in perimenopausal women ± HRT in the UK . A total of 3199 women from APOSS underwent bone densitometry in 1990-3 (mean ± SD age: 48.5 ± 2.4 y) and again 6.3 ± 0.9 y later and completed a food frequency questionnaire. We found significant associations between energy adjustested silicon intake and BMD at hip (FN) (r=0.054 P=<0.01) and lumbar spine (LS) (r=0.036, P=0.04). After adjusting for menopausal status/ HRT use, age, weight, height, smoking, and physical activity level, dietary silicon accounted for 0.1% of the variation in FN BMD but the association at the spine was no longer significant. When menopausal groups were analysed separately the association between energy adjusted silicon intake and FN BMD, was significant for premenopausal women (n = 333) and current HRT users (n = 1170) only. There are many common food sources for silicon and other nutrients such as folate, potassium, fiber and vitamin C. The Pearson correlation values for the association of these nutrients with silicon (energy adjusted) were: 0.48 for potassium, 0.40 for folate, 0.55 for fiber, 0.57 for magnesium and 0.37 for vitamin C (P<0.001 for all associations). However when we tested each of these nutrients in the linear regression model, only magnesium was found to be a significant predictor of FN BMD. These data support the earlier findings of the Framingham study and additionally indicate that dietary silicon intake is positively associated with BMD in HRT-using post-menopausal women, adding further weight to a possible interaction between estrogen status and effects of silicon on bone.

Vitamin D Content in Body Fat and the Consequences of Bariatric Surgery on Vitamin D Status. T. C. Chen[1], D. Ingersoll*[1], Z. Lu*[1], J. Mathieu*[1], A. Forse*[2], M. F. Holick[1]. [1]Vitamin D Research Laboratory, Boston University School of Medicine, Boston, MA, USA, [2]Department of Surgery, Boston University School of Medicine, Boston, MA, USA.

We have previously documented that obesity is associated with vitamin D deficiency because whether coming from sun exposure or diet the vitamin D bioavailability is reduced by more than 50% in obese compared to non-obese adults. It has been assumed that vitamin D being fat-soluble was being sequestered in body fat. However to date there has been no report of the isolation of vitamin D from human body fat. We recruited 10 morbidly obese adults who were schedule for bariatric surgery. After obtaining informed consent and at the time of surgery we obtained abdominal fat. The abdominal fat was extracted for its lipid content and then saponified. It was prepurified on a straight phase Sep pak column followed by reverse phase and straight phase high performance liquid chromatography. Blood was collected before the surgery and at 3-month intervals after the surgery. The vitamin D content in human fat ranged between 4-320 ng/g of fat. The human fat contained both vitamin D_2 and vitamin D_3. To determine whether the mobilization of vitamin D from body fat after bariatric surgery could substantially raise blood levels of 25(OH)D we measured circulating concentrations of 25(OH)D at 3 month intervals after the surgery. There was no significant change in circulating concentrations of 25(OH)D in subjects that blood was collected from 3 and 6 months after the surgery. These results provide evidence that body fat sequesters vitamin D and this is the likely explanation for why obesity is associated with vitamin D deficiency. Furthermore, the mobilization of body fat after bariatric surgery has little effect on vitamin D status suggesting that as the fat is being mobilized that the vitamin D is being metabolized and excreted.

The Effects of Once-weekly Alendronate 70 mg on Bone Metabolism of Postmenopausal Women in Korea. H. Kim*[1], H. Shon*[2], J. Choi*[2], H. Lee*[3], E. Kim*[4], I. Park*[5], I. Park*[6], B. Kim*[7], I. Lee[7]. [1]Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, Republic of Korea, [2]Internal Medicine, Catholic University of Daegu, Daegu, Republic of Korea, [3]Internal Medicine, Youngnam University, Daegu, Republic of Korea, [4]Internal Medicine, Daegu Fatima Hospital, Daegu, Republic of Korea, [5]Internal Medicine, Kyungpook National University, Orthopedic surgery, Republic of Korea, [6]Obstetrics & gynecology, Kyungpook National University, Daegu, Republic of Korea, [7]Internal Medicine, Kyungpook National University, Daegu, Republic of Korea.

Background: Once-weekly alendronate 70 mg is available for the treatment of postmenopausal osteoporosis. We performed a prospective study to evaluate the effect of once-weekly alendronate 70 mg on postmenopausal women with decreased bone mineral density (BMD). Methods: Participants had received once-weekly 70 mg dose of alendronate for twenty-four weeks with daily 1000 mg of calcium. BMD by dual energy X-ray absorbtiometry was measured to assess the effects of once-weekly alendronate on bone at the first and last visit. The biochemical bone markers were measured after 12- and 24 week treatment. Results: The BMD at the lumbar spine (L1-4) and femoral neck were significantly increased after 24-week treatment by 7.116% and 2.029% respectively. The bone-specific alkaline phosphatase was decreased significantly after 12- and 24-weak treatment by 15.5% and 21.1% respectively, and N-telopeptide crosslinks was decreased 22.8% and 18.9% respectively. The treatment was discontinued to one of the participants due to side effect. Overall, during the treatment, there were no significant side effect and laboratory abnormality. Conclusion: Once-weekly alendronate 70 mg significantly increased spine and femoral neck BMD and decreased biochemical marker of bone. The study proposes that alendronate 70 mg is effective and safe in preventing bone loss in postmenopausal women.

Effect of Risedronate on Bone Metabolism in Subacute Spinal Cord Injured Patients: Report of Two Cases. H. Kwak, S. Kim. Physical Medicine and Rehabilitation, Dong-A University College of Medicine, Busan, Republic of Korea.

Objective: To assess the effect of risedronate in subacute SCI patients. **Case 1:** For 6 months, 61-year-old spinal cord injured man with a L1 ASIA A (duration: 5 months) took a vitamin D 500 ng and calcium gluconate 1500 mg daily and risedronate 35mg weekly. In initial, his bone mineral density (BMD) was normal and serum osteocalcin (OC) level was borderline but urine deoxypyridinoline (u-DPD) level was markedly increased. After 6 months, u-DPD decreased about 46.5%. **Case 2:** For 8 months, 51-year-old spinal cord injured man with a C6 central cord syndrome ASIA D (duration: 3 months) took same medication and evaluation as case 1. In initial, BMD was -3.7 in lumbar spine, -2.2 in left femur and -2.0 in right femur. u-DPD level was markedly increased but serum OC level was normal. After 8 months, lumbar spine and femoral neck BMD were improved and u-DPD level became normalized. **Conclusion:** Risedronate show a preventive effect on bone loss in subacute SCI patients.

Prophylactic Administration of Bisphosphonate during Gn-RH Agonist Therapy for Endometriosis. K. Aisaka, Y. Ikezuki*, H. Uemura*, V. Takame*, S. Obata*. Obstetrics & Gynecology, Hamada Hospital, Tokyo, Japan.

Objectives: Gn-RH agonist therapy is widely used for treatment of endometriosis. However, it is well known that there are some side effects due to too much suppress of plasma sex steroid hormone levels. Present study was performed to elucidate whether bisphosphonate administration could prevent bone loss during Gn-RH agonist therapy for endometriosis. Materials & Methods: Forty-nine patients of endometriosis who were undertaken Gn-RH agonist treatment (leuprorelin, 1.88mg/4weeks) were subjected (Group A). They were administered bisphosphonate (risedronate 2.5mg/day) during Gn-RH agonist treatment for the prevention of bone loss. The bone mineral density (BMD) of the lumber spine was examined by DXA method before, 6 and 12 months after the treatment. Urinary and plasma levels of the biomarkers of bone metabolism; urinary cross-linked N-telopeptides of type I collagen (NTX), for bone resorption marker, and plasma bone alkaline phosphatase (BAP), for bone formation marker were also measured in the same time to evaluate the effects of these medications. The same examinations were also done in 45 cases of endometriosis who were undertaken Gn-RH agonist treatment with estrogen progestogen (EP) preparations for the add back therapy (group B). All study had been done under the enough informed consent. Results: Percent changes of the BMD values of the group A increased significantly during the treatment compared to those in the group B (A vs. B, 6 months after: 1.34+/-0.67, 1.12+/-0.59, 12 months after: 1.41+/- 0.46, 1.19+/-0.65%, $p<0.05$-0.02). Urinary NTX levels in the both groups decreased significantly on 6 months after the treatment compared to the previous values and there was also significant differences between group A and B after the treatment (before treatment, A vs. B: 42.6+/-12.0, 37.3+/-18.4, 6 months after: 19.0+/-9.5 vs. 29.5+/-10.1 nmolBCE/nmol cre., $p<0.05$). There was no significant change in plasma BAP levels between group A and B (before treatment: 20.5+/-7.7 vs. 19.6+/-10.3, 6months: 18.2+/-9.5 vs. 22.4+/-13.0 U/l). Conclusion: From these results, it was concluded that there was a beneficial effect for the BMD values during Gn-RH agonist treatment using bisphosphonate (risedronate) administration. In addition, it was suggested that this method might be a standard regimen during Gn-RH agonist therapy for the patients who could not take EP preparations.

One-Year Treatment of Alendronate Increases Bone Area, Bone Mineral Density, Bone Mineral Content in Osteoporotic Japanese Women. S. Takata, N. Yasui*, M. Takahashi*, A. Abbaspour*. Orthopedic Surgery, The University of Tokushima, Tokushima, Japan.

We studied the effects of one-year treatment of alendronate on bone area, bone mineral content (BMC) and bone mineral density (BMD) of whole body in osteoporotic Japanese women. Sixty-three women with primary osteoporosis, aged 55 to 79 years, were divided into two groups: women treated with alendronate for one year (5 mg/day; alendronate group, n=33) and women without treatment (control group, n=30). Bone area, BMC and BMD of whole body were measured using dual energy X-ray absorptiometry. The mean BMD of the 2nd to 4th lumbar vertebrae (L2-4BMD) of the alendronate and control groups were 107.4+/-5.0% and 100.0+/-6.1% compared to the respective pre-treatment levels, which was significantly different ($p<0.0001$). The percentage changes in whole body bone area of the alendronate and control groups were 102.5+/-4.0% and 99.4+/-2.8% compared to the respective pre-treatment levels, showing a significant difference ($p=0.0006$). The percentage changes in whole body BMC of the alendronate and control groups were 103.6+/-3.8% and 98.7+/-3.2% compared to the respective pre-treatment levels, showing a significantly difference ($p<0.0001$). The percentage changes in whole body BMD of the alendronate and control groups were 101.0+/-2.0% and 99.5+/-1.8% compared to the respective pre-treatment levels, showing a significant difference ($p=0.0033$). The results showed that the percentage changes in bone area, BMC, BMD of the alendronate group were significantly greater than those of the control group, and suggest that one-year treatment of alendronate increases bone area, BMC and BMD.

Factors Influencing Adherence to Bisphosphonates for Osteoporosis. P. Thompson[1], C. Cooper[2], A. Carr*[3]. [1]Rheumatology, Poole Hospital NHS Trust, Poole, United Kingdom, [2]MRC Epidemiology Unit, University of Southampton, Southampton, United Kingdom, [3]Clinimatrix, London, United Kingdom.

Non-adherence to bisphosphonate therapy is widely reported and clinically relevant but still common despite a once daily or weekly dosing regimen. This study was designed to identify factors influencing adherence to bisphosphonate therapy in the UK. Telephone interviews were conducted with 50 postmenopausal women aged over 50 with osteoporosis who had taken bisphosphonate therapy. A structured interview was conducted comprising: i) a validated questionnaire to collect detailed information about adherence (medication taking behaviours), patients' beliefs and expectations about osteoporosis and treatment (PHIT) ii) a utility-based rating scale to quantify patient preference and iii) an osteoporosis risk factor questionnaire. 48% of the women had sustained a previous fracture related to osteoporosis. 86% were currently taking bisphosphonates; 79% weekly and 21% daily. Non-adherence occurred with all bisphosphonates (19% of women took less than prescribed). Among the most frequently cited problems affecting adherence were: difficulty following the special instructions for taking bisphosphonates (46%); too frequent dosing (44%) and difficulty fitting treatment into daily routine (42%). Beliefs likely to influence adherence were prevalent; 54% of women were worried that if taken regularly the medication would stop working and 56% that they might become dependent upon bisphosphonates.44% were worried about taking long-term medication. Expectations of treatment were conservative: 46% expected prevention of fractures. Patient preferences for different dosing frequencies were elicited on a utility-based rating scale (values 0-100 where 0 is worst health state imaginable, 100, best health state imaginable). 77% of women expressed a preference for taking bisphosphonates monthly rather than daily or weekly. Mean values for dosing frequency on the utility based rating scale were: daily 46.84 (SD 26.66), weekly 68.20 (SD 31.14), monthly 77.96 (SD 25.53). Monthly dosing in combination with a patient support programme was the most highly valued treatment option (mean value 81.36 SD 21.86). Non-adherence is a problem with bisphosphonate therapy. Reasons for non-adherence include: difficulty following the special instructions and frequency of dosing. These factors operate against a background of beliefs about tolerance and addiction to bisphosphonates, unease about long term medication and conservative expectations of treatment efficacy. These factors and beliefs need to be addressed if adherence, and therefore clinical outcomes, of bisphosphonate therapy are to be improved.

Change in Markers of Bone Turnover in Patients on High Dose Glucocorticoids Treated with Bisphosphonate. K. E. Naylor, R. Eastell. Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom.

There has been concern that bone markers may be unsuitable for monitoring bisphosphonate therapy for glucocorticoid-induced osteoporosis because of the influence of underlying disease and changes in glucocorticoid dose on bone turnover marker variability. The aim of our study was to establish threshold values for the percentage change in biochemical markers, at a specificity of 90%, following risedronate treatment in patients treated with high dose glucocorticoids and postmenopausal women with low bone mass; this approach is a variant of the least significant change approach as it is based on the variability of bone turnover markers in the control group. Subjects were randomized to receive 5mg risedronate or placebo daily for 12 months. The study population consisted of 3 groups of patients. Patients initiating glucocorticoid treatment (prevention group RCP n=90), patients on established glucocorticoid treatment (treatment group RCT n= 120) and postmenopausal women (ROE) with low bone mass (T-score -2 or less, n=153). Bone turnover markers were measured at baseline and 6 months. The N-terminal telopeptide of type I collagen (NTX) was measured by Osteomark® ELISA (Ostex International, Seattle WA, USA). Bone alkaline phosphatase (BALP) was measured by IRMA, Tandem-R Ostase (Hybritech Inc., San Diego, CA, USA). A specificity of 90% for bone turnover marker change in the placebo group was used to determine the threshold. There was no significant difference between the baseline markers in the treatment and placebo groups for each study. Results for the baseline values and the percentage change in bone markers in the risedronate treated groups are shown in the table below.

Group	n	Baseline, mean (SE)	Threshold %	% change 6m
RCP NTX	47	66.5 (8.5)	-56.0	-49.4 (8.0)
RCT NTX	67	64.3 (5.5)	-56.3	-55.1 (3.8)
ROE NTX	79	66.7 (4.0)	-57.9	-49.9 (2.9)
RCP BALP	47	10.8 (0.5)	-50.7	-8.8 (6.2)
RCT BALP	67	11.3 (0.7)	-29.8	-20.1 (4.0)
ROE BALP	79	11.9 (0.5)	-44.4	-28.7 (3.0)

Biochemical markers of bone turnover can be used to monitor risedronate therapy in glucocorticoid treated patients. The least significant change thresholds and the mean changes in bone turnover markers are similar in patients treated with glucocorticoids and postmenopausal women with low bone density.

Large Proportions of Women with Postmenopausal Osteoporosis Respond to Once-Monthly Oral Ibandronate: 2-Year Results from MOBILE. R. R. Recker[1], M. Luckey*[2], J. A. Stakkestad*[3], R. Civitelli[4], C. Hughes*[5], N. Mairon[5], B. Bonvoisin[5], C. Cooper[6]. [1]Creighton University, Omaha, NE, USA, [2]Saint Barnabas Ambulatory Care Center, Livingston, NJ, USA, [3]CECOR AS, Haugesund, Norway, [4]Washington University School of Medicine, St Louis, MO, USA, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [6]MRC Epidemiology Resource Centre, University of Southampton, Southampton, United Kingdom.

In postmenopausal osteoporosis (PMO), bisphosphonate-induced increases in bone mineral density (BMD) and decreases in biochemical markers of bone turnover are significantly predictive for decreased fracture risk. In MOBILE, a randomized, double-blind, phase III study, once-monthly (50+50mg [single doses, consecutive days], 100mg [single day] and 150mg [single day]) and daily (2.5mg; active comparator) oral ibandronate (Boniva) regimens are being evaluated in 1,609 women (aged 55-80 years; ≥5 postmenopausal) with PMO (lumbar spine BMD T-score <-2.5 and ≥-5). All participants are receiving calcium (500mg) and vitamin D (400IU) supplements. To explore the likely antifracture benefit provided by the investigational regimens, the proportion of participants responding to treatment with increases in lumbar spine and/or total hip BMD ≥ baseline or ≥6% and ≥3%, respectively, and decreases in serum CTX (sCTX) of ≥50% or ≥70% was evaluated. As at 1 year, increases in lumbar spine and/or total hip BMD ≥ baseline or target values were observed in large proportions of participants at 2 years (**Table**). For all BMD endpoints, the proportion of responders was greatest with the 150mg regimen ($p<0.05$ vs daily; **Table**). Large proportions of patients also achieved clinically meaningful decreases in sCTX (**Table**). Again, the proportion of responders was largest with the 150mg dose ($p<0.05$ vs daily). In postmenopausal osteoporosis, these findings indicate that more women are likely to be responsive to once-monthly oral ibandronate than daily oral ibandronate, and that the 150mg dose provides additional treatment benefits.

Proportion (%) of participants responding to treatment with increases in BMD and decreases in sCTX				
	2.5mg daily	50/50mg monthly	100mg monthly	150mg monthly
LS BMD ≥baseline	86.4	87.8	87.8	93.5*
LS BMD ≥6% from baseline	35.4	41.2	45.3*	54.3*
TH BMD ≥baseline	78.4	83.2	88.8*	93.4*
TH BMD ≥3% from baseline	40.4	46.4	59.2*	65.1*
LS and TH BMD ≥baseline	70.5	75.3	79.3*	87.1*
sCTX ≥50% from baseline	65.6	60.9	63.5	78.7*
sCTX ≥70% from baseline	35.3	27.0	35.1	48.1*

LS = lumbar spine
TH = total hip
*p<0.05 vs 2.5mg

M347

Once-Monthly Oral Ibandronate Is at Least as Effective as Daily Oral Ibandronate in Postmenopausal Osteoporosis: 2-Year Findings from MOBILE. M. R. McClung[1], M. K. Drezner[2], J. Y. Reginster[3], M. Bolognese[4], C. Hughes*[5], N. Mairon[5], B. Bonvoisin[5], P. D. Delmas[6]. [1]Oregon Osteoporosis Center, Portland, OR, USA, [2]University of Wisconsin, Madison, WI, USA, [3]University of Liège, Liège, Belgium, [4]Bethesda Health Research, Bethesda, MD, USA, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [6]Claude Bernard University and INSERM Research Unit 403, Lyon, France.

Therapeutic adherence with weekly oral bisphosphonates, while improved compared with daily dosing, remains suboptimal, compromising therapeutic outcomes in postmenopausal osteoporosis (PMO). Given the strong patient preference for less frequent bisphosphonate dosing schedules, it may be expected that further reducing the frequency of dosing (beyond weekly) could provide additional adherence benefits. Ibandronate (Boniva) is a potent, nitrogen-containing bisphosphonate with proven antifracture efficacy when administered orally, either continuously (daily) or intermittently with a dose-free interval of >2 months. In MOBILE, a randomized, double-blind, phase III study, the efficacy and safety of once-monthly oral ibandronate (50+50mg [single doses, consecutive days], 100mg [single day] and 150mg [single day]) is being compared with daily oral ibandronate (2.5mg; 3-year vertebral fracture risk reduction: 52%) in women (aged 55-80 years; ≥5 years postmenopausal) with PMO (lumbar spine BMD T-score <-2.5 and ≥-5). At 2 years, substantial increases in lumbar spine BMD were observed in the once-monthly and daily treatment arms: 5.3%, 5.6% and 6.6% in the 50+50mg, 100mg and 150mg groups, respectively, versus 5.0% in the daily group. As at 1 year, all once-monthly regimens were proven at least as effective as the daily regimen by non-inferiority analysis. The 150mg regimen continued to be statistically superior ($p<0.001$) to the daily regimen. Sizeable increases in proximal femur BMD (total hip, femoral neck and trochanter) were also observed in all treatment arms, with the greatest gains obtained with the 150mg regimen (all sites). While corroborating the outcome of the primary efficacy analysis, e.g. therapeutic equivalence of once-monthly oral ibandronate and daily oral ibandronate (for BMD endpoints), these 2-year findings also suggest that the 150mg regimen may provide greater therapeutic efficacy in PMO than the daily and 100mg regimens. This advantage may be reinforced by the improved adherence to therapy that may accompany the once-monthly dosing schedule.

Effect of Pretreatment with Low-Dose Risedronate and/or Vitamin K2 on Early Cancellous Bone Loss after Ovariectomy in Rats. J. Iwamoto[1], T. Takeda*[1], C. L. Shen*[2], J. K. Yeh[3]. [1]Department of Sports Medicine, Keio University, Tokyo, Japan, [2]Department of Pathology, Texas Tech University Health Science Center, Lubbock, TX, USA, [3]Department of Medicine, Winthrop-University Hospital, Mineola, NY, USA.

The purpose of the present study was to examine the effect of pretreatment with low-dose risedronate and/or vitamin K2 on early cancellous bone loss induced by ovariectomy (OVX) in rats. Eighty female Sprague-Dawley rats, 4 months of age, were randomized by the stratified weight method into eight groups (n=10 in each group). Rats subjected to OVX, but not sham-operated rats, were treated with vehicle, risedronate, vitamin K2, or risedronate + vitamin K2 for 4 weeks before surgery, and the treatment was either discontinued (pretreatment groups) or continued after surgery (treatment continuation groups) for 2 weeks. Sham-operated rats were treated with vehicle throughout the experimental period. During the 4 weeks prior to surgery (pretreatment), risedronate and vitamin K2 (menatetrenone) were administered five times a week subcutaneously at the dose of 2.5μg/kg body weight and orally at the dose of 30 mg/kg body weight, respectively. During the 2 weeks after surgery (treatment continuation), risedronate and vitamin K2 were administered at the same doses, but only twice a week at the same doses. OVX decreased the bone volume/total tissue volume (BV/TV: 14.2±2.1[mean±SD]% vs. 17.8±1.9% in sham-controls, $P<0.001$) as a result of increased bone turnover. Both risedronate and vitamin K2 had an anti-resorptive effect on the cancellous bone. Treatment continuation with vitamin K2 (BV/TV: 16.1±1.8%), but not pretreatment (BV/TV: 14.4±1.9%), prevented the BV/TV loss. On the other hand, pretreatment with risedronate (BV/TV: 18.3±2.2%) prevented the BV/TV loss. Treatment continuation with risedronate alone increased BV/TV to beyond the values in controls (BV/TV: 21.2±2.7% vs. 17.8±1.9% in sham-controls, $P<0.001$). Furthermore, both pretreatment (BV/TV: 20.2±2.6%, $P<0.05$) and treatment continuation (BV/TV: 22.2±2.6%, $P<0.001$) with risedronate + vitamin K2 also increased the BV/TV to beyond the control values, with treatment continuation having a greater beneficial effect than pretreatment on the BV/TV and bone turnover. The present study demonstrates that pretreatment with low-dose risedronate had a beneficial effect on early cancellous bone loss after OVX in rats, and that treatment continuation with risedronate alone or risedronate in combination with vitamin K2 was effective at increasing cancellous bone mass, despite the reduced dosing frequency of the drugs.

Intravenous Pamidronate for Pain Relief in Recent Osteoporotic Vertebral Compression Fracture. A Randomized, Double Blind, Controlled Study. T. Armingeat*, R. Brondino*, T. Pham*, V. Legré*, P. Lafforgue. Rheumatology, Hopital de la Conception, Marseille, France.

Introduction: We performed a randomized, double-blind, controlled clinical trial comparing intravenous pamidronate and placebo for pain relief in fresh osteoporotic vertebral compression fractures(VCF). Patients and methods: Patients were suffering of recent (40/100 mm) VCF due to osteoporosis. They were randomized to receive either infusions of placebo or intravenous pamidronate (30 mg) on 3 consecutive days (in all, pamidronate 90 mg). The main criterion of response was the diminution of standing pain on a 100 mm VAS scale at day 7. Other criteria were standing pain at day 3 and 30, supine pain at day 3, 7 and 30; Patient self-assessment of improvement, mobility index, and number of 20 % and 50 % responders (corresponding respectively to 20 and 50 % improvement in standing pain at day 7). Statistical analysis was made in intention to treat with non parametric tests. Results: 32 patients were enrolled in the study, 16 were allocated to placebo, and 16 to pamidronate. Pain was significantly decreased in both groups at day 7 (Placebo -23 mm; Pamidronate -42 mm). Difference of pain between group was -23.25 mm (IC [-42.3; -4.2], p = 0.018) at day 7, and -29 mm at day 30 (p= 0.02) in favor of pamidronate. Responders 50 %: There were 4 and 12 responders respectively in the placebo and in the pamidronate groups at day 7 (likelihood ratio: 8.372; p = 0.004). Responders 20 %: There were 9 and 14 responders respectively in the placebo and in the pamidronate groups at day 7 (likelihood ratio: 4.038; p = 0.044). Patient's self-assessment of improvement was 37 +/- 26 mm in the placebo group and 59 +/- 30 mm in the pamidronate group at day 7 (p= 0.019), and respectively 43 +/- 26 mm and 72 +/- 21 mm at day 30 (p=0.07). Supine pain, Shöber index and finger ground distance showed no statistical difference between groups at day 7 and 30. No significant adverse reaction occurred. Conclusion: Pamidronate provides rapid and sustained pain relief in patients with acute painful osteoporotic VCF and is well tolerated. Its place within therapeutic armamentarium of painful fresh osteoporotic collapse has to be defined.

Safety and Tolerability of Intravenous Ibandronate Injections: DIVA 1-Year Analysis. M. K. Drezner[1], L. G. Ste-Marie[2], R. Nuti[3], C. Benhamou[4], C. Leigh*[5], P. Ward*[5], D. Masanauskaite*[5], E. M. Lewiecki[6]. [1]University of Wisconsin and GRECC, Madison, WI, USA, [2]CHUM Hopital Saint-Luc, Montreal, PQ, Canada, [3]University of Siena, Siena, Italy, [4]IPROS-CHR, Orleans, France, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [6]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

Oral bisphosphonates are the treatment of choice for postmenopausal osteoporosis (PMO), but may be unsuitable or contraindicated for some women. Use of an intravenous (i.v.) bisphosphonate preparation could be advantageous for these patients. Ibandronate (Boniva) is a potent, nitrogen-containing bisphosphonate that can be administered as a rapid (15-30 seconds) i.v. injection with extended dosing intervals. To establish the optimal regimen, the efficacy and safety of 2mg q2mo and 3mg q3mo i.v. ibandronate injections is being compared with an established active comparator regimen (2.5mg daily oral ibandronate) in the ongoing DIVA study. In this double-blind, double-dummy, phase III study, a total of 1,395 women with PMO (aged 55-80 years; ≥5 years since menopause; lumbar spine [L2-L4] BMD T-score <-2.5 and ≥-5.0) were randomized to one of three treatment arms, with all women receiving calcium (500mg) and vitamin D (400IU). Adverse events (AEs) were monitored throughout the study period. After 1 year, a similar overall incidence of adverse events (76-81%) and drug-related AEs (33-44%) was observed in the i.v. and oral treatment arms. The incidence of drug-related AEs leading to withdrawal was also low and similar (4.5-6.6%). A low and comparable incidence of drug-related serious AEs was observed (<1% in all arms; n=7). Flu-like illness, a combination of the investigator terms influenza-like illness and acute phase reaction, was reported with a slightly higher frequency in the i.v. arms (5.1% in the q2mo arm and 4.9% in the q3mo arm) than the daily arm (1.1%), but the overall incidence was low, with symptoms generally associated with the first injection only, mild to moderate in intensity and transient in nature. The incidence of clinical fractures observed across the treatment arms was similar. In summary, 2mg q2mo and 3mg q3mo i.v. ibandronate injections are well tolerated by postmenopausal women, and have a similar safety profile to an established daily oral ibandronate regimen that has previously shown tolerability similar to placebo. Thus, i.v. ibandronate injections are likely to be of utility for women who are unable to use oral bisphosphonates.

Potential Bone Mineral Binding Differences among Bisphosphonates Can Be Demonstrated by the Use of Hydroxyapatite Column Chromatography. M. A. Lawson*[1], J. T. Triffitt[1], F. H. Ebetino[2], B. L. Barnett*[2], R. J. Phipps*[2], R. M. Locklin*[1], R. G. G. Russell[1]. [1]Nuffield Dept Orthopaedic Surgery, University of Oxford, Oxford, United Kingdom, [2]New Drug Development, Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Bisphosphonates (BPs) are the most widely used class of antiresorptive agents for the treatment of metabolic bone diseases, and are known to bind strongly to bone mineral. There is a growing appreciation that small but potentially important differences exist among the BPs, not only in their relative potencies but also in their duration of action. Our recent studies (Nancollas et al, Bone, in press) suggest that unexpected differences in mineral binding affinities contribute both to potency and to reversibility of action. In order to study the differences in mineral binding that may relate more directly to the retention and diffusion through bone of BPs, and other phosphate-containing compounds, we have developed a method based on FPLC, using hydroxyapatite columns (3 x 25 mm) to which phosphate- containing compounds can adsorb and be eluted by using increasing phosphate buffer concentrations (1-1000mM) at pH 6.8. The individual compounds emerge as discrete peaks detectable by UV absorbance and/or mass spectrometry. Under the conditions used the retention times (RT) (mins; mean ± SEM) for the BPs were 22.0 ±0.1 for zoledronate, compared with the faster elution of 16.16 ± 1.17 for risedronate, and 7.33±0.08 for NE10790, a risedronate analogue in which one of the phosphate groups is replaced by a carboxyl group. These elution patterns were reproducible and the RTs statistically different ($p<0.05$). The known importance of the OH group at the C-1 position was verified in observed faster elution of the risedronate analog (13.16 ± 0.6) lacking this C-1 OH group and also for the 2-pyridyl analog of risedronate (18.6 ± 0.3 vs 14.4±0.5 with or without the C-1 OH group respectively). These results confirm that differences in hydroxyapatite-binding affinities are an important feature of BPs, and indicate that the side chains contribute to mineral binding affinities in addition to the P-C-P backbone. Indeed, modeling studies indicate that the N atoms in the BP side chains can co-ordinate with OH groups in HAP with bonding efficiencies related to their overall binding affinity. The differences among BPs in binding to HAP may go some way to explain the variations in retention and persistence of effects of BPs observed in animal studies as well as in clinical studies.

An International Comparison of the Impact of Dosing Frequency on Adherence with Bisphosphonate Therapy among Postmenopausal Women in the UK and Germany. N. O. Lynch*[1], M. Walker*[2], W. Cowell*[2], N. Suppapanya*[3], T. Hammerschmidt*[4], U. Rigney*[1]. [1]GlaxoSmithKline, Greenford, United Kingdom, [2]Roche Ltd, Welwyn, United Kingdom, [3]GlaxoSmithKline, Collegeville, PA, USA, [4]GlaxoSmithKline, Munich, Germany.

While high adherence (medication compliance and treatment persistence) to bisphosphonate (BP) therapies is necessary to maximize benefit, patients often omit doses or discontinue treatment for a variety of reasons. The objective of this study was to quantify adherence with daily and weekly BP regimens for postmenopausal osteoporosis (PMO), and compare findings in the UK and Germany. Mediplus databases in the UK (~2.5 million patients, 600 GPs) and Germany (~1.5 million patients, 500 GPs) (Jan 2001-Jan 2005) were used to identify postmenopausal women (≥50 years) newly-prescribed (no BP prescription for ≥12 [UK] or ≥6 [Germany] months prior to index prescription) a once-weekly (OW; alendronate 70mg [UK, Germany], risedronate 35mg [UK]) or once-daily (OD; alendronate 10mg, risedronate 5mg [UK]) BP. The OW and OD cohorts were followed for 12 months from the date of index prescription. Medication possession ratio (MPR) was used to estimate compliance. Persistence was calculated as the number of days from the initial prescription to the date of discontinuation of therapy. The number of women identified was 5,962 from the UK and 288 from Germany (UK: OW = 5,102, OD = 860; Germany: OW = 144, OD = 144). Mean age was 73 years in both the UK and Germany. MPR for the combined study cohort was 63.3% in the UK and 44.7% in Germany. However, in both countries OW users had a significantly higher MPR than OD users (UK: 70.3 vs 56.3%; Germany: 51.7 vs 37.7%; $p<0.0001$). Overall, average treatment persistence during the 12-month follow-up period was 207 days in the UK and 189 days in Germany. However, a significantly longer time to discontinuation was observed for OW users (UK: 228 days; Germany: 227 days) compared to OD users (UK: 186 days; Germany: 172 days; $p<0.0001$). At the end of 12 months in the UK, 43.6% of women on the OW regimen and 33.3% of women on the OD regimen had persisted with therapy. For Germany, the results were similar, with 46.5% of women still on the OW regimen and 27.8% on the OD regimen 12 months after BP initiation. Women with PMO prescribed a OW BP regimen had significantly higher rates of compliance and longer persistence compared with those taking a OD regimen. However, rates for both regimens were suboptimal. Results were consistent across both countries, indicating that a less frequent BP dosing regimen increases adherence. Continued development of more convenient regimens and health care initiatives to enhance adherence are needed to maximize the therapeutic potential of bisphosphonates.

The Effect of a Once-Weekly Tablet Containing Alendronate and Vitamin D_3 for the Treatment of Osteoporosis. P. T. Lips[1], R. R. Recker[2], C. J. Rosen[3], H. Bone[4], H. W. Minne[5], G. Callahan*[6], A. Lamotta*[6], W. He*[6], A. Santora[6]. [1]Department of Endocrinology, Vrijie University Medical Center, Amsterdam, The Netherlands, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [3]Maine Center for Osteoporosis Research, St. Joseph Hospital, Bangor, ME, USA, [4]Michigan Bone and Mineral Clinic, Detroit, MI, USA, [5]Metabolic Bone Disease, Clinic Der Furstenhof, Bad Pyrmont, Germany, [6]Merck Research Laboratories, Merck & Co., Inc., Rahway, NJ, USA.

Vitamin D is an integral part of effective osteoporosis therapy, but many osteoporosis patients have inadequate vitamin D and fail to recognize the need for supplementation. This study evaluated the efficacy, safety, and tolerability of a once weekly tablet containing 70 mg alendronate (ALN) and 2800 IU cholecalciferol (D) in osteoporosis patients. This

was a 15-week, randomized, double-blind, multi-center, controlled study in winter/early spring. Patients with baseline serum 25OHD <9 ng/mL were excluded. Postmenopausal women and men with osteoporosis (T≤-2.5) were randomized to once-weekly ALN with 2800 IU D (ALN+D; n=357) or ALN alone (n=351). Patients were instructed to avoid sunlight and not take vitamin D supplements. Serum 25OHD - the primary efficacy endpoint - and urinary N-telopeptides of type I collagen (NTx) were measured at Weeks 0, 5, 10, and 15. Safety and tolerability were assessed by a clinical review of adverse experiences (AEs). Serum 25OHD averaged 22 ng/mL at baseline and declined in the ALN only group, but was 26% higher in the ALN+D group at Week 15 vs ALN alone; mean 25OHD levels at Week 15 were 23.1 and 18.4 ng/mL, respectively ($p<0.001$). Thus, ALN+D reduced the risk of 25OHD deficiency (<9 ng/mL) vs ALN alone by 91% at Week 15 [1% vs 13% incidence, respectively; RR, 0.09 ($p<0.001$)] and reduced the risk of 25OHD <15 ng/mL by 64% [11% vs 32%, respectively; RR, 0.36 ($p<0.001$)]. Reductions in NTx were similar in both groups. The overall incidence of clinical AEs was not significantly different between treatment groups. Hypercalciuria (ie, >25% increase in 24-hour urine calcium excretion from baseline and urine calcium excretion value > ULN) was rare, and occurred at the same incidence in both treatment groups (n=7 per group). There were no cases of hypercalcemia. The serum 25OHD distributions in this study are not representative of all osteoporosis patients because the study excluded 25OHD <9 ng/ml and limited vitamin D from either sunlight or other supplements. However, even under these restrictive conditions, a once weekly tablet containing ALN and cholecalciferol improved vitamin D status, greatly reducing the risk of deficiency, with antiresorptive efficacy and a safety and tolerability profile similar to that of ALN alone.

Comparison of Alendronate and Raloxifene to Prevent Bone Loss when Estrogen Therapy Is Discontinued in Postmenopausal Women. M. R. McClung[1], M. Omizo[1], E. Mossman*[1], D. Conn*[1], L. Cole*[1], P. Workman*[1], E. Chen*[2], A. E. de Papp[2], M. Kocher*[3], N. Watts[3]. [1]Oregon Osteoporosis Center, Portland, OR, USA, [2]Merck & Co., Inc., West Point, PA, USA, [3]University of Cincinnati Bone Health and Osteoporosis Center, Cincinnati, OH, USA.

Estrogen prevents bone loss after menopause, but is no longer recommended for long term use solely for the prevention of bone loss. When women discontinue estrogen treatment, bone loss occurs, and some women are candidates for alternative treatments to prevent that loss of bone mass. Raloxifene and alendronate are both approved for the treatment and prevention of postmenopausal osteoporosis. This study compared the ability of these two treatment options to prevent bone loss in women who recently discontinued estrogen therapy. Postmenopausal women who were within 6 months of discontinuing estrogen therapy were randomly assigned to receive alendronate 70 mg weekly (n=61) or raloxifene 60 mg daily (n=63) with double placebo. Daily intakes of calcium and vitamin D were at least 1000 mg and at least 400 IU, respectively. BMD of the PA lumbar spine (LS) and total hip were measured at baseline, 6 and 12 months. Urinary N-telopeptide (NTX-u) was measured at baseline, 3 and 12 months. No differences were noted between treatment groups in these baseline characteristics: mean age (59.2 years); mean years since menopause (10.8); mean LS BMD (T-score -0.9), NTX-u (55.9 nmol/mmol) or mean months since stopping estrogen therapy (2.9). At 12 months, compared with baseline, statistically significant increases in BMD at the LS and total hip and a reduction of NTX-u were seen with alendronate treatment. In subjects who received raloxifene, a significant decrease occurred in LS BMD, but no change was noted in total hip BMD or NTX-u. The differences between groups in BMD and NTX-u were significantly different ($p<0.001$) at each time point. The proportion of women who experienced a decrease of LS BMD of at least 3% at 12 months was greater in subjects who received raloxifene (32.8%) than who took alendronate (1.8%). Both drugs were well tolerated. There were no differences between treatment groups in the incidence of upper GI adverse experiences or vasomotor symptoms.Alendronate was more effective than raloxifene in preventing bone loss and reducing bone resorption in postmenopausal women who recently discontinued estrogen therapy.

Percent Change from Baseline at 12 Months (Least Square Mean (95% CI))			
Treatment Group	PA Lumbar Spine BMD	Total Hip BMD	NTX-u
Alendronate	+2.3 (1.5, 3.1)	+1.1 (0.5, 1.6)	-48.2 (-55.2, -40.0)
Raloxifene	-1.4 (-2.1, -0.6)	-0.5 (-1.0, 0.1)	-3.1 (-16.6, 12.5)

Does Alendronate Reduce the Risk of Non-Vertebral Fracture in Women without Vertebral Fracture who Have Osteopenia and a History of Non-Vertebral Fracture? The Fracture Intervention Trial (FIT). K. M. Ryder*[1], D. C. Bauer[2], A. J. Bush*[3], S. Satterfield*[3], L. Palermo*[2], A. Schwartz*[2], A. Feldstein*[4], K. Ensrud*[5], S. R. Cummings[6]. [1]Int Med, UTHSC, Memphis, TN, USA, [2]PSG, UCSF, San Francisco, CA, USA, [3]Prev Med, UTHSC, Memphis, TN, USA, [4]CHR, Kaiser Permanente, Portland, OR, USA, [5]Int Med, VAMC, Minneapolis, MN, USA, [6]PSG, UCSF, CPMC Res Inst, San Francisco, CA, USA.

There is controversy about treatment of postmenopausal women with 'osteopenia.' Guidelines recommend treating women without existing vertebral fracture (VFx) who have T-scores below -1.5 if they also have a history of a postmenopausal non-vertebral fracture (non-VFx). However, the effectiveness of bisphosphonates on the risk of subsequent non-VFx in these women is not known. Among 2705 women in FIT without prevalent VFx with a FN T-score from -1.6 to -2.5, 880 reported any non-VFx after age 45. ALN substantially reduced the risk of non-VFx in women with a T-score ≤ -2.5, regardless of Fx history. However, treatment did not significantly reduce the risk of non-VFx in women with a FN T-score > -2.5, including no reduction in risk among those with a prior non-VFx (Table). Relative risk (95% C.I.) of non-VFx in women without VFx assigned to ALN, compared to placebo.

FN T-score	History of non-VFx	No history of non-VFx
Above -2.5 (n=2705)	1.3 (0.9, 1.8)	1.0 (0.8, 1.4)
≤ -2.5 (n=1727)	0.7 (0.6, 0.95)	0.6 (0.4, 0.9)

Among women without existing VFx and with a FN T-score between -1.5 and -2.5, ALN has been shown to reduce the risk of VFx; however treatment does not reduce the risk of non-VFx, even among those with a history of non-VFx fracture. Among women with a non-VFx, measurement of FN BMD identifies a subgroup (T ≤ -2.5) whose risk of non-VFx will be reduced by ALN.

Hip and Nonspine Fracture Risk Reductions Differ among Antiresorptive Agents. Evidence from Randomized Controlled Trials. U. A. Liberman[1], P. Geusens[2], M. C. Hochberg[3], A. Chattopadhyay*[4], P. D. Ross[4]. [1]Tel Aviv University, Petah-Tikva, Israel, [2]Limburg University & University of Maastricht, Diepenbeek, Belgium, [3]University of Maryland, Baltimore, MD, USA, [4]Merck Research Laboratories, Rahway, NJ, USA.

A number of antiresorptive agents reduce the risk of vertebral fractures (frx), but few have shown consistent effects on hip and other nonspine frx. Meta-analysis provides a more precise estimate than individual trials when results are consistent across pooled trials. Earlier meta-analyses summarized the results for vertebral and nonspine frx.[1] New data have emerged for hormone therapy (HT),[2,3] alendronate (ALN),[4] risedronate (RIS),[5] and ibandronate (IBN).[6] We surveyed recent reports of randomized, placebo-controlled trials with nonspine and/or hip frx, and used meta-analysis where appropriate to test for heterogeneity and derive pooled estimates. With RIS (n=12958), the relative risk (RR) reduction was 27% for nonspine frx (RR=0.73; 95% CI= 0.61, 0.87)[1] and 26% for hip frx (RR=0.74; 0.58, 0.94); there was no significant interaction of treatment and age >80. With ALN, heterogeneity existed; doses >5 mg/d were significantly more effective. The RR reduction with ALN >5 mg (n=3723) was 49% for nonspine frx (RR=0.51; 0.38, 0.69).[1] The hip frx RR reduction was 55%; (RR=0.45; 0.29, 0.72) when osteoporotic women in FIT (ALN 5 mg in years 1-2) were included (n=6804),[4] and 55% (RR=0.45; 0.18, 1.13) for doses >5 mg (n=3723).[1] With HT (n= 27347,[2,3] not limited to osteoporotic patients), risk was reduced by 36% for hip frx (RR=0.64; 0.49, 0.84) and 25% for nonspine frx (RR=0.75; 0.70, 0.81). For IBN, there was no consistent evidence of hip or nonspine frx risk reduction. The incidence of nonspine frx in the largest IBN trial (n=2946) was 9.2%, 8.9% and 8.2% in the 2.5 mg/d, intermittent dosing (240 mg every 3 mo), and placebo groups, respectively.[6] A post-hoc subgroup analysis reported a significant interaction between treatment and BMD with a nonspine frx RR reduction of 69% with daily 2.5 mg (but not intermittent dosing) among only those women with T-scores <-3.0 and prior vertebral frx.[6] The magnitude of effect on hip frx appears to be similar to that for nonspine frx for each drug, but differs among drugs. Based on current data, ALN reduces the risk of hip and nonspine frx by 49-55%, HT by 25-36%, and RIS by 26-27%. There is insufficient and/or inconsistent evidence of an effect on these frx for ibandronate,[6] calcitonin,[1] and raloxifene.[1]

M357

Persistence and Compliance with Bisphosphonate Therapy among Postmenopausal Osteoporotic Women: A Comparison between Daily and Weekly Regimens. K. F. Huybrechts*[1], K. J. Ishak*[2], I. Proskorovsky*[2], J. J. Caro*[1]. [1]Caro Research Institute, Concord, MA, USA, [2]Caro Research Institute, Montreal, PQ, Canada.

The purpose of this analysis was to compare the level of persistence and compliance among postmenopausal osteoporotic women treated with daily or weekly bisphosphonates in actual practice. Data were obtained from a managed care database which comprises claims and eligibility records for over ten million lives covered under various public and private benefit plans in the United States. The study cohort included women with a diagnosis of osteoporosis (ICD-9 code 733.0) followed by at least one prescription for alendronate 10mg once daily, alendronate 70mg once weekly, risedronate 5mg once daily, or risedronate 35mg once weekly between January 1, 2001 and June 30, 2002. The first prescription for either one of these medications was considered the index prescription. Non-persistence was defined as a gap of >30 days between two subsequent prescriptions. Time to non-persistence was defined as the time from the index prescription to the start of the gap in medication availability. Compliance was measured using the medication possession ratio (MPR), defined as number of days during which the patient had medication available within follow-up time considered, divided by the follow-up time. Analyses were conducted using a continuous as well as a categorical (<80%, ≥80%) definition of compliance. Outcomes were compared between daily and weekly regimens. Patients who switched from a daily to a weekly regimen during the course of their follow-up were censored at the time of the switch. Of the 2,905 new users identified based on a 6-month run-in window, 31% had an index prescription for a daily regimen, 69% for a weekly regimen. After 6 months, 46.7% of women on the once-weekly regimen and 41.9%

of women on the once daily regimen persisted with their therapies. At 12 months, the respective percentages were 27.7% and 18.9%. Longer persistence was thus observed for once-weekly (median:146 days) when compared to the once-daily users (median:120 days), but the differences were not statistically significant. At 12 months, once-weekly users had a significantly higher MPR than the once-daily users (53.7% vs. 46.9%, P=0.0022). Similarly, the proportion of highly compliant patients (≥80%) was 23% for the daily versus 32% for the weekly regimen (P=0.0025). Although higher rates of compliance and longer persistence are observed for the weekly compared to the daily regimen, rates for both regimens are suboptimal, and the social, clinical and economic implications of such behavior are known to be substantial. Until compliance is improved, we will continue to fail in meeting an important public health goal.

Alendronate Effects on Histomorphometric Parameters: Is There Evidence for Over-Suppression of Turnover? R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Alendronate (ALN) is a potent antiresorptive agent that decreases bone remodeling primarily through inhibition of osteoclast activity. Decreased bone resorption is prompt, robust, and sustainable through at least ten years of continued treatment. Because remodeling is essential for maintenance of skeletal integrity, it is important to examine whether treatment with ALN might impair this function. Studies that reported histomorphometric analyses of specimens following ALN treatment were reviewed. Iliac crest biopsies obtained after up to 10 years of ALN treatment[1,2] showed normal quality lamellar bone, with no evidence of impaired mineralization. Double-labeling, a clear indicator of active bone formation, was present in all specimens. Men and women with glucocorticoid-induced osteoporosis who were treated with ALN for one year had normal mineral apposition rates (MAR), although 3 biopsies failed to show tetracycline label[4]. In another study, ovariectomized baboons were treated with ALN for 2 years, after which biopsies were obtained from both the iliac crest and the lumbar spine[3]. Double label was present in all specimens, and the MAR was similar to that seen in non-ovariectomized animals. In studies of high-dose (5-6 times usual clinical dose) ALN in dogs, no evidence of impaired mineralization was seen, and the MAR was similar to that of control animals[5,6]. Further, in a study of pre- and post-fracture treatment with very high dose ALN (10 times usual clinical dose), label was present in all specimens, with no difference in MAR[7]. No evidence of over-suppression of bone turnover, as assessed by histomorphometry of specimens from participants in clinical trials of up to 10 years' duration, has been associated with the use of ALN in postmenopausal osteoporosis. Animal studies, in which much higher doses of ALN were used, confirm the safety of ALN. Although an increase in microcrack density of cortical bone has been reported by some authors, higher microcrack density has been associated with increased bone strength[8].

Rationale and Design of the MOTION Study (Monthly Oral Therapy with Ibandronate for Osteoporosis Intervention). F. Cosman[1], M. R. McClung[2], C. J. Rosen[3], S. Epstein[4], V. Devas*[5], B. El Azzouzi*[6], B. Bonvoisin[6], J. Zanchetta[7], C. Cooper[8], P. D. Delmas[9]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Oregon Osteoporosis Center, Portland, OR, USA, [3]Maine Center for Osteoporosis, Bangor, ME, USA, [4]Mount Sinai School of Medicine, New York, NY, USA, [5]GlaxoSmithKline, Collegeville, PA, USA, [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [7]Centro de Osteopatias Medica, Buenos Aires, Argentina, [8]MRC Epidemiology Resource Centre, University of Southampton, Southampton, United Kingdom, [9]Claude Bernard University and INSERM Research Unit 403, Lyon, France.

Active comparator studies are an accepted means for establishing the relative efficacy and safety of alternative treatment options. However, as clinical endpoints are often difficult to use (especially in chronic disease), comparison of validated surrogate markers is an accepted alternative. In light of its predictive value for fracture risk reduction within the class of bisphosphonates, the surrogate marker of change (%) in bone mineral density (BMD) has been used to establish the relative efficacy of weekly oral bisphosphonates in postmenopausal osteoporosis (PMO).[1] A similar comparative study (MOTION) is ongoing to compare the efficacy of once-monthly oral ibandronate, a potent, nitrogen-containing bisphosphonate with proven antifracture efficacy with extended dosing intervals, with weekly oral alendronate. In MOTION, a randomized, double-blind, double-dummy study, close to 1,900 women (55-84 years, ≥5 years postmenopause) with PMO (lumbar spine [L2-L4] BMD T-score <-2.5 and ≥-5.0) will receive either 150mg once-monthly oral ibandronate or 70mg weekly oral alendronate for 1 year. To maintain blinding, participants will also receive once-monthly or weekly oral placebo, plus daily calcium (500-1,500mg) and vitamin D (400IU). The co-primary study endpoints are change (%) from baseline in lumbar spine and total hip BMD at 1 year. Subsequent non-inferiority tests will explore the comparable efficacy of the once-monthly and weekly oral regimens (non-inferiority margin: 1.14% and 0.87%, respectively). Secondary endpoints include change (%) in hip trochanter BMD at 1 year and the biochemical marker of bone turnover sCTX in a subset of patients (30%) at day 7 and months 3, 6 and 12. Adverse events will be monitored throughout the study. Clinical vertebral and non-vertebral fractures will also be assessed, and their respective rates compared. In summary, MOTION will explore the relative efficacy and safety of once-monthly oral ibandronate and weekly oral alendronate. Data from the MOTION study will further assist physicians in identifying the most appropriate treatment option in PMO.

Current Treatment of Osteoporosis: Rationale for Inclusion of Vitamin D. S. Epstein. Medicine and Geriatrics, Mount Sinai School of Medicine, New York, NY, USA.

At present, oral bisphosphonates are the most widely used pharmacologic treatment for osteoporosis. Guidelines for their use stress the importance of concomitant use of calcium and vitamin D if dietary sources are inadequate. Low levels of vitamin D are associated with development of secondary hyperparathyroidism, increased bone turnover, and loss of bone Clinical trials of new drugs typically provide both calcium and vitamin D to all participants, in order to optimize treatment effects. Review of recommended serum vitamin D levels, estimates of prevalence of vitamin D insufficiency, and current treatment patterns and needs of patients with osteoporosis was performed. General consensus has evolved to suggest that serum vitamin D levels should be high enough to minimize serum parathyroid hormone (~30 ng/ml; 75 nmol/L)[1]. However the exact level at which this impacts on bone health has not been fully established. Vitamin D insufficiency has been reported in many studies of older adults[2]. Further, two recent parallel studies, one conducted in the United States and the other in 18 countries around the world, reported that 52% and 58%, respectively, of patients with osteoporosis, many of whom were receiving treatment, had levels <30 ng/ml (75 nmol/L)[3,4]. Adequate nutrition, including vitamin D, is recognized as essential to skeletal health. Frank deficiency is associated, in the child, with rickets and, in the adult, with osteomalacia; insufficiency with secondary hyperparathyroidism. In addition, vitamin D has an important role (amongst others) in neuromuscular function, balance, and sway, all of which may, through an effect on risk of falling, contribute to fracture risk. A number of observational studies have reported a high prevalence of low levels of vitamin D in such subjects. Guidelines for the management of osteoporosis recommend both calcium and vitamin D supplementation, in addition to treatment with bone-specific agents. Two recent large epidemiologic studies have confirmed the widespread prevalence of low serum 25-(OH)D levels in women with osteoporosis, including women receiving definitive treatment with anti-resorptive agents. Inclusion of vitamin D with the weekly dose of bisphosphonate will insure that patients receive the minimum recommended amount of vitamin D, helping to prevent deficiency in these women without compromising the absorption of either agent.

Cost-Effectiveness of Bisphosphonate Therapies for Women with Postmenopausal Osteoporosis: Implications of Improved Persistence with Ibandronate. B. Ettinger*[1], S. R. Earnshaw*[2], C. N. Graham*[2], M. M. Amonkar*[3], R. W. Baran*[4]. [1]UCSF, San Francisco, CA, USA, [2]RTI Health Solutions, Research Triangle Park, NC, USA, [3]GlaxoSmithKline, Collegeville, PA, USA, [4]Roche Laboratories, Nutley, NJ, USA.

Several studies have shown improved persistence with weekly bisphosphonate (BP) dosing compared to daily dosing yet >50% of patients on the weekly regimen discontinue therapy within a year[1]. Ibandronate, a monthly-administered oral BP, provides an opportunity to further improve persistence, a parameter not well modeled in previous analyses on the cost-effectiveness (CE) of osteoporosis therapy. We developed a Markov model to estimate the CE of BP treatment for women with established osteoporosis. The model, based on a 10 year time horizon and 3-year length of therapy, evaluated CE of three BPs: ibandronate, alendronate, and risedronate. Vertebral, hip and wrist fracture efficacy were assigned a class effect as estimated by the literature[2]. Persistence with weekly therapy was referenced to rates reported for natural populations[3] receiving weekly BPs (36% year 1, 24% years 2 and 3) and to an absolute 15% improved persistence (51% year 1, 39% years 2 and 3) for ibandronate. The analysis population was post-menopausal women aged ≥50 years with prevalent radiologic vertebral deformity and hip BMD T-score ≤-2.5. Yearly drug cost was referenced to wholesale acquisition cost for each BP. Direct health resource costs for fracture states were estimated from published literature and discounted at a 3% yearly rate[4] All costs were reported in 2004 US$. More fractures/1000 patients were avoided (vs. no treatment) with ibandronate (126) than with alendronate (87) or risedronate (87) resulting in lower fracture care costs/patient ($6,159, $6,448, and $6,448, respectively). Drug costs/patient increased from $759 with alendronate and $737 with risedronate to $1,059 under conditions of improved persistence with ibandronate. The incremental cost/fracture avoided (vs. no treatment) was lower with ibandronate ($1,018) compared to alendronate ($1,360) and risedronate ($1,111). Sensitivity analyses show improved outcomes with greater baseline fracture risk. A small improvement in persistence with BP therapy augments the benefit realized in patient populations. These benefits include fewer fractures for patients without a significant increase in cost to payers. Increased drug costs due to increased persistence are largely offset by reduced fracture care costs.

M362

Persistence With Bisphosphonate Therapy and Fracture Risk in Postmenopausal Women in a Managed Care Environment. D. Gold[1], F. Cosman[2], J. Frytak*[3], R. Baran*[4], M. Amonkar*[5], B. Martin*[6]. [1]Duke Univ Med Ctr, Durham, NC, USA, [2]Helen Hayes Hosp, West Haverstraw, NY, USA, [3]i3 Magnifi, Eden Prairie, MN, USA, [4]Roche Laboratories, Nutley, NJ, USA, [5]GlaxoSmithKline, Collegeville, PA, USA, [6]Univ of Arkansas for Med Sciences, Little Rock, AR, USA.

Oral bisphosphonates (BP) are the standard of care for postmenopausal osteoporosis (PMO). Current daily and weekly BP regimens are associated with poor persistence with therapy, which may affect clinical outcomes such as fracture. The purpose of this study was to investigate the correlation between persistence with BP therapy and claims diagnoses of fracture events using long-term managed care claims data. A retrospective analysis of claims data from a large health care plan affiliated with i3 Magnifi examined the relationship between persistence with BP therapy and fracture risk. Women, ≥45 yrs of age, who initiated new alendronate therapy and met other inclusion criteria (no Paget's disease, HIV, cancer or drug-induced osteoporosis) were considered for analysis. Patients with 24 months of follow-up were stratified into persistent (>6 months on therapy) and nonpersistent (<6 months on therapy) cohorts. Non-persistence was defined as a >30-day gap in medication supply. Osteoporosis-related fractures were identified through specified ICD-9 database codes. The risk for an osteoporosis-related fracture diagnosis was assessed using a Cox-proportional hazards model. A total of 4769 women were assigned to either persistent (n=2029) or nonpersistent (n=2740) cohorts. The persistent cohort had a 6-month persistence rate of 42.5%. During the follow-up period a total of 214 subjects had a claim with a diagnosis of fracture--79 (3.9%) in the persistent cohort and 135 (4.9%) in the nonpersistent cohort. Women in the persistent cohort had a 26% lower risk of a diagnosis of fracture during the follow-up period than those in the nonpersistent cohort (HR=0.739, P=0.047). Women age 45-54 yrs (n=1936, HR = 0.412, P=0.0001) and 55-64 yrs (n=2294, HR = 0.524, P=0.0015) experienced a lower risk of fracture compared to women 65 yrs and older (n=539). The greatest increase in risk of fracture during the follow-up period was observed in women with a fracture claim during the 6-month baseline period prior to initiating therapy (HR=10.846, P<0.0001). This analysis of medication usage among women initiating BP therapy for PMO in a managed care setting confirms that persistence with current therapeutic regimens is suboptimal and is associated with a risk of osteoporosis-related fracture. Strategies to improve persistence, such as simplified and less-frequent dosing, should be adopted and will likely provide greater treatment benefit with respect to protection against fractures.

Illustrating Drug Utilization Associated with the Weekly Oral Bisphosphonates for Osteoporosis Using the Drug-O-Gram. K. Kahler*, M. A. Omar*, D. Gause*. Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA.

Drug utilization patterns over time are commonly presented as persistency rates for longitudinally collected data. These analyses require the use of specific criteria regarding gaps between refills to categorize patients as still persistent with therapy. While this is valuable, another tool that allows a more liberal assessment of drug use is the Drug-O-Gram, which incorporates the many possible patterns of drug use that may occur within a follow-up period. The objective of this study was to use a visually friendly approach, the Drug-O-Gram, to illustrate the amounts and patterns of drug use in patients with osteoporosis. This was a retrospective analysis of MarketScan, a secondary medical and pharmacy claims database. We studied female osteoporosis patients in Medicare risk-managed care plans, newly treated with the once-weekly forms of the oral bisphosphonates (OB) alendronate and risedronate. Patients were selected based on a diagnosis of osteoporosis in 2002, and with first osteoporosis drug use occurring anytime between 7/1/2002 and 12/31/2002. The date of each prescription fill of the OB and the amount of drug dispensed for each fill was used to ascertain which of the following 365 days of the year each patient had drug available with them for consumption. The Drug-O-Gram was then created to plot the percentage of patients with drug available on each day. This was done separately for patients who had started on alendronate or risedronate. Alendronate (n = 4,029) and risedronate (n = 2,550) patients were included in the analysis. The Drug-O-Gram plots showed a sharp decline in drug use in the initial months following start of therapy, followed by a gradual but consistent decline for the remainder of the year. The pattern was similar for patients in both the alendronate and risedronate groups. The Drug-O-Gram plots suggest declining drug use associated with the weekly dosing regimens of both alendronate and risedronate. Osteoporosis is a chronic condition that necessitates patients to continue with their therapies in order to obtain adequate fracture risk reduction. Newer treatment approaches that help to promote longer exposure to drug therapy are clearly needed.

Treatment of Postmenopausal Osteoporosis with Oral Ibandronate Reduces Activation Frequency to Healthy Premenopausal Levels. R. R. Recker, K. M. Davies*, M. J. Barger-Lux*. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

The antifracture efficacy of oral ibandronate has been demonstrated in a large, multinational, double-blind, placebo-controlled, 3-year fracture-prevention study (the BONE Trial). However concerns remain as to whether over-suppression of bone turnover might occur in the course of such treatment. As part of the BONE Trial, transilial bone biopsies were obtained, in either month 22 or 34 of treatment, from a subset of subjects from each of the three treatment groups: placebo; continuous oral daily ibandronate (2.5mg/day); intermittent oral ibandronate (20mg every other day for 12 doses every 3 months). All participants, including those in the placebo group, received calcium 500 mg/d and vitamin D 400 IU/d. Here we compare a key measure of bone turnover - activation frequency (Ac.f) - in these subjects with Ac.f in transilial biopsies from other groups of women. All measurements of Ac.f were carried out in our histomorphometry laboratory. The table summarizes these data and the results of non-parametric tests of difference.

Activation Frequency, #/yr	n	Median	Inter-quartile range
Subjects in the BONE Trial, at least 5 yr postmenopausal, ages 55-80			
Placebo, ibandronate study	33	0.22*	0.11 - 0.39
Continuous ibandronate	33	0.10	0.04 - 0.20
Intermittent ibandronate	31	0.13	0.08 - 0.20
Subjects in other studies			
Premenopausal, healthy, >age 46	51	0.13	0.06 - 0.20
1 yr postmenopausal, healthy, age 55	51	0.24*	0.15 - 0.41
Postmenopausal, healthy, age 60	34	0.37**	0.22 - 0.66
Postmenopausal, osteoporosis, age 67	89	0.42**	0.29 - 0.72

*P<0.05 compared to premenopausal, continuous ibandronate, and intermittent ibandronate
**P<0.05 compared to 1 yr postmenopausal and to placebo

As the table indicates, both continuous and intermittent treatment with oral ibandronate yielded values for Ac.f that were equivalent to those in healthy premenopausal women; in the placebo group, values for Ac.f were similar to those in healthy women 1 year after menopause. We conclude that these dose regimens of ibandronate - which result in fracture reduction - do not over-suppress bone remodelling, given that the values for Ac.f are not different from those in healthy premenopausal women.

Effect of 10 Years of Alendronate on the Risk of Non-Spine Fracture. A Novel Approach to Modeling Long-Term Effects of Treatments. S. Cummings[1], C. Shinoff*[1], L. Palermo*[2], D. Sellmeyer[1], C. McCulloch*[3], K. Ensrud[4]. [1]CPMC Research Institute, UCSF, S.F. Coordinating Center, San Francisco, CA, USA, [2]UCSF, S.F. Coordinating Center, San Francisco, CA, USA, [3]UCSF, Epidemiol and Biostat, San Francisco, CA, USA, [4]U. Minnesota, Minneapolis, MN, USA.

There have been no 10 year placebo-controlled trials of the effect of bisphosphonates on fracture risk, this must be estimated from shorter placebo-controlled trials. The Fracture Intervention Trial (FIT) randomized 6,459 postmenopausal women to alendronate (ALN) or placebo (PBO). The trial (and PBO group) stopped after about 4 years. 1,099 of the FIT participants, all of whom had taken alendronate for 5 years, volunteered to continue in a 5 year extension (FLEX) and were randomly assigned to take 5 more years of ALN (10 yr total) or placebo (5 yr ALN then 5 yr PBO). Women who continued into FLEX had different characteristics than other women in FIT, so comparisons of rates of fractures in the FIT placebo group to the rates in the women who received 10 years of alendronate in FIT + FLEX would be biased. To avoid this bias, we developed a method to project the risk of fracture during 10 years of placebo. For every woman assigned to 10 years of alendronate in FLEX, we created a "virtual twin" with identical characteristics at FIT baseline; together comprising a virtual placebo group. The model projects the future risk of fracture in each virtual twin from the rate observed in the FIT placebo group, adjusted for the characteristics of the twin. We developed the model using baseline data and rates of fracture observed in a randomly selected half of the FIT placebo group and compared these to observed rates during FIT in the other half. We estimated an 18.6% cumulative incidence of fractures vs. 18.3% observed. Using the estimated placebo rates and observed rates for the treated group, we projected a 27% decreased risk of non-spine fractures vs. the 28% reduction observed during FIT. In the model, alendronate reduced the rate of non-spine fractures 27% during the first 5 years but continued treatment with alendronate did not reduce the risk of non-spine fractures during the next 5 years (R.R. = 1.0; 95% CI: 0.77, 1.23). Our analyses indicate that, among women resembling participants in FIT, alendronate reduces the risk of non-spine fracture during the first 4 to 5 years of treatment but beyond this period does not reduce the age-related increase in risk of non-spine fractures that occurs without treatment. This method may allow estimates of the long-term effectiveness of treatments tested in short-term placebo-controlled trials with long term extension of treatment groups.

Effect of Concomitant Statin Therapy in Bisphosphonate Treated Patients with Osteoporosis. J. L. Guyer*, M. I. Williams*, V. I. Petkov, R. A. Adler. Endocrinology and Bone Metabolism, McGuire VA Medical Center, Richmond, VA, USA.

Bisphosphonates, commonly used in osteoporosis treatment, work by inhibiting an enzyme in the mevalonate pathway which is required for the production of isoprenoids necessary for osteoclastic function. HMG-CoA reductase inhibitors (statins), used in the treatment of hypercholesterolemia, also interfere with the mevalonate pathway by inhibiting its first step. It is therefore thought that statins may also have an effect on bone resorption with some recent studies showing an increase in bone mineral density (BMD) and decrease in fracture risk. Our goal was to determine if the combination of a statin and bisphosphonate provides an additive, synergistic or no benefit over bisphosphonate treatment alone. Medical and BMD records of patients who had at least 2 BMD tests and received bisphosphonate therapy from a single Veterans Affairs Medical Center for at least 12 months between January 1995 and January 2003 were reviewed. Patients were divided into two groups; one with concurrent statin use, the other without. The change in bone mineral density at the spine and total hip was compared by student t-test. ANCOVA was used to adjust for covariates and differences between groups. Patients treated with both drugs (N = 115) were heavier and received a greater number of concomitant medications than patients treated with bisphosphonate only (N = 90). Age, gender and race distribution were similar. A significantly smaller proportion of patients died in the statin group (7% vs 21%). The average exposure to statins was 47 months, and to bisphosphonates: 43 months for statin users and 38 months for bisphosphonate only users. There was a non-significant trend toward greater increase in BMD at the spine and total hip in patients receiving both drugs. In the spine, the total percent change in BMD was 7.2% vs. 5.7% (p-value 0.058); per year of BMD follow-up 2.6% vs. 2.2%. In the total hip, the total percent change was 2.3% vs 1.1% (p-value 0.071); per year 0.8% vs 0.3%. However, when adjusted for differences in weight, length of bisphosphonate exposure and BMD follow-up, these differences become less prominent. Statins probably do not add any benefit toward increase in BMD over bisphosphonate treatment alone.

Risedronate Demonstrates Antifracture Efficacy over a Range of Baseline BMD Levels. R. Lindsay[1], S. Magowan[2], I. Barton*[3], D. Felsenberg[4], J. D. Adachi[5]. [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]P&G Pharmaceuticals, Mason, OH, USA, [3]P&G Pharmaceuticals, Egham, United Kingdom, [4]Univ Hospital Benjamin Franklin, Berlin, Germany, [5]McMaster University, Hamilton, ON, Canada.

Baseline BMD level and risk factors are important considerations in the decision to initiate osteoporotic therapy. The WHO commentary on the threshold for intervention is not the same as the diagnostic threshold for osteoporosis. Currently, there is little available information concerning the efficacy of osteoporotic therapies over a range of baseline T-scores. This study investigates the fragility fracture efficacy (vertebral and nonvertebral) of risedronate 5 mg/day in postmenopausal women over 4 ranges of femoral neck (FN) T-scores. This analysis included 2575 postmenopausal women from 4 phase III trials: VERT MN & NA, BMD MN & NA. Women were randomized to receive placebo or risedronate and treated for up to 3 years. Subjects were stratified into 4 subgroups based on level of baseline FN T-score. Fractures included in the analysis were vertebral and nonvertebral (composite of 6 sites). The fracture incidence and relative risk reduction for each baseline BMD range are summarized for each subgroup. In the four BMD strata, fracture incidence in the placebo group increased with decreasing baseline BMD values, potentially confounded by increasing age and an increased percentage of patients with prevalent vertebral fractures (PVF). Risedronate, however, demonstrated significant anti-fracture efficacy in postmenopausal women, regardless of baseline level T-score ranges (Table 1). Treatment by T-score interaction was p = 0.653. Although baseline BMD is an important predictor of fracture risk, Risedronate's demonstrated efficacy against fragility fractures appears to be independent of baseline BMD level.

Table 1: Osteoporotic Fracture Incidence in Placebo and Risedronate Patients with Baseline FN T-score Data < -1.5 (VERT-MN & NA, BMD-MN & NA)

Baseline T-score	N	Mean Age	Percent PVF	Placebo Incidence	Risedronate Incidence	Hazard Ratio	P value
≤ -1.5 to > -2.0	609	67	63.1%	20%	14%	0.58	<0.05
≤ -2.0 to > -2.5	822	68	68.7%	27%	19%	0.63	<0.01
≤ -2.5 to > -3.0	682	69	78.4%	36%	26%	0.61	<0.005
< -3.0	462	71	87.7%	46%	27%	0.44	<0.001

Alendonate Improved Bone Mineral Density in Patients with Juvenile Osteoporosis. P. Madyastha*, W. Ries, B. Hollis, F. Reed*, L. Key. Pediatrics, Medical University of South Carolina, Charleston, SC, USA.

The current study was designed to evaluate the safety and efficacy of therapy with alendronate (Fosamax), vitamin D, and calcium in treating juvenile osteoporosis. Ten children (age 6-13 years) with multiple fractures and osteoporosis [Z score ≤-2 SD based on bone mineral density (BMD) by dual energy x-ray absorptiometry (DEXA)] were treated with alendronate for 12 months. The BMD of the lumbar spine and hip (total hip, trochanter, and femoral neck) and markers of bone turnover, (serum bone-specific alkaline phosphatase and urinary N-telopeptide), mineral apposition rates (MAR) and micro-architecture of the iliac crest were followed to evaluate the safety of 12 months of alendronate administration. Alendronate therapy resulted in an improved Z-score for BMD measurements at 6 months and 12 months of therapy in assessments of both the spine and hip. There were no new fractures during the treatment period. Bone biopsy showed normal lamellar structure without mineralization defects and normal bone apposition rates. Normal or improved growth was observed in all patients. Alendronate therapy is safe and effective when used to increase the bone density of children with osteoporosis and two or more fractures.

Use of Upfront Loading Doses of Bisphosphonates: Novel Method to Advance the Beneficial Effects of Bisphosphonates on Enhancing Fracture Reduction. S. J. Wimalawansa. Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Introduction: Bisphosphonates are efficacious in enhancing BMD and decreasing fracture rates. However, the absorption of oral bisphosphonates is usually poor (<1%). Therefore, it may take about a year to get adequate amount of the bisphosphonate into bone, to be effective in fracture reduction. Rationale: We hypothesized that if adequate amount of the bisphosphonate gets into bones earlier in the course of a treatment, then one should see a rapid response and enhance the beneficial effects on BMD and fracture reduction. Method: We have examined the effectiveness of loading doses of oral and intravenous bisphosphonates on BMD in comparison with the standard doses of same agents. We have compared the effects of loading doses of alendronate, risedronate and pamidronate with their standard recommended doses for osteoporosis over a one-year period. Results: A statistically significant increase of BMD was observed in both oral and intravenously administered agents with in 3-6 months (with the biomarker changes within first 4 weeks), in comparison to 6 months with standard therapy. There was no statistical difference between the responses observed with alendronate and risedronate (Tables 1 and 2).

Table 1: Comparison of BMD increases with conventional and loading doses of risedronate

Increase in spinal BMD	Standard dose	Loading dose
3 months	+0.4%	+1.5%
6 months	+2.2%	+4.0%
12 months	+4.3%	+5.6%

Table 2: Comparison of BMD increases with conventional and loading doses of alendronate

Increase in spinal BMD	Standard dose	Loading dose
3 months	+0.4%	+1.2%
6 months	+1.1%	+3.6%
12 months	+4.5%	+5.8%

Conclusion: If the fracture efficacy of an anti-resorptive drug depends on the rapidity of the reduction of bone turnover and enhancement of the BMD, then this new approach of administration of bisphosphonates should significantly enhance the fracture reduction efficacy of bisphosphonates, especially for patients with fragility fractures. This novel approach of administering bisphosphonates should be cost-effective in prevention of fractures in high-risk patients, particularly beneficial for those patients with high bone turnover and who has been diagnosed with established osteoporosis.

Prolonged Hypocalcemia from Intravenous Zoledronic Acid: An Unusual Case. S. A. Talwar, J. F. Aloia. Endocrinology, Winthrop-University Hospital, Mineola, NY, USA.

A healthy 60 year-old white lady was enrolled in an osteorporosis prevention trial using intravenous bisphosphonate (zoledronic acid) at our center. Her past medical history included asthma, hypothyroidism, gastroesophageal reflux disease, anxiety disorder and significant surgical history included spinal surgery at L4-L5 for disc herniation, cholecystectomy and thyroidectomy for goiter at age 19. She was medically stable on medications that included Synthroid 112 mcg/d, Advair, singulair, albuterol prn, protonix 40mg once a day, Paxil 40mg daily, calcium and vitamin D supplements (1000-1200 mg/d) and a multivitamin supplement. She had a normal screening physical exam and laboratory assessment. The screening bone density revealed osteopenia at Lumbar spine (0.922 g/cm^2) and total femur (0.835 g/cm^2). Her screening labs revealed an H/H: 13.5/38, BUN/Cr: 19/0.7, S. Ca: 8.7 mg/dl, P: 4.1 mg/dl, Alb: 4.5 g/dl, Total protein: 7.2 g/dl, Mg: 2.3 mg/dl, Creatinine clearance : 100 ml/min, 25-OHD: 18.3 ng/ml (=45.75 nmol/L), TSH: 0.34mIU/ml A week after the patient was randomized in study, she developed symptoms of tiredness, perioral tingling and numbness, tingling in her hands. There was no evidence of Chvostek or Trousseu's sign. Serum calcium was found to be low (results below). She was advised to increase calcium supplement to a total of 2400 mg/d along with vitamin D 1000 IU/d. Her symptoms resolved with this intervention, however, the biochemical hypocalcemia persisted more than 3 months after the incident with slow improvement. Additional work up revealed a concomitant elevated phosphorus and an inappropriately low serum parathyroid hormone when serum calcium was low confirming inability of parathyroid gland to compensate for the biochemical abnormality.

Labs	Baseline	2 weeks	4 weeks	6 weeks	8 weeks	15 weeks
S. Ca	8.7	6.4	6.8	7.3	7.6	8.0
S. P	4.1		6.1	4.9	4.4	4.9
S. Albumin	4.5	4.3	4.5	4.0	4.2	4.2
S. Mg	2.3		2.3	2.1		1.9
PTH		37 (N-terminal)			27 (Intact)	
S. 25-OHD	18.3				13.2	
S. TSH	0.3	0.236			0.666	
S. 1,25-OHD					19.3 pg/ml (15.9-55.6)	
24 hour urine Calcium					288 mg/d	

Conclusion: History of previous thyroidectomy could result in incipient hypoparathyroidism that can manifest acutely when challenged. Use of bisphosphonates in patients with prior thyroidectomy should be accompanied by evaluation of serum calcium a week after the drug administration to avoid a fatal medication related adverse event.

Compliance with Osteoporosis Medications among 40,000 Medicare Beneficiaries. D. H. Solomon[1], J. Avorn*[1], J. N. Katz*[2], J. S. Finkelstein[3], J. Polinski*[1], M. Arnold*[4], M. A. Brookhart*[1]. [1]Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA, [2]Division of Rheumatology, Brigham and Women's Hospital, Boston, MA, USA, [3]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [4]Boston University School of Public Health, Boston, MA, USA.

Background: Long-term compliance with pharmacologic treatments for many asymptomatic conditions has been found to be sub-optimal, but little is known about compliance with medications used for osteoporosis. We assessed the level and determinants of compliance with drugs prescribed for osteoporosis. Methods: We conducted a retrospective cohort study using health care claims data from US Medicare and filled prescriptions from a state pharmaceutical benefits program. The study included 40,002 persons aged 65 or older who filled at least one prescription for a medication used for osteoporosis (alendronate, calcitonin, hormone replacement therapy, raloxifene, or risedronate) between 1996 and 2002. The outcome of interest was sub-optimal medication compliance, defined as less than 67% of days covered during a 60-day period. Other analyses examined the time until the first 120-day period without filling a prescription for an osteoporosis medication. Results: One year after initiating treatment for osteoporosis, 45% of patients went 120 days without filling any prescriptions for osteoporosis treatment. Five years after initiation, 52% of patients were not continuing to fill prescriptions for any osteoporosis drug. Several characteristics independently predicted sub-optimal compliance (described above): male gender, older age, more comorbid conditions, more non-osteoporosis medications prescribed, lack of testing for bone mineral density (BMD) before and/or after initiating a medication, and no fracture before and/or after initiating a medication. After controlling for these patient characteristics, patients begun on raloxifene were less likely to have sub-optimal compliance than those begun on a bisphosphonate; conversely, those started on HRT or calcitonin were more likely to have sub-optimal compliance. However, models adjusted for significant patient variables explained only 6% of the variation in compliance. Conclusions: Nearly half of the patients we studied had stopped pharmacologic treatment for osteoporosis within one year of initiation.While several patient characteristics were significantly correlated with sub-optimal medication compliance, patient variables explained little of the variation. Further studies are needed to better define factors contributing to non-compliance so that effective interventions can be developed.

A Randomized Controlled Trial of Mailed Osteoporosis Education to Older Adults: Survey Results. D. H. Solomon[1], J. Avorn*[1], J. Polinski*[1], M. Arnold*[2], J. S. Finkelstein[3], A. Licari*[1], C. Canning*[1], S. Gauthier*[4], J. N. Katz*[5]. [1]Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA, [2]Boston University School of Public Health, Boston, MA, USA, [3]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [4]Arthritis Foundation, Newton, MA, USA, [5]Division of Rheumatology, Brigham and Women's Hospital, Boston, MA, USA.

Purpose: To assess the effect of a mailed educational intervention on older adults' knowledge, attitudes, and preventive behaviors regarding osteoporosis. Methods: We conducted a public health trial in 31,715 Medicare beneficiaries from Pennsylvania who participated in a drug benefits program for low-moderate income elderly. All women over 65, and all men and women with a history of fracture or chronic oral glucocorticoid use were included. Approximately half of the participants were randomly selected to receive 2 mailings aimed at improving knowledge of osteoporosis and enhancing preventive activities, such as using calcium and vitamin D, reducing fall risks in the home, obtaining a BMD test, and taking medications when necessary. We surveyed a sample of intervention and control subjects to determine the effects of the intervention on knowledge, attitudes, self-efficacy (confidence in one's ability to perform a specific behavior), and behavior regarding osteoporosis prevention and treatment. Results: Six hundred randomly selected participants in the intervention and an equal number in the control group were invited to participate. 15 had died and 636 of the remaining 1185 (54%) completed the survey. Respondents and non-respondents did not differ significantly with respect to measured sociodemographic factors. All scales had good reliability (Cronbach's alphas > 0.7). Knowledge of osteoporosis was relatively strong and not different between intervention (mean = 62% correct responses) and control subjects (mean = 64%; p = 0.5). Perceived susceptibility to osteoporosis was high and similar across groups (p = 0.6). Self-efficacy for participating in osteoporosis prevention and treatment was very good in both the intervention (mean = 4.5, maximum = 5) and control groups (mean = 4.4, p = 0.3). On average, subjects in the intervention group reported participating in 3.1 of 6 preventive osteoporosis activities compared with 3.0 in the control group (p = 0.3). Conclusions: A mailed educational intervention for osteoporosis was not associated with better knowledge, higher perceived susceptibility, more self-efficacy, or performance of preventive behaviors among the at-risk older adults that we studied. More intensive patient interventions may be required to bring about changes that lead to reduced fractures.

Baseline Clinical Characteristics of Postmenopausal Women with Osteoporosis and an Inadequate Clinical Response to AntiOsteoporosis Drugs in the Observational Study of Severe Osteoporosis (OSSO): The French Cohort. P. Fardellone[1], I. Jamonneau*[2], S. Liu-Léage*[2], S. Tcherny*[2]. [1]CHRU, Amiens, France, [2]Lilly France, Suresnes, France.

The OSSO study is a 12 month prospective, observational study conducted in six European countries. Participants are postmenopausal women with osteoporosis and an inadequate clinical response to approved antiosteoporosis drug, defined as: (i) the presence of a new clinical fragility fracture despite prescription of any antiosteoporosis drug for at least 12 months before the fracture (index fracture cohort), and/or (ii) discontinuation of any antiosteoporosis drug due to compliance problems and/or side effects (compliance cohort). OSSO aims to evaluate changes in health-related quality of life (HRQoL), resource utilisation and risk factors associated with incident fractures. 418 women with a mean age of 71.4±8.9 years were enrolled in France. 196 women (46.9%) were recruited in the index fracture cohort, 222 (53.1%) women in the compliance cohort. The patients characteristics for both groups are presented in the table. The index fracture patients by comparison with the compliance patients were older, more glucocorticoids (GC) past users and had more fractures history. The vertebral fractures represented 46% of these fractures in the index fracture and 40% in the second group. Both groups had a low BMD at the different sites. In the index fracture group, the last clinical fragility fractures occurred despite an antiosteoporosis administrated treatment for at least 12 months, were mainly located at the spine (56.4%). Alendronate was the most commonly discontinued osteoporosis medication (31.5%) followed by risedronate (18.3%), hormone replacement therapy [HRT] (14.5%), raloxifene (13.6%), etidronate (12%), estrogen replacement therapy (5.7%). Gastrointestinal problems were the main reason for discontinuing alendronate (63.4%) and risedronate (46.4%), hot flushes for raloxifene discontinuation (26.8%). Discontinuation due to non compliance was the highest for HRT (42.2%). In conclusion, the baseline clinical characteristics of postmenopausal women with osteoporosis and an inadequate clinical response to antiosteoporosis drugs indicate that they have numerous risk factors for subsequent fracture, especially in the index fracture cohort at the highest risk for fractures.

	Patients Characteristics		
	Index Fracture n= 196	Compliance Side effects n= 222	p value
Age (years)	73.4±8.2	69.6±9.1	<.001

Nasal Salmon Calcitonin Reverses Post-Fracture Bone Loss in the Distal Radius Fractures and Retains its Mechanical Properties as Assessed with Peripheral Tomography (pQCT). G. P. Lyritis, P. Boscainos*, P. Giannoulis*, P. Raptou*, A. Galanos*, G. Kiniklis*. Laboratory for the Research of Musculoskeletal System, Athens, Greece.

Fracture of the distal forearm is a common incident that has been attributed to post-menopausal bone loss. A post-fracture decrease of bone mineral density has been described, but a limited number of authors have clinically investigated the orthopaedic indications of calcitonin in post-fracture disease. The purpose of this study is to examine the effect of salmon calcitonin on early post-fracture decrease of BMD and the mechanical parameters. 54 post-menopausal women with unilateral forearm fracture (28 patients receiving 200 IU daily salmon nasal spray (Miacalcic, Novartis) and 26 patients receiving matched placebo) started treatment immediately after the fracture for a period of 3 months.All patients were randomly assigned in the treatment groups. Fracture was immobilized after reduction with a plastic cast (ScotschCast Plus, 3M) allowing repeated bone measurements without an interference to the precision of the measurements. pQCT measurements (Stratec 2000) of the fractured as well as the intact forearm were made 2-3 days after the fracture and at 10, 45 and 90 days after fracture. All measurements were made at 10mm (ROI 1), 20mm (ROI 2) and 40mm (ROI 3) from a reference line placed at the most proximal point of the distal radioulnar joint. Parameters assessed were the BMD of cortical and cancellous bone, and Strength Strain Index at all directions. Statistical analysis included ANOVA for measuring percentile difference from baseline BMD and ANCOVA with initial measurements for confirmation of ANOVA results. A statistically

significant difference in favor of the calcitonin treated group was shown at the end of the third month of treatment in total density (p=0.05), total area (p=0.05), and cortical thickness (p=0.038) in the fracture arm at ROI 1. At the level of ROI 2 in the fractured arm it was found a protective effect in trabecular content (p=0.044), cortical content (p=0.044), cortical thickness (p=0.038), cortical area (p=0.05), SSI_Y (p=0.033) and SSI_P (p=0.041). It is interesting that women receiving calcitonin showed an additional protective effect in the non-fractured arm in bone content of ROI 1 (trabecular content p=0.035, total area=0.053), in bone content (trabecular content p=0.05, cortical density p=0.031) and mechanical properties (SSI_X p=0.06) in ROI 2 and in cortical content (p=0.05) and cortical area (p=0.06) of ROI 3. In conclusion after a wrist fracture immediate daily administration of nasal salmon for a period of 3 months has a beneficial protective effect in bone content and bone strength, as aassessed by peripheral tomography.

Compliance and Effect of Bone Protective Treatment in Elderly Females: 5 Year Follow-Up Study. S. M. Doherty, S. A. Steel, A. Goodby*. Centre for Metabolic Bone Disease, Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom.

We carried out a study to compare the logistical feasibility of undertaking diagnosis, risk assessment and treatment of osteoporosis among the young elderly (70 to 75 years) female population in a hospital (Group I) and primary care based settings (Group II). Of 695 females invited to participate, 491 (71%) attended. As part of this study the subjects underwent bone mineral density (BMD) of spine and hip (Group I only) and broad band ultrasound attenuation (BUA) of the heel. Data was collected on medical, drug and social factors thought to influence bone strength and fracture risk. Subjects were considered at increased risk of fragility fracture if T-score for spine or hip was below -2.5 (Group I) or if BUA was below 60 dB/MHz. These were randomised to bone protective treatment in the form of HRT, Bisphosphonates or Calcium and Vitamin D supplementation. The study pre-dates the change in recommendations regarding HRT. After 5 years, subjects were invited to attend the hospital for a follow-up visit that included BMD of spine and hip, BUA of heel. Data was collected on acceptance of and compliance with treatment and adherence to lifestyle and dietary advice. Falls and fractures since the previous visit were recorded. 379 subjects (77%) were invited to attend for follow-up bone densitometry. 112 subjects (23%) were not recalled - 53 (11%) had died, 53 (11%) had left their practice and 6 (1.2%) were not recalled for other reasons. Of 261 attending for follow-up, 110 had been defined osteoporotic and randomised to bone protective treatment. 96 (87%) were commenced on treatment and 57 (52%) remained on treatment at 5 years, 11 having changed treatment during the follow-up period (Table 1).

Table 1

	Calcium+Vit D	HRT	Bisphosphonate
Randomised	41	32	36
Prescribed	53 (12 from HRT group 2 from Bisph group)	12 (7 not prescribed)	28 (1 from HRT group 2 from Ca+D group 6 not prescribed)
Continued	34	2	10
Discontinued and on no treatment	15	7	14
Changed	4 to Bisph	2 to Ca+D 1 to Bisph	4 to Ca+D

There were 30 patients suffering incident fragility fractures: 17 defined osteoporotic (10 who were on treatment and 7 not on treatment) and 13 non-osteoporotic. **Conclusion** Osteoporosis screening of females aged 70 to 75 years identifies 1/3rd as being osteoporotic. General Practitioners are willing to prescribe and patients willing to accept bone protective treatment, particularly Calcium and Bisphosphonates. After 5 years, 52% of those defined at risk in our population were compliant with some form of bone protective treatment.

A Study Comparing Primary Care and Specialty Physicians' Approach to Diagnosis and Treatment of Osteoporosis. T. A. Karas*[1], C. Leman*[2], J. Sinacore*[2], P. Camacho[1]. [1]Endocrinology, Loyola University Medical Center, Maywood, IL, USA, [2]Statistics, Loyola University Medical Center, Maywood, IL, USA.

Objective: The objective of the study is to analyze the approach to screening, diagnosis and treatment of osteoporosis among physicians in various specialties, demographic locations, and practice settings who evaluate and treat patients at high risk for osteoporosis. Design Setting: Analysis of a cross-sectional survey developed to assess the practice of osteoporosis screening, diagnosis and treatment. Aims: To compare the approach to screening, diagnosis, and treatment of osteoporosis among six groups of physicians. To determine if gender, years in practice, and practice setting affects screening, diagnosis and treatment of osteoporosis within each group of specialists. Results: One hundred twenty-two surveys were returned electronically including 27 from geriatrics, 25 from endocrine, 23 from obstetrics/gynecology, 20 from rheumatology, 19 from primary care and 8 from orthopedics. In screening for osteoporosis, 94% of the physicians surveyed would order DXA for a patient with 2 or more risk factors. The three risk factors most likely to initiate DXA scanning were height loss (93%), chronic prednisone use (89%) and menopause (86.6%). Low testosterone (60%) and vertebral deformities (74%) in an elderly male were the risk factors least likely to instigate DXA. Endocrinologists and rheumatologists were more likely to order DXA given any risk factor or patient scenario as compared to the other specialties, while orthopedic surgeons were least likely. Rheumatologists were most likely to initiate treatment in patients followed by endocrinologists, geriatricians, primary care physicians and obstetrician/gynecologists. Alendronate and Risedronate were deemed the most efficacious treatments by >98% of all physicians while calcium/vitamin D and calcitonin were thought to be the least efficacious. In general, patients were more likely to be screened, diagnosed and treated for osteoporosis by female physicians practicing in urban, academic settings who had been in practice >6 years. Conclusions: Osteoporosis is a common disease that is underdiagnosed and undertreated despite published guidelines. The results of this survey teach us where to focus educational efforts to improve prevention and treatment of osteoporosis.

Magnitude of Change in BMD and Bone Turnover Markers after Cessation of Risedronate Treatment: Biological Effect or Statistical Phenomenon? D. Kendler[1], N. B. Watts*[2], X. Zhou*[3], S. T. Harris[4], A. Grauer[3]. [1]St. Vincent's Hospital, Vancouver, BC, Canada, [2]University of Cincinnati, Cincinnati, OH, USA, [3]P&G Pharmaceuticals, Mason, OH, USA, [4]UCSF, San Francisco, CA, USA.

Surrogate markers such as bone mineral density (BMD) and bone turnover markers (BTM) are important predictors of fracture risk in untreated subjects. Their predictive value after treatment cessation is unknown as are patient characteristics predicting post-therapy changes in those surrogates. The 4th year of the VERT-NA study provided patients who had received risedronate 5 mg daily (N=398) during the first 3 years and the original placebo group (N=361) with 1000 mg calcium and 500 IU vitamin D (if levels were low) during the discontinuation year (yr 3-4). Patients previously treated with risedronate showed an increase in NTX and a decrease in BMD in the discontinuation year. This analysis used stepwise linear regression model selection to investigate potential predictors of the magnitude of surrogate marker change after treatment cessation, including age, years since menopause and percent change in BMD and BTM over the original 3year treatment. The model showed, that greater BMD loss in the discontinuation year was associated with greater BMD gains in the initial 3 years of treatment (p<0.001 for LS, FN). Greater increases in NTX and BSAP after therapy cessation were also associated with more pronounced BTM suppression at the end of the 3-year treatment (p<0.001 for NTX, p=0.002 for BSAP). This inverse relationship was also observed in the control group. Age and years since menopause were not significantly associated with BMD or BTM percent changes during year 4 (p>0.2). Previously reported findings from this study have demonstrated that patients previously on risedronate for 3 years maintained a significant 47% reduction of vertebral fracture risk in the discontinuation year, despite significant increases in NTX and BSAP and significant declines in BMD. We conclude that patients return toward pretreatment BMD and BTM after discontinuing risedronate. Patient characteristics predictive of this change could not be determined. However, the magnitude of BMD and BTM changes 1-year after discontinuation are inversely related to the changes observed during the 3 years on treatment. As the same phenomenon was also evident in the placebo group, this is most likely consistent with a regression to the mean phenomenon. Following these surrogates in the year after risedronate cessation is therefore of limited predictive value for evaluation of individual patient's short-term fracture risk.

Utilization and Correlates of Osteoporosis Treatment in Postmenopausal Women: Observations from the National Osteoporosis Risk Assessment (NORA). E. S. Siris[1], P. D. Miller[2], E. Barrett-Connor[3], S. Sajjan*[4], T. W. Weiss[4], Y. Chen[4]. [1]Toni Stabile Osteoporosis Center, Columbia University Medical Center, New York, NY, USA, [2]Colorado Center for Bone Research, Lakewood, CO, USA, [3]Dept. of Family and Preventive Medicine, Univ. of California, San Diego, CA, USA, [4]Outcomes Research, Merck & Co., Inc., West Point, PA, USA.

Guidelines exist for the use of pharmacological agents to prevent bone loss and fracture. However, clinical gaps in osteoporosis treatment persist. We evaluated the utilization and correlates of osteoporosis treatment within one year of a bone mineral density (BMD) test using data from women in the National Osteoporosis Risk Assessment (NORA). Participants in NORA were postmenopausal women, >= 50 years old, had no prior diagnosis of osteoporosis, and were not on osteoporosis-specific treatment at the time of enrollment. Both participants and their physicians received education on osteoporosis and its management and treatment at enrollment. Current analysis included 32,383 women at increased risk for fracture (T-score < -2.0 or T-score < -1.5 with at least one risk factor) who reported osteoporosis treatment (alendronate, calcitonin, or raloxifene; risedronate was not yet available) status at the time of the one-year follow-up (5/1999-6/2000). New hormone therapy (HT) use, reported at follow-up, was not included in the primary analysis since it was not known if HT was specifically prescribed for osteoporosis. However, HT was included in sensitivity analyses. Correlates for osteoporosis treatment were selected based on logistic regression stepwise selection procedure. Among the 32,383 women at increased risk for fracture, 13,588 women (42%) reported being on osteoporosis treatment approximately one year after the BMD test. In multivariate analysis the following factors were associated with increased odds for treatment: a lower T-score, speaking to a doctor about risk of osteoporosis during follow-up, BMD testing during follow-up, lower body mass index, age between 60 and 79 years, and Asian ethnicity. In contrast, current smoking at baseline, current HT use at baseline, and African American ethnicity were associated with a decreased odds of treatment. Including new HT to the analysis increased the treatment rate to 62%; correlates for treatment did change significantly. In conclusion,

despite physician and patient education on osteoporosis, we found that less than one-half of NORA women who were at increased risk for fracture reported receiving treatment. Significant opportunity exists to improve care for women at high risk who should receive treatment to prevent fracture.

A Comparison of Self-Report and Pharmacy Data for Current Use of Anti-Osteoporotic Medications. J. R. Curtis[1], A. O. Westfall*[2], J. J. Allison*[3], A. Freeman*[4], K. G. Saag[1]. [1]Division of Rheumatology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Department of Biostatistics, University of Alabama Birmingham, Birmingham, AL, USA, [3]Division of Preventive Medicine, University of Alabama Birmingham, Birmingham, AL, USA, [4]Aetna Integrated Informatics, Blue Bell, PA, USA.

Purpose Pharmacy data is commonly used to assess population-based quality of care. Often used as a gold standard, pharmacy data may over or under-report **actual** drug use and has not been previously compared with self-report for osteoporosis medications (O-Rx). We examined agreement (Kappa), positive/negative predictive value (PPV/NPV), sensitivity (Se), specificity (Sp), and discordance between pharmacy data and self-reported current use of O-Rx among glucocorticoid (GC) users at risk for osteoporosis. **Methods** We mailed a questionnaire on current use of O-Rx to 6,282 chronic GC users (60+ days) with pharmacy benefits enrolled in a national managed care plan. Survey results were compared to 2.5 yrs of preceding pharmacy data. ROC curves examined Se/Sp of various pharmacy fill windows. Multivariable logistic regression identified factors associated with discordance between self-reported current bisphosphonate (BP) use and filled BP Rx. **Results** Respondents (n=2,363) were mean age 53 (SD=14) yrs, 70% women, 78% Caucasian, 55% employed, 61% college educated. Comparing pharmacy fills within 180 days of the survey to self-reported current O-Rx use (gold standard), the K (±95% CI); PPV, NPV, Se, and Sp of the pharmacy data was:
Alendronate (n=327): 0.80 (0.76,0.84); 93%, 96%, 74%, 99.1%
Risedronate (n=142): 0.78 (0.72,0.84); 91%, 98%, 70%, 99.5%
Calcitonin (n=63): 0.64 (0.53,0.75); 78%; 99%; 56%; 99.5%
Raloxifene (n=31): 0.70 (0.56,0.83); 77%, 99.5%, 65%, 99.7%
Area under the ROC was 0.96 (alendronate) and 0.92 (risedronate). Among self-reported current BP users, >90% filled a BP Rx at least once in the previous 2.5 yrs; the Se/Sp of pharmacy data was maximized using a ≤180 day fill window. Factors associated with lack of pharmacy data confirmation included non-Caucasian ethnicity (OR 1.7, 95%CI 1.0-2.9) and income <$20,000 (OR 1.7,0.9-3.3). **Conclusion** Among chronic GC users, agreement between self-report and pharmacy data for O-Rx was good. In contrast to under-reporting commonly observed in validation studies for other drugs that compare self-reported **past** use with pharmacy data, under-reporting of **current** O-Rx was rare. A 6 month pharmacy fill window failed to identify >25% of self-reported current bisphosphonate users. Self-report of current O-Rx is a good surrogate if pharmacy data are unavailable; longer pharmacy fill windows are needed in studies relying on pharmacy data to assess quality of care.

Impact of Depressive Symptoms on Treatment Adherence and Study Compliance in a Trial on Osteopenia and Osteoporosis in Elderly Postmenopausal Women. H. Boerst*, O. Bock, M. Kalbow*, D. Felsenberg. Centre for Muscle and Bone Research, Charite - Campus Benjamin Franklin, Berlin, Germany.

Long-term adherence with oral bisphosphonates is required for optimal and sustained therapeutic outcome in clinical practice. Study compliance is also a factor of general interest in clinical trials on osteoporosis. The aim of this study was to evaluate the impact of depressive symptoms in elderly postmenopausal women with osteopenia or osteoporosis on their adherence to oral bisphosphonate treatment and on study compliance. Data of 175 postmenopausal osteopenic and osteoporotic women, mean age (SD) 73.6 (3.8) years, participating in an investigator initiated trial with alendronate 70 mg weekly and calcium 500 mg daily in postmenopausal osteopenia and osteoporosis were analysed. The trial was conducted after institutional review board approval and in accordance with the Declaration of Helsinki. Depressive symptoms were evaluated at baseline by the Beck Depression Inventory (BDI), a validated and most widely used self-rating scale for measuring depression. Treatment adherence (> 80% of alendronate taken) and study compliance were assessed one year after baseline. The overall drop-out rate was 13.1 %. BDI mean value (SD) was 8.4 (5.2) in adherent and compliant patients and 12.6 (7.1) in drop-out patients. The drop-out rate in patients with pathological BDI values (>/= 18, equivalent to 2 SD above normal mean) was 43.7% and fourfold and therefore significantly higher than in patients with BDI < 18 ($p < 0.001$). There was no significant difference in drop-out rates between patients with normal BDI (< 12) and borderline BDI (12-17, equivalent to 1 - 2 SD above normal mean): 9.3% and 13.3% respectively. Depressive symptoms have a major impact on treatment adherence and study compliance in osteopenic and osteoporotic elderly women. Our data suggest the usefulness of a depression assessment, e.g. using BDI self-rating scale, before initiating antiresorptive treatment in osteoporotic elderly women, especially before recruiting these patients for clinical trials, in order to enhance treatment adherence and to improve study compliance. Furthermore, patients with depression should be identified to ensure their adequate treatment and to improve their overall quality of life.

Effects of Animal Rights Activism and the Women's Health Initiative Findings on the Well-Being of Mares Used in Premarin Production. E. J. B. Murray*. GRECC/Medicine, VAGLAHS/University of California, Los Angeles, Sepulveda/Los Angeles, CA, USA.

The purpose of this study was to determine the effects of animal rights activism and the reduced use of Premarin (pregnant mares' urine) on the welfare of horses used in the PMU (pregnant mares' urine) industry. On-line database and web searches were conducted to assess equine management practices and estimate the effects of truncating the high-dose estrogen and progestin arm of the Women's Health Initiative (WHI) trial and falling Premarin sales on the number of horses in the industry. At the height of Premarin production in 2002, there were approximately 437 PMU ranches in the prairie provinces of Canada (Alberta, Manitoba, and Saskatchewan) and N. Dakota with at least 36,000 mares in production. The gross revenue to ranchers was about $2,000 to $2,500/mare. NAERIC (the North American Equine Ranching Information Council) estimates that there are now 122 PMU ranches in Canada and N. Dakota, with < 12,000 broodmares in production. In the early decades of PMU production, animal rights activists reported serious deficiencies, including unclean housing; improperly fitted urine collection devices; inadequate nutrition, veterinary care, and exercise; and severe water rationing. Government, animal welfare organization, and industry investigations from the 1960s to the 1990s led to the development of the "Recommended Code of Practice for the Care and Handling of Horses in PMU Operations," which established voluntary, self-regulated guidelines for shelter, access to water and food, companionship, diagnosis and treatment of abnormal behavior, injury, and disease, and emergency planning. No serious incidents involving PMU ranches have been reported to SPCAs in Canada for about 5 years. While conditions improved for mares, over-production of foals remained a serious problem. An estimated 15,000 PMU foals were sold to feedlots and slaughterhouses each year for as little as $350/horse. NAERIC was created in 1995 to assist ranchers in breeding and marketing high-quality foals that could be sold as performance/companion stock. By 2002, 2/3 of the improved foals were sold for use in equine activities, rather than for food consumption. The severe decline in the Premarin market created a crisis, with horses selling for as little as $50-$100 at auction. In 2004, the industry agreed to help pay for transportation, Coggins testing, and health certification for displaced PMU mares/foals adopted in N. America. Horses are still available, with registered pregnant mares selling for about $650-$1,700 through on-line adoption agencies. Available strains include warm-bloods, quarter/paint horses, Appaloosas, any of several draft breeds, and mixes of these breeds.

Implementation of a Community-Based Post-Fracture Care Model: 'Behind the Break'. S. Jaglal[1], E. Bogoch*[2], D. Brooks*[1], J. Carroll*[3], G. Hawker[4], L. Jaakkimainen*[5], H. Kreder*[6], M. Zwarenstein*[7]. [1]Rehabilitation Science, University of Toronto, Toronto, ON, Canada, [2]Surgery, St. Michael's Hospital, Toronto, ON, Canada, [3]Family Medicine, Mount Sinai Hospital, Toronto, ON, Canada, [4]Osteoporosis Research Program, Sunnybrook and Women's College Health Sciences Center, Toronto, ON, Canada, [5]Family Practice, Sunnybrook and Women's College Health Sciences Center, Toronto, ON, Canada, [6]Surgery, Sunnybrook and Women's College Health Sciences Center, Toronto, ON, Canada, [7]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.

The purpose of this project was to implement a local resource-based post-fracture care model to facilitate continuity of care from the hospital where the fracture is first treated, to the primary care setting for osteoporosis investigation and management. This is the first phase of a research project to evaluate a model in four communities in Ontario, Canada. This project used participatory action research methodology. Communities with a shortage of family physicians, a sufficient volume of fracture and access to a bone density machine were invited to submit a letter of interest. Funding was provided to each hospital to hire a local site coordinator to assist with implementation. Dissemination strategies targeted health care professionals in the hospital and community and fracture patients. To facilitate health care professional education a toolkit was developed. To raise awareness among fracture patients, tear off pads, bookmarks and booklets were disseminated within the hospital and community. Strategies to increase awareness included presentations, one-on-one meetings with hospital staff and a quarterly project newsletter. Each site conducted 18 to 21 meetings and 3 to 9 presentations with hospital staff, management and community health care professionals and organizations. In addition, newspaper, radio and television media promoted key messages. Approximately 515 toolkits were disseminated through seven workshops with rehabilitation therapists and one-on-one educational outreach with family physicians (n=95) and other community-based health care professionals. Seventy-two percent of family physicians received educational outreach visits between February and April, 2005. These visits ranged in length from 5 to 30 minutes. Preliminary findings indicate that the materials were well received and that the program is a worthwhile initiative. For successful implementation, it is important that the hospital and surrounding community take ownership of the osteoporosis initiative. This will ensure that the project reflects local resources, meets the needs of the community and will facilitate buy-in of local health care professionals.

Reduction of Pain and Fracture Incidence after Kyphoplasty of Chronically Painful Vertebral Fractures: 1-Year Outcomes of a Prospective Controlled Trial of Patients with Primary Osteoporosis. I. Grafe*[1], K. Da Fonseca*[2], J. Hillmeier*[2], P. Meeder*[2], M. Libicher*[3], G. Noeldge*[3], P. Nawroth*[1], C. Kasperk[1]. [1]Internal Medicine I, Endocrinology, University of Heidelberg, Heidelberg, Germany, [2]Orthopedic Surgery, University of Heidelberg, Heidelberg, Germany, [3]Radiology, University of Heidelberg, Heidelberg, Germany.

Kyphoplasty has been shown to reduced pain and improve mobility in patients with chronically painful osteoporotic vertebral fractures. Since improvement of spinal biomechanics by restoration of vertebral morphology may affect fracture incidence, long term clinical benefit and thereby cost-effectiveness, we assessed occurrence of new vertebral fractures and clinical parameters one year after kyphoplasty compared to a conservatively treated control group in a prospective study. 60 patients with osteoporotic vertebral fractures due to primary osteoporosis were included: 40 patients were treated with kyphoplasty, 20 served as controls. All patients received standard medical treatment. Morphological characteristics, new vertebral fractures, pain (visual analog scale), physical function (EVOS score) (range 0-100 each) and back-pain-related doctor visits were assessed 12 months after kyphoplasty. There were significantly less patients with new vertebral fractures of the thoracic and lumbar spine after 12-months in the kyphoplasty group (P=0.0084). Pain scores improved from 26.2 to 44.4 in the kyphoplasty group and changed from 33.6 to 34.3 in the control group (P=0.008). Kyphoplasty treated patients required a mean of 5.3 compared to 11.6 back-pain-related doctor visits/patient in the control group during 12 months follow-up (p=0.006). Kyphoplasty as an addition to medical treatment and when performed in appropriately selected patients by an interdisciplinary team persistently improves pain and reduces occurrence of new vertebral fractures and health care utilization for at least 12 months in individuals with primary osteoporosis.

Lasofoxifene Phase 2 and Phase 3 Clinical Trial Design and Strategy. A. Lee[1], D. Radecki[1], K. Wolter[1], J. Proulx[1], M. Buonanno*[1], V. Dillon*[1], T. Houck*[1], M. Orri*[2], W. Day[3]. [1]Pfizer Global Research and Development, New London, CT, USA, [2]Pfizer Global Research and Development, Sandwich, United Kingdom, [3]Pfizer Global Research and Development, La Jolla, CA, USA.

Lasofoxifene, a next-generation selective estrogen receptor modulator (SERM), demonstrated estrogen agonist effects on bone and lipids, and estrogen antagonist effects on the breast and uterus in pre-clinical models.* The Phase 2 and Phase 3 clinical development program for lasofoxifene (Phase 2-3) is described in this overview. Early stage safety and efficacy of lasofoxifene was evaluated in 3 Phase 2 multiple dose studies conducted in young healthy postmenopausal women. Lasofoxifene was studied over a 600-fold dose range of 0.17 mg/d to 10 mg/d using 9 doses of lasofoxifene and 2 active comparators (Prempro and Evista). The studies ranged from 1 to 2 years. Lasofoxifene clinical effects were consistent with the preclinical models and demonstrated consistent increases in lumbar spine BMD (2%-4%) and reductions in LDL-C (15%-20%). Dose modeling from Phase 2 allowed selection of doses for Phase 3 development. The Phase 3 program includes studies conducted in postmenopausal women with either osteopenia or osteoporosis. Two identical, double-blind, placebo-controlled 2-year studies (OPAL) to support an application for the prevention of postmenopausal osteoporosis have been completed. These studies were conducted using lasofoxifene 0.5 mg/d, 0.25 mg/d (anticipated lowest fully-effective dose) and 0.025 mg/d (ED_{50}, 50% of effective dose). An ongoing fracture trial (PEARL) is being conducted with 2 doses of lasofoxifene (0.25 mg/d and 0.5 mg/d) and a comparative trial (CORAL) is being conducted with 0.25 mg/d compared to Evista. The basic study design inclusion and exclusion criteria and primary and secondary endpoints will be outlined.

M385

Lasofoxifene Phase 2 Dose Response Analysis in Postmenopausal Women. W. Day[1], J. Martel*[2], A. Lee[2]. [1]Pfizer Global Research and Development, San Diego, CA, USA, [2]Pfizer Global Research and Development, Groton, CT, USA.

Lasofoxifene is a next-generation selective estrogen receptor modulator (SERM) that prevents bone loss and affects the estrogen receptor differently in various tissues. During dose selection for the Phase 3 program, efficacy results from Phase 2 trials were analyzed to identify the lowest dose providing a maximal response for increasing bone mineral density (BMD) or lowering lipids (LDL-C) in postmenopausal women. Results of the dose modeling were also correlated with the safety data to provide assurances of a positive benefit:risk profile. Lasofoxifene dose selection utilized data from three active and/or placebo controlled Phase 2 trials. The trials were 1 to 2 years and spanned a 600-fold dose range (9 dose levels; 0.017 mg/d to 10 mg/d). An E_{MAX} model was fit to the data for lumbar spine BMD (LS-BMD), total hip BMD (TH-BMD), and LDL-C data to generate dose-response curves. Maximal placebo-adjusted treatment effects were obtained and were used to derive ED_{90}, (90% maximum effect dose), and ED_{50}, (50% of the maximal effect dose). Dose selection was based on, *inter alia*, the estimate of ED_{90} for various efficacy endpoints. A *Responders Analysis* was also utilized. It estimated lasofoxifene treatment effect on the probability for a positive outcome. Subjects were classified as strong, moderate or non-responders and were differentiated on the basis of LS-BMD, TH-BMD and LDL-C responses. The E_{MAX} model estimated the maximal placebo-adjusted treatment effects for the respective endpoints: LS-BMD, TH-BMD, and LDL-C, to be 1.6%, 1.4% and -17.3%. The theoretical doses predicted to achieve an ED_{90} were 0.19, 0.38, 0.18 mg/day, respectively. Although the E_{MAX} data suggested that the dose response in LS might be more sensitive than LDL-C and TH responses, the *Responders Analysis* suggested that maximal efficacy occurred with a dose of 0.25 mg/d and was associated with the occurrence of both LDL and BMD responses in a subject. *Responders Analysis* confirmed the ED_{50} dose of 0.025 mg/d as a low effect dose. Safety evaluations were also considered in the modeling; however, there were too few events to establish a dose response relationship for selected class related adverse events (DVTs, uterine or breast cancers and uterine prolapse). Moreover, there was no apparent evidence of a dose-related toleration effect on hot flushes or leg cramps over the dose range. The overall results of the dose selection analyses suggested that the lowest dose necessary to achieve a fully efficacious response on total hip BMD, lumbar spine BMD and LDL-C is 0.25 mg/d.

Multi-Disciplinary Group Education Increases Persistence with Pharmacological Treatment in Osteoporosis - Interim Analysis from a Randomised Trial. D. Nielsen*[1], J. Ryg*[1], N. Nissen*[1], L. Stilgren*[1], W. Nielsen*[2], B. Dahl-Andersen*[2], B. Knold*[1], A. R. Madsen*[1], K. Brixen[1]. [1]Endocrinology, Odense University Hospital, Odense, Denmark, [2]Physiotherapy, Odense University Hospital, Odense, Denmark.

Persistence with pharmacological therapy in osteoporosis is often low in clinical settings. Group education increases patients' knowledge, however, the effect of such programs on adherence with therapy remains to be demonstrated. We hypothesized that persistence with pharmacological treatment may be increased by a multi-disciplinary systematic group education program in patients with osteoporosis. This preliminary analysis comprised 280 patients (250 women and 30 men) aged 64 [47 to 81] years, recently diagnosed with osteoporosis. Participants were randomized to either the "school" (n=146) or "control" group (n=134). In the school group, patients attended classes for four days during 4 weeks. Each class had 8-12 participants. Teaching performed by nurses, physiotherapists, dieticians, and doctors covered "facts on osteoporosis", "fractures and pain", "diet", "preventive measures", "balance and exercise", and "medical treatment". Participants in the school group also received programmed telephone calls four times during 4 months and an invitation for a follow-up meeting after 12 months. The control group received standard care. DEXA was performed in all participants after 12 and 24 months. Persistence with pharmacological treatment was assessed using a self administered questionnaire at study entry and after 3, 12, and 24 months. Eighty-eight percent of the patients had started bisphosphonates, 10% raloxifen, and 1% teriparatide. Five and 7 patients were excluded from the control and school groups, respectively, since no specific pharmacological therapy was initiated. At the time of the interim analysis 229, 166, and 61 patients had completed at least 3, 12, or 24-months of follow-up, respectively. During the study, 8 patients (7%) in the control group and 1 patient (1%) in the school group stopped treatment prematurely and persistence with therapy was significantly higher ($p<0.02$) in the school group compared with controls (Kaplan-Meier). The persistence in both groups, however, was much higher (93-99 % at 24 months) compared with previous studies in clinical cohorts. This suggests that the participants in our study were more motivated than patients in an ordinary clinical setting. This, however, only underscores the significance of our finding in the intervention group. We conclude that a multi-disciplinary group education program increases the persistence with pharmacological therapy significantly in patients with osteoporosis.

Effect of an Information-Based Intervention on the Management of Minimal and Moderate Trauma Fractures: A Randomized Study. D. Bliuc*, J. A. Eisman, J. R. Center. Bone and Mineral Program, Garvan Institute of Medical Reasearch, St Vincent's Hospital, University of New South Wales, Sydney, Australia.

Despite the high risk for subsequent fracture following an initial osteoporotic fracture, the majority of subjects with fragility fractures receive no treatment for osteoporosis. This study aimed to firstly determine whether an information-based intervention could change post-fracture management of osteoporosis, and secondly define participant- and doctor-related barriers to osteoporosis management. Consecutive fracture patients (n=198) from the outpatient fracture clinic at St Vincent's Hospital, Sydney were interviewed over a 15 month period (February 2002-July 2003). Fracture risk factors, prior investigation and treatment for osteoporosis were collected at baseline. Participants were initially contacted after 3 months. Those not investigated or treated were randomized to either a personalized letter or the same letter plus a free BMD offer. Final follow-up was obtained after another 6 months. Less than 20% of participants had a primary care physician follow-up three months after the fracture, leaving 159 who were randomized to a personalized letter (n=79) and a personalized letter plus free BMD (n=80). Significantly more people were investigated for osteoporosis in the letter plus BMD offer group (38% vs. 7%; p=0.001), but treatment rates were very low in both groups (< 6%). Of those tested, 66% had low bone density, but only 24% were recommended therapy. Among the few individuals 36

(23%) who contacted their primary care physician, only 9 (25%) were recommended treatment. Independent predictors for management outcome were age over 50 for a primary care physician follow-up, female gender for having a BMD test, and having had a BMD test for treatment. Belief that their fracture was osteoporotic, although uncommon (12%) was the only independent predictor of having a BMD test, of primary care physician follow-up and of receiving treatment. In this study, an information-based intervention led to a modest increase in the proportion of people investigated for osteoporosis, however there was no significant effect on treatment rates. However, belief that their fracture was related to osteoporosis was the most consistent factor related to better management. Being female and over the age of 50 were independent predictors for follow-up and subsequent treatment. This randomized study demonstrates major patient and doctor-related barriers to effective osteoporosis management.

Baseline Clinical Characteristics of Postmenopausal Women with Osteoporosis and an Inadequate Clinical Response to Osteoporosis Drugs in the Observational Study of Severe Osteoporosis (OSSO). D. Sykes*[1], C. Cooper[2], S. Adami[3], P. Fardellone*[4], F. Jakob*[5], J. Melo-Gomes*[6], E. Martin-Mola*[7], T. Nicholson*[1], N. Thalassinos*[8], D. Torgerson*[9], F. Marin[1]. [1]Eli Lilly, Windlesham, United Kingdom, [2]MRC Environmental Epidemiology Unit, Southampton General Hospital, Southampton, United Kingdom, [3]University of Verona, Verona, Italy, [4]Hospital Nord, Amiens, France, [5]Julius-Maximilians Universitat, Wurzburg, Germany, [6]Servimed, Lisbon, Portugal, [7]Hospital La Paz, Madrid, Spain, [8]Evangelismos General Hospital, Athens, Greece, [9]University of York, York, United Kingdom.

OSSO is a 12-month, prospective, observational study conducted in six European countries. Participants are postmenopausal women with osteoporosis and an inadequate clinical response to osteoporosis drugs defined as: (i) the presence of a new clinical fragility fracture despite prescription of any approved osteoporosis drug for at least 12 months before the fracture (index fracture cohort), and/or (ii) discontinuation of any approved osteoporosis drug due to compliance problems and/or side effects (compliance/ side effect cohort). Patients who satisfied both criteria were analysed according to the first event. Data collected at baseline included patient demographics, medical and osteoporosis history, risk factors for osteoporosis and falls, medication use, disease status, HRQoL and medical resource utilisation. At baseline, the distribution by country of the 2314 women (mean (SD) age 70.2 (9.0) yrs, mean (SD) BMI 25.8 (4.4) kg/m^2) was: Germany (36%), Spain (18%), France (18%), UK (15%), Greece (11%) and Portugal (2%). Overall, (1309) 57% of patients were in the index fracture cohort and (1005) 43% in the compliance/side effect cohort. A significantly higher proportion of the index fracture cohort had a history of previous fractures (excluding index fracture) (73.8%) than the compliance/side effect cohort (59.9%, P<0.001). Mean BMD T-scores at the LS and FN were lower in the index fracture cohort than in the compliance/side effect cohort (-3.2 vs -3.1 for LS, P=0.005; -2.7 vs -2.5 for FN, P=0.039). Of the ARs discontinued alendronate was cited most commonly (37.2%), followed by risedronate (18.3%). Gastrointestinal problems were the main reason for discontinuing alendronate (62.7%) and risedronate (62.2%). Non-compliance was the most commonly cited reason for discontinuation for calcitonin (27.4%) and HRT (24.1%). 27% of participants had concurrent diseases, most commonly RA (10.4%) and COPD (6.7%). In conclusion, the baseline data indicate these patients have numerous risk factors for subsequent fracture, especially those in the index fracture cohort.

Generalized and Local Bone Loss in Patients with Rheumatoid Arthritis Treated with Infliximab. M. Vis[1], E. Haavardsholm*[2], G. Haugeberg*[2], A. Voskuyl*[1], T. Uhlig*[2], B. Dijkmans[1], A. Woolf[3], T. Kvien*[2], W. Lems[1]. [1]VU university medical center, Amsterdam, The Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Royal Cornwall Hospital, Truro, United Kingdom.

Object The aim of the present study was to assess in a large cohort of RA patients the effect of infliximab on generalized and local bone loss. **Methods** Patients with RA, 92 from Amsterdam and 10 from Oslo, who were treated with infliximab during one year were included. All patients had active RA at the start of treatment. Disease activity was measured before every infusion by the disease activity score of 28 joints (DAS-28). The BMD of the spine (n=102) and hip (n=89) measured by DEXA and hand (n=53) measured by DXR was determined before the start of treatment and after one year of treatment with infliximab. **Results** The patient group consisted of middle aged (mean age 53 years), mainly female, patients(83%). The median (range) disease duration was 8 (1 to 49) years, twenty-five (25%) patients used prednisone (median dose 7,5 mg). According to the EULAR response criteria 40 patients had a good response, 43 patients a reasonable response and 19 patient had a non response at 1 year. During treatment with infliximab the BMD of the vertebral spine and hip did not change. In contrast, BMD of the hand decreased significantly by 0.004 g/cm^2 (-0.8 percent) during the year ($p < 0.05$). The group of non and reasonable responders were taken together (n=62) and compared to the good responders (n=40). In the good responder group BMD at all sites showed a more favourable change than in the group of non and reasonable responders. This difference was statistically significant different for the hip. (Table 1) **Discussion** The main conclusions of the present study are that 1-year treatment with infliximab arrests generalized bone loss in RA patients, but does not stop the localized bone loss at the hands.

Table 1

	Non / reasonable response	Good response	p
BMD vertebral-spine (%-change))	-0.574 (5.02)	0.74 (5.3)	NS
BMD total hip (%-change)	-0.68 (3.8)	0.77 (3.4)	P < 0.05
BMD hand (%-change)	-1.2 (2.6)	-0.63 (2.3)	NS

Orally Administered ANABU™ (GlcNBu) Protects Joint Surfaces in Streptococcal Cell Wall Antigen (SCW)-Induced Arthritis in Lewis Rats. T. P. Anastassiades[1], M. Grynpas[2], J. Carran*[1], X. Wang*[2], A. Cherian*[2]. [1]Medicine, Rheumatology, Queen's University, Kingston, ON, Canada, [2]Mount Sinai Hospital, Toronto, ON, Canada.

In previous work we had shown that GlcNBu (N-butyryl glucosamine) decreases the inflammation of SCW arthritis and increases BMD in this model. This investigation explores the effects of GlcNBu on bone loss. Chronic SCW arthritis was induced in female rats by a single IP injection. The Groups studied were: (a) no arthritis, no treatment; (b) arthritis, no treatment; (c) arthritis, GlcNBu 20mg/kg/day; (d) arthritis, GlcNBu 200mg/kg/ day. The removed left tibiae were scanned using micro computed tomography to qualitatively and quantitatively measure the GlcNBu dosage effects on bone architecture. Isosurfaces generated from the scans show progressively less bone erosion with increasing dosages of GlcNBu.(Figure). Trabecular bone volume, number and thickness, and subchondral plate thickness increased with GlcNBu dosage, so that Group (d) was similar to Group (a). Significant increases occurred predominantly in the lateral epiphysis and the metaphysis of the high dose group. The structure model index values decreased significantly (p=0.030) in the metaphysis from the untreated SCW-induced group to the high dose group, indicating a less rod-like trabecular structure. Strut analysis showed a significant increase (p =0.034) in the length of node to node struts from the untreated SCW-induced group to the high dose group on the medial side of the proximal epiphysis. The Results indicate a dose-dependent increase in bone connectivity. The metaphyseal bone structure changes suggest that GlcNBu functions systemically. Comparison of the isosurfaces and the architectural parameters studied in this investigation demonstrate that GlcNBu effectively protects bone from further erosion in this model of chronic inflammatory arthritis.

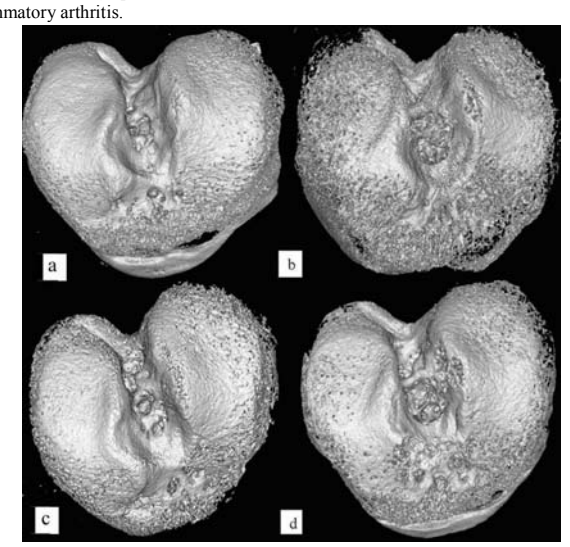

Figure: Isosurfaces of proximal rat tibia (a) No arthritis, no treatment; (b) arthritis, no treatment; (c) arthritis + low dose GlcNBu; (d) arthritis + high dose GlcNBu.

Barriers and Facilitators to Osteoporosis Medication Adherence: Patient Perceptions and Strategies. A. Papaioannou[1], A. Pathak*[1], K. Nair*[2], S. Burns*[2], E. Lau*[2], L. Dolovich*[2], A. Sawka[1], C. Kennedy[1], J. D. Adachi[1]. [1]McMaster University, Hamilton, ON, Canada, [2]Centre for Evaluation of Medicines, Hamilton, ON, Canada.

Medication non-adherence is a common problem that may lead to treatment failure and undesired clinical outcomes. Adherence with osteoporosis medication ranges from 8% to 70%. Despite the importance of medication adherence for fracture prevention, few studies have examined the implications of this from the patients' perspective. The purpose of this study was to explore barriers and facilitators of osteoporosis medication adherence and to explore adherence strategies from the patient's perspective. Participants were community dwelling, post-menopausal women (mean age = 71 years, SD 8.2) taking medication for osteoporosis treatment or prevention. Twenty-nine participants were recruited from family

medicine/specialist practices and community pharmacies. The mean length of time on osteoporosis medication was 2.9 years (SD 2.7), 38% had a previous fragility fracture, and 66% had drug plan coverage. Five focus groups of approximately 6 patients were conducted using a semi-structured interview guide. Participants were asked 9 open-ended questions regarding the importance of adherence, reasons for non-adherence, and their perceptions of different adherence strategies. Group sessions were digitally recorded, transcribed verbatim, and independently coded by two team members to identify common themes. An operational codebook was developed based on current literature and the emerging themes. QSR NVIVO software was used to organize the data. Common barriers included: denial about the condition; not realizing the seriousness; belief that lifestyle modifications are enough; fear/experience of side effects; feeling over-medicated; and feeling that healthcare providers did not provide enough medication-related information or monitoring of progress. Facilitators included: being informed and taking responsibility; perceiving benefits outweigh the risks; belief in the value of delaying the onset of osteoporosis; desire to avoid fractures, shrinking, stooping; planning ahead/daily routines; trust in the doctor's expertise; tracking BMD improvements; and receiving credible/ accessible information and follow-up from healthcare providers. Key aspects relevant to osteoporosis medications were the challenges of special administration requirements (i.e. timing with food and other meds, not lying down afterwards) and a preference for once weekly vs. once daily regimens. In conclusion, many adherence factors were modifiable and healthcare providers should consider ongoing medication-related discussions with patients regarding concerns and strategies.

Development of a Bone and Cartilage Stimulatory Peptide (BCSP™) with Bone Targeting Properties. D. R. Sindrey[1], P. T. Biessels*[1], R. R. Simon*[1], M. R. Doschak*[2], H. Uludag[2]. [1]Millenium Biologix Corp., Mississauga, ON, Canada, [2]Department of Chemical and Materials Engineering, University of Alberta, Edmonton, AB, Canada.

We have previously reported the discovery of a novel osteogenic peptide that in animal models has shown promise for the treatment of osteoporosis and as a bone stimulating agent for fracture healing. One of the difficulties in developing small molecule peptides for therapeutic use resides in their inherent short half-lives. An ideal agent would be one that could target bone, or in the case of fracture healing be retained within synthetic bone graft substitute materials. To address this issue we synthesized a number of peptide analogs of BCSP-1 with various C-terminal modifications designed to impart affinity to Skelite™, a resorbable BGS. 5 BCSP derivatives were synthesized and screened in vitro for their affinity to Skelite. Briefly, 5mm Skelite granules were incubated in a 1 mM solution of peptide in 70% methanol for 4 hrs, the amount of peptide bound to the scaffold was then assessed by measuring the final concentration in solution by HPLC analysis. The results tabulated below show that the BCSP-21 had the highest affinity for Skelite. In comparison to BCSP-1 where 95% of the protein remained in solution, only 5% of BCSP-21 remained in solution after the 4 hr incubation period.

Peptide	C-terminal modification	% Bound to Skelite
BCSP-1	-	4.5%
BCSP-21	-pSer-pSer-pSer-Glu-Glu	95.0%
BCSP-21b	-pSer	6.8%
BCSP-21c	-Glu-Glu-Glu-Glu	17.6%
BCSP-21d	-Gla-Gly-Gla-Glu	6.4%
BCSP-21e	-Gla-Glu	7.5%

pSer (phosphoserine); Gla (gamma-carboxyglutamic acid)

The binding affinity of BCSP-1 for Skelite was further explored through radiokinetic studies in vivo. 4 x 4mm porous Skelite scaffolds were coated with I-125 labeled BCSP-1 (1 mg) or BCSP-21 (1.2 mg) and implanted subcutaneously into the abdominal region of S.D rats. The amount of radioactivity was then assessed on days 1,2,4,7, and 10. As predicted in vitro, BCSP-1 showed almost no binding activity to Skelite with less than 1% of the original radioactivity remaining after 24hrs of implantation. Subsequent time-points show a logarithmic decrease in radioactivity over time, with approximately 0.1% of the peptide remaining at day 10. BCSP-21 however, showed a significant affinity for the implant retaining up to 15% of the starting radioactivity at day one and a gradual loss thereafter with up to 3% bound at day 10. The results of these studies indicate that pSer modification of BCSP-1 is an effective means to localize biologically active small peptides to hydroxyapatite-like surfaces and may represent a novel agent for the treatment of osteoporosis and/or fracture healing.

Short Term Effects of Estrogen, Tamoxifen and Raloxifene on Bone Density and Bone Turnover. M. Baz Hecht, J. W. Nieves, V. Shen, R. Lindsay, F. Cosman. Clinical Research/Regional Bone Centers, Helen Hayes Hospital, West Haverstraw, NY, USA.

Estrogen, tamoxifen and raloxifene are all known to have beneficial effects on the skeleton, however the relative effects of these agents have not been compared in a head to head trial. This randomized placebo controlled study compared the effects of these three treatments vs. placebo on bone mineral density (BMD) and bone turnover in 94 postmenopausal women, mean age 55.7 years, mean 5.7 years from menopause. After baseline measurements of bone mass, and blood and urine sampling, women were randomly assigned to receive oral estrogen (conjugated equine estrogen 0.625 mg; n=23), tamoxifen 20 mg (n=24), raloxifene 60 mg (n=24) or placebo (n=23) daily for 6 months. Markers of calcium homeostasis [serum ionized calcium, phosphorus, 1,25-dihydroxyvitamin D (1,25$(OH)_2$D) and intact PTH], bone formation [serum osteocalcin (OC), propeptide of Type I procollagen (P1CP) and bone specific alkaline phosphatase (BSAP)], bone resorption [crosslinked N-telopeptide of type I collagen (NTX)] and lumbar spine and hip BMD were measured at baseline and at 6 months of treatment. A subset of 45 patients also had body composition measurements. After 6 months, serum ionized calcium decreased with all 3 active therapies (greatest decline for estrogen, 1.7%; raloxifene 1.2%, $p<0.02$, 0.3% tamoxifen, NS). Serum intact PTH increased with all 3 active treatments (17%, 29% and 39% for estrogen, raloxifene and tamoxifen respectively, all $p<0.01$). Serum phosphorus decreased with estrogen and tamoxifen (9%, $p<0.09$ and 14%, $p<0.007$, respectively). 1,25$(OH)_2$D increased with estrogen (24%, $p<0.07$), but not with the other agents. Bone turnover markers decreased with all three treatments, however only the effects of estrogen and tamoxifen were significant compared to baseline values and to placebo. OC decreased 15% ($p<0.004$) and 27% ($p<0.0001$), BSAP decreased 21% ($p<0.0001$) and 25% ($p<0.0001$) and NTX decreased 10% ($p<0.0002$) and 17% ($p<0.0003$) with estrogen and tamoxifen respectively. P1CP decreased 17% with estrogen ($p<0.001$). Lumbar spine BMD and total body mineral content increased significantly only with estrogen at this time point (2.1%, $p<0.02$ and 1.3%, $p<0.03$, respectively). Total hip BMD increased with tamoxifen 1.2% ($p<0.03$) and with estrogen 0.7% ($p=0.11$). Total body fat was not affected by any of these agents. Six months treatment of non-osteoporotic women with estrogen and tamoxifen benefits the skeleton, producing decreases in bone turnover and increases in BMD, while raloxifene is a weaker antiresorptive agent, with effects of lower magnitude over this short time period.

Skeletal Effects of Bazedoxifene Acetate (BZA) in Ovariectomized Mice and Comparison of BZA's Effects with Raloxifene (RAL) and Lasofoxifene (LAS) in Intact Mice. Y. P. Kharode, P. D. Green*, C. L. Milligan*, P. V. N. Bodine, F. J. Bex, B. S. Komm. WHRI/Bone Metabolism, Wyeth Reserach, Collegeville, PA, USA.

Bazedoxifene acetate (BZA) is a novel, selective estrogen receptor modulator (SERM) that prevents osteopenia and reduces serum cholesterol without uterotropic effects. We conducted studies to evaluate the effects of oral administration of BZA in ovariectomized (ovx) and intact female C57BL6 mice. Ten week-old ovx mice were administered BZA daily (0.1 mg/kg, 0.3 mg/kg, 1.0 mg/kg, 3.0 mg/kg, 10 mg/kg) or vehicle for sixty days. A group of sham-operated mice served as controls. Ovx + vehicle resulted in significant bone loss in comparison to sham (392±8 mg/cm^3 vs.479±8 mg/cm^3 and 93±5 mg/cm^3 vs.149±5 mg/cm^3 for total and trabecular densities, respectively). Post-treatment total (466 to 502 mg/cm^3) and trabecular vBMD (121 to 136 mg/cm^3) measured by pQCT significantly increased in all treatment groups compared to the ovx +vehicle group. Uterine weight in ovx +vehicle group (16±1mg) was significantly lower than that for sham group (65±5 mg, $p<0.01$), but with the exception of the BZA, 0.1mg/kg group (25±1mg) was not different from any of the BZA groups (ranged 15 to 19 mg). In a similar study, 0.3 mg/kg/day, po ethinyl estradiol (EE) significantly increased total and trabecular densities and uterine weight compared to the ovx +vehicle group. To evaluate and compare the effects of BZA with raloxifene (RAL) and lasofoxifene (LAS) in an estrogen-replete setting, 10-week old ovary intact mice were treated with 3 mg/kg/day, po for 30 days. EE (0.3 mg/kg/day, po) served as a control. Post-treatment femoral evaluation revealed that, compared to the vehicle group, all treatment groups had significant accrual of trabecular bone as judged by pQCT and μCT analysis. BZA, RAL and LAS, significantly decreased while EE significantly increased the serum cholesterol. Uterine weights were lower in the BZA group (BZA, 46±1 mg, $p<0.05$ vs vehicle, 68±5 mg; RAL, 64±3 mg; LAS, 53±2 mg) and were significantly higher in EE group (198± 12 mg) compared to the vehicle group. Our results indicate that in C57BL mice, BZA prevented ovx-induced osteopenia without causing uterine stimulation. In ovary-intact mice, BZA, RAL and LAS produced accrual of bone, and significantly reduced serum cholesterol, but only BZA exhibited anti-estrogenic effects on the uterus. The mechanisms that are responsible for the ability of a SERM to increase bone mass in intact mice may be osteogenic but further work is needed to determine this. In conclusion, BZA is a novel SERM with tissue selective effects that may offer selective skeletal protection without uterine stimulation under quite different physiologic conditions.

Differential Effects of 5α-Dihydrotesterosterone (DHT) and a Novel Selective Androgen Receptor Modulator (SARM) on Prostate and Bone in Intact and Orchidectomized (ORX) Male Rats. H. Z. Ke, D. T. Crawford*, H. Qi*, H. A. Simmons, M. Li, T. A. Brown, D. D. Thompson, X. N. Wang*, E. D. Salter*, J. P. O'Malley*, C. T. Salatto*, R. J. Hill*, B. A. Lefker*, K. O. Cameron*. Pfizer Global R &D, Groton, CT, USA.

SARMs have been hypothesized to have beneficial effects on bone without causing prostate hypertrophy in men. CE590 is a newly identified SARM that selectively binds to the androgen receptor (AR) with an IC50 of 16 nM, and acts as a receptor agonist in AR-transfected C2C12 cells with an EC50 of 0.4 nM. The purpose of this study was to compare the different effects of CE590 and DHT on prostate and bone in intact and ORX rats. Male SD rats at 11 months of age were sham or ORX. Both sham and ORX rats were treated with CE590 at 30 mg/kg, twice daily by oral gavage or DHT at 8 mg/kg by s.c. injection for 8 weeks. Levitor ani weight increased significantly after treatment with CE590 or DHT in both sham and ORX rats, indicating that both CE590 and DHT act as an AR agonists on levitor ani regardless of endogenous androgen levels. Compared with sham controls, prostate weight decreased significantly by 26% in sham rats treated with CE590, while it increased significantly by 66% in sham rats treated with DHT, indicating CE590

acts as an AR antagonist while DHT acts as an AR agonist on prostate in intact rats. Although prostate weight in ORX rats treated with CE590 was significantly higher than that in ORX controls, it was still much lower than sham controls. However, prostate weight in ORX rats treated with DHT was significantly higher than that in sham or ORX controls. These data indicate that CE590 has much less of an effect on prostate than DHT in ORX rats. PQCT analysis of distal femoral metaphysis showed that DHT significantly decreased total bone content (-6%), total bone density (-8%) and trabecular density (-9%), while CE590 had no significant effect on these parameters in sham rats compared with sham controls, indicating DHT acts as an AR antagonist on bone while CE590 had has no effects in intact male rats. Treatment with CE590 in ORX rats for 8 weeks completely prevented ORX-induced decreases in trabecular content, trabecular density, cortical content, cortical area and cortical thickness. However, DHT had no significant bone effect in ORX rats at the dose administrated. Trabecular bone histomorphometry analysis showed that CE590 prevented ORX-induced increases in bone resorption and bone turnover. In summary, CE590 decreased prostate weight and had no significant effect on bone while DHT increased prostate weight but decreased bone density in intact male rats. In ORX rats, CE590 protected against bone loss and DHT had no effect on bone. These results suggest that SARMs have potentials for management of osteoporosis in men with lower gonadal function.

Lasofoxifene Protects against Ovariectomy-Induced Deterioration in Bone Microarchitecture and Geometry in Rats. H. Qi*, D. T. Crawford*, H. A. Simmons, T. A. Brown, D. D. Thompson, H. Z. Ke. Pfizer Global R &D, Groton, CT, USA.

We have previously reported that lasofoxifene (Laso), a new selective estrogen receptor modulator, currently in clinical development for management of osteoporosis, prevents ovariectomy (OVX)-induced bone loss and preserves bone strength in rats. However, the effect of Laso on bone microarchitecture and geometry has not been previously characterized in OVX rats. In this study, S-D female rats at 13 weeks of age were OVX and treated orally with Laso at 0.01, 0.05 or 0.25 mg/kg/d, or 17α-ethynylestradiol (EE) at 0.03 mg/kg/d for 8 weeks. Micro-CT and PQCT analysis were performed on the distal femoral metaphysis. OVX for 8 weeks induced a significant decrease in total volumetric density (TVD), total volumetric content (TVC), trabecular bone volume (BV/TV), thickness (TbTh), number (TbN), connectivity density (ConnD) and cross sectional moment of inertia (CSMI), and a significant increase in structure model index (SMI), bone surface to volume ratio (BS/BV), trabecular pattern factor (TBPf) and endocortical circumference (EndoC). These data indicate that OVX induced significant loss in trabecular and endocortical bone and deteriorated bone microarchitecture and geometry. Compared with OVX controls, OVX rats treated with Laso at all dose levels had significantly higher TVD, TVC, BV/TV (114% -128%), indicating Laso protects against bone loss in OVX rats. OVX rats treated with Laso at all dose levels had significantly higher TbTh and TbN, and significantly lower SMI (35% - 40%), BS/BV (18% - 23%), indicating Laso preserves plate-like trabeculae and protects against OVX-induced trabecular deterioration. Significantly higher ConnD (93% - 121%) and significantly lower TBPf (52% - 62%) in OVX rats treated with Laso signifies Laso preserves the surface connectivity of trabeculae. Significantly higher CSMI and significantly lower EndoC in OVX rats treated with Laso revealed that Laso preserved the geometrical properties of bone. Histomorphometry analysis of trabecular bone confirmed that Laso decreased osteoclast number, osteoclast surface and bone turnover rate. Efficacy observed in all above parameters did not differ among 3 dose groups for Laso. The protective effects found in Laso treatment were similar to those observed with EE in OVX rats. In summary, Laso at a dose as low as 0.01 mg/kg/d significantly protected against OVX-induced trabecular bone loss and deteriorations in bone microarchitecture and geometrical properties. The protective effects of Laso on bone strength in OVX rats as reported previously may stem from its protective effects on bone mass, bone turnover, microarchitecture and geometry.

Effects of Raloxifene on Bone Mineral Density and Biochemical Markers of Bone Remodeling in Postmenopausal Women Pre-treated with Raloxifene or Alendronate for One Year. J. Brown[1], K. W. Ng[2], G. Toss[3], C. Zhou*[4], M. Wong[4], M. W. Draper[4]. [1]Le Centre Hospitalier Universitaire de Quebec Pavilion Chul, Sainte-Foy, PQ, Canada, [2]University of Melbourne, Melbourne, Australia, [3]University Hospital, Linkoping, Sweden, [4]Lilly Research Laboratories, Indianapolis, IN, USA.

As several antiresorptive agents with differing mechanisms of action are now available to prevent and/or treat postmenopausal osteoporosis, transitions from one therapy to another often occur in clinical practice. In postmenopausal women (≤75 years of age, femoral neck BMD T-score <-2.0), the effects of treatment with placebo (PL), raloxifene 60 mg/d (RLX), alendronate 10 mg/d (ALN), or RLX+ALN on bone mineral density (BMD) and biochemical markers of bone remodeling after one year have been studied and previously reported [JCEM 87(2002):985-92]. After the initial year of therapy in this study, women in each of the 4 treatment groups were re-randomized to either PL or RLX, and treated for an additional year. This new report summarizes the second-year BMD and bone marker results for those women who had been randomized to RLX or ALN in the first year (RLX-PL, n= 34; RLX-RLX, n=35; ALN-PL, n=35; ALN-RLX, n=30). All women received elemental calcium 500 mg/d and vitamin D 400-600 IU/d supplements throughout the entire 2-year study. Lumbar spine, femoral neck, and total hip BMD were measured by DXA at baseline and at 6-month intervals. Biochemical markers of bone remodeling were measured at 0, 1, 6, 12, and 24 months. The Table shows the difference in mean percent change in BMD and bone markers in RLX versus PL from the end of year 1 to the end of year 2.

Variable	RLX in Year 1	ALN in Year 1
Lumbar Spine BMD	1.49*	2.02*
Femoral Neck BMD	1.46	1.17
Total Hip BMD	2.43*	1.63*
Osteocalcin	-38.1*	-39.3*
Bone-Specific Alkaline Phosphatase (BSAP)	-18.4*	-33.7*
N-Telopeptide	-60.3	-68.9
C-Telopeptide	-173.3*	-58.7

* p<0.05 between RLX and PL

In women treated with either RLX or ALN in year 1 (Table), RLX treatment in year 2 produced significant increases in lumbar spine and total hip BMD compared with PL. Irrespective of the therapy given in year 1, markers of bone remodeling in year 2 were lower in the RLX group compared with PL. Significant differences between the PL and RLX groups were seen for osteocalcin and BSAP in women given either RLX or ALN in year 1, but for C-telopeptide, these were seen only in women treated with RLX in year 1. In conclusion, RLX treatment exerts positive effects on BMD and biochemical markers of bone remodeling, compared with PL, regardless of prior treatment with either RLX or ALN.

Prevalence of Osteoporosis-Associated Skeletal Pain and its Further Course Following Initiation of Raloxifene Treatment: A Prospective Multicenter 6-Month Observational Study in a Naturalistic Setting. S. Scharla[1], H. Oertel*[2], K. Helsberg*[2], F. Kessler*[2], F. Langer*[2], T. N. Nickelsen[2]. [1]Practice for Internal Medicine and Endocrinology, Bad Reichenhall, Germany, [2]Medical, Lilly Deutschland GmbH, Bad Homburg, Germany.

In this 6-month observational study we assessed the prevalence of osteoporosis-associated skeletal pain and its course during treatment with the selective estrogen receptor modulator raloxifene in a naturalistic setting. 810 office-based physicians in Germany documented clinical, diagnostic, and pain data of 3,299 female patients with postmenopausal osteoporosis at baseline, after approx. 6 weeks and 6 months of treatment, or at premature treatment discontinuation. At each visit, the presence or absence of back, joint, and diffuse bone pain, as well as sleep quality and the use of analgesics were assessed. In addition, frequency and intensity of pain during the 4 weeks preceding each assessment were self-rated on a patient questionnaire using a 100 mm visual analogue scale (VAS). According to the physician documentation, 93.4% of 3,299 patients (mean age 67.6±9.3 years, 89.4% with reduced BMD, 39.8% with ≥1 confirmed fragility fracture) had skeletal pain at baseline, which had been preexisting for >10 months in 75%. 85.1% of patients had back pain, 41.8% joint pain and 32.5% diffuse bone pain. After 6 months, pain intensity (VAS) had decreased in 89% of patients and increased in 9.4%. The mean decrease in pain intensity (VAS) was -42% (95% CI -40%;-44%; p<0.0001; N=2,491). Need for analgesics and sleep quality improved in parallel. Subgroup analyses revealed relevant decreases in pain intensity after 6 months of raloxifene treatment in all subgroups assessed, including patients with pre-baseline pain for >6 months and regardless of the presence or absence of prior fractures (Table). The resulting hypothesis that raloxifene may exert a pain-alleviating effect in women with osteoporosis requires confirmation in a randomized, placebo-controlled trial.

	Pain intensity (100 mm VAS, mean +/-SD)			
Patient Characteristics	**N**	**Baaseline [mm]**	**% Change**	**95%CI**
Any old or recent (<6 months) fractures	1020	68.6±19.5	-43	-40;-46
Neither old nor recent fractures	1297	59.4±21.3	-42	-39;-44
Degenerative and/or inflammatory disease only	1050	60.9±20.6	-41	-39;-44
Fractures in absence of degen. and inflamm. dis.	46	69.4±22.7	-57	-50;-63
Preexisting pain (PEP) ≤ 4 weeks	29	73.5±20.4	-54	42;-65
PEP > 4 weeks but ≤ 6 months	304	63.4±21.3	-50	-46;-54

Progestins with No Glucocorticoid Activity May Be a Better Choice for Hormone Replacement Therapy to Achieve More Beneficial Effects on Bone Metabolism. Y. Ishida, T. Taguchi*. Department of Orthopaedic Surgery, Yamaguchi University School of Medicine, Yamaguchi, Japan.

A number of studies suggest that progestagens may have beneficial effects on bone metabolism. C21 Progestin medroxyprogesterone acetate (MPA) is one of the most commonly prescribed progestins for hormone replacement therapy (HRT). However, there appear to be that MPA with significant glucocorticoid (GC) activity may decrease bone density. We have previously argued that bone loss associated with MPA administration is caused by decreased osteoblast differentiation as a result of MPA occupying the GC receptor since increasing GC receptor occupancy beyond that reached at normal (= optimal) GC concentrations attenuates osteoblast differentiation. This randomized controlled trial was conducted to test the hypothesis that progestins with no GC activity, e.g. C19 progestin norethisterone (NET), may be a better choice for HRT to achieve more beneficial effects on bone metabolism. A total of 91 postmenopausal women aged 50-75 with osteoporosis were randomly allocated into three groups: 1) HRT-MPA (conjugated estrogen 0.625 mg/day plus MPA 2.5 mg/day); 2) HRT-NET (conjugated estrogen 0.625

mg/day plus NET 5 mg/day); or 3) control (no treatment). Thoracic and lumbar spine radiographs and bone mineral density (BMD) at distal 1/3 radius were assessed at baseline and at every 6 months during the 2-year study period, along with markers of bone turnover [serum bone specific alkaline phosphatase (BAP) and urinary N-telopeptide of type I collagen (NTX)]. Mean changes in BMD relative to baseline after the 2-year treatment in HRT-MPA, HRT-NET, and control was 1.6%, 2.7%, and -2.6%, respectively. Interestingly, the rate of increase in BMD in HRT-NET was significantly greater than that in HRT-MPA (p=0.01). The incidence of new vertebral fractures during the 2-year treatment was 13% (4/31) in HRT-MPA, 7% (2/29) in HRT-NET, and 27% (8/30) in control. There were significant decreases in BAP from baseline after the 2-year treatment in HRT-MPA (-23.8%, P<0.01) and HRT-NET (-19.2%, P<0.01) (4.6% difference, P=0.4). In control, no significant changes in BAP were found as compared with baseline. A significant reduction in NTX was seen in HRT-MPA (-45.4%, P<0.001) and HRT-NET (-47.9%, P<0.001) (2.5% difference, P=0.6), while no significant changes were found in control. We conclude that progestins with no GC activity may be a better choice for the HRT treatment to achieve more beneficial effects on bone metabolism than progestins with GC activity.

Effects of Raloxifene Treatment during One Year on OPG-RANK Ligand System in Postmenopausal Osteoporosis. D. Fernández-García*[1], P. Mezquita-Raya*[2], R. Reyes-García*[1], M. de la Higuera*[1], G. Alonso*[1], A. Martín García*[3], M. Ruiz-Requena*[4], M. Muñoz -Torres[1]. [1]Bone Metabolism Unit. Endocrinology Division, San Cecilio Hospital, Granada, Spain, [2]Endocrinology Division, Torrecárdenas Hospital, Almería, Spain, [3]Nuclear Medicine Division, San Cecilio Hospital, Granada, Spain, [4]Biochemistry Division, San Cecilio Hospital, Granada, Spain.

Previous in vitro studies suggest that the antiresorptive effect of raloxifene (a selective estrogen receptor modulator) might be mediated by changes in several cytokines involved in the bone remodelling process. In this context, the OPG-RANKL system is considered a key component in the osteoclastogenesis regulation. However, the long term effects of this treatment are not adequately established in osteoporotic patients.To determine the effects of raloxifene treatment on serum concentrations of OPG, RANKL, biochemical markers of bone turnover and BMD in untreated women with postmenopausal osteoporosis, we selected 47 postmenopausal women (mean age 63±7 years) with densitometric criteria of osteoporosis (T-score ≤-2.5 SD). We determined at baseline, 3, 6 and 12 months anthropometric parameters, biochemical markers of bone turnover, serum levels of OPG (OPG ELISA, BIO-MEDICA-GRUPPE Wien, Austria). RANKL (sRANKL ELISA BIO-MEDICA-GRUPPE Wien, Austria) and BMD (DXA; Hologic QDR 4500) in lumbar spine (LS) femoral neck (FN) and total hip was measured basal and 12 months after raloxifene (60 mg/day) treatment. BMD in LS increased significantly (2.5%) at the 12th month of treatment (p=0.031). The biochemical markers of bone turnover (total alkaline phosphatase, bone alkaline phosphatase, osteocalcin, TRAP, urine CTX) decreased significantly from the third month of treatment. Serum levels of OPG decreased at the third month of treatment (p = 0.001) and returned to basal levels at 6th and 12th month. Change of OPG levels between baseline and third month was related to the decrease of CTX between the same study point (r=0.33; p<0.05). There were a high percentage of undetectable serum RANKL levels (>60%) in all visits. The mean serum values of RANKL were significantly different between basal and 12 months (p<0.05). The treatment with raloxifene in osteoporotic postmenopausal women leads to a initial decrease in serum levels of OPG and changes in RANKl serum levels that might be attributed to the inhibitor effect on bone remodelling as anticatabolic drug.

Osteocyte Survival Is Affected by Raloxifene Treatment. H. W. van Essen*[1], P. J. Holzmann*[1], R. Blankenstein*[2], P. Lips[1], N. Bravenboer[1]. [1]Endocrinology, VU Medical Center, Amsterdam, The Netherlands, [2]Clinical Chemistry, VU Medical Center, Amsterdam, The Netherlands.

Increased osteocyte apoptosis, as the result of oestrogen deficiency, could play a role in the decrease of bone mass and bone strength seen in postmenopausal osteoporosis. We investigated whether raloxifene treatment of postmenopausal women affects osteocyte survival. In a substudy from the MORE[1] trial trans-iliac bone biopsies were taken from 24 women at baseline and after two years of treatment with either placebo or raloxifene. Goldner staining and tetracycline labelling were performed to evaluate static and dynamic histomorphometry. Immunohistochemical detection of cleaved caspase-3 was performed to visualize apoptosis. In the trabecular bone total osteocytes, positively stained osteocytes and empty lacunae were counted. Percent positive cells and percent empty lacunae were calculated. Differences between baseline and follow-up were tested with Wilcoxon paired t-test, treatment effect was tested with Mann-Whitney sign-rank test and association between osteocyte apoptosis and histomorphometrical indices were analysed with linear regression. There was no difference in percentage positive osteocytes between baseline and follow-up biopsies in both the placebo and the raloxifene groups. The percentage empty lacunae increased significantly in the placebo group (9.17 ± 2.30 vs 11.30 ± 1.43; p = 0.019), but not in the raloxifene group. There was no difference in percent change between the placebo and raloxifene groups. At baseline there was a negative association between bone remodelling indices and the percentage of positive osteocytes (BFR/BV: slope = -0.148; p = 0.008, ES/BS: slope = -0.628; p = 0.082). In the placebo group the change in bone remodelling in two years was negatively associated with the change in percent positive osteocytes (BFR/BV: slope = -1.915; p = 0.038, ES/BS: slope = -0.802; p = 0.085). In the raloxifene group this association was not observed. Analysis of the regression lines showed that the association between the change in percent positive osteocytes and the change in BFR/BV was significantly different in the raloxifene group compared to the placebo group (p = 0.045). The negative association of osteocyte apoptosis with bone remodelling indicates that a high bone remodelling quickly removes apoptotic osteocytes. This association is still intact after two years in the placebo group, but is lost in the raloxifene group. This suggests that raloxifene treatment has an effect on osteocyte survival but that direct measurement of apoptosis was unable to reveal this. Possibly the groups were to small to detect such a difference.

Effect of DHT (5-alpha-dihydrotestosterone) on Body Composition and Cortical Bone of the Adult Female Estrogen Deficient, Osteopenic Rat. T. Cusick, S. Harada, D. Kimmel. Merck & Co., West Point, PA, USA.

Elderly individuals may have increased osteoporotic fracture risk due to both low bone mass and increased frailty. Androgens may not only stimulate bone formation and increase bone mass, but also improve muscle mass. The purpose is to study the effects of DHT on cortical bone and body composition of adult, estrogen deficient, osteopenic rats. Female rats (N=76) were ovariectomized (age 14wks) and became osteopenic for 10 weeks. Rats (38/grp) were treated subcutaneously daily with vehicle (Veh) or 3mg/kg DHT. Whole body lean and fat mass (LBM & FBM) were measured monthly (EchoMRI-700; Echo Medical Systems; Houston, TX). After 17 weeks, 24 rats of each group were necropsied after in-life double calcein labeling. Treatment was halted and the remainder were necropsied 15 weeks later. Central femur BMD and BMC (bone mineral density and content) were measured (DXA; Hologic 4500). Periosteal mineralizing surface (pMS/BS), total periosteal area (TPA), marrow cavity area (MCA), and cortical area (Ct.Ar) were measured on 100µm non-decalcified central femur cross-sections. T-test of means, comparing Veh and DHT at each time (*P<.02;**P<.001), was executed.

Variable	Veh17wk	DHT17wk	Veh32wk	DHT32wk
BMD (mg/cm^2)	214±10	224±12*	222±13	226±20
BMC (mg)	118±11	128±10*	120±14	133±15*
MS/BS (%)	48.1±20.5	56.6±22.0*	41.6±12.8	37.1±17.6
TPA (mm^2)	9.94±1.02	10.26±0.80	9.74±0.86	11.09±0.83*
MCA (mm^2)	3.38±0.56	3.31±0.47	3.48±0.39	3.85±0.64
Ct.Ar (mm^2)	6.56±0.56	6.95±0.57*	6.37±0.53	7.25±0.67*

LBM became significantly greater in DHT than in Veh rats after 4wks (+4.1%*) and remained so during active treatment (+11.7%** @ 17wks). FBM was also less with DHT (-16% @4wks; -28% @17wks). pMS/BS is elevated by 3mg/kg/d DHT at 3.5wks (data not shown). BMD, BMC, pMS/BS, and Ct.Ar were greater with DHT after 17wks. DHT-related LBM/FBM and pMS/BS effects dissipated, but BMC, TPA, and Ct.Ar remained significantly greater after recovery. **Conclusion:** Body composition becomes leaner with DHT treatment, at the same time when periosteal bone formation is stimulated. These changes in LBM/FBM and pMS/BS precede increased cortical bone mass. Though body composition and bone formation return to normal after recovery, increased total periosteal and cortical area persist, suggesting that androgens improve cortical bone macroarchitecture in a way that increases cross-sectional moment of inertia, indicating permanent improvements in mechanical strength of cortical bone.

[Leu^{27}]cyclo(Glu^{22}-Lys^{26}) hPTH 1-31NH$_2$ Potently Preserves Bone Structure after Ovariectomy by Effectively Inhibiting Bone Resorption. H. Shen*, S. Maclean*, V. Ross*, C. Allen*, A. Burns*, G. E. Willick*, J. F. Whitfield, G. A. Candeliere. Institute of Biological Sciences, National Research Council of Canada, Ottawa, ON, Canada.

The parathyroid hormone (PTH) analogs hPTH-(1-31)-NH$_2$ (OSN), [Leu^{27}] cyclo (Glu^{22}-Lys^{26}) hPTH-(1-31)-NH$_2$ (OSC) and hPTH-(1-34)-NH$_2$ (FTA) show differences in receptor affinity and signaling, which suggests differences in bone-anabolic mechanism. PTH analog treatment increased serum osteocalcin and femoral trabecular thickness equally in sham and ovariectomized (OVX) rats, but unequally caused larger effects on bone volume, marrow space, and node-to-termini ratio in OVX. This indicates that all PTH analogs stimulated bone formation and inhibited the breakdown of the trabecular lattice after OVX. PTH analogs were injected daily into OVX rats at doses of 6, 10 and 20 nmoles/kg of body weight. FTA and OSC stimulated serum osteocalcin and increased trabecular thickness equally, whereas OSN was less potent. The FTA-induced changes in bone volume, node:termini ratio, and marrow space plateaued between 10 and 20 nmoles/kg of body weight. The changes induced by OSC, particularly the reduction of marrow space, continued to increase in this dose-range. Thus, OSC at 20 nmoles/kg of body weight was significantly more potent than FTA at preventing trabecular lattice breakdown and marrow space expansion in OVX rats, probably by effectively inhibiting osteoclasts. Cellular and kinetic indices showed that all PTH analogs significantly increased mineralizing surfaces and bone formation rate, but not osteoblast surface density or mineral apposition rate. Only, FTA and OSC significantly increased the reduction in osteoclast surface density and eroded space that normally occurs late after OVX. Therefore, PTH analogs stimulated osteoblast lineage cells at a non-mineralizing transitional stage and inhibited mature osteoclasts. In rat calvaria organ and cell cultures, and bone marrow co-culture models, intermittent pulsing with PTH analogs (10nM) showed that OSC, but not the other peptides, significantly increased parietal bone thickness and reduced calvaria eroded space, reduced TRAP stain intensity and increased the rate of bone nodule formation. RT-PCR also showed that the PTH analogs stimulated the expression of osteoblast differentiation markers, but reduced osteoclast markers, and

lowered the RANKL:OPG ratio. These results show that these primary in vitro systems can reproduce the cellular mechanisms underlying PTH analog actions in vivo. In conclusion, this study indicates that FTA, OSN and OSC drive committed osteoblast lineage cells toward bone-making, and OSC is the most effective osteoclast inhibitor that potently preserves bone structure after OVX.

Teriparatide Reduces Vertebral Height Loss in Women With Osteoporosis and Severe Prevalent Vertebral Fractures. H. K. Genant[1], S. Prevrhal[2], G. G. Crans*[3], E. V. Glass*[3], J. H. Krege*[3]. [1]UCSF-OARG and Synarc Inc., San Francisco, CA, USA, [2]UCSF-OARG, San Francisco, CA, USA, [3]Eli Lilly and Company, Indianapolis, IN, USA.

In the Fracture Prevention Trial, a randomized, placebo-controlled study of 1637 postmenopausal women with osteoporosis, teriparatide [rhPTH (1-34)] increased bone mineral density and reduced fracture risk (Neer 2001). Prevalent and incident vertebral fractures were defined using a visual semi-quantitative method (Genant 1993). To assess the effects of teriparatide on preservation of vertebral height, we assessed quantitative morphometry (QM) of baseline and study endpoint spine radiographs from teriparatide 20 mcg/day (TPTD20, N=95) and placebo (N=86) treated patients with prevalent severe vertebral fractures. An investigator blinded to patient group assignment determined anterior, middle, and posterior heights for each T4-L4 vertebra. For each patient, the difference in vertebral height (mm) from baseline to study endpoint was measured by QM at 3 locations (anterior, midpoint, and posterior) for each vertebra (L1-L4 and T4-T12). The outcome measure for each patient was the maximum height loss among all these height differences. Treatment group means, of the maximum height loss, were compared using a two-sided t-test at significance level 0.05. Vertebral height loss in the TPTD20 group was significantly reduced versus placebo (Figure, t-test P<0.001). In women with new vertebral fractures, height loss of fractured vertebrae in the TPTD20 group was significantly reduced versus placebo group, -3.4 mm versus -11.5 mm, respectively (Figure, P<0.001). In summary, teriparatide reduced vertebral height loss and fracture-associated vertebral height loss versus placebo.

The Cost-Effectiveness of Parathyroid Hormone and Alendronate in High-Risk Osteoporotic Women. H. Liu*[1], K. Michaud*[2], S. Nayak*[3], D. B. Karpf*[4], D. K. Owens*[3], A. M. Garber*[3]. [1]Endocrinology & Metabolism and Center for Primary Care and Outcomes Research, Stanford University, Stanford, CA, USA, [2]Center for Primary Care and Outcomes Research, Stanford University, Stanford, CA, USA, [3]Veterans Affairs Palo Alto Healthcare System and Center for Primary Care and Outcomes Research, Stanford University, Palo Alto, CA, USA, [4]Endocrinology & Metabolism, Stanford University, Stanford, CA, USA.

Osteoporosis is a common and costly disease. Parathyroid hormone [1-34] (PTH) is a promising new agent for the treatment of osteoporosis although its cost-effectiveness is unknown. The purpose of our study was to evaluate the cost-effectiveness of PTH-based treatment strategies compared to the current market leader, alendronate, for the first-line treatment of high-risk postmenopausal osteoporosis. We developed a microsimulation incorporating fracture-type and individual risk to compare placebo vitamin D and calcium sufficiency to three treatment strategies: life-long alendronate (ALN), two years of PTH (PTH-Alone), and two years of PTH followed by life-long alendronate (PTH->ALN). We used studies identified in a search of MEDLINE and U.S. data sources whenever possible. Long-term anti-fracture efficacy for PTH and alendronate was extrapolated from available data. Our reference population was treatment-naïve 70-year old osteoporotic Caucasian women with pre-existing vertebral fracture. We employed a lifetime horizon and societal perspective. Our primary outcome was cost per quality-adjusted life-year (QALY) gained. We discounted costs and QALYs at a 3% annual rate. In our reference case, the incremental cost-effectiveness ratio (ICER) was $42,000/QALY for ALN and $92,000/QALY for PTH->ALN. PTH-Alone was dominated and did not appear on the cost-effectiveness frontier even if its anti-fracture efficacy was assumed to persist for 20 years after cessation of PTH. In scenario analysis, PTH->ALN was consistently less cost-effective than ALN; under reference case assumptions for ALN, PTH->ALN would be less cost-effective than ALN even if PTH->ALN could reduce fracture rates to zero percent. Our results were sensitive to the cost of medication. If the cost of PTH was reduced by 50%, PTH->ALN would be more cost-effective than ALN; if the cost of alendronate was reduced by 75%, ALN would be cost-saving. The cost-effectiveness of PTH-Alone is inferior to ALN and PTH->ALN. While PTH->ALN is less cost-effective than ALN, significant reductions in the cost of PTH could substantially improve the cost-effectiveness of this treatment strategy.

Baseline Characteristics of Subjects Enrolled during the First 18 Months of DANCE: Direct Assessment of Non-Vertebral Fractures in Community Experience. D. T. Gold*[1], W. Shergy*[2], P. Chen*[3], D. A. Misurski*[3], R. B. Wagman[3]. [1]Department of Psychology, Duke University Medical Center, Durham, NC, USA, [2]School of Medicine, University of Alabama, Huntsville, AL, USA, [3]Eli Lilly and Company, Indianapolis, IN, USA.

The randomized placebo-controlled clinical trial experience may differ from community practice. When recombinant teriparatide (TPTD) studies were initiated, therapeutic options for osteoporosis were limited. DANCE examines the long-term effectiveness, safety, and tolerability of TPTD in a large diverse patient population, including subjects with co-morbidities, severe osteoporosis, and/or prior osteoporosis therapy. About 4000 men and women will ultimately participate in this prospective observational trial. They will receive TPTD 20 mcg/day for up to 24 months and will be followed for another 24 months. All aspects of patient care, including diagnostic and therapeutic interventions, will be conducted by study physicians. As of February 1, 2005, 1148 subjects enrolled. Baseline demographics and those of the TPTD clinical trial populations are provided (Table). Age and lumbar spine (LS) BMD values were similar to the clinical trials. 836 subjects had ≥ 1 prior fractures. There were a total of 522 prior non-vertebral fragility fractures in 257 subjects. The most common were: ribs (19.0%), foot/toes (13.6%), hip (12.5%). A total of 522 prior vertebral fragility fractures were documented in 244 subjects. The most common were: L1 (14.2%), T12 (13.6%), T7 (10.0%). 424/522 (81.2%) of prevalent vertebral fragility fractures were associated with back pain. 88.3% of subjects received prior osteoporosis therapy [bisphosphonates (79.1%), hormone replacement (26.1%), calcitonin (23.8%), raloxifene, (15.7%)]. 21.8% received both hormone replacement and bisphosphonates. 941/1144 (82.3%) had ≥ 1 active medical conditions including: corrective lenses (57.2%), hypertension (35.9%), pulmonary disease (17.1%), rheumatoid arthritis (11.9%). 217/1147 (18.9%) had a history ≥ 1 cancers including: breast (6.8%), skin (6.2%), colon (1.4%), uterine (1.2%), ovarian (0.9%). Further examination of this heterogenous population will provide information about the TPTD clinical experience, facilitating an evidence-based approach to patient management.

Baseline Subject Demographics

	DANCE (18 months) mean ± SD (n = 1146)	Fracture Prevention Trial[1] mean ± SD (n = 1637)	Orwoll et al.[2] mean ± SD (n = 437)
Age (Women)	69.5 ± 11.5 (n = 1023)	69.5 ± 7.0	/
Age (Men)	65.9 ± 12.7 (n = 123)	/	58.7 ± 13.0
Caucasian	92.9%	98.7%	99.1%

Rationale and Evidence for Initiating Teriparatide Therapy: Interim Results from DANCE. S. L. Silverman[1], P. D. Miller[2], N. B. Watts[3], P. Chen*[4], D. A. Misurski*[4], R. B. Wagman[4]. [1]Division of Rheumatology, Cedars Sinai Medical Center, Beverly Hills, CA, USA, [2]Department of Medicine, Colorado Center for Bone Research, Lakewood, CO, USA, [3]Bone Health and Osteoporosis Center, University of Cincinnati, Cincinnati, OH, USA, [4]Eli Lilly and Company, Indianapolis, IN, USA.

Recombinant teriparatide (TPTD) efficacy has been demonstrated in clinical trials, but experiences in community practice may differ. The Direct Assessment of Non-vertebral Fracture in Community Experience (DANCE) study is a prospective observational study examining the long-term effectiveness, safety, and tolerability of TPTD in a large heterogeneous population in the community setting. To better understand the rationale and evidence used to initiate TPTD, we reviewed baseline fracture status, baseline BMD T-scores, and a physician questionnaire for 1148 subjects at 89 sites enrolled in DANCE by

February 1, 2005. Physicians specializing in endocrinology, rheumatology, or internal medicine and those demonstrating an interest in osteoporosis have been invited. As of February 1, 2005, 1 to 50 subjects have been enrolled by any single site. Subjects invited were prescribed TPTD 20 mcg/day by their physician during routine practice. 257 subjects had prior non-vertebral fragility fractures (522 total non-vertebral fragility fractures), while 244 subjects had prior vertebral fragility fractures (522 total vertebral fragility fractures). Mean lumbar spine (LS) BMD T-score was -2.6 (n=817) and mean femoral neck BMD T-score was -2.5 (n=798). Distributions of LS T-scores, stratified by presence/absence of prevalent fragility fracture are shown (graph). When physicians were queried regarding reasons for TPTD initiation, 84.2% of subjects were felt to have multiple fracture risk factors; of these, 63.1% were believed to have very low BMD, 38.5% had previous osteoporotic fracture, 19.3% sustained a new osteoporotic fracture, and 12.6% cited height loss. Of the 71.4% of subjects who initiated TPTD because of failure on previous osteoporosis therapies, 42.6% had a decline in BMD, 20.4% had fractured while on other osteoporosis therapy, and 14.2% had no change in BMD.Several factors, in addition to BMD, seemed important in the decision to initiate TPTD therapy. Continued collection of data will help elucidate the rationale and level of evidence used when initiating TPTD therapy.

Bone Marker Changes in One Month Treatment with Teriparatide (LY 333334) Injections (rDNA origin) in Men and Post-Menopausal Women with Severe Osteoporosis. A. Acosta[1], M. Rivas[1], K. Roman*[2]. [1]PRSA Medical, Eli Lilly and Company, San Juan, Puerto Rico, [2]External Assessor, Eli Lilly and Company, San Juan, Puerto Rico.

There is evidence about calcium metabolism & fracture incidence variations across ethnic groups and geographic regions (Melton&Cooper 2001, Laudarle 1997,Bryan 2003). Overall weighted prevalence of osteoporosis among Puerto Rican postmenopausal women without vertebral fracture was 29% (95CI 25.4, 34.4%) in a population-based study (Haddock 2004). However, bone metabolism changes in response to osteoporosis treatment has not been studied in the Puerto Rican population. To answer this question, a prospective, multi-center, cohort, randomized trial of 60 severely osteoporotic patients was conducted in 10 specialty outpatient clinics primarily to evaluate bone metabolism marker changes (resorption and formation) after one month of treatment with 20 mcg of teriparatide. A secondary objective was to identify these patients' osteoporosis risk factors by using the Millennium One-Minute Osteoporosis Risk-Test. All patients received approximately 1000mg/day of elemental calcium and 400 to 1200 IU/day of vitamin D. A total of 57 patients were entered: 96% women and 4% men. Average age for all patients was 70 years, CI 95% (68,73). Fifty percent or more of the patients in this cohort had the following risk factors for osteoporosis: menopause before age 45 and a history of low impact fracture, 67.4% reported 1.2 inches lost in height. Forty-five (79%) patients received at least one dose of study drug; 41 (72%) completed the study. Two patients were discontinued early from the study by the investigators due to non-serious adverse events. A paired *t*-test was performed in order to evaluate P1CP changes after one month of teriparatide treatment. The average difference in P1CP levels was 40 ug/L, CI 95% (23.6, 57.1), (p=0.001). Adjusting for previous use of bisphosphonates and after a one-month washout period, statistically significant differences were observed between baseline and final P1CP values using a random effect model (p=0.000). The relationship between bisphosphonate use and P1CP values was not statistically significant (p = 0.30). The average difference in NTx levels was 0.20 nmol BCE/L, CI 95% (-1.16, 1.6), (p=0.76). In conclusion, statistically significant increase of a bone formation marker, P1CP, but no change of a bone resorption marker, NTx, were observed in severely osteoporotic Puerto Rican patients after one month of treatment with teriparatide and a one-month bisphosphonate washout period. NTx changes may not have been observed because of the relatively short bisphosphonate washout period or suggest an anabolic window effect.

Ostabolin-C™: A Novel Parathyroid Hormone Analogue Uncouples Bone Turnover in Monkeys Treated for 1-Year. J. Jolette*[1], S. Y. Smith[1], I. A. Moreau*[1], C. H. Turner[2], J. Mayer*[1], B. Rushton*[3], P. Morley*[4]. [1]Charles River Laboratories Preclinical Services•CTBR, Senneville, PQ, Canada, [2]Indiana University, Indianapolis, IN, USA, [3]Zelos, Stevenage, United Kingdom, [4]Zelos Therapeutics, Ottawa, ON, Canada.

Ostabolin-C™ (Leu[27], Cyclo[Glu[22]Lys[26]]-hPTH[1-31]amide), a novel parathyroid hormone (PTH) analogue being developed for the treatment of osteoporosis, was administered daily by subcutaneous injection to gonad-intact cynomolgus monkeys (4/sex/group) at dose levels of 0, 2, 10 and 25 µg/kg for 52 weeks to evaluate toxicity. Monkeys were 30 to 40 months of age (2.3-3.5 kg) at treatment start. Blood and urine samples were collected to measure biochemical markers of bone turnover and tibiae were retained for histomorphometry following labeling with calcein green 15 and 5 days prior to euthanasia. Ostabolin-C™ was well tolerated with no hypercalcemia observed in blood samples collected at Weeks 13, 26 or 39 or 52, approximately 24 hours post-dose. Bone turnover markers indicated a dual effect of Ostabolin-C™ since significant increases in the bone formation marker osteocalcin and significant decreases in the bone resorption marker C-telopeptide were observed. Another bone resorption marker, urinary DPD, did not differ from controls. In addition, bone mass, as measured by DXA and pQCT, was increased at the lumbar spine, femur and tibia. Changes in vertebral BMD translated into significant increases in bone strength. Ostabolin-C™ substantially increased osseous accretion in the cancellous and endocortical bone compartments of the proximal tibia at all doses. Tibial cancellous bone volume increased by more than 50% in all Ostabolin-C™-treated groups compared to controls and in the tibial mid-diaphysis, increases in cortical width and relative cortical area with concurrent decreases in medullary area were observed. Only minor increases in cortical porosity were observed at the two highest dose levels. The increase in bone mass appeared to be related to increases in bone formation and decreases in bone resorption as measured by a significant reduction in osteoclast surface. In conclusion, the results of this study are consistent with the anticipated anabolic effects of Ostabolin-C™ as a PTH analogue. However, increases in indices of bone formation were associated with decreases in indices of bone resorption (decreased bone resorption markers and decreased osteoclast surface area), consistent with the uncoupling of these events. To summarize, Ostabolin-C™ increased bone formation activity and reduced bone resorption in skeletally immature monkeys. This combination of anabolic and anti-catabolic actions may have significant therapeutic value in the treatment of osteoporosis.

What Percent of Women with Postmenopausal Osteoporosis Experience an Increase in Lumbar Spine BMD Following 18-Months of Teriparatide Treatment? J. C. Gallagher*[1], C. J. Rosen[2], P. Chen*[3], D. A. Misurski*[3], R. Marcus[3]. [1]Bone Metabolism Unit, Creighton University Medical Center, Omaha, NE, USA, [2]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA, [3]Eli Lilly and Company, Indianapolis, IN, USA.

Physicians frequently ask what BMD responses can be expected in their teriparatide-treated patients. We therefore determined the BMD response rate, defined as the proportion of women with postmenopausal osteoporosis (PMO) whose lumbar spine (LS) BMD responses after 18 months of TPTD met or equaled the least significant change (LSC), in two randomized controlled trials. The first involved teriparatide 20 mcg/day (TPTD20) and 40 mcg/day (TPTD40) (Neer et al. *N Engl J Med* 2001). The second trial involved TPTD20 (McClung et al. 2005 (in press)). Subjects in both trials had minimal prior exposure to bisphosphonates and all received supplemental calcium and vitamin D. We assumed the DXA index of precision to be 1%, giving an LSC value of 3%. Only women who had LS BMD measurements at all specified time points through 18 months were included in this analysis. For the commercially availableTPTD20 dose, 91% (118/129) of women achieved an increase in LS BMD ≥ 3% at 18 months. Of the 11 who did not, 3 had actually responded at 12 months. For TPTD40, 94% (118/125) achieved the 3% criterion at 18 months. Of the 7 who did not, 1 had responded at 12 months. There were no significant differences in the percent of women who responded to TPTD20 and TPTD40 at either 12 or 18 months. In the second trial, 94% (64/68) of women receiving TPTD20 had a LS BMD increase ≥ 3% at 18 months. 2 of the 4 patients who did not respond to TPTD20 at 18 months had responded at 12 months. Examination of baseline characteristics for women who were "non-responders" to TPTD showed no significant differences in age, baseline BMD, vitamin D status, or renal function compared to "responders". In addition, 73% (16/22) of BMD non-responders showed robust increases in the bone formation marker Procollagen Type I N-Propeptide (PINP) at 3 months, emphasizing the limitation of relying exclusively on BMD to identify responders. This analysis demonstrates that over 90% of treatment-compliant women with PMO and minimal prior bisphosphonate exposure have a LS BMD response to TPTD.

Combining Biomechanical Measures of Vertebral Strength with Estimates of Spinal Loading to Assess the Effects of Osteoporosis Therapies on Vertebral Fracture: A Pilot Study in PaTH. M. L. Bouxsein[1], D. M. Black[2], J. Muller*[1], J. Bilezikian[3], S. Greenspan[4], K. Ensrud[5], L. Palermo*[2], P. M. Crawford*[6], C. J. Rosen[7], T. M. Keaveny[6]. [1]BIDMC, Boston, MA, USA, [2]UCSF, San Francisco, CA, USA, [3]Columbia Univ., New York, NY, USA, [4]Univ of Pittsburgh, Pittsburgh, PA, USA, [5]Univ of Minnesota, Minneapolis, MN, USA, [6]ON Diagnostics, Berkeley, CA, USA, [7]MECORE, Bangor, ME, USA.

Osteoporosis therapies reduce vertebral fracture risk to a greater extent than are predicted based on changes in areal BMD (aBMD). One explanation for this discrepancy is that aBMD measurements do not adequately reflect effect of treatment on bone strength. An alternative, but complementary explanation is that changes in BMD alone do not reflect the relationship between skeletal loading and bone strength that ultimately determines the probability of fracture. Introduced by Hayes et al (1991), the 'factor of risk' approach proposed the ratio of applied load to whole bone strength as a method for fracture risk assessment. To explore the clinical utility of this biomechanically-based fracture risk assessment in the context of osteoporosis treatment, we conducted a pilot study in 19 randomly selected postmenopausal women from the PaTH study who were treated for 1 yr with PTH(1-84) 100 mcg sq daily plus calcium and vit D. QCT-based finite element models were used to measure lumbar vertebral strength before and after treatment. A biomechanical model of the spine was used to estimate the subject-specific compressive load on the lumbar vertebrae during forward flexion with 10 kg in the hands. The factor of risk for vertebral fracture (Φ) was computed as the ratio of spinal load to vertebral strength where theoretically, fracture occurs when $\Phi > 1$. **Results**: Following treatment the distribution of Φ shifted towards lower values (ie. to the left), indicating a reduced risk for vertebral fracture (Figure). The mean values, SD and range of Φ were 0.73 ± 0.16 (0.48-1.05) and 0.58 ± 0.15 (0.33 - 0.83), pre- and post-treament, respectively. Defining high fracture risk when $\Phi > 0.90$, 4 of 19 (21%) subjects were at high risk for fracture at baseline, whereas none were after treatment. In summary, this pilot study demonstrates the potential utility of an approach that combines biomechanical measures of bone strength with estimates of skeletal loading to assess the effects of osteoporosis therapies on fracture risk.

Early Change in Bone Turnover Following Teriparatide (RhPTH 1-34) in the Eurofors Study: Influence of Prior Therapy and Association with BMD Change at One Year. A. Blumsohn[1], K. Brixen*[2], G. Sigurdsson*[3], F. Marin*[4], P. Ochs*[4], S. Liu-Leage*[4], A. Graebe*[4], R. Eastell[1]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Dept of Endocrinology, Universitetshospital, Odense, Denmark, [3]Landspitalinn University Hospital, Reykjavik, Iceland, [4]Eli Lilly & Company, Windlesham, United Kingdom.

We examined the performance of three markers of bone formation following teriparatide. EUROFORS is an ongoing randomized prospective study of teriparatide in postmenopausal osteoporosis with or without prior antiresorptive (AR) therapy. During year one patients received open-label teriparatide (20 µg/d) with Ca (500 mg/d) and Vitamin D (400-800 IU/d). Participants were pre-defined as osteoporosis treatment-naïve (Group 1), or with adequate clinical response (Group 2) or inadequate response (Group 3) to prior AR therapy. 87.7% of patients with AR exposure used a bisphosphonate for a mean 33.5±30.7SD months. Markers of bone formation included serum procollagen I N-terminal Propeptide (PINP; Roche Diagnostics), bone specific alkaline phosphatase (BAP; Beckman Coulter Inc) and total alkaline phosphatase (TAP) at baseline, 1 month and 6 months of teriparatide. An additional sample was collected between 3-14 days of the 6 month visit in 82 women to determine repeat-test precision of assessment on teriparatide. The proportionate increases (mean,SEM) from baseline are tabulated by subgroup.

Group (N)	1 (182)	2 (177)	3 (398)
Pre Rx PINP ug/L	55.2±2.5	35.1±2.0	33.9±1.3
PINP %Δ1m	103±9	167±18	166±9
PINP %Δ6m	252±22	620±66	609±34
BAP %Δ1m	16.7±2.8	22.5±2.6	26.3±1.9
BAP %Δ6m	61.4±5.2	97.5±9.4	108.3±5.4
TAP %Δ1m	6.5±1.8	8.7±1.8	9.4±1.1
TAP %Δ6m	24.4±2.6	34.6±4.0	37.9±2.2

PINP showed by far the largest change in response to therapy. Individuals with prior AR had lower baseline values for each marker, but response after 6 months of teriparatide was not blunted. The absolute value of each marker on therapy at 6 months was independent of prior therapy (ANOVA all P>0.7). The repeat test CV of the three markers on therapy were similar (CV% nested ANOVA; PINP=9.9%; BAP=6.8%; Total AP=7.0%). The signal to noise ratio (%Response/CV%) was largest for PINP (S/N=53, 14 and 5 for PINP, BAP and TAP respectively at 6 months for all groups). Indices of bone formation or change in formation were only modestly predictive of change in BMD at the spine or total hip at 1 year. We conclude that PINP is likely to be the most sensitive marker to detect response to therapy. The response of bone formation markers in patients on teriparatide does not appear to be adversely influenced by prior antiresorptive therapy.

Structural Analysis of Vertebral Trabecular Bone Structure Allows to Assess the Effect of Teriparatide Treatment Independently of BMD. C. Graeff*[1], W. Timm*[1], J. Farrerons*[2], T. N. Nickelsen[3], E. Blind[4], J. Kekow*[5], R. Möricke*[6], S. Boonen*[7], M. Audran*[8], C. C. Glüer[1]. [1]Med. Physik, Klinik f. Diag. Radiologie, UK SH, Kiel, Germany, [2]Hospital Santa Creu I Sant Pau, Barcelona, Spain, [3]Eli Lilly & Company Europe, Bad Homburg, Germany, [4]Med. Universitätsklinik, Würzburg, Germany, [5]Fachkrankenhaus Rheumatologie, Vogelsang, Germany, [6]Endokrinolog. Praxis, Magdeburg, Germany, [7]University of Leuven, Leuven, Belgium, [8]Centre Hospitalier Universitaire, Angers, France.

We have developed a method based on High Resolution Computed Tomography (HRCT) for following treatment-induced changes in bone structure in the vertebrae in vivo[1)]. Here we demonstrate that the effect of teriparatide (TPTD) treatment over one year can be measured at a central fracture site, the T-12 vertebrae. In the Eurofors study, osteoporotic women received 20 µg/d of TPTD over one year. Prior to study start most patients had received antiresorptive treatment, and a large fraction of them had not showed adequate response to this treatment. A third group had not received such treatment. HRCT scans were conducted at baseline, 6 and 12 months. Microstructural variables were named analogous to standard histomorphometry nomenclature; a prefix "a" (for "apparent") was added to indicate that variables are affected by the limits in spatial resolution (e.g. aBV/TV). Complete structural data were available for 67 patients aged 69.4 ± 6.8 years, and BMD of L1-3 was measured by QCT in 59 patients. All measured structural variables showed significant ($p<0.0001$) improvements under TPTD, see table. Increases were consistently larger during the first 6 months of treatment. TPTD response did not differ among the three pre-study treatment groups. Changes in structure and BMD over 6 months correlated with $r^2 = 0.18$ to 0.25, over 12 months with $r^2 = 0.3$ to 0.5. Compared to BMD the increases in aBV/TV (normalized to standard deviations at baseline) were larger at 6 months ($p = 0.003$) and 12 months ($p = 0.001$).

Variable	Baseline	Increase over 6 months		Increase over 12 months	
		[SD baseline]	[%]	[SD baseline]	[%]
aBV/TV	0.10 ± 0.05	0.35 ± 0.40	20.8%	0.55 ± 0.63	34.3%
aTb.N	0.36 ± 0.16 1/mm	0.27 ± 0.36	16.5%	0.40 ± 0.52	25.8%
aTb.Th	0.29 ± 0.04 mm	0.2 7 ± 0.34	4.0%	0.41 ± 0.50	6.2%
aTb.Sp	2.72 ± 1.24 mm	-0.12 ± 0.19	-9.5%	-0.17± 0.31	-13.9%
BMD	51.2 ± 19.1 mg/cm^3	0.20 ± 0.47	10.4%	0.38 ± 0.48	16.8 %

Baseline results and increases in SD of baseline under TPTD treatment (mean±SD) TPTD treatment effects on bone structure can be monitored non-invasively. For aBV/TV treatment response is larger than for BMD, especially in the early phase of the treatment.

The Effect of Teriparatide Treatment on Quantitative Ultrasound in Women with Established Osteoporosis. S. Gonnelli, G. Martini, C. Caffarelli*, S. Salvadori*, A. Montagnani*, A. Cadirni*, R. Nuti. Department Internal Medicine, University of Siena, Siena, Italy.

Since BMD measurement by DXA does not seem able to register all the changes induced in bone by Teriparatide [hPTH (1-34)] and may give misleading results there is a pressing need to explore the utility of other diagnostic modalities in the non-invasive assessment of the effects of Teriparatide on bone. This study aimed to determine whether Teriparatide influences Quantitative Ultrasound (QUS) parameters and to compare the changes of QUS with that of BMD. Fifty-two postmenopausal women (aged 70.9 ± 8.1 years) with established osteoporosis under treatment with antiresorptive drugs for at least 12 months were studied. The patients, after a 1-month run-in phase during which they received only daily supplements of calcium(1000 mg) and vitamin D (400 IU), were randomly assigned to either once daily 20 µg Teriparatide (FORSTEO, Eli Lilly and Co) s.c. injection (n=26) or to continue the previous antiresorptive treatment (n=26). Here we report the 10 month interim results. At baseline and at 2-month intervals we measured QUS at calcaneus, by Achilles-GE, Lunar (speed of sound: SoS, broadband ultrasound attenuation: BUA and Stiffness: S), at phalanxes, by Bone Profiler-IGEA (amplitude dependent speed of sound: AD-SoS, bone transmission time: BTT, fast wave amplitude: FWA) and BMD at right hand (BMD-H) by DXA-GE Lunar. BMD at lumbar spine and at femur (GE Lunar) was measured on a 6 monthly basis. Teriparatide significantly reduced BMD-H at month 4 (-2.2%, $p<0.01$) and at month 6 (-3.9%, $p< 0.001$) thereafter BMD-H returned progressively to basal values. In the Teriparatide group AD-SoS showed significant change only at month 4 (-1.7%, $p<0.05$) whereas BTT decreased significantly

(p<0.01) at all time points and FWA increased at month 6 (13%) at month 8 (12,7%) and at month 10 (6%). At month 6 the changes in BTT and BMD were significantly(p<0.05) correlated. The patients treated with antiresorptives did not show any significant changes in QUS at phalanxes and BMD-H. At month 10 the changes in S was similar in patients treated with Teriparatide and in those treated with antiresorptive drugs (2.1 % vs 1.5%). The changes in BMD-LS at month 6 were significantly (p<0.01) higher in the Teriparatide group (5.6% vs 0.7%). In conclusion Teriparatide determined a notable, even though transient, decrease in BMD-H and differently influenced diverse ultrasound signal parameters (e.g. FWA increase and BTT decrease). This suggests that some QUS parameters (e.g. FWA/BTT ratio) could represent a potential instrument in monitoring bone response to Teriparatide in osteoporotic patients.

Treatment of Osteopenic Rhesus Monkeys with Parathyroid Hormone 1-84 for 16 Months Improves Vertebral Trabecular Bone Quantity and Quality. I. A. Moreau*[1], S. Y. Smith[1], R. E. Guldberg[2], C. H. Turner[3], M. K. Newman*[4], J. Fox[4]. [1]Charles River Laboratories Preclinical Services•CTBR, Senneville, PQ, Canada, [2]Georgia Institute of Technology, Atlanta, GA, USA, [3]Wyeth University, Indianapolis, IN, USA, [4]NPS Pharmaceuticals, Salt Lake City, UT, USA.

Densitometry, histomorphometry and biomechanical studies have shown that daily treatment of osteopenic rhesus monkeys with parathyroid hormone 1-84 (PTH) increased vertebral bone density and significantly improved biomechanical competency by stimulating new bone formation. To assess local mechanisms of altered function, PTH-induced changes in trabecular architecture in thoracic vertebrae were evaluated by micro-computed tomography (μCT). T10 vertebrae from Sham and ovariectomized (OVX) controls, and OVX animals treated with PTH at 5, 10 or 25 μg/kg/day (8 to 10 animals/ group) were scanned (VivaCT 40, Scanco). Results were compared with indices of bone strength from compression testing of T11/T12 vertebral cores. Relative to OVX controls, all PTH-treated groups demonstrated increased bone volume fraction (BV/TV) with associated increases in trabecular number (Tb.N), thickness (Tb.Th) and connectivity (Conn.D). Increasing the dose from 10 to 25 μg/kg/day caused further increases in Tb.N and Conn.D, but not BV/TV or Tb.Th. However, a 39% improvement of yield stress in T11/T12 cores from the 10 g/kg/day group was reduced to 29% in animals given 25 μg/kg/ day. This apparent reversal in strength may be due, in part, to increased bone turnover, activation frequency and osteoid synthesis. The dose-related decrease in the structural model index (SMI) in the 5 and 10 g/kg/day groups was also partially reversed with high dose PTH, possibly contributing to the reversal in strength at this dose. A decrease in SMI is consistent with tunneling of thickened trabeculae as the mechanism to increase Tb.N, and modification of architecture from a rod-like to more plate-like structure. High dose PTH in this monkey study uniquely showed that higher bone turnover rates were not associated with further increases in BV/TV, but were associated with increased Conn.D and partial reversal of effects on SMI and bone strength. Treatment at 25 μg/kg/day increased bone turnover resulting in a greater proportion of newly mineralizing bone that may have lower strength. Data for monkeys treated with PTH at 5 or 10 μg/kg/day are consistent with human iliac crest biopsy data where higher bone formation with trabecular tunneling also resulted in increased Conn.D and a decrease in SMI (ASBMR 2005). This study demonstrates that PTH treatment improves biomechanical integrity by altering both the quantity and quality of trabecular bone in a dose-dependent manner.

The Effect of Teriparatide on Bone Remodeling Is not Related to Serum Levels of Osteoprotegerin and RANKL. G. Martini, S. Gonnelli, B. Franci*, M. Campagna*, A. Avanzati*, S. Salvadori*, L. Gennari, R. Valenti, C. Caffarelli*, B. Lucani*, R. Nuti. Department of Internal Medicine, University of Siena, Siena, Italy.

In vitro studies indicate that parathyroid hormone (PTH) decreases osteoprotegerin (OPG) secretion by the osteoblasts and increases RANKL production. Studies in healthy men have shown a negative correlation between endogenus PTH and serum OPG; moreover a decrease of serum OPG with an increase of serum RANKL have been reported by an interventional study where postmenopausal women with glucocorticoid osteoporosis were treated with intermittent injections of PTH. The aim of this study is to evaluate the behaviour of serum OPG and RANKL in women with established postmenopausal osteoporosis treated for six months with teriparatide (20 μg/die).We enroled 21 women (aged 71.5 ± 7.8 years) with one or more vertebral fractures and a T-score at densitometric examination of lumbar spine or proximal femur lower than -2.5. Patients on treatment were included in the study after a three months wash-out period. As control group, we studied 15 age-matched women. A blood sample was drawn from each patient at baseline and after two, four and six months from the beginning of teriparatide administration. Bone turnover was evaluated by: specific bone alkaline phosphatase (BSAP), osteocalcin (BGP), and intact N-terminal propeptide of type I procollagen (PINP) as markers of bone formation; C-telopeptides of Type-I collagen (CTX) as markers of bone resorption. Serum OPG and RANKL were assessed using a sandwich enzyme immunoassay (Osteoprotegerin and RANKL, Biomedica, Austria). Precision intra and interassay was lower than 10%. Basal values of bone markers, serum OPG and RANKL in treated patients and control group did not differ significantly. No correlations were found between bone markers and serum OPG and RANKL at baseline. Patients on teriparatide treatment showed a significant increase in both formation and resorption markers. The increase of BGP and PINP resulted statistically significant after two months, while the increase of CTX became significant after four months. The highest values of all markers were found at sixth months. Serum OPG and RANKL levels did not change significantly, though they showed a tendency to increase. OPG peaked at fourth month, while the highest value of RANKL was found at sixth month. These data confirm that teriparatide stimulates bone formation by activating osteoblast function which leads, later, to osteoclast activation. Serum OPG and RANKL do not appear to be involved in parathyroid action on bone.

Evidence that the Cellular Mechanisms Responsible for the Anabolic Effect of Intermittent PTH Are Different in Murine Cancellous and Periosteal Bone. A. A. Ali, C. A. O'Brien, I. Gubrij, R. A. Wynne*, A. M. Parfitt, R. S. Weinstein, S. C. Manolagas, R. L. Jilka. Div. Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Intermittent administration of PTH to animals and humans stimulates bone formation on both cancellous and periosteal bone surfaces, but the underlying mechanisms are unclear. Intermittent PTH increases the number of osteoblasts on murine cancellous bone, at least in part, by attenuating their apoptosis (from a prevalence of ~12% to ~4% by ISEL labeling). To investigate the role of lining cell activation, we generated mice expressing thymidine kinase (tk) in cells of the osteoblast lineage under the control of the 3.6-kb fragment of the collagen promoter (Col3.6-tk mice). Immunolabeling indicated expression of the transgene in cancellous and periosteal bone cells. Consistent with earlier evidence for an osteoblast lifespan of ~10 days in murine cancellous bone, daily administration of ganciclovir (8 mg/kg) to 4-5 month old Col3.6-tk mice caused a gradual loss of cancellous osteoblasts over a 2 week period as they died naturally by apoptosis or became osteocytes, but could not be replaced by replicating progenitors. Lining cells were unaffected as determined by immunostaining for tk and the osteoblast lineage marker N-cadherin. Nevertheless, daily injections of 100 ng/g PTH(1-34) (along with ganciclovir) for an additional 2 weeks failed to stimulate bone formation in cancellous bone. Moreover, reactivation of the available lining cells to become osteoblasts did not occur. We now report that the prevalence of osteoblast apoptosis in periosteal bone is ~10-fold lower than in cancellous bone. Moreover, osteoblast number and bone formation rate (BFR) on the periosteal bone surface were unaffected by 2 weeks of ganciclovir administration to Col3.6-tk mice. Administration of PTH for an additional 2 weeks failed to stimulate periosteal bone formation in contrast to the 3-4-fold increase in BFR at this site in PTH-treated mice not given ganciclovir. These findings indicate that osteoblast lifespan in periosteal bone is much longer than in cancellous bone, reducing the potential importance of reduced apoptosis in the anabolic effect of PTH at this site. Moreover, maintenance of periosteal osteoblast number over a 4 week period is not as dependent on replacement by replicating progenitors as it is in cancellous bone. Hence, the anabolic effect of intermittent PTH on periosteal bone must involve actions of PTH on osteoblast progenitors that result in increased replication or differentiation, attenuation of their apoptosis, or a combination of these effects.

Oral Administration of ANABU™ (GlcNBu) to Ovariectomized (OVX) Rats Increases Bone Mineral Density (BMD), Long Bone Growth and Modulates Gene Expression in the Liver. T. P. Anastassiades, X. Yang*, J. Carran*, K. Rees-Milton*, D. Wainman*. Medicine, Rheumatology, Queen's University, Kingston, ON, Canada.

In previous studies, we had shown increased BMD in the long bones of an inlammatory arthritis model in the rat, by feeding GlcNBu (N-butyryl glucosamine). The aim of this study is to determine if oral admininistration of GlcNBu affects BMD, bone growth and gene expression in the non-OVX and the OVX-rat model. Female Sprague Dawley rats were randomized into four Groups (8 animals each). In addition to their normal diet, the animals were fed on a daily basis (once a day), with either of GlcNBu 200 mg/kg, or an equimolar amount of glucose (Glc) for 6 months. Groups 1, 2, 3 and 4 were, respectively: Glc-fed, non-OVX, (Control); GlcNBu-fed, non-OVX; Glc-fed, OVX; GlcNBu-fed, OVX. The BMD and body composition was measured by DXA (Hologic 4500, small animal software) every 2 months. At sacrifice (6 months), femurs were removed for physical measurements. The total RNA from the liver was extracted (RNeasy Kit,Qiagen) and gene expression was assessed by microarray (rat 8K gene, fluorescent Cy3 and Cy5), with Group 1 serving as the control for each of Groups 2-4. The Results showed that there was increased length of femurs for Group 4 vs 3 and in femoral wet weights (trends), as well as for Group 2 vs 1 (Figure). As expected, OVX led to increased body mass. The BMD of Group 4 femoral heads were higher than Group 3. Total body mineral content + lean body mass was also highest in Group 4. By microarray (all compared to Group 1), the number of regulated genes (> 2-fold) in the liver were: Group 2, 13; Group 3, 40; Group 4, 57. A small number of genes were highly regulated only in Group 3. We conclude that oral administration of GlcNBu results in enhanced growth and increased BMD of femurs in the OVX rat. The microarray analysis (rat 8K gene chip) showed that a number of genes in the liver were remarkably regulated by GlcNBu. Comparisons of the 4 experimental Groups suggest that GlcNBu feeding selectively regulates some genes post-ovariectomy. Since some of the selectively up-regulated genes in Group 4 encode for cirulating protein growth factors, we speculate that this may constitute a mechanism of action for the effects of GlcNBu on bone.

A Non-Prostanoid EP4 Receptor Selective Prostaglandin E_2 Agonist Restores Bone Mass and Strength in Aged Ovariectomized (OVX) Rats. H. Z. Ke[1], D. T. Crawford*[1], H. Qi*[1], H. A. Simmons[1], T. A. Owen[1], V. M. Paralkar[1], M. Li[1], L. C. Pan[1], B. Lu*[1], W. A. Grasser[1], T. A. Brown[1], K. O. Cameron*[1], B. A. Lefker*[1], P. DaSilva-Jordine*[1], D. O. Scott*[1], W. S. S. Jee[2], D. D. Thompson[1]. [1]Pfizer Global R &D, Groton, CT, USA, [2]Univ. of Utah, Salt Lake City, UT, USA.

We reported that knockout of EP4 receptor led to low bone mass in mice. The purpose of this study was to determine whether a newly discovered, non-prostanoid EP4 receptor selective agonist, CP432, could produce bone anabolic effects in aged OVX rats with established osteopenia. CP432 binds to the EP4 receptor with an IC_{50} of 8 nM, while does not bind to other prostanoid receptors. CP432 stimulates the EP4 receptor to initiate signaling by the cAMP pathway with an EC_{50} value of 0.6 nM. CP432 at 0.3, 1 or 3 mg/kg/d was given for 6 weeks by s.c injection to 12-month-old rats that had been OVX for 8.5 months. Total femoral bone mineral density (TF-BMD) by DEXA increased significantly by 8%, 20% and 20% in OVX rats treated with CP432 at 0.3, 1 and 3 mg/kg/d, respectively, as compared with OVX controls. TF-BMD did not differ in OVX rats treated with CP432 compared with sham controls. Trabecular bone histomorphometry of the 3rd lumbar vertebral body showed that CP432 completely restored trabecular bone volume back to the levels of sham controls, accompanied with an increase in trabecular thickness and trabecular number. Compared with OVX controls, a dose-dependent decrease in osteoclast number (-52 to -62%) and osteoclast surface and a dose-dependent increase in mineralizing surface, mineral apposition rate and bone formation rate-tissue reference (+42% to +130%) were found in OVX rats treated with CP432. CP432 at 1 and 3 mg/kg/d significantly increased total tissue area (+18% to +30%) and cortical bone area (+17% to +30%) in the tibial shafts compared with both sham and OVX controls. At these doses, CP432 significantly increased periosteal and endocortical bone formation and significantly decreased endocortical bone resorption. CP432 at all doses significantly and dose-dependently increased ultimate strength in lumber vertebral body (+17 to +53%) compared with both sham and OVX controls. At 1 and 3 mg/kg/d, CP432 significantly increased maximal load in three point bending test of femoral shaft (+11% to +44%) compared with both sham and OVX controls. In summary, CP432 completely restored trabecular bone mass and strength to levels equal to sham controls, and restored cortical bone mass and strength to the levels greater than sham controls in established osteopenic, aged OVX rats by stimulating bone formation and inhibiting bone resorption on trabecular and cortical surfaces. These results suggest that EP4 receptor selective agonists have therapeutic potentials for osteoporosis.

Development of Polymeric Drug Delivery Systems that Can Differentially Target Bone Formation and Resorption Surfaces. D. Wang[1], S. C. Miller[2], B. L. Anderson[2], M. Sima*[3], P. Kopeckova*[3], J. Kopecek*[3]. [1]Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE, USA, [2]Radiobiology Division, University of Utah, Salt Lake City, UT, USA, [3]Pharmaceutics and Pharmaceutical Chemistry/CCCD, University of Utah, Salt Lake City, UT, USA.

The targeting of therapeutic agents to the skeleton and its different functional surfaces remains a particular challenge. Achieving this may enhance the efficacy of various drugs while reducing systemic side effects. Biocompatible water-soluble polymers provide a platform to attach various targeting moieties and drugs. The purpose of this study was to determine the ability of recently developed bone-targeting polymeric delivery systems to differentially recognize bone resorption or formation surfaces. For this, two bone-targeting moieties were compared; a bisphosphonate (Alendronate, Alen) and D-aspartic acid octapeptide (D-Asp_8). *N*-(2-hydroxypropyl)methacrylamide (HPMA) copolymers containing D-Asp_8 or Alen were synthesized via free radical copolymerization or polymer-analogous reaction. Fluorescein isothiocyanate (FITC) was attached to the polymers to served as a drug surrogate and a fluorescence detection probe. The delivery systems were administered (iv) to young male balb/c mice and female rats that had been ovariectomized (Ovx) for 3 months. Forty-eight hours prior to polymer injection, tetracycline was given as a marker for active bone mineralization. Bones were collected 24 hours after the polymer injection and undecalcified sections were prepared for evaluation by fluorescence microscopy. The Alen-containing delivery system was found to extensively label bone surfaces with particular uptake on bone formation sites (TC labeled). However, the D-Asp_8-containing delivery system had a preferential uptake for resorption surfaces. When the fluorochrome patterns were compared with subsequent histological analyses, D-Asp_8-containing delivery system uptake sites were authentic resorption surfaces covered by osteoclasts. These findings demonstrate the preferential skeletal uptake of the novel delivery systems and differential uptake on formation and resorption surfaces using a bisphosphonate or D-aspartic acid octapeptide as targeting moieties. Many therapeutic agents may be attached to these delivery platforms via tissue specific releasing mechanisms (structures that are sensitive to cathepsin K, low pH, etc). The application of this novel technology may greatly enhance the delivery of promising new or established therapeutic agents to the affected sites for a variety of skeletal diseases, including osteoporosis and cancer bone metastases, and subsequently improve their efficacy and safety profile.

β-Antagonists Effects on Bone Architecture and Bone Cell Activity in the Tibia of Ovariectomized Rats. N. Bonnet*[1], H. Beaupied*[1], N. Laroche*[2], I. Vico[2], E. Dolleans*[1], L. Benhamou[1], D. Courteix[1]. [1]U658 Inserm & ATOSEP, Orleans, France, [2]E0366 Inserm LBTO, St Etienne, France.

β-antagonists have been suggested to induce therapeutical effects on bone, but their effects on bone properties remain controversial . The aim of this study was to assess the effects of propranolol on both the trabecular/cortical bone architecture and biomechanical properties of the tibia. Sixty 6-month old Wistar female rats were divided into 5 groups. During 10 weeks SC daily injections were performed : 14 Sham rats and 14 ovariectomized (OVX) rats receiving normal saline (placebo), 42 OVX rats receiving propranolol (PRO: 100µg/kg/day n=14; 5mg/kg/day n=14; 20mg/kg/day n=14). Cortical and trabecular microarchitectural parameters were assessed by 3D microtomography. Propranolol effects were analysed by sequential Bone Mineral Density measurements (BMD, QDR1000W). Histomophometry was performed on the proximal metaphysis. Mechanical properties were measured using three-point bending tests. On the tibia, propranolol 5mg and 100µg had significant higher BMD than placebo whereas propranolol 20mg and placebo groups had significant lower BMD compared to Sham. Compared to baseline, placebo rats displayed a lower BV/TV (-54.7%, $p<0.001$) whereas propranolol 100µg treatment lowered bone loss (BV/TV of -8.6%). Propranolol 100µg group had a higher Tb.Th (6.81%, $p<0.001$), Tb.N (46.15%, $p<0.001$), and a lower SMI (-54.0%, $p<0.01$) than placebo. Animals treated with propranolol 20mg did not differ from placebo group. The groups treated with propranolol 5mg had the same effect as propranolol 100µg except for the Tb.Th. In cortical bone of the mid-diaphysis, propranolol 100µg group had a significant higher cortical width (6.0%, $p<0.01$), lower cortical pore number (-52.4%, $p<0.01$) and cortical porosity (-63.63%, $p<0.01$) compared to placebo. Ultimate force was significantly higher only in Sham (92.56 N) and propranolol 100µg (94.12 N) groups compared to propranolol 20mg ($p<0.01$). Histomorphometric bone cell activities are shown in Table 1. These results point out the preventive effects of β-antagonists on the trabecular/cortical microarchitecture and bone marrow adiposity, suggesting a potential therapy in post menopausal women.

Table 1: Histomorphometric parameters of the proximal tibia of ovariectomized rats

Central Regulation of Cortical Bone: Opposing Effects of Y2 Receptor and Leptin Pathways. P. A. Baldock*[1], S. Allison*[1], A. Sainsbury*[2], R. Enriquez*[1], H. Herzog*[2], E. Gardiner[3], J. A. Eisman[1]. [1]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, NSW, Australia, [2]Neurobiology Program, Garvan Institute of Medical Research, Sydney, NSW, Australia, [3]School of Medicine, University of Queensland, Brisbane, Qld, Australia.

The hypothalamus is known to modulate potent bone anabolic signals. Y2 receptor knockout [Y2R KO] and leptin deficient [ob/ob] mice display increased bone volume and osteoblast activity in cancellous bone. As cortical bone plays a major role in bone strength, we examined the effects of these two major pathways on cortical bone and osteoblast activity. Male, 16 week old wild type [wt], Y2R KO, ob/ob and Y2R/ob knockout mice were examined in groups of 5-8 animals. In addition, conditional hypothalamic Y2R knockout was conducted at 11 weeks of age with collection at 16 weeks. Cortical bone was examined by DXA [BMC mg, BMD mg/cm²] in isolated whole femora, in mid shaft and in distal thirds and histologically at the femoral mid-shaft cross section. Osteoblast activity was measured by mineral apposition rate [um/d] in sagittal sections following dual tetracycline labelling. In Y2R KO, femoral shaft and distal BMC was significantly greater than wild type, consistent with greater cortical area and thickness. In ob/ob, despite significantly greater body weight, cortical area and thickness in the femoral shaft was

reduced compared to wild type and Y2R KO also for shaft and distal BMC compared to Y2R KO. In the Y2R/ob cross, despite shaft BMC being reduced compared to Y2R KO, shaft cortical area and thickness and distal BMC were similar to wild type levels. Due to comparable changes in BMC and bone area, BMD did not differ between groups at either site. Endocortical osteoblast activity was similar in Y2R KO and Y2R/ob and greater than in wt and ob/ob. Increased cortical osteoblast activity was also observed 5 weeks after hypothalamic ablation of Y2R in adult mice compared to controls (0.23 ±0.01 vs 0.17 ±0.02, p<0.05).

	wt	Y2R KO	ob/ob	Y2R/ob
Body weight (g)	26.7 ± 4	29.8 ± 1	52.4 ± 4 a b	47.3 ± 5 a b
Shaft BMC (mg)	7.8 ± 1	8.8 ± 1a	6.7 ± 1 b	6.6 ± 1 b
Shaft Cortical Area (mm^2)	0.9 ± 0.03	1.1 ± 0.04 a	0.7 ± 0.06 a b	0.9 ± 0.02 b
Shaft Cortical Thickness (μm)	191 ± 6	221 ± 7a	151 ± 13 a b	175 ± 7 b
Distal BMC (mg)	10 ± 1	12 ± 1a	9 ± 1 b	11 ± 1
Distal Endocortical MAR (μm/d)	0.21 ± 0.03	0.31 ± 0.03 a	0.24 ±0.01b	0.32 ±0.01a c

a p< 0.05 vs wt, b p< 0.05 vs Y2R KO, c p<0.05 ob/ob vs Y2R/ob.

Therefore, the Y2 receptor pathway represents an adult-inducible stimulator of cortical as well as cancellous bone formation. Y2R deficiency increased BMC and osteoblast activity in Y2R/ob mice, in part counteracting the leptin-deficient reduction in cortical bone. These data clearly delineate opposing effects of Y2R and leptin pathways on cortical bone.

Low-Dose Strontium Increased the Formation of New Lamellar Bone at the Periosteal Surface, with Normal Mechanical Competence. H. Oxlund, J. S. Thomsen*, T. T. Andreassen. Dept of Connective Tissue Biology, University of Aarhus, Inst of Anatomy, Aarhus, Denmark.

Low-dose strontium (Sr) has been shown to possess bone anabolic properties. In the present study the effects of Sr chloride on tibia cortical bone of intact and ovariectomised (OVX) rats were studied. Seventy-five Wistar female rats, 6 months old, were allocated to five groups: 1. Baseline control, 2. Sham operated group, 3. OVX, 4. Sr, 5. OVX + Sr group. Sr chloride, 4 mmol/day, was given in the drinking water for 140 days. The rats were injected with Alizarin Red 7 days after start of the experiment, and calcein 14 days and tetracycline 4 days before killing by exsanguination. The mechanical properties of the tibia diaphysis were studied by a 3-point-bending test. No differences were found in the stress, stiffness and deflection parameters between the groups. Mid-diaphyseal transverse sections were cut and dynamic histomorphometry was performed on the basis of the fluorochrome labels. The periosteal bone formation rate (BFR) was increased (P=0.01) in the Sr group (0.74 ± 0.13, mean ± SEM) compared with the control group (0.53 ± 0.09 μm^3 x 10^3/day). The periosteal BFR was increased (P=0.001) in the OVX group (1.74 ± 0.20 m^3 x 10^3/day) compared with the sham group (0.53 ± 0.09 μm^3 x 10^3/day). Likewise, the periosteal BFR was increased (P=0.02) in the OVX + Sr group (2.47 ± 0.21 m^3 x 10^3/day) compared with the OVX group. Sr did not increase the mid-diaphyseal endocortical bone formation. In conclusion, low-dose Sr given perorally increased the periosteal bone formation, but did not stimulate endocortical bone formation. The new cortical bone exhibited a normal lamellar structure, and the mechanical competence of the cortical bone seemed to be preserved.

Strontium Ranelate Effects on Osteoblasts: A Potential Role of Endogenous Prostaglandins. S. Choudhary[1], C. Alander*[1], P. Halbout*[2], L. Raisz[1], C. Pilbeam[1]. [1]UConn Center for Osteoporosis, University of Connecticut Health Center, Farmington, CT, USA, [2]Groupe Servier, Courbevoie Cedex, France.

Strontium ranelate is a new anti-osteoporotic treatment with a dual effect on bone formation and bone resorption. Previous studies have shown that strontium can increase prostaglandin (PG) production in osteoblasts by increasing the expression of the inducible cyclooxygenase (COX)-2. The present study was designed to assess the role of endogenous PG production in the anabolic response to strontium ranelate. Bone marrow stromal cells (MSC) from 7 to 8 wk old mice and primary calvarial osteoblast (POB) cells from neonatal mice were cultured under differentiating conditions for 10-14 d. Strontium was tested at 1 and 3 mM, mixed with ranelic acid at 10 and 30 μM, respectively, in order to reflect the ratio found in the human plasma of patients after dosing. Measurements included bone alkaline phosphatase (ALP) activity, normalized to total protein, and alizarin red staining for mineralization. In MSC cultures, continuous treatment with strontium ranelate (3 mM Sr^{2+}) for 10 and 14 d significantly increased ALP activity by 92% (p<0.01) and 63% (p<0.01), respectively, as well as mineralization. In the presence of NS-398 (0.1 μM), a selective inhibitor of COX-2 activity, there was no significant increase in ALP activity with strontium ranelate in MSC cultures. When MSC cultures were treated with strontium ranelate for varying intervals (first 3, first 7 or last 7 d) during 14 d of culture, treatment for the first 7 d with strontium ranelate (1 and 3 mM Sr^{2+}) increased ALP activity by 69% (p<0.05) and 110% (p<0.01), respectively. Cumulative PGE_2 levels in MSC cultures measured after a 7 d treatment with strontium ranelate (1 and 3 mM Sr^{2+}) were respectively elevated 2.4-fold (p<0.01) and 11.0-fold (p<0.01). NS-398 blocked all significant increases in PGE_2 production. In POB cells cultured for 14 d, treatment with strontium ranelate (3 mM Sr^{2+}) for 0-3, 0-7, or 0-14 d of culture significantly increased ALP activity by 186% (p<0.01), 95% (p<0.05) and 92% (p<0.05), respectively. NS-398 also inhibited the increase in ALP activity in this system (preliminary data). To summarize, strontium ranelate stimulated the anabolic response of MSC and POB as shown by the increased ALP activity and mineralization in both models, which was coupled to an endogenous PG production. We conclude that the ability of strontium ranelate to stimulate endogenous PG production represents one attractive hypothesis to support the beneficial effect of strontium ranelate on bone formation.

A Peptide Derived from Chemokine CXCL7 Stimulates Bone Formation and Increases BMD in OVX Rats. S. A. F. Peel, G. O. Ramirex-Yañez*, D. Squires*, L. T. Malek. Osteopharm Inc, Oakville, ON, Canada.

It was previously reported that a fragment of the human CXC chemokine neutrophil activating peptide-2 (NAP-2, CXCL7) stimulated bone mineral apposition in rats (Tam 2004, US Pat.No. 6,693,081). The purpose of this study was to determine whether the modified 8 amino acid peptide Ac-TTSGIHPK-amide derived from CXCL7 (OSB) would increase bone formation in ovariectomized (OVX) rats. Virgin SD rats were OVX or sham operated at 23 weeks of age and placed into groups (N=12) on the basis of DEXA measurements of bone and body composition. Eight weeks after surgery the rats in 3 groups received injections for 5 days a week of PBS (sham and OVX groups) or OSB (300 nmoles/kg) in PBS. Changes in bone were monitored monthly by DEXA (regional and whole body) and bimonthly by pQCT. After 26 weeks of treatment the rats were sacrificed, serum samples were collected for biomarker analysis and bones were collected for terminal analysis by pQCT or fixed for histology. Rats treated with OSB had significantly increased whole body BMC and BMD compared to OVX control by DEXA (p<0.03). Terminal analysis of the lumbar spine (L3) by pQCT demonstrated that OSB significantly increased total BMC and BMD (p<0.02) and cortical area and BMC (p<0.006) relative to the OVX control. For tibia and femur, the OSB treated group had significantly higher trabecular BMC and BMD (p<0.03) at metaphyseal sites, and higher cortical area and BMC (p<0.04) at diaphyseal sites. The OSB group had significantly higher total BMC and BMD (p<0.03) at the femoral neck than the OVX control. Analysis of blood samples for markers of collagen degradation showed no differences between OVX and OSB treated animals. Samples analyzed for osteocalcin showed an increase with OSB treatment that neared significance (p = 0.09). Based on these results we conclude that OSB stimulates bone formation and increases BMD in OVX rats. These results suggest that OSB may be efficacious as bone anabolic drugs for the treatment of osteoporosis.

Novel Peptides Stimulate Bone Formation *In Vitro* and *In Vivo*. G. O. Ramirez-Yañez*, S. A. F. Peel, D. Squires*, L. T. Malek. Osteopharm Inc, Oakville, ON, Canada.

The novel peptide OSA was derived from the sequence of a cDNA clone in a fetal human liver library. A series of structurally related 10 amino acid peptides were developed based on the active region of the original peptide (Tam 2004 patent WO2004/050701). The aim of the present study was to test the efficacy of these novel peptides in bone formation. Neonatal rat calvaria (3-5 days old) were either treated with OSA peptides (10^{-9} M), or IGF-1 (50 ng/ml) or left untreated. Mineralization and matrix synthesis were evaluated based on incorporation of ^{45}Ca and ^{3}H-proline. Calvaria treated with OSA peptides had a significantly higher incorporation of ^{45}Ca and ^{3}H-proline compared with the untreated control (p<0.05), similar to the IGF-1-treated calvaria. Virgin SD rats were OVX or sham operated at 23 weeks of age and placed into groups (N=12) on the basis of DEXA measurements of bone and body composition. Eight weeks after surgery the rats received injections for 5 days a week of PBS (sham and OVX groups) or 1 of 3 OSA peptides (117M, 153M or 155M; 300 nmoles/kg) in PBS. Changes in bone were monitored monthly by DEXA (regional and whole body) and bimonthly by pQCT. After 26 weeks of treatment the rats were sacrificed, serum samples were collected for biomarker analysis and bones were collected for terminal analysis by pQCT or fixed for histology. OSA treated rats showed significant increases in whole body BMC and BMD after 3 and 6 months of treatment as compared with the OVX control (p<0.05). Terminal pQCT analysis indicated that rats treated with one OSA peptide analog (155M) had significantly higher trabecular BMD at lumbar vertebrae (p<0.05) and at metaphyseal sites in the tibia (p<0.007) and femur (p<0.03) than the OVX rats treated with vehicle. Total BMD of the femoral neck was significantly higher (p<0.04) in the group treated with OSA 155M than in the OVX control. Serum samples tested for markers of bone resorption (RatLaps) or formation (osteocalcin) showed no significant differences between the groups, possibly due to the large variations observed within each group. These results demonstrate that OSA peptides stimulate bone formation *in vitro* and *in vivo*. Further these peptides may be useful in the treatment of osteoporosis.

Characterization of Osteogenic Oxysterols and their Molecular Mechanism(s) of Action. J. A. Richardson*[1], C. M. Amantea*[1], K. Nguyen*[2], M. E. Jung*[2], T. J. Hahn[1], F. Parhami[1]. [1]Medicine, UCLA, Los Angeles, CA, USA, [2]Chemistry, UCLA, Los Angeles, CA, USA.

Identification of anabolic agents that enhance bone formation is critical for the better management of bone fractures and osteoporosis. We previously reported that specific oxysterol compounds, products of cholesterol oxidation, used in combination have potent osteogenic properties when administered to osteoprogenitor cells *in vitro* and to neonatal mouse calvarial organ cultures *ex vivo*. The oxysterol combinations with osteogenic

activity consisted of 22(*R*)- or 22(*S*)-hydroxycholesterol with 20(*S*)-hydroxycholesterol (RS and SS, respectively). Recently we found that the oxysterol 20*S*, when used alone at doses of 5-15 μM in cultures of marrow stromal cells, M2-10B4 (M2), induced the formation of mature osteoblastic cells demonstrated by the induction of alkaline phosphatase (ALP) activity, Runx2 DNA binding and protein expression, osteocalcin (OCN) mRNA expression, and mineralization. Pre-treatment or co-treatment of cells with 22*S* or 22*R* oxysterols greatly enhanced the osteogenic effects of 20*S* suggesting that 22*S* and 22*R* prime the osteoprogenitor cells for better responsiveness to 20*S*. We have identified other oxysterols with osteogenic properties when used alone or in combination with 22*R* or 22*S*. These newly identified oxysterols are 5-cholesten-3β, 20α-diol 3-acetate, 24(*S*),25-epoxycholesterol, 24(*S*)-hydroxycholesterol (also known as cerebrosterol), and 26-hydroxycholesterol, all of which induced the markers of osteogenic differentiation in M2 cells. In contrast, 4β-hydroxycholesterol and 7α-hydroxycholesterol did not have osteogenic properties suggesting that the carbon side chain of the sterols and the position of the hydroxyl groups are important characteristics of the osteogenic sterols. Structurally similar molecules to oxysterols, estren, estrone, and β-estradiol, which do not have the carbon side chain and have differences in the position and number of their double bonds, did not have any osteogenic properties. Pretreatment of M2 cells with the hedgehog signaling inhibitor, cyclopamine (1-10 μM), significantly inhibited SS-induced ALP activity, Runx2 protein and OCN mRNA expression, and mineralization. In addition, pretreatment of cells with the inhibitor of Wnt signaling, DKK-1 (1 μg/ml), significantly inhibited SS-induced ALP activity, OCN expression and mineralization but not Runx2 protein expression. These results suggest that the oxysterol-induced osteogenic differentiation of cells is mediated through hedgehog- and Wnt-dependent mechanisms. Oxysterols form a new class of osteoinductive agents that may be useful in the enhancement of local and/or systemic bone formation.

Systemic Administration of Thyroid Stimulating Hormone (TSH) Prevents and Restores Bone Loss in Rats Following Ovariectomy. K. T. Sampath[1], P. Simic*[2], R. Sendak[1], N. Draca*[2], S. Schiavi*[1], J. McPherson*[1], S. Vukicevic[2]. [1]Genzyme Corporation, Framingham, MA, USA, [2]Laboratory for Mineralized Tissues, Zagreb Medical School, Zagreb, Croatia.

Thyroid stimulating hormone (TSH) affects bone remodeling as demonstrated by reduced bone mass in TSH receptor knockout mice (Abe E, et al Cell, 115: 130-140, 2003) and in post-menopausal euthyroid patients following single administration of human TSH (Mazziotti G, et al., JBMR 20: 480-486, 2005). In the present study, we examined whether the systemic administration of TSH could prevent and restore bone loss in an osteoporosis animal model. Female SD rats were ovariectomized (OVX) at 6 months and the TSH therapy was started immediately (prevention mode), and 3 months following OVX (restoration mode). Animals were divided into six groups (12 rats/group): (1) Sham, (2) Ovariectomized (OVX), (3) OVX + TSH (low dose), (4) OVX + TSH (medium dose), (5) OVX + TSH (high dose) and (6) OVX + 17-ß estradiol. Recombinant human TSH (Thyrogen®) (0.7, 7.0 and 70 μg/rat) or rat pituitary-derived native TSH (0.01, 0.1, 0.3, 1, 3 and 10 μg per rat) were administered i.p., three times per week. The whole body, lumbar spine and hind limbs bone mineral density (BMD) were measured at 2 week intervals in vivo, following 8-16 weeks of therapy. Results show that TSH significantly increased BMD at all measured sites both in the prevention and restoration mode. Doses of 0.1 and 0.3 μg/rat of TSH significantly increased the BMD of the hind limbs whereas the dose of 0.01 μg/rat of TSH did not have an effect on BMD. High doses of human and rat TSH had lesser effect on BMD. Ex vivo BMD values of excised femur, tibia and lumbar spine confirmed the in vivo measurements. Compared to OVX, OVX plus TSH increased cortical thickness of femurs by 14.5% as measured by pQCT, and increased BV/TV by 163%, trabecular thickness by 21.1% and trabecular number by 125% as determined by μCT analyses. Serum biochemical analyses suggest that TSH suppresses the ovariectomy-induced bone turnover by decreasing osteocalcin and C-telopeptide levels to sham values. Importantly, low TSH doses had no effect on serum T3 and T4 values, suggesting TSH at these levels may have a direct effect on bone without affecting the thyroid axis. In vitro studies demonstrate that TSH inhibits RANKL induced-osteoclast formation, osteoclast-mediated resorption, promotes osteoblast differentiation and provides protection against apoptosis in osteoblast enriched cultures. These results demonstrate for the first time that systemically administered TSH can suppress high bone turnover following ovariectomy and exert both anti-resorptive and anabolic effects on bone remodeling, resulting in both prevention and restoration of bone loss in aged OVX rats.

Characterization of Bone and Cartilage Stimulating Peptide Derived from the Collagen Type I Alpha I Chain. D. Sindrey, E. Plawinski*, R. R. Simon*, J. Auluck*, J. Terryberry*. Millenium Biologix Corp, Mississauga, ON, Canada.

We have previously reported on the bone stimulating effects of Bone and Cartilage Stimulating Peptides for the treatment of bone trauma and other bone diseases like osteoporosis. Originally extracted from bovine bone as BCSS (Bone Cell Stimulating Substance, Clark I. et al 1988) we have demonstrated through extensive purification and structure function studies, one of the active components as being a fragment of procollagen 1A1 1156-1174. Purification of BCSS bovine extracts by RP-LC, ion exchange and size exclusion chromatography, identified an active collagen fragment that was confirmed by identification from digests of collagen Type I. Several overlapping candidate peptides ranging from a 4mer to 16mer were synthesized with different N and C terminal truncations and/or additions to optimize biological activity in a rat tibia model of bone formation. No ectopic bone formation was noted in any of the animals. Histologically, the change in bone size was a result of periosteal bone proliferation and was peptide related. A noticeable intra-medullar bone proliferation was also seen in rats treated with the most active peptides and was considered peptide-related as it was not observed in any rats treated with carrier or Saline. Typical increases in local BMD were 10-12% above controls with peptides as small 450 kD. In vitro testing demonstrated two basic cellular responses in rat calvaria cells of increased proliferation and differentiation as seen by the 3 fold increase in WST assay; a 36% increase in the number of bone nodules and a 71% increase in bone area formed in calvaria cultures. These data corresponded well with observations in vivo of a rapidly proliferating periosteum and its subsequent mineralization. Bioactivity was sequence dependent and resided in two novel and complimentary sequence motifs in the BCSP-1 molecule. The synthesis of these molecules by solid phase peptide chemistry and their subsequent testing in a rat tibia model of bone formation validated the collagen origin of the original BCSS bovine extracted material. The actions of BCSP peptides on cell interactions in osteogenesis demonstrated specificity toward bone cells present in the periosteum as noted by the absence of heterotopic or ectopic bone formation. The rapid onset of the stimulatory effect and the absences of ectopic bone formation make the BCSP peptides a potent site-specific candidate for the treatment of bone fracture and trauma. Osteoinductive BCSP is currently in development for the treatment of local bone repair and systemic treatment of various skeletal diseases.

Retrovirus-Mediated Gene Transfer of RANK-Fc Ameliorates Bone Resorption in Ovariectomized Mice. D. Kim*[1], S. Her*[2], S. Cho*[2], S. Kim[2], S. Kim*[2], C. S. Shin[2]. [1]Department of Internal Medicine, Dankook University College of Medicine, Cheon-An, Republic of Korea, [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

Postmenopausal osteoporosis is characterized by increased bone resorption due to estrogen deficiency. RANK-Fc, a fusion protein that specifically blocks RANKL binding to RANK, has been known to be efficient and well-tolerated in animal models of osteoporosis. Here we show that cell-based gene therapy with RANK-Fc effectively prevented bone loss in ovariectomized (OVX) mice. Twenty-four young adult female C57B mice were used and repeated intraperitoneal injection of mesenchymal stem cells(MSCs) transduced with retrovirus was performed as follows: (1) Sham-operated mice (SHAM, n=6) (2) OVX mice treated with PBS (OVX-P, n=6) (3) OVX mice injected with MSCs cells transduced with control retrovirus (OVX-GFP, n=6) (4) OVX mice injected with MSCs transduced with RANK-Fc (OVX-RANK-Fc, n=6). Cellular expression of RANK-Fc was confirmed by Western blot analysis of cell lysates and conditioned medium, and also by ELISA for the mice serum. Measurement of BMD by dual energy x-ray absorptiometry (PIXImus) revealed that OVX-RANK-Fc group showed significantly higher BMD ($p<0.05$) than either the OVX-P group or OVX-GFP group after 8 weeks. The expression of GFP, which is co-expressed with RANK-Fc was observed in the liver, spleen, and intra-abdominal fat of mice but not in femur or freshly isolated bone marrow. Our results suggest that expression of RANK-Fc by genetically modified MSCs may be a feasible option for ameliorating the OVX-induced bone loss.

Lumbar Spinal Mobility and Back Extensor Strength Are Important Factors for Quality of Life in Patients with Osteoporosis. N. Miyakoshi, M. Hongo, S. Maekawa, Y. Ishikawa*, Y. Shimada*, E. Itoi*. Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

We have recently demonstrated that quality of life (QOL) in patients with osteoporosis is affected by the total spinal mobility and that the back extensor strength is the most significant contributor to the total spinal mobility. However, how much thoracic and lumbar spinal mobilities affect QOL has not been clarified. In this study, we evaluated the relation between QOL and thoracic and lumbar spinal mobilities and their related factors in patients with osteoporosis. A total of 174 postmenopausal women with osteoporosis aged over 50 years (mean, 68 years) were included in this study. Their QOL was evaluated using the Japanese Osteoporosis QOL Questionnaire (JOQOL) proposed by the Japanese Society for Bone and Mineral Research. JOQOL contains six domains with higher scores indicating higher levels of QOL. Bone mineral density (BMD) of the lumbar spine, proximal femur, and whole body were measured with dual-energy X-ray absorptiometry. The kyphosis angle and range of motion (ROM) of thoracic and lumbar spine were measured in the upright position and at maximum flexion/extension with a computer-assisted device (SpinalMouse®). The number of vertebral fractures was evaluated with lateral radiographs of the spine. Bilateral grip strengths and isometric back extensor strength were evaluated with dynamometers. JOQOL showed significant correlation ($p<0.05$) with age ($r=-0.303$), back extensor strength ($r=0.455$), grip strengths of dominant and non-dominant hands ($r=0.273$ and $r=0.255$, respectively), number of vertebral fractures ($r=-0.282$), BMDs of proximal femur and whole body ($r=0.200$ and $r=0.157$, respectively), lumbar kyphosis angle ($r=-0.296$), and lumbar spinal ROM ($r=0.345$). Among these factors, the multiple regression analysis revealed that the back extensor strength and lumbar spinal ROM were the significant contributors to the JOQOL. We conclude that back extensor strength and lumbar spinal mobility (but not thoracic mobility) are the important factors for QOL in patients with postmenopausal osteoporosis.

Calcium Phosphate versus Polymethylmethacrylate - A Prospective, Randomized, Clinical Trial of Percutaneous Balloon Kyphoplasty. T. R. Blattert*[1], A. Weckbach*[2]. [1]Trauma & Reconstructive Surgery, Leipzig University, Leipzig, Germany, [2]Trauma Surgery, Wuerzburg University, Wuerzburg, Germany.

In kyphoplasty and vertebroplasty, polymethylmethacrylate (PMMA) currently represents the standard augmentation material. It is characterized, however, by a lack of osteointegration and its limited biocompatibility. This prospective, randomized trial investigated the feasibility of calcium phosphate (CaP) for augmentation of osteoporotic vertebral body fractures by means of percutaneous balloon kyphoplasty in comparison to PMMA. Inclusion criteria were osteoporotic fractures of vertebral bodies in the thorocolumbar spine, patient age ≥65 years, and fracture age ≤4 months. Exclusion criteria were tumor lesions and additional posterior instrumentation. A total of 60 osteoporotic vertebral body fractures in 56 patients were included. CaP and PMMA were randomly applied in 30 cases each. All 60 fractures were classified type A (acc. to Magerl et al.). Of these, 19 were classified type A3. 52/56 patients experienced p.op. pain relief (2.1 ± 1.9 to 8.2 ± 1.5 on a Visual Analogue Scale from 0 "worst" to 10 "best"). Endplate angles were restored by 6.2° ± 2.9 on average. For both parameters (pain relief and restoration of endplate angle), no statistically significant difference was found between the groups. Cement-specific complications were vascular embolism using PMMA (n=2); subtotal "cement-washout" using CaP (n=1); and substantial loss of correction on radiographs 6 weeks p.op. due to cement failure in all fractures type A3, if CaP had been applied (n=9). There was no case of cement failure, when PMMA had been used. Currently in kyphoplasty, a routine use of CaP cannot be recommended. Due to its minor resistance to bending, extension, and shear forces compared to PMMA, there is a high risk for cement failure and subsequent loss of correction in the well defined clinical setting of osteoporotic vertebral body fractures type A3.

Health-Related Quality of Life in Postmenopausal Women with Osteoporosis and an Inadequate Response to Anti-Osteoporosis Medication: Baseline Results of the French Cohort from the Observational Study of Severe Osteoporosis (OSSO). P. Fardellone[1], I. Jamonneau*[2], A. Alfonsi*[2], S. Liu-Léage*[2]. [1]CHRU, Amiens, France, [2]Lilly France, Suresnes, France.

Osteoporosis-related fractures can cause pain, physical impairment and loss of functional ability, thereby significantly impairing patient quality of life. However, the impact of an inadequate response to anti-osteoporosis treatment, especially on patient quality of life, is not well understood. The Observational Study of Severe Osteoporosis (OSSO) is a 12-month, European, prospective, observational study of postmenopausal women with osteoporosis and an inadequate response to anti-osteoporosis therapy, defined as: (i) the presence of a new fragility fracture (vertebral or non-vertebral) despite prescription of any approved anti-osteoporosis therapy for at least 12 months before the fracture, and/or (ii) discontinuation of any approved anti- osteoporosis therapy due to compliance problems and/or side effects. The primary objective of OSSO is to evaluate changes in health-related quality of life (HRQoL). A total of 418 women enrolled in France were included in the baseline analysis: 196 (46.90%) in the index fracture cohort and 222 (53.10%) in the compliance/side effect cohort, a less severe patients' group based upon the patients characteristics. HRQoL was assessed using the osteoporosis disease-specific QUALEFFO questionnaire (Lips et al, Osteoporos Int 1999). At baseline, the mean (SD) total QUALEFFO score for the OSSO French population (n= 418) was 42.7 (18.8), and the mean (SD) scores for the five domains were: pain 46.2 (27.4), physical function 33.0 (23.0), social function 56.9 (25.9), general health 62.7 (20.7) and mental function 42.4 (19.2). The mean total QUALEFFO score was significantly higher in the index fracture cohort than in the compliance/side effect cohort (47 vs 38.8, P<0.001). Similarly, the scores for each of the five domains were significantly higher in the index fracture cohort. In the subgroup of index patients who sustained a vertebral fracture a few months before enrolment in the study, the mean total QUALEFFO score was higher and respectively 55.4 (17) in those with a lumbar vertebral fracture, 53.1 (15.8) with a thoracic vertebral fracture, 49.4 (15) with a lumbar and thoracic vertebral fracture. In conclusion, there is a clear impairment of quality of life at baseline in the French postmenopausal women with osteoporosis taking part in the OSSO study. The impairment is more pronounced in the index group as it was the most severe group with a higher proportion of patients with multiple fractures history. The vertebral fracture worsens the quality of life.

Health-Related Quality of Life in Postmenopausal Women with Osteoporosis and an Inadequate Response to Anti-Resorptive Medication: Baseline Results from the Observational Study of Severe Osteoporosis (OSSO). D. Sykes*[1], C. Cooper[2], S. Adami[3], P. Fardellone*[4], F. Jakob*[5], J. Melo-Gomes*[6], E. Martin-Mola[7], T. Nicholson*[1], N. Thalassinos*[8], D. Torgerson*[9], F. Marin[1]. [1]Eli Lilly, Windlesham, United Kingdom, [2]MRC Environmental Epidemiology Unit, Southampton, United Kingdom, [3]University of Verona, Verona, Italy, [4]Hospital Nord, Amiens, France, [5]Julius-Maximilians University, Wurzburg, Germany, [6]Servimed, Lisbon, Portugal, [7]Hospital La Paz, Madrid, Spain, [8]Evangelismos General Hospital, Athens, Greece, [9]Univeristy of York, York, United Kingdom.

Osteoporosis-related fractures can cause pain, physical impairment and loss of functional ability, thereby adversely affecting HRQoL. However, the impact of an inadequate response to osteoporosis treatment, especially on HRQoL, is not well understood. OSSO is a 12-month, European, prospective, observational study of postmenopausal women with osteoporosis and an inadequate response to anti-resorptive therapy, defined as: (i) the presence of a new fragility fracture despite prescription of any approved anti-resorptive therapy for at least 12 months before the fracture, and/or (ii) discontinuation of any approved anti-resorptive therapy due to compliance problems and/ or side effects. Patients who satisfied both criteria were analysed according to the first event. The primary objective of OSSO is to evaluate changes in HRQoL. 2314 women were included in the baseline analysis: 1309 (57%) in the index fracture cohort and 1005 (43%) in the compliance/side effect cohort. HRQoL was assessed using QUALEFFO. Each domain score and the total QUALEFFO score are expressed on a scale from 0 to 100, with 0 corresponding to the best HRQoL. At baseline, the mean (SD) total QUALEFFO score for completers (n=2279) was 46.9 (18.6), and the mean (SD) scores for the five domains were: pain 52.4 (26.5), physical function 39.0 (22.9), social function 56.7 (25.5), general health 68.9 (20.9) and mental function 44.7 (18.0). The mean total QUALEFFO score was significantly higher in the index fracture cohort than in the compliance/side effect cohort (49 vs 44, P<0.001). Similarly, the scores for each of the five domains were significantly higher in the index fracture cohort. The mean total QUALEFFO scores varied across the participating countries, ranging from 42.7 in France to 50.7 in Germany. The median total QUALEFFO score of the OSSO population (47.0) is higher than that reported previously in control subjects (20.3) and osteoporosis patients with vertebral fracture (35.3) (Lips et al, Osteoporos Int 1999). In conclusion, there is a clear impairment of HRQoL at baseline in the postmenopausal women with osteoporosis taking part in OSSO.

BALTO I: Women Treated for Osteoporosis Rate Preference and Convenience for Once-Monthly Ibandronate versus Once-Weekly Alendronate. R. Emkey[1], N. Binkley[2], L. Seidman[3], C. Rosen[4]. [1]Reading Hospital, Reading, PA, USA, [2]Institute on Aging, University of Wisconsin-Madison, Madison, WI, USA, [3]Philadelphia Women's Research, Philadelphia, PA, USA, [4]Saint Joseph Hospital, Bangor, ME, USA.

Adherence to oral bisphosphonate therapy for osteoporosis treatment is suboptimal. Whereas prior studies have evaluated the impact of treatment adherence on outcomes such as fracture risk and bone mineral density, few have investigated patient-reported preferences for available dosing regimens. The purpose of the BALTO I study was to evaluate patient reports of preference and convenience for once-monthly ibandronate versus once-weekly alendronate. Women with PMO (n=342) were enrolled in a 6-month, prospective, randomized, open-label, 2-sequence, 2-period, crossover study (BALTO I) which examined their preferences for once-monthly oral ibandronate (150 mg) or once-weekly oral alendronate (70 mg). In sequence A (n=170) patients received once-monthly ibandronate for 3 calendar months followed by once-weekly alendronate for 12 weeks. In sequence B (n=172), the 2 treatment periods were reversed. There was no washout period between the 2 treatment regimens. Subjects completed a self-administered questionnaire at the final study visit during which they were asked to rate preference and convenience for monthly ibandronate and weekly alendronate. The intent-to-treat population (n=298) included women who received at least one dose of each study medication and completed the preference question. The majority of women preferred the once-monthly ibandronate treatment regimen and found it more convenient than once-weekly alendronate. Of those women expressing a preference (n=276), 71.4% preferred monthly ibandronate while 28.6% preferred weekly alendronate. Of subjects reporting on convenience (n=264), 74.6% found the monthly ibandronate dose more convenient compared with 25.4% who found weekly alendronate more convenient. Significantly more women with PMO preferred monthly ibandronate therapy and found it more convenient when compared with once-weekly alendronate. These findings suggest that once-monthly ibandronate treatment may be associated with improved medication adherence.

Genetic, Clinical and Cellular Analysis of Forty-Seven Osteopetrotic Patients. A. Del Fattore*, B. Peruzzi*, C. Di Giacinto, A. Cappariello*, D. Fortunati*, M. Iacobini*, M. Luciani*, E. Lanino*, C. Messina*, S. Cesaro*, H. Fryssira*, P. Grabowski*, R. P. Kapur*, H. K. Datta*, A. Taranta*, S. Migliaccio*, M. Longo, A. Teti. Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

Osteopetrosis (OP), a genetic bone disease characterized by osteoclast failure, is classified in three forms: infantile malignant Autosomal Recessive OP (ARO), Intermediate autosomal Recessive OP (IRO), and Autosomal Dominant OP (ADO) I and II. Among 47 patients admitted to this study, 19 were diagnosed with ARO, 1 with IRO and 27 with ADOII. Five ARO patients had known ATP6i gene mutations, 1 had a novel mutation (delC8807 DNA) and 3 were negative. Fourteen ADOII patients bore heterozygous mutations of the ClCN7 gene and 6 were negative, suggesting additional genes are also involved in this form. Identical ClCN7 mutations associated with variable severity, with no apparent correlation with gene polymorphism. Most ADOII patients showed decreased bone ALP but increased osteocalcin, and all patients had elevated TRAcP. Increased ALP was instead observed in ARO patients, so we examined whether osteoblasts were affected in iliac crest biopsies. Ob.S/BS was increased in 3 cases and near the max normal value in 2. Four patients showed increased serum PTH indipendently of Ob.S/BS status, suggesting no correlation between the two events. Most patients had elevated osteoclasts, except three with no osteoclasts, suggesting a defect in osteoclastogenesis. Bone marrow transplantation in the latter patients was without effect, consisting with a microenviromental defect. In vitro, osteoclasts from patients generally showed no significant changes in formation rate, morphology or intracellular acidification. However, we observed altered adhesion to substrate and podosome formation in an IRO patient, and increased motility in three ADOII patients. As expected, the ADOII and ARO osteoclasts degraded bone matrix significantly less than controls, but bone resorption by ARO osteoclasts was not abolished. To test whether residual resorption activity could rely on the Na+/H+ antiport, control osteoclasts were treated with 75 nM of the H-ATPase inhibitor Bafilomycin, which reduced resorption to the ARO level, and 50 microM of the Na+/H+ antiport inhibitor EIPA. Pit formation was eliminated, without cytological alteration of osteoclast, which suggests an important physiological role for the antiport in the residual bone resorption in ARO. Extracellular acidification increased pit formation both in controls (>2fold) and in patients (~2fold in ADOII and ~3fold in ARO), providing a rationale for new therapies based on pH and Na+/H+ antiport manipulation.

M437

Fibrous Dysplasia: Pain Prevalence Increases with Age but Is not Due to an Increase in Bone Disease. M. H. Kelly*[1], B. A. Brillante*[1], X. Cineceros*[2], S. Guirguis*[3], M. T. Collins[4]. [1]Nursing and Patient Care Services, National Institutes of Health, Bethesda, MD, USA, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Rockville, MD, USA, [3]Wooten High School, Bethesda, MD, USA, [4]Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA.

Fibrous Dysplasia (FD) is a congenital, non-heritable skeletal disorder in which normal bone and bone marrow are replaced by fibro-osseous tissue. Skeletal abnormalities associated with FD include pain, bowing, fractures and limb length discrepancy. We observed that pain appeared to be a more frequent complaint in adults than children, and that this difference did not appear to be attributable to the development of new FD lesions. To test if these observations were true, we assessed the differences in the prevalence of pain and the number and location of FD lesions in a cohort of children and adults with FD. A population of 33 children and 43 adults was studied. Radioisotopic bone scans were used to identify the sites of skeletal involvement. The self report Brief Pain Inventory was used to determine overall pain and which FD sites were painful. The following measures were assessed: 1) pain prevalence in adults and children, 2) pain distribution, 3) distribution of skeletal lesions, 4) differences in the distribution of skeletal lesions between adult and pediatric patients. The data confirmed that pain is a common feature of FD, reported by 67% of the population, and that pain is more common in adults than children (children 45%, adults 83%, p<.0005). The lower extremities were the sites most likely to be painful (children 56%, adults 89%, p=.005). The sites most commonly involved with FD were the head (children 94%, adults 86%, p=NS) and lower extremities (children 97%, adults 86%, p=NS). FD lesions were found less frequently in upper extremities, (children 88%, adults 62%, p<.05), ribs (children 64%, adults 71%, p=NS) and the spine (children 45%, adults 71%, p<.05). The spine was the only site at which there was a significant increase in FD involvement over time, but this site did not appear to be a significant source of overall pain morbidity. FD is more commonly associated with pain in adults than in children. The reason for this is not clear, as fractures are more common in children and the occurrence of new lesions (other than in the spine) is not a significant feature of aging. Parents and practitioners should be cognizant of the high prevalence of pain and treat it appropriately. The mechanism of bone pain in FD, its increase in adulthood, and the apparent ability of bisphosphonates to relieve pain are unknown and represent an area which warrants further investigation.

Mechanical Consequences of the *Col1a2^{oim}* Mutation in Mouse Dentin. G. E. Lopez Franco[1], D. Stone*[2], A. Huang*[3], N. Pleshko Camacho[3], R. D. Blank[1]. [1]Medicine, University of Wisconsin-Madison, Madison, WI, USA, [2]Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI, USA, [3]Research Division, Hospital for Special Surgery, New York, NY, USA.

Mice harboring the *Col1a2^{oim}* mutation (*oim*) express dentinogenesis imperfecta (DI). As we have described before, both *oim/oim* and *oim*/+ mice display a reduction in the density and regularity of dentinal tubules in the matrix adjacent to the pulp. It is not yet clear what the mechanical consequences of the *oim* mutation in dentin are. Moreover, dentin's maturity varies with distance from the pulp, with the dentin farther from the pulp deposited earlier than that closer to the pulp. In order to compare the effect of *Col1a2* genotype and position on mechanical properties, we compared Young's modulus (E) and hardness (H) of dentin at different locations (near and far from the pulp chamber) in the three *Col1a2* genotypes. Upper incisors fractured at the junction epithelium were polished prior to testing. Nanoindentation was performed by using a TriboScope and a diamond Berkovich tip at 3000μN following experimental calibration with a fused quartz standard. Data were analyzed by the Oliver and Pharr method and groups compared by 2 factor ANOVA. E and H data are summarized in the table below. We found that dentin was harder and stiffer far from the pulp ($P < 0.001$). We believe that this reflects the effect of dentin maturity. The effect of genotype on E and H is also significant ($P = 0.003$), but there is not a clear-cut mutant allele dosage effect. For E, the effect of genotype was statistically significant at both locations, whereas on H, it was only significant near the pulp (interaction $P < 0.001$). Near the pulp, the presence of two mutant alleles caused dentin to be harder and stiffer. Far from the pulp, heterozygosity for the *oim* mutation led to the greatest E and H. These data suggest that the effect of α2(I) content on dentin mechanics depends on matrix maturity.

	E (GPa) ± sd		H (GPa) ± sd	
Position	**Far**	**Near**	**Far**	**Near**
+/+	22.5 ± 3.1	19.4 ± 4.8	1.5 ± 0.4	0.6 ± 0.1
+/oim	37.1 ± 4.3	17.9 ± 3.3	2.2 ± 1.2	0.5 ± 0.1
oim/oim	28.7 ± 6.9	26.2 ± 3.2	1.6 ± 0.6	0.9 ± 0.1

GNAS mRNAs from the Paternally-Inherited Allele Are Decreased in Progressive Osseous Heteroplasia (POH), a Human Disorder of Ectopic Ossification. M. Xu*, F. S. Kaplan, E. M. Shore. Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA.

Progressive osseous heteroplasia (POH) is an autosomal dominant disorder of extensive dermal ossification during childhood followed by progressive and disabling bone formation within skin, skeletal muscle, and deep connective tissue. POH is a rare condition, with most cases arising as a spontaneous mutation. However, in each of the few families that show inheritance of POH, transmission is from fathers. Heterozygous inactivating mutations of *GNAS* have been found in both familial and sporadic cases of POH. In all cases of POH examined, *GNAS* mutations consistently occur on the paternally-inherited allele. The *GNAS* gene is transcriptionally complex, initiating mRNA synthesis from multiple promoters and unique first exons that splice into common exons 2-13. The most abundant product of the *GNAS* gene is Gsα mRNA, which is biallelically expressed in most tissues. The *GNAS* mutations in most patient cell lines produce an unstable mRNA, and levels of Gsα mRNA and protein are reduced. Unlike Gsα mRNA, other *GNAS* transcripts are synthesized from only one of the two alleles. The GNAS-Nesp55 transcript is only expressed from the maternally-inherited allele, and the GNAS-XLαs and GNAS-1A transcripts are paternally expressed. We used quantitative RT-PCR to examine *GNAS* transcript levels in lymphocyte cell lines from POH patients and controls. While the Nesp55 mRNA is expressed at similar levels in patients and controls, POH cells express the XLαs and 1A mRNAs at reduced levels. These data suggest that the clinical expression of *GNAS* inactivating mutations in POH patients is not solely dependent on the level of Gsα expression but may be influenced by the expression levels of other *GNAS* transcripts.

Fibrodysplasia Ossificans Progressiva: Middle-Age Onset with Poor Response to Aggressive Immunosuppressive Therapy. S. J. DiMartino*[1], E. F. DiCarlo*[1], A. L. Boskey[1], M. P. Whyte[2]. [1]Hospital for Special Surgery-Weill Medical College, Cornell University, New York, NY, USA, [2]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Fibrodysplasia ossificans progressiva (FOP) is a rare, genetic disorder characterized by ectopic bone formation and congenital malformation of the great toes. The gene defect is unknown and there is no established medical treatment. Early lesions of heterotopic bone present over the neck, spine, or shoulder as painful nodules that are warm, erythematous, and tender. Histology shows proliferating fibroblasts with sparse inflammatory cells. Within a few months, the lesions ossify by an endochondral process. Most patients first develop ossification before 15 years of age (mean onset 3 - 5 years). We report a middle-age woman with FOP who first developed ectopic ossification at age 47 years. Symptoms began with progressive pain, redness, warmth, and swelling over a scapula. CT showed asymmetric thickening of the muscles and fascial planes, but no ectopic bone formation. Biopsy revealed proliferating fibroblasts with scattered inflammatory cells. Prednisone, 60 mg daily, was started for a suspected inflammatory fasciitis. Symptoms initially improved, but returned during steroid taper - now involving several regions over the posterior thorax, flank, and chest. Despite high dose corticosteroids, immunosuppressive agents, and alendronate early in the course of this ossification, ectopic bone deposition progressed rapidly. She had the typical hallux valgus deformity of FOP. Methylprednisone (24 mg BID), methotrexate (maximum dose: 25 mg weekly), and alendronate (35 mg weekly) appeared to improve symptoms. Subsequently, however, these worsened, and methotrexate was discontinued due to non-efficacy (total time of treatment: 14 weeks). While continuing high dose steroids and alendronate, she developed new, larger lesions during trials of azothiaprine (maximum dose: 125 mg daily, total time of treatment: 10 weeks) and mycophenolate mofitil (maximum dose: 1 g BID, total time of treatment: 10 weeks). CT 13 months after onset of symptoms showed many regions of ectopic bone involving the fascial planes of the thoracic, abdominal, and pelvic walls. Our patient demonstrates that FOP may present well into adulthood when progression may seem inexplicably rapid despite early intervention with high dose steroid, immunosuppressive, and bisphosphonate therapy. It is important to recognize an adult-onset presentation for FOP because early diagnosis can help avoid harmful procedures (e.g. biopsy or surgical excision typically exacerbates the disorder) and unnecessary treatment.

High-Normal Bone Mass in a Child with Insulin-Resistance Syndrome (Rabson-Mendenhall) despite Severe IGF-I, IGF-II and IGFBP-3 Deficiency. J. L. Fowlkes, H. N. Coleman*, R. C. Bunn*, K. M. Thrailkill. Pediatrics, UAMS and ACHRI, Little Rock, AR, USA.

Rabson-Mendenhall syndrome is a rare genetic disorder characterized by severe insulin resistance due to defects in signaling through the insulin receptor (IR). Phenotypically, these individuals display characteristic features including premature and dysplastic dentition, coarse facial features, lack of subcutaneous fat, acanthosis nigricans, enlarged genitalia, hypertrichosis, paradoxical hypoglycemia with postprandial hyperglycemia, and circulating insulin levels which have been reported to be as high as 1000 times normal. Investigations of the growth hormone (GH) - insulin-like growth factor (IGF) axis in this individual, revealed severe deficiencies in IGF-I, IGF-II and IGFBP-3, and hyperinsulinemia (see Table). Thus, it was anticipated that this child would have severe bone deficits, as has been described in other clinical scenarios where the IGF axis is similarly perturbed (e.g. growth hormone resistance syndrome, IGF-I deletion). While long-bone studies revealed no gross malformations (with the exception of short 4th metacarpals) and the bone age was delayed at -2.0 STD, DEXA scanning revealed a total body bone density Z-score of +2.0 (800 gm/m^2), suggesting an overall high-normal BMD for age. We propose a mechanism by which supra-normal concentrations of insulin may substitute for the actions of IGFs in bone formation by signaling though the IGF-I receptor.

Age (months)	GH (ng/ml)	IGF-I (ng/ml)	IGF-II (ng/ml)	IGFBP-1	IGFBP-3 (mg/L)	Insulin (uU/ml)

Hypophosphatasia: Misleading *In Utero* Presentation for the Childhood and Odonto Forms. D. Wenkert[1], W. H. McAlister*[2], J. H. Hersh*[3], S. Mumm[4], M. P. Whyte[1]. [1]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA, [2]Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO, USA, [3]Weisskopf Center for the Evaluation of Children - Department of Pediatrics, University of Louisville, Louisville, KY, USA, [4]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Hypophosphatasia (HPP) is a rare, heritable rickets/osteomalacia featuring deficient activity of the "tissue nonspecific" isoenzyme of alkaline phosphatase (TNSALP) from deactivating mutation of the *TNSALP* gene. We warn that skeletal deformity *in utero* may not imply a severe outcome. Patients assessed with severe skeletal findings on fetal ultrasound (u/s) from 3 separate families were referred with mild bone disease *ex utero*. Abortion had been discussed for each. These 3 boys, described below, and 5 previously reported girls distinguish "benign prenatal HPP" (BP-HPP) from "perinatal" HPP, a typically lethal, autosomal recessive form of HPP which also manifests *in utero*. The 3 mothers carry different *TNSALP* missense mutations. At birth, each boy had mild limb bowing and shortening and then manifested delayed walking and early tooth loss. *Family 1*: Fetal u/s of 2 pregnancies to a mother with "childhood" HPP (C-HPP) showed severe "skeletal bowing" and demineralization. The 1st was terminated. The 2nd produced a boy with C-HPP. He, his mother, and the aborted fetus each carried a single *TNSALP* mutation (A1133T; Asp361Val). *Family 2*: Fetal u/s showed oligohydramnios, small size, and "extremity fractures" interpreted as OI. By age 3 years, long bone bowing had spontaneously improved. Developmental delay, failure to thrive, and cataracts were unexplained. X-rays showed no rickets ("Odonto-HPP"). The subsequent pregnancy, w/o oligohydramnios, showed no u/s abnormalities. The patient, mother, and sibling each carried a single *TNSALP* mutation (G188T; Gly46Val). *Family 3*: Fetal u/s of a boy with C-HPP showed *in utero* bowing and dwarfism. He had 2 *TNSALP* mutations (G526A; Ala159Thr and A881C; Asp277Ala). In each of these BP-HPP families, with either autosomal dominant or recessive inheritance, mothers carried a *TNSALP* mutation. The BP-HPP skeleton seems to improve during the 3rd trimester of pregnancy. Thus, BP-HPP must be considered when prenatal u/s shows fractures or bowing. Analysis of fetal or parental *TNSALP* would identify possible BP-HPP. A single mutation in the fetus or only 1 parent would suggest this outcome. With two *TNSALP* mutations, normal chest size, adequate skull mineralization, or presence of *in utero* packing may help distinguish BP-HPP from severe perinatal, but not infantile, forms of HPP.

Deactivating Germline Mutations in LEMD3 Cause Osteopoikilosis and Buschke-Ollendorff Syndrome, but not Melorheostosis. S. Mumm[1], X. Zhang*[1], W. H. McAlister*[2], D. Wenkert[3], M. P. Whyte[3]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, [2]Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO, USA, [3]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA.

In 2004, heterozygous loss-of-function mutations in the LEMD3 gene (also called MAN1), which encodes an inner nuclear membrane protein, were shown to be a cause of osteopoikilosis (a benign, autosomal dominant, skeletal dysplasia featuring multiple hyperostotic lesions symmetrically throughout the skeleton) and Buschke-Ollendorff syndrome (BOS) (a benign, autosomal dominant disorder combining osteopoikilosis with disseminated connective tissue nevi). In some of these families, unusually large areas of dense bone were called "melorheostosis" which typically refers to a troublesome sporadic skeletal dysostosis characterized by asymmetrical "flowing hyperostosis" of the cortex of long bones often with overlying soft tissue abnormalities. Others had previously proposed that melorheostosis results from a second, post-zygotic, somatic mutation in the putative osteopoikilosis gene. We investigated patients representing 9 separate families with sclerosing bone disorders where LEMD3 represented a candidate gene abnormality: 1 osteopoikilosis, 2 BOS, 2 melorheostosis, 1 reported with both osteopoikilosis and melorheostosis, and 3 additional patients with other bone dysplasias including 1 mixed-sclerosing-bone dystrophy, 1 osteomesopyknosis, and 1 polycystic osteosclerosis with hypercalcemia. Genomic DNA, isolated from blood lymphocytes, was amplified by PCR and sequenced for all the coding exons and adjacent splice site regions for the LEMD3 gene. We did not study melorheostosis lesional tissue. A heterozygous nonsense mutation (T1433A, Leu478Stop) was found in exon 1 for the osteopoikilosis patient, and a heterozygous nonsense mutation (exon 1, C1323A, Tyr441Stop) and another heterozygous mutation (insertion or deletion in exon 1) were found in the 2 BOS patients. Likewise, a heterozygous nonsense mutation (C1963T, Arg655 Stop) in exon 7 was detected for the patient with osteopoikilosis and "melorheostosis". However, no LEMD3 mutations were detected for any other patient, including the 2 patients with classic melorheostosis. We conclude that osteopoikilosis and BOS are caused by heterozygous deactivating LEMD3 mutations, however, melorheostosis remains of unknown etiology.

Metabolic Bone Disease in Patients Presenting Short Bowel Syndrome. R. Javier*[1], A. Ledit*[2], J. Reimund*[2], J. Kuntz*[1]. [1]Rheumatology, Universitary Hospital, Strasbourg, France, [2]Hepatogastroenterology, Universitary Hospital, Strasbourg, France.

Despite its pathophysiology remains incompletely understood, metabolic bone disease (MBD) is a frequent complication of home parenteral nutrition (HPN) needed by short bowel syndrome (SBS). Patients with SBS not needing HPN may also be at risk for developing bone complications. Therefore, we analyse bone status in SBS patients without HPN and compared them to HPN patients trying to identify some favouring factors in each group. AIMS & methods : Fourteen SBS patients (mean age 53 years, 25-80) which do not need HPN have been compared to 18 HPN (mean age 57 years, 17-79).The mean duration of HPN was 40 months. Clinical symptoms were recorded as well as laboratory parameters including markers of bone metabolism, hormonal, inflammatory and nutritional status, radiological studies and bone mineral density (BMD) measured by dual absorptiometry. Statistics used non parametric tests. Results : In HPN group, bone pain was present in 11 patients (61 %) and 4 (22 %) had a fracture (mostly vertebral fractures). In SBS without HPN group, 4 experienced bone pain (29 %) and 1 had a vertebral fracture. Clinical nutritional status and nutritional proteins were normal and comparable in both groups. In both groups, BMD was decreased : in HPN group, no patient had normal BMD, 10/18 (56 %)were osteoporotic (T score < - 2.5) and 8/18 (44%) were osteopenic (-2,5< T score< -1) compared with respectively 5/14 (36%) and 8/14 (57%) in SBS without HPN group (difference not statistically significative). In HPN group, BMD was negatively correlated to duration of SBS (mean duration of SBS :72 months ,6-240 months) and orosomucoïd suggesting that a long duration of malnutrition combined with persistant and unexplained inflammation can be deleterious for bone status. In SBS without HPN, BMD was associated with low body mass index, low 25OH vit D3, low serum albumin, vitamine A and IGF-1 concentrations. Conclusion : Most SBS patients with and without HPN had metabolic bone disease often with pain and fractures. In SBS without HPN patients, MBD seems to be related to subclinical malnutrition. This was not the case in HPN patients in whom no particular favouring factor could be identified. Therefore, we recommend to assess systematically bone status in SBS patients with and without HPN also in those having an apparently normal nutritional status. Attention must be given to 25OH vit D3 levels

Cytokine-Mediated Osteoclastogenesis: A Possible Mechanism for Excess Bone Loss in Postmenopausal HIV Infected Women. M. T. Yin*[1], J. Laurence*[2], J. M. Fakruddin*[2], D. Irani*[3], J. F. Dobkin*[1], E. Shane[3]. [1]Infectious Diseases, Columbia University, NY, NY, USA, [2]Laboratory for AIDS Virus Research, Weill Medical College of Cornell University, NY, NY, USA, [3]Endocrinology, Columbia University, NY, NY, USA.

Low bone density (BMD) is a complication of HIV/AIDS and may be accelerated by certain types of antiretroviral (ARV) therapy. Excess bone loss may be related to HIV-associated upregulation of bone resorbing cytokines (TNF-α, RANKL) or to direct effects of ARVs on osteoclasts (OC). We have reported that ritonavir (RTV), at concentrations (1-5 μM) found in HIV+ patients, increases osteoclastogenesis in vitro, likely by facilitating downstream RANKL signaling mechanisms. To investigate the pathogenesis of the bone loss, we measured serum bone turnover markers and cytokines, and BMD by DXA in 51 HIV+ and 31 HIV- postmenopausal (PM) women of similar age and ethnicity. We also compared OC differentiation from subject's peripheral blood mononuclear cells, cultured in the presence of their own sera (Autologous Serum-induced OC Induction or AOI assay). Serum osteocalcin, N-telopeptide (NTX), RANKL, TNF-α and AOI were significantly higher and total hip (TH) BMD lower in HIV+ PM women (Table). Bone alkaline phosphatase (BAP) was significantly higher (42.3±22 v 32.9±8, p=0.04) and spine (LS) BMD lower (0.856±0.14 v 0.968±0.16, p=0.02) among HIV+ PM women currently receiving ARVs (N=40) than not. Women on RTV (N=8) had higher serum osteocalcin (10.5±3 v 7.4±6, p=0.03), TNF-α, (115.2±28 v 50.7±26, p<0.001) and AOI (1.81±0.3 v 1.22±0.2, p=0.01) than HIV+ women not on RTV. AOI and TNF-α levels were positively correlated (r=0.61, p=<0.001). In summary, serum bone-resorbing cytokines are higher in HIV+ than HIV- PM women and associated with lower BMD and increased OC induction *in vitro*. RTV is associated with higher serum TNF-α, osteocalcin, and OC activity. We conclude that HIV infection is associated with greater propensity for osteoclastogenesis, which may be mediated by TNF-α and RANKL and further increased by RTV. Such conditions may favor excess bone loss in HIV+ PM women.

Table. Biochemical indices and BMD in HIV+ and HIV- PM women, Mean+SD

	HIV+	HIV-	P values
BAP	40.4±20 ng/ml	34.4.±16	0.16

Comparing Risk Factors for Hip and Knee Osteoarthritis in Japan and Britain. N. Yoshimura[1], H. Oka*[1], H. Kawaguchi[2], K. Nakamura[2], C. Cooper[3]. [1]Department of Joint Disease Research, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Faculty of Medicine, the University of Tokyo, Tokyo, Japan, [3]MRC Epidemiology Resource Centre, University of Southampton, Southampton General Hospital, Southampton, United Kingdom.

Osteoarthris (OA) is a frequent course of pain and disability in both Japan and Britain, however, there is little comparative study of the hip and knee OA among different ethnic groups. We therefore performed parallel case-control studies of hip and knee OA in Britain and Japan, with the objective of exploring differences in the risk factors profile between the two countries. In each country, we selected representative population samples (Japan: Wakayama, Arita, Sennan; Britain: Portsmouth and North Staffordshire). A case register was established in each district whereby the orthopaedic surgeons recorded all men and women aged 45 years and over, who were listed for hip/knee arthroplasty. For each case, a control of the same sex, age (to within three years) was selected randomly from the list of resident registrations of the same city where the case lived. Cases and controls completed a structured interviewer-administered risk factor questionnaire. One hundred and fourteen in hip OA (11 men and 103 women) and 138 (37 men and 101 women) in knee OA completed the study in Japan. In the hip study, there was a statistically significant association between occupational lifting and OA, such that regular lifting of 25 kg in the individual's first job (OR=3.0, 95% CI 1.1-8.4) was associated with an increased risk of hip OA. In the British study of hip OA, independent risk factors included obesity, previous hip injury, the presence of Heberden's nodes, and occupational lifting. In the Japanese knee study, the heaviest weight in the past (OR 2.9, 95% CI 1.2-7.1), previous knee injury (OR 4.1, 95% CI 1.9-8.9), and total working period (OR 1.03, 95% CI 1.01-1.06) represented independent factors associated with knee OA after controlling for other risk factors. In the British study for knee OA, independent risk factors included obesity, previous knee injury, the presence of Heberden's nodes, and occupational kneeling/squatting. These data suggest that obesity, previous injury and occupational factors are risk factors for knee OA in Britain and Japan. The data provide a marked contrast with hip OA, which was associated with obesity in Britain, but not in Japan.

Defective Implant Osseointegration under Protein Undernutrition: Reversal by PTH or Pamidronate. R. Dayer*, R. Rizzoli, P. Ammann. Department of rehabilitation and geriatrics, Division of bone diseases, Geneva, Switzerland.

Protein deficiency is highly prevalent among patients in orthopedic wards. We previously demonstrated that isocaloric low protein intake impairs titanium implant osseointegration in rats, with a decreased strength needed to loose the implant and altered bone microarchitecture in the implant vicinity. This is associated with decreased bone formation and increased bone resorption. Whether stimulator of bone formation or inhibitor of bone resorption could improve titanium implant osseointegration under protein undernutrition conditions is not known. We measured the resistance to pull-out of 1 mm diameter titanium rods implanted into proximal tibia of 10 month-old female rats receiving a normal (n=27) or isocaloric low protein diet (n=27). After 2 weeks on either diet, the implants were inserted, and the rats received PTH (1-34) (40 μg/kg, 5/7 days), pamidronate (0.1mgP/kg, 5/28 days) or the corresponding vehicles for 8 weeks. Then, the tibias were removed for microtomographic histomorphometry. For pull-out strength resistance to implant pull-out was tested by recording the maximal force necessary to completely loose the implant. All results are expressed as means±SEM. Significance of difference was evaluated with an analysis of variance (* vs 15% casein, ° vs 2.5% casein). Pull-out strength was significantly lower in rats fed an isocaloric low protein diet compared with control rats. PTH and pamidronate markedly increased pull-out strength in animal fed a normal or a low protein diet; the effect of PTH being of higher magnitude. The PTH- or pamidronate increase in pull-out strength were associated with significant changes of trabecular bone volume, trabecular number and thickness, connectivity and bone contact Index in the vicinity of the implant. A structure model index (SMI) analysis revealed a significant shift to a more plate-like pattern in the rats treated with PTH or pamidronate, irrespective of the diets. We confirm that isocaloric low protein intake reduces the osseointegration of titanium implant. Treatments with PTH or pamidronate prevent the deleterious effect of protein undernutrition and even markedly improve the implant osseointagretion. These results indicate potential problems of prosthetic replacement in protein undernourished patients and suggest some systemic treatments to prevent them.

	Pull-out strength Casein normal	Pull-out strength Casein low	BV/TV Casein normal	BV/TV Casein low
control	31.3±2.7	22.1±2.0 *	0.20±0.02	0.11±0.01 *
pamidronate	52.8±4.6 *	43.0±3.0 *°	0.44±0.03 *	0.36±0.02 *°

Bone Density and Vitamin D Status in Men and Women with Lower Extremity Stress Fractures. N. A. Glass*[1], T. Martin*[2], M. Walcott*[1], J. Glowacki[2], M. S. LeBoff[1]. [1]Endocrine, Brigham and Women's Hospital, Boston, MA, USA, [2]Orthopedics, Brigham and Women's Hospital, Boston, MA, USA.

Stress fractures, which account for 10% of all sports injuries, are caused by repetitive strain that exceeds the compensatory threshold of bone. Vitamin D deficiency can lead to low bone density, and if severe, rickets or osteomalacia, with associated skeletal abnormalities such as pseudofractures or stress fractures. Data on the vitamin D status of otherwise healthy adults with stress fractures are limited. This study was designed to determine the bone health and prevalence of vitamin D deficiency in otherwise healthy adults with stress fractures. We enrolled 25 men and women between the ages of 18-40 years, 11 with stress fractures of the lower extremity (Fx) and 14 without stress fractures (NFx.) All subjects were screened for secondary causes of low bone mass. Bone mineral density (BMD) and body composition were measured by dual x-ray absorptiometry (DXA). Lab evaluations for 25 (OH) vitamin D (DiaSorin RIA, Stillwater, MN; normal 20-57 ng/ml), and n-telopeptides (NTX) were completed. Heights and weights were obtained and body mass index (BMI) was calculated.

Variable	Fracture (mean±SD)	Control (mean±SD)	p value
BMD Spine (g/cm^2)	0.969 ±0.022	1.079±0.022	0.002
BMD Femoral Neck (g/cm^2)	0.826±0.024	0.959±0.032	0.005
BMD Trochanter (g/cm^2)	0.694±0.024	0.801±0.027	0.009
BMD Total Hip (g/cm^2)	0.948±0.034	1.067±0.031	0.018
BMD Whole Body (g/cm^2)	1.138±0.020	1.185±0.019	0.120
25(OH)D ng/ml (median, range)	34.82, (11.85-76.68)	32.94, (13.22-63.16)	0.395
NTX nmol/mmol Cr (median, range)	51.50, (25-109)	37.00, (5-123)	0.426

There was an equal distribution of men and women in each group, and the groups did not differ in age (Fx=26.2±2.2, NFx= 21.8±2.5, p=0.087,) BMI (Fx=21.8±0.92, NFx=22.3±0.41, p= 0.603,) percent body fat (Fx=21.2±2.4, NFx=19.8±2.1, p=0.664 ,) or weight (Fx=64.1±3.26, NFx=67.9±2.06, p=0.310.) Men and women with stress fractures had low BMD of the hip and spine with normal vitamin D levels compared with controls. With the numbers available, there were no significant differences in vitamin D status or NTX levels between groups. With continued enrollment, the lack of differences in vitamin D levels between groups will be tested. In conclusion, men and women with stress fractures of the lower extremity have significantly lower BMD of the hip and of the spine compared with controls.

Mechanism of Bone Formation in Non-Hereditary Heterotopic Ossification. K. L. Foley*[1], N. Hebela*[2], R. K. Suda*[1], M. Keenan*[2], R. J. Pignolo[1]. [1]Department of Medicine, University of Pennsylvania, Philadelphia, PA, USA, [2]Department of Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA.

In postnatal life, new bone formation is normally restricted to regeneration of osseous tissue at sites of fracture. However, heterotopic ossification, or the formation of bone outside the normal skeleton, can occur within muscular, adipose, or non-muscle fibrous connective tissue. Ectopic bone formation is the only example of complete recapitulation of an organ system, replete with hard tissue, vascular, and marrow elements. Non-hereditary heterotopic ossification (NHHO) may occur after musculoskeletal trauma, following CNS injury, with certain arthropathies, or following injury or surgery that is often sustained in the context of age-related pathology. Histological development of heterotopic ossification has not been adequately described. We performed a histological analysis of 20 bone specimens from 17 patients with NHHO secondary to common precipitating conditions, including traumatic brain injury, spinal cord injury, trauma without neurologic injury, and total hip or knee arthroplasty. All bone specimens revealed normal endochondral osteogenesis at heterotopic sites. In order of sequence progression, the histological stages of NHHO lesion formation are: (1) perivascular lymphocytic infiltration, (2) lymphocytic migration into soft tissue, (3) reactive fibroproliferation, (4) neovascularity, (5) cartilage formation, and (6) endochondral bone formation. This study establishes the predominant histopathological findings associated with NHHO and can serve as a basis for elucidation of candidate gene(s) in the pathogenesis of this disorder.

Fluoride in Bottled Teas. M. P. Whyte. Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

In January 2005, we reported skeletal fluorosis (SF) in an otherwise healthy, middle-age, American woman who consumed inordinate amounts of double-strength *instant* tea throughout her adult life. Although SF is rare in the U.S., it is common in Asia when inferior quality, F^- rich, "brick" tea is consumed. SF causes axial skeletal pain and ligament ossification. There is no established treatment. At that time, we found that the fluoride (F^-) concentration in beverages made regular strength in distilled water using several U.S. commercial instant tea mixes exceeded FDA limits (1.4-2.4 ppm) for bottled water and beverages, and for one preparation of one brand the EPA limit (4.0 ppm) for drinking water. We cautioned that SF could result from long-term consumption of excessive amounts of some *instant* teas. Here, the F^- content is reported for commercial, ready-to-drink, *bottled*, liquid teas purchased from a supermarket and assayed, once again, using "ion-specific electrode with known additions" methodology *(Table)*. We find (single examination of 11 individual bottled teas) 4 of 11 were at, or exceeded, FDA limits for F^- in bottled beverages. Tea drinking remains popular in the U.S. and increasingly is suggested to promote health. Intake of at least 10 mg F^- daily for 10 yrs seems necessary for "preclinical SF", i.e. the "no-observed-adverse-effect level" for adults. EPA National Primary Drinking Water Regulations stipulate a maximum F^- of 4.0 ppm, i.e., the lowest effect level for crippling SF of 20 mg/d with continuous exposure for at least 20 years. Accordingly, the Public Health Service regulates community water fluoridation stipulating optimum levels 0.7 -1.2 ppm depending on average air temperature. Preference for commercial drinks is diminishing per capita consumption of tap water. Our concern is that SF may result from prolonged drinking of excessive amounts of some teas. Our findings call for better understanding of amounts and systemic effects of F^- in teas.

Osteoporosis, Dental Status and Disability in an Elderly Population of Northeastern Italy. E. Musacchio*[1], E. Perissinotto*[2], P. Binotto*[3], L. Sartori[1], F. Silva-Netto*[1], S. Zambon*[1], M. Corti*[4], E. Manzato*[1], G. Baggio*[5], G. Crepaldi[6]. [1]Medical & Surgical Sciences, University of Padova, Padova, Italy, [2]Enviromental Medicine & Public Health, University of Padova, Padova, Italy, [3]University of Padova, Padova, Italy, [4]ULSS n.16, Padova, Italy, [5]Medicina Generale, Padova Hospital, Padova, Italy, [6]Aging Branch, CNR, Padova, Italy.

The diagnosis of osteoporosis and the evaluation of fracture risk are currently based on bone mass assessment. X-ray evaluation of dental arches has been suggested as a reasonable alternative to densitometry. The risk factors for osteoporosis include risk factors associated with periodontal disease and related tooth loss. Moreover, dental impairment *per se* is a risk factor for the progression to disability. To evaluate the usefulness of dental status assessment for identifying subjects at risk of low bone mass and disability, we studied 3,099 elderly (age 76.8±8.7) participating in the PRO.V.A., a large epidemiological study carried out in Northeastern Italy. All subjects underwent home interview and clinical visit with oral examination and physical performance measures. Ultrasonographic assessment of bone mass as well as biochemical determination of bone parameters were performed. The mean number of residual teeth was 7.3 (M 7.9, F 6.9) while the prevalence of edentulism was 43.7%, increased with age and was more pronounced in the females. Prostheses of both arches were largely used (78.7%), yet 17.6% of the edentulous subjects did not wear any artificial denture. Difficulty at chewing food was reported by 47.4% and at swallowing by 14.0% of the total population. Residual teeth number showed significant correlations with instrumental and biochemical parameters as well as with functional indexes such as grip strength, knee extension and ADL disability. Logistic regression analysis adjusted on age and vit. D levels demonstrated a significant association between high teeth number and bone mass (O.R. 1.6; 95% CI 1.2-2.1). Subjects with conserved dentures and without osteoporosis had less disability and depression but low residual teeth number alone identified a larger proportion of impaired subjects compared to the presence of osteoporosis alone. In particular, in the oldest class of age (85+yrs), disability was reported by 55.7% of the subjects but only by 29% of those with more than 20 teeth and the same results were found in the case of previous falls (40.8% vs 24.7%). Our data demonstrate that oral disorders could have significant effects on frailty and disability markers in the elderly. Moreover, the correlations with bone remodelling and instrumental parameters suggest a possible clinical use of dental evaluation, at least in epidemiological studies.

Regional Changes in Body Composition 3 Months to 30 Years after Traumatic Spinal Cord Injury (SCI): Results of a Cross Sectional Study in 100 Paraplegic Men. C. Senn*[1], O. Franta*[1], A. W. E. Popp[1], D. Michel*[2], H. Knecht*[2], R. Perrelet*[1], G. Zaech*[2], K. Lippuner[1]. [1]University Hospital of Berne, Osteoporosis Policlinic, Berne, Switzerland, [2]Swiss Paraplegic Center, Nottwil, Switzerland.

It has been shown earlier that paraplegia induces severe and sustained infralesional cortical and trabecular bone loss (Osteoporosis Int 2004; 15:180-9). However, little is known on the long-term changes in body composition (lean mass, fat mass and bone mass) at the supra- and infralesional levels. The aim of the study was to document the long-term supralesional (arms) and infralesional (legs) changes in body composition with time since SCI in paraplegic men. One hundred paraplegic men (age 18-60ys) with complete motor posttraumatic medullary lesion T1-L3 and total motor and total or partial sensory loss (Frankel stage A or B) since 3 months to 30 years were included in this cross-sectional study. Body composition was assessed on whole body scans performed by DXA (Hologic QDR 4500A™). Total mass (TM), lean mass (LM), fat mass (FM), and bone mass (BM) of arms and legs were determined and expressed as grams. In addition, the ratios of LM/TM,

FM/TM, and BM/TM were calculated in percent. The influence of time since SCI on these parameters was then tested using logarithmic regression analysis. Means ± SD of the relative distribution of tissues in arms and legs are shown in the table.

	Supralesional (arms)	Infralesional (legs)
LM/TM (%)	78.9 ± 6.5	64.6 ± 10.2
FM/TM (%)	16.5 ± 6.8	32.3 ± 10.6
BM/TM (%)	4.6 ± 0.6	3.1 ± 0.8

With time since SCI, TM, LM, FM, and BM of the arms increased (r^2=0.3, p<0.0001; r^2=0.2, p<0.0001; r^2=0.1, p<0.01 and r^2=0.1, p<0.01, resp.). A non significant trend towards a decrease in LM/TM was accompanied by a non-significant trend towards an increase in FM/TM with time since SCI (both p<0.1), while BM/TM was significantly reduced (r^2=0.15, p<0.0001). In the legs, TM, and LM did not change significantly with time since SCI, while FM increased (r^2=0.1, p<0.05) and BM dramatically decreased (r^2=0.4, p<0.0001). Furthermore, with time since SCI, LM/TM, and BM/TM decreased (r^2=0.1, p<0.05, and r^2=0.5, p<0.0001, resp.), whereas FM/TM increased (r^2=0.1, p<0.01). In paraplegic men, 3 months up to 30 years post SCI, total, lean, fat, and bone mass increase with time since SCI in the arms, possibly as a result of intensive physical training and use of the arms. In the legs, total mass remains unchanged, bone mass is lost extensively, while lean mass is partly substituted by fat mass.

Improved Biocompatibility of Niobium-Containing Titanium Alloys with Respect to Macrophage Activation and Inflammatory Osteolysis. K. A. Rider*[1], C. J. Boehlert*[2], L. M. Flick[1]. [1]Biology, Alfred University, Alfred, NY, USA, [2]Chemical Engineering and Materials Science, Michigan State University, Lansing, MI, USA.

Biocompatibility of implant materials is a critical issue in the design and success of any orthopaedic implant. In this study, the biocompatibility of two vanadium-free Ti-Al-Nb alloys, Ti-15Al-33Nb and Ti-21Al-29Nb, was tested and compared to that for commercially pure titanium (CP Ti) and alumina ceramic (Al_2O_3). Previous work in this area has shown that CP Ti induces significant inflammatory osteolysis while alumina ceramic has been described as biologically inert. Biocompatibility was assayed using in vitro cell culture techniques to examine macrophage-mediated phagocytosis and production of inflammatory cytokines. In addition, particles of each material were used in a small-animal model of wear debris-induced osteolysis to measure the osteolytic response and to assess the degree of T-cell infiltration. RAW 264.7 cells phagocytosed all types of particles readily and did not experience a loss of viability as a result. High levels of TNFa were produced in response to the CP Ti particles after only 24 hours but not in cultures with either niobium alloy or the alumina ceramic particles. In vivo, substantial osteolysis was observed 10 days post particle implantation with the CP Ti and alumina particles but not with either alloy. The osteolysis correlated with an extensive T-cell infiltrate in the CP Ti group but not the Al_2O_3 animals. The results showed that there was no significant difference in the biocompatibility of the two alloys compared to each other. However, despite equivalent phagocytosis by the macrophage cell line, the amount of TNFa and osteolysis was reduced in response to the alloys compared to commercially pure titanium. In addition, the immune system appears to discriminate between the alloys and the CP Ti, as immunohistochemistry demonstrated reduced staining for T-cells in the soft tissue surrounding the implanted particles in the alloy-treated groups but not the CP Ti animals. These results suggest that these alloys would be potentially useful for orthopaedic applications due to their improved biocompatibility.

Metabolic Bone Disease as a Result of Pregnancy and or Famine in an Ancient Egyptian Mummy. J. Denton, A. R. David*. KNH Centre for Biomedical and Forensic Studies in Egyptology, University of Manchester, Manchester, United Kingdom.

Skeletal remains of ancient cultures are often the only human remains useful for examination. External osteometric measurement is a commonly practiced method of examination but it is limited in its application. Much more scientific information can be obtained by the histological examination of soft tissues and skeletal remains. The KNH centre at Manchester University houses the International Human Mummy Tissue Bank, some of the Nubian specimens from this collection were used in this study. All femurs were assessed using osteometric parameters to be female. Trephine samples were taken from the lateral femoral condyles of 10 of the Nubian Mummies. The samples were decalcified in EDTA and LR White acrylic resin embedded. Sections 5 micron thick was stained by Toluidine blue. Histological examination of the femoral condyle from one of the Nubian mummies showed the presence normal lamellar bone in the centre of most of the trabeculae. The surface of this normal bone showed evidence of extensive osteoclastic resorbtion. On cessation of the resorbtion there was a period of new bone formation, following a prolonged apposition of new bone the cycle of osteoclastic resorbtion was repeated involving the new woven bone and extending down to and through the old normal lamellar bone. However, this time there was no period of subsequent new bone formation and it can be assumed that death of the individual stopped this continuing cycle. In addition to the altered function of the bone there was marked osteopenia. Pregnancy and lactation are both causes of cyclic osteoclastic resorbtion with subsequent new bone formation. Concurrent poor nutrition will exacerbate the osteoclasis and have an influence on the properties of the new bone formation in the healing phase. The remaining nine bone specimens were unremarkable.

Vancomycin Covalently Bound to Ti6Al4V Pins Eradicates Bacterial Colonization. V. Antoci*[1], B. Jose*[2], N. Hickok*[1], E. Wickstrom*[2], A. Zeiger*[2], I. M. Shapiro[1], J. Parvizi*[1], C. S. Adams[1]. [1]Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA, [2]Biochemistry, Thomas Jefferson University, Philadelphia, PA, USA.

Despite immense improvements, periprosthetic infection continues to compromise the success of joint arthroplasty. We have developed a novel method to covalently tether vancomycin to metal (Ti powder and Ti6Al4V pins) surfaces using solid phase peptide synthesis. The reaction efficiency was monitored suggesting that vancomycin was present in saturating concentrations on both the powder and pins. Based on immunohistochemical staining, vancomcyin was evenly distributed over the surface of the Ti powder and Ti6Al4V pins, while controls exhibited no staining. To determine bactericidal activity, quantitative culture of *S. aureus* was performed after 30, 60, 90, and 120 min static incubation at 37° C, and followed by serial dilution plating. Table 1 reports the normalized colony counts from this experiment (* = significantly different from Ti). The vancomycin-tethered Ti powder reduced colony formation by 75% at 1 h and 88% at 2 h when compared to Ti control. Viability of adherent bacteria on vancomycin-tethered Ti6Al4V pins was determined by confocal laser microscopy (Olympus Fluoview 300) after staining using the Live/Dead BacLight Viability Kit (Molecular Probes). Based on the Live/Dead assay, *S. aureus* readily adhered to control surfaces, emitting extensive green fluorescence (green = live and red = dead bacteria). In contrast, *S. aureus* attachment was nearly abolished on vancomycin-tethered surfaces (powder and pins). When either surface that had been previously exposed to *S. aureus* were washed, re-challenged and analyzed, the vancomycin-tethered surfaces retained their ability to kill *S. aureus*. Our surface modification shows potent antibacterial activity able to actively eradicate bacteria on the surfaces while showing long term stability resistant to physical stress. This technology is likely to provide the answer for the manufacturing of targeted implants that can be self-protective against periprosthetic infection and may remedy the shortcomings of the current antibiotic delivery methods including unpredictable elution kinetics, lack of long-term activity, and inactivation of antibiotics by methylmethacrylate cement.

Table 1. Ti-tethered vancomycin inhibits proliferation of S. aureus.

	30 min	60 min	90 min	120 min
Ti	100.00	140.84	128.80	100.52
VAN-Ti	39.41	34.08	22.90	11.72

RAGE Null Mice Exhibit Enhanced Bone Turnover. K. H. Ding[1], Z. Z. Wang*[2], Z. Deng*[2], M. W. Hamrick*[3], P. P. Nawroth*[4], J. X. She*[2], D. M. Stern*[5], C. M. Isales[6], Q. S. Mi*[2]. [1]Medicine, Medical College of Georgia, Augusta, GA, USA, [2]Center for Biotechnology and Genomic Medicine, Medical College of Georgia, Augusta, GA, USA, [3]Cellular Biology, Medical College of Georgia, Augusta, GA, USA, [4]Medicine and Neurology, University of Heidelberg, Heidelberg, Germany, [5]Medical College of Georgia, Augusta, GA, USA, [6]Medicine and Orthopedic Surgery, Medical College of Georgia and the Augusta VA Hospital, Augusta, GA, USA.

To test the hypothesis that activation of RAGE (Receptor for Advanced Glycation End products) contributes to normal bone turnover, we examined RAGE knockout mice on bone densitometry (DEXA), bone imagine (X-ray), bone biomechanics, and blood serum biochemistry. Compared to age-matched 1- and 3-month-old male C57Bl/6J controls, RAGE-/- mice exhibited a significant increase in bone density in whole body, spine, and right femur measured PIXImus (Whole body: 1 M: wild-type: .0290 ± .0015; RAGE-/-: .0327 ± .0005, P < .001; 3 M: wild-type: .0474 ± .0016; RAGE-/-: .0509 ± .0023, P < .001; Spine: 1 M: wild-type: .0311 ± .0031; RAGE-/-: .0348 ± .0011, P < .01; 3 M: wild-type: .0531 ± .0035; RAGE-/-: .0550 ± .0043, P > .05; Right femur: 1 M: wild-type: .0324 ± .0023; RAGE-/-: .0387 ± .0011, P < .001; 3 M: wild-type: .0649 ± .0036; RAGE-/-: .0700 ± .0043, P < .01; Data are Means ± SD, g/cm^2, n=9-15). Consistent with these bone density data, RAGE-/- mice also had significantly lower levels of bone breakdown marker pyridinoline (1 M: wild-type: 1.95 ± .2; RAGE-/-: 1.71 ± .2, P < .05; 3 M: wild-type: 2.20 ± .3; RAGE-/-: 1.72 ± .3, P < .01, nmol/L, n= 9-15) and a significant decrease in IL-6 level at 3-month old (wild-type: 11.62 ± 5.6; RAGE-/-: 6.34 ± 3.1, P < .05), although there are no significant changes between these two group animals at age 1- and 3-month old in blood serum alkaline phosphatase, calcium, and glucose. Biomechanics study reveled that RAGE-/- mice at 3-month-old had a significant increase in energy to break point (wild-type: .004 ± .001; RAGE-/-: .007 ± .002, P < .01), in strain at user break (wild-type: .0071 ± .014; RAGE-/-: .093 ± .020, P < .05), in displacement at user break (wild-type: .477 ± .060; RAGE-/-: .610 ± .125, P < .01), and in modulus of toughness (wild-type: .152 ± .032; RAGE-/-: .212 ± .058, P < .05). Together, these data suggest that RAGE plays an important role in normal bone turnover, it may inhibit bone breakdown and/or stimulate bone formation. To our knowledge, this is the first evidence to show RAGE's role in bone *in vivo*.

Three-Year Treatment with Intravenous Pamidronate in a Woman with Hepatitis C Associated Osteosclerosis. S. Ortolani, S. Vai*, R. Cherubini*, S. Saraifoger*. Centre for Metabolic Bone Disease, Istituto Auxologico Italiano, Milan, Italy.

Hepatitis C-associated osteosclerosis (HCAO) is an impressive example of acquired diffuse osteosclerosis in adults firstly described in 1992. Only twelve cases have been reported since then and we presented at 2002 ASBMR meeting the first HCAO case from Europe, with 1 year follow-up without treatment. She was a 65-yr-old woman, with hepatitis C virus infection from blood transfusion more than 13 years earlier, referred to us in January 2001 for severe pain of thighs, legs and upper arms and significant walking disability, requiring high doses of analgesics. Diagnosis of HCAO was based on marked and diffuse cortical and trabecular osteosclerosis involving all the skeleton except the cranium, with high remodeling osteosclerosis but lamellar bone texture at bone biopsy. Biochemical markers of bone turnover were 4 to 20 times the upper normal limits and DXA bone mineral density at different skeletal sites ranged from +1.7 to +5.3 T-score. After 1 year without treatment bone density increased by 15.0% at lumbar spine and 10.2% at total hip. We report now a three-year follow-up of intermittent intravenous pamidronate treatment. The rationale for using a potent bisphosphonate was based on the assumption that reducing the number of remodeling cycles could result in a lower rate of bone gain. Intravenous pamidronate (45 mg every other month) was administered for 3 year associated with oral calcium 1.2 g/day and calcitriol 0.5 mcg/day. Clinical improvement of bone pain was observed starting from the first pamidronate infusion and was maintained. All the bone turnover markers (serum total AP and OC, urine NTx) decreased slowly but continuously during the whole 3-year treatment. Bone density at different skeletal sites markedly increased during the first year of pamidronate treatment, with changes even larger than those observed during the previous 1-year non treatment period: +18.5% at lumbar spine and +15.5% at total hip. During the two following years of pamidronate treatment the yearly rate of gain in bone density was less than half the rate recorded during the first treatment year: + 7.0% at lumbar spine and +6.9% at total hip. This case indicates that pamidronate, after the expected early increase in bone density due to remodeling space contraction, is able to slow down but not to prevent further bone gain in HCAO. This behavior supports the concept that pamidronate reduces the number of active BMUs, while the balance at BMU level remains positive. We also hypothesize that the addition of corticosteroid to bisphosphonate treatment could reverse bone gain in HCAO.

Alterations in the Mechanical Properties of Bone due to Type II Diabetes. H. A. Hogan[1], B. A. Vyvial*[1], J. D. Alcorn*[1], J. M. Swift*[2], R. D. Prisby*[2], S. A. Bloomfield[2], M. D. Delp*[2]. [1]Mechanical Engineering, Texas A&M University, College Station, TX, USA, [2]Health and Kinesiology, Texas A&M University, College Station, TX, USA.

The purpose of this study was to investigate the effects of Type II diabetes on cortical bone properties using the Zucker Diabetic Fatty (ZDF) rat animal model. Age-matched groups of ZDF and lean controls (CON) were terminated at 3 developmental stages: pre-diabetes (7wks) with normal serum glucose (GLU) and high serum insulin (INS); acute diabetes (13 wks) when both GLU and INS are high; and chronic diabetes (20 wks), with normal INS and high GLU. Mechanical properties of the femur were measured by 3-point bending tests to characterize mid-diaphyseal cortical bone. As animal age increased and the effects of diabetes become more pronounced, cortical bone properties were lower than in CON rats. More specifically, whole-bone, or extrinsic properties, were affected more than tissue material properties. For example, the bone stiffness was 17% lower for ZDF vs. CON at 13 wks and 22% lower at 20 wks, yet the tissue elastic modulus was 22% lower at 13 wks but not significantly different at 20 wks. The ultimate (or maximum) breaking force was not different at 13 wks but 19% lower at 20 wks. In contrast, the tissue ultimate stress was not different at 13 or 20 wks. The greater effects of diabetes at the whole bone level can be attributed largely to smaller cross-sectional geometry for ZDF, particularly at 20 wks in which case the cross-sectional moment of inertia was 20% lower. Toughness was quantified by taking the energy absorbed from yield to ultimate load and normalizing it by the total energy absorbed to ultimate. This normalized post-yield energy should be indicative of material tissue toughness. The resulting post-yield energy values were not significantly different at either 13 or 20 wks, but the trend suggests more brittle behavior for the ZDF animals (means were 7% lower at 13 wks and 20% lower at 20 wks). The reductions in mechanical properties observed in this study may be associated with alterations in blood flow caused by Type II diabetes, as others have observed [Prisby et al., FASEB J. 47(4): 286, 2004].

Ectopic Secretion of Parathyroid Hormone (PTH) by Thymus Epithelium Cells. M. P. Garcia*[1], M. H. D'Adamo*[1], A. D. Jaen*[2], M. R. Barbich*[1], L. S. Algranati*[3], E. Mazzaro*[4], P. F. Argibay*[1], L. C. Plantalech[5]. [1]Instituto de Ciencias Basicas y Medicina Experimental, Hospital Italiano, Buenos Aires, Argentina, [2]Pathology, Hospital Italiano, Buenos Aires, Argentina, [3]Nephrology, Hospital Italiano, Buenos Aires, Argentina, [4]Surgery, Hospital Italiano, Buenos Aires, Argentina, [5]Endocrynology, Hospital Italiano, Buenos Aires, Argentina.

Introduction: Supernumerary and ectopic thymus localization of parathyroid glands are a common finding in uremic hyperparathyroidism (HPTu). A hypothesis sustained that ectopic localization of parathyroids are vestiges of a common development of the thymus and the parathyroids. In other hand we hypothesized that equal embryologic cell could involutedly to primitive stadium and secrete others hormones (PTH) with an appropriate stimulus. Objective: to demonstrate PTH secretion by thymus epithelial cells in pathological circumstances. Material And Methods: Thymus epithelial cells and parathyroid intratymic adenoma obtained by surgical resection of a patient with renal transplant and HPTu, were fractionated for fixation and tissue culture (only thymus cells) in a regular medium. Conventional histology, Immunohistochemistry for PTH and TÚNEL assay were performed in the fixed tissue. The presence of PTH was evaluated by radio-immune assay (RIA middle molecular fraction n v: 20-100pg/ml) in the culture medium of thymus and human fibroblast culture (control). Results: PTH hormone was detected in the culture medium from the thymus tissue (0hs: 85 pg/ml, 24 hs:251pg /ml, 96 hs: 106 pg/ml) Those values contrasts with the PTH levels from human fibroblasts culture medium (PTH range: 25 - 40 pg/ml). Conventional cells (epithelium and lymphocyte) was observed in the patient's thymus. Positive immunohistochemistry for PTH was verified only in the parathyroid tissue and in the thymus epithelial cells of the patients, and did not seen in control thymus. No apoptosis was detected by TUNNEL assay in any tissues. Conclusion: Our preliminary data suggests that under pathological conditions, epithelial cells from the thymus could secrete spontaneously PTH hormone, suggesting a common origin among parathyroid glands and the thymus. New molecular biology and functional studies are in development to research the origin and the conditions that induce the PTH production by thymic cells.

Perifusion Analysis of PTH Secretion from Normal and Pathological Human Parathyroid Cells. A. D. Conigrave*[1], H. Mun*[1], L. Delbridge*[2]. [1]School of MMB, University of Sydney, University of Sydney, NSW, Australia, [2]Department of Surgery, Royal North Shore Hospital, St Leonards, NSW, Australia.

We have developed a perifusion technique for the analysis of PTH secretion from cells prepared from small samples of normal and pathological human parathyroid tissue. All tissue samples were obtained according to ethics guidelines established by the Northern Sydney Area Health Service of NSW, Australia. Cells were prepared from one or more small tissue pieces (1-2 mm^3) using a modification of a standard collagenase/DNase method (Brown et al., Am. J. Med. 71, 565-570; 1981) taking care to remove the digested tissue from the protease-rich medium and resuspend it in fresh albumin-containing medium prior to trituration. After release of the cells in variably sized clumps by trituration, they were recovered by centrifugation (100 g, 2 min). In this way, yields of around 40,000 high quality cells were obtained from single samples of normal parathyroid tissue and up to 1 million cells or more were obtained from samples of pathological human parathyroid tissue. A yield of 40,000 cells was sufficient to detect intact human PTH secretion from 1 mL bed volume columns of sephadex perifused at a rate of 1.5 mL min^{-1} with 37 °C equilibrated physiological saline solutions containing 1 mg mL^{-1} albumin as a carrier for PTH. Samples were processed using a high throughput intact PTH autoanalyzer (Immulite 2000). PTH secretion rates from perifused cells were found to respond to variations in the concentrations of two recognised activators of the extracellular Ca^{2+}-sensing receptor: Ca^{2+} and L-amino acids (Conigrave et al., J. Biol. Chem. 279, 38151-38159; 2004). The IC_{50} for extracellular Ca^{2+} was approximately 1.1 mM in normal cells and was variably elevated in cells prepared from samples of adenomatous tissue. Typically, high extracellular Ca^{2+} concentrations (> 1.4 mM) maximally suppressed PTH secretion from normal parathyroid cells by 80-90%. Brown et al. (Endocrinology 116, 1123-1132; 1985) previously described a method for the perifusion of bovine parathyroid cells. The current results indicate that the perifusion technique can also be used reliably for the analysis of acute changes in PTH secretion from small samples of human parathyroid tissue.

Bone Microarchitecture in Mild Primary Hyperparathyroidism. L. Dalle Carbonare*[1], P. Ballanti*[2], F. Bertoldo*[1], S. Giannini[3], M. Valenti*[1], M. Zanatta*[1], S. Zenari*[1], G. Realdi*[3], V. Lo Cascio[1]. [1]Dpt. of Biomedical and Surgical Sciences, Medicina Interna D, Verona, Italy, [2]Dpt. of Experimental Medicine and Pathology, Section of Pathology, Roma, Italy, [3]Dpt. of Medical and Surgical Sciences, Clinica Medica I, Padova, Italy.

Primary hyperparathyroidism (PHPT) is a common endocrine disease and the high levels of parathyroid hormone cause demineralization of bone and increased risk of fracture. On the other hand, the effect of mild PHPT on bone structure is more ambiguous. Aim of this study was to evaluate the effect of PHPT on cancellous bone volume, structure and microarchitecture in the Italian population. Twelve transiliac biopsy specimens taken in untreated postmenopausal women aged 67±2 years with primary hyperparathyroidism were compared with 14 biopsies taken in normal women aged 71±1 years. None of the women presented any other disorder affecting bone metabolism. In these samples we evaluated the direct and indirect histomorphometric parameters of bone microarchitecture using an image analysis system consisting of an epifluorescent microscope (Leica DMR) connected to an analogic 3 CCD camera (Sony DXC 390P) and a computer equipped with a specific software for histomorphometric analyses. Preliminary results on the first 8 samples of each group showed no significant differences between PHPT patients and controls in cancellous bone volume, trabecular thickness and number. Connectivity parameters were higher in PHPT patients than in controls. The results of strut analysis are reported in the table.

.	PHPT	Controls	P
Total Skeletonized Length (μm)	13834±2129	8844±313	<0.05
NodeNumber/Tissue Volume (#/mm2)	4.22±1.39	2.02±0.20	=0.05
NodetoNode Length/Total Skeletonized Length (%)	36.99±6.50	22.63±3.52	<0.05
NodetoTermini Number	25.91±5.83	11.73±1.61	<0.05
Node/Termini	0.68±0.13	0.59±0.16	NS

Indirect parameters of microarchitecture (Trabecular Bone Pattern Factor, Marrow Star Volume and Fractal Dimension) were similar in the two groups. In conclusion, preliminary histomorphometric data showed that cancellous bone volume is preserved in the PHPT women, and microarchitecture seemed to be better than in normal women.

Genetic Testing In Familial Isolated Hyperparathyroidism. F. Cetani[1], E. Pardi*[1], S. Borsari*[1], E. Ambrogini*[1], M. Lemmi*[1], E. Vignali[1], A. Picone*[1], G. Viccica*[1], S. Mariotti*[2], L. Deiana*[2], P. Miccoli*[3], A. Pinchera*[1], C. Marcocci[1]. [1]Endocrinology and Metabolism, University of Pisa, Pisa, Italy, [2]Endocrinology, University of Cagliari, Cagliari, Italy, [3]Surgery, University of Pisa, Pisa, Italy.

Primary hyperparathyroidism is usually a sporadic disorder, but in a minority of cases (<10%) occurs as part of hereditary syndromes, including multiple endocrine neoplasia types 1 and 2A (MEN1 and MEN2A), hyperparathyroidism-jaw tumor syndrome (HPT-JT), familial hypocalciuric hypercalcemia (FHH), and familial isolated hyperparathyroidism (FIHP). Four of these syndromes have a well recognized molecular etiology, while it is still unclear whether FIHP is an incomplete expression of these syndromic forms or a distinct genetic entity. Indeed, although the majority of FIHP cases have currently unrecognized causes, some FIHP kindreds have been associated with mutant MEN1, HRPT2 and calcium-sensing receptor (CASR) genotypes. In this study we report the results of *MEN1*, *CASR*, and *HRPT2* gene sequencing of 13 subjects with FIHP belonging to 6 unrelated families (A, B, C, D, E and F). The clinical diagnosis of FIHP was based on the absence of typical MEN1 or HPT-JT manifestations. Genomic DNA was isolated from tumor samples and peripheral leukocytes. Highly polymorphic microsatellite loci located within *HRPT2* gene and flanking *MEN1* gene were PCR amplified and examined for loss of heterozigosity. Four of the 6 probands of the FIHP families were found to have germ line mutations in the *MEN1* gene. These consisted of a missense mutation in exon 9 (D418H) in family A, an acceptor splice site mutation in intron 4 (IVS4-9G>A, producing an aberrant splicing of mRNA that would result in prematurely truncated protein) in family B, a new intronic deletion of two bases located 20 nucleotides upstream exon 5 (IVS4-20delCT), in family C, and a splice donor site in intron 1 (IVS1+1 G>A) in family E. The *MEN1* mutations were also found in all affected family members. No mutation was identified in *MEN1* and *HRPT2* genes in the probands of family D and F. LOH analyses at *MEN1* and *HRPT2* loci revealed no evidence of allelic loss in any of the parathyroid tumors studied. In summary, 4 of the 6 FIHP kindreds showed a germline mutation of *MEN1* gene, while no molecular defect could be identified in the remaining 2 families. Our confirm that a substantial proportion of FIHP families represent a phenotypic variant of MEN1 syndrome.

TGFα/EGFR Induction Is Essential for Low Ca-induced Parathyroid Hyperplasia in Early Kidney Disease in Rats. T. Sato*, I. Gonzalez-Suarez*, J. Yang*, E. Slatopolsky, A. S. Dusso. Internal Medicine/Renal, Washington University, St. Louis, MO, USA.

Persistent hypocalcemia is the most powerful stimulus for parathyroid hyperplasia. Since enhanced parathyroid expression of transforming growth factor-α (TGFα) and its receptor, the epidermal growth factor receptor (EGFR), was identified as the main contributor to high P-induced parathyroid hyperplasia in kidney disease, the present studies assessed the contribution of TGFα/EGFR-driven growth to the severe parathyroid cell growth induced by kidney disease and low dietary calcium (Ca). 5/6 nephrectomized rats were fed either a low (0.1% Ca) or a high Ca (2 % Ca) diet to further aggravate or completely block the mitogenic signals triggered by the onset of kidney disease, respectively, for one week. Rats fed low dietary Ca also received either vehicle or Erlotinib, a potent and highly specific inhibitor of EGFR-tyrosine kinase, which catalizes a mandatory step for TGFα activation of the EGFR. A 3.7-fold increase in parathyroid cell proliferation, as measured by the number of nuclei staining positive for PCNA or Ki67, was induced by kidney disease and low Ca-intake compared to that observed in 5/6 nephrectomized rats fed the high Ca diet. The increase in parathyroid cell proliferation in the 5/6 nephrectomized rats fed the low Ca diet coincided with simultaneous 3-fold increases in parathyroid TGFα and EGFR content. Importantly, suppression of TGFα/EGFR-signaling, through intraperitoneal daily doses of 6 mg of Erlotinib/kg body weight, not only prevented parathyroid hyperplasia but also low Ca-induced increases in parathyroid TGFα with an efficacy comparable to that of the high Ca diet. We conclude that TGFα induction of its own expression and EGFR-driven growth constitutes the main pathogenic mechanism for the severe parathyroid hyperplasia induced by low dietary Ca in early experimental kidney disease.

Unexplained 4 Year Increase in Parathyroidectomies in the United States. T. L. Cantor. President, Scantibodies Laboratory, Inc., Santee, CA, USA.

Since the mid 1990's there has been an increase in the use of vitamin D sterol analogs to accomplish a "medical parathyroidectomy" for ESRD (end stage renal disease) patients. The overall expectation was that there would be a subsequent decrease in the number of parathyroidectomies among ESRD patients. Therefore, the USRDS (US Renal Data Services) database on parathyroidectomies was examined for its most recent rate of parathyroidectomies among Medicare beneficiaries to see if this expectation was, indeed, realized. From 1995 through 1998 the number of parathyroidectomies declined steadily among the Medicare ESRD patients in the US as expected. However, in 1999 the trend changed, with an increasing number of parathyroidectomies. This trend has persisted through 2001 (the latest data available). From 1999 to 2000 there was a 17% increase in parathyroidectomies and from 2000 to 2001 there was a 29% increase in parathyroidectomies. For 2002 there was a further increase in parathyroidectomies. K/DOQI (Natlonal Kidney Foundation's Kidney Disease Outcome Quality Initiative) guideline 14 states that "parathyroidectomy should be recommended in patients with severe hyperparathyroidism (serum levels of intact PTH >800 pgm/ml)." Therefore, the predominant intact PTH assay used should be examined for any changes that might explain this increase in parathyroidectomies. Meanwhile, this data indicates a reason for caution before prescribing a parathyroidectomy.

Cortical PQCT Measures Are Associated with Fractures in Dialysis Patients. S. A. Jamal[1], C. Gordon[2], D. C. Bauer[3]. [1]Medicine, University of Toronto, Toronto, ON, Canada, [2]Radiology, McMaster University, Hamilton, ON, Canada, [3]S.F. Coordinating Center, CPMC Research Institute, and UC San Francisco, San Francisco, CA, USA.

Fractures are common in hemodialysis (HD) patients yet DXA of the hip and spine are not associated with fractures in this group. One explanation is that HD patients have a selective decrease in volumetric cortical bone density, not identified by standard DXA

testing. We used peripheral quantitative computed tomography (pQCT) of the distal radius to examine associations between volumetric cortical and trabecular densities and fracture in 36 men and 16 women, 50 years and older, on HD for at least one year. We inquired about low trauma fractures since starting HD and confirmed self reported fractures by review of radiology reports. Prevalent vertebral fractures were identified by morphometry. pQCT measurements were taken of the non-dominant radius using the Stratec XCT 2000. At 4% of the ulna length we assessed volumetric trabecular density (mg/cm^3), and at 20% we assessed volumetric cortical density (mg/cm^3), total area (mm^2), cortical area (mm^2), and cortical thickness (mm). We used logistic regression analyses to examine the relationship between fracture (prevalent vertebral and /or self-reported non-spine) and each of the pQCT measures described above. Results are adjusted for age, weight and gender and reported as Odds Ratios (OR) per standard deviation decrease in the independent variable. The mean (± SD) age was 65.9 ± 8.9 years, the mean weight was 72.9 ± 15.2 kg and most (35 of 52 subjects) were Caucasian. The mean PTH was 33.8 pmol/L (12.6 - 57.2). Of the 52 subjects 27 subjects had either a prevalent vertebral fracture or low trauma fracture since starting dialysis. The mean trabecular density was 159.7 ± 60.6 cm^3, cortical density 1119.7 ± 72.9 cm^3, total area 320.1 ± 121.3 mm^2, cortical area 66.4 ±22.8 mm^2 and cortical thickness 1.8 ± 0.6 mm. There was no association between fractures and trabecular density (OR = 1.2; 95% Confidence Interval (CI): 0.43 to 1.7) or total area (OR = 1.1; 95% CI: 0.49 to 1.7). A decrease in cortical density was associated with an increased odds of fracture (OR = 15.7; 95% CI: 2.9 to 83.9), as was a decrease in cortical area (OR = 3.0; 95% CI: 1.3 to 7.2), and a decrease in cortical thickness (OR= 3.3; 95% CI: 1.4 to 7.8). Serum PTH was inversely correlated (r = 0.6) with cortical density but was not associated with fractures. Cortical, but not trabecular parameters are associated with fractures in HD patients. These findings may explain the lack of association between fracture and DXA measured at the hip and spine. Further studies are needed to determine the relationship between PTH and other determinants of cortical bone density and fracture in HD patients.

Skeletal Resistance to Parathyroid Hormone Induced by Uremic Toxins Causes Adynamic Bone Disease in Chronic Renal Failure. Y. Iwasaki[1], H. Yamato[2], T. Nii-Kohno[3], M. Fukagawa[3]. [1]Health Sciences, Oita University of Nursing and Health Sciences, Oita, Japan, [2]Development, Kureha Special Laboratory Co, Ltd., Fukushima, Japan, [3]Nephlorogy & Dialysis center, School of Medicine, Kobe University, Kobe, Japan.

Adynamic bone disease (ABD), which is characterized by reduced bone formation and resorption, has become an increasingly common manifestation of bone abnormalities in patients with end-stage renal failure. It has been recognized that skeletal resistance to parathyroid hormone (PTH) underlies the pathogenesis of ABD; however, the mechanisms of such resistance remain unclear. To elucidate the pathogenesis of ABD under uremic condition, we established a rat model simulating low turnover bone disease secondary to renal failure, using thyroparathyroidectomy (TPTx) and partial nephrectomy (Nx). TPTx-Nx rats were infused physiological doses PTH and injected thyroid hormone. We analyzed bone histomorphometric parameters and demonstrated gene expression using semi-quantitative RT-PCR. In TPTx-Nx rats, reduced bone formation was observed, which was ameliorated by pharmacological dose intermittent PTH injection in dose dependent manner. The expression of parathyroid/parathyroid-related peptide (PTH/PTHrP) receptor and alkaline phosphatase (ALP) genes was reduced significantly in TPTx-Nx compared with TPTx rats. Since reduction of bone formation was dependent on the degree of renal dysfunction, we evaluated whether the uremic toxin, which accumulated in blood with development of chronic renal insufficiency, influenced bone metabolic turnover. Although many uremic toxin was known, we focused on indoxyl sulfate (IS), which is known uremic toxin, and measured serum concentration of IS in our model. IS accumulated in the serum was dependent on renal dysfunction. Treatment with oral charcoal absorbent (Kremezin, Kureha Chem. Ind, Japan) not only reduced serum IS concentration, but also reversed the decreased bone formation. In addition, IS suppressed the production of cAMP stimulated by PTH treatment in mouse primary osteoblastic cells with dose dependency in vitro. IS also increased oxidative stress and inhibited cell proliferation in a dose dependent manner. In these cells, expression of organic anion transporter-3, which mediates cellular uptake of indoxyl sulfate, was also confirmed. Our data suggest that the accumulation of uremic toxins might cause dysfunction of osteoblastic cell and lead to decreasing response to PTH. Skeletal resistance to PTH may induce, at least in part, by accumulation of uremic toxins including IS.

CSF-1R in the Pathogenesis of Osteoporosis in Idiopathic Hypercalciuria. R. Pramanik[1], J. Asplin*[1], C. Lindeman*[1], S. Donahue*[1], S. Sprague*[2], M. Favus[3], F. Coe*[3]. [1]Litholink Corporation, Chicago, IL, USA, [2]Evanston Northwestern Healthcare, Northwestern University, Evanston, IL, USA, [3]University of Chicago, Chicago, IL, USA.

Idiopathic hypercalciuria (IH) is a state of excess urine calcium excretion with normal serum calcium, in the absence of other known mineral disorders. IH is the most common metabolic abnormality found in kidney stone patients. Many kidney stone patients with IH have low bone mineral density (BMD) and epidemiologic studies show an increased risk of fracture in stone formers. Excess urine calcium may be from intestinal calcium hyperabsorption and bone resorption. Low BMD in IH is thought to be due to excessive osteoclastic bone resorption, but the underlying molecular mechanisms which drive high osteoclastic bone dissolution are unknown. Differentiation of peripheral blood monocytes (PBMs) into functional osteoclasts can be demonstrated in vitro in the presence of macrophage colony stimulating factor (M-CSF) and soluble RANKL. The M-CSF receptor (CSF-1R) is necessary for osteoclast differentiation and is expressed in the PBM. Therefore, we have investigated the potential role of PBM CSF-1R in the urinary calcium excretion in stone forming IH probands, family members and non-stone forming normocalciuric subjects. The protocol was approved by an institutional review board. IH was defined as 24-h urine calcium excretion greater than 250 mg and 300 mg, for women and men respectively, while on a non-restricted diet. PBMs were isolated using Dynabeads conjugated with CD14 monoclonal antibody and CSF-1R levels measured by quantitative Western blotting. Cellular total protein from THP-1 monocytic cells was used to create a standard curve. Each microgram of THP-1 cell lysate protein was assigned an arbitrary value of 50 units of CSF-1R since the actual amount was not known. Serum M-CSF levels were measured using a commercial ELISA kit. PBM from stone forming IH patients had higher levels of CSF-1R, 38.27±1.14 unit/microgram vs. 18.28±0.81 unit/microgram (±SE, n=23, p=0.04). CSF-1R levels were positively correlated with the 24-h urine Ca excretion (R^2 = 0.26 and p=0.01). Although serum M-CSF levels were not different between stone formers and non-stone formers, serum M-CSF levels were positively correlated with the urine calcium excretion (R^2 = 0.19, p=0.03). However, serum MCSF levels and PBM CSF-1R levels were not correlated. The results suggest that higher levels of CSF-1R in the PBMs of IH patients may mediate their increased differentiation to mature osteoclasts, resulting in increased bone resorption and bone loss.

High Rate of Hypogonadism and Vitamin D Insufficiency in Males on Dialysis. U. Gruntmanis[1], B. Leach*[2], C. V. Odvina[3], J. E. Zerwekh[3], K. Sakhaee*[3]. [1]Endocrinology, UT Southwestern Medical Center and Dallas VA Medical Center, Dallas, TX, USA, [2]UT Southwestern Medical School, Dallas, TX, USA, [3]Center for Mineral Metabolism and Clinical Research, UT Southwestern Medical Center, Dallas, TX, USA.

It has been recently postulated, that in dialysis patients not only 1,25 dihydroxy vitamin D but low 25 hydroxy vitamin D contributes to elevated PTH levels. Frequency of hypogonadism has not been well studied in dialysis dependent men. In this study our goal was to determine frequency of vitamin D insufficiency/deficiency and hypogonadism in dialysis dependent men. We screened 67 dialysis dependent men as part of a double blind prospective controlled trial of testosterone replacement and its role on bone mineral density in this population. Data presented here are from screening visit only. We screened 45 African American, 14 Hispanic and 8 Caucasian men. All patients who did not have history of hormone sensitive cancer, sleep apnea, drug or alcohol use, elevated prostate specific antigen, intact PTH level above 600pg/ml, were medically stable, and did not have glucocorticoid use in last three months were invited for a screening visit. Levels of intact PTH, calcium, phosphorus, 25 hydroxy vitamin D, 1,25 dihydroxyvitamin D, total testosterone, estradiol, bone specific alkaline phosphatase and tartrate-resistant acid phosphatase-5b were measured in morning fasting blood sample. In our study population, median age was 52 and length of dialysis was 22 months. Median 25 hydroxy vitamin D level was 23ng/dl. 66.6% of men had 25 hydroxy vitamin D levels below 25ng/ml and 5.2% below 10ng/ml. Levels were not statistically different between racial groups. 38.8% of men had testosterone level below 300ng/dl. Estradiol level was low (below 20pg/ml) in 15.2% of men. Median bone specific alkaline phosphatase (BAP) and intact PTH levels were 21.5 U/L and 170pg/ml, respectively. There was positive correlation between intact PTH and BAP levels (p=0.03). There were no other statistically significant correlations between any measured parameters. We conclude that vitamin D deficiency and hypogonadism are common in men on dialysis.

Impact of Parathyroidectomy on the Morphology and the Number of Osteocyte in Hemodialysis Patients with Secondary Hyperparathyroidism. A. Yajima[1], H. E. Takahashi[2], Y. Ogawa*[3], T. Inou*[1], O. Otsubo*[1], S. Yagi*[1], K. Otsubo*[1], Y. Tominaga*[4]. [1]Nephrology, Towa Hospital, Tokyo, Japan, [2]Niigata University of Health and Welfare, Niigata, Japan, [3]Urology, University of the Ryukyus, Okinawa, Japan, [4]Surgery, Nagoya Second Red Cross Hospital, Nagoya, Japan.

Purpose: Basic Multicellular Unit (BMU) with osteoid seam is considered to be a newly formed bone, and the other bone is an older one. Life-cycle of osteocyte was divided into the two groups, namely, the presence or the absence of osteocyte in lacunar. We compared these two stages of osteocytes in BMU or in an older bone by assessing the differences of the morphology and the number of osteocyte early after parathyroidectomy with immediate autotransplantation (parathyroidectomy) for secondary hyperparathyroidism. Methods: The patients were 14 hemodialysis patients with secondary hyperparathyroidism treated by parathyroidectomy, and the mean age of the patients was 57.3 years and serum intact PTH was 1225.8 pg/ml. In addition, iliac bone biopsies were performed before and at 3-9 weeks after parathyroidectomy. Bone histomorphometric analysis was also performed to measure the primary parameters including (1) Bone volume (BV), (2) Bone volume of BMU with osteoid seam (BV_{BMU}), (3) Number of osteocyte (N.Ot), and (4) Number of empty lacunar (N.Empty Lc) and the derived indices including (1) Number of osteocyte per BV_{BMU} ($N.Ot/BV_{BMU}$), (2) Number of osteocyte in bone exclusive of BMU with osteoid seam ($N.Ot/BV\text{-}BV_{BMU}$), (3) Number of empty lacunar (N.Empty Lc/BV). Results: (1) $N.Ot/BV_{BMU}$ significantly decreased from 355.5 ± 103.5 to 249.7 ± 91.9 N/mm^2 ($p<0.01$), (2) $N.Ot/(BV\text{-}BV_{BMU})$ also decreased from 176.4 ± 46.3 to 150.0 ± 53.0 N/mm^2 ($p<0.01$), (3) N.Empty Lc/BV significantly increased from 12.1± 8.2 to 38.7 ± 15.9 N/mm^2 Conclusions: It was considered that the number of osteocyte in BMU and bone exclusive

of BMU with osteoid seam were decreased by an abrupt declination of serum PTH levels. An increase of N.Empty Lc/BV was thought to be caused by an enhanced apotosis of osteocyte after parathyroidectomy.

Renal Failure Aggravated by Extensive Phosphate-Loading - An Ultimate Test for the Bone Mechanostat. J. Jokihaara, I. Pajamäki, T. Vuohelainen*, P. Kööbi*, P. Jolma*, J. Kalliovalkama*, P. Kannus*, H. Sievänen*, I. Porsti*, T. L. N. Järvinen. University of Tampere, Tampere, Finland.

A built-in system called the Mechanostat adapts the strength of bones to incident loading through changes in the mineral mass and geometry. Should it be of evolutionary origin, we hypothesized that it maintained the mechanical integrity of bones even under the extreme metabolic challenge of end-stage renal failure and phosphate overload. Accordingly, 67 eight-week old male rats were randomized and subjected to 5/6 nephrectomy (NTX) or sham-operation. After a 15-wk period of disease progression, the NTX'd rats were assigned to receive either normal chow (NTX), chow with excessive phosphate (NTX+P), chow containing phosphate-binding calcium salts (NTX+Ca), or normal chow and parenteral injections of non-calcemic vitamin-D analog (paricalcitol, NTX+Pari) for the subsequent 12 wks. At the end of this 27-wk experiment, a comprehensive structural analysis of the femoral midshaft was performed (pQCT scanning and mechanical testing). In both the NTX and NTX+P groups, there was an approximately 50% mortality rate (7/13 survived in both groups), whereas in the NTX+Ca and NTX+Pari groups 9/13 and 11/13 survived, respectively. Dramatic increases were found in the PTH values in both the NTX and NTX+P groups (1173 ± 978 and 3620 ± 675, respectively) compared to 99 ± 53 in the Sham-operated. However, the Ca2+-supplementation effectively suppressed the PTH levels (4 ± 2), while the PTH was clearly increased in the NTX+Pari group (620 ± 762). These dramatic changes resulted in a NTX-induced decrease in the volumetric bone density (cBMD) of the femoral midshaft (-7%, $p<0.05$ vs. Sham), an effect that was further aggravated by phosphate-loading (-25%, $p=0.000$ vs. Sham; -19%, $p=0.000$ vs. NTX). However, despite these dramatic reductions in bone mass, the structural strength of the midshaft was maintained in both NTX and NTX+P groups by an apparent compensatory increase in the cortical cross-sectional area (cCSA) (+29%, $p=0.000$ vs. Sham; +23%, $p=0.000$ vs. NTX). In conclusion, the preservation of the structural strength of femoral midshaft - even under these extreme circumstances of end-stage renal failure and severe phosphate-loading (e.g., a 40-fold increase in plasma PTH) - quite persuasively suggests that the bone Mechanostat remains functional till the very end of animal life.

Fibroblast Growth Factor 23 and Bone Mineral Density in Normal and Patients with End Stage Renal Disease. S. B. Hong[1], E. Kim*[1], M. Nam*[1], W. Park[1], B. Lee*[2], Y. Kim*[1]. [1]Internal medicine, Inha University, Incheon, Republic of Korea, [2]Gynecology, Inha University, Incheon, Republic of Korea.

Introduction: In addition to parathyroid hormone and vitamin D, phosphate-regulating factor, phophatonins have been shown to be associated with the hypophosphatemic rickets(XLH) and autosomal dominant hypophosphatemic rickets(ADHR). Fibroblast growth factor 23(FGF23), circulating phosphaturic factor increased in ADHR, tumor induced osteomalacia(TIO) and end stage renal disease(ESRD). However, the role of FGF23 in pathologic condition is not yet clear. We investigated association of FGF23 and phosphate regulation in patients with ESRD. Methods: Fasting serum FGF23 levels and serum biochemical parameters were measured using a human FGF23 (C-terminal) ELISA assay in 62 subjects with hyperphosphatemic subjects with ESRD and 10 age-matched controls. Bone mineral density, percent body fat and intact PTH and 25(OH)D3 were measured. Results: FGF23 (RU/ml) concentrations were higher in patients with ESRD ($p < 0.001$). Serum phosphorus levels were not correlated with FGF23, but have positive correlation with serum BUN($r=0.644$, $p<0.01$) and creatinine($r=0.628$, $p<0.01$). Intact PTH and 25OH D3 had no association with BMD of femur and neck. Conclusion; These findings suggest that FGF23 and serum phosphorus are independently regulated and have little role in bone metabolism in patients with ESRD.

Disclosures: ***S.B. Hong****, None.*

Evaluation of 25(OH) Vitamin D Serum Levels in Uremic Patients in Hemodialysis (HD). A. L. Negri*[1], E. Del Valle*[1], E. Fradinger*[2], J. R. Zanchetta[1]. [1]Nephrology, Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina, [2]Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina.

Little is known about the magnitude of vitamin D deficiency in patients with stage 5 Chronic Kidney Disease (CKD). Thus we evaluated serum 25(OH) vitamin D levels in 84 stable patients in chronic HD (41 months) of both sexes, with a mean age 58.9 ± 16.6 years, during the month of September (end of winter in the Southern hemisphere). 25(OH) vitamin D serum levels were measured by RIA (Diasorin Stillwater, Minesotta,USA; Interassay CV <15%). Intact PTH was measured by an automated method (Elecsys). We also determined serum albumin, creatinine, PCR and BMI as nutritional parameters and Functional capacity (FC) according to Karnofsky index. We considered adequate vitamin D levels those >30 ng/ml; vitamin D insufficiency 30 to 10 ng/ml and vitamin D deficiency <10 ng/ml. We found vitamin D insufficiency in 64,2% of the patients and vitamin D deficiency in 11,9%. There was no correlation between 25(OH) vitamin D serum levels and serum iPTH levels ($r=0.08$) or age ($r=-0.14$), but there was a positive correlation with serum albumin ($r=0,22$) and with creatinine ($r=0,38$). Patients with FC 1-2 (n:70, 83,3%) had a significantly higher 25 OH D serum levels compared with patients FC 3-4 (n:14, 16,6 %): 25,9 vs 17,1 ng/ml ($P=0.03$). These data indicate that vitamin D insufficiency/ deficiency is highly prevalent in patients stage 5 CKD on dialysis (76,1%) at the end of winter and it seems to be related to poorer nutrition and worse functional class.

Nano SIMS as an Analytical Tool for Trace Metal Detection in Bone from Patients Receiving Long Term Haemodialysis. J. Denton[1], F. Hillion*[2], F. Horreard*[2], A. G. Cox[3]. [1]Laboratory Medicine, University of Manchester, Manchester, United Kingdom, [2]CAMECA, Paris, France, [3]Centre Analytical Sciences, University of Sheffield, Sheffield, United Kingdom.

The purpose of this study is to investigate the potential of the NanoSIMS 50 instrument in the identification of trace elements in bone at an ultrastructural level coupled with high sensitivity to parts per billion levels of the test element. Quantitative bulk analysis of bone by solution ICP-MS is of limited usefulness in the understanding of the biological processes underlying the possible accumulation of the element. In order to identify and spatially resolve the elements present at the cellular level it is necessary to use complex ion or other beam techniques. The NanoSIMS 50 instrument offers this ability to map ions in mineralised tissues at extremely low concentrations <1ppm with a spatial resolution of between 50 and 500 nm depending on the size of the square ion beam used. Samples of trabecular bone derived from a trans-iliac biopsy from an end stage renal failure patient treated by haemodialysis and receiving lanthanum carbonate as a phosphate binder were used as a test specimen. A sample of trabecular bone from a haemodialysis treated renal patient receiving aluminium hydroxide as a phosphate binder was used as control. The specimen was ethanol fixed and Araldite CY 212 embedded. A block 10mm diameter and 100 micron thick was taken by diamond blade, polished by diamond abrasion techniques and gold coated. Using a 400 X 400 nm primary O- beam areas 40x40micron were examined by raster mapping. There was a discrete deposition of lanthanum highly localised at the surface of the test bone, 2 micron in depth and no detected lanthanum other than natural background within the deeper matrix when compared to the control specimen.

Disclosures: ***J. Denton****, None.*

Laser Ablation -Inductively Coupled Plasma - Mass Spectrometry as an Analytical Tool for Trace Metal Analysis in Bone from Renal Haemodialysis Patients. A. G. Cox[1], J. Denton[2]. [1]Centre Analytical Sciences, University of Sheffield, Sheffield, United Kingdom, [2]Laboratory Medicine, University of Manchester, Manchester, United Kingdom.

The purpose of this study is to investigate the potential use of Laser Ablation -Inductively Coupled Plasma - Mass Spectrometry (LA-ICP-MS) as a technique for the identification of metals in bone at ultra trace concentrations in the sub parts per billion range linked to a spatial resolution capability of < 5 micron. Samples of bones from an end stage renal failure patients treated by haemodialysis and receiving lanthanum carbonate as a phosphate binder were used as test specimens and samples from haemodialysis patients receiving aluminium hydroxide as a phosphate binder were used as controls. Analytical calibration standards were prepared by adding known lanthanum concentrations to co-precipitating calcium phosphate solutions and drying the resulting precipitate. The bone specimens were ethanol fixed and LR White embedded for subsequent bone histomorphometry. The analytical calibration pellets were processed in an identical manner. Using a 4 micron diameter laser beam to provide high resolution analysis both samples and standards were examined. There was a discrete deposition of lanthanum highly localised at the surface of the bone and occasional localisations of the metal deep within bone at areas thought to be reversal lines. Lanthanum concentrations deep within the bone matrix were no different to endogenous lanthanum concentrations found in the control group treated with aluminium. When the data was compared to the analytical calibration standards the maximum localised concentrations in the test specimens was shown to be in the low parts per billion range indicating the presence of lanthanum but at a very low concentrations.

25-Hydroxyvitamin D_3 Suppresses PTH Synthesis and Secretion by Cultured Bovine Parathyroid Cells: Potential Role for Autocrine 1,25-Dihydroxyvitamin D_3. C. S. Ritter*[1], H. J. Armbrecht[2], E. Slatopolsky[1], A. J. Brown[1]. [1]Renal Division, Washington University Medical School, Saint Louis, MO, USA, [2]Biochemistry, Saint Louis University, Saint Louis, MO, USA.

Reduction of parathyroid hormone (PTH) levels by 1,25-dihydroxyvitamin D_3 [$1,25(OH)_2D_3$] is believed to function as part of an endocrine feedback loop. PTH enhances the renal conversion of 25-hydroxyvitamin D_3 to $1,25(OH)_2D_3$ by the 1α-hydroxylase, and $1,25(OH)_2D_3$, acting through the vitamin D receptor (VDR) of the parathyroid glands reduces PTH gene transcription. However, PTH levels are known to correlate better with $25(OH)D_3$ than $1,25(OH)_2D_3$. The recent discovery of 1α-hydroxylase mRNA and protein in parathyroid tissue suggests the possibility of an autocrine action of locally-produced $1,25(OH)_2D_3$, but this has not been demonstrated. In the present study we demonstrated 1α-hydroxylase activity in parathyroid cells by incubating with $25(OH)D_3$ (10^{-6} M) and measuring $1,25(OH)_2D_3$ secreted into the medium using a RIA (IDS Inc., Fountain Hills, AZ). The presence of 1α-hydroxylase was confirmed by immunohistochemistry of parathyroid cells using an antibody raised against a C-terminal peptide of the human 1α-hydroxylase. Incubation with $25(OH)D_3$ (10^{-6} M) for 72 h reduced PTH secretion by 54 ± 23 % (p = 0.012) and PTH mRNA by 57 ± 6%; these decreases are comparable to the maximal suppression by $1,25(OH)_2D_3$ in this system. In summary, $25(OH)D_3$ can act directly on parathyroid cells to reduce PTH secretion and synthesis. Parathyroid cells appear to be capable of metabolizing $25(OH)D_3$ to 1α-hydroxylated metabolites, but whether this activation is required for the suppressive effects of $25(OH)D_3$ remains to be determined.

Prevalence of Vitamin D Insufficiency and Osteoporosis in Patients with Severe Chronic Liver Disease and Liver Transplantation. M. Rodriguez-Garcia*[1], C. Gomez[1], L. G. Dieguez*[2], M. Rodriguez*[2], M. Naves*[1], A. Rodriguez-Rebollar*[1], M. T. Fernandez-Coto*[3], J. B. Cannata-Andia[1]. [1]Bone and Mineral Research Unit. Instituto Reina Sofia de Investigacion., HUCA, Oviedo, Spain, [2]Gastroenterology, HUCA, Oviedo, Spain, [3]Biochemistry, HUCA, Oviedo, Spain.

Bone loss and vertebral fractures (Vt Fx) are common complications after liver transplantation (Tx); both pre- and post-transplant factors may be implicated in its pathogenesis. This study aimed to compare relevant bone markers, such as vitamin D status, bone mass and Vt Fx in patients with severe chronic liver diseases waiting for liver Tx (Pre-Tx group), with patients after the first year of liver Tx (Post-Tx group). Forty patients who received a liver Tx in the previous year (mean time of Tx 9±3 months) were compared with 38 patients with chronic liver disease waiting for liver Tx. For both groups, the study included measurement of fasting serum biochemical markers [25-OH D_3, 1-25 (OH) D_3, iPTH, Ca, P, alkaline phosphatase and others], bone mineral density (BMD) at lumbar spine and hip (Hologic QDR-1000) and X-ray evaluation of thoracic and lumbar spine. Other demographic, anthropometric and relevant clinical data were also registered. A population-based cohort of the same geographical area, age and gender was also used as a comparator (n=309). The prevalence of Vt Fx was 25% in pre-Tx, 29% post Tx and 15.7% in the general population. In pre-Tx patients, the rate of Vt Fx did not differ between sexes. By contrast, post-Tx women suffered a significantly higher rate of Vt Fx (42.1%) compared with post-Tx males (8.3%) and also with women of the general population (18.7%, p<0.05). At total hip, densitometric osteoporosis (WHO criteria) in pre-Tx women was higher (28.6%) compared with men (10.3%). Also at the total hip, BMD was significantly lower in Pre-Tx patients having Vt Fx (Z-score -1.78±0.45 vs 0.17±1.32, p<0.005). By contrast there were no differences at any site in the Post-Tx group. The mean 25 (OH) D_3 serum levels in pre-Tx patients were low (18±12 ng/ml) although similar to post-Tx patients (18±9.4 ng/ml) and general population (19±10 ng/ml). However, there was more prevalence of severe deficiency (< 10 ng/mL) in the pre-Tx patients (34.5%) compared with post-Tx (23.8%) and general population (21.5%). In addition, in pre-Tx women, a significant positive relationship was found between 25 (OH) D_3 and 1.25 $(OH)_2$ D_3(r=0.83, p<0.05). In summary, severe chronic liver disease is associated with low bone mass, a high rate of Vt Fx and lower 25 (OH) D_3 serum levels even before the liver transplantation. Although several other factors may be involved, an adequate vitamin D supplementation is mandatory to reducing bone abnormalities in chronic liver disease.

Alendronate Treatment in Long-Term Liver or Cardiac Transplanted Osteoporotic Patients. G. Martínez*[1], L. Gil-Fraguas*[2], E. Jódar[1], A. Escalona*[1], A. Moreno*[3], E. García*[1], E. Moreno*[3], M. Gómez*[4], F. Hawkins[1]. [1]Endocrinology Service, University Hospital 12 de Octubre, Madrid, Spain, [2]Rehabilitation Service, University Hospital 12 de Octubre, Madrid, Spain, [3]Digestive Surgery Dpt, University Hospital 12 de Octubre, Madrid, Spain, [4]Cardiology Service, University Hospital 12 de Octubre, Madrid, Spain.

Background: early institution of therapy may prevent bone loss after transplantation (Tx). However, the best therapeutic option in long-term transplanted patients with osteoporosis has not been defined yet. Our aim was to investigate the effects of alendronate on bone mineral density in long-term Tx patients with osteoporosis. Patients and Methods: Forty-four patients (17 liver and 27 cardiac recipients), mean age 56 y., with densitometric osteoporosis (T-score < -2.5) more than 2 years after Tx were treated with alendronate (70 mg p.o. once weekly) and minimum of 1000 mg of calcium and 400 IU vitamin D_3 daily p.o.. Mean time since Tx was similar in both groups (56 months in liver recipients, 52 months in cardiac Tx patients). In liver recipients immunosuppressive therapy included tacrolimus in 65% and Cyclosporine A in 35% of patients, but none was receiving corticosteroids at the time of study. In cardiac recipients > 90% of patients was on prednisone treatment (mean dose 5.7 mg/day, mean accumulate dose 11505 mg). BMD changes were assessed after one year of treatment at lumbar spine and hip (DXA, Hologic QDR 4500). Results: In liver recipients mean lumbar BMD increase was + 8.1± 7.1%, whereas mean total hip BMD increased +3.8± 4.3% , femoral neck BMD increased +3.3± 6.9% and trocanteric BMD increased +7.3± 6.0 %. In contrast, BMD responses in cardiac recipients were less impressive; mean lumbar BMD increase was +2.1± 3.6%, mean total hip BMD -1.1± 6.4%, and femoral neck BMD increased +1.2 ± 4.6%. Treatment was well tolerated in all the patients. Conclusion: Weekly oral alendronate plus calcium and vitamin D_3 is an effective treatment in long-term Tx-related osteoporosis, particularly in liver recipients. Concomitant immunosuppressive drugs used could influence the response to the antirresorptive treatment in these patients.

Evolution of Bone Density after Heart Transplantation: Influence of Anti-Resorptive Therapy. L. Gil-Fraguas*[1], E. Jodar[2], G. Martinez*[2], M. A. Escalona*[2], J. Vara*[1], E. Robles*[1], F. Hawkins[2]. [1]Rehabilitation, University Hospital 12 de Octubre, Madrid, Spain, [2]Endocrinology, University Hospital 12 de Octubre, Madrid, Spain.

Osteoporosis and osteoporotic fractures are common complications after heart transplantation. The purpose of this study was to evaluate the effects of antiresorptive therapy (calcium and vitamin D [CaVD], calcitonin [CT], etidronate [ETN] or alendronate [ALN]) at standard doses in the evolution of bone mineral density (BMD) in heart transplant recipients. Patients and Methods: We studied 216 patients (aged [mean (SD)] 54(10) years, 85% males, BMI 24.25(3.25) kg/m^2) undergoing heart transplantation. BMD was assessed by DXA (Hologic 4500) in lumbar spine (LS) and total femur (TF) sites at baseline, 6, 12 and 24 months. Patients with normal BMD at baseline were placed in CaVD group and served as controls, the rest of the patients were random allocated in CT, ALN or ETN group. 152 patients had 24 months of follow-up. The statistical analysis included the following tests: Scheffe, Manova and Wilks´Lambda. Results: As expected, baseline LS and TF BMD (gr/cm^2) was higher in CaVD group (LS/TF: 0,973(0,114)/ 0,925(0,129), respectively; p<0.05) without significant differences among the rest of the groups (LS/TF: CT: 0,873(0,157)/ 0,820(0,116); ETN: 0,882(0,121)/ 0,893(0,121); ALN: 0,884(0,147)/ 0,832(0,109)). The changes in BMD (%) are showed in the table:

Table: Changes in BMD (%)

Group/Site	6 Mo	12 Mo	24 Mo
CaVD LS	-3,34(5,55)	-3,97(5,65)	-3,07(7.0)
CaVD TF	-1,66(3,71)	-3,41(4,06)	-3,15(3,89)
CT LS	-4,3(6,4)	-4,94(5,26)	-0,93(6,39)
CT TF	-3,85(5,83)	-4,85(6,10)	-3,59(5,87)
ETN LS	-5,27(4,85)	-5,42(5,66)	-1,87(6,22)
ETN TF	-3,67(5,55)	-5,54(4,97)	-4,65(5,46)
ALN LS	0,53(5,16)	0,79(5,17)*	4,90(8,42)*
ALN TF	-0,39(4.0)*	-0,63(4,14)*	-0,46(5,16)*

*p<0.001 vs any other group.

Conclusions: According to other studies, heart transplantation produces a high bone loss with a recovery phase beginning 6 (LS) to 12 (TF) months after the procedure. Alendronate is associated with lower bone loss at femoral neck and even with a relative increase in lumbar spine bone density.

Cyclosporine A Increases Growth but Leads to Secondary Hyperparathyroidism in Young Rats. C. P. Sanchez, Y. He*. Pediatrics, University of Wisconsin Medical School, Madison, WI, USA.

Cyclosporine A (CsA) is a potent and frequently used immunosuppressive agent in the maintenance of renal allograft. A decline in bone mass has been reported with CsA therapy, but its effect on growth has not been evaluated. Thus, 38 male weanling Sprague-Dawley rats were randomly divided into 3 groups: Control (N=13), Pred (N=6) and CsA (N=13). Half of the animals from each group were treated for 2 weeks and the remaining animals received treatment for 4 weeks. Prednisone was given at 3 mg/kg/day, CsA at 10 mg/kg/day and Control animals received saline at the same volume by gavage route. The animals underwent cardiac perfusion with 4% PFA/PBS at the time of sacrifice. Blood was obtained for serum calcium, phosphorus, creatinine and intact PTH. The proximal tibia was collected for growth plate morphometry and immunohistochemistry studies. Change in body weight, body length and tibial length measurements were obtained at the end of the study period (Table I).

Parameters	Two weeks			Four weeks		
	CsA, N=6	Pred, N=6	Control ,N=6	CsA, N=7	Pred, N=6	Control, N=7
Delta Weight, gm	78 ± 3	70 ± 8	73 ± 8	156 ± 5	150 ± 9	159 ± 4
Delta length, cm	9.3 ± 0.7*	8.3 ± 0.4	8.5 ± 0.5	15 ± 0.5	15 ± 0.8	16 ± 0.9**
Tibial Length, cm	3.3 ± 0.05*	3.1 ± 0.05	3.1 ± 0.1	3.6 ± 0.09	3.5 ± 0.08	3.7 ± 0.06**
Intact PTH, pg/ml	76 ± 10	84 ± 20	56 ± 20	220 ± 50	172 ± 23	99 ± 25**
Serum Calcium, mg/dl	9.8 ± 1.0	9.4 ± 1.0	10 ± 0.4	10 ± 0.5	10 ± 0.3	10 ± 0.2
Serum Phosphorus, mg/dl	11 ± 0.5	12 ± 0.3	12 ± 0.5	11 ± 0.5	11 ± 0.3	11 ± 0.7

*p<0.02 vs Pred, Control; **p<0.01 vs CsA, Pred

After 2 weeks, CsA increased bone growth in the proximal tibia (using tetracycline labeling); 275±75 um/day versus 154±53 um/day and 120±20 um/day in Control and Pred groups, p<0.01. At the end of 4 weeks, bone growth declined in both CsA and Pred groups compared to Control, 220±50 um/day and 150±43 um/day versus 313±70 um/day, respectively, p<0.04. The width of the growth plate cartilage did not differ in all groups. Histochemical staining for TRAP did not change, however, RANKL expression in the chondro-osseous junction increased in the CsA group compared to Control, 0.5±0.06 and 0.3±0.02, p<0.02. The increase in bone growth during CsA therapy may in part be due to an increase in chondroclastic resorption. The mechanisms that may lead to the development of secondary hyperparathyroidism with prolonged therapy need further investigation.

Body Composition and Serum IGF-1, IGFBP- 3 and Leptin in Children before and after Liver Transplantation. E. Karczmarewicz*[1], J. Pawowska*[2], E. Skorupa*[1], E. Krykiewicz*[1], H. Matusik*[1], H. Ismail*[3], J. Ryko*[2], J. Jankowska*[2], M. Teisseyre*[2], P. Kaliciski*[3], J. Lukaszkiewicz*[4], J. Socha*[2], R. Lorenc[1]. [1]Department of Biochemistry and Experimental Medicine, The Children's Memorial Health Institute, Warsaw, Poland, [2]Department of Gastroenterology, Hepatology and Immunology, The Children's Memorial Health Institute, Warsaw, Poland, [3]Department of Pediatric Surgery and Transplantation, The Children's Memorial Health Institute, Warsaw, Poland, [4]Department of Biochemistry, Medical Academy Warsaw, Pharmacy Faculty, Warsaw, Poland.

The aim of the study was to investigate body composition and serum IGF-1, IGFBP-3 and leptin in children qualified for liver transplantation (Ltx) before Ltx and during 6, 9, 12 months after transplantation. 24 children aged 1.3-5 years before performed living related liver transplantation were enrolled into the study. Serum levels of IGF-1, IGFBP-3 and leptin were determined by automated and manual immunoassays. Body composition (total body bone mineral content -TBBMC, lean mass, fat mass) were determined using densitometric measurement (Lunar - DPX). All patients were supplemented with 25(OH)D (1-2 μg/kg body weight). After transplantation immunosuppressive treatment was introduced with tacrolimus (to keep the serum level 8-19 ng/dl) and prednisone (0.1 mg/kg body weight). Statistical tests were considered significant with a *p* value 0.05 or less. Before Ltx serum IGF-1 and IGFBP-3 as well as TBBMC were significantly decreased in comparison to control values (10-60 vs. 17-248 ng/ml, 200-680 vs. 1300-2078 ng/ml, 49 - 268 vs. 110-308 g for IGF-1, IGFBP-3 and TBBMC respectively). Content of lean mass (6342-10167 vs. 4811-9846 g) and fat mass (719-2266 vs. 517-1959 g) in cholestatic children are comparable with those of age matched control group. After Ltx IGF-1 and IGFBP-3 significantly increased, reaching values of healthy control group (IGF-1: 99-300 vs. 88-747 ng/ml, IGFBP-3: 1895-3545 vs. 1433-2059 ng/ml). This increase is observed as early as 1-6 months after Ltx, and it is stable during 18 months of observation. Serum leptin level is stable and comparable to control values after Ltx (0.7-10.2 vs. 0.4-5.5 ng/ml). The rates of changes in body composition in children after Ltx were compared to changes in healthy children: lean body mass - 40% decrease, fat body mass - 20% increase, BMC - not significantly different. Successful transplantation in cholestatic children, despite normalization of IGF-1, IGFBP-3, and leptin, does not induce acceleration in BMC growth rate. It indicates that children after Ltx will not normalize their bone mineral content (BMC) before puberty.

Bone Mineral Density after Renal Transplantation in Adolescents. M. Matsuda-Abedini*[1], J. Shepherd*[2], R. Mathias*[1], E. von Scheven[1], A. A. Portale[1]. [1]Pediatrics, University of California, San Francisco, San Francisco, CA, USA, [2]Radiology, University of California, San Francisco, San Francisco, CA, USA.

Loss of bone mineral occurs after renal transplantation in children, but the magnitude and duration of loss are unclear. Most studies to date have employed AP DXA of the lumbar spine to assess areal BMD (aBMD), but this technique is confounded by changes in skeletal size and maturation during growth, limiting its use in cross-sectional studies of growth-retarded patients. Serial measurements of aBMD might overcome this problem by comparing subjects to themselves. The shortcomings of planar densitometry might also be circumvented by measuring volumetric BMD (vBMD), using AP combined with lateral DXA (latvolDXA) or quantitative computed tomography (QCT). The objectives of the current prospective study were to: 1) determine the magnitude of decrease in BMD after renal transplantation in adolescents, and 2) compare aBMD and two estimates of vBMD, latvolDXA and QCT. We measured BMD of the lumbar spine in 20 ethnicically diverse renal transplant recipients (11M), aged 16 ± 2.9 years (SD), at time of transplant and 9 and 18 months afterwards. Immunosuppression included corticosteroids in all patients; cumulative corticosteroid dose at 9 months was 92 ± 32 mg/kg. aBMD of the lumbar spine was determined by AP DXA (Hologic), and vBMD was determined by lumbar latvolDXA and QCT (GE 9800 Quick Scanner). To date, 18 subjects completed the 9 month visit and 10 subjects the 18 month visit. At transplant, aBMD z-score determined for chronologic age and gender (Hologic QDR-Delphi/A research reference data) was 0.06 ± 1.02. At 9 months post-transplant, aBMD decreased by 4.9 ± 10%, and the z-score decreased by 0.68 ± 0.73 (p<0.001). At 18 months, aBMD z-scores remained below baseline by 0.63 ± 0.8. vBMD determined by latvolDXA at 9 months post-transplant decreased slightly, 3.9 ± 11.6%, but not significantly, with little further change at 18 months. By contrast, vBMD determined by QCT decreased by 12.8 ± 16% (p<0.01) at 9 months and 14.4 ± 21% at 18 months. The correlation between latvolDXA and QCT was 0.6 (p<0.001). Bland-Altman comparison of paired measurements by these two methods revealed a mean difference of 0.036 g/cm^3 (95% CI: 0.026 to 0.046), with wide limits of agreement (-0.03 to 0.10). These data show that lumbar BMD decreases significantly in the first 9 months after renal transplantation in adolescents and remains decreased at 18 months post-transplant. The magnitude of loss in BMD is substantially underestimated by both AP and latvolDXA compared with that determined by QCT. The poor correlation between latvolDXA and QCT and the large limits of agreement do not support using the two methods interchangeably.

Normal Circulating Levels of C-PTH Fragments in Parathyroidectomized (PTX) Rats during the IV Infusion of hPTH(1-84) over 48 h. M. Usatii*[1], J. H. Brossard[1], L. Rousseau*[1], J. R. Lavigne[2], R. J. Zahradnik*[2], P. D'Amour[1]. [1]Department of Medicine, Centre de recherche du CHUM, Hôpital Saint-Luc, Montréal, PQ, Canada, [2]Immutopics Int., San Clemente, CA, USA.

The contribution of hPTH(1-84) peripheral metabolism to circulating C-PTH fragments remains quantitatively uncertain. Early studies were performed in pentobarbital anesthetized animals with impaired hepatic blood flow, hPTH(1-84) clearance and probably C-PTH fragments formation (D'Amour et al., JBMR 11:1075, 1996). We have reevaluated C-PTH fragments formation in non anesthetized PTX rats infused IV over 48 h with hPTH(1-84). Groups of 8 rats, maintained on a normal chow diet supplemented with 1% Ca gluconate in drinking water, were PTX and implanted SC, one week later, with an osmotic minipump which delivered hPTH(1-84) IV at 0.12 or 0.24 nmol/kg/h or vehicule alone. Rats were sacrified at 48 h by exsanguination through the abdominal aorta. Circulating PTH molecular were separated by HPLC. Serum and HPLC fractions were assayed with Bio-Intact (BI), Intact (I) and Carboxyl (C) human (h) or rat (r) PTH ELISAs (Immutopics Int. San Clemente, CA). Molecular forms identified by the hPTH assays were quantitated by planimetry. Results are means ± SD. Sham-vehicule rats had a mean Ca^{++} of 1.24 ± 0.03 mmol/L with mean PTH levels of 4.99 ± 1.29 (rBI), 15.33 ± 4.03 (rI) and 16.52 ± 8.44 pmol/L (rC) while PTX-vehicule rats a Ca^{++} of 0.98 ± 0.07 mmol/L (p <0.001) with undetectable rPTH levels (p <0.001). hPTH(1-84), 0.12 nmol/kg/h increased Ca^{++} to 1.11 ± 0.09 mmol/L (p < 0.001) and hPTH levels to 22.4 ± 13 (hBI), 30.5 ± 16.8 (hI), and 71 ± 35 pmol/L (hC) while 0.24 nmol/kg/h increased Ca^{++} to 1.33 ± 0.07 mmol/L (p < 0.001) and hPTH levels to 46 ± 26 (hBI), 51 ± 34 (hI) and 208 ± 110 pmol/L (hC). HPLC fractionation disclosed 14.4% of hPTH(1-84) with the lower infusion rate and 11.8% with the higher. N-PTH was 1.3 and 1.1%, non-(1-84) PTH 2.7 and 2.9% and smaller C-PTH fragments 81 and 84% during the same infusions. This composition is very similar to the one of a normocalcemic individual and suggests a major contribution of peripheral metabolism to C-PTH fragments formation. Peripheral metabolism appears as important as parathyroid gland secretion in the generation of circulating C-PTH fragments. Our study may even suggest a reciprocal control between both processes since a normal pattern of circulating PTH was observed during hPTH(1-84) infusions. These results will be useful to design experiments on PTH fragments biological effects in PTX rats. This work was made possible by grants from Canadian Institutes of Health Research (CIHR) (MOP-7643) and NPS Pharmaceuticals.

Measurement of PTH-Induced ERK and Akt Activation and Phosphorylation of Downstream Targets Using Phosphospecific Antibody Cell-Based ELISAs (PACE). C. K. Vance*, J. A. Cole. Biology, University of Memphis, Memphis, TN, USA.

Growth factor and G protein-coupled receptor signaling converge on ERK and Akt (or PKB) to regulate proliferation, differentiation and cell survival. Recent studies have shown that PTH-induced ERK and Akt activation may involve cAMP, PKC, Ca^{2+} and/or EGF receptor transactivation but most techniques used to identify pathways involved in PTH signaling are low throughput and labor-intensive. We modified the PACE protocol described by (*Versteeg et al, Biochem. J. 350:717)* to rapidly assay ERK and Akt and identify substrate molecules. Antibody selectivity was determined by treating 3T3 fibroblasts, renal LLC-PK_1 and renalOK cells with EGF± the PI3K inhibitor wortmannin (to confirm Akt activation) or PMA ± the MEK inhibitor PD98059 (to confirm ERK activation). Cells were fixed in 4% formaldehyde, blocked in 10% FBS and primary (polyclonal anti-pS^{473} Akt or monoclonal $pT^{203}pY^{204}$ERK) and secondary antibodies (HRP-coupled goat anti-mouse- and goat anti-rabbit IgG, respectively) were titered. EGF-stimulated wortmannin-sensitive Akt activity and PMA-induced PD98059-sensitive ERK activity were detected in each cell line. In OK cells, PACE assays of PTH-, EGF-, cAMP- and phorbol ester-mediated ERK and Akt activation produced results identical to those of immune complex assays and/or Western blotting. Downstream signaling molecules were identified by assaying the phosphorylation state of the non-receptor tyrosine kinases Pyk2 (anti-pY^{402}Pyk) and Src (anti-pY^{527}Src), the Akt substrates BAD (anti-pS^{136}BAD) and GSK (anti-pS^{219}GSKα/β), the ERK-activating MEK1/2 (anti-$pS^{217/221}$) and the ERK substrate p90RSK (anti-pT^{573}p90RSK). EGF and PTH caused time-and dose-dependent phosphorylation of Src, BAD, GSK, MEK and p90RSK. Although pPyk2 was detected, neither EGF nor PTH changed its phosphorylation state. These data demonstrate that the PACE assay is readily adaptable to a variety of cell lines. In addition, this assay can be used to rapidly identify the signaling pathways leading to Akt and ERK activation as well as the phosphorylation state of downstream signaling molecules. Finally, PACE should allow for the rapid identification of the phosphorylation state of any molecule for which a phosphospecific antibody is available.

Dynamics of PTH Secretion in Normal Individuals. Differences Related to 3 Generations of PTH Assay. P. D'Amour[1], A. Räkel*[1], J. H. Brossard[1], L. Rousseau*[1], T. Cantor[2]. [1]Department of Medicine, Centre de recheche du CHUM, Hôpital Saint-Luc, Montreal, PQ, Canada, [2]Scantibodies Laboratory Inc., Santee, CA, USA.

The parathyroid function of 8 normal individuals was studied with 3 different generations of PTH assay to seek better quantitative information on the composition and control of circulating PTH molecular forms by ionized calcium (Ca^{++}). Eight volunteers, 4 males and 4 females, were infused with $CaCl_2$ and Na citrate over 2 h, one week apart, to modulate Ca^{++} by ± 0.2 mmol/L. A cyclase activating (CA) PTH IRMA with a 1-4 epitope which recognizes hPTH(1-84) and N-PTH, a total (T) PTH IRMA with a 12-18 epitope which recognizes hPTH(1-84) and non-(1-84) PTH and a carboxyl-terminal (C) RIA which reacts mainly with small C-PTH fragments, were used to measure PTH in serum and in HPLC fractions. Circulating PTH molecular forms present in serum at various Ca^{++} concentrations were separated by HPLC, revealed by the various PTH assays and quantitated by planimetry using results of the most appropriate assay for each molecular form. A 4 parameters sigmoidal mathematical model was used to analyze the parathyroid function measured with each assay as well as the evolution of various PTH fragments/ PTH(1-84) ratios. Results are means ± SD. Stimulated (CA = 7.37 ± 1.65; T = 8.60 ± 1.91; C = 14.06 ± 3.29 pmol/L) and non suppressible (CA = 0.52 ± 0.18; T = 0.75 ± 0.22; C = 4.28 ± 1.50 pmol/L) PTH values were highest in the C-PTH assay ($p < 0.001$) while slope and set point values did not differ among assays. PTH fragments/PTH (1-84) ratio values going from hypo to hypercalcemia were highest for the C/CA ratio (1.92 ± 0.29 to 9.75 ± 3.98) and the C/T ratio (1.69 ± 0.23 to 6.11 ± 1.33) and much lower for the T/CA ratio (1.15 ± 0.04 to 1.86 ± 0.73; $p < 0.01$). The set point of each ratio modulation by Ca^{++} (1.26 ± 0.11 to 1.29 ± 0.03) was higher than the set point of PTH secretion by Ca^{++} (1.21 ± 0.02 to 1.22 ± 0.02; $p < 0.001$). A planimetric evaluation of HPLC profiles disclosed that hPTH(1-84) represented only 4.1, 16.5 and 31.2% of circulating PTH in hypercalcemia, normocalcemia and hypocalcemia respectively. Similar values were 1.1, 2.7 and 6% for N-PTH, 6.8, 7.8 and 8.3% for non-(1-84) PTH and 88.1, 73.1 and 54.4% for smaller C-PTH fragments. These results confirm that the bulk of circulating PTH is made of smaller C-PTH in all circumstances, hPTH(1-84) representing at most 31% of circulating PTH. N-PTH and non-(1-84) PTH represent at most 15% of circulating PTH. These values will be useful to design in vivo and in vitro experimental to study the role of PTH (1-84) and PTH fragments in PTH physiopathology. Work supported by grant MOP-7643 from Canadian Institutes of Health Research (CIHR).

Stimulation of Cyclic AMP/PKA Signaling Induces the Activation of Canonical Wnt Pathway in Osteoblastic Cells. A. Suzuki*[1], T. Michigami[1], T. Kubota*[1], K. Ozono[2]. [1]Department of Environmental Medicine, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, [2]Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan.

Although it is well known that intermittent administration of parathyroid hormone (PTH) stimulates bone formation, the underlying molecular mechanisms are not fully understood. Since accumulating evidences have indicated the critical roles of Wnt/LRP signaling pathway in bone formation, it is reasonable to hypothesize that Wnt/LRP pathway might mediate the anabolic effect of PTH on bone. Therefore, in the current study, we have investigated the effect of stimulation of cyclic AMP (cAMP)/PKA signaling, one of the signaling pathways downstream PTH, on the canonical Wnt signaling pathway. To address this issue, we utilized a human osteoblastic cell line SaOS-2. In the reporter assays using a T-cell Factor (TCF)-reporter plasmid Super(8x)TOPflash and a control plasmid phRL-TK, treatment with 5-50 μM forskolin, an activator for adenylyl cyclase, induced TCF-dependent transactivation in a dose-dependent manner. The relative reporter activity of Super(8x)TOPflash reached maximum in 5 hours and began to decline at the 12-hour time point. As to the intracellular cAMP content determined by ELISA, it peaked within 1 hour and then decreased by the treatment with forskolin. A western blot analysis demonstrated the intracellular accumulation of β-catenin by treatment with forskolin, suggesting that the stimulation of cAMP/PKA signaling induced the activation of canonical Wnt pathway. We next examined the effect of the simultaneous treatment with Wnt3a and forskolin on the TCF-dependent transactivation using Super(8x)TOPflash. Wnt3a was prepared as the conditioned media obtained from L cells expressing Wnt3a. Wnt3a induced the TCF-dependent reporter activity in a dose-dependent manner as expected. Of note, treatment with both Wnt3a and forskolin synergistically increased the reporter activity. Finally, we performed RT-PCR analyses to examine the effects of forskolin on the expression of the molecules involved in Wnt/LRP signaling pathway, and found that the expression of dikkopf-1 (DKK-1), which acts as an antagonist of Wnt/LRP signaling, was markedly decreased by treatment with forskolin. Pretreatment with PKA inhibiter H89 abolished the down-regulation of DKK-1 expression by forskolin, confirming that PKA is involved. Taken together, these results strongly suggest that there might be a crosstalk between cAMP/PKA signaling and Wnt/LRP pathway, and that Wnt/LRP pathway might be involved in bone formation induced by PTH.

Regulation of Rheumatoid Fibroblast-Like Synoviocyte Apoptosis: A Role for Adrenomedullin-Calcitonin Receptor-Like Receptor Pathway. B. Uzan*[1], J. M. Launay*[2], J. M. Garel*[1], R. Champy*[1], H. K. Ea*[1], M. Cressent*[1], F. Lioté*[1]. [1]Hospital Lariboisière, INSERM 606, Paris, France, [2]Hospital Lariboisière, IFR 139, Paris, France.

Pathogenesis of rheumatoid arthritis is incompletely understood: defective fibroblast-like synoviocyte (FLS) apoptosis and increased cell proliferation have been considered. A Fas apoptosis signaling defective pathway and the expression of mutant p53 tumor suppressor gene are the two current mechanisms for defective RA FLS apoptosis. Adrenomedullin (ADM) is a 52-amino acid peptide with angiogenic, anabolic and anti-apoptotic properties. ADM binds to plasma membrane receptors composed of calcitonin receptor-like receptor (CRLR), coupled to adenylate cyclase (AC)-protein kinase A (PKA), and receptor activity modifying protein (RAMP) type 2 or 3. To date, only ADM has been detected at high concentrations in RA plasma, synovial fluid and tissues compared to osteoarthritis (OA). In this first study, we investigated ADM, CRLR and RAMP mRNA and protein expression in RA and OA cultured FLS, as well as its functional role in regulating FLS-induced apoptosis. ADM, PAM (peptidylglycine a-monoxygenase, its activating enzyme), and receptor CRLR, RAMPs, mRNA, and CRLR protein expressions were evaluated in RA and OA FLS by RT-PCR and Western blotting, respectively. Under ADM stimulation, CRLR-coupled AC activity was measured in RA FLS cell lysates, and RA FLS serum-free and TNF-a-induced apoptosis was evaluated by caspase-3 (Cas-3) activity and MTT assays. Cultured RA and OA FLS constitutively expressed ADM, PAM, and RAMP 2 and 3 mRNAs. By contrast, CRLR mRNA expression was up-regulated in RA FLS compared to OA FLS, and only RA-FLS expressed various detectable CRLR protein expression in all cultured samples. The ADM receptor, CRLR, was functional since increased cAMP was measured in cell lysates after ADM stimulation. An early stimulation was achieved at low ADM concentration (10-10M). ADM inhibited the combined (e.g., serum privation and TNF-a stimulation)-induced RA FLS apoptosis in a dose-dependent manner as assessed by Cas-3 expression and MTT viability assay. The anti-apoptotic effect of ADM on RA-FLS was related to AC activation and cAMP production, since these effects were inhibited by the pretreatment with H-89, a protein kinase A inhibitor, and mimicked by forskolin. This study has shown for the first time that: 1) ADM and activating enzyme mRNAs are expressed in FLS, 2) CRLR, its receptor, is functionally expressed by RA-FLS. The expression of the receptor in RA-FLS is consistent with the evidence that its endogenous ligand, ADM, may influence cell apoptosis and contribute to the defective apoptotic process in RA synovium.

Temporal Dependence of PTH (1-34) for Anabolic Actions in an Osteoregeneration Model. G. J. Pettway*[1], C. L. Wei*[2], L. K. McCauley[2]. [1]Biomedical Engineering, University of Michigan, Ann Arbor, MI, USA, [2]Periodontics/Prevention/Geriatrics, University of Michigan, Ann Arbor, MI, USA.

Parathyroid hormone (PTH) is currently the only anabolic agent in clinical use for the treatment of osteoporosis, but the mechanisms of its anabolic actions are still unclear. In this study, an innovative osteoregeneration model was used to investigate the temporal effects of intermittent PTH treatment on tissue engineered bone. Ectopic ossicles containing cortical and trabecular bone and a hematopoietic marrow were generated from implanted bone marrow stromal cells (BMSCs). Three weeks of PTH (40μg/kg/day) or vehicle treatment were initiated 1 day (group 1), 1wk (group 2), 2wks (group 3), or 3wks (group 4) after implanting BMSCs. Calcein flurochrome was administered to mice 10 and 3 days prior to sacrifice. Microradiographic and histomorphometric analyses of plastic embedded tetrachrome stained ossicle sections revealed an anabolic response in all PTH-treated ossicles, regardless of when treatment was initiated. Flurochrome labeling also revealed an increase in bone formation in PTH versus vehicle treated ossicles in all groups. However, the anabolic response to PTH was the most pronounced in ossicles where treatment was initiated 1wk after cell implantation (group 2). A qualitative increase in tartrate resistance acid phosphatase (TRAP) positive cells was observed in PTH-treated ossicles in this group. In addition, qRT-PCR revealed a 2-fold increase in RANKL mRNA expression in ossicles treated with PTH for 1wk initiated 1wk after implanting cells, suggesting that PTH stimulates osteoclastic activity in early stages of ossicle development. Other early events of PTH action in 1wk and 2wk old ossicles were also evaluated. Osteocalcin (OCN) mRNA was low in 1wk old ossicles and increased significantly at 2wks, suggesting that PTH targets cells at the stage of transition from pre-osteoblasts to mature matrix producing osteoblasts. These data indicate that anabolic actions of PTH in tissue engineered ossicles are temporally dependent on the differentiation of implanted BMSCs and suggest that cells such as osteoclastic cells may also contribute to PTH anabolic actions.

PTHrP Induces Smurf2 and Inhibits TGF-Beta Signaling in Growth Plate Chondrocytes. M. Hereg*, M. Mulcahey*, K. Kim*, Q. Wu, E. M. Schwarz, J. E. Puzas, R. J. O'Keefe, H. Drissi, M. J. Zuscik, R. N. Rosier. Orthopaedics, University of Rochester, Rochester, NY, USA.

Parathyroid hormone related peptide (PTHrP) and transforming growth factor-beta (TGF-beta) are potent inhibitors of chondrocyte maturation. The influence of these factors is critical for normal phenotypic behavior of chondrocytes in the articular surface and in the growth plate, evidenced by accelerated chondrocyte maturation in mouse models of reduced TGF-beta or PTHrP signaling. Furthermore, it is established in growth plate chondrocytes (GPCs) that TGF-beta induces PTHrP expression, indicating that there is cross-talk between these pathways leading to enhanced inhibitory effects of TGF-beta on the maturational program. Since inhibition of terminal differentiation in GPCs is the result of an interaction between these two pathways, a strong signal must be required to induce these cells to ultimately reach the hypertrophic stage, a required step during normal endochondral ossification. Recently, we have discovered that PTHrP induces Smurf2, an E3 ubiquitin ligase that targets the type I TGF-beta receptor and phopho-Smad2 for degradation in the proteasome. Based on this, we hypothesize that PTHrP induction of Smurf2 expression, leading to inhibition of the TGF-beta signaling cascade, ultimately allows GPCs to overcome the maturational inhibition exerted by both TGF-beta and PTHrP. Confirming induction of Smurf2 expression/function, treatment of GPCs with PTHrP i) up-regulates Smurf2 mRNA as measured by real time RT-PCR and ii) decreases TGF-beta-induced signaling on the P3TP-luciferase reporter. To elucidate the mechanism behind this effect of PTHrP on TGF-beta signaling, we performed western blots to assess type I TGF-beta receptor and phospho-Smad2 protein levels in cells treated with PTHrP. Consistent with our hypothesis, PTHrP mimics Smurf2 by strongly inducing degradation of both of these substrates. Use of RNA interference (RNAi) to knock-down Smurf2 expression was then performed to directly determine the role of Smurf2 in these effects of PTHrP. After confirming successful knockdown of the Smurf2 mRNA (70%), western Blot analysis showed that in the presence of a Smurf2 RNAi-oligo retrovirus, the effect of PTHrP on type I TGF-beta receptor and phospho-Smad2 levels was abrogated. These findings support our hypothesis that through an induction of Smurf2, PTHrP can turn off TGF-beta signaling, which should lead to down-regulation of PTHrP and removal of the two main roadblocks to terminal maturation in GPCs. This signaling interplay represents a novel regulatory paradigm that may be critical for maintenance of the temporal progression of chondrocyte hypertrophy during skeletal development and repair processes.

Cortical Bone Effects of PTH or Alendronate in Senile and Severely Osteopenic Ovariectomized Rats. Y. L. Ma, A. Schmidt*, R. Cain*, Q. Q. Zeng, J. Oskins*, H. U. Bryant, M. Sato. Lilly Research Labs, Indianapolis, IN, USA.

Intact or ovariectomized (Ovx) rats at about 19 months of age were treated with hPTH (1-38) (10 (Ovx only), 30μg/kg/d sc) or alendronate (ABP 28μg/kg twice weekly sc) during the latter 4 months of life. Ovx rats were severely osteopenic, having been ovariectomized at 6 months of age and allowed to lose bone for 13 months before initiating treatment. Cortical bone effects of PTH or ABP were evaluated in femora or tibia by QCT, biomechanics, and histomorphometry. Evaluation of body weight- as a measure of normal loading- showed a 12% reduction for PTH but not ABP relative to intact controls; no differences in body weight were observed between Ovx rat groups. In intact animals, load to failure analyses showed that PTH 30μg/kg increased midshaft strength by 15% and femoral neck strength by 14% relative to intact controls, whereas ABP had no effect on midshaft or femoral neck strength in intact animals. In Ovx rats, PTH dose dependently increased midshaft strength (20% and 34%) and femoral neck strength (25% and 23%) over Ovx controls. Strength parameters were restored by PTH to the level of age-matched Sham controls. For both intact and Ovx rats, PTH strength benefits resulted from significant increases in midshaft BMD (11 to 21%), midshaft BMC (10 to 22%), cortical area (7% to 16%), cortical thickness (11% to 21%), and periosteal bone formation rate (330% to 370%). In aged ovariectomized rats, ABP had no effect on midshaft strength or femoral neck strength. ABP had no effect on midshaft BMD, BMC, cortical area, or periosteal bone formation rate relative to respective intact or Ovx controls. Therefore, the ABP effects on bone formation activity in cortical bone were unlike the ABP cancellous bone effects (vertebra) where bone formation activity were markedly reduced, BFR/BS, by -79% and -75% relative to intact and Ovx controls, respectively. Nevertheless, the data taken together showed that PTH was superior to ABP in enhancing strength, increasing bone mass, and improving the spatial architecture of cortical bone sites such as the diaphysis and proximal femur in senile intact and in aged, severely osteopenic rats, even towards the end of their lifespan.

Parathyroid Hormone Stimulation of Syndecan-4 in Osteoblastic Cells. L. J. Raggatt[1], L. Qin[2], S. Cool[3], V. Nurcombe*[3], N. Partridge[2]. [1]Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia, [2]Department of Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, [3]Institute of Molecular and Cellular Biology, Proteos, Singapore.

Syndecan-4 is a membrane bound heparan sulphate proteoglycan that binds a number of growth factors, cytokines, proteases and cell adhesion molecules. The expression of the syndecan core proteins and their specific heparan sulphate attachments occurs in cell-, tissue- and developmentally specific patterns. In a screen to identify novel PTH regulated genes using cDNA microarray technology, we identified that syndecan-4 expression is increased in osteoblastic UMR-106-01 cells in response to parathyroid hormone (rPTH 1-34). Confirmation of these data using real time RT-PCR showed that steady state levels of syndecan-4 mRNA increased by 2 h, peaked at 4 h (4 fold) and had diminished by 12 h. The influence of PTH was restricted to syndecan-4 as the mRNA expression of the other members of the syndecan family were unchanged after PTH treatment of UMR 106-01 cells. The cAMP analogue 8Br-cAMP and the PKA activator PMA were used to investigate which of these classical PTH signal transduction pathways regulate expression of syndecan-4. The cAMP analogue 8Br-cAMP mimicked the PTH induction of syndecan-4 suggesting that the cAMP signal transduction pathway is utilized by PTH to regulate expression of the syndecan-4 gene. In contrast, PMA, which activates the PKC pathway, did not stimulate syndecan-4 mRNA expression. Cycloheximide did not affect expression of syndecan-4 mRNA in response to PTH treatment suggesting that the increase in steady state mRNA levels was due to transcriptional activation of the gene and did not require de novo protein synthesis. Interestingly regulation of syndecan-4 in osteoblastic cells also occurred in response to the pro-osteoclastic agents vitamin D_3 and PGE_2 suggesting syndecan-4 may have a broader role in bone biology. To confirm the in vivo significance of the PTH regulation of syndecan-4, 4 week old Sprague-Dawley rats were injected subcutaneously with vehicle (0.9% saline solution) or hPTH(1-38) (8 μg/100 g). The primary spongiosa was removed from the distal femur 0.5, 1, 4, or 8 h after injection and RNA harvested. A very rapid increase in syndecan-4 expression occurred at 0.5 h post injection, peaked at 2 h (10 fold) and had returned to base line by 4 h post injection. Taken together these data show that PTH can regulate the expression of syndecan-4 in osteoblastic cells and we therefore propose that syndecan-4 may act as a co-receptor for growth factors and cytokines in the anabolic bone response to PTH.

Parathyroid Hormone 1-34 Enhances Titanium Implant Osseointegration and Peri-Implant Bone Parameters in Rat Tibial Model of Low Density Trabecular Bone: A Micro CT Analysis. Y. Gabet*[1], D. Kohavi*[2], J. Levy*[3], R. DiMarchi*[3], M. Chorev*[4], R. Müller[5], I. Bab[1]. [1]Bone Laboratory, The Hebrew University of Jerusalem, Jerusalem, Israel, [2]Dental Implantology Center, Hebrew University-Hadassah School of Dental Medicine, Jerusalem, Israel, [3]Department of Chemistry, Indiana University, Bloomington, IN, USA, [4]Laboratory for Translational Research, Harvard Medical School, Cambridge, MA, USA, [5]Swiss Federal Institute of Technology (ETH) and University of Zürich, Jerusalem, Switzerland.

The use of endosseous titanium implants in dentistry and orthopaedic surgery has been the standard of care for several decades. However, implantation in low density bone has a poor prognosis and experimental studies show delayed implant integration following gonadectomy-induced bone loss. Intermittently administered parathyroid hormone 1-34 [iaPTH(1-34)] is the leading bone anabolic therapy, reversing bone loss and enhancing fracture healing. Hence, the aim of the present study was to assess whether iaPTH(1-34) stimulates the integration of titanium implants in low density bone. Threaded titanium implants, 0.9 mm in diameter, were inserted horizontally into the proximal tibial metaphysis of 5 months old rats, 7 weeks after orchiectomy. Treatment with PTH(1-34), at 5, 25 and 75 µg/Kg/day commenced immediately thereafter and lasted for 8 weeks. Thereafter, the implantation site was subjected to a quantitative micro CT analysis. The specimens were scanned at 15 µm resolution using maximal energy and integration time to minimize artifacts resulting from the highly radio-opaque metal implant. Osseointegration was calculated as the percent implant surface in contact with bone (%OI) quantified as the ratio of "bone"-to-total voxels in contact with the implant. In addition, we measured in the peri-implant bone the trabecular bone volume density (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th) and connectivity density (Conn.D). Using a curve-fit analysis all parameters were corrected for variation in implant position to compensate for the growth plate-diaphyseal decreasing gradient in trabecular bone content. iaPTH(1-34) stimulated all of these parameters dose-dependently. The maximal enhancement of the %OI, BV/TV, Tb.N, Tb.Th and Conn.D was 154%, 263%, 142%, 150% and 200%, respectively. There were no significant differences between the 25 and 75 µg/Kg doses, other than in the case of Tb.Th that was significantly higher at 75 µg/Kg. These findings suggest that iaPTH(1-34) effectively enhances implant anchorage in low density trabecular bone and demonstrate the feasibility of improving the clinical prognosis of endosseous implantation in the osteoporotic skeleton.

The Stimulation of Amphiregulin Expression in Osteoblastic Cells by Parathyroid Hormone Requires the Protein Kinase A and cAMP Response Element-Binding Protein Signaling Pathway. L. Qin, N. C. Partridge. Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

Parathyroid hormone (PTH), an anabolic and catabolic agent for bone metabolism, has profound effects on gene expression in the osteoblast. Recently, we identified that amphiregulin (AR), an epidermal growth factor (EGF)-like ligand, is induced by PTH as an immediate early gene. AR has important roles in bone metabolism: stimulating preosteoblast proliferation while inhibiting osteoblast differentiation. We hypothesized that one mechanism of PTH's anabolic action is to increase AR expression resulting in expansion of the number of bone marrow stromal stem cells and their derived osteoblast progenitors. In the present report, we studied the signaling pathway PTH uses to regulate AR expression in osteoblastic cells. Only PTH (1-34, activates both PKA and PKC) and PTH (1-31, activates PKA), but not PTH (13-34, activates PKC) were able to stimulate AR mRNA levels in UMR 106-01 cells by real-time RT-PCR. In the presence of the PKA inhibitor H89, but not in the presence of the PKC inhibitor GF109203X, PTH(1-34) lost its ability to induce AR expression. The cAMP analog, 8-BrcAMP, strongly stimulated AR expression. Injection of rats with PTH (1-38, activates both PKA and PKC) or PTH(1-31), but not PTH (3-34, activates PKC), highly and transiently stimulated AR mRNA levels in the osteoblast-rich femoral metaphyseal primary spongiosa. These results demonstrated that PTH regulates AR in a cAMP-PKA-dependent manner both *in vitro* and *in vivo*. Alignment of human, mouse and rat AR promoters revealed a highly conserved cAMP-response element (CRE) just upstream of a TATA box. In UMR 106-01 cells, Western blots demonstrated that after PTH treatment the phosphorylation of CRE-binding protein (CREB) peaked at 45 min, preceding the peak of AR mRNA synthesis (60 min). Moreover, luciferase reporter assays using human AR promoter-luciferase constructs revealed that the binding of phosphorylated CREB to the CRE site in the AR promoter plays an important role in basal, PTH-induced and prostaglandin E_2 (PGE_2)-induced AR expression in osteoblastic cells. Mutation of this CRE site resulted in a significantly lower basal AR promoter expression and a much lower PTH and PGE_2 responsiveness of the AR promoter. Co-transfection with a dominant-negative CREB (KCREB) along with AR promoter constructs completely eliminated the PTH and PGE_2 stimulation of the AR promoter. In summary, our data suggest that PTH-induced AR mRNA expression in osteoblastic cells is mediated primarily through cAMP-PKA-CREB signaling.

Interference with Connexin43 Function Attenuates Parathyroid Hormone Regulation of the Rat Osteocalcin Promoter. A. De Marzo*[1], J. P. Stains[2], R. Civitelli[1]. [1]Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA, [2]University of Maryland Sch. Med., Baltimore, MD, USA.

Interference with connexin43 (Cx43) decreases PTH stimulation of cAMP production and osteoblast differentiation in vitro; and we find that the osteoanabolic effect of PTH in vivo is also attenuated in mice with conditional deficiency of osteoblast Cx43. Using the osteocalcin (OC) gene as a model, we explored the molecular bases of Cx43 modulation of PTH action in osteoblasts. Exposure of ROS 17/2.8 cells to 10^{-8} M PTH (1-34) for 16-24 hours induced a ~ 6.8 fold stimulation of OC mRNA accumulation, measured by real time PCR. By contrast, in ROS 17/2.8 cells stably expressing chicken connexin45 (cCx45), which interferes with Cx43 function, PTH treatment induced only a ~1.4 fold increase of OC mRNA. We then studied gap junction sensitivity of OC gene transcription in response to PTH, and transiently co-transfected ROS 17/2.8 cells with cCx45 and a series of 5' deleted rat OC promoter-luciferase reporter constructs (OCLUC). Treatment (16-24h) of cells with PTH induced a ~1.8 fold increase in -637OCLUC and -199OCLUC promoter activities, confirming that proximal regions of the OC promoter are PTH responsive. Importantly, cCx45 overexpression decreased both basal and PTH-stimulated -199OCLUC activity by 60 and 70 percent, respectively. Further, a -92OCLUC reporter, which spans a known CT-rich element and OSE1, still retained PTH responsiveness, though to a lesser degree than the -199OCLUC; and overexpression of cCx45 repressed the PTH response of this fragment by 80%. Deletion of the previously characterized gap junction responsive CT element from this construct (-92ΔCTOCLUC) did not affect PTH responsiveness in cells transfected with empty vector, although PTH response was abrogated when cCx45 was co-transfected with -92ΔCTOCLUC, suggesting that OSE1 activation by PTH (but not basal activity) is gap junction sensitive. Accordingly, cCx45 co-transfection abolished PTH stimulated activity from a heterologous promoter-reporter construct containing 6 copies of OSE1 (1.5 vs. 1.0 fold stimulation), whereas a CTLUC construct was insensitive to PTH, although it was down-regulated by cCx45. In contrast, co-transfection cCx45 actually synergized with PTH or forskolin in activating a non canonical cAMP response region present in the proximal OC promoter (ROCRR), and a canonical cAMP response element (CRE). Thus, the ability of cCx45 to attenuate PTH effect on osteocalcin transcription mediated through OSE1 seems to be independent of ROCRR and CRE. However, the net effect on OC gene transcription and the signals converging on OSE1 during PTH stimulation are modulated by changes in Cx43 function.

Cross-Linking of Modified PTH(1-15) Antagonist Analogs to the Juxtamembrane Portion of the PTH/PTHrP Receptor. R. C. Gensure[1], T. Dean*[2], T. J. Gardella[2]. [1]Pediatrics, Ochsner Clinic Foundation, New Orleans, LA, USA, [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

We recently described a new class of conformationally constrained, N-terminal PTH fragment analogs that bind exclusively to the juxtamembrane (J) domain region of the PTH/PTHrP receptor and function as competitive antagonists (Shimizu, et. al., J Biol Chem., 2005). These PTH(1-15) analogs contain multiple, affinity-enhancing substitutitions, together the *p*-benzoyl-**L**-phenylalanine (Bpa) substitution at position 2, which blocks receptor activation and renders the ligand photoreactive. To explore whether these N-terminal PTH antagonists occupy the same receptor-binding site as that used by the N-terminal portion of the unmodified intact ligand, we covalently cross-linked [$Deg^{1,3}$,Bpa^{2},Gln^{10},Ala^{12},Har^{11},Trp^{14},Tyr^{15}]PTH(1-15)NH_2 to the receptor and mapped the site of photo-insertion. Parallel studies were performed with [Ac_3c^{1},Bpa^{2},Aib^{3},Gln^{10},Ala^{12},Har^{11},Trp^{14},Tyr^{15}]PTH(1-15)NH_2. Both of these antagonists cross-linked to the receptor segment Phe^{415}(TM6)-Met^{441}(third extracellular loop). Cyanogen bromide failed to cleave the cross-linked complexes at Met^{425}, and mutation of this methionine to Ala reduced cross-linking efficiency of each peptide, suggesting that cross-linking occurred at or near Met^{425}. This same receptor residue is the cross-linking site identified previously by us and others for the intact antagonists [Bpa^{2}]PTH(1-34) and [Bpa^{2}]PTHrP(1-36), as well as the agonist [Bpa^{1}]PTH(1-34). We thus conclude that the modified PTH(1-15) scaffold occupies approximately the same space in the J domain-binding pocket as does the N-terminal residues of unmodified PTH(1-34) and PTHrP(1-36) ligands. This same binding pocket appears to be used by the N-terminal residues of both agonist and position 2-modified antagonist analogs of both PTH and PTHrP, and is therefore likely to play a critical role in receptor activation. Further studies with additional PTH ligands, including J domain-selective agonist and antagonists, may yield additional information regarding the configuration of this binding pocket and thus facilitate the design of new PTH/PTHrP receptor agonists and antagonist ligands.

Disclosures: ***R.C. Gensure****, None.*

Receptor-Like Binding Activity for Non-Amino Terminal PTHrP. R. H. Hastings*[1], D. W. Burton[2], J. J. Grzesiak*[3], M. Bouvet[3], L. J. Deftos[2]. [1]Anesthesiology, Veterans Administration San Diego Healthcare System (VASDHS) and University of California, San Diego, San Diego, CA, USA, [2]Medicine, VASDHS and UCSD, San Diego, CA, USA, [3]Surgery, VASDHS and UCSD, San Diego, CA, USA.

The most widely studied effects of PTHrP have been of its amino terminus, which signals through the PTH/PTHrP type 1 receptor that it shares with PTH. However, there is accumulating and compelling evidence that non-amino terminal peptides of PTHrP, generated through processing of the native isoforms, can also exert biological effects that include growth regulation and tumor progression. Some actions of these various PTHrP domains are exerted at the cell surface and presumably result from activation of cell-surface receptors, likely G-protein coupled. The nature of the non-amino terminal PTHrP receptor(s) is unknown, but preliminary data regarding the effects of different PTHrP moieties on important cell functions such as proliferation and apoptosis open the possibility of novel PTHrP receptors in many cell types. In this study, we measured the specific binding of radioiodinated PTHrP38-94 to isolated plasma membranes from prostate cancer cells (DU 145, LNCaP and PC-3) and lung type II epithelia cells (RLE and MB 48) using a 96-well plate filtration system for receptor-ligand interactions. Non-specific binding was measured in the presence of 5 μM unlabeled peptide. Unlabeled PTHrP38-94 and 67-94 peptides displaced binding of the labeled peptide to the cell membranes, with 38-94 being more effective than 67-94. The competitive displacement curves appeared to be rectangular hyperbolas, with saturable binding and IC50 values of 50-100 nM for displacement of the radioligand in the cell lines, similar for those reported for the carboxyl-terminal PTH receptors (Divieti et al. Endo 146:1863-70, 2005). Conversely, PTHrP1-34 and 140-173 peptides did not displace the midmolecule PTHrP radiolabeled peptide using the same concentration range. Saturable dose response curves within physiologic concentration ranges of peptide suggest the existence of PTHrP midmolecule receptor-like binding proteins in prostate cancer and alveolar type II derived cell membranes.

A Novel Member of the Calcitonin Gene-related Peptide Family, Calcitonin Receptor-stimulating Peptide, Inhibits Osteoclastogenesis. H. Hagiwara[1], M. Notoya*[2], R. Arai*[2], T. Katafuchi*[3], N. Minamino*[3]. [1]Dept. of Biomedical Engineering, Toin University of Yokohama, Yokohama, Japan, [2]Dept. of Biosciences and Biotechnology, Tokyo Institute of Technology, Yokohama, Japan, [3]Dept. of Pharmacology, National Cardiovascular Center Research Institute, Osaka, Japan.

We isolated a novel peptide, calcitonin receptor-stimulating peptide (CRSP), from porcine brain and the administration of this peptide into rats induced a transient decrease in the plasma calcium concentration. Therefore, we investigated the effects of CRSP on osteoclastogenesis. Osteoclast-like cells were formed from spleen cells or bone marrow cells by a combination of the receptor activator of nuclear factor-κB ligand (RANKL) and macrophage colony-stimulating factor (M-CSF). CRSP dose-dependently inhibited the formation of multinuclear osteoclast-like cells with expression of CT receptor. CT receptor inhibitor antagonized in part inhibition of osteoclast formation by CRSP. Furthermore, CRSP destroyed the actin ring that is a typical index of osteoclast activity, and this inhibitory action was due to signal pathways of protein kinase A. Our findings indicate that CRSP inhibits osteoclastogenesis *via* the inhibition of the formation and the activity of osteoclastic cells. The inhibitory effects of CRSP on osteoclast metabolism were similar degree to those of calcitonin. CRSP might provide a clue to the development of tools useful in the prevention and treatment of osteoporosis.

PTHrP Gene-Driven lacZ Expression in Chondrocytes and Bone Cells. X. Chen[1], B. E. Dreyer*[1], V. Hammond*[2], W. M. Philbrick*[1], A. E. Broadus[1]. [1]Department of Medicine, Endocrine Division, Yale University, New Haven, CT, USA, [2]Florey Institute, University of Melbourne, Parkville, Australia.

We have created CD-1 mice with an allelic lacZ-PTHrP gene insertion. Based on the elimination of PTHrP instability sequences in the 3 end of the construct and the sensitivity of lacZ methods, we guesstimate that the system provides a 5-to10-fold increase in PTHrP detectability at most sites. Here, we focus on sites relevant to bone. First, we studied chondrocyte (C) lacZ expression from development through adulthood. LacZ expression was polarized at the proximal and distal ends of C condensations. This polarization was maintained in subarticular locations after the formation of the primary ossification center. Two populations of lacZ-expressing Cs appeared with formation of the secondary center: one was a subarticular layer one to several cells deep just at the articular surface and the second a layer 4 to 6 cells deep at the junction of the resting and proliferative zones at the top of the C columns. These sites were maintained through adulthood. The perichondrium was strongly lacZ-positive around the costal cartilage but not elsewhere. Second, we expected to identify lacZ-expressing osteoblasts but have thus far not detected such cells in the primary bone collar, primary spongiosa, trabeculae or periosteum. Third, we identified strong lacZ expression in the periosteum and in fibrous tendon insertion sites, with weaker expression at fibrocartilagenous sites. In simple periosteum of only two fibroblast-like cell layers, lacZ was expressed in the peripheral layer; at osteochondral junctions there was an abrupt transition from lacZ-positive periosteal to lacZ-negative cells at the margin of a synovial joint space. Fibrous tendon insertions comprise so-called bony sites, at which a cord-like tendon inserts into bone at an acute angle, and so-called periosteal sites, at which a layer of periostum joins muscle to bone over a large surface area. LacZ was strongly expressed at both such sites in a layer of cells that lay between the muscle cells and the internal bone cells. This localization was suggestive of both putative force induction of PTHrP and putative paracrine PTHrP function, and we speculate that PTHrP in these locations might be associated with periosteal bone accretion during growth and/or in response to mechanical force and also in the tethering of muscle insertions to bone.

Brain, Breast and Bone Circuit: Interactions of Prolactin, PTHrP and Calcitonin during Lactation. J. P. Woodrow[1], A. O. Hoff[2], R. F. Gagel[2], C. S. Kovacs[1]. [1]Memorial University of Newfoundland, St. John's, NF, Canada, [2]University of Texas MD Anderson Cancer Center, Houston, TX, USA.

PTHrP is abundantly expressed by lactating mammary tissue, from which it reaches the maternal circulation to upregulate bone resorption and thereby provide calcium to milk. In addition to PTHrP, lactating mammary tissue expresses the calcium receptor (CaR), calcitonin (CT), CT receptor (CTR), VDR, and 1-alpha-hydroxylase (1α). Prolactin and CaR both regulate mammary PTHrP expression; in turn, CT inhibits prolactin by direct actions on pituitary lactotrophs. Furthermore, CT has recently been shown to regulate bone metabolism during lactation: *Ct*-null mice lost twice as much trabecular bone mineral content during lactation as wt siblings, and the loss was normalized by daily sc treatment with CT but not by vehicle or CGRP. The present studies were designed to examine if PTHrP is upregulated in mammary tissue of *Ct*-null mice, and to determine if local or systemic factors might explain any alteration in PTHrP expression. *Ct* null mice and wt sisters were mated to the same *Ct*+/- males, and followed through full 70 day cycles of pregnancy, lactation and recovery. Time points included non-pregnant (baseline), late pregnancy/early lactation (peak) and late lactation (trough). Serum and plasma were collected by cardiac puncture. Mammary tissue was surgically excised, snap-frozen, and then RNA was extracted. Real time quantitative RT-PCR was performed in triplicate using the ABI Prism 7000 Sequence Detection System. mRNAs included PTHrP, 1α, VDR, CTR, CaR, and the epithelial calcium transporters (CaT1 and CaT2/ ECAC). Serum prolactin was measured using a murine prolactin RIA developed by the National Hormone Peptide Program. PTHrP mRNA was upregulated in *Ct*-null versus wt by a fold increase of 3.28 ± 0.09 (SD) at the trough point ($p<0.01$). No differences between *Ct*-null and wt were observed for 1α, VDR or CaR, whereas CTR, CaT1 and CaT2 were not detectable. Mean serum prolactin [ng/ml] was elevated in *Ct*-null at each time point vs wt: 64.8 vs 23.2 [baseline], 251.6 vs 173.0 [peak], and 44.8 vs 29.0 [trough] ($p<0.02$ by ANOVA). *Ct*-null mice have enhanced bone resorption during lactation that is not simply due to loss of the inhibitory effect of CT on osteoclasts. PTHrP expression is increased in mammary tissue of *Ct*-nulls, which in turn should further augment bone resorption. Increased PTHrP expression may result from loss of local actions of CT within mammary tissue and within the pituitary. In conclusion, mammary expression of PTHrP is enhanced during lactation in the absence of calcitonin, revealing a physiological loop through which brain and breast control bone during lactation.

Regulation of Granulocyte-Macrophage Colony-Stimulating Factor Receptor Beta in the CT/CGRP Null Mouse. A. O. Hoff, E. Huang*, G. J. Cote, R. F. Gagel. Endocrine Neoplasia & Hormonal Disorders, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA.

There is evolving evidence that interleukin 3 (IL3) plays an important role in the differentiation of osteoclasts. Absence of IL3 in marrow cultures causes differentiation of monocytic hematopoietic precursors toward an osteoclast lineage; addition of IL3 reverses this effect, leading to macrophage differentiation (J Immunol 171:142, 2003; J Biol Chem 280:11759, 2005). In an attempt to better understand why PTH stimulates greater bone resorption and calcemic response in the CT/CGRP null mouse, we performed gene microarray analysis of RNA from bone marrow of CT/CGRP KO and WT animals. The RNA was obtained by perfusing the marrow cavity of long bones with a lysis buffer. Samples obtained from 3 WT and 3 KO animals were analyzed by gene microarray analysis using the Affymetrix Gene Chip Mouse Genome 430 2.0 Array. Fifty-three genes were found to be differentially expressed as defined by a greater than 2-fold change and 2722 genes had a greater than 1.5-fold change (both $p<0.05$). When this gene set was analyzed using the Ingenuity Pathways Analysis™ application, we identified greater than a 2-fold increase in colony stimulating factor 2 receptor β1 and β2 (CSF2RB1 and CSF2RB2) gene expression, the receptors for IL-3, IL-5 or GM-CSF. In addition, there was increased expression of several downstream signaling proteins. IL-3 expression was decreased (-1.55 fold; $p<0.05$). Prior studies indicate that regulation of this receptor system is important in delineation of the osteoclast phenotype. The finding that the receptor system is upregulated and IL-3 downregulated in the marrow of CT/CGRP KO mice with a greater calcemic response to PTH suggests that CT or CGRP, either directly or indirectly, regulates this receptor system.

EBP50 Regulates PTH1R-mediated Effects on Vascular Smooth Muscle Cell Proliferation. L. Zhang*, C. A. Syme*, A. Bisello. Department of Medicine, University of Pittsburgh, Pittsburgh, PA, USA.

The parathyroid hormone (PTH) type 1 receptor (PTH1R) and its ligands PTH and PTHrP play diverse and important roles in the pathophysiology and pharmacology of the vascular system. The signaling activities of the PTH1R are remarkably cell-specific, and, indeed, the cellular responses of "classical" PTH targets (osteoblasts and kidney cells) are fundamentally different from those of vascular smooth muscle cells (VSMC). In particular, while PTH and PTHrP typically stimulate MAPK activity and proliferation in bone and kidney cells (where the PTH1R signals through both Gs and Gq proteins), they potently inhibit VSMC proliferation (where only Gs coupling occurs). Recent evidence shows that ezrin-binding protein 50 KDa (EBP50), also known as NHERF1, contributes to signaling specificity and trafficking of the PTH1R. We found that in vascular tissue EBP50 was expressed predominantly by the endothelial cells, whereas extremely low levels were detected in VSMC. In clonal A10 VSMC, PTH(1-34) and PTHrP(1-36) stimulated cAMP formation in a regulated fashion: both receptor desensitization and resensitization occurred. Stimulation with 100 nM PTHrP(1-36) induced membrane clustering and partial internalization of the PTH1R-GFP within 5 min. After 15 min virtually all of the membrane receptor was internalized. Stimulation of A10 cells maintained in 1% serum with 100 nM PTH(1-34) or PTHrP(1-36) led to a significant reduction (approx. 35%) of cell proliferation (determined by ^{3}H-Thymidine incorporation). In similarly prepared A10 cells, inhibition of the ERK1/2 pathway by 10 μM PD98059 caused a 33±2% reduction in ^{3}H-Thymidine incorporation. Inhibition of PI3K by 20 μM LY294002 resulted in a 75±2% reduction in DNA synthesis, indicating that both ERK1/2 and PI3K contribute to VSMC proliferation. Consistent with these observations, PTHrP(1-36) inhibited phosphorylation of ERK1/2 and PKB both in A10 and primary VSMC. Moreover, PTHrP rapidly (5 min) decreased the nuclear staining of phosphorylated ERK1/2. Expression of EBP50 in A10 cells (either transiently or stably) affected neither the cAMP activity of the PTH1R nor its ability to internalize upon agonist occupancy. However, EBP50 expression reduced the anti-proliferative effect of PTHrP such that no differences in thymidine incorporation were observed upon treatment with PTHrP. In summary, these data indicate that cAMP-mediated inhibition of ERK1/2 and PI3K activity occurs in VSMC in response to PTH1R agonists, resulting in inhibition of cell proliferation. In addition, the expression level of EBP50 in VSMC determines the mitogenic responses to PTH1R stimulation.

Novel Ligands for Analysis of Carboxyl-PTH Receptors in Bone Cells.

S. Banerjee*, G. Suliman*, H. Jüppner, F. R. Bringhurst, P. Divieti. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

The major secreted form of parathyroid hormone is intact PTH (1-84), although various N-terminally truncated fragments (Carboxy-terminal PTH; CPTH) are present in the blood stream as well. These CPTH fragments are either secreted from the parathyroid glands or released following proteolysis of the intact hormone in the peripheral organs. A physiological role of these CPTH fragments is suggested by the fact that their secretion is regulated by serum calcium and by evidence of biological responses to CPTH peptides in vivo and in vitro. In this study, we have characterized 4 synthetic CPTH peptides for binding to the osteocytic cell line OC59 (PTH1R-null murine osteocytic cells) and ROS17/2.8 to assess their utility in identifying and cloning CPTH receptors from these cell lines. The peptides used were [Tyr34]hPTH(23-84) ±benzylphenylalanine (Bpa) at position 24 and [Tyr34]hPTH(24-84) ± Bpa at position 26 to facilitate photoaffinity crosslinking of the receptor during subsequent purification attempts. All peptides were C-terminally biotinylated at 84. The function of these synthetic peptides was addressed by analyzing specific binding of 125I-radiolabeled peptides, in the absence vs. presence of homologous nonradioactive peptide(s), to intact cells or isolated plasma membranes. For the whole cell binding, the IC50 values for all the peptides tested were found to be in the range of 20-40nM, as previously reported, whereas a higher value was seen with membranes. Both whole cells and membranes were incubated with 125I-labeled Bpa-containing peptide and photoaffinity crosslinking was carried out using high wavelength UV radiation for 15-20 minutes, followed by lysis in SDS-PAGE sample buffer and electrophoresis. Upon autoradiography, ~220 kDa and ~80 kDa bands were found and hypothesized to be putative CPTH receptors. Alternatively, western blot analysis was carried out with Streptavidin-HRP, and identical bands were detected. Partial purification of the CPTH receptor(s) was attempted using immobilized hPTH antibody-agarose matrix or immobilized streptavidin matrix, or a combination of both. Surprisingly, upon 2-step purification, only the ~80 kDa protein could be purified, implying that the ~220 kDa protein is likely a transient aggregate. This was further verified by guanidium hydrochloride treatment of the electroeluted ~220 kDa band, which was seen to resolve into ~80 kDa protein. On preliminary characterization, the ~80 kDa protein was found to exhibit be having a slightly acidic pI and most likely to be non-glycosylated. Further analysis by high-resolution 2D electrophoresis is ongoing to attempt isolation of the CPTHR and subsequent identification by mass spectrometry.

Type 1 Paratrhryoid Hormone Receptor Nuclear Trafficking: Association of PTH1R with Karyopherin Alpha2 and Beta1. B. W. Pickard*, A. B. Hodsman, L. J. Fraher, P. H. Watson. Medicine, University of Western Ontario, London, ON, Canada.

Advances in the study of GPCRs have revealed that several members of the Class A Rhodopsin like receptors demonstrate the ability to translocate to the nucleus, in addition to their traditional membrane bound signalling properties. Previous studies in our laboratory have shown that the PTH1R, a class B Secretin like GPCR, appears in the nucleus of target cells. Proteins, such as PTH1R, destined for the nucleus or nuclear envelope contain intrinsic nuclear localization signals (NLS) which specify their ultimate destination. Many receptors and ligands are targeted to the nucleus through the interaction of their NLS with proteins of the karyopherin family and it is likely that PTH1R transport is also regulated by the karyopherins. The purpose of this study is to demonstrate the interaction of PTH1R with the karyopherins. Using immunoprecipitation and affinity chromatography we show that the PTH1R forms a complex with both karyopherin alpha2 and beta1. Total cell protein from random cycling wild type MC3T3-E1 and ROS 17/2.8 cells were immunoprecipitated with antibodies for PTH1R, karyopherin alpha2 or karyopherin beta1. When the immunoprecipitates were separated and subsequently exposed to biotinylated PTH (1-84) a single band was present on the gel at 66.3 kDa corresponding to the PTH1R. To confirm the interaction between PTH1R and both karyopherin alpha2 and beta1 the complex was purified from total cell protein using a PTH linked affinity chromatography column. PTH1R was purified from wild type random cycling ROS 17/2.8 and MC3T3-E1 cells. Using an anti-karyopherin alpha2 antibody, western blots detected karyopherin alpha2 at 58 kDa in the sample. Also, using an anti-karyopherin beta1 antibody western blots detected karyopherin beta1 at 94 kDa. These results indicate that the karyopherins were associated with the PTH1R at the time of the purification. In random cycling wild type SaOS-2 and MC3T3-E1 cells immunofluorescence demonstrated that the PTH1R was detected in the nucleus. Both karyopherin alpha2 and beta1 can be detected in the nucleus as well as in the cytoplasm. The overlay of the immunofluorescent images demonstrates the spatial overlap of the three proteins consistently within the cell in areas such as the nucleus. Examination of the z-sections obtained from deconvolution microscopy revealed that the nuclear PTH1R and karyopherins were localized to the nucleoplasm. Our interest in PTH1R lies in the fact that the mechanism of action of the anabolic response of bone to intermittent PTH therapy is not well understood. The nuclear trafficking of the PTH1R provides a new avenue of investigation into the pleiotropic actions of PTH.

Expression of a PTH1R-GFP Construct in F1 PTH1R-Null Osteoblasts: Restoration of cAMP Responsiveness to PTH(1-34). E. K. Patterson*[1], P. H. Watson[1], A. B. Hodsman[1], G. N. Hendy[2], L. Canaff*[2], P. A. Divieti[3], L. J. Fraher[1]. [1]Medicine, University of Western Ontario, London, ON, Canada, [2]Medicine, McGill University, Montreal, PQ, Canada, [3]Endocrine Unit, Mass General, Harvard University, Boston, MA, USA.

Previous immunocytochemical studies in our laboratory demonstrated the unexpected result that the Type I Parathyroid Hormone Receptor (PTH1R) is apparently able to localize to the nucleus of cells in the gut, ovary, testes, liver and kidney in the rat. Further studies in the clonal cell line MC3T3-E1, demonstrated that this localization to the nucleus occurs in a cell-cycle dependent manner, moving into the nucleus just before S-phase. An analysis of the amino acid sequence of all available PTH1Rs revealed a putative NLS of the bipartite type first described in nucleoplasmin. We have been employing various PTH1R constructs tagged with green fluorescent protein (GFP) to determine the mechanism of import of the PHT1R. The purpose of this study is to demonstrate that our GFP tagged PTH1R constructs are capable of restoring cAMP signaling in PTH1R knock-out cells, and that the fusion protein appears in the expected location in the plasma membrane as a preliminary step to further studies of nuclear trafficking of the PTH1R. The PTH1R construct used for these studies represents amino acids 1 to 577 of the mature peptide with a C-terminal GFP tag. F1 osteoblast cells were cultured in 24-well plates for 24 hours prior to transfection in alpha-MEM with 10% FBS. F1 cells were transiently transfected with a PTH1R-GFP plasmid using Lipofectamine 2000, according to the manufacturer's protocol and transfection reagent alone was used as a control. Twenty-four hours post-transfection, cultures were treated with various concentrations of PTH(1-34) for 15 minutes and the resulting cAMP response per well measured. While control cells showed no response to PTH, the transfected F1 cells demonstrated a dose-dependent increase in cAMP from 20 fmol/well to 800 fmol/well at a PTH concentration of $1x10^{-8}$ M. Localization of fusion protein constructs was determined 24 and 48 hours post-transfection using fluorescence microscopy showing cells to have strong signal in the plasma membrane. These results demonstrate that our fusion protein construct is able to restore cAMP responsiveness to PTH in F1 cells and the fusion protein is also properly inserted into the plasma membrane.

NHERF1/EBP50 and NHERF2/E3KARP Regulate PTH1R Endocytosis. W. B. Sneddon[1], B. Wang*[1], P. A. Friedman[2]. [1]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Depts. of Pharmacology and of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

Parathyroid hormone (PTH) is the principal regulator of extracellular calcium homeostasis. Its effects on kidney and bone are mediated by the Type 1 PTH receptor (PTH1R). The PTH1R is internalized in a cell- and ligand-specific manner in PTH target cells. In kidney distal tubule (DT) cells and some bone cell lines (e.g. ROS17/2.8), both the agonist PTH(1-34) and the antagonist PTH(7-34) induce PTH1R internalization. Progressive truncation of PTH fragments from N terminus positions 1-7 leads to reduced cyclic AMP formation and increased PTH1R internalization in DT cells. We also demonstrated that the Na/H exchanger regulatory factor (NHERF1:EBP50) blocks PTH1R endocytosis by antagonist PTH fragments. Mahon et al reported that both NHERF1 and NHERF2 (E3KARP) bind to the PTH1R through an atypical C-terminal PDZ-binding domain. We hypothesized that NHERF1 and NHERF2 are functionally redundant and are able to substitute for one another. We further hypothesized that truncation of PTH(7-34) from its N terminus impairs its ability to induce PTH1R internalization in the absence of NHERF. PTH1R internalization was measured by real-time confocal fluorescence microscopy of mouse DT cells stably expressing 10^6 EGFP-tagged PTH1R/cell. PTH(7-34), (8-34) and (9-34) internalized the PTH1R 65%, 47% and 44%, respectively. PTH1R endocytosis was abolished in the presence of either NHERF1 or NHERF2. Neither PTH(10-34) nor PTH(7-31) internalized the PTH1R. We, therefore, conclude that positions 1-9 and 32-34 of PTH are required for induction of PTH1R internalization in the absence of NHERF. We additionally conclude that NHERF1 and 2 are functionally equivalent in terms of their ability to inhibit PTH1R internalization by antagonist PTH fragments. NHERF1 and 2 are expressed in mouse proximal but not distal renal tubules. The magnitude and pattern of NHERF1 and 2 expression may, therefore, have important implications for understanding PTH1R function in kidney and bone in states of calcium wasting and aging.

PTH1R Activation of ERK Requires Transactivation of the Epidermal Growth Factor Receptor. W. B. Sneddon[1], Y. Yang*[1], P. A. Friedman[2]. [1]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Depts. of Pharmacology and of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

The Type 1 PTH receptor (PTH1R) activates multiple signaling pathways, including mitogen-activated protein kinase (MAPK, ERK), in a cell- and ligand-specific manner. In previous work we showed that PTH stimulated ERK1 and ERK2 in kidney distal tubule cells. Blockade of ERK1/2 inhibited PTH-stimulated calcium transport. There is evidence that some G protein-coupled receptors, such as the ß2 adrenergic receptor, transactivate the Epidermal Growth Factor Receptor (EGFR) and that this is required for activation of ERK1/2. In the present work we examine the role of EGFR in ERK1/2 activation by PTH. ERK1/2 activation was measured by phosphospecific immunoblotting. Results were normalized to total ERK1/2. In distal tubule kidney cells expressing 10^6 PTH receptors/cell (D1 cells), PTH(1-34) (100 nM) stimulated ERK2 phosphorylation 4-6-fold after 10 min. This was blocked completely by the EGFR inhibitor, AG1478 (1 µM) but not by the Platelet Derived Growth Factor Receptor inhibitor, AG1295 (25 µM). One mechanism whereby a GPCR can transactivate the EGFR is by metalloprotease cleavage of membrane-bound HB-EGF, a potent EGFR ligand. We examined this mechanism by first activating the PTH1R in D1 cells and then applying the conditioned media to HEK293 cells, which do not express the PTH1R. Conditioned media from PTH(1-34)-treated D1 cells activated ERK1/2 3-4 fold in HEK293 cells. AG1478, when applied to HEK293 cells, completely inhibited transactivation of ERK1/2 by the conditioned media. PTH(1-34) (100nM), when applied directly to HEK293 cells, had no effect. This indicates that the conditioned media from the D1 cells contains a factor that activates ERK1/2 in HEK293 cells in an EGFR-dependent manner. HB-EGF (1 ng/ml) directly activated ERK1/2 in HEK293 cells. Pretreatment of the D1 cells with the matrix metalloprotease inhibitor GM-6001 (10 µM) abolished the transactivation of ERK1/2 by PTH in HEK293 cells. We, therefore, conclude that ERK1/2 activation in distal kidney cells by PTH(1-34) requires PTH1R activation of a metalloprotease that leads to cleavage of HB-EGF and transactivation of the EGFR.

The Role of the PTH Receptor C Terminus and Pertussis Toxin-Sensitive G Proteins on MAP Kinase Activation. Y. Yang*[1], W. B. Sneddon[1], B. Wang*[1], P. A. Friedman[2]. [1]Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [2]Depts. of Pharmacology and of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.

The Type 1 PTH receptor (PTH1R) activates multiple signaling pathways, including mitogen-activated protein kinase (MAPK, ERK), in a cell- and ligand-specific manner. In previous work we showed that PTH stimulated ERK1 and ERK2 (ERK1/2) in kidney distal tubule cells. Blockade of ERK1/2 inhibited PTH-stimulated calcium transport. In the present study we examine the role of pertussis toxin (PTX)-sensitive G proteins in ERK1/2 activation by PTH. ERK1/2 activation was measured by phosphospecific immunoblotting. Results were normalized to total ERK. In distal tubule kidney cells expressing 10^6 PTH receptors/cell (D1 cells), PTH(1-34) (100 nM) stimulated ERK2 phosphorylation 4-6-fold after 10 min. No consistent change of ERK1 was noted. ERK2 activation was blocked by overnight pre-treatment with PTX. A dominant negative minigene for $G\alpha_{i13}$ blocked both basal and PTH-stimulated ERK1/2 activation in D1 cells. We then characterized the role of the C terminus of the PTH1R in PTX-sensitive ERK1/2 activation by PTH. We used HEK293 for these studies because they do not express endogenous PTH1Rs. Cells were transiently transfected with either the wild type PTH1R (ETVM), a PTH1R where the C-terminal methionine was mutated to alanine (ETVA), or a PTH1R truncated at position 480 lacking most of the C terminus distal to transmembrane domain 7 (480stop). Transfections were optimized such that receptor expression was equivalent as determined by PTH1R immunoblotting. PTH(1-34) (100 nM) stimulated ERK1/2 by the ETVM, ETVA and 480-stop PTH1Rs 21-fold, 27-fold and 57-fold, respectively. Overnight pre-treatment with PTX inhibited PTH(1-34)-stimulated ERK1/2 by the ETVM and 480-stop PTH1Rs by 60%. In contrast, PTX abolished ERK1/2 activation by the ETVA PTH1R. The M-A mutation at the C terminus (a PDZ recognition motif) of the PTH1R abrogates the interaction between the PTH1R and the sodium proton exchanger regulatory factor (NHERF1). It is not known if NHERF plays a role in PTH1R activation of ERK1/2. These data suggest that mutation of the PDZ-interaction motif of the PTH1R may interfere with a NHERF-dependent pathway for ERK1/2 activation. Furthermore, the 2-fold increase in ERK1/2 stimulation by the truncated 480stop PTH1R over the wild type ETVM PTH1R suggests a modulatory role for the C terminus. We conclude from these experiments that there are multiple signaling pathways for PTH-stimulated ERK1/2 activation and that PTH1R-mediated stimulation of the PTX-sensitive G protein G_i is a key mediator of this process.

PTH/PTHrP Receptor Phosphorylation Regulates PTH Activation of ERK1/2 MAP Kinases and Gene Expression. H. A. Tawfeek*, A. B. Abou-Samra. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

PTH activates ERK1/2 MAP kinases in renal and osteoblastic cells. The regulatory mechanisms involved in PTH activation of ERK1/2 have not been elucidated. The goal of the current study was therefore to examine the role of PTH/PTHrP receptor phosphorylation in regulation of ERK1/2 response. The effects of PTH on ERK1/2 activation were examined in LLCPK-1 renal tubular cells stably expressing a wild type (WT-PPR cells) or a phosphorylation-deficient (PD-PPR cells) mutant PTH/PTHrP receptor. ERK1/2 activation was assessed by immuno-blot analysis, using anti-phospho-(active) ERK1/2 antibody. The data demonstrated that PTH activation of ERK1/2 in the PD-PPR cells was similar to that in the WT-PPR cells during early time points (0-40 min). In the WT-PPR cells treatment with PTH for longer time periods (60-120 min) resulted in down-regulation of ERK1/2 activation response; ERK1/2 activity returned to basal levels at 60 min and decreased below basal levels at 90-120 min. Interestingly, in contrast to the WT-PPR cells, the PD-PPR cells exhibited sustained activation of ERK1/2 in response to PTH treatment. ERK1/2 activity in the PD-PPR cells remained elevated over basal at 60-90 min and returned to basal levels at 120 min of PTH treatment. We further examined whether the effects of PTH on ERK1/2 activation in the PD-PPR cells modulate gene expression. Strikingly, PTH treatment caused higher expression of c-fos gene in the PD-PPR cells than in the WT-PPR. The effects of PTH on c-fos gene expression in the WT- and PD-PPR cells were attenuated by U0126, a specific ERK1/2 pathway inhibitor. It has been shown that ß-arrestin2 recruitment is involved in ERK1/2 nuclear translocation; the effects of PTH on ß-arrestin2 translocation were therefore examined in the WT- and PD-PPR cells stably expressing green fluorescent protein (GFP)-tagged ß-arrestin2. Compared to the WT-PPR cells, PTH treatment caused a weak ß-arrestin2 translocation in the PD-PPR cells. This finding suggests a possible role for ß-arrestin2 in the effects of PTH/PTHrP receptor phosphorylation on ERK1/2 regulation. Altogether, these data suggest that PTH/PTHrP receptor phosphorylation, via its regulatory role in PTH activation of ERK1/2 MAP kinases, influences gene expression.

The Use of Mixture-Based Combinatorial Libraries for the Development of Novel Calcitonin and/or Parathyroid Hormone Analogues. R. Houghten. Torrey Pines Institute for Molecular Studies, San Diego, CA, USA.

The approaches and concepts that encompass combinatorial chemistry represent a paradigm shift in drug discovery and basic research. Viewed initially as a curiosity by the pharmaceutical industry, combinatorial chemistry approaches are now recognized as essential drug discovery tools that decrease the time taken for discovery and increase the throughput of chemical screening by as much as 1000-fold. Although the use of mixture-based synthetic combinatorial libraries was one of the first approaches presented, its inherent strengths are only recently being recognized. Numerous mixture-based libraries of peptides, peptidomimetics and heterocycles have been synthesized and deconvoluted using the positional scanning approach. Mixture-based library approaches for drug discovery and vaccine development will be discussed. The results presented demonstrate that combinatorial mixture synthesis and screening can play a vital role in the discovery of new leads for a variety of targets, ranging from antimicrobial and to new calcitonin and/or parathyroid hormone analoges.

A Methionine Scan of Region [168-176] of the Parathyroid Hormone Receptor 1 - The "Magnet Effect". A. Wittelsberger[1], B. E. Thomas*[1], D. F. Mierke*[2], M. Rosenblatt[1]. [1]Department of Physiology, Tufts University School of Medicine, Boston, MA, USA, [2]Department of Chemistry and Molecular Pharmacology, Brown University, Providence, RI, USA.

Parathyroid hormone (PTH) 1-34 contains two α-helical domains associated with specific functions: the N-terminal helix is required for activation of its G protein-coupled receptor, and the C-terminal helix is mainly responsible for receptor binding. We recently focused on the role of the mid-domain of PTH. From photoaffinity-crosslinking studies, we found that a *p*-benzoylphenylalanine (Bpa) residue at either position 11 or 21 crosslinked to the same receptor region [165-176]. We now present a "methionine scan" of receptor region [168-176]. This region has amphipathic helical character (see Figure), and is expected to lie on top of the membrane [1]. The two ligands, [Bpa^{11}]-PTH and [Bpa^{21}]-PTH, were crosslinked to the mutant receptors [S168M]-, [E169M]-, [V171M]-, [K172M]-, [F173M]-, [L174M]-, and [N176M]PTHR1, transiently expressed on Cos-7 cells. The ligand-receptor conjugates were then isolated, digested with endoglycosidase F and cyanogen bromide, and analyzed by SDS-PAGE. A band similar in size to free ligand was obtained for the whole range of mutants when crosslinked to Bpa^{11}-PTH, and for [S168M]-up to mutant [L174M]PTHR1 when crosslinked to Bpa^{21}-PTH. Such a ligand fragment (ligand + CH_3SCN) is generated by crosslinking to the methyl group of methionine [2]. We conclude that the reactivity of Bpa towards methionine is significantly increased compared to other residues. We call this the "Magnet Effect" of methionine. Outside the above-mentioned range, i.e. with receptor mutant [V183M], we do not observe the characteristic band with either Bpa^{11}-PTH or Bpa^{21}-PTH. Hence, crosslinking contact points can be shifted by the presence of methionine in a receptor domain.

Optimizing Vitamin D Nutrition in Healthy Adults. M. R. Patel*, S. A. Talwar, J. F. Aloia, S. Pollack*, J. Yeh. Bone Mineral Research Center, Winthrop-University Hospital, Mineola, NY, USA.

Purpose: While there is emerging consensus that the optimal serum 25-hydroxyvitamin D (25-OHD) level is 80 nmol/L, the adequate daily intake of vitamin D_3 to achieve this level is unknown in a multiethnic population. Methods: We are reporting preliminary data on 16 black (8 active, 8 placebo) and 46 white (24 active, 22 placebo) subjects enrolled in an ongoing randomized placebo-controlled study of vitamin D_3 dosing in healthy subjects with suboptimal 25-OHD. Those with chronic medical conditions, morbid obesity, disorders of bone metabolism, or those taking medications known to interfere with bone or vitamin D metabolism were excluded. Subjects were randomized 1:1 to vitamin D_3 or placebo. The dose was based on initial 25-OHD level. For 25-OHD <50 nmol/L, subjects were given 100 µg/d, and for 25-OHD between 50-80 nmol/L, subjects were given 50 µg/d. Fasting urine and serum calcium were measured at each visit. 25-OHD was measured by RIA using the DiaSorin assay. Dietary intake of vitamin D and calcium were estimated using 3-day diet logs. We are reporting data after 8 weeks of supplementation. Results: There were no baseline differences between active and placebo subjects. Basal weight and BMI were significantly higher in blacks than whites. Vitamin D intake was similar in all groups. 7/8 blacks and 10/24 whites had basal 25-OHD <50 nmol/L and were started on 100µg/d of vitamin D_3. The remaining active subjects were started on 50µg/d. After 8 weeks of either 50 or 100µg of vitamin D_3 supplementation, the achieved serum 25-OHD level was 81.7 and 73.8 nmol/L for whites and blacks, respectively (See Table). 25-OHD did not change significantly from baseline for placebo subjects. 25% of blacks and 54% of whites achieved the optimal 25-OHD level. 6/8 active black subjects and 11/24 active white subjects require additional daily vitamin D_3 supplementation. Serum calcium and fasting urine Ca/Cr did not change significantly from baseline and was not different from placebo. No adverse events were reported. Conclusion: If the goal is to achieve 25-OHD >80 nmol/L for the majority of people, we would recommend >50µg/day for whites and >100µg/day for blacks during the winter. As seasonal influence on 25-OHD is less in blacks, they may require >100µg/day for most of the year. The dose-response to oral vitamin D_3 supplementation appears similar between blacks and whites.

Response to vitamin D3 supplementation

Parameter	Blacks Mean (SE) n=16	White Mean(SE) n=46	P value (blacks vs. whites)

Effect of Caffeine on Vitamin D Receptor Expression and Estrogen Receptor Transcriptional Responses in Osteoblast Cells. P. B. Rapuri[1], J. C. Gallagher[1], Z. Nawaz*[2]. [1]Bone Metabolism, Creighton University, Omaha, NE, USA, [2]Department of Biochemistry and Molecular Biology, University of Miami School of Medicine, Miami, FL, USA.

Of the various risk factors contributing to osteoporosis, dietary/lifestyle factors are important. In a clinical study we reported that women with caffeine intakes >300mg/d had higher bone loss and women with one particular variant (tt) of vitamin D receptor (VDR) are at a greater risk for this deleterious effect of caffeine. However, the mechanism of how caffeine effects bone metabolism is not clear. Both estrogen and 1,25-dihydroxy vitamin D_3 ($1,25(OH)_2D_3$) play a critical role in regulating bone metabolism. The receptors for both these hormones, VDR and estrogen receptor (both ERα and ERβ) have been demonstrated in osteoblasts and they belong to the same superfamily of nuclear hormone receptors. We hypothesized that caffeine may effect the ER and VDR expression, transcriptional activity and estrogen and $1,25(OH)_2D_3$ mediated actions in bone. We therefore examined the effect of different doses of caffeine (0.2, 0.5, 1.0 and 10 mM) on endogenous and $1,25(OH)_2D_3$ induced VDR protein expression in osteoblast-like cells, U2-OS. We also tested the effect of different doses of caffeine on ERα transcriptional responses in U2-OS cells. In U2-OS cells testing the effect of caffeine on VDR, caffeine treatment resulted in appearance of a higher molecular weight band (probably phosphorylated form of VDR) whose intensity increased with increasing dose of caffeine. In cells treated with 10 mM caffeine the higher molecular weight band was the only prominent band visible. Caffeine also dose dependently decreased the $1,25(OH)_2D_3$ induced VDR expression by about 50 to 70% at doses of 1 and 10 mM respectively. The effect of caffeine on ERα transcriptional responses was tested using transient transfection assays in U2-OS cells. U2-OS cells were transfected with ERα and ERE linked to luciferase reporter gene. Cells were treated with different doses of caffeine alone or different doses of caffeine + estradiol and luciferase activity was determined in cell lysates. Caffeine at highest dose tested decreased ERα basal transcriptional activity and dose dependently decreased the estrogen stimulated ERα transcriptional activity. At a dose of 10 mM caffeine, estrogen stimulated transcriptional activity of ERα was decreased by about 60% . Our results suggest that caffeine effects the endogenous and $1,25(OH)_2D_3$ stimulated VDR expression in osteoblast cells. We also demonstrated that caffeine effects the basal and estrogen stimulated ERα transactivation in osteoblast cells.

Effects of PTH and $1\alpha,25(OH)_2$-Vitamin D_3 on JNK and P38 MAPK in Rat Intestinal Cells. N. Buzzi*, V. Gonzalez Pardo*, R. Boland*, A. Russo de Boland*. Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina.

We have previously demonstrated that parathyroid hormone (PTH) and the steroid hormone $1\alpha,25(OH)_2$-vitamin D_3 [$1\alpha,25(OH)_2D_3$] activate the cytosolic tyrosine kinase c-Src in rat intestinal cells (enterocytes), which, in turn, participates in the phosphorylation and activation of the MAP kinases ERK1 and ERK2. In the present study we examined whether these hormones are able to stimulate other members of the MAP kinases family. Our results show that, $1\alpha,25(OH)_2D_3$ induces the phosphorylation and activation of p38 MAPK in rat enterocytes. This effect was time and dose-dependent, with maximal stimulation at 2 min (+3 fold) and 1 nM. Opposite to the steroid hormone, PTH decreases, within 15 to 30 min, the basal phosphorylation and activity of p38 MAPK. $1\alpha,25(OH)_2D_3$-dependent p38 phosphorylation was suppressed by SB 203580, a selective inhibitor of p38 MAPK. Ca^{2+} chelation with EGTA, inhibition of c-Src- family tyrosine kinase with PP1 or protein kinase A (PKA) inhibition with Rp-cAMP, attenuated hormone effects. Stimulation of rat enterocytes with $1\alpha25(OH)_2D_3$ (1 nM) or PTH (10 nM) also resulted in the phosphorylation and activation of c-jun N-terminal protein kinases (JNK 1/2). The effect of either hormone on JNK1/2 was transient, peaking at 1min (+200%) and 2 min (+300%) for $1\alpha25(OH)_2D_3$ and PTH, respectively. Incubation of enterocytes with $1\alpha25(OH)_2D_3$ was followed by a rapid induction of c-Fos expression (+1 fold, 5 min) which was blocked by SB 203580 and partially suppressed by the ERK1/2 inhibitor, PD 98059, while incubation

with PTH did not altered the levels of the oncoprotein. Collectively, these data suggest that PTH and 1α25(OH)$_2$D$_3$ differentially regulate p38 MAPK and JNK1/2 in rat intestinal cells and that p38 MAPK has a central role in 1α25(OH)$_2$D$_3$-induction of the oncoprotein c-Fos.

MAP KINASES p38 and JNK Are Activated by the Steroid Hormone 1α,25(OH)$_2$D$_3$ in the C2C12 Muscle Cell Line. C. Buitrago*, A. C. Ronda*, A. Russo de Boland*, R. Boland*. Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina.

In chick skeletal muscle cell primary cultures we previously demostrated that 1α,25(OH)$_2$-vitamin D$_3$ [1α,25(OH)$_2$D$_3$], the hormonally active form of vitamin D, increases the phosphorylation and activity of the extracellular signal-regulated mitogen-activated protein (MAP) kinase isoforms ERK1 and ERK2, their subsequent translocation to the nucleus and involvement in DNA synthesis stimulation. In this study we show that other members of the MAP kinase superfamily are also activated by the hormone. Using the muscle cell line C2C12 we found that 1α,25(OH)$_2$D$_3$ within 1 min phosphorylates and increases the activity of p38 MAPK. The immediately upstream kinases MKK3/MKK6 were also phosphorylated by the hormone suggesting their participation in p38 activation. 1α,25(OH)$_2$D$_3$ was able to dephosphorylate/activate the ubiquitous cytosolic tyrosine kinase c-Src in C2C12 cells and studies with specific inhibitors imply that Src participates in hormone induced-p38 activation. Of relevance, 1α,25(OH)$_2$D$_3$ induced in the C2C12 line the stimulation of MAPKAP-kinase 2 and subsequent phosphorylation of HSP27 in a p38 kinase activation-dependent manner. Treatment with the p38 inhibitor, SB203580, blocked p38 phosphorylation caused by the hormone and inhibit the phosphorylation of its downstrean substrates. 1α,25(OH)$_2$D$_3$ also promotes the phosphorylation of c-jun N-terminal protein kinases (JNK 1/2), the response is fast (0.5-1 min.) and maximal phosphorylation of the enzyme is observed at physiological doses of 1α,25(OH)$_2$D$_3$ (1 nM). The relative contribution of ERK-1/2, p38 and JNK-1/2 and their interrelationships in hormonal regulation of muscle cell proliferation and differentiation remain to be established.

Influence of 1αOH Vitamin D$_2$ on Insulin and PPARγ Mediated Glucose Transport. N. Fleming*[1], C. Corley- Mastick*[1], R. S. Fredericks[2]. [1]Biochemistry, University of Nevada Reno, Reno, NV, USA, [2]Endocrine Associates, Reno, NV, USA.

Glucose transport and its subsequent processing within 3T3L-1 adipocytes provides insight to fundamental processes of cellular signaling. We are particularly interested in the effects of 1αD$_2$ as differentiated from 1-25 αD$_3$ as interactants with insulin stimulated and PPARγ driven processing. It is possible that 1αD$_2$ has intracellular signaling capabilities mediated non-genomically. We have observed that 2-deoxyglucose uptake mediated by insulin can be suppressed by either 1αD$_2$ or 1-25 D$_3$ in a dose dependent manner. These effects are reversed by rosiglitazone, a PPARγ agonist, and are associated with accelerated triglyceride production. The effect of 1αD$_2$ in the absence of insulin or rosiglitazone reveals a u-shaped response suggesting a reversal mechanism mediated by the induction of 24-hydroxylase consistent with known effects of a membrane receptor as a mediator of direct actions of 1αD$_2$. The data supports an integrated model which includes the scaffolding protein MNAR as the modulator for insulin induced glucose uptake under the influence of both 1αD$_2$ and 1-25 D$_3$ providing a drive for selection of 1 hydroxylation as a down stream signal of glucose oxidation independent of 25 hydroxylation. Both membrane and nuclear actions are mediated through the VDR, with those of 1αD$_2$ restricted to MNAR. 25 hydroxylation has evolved as an effect which is downstream of PPARγ to provide nuclear selective action of 1αhydroxylated Vitamin D. Subsequent influences of both membrane and nuclear activity on energy partitioning should be applicable to explanation of Vitamin D influence on cell behavior including cell differentiation, immune regulation, phosphate transport via MARRS, and the endocrine role of 1-25 D$_3$ as a systemic signal.

Identification and Characterization of Vitamin D Response Elements in Human and Mouse Epithelial Calcium Channel-2 Genes. J. Lu*[1], K. R. Stayrook*[1], X. Bu*[1], B. Khalifa*[1], T. Wei*[1], C. A. Frolik[1], T. P. Burris*[1], Z. Zhang*[2], J. C. Fleet*[2], S. Nagpal*[1]. [1]Lilly Research Laboratories, Eli Lilly & Company, Indianapolis, IN, USA, [2]Dept. of Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

1,25-dihydroxyvitamin D3 [1,25-(OH)$_2$D$_3$] plays a pivotal role in calcium homeostasis and bone mineralization by facilitating intestinal calcium absorption. 1,25-(OH)$_2$D$_3$ increases calcium absorption from gut by inducing the duodenal expression of epithelial calcium channel-2 (ECaC2). Here, we describe the molecular mechanism involved in 1,25-(OH)$_2$D$_3$-mediated regulation of ECaC2 expression, and identify functional vitamin D response elements (VDREs) in the promoter regions of human and mouse ECaC2 genes. We show that VDR and retinoid X receptor (RXR) heterodimers bind *in vitro* to these VDRE sequences. In transactivation assays, human and mouse ECaC2 VDREs when coupled to a heterologous minimum promoter, exhibited 1,25-(OH)$_2$D$_3$-dependent transcriptional activation. Further, chromatin immunoprecipitation assays demonstrate 1,25-(OH)$_2$D$_3$-dependent recruitment of RXR-VDR heterodimers to the human ECaC2 VDRE in intestinal cells. We also demonstrate that the rat ECaC2 gene does not contain any putative VDREs in the 5kb upstream region and its expression is also not induced by the VDR ligand in a rat duodenal cell line that shows 1,25-(OH)$_2$D$_3$-dependent induction of other vitamin D-responsive genes including calbindin-9k. Finally, *in vivo* 1,25-(OH)$_2$D$_3$ was less efficacious in rat in inducing the expression ECaC2 than mouse duodenum, indicating species context-dependent regulation of ECaC2 expression by vitamin D.

Gender- and Tissue-Specific Effects of 1,25-Dihydroxyvitamin D and EB1089 in Intestine and Bone of Mature Rats. S. Karmakar*[1], R. Narayanan*[1], D. S. Perrien*[2], L. J. Suva[2], N. L. Weigel[1], C. L. Smith[1]. [1]Molecular & Cellular Biology, Baylor College of Medicine, Houston, TX, USA, [2]Orthopaedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Use of the natural vitamin D receptor (VDR) ligand, 1,25-dihydroxyvitamin D (1,25-D) as a bone protective agent is restricted by hypercalcemia, prompting the development of vitamin D analogs such as EB1089 that are less calcemic than 1,25-D. In our previous studies of male rats, 1,25-D more effectively attenuated disuse-induced osteoporosis than EB1089. Conversely, studies in female rats demonstrated that the same dosage of EB1089 prevented disuse-induced osteoporosis, while 1,25-D was ineffective. Based on these previous results, a direct comparison of the effects of EB1089 and 1,25-D on male and virgin female Sprague-Dawley rats was initiated. Animals were obtained at 4 months of age, and fed a diet containing 1% calcium, 0.5% phosphorus and 1000 IU/kg vitamin D for two months prior to study initiation. At 6-months of age, male and female rats were each divided into groups (n=8), that received either vehicle (80% polypropylene/20% 0.05 M sodium phosphate), 0.03 μg/day/kg BW 1,25-D or 0.3 μg/day/kg BW EB1089 (Leo Pharmaceuticals) via Alzet mini-osmotic pump. Serum calcium measurements at the experiment conclusion confirmed that neither 1,25-D or EB1089 induced hypercalcemia in male or female rats. After 28 d of treatment, animals were euthanized, and the left proximal tibia excised for *ex vivo* evaluation by micro-computed tomography (μCT). A 33% increase in bone volume/total volume ($p<0.05$) was observed in EB1089 female rats in comparison to vehicle controls, and a corresponding 18% decrease in bone surface/bone volume ($p<0.05$) indicated a positive response, consistent with the 62% decrease in the structure model index signifying increased mechanical strength. No significant changes in μCT values for 1,25-D-treated females were found, nor were differences observed for either treatment group of male rats. Both VDR agonists induced comparable expression of the VDR target genes, 1α-hydroxylase and 24-hydroxylase in the kidneys of male and female rats. However, significant decreases of PTH levels were observed only in EB1089 treated females (71%, $p<0.05$) and 1,25-D treated males (50%, $p<0.05$). Expression of the calbindin D$_{9k}$ calcium transporter was significantly increased in the duodenum of EB1089, but not 1,25-D treated females, while the converse was observed for male rats. The ability of EB1089 to increase calbindin D$_{9K}$ and suppress PTH levels in female but not male rats suggests that enhanced calcium transport in the female intestine may contribute to the improved efficacy of EB1089 in the female *versus* male skeleton.

Plasma 24,25-Dihydroxyvitamin D and Urinary 25-Hydroxyvitamin D Binding Activity of Black and White Female Adolescents. M. Thierry-Palmer[1], V. Henderson*[1], R. El Hammali*[1], S. Cephas*[1], C. Palacios*[2], B. R. Martin[2], C. M. Weaver[2]. [1]Biochemistry, Morehouse School of Medicine, Atlanta, GA, USA, [2]Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

African Americans have been demonstrated to have significantly lower mean plasma 25-hydroxyvitamin D (25-OHD) concentrations, compared with Caucasian Americans in reports based on the Third National Health and Nutrition Examination Survey. We tested the hypothesis that plasma 24,25-dihydroxyvitamin D (24,25-(OH)$_2$D) concentrations would be lower in black female adolescents than in white female adolescents, because of greater sensitivity of the vitamin D endocrine system of black adolescents to salt. Plasma 24, 25(OH)$_2$D concentration, urinary vitamin D metabolite content, and urinary 25-OHD

binding activity were determined for 11 black and 10 white female adolescents (11-15 years old), who were participants in a dietary study that involved three-week low salt (1.3 g, 56 mmol/24 hr sodium) and three-week high salt (3.86 g, 168 mmol/24 hr sodium) intake in a randomized, crossover design. Plasma 24,25-$(OH)_2$D concentrations of the white female adolescents were significantly higher than that of the black female adolescents ($P < 0.001$). Plasma 24,25-$(OH)_2$D concentrations of five black adolescents (45%) and three white adolescents (33%) at week 3 of high salt intake were approximately half the values at week 3 of low salt intake. Urinary 25-OHD binding activities of these "responders" were approximately doubled at week 3 of high salt intake. Urinary 25-OHD binding activities of the black adolescents, but not the white adolescents, were directly correlated with urinary sodium ($r = 0.57$, $P = 0.009$, $n = 10$). Urinary 25-OHD binding activities of the adolescents were variable (0 - 1.8 nmol/h), and the means did not significantly differ between black and white adolescents. White adolescents had higher mean urinary vitamin D metabolite content than black adolescents at week 2 ($P < 0.05$), perhaps because of higher vitamin D metabolite concentrations in plasma. We conclude that lower plasma 24,25-$(OH)_2$D concentrations of the black female adolescents, compared with the white female adolescents, can not be explained by difference in urinary loss of vitamin D metabolites.

A Role for Substrate 25-hydroxyvitamin D in Post-Translational Targeting of the Vitamin D 24-Hydroxylase to Mitochondria. S. Ren, L. Nguyen*, J. S. Adams. The Burns and Allen Research Institute and Division of Endocrinology, Cedars-Sinai Medical Center and David Geffen School of Medicine at UCLA, Los Angeles, CA, USA.

The vitamin D-24-hydroxylase (CYP24) gene product requires post-translational transport to the inner mitochondrial membrane in order to access key co-factors and achieve functional capacity. Like most mitochondrial proteins encoded by nuclear genes, mitochondrial import of CYP24 gene product is directed by an N-terminal, mitochondrial targeting sequence. We have previously shown (J Biol Chem, Papers in Press, March 23, 2005, M414522200) that naturally occurring splice-variants of the CYP24 will encode substrate binding isoforms of the 24-hydroxylase that lack mitochondrial import potential and hence catalytic capability. On the other hand, factors other than the presence of an N-terminal targeting sequence, which promotes mitochondrial importation of the vitamin D hydroxylases, are not well understood. Here we investigated the potential for 24-hydroxylase substrates 25-hydroxyvitamin D (25-D) and 1, 25-dihydroxyvitamin D (1, 25-D) to alter the distribution of the 24-hydroxylase between the cytoplasmic and mitochondrial compartments of the cell. Chick myelomonocytic HD-11 cells were pre-incubated without (vehicle alone) or with 200 nM 1, 25-D and/or 25-D before obtaining whole cell or mitochondrial protein extracts for Western blot analysis and total cellular RNA for quantitation of CYP24 gene expression. Western blots were probed with anti-chick 24-hydroxylase and anti-grp75 antibody; grp75 is a resident mitochondrial chaperone protein and used here to control the loading of mitochondrial extract. CYP24 gene expression increased > 10-fold ($p< 0.01$) and 24-hydroxylase protein level increased to 2.3-fold ($p< 0.05$) in whole cell extracts of 1, 25-D-treated compared to vehicle-treated HD-11 cells. However, there was no increase in the mitochondrial content of 24-hydroxylase after exposure to 1, 25-D alone. When the HD-11 cells were pretreated with 1, 25-D to induce CYP24 gene expression and then exposed to substrate 25-D or vehicle for 3 hr, whole cell 24-hydroxylase levels remained constant, but 24-hydroxylase protein was significantly ($p< 0.01$) redistributed to mitochondria. Redistribution of the 24-hydroxylase to the mitochondrial compartment could be detected as early as 30 min after exposure of the cell to substrate 25-D. These data suggest that extra-mitochondrial interaction of the 24-hydroxylase with substrate 25-D, but not 1, 25-D, facilitates mitochondrial importation of the CYP24 gene product and the subsequent synthesis of 24, 25-dihydroxyvitamin D.

Substrate-Mediated Mitochondrial Localization of the 25-Hydroxyvitamin D-1-Hydroxylase. S. Wu, L. Nguyen*, J. S. Adams. Burns and Allen Research Institute and the Division of Endocrinology, Cedars-Sinai Medical Center, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA.

The CYP27B1 gene product is responsible for the synthesis of the active vitamin D metabolite, 1,25-dihydroxyvitamin D (1,25-D; calcitriol) from substrate 25-hydryoxyvitamin D (25-D; calcidiol). Synthetic activity of this cytochrome P_{450}-mono-oxygenase requires its transfer from the cytoplasm to the inner mitochondrial membrane, the site of residence of crucial enzyme co-factors. This translocation process for the 1-hydroxylase is facilitated, in part, by the presence of an N-terminal mitochondrial targeting sequence encoded by the first exon of the CYP27B1 gene. We have previously reported (J Bone Miner Res, 19:S202, 2004) that overexpression of an N-terminally-truncated 1-hydroxylase, devoid of its mitochondrial localization signal, significantly decreased 1,25-D synthesis in CYP27B1-expressing HKC-8 human kidney cells. These results suggested that the N-terminally-truncated 1-hydroxylase served as a dominant-negative inhibitor of hormone synthesis by competitively binding substrate 25-D in the cell cytoplasm. These data also suggested that the interaction of enzyme and substrate might 1] occur extramitochondrially and 2] modulate synthesis of product 1,25-D by controlling the transfer of the 1-hydroxylase from cytoplasm to mitochondria. CYP271B specific primers and anti-1-hydroxylase antibody were used to quantitate CYP271B mRNA and mitochondrial 1-hydroxylase content by RT-PCR and Western blot analysis, respectively, in human HKC-8 and mouse TCMK-1 kidney cells before and after exposure to 0.2 to 200 nM 25-D substrate. Incubation with 25-D led to a significant dose- and time-dependent increase in the mitochondrial content of 1-hydroxylase protein without a change in CYP27B1 transcript expression in these cells; 120 minutes post 25-D exposure, mitochondrial enzyme content was increased 5-fold above basal levels ($p<0.001$). Mitochondrial localization of the 1-hydroxylase was blocked and cytoplasmic 25-D content increased significantly ($p<0.02$) by stable overexpression of an exon-1-deficient construct, explaining the previously-observed dominant-negative action of this N-terminally-truncated 1-hydroxylase. We conclude that mitochondrial localization and subsequent enzymatic synthesis of 1,25-D can be promoted by interaction of the 1-hydroxylase with substrate 25-D in the cell cytoplasm; events that can be blocked by altering the N-terminal targeting sequence of the 1-hydroxylase.

Age-Related Changes of the Expression Level of CYP2R1 in Growing Male Mice. M. Kamao*[1], M. Shimomukai*[1], N. Kubodera[2], T. Okano[1]. [1]Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [2]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Purpose: Vitamin D must be hydroxylated at C-25 and C-1α positions before acquiring its full activity. It has been reported that at least six cytochrome P450 (CYP), namely CYP2C11, CYP2D25, CYP2R1, CYP2J3, CYP3A4 and CYP27A1 are involved in the C-25 hydroxylation step of vitamin D. Although, mitochondrial CYP27A1 used to be regarded as a physiologically important C-25 hydroxylase, CYP2R1 is thought to play a substantial role due to the absence of sex and species differences and catalytic ability toward both vitamin D_2 and D_3. However, the basic properties of CYP2R1 including age-related changes of expression level have not been fully characterized. In the present study, we examined and compared the changes of CYP2R1 mRNA expression with those of the other metabolic enzymes of vitamin D, CYP27A1, CYP27B1 (C-1α hydroxylase) and CYP24 (C-24 hydroxylase) in growing mice. Materials and Methods: Male C57BL/6 mice were fed regular rodent chow. The liver, kidney and testis were taken from mice aged 0, 2, 3 and 7 weeks old. The mRNA levels of CYP2R1, CYP27A1, CYP27B1 and CYP24 were measured by real time RT-PCR. Results: The mRNA expression levels of both CYP2R1 and CYP27A1 in the liver increased until 7 weeks after birth. The plasma levels of 25-hydroxyvitamin D were gradually increased from 3 to 7 weeks after birth in association with the mRNA levels of CYP2R1 and CYP27A1. On the other hand, there was no change in the mRNA levels of both CYP27B1 and CYP24 in the kidney from 3 to 7 weeks old. The expression of CYP2R1 mRNA was similar to or even higher in the testis than in the liver and increased until 7 weeks after birth. Conclusion: These results suggest that CYP2R1 as well as an already-known enzyme, CYP27A1 might be a nutritionally-important vitamin D C-25 hydroxylase for the regulation of calcium metabolism in growing mice. Moreover, CYP2R1 in the testis is likely to play a role in maturation of male mice.

Parathyroid Hormone and Calcitonin Increase Protein Levels of the Renal Vitamin D 1alpha-Hydroxylase Cytochrome P450 (CYP27B1) in Renal Tubular Cells. H. J. Armbrecht, M. A. Boltz*. Geriatric Center (11G-JB), St. Louis VA Medical Center, Saint Louis, MO, USA.

Previous studies have shown that a number of factors regulate CYP27B1 mRNA levels in renal tubular cells, but there have been few studies on the regulation of CYP27B1 protein. We have developed and characterized a polyclonal antibody against a C-terminal synthetic peptide that recognizes both mouse and pig CYP27B1 protein on Western blots. To study the regulation of the protein, we have used the AOK-B50 renal cell line. This is the porcine proximal tubule LLC-PK1 cell line stably transfected with opossum PTH receptors. PTH treatment resulted in a large increase in a single band of 53,000 molecular weight, as evidenced by Western blotting. This band disappeared when the antisera was pre-absorbed with synthetic peptide. PTH (100 nm) rapidly increased CYP27B1 protein levels 3-4 fold by 6 hours with a peak at 24 hours and levels still elevated at 48 hours. On the other hand, PTH treatment resulted in only a transient increase in CYP27B1 mRNA levels that peaked at 4 hours and was largely gone by 24 hours. In dose response studies, PTH increased CYP27B1 protein levels at concentrations as low as 1 nM. By using cycloheximide to block translation, the half life of the CYP27B1 protein was estimated to be 6 hours. CT (100 nM) treatment for 6 hours increased CYP27B1 protein to levels comparable to those seen with PTH. With regard to mechanisms, CYP27B1 protein levels were markedly stimulated by forskolin and 8-bromo-cAMP but not by phorbol esters. This suggests that the action of PTH and CT may be via a cAMP-mediated pathway. Preincubation with 1,25(OH)2D (100 nM) for 16 hours did not decrease the stimulatory effect of PTH on CYP27B1 protein. These studies demonstrate that in this cell line PTH produces a transient increase in CYP27B1 mRNA followed by a sustained increase in CYP27B1 protein via a cAMP-mediated pathway. Since the CYP27B1 protein normally has a short half life, the factors responsible for this sustained increase remain to be elucidated.

Elevated Expression of the Vitamin D Nuclear Receptor and of the 25-Hydroxyvitamin D 1a-Hydroxylase in Colorectral Hepatic Metatases. C. Demers*[1], P. M. Huet*[1], J. Bolduc*[1], M. Bilodeau*[1], D. Ménard*[2], R. Lapointe*[3], A. Roy*[3], R. Létourneau*[3], M. Gascon-Barré[1]. [1]Centre de recherche, Hôpital St-Luc, CHUM, Montreal, PQ, Canada, [2]Anatomie et Biologie cellulaire, Université de Sherbrooke, Sherbrooke, PQ, Canada, [3]Chirurgie, Hôpital St-Luc, CHUM, Montreal, PQ, Canada.

Colorectal carcinoma are among the most common causes of cancer death while vitamin D (D) and its hormone $1,25(OH)_2D$ have been shown to decrease tumour growth and prolong survival. To exert its bioactivity, D must be captured by tumour cells containing the D activating enzymes and express the $1,25(OH)_2D$ receptor (VDR_n). While fairly differentiated primary colon cancer cells express both the VDR_n and D-1 α-hydroxylase, no report has yet identified their presence in extracolonic metastases. The study aimed at investigating whether colorectal hepatic metastases process the cellular effectors necessary to respond to D. **Methods:** The study was carried out in 19 subjects bearing colorectal hepatic metastases who underwent liver resection. Samples of tumoral and adjacent normal livers were evaluated for the presence of the VDR_n, the D 1α-(CYP27B1) and 25-(CYP27A1) hydroxylases. Normal adult kidneys, foetal intestines and hepatic tumours of non-colorectal origin were used as controls. **Results:** Compared to adjacent normal liver tissue, VDR_n mRNA and protein levels were markedly increased in colorectal hepatic metastases (14 and 10 fold respectively compared to normal liver tissue) and comparable to that of normal human kidneys. Similarly, CYP27B1 was significantly increased in hepatic colorectal hepatic metastases (4 and 2 fold for mRNA and protein respectively) with expression levels comparable to that of the normal human foetal intestine. In contrast, hepatic lesions of other origin expressed both VDR_n and CYP27B1 at a level comparable to normal liver tissue. CYP27A1 was also found in colorectal hepatic metastases albeit at levels lower than in the normal liver but at levels similar to that of the normal kidney or of hepatic non-colorectal tumour specimens. **Interpretation:** The study illustrates that colorectal hepatic metastases possess the enzyme machinery necessary for D anabolism and express VDR_n indicating that they stand to respond to D or the hormone $1,25(OH)_2D$. These observations thus suggest that the maintenance of an optimal D status may be an important preventive factor following resection of malignant colorectal tumours. They also provide a rationale for the use of $1,25(OH)_2D$ or its analogs as adjuvant therapy for non-resectable colorectal hepatic metastases.

Tandem Construct and Recombinant Stable Expression of Vitamin D C-1alpha (CYP27B1) and C-24 (CYP24) Hydroxylase Fusion Products with Their Cofactors Adrenodoxin and Adrenodoxin Reductase. E. Kim*, R. Oyesanya*, C. Wong*, C. Chakarun*, M. J. Beckman*. Biochemistry, Virginia Commonwealth University, Richmond, VA, USA.

The 25- hydroxyvitamin D 1 α-hydroxylase (CYP27B1) and the 25- hydroxyvitamin D_3-24-hydroxylase (CYP24), are enzymes that regulate, activity and catabolism of 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$), respectively. Both enzymes require adrenodoxin (AdX) and adrenodoxin reductase (AR), generic electron transport proteins for all mitochondrial forms of cytochrome P450, for enzyme activity. In the this study, a recombinant DNA assembly of CYP27B1 fused with AR and AdX in tandem and CYP24 fused with AR and AdX in tandem were engineered. Each tandem construct was cloned into the pIZT insect cell vector bearing zeocin resistance. The resulting pIZT-1α-AR-AdX and pIZT-24-AR-AdX constructs were transfected in the presence of insectin plus into *Spodoptera frugiperda* (*Sf-9* insect cells). To isolate stable lines, monolayers of *Sf-9* cells were grown for 24 h and washed with PBS before treatment with zeocin (500 μg/ml) in serum-free insect cell medium. Individual colonies, obtained at 3-4 weeks were expanded in a 6-well plate in the zeocin selection medium. *Sf-9* cells with stable P450 activity and product formation were confirmed by growth of cells in the presence of iron (Fe) via IronMax 100 (IM-100) containing media and conversion of [^{3}H]-25-OH-D_3 to 1α- and 24-hydroxylated side-chain products. Previously, cholesterol side-chain cleavage enzyme (P450scc) and vitamin D 25-hydroxylase (CYP 27) have successfully been fused with AR and AdX and shown to be fully functional in transfection experiments. Therefore, these recombinant plasmids were made in order to establish new stable transfectant P450 systems for study in insect cells. These new systems will provide novel *in vitro* models to allow further detailed investigation of the function of the enzymes as well as the metabolism of vitamin D and its analogs.

Isolation and Identification of 3-epi Vitamin D3: A Novel Metabolite of Vitamin D3. G. Wang*[1], G. T. Palmore*[1], C. Ceailles*[2], P. Vouros*[2], R. Ray*[3], R. Horst[4], G. S. Reddy[5]. [1]Engineering, Brown University, Providence, RI, USA, [2]Chemistry, Northeastern University, Boston, MA, USA, [3]Boston University, Boston, MA, USA, [4]National Animal Disease Center, Ames, IA, USA, [5]Chemistry, Brown University, Providence, RI, USA.

Since our original demonstration of the metabolism of $1,25(OH)_2D_3$ into $1,25(OH)_2$-3-epi-D_3 in human keratinocytes, there have been several reports indicating that epimerization of the 3 hydroxyl group of vitamin D compounds is a common metabolic process. Recent studies reported the metabolism of $25OHD_3$ and 24, $25(OH)_2D_3$ into their respective C-3 epimers, indicating that the presence of 1 hydroxyl group is not necessary for the 3-epimerization of vitamin D compounds. In our most recent study, we also reported the metabolism of $1OHD_3$, a non 25-hydroxylated vitamin D_3 compound into its 3 epimer. From these studies, it became obvious that the presence of neither 1 hydroxyl group nor 25 hydroxyl group is required for C-3-epimerization of vitamin D coumpounds, and that vitamin D_3 itself can be 3 epimerized. To provide direct proof of the metabolism of vitamin D_3 into its C-3 epimer we studied the metabolism of vitamin D_3 in the human hepatocellular carcinoma (Hep G2) cell line, which is known to express the C-3 epimerization pathway. We noted the conversion of vitamin D_3 into a new metabolite, the identity of which was established to be 3 epi vitamin D_3 by its comigration with synthetic 3-epi vitamin D_3 standard in two different HPLC systems and GC/MS analysis. Furthermore, we also isolated 3 epi vitamin D_3 from the serum of vitamin D_3 intoxicated rats. Thus for the first time we show that vitamin D_3 itself can be metabolized into its C-3 epimer both *in vitro* and *in vivo*.

Importance Of Ruling Out Osteoid Osteoma In Hip Pain Syndrome. R. Mastaglia*[1], G. Aguilar*[2], B. Oliveri*[1]. [1]Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Servicio de Diagnóstico por Imágenes, Universidad de Buenos Aires, Buenos Aires, Argentina.

Hip pain is a frequent presenting complaint in the clinical practice. Osteoid osteoma must be considered a likely diagnosis in young patients presenting chronic unspecific pain in this area. A 29 year -old Caucasian man was seen in the clinic offices due to pain in the right groin. Onset of pain was two years prior to consultation, and it increased with exercise. The patient had interrupted his usual sports practice (Rugby) due to progressively increasing pain. He had not traveled or been exposed to infectious disease. He had no antecedents of fever, trauma, or other musculoskeletal pain. The pain was dull and aching, was not associated with any specific activity or time of day, and decreased with anti-inflammatory drugs (AINES). On physical examination, he appeared to be a healthy man. He reported tenderness in the groin and right upper thigh but no palpable mass or inguinal lymphadenopathy was found. Abduction and internal and external rotation of the right hip caused slight pain. A traumatologist who evaluated the patient two years previously indicated magnetic resonance imaging (MRI) of the right leg. Sequence T2 -weighting showed bone edema in the right femoral neck characterised by hyperintense signal in cancellous bone, without alteration in the femoral head. Diagnosis at the time was "transient osteoporosis". Avascular necrosis of the hip was ruled out. Further MRI studies were performed for follow-up. The second MRI showed persistence of cancellous bone edema without alteration in the femoral head despite time. Routine and mineral laboratory, bone densitometry and spine X-rays were normal. Pelvic radiography revealed slight bone sclerosis with thickening of the medial cortex at the level of the right femoral neck. The Computed Tomography scan revealed a lucent lesion (nidus) in close contact with the medial cortex of the femoral neck, which presents reactive sclerosis and thickening. "Osteoid osteoma " was diagnosed. Choice therapy is complete excision of the nidus. Osteoid osteoma is one of the most frequent and characteristic bone tumor lesions. The typical symptom is permanent pain, and symptom severity increases peaking at night. In the case of our patient, clinical presentation was not typical and diagnosis was possible because the physician strongly suspected it to be osteoid osteoma. Thus, image diagnosis studies other than x-rays must be performed, allowing correct diagnosis of "Osteoid osteoma" in a young person presenting bone pain.

VITAMIN D WORKING GROUP

WG1

Fgf-23 and Vitamin D Interactions In Vivo. D. Sitara[1], R. St-Arnaud[2], R. G. Erben[3], M. S. Razzaque*[1], B. Lanske[1]. [1]Oral & Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, [2]Genetics Unit, Shriners Hospital, Montreal, PQ, Canada, [3]Dept. of Natural Sciences, University of Veterinary Medicine, Vienna, Austria.

FGF-23 has been identified as the circulating phosphaturic factor associated with renal phosphate wasting leading to rickets and osteomalacia, as found in patients with autosomal dominant hyposphophatemic rickets, oncogenic osteomalacia, and X-linked hyposphosphatemia. We recently reported the generation of Fgf-23 null animals resulting in a phenotype including growth retardation, severe hyperphosphatemia, increased serum ALP activity and 1,25(OH)2D3 concentrations, abnormal bone mineralization, and tissue calcifications. A similar phenotype has been reported in patients with familial tumor calcinosis, caused by inactivating mutations in the FGF-23 gene. In the current study we studied the expression of Fgf-23 postnatally by lacZ staining of various adult tissues of Hyp/Fgf-23+/- and Hyp/Fgf-23-/- mice, and were able to detect strong signals in all bones. We also investigated whether part of the abnormal Fgf-23 null phenotype is due to the increased 1,25(OH)2D3 levels. Thus, we established a new mouse model in which we eliminated vitamin D dependent mechanisms in Fgf-23 null mice by generating double mutant animals which were deficient for both Fgf-23 and 1α (OH)ase, the enzyme that converts the inactive form of vitamin D to the active form. Our data demonstrate for the first time that deleting the 1α hydroxylase gene from Fgf-23 null mice reverses the severe hypersphosphatemia to hyposphosphatemia, suggesting that regulation of phosphate homeostasis by Fgf-23 is at least partly vitamin D-dependent. In addition to the biochemical measurements, we performed routine histological analysis and analyzed the mineralization pattern of the long bones of Fgf-23-/-, 1α (OH)ase-/-, and Fgf-23-/-/1α (OH)ase-/- double mutant animals, by von Kossa staining on methylmetacrylate sections and Alizarin Red S staining on full body skeletons. Our findings suggest that Fgf-23-/-/1α (OH)ase-/- double mutant mice resemble the phenotype of 1α (OH)ase-/- single knock-out animals as they exhibit ricketic appearance such as a wider growth plate with an expansion of hypertrophic chondrocytes, and a decrease in mineral deposition. Alizarin staining of all compound mutant skeletal elements clearly illustrated that the abnormal nodule formation previously observed in many Fgf-23 null bones had completely disappeared indicating that 1,25(OH)2D3 must have caused these features. We are currently measuring proliferation and apoptosis rates and are evaluating the expression of skeletal marker genes by in situ hybridization.

WG2

1,25(OH)2D3 Induces Rapid Response in Growth Plate Chondrocytes and Osteoblasts through Its Membrane-Associated Binding Protein, ERp60. L. Wang, R. A. Chaudhri*, K. L. Wong*, Z. Schwartz, B. D. Boyan. Georgia Institute of Technology, Atlanta, GA, USA.

Steroid hormones act via traditional nuclear receptor mechanisms, as well as rapid non-genomic pathways by activating membrane associated protein kinases. 1,25-dihydroxyvitamin D3 [1,25] activates the PKCα signaling pathway in prehypertrophic and upper hypertrophic zone (growth zone) growth plate chondrocytes via activation of phospholipase A2 (PLA2), cyclooxygenase-1 (Cox) and PLC. Factors that upregulate responsiveness to 1,25 in growth plate chondrocytes increase expression of PLA2 activating protein (PLAA), suggesting that it links ERp60 to PLA2. Antibodies to the N-terminal amino acid sequence of ERp60 (Ab100), a 1,25 binding protein present in chondrocyte and osteoblast plasma membranes, block the signaling cascade. Growth zone chondrocytes from VDR-/- mice also respond to 1,25 with a rapid increase in PKC via the same PLC-dependent mechanism. To better understand the role of ERp60, we examined its tissue distribution in the tibial growth plate of VDR-/- mice using immunohistochemistry and compared this to PLAA; we determined its subcellular localization and relationship to the caveolar scaffolding protein caveolin-1 and to the nVDR by confocal microscopy of rat growth zone cells; we assessed the relative contributions of the N and C terminals to the overall mechanism; and we examined response to 1,25 in osteoblast-like ROS 17/2.8 cells (stable) after silencing ERp60 expression with siRNA. Immunohistochemistry using Ab100 showed that ERp60 and PLAA were limited to the prehypertrophic and upper hypertrophic cell zones of the growth plate and to the metaphyseal osteoblasts, both of which are responsive to 1,25. Immunostain was absent from the resting zone, which lacks a rapid PKC response. ERp60 and caveolin-1 were present in the plasma membrane whereas the nVDR was primarily in the nuclei of growth zone cells. Ab100 and Ab101 (generated to the C-terminus of ERp60) both blocked PLC and PKC activation and downstream biological responses, suggesting that both termini are involved in the mechanism. Compared to scrambled siRNA treated cells, Erp60 siRNA significantly decreased the effect of 1,25 on PKC activity in ROS 17/2.8 cells. Additional studies showed that activation of PKC in ROS 17/2.8 cells was via PLC and Cox. In conclusion, 1,25 binding protein ERp60 and PLAA are present in 1,25-responsive chondrocytes and osteoblasts in vivo and in vitro, ERp60 and Cav-1 are present in the plasma membrane, and rapid PKC signaling requires functional activation of ERp60 signaling via PLC and COX.

POST TRANSPLANTATION AND BONE DISEASE WORKING GROUP

WG3

Management of Metabolic Bone Disease in the Kidney Transplant Recipient: Practice Patterns in 2005 and Recommendations for Therapy. Paul J. Scheel Jr., M.D., Department of Medicine, Johns Hopkins Medical Institute, Baltimore, Maryland, USA.

Patients who undergo renal transplant are at high risk of several forms of metabolic bone disease and subsequent fractures following kidney transplant. This increase risk can be attributed to the multiple metabolic derangements that occur during the various stages of chronic kidney disease (CKD) leading up to the transplant and the skeletal toxic effects of medication used post transplant to prevent allograft rejection. Patients with CKD who progress to ESRD are known to have histolgic evidence of both high and low turnover bone disease. High turnover bone disease is secondary to decreased production of 1:25 OH vitamin D from the failing kidney and subsequent hyperparathyroidism (HPT). Depending on the length of time HPT is present and the type of, and duration of therapy, this elevated level of PTH may or may not regress to normal levels following the transplant. Low turnover or adynamic bone disease has been attributed to Aluminum containing phosphate binders, deposition of beta 2 microglobulin, over treatment with vitamin D compounds, nutritional defects associated with ESRD and in patients who were treated with peritoneal dialysis. Other metabolic problems associated with CKD that affect skeletal heath prior to transplant include hypogonadism, chronic acidosis, and in hemodialysis patients, chronic exposure to Heparin. Patients who receive a kidney transplant therefore enter transplantation with significant bone disease of varying histology. Following a successful transplant there is resolution of many of these metabolic derangements that are attributed to a failing kidney. There are however new insults that affect skeletal health. The agents used to prevent allograft rejection; glucocorticoids and calcineurin inhibitors have both been shown to decrease bone mineral density (BMD). This demineralization occurs primarily during the periods of high corticosteroid use and is associated with increased fracture risk. Additional insults that occur post transplant include hypophosphatemia, metabolic acidosis and in some persistent hyperparathyroidism associated either with decreased vitamin D or secondary to persisistent HPT. Therapies aimed at reducing post transplant bone demineralization and fracture include: minimizing glucocorticoid use and rapid taper to < 10 mg in patients with stable renal function, monitoring and replacement of 25- OH and 1:25 OH vitamin D deficient patients, adequate dietary calcium intake, the use of biphosphonates , especially in the first six month post transplant, and recognition and treatment of persistent CKD and associated complications.

WG4

Treatment of Bone Loss after Renal Transplantation in Children: Alfacalcidol versus Calcitonin Therapy. A. A. M. El-husseini. Nephrology, Mansoura Urology and Nephrology Center, Mansoura, Egypt.

Background. Osteoporosis is a well-known complication of renal transplantation in children. We conducted a randomized trial comparing alfacalcidol with calcitonin for the treatment of bone loss. Methods. Among 59 young patients who received live related renal transplant and were subjected to dual energy x-ray absorptiometry (DEXA), 30 patients had low bone mineral density (BMD) (z-score < -1) were enrolled onto the study. Their mean age at time of transplantation was 13.5 ± 3.4 years and the mean duration after transplantation was 46 ± 32 months. Patients with low BMD were randomized into two equal homogeneous groups: group 1 received daily alfacalcidol 0.25 microg by mouth and group 2 received 200 IU /day nasal spray calcitonin. Every patient in both groups received daily 500-mg calcium carbonate supplements. Parameters of bone metabolism (intact parathyroid hormone, serum osteocalcin and urinary deoxypyridinoline) and BMD were assessed before and after the study period. Estimates of bone loss and the incidence of fractures among untreated patients were obtained from a reference group of 15 prospectively recruited patients who received renal transplants within the same period as the intervention groups. Results. At one year, the BMD at the lumbar spine had increased from -2.3 to -0.5 in the alfacalcidol group and from -2.3 to -1.0 in the calcitonin group while it was decrease from -2.2 to -2.5 in the reference group. Incidence of vertebral fractures did not differ significantly among the groups (13.3 percent in the calcitriol group, 6.7 percent in the calcitonin and the reference groups). Serum intact parathyroid hormone level decreased significantly in the alfacalcidol group compared with the calcitonin group (P = 0.042). Apart from transient hypercalcemia in 1 patient in the alfacalcidol group, no other significant adverse effects were noted. Conclusion. This study suggested the value of alfacalcidol and calcitonin agents in the treatment of osteopenia and osteoporosis in young renal transplant recipients. These therapies were safe, tolerable, simple to administer and potentially applicable to other renal transplant patients.

WG5

Prevalence of Vitamin D Insufficiency and Osteoporosis in Patients with Severe Chronic Liver Disease and Liver Transplantation. M. Rodriguez-Garcia*[1], C. Gomez[1], L. G. Dieguez*[2], M. Rodriguez*[2], M. Naves*[1], A. Rodriguez-Rebollar*[1], M. T. Fernandez-Coto*[3], J. B. Cannata-Andia[1]. [1]Bone and Mineral Research Unit. Instituto Reina Sofia de Investigacion., HUCA, Oviedo, Spain, [2]Gastroenterology, HUCA, Oviedo, Spain, [3]Biochemistry, HUCA, Oviedo, Spain.

Bone loss and vertebral fractures (Vt Fx) are common complications after liver transplantation (Tx); both pre- and post-transplant factors may be implicated in its pathogenesis. This study aimed to compare relevant bone markers, such as vitamin D status, bone mass and Vt Fx in patients with severe chronic liver diseases waiting for liver Tx (Pre-Tx group), with patients after the first year of liver Tx (Post-Tx group). Forty patients who received a liver Tx in the previous year (mean time of Tx 9±3 months) were compared with 38 patients with chronic liver disease waiting for liver Tx. For both groups, the study included measurement of fasting serum biochemical markers [25-OH D3, 1-25 (OH) D3, iPTH, Ca, P, alkaline phosphatase and others], bone mineral density (BMD) at lumbar spine and hip (Hologic QDR-1000) and X-ray evaluation of thoracic and lumbar spine. Other demographic, anthropometric and relevant clinical data were also registered. A population-based cohort of the same geographical area, age and gender was also used as a comparator (n=309). The prevalence of Vt Fx was 25% in pre-Tx, 29% post Tx and 15.7% in the general population. In pre-Tx patients, the rate of Vt Fx did not differ between sexes. By contrast, post-Tx women suffered a significantly higher rate of Vt Fx (42.1%) compared with post-Tx males (8.3%) and also with women of the general population (18.7%, $p<0.05$). At total hip, densitometric osteoporosis (WHO criteria) in pre-Tx women was higher (28.6%) compared with men (10.3%). Also at the total hip, BMD was significantly lower in Pre-Tx patients having Vt Fx (Z-score -1.78±0.45 vs 0.17±1.32, $p<0.005$). By contrast there were no differences at any site in the Post-Tx group. The mean 25 (OH) D3 serum levels in pre-Tx patients were low (18±12 ng/ml) although similar to post-Tx patients (18±9.4 ng/ml) and general population (19±10 ng/ml). However, there was more prevalence of severe deficiency (< 10 ng/mL) in the pre-Tx patients (34.5%) compared with post-Tx (23.8%) and general population (21.5%). In addition, in pre-Tx women, a significant positive relationship was found between 25 (OH) D3 and 1.25 (OH)2 D3($r=0.83$, $p<0.05$). In summary, severe chronic liver disease is associated with low bone mass, a high rate of Vt Fx and lower 25 (OH) D3 serum levels even before the liver transplantation. Although several other factors may be involved, an adequate vitamin D supplementation is mandatory to reducing bone abnormalities in chronic liver disease.

WG6

Alendronate Treatment in Long-Term Liver or Cardiac Transplanted Osteoporotic Patients. G. Martínez*[1], L. Gil-Fraguas*[2], E. Jódar[1], A. Escalona*[1], A. Moreno*[3], E. García*[1], E. Moreno*[3], M. Gómez*[4], F. Hawkins[1]. [1]Endocrinology Service, University Hospital 12 de Octubre, Madrid, Spain, [2]Rehabilitation Service, University Hospital 12 de Octubre, Madrid, Spain, [3]Digestive Surgery Dpt, University Hospital 12 de Octubre, Madrid, Spain, [4]Cardiology Service, University Hospital 12 de Octubre, Madrid, Spain.

Background: early institution of therapy may prevent bone loss after transplantation (Tx). However, the best therapeutic option in long-term transplanted patients with osteoporosis has not been defined yet. Our aim was to investigate the effects of alendronate on bone mineral density in long-term Tx patients with osteoporosis. Patients and Methods: Forty-four patients (17 liver and 27 cardiac recipients), mean age 56 y., with densitometric osteoporosis (T-score < -2.5) more than 2 years after Tx were treated with alendronate (70 mg p.o. once weekly) and minimum of 1000 mg of calcium and 400 IU vitamin D3 daily p.o.. Mean time since Tx was similar in both groups (56 months in liver recipients, 52 months in cardiac Tx patients). In liver recipients immunosuppressive therapy included tacrolimus in 65% and Cyclosporine A in 35% of patients, but none was receiving corticosteroids at the time of study. In cardiac recipients > 90% of patients was on prednisone treatment (mean dose 5.7 mg/day, mean accumulate dose 11505 mg). BMD changes were assessed after one year of treatment at lumbar spine and hip (DXA, Hologic QDR 4500). Results: In liver recipients mean lumbar BMD increase was + 8.1± 7.1%, whereas mean total hip BMD increased +3.8± 4.3% , femoral neck BMD increased +3.3± 6.9% and trocanteric BMD increased +7.3± 6.0 %. In contrast, BMD responses in cardiac recipients were less impressive; mean lumbar BMD increase was +2.1± 3.6%, mean total hip BMD -1.1± 6.4%, and femoral neck BMD increased +1.2 ± 4.6%. Treatment was well tolerated in all the patients. Conclusion: Weekly oral alendronate plus calcium and vitamin D3 is an effective treatment in long-term Tx-related osteoporosis, particularly in liver recipients. Concomitant immunosuppressive drugs used could influence the response to the antirresorptive treatment in these patients.

Evolution of Bone Density after Heart Transplantation: Influence of Anti-Resorptive Therapy. L. Gil-Fraguas*[1], E. Jodar[2], G. Martinez*[1], M. A. Escalona*[2], J. Vara*[1], E. Robles*[1], F. Hawkins[2]. [1]Rehabilitation, University Hospital 12 de Octubre, Madrid, Spain, [2]Endocrinology, University Hospital 12 de Octubre, Madrid, Spain.

Osteoporosis and osteoporotic fractures are common complications after heart transplantation. The purpose of this study was to evaluate the effects of antiresorptive therapy (calcium and vitamin D [CaVD], calcitonin [CT], etidronate [ETN] or alendronate [ALN]) at standard doses in the evolution of bone mineral density (BMD) in heart transplant recipients. Patients and Methods: We studied 216 patients (aged [mean (SD)] 54(10) years, 85% males, BMI 24.25(3.25) kg/m2) undergoing heart transplantation. BMD was assessed by DXA (Hologic 4500) in lumbar spine (LS) and total femur (TF) sites at baseline, 6, 12 and 24 months. Patients with normal BMD at baseline were placed in CaVD group and served as controls, the rest of the patients were random allocated in CT, ALN or ETN group. 152 patients had 24 months of follow-up. The statistical analysis included the following tests: Scheffe, Manova and Wilks´Lambda. Results: As expected, baseline LS and TF BMD (gr/cm2) was higher in CaVD group (LS/TF: 0,973(0,114)/ 0,925(0,129), respectively; $p<0.05$) without significant differences among the rest of the groups (LS/TF: CT: 0,873(0,157)/ 0,820(0,116); ETN: 0,882(0,121)/ 0,893(0,121); ALN: 0,884(0,147)/ 0,832(0,109)). The changes in BMD (%) are showed in the table:

Group/Site	6 Mo	12 Mo	24 Mo
CaVD LS	-3,34(5,55)	-3,97(5,65)	-3,07(7.0)
CaVD TF	-1,66(3,71)	-3,41(4,06)	-3,15(3,89)
CT LS	-4,3(6,4)	-4,94(5,26)	-0,93(6,39)
CT TF	-3,85(5,83)	-4,85(6,10)	-3,59(5,87)
ETN LS	-5,27(4,85)	-5,42(5,66)	-1,87(6,22)
ETN TF	-3,67(5,55)	-5,54(4,97)	-4,65(5,46)
ALN LS	0,53(5,16)	0,79(5,17)*	4,90(8,42)*
ALN TF	-0,39(4.0)*	-0,63(4,14)*	-0,46(5,16)*

*$p<0.001$ vs any other group.

Conclusions: According to other studies, heart transplantation produces a high bone loss with a recovery phase beginning 6 (LS) to 12 (TF) months after the procedure. Alendronate is associated with lower bone loss at femoral neck and even with a relative increase in lumbar spine bone density.

Bone Mineral Density after Renal Transplantation in Adolescents. M. Matsuda-Abedini*[1], J. Shepherd*[2], R. Mathias*[1], E. von Scheven[1], A. A. Portale[1]. [1]Pediatrics, University of California, San Francisco, San Francisco, CA, USA, [2]Radiology, University of California, San Francisco, San Francisco, CA, USA.

Loss of bone mineral occurs after renal transplantation in children, but the magnitude and duration of loss are unclear. Most studies to date have employed AP DXA of the lumbar spine to assess areal BMD (aBMD), but this technique is confounded by changes in skeletal size and maturation during growth, limiting its use in cross-sectional studies of growth-retarded patients. Serial measurements of aBMD might overcome this problem by comparing subjects to themselves. The shortcomings of planar densitometry might also be circumvented by measuring volumetric BMD (vBMD), using AP combined with lateral DXA (latvolDXA) or quantitative computed tomography (QCT). The objectives of the current prospective study were to: 1) determine the magnitude of decrease in BMD after renal transplantation in adolescents, and 2) compare aBMD and two estimates of vBMD, latvolDXA and QCT. We measured BMD of the lumbar spine in 20 ethnically diverse renal transplant recipients (11M), aged 16 ± 2.9 years (SD), at time of transplant and 9 and 18 months afterwards. Immunosuppression included corticosteroids in all patients; cumulative corticosteroid dose at 9 months was 92 ± 32 mg/kg. aBMD of the lumbar spine was determined by AP DXA (Hologic), and vBMD was determined by lumbar latvolDXA and QCT (GE 9800 Quick Scanner). To date, 18 subjects completed the 9 month visit and 10 subjects the 18 month visit. At transplant, aBMD z-score determined for chronologic age and gender (Hologic QDR-Delphi/A research reference data) was 0.06 ± 1.02. At 9 months post-transplant, aBMD decreased by 4.9 ± 10%, and the z-score decreased by 0.68 ± 0.73 ($p<0.001$). At 18 months, aBMD z-scores remained below baseline by 0.63 ± 0.8. vBMD determined by latvolDXA at 9 months post-transplant decreased slightly, 3.9 ± 11.6%, but not significantly, with little further change at 18 months. By contrast, vBMD determined by QCT decreased by 12.8 ± 16% ($p<0.01$) at 9 months and 14.4 ± 21% at 18 months. The correlation between latvolDXA and QCT was 0.6 ($p<0.001$). Bland-Altman comparison of paired measurements by these two methods revealed a mean difference of 0.036 g/cm3 (95% CI: 0.026 to 0.046), with wide limits of agreement (-0.03 to 0.10). These data show that lumbar BMD decreases significantly in the first 9 months after renal transplantation in adolescents and remains decreased at 18 months post-transplant. The magnitude of loss in BMD is substantially underestimated by both AP and latvolDXA compared with that determined by QCT. The poor correlation between latvolDXA and QCT and the large limits of agreement do not support using the two methods interchangeably.
